Minerals Yearbook

1980

Volume III

AREA REPORTS: INTERNATIONAL

Prepared by staff of the

BUREAU OF MINES

UNITED STATES DEPARTMENT OF THE INTERIOR • James G. Watt, Secretary

BUREAU OF MINES • Robert C. Horton, Director

As the Nation's principal conservation agency, the Department of the Interior has basic responsibilities to protect and conserve our land and water, energy and minerals, fish and wildlife, and park and recreation areas, and for the wise use of all those resources. The Department also has a major responsibility for American Indian reservation communities and for the people who live in Island Territories under U.S. administration.

Foreword

Through the Minerals Yearbook and its predecessor volumes, the Federal Government has reported annually on mineral industry activities since 1882. This edition discusses the performance of the worldwide mineral industry during 1980 and provides background information to assist in interpreting developments during the year being reviewed. Content of the individual volumes follows:

Volume I, Metals and Minerals, contains chapters on virtually all metallic and nonmetallic mineral commodities important to the U.S. economy. In addition, it includes a chapter on mining and quarrying trends.

Volume II, Area Reports: Domestic, contains chapters on the mineral industry of each of the 50 States, the U.S. island possessions in the Pacific Ocean and the Caribbean Sea, and the Commonwealth of Puerto Rico. This volume also has a statistical summary.

Volume III, Area Reports: International, contains the latest available mineral data on more than 130 foreign countries and discusses the importance of minerals to the economies of these nations. A separate chapter reviews the international minerals industry in general and its relationship to the world economy.

The Bureau of Mines continually strives to improve the value of its publications to its users. Therefore, the constructive comments and suggestions of readers of the Yearbook will be welcomed.

Robert C. Horton, *Director*

Acknowledgments

In preparing this volume, the Bureau of Mines utilized extensively statistical and other data on mineral production, consumption, and trade provided by various foreign government mineral and statistical agencies through a variety of official publications. The cooperation and assistance of these organizations is gratefully acknowledged. Statistical and informational material was also obtained from airgrams of the U.S. Department of State, from United Nations publications, and from the domestic and foreign technical and trade press. Of particular assistance were the routine and special reports submitted by the minerals, petroleum, economic, and commercial officers and other members of the Department of State. Their contributions are sincerely appreciated.

The text and tables of this volume were prepared by the staff of the Branch of Foreign Data, Division of Production/Consumption Data Collection and Interpretation. Final correlation and checking of this volume was performed by the Division of Publication.

The regimes of some countries reviewed in this volume are not recognized by the U.S. Government. The information contained herein is technical and statistical in nature and is not construed as conflicting with or being contradictory of U.S. policies toward these countries.

Albert E. Schreck, *Chief, Division of Publication*

Minerals in the World Economy

By Charles L. Kimbell[1] and John Panulas[2]

The year 1980 on the whole was not a good year for the world's mineral industry. The general upturn of activities in 1979 after a rather poor 1978 showing was not maintained with a number of key measurement standards showing downturns. Most notably, the world's steel and petroleum industries recorded significant reductions in output, the former in response to markedly lower demand levels and the latter partly in response to lower industrial consumption owing to general economic conditions and partly owing to successes in campaigns for the reduction of energy use in general and petroleum product use in particular among major importing nations that were feeling the trade balance pinch of ever-higher oil prices.

During 1980, a number of political events—some international in scope, some confined to single nations—had significant influence upon world mineral industry activities and mineral commodity supplies, and other political happenings had the potential to significantly affect the industry in future times.

Unquestionably the most notable events were those occurring in Iran and Iraq. At the start of the year, the spotlight was on Iran alone, where, with the tacit approval of the Khomeini regime, highly militant so-called students continued to hold U.S. Embassy personnel as prisoners, with no regard for accepted international diplomatic practice. As the year progressed, with U.S. embargoes on shipments of industrial materials (including much-needed oil and gas industry equipment) and with the freeze on Iranian assets in the United States, the civil turmoil in Iran seemed outwardly to calm somewhat, and mineral industry activity, particularly that of the oil industry, began to pick up from the drastically curtailed levels of late 1979 and early 1980. In September, however, following several major border clashes between Iran and Iraq, open warfare broke out between these countries, with each side attacking not only military targets, but industrial installations, including oilfields, refineries, pipelines, and oil loading facilities. Iraq seized substantial areas of Iran's Khúzestán Province. This warfare, which drew a number of soldiers on each side from civilian positions including some in the mineral industry and which seriously damaged mineral industry facilities in both countries, sharply reduced oil output in both nations and presumably had an adverse effect on all other economic activity through yearend.

Elsewhere in the Near East, continued border clashes, guerrilla warfare, and retaliatory airstrikes hampered industrial activity, including the minerals sector, in Israel, Syria, Lebanon, and Jordan.

In Western Europe, internal economic problems, including inflation, growing unemployment, spiraling energy costs, and attendant reduced consumer demand for finished goods served almost as effectively as did the Near East's warfare as a deterrent to increased mineral industry activity.

Japanese mineral industry activity was somewhat curtailed as a result of increasing energy costs that contributed to an increasingly unsatisfactory trade balance and by reduced demand for at least some mineral-based export products. It was questionable if recessionary trends that were evident could be curbed by the traditional method of increasing exports.

In Eastern Europe, Poland's simmering labor dissatisfaction with general economic and sociopolitical conditions burst into the

open with major strikes beginning about midyear that had significant impact on the production of several mineral commodities. Moreover, the successes of the early strikes, which led to major governmental shakeups and policy changes, enhanced the worker's feelings of the ability to accomplish changes in this manner. Thus, through yearend, the threat of additional strikes loomed on the horizon, despite threats of intervention in Polish internal affairs from the U.S.S.R.

On the African Continent, problems of civil strife and externally backed guerrilla activities that were adverse to mineral industry operations were again noted in the Angola-Namibia area and in the Ethiopia-Sudan area, but in the latter case at least, some degree of improvement in the Ethiopian-Eritrean internal strife seemed likely as a result of successful meetings between Ethiopian and Sudanese officials. These meetings resulted in Sudan cutting off supplies to some of the rebellious Eritreans and in a corresponding reduction in Ethiopian-Sudanese international tensions. In Zaire, there was none of the open warfare of the late seventies, and guerrilla activities apparently were minimal, with a resulting improvement in continuity of mineral industry operations.

In Latin America, the continued instability of the Near East stimulated oil industry activities, most notably in Mexico but to a measurable extent elsewhere. The Central American republics continued to experience largely internal political problems; while Nicaragua seemed to edge toward some degree of stability under its new regime, Costa Rica, El Salvador, and Guatemala suffered from intensified civil unrest, all of which had an unavoidable effect on mineral industry activity there.

In China, despite some apprehensions over possible changes in United States-Chinese relations when the Reagan administration came into office, relations with the West continued to improve, with increases in trade, including mineral commodities, being quite evident. Mineral industry operations in the industrial north were somewhat hampered by water shortages resulting from drought conditions.

PRODUCTION

The estimated value of world crude mineral production in 1980 was $549,300 million in terms of 1978 dollars, an amount that was $11,000 million or 1.9% below the 1979 level, reflecting a downturn in the volume of production of several major commodities. The following tabulation summarizes approximate data on the value of world mineral production for selected years:

Year	Billion constant 1978 dollars	
	Value of 53[1] major crude mineral commodities[2]	Value of all crude mineral commodities[3]
1950	67.8	77.2
1953	88.5	101.7
1958	113.6	136.5
1963	125.7	154.0
1968	145.6	176.5
1973	234.0	281.6
1978	478.9	539.7
1979	497.2	560.3
1980	487.4	549.3

[1]The list of commodities included appears in table 3 of this chapter; one commodity covered in 1950-68 (beryl) is excluded from the 1973-80 figures, but the overall impact of this omission is regarded as insignificant.

[2]Data for all years except 1979 and 1980 are as reported in Annales des Mines, November-December 1980, p. 173; data for 1979 and 1980 are extrapolated from the 1978 Annales des Mines figures on the basis of the United Nations index of extractive industry production in the United Nations Monthly Bulletin of Statistics, August 1981, p. xiv.

[3]Data extrapolated from values for 53 commodities to compensate for other mineral products. For details on the basis for this extrapolation, see accompanying text under "Value of World Mineral Production."

The foregoing data belittle the role of the mineral industry in the world economy, however, by representing only an approximation of the value of crude production from mines, quarries, and wells, rather than the enhanced value that results from

beneficiation, smelting, refining, and other equivalent downstream processing. Moreover, these data do not reflect value added owing to transporting mineral materials from production areas to consuming areas. If the value added through processing—smelting of metals, refining of oil, and manufacture of basic materials such as cement and fertilizers—were included, a 1980 figure on the order of $1,300,000 million (1978 dollars) could be regarded as a conservative estimate of the value of output of primary mineral-processing plants. An additional, unestimated increment should also be added for the value of secondary metals produced. It should be stressed that crude and processed mineral commodities constitute not only the overwhelming dominant share of the total raw material base for all manufacturing endeavors, but also represent a significant requirement for the agricultural industries because of that industry's need for fertilizers of mineral origin, as well as the overwhelmingly dominant source of energy for industry throughout the world and for individual energy requirements in all developed countries and a number of developing countries as well.

PRODUCTION INDEX PATTERNS

The following tabulation summarizes the growth in world mineral industry output as reflected by the United Nations indexes for extractive mineral industry components:

Year	Index numbers (1975=100)			
	Coal	Crude petroleum and natural gas	Metals	Total
1978	101.0	116.1	101.6	112.6
1979	106.1	120.3	104.1	116.9
1980:				
January to March	109.4	121.8	104.7	118.3
April to June	110.7	115.9	105.9	114.9
July to September	107.4	114.6	103.0	112.7
October to December	112.1	112.7	104.2	112.5
Annual	109.9	116.3	104.5	114.6

Source: United Nations. Monthly Bulletin of Statistics. V. 35, No. 8, August 1981, p. xiv.

Particularly notable is the fact that the overall total index number for the first quarter of 1980 exceeded the 1979 average (largely on the strength of the fuels sectors), and that there was a continual decline through the remaining quarters, this due almost entirely to the continued decline in the petroleum and natural gas sector. It was further notable that the modest decline registered for coal and metals in the third quarter was more than compensated by increases in these sectors in the fourth quarter.

Comparison between the world extractive industry indexes in the foregoing tabulation and the indexes for processing sectors of the mineral industry that are presented in the following tabulation reflect the substantially higher unit prices for downstream products as well as the higher profitability of secondary metal production (in the base metal index):

Year	Index numbers (1975=100)		
	Nonmetallic mineral products	Chemicals, petroleum, coal, and rubber products	Base metals
1978	117.3	124.9	114.7
1979	121.4	131.0	119.5
1980:			
January to March	120.4	133.3	122.3
April to June	126.3	131.4	120.4
July to September	121.3	124.3	108.8
October to December	121.4	128.0	114.1
Annual	122.4	129.3	116.4

Source: United Nations. Monthly Bulletin of Statistics. V. 35, No. 8, August 1981, p. xv.

For details on differences in mineral industry index growth patterns for various

geographic areas, see the source publication for the foregoing tabulations.

QUANTITATIVE COMMODITY OUTPUT

Total world production of 95 distinct mineral commodities and/or specific forms of mineral commodities is given in table 1 for 1976-80. Of these commodities, 53 registered gains and 41 recorded declines relative to 1979 output levels (1 commodity registered no change). These figures contrast rather sharply with results comparing 1979 output levels with those of 1978, when 77 commodities showed gains and only 18 registered declines. Of the 50 metallic commodities listed, 28 were produced in greater quantities in 1980 than in 1979, and 22 were produced in lesser quantities, but among those recording declines were iron ore, pig iron, ferroalloys, crude steel, mine copper, smelter copper (both primary and secondary), mine lead, smelter lead (both primary and secondary), refined lead (both primary and secondary), mine silver, mine zinc, and smelter zinc (both primary and secondary)—virtually all major metals save aluminum and its ores and intermediate products.

Among the 34 listed nonmetals, 18 registered gains between 1979 and 1980; 15 recorded declines; and 1 was unchanged, but in contrast to the situation among the metals, several major nonmetallics recorded increases—notably cement, nitrogen, phosphate rock, and sulfur (all 3 listed forms).

Of the 11 fuel commodities listed (not counting uranium, included among the metals), 7 showed increases and 4 registered declines, including, most notably, crude and refined oil.

No viable means exist to sum up the overall production performance of the nonfuel mineral industry except on a value basis, and for these commodities, exactitudes on value are not available for detailed review for 1979 and 1980. Among the fuel commodities, however, a pattern of overall growth can be demonstrated by United Nations data in which all fuels are reduced to a common energy equivalent basis. The following tabulation summarizes world energy material output for 1975-80 (1980 data partly estimated):

Table 1.—World production of major mineral commodities[1]

Commodity and unit of measure	1976	1977	1978	1979[p]	1980[e]
METALS					
Aluminum:					
Bauxite, gross weight[2] thousand metric tons	78,942	83,648	81,431	89,256	91,513

Gas, natural, marketed billion cubic feet	47,855	49,618	51,405	54,497	55,550
Natural gas liquids[4] million 42-gallon barrels	1,070	1,102	1,118	1,174	1,206
Peat[14] thousand metric tons	202,325	202,319	203,442	202,471	202,362
Petroleum:					
Crude million 42-gallon barrels	21,089	21,891	22,063	22,916	21,771
Refined do	21,356	22,402	22,526	23,506	22,826

[e]Estimated. [p]Preliminary.

[1]Incorporates numerous revisions from the table corresponding to this table in previous editions of this chapter. Figures generally conform to those published in appropriate commodity chapters of volume I of the Minerals Yearbook, 1980 edition.

[2]Includes bauxite equivalent of nepheline syenite and alunite produced in the U.S.S.R. (the only producer on record of such materials as a source of aluminum).

[3]Excludes data for the United States (withheld to avoid disclosing company proprietary data).

[4]Excludes data for mainland China (no adequate basis for estimation available).

[5]Excludes data for the U.S.S.R. (no adequate basis for estimation available).

[6]Includes all metal clearly identified as primary as well as all metal that cannot be subdivided clearly between primary and secondary (see footnote 7).

[7]Includes only that metal that is clearly identified as secondary. Some countries do not distinguish between primary and secondary and for some of these, no basis is available for estimating the breakdown of total production. For such countries, the total has been included under primary (see footnote 6).

[8]Excludes data for the United States (withheld to avoid disclosing company proprietary data), which in previous years accounted for approximately 50% of the world total.

[9]Includes leucoxene.

[10]Data are for years ending June 30 of that stated.

[11]Comprises sulfur produced by the Frasch process plus sulfur mined in the elemental state from ores.

[12]Comprises sulfur recovered from coal gasification, metallurgical operations (except pyrite processing), natural gas, petroleum, tar sands, spent oxides, and gypsum, whether recovered in the elemental state or as a sulfur compound.

[13]Production of coke other than metallurgical by mainland China and the U.S.S.R. is included with metallurgical coke production.

[14]Of which fuel peat, as follows, in thousand metric tons (balance for agricultural use): 1976—66,450; 1977—66,178; 1978—66,911; 1979—65,326; and 1980—65,228. Unrevised versions of these figures inadvertently were published in the table corresponding to this table in the 1978-79 edition of volume III, Minerals Yearbook.

VALUE OF WORLD MINERAL PRODUCTION

The comprehensive study on value of world mineral production that has been prepared periodically during the past 28 years for the French language monthly mineral industry publication Annales des Mines was extended for another 5-year increment in the November-December 1980 issue of that publication. The series now provides nearly uniform data for the years 1950, 1953, 1958, 1963, 1968, 1973, and 1978. The study fixes the constant 1978 dollar value of total world production of a selected list of crude mineral commodities[3] at $478,917.9 million for 1978, an increase of nearly 105% over the 1978 constant dollar value of output in 1973, equivalent to an annual average increase of 15.4%, which the source publication attributes to a 1.9% annual average increase in volume of out-

put and a 13.3% annual average increase in the inflation-corrected price index for crude minerals. The figures in the French source have been roughly extrapolated by the U.S. Bureau of Mines to cover the full range of crude mineral commodities covered in the Minerals Yearbook on the basis of the share of total U.S. crude mineral output value accounted for by those selected commodities covered by the French source. The data upon which the extrapolations were based are as follows:

Year	Million current U.S. dollars		
	Value of total U.S. crude mineral output	Value of U.S. output of selected minerals covered in Annales des Mines[1]	Percentage of total accounted for by selected commodities
1950	11,835	10,405	87.8
1953	14,382	12,511	87.0
1958	16,526	13,754	83.2
1963	19,620	16,002	81.6
1968	24,974	20,591	82.4
1973	36,788	30,579	83.1
1978	[2]19,821	[2]10,008	[2]50.5

[1]Values as reported by U.S. Bureau of Mines, not as reported in Annales des Mines. Corresponding values as reported in Annales des Mines in million dollars were 1950—$10,406; 1953—$12,435; 1958—$12,440; 1963—$15,742; 1968—$20,232; 1973—$29,876; and 1978—$8,766 (the last excluding fuels for comparability—see footnote 2).

[2]Excluding fuel minerals, no longer the primary responsibility of the U.S. Bureau of Mines, and for which 1978 data corresponding to that for 1950-73 inclusive was not published.

The published figures for total value of world production appearing in Annales des Mines for the selected group of commodities were increased on the basis of the percentages in the right hand column of the foregoing tabulation for each year shown, 1950 through 1973, inclusive. For 1978, where U.S. fuels value data were not available, the French published value for metals and nonmetals only was increased in a similar fashion and then added to the existing French-published fuels value. This method, using the U.S. experience as a basis for the extrapolation to full commodity coverage in order to obtain at least a rough approximation of the latter, even though it is recognized that, in all likelihood, the ratio between (1) the value of commodities included in the French study and (2) the value of commodities excluded from that study is not at all consistent from country to country around the world. The results of this extrapolation appear in the first tabulation under the heading "Production" in a preceding part of this chapter. That tabulation also includes an extrapolation of the Annales des Mines 1978 figure to 1979 and 1980, this extrapolation based on the United Nations index of world extractive industry production.

Year	Million metric tons of standard coal equivalent				
	Coal	Crude petroleum and natural gas liquids	Natural gas	Hydro and nuclear electricity	Total
1975	2,427	3,981	1,583	224	[1]8,214
1976	2,482	4,313	1,645	231	8,671
1977	2,570	4,467	1,685	250	[1]8,973
1978	2,608	4,517	1,743	277	9,145
1979	2,737	4,693	1,843	287	9,560
1980	2,761	4,450	1,857	299	9,367

[1]Detail does not add to total shown because of independent rounding.

Sources: Data for 1975-79 are taken directly from United Nations. Yearbook of World Energy Statistics. New York, 1981, p. 2; data for 1980 are extrapolations of 1979 United Nations figures based on data collected by U.S. Department of Energy and published in 1980 International Energy Annual. Washington, D.C., 1981, pp. 14, 18, 20, 22, and 24.

GEOGRAPHIC DISTRIBUTION OF WORLD MINERAL OUTPUT VALUE

Available information is inadequate to extrapolate to 1980 the 1978 data on the geographic distribution of world mineral output published in Annales des Mines. However, those data, together with corresponding data for 1973 and 1950, are presented in table 2 of this chapter to demon-

strate the shifts in relative importance of the various countries, particularly the changes that occurred during the 1973-78 period.

The most notable change was the U.S.S.R.'s move into first place, displacing the United States. The U.S.S.R., with 19.89% of the 1978 world total value, not only displaced the United States, but also continued to increase its share of the world total; while, in contrast, the U.S. share of the total again diminished as it has with each periodic study (1953, 1958, 1963, 1968, and 1973) since the first, made in 1950, when the United States accounted for 39.31% of world output value. Saudi Arabia firmed its position as the third-ranked nation, increasing its share of the total from almost 5.7% in 1973 to 8.2% in 1978; similarly, both fourth-ranked mainland China and fifth-ranked Iran firmed up their positions, registering higher shares of the total in 1978 than in 1973. In contrast, Canada retained sixth rank in 1978, but accounted for a smaller share of the year's total than it did of the 1973 total. As a result of oil output from the North Sea fields, the United Kingdom moved markedly higher in 1978, rising from 13th rank in 1973 (1.76% of total) to 7th rank in 1978 (2.58% of total), reattaining the ranking that it held in 1968, which was based very largely on its coal output. Iraq, ranking 8th in 1978, also registered a substantial improvement in its position (17th in 1973); 9th-ranked Libya was unchanged in position since 1968; and rounding out the leading 10 1978 producers, Venezuela, with declining oil output, fell from 7th rank in 1973.

The significance of crude oil as the principal factor in national rankings is evidenced by the fact that of the 10 leading countries in value of world mineral output in 1978, only two—Canada and the United Kingdom—were not among the 10 leading oil producers in that year, and these 2 ranked 13th and 16th, respectively, as crude oil producers in that year. The growth in the significance of oil is also demonstrated by the decline in rank of the Republic of South Africa, 8th in 1963, 10th in 1968 and 1973, and 17th in 1978, for throughout this time, the Republic has shown substantial growth on a quantitative basis in output of a number of significant nonfuel minerals as well as in coal.

Despite the changes in ranking, however, it is perhaps significant to note the consistency of ranking for leading countries. Of the 20 leading nations in crude mineral output value in 1978, 13 held a rank of 20 or higher since 1963 (the U.S.S.R., the United States, Saudi Arabia, mainland China, Iran, Canada, the United Kingdom, Iraq, Venezuela, the Federal Republic of Germany, Kuwait, Poland, and the Republic of South Africa), and 4 more were among the top 20 in 3 of the 4 surveys (Libya, Australia, and Algeria in 1968, 1973, and 1978; and Mexico in 1963, 1968, and 1978).

The following tabulation summarizes the changes in distribution of total world crude mineral output value in terms of major groups of countries:

Country group	Share of total world value of listed commodities		
	1950	1973	1978
Market economy countries:			
Developed	67.46	36.19	30.20
Developing:			
Organization of Petroleum Exporting Countries (OPEC)	9.98	27.04	30.56
Other	5.99	9.75	9.69
Centrally planned economy countries	16.57	27.02	30.55

The most notable trends are the decline in the share of total accounted for by developed market economy countries, the nearly parallel growth in share of total accounted for by the developing Organization of Petroleum Exporting Countries (OPEC) and the centrally planned economy countries, and the at first increasing and then declining share of total accounted for by non-OPEC developing market economy nations.

Examining the 1978 total from the viewpoint of continental distribution, Asia (less Asiatic U.S.S.R.) accounted for the largest single segment, 32% (including 21.1% for the Near East, 7.1% for mainland China and other centrally planned economy countries of Asia, and 3.8% for Japan and other market economy nations of the Far East). The U.S.S.R. and the other centrally planned economy nations of Europe collectively provided 23.5% of the total; Canada and the United States together supplied 18.5%; Africa accounted for 9.6%; market economy Europe was the source of 8.3%; Latin America contributed 6.4%; and the remaining 1.7% was from Oceania.

COMMODITY DISTRIBUTION OF WORLD MINERAL OUTPUT VALUE

As in the case of the geographic distribution of world mineral output value, the inadequacy of data precludes any reliable extrapolation of the various commodities'

shares of the totals published for 1978 in Annales des Mines to 1979 or 1980. Therefore, the commodity breakdown in that source for 1978 has been included in this chapter as table 3, to provide the most recent reliable measurement of the relative value of the various mineral commodities.

The growing preeminence of the fuel minerals is immediately evident: Crude oil alone accounted for 55.57% of the 1978 total of the reported commodities (47.44% in 1973); crude oil together with anthracite, bituminous, and lignite coal, natural gas, natural gas liquids, and uranium accounted for 87.05% of the total value of listed commodities in 1978 (76.98% in 1973).

The following tabulation summarizes the shares of total value of listed commodities accounted for by each of the major commodity groups:

Commodity group	Percent of value of all listed commodities				
	1950	1963	1968	1973	1978
Mineral fuels	76.43	76.62	72.91	76.98	87.05
Metals	19.18	17.98	20.96	18.64	9.32
Industrial nonmetals	4.39	5.40	6.13	4.39	3.63

At this point, it should be noted that had the Annales des Mines staff had available to them comprehensive worldwide data on the mineral commodities mentioned previously in the section of this chapter on value of world mineral production, and had such data been included in this study, the shares reported for mineral fuels and metals would be marginally lower than those given, while the share reported for industrial nonmetals would probably more than double. Thus, the foregoing data array tends to belittle the significance of nonmetallics and somewhat overstates the relative importance of fuel minerals and metals as a result of incomplete data.

Among individual nonfuel commodities, probably the most significant changes between 1973 and 1978 were (1) the higher ranking of iron ore (up to 4th from 5th); (2) the decline of copper (from 4th to 6th); (3) the rise of phosphate rock (from 16th to 9th); (4) the decline of lead (from 11th to 16th); (5) the decline of zinc (from 9th to 16th); and (6) the decline of nickel (from 10th to 20th).

TRADE

In 1979, the aggregate value of total world trade in mineral commodities reached an estimated $473,341 million (current dollars), a very substantial increase (42.5%) above the previous record high set in 1978. Comparable data for 1980 were not available in time for inclusion in this chapter; available information clearly suggested a significant increase, but in all likelihood a much less substantial increase than that between 1978 and 1979. At this writing, data were far too sparse to provide a basis for a reasonable estimate of the percentage growth. The following tabulation summarizes the growth pattern in mineral commodity trade for 1975-79, as well as the role of that trade in total commodity trade:

Year	Estimated value of all mineral commodities traded (millions)	Change from previous year (percent)	Mineral commodities share of all commodities traded (percent)
1975	r$312,400	-3.8	35.8
1976	r353,200	+13.1	35.7
1977	385,900	r+9.3	r34.3
1978	r407,500	r+5.6	r31.4
1979	508,800	+24.9	35.4

rRevised.

The huge gain was due, in substantial part, to the inflationary spiral, particularly advances in the unit prices for oil, but the increased level of industrial activity, reflected as previously mentioned, in 1979 production levels for many commodities, contributed also. Although 1980 data are not yet available, the growth in trade will undoubtedly reflect the cutbacks in output of those major volume commodities, such as iron ore and crude oil.

Table 4, which served as the basis for the estimates of total mineral commodity trade appearing in the foregoing tabulation, provides reported data on the value of trade in major mineral commodity groups and total commodity trade for 1975-79. Table 5 shows the percentage share of major mineral commodity groups in the total trade of these commodities for 1975-79 and table 6 provides individual growth (or decline) rates for each of the major mineral commodity groups for the same years.

Major mineral commodity trade by region (such as tables 8-10 in the 1976 edition of this chapter) may be obtained for 1965, 1970, and 1975-79 directly from the United Nations Monthly Bulletin of Statistics for May 1981.

CONSUMPTION

NONFUEL MINERAL COMMODITIES

Virtually worldwide cutbacks, or at the very least stagnation in downstream industrial growth in 1980, were reflected in available statistics on consumption of metallic commodities in 1980. The following tabulation, which provides data on estimated world use for seven prominent nonferrous metals for recent years, clearly demonstrates this drop:

Commodity	Thousand metric tons				
	1976	1977	1978	1979	1980
Aluminum, primary refined	14,076	14,511	15,334	15,963	15,245
Cadmium	18	16	16	18	17
Copper, refined[1]	8,539	9,078	9,502	9,838	9,526
Lead refined[1]	5,094	5,401	5,463	5,566	5,288
Nickel[2]	670	642	697	779	718
Tin refined[1]	239	231	231	232	224
Zinc, slab[1]	5,674	5,825	6,150	6,327	6,069

[1]Primary and secondary combined.
[2]Nickel content of refined nickel, ferronickel, and nickel oxide.

Source: World Bureau of Metal Statistics. World Metal Statistics. V. 34, no. 9, London, Sept. 17, 1981, pp. 12, 33, 38, 73, 87, 97, and 101.

The seven commodities listed registered an unweighted average consumption decline of 4.8% between 1979 and 1980 (weighted average consumption was down 4.2%). The individual commodity declines resulted in consumption levels below those of 1979 but above those of 1978 for cadmium, copper, and nickel, below those of both 1978 and 1979 but above the 1977 level for aluminum and zinc, a lower level for lead than in any year since 1976, and a lower level for tin than in any year since 1975.

Regarding the ferrous metals, less current and less complete data are available; nonetheless, the downturn in 1980 was clearly evident. A total world decline in iron ore consumption of 5% or more was indicated and a decline in the use of iron and steel scrap of 4% to 5% comparing 1980's level to that of 1979 seemed likely on the basis of partial returns. Despite an increase in output of manganese ore, a decline in the consumption level of 3% to 5% seemed likely.

Considering major nonmetallic commodities, the small growth in total world cement output (1.5%) was evidently, at least in part, utilized; thus, cement consumption evidently edged marginally upward, running counter to the trend in metals. Among the fertilizer commodities, consumption of nitrogenous and phosphatic materials continued to increase through the end of the crop year 1980 (July 1, 1979, to June 30, 1980), while that of potassic fertilizers edged downward slightly as shown in the following summary tabulation:

Commodity	Crop (ending June 30 of year stated)		
	1978	1979	1980
Nitrogenous ---------- million metric tons N	49.8	53.8	57.0
Phosphate ---------- million metric tons P_2O_5	27.9	29.9	31.2
Potassic ---------- million metric tons K_2O equivalent	23.0	24.5	23.5

Source: British Sulphur Corp. Ltd. Statistical Supplement No. 22, January-February 1981, London, p. 1.

Data on worldwide sulfur consumption for 1980 are incomplete, but a slight increase over the level of 55.5 million tons of sulfur in all forms estimated by British Sulphur Corp. was expected. The 1979 level was 5.1% above their estimated 1978 level and 11.4% above their estimated 1977 level.

MINERAL FUEL COMMODITIES

On a worldwide basis, energy consumption in 1980 fell by an estimated 2.3% relative to the 1979 level, compared with a 3.7% growth registered between 1978 and 1979. Thus, the overall world energy consumption level in 1980 was nearer that of 1978 than that of 1979. The entirety of the decline was the result of diminished use of petroleum, as shown in the following tabulation, which summarizes world energy consumption subdivided by major fuel types for 1975-80:

Year	Million metric tons of standard coal equivalent				
	Solid fuels	Liquid fuels	Natural gas	Hydro and nuclear electricity	Total
1975	2,397	3,348	1,561	223	7,529
1976	2,476	3,578	1,645	231	7,930
1977	2,560	3,692	1,666	250	8,168
1978	2,612	3,768	1,738	277	8,395
1979	2,738	3,834	1,846	288	8,706
1980[e]	2,750	3,600	1,855	298	8,503

[e]Estimated.

Source: Data for 1975-79 are taken directly from United Nations Yearbook of World Energy Statistics. New York, 1981, p. 3; data for 1980 are estimates by senior author.

The tabulation reflects the modest advances in worldwide use of coal, natural gas, and hydro- and nuclear-generated electric power in sharp contrast to the decline in liquid fuels (chiefly petroleum refinery products, but also including natural gas plant-derived liquefied petroleum gas and so-called natural gasoline). As a result of these changes in consumption levels, solid fuels accounted for over 32.4% of total energy in 1980 (31.5% in 1979), liquid fuels for 42.3% in 1980 (44% in 1979), natural gas for 21.8% in 1980 (21.2% in 1979), and hydro- and nuclear-generated electricity for 3.5% in 1980 (3.3% in 1979).

INVESTMENT

Data published by the U.S. Department of Commerce relating to U.S. foreign investment in mineral industry activities show continued growth in both petroleum and mining-smelting-refining from 1978 through 1980, but the gains, reported in current dollars, would be considerably reduced if they were deflated to adjust for the inflation rate.

Unfortunately, reasonably comprehensive data on worldwide mineral industry activity are not available for 1980, and for 1979, such figures are available for only a few geographic and commodity areas. Table 7 shows steel industry investment data for nations of the Organization for Economic Cooperation and Development, showing a substantial downturn in 1979, almost entirely as a result of a dramatic drop in the Japanese investment level (although the

European Economic Community (EEC) as a whole registered a slight drop, as did Australia and Spain).

Information on Brazil's extractive mineral industry investment for 1980 indicated a total level equivalent to $660 million, including $240 million for phosphates, $120 million for iron ore, $110 million for nickel, $70 million for copper, $60 million for kaolin, and $60 million for expansion and improvement of existing iron ore mines and related facilities. Clearly these expenditures were for major projects only and exclude much downstream processing, but it is indicative at least of activity in what is one of the more stable Latin American investment areas. A somewhat more modest extractive industry investment level was reported for the Republic of South Africa—a level equivalent to $402 million, of which the largest share was for new gold production facilities, a substantial amount of the remainder for new uranium projects, with small amounts for new chromite facilities and improvement of existing tin facilities. Investments of $435 million in Greece in 1980 were chiefly for new bauxite and nickel facilities.

Worldwide petroleum industry investment for 1980 had not been summarized at the time of this writing, but particulars for 1979 are provided divided on a regional basis in table 8 and on a worldwide basis divided by the various sectors of the industry in table 9. Table 10 provides data on U.S. direct foreign investment in mineral industry activities (mining, smelting and refining, and petroleum) for 1977-80, with regional detail of the last 2 years of the period.

TRANSPORTATION

MARINE TRANSPORT

Tankers, bulk carriers, and freighters are the three classes of vessels engaged in transporting mineral commodities. The number, gross tonnage, and deadweight tonnage of these vessels, as well as similar data for other vessels of the world's merchant fleet, as reported by the U.S. Maritime Administration for 1975-79, are given in table 11.

It should be noted that vessels in each of the three categories are not devoted wholly to mineral commodity transport. Tankers, although largely engaged in moving crude oil and refinery products, also transport liquid chemicals, wine, molasses, and whale oil. Bulk carriers move agricultural products as well as crude minerals and mineral fertilizers, while freighters, because of their great variety, can be devoted wholly to hauling mineral products or wholly to moving nonmineral goods, as well as to carrying mixed mineral and nonmineral cargos.

Table 12 gives information on total loadings and unloadings of vessels, divided between tanker-type cargo and dry cargo, for the years 1975-79. Although it is recognized that these figures on loadings and unloadings include goods other than minerals, they nevertheless serve as a reasonable measure of mineral commodity shipments, because the preponderance of total weight of all goods moved is accounted for by minerals. Some measure of the significance of mineral commodity movement to total commodity movement is apparent in data for the world's two major canals, the Panama and the Suez, and it should be noted that figures for these waterways are skewed in favor of nonmineral commodities by both waterways' inability to handle large supertankers and bulk cargo vessels engaged in ore trade. Although exact recent figures are not available, it appears likely that minerals and mineral products account for three-quarters or more of total cargo carried in any single year on a weight basis.

Tables 13 and 14 provide a geographic breakdown of loadings and unloadings of dry cargo and tanker cargo, respectively, for 1977-79 on a tonnage basis. Again recognizing that both tables include mineral and nonmineral goods, but also recognizing the dominance of mineral materials from the viewpoint of tonnage, these tables give some idea of the relative importance of various world areas as origins and destinations for mineral materials.

Although physical characteristics of vessels—size, draft, age, crew requirements, type of propulsion system, etc.—as well as fuel costs have an undeniable influence on shipping industry performance, problems of and changes in the quantity and type of material being moved also significantly affect the shipping sector of the world economy. Therefore, before detailing changes in composition of the merchant fleet that serves the mineral industry, some observations on major mineral cargoes seem in order. First in importance because of the volume of material moved was oil, and in

this case, preliminary figures indicated an 8.4% decline in total movement of crude oil and oil products relative to 1979 levels. The total of 1,665 million tons included 1,420 million tons of crude and 245 million tons of products and represented the lowest overall level of oil shipment since 1975.

The decline in transport performance was even more marked. Haul length in 1980 was 5,750 miles, down from 5,850 miles in 1979. This can be attributed to three factors. First, there was an increase in short-haul crude movements. Second, there was a reduction in use of the Persian Gulf region working in tandem with increased use of the Suez Canal. Third, erratic growth in export movements of Middle East oil from the eastern Mediterranean increased.

A major factor in the changes in world oil trade practices and patterns was the internal economic disorder in Iran that prevailed through the early months of the year as the Khomeini regime took control, and that was heightened by the outbreak of open warfare between Iran and Iraq in the fall. These political and military conditions produced a significant drop in secure long-term oil supplies and intensified competition for potentially available supplies from other producers. At least momentarily, the quest for supply assurance rather than strict price considerations became a dominant consideration. However, as demand levels for oil diminished as a result of both conscious planning at energy conservation and cutbacks in use resulting from general industrial slowdowns in many nations, it became evident that adequate reasonably assured supplies of crude oil were available from producers other than Iran and Iraq.

Another mineral commodity with considerable significance to seaborne transport was phosphate rock. Preliminary 1980 statistics indicate that total seaborne trade of phosphate rock was around 49 million metric tons, the highest level yet recorded. Demand was relatively high during the first half of 1980, dropped slightly as a result of price increases during the third quarter, but rebounded in the fourth.

The United States, Jordan, Morocco, the Republic of South Africa, and Israel were the primary phosphate rock exporters in 1980. About 33% of total U.S. phosphate rock exports went to Europe with the remainder sent to Japan and to South and East Asia. Jordan's primary export markets were Poland, Romania, and Yugoslavia. Morocco, the world's leading phosphate rock exporter, experienced a 1.5% drop in exports owing to reduced demand by Latin American nations.

Because of the large volume of trade between North Africa and Europe, phosphate rock shipments of a short-haul nature remained unchanged. About 62% of total seaborne phosphate rock trade was moved by bulk carriers over 18,000 deadweight tons, and 85% was carried by ships below 40,000 deadweight tons. Only 2% of all shipments were made by vessels over 10,000 deadweight tons, indicating the continued inability of the phosphate rock trade to utilize large bulk carriers, which stems from the nature of port facilities in phosphate rock loading areas.

Bauxite and alumina also were among the mineral commodities accounting for substantial seaborne trade; preliminary statistics indicate total shipments of these materials in 1980 approached 47 million metric tons, of which 30% was alumina. Of the total, Australian exports accounted for nearly one-third, West African shipments for about one-fourth, Caribbean shipments for another one-fourth, and Guyana-Suriname-Brazil shipments for about one-sixth. Roughly 60% of the total bauxite-alumina shipped by sea was moved in vessels below 40,000 deadweight tons, with about 20% moving in vessels of 40,000 to 80,000 deadweight tons and the remainder in vessels of 60,000 to 80,000 deadweight tons. The average haulage distance for vessels in the bauxite-alumina trade was only about 3,700 miles, this as a result of the relatively large volume of material shipped over the relatively short distance from the Caribbean and northern South America into the United States and Canada.

Owing to long-term freight contracts, of which over 90% of all 1980 maritime iron ore trade was conducted, the first half of 1980 saw a surge in seaborne iron ore movements. This increase diminished during the second half of the year as importers utilized their contractual option to reduce shipments to avoid excessive inventories.

Total iron ore shipments amounted to about 310 million metric tons in 1980, 17 million metric tons below the 1979 level but 25 million metric tons above the 1975-78 annual average. Accounting for more than 80% of the export segment of this total were Australia, Brazil, the Republic of South Africa, Liberia, Sweden, India, and Canada. On the demand side, 85% of the iron ore was imported by principal steel producers,

EEC, Japan, and the United States. Other Western European countries, nations of the Far East, and mainland China took the remaining 15%. The average haul length in 1980 was 4,870 miles, unchanged from that of 1979, with over 50% of the total seaborne movement carried in vessels above 100,000 deadweight tons.

There was a sharp upturn in demand for steam coal in 1980, a direct result of that commodity's better competitive position vis-a-vis oil, both from the viewpoint of price and the viewpoint of assurance of supply. One result was the record seaborne movement level of 172 million metric tons, 8.2% over the 1979 level.

In terms of seaborne movements, North America was the leading regional coal exporter. Following were Eastern Europe, Australia, the Republic of South Africa, and Western Europe. Shipments from Australia fell off severely in 1980 owing to labor problems. Most prominent among these was a 10-week strike staged by Queensland coal workers. The reduced Australian shipments resulted in a large increase in seaborne coal exports from the United States and the Republic of South Africa.

With regard to the United States, exports of steam and metallurgical coal shipped reached an estimated 75 million metric tons in 1980, reflecting a near doubling in sales during the period 1978-80. Of the 75 million metric tons, steam coal represented 20% compared with 5% in 1979. The other 80% was of metallurgical quality.

South African total seaborne coal exports increased 14% to 25 million metric tons; 18 million metric tons of this amount went to the EEC nations, reflecting a 30% increase over the 1979 level.

Bulk Carriers.—In 1979, the world's bulk carrier fleet increased by 63 vessels, compared with a 281-vessel decrease in 1978. The 1979 growth represented a 13% gain on the basis of number of vessels. There was a 1% decrease in the average gross tonnage and deadweight tonnage of such vessels, reversing a trend prevalent for a number of years. In 1979, the average bulk carrier grossed 22,346 tons and had a deadweight tonnage of 38,676, compared with 1978 figures of 22,423 and 38,795, respectively. Toward the end of 1979, orders for new bulk carriers increased, and that trend continued through the end of 1980.

The following tabulation shows the distribution of the world bulk carrier fleet by country of registry for 1979:

Country	Number of vessels	Deadweight tonnage (thousand tons)
Liberia	920	44,729
Japan	500	21,814
Greece	857	15,026
United Kingdom	236	11,459
Norway	163	10,779
Panama	369	9,350
Italy	149	7,508
India	105	4,462
U.S.S.R.	156	3,106
Germany, Federal Republic of	49	2,886
France	50	2,869
China, mainland	85	2,839
Singapore	82	2,683
Brazil	39	2,405
Spain	68	2,261
Poland	78	2,048
Sweden	31	1,320
Other	777	34,775
Total	4,714	182,319

Freighters.—In 1979, the world's freighter fleet increased by only 188 vessels, a 1.3% increase. In terms of total gross tonnage and deadweight tonnage, there were 2.2% increases over the 1978 levels. The average freighter in 1979 had a gross weight of 6,256 tons (6,202 tons in 1978) and a deadweight tonnage of 8,409 tons (8,341 tons in 1978), a modest increase when the number of vessels involved is considered. The following tabulation shows the distribution of the world's freighter fleet by country of registry in 1979:

Country	Number of vessels	Deadweight tonnage (thousand tons)
Greece	1,564	15,042
Panama	1,666	12,766
U.S.S.R.	1,828	10,996
Japan	756	6,838
United States	469	6,723
Liberia	567	6,357
United Kingdom	514	5,387
China, mainland	462	4,665
Singapore	458	4,042
Germany, Federal Republic of	386	3,946
India	221	2,599
Netherlands	357	2,481
Cyprus	404	2,302
Norway	192	1,944
Other	4,485	34,406
Total	14,329	120,494

Tankers.—In 1979, the world's tanker fleet was 27 vessels greater than that of 1978. The average vessel's gross tonnage declined from 34,849 tons in 1978 to 34,815 tons in 1979, and deadweight tonnage similarly declined, from 65,885 tons in 1978 to

65,756 tons in 1979.

Accounting for the lack of growth in the world's tanker fleet in 1979 was the meager 2.5% increase in transport demand, relative to 1978. This was the result of a 1.5% decline in average haul length caused by the increased use of crude oil pipelines and by the higher level of oil exported by countries outside the Middle East.

Haul length continued to diminish into and throughout 1980 and, coupled with the aforementioned 8.4% drop in oil tonnage carried, effected a significant increase in the number of tankers scrapped. Noteworthy is the fact that, among the 1980 scrappings, 25 ships were of the large crude carrier size (over 150,000 deadweight tons), resulting in a loss of about 3.66 million deadweight tons. Consequently, deadweight tonnage for this tanker class fell 2.2% in 1980.

The following tabulation distributes the world's tanker fleet by country of registry for 1979:

Country	Number of vessels	Deadweight tonnage (thousand tons)
Liberia	887	107,569
Japan	487	32,506
Norway	254	26,703
United Kingdom	348	25,018
Greece	395	22,002
United States	307	15,784
France	124	14,961
Panama	273	12,894
Italy	234	9,323
Spain	122	8,925
U.S.S.R.	470	7,349
Germany, Federal Republic of	64	5,644
Singapore	116	5,564
Denmark	72	5,429
Netherlands	62	4,611
Sweden	65	4,220
Other	980	37,378
Total	5,260	345,880

OCEAN FREIGHT RATES

In 1980, two separate patterns emerged relating to ocean freight rates. On the one hand, tanker rates fell significantly when compared with those of 1979. Among the reasons for this were cutbacks in OPEC oil production, reduced consumption resulting from the implementation of conservation policies by many nations and from high oil prices, and a reduction in long-haul crude oil shipments.

On the other hand, 1980 rates for dry cargo increased considerably. At least two factors were responsible for this. First, there were a number of port strikes as, for example, at New South Wales, Australia, where work stoppages and slowdowns were frequent throughout 1980. Second, the strong demand for coal and iron ore, as well as for other mineral and nonmineral commodities, and the concomitant increase in bulk carrier demand placed considerable stress on numerous ports around the world, the facilities of which were incapable of handling the increased shipping loads.

Specific indices for 1980 ocean freight rates may be found in the March, June, and September issues of the 1981 United Nations Monthly Bulletin of Statistics.

PANAMA AND SUEZ CANALS

Owing to the significantly higher level of crude oil and coal shipments passing through the Panama Canal, 1980 was a landmark fiscal year (ending September 30) for the Panama Canal Company. The following table indicates the general traffic condition of the canal, both in terms of the number of vessels transiting the canal and in terms of the amount of cargo moved. Included are mineral commodities and other commodities:

	Fiscal year[1]		
	1978	1979	1980
Number of transits:			
Commercial ocean traffic	12,677	12,935	13,507
Other traffic	1,131	1,427	1,218
Total	13,808	14,362	14,725
Cargo moved (thousand metric tons):			
Commercial ocean traffic:			
Mineral commodities	83,614	90,082	99,481
Other commodities	61,191	66,503	70,418
Subtotal	144,805	156,585	169,899
Other traffic	304	370	403
Total	145,109	156,955	170,302

[1]Year ending September 30 of that stated.

Shipments of petroleum and petroleum products accounted for 28.3% of all cargo shipments. The sharp rise in Alaskan North Slope (ANS) crude oil shipments moving through the canal accounted for a 10.6% increase over that of the previous year in the level of shipments for total canal seaborne movement of the commodity group. ANS crude petroleum shipments totaled 22.5 million metric tons, reflecting a 40% increase over that of 1979. In 1980, 35.9 million metric tons of crude petroleum moved through the canal, 5.4 million metric tons more than the amount shipped in 1979. Shipments of petroleum products amounted to 12.2 million metric tons in 1980, reflecting a decline of 6.8% relative to those of 1979.

In 1980, 17.3 million metric tons of coal and coke were carried through the Panama Canal, an increase of 22.3% over that of 1979 and the highest shipment level in 5 years. The aforementioned Australian coal strike was, in large part, responsible for the rise, as shipments from the U.S. east coast to Japan increased in order to satisfy Japanese demand for coal.

Iron and steel semimanufactures were the largest nonfuel mineral commodity class carried, accounting for 10.2 million metric tons.

The following tabulation distributes mineral commodity trade through the canal during 1978-80 by major group:

Commodity group	Thousand metric tons		
	1978	1979	1980
Metals:			
Ores and concentrates:			
Bauxite	1,414	1,184	1,243
Chromite	134	160	107
Copper	696	508	634
Iron	1,600	1,163	1,748
Lead	117	144	136
Manganese	314	485	625
Tin	63	55	50
Zinc	685	739	664
Other and unspecified	1,383	1,524	2,013
Total	6,406	5,962	7,220
Ingots and semimanufactures:			
Aluminum	100	280	328
Copper	838	895	1,003
Iron and steel [1 2]	11,478	10,763	10,173
Lead	147	120	78
Tin[1]	160	141	94
Zinc	157	98	143
Other	244	234	217
Total	13,124	12,531	12,036
Nonmetals:			
Borax	465	462	466
Cement	369	309	177
Clays, fire and china	266	423	416
Fertilizers	8,059	9,350	9,953
Salt	853	931	713
Sulfur	1,277	1,481	2,380
Other[3]	398	798	511
Total	11,687	13,754	14,616
Mineral fuels:			
Carbon black	84	154	182
Coal and coke	11,093	14,111	17,281
Petroleum:			
Crude	32,843	30,478	35,911
Refined	8,377	13,092	12,235
Total	52,397	57,835	65,609
Grand total	83,614	90,082	99,481

[1]Tinplate is included under tin in source publication.
[2]Includes a category identified simply as "scrap" in source publication, which may include scrap other than iron and steel scrap.
[3]Includes slag, clinkers, and dross.

For greater detail on mineral movements through the Panama Canal, the reader is directed to the Panama Canal Company Annual Report series.

At the Suez Canal, a total of 20,363 vessels transited the canal in 1979, a decrease of 903 vessels relative to 1978 transits (down 4.2%), but in contrast, the tonnage passing through the waterway increased from 248,260,000 tons to 266,171,000 tons (up 7.2%). Of the total number of vessel transits, tankers accounted for 2,698, a figure 8.4% above that of 1978. The net tonnage credited to tankers increased by 16.7% from 73,924,000 tons in 1978 to 86,278,000 tons in 1979. The following tabulation indicates the distribution of tankers by number, direction, net tonnage, and status (loaded or in ballast):

Direction	Number		Net tonnage (thousand metric tons)	
	1978	1979	1978	1979
Southbound:				
In ballast	1,049	1,026	48,176	55,913
Laden	400	518	4,792	6,867
Total	1,449	1,544	52,968	62,780
Northbound:				
In ballast	198	304	2,106	3,886
Laden	842	850	18,850	19,612
Total	1,040	1,154	20,956	23,498

Freighters ranked next after tankers in terms of number of transits and net tonnage, with bulk carriers following in third rank. The following tabulation summarizes transits by these vessel classes:

Vessel class	Number		Net tonnage (thousand metric tons)	
	1978	1979	1978	1979
Freighters:				
In ballast	2,180	1,678	11,049	8,422
Laden	9,541	8,884	63,472	60,958
Total	11,721	10,562	74,521	69,380
Bulk carriers:				
In ballast	386	343	5,282	5,673
Laden	2,127	2,050	31,501	30,717
Total	2,513	2,393	36,783	36,390

Source: Suez Canal Authority.

In terms of goods transited in a southbound direction on the Suez, 81,919,000 tons were shipped in 1979, a 2.2% increase over the 1978 figure of 80,128,000 tons. Of the 1979 total, oil and oil products totaled 8,970,000 tons, an 86.3% increase over the 1978 figure of 4,816,000 tons. This increase was due to a doubling in the quantities of kerosine and diesel oil. In 1979, 916,000 tons of metal and ores were carried southbound through the Suez, a 42.1% drop from the 1978 level of 1,581,000 tons. Southbound coal shipments transiting the Suez amounted to 192,000 tons in 1979, compared with 272,000 tons in 1978.

With regard to northbound movement of commodities through the Suez, 78,730,000 tons were carried in 1979, a 13.1% increase over the 1978 figure of 69,597,000 tons. Of the total northbound 1979 commodity volume, crude oil and oil products accounted for 27,284,000 tons or 34.7%. This constitutes a 3.8% decline from the 1978 figure of 28,363,000 tons. Northbound metals and ores moved on the Suez increased from 7,203,000 tons in 1978 to 9,906,000 tons in 1979, a surge of 37.5%. Finally, whereas 1,543,000 tons of northbound coal and coke

transited the Suez in 1978, 2,201,000 tons did so in 1979.

PIPELINES

Limitations of time and space preclude a comprehensive assessment of international pipeline activities. Major projects in individual countries are treated within the individual country chapters.

PRICES

Comprehensive data on world prices for crude minerals and mineral products are not available; tables 15, 16, and 17 summarize major nonferrous metal prices in the United States, the United Kingdom, and Canada, respectively, for 1977 to 1980, inclusive, with monthly data provided in each case for 1979 and 1980. The general upward trend of 1978-79 for these metals in all three markets that was noted in the previous edition of this chapter was clearly broken in 1980. Aluminum registered a modest increase across the year in the United States, while generally trending downward across the year on the London market. Copper prices reached record peaks in all three markets in February of 1980 and thereafter generally turned downward, with a brief sharp upturn in July, and as the year closed, fell to levels below the 1979 average. Lead prices generally trended downward from January 1980 until August or September when there was a brief upturn, followed again by declines through yearend. Lead's comparison metal, zinc, recorded increases generally in the first quarter, followed by declines until July or August, and then modest upturns through yearend (except in London, where there was a sharp decline in December). Tin prices in both the United States and London reached their 1980 high in March and then, with some minor fluctuations, trended gradually lower until December, when they dropped very sharply in both markets.

In the case of silver, January 1980 was the month of the record silver price within any recent period of history, with the monthly average price topping $38 per troy ounce in all three markets. The decline set in February, although the monthly average for that month in all three markets still topped $30 per troy ounce, then moved down to little better than $24 in March, $14 to $15 in April, and $12 to $13 in May. During June to October, silver prices again edged up to a little above $20 per ounce, but then fell again in the last 2 months. Although there is no detailed presentation in this chapter on the fluctuations in the price of gold, it is worthy of note that on January 21, 1980, the price of gold reached a record high on reputable world markets for recent historical time—$875 per troy ounce in New York. As with the illogically high silver prices of early 1980, however, the decline rapidly set in and by March was under $500 per ounce, a level that was touched again briefly in late summer.

Some approximations of oil prices appear in the U.S. Department of Energy's 1980 International Energy Annual. That publication lists 15 types of crude oil for which it quotes prices as of January 1. At the start of 1980, these prices ranged from a low of $25.20 per barrel for one Venezuelan crude to a high of $34.50 per barrel for a Libyan crude; as of January 1, 1981, the selling price for the Venezuelan crude had been increased nearly 30.5% to $32.88 per barrel, and the Libyan crude, still the most costly, increased 18.2% to $40.78 per barrel. The smallest increase for any of the crudes listed was a 19.6% growth for an eastern Ecuadorian crude oil, but its price was already very high at the start of the year. Crude oils from Nigeria, Algeria, and the United Kingdom all showed price increases during 1980 exceeding 30%. Readers interested in greater detail on crude oil prices and/or in information on foreign petroleum refinery product prices are referred to the aforementioned Department of Energy publication.

STATISTICAL SUMMARY OF WORLD PRODUCTION AND TRADE OF MAJOR MINERAL COMMODITIES

The final 24 tables of this chapter (tables 18-41) extend the statistical series on production that was started in the 1963 edition of the International Area Reports volume of the Mineral Yearbook and was subsequently updated and expanded in the 1965 and

1967-79 editions. They are primarily a supplement to other statistical data within this chapter, but also serve as a summary of international production data for major mineral commodities covered in greater detail, on a commodity basis, in volume I of the 1976 Minerals Yearbook and on a country basis in the balance of volume III.

In this edition, the data presented in these tables, in most instances, correspond with the data in the individual commodity world production tables appearing in volume I and may differ somewhat from a total that might be obtained by adding figures presented for any single commodity in each of the country chapters of volume III. This apparent disparity results from problems of scheduling compilation of tables in the numerous commodity and country tables in the two volumes. In an effort to provide the user with the most up-to-date information possible, data received after completion of worldwide commodity production tables have been included in many of the individual country production tables. Limitations of time, however, have prevented the incorporation of these revisions in the abbreviated versions of the world commodity tables included here. Thus, a more precise figure for total world production of any commodity could be obtained by adding figures presented in the individual country chapters. For summary purposes, however, it is felt that tables 18-41 of this chapter are sufficiently correct without the inclusion of these generally minor revisions.

The series of data on world trade in major mineral commodities that has appeared in most previous editions of this chapter (tables 57-69 in the 1976 edition) could not be included for a third time owing to scheduling problems. It is hoped that these tables will be resumed in the 1981 edition.

[1]Supervisory physical scientist, Geographic Statistics Staff, Branch of Foreign Data.
[2]Foreign mineral specialist, Geographic Statistics Staff, Branch of Foreign Data.
[3]For commodities included, see table 3 of this chapter.

Table 2.—Geographic distribution of world crude mineral production value, by country

Country	Value of production[1] (million 1978 U.S. dollars)			Country's share of total[2] (percent)			Country's rank among world producers[3]		
	1950	1973	1978	1950	1973	1978	1950	1973	1978

XX Not applicable.

[1]Values are as reported in source except that the value assigned therein to Puerto Rico has been added to that for the United States, and the values assigned therein for Abu Dhabi, Dubai, and Sharjah have been combined under the heading United Arab Emirates.

[2]Percentages are as reported in source except for the inclusion of that for Puerto Rico with that for the United States and for the summation of the percentages for Abu Dhabi, Dubai, and Sharjah under the heading United Arab Emirates. Some percentages differ slightly from percentages calculated from corresponding value data in this table because of rounding value data.

[3]Rankings are as reported in source except for the adjustments necessary to correspond with the grouping of Abu Dhabi, Dubai, and Sharjah under the heading United Arab Emirates.

[4]Includes Puerto Rico.

[5]Includes allowance for production in the Kuwait-Saudi Arabia Partitioned Zone.

[6]Values and percentages derived by difference between the sum of figures for individually listed countries above and totals reported in source; for this reason percentages given may not be calculable from listed values.

Table 4.—Value of world export trade in major mineral commodities[1]

(Million U.S. dollars)

Commodity group	1975[r]	1976[r]	1977[r]	1978[r]	1979
Metals:					
All ores, concentrates, scrap	14,367	15,692	15,803	16,484	23,400
Iron and steel	45,757	44,700	46,688	57,155	70,706
Nonferrous metals	18,691	21,546	24,126	27,554	36,920
Subtotal	78,815	81,938	86,617	101,193	131,026
Nonmetals, crude only	6,228	6,279	6,994	7,723	9,631
Mineral fuels	169,533	199,625	220,933	223,203	332,684
Total	254,576	287,842	314,544	332,119	473,341
All commodities	872,959	989,162	1,123,445	1,298,585	1,638,392

[r]Revised.

[1]Data presented are for selected major commodity groups of the Standard International Trade Classification Revised (SITC-R) and as such exclude some mineral commodities classified in that data array together with other (nonmineral) commodities. SITC-R categories included are as follows: All ores, concentrates, and scrap—SITC Div. 28; iron and steel—SITC Div. 67; nonferrous metals—SITC Div. 68; nonmetals (crude only)—SITC Div. 27; and mineral fuels—SITC Div. 3. Major items not included are the metals, metalloids, and metal oxides of SITC Group 513; mineral tar and other coal-, petroleum-, and gas-derived crude chemicals of SITC Div. 52; manufactured fertilizers of SITC Div. 56; and nonmetallic mineral manufactures of SITC Groups 661, 662, 663, and 667. Data include special category exports, ships' stores and bunkers, and other exports of minor importance, and exclude the intertrade of the centrally planned economy countries of Asia and trade between the Federal Republic of Germany and the German Democratic Republic.

rRevised. NA Not available.
[1]Source reports that values for European Economic Community (EEC) countries are in terms of "million units of account." For the Federal Republic of Germany (included in EEC in this tabulation), the source indicates that for 1976, 823.1 million "units of account" was equivalent to $885.3 million (no conversion rate given for other countries for 1976 and no conversion rate given for any country for 1977-79, and no further explanation is offered).
[2]European Free Trade Association (EFTA) figures exclude data for Switzerland.
[3]Figures have been totaled as if EEC data were in U.S. dollars, in keeping within totals appearing in a graph in source publication (see footnote 1).

Table 36.—Leading world producers of elemental sulfur[1] —Continued

(Thousand metric tons)

Country	1977				1978				1979[p]				1980[e]			
	Native	From pyrite	Byprod-uct	Total	Native	From pyrite	Byprod-uct	Total	Native	From pyrite	Byprod-uct	Total	Native	From pyrite	Byprod-uct	Total
Other	[r]121	[r]573	[r]1,037	[r]1,731	121	537	1,199	1,857	219	507	1,071	1,797	114	535	1,186	1,845
Grand total	[r]16,476	[r]9,675	[r]26,232	[r]52,383	17,105	9,973	26,870	53,948	17,708	10,110	27,389	55,207	17,710	10,149	28,218	56,077

[e]Estimated. [p]Preliminary. [r]Revised.

[1]Includes all recorded production of sulfur, regardless of the form in which it is recovered. Thus, it includes elemental sulfur, whether mined by conventional methods or by the Frasch process, as well as (1) elemental sulfur and the S content of compounds such as H_2S, SO_2, and H_2SO_4 recovered as a principal product of pyrite mining and as a byproduct of the recovery of crude oil and natural gas and as a byproduct of petroleum refining, coal treatment, and metal smelting and/or refining; and (2) sulfur recovered from tar sands, spent oxides, and other miscellaneous sources. Table includes data available through June 8, 1981.

[2]Entirely Frasch process sulfur.

[3]Includes Frasch process sulfur as follows, in thousand metric tons: Poland: 1977—4,321, 1978—4,546, 1979—4,310, and 1980—4,000; the U.S.S.R. (estimated): 1977—500, 1978—800, 1979—800, and 1980—900; and total of individually listed countries and grand total: 1977—13,080, 1978—13,412, 1979—14,277, and 1980—14,007. The balance is mined elemental sulfur.

[1]Every effort has been made to include only those natural gas liquids produced by natural gas processing plants and to exclude natural gas liquids obtained from field treatment facilities including wellhead separators, because the latter are normally blended with crude oil and thus are included in crude oil output statistics. In some cases, however, sources do not clearly specify whether data presented represent only output of natural gas processing plants or if they include field output. Thus, some of the figures may include field condensate. Table includes data available through Sept. 15, 1981.

[2]In addition to the countries listed, mainland China may also produce natural gas liquids, but available information is inadequate to make reliable estimates of output levels.

The Mineral Industry of Albania

By Walter Steblez[1]

1980 brought to a close Albania's sixth 5-year plan, which was shaped by policies of political nonalinement and economic self-sufficiency, following the breakoff of commercial relations with mainland China.

The country's planned economy registered production increases in 1980, however, only a few industrial sectors were able to meet their planned targets.

Albania's 1980 planned gross industrial output increased 7.1% over that of 1979, but was 30% below the planned goal. Revenues to the state budget, the main source for financing the national economy, increased 3.5%, resulting in a budget surplus of 80,000,000 leks.[2] Capital investment increased by 8.4% in 1980, and a number of industrial projects were completed and commissioned. Among these was the Rehove (Korçë District) copper beneficiation plant with a 2 1/2 year construction time, costing 16,165,000 leks, and with a reported 80,000-ton-per-year of ore capacity. Other projects included the completion of an electric furnace at the Laç copper pyrometallurgical plant; the Memaliaj phosphate processing plant in the Tepelenë District, costing a reported 4,000,000 leks (not including machinery and equipment); the laying of a petroleum pipeline for fuel export and the construction of Ballësh-Fier-Elbasan gas main, and the completion of a metal rolling mill at Kukës. In addition, the first stage of a olivenite refractory brick plant at the Elbasan metallurgical complex and the first stage of the new Prrenjas iron-nickel ore mine, designed to supply the Elbasan complex with ore, were completed.[3] It was reported that during the 5-year construction time of the Prrenjas Mine, in addition to the sinking of the mine shaft, rails and surface buildings, 11,000 meters of workings were constructed.

In the 1975-80 period, geological prospecting and exploratory drilling was conducted in 37 commercial ore deposits, constituting a reported 31% to 70% survey and exploration increase in solid minerals over the fifth 5-year plan (1970-75). There was also a 23% increase in the number of mine workings that were drifted in operating mines.[4]

Results of geological survey and exploration work conducted between 1976 and the first half of 1980 were analyzed, and technical studies prepared on nickel-free iron, radiometric assay, and bauxites; the study on polymetals, however, is to be carried over into the seventh 5-year plan period. The sixth 5-year plan survey and exploration activity is said to have determined new commercially viable deposits and corresponding mining sites for chrome, coal, nickel silicate, ferronickel, phosphorites, polymetals, bauxite, precious metals, argil, kaolin, iron, petroleum, natural gas, asbestos, and titanomagnetite.[5] In comparison with the previous 5-year plan period, when only 6 minerals were extracted, this plan period witnessed the extraction of 23 minerals, at 60 mines, of which 35 were reported to be open pits. In the seventh 5-year plan (1981-85), an expansion of Albania's mining industry is forecasted to include nickel-silicate, bauxite, polymetals, bituminous sands, asbestos, and titanomagnetite.

Together with these achievements, serious shortcomings were observed in both geological survey work and mining operations during this time. A lack of qualified technicians and specialists in the geological and mining sectors was a problem endemic to Albania's mineral economy. Professional qualifications of workers and employees in this field were reported to have not met

rated job requirements, and a number of accidents (without specific detail as to traumatism) were attributed to low competence levels of drill operators. Instances were cited in which machinery and equipment were not handled properly and not overhauled according to maintenance schedules at Belqizë (chrome), Burrel (chromë), Pukë (copper), and Rubic (copper) enterprises.[6] To improve the situation, special professional training programs have been instituted at various geological enterprises to upgrade drillers, equipment operators, miners, and other workers.

The best exploratory drilling results during the sixth 5-year plan, were achieved for ferrochrome at Tirana and Korçë, and for copper at Rubic, Pukë, and Kukës.

The overall volume of transportation in 1980 increased 4.4% over that of 1979, of which the volume of rail freight movement increased 9.9%. During this period, construction work proceeded with the help of young volunteers on the 22-kilometer Laç-Lezhe leg of the Laç-Shkoder Railroad project, designed to link the country's copper mining and copper processing areas. Furthermore, it was reported that construction started at a new port facility at Vlore. It is to have a 4,000,000-ton-per-year cargo handling capacity and is to be completed in 1985.

Government Policies and Programs.—In 1981, the gross industrial output is set to grow 7.2%; budget revenues are to increase 9.1%; total investment is to increase 5.8%; freight transportation is to grow 8.8%; industrial labor productivity is to increase 2.8%; and construction and installation work is to increase 4.9%.

In 1981, construction work will continue on the 600-megawatt Koman hydropower station on the Drin River; the "Steel of the Party" metallurgical complex in Elbasan; the new chrome and copper beneficiation plants at Diber, Pukë, and Midrite; and on the Laç-Shkoder Railroad. Plans call for the mining sector to make improvements in the utilization of mining equipment and beneficiation technology, and to reduce ore losses and dilution. In the petroleum sector, greater emphasis is to be placed on geological, geophysical, and seismological developments to raise drilling efficiency and increase discovery of new hydrocarbon reserves. Petroleum production is planned to increase 19% over that of 1980, which is to be based on further capital outlays for exploration, as well as on further development of recently discovered petroleum deposits.

The 1981 plan also provides for increases in coal output and electric power generation. The mechanization of coal mines is to be increased, and losses during extraction are to be significantly reduced. Furthermore, the 1981 plan requires improvement in the utilization of existing capacities in the chrome and steel industries.

PRODUCTION

In 1980, Albania produced more chrome ore, coal, blister copper, steel, rolled stock, and pig iron; more machine building industry products; and more electric power than in 1979. Domestic coke for nonferrous metallurgy was also produced for the first time. The 1980 planned output for petroleum, coal, and chrome ore, however, was not met.[7]

Currently, Albania has eight beneficiation plants: Three for copper, two for chrome, two for coal, and one for iron-nickel; plans are urgently being formulated for the design and construction of facilities for treating bauxite, polymetals, asbestos, and other minerals. Future Albanian plans also call for placing greater emphasis on the recovery of associated components. For example, complex copper-bearing ores are claimed to contain cobalt, sulfur, arsenic, zinc, selenium, tellurium, and precious metals in sufficient quantities to warrant their extraction during ore processing. At present, not all of these components are extracted, and greater effort is being extended to upgrade the technology for extracting the rest.

In 1980, 70% of the copper ore, 20% of the chromium ore, and 40% of the mined coal was beneficiated. Although coal extraction increased during the sixth 5-year plan, its treatment is unsatisfactory: Approximately 60% of the yield is consumed as uncleaned run-of-mine coal, thus reducing its caloric potential by 20% to 40%.[8]

Production shortfalls are generally attributed to the following factors: Labor shortages and a lack of skilled labor, the low quality of some of the domestically produced machinery and equipment, and construction bottlenecks.

In Albania, the material production labor force comprises approximately 87% of the total industrial labor force, and 16.3% of the total are involved in auxiliary work. In a number of mining enterprises, however, one-third to one-half of the workers are auxiliary, creating conditions for lower labor productivity at the enterprise level. The

mining industry also suffers from absenteeism, a problem that appears to plague the country's entire industrial work force. During the first 9 months of 1980, Albania's industrial losses, because of unjustified absenteeism, were 93,000 work days, or an average of 500 workers per day.[9]

Given significant world market price increases for imports of machine tools and producer durables, a number of complaints have been made concerning production waste and the low quality of Albania's domestically produced durable goods, including mining machinery. Steel conservation in the machine-building sector is described as an "unsolved problem," with the coefficient of steel utilization in the general range of 55% to 70%. The 1980 overruns for fuel and raw materials at machine-building enterprises were extensive and only 40% of the set standards for material and energy usage were met.

Construction bottlenecks also have had a detrimental impact on production. Considerable idle time and inefficient usage of bulldozers and excavators were alleged. Instances were reported where the work front was not prepared in advance, and machinery had to be transported to the work site at great expense and loss of time; such problems were reported to have occurred a number of times at the Belqizë chrome beneficiation plant.[10]

Timely delivery of cement presented further difficulties for the construction sector. For example, the Elbasan cement plant experienced both a lack of raw materials for cement production and transportation for delivery, which in both cases caused production stoppages at the cement plant and delays at construction sites.

Table 1.—Albania: Production of mineral commodities[1]

[e]Estimated. [p]Preliminary. [r]Revised.

[1]Table includes data available through Sept. 21, 1981.

[2]In addition to the commodities listed, a variety of crude construction materials (common clay, sand and gravel, and stone) is undoubtedly produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels. Also, metallic nickel production reportedly began in 1978, but data on the level of production are not available.

[3]Includes petroleum refinery-produced asphalt and bitumen.

[4]Calculated from reported and estimated weight of nickeliferous ore; the amount of cobalt recovered, if any, is conjectural.

[5]Separate data on marketable production are not available, but gross and marketed output are regarded as nearly equal.

[6]Based on estimated tonnages reported in United Nations, World Energy Supplies 1972-76. Statistical Papers, ser. J, No. 21, New York, 1978, 233 pp.

[7]Sums of listed products only; no estimates have been made for other products produced.

TRADE

In 1980, Albania maintained a foreign commercial policy forbidding foreign credit borrowing, joint industrial ventures, mixed enterprises, and similar routine international business transactions, stipulating trade on a bilateral import-export basis only.

During the sixth 5-year plan period (1976-80), Albania increased exports by a total of 33%, or 3% to 4% above the planned level. Processed and semiprocessed commodities accounted for 70% of the total exports, and products such as gas oil, ferrochrome, pyrite concentrate and ore, coal, urea, and newsprint were exported for the first time. The 1980 export plan, however, was not met.

In 1981, the total volume of exports is expected to grow 18%, and during the seventh 5-year plan, exports of petroleum products, electric power, and minerals are planned to increase.

Currently, two-thirds of Albania's import funds are allocated toward the procurement of raw materials and one-third for essential machinery and equipment. The Eighth Plenum of the Party Central Committee of Albania set measures to alter this ratio in favor of reducing purchases of raw materials and increasing imports of machinery and equipment to upgrade domestic industrial output.[11]

In 1980, Yugoslavia remained Albania's principal trading partner, with a reported $170 million turnover. Trade between the two countries is extensive and, in part, consists of Albanian exports of chromium ore, petroleum, asphalt, copper wire, sulfur, gasoline, electric power, and consumer goods in exchange for steel strip, steel wire, cable and sheets, pipes, ferrous and nonferrous metals, transportation and communication equipment, and consumer goods. However, in light of the strained political atmosphere created by episodes of national irredentism of Kosovo's (Yugoslavia) Albanian population, the further development of Albanian-Yugoslav trade relations faces an uncertain future.

Among Albania's other trading partners in 1980 were Austria, which imported copper in exchange for paper and steel, and Romania, which imported Albanian oil in exchange for oilfield equipment. In 1980, Albania was reported to have held talks with Spain regarding the possible purchase of Albanian chrome ore and ferrochrome and a reported 1,700 tons of hot coil was imported by Albania from Spain. Also, Albania was reported to have purchased a merchant mill to expand its facilities at the Elbasan metallurgical complex in 1980 from the Italian manufacturer Danieli. During 1980, the United States continued to export low-volatile bituminous coal to Albania in exchange for chrome ore.

As part of its 1981 foreign trade plan, Albania signed an agreement with Turkey calling for imports of industrial goods and agricultural produce in exchange for chemical products; its trade agreement with Czechoslovakia calls for imports of vehicles and machine tools in exchange for agricultural produce and consumer goods. A 1981 trade agreement with Poland calls for Albanian import of mining machines and equipment, electrotechnical equipment, metallurgical installations, automotive industry products, coking coal, rolled products, refractories, and other goods in exchange for asphalt, chromium ore, cables and copper conduits, agricultural produce, and consumer goods.

COMMODITY REVIEW

METALS

Chromite.—In 1980, Albania remained the world's third largest producer of chromite, with 15 operating mines. Production of chromite has been growing steadily over the sixth 5-year plan, although the 1980 production plan was not met.

Albanian ore is mainly exported at a current 42% Cr_2O_3 average grade level. The chief importers of Albanian ore are Yugoslavia, the Federal Republic of Germany, Poland and Romania. Domestic consumption is small, but steadily increasing: Chromium ore is used chiefly for refractories and ferrochrome production.

With the breakoff of commercial relations with mainland China, Albania found itself short of skilled personnel, which had a negative impact on the general economy including the chromium industry. In recent years, the chromium content of Albania's exported ore decreased from 51% to an average 42% to 43%.[12]

Marketable Albanian ore is generally viewed as a less expensive product in respect to metal content and having lower freight rates. However, assays occasionally have differed substantially from contract specifications. Reportedly, buyers are permitted to make quayside preshipment inspections and have often been provided with high-graded samples of ore differing markedly from the rest of the consignment.[13]

This policy has led to a wide variety of comments from consumers, ranging from *caveat emptor* to high marks for good quality. Since chrome ore is the country's chief source of foreign exchange, Albanian sources have expressed concern regarding chrome ore quality by calling for improved grading of ore and for the reduction of ore dilution to assure its marketability. Significantly, average annual mine losses of chromite amount to 10% to 15%.

Furthermore, in 1980 the construction of a new chrome beneficiation plant was begun at Belqizë.

Copper.—The copper extraction and processing industry with beneficiation, smelting, and refining facilities is one of the more developed branches of Albanian mineral industry. In 1980, Albanian copper products designated for export consisted of 85% refined and 15% blister copper, and the planned output for the industry in 1980 was fulfilled. These achievements did not prevent criticism of the industry for high-grading rich ore deposits, leaving 15% to 20% of the reserves unmined and out of reach of mining machinery and, consequently, raising production costs. The smelting of unbeneficiated copper ore was also criticized because this resulted in the loss of pyrite which might have been used to manufacture sulfuric acid. For this reason, emphasis is being given for the expansion of the industry's beneficiation capacity. Apart from the newly commissioned concentrator at Rehove, the construction of a beneficiation plant at Pukë, scheduled to go on-stream in 1980, is to continue in 1981.

Iron Ore (Nickeliferous).—In 1980, Albania mined a little over one-half million tons of iron ore, which is primarily used to supply the Elbasan metallurgical complex. The ore contains sufficient quantities of nickel and cobalt to warrant extraction by means of recently expanded capacities at this facility. With the completion of the second stage of Prrenjas Mine and achievement of its full capacity, the output of nickeliferous iron ore is expected to increase 2.5 times compared with the sixth 5-year plan output levels. However, if full production capacities are to be achieved, significant improvements in the efficiency of mining operations will be required; currently mining losses of iron-nickel ore are in the range of 26% to 30% for the industry.

Iron and Steel.—In 1980, production increases were reported for pig iron, steel, and rolled stock. Expanded facilities included a second blast furnace, a second coking battery, a rolling mill, and a refractory plant at the Elbasan complex. Although Albania, in past years, expanded its variety of steels, it nevertheless did not produce all of the grade steels required by the machine-building industry, thereby necessitating imports of steel and equipment. In 1980, Albania reportedly began producing ferrochromium at Burrel and offering some of it on the international market.

NONMETALS

Cement.—The Albanian cement industry, located at Elbasan, Fushe-Kruje, Shkoder, Tirana, and Vlore, in the western part of the country, did not meet the 1980 production plan. Production delays were attributed to snags in raw materials delivery and

transportation.

Fertilizer Materials.—In 1980, Albania put onstream a phosphate rock grinding plant in Memaliaj (Teplenë District), for the production of fertilizer. Although unspecified phosphorite reserves were discovered during the sixth 5-year plan, currently all raw material supplies are imported from Algeria and Egypt, and are used in fertilizer production at the 30,000-ton-per-year Durres superphosphate plant. In addition, nitrogenous fertilizer is manufactured at the Fier urea plant.

MINERAL FUELS

In 1980, Albania remained self-sufficient in energy production and was a net exporter of hydrocarbons and electric power.

Hydroelectric power provides Albania with 80% of its electricity requirements, with only 20% of the country's hydroelectric power potential utilized in 1980. With the completion of the Fierze power station on the Drin River in 1979, work continued on the 600-megawatt Koman hydropower station in 1980—the third of the projected five hydroelectric power stations on the Drin River. In view of Albania's efforts to develop a domestic aluminum industry, hydroelectric power is to play a significant role in its economic development during the seventh 5-year plan.

Table 4.—Albania: Estimated total primary energy balance, 1979 and 1980

(Million tons of standard coal equivalent)[1]

	Total primary energy	Coal (lignite, anthracite, bituminous) coke	Crude oil and petroleum products	Natural and associated gas	Hydropower
1979:[2]					
Production	3.77	0.72	2.30	0.49	0.26
Imports	.12	.12	--	--	--
Exports	.18	.01	.10	--	.07
Apparent consumption	3.71	.83	2.20	.49	.19
1980:[2]					
Production	3.65	.79	2.06	.49	.31
Imports	.12	.12	--	--	--
Exports	.19	.01	.10	--	.08
Apparent consumption	3.58	.90	1.96	.49	.23

[1]1 ton of standard coal equivalent (SCE)=7,000,000 kilocalories. Conversion factors used are: Lignite, 0.7; crude oil, 1.47; natural gas, 1.33 (per 1,000 cubic meters); hydroelectric power, 0.125 (per kilowatt-hour).
[2]Estimates based on data from various Albanian sources.

Source: United Nations—World Energy Supplies. Statistical papers, Series J, No. 18, 1976.

Coal.—In 1980, the Memaliaj (Teplenë District) and the Mborje-Drenova (Korçë District) coal mines underwent expansion and modernizaton, and the development of five new mines was commenced in the Tirana, Pogradec, Korçë, and Kolonja Districts. This was part of an effort to meet a planned coal output increase of 25%. However, owing to shortages of labor and other unspecified problems, only 40% of the coal production plan was met in 1980. Coal mine losses in 1980 amounted to 20%.

Natural Gas.—New unspecified gas deposits were claimed to have been discovered in 1980. Gas is consumed domestically by the chemical sectors of the economy and by thermal electric power generating units. Albania's current estimated natural gas reserves are under 12 billion cubic meters.

Petroleum.—Albania's petroleum industry not only failed to meet the 1980 plan target, but also produced crude at about twice the 1960 level or under 1.5 million tons per year, which falls significantly below previous output estimates. This industry has been negatively affected by a lack of skilled labor, shortages of refinery capacity, and spare parts for drilling equipment. Many of the old oilfields are nearing depletion and are contributing only 0.25% of the total crude output, and the planned 19% production increase in 1981 is expected to be met by increasing production from newer fields as well as by putting onstream recently discovered reserves.

The Mineral Industry of Algeria

By Suzann C. Ambrosio[1]

The hydrocarbon sector continued to dominate the mineral industry and fuel the Algerian economy during 1980. Petroleum and natural gas accounted for approximately 40% of the total gross domestic product (GDP), estimated at $36 billion in 1980.[2] Mining and manufacturing comprised nearly 15% of the GDP, with iron, steel, and fertilizers representing the leading industries. Other minerals produced, including cement, mercury, lead, and zinc, continued to be significant in the development of Algeria's heavy industries.

Algeria was the third largest crude oil producer and the largest natural gas producer in Africa during 1980. Only 4% of the Organization of Arab Petroleum Exporting Countries' total oil production was contributed by Algeria. Although production of liquefied natural gas (LNG) was stable between 1977 and 1980, the ratio of exports to production declined throughout the period. Algeria's proven gas reserves were the fourth largest in the world. The natural gas reserves, estimated at 105 trillion cubic feet, were equivalent to nearly two-thirds of the country's proven hydrocarbon reserves. Crude oil reserves were projected to last less than 20 years even though phased production cuts of 10% to 15% were expected to occur in subsequent years.

Petroleum production has apparently peaked, and future rates of economic growth were expected to hinge on the exploitation of natural gas resources and development of the agricultural sector. The new 5-year plan, 1980-85, envisioned a growth rate of 8.2% for real GDP, with industry growing at 12% to 13% per year and agriculture growing at 4% per year. Although the Algerian Government does not publish GDP statistics, 1980 estimates compared with 1979 were reported to have increased 18% to $36 billion for nominal GDP and increased 5% to 1.9 billion for real GDP, measured in constant 1974 prices.[3] The decline in the growth rate of real GDP in 1980 reflected the decrease in crude oil production.

Over 95% of the Government's current revenues were derived from petroleum exports. During the period between 1973 and 1979, revenues increased nearly fivefold to $13 billion. Hydrocarbon export receipts increased over 50% for the second straight year in 1980, and provided 90% of the country's foreign exchange earnings. In December 1980, crude oil was priced at $37 per barrel and the interim natural gas price was $4.60 per thousand cubic feet. Algeria's trade surplus increased to approximately $2.3 billion in 1980, despite the sustained growth in imported goods and services. The 1980 rate of growth of goods and services at 1979 prices was 50%, where food product imports increased by 45% and capital goods rose by 33%.

The new 1980-85 development plan projected investments worth $104 billion over the entire period. Hydrocarbon exports were expected to be capable of financing 60% of the country's 1981 budget, which was approved at $21.7 billion. Although a large share of the allocations were expected to continue to be made to industry (36%), agricultural and social programs received greater emphasis in the new 5-year plan. Expenditures for housing and education were expected to increase sharply to nearly one-third of the total budget. Agriculture investments were projected to nearly double the levels in the previous plan. The ratio of expenditures of hydrocarbons to other industries was expected to rapidly decline

from 65% in 1980 to 33% in 1984. This was expected to correspond with a steady increase in the volume of new investments for total industry. Greater attention was given to light industries and infrastructure, with the private sector expected to play a larger role in their development, along with consumer goods, tourism, and retail trade.

In review of the previous 5-year plan, the Algerian Goverment recognized the need to consolidate and improve the efficiency of State-run organizations. New policy initiatives imposed greater financial controls on nationalized industries, including the Société Nationale de Recherches et d'Exploitations Minières (SONAREM), Société Algerienne de Electricité et du Gaz (SONELGAZ), and Société Nationale pour la Recherche, la Production, le Transport, la Transformation, et la Commercialisation des Hydrocabures (SONATRACH). As part of the effort to decentralize Government decision-making, the hydrocabon monopoly SONATRACH was the first among other targeted agencies to be split up.

In May 1980, SONATRACH was trimmed and new companies were formed; Entreprise Nationale des Grands Travaux Pétrolières, Entreprise Nationale de Raffinage et de Distribution des Produits Pétrolières, and Entreprise Nationale des Plastiques et Caoutchouc. The three companies were expected to study and implement petroleum industrial projects; process, distribute, and export oil and gas; and produce and sell petrochemical products. SONATRACH retained responsibility for exploring, producing, transporting, and selling hydrocarbons on the international market. These interim organizations were expected to undergo further decentralization during 1981.

The labor problems associated with the reorganization schemes and the dismissal of many senior officials at SONATRACH since 1979 have adversely affected hydrocarbon and other industrial production. The total number of energy and petrochemical workers was 120,000 during 1980. SONATRACH employment, comprising nearly 80% of the total, was projected to increase to 125,000 by 1984. Work force inadequacies were expected to continue, since training facilities and skills distribution within most of Algeria's industries were deficient.

PRODUCTION AND TRADE

Mineral production in the nonhydrocarbon sector remained stable over the past decade. Major deposits of iron, mercury, lead, zinc, and phosphates and smaller deposits of copper, barite, salt, clays, and rare earths were exploited during 1980. Approximately 60% of the mineral output was consumed locally and an estimated $50 million in foreign exchange was attributed to 1980 nonhydrocarbon mineral exports.

Iron ore, steel, cement, and fertilizer output increased to meet rising domestic demands. Facility expansions planned for and constructed during 1978 through 1980, were primarily responsible for increased production and corresponding declines in the growth of mineral imports. Production capacities achieved at the new facilities were rated beween 40% to 75%. Inadequacies in transportation, storage capacity, and lack of skilled labor adversely affected production and trade in most mineral industries.

Production of crude oil declined by approximately 9.4% during 1980, while the proportions of condensate and other refined petroleum products increased over 1979 levels. The Skikda refinery was completed in August 1980. Algeria's refinery capacity was increased by 300,000 barrels per day and plans were made to expand the facility by another 400,000 barrels per day. The nature of Algeria's light crude was such that various refinery products, such as tar, could not be produced in sufficient quantities and were therefore imported.

Natural gas production declined slightly during 1980 because operations ceased at the largest liquefaction plant. However, less gas was flared and production capacities of liquefaction units were increased overall. The Arzew 3 LNG project was cancelled and a shift in exporting gas in its nonliquefied form to Europe was expected. During 1980, the export capacities for natural gas facilities in place and under construction, were 1,165 billion cubic feet of LNG and 530 billion cubic feet of liquefied petroleum gas (LPG). The Algerian-Italy trans-Mediterranean pipeline when completed was expected to transport an additional 1,518 billion cubic feet of LNG per year.

Petroleum products comprised 97% of Algeria's total exports. Hydrocarbon export receipts in 1980 increased 58% over 1979

levels to nearly $13 billion. The distribution of revenues were: 71.4% crude oil, 10.2% condensate, 12.2% refined products, and 6.2% LNG. Projections for 1981 were estimated to reach $18 billion, with increased revenues expected primarily from natural gas and refined products.

The majority of SONATRACH's investments have been devoted to hydrocarbon activities linked to exports. Approximately 62% of the sector's total investment of $94 billion went to exports and related activities, over the second development period, 1974-79. Exports of LNG during the same interval increased by 17%, while LPG increased by 70%.

The United States imported approximately 486,000 barrels per day of Algerian crude oil in 1980. This was equivalent to 7.2% of the total U.S. crude imports and nearly half of Algeria's production. In addition, the United States had long-term LNG contracts for approximately 1 billion cubic feet per day. U.S. petroleum imports declined however in 1980 because of the LNG pricing disputes. Although Algeria imported grains, mechanical machinery, iron and steel products, and construction and mining machinery, the U.S. trade deficit increased by 33% to over $6 billion during 1980.

COMMODITY REVIEW

METALS

Aluminum.—Construction plans continued to be made for Algeria's first aluminum smelter located at M'Sala. Late in 1980, the Algerian Government and the U.S.S.R. were reported to be ready to build a 140,000-ton-per-year reduction plant.[4] A larger, 600,000-ton-per-year alumina project worth $500 million was proposed as a joint venture between Algeria, Jamaica, and Mexico.

Iron Ore.—The Ouenza Mine doubled the previous year's iron ore output to 2 million tons per year. Production was expected to increase commensurate with domestic demand for steel. Total output from the Ouenza Mines was expected to be exhausted by the El Hadjar steel complex in 2 years. Nearly 5 million tons of iron ore was expected to be required for steel production in 1985.

Feasibility studies and overall project design plans for the Gara Djebelet iron ore deposits, continued to be formulated by Tiajpromexport (U.S.S.R.) and Bechtel Inc. (United States). Production from the Gara Djebelet Mines were expected to significantly contribute to projected domestic iron and steel demands, however, development of the deposits were postponed during 1980.

Iron and Steel.—Expansion of the production line and capacities at the El Hadjar Steelworks continued throughout 1980. The major components of the enlarged cast-iron production facilities included 2 coking workshops with 65 furnaces in each, 2 iron ore agglomeration workshops, and 2 blast furnaces with capacities 400,000 tons per year and 1.4 million tons per year, respectively. The second set of coking works and blast furnaces were expected to be put into service before the second half of 1981. The flat-product process capacity expansions consisted of, Steelworks No. 1 with a capacity of 1.3 million tons per year, a hot-rolling mill of 1.2-million-ton-per-year capacity, and a cold-rolling mill expected to reach 700,000-ton-per-year capacity when completed.

Other improvements included raising spiral pipeworks capacity to 100,000 tons per year, seamless piping to 110,000 tons per year, and seamless pipeworks to 70,000 tons per year. Steelworks No. 2 at the end of 1980, had the capacity to produce 700,000 tons per year of billets used in long products and a 540,000-ton-per-year concrete rolling mill for round wires. A complex of general technical services was organized to coordinate the operations of the various production workshops. The complex utilized electricity and natural gas furnished by SONELGAZ. The Ben Azouz quarry in Skikda provided all the limestone required for the steelworks. Coke, which was previously imported, was expected to be increasingly replaced by the new cokeworks.

Negotiations were underway to construct an additional 2-million-ton-per-year direct-reduction steelwork at Jijel. Originally the Jijel plant was expected to supply semimanufactures to the proposed 900,000-ton-year rolling mill at Moulay Slissen. The mill negotiations were suspended in 1980, but were expected to resume during 1981. The engineering services contract for the Jijel plant was awarded to Tractionnel (Belgium), with assistance expected to be provided by Nippon Steel Corp. (Japan).

Other Metals.—Exploration for minerals in the Hoggar Mountains continued during 1980. Investigations were conducted on possible lead, zinc, tungsten, and uranium deposits. SONAREM selected Cotecna Engineering (Switzerland) as the main contractor to develop uranium mining at Tingaouine. The company was expected to conduct a topographical survey and design infrastructure for a mining town. A U.S. company, A.G. McKee, was contracted to supply a uranium ore processing plant. Tractionnel and Union Minière, two Belgium firms, conducted infrastructure assessments and were expected to supply power and telecommunications systems. The Hoggar uranium reserves, estimated at 25,000 tons, were projected to be capable of supplying 5,400 megawatts of electricity for a total of approximately 30 years. Roughly 1,200 tons of uranium concentrate was expected to be produced by 1984. The projected production level may be difficult to achieve when considering the lack of water and the overall remoteness of the area.

NONMETALS

Cement.—Algeria's public construction corporation, Société Nationale des Matériaux de Construction continued to close the gap between domestic cement production and imports. Despite the raising of annual production to approximately 5.6 million tons by 1980, nearly 1.5 million tons per year of cement still had to be imported. Projects were underway to increase cement production capacity to 12.5 million tons per year. Numerous cement facilities were completed over the past few years and new cement projects were at various stages of completion by yearend 1980.

Fertilizer Materials.—SONATRACH's fertilizer expansion projects at Arzew, Annaba, and Tebassa continued to be constructed during 1980. The first two facilities were expected to raise existing production capacities of ammonia by 630,000 tons per year and urea by 660,000 tons per year. The new Tebassa fertilizer plant and Annaba's expanded facilities were expected to add 330,000 tons per year of phosphoric acid, 280,000 tons per year of triple superphosphate, and 1.1 million tons per year of sulphuric acid. The nitrogenous and phosphatic fertilizer units were expected to be brought online in two phases during 1981 and 1983. The second urea facility for Arzew was still in the planning stage by yearend 1980. Technical difficulties at the Arzew and Annaba plants resulted in output efficiencies of approximately 40%.

MINERAL FUELS

Natural Gas.—SONATRACH operated 109 gas wells and produced approximately 517 billion cubic feet of natural gas in 1980. Two gas treatment modules, two LPG extraction units, and three liquefaction units were also operating during the year. The three existing LNG units had a total annual capacity of 600 billion cubic feet and three larger units were under construction during 1980. The cumulative production of gas as of December 1980 was 3.3 trillion cubic feet, for a level of proven recoverable reserves estimated at over 100 trillion cubic feet.

Natural gas comprised 29% of Algeria's total energy consumption in 1969, and a decade later, consumption nearly doubled to 54%. During the same period, total domestic consumption of energy quadrupled to an equivalent of 108 million barrels of oil. The continuing trend of increasing natural gas production and replacing oil by natural gas to meet domestic demand was expected. Applications of natural gas were expected to be broadened from mostly industrial projects to residential use.

Numerous long-term natural gas supply contracts were signed over the past few years, and renewals were negotiated during 1980. High crude oil prices stimulated demand in the LNG market. Algeria subsequently entered into price negotiations that would nearly double the rates accepted in previous agreements. SONATRACH attempted to raise the export price of LNG to a parity level with crude oil f.o.b. Arzew; The price was to be raised to $6.11 per thousand cubic feet or million British thermal units (Btu). When considering transportation and regasification costs, the proposed U.S. cost for Algerian natural gas would be equivalent to nearly $8 per thousand cubic feet. Due to a failure to reach a compromised natural gas price, LNG shipments to the United States through the El Paso contract were halted in April 1980. The El Paso contract comprised 1% to 1.5% of the total U.S. supplies during 1980.

[2]Foreign company share of expenditures.

Construction on the trans-Mediterranean pipeline continued during 1980, and negotiations were taking place between SONATRACH and Italy to expand the pipeline's annual capacity from the originally designed 423 billion cubic feet to 637 billion cubic feet. The initial agreement called for a total of 10.4 trillion cubic feet over a 25-year period, with deliveries of 438 billion cubic feet per year beginning late in 1981. Algeria's projected cost was $702 million for a pipeline 550 kilometers long, running from Algeria's Hassi R'Mel fields to Oued Safsaf on the Tunisian border. In addition, Algeria would pay $266 million or one-half the cost for the 158-kilometer-long underwater section from Cap-Bon, Tunisia, to Sicily. The expansion scheme would require a fourth 50-centimeter underwater line, and a second Italy-Algeria gas pipeline, which would connect with an existing network in the Alps.

Whether or not the pipeline is put into operation will depend on adjusted gas price agreements. The large investments required for increased gas exports hinged on assured price development and depended on the Algerian Government maintaining control over supplies and exploitation of the wells.

Petroleum.—Algeria had 1,015 oil wells, 4 refineries, 2 petrochemical complexes, and several plastic processing units operating in 1980. Proven crude oil reserves were estimated at 8.2 billion barrels and refining capacity increased to approximately 150 thousand barrels per day. The oil equivalent of recoverable gas reserves were 2.5 times the proven reserves of crude. Cumulative production at the start of 1979 was 5.4 billion barrels of crude oil and 153 million barrels of condensate.

Oil consumption during 1980 was estimated at 123 million barrels and represented 21% of the 575 million barrels produced.[5] Domestic demand for crude oil and refinery products were projected to comprise 30% of the total production by 1990 and 77% by 2000. The increasing percentages primarily reflect a planned production cutback over the decade.

Exploration efforts were ambitious and a $3 per barrel surcharge applied to oil exports in the first half of 1980 financed the drilling of approximately 20 to 30 wells. Over the past decade, little was discovered in Algeria's huge sedimentary basins, measuring 1.5 million square kilometers. Agreements signed with foreign companies have generally been in difficult access and high-risk areas, resulting in less than 1/16 exploration of the sedimentary basin. In 1980, there were 11 partnership agreements with 15 foreign companies. Greater incentives were expected to be offered to foreign investors through the granting of larger exploration tracts and improved contract terms.

During the first half of 1980, eight explo-

ration deals were concluded. The agreements obliged SONATRACH to repay its share of the expenditures if commercial production was to be established. SONATRACH assumed total control of operations during the development-production phase, and the foreign partner's share of production was subject to Algeria's statutory tax and royalty payments. Nearly 50,000 square kilometers were expected to be explored under the new contracts, at an estimated total cost of nearly $700 million.

The Mineral Industry of Angola

By George A. Morgan[1]

In 1980, despite continued unstable conditions in part of the country because of the ongoing civil war, the mineral industry showed some signs of progress. Exports of crude oil gained in value by 138% to $2 billion,[2] due in large part to oil price increases. Angola became the fifth leading producer of oil in Africa. The major portion of Government revenue was from oil exports, which also provided a favorable balance of trade.[3]

Revenue from the sale of oil was being channeled into infrastructure development. Port congestion was experienced in Luanda because of the large volume of imports. Vessels were delayed in offloading 100,000 tons of merchandise, and 64,000 tons was confined to warehouses. Most of the material was new machinery and parts.

Changes in the 1979 investment code permitted the participation of foreign interests, particularly in oil exploration and exploitation. Private firms were also permitted to qualify as importers in 1981 provided that application for such was received by March 1981. Previously only state-owned enterprises were allowed import rights.

PRODUCTION AND TRADE

Production data for the mineral industry continued to be generally unavailable with output of most commodities estimated on the basis of limited information. Diamond output continued to increase, although investment requirements were rising because of declining ore grade. The Government concentrated its efforts on increasing the return from the energy sector and to that end granted exploration and production sharing rights to a number of companies, mainly for offshore areas. Reestablishment of iron ore production was proposed, apparently from the Cassinga area in the south of the country. Angola, Zaire, and Zambia, although in agreement on measures to renovate the Benguela railroad, continued to be hampered by the reluctance of major mining concerns to send exports over the line because of security risks. Iron ore development at Cassinga, located south of the Benguela line, would presumably also be subject to similar security problems.

The supply of electricity to Huambo, Benguela, and Bie was interrupted for an extended period, ostensibly owing to a shortage of rainfall. However, the backup powerplant near Biapio was also out of service because of damage from unspecified causes.

Although official trade data continued to be unavailable, Western nations accounted for most of the value of trade. Commercial trade with France alone amounted to about $89 million in 1980, and contracts totaling over $220 million were also signed between the two countries.

[1]Table includes data available through Sept. 29, 1981.

[2]In addition to the commodities listed, a variety of crude construction materials (clays, sand and gravel, and broken stone) presumably is produced for local consumption, but information is inadequate to make reliable estimates of output levels.

[3]Reported figure.

COMMODITY REVIEW

METALS

Iron Ore.—The creation of a national iron company was planned following decrees in late 1979. All assets and rights of Companhia Mineira do Lobito, S.A.R.L., which owned and operated the Cassinga Mine, and Companhia do Manganes de Angola (CMA), which owned and operated iron mines at Cassala, were nationalized. Austromineral, a subsidiary of Voest-Alpine A.G., was to conclude studies regarding the exploration of additional high-grade iron ore reserves at Cassinga as well as at Cassala. Initial rehabilitation of Cassinga was planned for 1981 and would involve extraction and treatment of 2 million tons of crude ore. Iron ore reserves at Cassinga were estimated at 100 million tons of eluvial hematite grading 62% to 64% iron and 2 billion tons of itabirite-type ore. The Cassala-Quitungo magnetite deposits contained 92 million tons of ore grading 32% iron. Earlier plans for developing the Cassala-Quitungo deposits involved the production of 4 million tons of ore to yield about 1.8 million tons of concentrate grading 67.5% iron for pelletization.

Manganese.—Little information has been available on the manganese industry in Angola. Reported production from thin, tabular, steeply dipping surface ore bodies in the vicinity of Salazar and Nova Lisboa peaked in the early 1950's at about 70,000 tons per year. Output was adversely affected by low manganese prices and difficulties in locating markets because of high silica and sulfur content. Most production was by CMA from the Salazar area, where about 48 million tons grading 44% to 56% manganese existed. Output was estimated to have been nonexistent since 1973. In 1980, the Government nationalized CMA because of the company's poor financial condition. Al-

though there have been some reports of manganese ore finds, nothing has been realized in terms of development.

NONMETALS

Cement.—In 1980, only about 56% of the 720,000 tons per year cement production capacity was utilized. Old equipment, lack of spare parts, and limited financial resources were cited for the poor showing. Government planning called for production of another 650,000 tons by yearend 1982. The increased output was to be made possible by a $36 million loan agreement with Danish interests. Refurbishing the Luanda cement plant as well as improving the ship loading facilities were part of the agreement. Because of limited local demand, exports were expected to increase to about 336,000 tons from the current level of several thousand tons per year. Plant capacity would also increase to 1.26 million tons per year by the addition of a fourth kiln. No time frame was reported for installation of the kiln.

Diamond.—Production of diamonds increased but continued to be well below planned output levels and was still well below the 2.4 million carats achieved in 1971. A new washery costing $1.5 million was inaugurated in the Lucapa mining areas of Luanda Norte Province. The new washery will allow a production increase of about 14,000 carats from the Camagico Mines.

Nearly all diamond mining was by mechanized methods except in the Audrada area. About 2.8 million cubic meters of gravel were treated in 1979 compared with a planned 3.7 million cubic meters. Actual output in 1979 was well below the planned 1.2 million carats. Failure to meet planned production levels was attributed to a shortage of qualified personnel and a lack of accessories and parts for washeries and machinery. Increased financial commitments were required to expand diamond output because of declining ore grade. Additional expenditures for equipment and machinery were required both for continued exploration and for additional washeries to treat larger amounts of low-grade material.

Phosphate Rock.—The indentification of potentially exploitable phosphate rock deposits in Angola was recorded as early as 1949, and the existence of coastal phosphate formations was known much earlier. Phosphate resources were located in several areas including the Calinda area, at Quindonacache, near Luanda, and at the mouth of the Cunene River. Several exploration concessions were granted and plans actually made for exploitation of the Cabinda phosphates by Ammoniaco Portuguese. However, no production has occurred in Angola. In 1980, the Government formed the Phosphate Extraction Co. (Fosfang) to mine phosphate at Quindonacache in Zaire district. Bulgareomina of Bulgaria was contracted to mine the deposits totaling 200 million tons. Initial output of 30 tons per day was to commence June 1981 with a total employment of 500 people.[4]

MINERAL FUELS

Petroleum.—The Government placed heavy emphasis on its petroleum sector, which was a significant source of foreign exchange. Production for 1981 was expected to increase about 8% from a level of 164,000 barrels per day in 1980. Direct Government investment in the industry was estimated at $150 million. About two-thirds of the total output of crude oil was from Cabinda by Gulf Oil Co. and Sociedade Angolane de Combustiveis de Angola.

A number of international oil firms were interested in exploration and production in Angola. Several firms were negotiating for exploration blocks offshore central and southern Angola.

Texaco Angola Prospeccão e Pruducas (Teipac) S.A.R.L. was developing the Essungo Field. A production platform with a capacity to handle 20,000 barrels per day along with 23 miles of marine pipeline was under construction. Construction was to be completed by mid-1981, with output planned at 17,000 barrels per day by yearend 1981. The Government requested that uses be found for associated gas production rather than the current practice of flaring.

Petrobas of Brazil signed a contract with Sonangol for oil exploration offshore Angola. Crude oil sales to Brazil were to be increased 25%. Exports to Brazil in 1980 were 2.5 million barrels of crude oil.

The Luanda crude oil refinery achieved a record throughput of 1,224,000 tons in 1980, up 8.5% from the previous year's throughput.

The Mineral Industry of Argentina

By Pablo Velasco[1]

Over the last 25 years, Argentina's economic development has fluctuated between periods of rapid growth and stagnation. In 1980, Argentina's gross domestic product (GDP) declined between 1.0% and 1.5% to $127 billion[2] at current prices. The inflation rate declined for the first time since 1974, but still remained high at over 87%. Agricultural production in 1980 declined 3%, while manufacturing output fell 4%. In contrast, mining production was up 2%, services 15%, and construction 4%. The aluminum industry and oil refineries registered high production. Capacity utilization in the entire industrial sector averaged only 50%. The steel industry output declined 11% in 1980, compared with the 1979 output. The mineral industry of Argentina, with the exception of minerals fuels (petroleum, natural gas, and coal), represented less than 1% of the GDP in 1980. Exports of industrial minerals, including products for the construction industry, also have increased in volume and value. Aluminum exports rose by 40%, or 67,000 metric tons, compared with 1979 exports.

The Argentine Government is considering building a second aluminum smelter at Río Gallegos in Santa Cruz Province, taking advantage of the abundant energy resources (natural gas, coal, and later hydroelectric power). The cost of the project will be approximately $800 million, and output is predicted to be 100% for export. The Comisíon Nacional de Energía Atómica (CNEA) reported that uranium oxide reserves increased 6% in 1980 to 28,000 metric tons. Several contracts have been signed to mine several uranium deposits in Córdoba, Mendoza, and most recently in San Luis. CNEA's $10 billion 20-year nuclear power program calls for the installation of six nuclear power units by the year 2000, which will provide 3,400 megawatts of nuclear generating capacity. Argentina intends to sign an arrangement with Brazil for offering nuclear systems to the rest of Latin America.

Argentina has abundant natural gas reserves, which could be exploited for another 50 years. A good start in providing the greatly expanded pipeline network needed to bring this gas to consumption centers was made in 1980. Additional pipelines will eventually be constructed to exploit deposits in Salta and Jujuy, making it possible to export natural gas to Paraguay, Uruguay, and Brazil. Argentina continued as the third largest producer of crude oil in Latin America with new discoveries of oil offshore in the southern sea basin.

Yacimientos Petrolíferos Fiscales (YPF) and Gas del Estado were active in exploration and expansion of production of petroleum and natural gas. Argentina is already 95% self-sufficient in oil.

Total electric power generated in Argentina in 1980 increased 8.1% to 35.8 million megawatt-hours. The breakdown in electric power sources in 1980 and 1979 follows, by percent:

	1979	1980
Thermal energy	59.8	51.2
Hydroelectric	32.0	42.2
Nuclear	8.2	6.6
Total	100.0	100.0

Nuclear power capacity at this stage remained unchanged with only the Atucha I nuclear reactor in operation. The Embalse and Atucha II nuclear powerplants were still under construction.

Government Policies and Programs.—The Mining Promotion Law No. 22,095, issued in October 1979, aims at reaching the full and sustained development of mining by enlarging tax benefits contained in former laws, for both promotion in general and special promotion. The law contemplates benefits for both national and foreign investments. Special benefits provided by the law to mining companies include reduction of the profits tax, the tax on capital, and the tax on net worth, for not more than 51 years from the start of production, on a scale ranging from 100% to 10%; exemption of taxes and duties on imports of equipment, accessories, and spares necessary for the execution of the project; and loans from the Mining Promotion Fund for research and exploration. Up to 80% of the amount of the loan may be written off should the exploration prove to be unsuccessful. These loans are to be granted preferentially to small- and medium-size mining firms with Argentine ownerships. Certain benefits are also provided for investors who invest in mining operations. The reforms to the Mining Code, which entered into force on November 29, 1980, have different purposes. One refers to an adjustment to the present system which grants the property rights of the mines to the discoverer prior to exploration. The reformed mining code also updates the amount of capital to be invested as a condition for the concession. Larger concessions to explore will be granted. Two chapters are added to the Mining Code empowering the national state, with the prior agreement of the respective Provinces, to call for international tenders for the exploration and exploitation of large mining areas or deposits discovered by the state. The Argentine Mining Code has adopted the system of concession for royalties, which was instituted in America by the Spanish colonizers in the 18th century. Under the reforms to the Mining Code, the following metals are transferred to the first from the second category: Molybdenum, lithium, potassium, sulfur, and borates. Asbestos, bentonite, and zeolite are transferred from the first to the second category. The maximum exploration area is increased from 2,000 to 10,000 hectares, and the maximum duration of permits is extended from 300 to 1,100 days. Those exceeding 300 days will suffer area reductions. The possession of deposits in the first category is increased from 6 to 100 hectares. The investment of a minimum fixed capital as a condition for the concession is left to the criterion of the concessionaire or owner of the mine, instead of being fixed by mining authorities. In any case, the investment may not be less than 500 times the annual royalty corresponding to the mine according to its category and the number of units. Should the mine have been completely inactive for more than 4 years, the authorities may demand the submittal of a plan for reactivating the mine under penalty of losing the concession. The concessionaire will have 5 years to perform the different stages of the project.

Now that the revised code has become operative, no time is being lost in seeking foreign expertise, technology, and equipment to explore and develop Argentina's mineral resources. The Department for Promotion of Mining of the Mining Secretariat has defined a number of metal-mineral deposits as being of special interest, and these are being offered to national as well as international groups. (More details on this matter are given under Commodity Review—Copper.)

PRODUCTION

Output from the mining industry in Argentina during 1980 was at the level of the past several years. The country produced enough nonmetallic minerals to meet domestic demand but continued to import large tonnages of iron, manganese, bauxite, chromium, and coal.

The modest amount of metallic minerals produced included copper, lead, zinc, iron ore, manganese, uranium, gold, and silver. The steel industry output declined 11% in 1980, and was strongly affected by the high rate of exchange of the peso against the U.S. dollar. A number of small steelmakers, notably Aceros Ohler S.A., have gone out of business. Aluminum production from the smelter at Puerto Madryn increased 9.1% to 138,000 metric tons in 1980. Argentina ranks third in production of cement in Latin America, after Brazil and Mexico. Production of cement in Argentina in 1980 was the largest in the past 10 years. Installed capacity for the entire industry in 1980 was 9.8 million metric tons per year, and production reached 7.0 million metric tons, a 7% increase over that of 1979. Yacimientos Carboníferos Fiscales, the Government-owned coal company, re-

ported that production of coal from Río Turbio declined by 46% owing to lack of local demand, mainly from the steel industry, and to the increase in imports from the United States and Poland. Argentina continued as the third largest producer of crude oil and natural gas in Latin America with new discoveries of oil offshore near the Strait of Magellan and at the Neuquén Gasfields.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through June 26, 1981.

[2]In addition to the commodities listed, cadmium, lime, and perlite are produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

[3]Reported figure. It should be noted that although most of these figures are officially reported, they are of a preliminary nature, subject to substantial revision.

[4]Hot-rolled semimanufactures only; excludes castings and cold-rolled semimanufactures produced from imported hot-rolled semimanufactures.

[5]Revised to none.

[6]Includes plastic, semiplastic, and/or ferruginous clays used totally in the manufacture of portland cement.

TRADE

For the first time since the present military government took power, Argentina's trade surplus disappeared, giving way to a deficit estimated at approximately $2.4 billion. This deficit was caused by the rapid growth of imports stemming from the programed reduction of tariffs and the stagnation of exports caused by the maintenance of an overvalued peso consistently lagging behind the domestic inflation rate. Total export value rose 3% from $7.8 billion in 1979 to $8.06 billion in 1980, while the total import value rose from $6.7 billion to $10.4 billion, a 55% increase. Higher international prices were the main factor accounting for the rise in export value. According to statistics published by the Secretaría de Estado de Minería and the Secretaría de Estado de Energía, exports of minerals, mineral products, and metals in 1980 earned a record high of $71.2 million, an increase of 104% compared with 1979 values.

The volume of mineral exports increased 6.1% to 114,200 metric tons. Exports of metallic minerals in 1980 increased to 55,000 metric tons, or 102%; the value of these exports increased to $37.2 million, or 164%. Exports of minerals were mainly concentrates of lead, zinc, tin, and silver. Exports of aluminum rose 40% to 67,000 metric tons. Exports of nonmetallic minerals declined 70%. Exports of petroleum products and residual coal in 1980 were valued at $266 million, a substantial increase compared with $51 million in 1979.

Petroleum imports during 1980 increased 26% to 16 million barrels. Imports of petroleum products, natural gas, liquefied gas,

and mineral coal in 1980 were valued at $1.06 billion 5.2% less than in 1979.

YPF, the State oil company, purchased 60% of Argentina's imported oil in 1980 from Saudi Arabia and Iraq. The remainder was imported by private firms and from other sources. Gas imports from Bolivia increased 12% to 73.6 billion cubic feet in 1980. Argentina's main fuel import from the United States in 1980 was bituminous coal, valued at $26 million.

COMMODITY REVIEW

METALS

Aluminum.—For several years Aluminio Argentino S.A.I.C. has operated a 140,000-ton-per-year aluminum smelter at Puerto Madryn based on local hydroelectric power. The Argentine Government in a recent international aluminum congress held in Madrid, Spain, announced that a second multibillion-dollar project to build up a new aluminum industry in the south of the country is being planned based on local

hydroelectric resources that are estimated at up to 6,000 megawatts. The Argentine Government was expected to call for prequalifying bids in early 1981 for the construction of a 140,000-ton-per-year aluminum smelter and related infrastructure costing $800 million. The smelter output would all be exported. Argentina's present Puerto Madryn smelter can cover local demand for some time to come. Current demand is 70,000 to 80,000 tons per year. The Government is looking for foreign investors to develop the massive hydroelectric resources of the Santa Cruz River. Initially, the proposed aluminum installation would use natural gas and coal, which are available locally, but it would use hydroelectric power once generating capacity was installed (taking about 10 years). Suggested locations for the aluminum smelter installation are the ports of Río Gallegos or Puerto Santa Cruz.

Production of primary aluminum during 1980 increased 9%, while exports rose 40% to 67,000 tons.

Copper.—Of great significance to the future of Argentina's mining industry is the massive El Pachón porphyry copper deposit under development by the St. Joe Minerals Corp. Drilling has revealed approximately 800 million tons of mineralization averaging 0.67% copper and 0.016% molybdenum, together with minor gold values. Further work on the project had been delayed pending the issuance of a new Argentine Mining Promotion Law. This law has now been enacted and has given St. Joe a basis for negotiating with the Government the terms for full development of El Pachón. The project involves a fully integrated operation to produce 100,000 tons per year of electrolytic copper (at a mining rate of 35,000 tons per day), 350,000 tons per year of sulfuric acid; 1,700 tons per year of molybdenum concentrate; and 200 tons per year of anodic bars with values in silver, gold, selenium, and tellurium. At this rate of annual production, the verified reserves insure a minimum life of 43 years. The estimated cost to build and start the El Pachón complex is $1,400 million. St. Joe's operating company, Cía Minera Aguilar S.A. (CMA), has withdrawn as the principal financier but is desirous of retaining management of the project. Other major mining companies and the State have been invited to participate in this project in San Juan Province. Latest projections, assuming all tentative investment commitments are met, envisage startup of production in late 1984, reaching a full-capacity production of 1,000 tons per day of concentrate by mid-1985.

Three of Argentina's largest known copper and precious metal deposits will be tendered in early 1981 to private international and local companies under provisions of the code. The Bajo de la Alumbrera copper-gold deposits in Catamarca Province and the Famatina copper-molybdenum deposit in La Rioja Province will be tendered internationally. The Farallón Negro Mine (gold, silver, and manganese) in Catamarca will be offered to a local firm, which may be formed with up to 40% foreign capital: The Bajo de la Alumbrera prefeasibility study made by Kaiser Engineers Co. of the United States summarized the outstanding aspects of the project study as follows: The reserves are estimated at approximately 450 million

tons; the overall grade of 0.85% equivalent copper corresponds to an average grade of 0.56% copper, plus 0.68 gram per ton of gold, 2.5 grams per ton of silver, and 0.08% molybdenum; the La Alumbrera deposit has a favorable geographical situation near the Farallón Negro project and other potential copper deposits of the same type and has access to railways and roads. In the project, the most favorable operative stage compatible with reserves and needs of the country, is the production of 60,000 tons of electrolytic copper per year. For this production it is necessary to treat 12 million tons per year, or 37,000 tons per day, of ore. The byproducts would be approximately 8 tons of gold, 10 tons of silver, 220,000 tons of sulfuric acid, and 500 tons of molybdenum concentrate per year. The estimated reserves indicate that exploitation may last from 25 to 30 years.

The Famatina copper-molybdenum deposit has been under exploration by the Mining Secretary of State since 1975. A drilling program is underway to determine its economic feasibility. In 1978 Fabricaciones Militares joined the exploration committee formed by the Province and the Mining Secretary of State. Drilling results obtained to date are encouraging. In the mineralized levels, molybdenum disulfide exceeds 0.06% and under extreme conditions reaches 0.1%. Copper grade levels range between 0.2% and 0.5%.

Iron Ore.—The iron and steel industry made a new advance in 1979 with the startup of iron ore and pellet production from the Sierra Grande magnetite deposits in Río Negro Province. Iron ore reserves published by the operating company, Hierro Patagónico S.A., amount to 139 million tons (proven) and 124 million tons (probable), averaging 55% iron and approximately 1.4% phosphorus. Production for 1980 was 710,000 metric tons compared with the initial output of 611,000 metric tons in 1979, increasing ore stocks to 3 million tons. The concentrator produced 581,000 metric tons of concentrate and 350,000 metric tons of pellets averaging 68% iron and 0.17% phosphorus. Pellet production commenced in June 1979, and the first 30,000 tons was shipped through Puerto Buitrago in September. A pellet production of over 2 million tons is projected for 1981.

Other production of iron ore is derived from mines at Nueve de Octubre (Jujuy) and Unchime (Salta) for the Zapla smelter; reserves were estimated at 700 million tons. Output amounted to approximately 500,000 metric tons per year. Imports of iron ore to satisfy the steel industry required a $75.9 million expenditure in 1980. According to Argentine expansion plans for the steel industry, iron ore requirements will grow as shown below, in million tons of iron ore and million U.S. dollars:

Year	Total demand (million tons)	Domestic production capacity (million tons)	Imports required (million tons)	Estimated total value of imports (million U.S. dollars)
1980	4.5	2.2	2.3	75.9
1985	6.6	2.2	4.4	145.2
1990	8.7	2.2	6.5	214.5

Iron and Steel.—Crude steel output in 1980 declined 12%. Pig iron output decreased 5.0% compared with 1979 levels. Sponge iron production increased slightly (2.0%). There were two operating direct-reduction facilities in Argentina, ACINDAR S.A. and Dalmine-Siderca S.A.I.C.; both used the Midrex process and natural gas fuel, and both produced billets used in electric arc furnaces.

ACINDAR S.A., Argentina's largest private sector steelmaker, has an annual capacity of 462,000 metric tons of sponge iron (93% iron) per year. ACINDAR is currently uprating its No. 2 rodmill. When the expansion is completed in late 1981, ACINDAR's Nos. 1 and 2 rodmills are expected to have a combined output of 900,000 metric tons per year.

Dalmine-Siderca S.A.I.C., part of the Italian Techint Group, has a annual capacity of 330,000 metric tons of sponge iron. No expansion plans have been reported. Siderúrgica del Sur (SIDERSUR), a consortium of Argentine minimills, has signed a letter of intent with Hojalata Y Lamina (HYL) (Alfa Group) of Mexico for a direct-reduction plant to be built on one of two coastal sites south of Buenos Aires, depending on studies on the availability of natural gas. The consortium plans to install a 500,000-metric-ton-per year HYL III continuous direct-reduction plant. The plant could be in operation by late 1983.

Japan's involvement in Argentina's Sociedad Mixta Siderúrgia Argentina (SOMISA) project may be frozen following the breakdown of talks over the supply of Japanese equipment for a hot strip mill at the plant. Japanese companies earlier

agreed to invest $30 million in the project, and $20 million was to come from Japan's Overseas Economic Cooperation Fund and the Export Import Bank; however, there are indications that this funding is dependent on the satisfactory conclusion of the contract for the hot strip mill. The Federal Republic of Germany is also involved in funding $800 million worth of German equipment. The Argentine Government was expected to request $125 million worth of Japanese equipment and had asked Japan to install not only its own equipment but also the German equipment. The collapse of negotiations between Argentina and Mitsubishi Heavy Industries Inc., Mitsubishi Corp., and Ishikawa-Jima-Harima Heavy Industries Co. could mean that the agreement on Japanese financing will be delayed. SOMISA plans to raise raw steel capacity from 2.7 million tons to 4 million tons per year.

Table 5.—Argentina: Iron and steel production

(Thousand metric tons)

Year	Pig iron	Sponge iron	Crude steel[1]	Hot-rolled steel			Cold-rolled steel
				Total	Nonflats[1]	Flats[1]	Flats[2]
1975	1,042	--	2,300	2,196	1,404	792	760
1976	1,288	8	2,406	2,004	1,244	760	712
1977	1,100	285	2,678	2,356	1,323	1,033	871
1978	1,435	390	2,780	2,205	1,370	835	795
1979	1,114	803	3,197	2,593	1,576	1,017	870
1980[e]	1,068	816	2,808	2,036	1,376	660	648

Lead, Silver, and Zinc.—CMA, St. Joe's subsidiary, which has operated since the 1930's, produced 73,200 tons of zinc concentrate and 43,900 tons of lead concentrate containing 1.7 million troy ounces of silver compared with 80,700 tons, 42,500 tons, and 1.7 million troy ounces, respectively, in 1979. CMA's higher profitability in 1980 was due primarily to higher silver prices and sales from inventory. Driving of a new adit (tunnel) at Aguilar to facilitate ore extraction and to gain access to mineralization at lower levels continued in 1980. The lower tunnel should be completed in 1982 and is expected to reduce ore and material handling costs.

Manganese.—Within the mining property of Yacimientos' Mineros de Agua de Dionisio, located in the Belén Department, Catamarca Province, there are two types of ore mineral deposits: Very long and strong veins (Farallón Negro, Alto de la Blenda), and an area of hydrothermal alteration with a disseminated mineralization (Bajo La Alumbrera, El Durazno, San Lucas, etc.). At the Farallón Negro area the estimated reserves are: 801,400 tons (proved) with 9 grams per ton of gold, 161 grams per ton of silver, and 15.9% manganese with 500,000 tons of probable reserves.

At the area of hydrothermal alteration, suitable for leaching with possibilities for open pit mining, proved reserves amount to 355,000 tons with 3 grams per ton of gold, 72 grams per ton of silver, and 12.2% manganese. The Alto de la Blenda discovery in the Farallón Negro area has 3 million tons of indicated reserves, grading only 8.7% manganese, with gold and silver values. The current work schedule of the project involves the processing of 350 tons per day of ore, with a production of 25,000 tons per year of manganese concentrate containing 38% manganese, 19,870 troy ounces of gold, and 80,400 troy ounces of silver.

In 1980, production of manganese declined 5%. Consumption of manganese in steelworks and ferroalloy plants continued high and was estimated at 76,000 tons per year, most of which has to be imported.

NONMETALS

Cement.—Among the many important construction projects during 1979-80, the following were outstanding. Cementos Loma Negra S.A. invested $32 million in the Olavarría plant, to expand capacity to 500,000 tons per year. In 1980, the company set up a new cement plant in Catamarca Province at a cost of $60 million.

Juan Minetti S.A. initiated the construc-

tion of a new $150 million cement plant in the locality of Puesto Viejo, in the Province of Jujuy, with an annual capacity of 720,000 tons. This company started its activities in 1932 under the name of Compañía Sudamericana de Cemento Portland Juan Minetti e Hijos Ltda. S.A., and has since expanded its production capacity steadily.

Production of cement in Argentina increased 5.6% in 1980, exceeding 7 million tons, and was the largest output in the last 10 years. The five portland cement production areas in the country follow:

Production area	Installed annual capacity (thousand metric tons)	Production (thousand metric tons)	
		1979	1980
Buenos Aires and Neuquén	5,785	4,453	4,729
Córdoba and Entre Ríos	1,967	1,199	1,129
Mendoza and San Juan	710	574	522
Catamarca, Santiago del Estero, and Salta	1,224	341	536
Chubut	163	135	142
Total	9,849	6,702	7,058

Boron Minerals.—Several studies were made on borate deposits in the Provinces of Jujuy and Salta by the Government of Jujuy, including the deposits known as La Angelina, La María, La Leonor, La Miguela, La Teresa, Las Afortunadas, and Demasía Federico, and the group of deposits known as the Salta Group located in the Guayatayoc Lake in the locality of Tumbaya and Cochinoca in Jujuy Province.[3] Production of borates in Argentina increased 4% in 1980.

Fluorspar.—The Mining Secretariat has approved a new development project for fluorspar in Guanaquinto, Chubut, which will be investigated for 14 months by Puerto Lobos S.A. In accordance with the new mining legislation, the Government will assume 80% of the exploration risks. The Government also granted a loan for a fluorspar prospecting venture at the María and Facundo Mines in Santa Cruz Province. This loan of $541,000 was granted to Construcciones, Estudios y Proyectos S.A., which must finish excavation and drilling and provide samples within 19 months. Fluorspar production in 1980 increased 10%.

Sulfur.—In 1978, Argentina imported $5.2 million worth of sulfur for the manufacturing of fertilizer. The last production of sulfur on record in Argentina was 17,771 metric tons of concentrates derived from Caliche in 1978, before main production centers in Mendoza and Salta were shut down because of high production costs. From 1979 to date, the total domestic consumption of sulfur has been imported. A great amount of the imported sulfur is utilized in manufacturing sulfuric acid. Sulfur imports are expected to decrease when the new copper projects are in production.

MINERAL FUELS

Coal.—In 1980 production of run-of-mine coal decreased 31%, or 436,463 metric tons, while output of salable coal after beneficiation decreased 46%. Coal transported by rail from the mines at Río Turbio, where 99% of Argentina's known coal deposits are located, to the port of Río Gallegos amounted to 308,436 metric tons, a 42% decrease. The following table shows the breakdown of sales of coal produced at Río Turbio during 1980, in metric tons:

Consumer	Quantity
Agua y Energía Electria	198,183
SEGBA (Buenos Aires Electric Co.)	83,708
FF. CC. A. (railroad)	2,018
Exports to Uruguay	650
Buenos Aires	3,549
Río Gallegos (port)	11,844
Río Turbio (mine site)	8,484
Total	308,436

Imports of bituminous coal in 1980 amounted to about 922,000 tons valued at $73 million. Most of the coal imports (84%) were from the United States, with the balance from Poland (9%), and elsewhere (7%).

Natural Gas.—The Inter-American Development Bank granted a loan of $87 million to Gas del Estado (the State gas company) for the construction of the General San Martín gas pipeline (planned to begin operation in early 1981) to transport Tierra del Fuego gas, which until now was either reinjected or flared. The pipeline consists of three sections. The first section,

about 100 kilometers in length, joins the production area at San Sebastían in Tierra del Fuego with Cabo Santo Espíritu at the southern entrance to the strait of Magellan; the second section, 37 kilometers long, is an underwater arc joining the north of the island with Cape Vírgenes, at the extreme continental end of Santa Cruz; and the third section, 40 kilometers long, runs from Cabo Vírgenes to the compressor plant at El Cóndor, where it joins the Austral pipeline to Buenos Aires.

While this work was in progress, Gas del Estado enlarged the compressor plant at Pico Truncado, installed a new one at San Julían, and carried out various accessory works for the General San Martín pipeline, thus increasing the injection and transport capacity of the Austral pipeline. Similar work was carried out on the North pipeline to increase gas volumes from Bolivia and the north.

The General Cerri petrochemical plant was completed in 1980 and is of outstanding importance to the Argentine economy, because it will handle 18 million cubic meters per day of natural gas from which high-quality gases will be extracted. General Cerri will provide about 300,000 tons of liquid petroleum gas per year, and the estimated savings are about $120 million.

The Center West gas pipeline, approximately 1,100 kilometers long, was under construction. The line will transport natural gas under toll charges from the Neuquén Basin, at the Loma de la Nata Field, to the consumption centers of the Provinces of Mendoza, San Juán, San Luís, and Córdoba, the littoral area, Santa Fé, and the Buenos Aires area at a rate of 5 million cubic meters per day in the first stage, at 7 million cubic meters per day 1 year after commissioning, and at 10 million cubic meters per day 2 years later. YPF has been granted a $560 million loan from a consortium headed by the Deutsche Genossen-Schaft Bank and Lloyds Bank International to help finance the Center West natural gas pipeline.

The Government has approved a feasibility study for the construction of a $2.5 billion petrochemical complex 400 kilometers north of Buenos Aires. The plant is to be built by Petroquímica San Lorenzo and would be Argentina's first petrochemical plant owned entirely by private interests. Output of the San Lorenzo plant would include 300,000 tons per year of ethylene, 165,000 tons per year of propylene, 107,000 tons per year of butylene and butadiene mixture, and 261,000 tons per year of benzene, toluene, and xylene. Cost of the main cracking plant is estimated at $500 million.

Argentina is to increase its imports of natural gas from Bolivia from 180 million to 230 million cubic feet per day; at the same time the price will go up from $3.44 to $4.06 per thousand cubic feet. An agreement was reached by Argentina and Brazil to study the feasibility of building a pipeline to ship natural gas to Brazil. The project, involving 2,200 kilometers of pipe, would cost $2 billion and involve 10 million cubic meters per day. Gas del Estado and Petroleo Brasileiro S/A of Brazil were to produce a feasibility study before the end of 1981.

The World Bank made a loan of $27 million to Argentina for oil and gas engineering projects in order to support the Government's effort to achieve energy self-sufficiency. The project is the World Bank's first operation in Argentina's hydrocarbon sector.

Proven reserves of natural gas at yearend were estimated at 641.1 billion cubic meters (22.6 trillion cubic feet), up from 600.3 billion cubic meters (21.2 trillion cubic feet) in 1979 and 432.2 billion cubic meters (15.3 trillion cubic feet) in 1978. The notable increase in 1979 was attributed to the discovery of two large fields in Neuquén Province with proven reserves of 314,000 million cubic meters.

Natural gas wellhead injection to pipelines rose 7.5% to 9,871.5 million cubic meters in 1980.

Imports of petroleum, petroleum products, natural gas, liquid gas, and coal amounted to $1.06 billion in 1980 compared with $1.12 billion in 1979, a decrease of 5.4%. The sharpest decrease in imports was in gas and oil, 98%.

Exports of petroleum products and residual coal in 1980 rose to $266 million compared with $51 million in 1979.

Petroleum.—Although crude oil production increased 6.8%, imports of oil reached 16.0 million barrels in 1980 valued at $539 million, or 52% above the 1979 import cost. Secondary recovery is expected to account for 27% of total production in 1983 versus 15% in 1980. The number of operators involved in secondary recovery operations in Argentina rose to 28 from only 6 in 1977. Private rig utilization jumped to 50 units, up 50% from 1977. YPF cut its number of rigs in operation 20%, but increased drilling

productivity.

Argentina has launched an ambitious effort to become energy self-sufficient by the end of the century. That effort involves an increase in the Nation's oil reserves to 6.3 billion barrels by the year 2000 from its current 2.5-billion-barrel reserve level.

Argentina's new incentives in the oil sector have resulted in the growth of private firms and the influx of foreign capital into Argentina. Private operators invested more than $1.2 billion in the Nation's oil and gas development areas during 1978-80. They are expected to produce 44% of total output, or 82 million barrels per year by 1983, up from 36% of the current total.

Twenty-two new operators began operations in Argentina during the past 4 years, as oil production by private companies increased to 62.9 million barrels in 1980 from 37.7 million in 1976. Of the 19 international and 35 domestic firms operating under exploration and development contracts in Argentina, the biggest producers are Amoco Argentina Oil Co., with 30% of private output; Petrolera Perez Companc S.A., 27%; Argentina-Cities Service, 18%; and Bridas S.A.P.I.C., 10%.

Since issuance of Law 21.788 on "risk contracts" in 1978, the exploration of offshore and certain land areas has been undertaken by the private sector. To date, 7 offshore areas and 11 land areas have been tendered, and by March 1981, it is expected that a total of 21 areas will be tendered.

Drilling in a nearby offshore block by a consortium comprising Esso Exploradora Inc., Astra C.A.P.S.A., Petrolera Perez Companc S.A., and C.A.D.I.P.S.A. has been unsuccessful. A third group formed by Total, Bridas S.A.P.I.C., and Deminex S.A. has ordered a jack-up rig from the United States and will soon begin drilling in an offshore block near the Island of Tierra del Fuego. Private contractors have so far bid more than $200 million for exploration rights in four Tierra del Fuego offshore blocks.

The Argentine Government has signed an exploration and production contract covering a 927-square-mile area in west-central Argentina with Union Oil Co. of California. Union plans to drill five wells in a 171-square-mile sector of the area to determine feasibility of a thermal recovery process in a previously discovered heavy-oil reservoir and also plans to make a seismic survey in the rest of the area before beginning exploratory drilling. Union has a 50% interest in the area, which is in the Llancanelo region of the Neuquén Basin, about 25 miles east of Malargue.

An oil-drilling consortium led by Shell Hydrocarbons B.V., discovered oil in offshore coastal waters east of Tierra del Fuego. The well was drilled to a depth of 5,248 feet in 229 feet of water by the Interocean II jack-up rig and initially yielded 5,032 barrels of oil per day. The consortium, comprising Shell Hydrocarbons B.V., Shell C.A.P.S.A., and Petrolar S.A., is expected to drill another 14 wells under its 27-year contract. The group has already invested $50 million of the $160 million earmarked for the exploration phase of the contract.

Uranium.—*Nuclear Energy.*—According to CNEA the proved reserves amount to 28,000 tons of uranium oxide (U_3O_8, yellowcake), an increase of 6% compared with that of 1979. This increase resulted from expanded prospecting by CNEA with the assistance of private companies. A contract has been signed for the exploitation of the Los Gigantes deposit in Córdoba Province in an area that includes three uranium mines with estimated reserves of 1,500 tons of yellowcake. The exploitation of El Tigre I La Terraza zone in Sierra Pintada (Mendoza) is in the final negotiation stage, and operation is expected the first or second quarter of 1983. The country's requirements would then be supplied by these two projects, with an output of 100 tons per year of yellow cake from Los Gigantes and 700 tons from El Tigre I.

Prospecting continues at Los Adobes, near the Chubut River, where drilling has been done on three anomalies with results unknown. A 15-year contract to mine and process uranium ore in San Luis Province has been signed recently with Uranco, an Argentine mining company. The plant will be set up on the mining site to process an estimated 5,000 tons of uranium ore annually. Total production of uranium ore in Argentina has increased 7.5% to 210,877 tons.

CNEA, has announced a $10 billion, 20-year nuclear power program that calls for the construction of six nuclear power units by the year 2000. This will provide Argentina with 3,400 megawatts of nuclear generating capacity by the end of the century, which will account for at least 15% of the country's total electrical energy output. Argentina in 1974 became the first Latin American country to install a 374-megawatt nuclear reactor, Atucha I near Buenos Aires. Atucha I is a heavy-water plant, fueled by natural uranium in a Kraftwerk Union (KWU) West German-designed

reactor. Work is almost completed on a plant with similar capacity at Embalse, near Córdoba. The Atucha I nuclear plant is scheduled to get a twin Atucha II by 1988, which will be built in Zarate Province of Buenos Aires. In 1980, KWU won the contract to build the third nuclear plant, the 682-megawatt Atucha II unit. Two more plants are scheduled for construction in Cuyo and Noa Provinces by 1995 and three more plants may be added to the list by the end of the century. Argentina has 28,000 metric tons of proved reserves of uranium (yellow cake), enough to fuel eight 600-megawatt reactors for 30 years. A contract was awarded for the first commercial-scale, heavy-water production facilities which will be built in Arroyito, Provincia Neuquén to Switzerland's Sulzer Bros. Ltd., and Argentina has committed itself to safety checks on the plant by the International Atomic Energy Agency.

Argentina has already bought and taken delivery of 5,000 metric tons of heavy water (used for moderating and cooling nuclear reactors) from the U.S.S.R., and more will be purchased until the country has its own heavy-water plant in operation. The U.S.S.R. will provide components for future nuclear plants, as well as low-grade enriched uranium.

Argentina was negotiating with Brazil to put together a bidding consortium, based on KWU technology, to offer nuclear systems to the rest of Latin America. CNEA is also forming a joint engineering company with KWU (25% West German, 75% Argentine). Mexico and Chile have expressed active interest in the forthcoming Argentine-Brazilian bidding consortium.

Bolivia and Uruguay are beginning nuclear research programs with the help of Argentina. Argentina has agreed to provide Bolivia and Uruguay with a 10-megawatt research reactor in 5 years, and to train nuclear engineers and technicians. Argentina also has agreed to provide Uruguay with a feasibility study on building a larger scale nuclear reactor in the near future.

Argentina is about to take a further step in developing its nuclear technology by building an experimental plutonium reprocessing plant at the Ezeiza atomic center in Buenos Aires. The plant will be built entirely without foreign assistance.

---

[3]De Los Hoyos, L. The Recoverable Reserves of Boron Minerals in the Lake of Guayatayoc.

The Mineral Industry of Australia

By Charlie Wyche[1]

The overall improved performance of the Australian minerals industry in 1980 exceeded the high level of production and expansion established during 1979. While these improvements were influenced mostly by world conditions, they were also affected by the Federal Goverment's favorable domestic mineral policy, such as investment allowances and various tax concessions. With the Federal Government's approval to develop several new uranium mines, production began at one mine in May and is scheduled to commence at another in late 1981.

Diamond production commenced in 1980, with most of the activity concentrated around the Kimberlite pipes, in Western Australia. The Federal Government's efforts to tax the imputed value of subsidized mine housing resulted in a 10-week strike by Queensland coal workers. Also, in New South Wales, the railways and inadequate port facilities, and frequent industrial interruptions to the operations of these facilities, had a very damaging effect on the mining industry.

In 1980, the value of mine and quarry production was a record $5.8 billion,[2] an increase of 14% compared with the $5.1 billion reported in 1979. The approximately $6.5 billion value added by domestic smelting and other processing of mineral commodities credited the mineral industry with a total production value of $12.3 billion. This figure represents 9.3% of the $132 billion adjusted gross national product in 1980.

The Government has granted authority to the States to raise loan funds for infrastructure. As a result, New South Wales was planning to spend $89 million on improving coal loading facilities at Port Kembla and $200 million on the Eraring electric power stations and associated coal mines by 1983. Queensland was planning to invest over $2 billion in improving its coal loading facilities, expanding the aluminum industry, and in various electric powerplant extensions. Victoria was to spend $350 million on the Loy Yang brown coal powerplant and mine. Tasmania would invest $78 million on further hydroelectric works, and Western Australia was planning to borrow $420 million to construct a pipeline to carry North West Shelf gas to Perth and a further $110 million to integrate the electric power supply in the Pilbara iron mining area.

Private enterprise investment projects in the mining and manufacturing industries during the next 5 years, totaling more than $33 billion, are either ready to proceed or are in final feasibility stages. Expenditure for exploration remained at the previous year's level of $1 billion. In addition, a loan was made to the Federal Government of nearly $100 million to assist financing of infrastructure.

PRODUCTION

Mine output of most of the approximately 70 minerals produced in Australia in 1980 was at or above the level for 1979. The main exceptions were bauxite, alumina, and zinc. Despite a decrease in world steel output in 1980, Australian production of iron ore rose slightly; however, domestic pig iron and crude steel production declined as a result of industrial disputes. For the second time since the Australian aluminum industry

started to grow in the early 1960's, output of bauxite declined. Industrial disputes in the Darling Range, Western Australia, where production declined, and a cutback at Weipa, Queensland, were primarily the reasons for the decline. Mine production of nickel increased by 3%, and higher prices resulted in a 27% increase in export earnings in 1980. Lead production in all categories was down slightly in 1980, and mine production of zinc declined from the record output in 1979 owing to prolonged industrial stoppages. Copper ore and concentrate production declined slightly, but blister and refined copper production rose. This industry has been severely affected by depressed conditions in the market in recent years. As markets for titanium production firmed up in 1980, Australian production of rutile concentrates increased about 8% over the 1979 level. Production of zircon increased significantly as the decrease in Western Australia was more than offset by increased production on the east coast.

Western Australia and Queensland were Australia's largest mineral-producing States, accounting for 38% and 25%, respectively, of the total value of mineral output in 1980. New South Wales ranked third, accounting for 18% of the total value.

Production of the principal mineral-producing States and their respective values were as follows:

State	Minerals produced	Value (millions)
Western Australia	Iron ore	1,040
Do	Alumina (from bauxite).	422
Do	Nickel	227
Do	Petroleum (crude oil).	161
Queensland	Coal	748
Do	Copper	257
Do	Lead	157
Do	Silver	132

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Includes data available through Sept. 29, 1981.
[2]Exports (production not officially reported).
[3]Data are for years ending Nov. 30 of that stated for plants owned by The Broken Hill Pty. Co. Ltd.
[4]Revised to zero.
[5]Western Australia only. Metal content of nickel ore.
[6]Excludes production from Western Australia.
[7]Data are for years ending June 30 of that stated.
[8]Excludes production from Northern Territory and Australian Capital Territory.
[9]Excludes production from Northern Territory, Australian Capital Territory, and Western Australia.
[10]Excludes natural gasoline and liquefied petroleum gas, which are produced on Barrow Island, off the Western Australia coast. An unspecified portion of the liquefied petroleum gas extracted is apparently marketed locally, but this quantity is limited. The bulk of the liquefied petroleum gas and all of the natural gasoline is blended with crude oil and presumably is counted with crude oil from that area. Gross production of liquefied petroleum gas on Barrow Island was as follows, in thousand barrels: 1976—22, 1977—31, 1978—29, 1979-80—NA; and of natural gasoline: 1976—21, 1977—26, 1978—33, 1979-80—NA. Natural gas liquid output from several gasfields in Western Australia is excluded for similar reasons. Condensate production from these fields was as follows, in thousand barrels: 1976—25, 1977—23, 1978—19, 1979-80—NA.
[11]Residual fuel oil equivalent.

TRADE

Mineral commodities supplied 37% of Australia's total export value in 1980. Coal remained Australia's largest export commodity. The value of Australia's exports of coal was $1.9 billion in 1980. The value of iron ore and pellets was about $1.3 billion and the value of alumina was about $1.1 billion. These three commodities represented 24%, 16%, and 14%, respectively, of the 1980 mineral export value. Other large export earners were copper, lead, zinc, mineral sands, gold, nickel, and tin.

The value of mineral imports was about $1.7 billion in 1980; crude oil accounted for about 80% of the total value. The other principal import categories were phosphate rock, asbestos, and diamond.

Table 2.—Australia: Exports and reexports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1977-78	1978-79	Destinations, 1978-79	
			United States	Other (principal)
METALS —Continued				
Lead —Continued				
Metal including alloys —Continued				
Unwrought —Continued				
Refined	138,595	152,240	16,324	India 30,242; Italy 16,416; United Kingdom 15,262.
Other	8,762	10,401	--	Malaysia 3,872; New Zealand 1,448; Philippines 1,262.
Semimanufactures	1,118	2,635	--	Thailand 584; Singapore 425; Philippines 385.
Manganese ore and concentrate	436	424	--	New Zealand 423.
Nickel:				
Ore and concentrate value, thousands	r$8,986	$3,126	NA	NA.
Matte, speiss, similar materials do.	r$185,799	$143,983	NA	NA.
Metal including alloys:				
Waste and scrap do.	NA	$996	$80	United Kingdom $854.
Unwrought do.	r$29,195	$104,188	NA	NA.
Semimanufactures do.	r$19,767	$10,918	NA	NA.
Platinum-group metals including alloys, unwrought and partly wrought[2] troy ounces	64,290	9,999	--	Hong Kong 3,962; New Zealand 2,536; Singapore 1,253.
Rare-earth metals: Monazite, gross weight	7,793	35,493	25,551	France 8,884.
Silver:				
Ore and concentrate[3] value, thousands	$2,673	$7,802	$33	United Kingdom $7,712.
Waste and sweepings[3] do.	NA	$1,539	--	United Kingdom $888; New Zealand $488.
Metal including alloys:				
Refined bullion do.	$16,360	$18,826	$9	United Kingdom $10,446; Japan $6,770.
Other do.	$2,634	$9,200	--	United Kingdom $2,268; Singapore $2,178.
Tin:				
Ore and concentrate, gross weight	20,672	18,027	--	Malaysia 17,741.
Oxides	9	NA	NA	NA.
Metal including alloys:				
Waste and scrap	3,624	940	2	Belgium-Luxembourg 891.
Unwrought	2,821	1,811	--	United Kingdom 1,002; Netherlands 410.
Semimanufactures	374	29	--	New Zealand 18.
Titanium ore and concentrate, gross weight:				
Ilmenite excluding beneficiated ilmenite	1,003,379	892,331	215,595	United Kingdom 186,903; France 123,574; Spain 94,091.
Leucoxene	12,091	10,644	4,200	United Kingdom 5,000; Japan 1,009.
Rutile	318,379	364,121	190,416	United Kingdom 46,529; Japan 28,355; Netherlands 23,460.
Tungsten ore and concentrate, gross weight:				
Scheelite	3,366	4,082	208	West Germany 2,277; U.S.S.R. 739; Sweden 506.
Wolframite	786	1,836	190	West Germany 1,234; Singapore 144; United Kingdom 120.
Uranium and thorium ores and concentrates	7,609	2,012	850	Canada 708; United Kingdom 379.
Vanadium ore and concentrate[4]	88	438	--	Taiwan 157; Indonesia 100; Argentina 100.
Zinc:				
Ore and concentrate, gross weight	417,745	485,726	15,710	Japan 250,091; Netherlands 62,491; Republic of Korea 36,877.
Oxides and hydroxides	323	606	--	Philippines 247; Taiwan 144; Singapore 113.
Slag and residue	5,485	3,476	--	Taiwan 2,199; Republic of South Africa 612.
Metal including alloys:				
Waste and scrap	NA	70	--	Philippines 34.
Unwrought	184,315	194,424	32,425	Taiwan 31,680; Indonesia 24,497; Thailand 19,802.
Semimanufactures	3,717	15,016	--	Indonesia 4,736; New Zealand 3,090; Thailand 2,485.
Zirconium ore and concentrate, gross weight	361,549	450,767	64,465	Japan 160,349; Italy 67,459; Canada 27,145.

See footnotes at end of table.

Table 2.—Australia: Exports and reexports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1977-78	1978-79	Destinations, 1978-79	
			United States	Other (principal)
METALS —Continued				
Other:				
Ores and concentrates value, thousands	$137,534	$139,743	NA	NA.
Waste and scrap containing nonferrous metals	2,388	3,685	--	United Kingdom 3,033; Belgium-Luxembourg 305.
Oxides, hydroxides, peroxides value, thousands	r$10,843	$12,907	$2,610	Taiwan $2,042; Indonesia $1,488; New Zealand $1,261.
Metals including alloys, all forms: Tungsten, molybdenum, tantalum, magnesium	31	201	31	West Germany 55; United Kingdom 53; Netherlands 33.
Unspecified value, thousands	$169	$411	$75	Singapore $246; New Zealand $53.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc do	$65	$1,840	--	Thailand $1,812.
Artificial corundum do	$388	NA	NA	NA.
Dust and powder of precious and semi-precious stones do	r$25	$43	--	New Zealand $18; Hong Kong $16.
Grinding and polishing wheels and stones do	r$391	$1,014	$22	Papua New Guinea $405; Thailand $174.
Asbestos, crude	32,145	38,348	--	Thailand 7,309; India 7,301; Singapore 4,714.
Barite and witherite	1,467	1,002	--	New Zealand 665; Republic of South Africa 160.
Cement	6,914	103,726	32,847	Singapore 44,275; Papua New Guinea 10,727.
Clays and clay products:				
Crude	12,044	9,687	--	United Kingdom 3,395; Japan 2,009; Indonesia 1,967.
Products:				
Refractory including nonclay brick:				
Brick	2,759	7,585	--	New Zealand 3,651; New Caledonia 1,539; Indonesia 831.
Other value, thousands	r$1,452	$1,170	--	New Zealand $488; New Caledonia $140; Singapore $135.
Nonrefractory do	r$395	$831	--	Malaysia $361; Singapore $89; Papua New Guinea $89.
Diamond:				
Gem, not set or strung carats	13,597	16,415	338	Belgium-Luxembourg 4,595; Hong Kong 4,276; Israel 2,312.
Industrial do	297,018	233,684	3,747	Ireland 153,747; Hong Kong 35,000; Philippines 13,008.
Diatomite and other infusorial earth value, thousands	NA	$2	NA	NA.
Fertilizer materials:				
Crude	298,478	121,122	--	Japan 64,000; Republic of Korea 29,400; Malaysia 19,200.
Manufactured:				
Nitrogenous	7,228	8,239	--	New Zealand 5,908; Papua New Guinea 1,645.
Phosphatic	249	2,105	--	Papua New Guinea 1,596; Malaysia 285.
Potassic	33	35	NA	NA.
Other including mixed	787	3,132	--	New Zealand 1,741; Papua New Guinea 1,278.
Ammonia value, thousands	r$195	$471	--	New Zealand $237; Malaysia $210.
Graphite, natural	NA	17	--	New Zealand 10.
Gypsum and plasters	193,750	263,567	--	New Zealand 73,712; Indonesia 60,397; Singapore 32,793.
Lime	37	1,031	--	Papua New Guinea 969.
Magnesite, other magnesium carbonate, magnesium oxide	3,443	3,598	427	New Zealand 2,596; Philippines 270.
Mica, worked including agglomerated splittings value, thousands	r$102	$65	--	New Zealand $43.
Pigments, mineral:				
Natural, crude	53	--		
Iron oxides, processed	28	192	--	New Zealand 125; Indonesia 29.

See footnotes at end of table.

Table 2.—Australia: Exports and reexports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1977-78	1978-79	Destinations, 1978-79	
			United States	Other (principal)
NONMETALS —Continued				
Precious and semiprecious stones except diamond:				
Opal ____ value, thousands	$23,104	$32,417	$4,858	Hong Kong $14,093; Japan $7,285.
Sapphire ____ do.	$7,602	$16,059	$206	Thailand $11,986; Hong Kong $2,083.
Other ____ do.	$2,155	$2,878	$450	Hong Kong $658; Singapore $419.
Pyrite, gross weight	261	347	--	New Zealand 281.
Salt and brines ____ thousand tons	4,154	4,512	--	Japan 3,297.
Sodium and potassium compounds, n.e.s.:				
Caustic soda	301	98	--	Saudi Arabia 46; Western Samoa 22.
Caustic potash, sodic and potassic peroxides	3	18	NA	NA.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked	193	1,086	--	Italy 916; Japan 153.
Worked ____ value, thousands	$138	$32	--	Japan $22.
Dolomite, chiefly refractory grade	20,037	20,119	--	Taiwan 19,957.
Gravel and crushed rock	409	936	NA	Brazil 299; Hong Kong 177; Argentina 150.
Limestone except dimension	NA	11,351	--	Singapore 11,192.
Sand, silica	467,073	657,887	59,997	Japan 471,441; Republic of Korea 102,397.
Sulfur: Sulfuric acid, oleum	120	1,428	--	New Zealand 991; Papua New Guinea 207.
Talc, steatite, soapstone, pyrophyllite	93,104	118,047	--	Japan 97,722; Netherlands 12,059.
Other:				
Crude:				
Quartz, mica, feldspar, fluorspar, cryolite	81	152	--	New Zealand 122.
Unspecified value, thousands	$598	$37,834	$2,251	Japan $16,704; West Germany $7,523; United Kingdom $5,650.
Oxides, hydroxides, peroxides of strontium and barium	8	4	NA	NA.
Slag, dross, similar waste, not metal-bearing ____ value, thousands	NA	$24	--	Malaysia $14.
Building materials of asphalt, asbestos and fiber cements, and unfired nonmetals ____ do.	r$5,359	$11,488	--	Canada $4,552; Taiwan $1,395; New Zealand $1,358.
MINERAL FUELS AND RELATED MATERIALS				
Carbon black	42,799	39,950	--	Thailand 11,517; Indonesia 11,259; New Zealand 6,330.
Coal including briquets:				
Bituminous coal and briquets thousand tons	45,163	39,103	523	Japan 25,739; France 1,958; United Kingdom 1,807.
Lignite, peat and briquets thereof	29,049	52,474	--	Japan 27,314; Norway 12,000
Coke and semicoke	149,435	147,397	--	Philippines 102,649; Greece 28,892.
Petroleum:				
Crude and partly refined thousand 42-gallon barrels	1,324	2,330	463	New Zealand 1,751.
Refinery products:				
Gasoline ____ do.	2,114	2,475	--	New Zealand 1,709; Fiji 384.
Jet fuel ____ do.	r1,833	1,913	--	New Zealand 1,271.
Kerosine ____ do.	r705	530	--	New Zealand 399; Fiji 89.
Distillate fuel oil ____ do.	4,685	5,424	--	New Zealand 1,421; Fiji 798; Japan 604.
Residual fuel oil ____ do.	1,460	1,593	1,053	Panama 384.
Lubricants ____ do.	1,742	1,616	568	New Zealand 252; Singapore 151; Malaysia 143.
Unspecified ____ do.	r20	[5]745	730	NA.
Mineral tar and other coal-, petroleum-, and gas-derived crude chemicals value, thousands	r$8,232	$17,156	--	New Zealand $10,674; Singapore $3,489.

rRevised. NA Not available.
[1]Data are for fiscal years beginning July 1.
[2]Ore and concentrate waste and sweepings are included in those of silver.
[3]May include platinum-group metals.
[4]May include molybdenum.
[5]Excludes an unreported quantity valued at $31,390.

Table 3.—Australia: Imports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1977-78	1978-79	Sources, 1978-79	
			United States	Other (principal)
METALS				
Aluminum:				
Ore and concentrate	11,426	15,634	--	Guyana 8,230; China, mainland 7,358.
Oxides and hydroxides	4,626	8,610	1,845	Japan 4,877; United Kingdom 546; Austria 455.
Metal including alloys:				
Scrap	1,369	1,223	2	New Zealand 1,168; United Kingdom 34.
Unwrought	178	3,392	53	New Zealand 2,925; United Kingdom 385.
Semimanufactures	4,150	5,258	2,520	United Kingdom 819; New Zealand 667.
Antimony:				
Oxides and hydroxides	186	212	6	United Kingdom 144; France 45.
Metal including alloys, all forms	117	29	--	Mainly from China, mainland.
Arsenic trioxide and pentoxide, acid	908	744	--	France 607; Belgium-Luxembourg 71; China, mainland 48.
Beryllium metal including alloys, all forms value	$43,605	$7,848	NA	NA.
Bismuth metal including alloys, all forms	18	25	--	Japan 9; United Kingdom 9.
Chromium:				
Chromite	13,466	10,746	--	Philippines 8,725; Republic of South Africa 2,020.
Oxides, hydroxides, trioxides	737	889	155	U.S.S.R. 462; West Germany 228.
Metal including alloys, all forms	26	53	--	Mainly from Japan.
Cobalt:				
Oxides and hydroxides	7	13	4	Belgium-Luxembourg 8.
Metal including alloys, all forms	48	44	8	United Kingdom 18; Belgium-Luxembourg 9.
Copper:				
Ore and concentrate	355	(2)	--	NA.
Matte	3	--		
Sulfate	197	162	--	New Zealand 109; United Kingdom 52.
Metal including alloys:				
Scrap:				
Unalloyed	329	500	--	New Zealand 353; Papua New Guinea 95.
Alloyed	458	662	--	New Zealand 354; Papua New Guinea 206.
Unwrought	204	4,576	4	Belgium-Luxembourg 4,001.
Semimanufactures value, thousands	$12,873	$18,874	$2,425	United Kingdom $4,828; West Germany $1,586; New Zealand $952.
Gold:				
Ore and concentrate do	$29	$20	--	All from Fiji.
Metal:				
Crude bullion, Au content troy ounces	44,262	19,110	--	Fiji 17,102; Papua New Guinea 1,994.
Refined bullion do	7,319	42	NA	NA.
Other including alloys: Unwrought, partly wrought, waste, sweepings value, thousand	$2,095	$1,344	--	Malaysia $646; Papua New Guinea $574.
Iron and steel:				
Ore and concentrate including roasted pyrite	27,590	42,783	91	Canada 40,981; Philippines 1,500.
Metal:				
Scrap	659	1,049	--	Papua New Guinea 434; West Germany 247; Belgium-Luxembourg 214.
Sponge iron, powder, shot	6,620	8,786	298	Sweden 3,823; Japan 1,656.
Spiegeleisen	60	60	--	All from West Germany.
Ferroalloys:				
Powder:				
Ferromanganese	191	319	--	Japan 255; Republic of South Africa 26.
Other	84	157	19	France 51; Japan 47.
Shot:				
Ferrochromium	12,967	10,178	9	Republic of South Africa 8,451; Brazil 1,500.
Ferromanganese	966	7,314	204	Japan 4,203; Republic of South Africa 2,726.
Ferromolybdenum	201	133	119	Chile 8.
Ferrosilicon	5,188	5,620	2,533	Republic of South Africa 1,891; France 360; Canada 257.
Ferronickel	19	--		
Other	1,723	2,579	123	United Kingdom 1,122; Brazil 531; Spain 309.

COMMODITY REVIEW

METALS

Aluminum, Alumina, and Bauxite.— Australia's bauxite and alumina production in 1980 declined for the second time in 17 years, but aluminum production continued the upward trend. The decline was attributed to industrial unrest at the mine of one major producer. For some years Australia has been the world's leading producer of bauxite from mines located at Weipa, Gove, Northern Territory, and the Darling Range. Production of alumina, however, decreased slightly in 1980 as a result of labor disputes at Pinjarra, Western Australia. Slight increases in output by Queensland Alumina Ltd. at Gladstone and by Nabalco Pty. at Gove, failed to offset the decline in Western Australia. Expanded smelter capacity by Alcan Australia Ltd. at Kurri Kurri, New South Wales, and Alcoa of Australia Ltd.'s smelter at Point Henry, Victoria, resulted

in a record output of primary aluminum in 1980.

At Weipa, on Cape York Peninsula, Comalco Pty. Ltd. produced about 15% of the Western World's total bauxite output. At Comalco, which is owned 45% by Conzinc Riotinto of Australia Ltd., 45% by Kaiser Aluminum and Chemical Corp., and 10% by the Australian public, output was slightly above that of 1979. Both production of bauxite and shipments from Weipa in 1979 were below the level of 1980, owing to an industrial dispute that restricted operations at the docks. In 1980, the company shipped about 9 million tons of bauxite to international markets, principally Japan and Europe. The largest single outlet was the Gladstone alumina refinery operated by Queensland Alumina Ltd. (QAL). Comalco supplied the total bauxite demand for QAL, which in 1980 totaled about 5.5 million tons. All of Alcoa's bauxite output was converted to alumina at nearby refineries located at Pinjarra and Kwinana, which have a combined annual capacity of 3.4 million tons. Roughly half of Nabalco Pty. Ltd.'s bauxite was exported. The remainder was refined to alumina in an adjacent refinery at Gove, which has an annual capacity slightly in excess of 1 million tons.

Australia's three aluminum smelters operated at near capacity levels throughout 1980, and production increased during the year. Production of primary aluminum by Alcan and Alcoa was appreciably higher than that of 1979. This increase resulted from new potlines commissioned in 1979-80 by both companies. The annual rated capacities of the three plants were Comalco at Bell Bay, 112,000 tons; Alcoa of Australia Ltd. at Point Henry, 165,000 tons; and Alcan at Kurri Kurri, 68,000 tons.

Prospects for Australia to occupy a more prominent position in the world aluminum smelting industry continued to improve. Higher prices for crude petroleum have made some oil-fired power stations uneconomic as sources of energy for aluminum production. As a result, Australia's extensive coal resources were recognized as having valuable potential for thermal power generation. Consequently, a number of new aluminum smelting ventures, which would use power from coal-fired stations, were under consideration. Comalco's 180,000-ton-per-year plant at Gladstone proceeded on schedule. The project will cost $500 million and was scheduled to be onstream in mid-1982. Nabalco began a feasibility study for a smelter to use alumina from Gove. During July, Alumax Pty. Ltd. finalized land purchases for the site of its proposed smelter at Lochinvar in the Hunter Valley of New South Wales, Australia. The smelter is planned for commissioning in 1984, with an annual production capacity of 236,000 tons and a capital cost of $650 million. Alumax is controlled 50% by Alumax of the United States, 45% by Mitsubishi, and 5% by Nippon Steel. Alcoa began a feasibility study for a smelter, probably to be located in the Pinjarra-Wagerup-Bunbury District of Western Australia. Alcoa was considering a minimum economic capacity of 100,000 tons annually, which could be increased to 200,000 to 240,000 tons. The project will depend on the availability and cost of power, and involve ultimately an expenditure of around $900 million.

Apart from the smelter developments, Alcoa planned to build a $200 million, 200,000-ton-per-year alumina plant at Wagerup. Nabalco was modifying its Gove alumina plant to produce sandy alumina, for which contracts have already been obtained. The company has also formed a subsidiary to make a study of the feasibility of establishing a smelter in the immediate vicinity of the alumina plant.

Australia has very large resources of bauxite, and production from Comalco's Weipa deposit was a significant source of the Western World's requirements. The company's proved, probable, and possible ore reserves at the beginning of 1980 comprised 3 billion tons with a recoverable bauxite content of 2.5 billion tons. The grade of recoverable bauxite in the 599 million tons of proved reserves ranged from 53% to 56% alumina. The alumina content in the probable reserves was in the range of 48% to 56%.

Copper.—Although the Australian copper industry showed signs of improvement in 1980, output from the various sectors was mixed. While mine output and primary refinery output declined in 1980, primary smelter production increased. Mine production by Mount Isa Mines Ltd. (MIM) in Queensland, which accounts for about 75% of Australia's output, increased 6%. Higher production was also reported by Mount Lyell Mining and Railway Co. Ltd. in Tasmania; Mount Morgan Ltd. in Queensland; and Peko-Wallsend Ltd., Northern Territory.

Lower mine output was attributed to a decrease in the quantity and grade of ore

treated. The decline at refineries was attributed to modernization of facilities, at which time operations were reduced and production declined. Production at MIM's refinery at Townsville, Queensland, was interrupted by commissioning problems after the modernization of the tankhouse. The supply of concentrates to Electrolytic Refining and Smelting's refinery at Port Kembla, New South Wales, was reduced.

The Townsville copper refinery produced 120,500 tons of refined copper in 1980. Output was marginally lower to enable work associated with the $15 million tankhouse modernization program to be completed during the year. The refinery now receives unrefined copper from Mount Isa in the form of anodes. Conversion of blister copper to anodes in the Townsville refinery's reverberatory furnaces ceased in December 1979. Both furnaces were then closed down and dismantled. The anode shaft furnace, installed to treat anode scrap produced in the tankhouse, is fully operational and performing to design parameters.

Peko-Wallsend Ltd. was making plans to develop the Gecko Mine at Tennant Creek, Northern Territory. The mine is expected to begin production in early 1981, at a rate of 385,000 tons annually. Concentrate from this mine will be smelted in the modified Tennant Creek smelter, which was recommissioned in October 1980. Peko-Wallsend produced about 16,500 tons of copper concentrate as a byproduct of mining gold-bismuth ore at its Warrego Mine.

Although several old mines could be reopened in the early 1980's the most significant copper production may involve new developments, in particular, the Olympic Dam project in South Australia and the Benambra deposit in Victoria. Western Mining Corp. (WMC) continued diamond drilling at the Olympic Dam project near Roxby Downs, where about 15 vertical holes were completed during 1980. Several of these holes intersected an extensive zone of copper and uranium mineralization at about 350 meters below the surface, ranging between 10- and 250-meters thick, and with grades generally between 1.0% to 3.3% copper with some lead, zinc, and silver.

Output of the principal copper producers in recent years is summarized in the following tabulation:

Table 4.—Australia: Major copper production, by company

Company	Production (metric tons)[1]		
	1978	1979	1980
Mines:			
Mount Isa Mines Ltd	159,064	152,000	161,000
Mount Morgan Ltd	4,399	1,916	2,074
Cobar Mines Pty. Ltd	8,153	8,100	6,540
Mount Lyell Mining & Railway Co. Ltd	18,444	19,405	16,299
Electrolytic Zinc Co. of Australia Ltd. (EZ Co.)	1,585	1,625	3,120
Peko-Wallsend Ltd	3,334	4,330	8,172
Smelters:[2]			
Mount Isa Mines Ltd	147,430	152,400	142,000
Mount Morgan Ltd	4,920	5,800	4,200

Gold.—The increased gold price has stimulated resurgence in gold prospecting and the redevelopment of old mine workings. However, Australia's mine production of gold in 1980 was below that of 1979. An increase in output by Central Norseman Gold Corp. Ltd. and the start of production from several reopened mines failed to offset decreased production from the Telfer and Mount Charlotte Mines, in Western Australia, where ore grades were lower than a year ago. Also, ore grades were lower at Tennant Creek since Peko-Wallsend Ltd. shifted emphasis from gold to copper production.

The Telfer Mine in the Paterson Range in Western Australia operated throughout 1980. The open pit project owned by Newmont Pty. Ltd. and Broken Hill Pty. Ltd. Co. (BHP), mined about 4 million tons of ore, averaging 0.20 troy ounce of gold per ton in 1980. The ore was completely oxidized,

and the gold occurred as discrete particles of varying sizes but mostly as fine grain. The ore was partially free milling, and up to 40% of the gold was recoverable by a gravity process. The remainder was recovered by conventional cyanide leaching. The Telfer ranks as one of the most import gold producers in Australia.

Several old mines were reopened during the year, including Marvel Loch, Comet, and Haveluck in Western Australia, and Wattle Gully Gold Mines NL in Victoria. Kia Ora Gold Corp. NL began production from Marvel Loch in May, completed commissioning of a new cyanidation plant in July, and near the end of the year announced plans to double treatment capacity to 120,000 tons annually. Reserves at yearend were 347,000 tons of ore averaging 0.27 troy ounce per ton.

Kalgoorlie Mining Associates (Kalgoorlie Lake View Pty. Ltd.-Homestake Gold Ltd.) continued to operate the Mount Charlotte Mine at Kalgoorlie. The company began a rehabilitation program involving repairs and additions to the treatment plant at Fimiston and the installation of a crushing section. A decision to construct a new refractory ore treatment plant and a new shaft to 1,200 meters in depth at Mount Charlotte, which would increase mine capacity and ultimately replace the two existing shafts, was announced. Kalgoorlie Mining Associates expect to reduce the cost of producing gold by about $10 per ounce when the program is completed.

Central Norseman Gold Corp. Ltd., near Kalgoorlie, remained Australia's largest gold producer. The company produced approximately 125,000 troy ounces of gold in 1980. Development work continued on the No. 4 and No. 5 levels of the North Royal Mine, which was the main source of the gold production. The company was also producing gold from an open pit operation near the surface. Central Norseman encountered encouraging diamond-drill intersections in the program to extend its ore reserves at the mine. Ore reserves were estimated at 350,000 tons averaging 0.53 troy ounce of gold per ton in 1979.

The Warrego Mine (formerly a copper mine), operated by Peko-Wallsend Ltd., was the only producing gold mine at Tennant Creek. The Warrego copper concentrator was modified to treat Warrego gold ore. During the year, 202,500 tons of gold ore was treated, assaying 0.58 troy ounce per ton, with gold recoveries of 91.60%. In 1980, the company treated 390,300 tons of ore yielding 122,600 troy ounces of gold.

Wattle Gully near Castlemaine, Victoria, was reopened and an ore treatment plant was set up. The plant can treat 100,000 tons per year of ore and has a potential recovery of 85,000 troy ounces of gold. When the mine closed it was treating 200 tons of ore per week and producing grades of over 1 troy ounce per ton.

Newly won gold of domestic origin accounted for about 77% of Australia's total output in 1980, and refined gold produced from imported crude bullion and domestic and imported scrap accounted for the remainder. The Perth Mint, which refines crude gold bullion from gold mines in Western Australia and the Northern Territory as well as some bullion and scrap of overseas origin, was the largest domestic refinery of gold. Other gold refiners were Matthey Garrett Ltd. in Sydney and Engelhard Industries Ltd. in Melbourne. Most of the crude bullion from Fiji and Papua New Guinea was refined by Matthey Garrett. Base metal refineries were the only other sources of refined gold. In 1980, the Electrolytic Refining and Smelting Co. recovered about 12,000 troy ounces of gold from tankhouse sludges resulting from the electrolytic refining of copper at Port Kembla, and BHP recovered about 7,000 troy ounces from lead concentrates refined at Port Pirie, South Australia.

Iron and Steel.—Despite a decrease in world steel output in 1980, Australian production of iron ore rose because of increased Japanese purchases. Both domestic pig iron and crude steel production declined slightly, mainly as a result of industrial disputes. Discussions between Australian Pilbara iron ore producers and Japanese steel mills over proposals to open a new iron ore mine in the Pilbara region continued during 1980. Five areas are in competition as possible locations for the new mine.

As in recent years, most of the iron ore was produced in the Pilbara region in northwest Western Australia. In this area, five major companies produced about 90% of Australia's total iron ore output. They were Hamersley Iron Pty. Ltd. (Mount Tom Price and Paraburdoo); Mount Newman Iron Ore Pty. Ltd. (Whaleback Hill); Cliffs Western Australian Mining Co. Pty. Ltd. (Robe River); Goldsworthy Mining Ltd. (Mount Goldsworthy, Shay Gap, and Sunrise Hill); and Dampier Mining Co. Ltd. (Koolan Island and Yampi Sound). In addition to the Pilbara region, iron ore was

mined at Kollyanobbing by Dampier for use in the Kwinana blast furnace. In South Australia, BHP produced ore from the Middleback Ranges for steel plants in South Australia (Whyalla) and in New South Wales (Newcastle and Port Kembla). In a relatively small project, the iron ore at Savage River, Tasmania, was slurried and pumped to a pelletizing plant at Port Latta for shipment to Japan.

Production of iron ore by Hamersley in 1980 totaled a record level of 39.4 million tons compared with 32.8 million tons in 1979. This reflected a more stable industrial relations climate and efficient operation, particularly in the first half of the year. Four cyclones and resultant tropical rains caused the loss of 5 days of production at the mine in late 1980. The overall recovery of salable ore from material mined, at 59%, was equivalent to the rate achieved in 1979. Recovery will increase when the concentrator is brought up to full capacity. Output of salable ore from Mount Tom Price Mine was 24.5 million tons, compared with 19.5 million tons in 1979. Production included 10.8 million tons of high-grade fines. Total material mined was 41.6 million tons.

Salable ore production at Paraburdoo was 14.9 million tons, compared with 12.9 million tons in 1979. Production of high-grade fines was 7.4 million tons. Total material mined was 24.8 million tons. The operating performance of both mines and the crushing and screening plants was satisfactory. However, productivity for the year was adversely affected by longer haul distances in the mines. Development of the 4-West ore body at Paraburdoo continued during the year and production from this ore body commenced in December. Commissioning of the concentrator continued throughout 1980. Design expectations have not been reached on a continuing basis although the plant has operated at design levels over short periods.

In 1980, Mount Newman Mining Co. Pty. Ltd., being plagued with numerous production disruptions, produced about 28 million tons of iron ore. Sales totaled 32 million tons and the quantity of ore in stockpile totaled 2 million tons. Mount Newman's newly constructed heavy-media beneficiation plant was operational in 1980. The total cost of the plant and associated infrastructure was about $100 million. The plant recovers ore from contaminated waste material and provides Mount Newman with greater flexibility to increase capacity at a later date.

The principal Australian iron ore producers and their output in 1980 were as follows, in thousand tons:

Table 5.—Australia: Major iron ore production, by company

Company	Location	Products	Output	
			1979	1980
Hamersley Iron Pty. Ltd	South Australia	Lump and pellets	32,794	38,900
Mount Newman Mining Co. Pty. Ltd	Western Australia	Lump	35,000	27,300
Broken Hill Pty. Co. Ltd	South Australia	Lump and pellets	4,000	4,528
Do	Western Australia	Lump	2,000	2,000
Goldsworthy Mining Ltd	do	do	1,500	5,400

Australian reserves of iron ore were estimated at 35 billion tons, consisting of 25 billion tons of hematite, with 54% or more iron content, and 10 billion tons of limonite, with 50% or more iron content. Most of Australia's reserves occur in the Pilbara region, which accounted for over 90% of production in 1980. New mines in the region are being planned since iron ore prices have risen. Australian iron ore exporters and Japanese steelmakers concluded negotiations early in the year on prices of iron ore for delivery to Japan from April 1980. Prices of both lump and fines for delivery by major producers were increased by an average of about 20% above 1979 prices.

BHP remained the only steel producer in Australia, with plants at Newcastle and Port Kembla in New South Wales, Whyalla in South Australia, and Kwinana in Western Australia. Production of raw steel in 1980 totaled 7.8 million tons compared with 7.5 million tons in 1979. It is estimated that 715,000 tons of raw steel output was lost during the year because of strikes, including 522,000 tons in the second half of the year. Total capacity was about 9 million tons per year. Despite idle capacity, the company was expanding capacity to follow estimated future market requirements. Major measures taken to meet changing customer requirements at Newcastle in 1980 included the commissioning of leaded steel manufacturing facilities at Newcastle.

Projects still in progress in 1980 included the No. 5 coke ovens battery and modifications to the coal cleaning plant and steelmaking shop. At Port Kembla, work on the continuous slab caster with vacuum degasser and modifications to the No. 5 blast furnace were in progress during 1980. These installations represent large investments in the steel industry and in each case provide the benefits of the latest technology, which should result in quality improvements. Work was also continuing on modifications of the basic oxygen steelmaking plant. At Whyalla, work was continuing on the construction of the coke oven extensions and the installation of a waste-heat recuperator on the pellet plant.

BHP announced in September that it was proceeding with plans for the establishment of a small steel mill at Geelong, Victoria. Detailed engineering studies have been authorized and negotiations with Government officials were proceeding. A steel mill with a capacity of 200,000 tons annually was planned, and will comprise an electric arc furnace to treat scrap available in Victoria. The plant will include a continuous caster to produce billets suitable for rolling in the existing Geelong rodmill, which currently receives its billets for rolling from the Whyalla steelworks. The rodmill, which has a production capacity of 220,000 tons annually, produces feed for the nearby plant of Australian Wire Industries, which produces about one-third of Australia's wire products.

Conzinc Riotinto of Australia and Korf Stahl AG of the Federal Republic of Germany were also studying the feasibility of establishing a 200,000-ton steel mill at Geelong. The mill would have two electric furnaces and use scrap metal as raw material.

Lead and Zinc.—In 1980, mine production of lead was 4% lower than in the previous year. Both Broken Hill and Mount Isa recorded lower output in 1980 owing to mining of lower grade ores. Production from the Tasmanian west coast mines was adversely affected by a prolonged industrial stoppage in the final quarter of the year. The sole domestic producer of primary refined lead, Broken Hill Associated Smelters (BHAS) at Port Pirie, operated at a reduced capacity throughout the second half of the year.

Mine production of zinc was 7% below the record output of 1979. Lower first quarter output from Broken Hill Mines, and a drop in final quarter production from Rosebery, as a result of a prolonged industrial stoppage, accounted for the decline. The three primary zinc refineries operated at near capacity throughout the year, producing slightly less refined zinc than in 1979. A worldwide shortage of concentrates resulted in a substantial increase in concentrate exports, which increased by over 40%. The increase came largely from the Broken Hill Mines of Australian Mining & Smelting Ltd. (AM&S) comprising mainly shipments to Japan. Exports of refined zinc were also higher than in 1979.

MIM was Australia's largest single producer of lead and zinc. About 2.5 million tons of lead-zinc ore was mined in 1980 containing 6.8% lead and 5.7% zinc. Mining was concentrated between the 13 level (670 meters) and the 15 level (730 meters). The Mount Isa mining methods of cut and fill and open stoping were modified to achieve greater ore recovery and better utilization of workers and equipment. Drilling of the lead-zinc mineralized area continued in the northern part of the Mount Isa Mine throughout 1980 and some drilling was done in the foot-wall region. The drilling in the latter area was quite deep, about 1,100 meters below the surface. As a result of the drilling, over 1 million tons of ore were added to the zinc and lead reserves.

Modernization of the flotation section of the lead-zinc concentrator was well advanced with more than half of the new flotation cells of the single circuit installed at yearend. The desired levels of metallurgical recovery were achieved by the end of 1980.

Results of the feasibility study on the McArthur River zinc-lead deposit was presented to the Northern Territory Government in early 1980. The report indicated that development of the large mineralized area was not feasible under present economic conditions using presently known technology. Feasibility studies commenced on the Lady Loretta lead-zinc project, north of Mount Isa, held by agreement with Triako Mines NL These included metallurgical and rock mechanic studies.

In 1980, mine output by AM&S and two subsidiaries, Zinc Corp. Ltd., and New Broken Hill Consolidated Ltd. (NBHC), decreased from the 1979 level. The lower output was attributed to lower ore grade mined, and labor problems, which resulted in one work stoppage. Some new mining equipment was introduced in 1980. The successful commissioning of an additional large ball-

mill in the NBHC grinding circuit has overcome the problems resulting from the treatment of large quantities of hard, low-grade ore. This has enabled plant capacity to be maintained and metallurgical performance to be improved. Installation of the new crushing and screening plant at NBHC proceeded on schedule. The commissioning during January 1980 completed the first stage of the 3-year program to extend mine life by expansion of production while lowering the average grade of the ore mined.

A consortium, consisting of Conzinc Riotinto of Australia, St. Joe Minerals Corp., and Phelps Dodge Corp. of the United States, formally inaugurated the Woodlawn, New South Wales, mine project in December 1978. Following the commissioning, difficulty was experienced in obtaining satisfactory grades and recoveries in concentrate production from the complex ore body. Major deficiencies in plant design specifications complicated the task of achieving metallurgical improvements. A program of capital expenditure was initiated during 1979 to correct the plant deficiencies. Although this program continued throughout 1980, substantial improvements were apparent and steadier plant operating conditions were achieved. When operating at capacity, the mill would produce about 120,000 tons of zinc concentrates, 40,000 tons of lead concentrates, and 35,000 tons of copper concentrates annually. Output would be divided among the three joint venture partners, each of which would arrange its own sales. Diamond drilling in 1979 revealed ore reserves of 10 million tons, averaging 12% zinc, 4.5% lead, 1.8% copper, and 1.8 troy ounces of silver per ton.

The BHAS refinery operated below capacity in 1980 and primary lead production declined 7%. Operations at Port Pirie benefited from recent substantial expenditure. The tall stack and debismuthizing plant were the major projects undertaken. The debismuthizing plant was commissioned in June 1980 and will allow BHAS to produce an increased quantity of 99.99% purity lead. In late 1980, production of refined lead was augmented by treatment at Port Pirie of lead bullion from the Sulphide Corp. In addition, the new sinter breaker installed allowed the sinter plant to operate at a high level of efficiency.

EZ Industries Ltd. operated two mines, Rosebery and Hercules, both located in Tasmania. These are zinc-lead-copper deposits in association with gold, silver, and pyrite. The combined output of ore mined totaled about 653,400 tons in 1980, slightly less than that of 1979. The small increase at the Hercules Mine was insufficient to offset the decline at the Rosebery Mine, where more than 85% of the total ore was produced. The average grade of ore production from all mines was 11.8% zinc, 3.7% lead, and 4.3 ounces of silver per ton. Products of the concentrating mill were zinc, lead, copper, silver, gold, and pyrite concentrates, which were railed to the Port of Burnie.

The principal lead and zinc companies and the quantities produced during 1978-80 were as follows:

Table 6.—Australia: Lead-zinc production, by company

(Metric tons)

Company	1978		1979		1980	
	Lead	Zinc	Lead	Zinc	Lead	Zinc
North Broken Hill Ltd	51,080	38,685	52,000	39,400	52,877	39,442
Zinc Corp. Ltd	79,400	61,000	80,000	63,000	86,240	56,700
New Broken Hill Consolidated Ltd	61,600	121,000	64,000	127,000	78,240	137,200
Mount Isa Mines Ltd	127,600	105,540	130,000	109,000	131,390	101,027
Electrolytic Zinc Co. of Australasia Ltd. (Read-Rosebery).	21,500	70,850	22,300	69,700	20,459	70,341

Manganese Ore.—The Groote Eylandt open pit manganese mine, located on an island in the Gulf of Carpentaria, accounted for virtually all of Australia's manganese production. The mine was operated by the Groote Eylandt Mining Co. Pty. Ltd. (GEMCO), a wholly owned subsidiary of BHP. The manganese ore occurs as a flat tabular-stratum, overlain by lateritic overburden up to 24 meters thick.

GEMCO produced 1.9 million tons of manganese ore from this operation, located in the Northern Territory, during 1980. Exports increased to 1.3 million tons in 1980, and shipments to most major markets increased. The largest tonnage (625,000

tons) went to Japan. About 430,000 tons was shipped to Europe, 130 tons to the United States, and 119 tons to the Republic of Korea. The remaining 600,000 tons was domestically consumed and processed by the Bell Bay plant, operated by Tasmanian Electro Metallurgical Co. Pty. Ltd., a subsidiary of BHP. The plant produced about 133,000 tons of ferroalloys, exceeding that of the previous year by 5%. Approximately 45,000 tons of ferroalloys were exported in 1980, compared with 35,000 tons in 1979.

Most ore for export was sold on a contract basis with prices being negotiated between buyer and seller. Price increases were negotiated during the year, but rapid escalation of freight rates and aggressive competition restricted profitability.

Currently, all of GEMCO's mine output is sold to the steel industry. However, BHP has built a pilot plant at its Newcastle research center to test the feasibility of producing manganese dioxide suitable for the battery industry. This could eventually provide an important second outlet for the company's product.

Australian manganese reserves were estimated at about 889 million tons in 1980, the main part of which was on Groote Eylandt. The remainder was located principally in the east Pilbara and Peak Hill regions of Western Australia and at Pernatty Lagoon in South Australia. Known deposits in the Northern Territory were subeconomic. Large secondary enrichment deposits along the outcrop of the Marra Mamba iron formation in the Pilbara region were being evaluated. These deposits were low in silica and consisted of about equal proportions of high-grade ore (40% manganese) and lower grade ores suitable for benificiation.

Nickel.—The decline in demand for nickel during 1980 caused some producers to close plants, and mine output declined by 5%. By reducing output, producers aimed to avoid an accumulation of surplus stocks and thereby assist price stability. Increased output at Agnew, Western Australia, by Agnew Nickel Co. Pty. Ltd., which rose by about 74%, and at Greenvale, Queensland by Queensland, Nickel Pty. Ltd., up 8%, was not sufficient to offset reduced output by WMC. Also, production at Spargoville, Western Australia, ceased in January when economic ore reserves became exhausted. Sulfide-based mines in Western Australia accounted for 60% of total production, with the remainder coming from the Greenvale lateritic mine in Queensland.

At the end of 1980, the Kambalda Mine at Kalgoorlie was still the principal nickel producer, accounting for more than 55% of the Australian production. The Greenvale operation in Queensland was the next largest. The Nepian, Spargoville, and Agnew Mines in Western Australia together produced less than 10% of the Australian total.

In 1980, WMC treated 1.3 million tons of ore from its Kambalda operations and produced 260,000 tons of concentrate containing 30,700 tons of nickel. The nickel mining and processing in Western Australia is WMC's main income-producing activity. The operations comprise nine underground mines and a concentrator at Kambalda, a nickel smelter at Kalgoorlie, and a nickel refinery at Kwinana. WMC also owns 50% of the Windarra nickel project consisting of mines and a concentrator at Windarra. Development of the Mount Windarra Mine continued with the aim of resuming production gradually as market conditions warrant.

In addition to operating the Kambalda and Scotia Mines, WMC owned the smelter at Kalgoorlie and the refinery at Kwinana. The company treated ore and concentrates from other mines on a toll basis and also smelted the half of Windarra production owned by the Shell Co. of Australia Ltd. Throughput for 1980 was 263,000 tons of nickel concentrate and 67,300 tons of nickel-bearing laterite. Expansion of the smelter capacity to 450,000 tons annually (concentrate) was completed.

This was the first full year of operation for Agnew Nickel Co. Pty. Ltd. Under agreement with WMC, concentrate was toll smelted to produce nickel matte, which was shipped to the United States under an agreement with Amax Nickel Inc. The transportation of concentrates to WMC's Kalgoorlie smelter was interrupted on many occasions by road closures owing to an abnormally high rainfall between February and June. The Agnew nickel deposit is one of the major sulfide nickel deposits of the world, and it is expected to become a substantial supplier of nickel. During the year, exploration was carried out into the mineralized zone below the depth originally planned. Exploration so far has been by surface drilling only. It was decided to extend the exploration shaft beyond the original 900 meters planned depth by 270 meters. This will enable the No. 2 and

No. 3 shoots of the deposit to be fully explored. When the work is completed it will be possible to make detailed plans for future production.

The Greenvale Mine in Queensland, owned equally by Metals Exploration Ltd. and Freeport of Australia Inc., was operated at about 75% of the designed capacity during 1980. The operation, which treats lateritic ore (acid leach), has overcome most of the early technical problems, but serious financial difficulties persist. Operations have generated a positive cashflow, but this has been totally inadequate to meet the cost of servicing the development loans. Some relief was obtained when the financiers agreed to a deferment of interest payments, but the financial viability of the whole project remains in doubt.

Some exploration work for nickel was in progress, mainly in Western Australia. Cliffs International Inc. reported it had intersected massive sulfides at Mount Keith, Western Australia, assaying between 1.7% and 6% nickel. The deposit averaged 3.5% nickel over a strike length of 1,200 meters and a depth between 100 and 450 meters.

Silver.—Most silver was produced as a byproduct of lead-zinc mining with gold and gold-copper mining making a contribution. Total silver production in 1980 was slightly below the 1979 output. More than 85% of the output came from mines in Mount Isa and Broken Hill. Silver was also produced as a byproduct of copper mining at Tennant Creek, Mount Morgan, Cobar, Woodlawn, and Mount Lyell.

MIM remained Australia's largest producer of silver. In 1980, about 2.5 million tons of lead-zinc ore, averaging 5.7 troy ounces of silver per ton, was treated to produce 14.6 million troy ounces of silver in concentrates. About 87% of the silver was recovered from lead concentrates and the remainder from zinc and copper concentrates. The lead concentrates were smelted to lead bullion at Mount Isa and exported to the company's lead refinery at Northfleet, United Kingdom, where the silver metal was recovered. Over 70% of the zinc concentrate was exported; the remainder was shipped to the zinc refinery at Risdon, Tasmania. Silver in copper and lead residues from the electrolytic tankhouse slimes from the Townsville copper refinery were either recovered by Electrolytic Refining and Smelting Co. or exported.

The Broken Hill area remained Australia's second largest source of silver in 1980. Production of silver from the lead-zinc concentrates in 1980 by several companies declined because of plant repairs and a lower overall grade of ore mined. The grade of ore treated contained 6.3 troy ounces per ton of silver, compared with 7.4 troy ounces per ton in 1979. Most of the silver produced at Broken Hill was contained in lead concentrates, which were treated at the BHAS smelting and refining plant at Port Pirie.

EZ Co. produced silver as a byproduct of copper-lead-zinc mining at Rosebery. In 1980, the company treated about 579,196 tons of Rosebery ore and 74,250 tons of Hercules ore. The average silver grade of the complex copper-lead-silver-gold ore treated was 3.7 troy ounces per ton, marginally lower than that of 1979. The ore yielded 132,000 tons of zinc concentrate containing 334,312 troy ounces of silver, 18,600 tons of lead concentrate containing 433,427 troy ounces of silver, and 24,000 tons of copper concentrate containing 1.4 million troy ounces of silver.

The introduction underground of electric powered loaders in stoping operations was successfully achieved late in the year. The 17-level decline operation using diesel-powered, rubber tired equipment commenced early in 1980 and progress was satisfactory. Mine development totaled 7,170 meters, compared with 6,967 meters for the previous year.

About 80% of all silver exported in 1980 was contained in lead bullion; lead, zinc, and copper concentrates; blister copper; and various slags, mattes, and residues. The remainder was exported as refined silver and mint bullion.

Principal producers of silver and output, in thousand troy ounces, during 1978-80, were as follows:

Table 7. Australia: Major silver production, by company

Company	1978	1979	1980
Electrolytic Zinc Co. of Australasia Ltd	2,481	2,470	2,168
Mount Isa Mines Ltd	14,720	14,496	14,592
New Broken Hill Consolidated Ltd	2,163	2,200	1,774
North Broken Hill Ltd	3,371	3,412	2,703
Zinc Corp. Ltd	1,155	1,300	1,650

Tin.—In 1980, mine production of tin-in-concentrates fell 10%, partly owing to industrial disputes at Renison, Tasmania. Production of primary refined tin was about 14% below the 1979 level. Although the strength of world tin prices in 1980 brought prosperity to Australian tin miners, the Australian Tin Producers' Association expressed concern that high prices and shortage of supplies could encourage technical developments to reduce the use of tin.

Renison Ltd. remained by far the largest tin producer in Australia, accounting for over 45% of the total production. Production in 1980 was affected by a number of industrial disputes and declined slightly. The mine is located at Renison Bell, Tasmania, and in 1980 the mill treated 551,105 tons of ore at an average head grade of 1.27% tin, with a recovery of 5,135 tons of tin in high-grade concentrate. The mill recovery of tin metal in concentrates was lifted from 71.2% to 73.6%. Renison completed construction associated with the expansion of milling capacity to 850,000 tons annually and began commissioning the plant. Following successful matte fuming trials on low-grade material, a detailed engineering study was begun to permit final assessment of the feasibility of a fuming plant. Renison's combined proved and probable ore reserves increased 10% to over 1.3 billion tons in 1980, but the grade dropped from 1.14% to 1.13% tin. The increase in tonnage and reduction in grade was largely a result of the addition of several million tons of lower grade ore added to the reserves.

Aberfoyle Ltd., Australia's second largest tin mining group, wholly owns and operates the Cleveland tin mine at Luina, Tasmania; the Ardlethan Mine, in New South Wales; and the Aberfoyle Mines at Rossarden and Storeys Creek, Tasmania. Although the total output by the Aberfoyle group declined about 14% in 1980, performance at individual mines varied. The Cleveland mill treated 367,900 tons of ore at at an average head grade of 0.47% tin and recovered 1,079 tons of tin in concentrate. The mill at Rossarden treated 49,311 tons of ore to produce 178 tons of tin in concentrate. At Ardlethan, the mill treated 552,000 tons of ore with a head grade of 0.51% tin, and recovered 1,714 tons of tin in concentrate.

Aberfoyle announced that a flotation plant would be installed at the Ardlethan Mine to increase metallurgical recovery. The plant was estimated to cost $3.4 million, and was to be in operation by March 1981.

In June 1980, Greenbushes Tin NL began to operate a small electric arc furnace (the second tin smelter to begin production in Australia) at its mine south of Perth, Western Australia, treating its concentrates and some from the Northern Territory. The smelter produces metallic tin and tantalum-bearing slags. In October, Greenbushes announced a discovery of a large tantalite resource with 21.8 million tons of ore assaying 0.11% tin, and 0.44% tantalum over a width of 14.7 meters. At present, this is augmented by 9.7 million tons of probable ore assaying 0.15% tin and 0.06% tantalum. In addition to production of primary refined tin, the new smelter produced about 150 tons of antimonial tin (99.5% tin).

Associated Tin Smelters Pty. Ltd. (ATS) operating at Alexandria, New South Wales, was the primary tin smelter. The smelter is owned equally by O.T. Lempriere & Co. Ltd, Consolidated Tin Smelters Pty. Ltd (Australia), and Australian Iron & Steel Pty. Ltd. Output of the smelter is limited by the low average grade of concentrates currently available, and can effectively produce about 7,000 tons of refined tin. In 1980, production by ATS was affected by industrial disputes and only 4,700 tons of primary refined tin was produced. Plants in Sydney, Wollongong, and Melbourne produced nearly 500 tons of secondary tin from tinplate scrap and tinplating wastes.

Titanium and Zirconium.—World demand for titanium and zirconium concentrates increased during the early half of 1980, following a protracted period of depressed demand, low prices, and erratic production. Australia's production of ilmenite, rutile, and zirconium exceeded the totals reported for 1979. While production in Western Australia decreased by about 10%, there was a marked recovery in production from operations on the east coast, particularly on North Stradbroke Island in Queensland. Production of salable-grade ilmenite concentrates continues to be confined mostly to operations in the Capel and Eneabba areas of Western Australia.

Weak demand for rare-earth oxides in the United States and Europe resulted in a decline in monazite concentrates. Virtually all of the rutile, zircon, and monazite output was exported, along with about 50% of the ilmenite. The remainder of the ilmenite was consumed within Australia for the production of titanium dioxide pigments and for the production of synthetic rutile. The principal destinations for the products were

Western Europe, Japan, and the United States.

A proposal to build a $100 million titanium metal plant in New South Wales was attracting interest from Australian and foreign companies. The proposal was strongly supported by the New South Wales Government. New South Wales has abundant rutile and cheap electricity.

Australia produces over 90% of the world's natural rutile, about 80% of the zircon, 70% of the monazite, and over 25% of the world's ilmenite. The industry was divided, generally, into three groups, the east coast producers of rutile and zircon, the west coast producers of ilmenite and zircon, and the new west coast producers of rutile, zircon, and ilmenite. On the east coast, four main groups (Associated Minerals Consolidated Ltd., Consolidated Rutile Ltd., Mineral Deposits Ltd., and Rutile & Zircon Mines Ltd.) accounted for most of the output. In 1980, Associated Minerals Consolidated Ltd. produced 100,900 tons of rutile, 174,380 tons of zircon, and 373,300 tons of ilmenite from plants in New South Wales and Queensland. Consolidated Rutile Ltd. produced about 30,000 tons of rutile in 1980, but has expanded plant facilities and expects to produce about 60,000 tons of rutile and 45,000 tons of zircon in 1981. Production by Mineral Deposits Ltd. totaled about 45,000 tons each for both rutile and zircon. Combined production by two plants operated by Rutile & Zircon Mines Ltd. totaled about 52,000 tons of zircon and 40,000 tons of rutile in 1980.

On the west coast, two major producers, Allied Eneabba Pty. Ltd. and Westralian Sands Ltd., supplied most of the output of mineral sands in 1980. Westralian Sands produced about 394,00 tons of ilmenite. The other main products were 36,000 tons of zircon, 15,000 tons of leucoxene, and 1,900 tons of monazite. Allied Eneabba's output consisted of 294,900 tons of ilmenite, 101,500 tons of zircon, 54,900 tons of rutile, and 9,000 tons of monazite. Small quantities of xenotime and garnet were also produced. Three other west coast companies (Western Titanium Ltd., Jennings Mining Ltd., and Cable Sands Ltd.) also produced titanium and zirconium concentrates during 1980. Western Titanium's main product was rutile, both Jennings Mining and Cable Sands produced rutile, ilmenite, and zircon.

One reason for the involvement of so few companies in Australia's mineral sands operations was attributed to the declining grade of ore reserves. The high-grade deposits have been mined out, and the mining companies have moved toward lower grade reserves that require larger and more expensive processing facilities. Also, large areas containing known reserves of rutile and zircon have been precluded from mining by being incorporated into new national parks. Australia's Bureau of Mineral Resources estimates that over 40% of identifiable economic resources of zircon and rutile on the east coast were unavailable for mining because of environmental considerations.

At yearend 1980, proven and probable reserves of heavy mineral sands totaled about 65 million tons in Western Australia, 20 million tons in Queensland, and 20 million tons in New South Wales. The content of heavy minerals ranged from 1% near Newcastle, to 80% at Eneabba. Most producers continued exploration in 1980, and most of the activity was in Western Australia.

NONMETALS

Diamond.—Diamonds have been discovered in the Kimberley region of Western Australia and a very intensive exploration and evaluation program has been undertaken. Sampling in 1980 produced about 48,000 carats. The major group in this activity is Ashton Joint Venture (AJV), consisting of CRA (56.8%), Ashton Mining NL (24.2%), A.O. PTY Ltd.(Australia) (4.9%), Tanaust Pty. Ltd. (9.1%), and Northern Mining Corp. NL (5.0%). During 1980, the AJV's activities were centered south on Lake Argyle. The Argyle prospect comprise a Kimberlite pipe, designated AK1 (surface area approximately 45 hectares), and two associated alluvial deposits, Upper Smoke Creek and Lower Smoke Creek, which extend 32 kilometers from the pipe to Lake Argyle. Preliminary sampling of the surface of pipe AK1 was completed and a program of more intensive bulk sampling was commenced near the end of the year. A drilling program to obtain an indication of grades at depth was also commenced. Sampling from pipe AK1 produced 11,560 carats from approximately 2,600 tons of material.

The Upper Smoke Creek alluvial deposit has estimated reserves of 500,000 cubic meters containing an average yield of 8 carats per cubic meter. Approximately 15% of the diamonds from the Upper Smoke Creek deposit have been assessed as gem quality, while the remainder were assessed as industrial quality. Sampling of the Lower

Smoke Creek alluvial deposits in 1980 resulted in a yield of 6,050 carats from approximately 20,000 tons of treated material. Preliminary feasibility studies are underway on various alternatives for the development of pipe AK1 and the Lower Smoke Creek deposit. A feasibility study for commercial production from the Upper Smoke Creek deposit has been completed. No decision to mine has yet been made. Initial investigations of potential markets for diamonds from AJV commenced during 1980 and will continue in 1981.

Phosphate Rock.—The Australian fertilizer industry consumes about 2.6 million tons of phosphate rock annually. Australia's first company to produce and export phosphate rock ceased operations in June 1978, but efforts are being made to resume operations. The decision by BH South Ltd. to close down the operation of its subsidiary, Queensland Phosphate Ltd. at Duchess, came after both the Australian Government and the Queensland State Government refused financial assistance to the company. When Duchess came into production in 1975, it was unable to establish long-term export sales contracts so essential to its economic viability, and it consistently operated well below its design capacity of 2 million tons annually. BH South became a subsidiary of WMC in late 1979, and the Duchess phosphate project was reviewed. Laboratory-scale work towards the development of an economic beneficiation process neared completion at the end of the year and full-scale field tests were planned. Feasibility studies were undertaken with a view to recommence shipments of quality rock at a rate of 250,000 tons annually. Discussions with consumers and the Queensland Government were underway.

In 1978, Queensland Phosphate produced 250,000 tons of phosphate rock averaging 32.17% P_2O_5. Production came mainly from the southern area where thicker sections of direct-shipping-grade rock gave a more favorable waste-to-ore ratio. The performance of the treatment plant steadily improved as operating techniques were refined and minor technical improvements were made. The Townsville facilities processed about 252,000 tons of phosphate rock through the dryer. Shipments during the year totaled about 275,000 tons. A total of 215,000 tons were taken by south and east Asian markets and 60,000 tons were shipped to Australian ports. The major share of export sales were to Japan, Republic of Korea, and Malaysia. Sales to Australia were mainly for testing purposes.

Domestically, Queensland Phosphate will have to compete with rock imported from British Phosphate Commission operations in Nauru and the Christmas Islands. The characteristics of rock from these three different sources are different and require slightly different processing methods. The Queensland Phosphate rock had a high silica content, was difficult to grind, and caused adverse chemical reactions in domestic manufacturing plants. The Australian fertilizer manufacturers were unwilling to undertake the necessary capital expenditure in changing from their established source of supply to the Queensland material.

An estimated 11,000 tons of phosphate rock was produced in South Australia in 1980, but the material was not suitable for superphosphate manufacture because of its high iron and aluminum content and was used directly as fertilizer.

Salt.—In 1980, both production and export of salt increased owing to the upturn in the world economy. Four major companies, Dampier Salt Ltd., Leslie Salt Co., Lefroy Salt Pty. Ltd., and Shark Bay Salt Pty. Ltd. (all based in Western Australia), produced about 80% of the total domestic output. Producers in South Australia, Victoria, and Queensland supplied the remainder. Production was by solar evaporation from seawater, saline lake water, and underground brines; salt was also harvested from dry lake beds. Virtually the entire Western Australian output was exported, mainly to Japan, while salt produced in Queensland, Victoria, and South Australia was generally for local consumption. Less than 2% of Australia's total output was consumed as table salt.

In Western Australia, salt production totaled about 4.3 million tons in 1980, and shipments totaled 3.8 million tons. Dampier Salt Ltd. was the principal producer contributing over 2.8 million tons of salt to the State's output. Dampier Salt took over the operations previously controlled by BHP at Lake McLeod and now operates two subsidiary companies, Dampier Salt Pty. Ltd., Dampier Div., and Dampier Salt Pty. Ltd., Lake McLeod Div. The Dampier Div. supplied over 90% of the total production. Lake McLeod was damaged by a cyclone in March 1979 and reconstruction work began in April and continued throughout 1979 and most of 1980. The major components of the

reconstruction program were completed late in 1980 enabling production of about 200,000 tons of salt to be achieved prior to yearend. The Dampier Salt Ltd. output in 1980 came from evaporation pans at Lake McLeod, north of Carnarvon, where extensive reserves of evaporites occur in brines over a 225,000-hectare area. The strata below the lake consisted of a layer of impure gypsum approximately 2 meters thick, underlain by halite (rock salt) ranging in depth to 15 meters. The amount of halite was estimated to exceed 3 million tons.

The halite was impregnated with saturated brine containing about 21% sodium chloride. The brine was extracted from the halite bed by large capacity pumps and flowed to the crystallizing pan area. About 25 crystallizer pans, covering an area of 800 hectares, were used for production. Each pan, with salt deposited about 300 millimeters thick, was harvested once a year. Harvesting proceeded throughout 1980 as various pans were cleared in sequence and then refilled with brine.

Cargille Inc. (formerly Leslie Salt Co.) of Minneapolis, Minn., United States, produced about 1.1 million tons of salt in 1980. This solar salt installation consisted of a series of concentrating and evaporating ponds with associated pumps, a salt washing plant, and shiploading facilities. The operation involved pumping seawater at a rate of up to 180,000 gallons per minute into the evaporation ponds. Solar evaporation brought seawater to a concentrated brine that was nearly the saturation point for sodium chloride. The brine was pumped to crystallizing ponds where further evaporation caused the sodium chloride to precipitate. When the depth of salt in the crystallizing ponds reached approximately 20 centimeters the brine was drained off and the bed of salt harvested.

In 1980, Lefroy Salt produced 200,000 tons from its operations on Lake Lefroy, where reserves were estimated at several hundred million tons. Four new crystallizers were in use during 1980.

Responding to increased domestic requirements, South Australia's salt output in 1980 was significantly above that for 1979. The State's major producers were Imperial Chemical Industries of Australia and New Zealand Ltd. (ICIANZ), Waratah Gypsum Pty. Ltd., Ocean Salt Pty. Ltd., and BHP. ICIANZ produced a combined total of 600,000 tons from seawater by solar evaporation at Dry Creek in 1980. Waratah Gypsum Pty. Ltd. produced around 85,000 tons of salt from Lake MacDonnell, while BHP produced about 60,000 tons at Whyalla. These three companies accounted for about 75% of the State's total output.

Queensland's principal producer was ICIANZ, which operated a solar evaporation project near Rockhampton, utilizing underground brine. Production capacity was about 150,000 tons annually. In Victoria, virtually all of the State's output was produced by Cheetham Salt Ltd. The company operated solar evaporation pans near Laverton on Port Phillip Bay, at Lara and Geelong on Corio Bay, and at Sea Lake near Lake Tyrrel. In 1980, the company produced about 115,000 tons of salt.

Sulfur.—There were no known deposits of native sulfur in Australia, but pyrite was mined for its sulfur content at several locations, and four oil companies have sulfur recovery units. Sulfur was consumed mainly (93%) in the form of sulfuric acid to produce fertilizer, particularly superphosphate. Approximately 70% of the sulfuric acid production was from imported brimstone and 30% was from indigenous raw materials, principally zinc, pyrite, and lead concentrates.

Sulfur was also obtained from petroleum by Petroleum Refineries Pty. Ltd. (Australia) at Altona, Victoria, and Hallett's Cove, South Australia; Shell Refining Pty. Ltd. (Australia) at Clyde, New South Wales, and Geelong, Victoria; Australian Oil Refining Pty. Ltd. at Kernell, New South Wales; and Amoco Pty. Ltd. (Australia) at Bulwer Island, Queensland. The combined capacity of the plants was up to 52,000 tons per year, but the total output from petroleum in 1980 was about 13,000 tons.

Only Electrolytic Zinc Co. of Australia Ltd. at Rosebery and the Mount Lyell Mining and Railway Co. Ltd. produced pyrite for acid production as a byproduct of base-metal mining. Acid from the pyrite was produced at Burnie, Tasmania, by North-West Acid Pty. Ltd. in which the mining companies each have a half interest. The production by North-West Acid totaled 273,018 tons of sulfuric acid in 1980, compared with 252,539 tons in 1979. Progress on construction of the new No. 6 North-West Acid plant was maintained and was virtually completed at yearend.

Exploration work continued on pyrite black slate occurrences near Port Sorell and at Dial Range, both located in Tasmania. Tin deposits at Mount Bischoff and Renison

Bell, also in Tasmania, are associated with enormous deposits of pyrite and pyrrhotite and were being ivestigated.

MINERAL FUELS

Coal.—Despite an extended industrial dispute in the Queensland coalfields in mid-1980, with an estimated 3 million tons in lost production, Australian production of black coal reached a record level in 1980. Increased production from the largest coal-producing State (New South Wales) more than offset the decrease in Queensland. Production also increased in Western Australia and South Australia, but output in Tasmania remained at about the 1979 level. Firm plans were announced for the development of several new mines in Queensland. According to the Australian Joint Coal Board, continued growth is expected in the coal industry, with domestic demand climbing from 35 million tons in 1979 to 75 million to 100 million tons in 1990. Exports are forecast to grow to 115 million to 180 million tons in 1990.

The consumption of coal rose 4% in 1980, mainly as a result of increased electricity generation in New South Wales and Queensland. Black coal exports in 1980 rose by 4%, owing to increased shipments of steaming coal to Japan from New South Wales; exports of coal from New South Wales rose by 16% to 23 million tons. Exports from Queensland were 20 million tons, a 6% decrease from 1979. Japan remained the main market for Queensland coal although shipments were slightly reduced in 1980.

New South Wales currently produces 54% of all coal mined in Australia. Production in 1980, was about 51 million tons, owing to a substantial increase in output in the South Coast district and the Singleton North West district. The industry was preparing for large-scale expansion to serve the expanding markets both at home and abroad. In 1980, 10 major mines were under development, and a number of other mines were being planned or under investigation. These included a number of large surface mines in the Singleton district and proposals by the Electricity Commission for the establishment of new underground mines near Lithgow and Wakefield. The total planned production capacity for these new mines was 12 million tons of coal annually. A significant proportion of this new capacity would serve to replace declining output from existing mines. All of these projects were scheduled to be in production by mid-1980.

Output in Queensland, which accounted for 41% of Australia's coal production, declined in 1980 because of industrial problems. In 1980, 20 underground and 23 surface mines were operating in the State. The upsurge in surface mining began in Queensland in the early 1970's when Utah Development Co. (owned 89.2% by Utah International Inc. of the United States and 10.8% by Utah Mining Australia Ltd.) started coal production. The company operated three open pit coal mines on the western side of the Bowen Basin, at Goonyella, Peak Downs, and Saraji in the Mackay coal mining district, producing over 50% of Queensland's total coal output; most of which was exported. Development work in a fourth open pit mine at Norwich Park, near Saraji began in 1980.

Another Queensland coal producer, Thiess Dampier Mitsui Coal Pty. Ltd., began a $25 million expansion program to boost output at its Moura-Kianga surface mine from 3 million to 5 million tons by 1985. The company also planned to develop two new underground mines in addition to its two existing underground mines. The company has exported coal only to Japan but was examining the prospects in other markets including the Republic of Korea, Taiwan, Europe, the United Kingdom, and the Pacific Basin.

Black coal reserves in Australia were estimated at 229 billion tons at yearend 1980, of this 35 billion tons was indicated and 194 billion tons was inferred. Indicated reserves were located in New South Wales (16 billion tons), Queensland (15.6 billion tons), Western Australia (1.8 billion tons), South Australia (730 million tons), and Tasmania (140 million tons). Substantial deposits of coal have also been delineated in areas not being mined, notably in the Surat Basin (Queensland), at Lake Phillipson in the Arckaringa Basin (South Australia), and in the Corrabin-Oaklands Basin (New South Wales).

Lignite.—Victoria was the only State that produced lignite in 1980. The major deposits in Victoria were in the Latrobe Valley, 130 to 200 kilometers southeast of Melbourne, where the State Electricity Commission, at Yallourn and Morwell, produced more than 95% of the State's total output. The remainder was produced by privately owned mines at Anglesea and Bacchus Marsh. Coal was won by large

draglines with an excavating capacity of 2,000 tons per hour. The Yallourn open pit produced at a rate of 13 million tons annually. Traditionally, production from Yallourn has been used to produce a high-grade solid fuel in the form of briquets for domestic and industrial use. However, briquets were also used as a basis for the production of high-grade char, gas, liquid fuel products, and other chemical industry feedstocks.

Research into production of oil from coal was being sponsored by several governments and private companies. Japanese interests were reported to be willing to establish a demonstration plant for conversion of Victorian lignite into solvent-refined coal suitable for steelmaking. Establishment of a full-scale plant was proposed if the demonstration proves successful.

In 1980, brown coal reserves were estimated at 109 billion tons (40 billion tons indicated and 69 billion tons inferred). Although South Australia has some brown coal deposits, Victoria accounted for all of Australia's brown coal production and about 99% of the country's reserves and resources.

Petroleum and Natural Gas.—Crude oil production decreased compared with 1979, but natural gas output was significantly higher. The Victorian offshore fields (Bass Strait) produced 92.5% of total oil production. The remainder came from Barrow Island, Western Australia, and the nearly exhausted field at Moonie, Queensland. Total oil production represented about 70% of current domestic requirement. With recent discoveries and revised estimates of reserves, it was estimated that this degree of self-sufficiency could be maintained until the mid-1980's.

Australian refineries totaled about 223 million barrels in 1980. Indigenous crude oil comprised about 70% and the remainder was imported, mainly from the Middle East.

An annual summary of petroleum industry statistics produced by the Australian Petroleum Exploration Association showed that in 1980 a total of 27 development wells were drilled, of which 22 were onshore and 5 offshore. There were 82 exploration wells drilled, of which 68 were onshore and 14 offshore. The total exploration expenditure amounted to $300 million. Forecasts for 1981 showed that 137 exploration wells were planned under an exploration budget of $460 million and 86 development wells were scheduled to be drilled under a $1.2 billion budget for development.

Australia's massive North West Shelf Natural Gas Development Project in Western Australia continued to move ahead, despite the absence of firm export contracts. A consortium comprising the BHP Co., Shell Co., Woodside Petroleum Co., British Petroleum, and California Asiatic Oil Co. was continuing a feasibility study that could lead to production by 1984. The aim of the North West Shelf project is to produce gas and condensate from the North Rankin Field, pipe it to shore, and process it into pipeline-quality gas, liquefied natural gas (LNG), and condensate suitable for markets in Australia and abroad. In 1979, the Federal Government approved the export of 55% of the current estimated reserves from the project. About 6.5 million tons of LNG could thus be exported annually over a 20-year period. A contract has been signed between the consortium and the Western Australian State Energy Commission for the sale of up to 10.5 million cubic meters of gas per day over a 20-year period. This would be delivered to customers in the southwest of the State through a 1,300-kilometer-long pipeline from Dampier. Current estimates of the cost of the project now range about $5.8 billion.

Two new development techniques were implemented in the Bass Strait Field during the year that could have important future implications. The first of these, a subsea production installation, was brought into operation on the Cobia 2 well and has enabled limited production from Cobia in advance of the completion of the platform, expected about June 1982.

The second development was the drilling of two high deviation wells from the Mackerel platform into a remote section of the field to recover oil which would be otherwise uneconomic.

Uranium.—Production of U_3O_8 increased in 1980 because Queensland Mines Ltd.'s new concentrator at Nabarlek commenced production in June. For years, Mary Kathleen Uranium Ltd. (MKU) was the only operating uranium mine in Australia. Construction of the Ranger Uranium Mines Pty. Ltd. project is proceeding and is now scheduled to produce U_3O_8 in late 1981. The WMC's Yeelirrie deposit in Western Australia has commenced small-scale mining for use in a research plant at Kalgoorlie. WMC's plant could commence production of U_3O_8 by 1986.

MKU produced 834.5 tons of U_3O_8 in 1980, similar to the 1979 level of 832.0 tons. While

MKU's production is expected to be maintained in 1981, the quantity scheduled to be delivered is significantly lower. MKU is an open pit mine in which ore was mined by conventional drilling, blasting, loading, and hauling equipment. The mine consisted of a series of benches cut into the hill slope to a height of 105 meters above the valley floor and extends to 60 meters below. The ore was processed onsite, and high-grade yellow cake was railed from the mine to Brisbane and shipped to the United States, the Federal Republic of Germany, and Japan.

Queensland Mines Ltd. (Nabarlek) produced 1,006 tons of U_3O_8 during 1980. The company has a contract with the Kyushu Electric Power Co., and the Shekoku Electric Power Co. both of Japan, for the supply of U_3O_8 during the next 10 years. The Nabarlek mill was designed to meet the environmental requirements that was imposed on the Australian uranium industry. The grade of ore is about 2% U_3O_8, and was mined by open pit methods. The mill has a capacity of 200 tons per day and the operation has a life expectancy of approximately 10 years.

In January 1980, the Federal Government announced the formation of the Uranium Enrichment Group in Australia. The group, comprising BHP, CSR Ltd, Peko Wallsend Ltd., and WMC, is studying available enrichment technology and the resultant implications of an enrichment plant in Australia.

Measured reserves in four large deposits in Northern Territory total 297,000 tons of U_3O_8 comprising Jabiluka, 127,000 tons; Ranger, 100,000 tons; Koongarra, 15,000 tons; and Nabarlek, 10,000 tons. The planned initial rate of production was 9,000 tons per year.

The Yeerlirrie deposit in Western Australia has measured reserves of 46,000 tons of U_3O_8, the Beverley and Mount Painter deposits in South Australia have 16,000 tons, and the remaining reserves at MKU were about 7,500 tons. This total of 366,500 tons of U_3O_8 in seven deposits was considered available for immediate development. Numerous other prospects were under investigation throughout the country.

The Mineral Industry of Austria

By William F. Keyes[1]

The Austrian economy grew at the rate of about 3.5% in real terms in 1980, after expanding 5.1% in 1979. This was an unexpectedly strong performance, and a growth rate higher than that of most industrialized countries. Labor-management relations were harmonious, and unemployment was only about 1.9% in 1980. Economic activity diminished somewhat late in the year and was expected to continue to decline in 1981, along with employment. Like the economy, the mining and basic chemical industries showed relatively good results in 1980, except that the repercussions of the international steel crisis were being felt late in the year, leading the Austrian Government to examine measures to achieve a restructuring of the domestic steel industry.

The Government enacted a new Federal law (Bergbaufoerderungsgesetz 1979) designed to promote the domestic production of mineral raw materials, which entered into force retroactively to January 1, 1979, and was to expire on December 31, 1983. The law authorizes financial assistance for the exploration, exploitation, and continuation of mining operations, and for environmental purposes. The legislation is similar to the previous law, which was in effect until the end of 1977, but a major change is the additional inclusion in the types of operations eligible of all nonferrous ores and any ores used in the production of special steels.

The Austrian Ministry of Trade, Commerce, and Industry finished a draft of a plan designed to safeguard the country's raw material supply, about two-thirds of which is imported. Of 52 products that could pose problems if in short supply, 12 were listed as particularly critical, including metallurgical coal, copper, fluxes for the aluminum industry, manganese, alumina, asbestos, chromium, fluorspar, molybdenum, nickel, phosphates, and prime-grade mica. None of the 52 are produced in Austria in significant quantities, although, in a symposium on raw material supply early in 1980, it had been agreed that self-sufficiency could be improved to some extent through exploration and exploitation of domestic raw materials, application of recycling techniques, and development of new processes to conserve and replace materials in short supply. The plan, first of its kind in Austria, was to be distributed for comment to appropriate sectors of the economy during the year.

PRODUCTION

Several industries set production records in 1979, but by late 1980 demand had tapered off, and total minerals output was not expected to reach the 1979 level. Indexes of mining, nonferrous manufacturing, and magnesite were up slightly, but the crude oil production index declined.

Table 1 gives production of minerals and metals in Austria for 1976-80.

TRADE

Diminished demand for Austrian exports showed up in the second half of 1980. Another cause for concern was the fact that the mix of exports continued to be dominated by raw materials and semiprocessed goods, such as nonmetallic minerals and forest products, rather than the higher value manufactured products exported by other industrialized nations. With huge fuel imports, commodities thus dominated Austria's foreign trade.

Tables 2 and 3 report the mineral trade of Austria for 1978 and 1979, the latest years for which data are available.

Metal including alloys:				
Scrap	42,570	38,864	--	Italy 24,531; West Germany 14,068.
Unwrought	11,685	10,306	--	West Germany 6,638; Bulgaria 1,149; Italy 1,116.
Semimanufactures	65,393	72,425	3,639	West Germany 18,644; Belgium 3,800; Switzerland 3,658.
Antimony ore and concentrate	414	493	NA	NA.
Cadmium metal including alloys, all forms	20	25	--	Czechoslovakia 20; West Germany 5.
Chromium:				
Chromite	923	1,028	--	West Germany 960.
Oxides	1	1	--	NA.
Columbium and tantalum: Tantalum metal including alloys, all forms	10	15	NA	NA.
Copper:				
Ore and concentrate	91	116	--	All to West Germany.
Sulfate	1,618	864	--	Italy 859.
Metal including alloys:				
Scrap	2,474	3,242	98	West Germany 1,055; Switzerland 1,052; United Kingdom 601.
Unwrought	18,663	20,142	--	West Germany 8,009; Italy 7,930; Hungary 2,626.
Semimanufactures	13,655	15,470	33	Italy 3,183; West Germany 2,429; France 1,870.
Gold metal including alloys, worked or partly worked, troy ounces	12,249	24,274	--	West Germany 17,201.
Iron and steel:				
Ore and concentrate except roasted pyrite	85	2	NA	NA.
Metal:				
Scrap	7,344	13,904	--	Italy 8,797; Switzerland 3,489; West Germany 1,509.
Pig iron, ferroalloys, similar materials	11,312	12,848	NA	NA.
Steel, primary forms	430,668	506,501	3,160	West Germany 260,025; Yugoslavia 107,091; Italy 87,581.
Semimanufactures:				
Bars, rods, angles, shapes, sections	304,717	366,715	4,746	West Germany 107,299; Italy 90,630; Switzerland 39,455.
Universals, plates, sheets thousand tons	1,063	1,172	9	U.S.S.R. 369; West Germany 331; Italy 119.
Hoop and strip	82,196	105,488	239	Switzerland 18,430; Poland 16,660; West Germany 16,087.
Rails and accessories	86,559	118,877	--	Yugoslavia 32,143; Switzerland 27,091; Romania 16,588.
Wire	54,980	65,993	206	West Germany 17,066; Italy 10,512; Switzerland 6,928.
Tubes, pipes, fittings	162,593	194,084	63	West Germany 38,167; United Kingdom 28,184; Sweden 25,732.
Castings and forgings, rough	r10,978	12,744	674	West Germany 4,070; Sweden 1,665; Netherlands 1,483.
Lead metal including alloys, all forms	686	492	--	Yugoslavia 265; Italy 120; West Germany 47.
Magnesium metal including alloys, all forms	702	694	--	West Germany 362; Italy 233.
Manganese oxide	78	58	--	Mexico 24; Brazil 21.
Mercury, 76-pound flasks	818	438	--	West Germany 209; Belgium 154.
Molybdenum metal including alloys, all forms	872	1,101	NA	NA.
Platinum and platinum-group metals including alloys, all forms, troy ounces	7,652	5,755	--	West Germany 2,733; Romania 2,476.
Silver metal including alloys:				
Bullion, thousand troy ounces	775	1,523	--	West Germany 1,365; Switzerland 126.
Other (powder), do	(1)	3	NA	NA.
Semimanufactures, do	1,138	1,111	--	Yugoslavia 1,051; West Germany 29.
Tin metal including alloys, all forms	96	65	--	United Kingdom 50.
Titanium oxide	65	37	1	West Germany 25.
Tungsten:				
Ore and concentrate	130	25	--	All to United Kingdom.
Metal including alloys, all forms	591	848	NA	NA.
Zinc:				
Oxides	34	636	--	Hungary 600.
Metal including alloys, all forms	863	1,339	--	Czechoslovakia 500; West Germany 474; Italy 129.

See footnotes at end of table.

Table 2.—Austria: Exports of mineral commodities —Continued

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS —Continued				
Other:				
Ores and concentrates	78	54	--	West Germany 51.
Ash and residue containing nonferrous metals	64,346	68,290	--	Italy 49,012; West Germany 15,035; Spain 2,182.
Waste and sweepings of precious metals including old metals kilograms	r37,178	40,698	--	West Germany 40,165; United Kingdom 302; France 128.
Oxides, hydroxides, peroxides	1,582	1,044	21	Italy 580; West Germany 415.
Base metals including alloys, all forms	4,719	2,975	322	United Kingdom 1,190; Italy 1,076.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	17	11	NA	NA.
Grinding and polishing wheels and stones	12,934	12,792	31	West Germany 2,047; Italy 1,294; Sweden 967.
Dust and powder of precious and semiprecious stones including diamond kilograms	2	(2)	--	NA.
Asbestos	80	2	--	NA.
Cement	29,242	20,631	--	West Germany 15,526.
Chalk	5,980	3,406	--	Hungary 2,660; Italy 322.
Clays and clay products:				
Crude clays:				
Kaolin (china clay)	21,271	25,269	--	Italy 12,338; Hungary 8,565; Yugoslavia 3,242.
Other	199	155	--	Hungary 40; Trinidad and Tobago 25.
Products:				
Refractory including nonclay bricks	168,117	172,887	648	West Germany 30,864; France 20,130; Sweden 13,013.
Nonrefractory	26,280	85,589	--	West Germany 80,072.
Diamond:				
Industrial value	$6,680	$38,674	--	Yugoslavia $37,926.
Other:				
Crude do	$20,176	$35,907	$31,344	NA.
Worked carats	(3)	5,000	--	NA.
Diatomite and other infusorial earth	1,027	1,031	--	Yugoslavia 848; Czechoslovakia 116.
Fertilizer materials, manufactured, phosphatic	38,511	15,077	--	Hungary 12,468; Czechoslovakia 2,606.
Graphite, natural	17,787	17,870	--	Poland 9,755; West Germany 5,631; Italy 1,146.
Gypsum and plasters	189,752	250,801	--	West Germany 207,670; Italy 15,098; Hungary 13,237.
Lime	1,955	1,424	--	West Germany 1,131.
Magnesite	109,536	112,021	--	West Germany 21,983; Hungary 13,771; Poland 11,060.
Mica, all forms	156	312	--	Greece 95; United Kingdom 65.
Pigments, mineral including processed iron oxides	6,905	7,788	106	West Germany 2,172; United Kingdom 1,366; Netherlands 1,002.
Precious and semiprecious stones:				
Crude excluding diamond thousand carats	11,525	5,355	60	West Germany 2,850; Switzerland 1,510.
Manufactured including diamond do	10,820	9,600	2,965	West Germany 1,575; Switzerland 680; Yugoslavia 425.
Pyrite	44	93	--	Spain 35; West Germany 29.
Salt	48	90	--	Italy 87.
Sodium and potassium compounds, n.e.s.:				
Caustic potash	(2)	30	--	NA.
Soda ash	2,100	2,665	NA	Hungary 2,260; Romania 350; Bulgaria 6.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked:				
Calcareous including marble and limestone	76,671	75,222	--	West Germany 59,012; Switzerland 16,134.
Slate	37	27	NA	NA.
Other	70,863	44,951	--	West Germany 44,108.
Worked:				
Paving and flagstone	13,114	25,429	--	West Germany 16,538; Switzerland 8,430.
Slate	27	46	NA	NA.
Other	2,942	2,334	129	West Germany 1,871; Yugoslavia 129.

See footnotes at end of table.

Table 2.—Austria: Exports of mineral commodities —Continued

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
NONMETALS —Continued				
Stone, sand and gravel —Continued				
Dolomite	8,508	10,597	--	West Germany 7,457; Yugoslavia 971.
Gravel and crushed rock	430,665	486,511	--	Switzerland 293,344; West Germany 187,157.
Limestone except dimension	30	48	--	NA.
Quartz and quartzite	134	93	--	West Germany 55.
Sand excluding metal-bearing	126,716	160,860	--	West Germany 88,890; Switzerland 62,909.
Sulfuric acid, oleum	8,111	12,074	--	Yugoslavia 5,512; Italy 4,237; Czechoslovakia 1,922.
Talc, steatite, soapstone, pyrophyllite	87,097	98,139	--	West Germany 52,029; Italy 13,495; Netherlands 7,964.
Other:				
Crude	4,028	4,905	--	West Germany 3,716; Switzerland 652.
Slag, dross, and similar waste, not metal-bearing	34,648	42,395	--	West Germany 36,082; Italy 6,099.
Oxides and hydroxides of magnesium, barium, strontium kilograms	300	100	NA	NA.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	15	72	NA	NA.
Carbon black and gas carbon	10	13	NA	NA.
Coal including briquets:				
Anthracite and bituminous coal including briquets	28	97	NA	NA.
Lignite and lignite briquets	5,433	11,581	NA	West Germany 11,531.
Coke and semicoke	63,805	12,090	--	Romania 10,981; West Germany 700.
Hydrogen, helium, rare gases thousand cubic feet	54,089	68,216	--	Hungary 37,554; West Germany 10,758; Czechoslovakia 6,990.
Peat including briquets and litter	3	290	--	Italy 220.
Petroleum refinery products:				
Gasoline, aviation and motor thousand 42-gallon barrels	r48	126	--	Yugoslavia 116.
Kerosine and jet fuel do	(2)	(2)	--	NA.
Distillate fuel oil do	1	3	--	Switzerland 2.
Residual fuel oil do	239	5	--	Czechoslovakia 4.
Lubricants do	642	551	--	Czechoslovakia 212; Yugoslavia 98; Poland 91.
Mineral jelly and wax do	90	188	--	Netherlands 130.
Liquefied petroleum gas do	419	484	--	Italy 278; Czechoslovakia 80; West Germany 52.
Other do	50	64	--	Yugoslavia 40; Poland 6; Czechoslovakia 5.
Total do	r1,489	1,421		
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	14,526	17,179	--	West Germany 8,733; Yugoslavia 4,578; France 1,882.

rRevised. NA Not available.
[1]Unreported quantity valued at $3,718.
[2]Less than 1/2 unit.
[3]Unreported quantity valued at $136,896.

Table 3.—Austria: Imports of mineral commodities

COMMODITY REVIEW

METALS

Iron and Steel.—Although the steel industry set a new record in 1979 with production of 4.9 million metric tons of crude steel, declining demand late in 1980 led to production cutbacks of at least 15%. Significant financial losses were suffered during the year, and according to the chairman of the major steel producer, Vöest Alpine Montan AG (VAM), prospects for 1981 were also unfavorable. VAM at yearend was operating at 80% of capacity.

VAM continued to shift to advanced technology. Basic oxygen steel production increased in 1979 to 4.1 million tons, or 84.9% of the total, while continuous casting continued to expand its proportion of steel produced. The output of electric steel also grew 12.7% in 1979, compared with the 1978 level.

The Oesterreichische Industrieverwaltungs AG, the state holding company, commissioned a study of Vereinigte Edelstahlwerke AG (VEW), the nationalized specialty steel producer, from Booz, Allen, and Hamilton Inc. in mid-1980. The report was finished early in 1981, and while it was not immediately published, its conclusions were widely discussed.

Reportedly, Booz-Allen considered VEW to be overstaffed and burdened with identical production lines in too many locations. The survey proposed the complete closure of the Judenburg plant, which employed 1,600 persons producing rolling mill products, springs, and forgings; transfer of production of steel bars at Muerzzuschlag-Hoenigsberg to Kapfenberg, thus making redundant 450 workers out of 2,100, but continuation of sheet production at Muerzzuschlag; closing of departments making high-speed tools and heavy forgings at Kapfenberg-Deuchendorf, thus idling some 850 out of 7,300, including employees of the finishing departments and VEW's research center at Deuchendorf; closing the casting plant at Ternitz, causing 550 persons out of 4,000 to lose their jobs; closure of the departments for die forgings and steel tubes at the Ybbstahl works, and transfer of this work to VAM's main plant in Linz, at a cost of 300 jobs out of 1,500; and transfer of some administrative responsibilities, including sales, from Vienna to plant offices, thus eliminating between 250 and 500 white collar positions. The Booz-Allen plan, if adopted, would reduce employment at VEW from 19,000 to about 15,000, or 20%.

It was not immediately apparent what the ultimate reaction of VEW management and the Government would be to the Booz-Allen plan, but reaction from workers' councils was strongly adverse and local communities appealed to the Government to consider the impact on the entire regional economy.

NONMETALS

Graphite.—Almost all the graphite produced in Austria is amorphous. Production from two distinct regions has been declining in the past two decades, and is currently about 40,000 tons of crude graphite. The largest producer, the Kaiserberg Mine of Graphitbergbau Kaisersberg Franz Mayr-Melnhof & Co., 10 miles southwest of Leoben, mined graphite containing 40% to 88% carbon. Production was largely foundry grades with a small production of microcrystalline flotation concentrate. The company also operated the Trieben-Hohentauern Mine 20 miles west of Leoben.

Production in Lower Austria, near Muhldorf and Zettlitz, of a more crystalline variety was from old dumps by the firm Pryssok & Co. KG.

MINERAL FUELS

The 1980 Energy Report of the Austrian Trade Ministry was published at yearend. It forecast a level of 1985 gross domestic energy consumption of 24.9% above 1976, compared with 35.4% above 1976 estimated in the 1979 Energy Report. Nevertheless, the overall energy consumption was forecast to increase at a rate of 2.7% annually through 1985 and 2.2% annually from 1985 through 1990. In 1979, some 67.5% of energy needs were met through imports; this figure will reach 70% in 1985 and 75% by 1990.

A major target of Austrian energy policy is compliance with the recommendation of the International Energy Agency that calls for substitution of coal for petroleum products. Other major goals include exploration and exploitation of domestic energy resources to the largest extent possible, a reduction in the rate of energy growth, and diversification of foreign supplies. According to the Energy Report, protection of energy supply was accorded the same im-

portance, in the public eye, as protection of the environment.

Coal.—Production (all of lignite) continued to decline in 1979, by over 10% to 2.7 million tons, as a result of the 1978 closing of the major Fohnsdorf Mine. This level of output was expected to continue until the new open pit at the Oberdorf Mine at Barnbach, in the area of Graz, comes into operation, about 1983, at an ultimate production rate of 1 million tons per year. Study of a possible mine on the Hungarian border was underway; both developments were being undertaken by the Graz-Köflacher Eisenbahn und Bergbaugesellschaft, the Government's largest coal company. Coal was also produced by Wolfsegg-Traunthaler Kohlenwerk AG at two mines near Ampfelwang, and by Salzach Kohlenbergbau GmbH at Trimmelkam; all three mines are near Salzburg.

In June, a contract was signed for annual deliveries of 1.2 million tons of Polish coal for 20 years, beginning in 1983. An Austrian coal delegation visited the United States in November to discuss possible purchases of U.S. coal as part of the Government's policy to diversify sources of supply. The only Austrian imports from the United States hitherto had been initial small shipments from the West Virginia mine purchased recently by VAM, the Government's steel company.

Natural Gas.—Natural gas provides about 20% of Austria's energy. In 1979, almost half of the 4.6 billion cubic meters consumed was domestic production, but 99% of the remainder came from the Soviet Union, the highest dependence of any nation in Western Europe on Soviet gas. Reports of irregularities in deliveries of these imports caused the Austrian Government to reassure the public that fluctuations were a result of seasonal factors. Austrian officials were also endeavoring to obtain Soviet agreement to expand future deliveries.

Austria has imported natural gas from the Soviet Union since 1968, when it signed a contract for 1.5 billion cubic meters annually until 1990. Subsequent agreements were signed in 1974 for an additional 500 million cubic meters annually from 1978 to 2000, and in 1975 for a further 500 cubic meters annually until the year 2000. The present desire of the Austrian Government was to obtain a further 1.5 to 3 billion cubic meters annually beginning about 1985. Negotiations with the Soviets were focused on the price to be paid because the rising cost of energy imports had led to an Austrian deficit in the bilateral trade account of AS6.3 billion[2] ($470 billion) in the first 10 months of 1980, compared with AS2.9 billion ($220 billion) in the same period of 1979.

Reserves of natural gas in Austria were estimated at about 10.6 billion cubic meters (375 billion cubic feet) as of January 1, 1980, not including associated gas, which was currently about 16% of total production.

Petroleum.—The state oil company, Österrerchische Mineralölverwaltungs AG (OMV), had six exploratory drill rigs operating on existing fields, chiefly in the Vienna basin. Two gas finds and one oil find were made in 1979; the gas finds were Aderklaa West 1, 5 miles northeast of Vienna, and Stockerau Ost 2, 12 miles northwest of Vienna; the oil find was Wolkersdorf 6, 10 miles northeast of Vienna. The Zistersdorf UT (Uebertief) 1 well, near the Czechslovakian border, struck gas at 7,544 meters, the target depth, early in 1980.

The Austrian Government during the year made several technical changes in the terms of concession agreements. Existing rights of the companies involved, however, were extended until negotiations could be completed. OMV was by far the largest of these companies, holding 100% interest in 9,555 square miles. Rohoel-Aufsuchungs GmbH had interests in 2,480 square miles. A third group, consisting of Vorarlberger Erdoel und Ferngas GmbH (51%), Elwerath (14.16%), Deutsche BP (11.97%), Preussag AG (14.7%), and Wintershall AG (8.17%), holds about 385 square miles. Two other small tracts, both less than 1 square mile, are held by Van Sickle GmbH and by Erdgasbergbau Wels.

Austria's domestic production of crude oil declined to about 1.5 million metric tons in 1980 from 1.7 million in 1979, but the value of production rose from AS3.2 billion ($240 million) to AS4.2 billion ($330 million). Consumption of petroleum products also declined, from 11.7 million metric tons in 1979 to 11.2 million in 1980. Reasons given for the decline in consumption were higher prices and a decline in the growth rate of the gross domestic product from 5.1% in 1979 to 3.5% in 1980.

The Mineral Industry of Belgium-Luxembourg

By William F. Keyes[1]

By late 1980, the Belgian economy, with a gross national product (GNP) of about $120 billion, appeared headed into a new recession, following the downturn in the economies of some of its major trading partners, particularly the Federal Republic of Germany, and the upturn that took place in 1979 appeared to have ended. Added to the problems were political instability, with the fourth Government (administration) in 18 months, high unemployment, and Government deficits.

Except for coal, Belgium lacks significant mineral resources of its own, but the production of steel and nonferrous metals from imported ores is important. Both coal and steel were in trouble during the year. The coal mining industry has been kept viable for years by Government assistance and continued assistance was anticipated. The steel industry which, with nonferrous metals, added about 2% to the GNP in 1980 compared with 4.3% in 1974, and 18% to Belgian exports, was in serious trouble because of the continued imbalance between worldwide capacity and demand and because of the age, inefficiency, and labor-intensiveness of much of the installed capacity. The Government devoted a great deal of attention to steel during the year, and a costly rescue plan was evolving.

PRODUCTION

The general production index, which rose somewhat to 126.0 in 1979, was 124.0 in the first 9 months of 1980; coal was similarly steady at 40.0 in both periods. The index of nonferrous metals production rose from 155.8 in 1979 to 169 in the first half of 1980. The steel index declined from 109.1 in 1979 to 107.0 in the first 9 months of 1980; in September it reached the extraordinarily low level of 71.0 (all indexes are based on 1970=100).

Production of minerals and metals in Belgium from 1976 to 1979, and estimates for 1980, are given in table 1.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through June 23, 1981.

[2]In addition to the commodities listed, Belgium produces a number of other metals for which only aggregate output figures are available. These aggregates are included under "Other nonferrous metals."

[3]Reported figure.

[4]Known to include gold and silver and may include platinum-group metals.

[5]Derived by subtracting aluminum data from a reported total for unspecified base metals.

TRADE

Belgian minerals trade is detailed in tables 2 and 3 for the years 1978 and 1979, the latest for which complete data are available.

Table 2.—Belgium-Luxembourg: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destination, 1979	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite and concentrate	689	4,531	--	West Germany 4,467.
Oxide and hydroxide	185	1,151	NA	France 625.
Ash and residue containing aluminum	5,475	7,508	--	West Germany 6,170.
Metal including alloys:				
Scrap	28,726	33,532	NA	France 14,342; West Germany 8,850; Netherlands 7,063.
Unwrought	10,185	10,842	NA	West Germany 5,303; France 4,642.
Semimanufactures	227,256	242,534	23,857	France 52,470; West Germany 40,646; Netherlands 26,435.
Antimony:				
Ore and concentrate	--	5	--	NA.
Metal including alloys, all forms	52	6	--	NA.
Beryllium metal including alloys, all forms kilograms	500	14	--	NA.
Cadmium metal including alloys, all forms	735	809	195	West Germany 271; France 192.
Chromium:				
Chromite	447	19	--	NA.
Oxide, hydroxide, trioxide	50	97	NA	NA.
Metal including alloys, all forms	422	509	NA	West Germany 263; United Kingdom 69; France 55.
Copper:				
Ore and concentrate	3,443	733	NA	Netherlands 282; West Germany 206; Denmark 80.
Copper sulfate	12,359	13,095	NA	Netherlands 2,938; West Germany 2,760; Denmark 1,496.
Ash and residue containing copper	1,479	1,886	--	France 841; West Germany 502; United Kingdom 216.
Metal including alloys:				
Scrap	19,912	26,846	NA	West Germany 12,140; France 5,821.
Unwrought	313,376	306,934	1,681	France 106,317; West Germany 76,502.
Semimanufactures	282,534	282,518	15,276	France 107,408; West Germany 77,421.
Gold:				
Waste and sweepings value, thousands	$109	$806	--	Netherlands $457; West Germany $349.
Metal, unworked or partly worked thousand troy ounces	894	583	1	Switzerland 315; United Kingdom 113; West Germany 110.
Iron and steel:				
Ore and concentrate, except roasted pyrite	r83,851	3,172	--	NA.
Roasted pyrite	r153,437	154,153	NA	West Germany 144,883.
Metal:				
Scrap thousand tons	532	550	NA	West Germany 225; France 177.
Pig iron including cast iron do	37	23	NA	Netherlands 9; West Germany 8; France 5.
Sponge iron, powder, shot do	351	776	NA	West Germany 136; France 128.
Spiegeleisen	235	61	--	NA.
Ferroalloys:				
Ferromanganese thousand tons	30	44	NA	France 21; West Germany 14.
Other do	42	46	NA	West Germany 6; France 2; Italy 1.
Steel, primary forms do	2,676	3,224	NA	France 1,475; West Germany 696; Italy 353.
Semimanufactures:				
Bars, rods, angles, shapes, sections do	4,172	4,177	424	West Germany 1,046; France 613; Netherlands 474.
Universals, plates, sheets do	5,239	5,414	235	France 1,390; West Germany 1,276; Netherlands 590.
Hoop and strip do	770	800	(1)	West Germany 327; France 209; Netherlands 27.
Rails and accessories do	81	86	7	France 21; Italy 18; Netherlands 2.
Wire do	465	476	52	West Germany 98; France 78; Netherlands 46; Italy 27.
Tubes, pipes, fittings do	357	370	6	West Germany 85; Algeria 63; Netherlands 49.
Castings and forgings, rough do	11	13	1	Netherlands 6; West Germany 4.
Total do	11,095	11,336		
Lead:				
Ore and concentrate	25	1,196	--	All to Romania.
Oxide	5,778	5,406	NA	Netherlands 2,583; West Germany 1,733.
Ash and residue containing lead	8,568	4,678	--	Italy 1,640; France 1,366; West Germany 936.
Metal including alloys:				
Scrap	15,653	22,531	NA	France 15,886; West Germany 3,742.
Unwrought	85,987	74,180	2,539	West Germany 19,331; Netherlands 17,970; U.S.S.R. 10,353.
Semimanufactures	5,716	6,597	NA	Netherlands 5,062.

See footnotes at end of table.

Table 2.—Belgium-Luxembourg: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destination, 1979	
			United States	Other (principal)
METALS —Continued				
Magnesium metal including alloys:				
Scrap	368	524	115	Netherlands 125.
Unwrought and semimanufactures	145	3	NA	NA.
Manganese:				
Ore and concentrate	11,324	6,107	NA	United Kingdom 2,840; Netherlands 2,157; Italy 554.
Metal including alloys, all forms	76	26	NA	NA.
Mercury 76-pound flasks	1,633	516	NA	NA.
Molybdenum:				
Ore and concentrate	5,872	5,945	NA	West Germany 1,688; Italy 1,310; Austria 680.
Metal including alloys, all forms	121	177	6	Netherlands 76; United Kingdom 35; West Germany 31.
Nickel:				
Ore and concentrate	1	--		
Matte, speiss, similar materials	1	1	--	NA.
Metal including alloys:				
Scrap	1,220	1,656	129	India 682; West Germany 526.
Unwrought	331	406	20	West Germany 149; United Kingdom 80; Poland 48.
Semimanufactures	1,902	1,040	NA	West Germany 35; United Kingdom 13.
Platinum-group metals including alloys, all forms troy ounces	117,668	113,239	27,196	West Germany 42,711; France 16,507; Netherlands 13,992.
Selenium, elemental kilograms	157,200	NA	NA	NA.
Silver metal including alloys, all forms thousand troy ounces	20,994	21,262	2,491	United Kingdom 6,112; France 3,346; Switzerland 3,106.
Tin:				
Ore and concentrate	56	75	--	Spain 56; France 19.
Oxide kilograms	r1,200	300	--	NA.
Metal including alloys:				
Scrap	149	92	--	Netherlands 34; West Germany 12.
Unwrought	2,417	2,372	NA	France 770; West Germany 415; Netherlands 347.
Semimanufactures	71	23	NA	Netherlands 9; Burundi 7.
Titanium:				
Ore and concentrate	3	--		
Oxide	28,457	23,304	1,672	West Germany 8,613; Italy 2,118; France 1,897.
Metal including alloys, all forms	164	191	NA	West Germany 68; France 18; Netherlands 16.
Tungsten:				
Ore and concentrate	45	9	NA	NA.
Metal including alloys, all forms	215	159	NA	Netherlands 70; West Germany 69.
Uranium ore and concentrate	547	403	--	All to France.
Vanadium oxide	105	211	NA	Czechoslovakia 121; West Germany 36; United Kingdom 36.
Zinc:				
Ore and concentrate	11,676	60,645	NA	France 47,803.
Oxide	4,862	7,119	NA	France 1,753; Hungary 1,254; West Germany 1,247.
Ash and residue containing zinc	42,685	34,727	NA	France 14,009; West Germany 13,400; Netherlands 514.
Metal including alloys:				
Scrap	4,147	5,369	NA	Netherlands 2,343; France 2,070.
Blue powder	18,405	18,765	NA	West Germany 11,634; France 1,710.
Unwrought	187,102	193,626	10,305	West Germany 76,748; France 48,925.
Semimanufactures	9,108	9,294	17	West Germany 5,079; Netherlands 1,958.
Other:				
Ores and concentrates:				
Of niobium, tantalum, vanadium, zirconium	51	79	NA	West Germany 40; Japan 2.
Of precious metals kilograms	200	NA	NA	NA.
Of base metals, n.e.s	72	3,427	NA	West Germany 3,426.
Ash and residue containing nonferrous metals, n.e.s	43,969	60,384	NA	Netherlands 47,494; West Germany 10,881.
Waste and sweepings of precious metals, n.e.s value, thousands	$7,421	$5,256	--	United Kingdom $3,546; West Germany $1,441.
Oxides, hydroxides, peroxides of metals, n.e.s	2,486	2,807	260	Netherlands 1,113; West Germany 453; France 201.

See footnotes at end of table.

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destination, 1979	
			United States	Other (principal)
METALS —Continued				
Other —Continued				
Metals including alloys, all forms:				
Metalloids:				
Tellurium and arsenic	24	22	NA	West Germany 12; France 7.
Other	119,636	162,617	(1)	Netherlands 112,568; France 38,745.
Alkali, alkaline-earth, rare-earth metals	69	20	NA	NA.
Pyrophoric alloys	1	--		
Base metals including alloys, all forms, n.e.s	293	307	31	West Germany 112; Austria 92; Finland 24.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	245	1,137	NA	NA.
Dust and powder of precious and semiprecious stones, natural and manufactured kilograms	958	1,080	318	United Kingdom 192; Israel 83; Netherlands 74; Spain 61.
Grinding and polishing wheels and stones	2,381	2,358	NA	France 1,440; West Germany 278; United Kingdom 259.
Asbestos	221	130	NA	NA.
Barite and witherite	408	429	NA	NA.
Boron materials:				
Crude natural borates	9,503	13,982	NA	West Germany 6,476; Netherlands 6,269.
Oxide and acid	423	242	NA	NA.
Bromine	138	412	NA	Netherlands 398.
Cement thousand tons	2,762	2,871	7	Netherlands 1,681; West Germany 364; France 256.
Chalk	64,813	57,203	NA	Netherlands 15,403; West Germany 13,828; Saudi Arabia 7,166.
Clays and clay products (including all refractory brick):				
Crude:				
Bentonite	8,273	11,574	NA	West Germany 5,113; France 4,300.
Kaolin	3,175	20,345	NA	West Germany 17,034; Netherlands 1,818.
Other	3,663	20,661	NA	Netherlands 19,004.
Products:				
Refractory (including nonclay brick)	96,215	107,505	NA	France 51,860; West Germany 23,456; Italy 8,857.
Nonrefractory value, thousands	$53,459	$51,205	NA	West Germany $17,191; Netherlands $15,957; France $9,538.
Cryolite and chiolite	16	50	--	NA.
Diamond:				
Gem:				
Unworked thousand carats	24,564	22,370	NA	United Kingdom 10,733; India 7,279; Switzerland 2,870.
Worked do	3,077	2,875	711	Hong Kong 351; West Germany 308; Switzerland 301.
Industrial:				
Unworked do	8,641	9,140	2,096	United Kingdom 3,010; Ireland 1,559; West Germany 596.
Worked do	9	11	NA	United Kingdom 6; Switzerland 3.
Diatomite and other infusorial earth	3,567	1,350	NA	Netherlands 1,082; France 112.
Feldspar, leucite, nepheline, nepheline syenite	8,543	7,462	NA	Netherlands 7,367.
Fertilizer materials:				
Crude:				
Nitrogenous	9,816	11,999	NA	Italy 6,115; West Germany 4,752.
Phosphatic	14,203	18,434	NA	West Germany 7,179; France 5,500.
Potassic, K_2O content	138	566	--	Netherlands 544.
Manufactured:				
Nitrogenous, N_2 content thousand tons	516	486	5	France 165; West Germany 114.
Phosphatic, P_2O_5 content do	280	276	NA	France 147; West Germany 91.
Potassic, K_2O content do	283	303	NA	France 77; Norway 42; Netherlands 19.
Other including mixed do	1,641	1,728	NA	France 907; West Germany 281; United Kingdom 70.
Ammonia	84,791	94,507	NA	France 86,947.
Fluorspar	4,540	4,984	--	West Germany 4,813.
Graphite, natural	68	49	--	NA.
Gypsum and plasters	54,905	97,048	NA	West Germany 48,540; Netherlands 37,795.
Lime	590,408	662,265	NA	Netherlands 565,499; Ivory Coast 3,505.
Magnesite	3,594	4,696	NA	France 2,115; West Germany 241.

Table 2.—Belgium-Luxembourg: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destination, 1979	
			United States	Other (principal)
NONMETALS —Continued				
Mica:				
Crude including splittings and waste	94	160	NA	NA.
Worked including agglomerated splittings	2	(1)	NA	NA.
Pigments, mineral, including processed iron oxide	9,055	11,633	NA	France 7,655; Netherlands 1,095; Iraq 626.
Precious and semiprecious stones:				
Natural, except diamond:				
Unworked grams	6	213	NA	NA.
Worked:				
Gem kilograms	r3,980	2,553	NA	Switzerland 2,170; France 176; West Germany 83.
Industrial do.	(1)	(1)	NA	NA.
Manufactured do.	299	1,695	25	Republic of Korea 1,289.
Pyrite, gross weight	53	522	NA	NA.
Salt and brines	139,471	144,224	NA	France 122,545.
Sodium and potassium compounds, n.e.s.	43,656	53,846	NA	France 11,464; Netherlands 10,300.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked:				
Calcareous	583,981	600,716	NA	Netherlands 549,153.
Slate	4,642	6,278	NA	Netherlands 3,427; West Germany 2,582.
Other	18,908	4,735	NA	NA.
Worked:				
Slate	979	918	NA	West Germany 560; Netherlands 81.
Paving stone and flagstone	11,934	7,407	NA	Netherlands 5,855; France 942.
Other	10,251	12,748	92	West Germany 3,070; Saudi Arabia 2,758.
Dolomite, chiefly refractory grade thousand tons	1,602	1,646	NA	Netherlands 835; West Germany 558; France 47.
Gravel and crushed rock do.	12,284	7,946	NA	Netherlands 4,100; France 3,239.
Limestone, except dimension do.	536	538	--	Netherlands 346; France 191.
Quartz and quartzite do.	10	14	NA	West Germany 7; Netherlands 1.
Sand, excluding metal-bearing do.	2,975	3,104	NA	France 914; Netherlands 785; Italy 363.
Sulfur:				
Elemental, all forms	10,661	11,621	NA	West Germany 4,027; Netherlands 1,307; France 1,042.
Sulfuric acid	125,624	190,805	NA	France 100,734; Netherlands 53,139.
Talc, steatite, soapstone, pyrophyllite	18,286	21,186	NA	West Germany 5,464; United Kingdom 2,832; France 2,821.
Other:				
Crude:				
Vermiculite, perlite, chlorite	1,134	1,338	NA	NA.
Other	151,608	151,478	NA	Netherlands 129,506; France 15,539.
Slag, dross, and similar waste, not metal-bearing thousand tons	2,185	2,181	NA	Netherlands 882; West Germany 750; France 540.
Oxides and hydroxides of magnesium, strontium, barium	194	153	NA	NA.
Iodine and fluorine	8	6	NA	NA.
Building materials of asphalt, asbestos, and fiber cement, and unfired nonmetals, n.e.s thousand tons	1,370	1,784	2	Netherlands 700; United Kingdom 330; France 262.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	4,465	9,254	NA	West Germany 8,089; France 739.
Carbon black and gas carbon	947	686	NA	France 212; Netherlands 158; West Germany 110.
Coal and briquets:				
Anthracite and bituminous	245,535	445,248	50,914	West Germany 171,827; France 112,846.
Briquets of anthracite and bituminous coal	25,622	58,927	NA	France 54,246.
Lignite and lignite briquets	8	138	--	NA.
Coke and semicoke	195,843	638,510	238,355	France 177,641; West Germany 108,338.
Gas, natural million cubic feet	1,596	7	NA	NA.
Hydrogen, argon, rare gases	39,981	43,100	NA	France 24,200; West Germany 13,382.
Peat including peat briquets and litter	1,984	4,394	NA	Netherlands 2,170.
Petroleum:				
Crude and partly refined thousand 42-gallon barrels	591	62	NA	Netherlands 59.

See footnotes at end of table.

COMMODITY REVIEW

METALS

Copper.—Belgium, whose chief sources of copper have traditionally been Zaire and other western nations, signed a contract with Poland, through the Société Generale des Mines and the Polish Impexmetal, to import 42,000 tons of copper by 1984; this continued a contract signed in 1978 for 28,000 tons over 4 years.

Iron and Steel.—The mild recovery in Belgian steel production, which began in 1978 and continued in 1979, was abruptly reversed in 1980, and production fell by about 1 million tons, to somewhat more than 12 million tons. The decline was largely concentrated in the second half of the year. A program of mandatory production cuts was instituted by the European Economic Community (EEC) in the last quarter, and this was generally successful, but the objective of raising prices was not effective throughout the EEC, according to Etienne Davignon, the EEC's Commissioner for Industry.

In spite of reorganization during 1979 and the 44 billion franc ($1.4 billion)[2] investment program approved by the National Commission for Planning and Control in January 1980, to be financed equally by the Government and private steel interests, the steel industry's restructuring plan was not completed in 1980. A sharp drop in orders, short working time, and persistent financial problems continued to plague the industry and to complicate the task of restructuring. The interest of the Belgian Government, both financial and otherwise, continued to

grow.

In September, the Economics Minister, Willy Claes, proposed a series of strong measures to accompany a further short-term financial package of 5 to 7 billion francs ($170 million to $241 million). These included a forced breakup of Cockerill S.A., the major producer in the Liege area; closure of marginal operations in the Charleroi area by the end of 1980; and recognition of their responsibilities by the private financial interests in the steel industry. The steps were proposed amid reports that the steel industry was losing 1,500 to 2,000 francs ($50 to $70) on each ton of steel, and that the purpose of the breakup of Cockerill was to isolate money-losing operations.

The Government later the same month approved its share of the economic assistance, amounting to 22.9 billion francs ($789 million), while dropping for the moment the attempt to break up Cockerill; apparently it still intended to encourage the private investors in the steel industry to contribute to meeting the cost of restructuring.

At the end of the year, reorganizations and mergers, along with recent Government financial aid, had resulted in the following alignment of the major raw steel producers in Belgium and Luxembourg:

	Approximate production 1979 (million tons)	Percent held by Belgian Government	Percent held by private holding companies	Percent held by others
Cockerill S.A.	4.0	28.9	[1]19.3	51.8
Hainaut-Sambre S.A.	2.6	30.9	[2]20.6	48.5
Forges de Thy-Marcinelle et Providence, S.A.		42.3	[2]28.2	29.5
Sidmar S.A.	2.8	22.0	[3]2.5	[4]75.5
Arbed (Luxembourg)		[5]14.8	[3]14.8	70.4

[1]Ste. Generale, Fibelpar, Cie. Bruxelles-Lambert.
[2]Cie. Bruxelles-Lambert, Cobepa, Frere-Bourgeois.
[3]Ste. Generale.
[4]Arbed 62%, Union Miniere 7%, Falck 5%.
[5]Empain-Schneider.

Smaller steel producers in Belgium included principally the private Usines Gustave Boel S.A. (1.0 million tons produced in 1979) and the related Fabrique de Fer de Charleroi S.A.; and Forges de Clabecq S.A. (700,000 tons), in which the Belgian Government took a financial interest in October in exchange for assuming its debts.

At the end of 1980, reports circulated in Brussels that the European Commission had notified the Belgian Government that its steel aid plans appeared unacceptable to the EEC, because they would lead to an increase in capacity, even taking into account related closings, and would not make the Belgian industry competitive and able to function without continued aid. With the Government's growing inablity to finance all the demands made on it by the industry, it appeared that 1981 would be a year of significant decisions.

Lead and Zinc.—Belgium's custom smelters, while efficient and modern, are beset by high labor and energy costs, with the result that some smelters found prices much below $1,000 per ton insufficient to make a profit. A shortage of zinc concentrates, especially compared with integrated smelters (owned by mining companies), and the severe competition in third country markets with Canada and Australia, foretold continued surplus capacity, and perhaps some plant closures.

Ste. de Prayon S.A., the third largest Belgian producer of zinc, was reported close to ceasing production of slab zinc, but was expected to continue its zinc products, cadmium production, and other operations. The company lost about 300 million francs (about $10 million) in 1979, and was forced to borrow to continue operations in 1980.

The Ste. des Mines et Fonderies de Zinc de la Vieille Montagne S.A., the largest Belgian zinc producer, brought into full production a new electrolysis hall at its plant at Balen. The automated operations used Super Jumbo cathodes, which were much larger (3.2 square meters of surface) than the Jumbo (2.6 square meters) cathodes that represented a major advance when introduced in 1969. Capacity of the new installation was reported at 110,000 tons per year. During 1980, the company reported a profit of 66 million francs (about $21 million) for 1979 after 2 years of heavy losses.

Minor Metals.—Metallurgie Hoboken-Overpelt S.A. commissioned a hydrometallurgical plant at its Olen works to recover minor products, mainly nickel, copper, cobalt, arsenic, antimony, and precious metals from about 6,000 tons per year of complex substances from its lead and copper metallurgical plants. Some material formerly dumped, as well as material from old dumps, will also be treated, thus benefiting the environment. Final products will be in the form of sodium aluminate, copper, impure nickel sulfate, arsenic trioxide, and sulfuric acid. The end residue was to be sent to the Hoboken plant of the same company for recovery of precious metals. The impure nickel sulfate contained, among other elements, cobalt which will be separated when a new facility comes onstream in 1982. Some 78 jobs were created at the plant, for an investment of 1.3 billion francs (about $40 million).

Tin.—The only tin smelter in Belgium, the 18,000-ton-per-year (tin metal) capacity plant at Hoboken, belonging to Metallurgie Hoboken-Overpelt S.A., was to cease operations at the end of 1980 or early in 1981. The smelter, established in 1908, had been operating at least 25% under capacity for many years, and was producing only about 2,000 tons per year towards the end. The closure was seen as another indication of the transition of tin smelting away from developed countries to tin-mining countries. European smelter tin production has declined from about 30% of world production in 1960 to about 10% in 1980.

NONMETALS

Potash.—Entreprise Miniere et Chimique S.A. (EMC), the French mining and chemicals group which controls the Alsace potash mines, installed a 100,000-ton-per-year compaction unit at each of its three Belgian potassium sulfate plants, to provide for the increasing demand for granulated, rather than pulverized product. Belgium was one of the world's leading producers of potassium sulfate, with about one-quarter of the total. EMC's subsidiaries in Belgium were Produits Chimiques de Limbourg S.A., with a plant at Kwaadmechelen, and Tessenderlo Chemie N.V., with plants at Vilvoorde and Tessenderlo.

MINERAL FUELS

Coal.—A study released by the European Commission of the EEC showed that Belgium metallurgical coal was the most heavily subsidized in the EEC. The subsidy by the Belgian Government was put at 22 Units of Account (UA), equivalent to about $30, per ton of coking coal delivered to EEC steel plants. In the Federal Republic of Germany, the figure was UA16; in France, UA13; and in the United Kingdom, UA3.

Drilling continued at Thulin, the site of the proposed in situ coal gasification project. The Institut National des Industries Extractives (INIEX) announced that the project would cover a 6-year span and cost about $35 million; INIEX had a 51% interest, while Kernforschungsanlagen Julich GmbH of the Federal Republic of Germany had the remaining 49%. It was anticipated that up to 40% of the cost would be contributed by the EEC.

An economic study of coal gasification at the Thulin site was published.[3] The study concluded that production of gas or electricity (from gas) would be competitive with other advanced energy sources under study. It also concluded that drilling expense was the prime element in production cost and that use of oxygen and steam to produce pipeline quality gas was justified because of the wider market.

Natural Gas.—The Ministry of Economic Affairs allocated 320 million francs (about $11 million) for exploratory work and further drilling for natural gas near Havelange, southeast of Namur. Earlier drilling had located an apparently promising deposit in this area, following other drilling at Focant, southeast of Dinant, and at St. Ghislain, near Mons, 2 years before.

Construction delays at the liquefied natural gas terminal being constructed at Zeebrugge to receive Algerian gas caused a postponement of the scheduled completion date from late 1982 to 1985.

Petroleum.—The Belgian Government, in an attempt to insure that the fuel oil shortage experienced by independent dealers in 1979 was not repeated, concluded a deal with Saudi Arabia to buy 13.5 million tons of crude oil, of which 3.5 million were to be purchased in 1980, and 5 million each year in 1981 and 1982, at the Saudi Arabian official price. Belgian independent dealers had been squeezed between rising prices for their traditional Rotterdam spot crude and domestic prices permitted under the agreement between the Government and the Belgian Petroleum Federation to control retail prices.

In the ailing Belgian refining industry (which consisted of eight refineries with a total capacity of about 1 million barrels per day), the U.S. firm, Coastal States Gas Inc., bought the Antwerp refinery of Raffinerie

Belge des Petroles S.A. (92,000-barrel-per-day capacity) for $25 million; the refinery had been closed since August 1978. West German oil distributor, Mabanaft GmbH, also agreed to acquire and modernize the Albatros refinery (also about 92,000-barrel-per-day capacity) owned by Wintershall AG, also near Antwerp, which might involve investments of $120 million.

Uranium.—Umipray S.A., a subsidiary of Société de Prayon S.A. (50%), Union Miniere S.A. (38%), and Metallurgie Hoboken-Overpelt S.A. (12%), was constructing a uranium extraction plant at Sauvegarde, between Antwerp and Brussels; processing was then to be completed at a Prayon subsidiary at Angis and in France. The plant was to use the IMC/Prayon (activated charcoal) process to treat phosphoric acid from Prayon's subsidiary, Chemie Rupel N.V. By 1985, Umipray was expected to supply Synatom S.A., the Belgian nuclear power company, with about 250 tons per year of yellow cake, or about 25% of Belgium's projected consumption.

Union Miniere, in cooperation with Société des Mines et Fonderies de la Vieille Montagne S.A. and Compagnie Royale Asturienne des Mines S.A., began prospecting for uranium in the Province of Liege.

Four nuclear powerplants operated in Belgium in 1980: the BR-3 Mol, 11.5 megawatts electrical (MWe), which started in 1962; Doel-1, 410 MWe, 1974; Tihange-1, 920 MWe, 1975; and the Doel-2, 410 MWe, 1975. Total net generation of electricity in Belgium amounted to 54 million megawatt-hours in 1980, of which nuclear energy provided about 22%.

LUXEMBOURG

Iron and Steel.—Iron and steel production by Acieries Reunies de Burbach-Eich-Dudelange S.A. (Arbed) accounted for about 20% of the GNP of Luxembourg and 70% of its industrial employment. Other production of metals and minerals is minor. Arbed operates steel plants at four major sites in southern Luxembourg: Esch-Belval, Esch-Schifflange, Dudelange, and Differdange. Although iron ore mining is now relatively unimportant, European ore from neighboring countries, such as France, provides a significant share of Arbed's supply.

Arbed had made good progress in fulfilling its steel investment plan in 1979, but in 1980, the world steel crisis made the plan appear too ambitious, and revisions were instituted. As temporary measures, a blast furnace at Dudelange, closed for the summer, was not reopened, cutbacks were made in the output of the medium section mill at Esch-Belval and short-time working was adopted at several plants. Arbed's plans for an intermediate mill at Esch-Belval and a cold-rolling mill at Dudelange were reconsidered. By late 1980, plans called for expenditures of about 23.2 billion francs (around $790 million) for new facilities including 3 billion francs ($100 million) for the cold-rolling mill at Dudelange and the second of two 50,000-ton-per-month continuous slab casters at Esch-Schifflange, where it would feed the hot rolling mill at Dudelange; the first hot mill started up in November.

Arbed's financial position deteriorated during the year, and a loss of about 1 billion francs was anticipated for all operations both within Luxembourg and outside. The Luxembourg Government was thus necessarily involved in financing the investment plan; agreement on assistance of about one-third of the 23.2 billion francs needed was tentatively reached by a tripartite commission composed of representatives from the Government, the labor unions, and the steel industry. This was lower than the 10.8 billion francs requested by Arbed, and might mean a further cutback in investment, according to the company.

The Mineral Industry of Bolivia

By Orlando Martino[1]

Political instability and labor unrest continued to impact upon the Bolivian economy. The downtrend in economic growth that began in 1977 continued into 1980 so that Bolivia was not able to meet the target of 7%-per-year growth specified in the 5-year development plan, 1976-80. In real terms, the economy in 1980 grew by just under 1% to an estimated $4.9 billion.[2] The rate of inflation increased to 47%, the highest of recent years.

The mineral industry contributed about 7% of the gross domestic product (GDP) in 1980. Bolivia's export sector continued to be dominated by its mineral industry. Exports of minerals and mineral fuels in 1980 accounted for almost 86% of foreign exchange earnings to a record high of $887 million. This increase reflects higher world commodity prices since the volume of production and exports in 1980 was generally disappointing. The downtrend in tin output was not reversed in 1980 as earnings from tin exports fell for the first time in recent years.

In 1980, Bolivia continued as an important world producer of tin, antimony, and tungsten and a notable producer of silver, zinc, and lead. In 1979 and 1980, Bolivia ceased to be one of the leading producers of bismuth in response to weakened world demand. Although small in terms of volume, exports of natural gas to Argentina were very important to Bolivia's economy, ranking second after tin. There was limited response in production during the year to higher mineral prices. Declining yields in the more depleted mines were being extracted at higher labor and energy costs. A low level of mine development and exploration to increase reserves continued to characterize both the State mining sector and most of the private sectors. There was also concern in the Bolivian mining community that tin prices might be depressed by authorized sales from the tin stockpile of the U.S. General Services Administration.

State-owned Corporación Minera de Bolivia (COMIBOL), established in 1952, continued as Bolivia's major mineral producing corporation. Operating through 12 subsidiary mining companies, two mixed cooperatives, and several leased small mines, COMIBOL is Bolivia's leading producer of tin, silver, tungsten, zinc, and lead. During 1980, its subsidiaries were engaged in a variety of projects to increase mine productivity and safety, improve milling operations, recover metal values in tailings, and increase reserves.

COMIBOL was preparing a 5-year (1981-85) investment program estimated at $450 million covering exploration, mine rehabilitation, metallurgical projects, civil works, as well as management improvement and technical training. This comprehensive proposal will be studied by outside consultants under a $1.5 million loan granted to COMIBOL by the United Nations Development Program (UNDP). COMIBOL initiated negotiations with the World Bank as a possible source of financing. Bolivia's political instability was reflected in COMIBOL's management. During 1978-80, the general manager was changed eight times, each introducing different administrative and policy directions.

The National Association of Medium Miners (NAMM), comprised of 23 private companies, produced about 25% of the value of nonfuels mineral output in 1980. NAMM was the leading producer of antimony and the second most important producer of tin, tungsten, zinc, lead, and silver. In

spite of favorable market prices in recent years, mineral production by this group has not changed significantly except for antimony and tungsten. The causal factors analyzed by NAMM include (a) political instability and worker unrest, (b) exhaustion of mineral reserves, (c) higher production costs, (d) lack of incentives for new investments and exploration, (e) deficient mill recovery, (f) management problems, and (g) excessive tax burdens. The NAMM group employed about 7,800 workers compared with 26,500 workers employed by COMIBOL.

State-owned Empresa Nacional de Fundiciones (ENAF) was responsible for practically all the smelting and refining activity in Bolivia—particularly tin and antimony. ENAF achieved a record high in output from its high-grade tin smelter at Vinto and approached full utilization of its 20,000-ton-per-year capacity. In 1980, ENAF started its 10,000-ton-per-year low-grade smelter, giving Bolivia a capacity to process all of its tin concentrate.

The State oil company Yacimientos Petrolíferos Fiscales Bolivianos (YPFB) did not reverse the downtrend in petroleum production in 1980, and Bolivia was close to losing its self-sufficiency in oil that it has enjoyed since the early 1950's. Output of natural gas, on the other hand, continued to increase. YPFB has proposed a new 5-year development plan to reverse the decline in liquids production. YPFB did not sign any new operations contracts with foreign oil companies in 1980. Only two foreign companies remain holding operations contracts for oil exploration and development: Occidental Boliviana Inc., a subsidiary of Occidental Petroleum Corp., and Tesoro Bolivia Petroleum Co. in a joint venture with Zapata Exploration Co. and Canadian Superior Oil Ltd. Several U.S. firms indicated an interest in future contracts depending upon improved terms and market shares of any future gas sales to Brazil. The oil and gas sector in 1980 contributed 2.7% of the GDP and almost 24% of the value of exports.

Government Policies and Programs.—The mining industry did not succeed in meeting the production goals set by the Government's 5-year development plan that ended in 1980. During 1978-1980, seven different ministers held office at the Ministry of Mines and Metallurgy. Despite these changes in executives, no major policy changes occurred in the mining sector.

The Ministry completed a review of the proposed Mining Development Law that included a study on mining taxation and recommended reforms to the current Mining Code. In early 1980, the Ministry was expected to present for Government consideration a Mining-Metallurgy Policy for the decade 1981-90.

To stimulate investment in the mining industry, on March 5, 1980, a long-awaited supreme decree was signed, Supreme Decree No. 17248, abolishing the special export tax created in 1972 and establishing a new mining tax (royalty) schedule. The new rate is 53% (formerly 38%) on the presumptive profit, charged on the selling price minus a Government-set presumptive mining cost. The presumptive cost is calculated on available data on costs, but does not always reflect the real cost—sometimes it is higher and other times it is lower. The presumptive tin cost is to vary with any change in the floor price of the buffer stock of the International Tin Council (ITC). In early 1981, the Government was expected to raise the presumptive mining cost schedule by an average of 18%. Under this new schedule, the presumptive cost for tin for COMIBOL would be $4.48 per pound.

Two supreme decrees were signed during 1979 to encourage mechanization and modernization of producing mines with some economic incentives (Supreme Decree Nos. 16414 and 16618). These decrees have been little utilized by the Mining Sector.

Bolivia's position in the ITC did not change, and it maintained its usual hard line on periodic reviews of buffer-stock floor and/or ceiling prices. Regular meetings with other tin producing countries' representatives were held in La Paz and Southeast Asia aimed at organizing a solid front of the tin producing countries. Bolivia's stand on the floor and ceiling price range issue is that such prices should be related to current tin market prices as opposed to the consumers stand that would maintain the price ranges according to production costs.

Several projects were under the direct control of the Ministry of Mines and Metallurgy. The Mining Accounting Project was started to develop an appropriate accounting system for each of the different sectors of the mining industry. Under current legislation, only COMIBOL and the medium miners are compelled to keep books. The project has selected 3 mining companies, out of 20, as pilot units for data research. The World Bank is financing this project.

The Usage of Geothermal Resources project started in 1975 and financed by the Italian Government, concluded its third phase of operations in 1979, with shallow diamond drilling in the areas of Empexa and Laguna Colorada (Department of Potosí). The Italian firm AQUATER was directly in charge of the project. Results obtained so far are very encouraging.

Preliminary studies on the Cotagaita, Tumusla, Tupiza, Blanco, Quechisla, and Arque-Caine Rivers, all draining and running through mining districts, described the lack of waste control on waters used by the mine mills and the urgent need for an environmental protection law.

In June 1980, the World Bank approved a $50 million loan to Bolivia to support a program of economic recovery and structural adjustment. This was the first structual adjustment loan to a Latin American nation. Part of the loan is to finance technical studies on mining tax reforms, and it is also designed to help Bolivia formulate and adopt more export-oriented long-term development strategy based on selective action in the agricultural and mining sectors.

PRODUCTION

Despite political instability and some labor unrest during 1980, mineral output generally rebounded from the depressed levels of 1979. The significant increases in metallic antimony and tin reflect better utilization of installed smelter and/or refinery capacity. On the other hand, mine output of tin dropped to a new low relative to recent years. The notable increase in gold output indicates a strong response to the recent surge in world prices.

Although production of natural gas continued its gradual upward trend; output of crude petroleum and condensate remained in a serious downtrend since the peak year of 1973. In both 1979 and 1980, oil output decreased 14%.

COMIBOL's chief mineral output, summarized in table 2, came primarily from over 90 mines organized under 12 mining companies. Tin output by COMIBOL declined again to the lowest level since 1968. A record high was achieved in tungsten output, and a notable rebound occurred in lead production.

As shown in table 3, the medium miner's group produced a record level of antimony. Its silver output increased sevenfold since 1976—reflecting the growth in lead and zinc output. In 1979, the medium miner's share of Bolivia's total output was antimony—81%, tungsten—49%, zinc—38%, cadmium—25%, lead—23%, tin—21%, and silver—13%.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through July 16, 1981.

[2]In addition to the commodities listed, salt and a variety of crude construction materials (clays; crushed, broken, and dimension stone; and sand and gravel) are produced, but available information is inadequate to make reliable estimates of output levels.

[3]Unless otherwise specified, data represent actual production by COMIBOL and small- and medium-scale mines.

[4]Data represent exports and are regarded as being virtually equal to production.

[5]Cadmium contained in zinc concentrates produced by COMIBOL. (Cadmium is not recovered in elemental form in Bolivia.)

[6]COMIBOL output plus sales by placer mines. (Small- and medium-scale mines cannot legally export gold.)

[7]Includes topped crude (presumably further processed outside of refineries reported in this table, or used without further processing) as follows, in thousand 42-gallon barrels: 1979—669; and 1980—481.

[8]Refinery fuel not reported separately, if at all, in recorded data.

TRADE

By 1980, the value of mineral exports projected in the Government's 5-year economic plan (1976-80) was surpassed mainly because of significant increases in world prices of tin, silver, and tungsten. On the other hand, the projected volume of production and exports was not achieved.

As shown in table 5, the value of mineral exports was at a record high in 1980, primarily because of higher world prices. However, the volume of mineral exports was generally lower than in 1978 and 1979, with the exception of tungsten which increased 30% in volume and 35% in value. Although the volume of silver exports decreased slightly, the export value more than doubled because of sharply higher prices.

The volume of tin exports dropped 12%. Its value also declined (despite high tin prices), reversing a rising trend since 1976. The relative importance of tin in Bolivia's export sector also decreased—almost 37% in 1980 relative to 47% in 1979. Tin exports in 1980 were distributed as follows: By smelters as refined tin—14,218 tons, as concentrate by COMIBOL—4,991 tons, medium miners—1,036 tons, and small miners—2,285 tons, through The Banco Minero (BAMIN). Exports of minerals and mineral fuels in 1980 accounted for almost 86% of the country's total.

Excluding sales of concentrate to ENAF, the value of COMIBOL's exports in 1980 (chiefly tin, silver, tungsten, zinc, and lead) amounted to $238 million or 37% of total mineral exports. COMIBOL's export earnings increased 21% in 1980 mainly because of silver and tungsten.

For the second year, exports of natural gas exceeded exports of petroleum (white gasoline). Since 1975, natural gas has been Bolivia's second most valuable export after tin. Exports of natural gas, currently to Argentina, will become even more important when the proposed gas pipeline to São Paulo, Brazil, is completed. Because of declining crude oil output, Bolivia was expected to have to import petroleum products in 1981, especially diesel, fuel oil, and lubricants.

COMMODITY REVIEW

METALS

Antimony.—Mine output of antimony rebounded from the depressed levels of 1978-79 but fell below the record high of 1976. As detailed below in tons, the medium miner's group accounted for 75% of national output.

Company	1979	1980	Percent change
Empresa Minera Unificada S.A	7,506	7,808	+4
San Juan Limitada	2,060	2,825	+37
Churquini Enterprises Inc	458	423	-8
Bernal Hermanos	496	385	-22
Cía. Minera del Sur S.A	69	110	+59
Total	10,589	11,551	+9
Other	2,430	3,914	+61
Grand total	13,019	15,465	+19

In 1980, ENAF's antimony smelter at Vinto near Oruro approached full capacity, with an output of 4,256 tons of metallic antimony and 843 tons of antimony trioxide. The smelter, built by Skoda Export of Czechoslovakia, started up in 1976. The only active private smelter was Bernal's Palada antimony smelter, which exported 854 tons of antimony in 1980.

Cadmium.—Cadmium was produced as a byproduct of zinc mining operations. COMIBOL produced 77% of the country's total primarily at its subsidiary, the Quechisla Mining Co., followed in importance by the Matilde and Bolivia subsidiaries.

Gold.—Bolivia's gold output showed a notable response to increased world prices. A total of 20 gold cooperatives working in the Tipuani, Guanay, and Cangalli Rivers produced almost 80% of the country's total compared with the 55% share in 1977. The balance was accounted for by Compañia Minera del Sur (COMSUR) operating a dredge in the Kaka River. It was reported that a gold deposit was discovered in the Beni River, and the Cooperativa Aurífera Cachuela Experanza was formed to exploit it.

The Government was financing an evaluation of an alluvial gold deposit in a small area of the Chimate region in the Larecaja Province north of La Paz. As of December 1980, 12 pits were dug with gold values ranging from 0.0128 to 0.3377 gram per cubic meter. Reserves are being determined.

Iron Ore.—Empresa Siderúrgica Boliviana S.A. (SIDERSA) exported during 1978 and 1979 36,700 tons of iron ore, with an average iron content of 63.7%, from the Mutún Mine site to Altos Hornos Zapla in Argentina. Most of this ore was mined and stocked when Mutún was under COMIBOL control. SIDERSA endorsed a program to produce 1 million tons per year of iron pellets from the Mutún deposit. The weathered enriched ore layer at Mutún is estimated to contain reserves of 600 million tons grading 56% iron with low silica content.

On the basis of geological studies completed by Kaiser Engineers of Oakland, Calif., in September 1978, proven iron ore reserves at the Changolla deposit are estimated at 3 million tons; and another 3 million tons were indicated, with a 45% iron content. About $37 million is required for a project to produce 140,000 tons per year of ore.

Iron and Steel.—SIDERSA's iron and steel plan based on the Mutún iron ore deposit was revised downward, and the company now comtemplates construction of a plant in Santa Cruz to produce 170,000 tons per year of sponge iron using natural gas from nearby gasfields. The sponge iron plant would require about 300,000 tons per year of iron pellets produced at Mutún. The balance of 700,000 tons would be exported to Argentina each year. Output from the sponge iron plant would feed a 100,000-ton-per-year laminated products plant to be installed in Cochabamba, all for domestic consumption. SIDERSA proposes to build the $60 million rolling mill first by late 1982 to be fed with imported steel billets. Once this mill is producing, the mining and other plants will be brought online. The total project is estimated to cost $300 million.

Lead.—The Karachipampa lead-silver smelter continued under construction in Karachipampa, 7 kilometers from Potosí. The smelter will be operated as a COMIBOL-ENAF joint venture under Sociedad del Complejo Metalúrgico de Karachipampa. It was orginally scheduled for completion in March 1979, then rescheduled to start up in early 1980. The $250 million plant is now scheduled for startup in late 1982. It is projected to produce 24,200 tons of lead, 6.4 million troy ounces of silver, 1,950 tons of antimony, 780 tons of tin, 3,300 tons of zinc, and small amounts of copper and bismuth.

The plant will require a feed of 51,100 tons per year of lead concentrate, 70% from COMIBOL mines and 30% from the private sector mines. Considering that COMIBOL in 1980 produced 10,153 tons of fine lead from its mines (chiefly Tatasi, San José,

Telamayu, Matilde, and Bolivar), and the private mines (chiefly Quioma) produced 7,594 tons, the deficit in lead production for the new smelter amounts to about 6,450 tons.

In November, the Sociedad del Complejo Karachipampa signed a contract with the Fondo Nacional de Exploración, Instituto de Investigaciones Minero-Metalúrgico (IIMM) and Servicio Geológico de Bolivia (GEOBOL) to start intensive mine exploration in known lead-silver small and medium mines.

Silver.—The value of exports of silver in ore and concentrate has grown almost fivefold since 1976, reflecting elevated world prices, and has become Bolivia's third most valuable mineral export after tin and natural gas. Bolivia is the fourth most important silver producer in Latin America after Mexico, Peru, and Chile.

Silver output in 1980 came mostly from COMIBOL companies—84%, medium mines—11%, and small mines—5%. Empresa Minera Quenchisla, COMIBOL's second largest mining company, was its largest silver producer at almost 3.1 million troy ounces, followed by Empresa Minera San José. During 1980, a rich silver vein was discovered at San José. The Ventillas zinc-silver mill completed in 1978 at the Quechisla Co. is programmed to produce 1.7 million troy ounces of silver per year.

Tin.—Although Bolivia is the major tin producer in Latin America, it fell from second to fourth rank as a world producer behind Malaysia, Thailand, and Indonesia. In 1980, Bolivia's main producers in tin content were COMIBOL (18,621 tons), medium mines (5,880 tons), and small mines (2,771 tons). COMIBOL accounted for 68% of total output primarily from the subsidiary companies in the tin belt of Huanuni (its most profitable), Catavi, Quechisla, Unificada, and Colquiri. The mining cooperatives associated with COMIBOL produced 1,467 tons or 8% of the State company's total.

Practically all of the 23 medium miners in the NAMM produced tin. Table 6 provides tin output data for the leading companies.

COMIBOL's production of tin concentrate was of three grades—about 70% so-called high-grade (42% tin), 10% was medium-grade (32.6% tin), and 20% was low-grade (below 14% tin). COMIBOL's average mill recovery was 55%, the balance of the tin mined going as waste in mill tailings and slimes. Most of the low-grade tin concentrate is used as direct feed to the volatilization plant.

COMIBOL's cost of producing and marketing of tin continued to increase, as summarized in table 7. Total costs increased 25% in both 1978 and 1979. A detailed study of production costs incurred by COMIBOL's subsidiaries shows that 75% of COMIBOL's tin production is above the average London Metal Exchange (LME) price for April 1979, indicating that most of COMIBOL's companies were not operating at a profitable level. In 1979, railway freight costs from production centers to Arica and Antofagasta in Chile increased over 18%. Consequently, some export traffic was directed to Peruvian seaports. The expansion of the smelting industry has reduced the volume of minerals shipped to the Pacific coast by railway.

Source: COMIBOL.

COMIBOL's tin volatilization (fuming) plant continued under construction at La Palca, 17 kilometers southwest of Potosí. The $65 million plant was designed and supervised by the U.S.S.R. under a $27.5 million credit granted to the Government in 1970. The plant will have an input capacity of 400 tons per day of 3% to 6% tin concentrate and an annual output of 3,500 tons of 50% tin powder. Feed to the plant will be from Unificada-Pailaviri preconcentration plant and the Catavi-Canutillos Mine. The plant is estimated to require 600,000 barrels per year of fuel oil. YPFB produced and sold 935,000 barrels of fuel oil in 1979 for internal market demand. Conversion to natural gas use was under study. In mid-1979, COMIBOL signed a contract with the Soviet firm Machino-Export for a second volatilization plant to be built at Machacamarca.

During 1980, ENAF fired its second tin smelter for treating low-grade (10% to 35% tin) concentrate at Vinto, 10 kilometers from Oruro. The low-grade smelter with a capacity of 10,000 tons per year was designed and built by Klöckner Humblod Deuz A.G., Novosikusk, Machino-Export, and P. Bergsoe and Sons under a $49 million contract. At yearend, the new plant was undergoing trials with full operation expected in July 1981.

ENAF achieved a record high output of refined tin from its high-grade (42% tin) smelter also at Vinto. This 20,000-ton-per-year plant was first fired in 1970, with an initial capacity of 7,500 tons per year. The following tabulation shows the rising trend in refined tin output in metric tons.

Year	Refined tin	Percent of mine output
1975	7,533	29
1976	9,185	30
1977	12,788	39
1978	16,180	52
1979	15,696	57
1980	17,648	65
1981[e]	21,220	75

[e]Estimated.

Tungsten.—Bolivia is the leading producer of tungsten in Latin America. Output by COMIBOL in 1980 increased 16%, replacing the medium miners as the main producer. Output by the medium miner's group increased 4% through only two companies—International Mining Co. and San José de Berqué.

Exports of tungsten increased sharply by 30% and replaced zinc as Bolivia's third most valuable nonfuels mineral export after tin and silver.

Zinc.—In July 1979, Klöckner Industrie Anlagen presented to ENAF the feasibility study of the 68,300-ton-per-year zinc refinery plant to be located in the Department of Potosí. The $220 million plant will also produce 72,600 tons per year of sulfuric acid, of which 63,600 tons would be available for sale. At yearend, the feasibility study was under final review by the Canadian firm Surveyer, Nenninger and Chenevert Inc.

NONMETALS

Barite.—The Baroid Div. of NL Industries Inc., in a joint venture with Mosamar of Bolivia, initiated production from a new

grinding plant located at Oruro. A local barite source provides feed to the mill.

Cement.—Bolivia was engaged in a program to expand its cement capacity to meet requirements of its development projects, to reduce imports, and to set the stage for eventual exports to Brazil. Construction continued on the new $88 million plant in Yacuces, 120 kilometers west of Corumbá on the Brazilian border. The 335,000-ton-per-year plant being built by the Comite de Obras Publicas de Santa Cruz under 55% financing by the Inter-American Development Bank is scheduled for completion in 1981. Lafarge Consultoria et Estudos has the consulting engineering contract.

At the end of 1978, Bolivia's three operating cement companies had a combined capacity of 810,000 tons per year.

MINERAL FUELS

Natural Gas.—Bolivia continued the historical reversal begun in 1978 of earning more from exports of natural gas than from petroleum. In 1980, the value of gas exports to Argentina increased to $223 million compared with the $29 million of gas exports in 1974, a sevenfold growth.

In early 1980, the Governments of Bolivia and Argentina renegotiated the price of natural gas from $1.54 per thousand cubic feet to $2.50 per thousand cubic feet by June 1980, through monthly adjustments. In September, further monthly price increases were agreed upon so that by December 1980 the rate was $2.80 per thousand cubic feet, and by March 1981 the price would rise to $3.30 per thousand cubic feet. It was also agreed that the exported volume would change from 195 to 230 million cubic feet per day, effective April 1981.

Table 8 provides data on the distribution of natural gas production. YPFB gasfields of Río Grande and Colpa were the major producing gasfields followed by the Tita Field of Occidental Boliviana Inc. and the La Vertiente Field of Tesoro Bolivia Petroleum Co. The Tita Field continued to produce natural gas slightly above the average contract rate of 50 million cubic feet per day.

Plans remained indefinite regarding installation of distribution lines to households in Cochabamba, Sucre, Oruro, Potosí, and Santa Cruz.

After many years of negotiations, a provisional agreement was expected in early 1981 regarding construction of a 1,940-kilometer natural gas pipeline between Santa Cruz, Bolivia, and São Paulo, Brazil. The project, estimated to cost $1.7 billion, was expected to be initiated during the first half of 1982 and be ready for use by yearend 1985. Brazil will probably import about 400 million cubic feet per day. This project offers Bolivia the best opportunity of increasing export earnings in the near future.

[2]Includes sales to Argentina and domestic users. In 1980 this amounted to 72,029 million cubic feet for Argentina, 18% higher than in 1979.

Source: YPFB Annual Reports.

Petroleum.—The downtrend in the production of crude oil and condensate continued since the peak year of 1973. In 1980, crude oil output declined 26%, representing 37% of total hydrocarbons produced, while condensate accounted for 63% of the total. The total daily average of crude plus condensate was 23,850 barrels in 1980. Output was projected to increase to 38,400 barrels per day in 1985. The Monteagudo Field was the main crude oil producer, followed in importance by La Peña, Caranda, and Camiri. By far, the Río Grande Field was the main producer of condensate, followed by Tita, La Vertiente, and Colpa Fields.

Sharply reduced domestic output (50% down from 1973 levels) and increased domestic consumption have forced Bolivia to discontinue exports of crude oil. In 1973, these exports had been as high as 11.8 million barrels. According to revised figures, Bolivia did export 165,000 barrels of crude oil in 1979, while in 1980 only gasoline was exported to Argentina.

In 1980, no new operations contracts were signed with foreign oil companies following issuance of the Government's new hydrocarbons policy of June 1977. On July 30, 1980, the Government approved two contracts between YPFB and Occidental Boliviana Inc. concerning the transport of liquid petroleum products and the sale of natural gas. The major new element centered on the opening of substantial production by Occidental at the Porvenír Field discovered in 1978 in the Department of Chuquisaca near Luis Calvo. Occidental began drilling additional gas-condensate wells at Porvenír. Construction began on a treatment plant for processing 100 million cubic feet per day of natural gas in order to extract an estimated 8,200 barrels per day of condensate. The gas will be reinjected for future marketing.

In mid-1980, the Government appointed a committee to study and make recommendations within 6 months relative to a national energy policy.

In May, the International Development Association, the World Bank's affiliate for concessionary lending, approved a $16 million credit for a gas and oil engineering project in Bolivia. The Inter-American Development Bank made a parallel loan of $16 million for the same project. The $41.8 million project is an important precondition for achieving a significant increase in gas exports. The project seeks to establish by 1982 whether there are sufficient reserves of natural gas in the Departments of Santa Cruz, Chuquisaca, and Tarija to enable YPFB to cover future requirements of Bolivia's growing domestic market and gas exports to Brazil, as well as the existing contracts for gas exports to Argentina. The project includes the initial phase of a secondary recovery (water injection) program for the Monteagudo oilfield. Also included is an engineering study of the proposed Bolivia-Brazil gas pipeline and of the Bolivian gas market.

Retail prices of petroleum products prevalent during 1980 were those established in November 1979, after a 4-year period without any price changes. Motor gasoline (92 octane) was priced at $0.24 per liter, and diesel and fuel oil were priced at $0.16 per liter. In 1980, Bolivia was generally self-sufficient in petroleum products. During the year, however, shortages were experienced in diesel and fuel oil and lubricants. In December, the Minister of Energy and Hydrocarbons reportedly asserted that the Government would terminate price subsidies on all petroleum products. YPFB had a monopoly on the refining and sale of hydrocarbons in the country. Surprisingly, in 1980 domestic consumption fell almost 11% compared with that of 1979.

The Minister also stated that the Soviet Union offered to assist Bolivia in the exploration for and production of hydrocarbons.

The Mineral Industry of Botswana

By George A. Morgan[1]

The mineral industry of Botswana continued to be the fastest growing sector of the economy in 1980, providing a major portion of foreign exchange earnings and a substantial share of Government revenue. Income from diamond production alone accounted for one-third of Government revenue. Average real growth for the country's economy was estimated at 10%. Due in large part to the performance of the mining industry, foreign exchange reserves were $380 million[2] at midyear 1980, equivalent to the value of about 6 months' imports. The debt-service ratio was 1%, while inflation was 16%. The 1979-85 national development plan (NDP) was to emphasize employment creation and rural development because 80% of the country's population was in rural areas. Mine worker recruitment by the Republic of South Africa declined from 40,000 in 1976 to about 20,000 in 1979, increasing the unemployment problem. The Government had a greater responsibility for assessment and supervision of projects despite a serious shortage of skilled personnel, with expenditures of $1,310 million planned for the period of the NDP. A budget deficit of $81 million was expected in 1981 because of rapid growth in Government spending compared with 3 previous years of surplus. Industrial expansion projects, whether Government funded or privately financed, had to contend with the high cost of utilities and housing, as well as a high minimum wage and high taxes.[3]

PRODUCTION AND TRADE

The index of mining production increased by 9.5% in 1980. Value of production of the leading mineral products in 1980 was as follows: Diamonds, $302 million compared with $208 million in 1979; copper and nickel, $112 million compared with $94 million in 1979; and coal, $5.5 million compared with $3.4 million in 1979. Diamond production in Botswana was expected to increase significantly upon opening of the new Jwaneng Mine, as was output of copper-cobalt-nickel matte from the Selebi and Phikwe Mines. Interest was being shown in expanding output of coal, both for domestic consumption and for export. Although magnetic and gravity surveys conducted in 1979 indicated substantial sediment thickness in the western part of Botswana, no permits were held for exploration of petroleum.

The Government began to take control of the railroads formerly operated by the National Railways of Zimbabwe. An agreement was also signed with the Federal Republic of Germany whereby $19 million would be made available as funding for locomotives and railroad maintenance facilities in Francistown. The value of exports in 1980 was estimated at $527 million compared with imports estimated at $709 million. The trade imbalance was expected to continue in 1981. Principal trading partners in order of importance were the Republic of South Africa, the United Kingdom, Western Europe, and Zimbabwe.

COMMODITY REVIEW

METALS

Copper-Nickel-Cobalt.—Botswana RST Ltd. (BRST), owner of the Selebi and Phikwe Mines, had a 14% increase in both mine output and mill throughput in 1980. Production of concentrates was up by nearly 78,000 tons, while matte production increased slightly to 40,099 tons. Ore production from underground operations at the Phikwe Mine was 1.57 million tons grading 1.16% nickel and 0.8% copper. The decline in grade from that of the previous year was compensated by slightly higher production. The Selebi Mine's underground operation was in full production by midyear, while the open pit mine at Phikwe ceased production in August. Total output from the open pit mine was 0.34 million tons grading 0.75% nickel and 0.66% copper. Underground ore from the Selebi Mine graded 0.46% nickel and 0.94% copper. The sinking of the third shaft at the Selebi Mine continued but encountered water at the 750-meter depth. Production from the shaft was to commence in 1982 following commissioning in late 1981. Overall, 2.5 million tons of ore were milled, grading 0.93% nickel and 0.82% copper. Matte output and average metal content of matte for the period 1977-80 are listed in the following tabulation.

	1977	1978	1979	1980
Matte production metric tons	30,772	39,517	39,823	40,099
Matte content:[1]				
Nickel percent, average	39.3	40.6	29.9	38.5
Copper do.	38.3	36.9	28.5	38.8
Cobalt do.	.54	.66	.55	.56

[1]Average content for sulfur and impurities was 22% for each of the years shown.

Total sales reported by BRST for the year ending December 31, 1980, were $144 million compared with $69 million in 1979. Mining assets and other capitalized expenditures amounted to $362 million in 1980 compared with $326 million in 1979. However, total liabilities amounted to $464 million at yearend 1980. The adjusted accumulated deficit was reported at $192 million, up 11% from that of the previous year. Based on terms of an amendment to the mining lease that provided a royalty payment of 3% on the gross value of recoverable metal, BCL Ltd., which operated the mines and was 85% owned by BRST, owed the Government $6.2 million in 1980. However, a deed of deferral, effective December 31, 1979, provided for deferral of loan principal payments and royalty payments during the

period to December 31, 1983, if BCL had a negative cash flow position. Loan principal repayments and royalty payments of an estimated $17.5 million, falling due in 1981, were also expected to be deferred. As of December 31, 1980, BCL had an estimated loss for tax purposes of about $221 million available to be carried forward against future taxable income. Capital cost of $275 million may also be amortized against future income subject to the limitation of a maximum relief of 75% of taxable income in any year.[4]

NONMETALS

Diamond.—At the Orapa Mine of De Beers Botswana Mining Co. (Proprietary) Ltd., diamond output in 1980 amounted to 4,699,608 carats from a throughput of 7,329,600 tons of ore, yielding a recovery rate of 64.12 carats per 100 tons of ore. The company's Letlhakane Mine yielded 401,423 carats from a throughput of 2,112,900 tons of ore for a recovery rate of 19 carats per 100 tons of ore. The decline in diamond yield at the Letlhakane Mine from 23.22 carats per 100 tons of ore in 1979 was due in part to lower diamond content of kimberlite treated and to treatment of residual ferruginous gravels earlier in the year. Production startup at the main treatment plant at the Jwaneng Mine was planned for early 1982. Geological investigation and stripping of sand overburden continued in 1980, and blasting of rock overburden began at midyear with the commissioning of rotary drills and electric shovels.

Total waste removal amounted to 0.580 million cubic meters compared with a target of 1.5 million cubic meters due to unspecified difficulties. However, a revised production schedule was expected to be met with the aid of additional equipment in 1981. The bulk sampling plant and ancillary workshops, roads, and services were substantially completed, as well as the mine township. A rail siding was completed at Lobatse, and a tarred road to Kanye and a tarred airstrip at the mine were put into operation.[5] When the Jwaneng Mine is in full production, total output for Botswana may double from present levels to about 10 million carats per year. Employment at the Orapa and Letlhakane Mines was about 2,400 people in 1980, and the Jwaneng Mine was expected to employ about 1,300 people.

Diamond production in Botswana was shipped to the Botswana Diamond Valuing Co. in Gaborone for grading. Graded diamonds were then purchased by the Diamond Corp. Botswana (Pty.) Ltd., part of the De Beers Central Selling Organization, for eventual marketing worldwide. It was reported at yearend 1980 that the diamond agreement between the Government and the De Beers Central Selling Organization was being renegotiated.

Exploration continued at a small kimberlite site near the Jwaneng occurrence, and two additional sites near the Orapa Mine were being evaluated for possible development.

MINERAL FUELS

Coal.—Coal production was estimated at 380,000 tons for 1980, up about 40,000 tons from that of the previous year but short of the expected goal of 1 million tons. No coal was exported; all production was used for electric power generation or for consumption at the Selebi-Phikwe furnace as a replacement for diesel fuel.[6] The Ministry of Mineral Resources and Water Affairs reported that it intended to foster the production of coal for export. Several firms were interested in coal exploitation near Morupule, and Shell Coal Botswana submitted a feasibility study for the opening of a coal mine in its prospecting area between Morupule and Serowe.

The Government also decided to build a coal-fired power station at Morupule. Feasibility and preliminary engineering studies neared completion, and funding discussions had been held with the World Bank.

Petroleum.—Construction of oil storage tanks located in Gaborone and Francistown was completed. When filled, the tanks were to provide a 3-month supply of oil to cover the country's petroleum needs in case of a supply interruption. The cost for their construction was $4.2 million, and the cost to fill the tanks was put at $1.2 million.

The Mineral Industry of Brazil

By Orlando Martino[1]

In real terms, the Brazilian economy in 1980 grew by 8%, surprising most economic observers who had expected a growth closer to the 6.4% rate of 1979. Brazil's gross domestic product (GDP) in current prices expanded to an estimated $237 billion.[2] At yearend the rate of inflation was 110% compared with 77% in December 1979.

In 1980, Brazil made further progress in expanding its mineral industries and was a leading or important supplier of mineral commodities in the Latin American region and in world markets. Particular gains were achieved in exploiting Brazil's relatively recently evaluated mineral potential in gold, bauxite, phosphate rock, and coal.

In value terms, Brazil's diversified mineral output, not including petroleum, is among the largest in Latin America, but is comparatively a small part of the national economy where agriculture and manufacturing dominate. The mineral sector in 1980 contributed about 1.8% of the GDP. The importance of the mineral sector was more apparent in Brazil's international trade where the share of mineral exports was over 10%. Exports of iron ore alone in 1980 was 8% of the total as in 1979.

Besides iron ore, Brazil continued as an important producer and exporter of manganese, pyrochlore concentrate, beryl, ferroalloys (particularly ferrocolumbium), electronic-grade quartz crystal, and gem stones. For the first time in 1980, Brazil became a significant exporter of bauxite from the Trombetas operation in the Amazon Basin. Record production levels were achieved in phosphate rock, coal, crude oil, and natural gas. Gold output escalated because of the Serra Pelada discovery.

The dominant mineral company in Brazil and the world's largest producer and exporter of iron ore was Companhia Vale do Rio Doce (CVRD). CVRD was engaged in the important Carajás iron ore project as well as the production of phosphate rock and bauxite through associated companies. As a mixed capital company, CVRD was 80% owned by the Government and 20% by private Brazilian shareholders.

The mineral fuels sector was dominated by the state oil monopoly, Petróleo Brasileiro S.A. (PETROBRAS), owned 75% by the Government and 25% by local private interests. As a result of intensified exploration and development, PETROBRAS had some success in achieving record levels in the production of crude oil and natural gas as well as their corresponding proven reserves.

Companhia de Pesquisa de Recursos Minerais (CPRM), an autonomous state entity, continued its extensive program of geological exploration.

Government Policies and Programs.—A major event in the mineral sector was the decision by the Government in November 1980 to approve a 10-year plan to develop the large and varied resources of the Carajás Mineral Province, Pará State, in the south Amazon Basin. In addition to massive high-grade iron ore reserves, Carajás includes substantial reserves of manganese, bauxite, copper, nickel, tin, and gold. The global project covering mineral and agricultural resources would absorb $61 billion, of which $26 billion would be required for mineral development. Mineral processing facilities (smelters) are contemplated in the program. A new railroad and shipping port near São Luis are included for transport of mineral output to domestic and world markets.

The Government assigned development of the Carajás iron ore deposit to CVRD.

Indications were that exploitation of the remaining mineral resources would be assigned to the private Brazilian mineral sector and foreign interests.

For 1981, the Government announced a goal of limiting petroleum imports to 750,000 barrels per day. Brazil consumed an average of 1.1 million barrels of oil per day, of which 929,000 barrels per day were imported in 1980.

The Brazilian Government has been reluctant to allow foreign participation in the national alcohol fuel program. It appeared likely that foreign investment in this area would be limited to producing alcohol fuel for export.

The Government was considering changes in rules on the registration of foreign capital, particularly reinvestments, which would have implications for the foreign remittance of profits.

Foreign direct investment and reinvestment in the mining sector was $372 million in 1979 compared with a total of $155 million in 1975. Total foreign investment in Brazil in 1979 in minerals and energy related sectors is detailed below in million U.S. dollars:

Sector	Total investment and reinvestment	Percent share
Mineral extraction	372.4	2.3
Iron and steel	345.8	2.2
Metallurgy	969.5	6.1
Cement	119.4	0.7
Fertilizers	170.3	1.1
Basic chemicals	1,728.0	10.8
Petroleum derivatives	337.7	2.1
Total	4,043.1	25.3
Total foreign investment in all sectors of economy	15,962.9	100.0

Within the mining and related sectors, the foreign investment from the United States totaled $1.04 billion and accounted for about 28% of the total. Next in importance were the Federal Republic of Germany, 14.8%; Switzerland, 9.1%; United Kingdom, 8.4%; and Japan, 8.1%.

PRODUCTION

Preliminary data indicate that in real terms the value of output of the extractive industries grew by almost 13% in 1980. The latest available official data reported by the Departamento Nacional da Producão Mineral (the National Department of Mineral Production, DNPM)[3] of the Ministry of Mines and Energy shows that in real terms the value of mineral output grew by 11.2% in 1979 compared with the 4.6% growth in 1978.

Total value of mineral output in 1979 was comprised of crude oil, 28%; iron ore, 20%; crushed rock, 10%; coal, 4.6%; phosphate rock, 3%; natural gas, 2.7%; pyrochlore, 2.5%; and tin, 2.3%. Overall in 1979, mineral fuels contributed 35.6% of total mineral output, followed by metallic minerals, 31.6%; nonmetallic minerals, 31.4%; and diamond and gems, 1.4%.

Table 1 provides reported and revised production data for 1976-80. Where reported data is not available for certain minerals in 1980, estimates are given.

Gold production escalated because of the Serra Pelada discovery in the Carajás region. Output of iron ore continued its upward trend as new capacity was utilized. The rate of growth of crude steel output slowed somewhat to 10.3%, while output of ferroalloys continued its strong expansion by increasing 14%. In 1980, Brazil became Latin America's third most important producer of bauxite after Jamaica and Suriname and was the leading aluminum producer.

Among nonmetallics, mine output of phosphate rock increased almost 60% because of the startup of several new projects in 1979. Sulfur output from oil shale and refinery operations increased but remained far below domestic demand.

Brazil's drive to reduce dependency on petroleum imports was manifested in the 14% increase in production of marketable coal. Output of metallurgical and steam coal has risen sharply since 1973 when the world energy crisis began. Output of crude oil and natural gas reached record levels.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Oct. 13, 1981.

[2]In addition to the commodities listed, molybdenite, bismuth, and uranium oxide are produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[3]Reported figure.

[4]Figure represents sum of (1) crude material sold directly and (2) production of concentrate. (Sale of crude material in any given year may exceed production in that year as a result of the sale of stocks of crude material mined but not sold or beneficiated in previous years. Similarly, output of concentrates in any given year may exceed the amount of crude material mined in that year owing to treatment of previously mined but not yet processed ores.

[5]Represents total estimated production, including the amount reported as sold by the Garimpos to Government agencies.

[6]Includes sponge iron as follows, in thousand metric tons: 1976—262; 1977—358; 1978—270; 1979—324; 1980—275.

[7]Smelter and/or refined metal.

[8]Includes baddeleyite-caldasite.

[9]Figures represent officially reported output plus official Brazilian estimates of output by nonreporting miners; officially reported output was as follows, in thousands of carats: 1976—76; 1977—65; 1978—86; 1979—83.

[10]Includes the following quantities sold directly without beneficiation, in metric tons: 1976—110; 1977—2,650; 1978—6,051; 1979—5,177; 1980—not available.

[11]Exports.

[12]Less than 1/2 unit.

[13]Listed under dimension stone in previous editions, but only a small part of the 1976 total and none of the output for the other years was dimension stone. Data on output in gravimetric units are not available for 1978 and later years but output on a volumetric basis was reported as follows, in thousand cubic meters: 1978—37,842; 1979—42,684; 1980—not available.

[14]Apparently includes crude quartz used to produce quartz crystal (listed separately in this table) as well as additional unreported quantities of common quartz.

[15]Produced from a portion of the crude quartzite listed above; crude quartzite processed was as follows, in metric tons: 1976—206,036; 1977—157,531; and 1978-80—not available.

TRADE

The overall trade deficit in 1980 was the same as that of 1979. Total exports increased 32% to $20.1 billion while imports increased 28% to $23.0 billion. Brazil's imports of oil and other fuels increased in value almost 50% to $10.2 billion. Exports of iron ore in 1980 valued at $1.6 billion were, by far, the country's most important mineral export accounting for about 8% of the total.

DNPM's annual report shows that in 1979 Brazil's trade deficit in mineral commodities continued to grow. Total mineral imports (including petroleum) were valued at $9.8 billion while mineral exports were valued at $2.7 billion. If mineral fuels (oil and natural gas) are eliminated, Brazil had a surplus of $706 million in its mineral trade. Mineral imports in 1979 comprised crude oil, 68%; steel and ferroalloys, 5%; copper, 4%; and coal 3%. Mineral exports comprised iron ore, 86%; manganese, 4%;

and gems and diamond, 2.7%. Exports of steel and ferroalloys in 1979 amounted to $825 million and petroleum products were $212 million. In 1980, Brazil became a significant exporter of bauxite for the first time.

Brazil's mineral trade shows a trend away from simple beneficiated ore toward exports of mineral-related, semimanufactured commodities such as crude steel and ferroalloys with value added by further processing. The proportion of these commodities had increased from 28% of total mineral exports in 1977 to 45% in 1979.

Brazil's major partners in mineral trade in 1979, including mineral fuels, are shown below in million U.S. dollars:

Export markets		Import sources	
Japan	500	Iraq	2,283
United States	363	Saudi Arabia	1,945
Germany, Federal Republic of	252	United States	902
Argentina	168	Iran	884
Italy	104	Kuwait	295
Great Britain	100	Germany, Federal Republic of	251
Zaire	88	Venezuela	232
Colombia	84	Canada	210

METALS —Continued				
Iron and steel —Continued				
Metal —Continued				
Semimanufactures:				
Bars, rods, angles, shapes, sections	382,320	383,685	64,568	Nigeria 60,486; Colombia 55,017; Uruguay 49,534.
Universals, plates, sheets	148,868	444,484	195,343	Uruguay 49,879; Canada 38,962; Japan 28,544.
Hoop and strip	768	6,020	--	Argentina 2,118; West Germany 1,539; Uruguay 862.
Rails and accessories	95	4,115	--	Bolivia 3,998.
Wire	18,675	24,058	1,126	Colombia 11,483; Nigeria 5,207.
Tubes, pipes, fittings	53,134	150,480	43,947	Mexico 46,005; China, mainland 8,421; Argentina 5,625.
Castings and forgings, rough	341	887	535	Argentina 105; Costa Rica 82.
Lead:				
Pentoxide	NA	1	--	All to Argentina.
Metal including alloys, all forms	(2)	247	--	Uruguay 142; Argentina 100.
Manganese:				
Ore and concentrate thousand tons	894	1,187	100	Japan 163; United Kingdom 153; Norway 140.
Oxide	978	1,822	--	Argentina 1,000; Colombia 570.
Molybdenum metal including alloys all forms kilograms	170	196	--	All to Mexico.
Nickel metal including alloys, all forms	7	6	5	NA.
Platinum-group metals including alloys, unwrought and partly wrought:				
Platinum troy ounces	17,458	3 1,511	--	Spain 1,286.
Rare-earth metals:				
Oxide	530	120	78	Austria 25; United Kingdom 17.
Metals including alloys, all forms: Cerium	29	4	--	All to Argentina.
Silicon metal	NA	1,759	--	Japan 1,300; Argentina 237.
Silver metal including alloys, unwrought and partly wrought troy ounces	257	2,765	--	Paraguay 1,608; Mexico 964.
Tin metal including alloys, all forms	3,756	4,727	3,510	Argentina 451; Venezuela 281.
Titanium oxides kilograms	--	560	--	All to Venezuela.
Tungsten:				
Ore and concentrate	992	538	--	Sweden 240; West Germany 238.
Metal including alloys, all forms kilograms	25,000	435	--	All to Mexico.
Zinc:				
Ore and concentrate	5,688	9,108	--	Belgium-Luxembourg 6,176; Algeria 2,933.
Oxide and hydroxide	13	17	--	Mainly to France.
Metal including alloys, all forms	49	103	--	Mozambique 80; Uruguay 17.
Other:				
Ores and concentrates	861	--		
Ash and residue containing nonferrous metals	383	3,521	65	West Germany 3,096; Netherlands 163.
Oxides, hydroxides, peroxides kilograms	2,000	560	--	All to Ecuador.
Waste and sweepings of precious metals value, thousands	$882	$1,044	$767	West Germany $277.
Metals:				
Pyrophoric alloys	593	601	--	Japan 114; Austria 80; Netherlands 70; Norway 70.
Metalloids	2,201	--		
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	1	51	--	Mainly to Japan.
Artificial corundum	9,594	13,648	560	Japan 4,018; Argentina 3,648; Mexico 3,229.
Grinding and polishing wheels and stones	845	1,124	90	Philippines 171; Hong Kong 171; Chile 141.
Asbestos, crude	30	(2)	--	All to Bolivia.
Barium: Natural compounds	34,000	43,520	27,537	Trinidad and Tobago 7,781; Nigeria 4,500.

See footnotes at end of table.

NONMETALS —Continued				
Boron:				
Crude natural borates kilograms	5,000	700	--	All to Canada.
Oxide and acid do	140	1,250	--	Paraguay 1,000; Uruguay 250.
Cement	144,172	215,244	--	Paraguay 138,156; Argentina 40,592; Bolivia 36,376.
Clays and clay products:				
Crude clays:				
Bentonite	344	23	--	Argentina 15; Paraguay 8.
Kaolin	21,445	46,543	--	Netherlands 27,000; Italy 9,550; Uruguay 2,090.
Other	3,231	4,914	--	Italy 3,283; Uruguay 1,455.
Products:				
Refractory including nonclay brick	13,941	18,185	--	Argentina 5,665; Romania 3,551; Colombia 1,756.
Nonrefractory	40,271	80,882	2,420	Paraguay 40,252; Argentina 20,038.
Diamond:				
Gem, not set or strung value, thousands	$4,412	$1,044	$600	Belgium-Luxembourg $202; Switzerland $74; Israel $56.
Industrial do	--	$4	--	All to Netherlands.
Fertilizer materials:				
Manufactured:				
Nitrogenous	2,430	177	--	Bolivia 100.
Phosphatic	3,358	7,031	--	Argentina 4,000; Uruguay 1,500; Paraguay 1,072.
Potassic	100	1,732	--	Uruguay 1,612.
Other including mixed	4,357	8,627	--	Argentina 4,520; Uruguay 3,857.
Ammonia	145	108	--	Uruguay 69; Paraguay 38.
Feldspar, fluorspar, etc	2,500	--	--	
Graphite, natural	1,026	3,437	2,765	Japan 417; Argentina 182.
Gypsum and plasters	15	48	--	All to Paraguay.
Lime	6,444	8,842	--	Paraguay 6,812; Argentina 2,000.
Magnesite	56,219	104,399	5,700	Poland 60,650; India 10,000; Argentina 7,020.
Mica:				
Crude including splittings and waste	4,553	4,074	468	United Kingdom 1,527; West Germany 777; Belgium-Luxembourg 650.
Worked including agglomerated splittings kilograms	110	1,753	--	Argentina 1,700.
Pigments, mineral: Processed iron oxides	56	275	20	Paraguay 90; Argentina 80; Chile 64.
Precious and semiprecious stones except diamond:				
Agate	1,771	1,595	546	West Germany 387; Japan 256.
Amethyst kilograms	357,384	328,007	48,115	Japan 92,622; West Germany 73,042.
Aquamarine do	2,546	1,564	113	West Germany 812; Republic of South Africa 275; Japan 272.
Cat's eye do	68	[4]3	--	Mainly to Senegal.
Citrine do	49,796	60,858	11,475	West Germany 16,700; France 12,708; Japan 5,747.
Emerald do	16,729	7,471	6,918	India 296; Republic of South Africa 98.
Garnet do	2,907	840	125	West Germany 395; Republic of South Africa 168; Thailand 80.
Opal do	619	1,383	1,086	West Germany 271.
Ruby do	1	[5]20	--	All to India.
Topaz do	4,231	15,741	14,505	West Germany 621; United Kingdom 227.
Tourmaline do	2,536	2,144	53	West Germany 1,170.
Other do	482,737	406,379	27,505	West Germany 228,873; Hong Kong 33,581.
Salt and brine	111,684	138,240	95,790	Hungary 15,510; Nigeria 12,800.
Sodium and potassium compounds, n.e.s	17,204	37,953	--	Argentina 17,555; Uruguay 9,623; Venezuela 7,342.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked	70,146	85,270	350	Italy 53,154; Japan 20,259.
Worked	2,864	4,179	316	Japan 2,168; Paraguay 300.
Dolomite, chiefly refractory grade	800	5	--	All to Ecuador.
Gravel and crushed rock	11,230	1,471	--	Bolivia 1,370; Argentina 48.
Limestone excluding dimension	1,110	2,698	--	Paraguay 2,350; Uruguay 348.
Quartz and quartzite	2,492	4,764	224	West Germany 1,628; Belgium-Luxembourg 1,262; Poland 700.
Sand excluding metal-bearing	1	701	--	Argentina 700.

See footnotes at end of table.

NONMETALS —Continued				
Sulfur:				
Elemental, colloidal	15	--		
Sulfuric acid, oleum	228	15,839	--	Spain 14,530; Uruguay 1,200.
Talc, steatite, soapstone, pyrophyllite	159	320	--	Argentina 156; Paraguay 50; Colombia 42.
Vermiculite	--	17	--	Bolivia 11; Uruguay 4.
Other:				
Crude	8	1,163	(2)	Japan 1,075.
Building materials of asphalt, asbestos and fiber cements, and unfired nonmetals	5,778	122	--	Paraguay 121.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural kilograms	3,000	75	--	All to Paraguay.
Carbon black do	9	4,376	--	Chile 2,200; France 2,000.
Coal, all grades including briquets	25	125	--	All to Argentina.
Hydrogen, helium, rare gases	2,515	189	--	Argentina 182.
Petroleum and refinery products:				
Crude and partly refined thousand 42-gallon barrels	3,130	--		
Refinery products:				
Gasoline, motor do	5,118	4,709	--	Colombia 2,393; Netherlands Antilles 748; Zaire 700.
Kerosine do	1,208	1,773	--	Zaire 1,135; Nigeria 264.
Distillate fuel oil do	2,739	1,965	--	Paraguay 306; Congo 212; Nigeria 170.
Residual fuel oil do	113	66	--	All to Argentina.
Lubricants do	24	6	--	Paraguay 5.
Other:				
Liquefied petroleum gas do	250	739	--	Paraguay 163; Argentina 118; Morocco 86.
Mineral jelly and wax do	75	100	27	United Kingdom 17; Peru 12; Mexico 8.
Nonlubricating oils do	2	--		
Bitumen do	85	66	--	Paraguay 56.
Bituminous mixtures do	6	27	--	Bolivia 21.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	r1,725	3,868	--	Argentina 2,979; Uruguay 826.

rRevised. NA Not available.
[1]May include some tantalum.
[2]Less than 1/2 unit.
[3]Excludes an unreported quantity valued at $1,787.
[4]Excludes an unreported quantity valued at $781,425.
[5]Excludes an unreported quantity valued at $5,229.

COMMODITY REVIEW

During 1980, DNPM published two important and basic mineral balance studies for Brazil covering metallic and nonmetallic minerals.[4] The studies include historical data on Brazil's supply-demand position during 1970-79 and projections of domestic supply and demand for 1980-89. Information on prices, international trade, and reserves are also included, as well as a bibliography for each mineral studied.

METALS

As a result of exploration activities by Government agencies and private companies, DNPM reported substantial increases in the measured reserves of a number of metallic minerals headed by uranium, 65%; and followed by beryllium, 63%; gold, 31%; tin, 30%; bauxite, 26%; tungsten, 18%; manganese, 12%; copper, 11%; titanium, 6%; and chromium, 5%.[5] Measured reserve figures published by DNPM are those that are officially approved by the Government on the basis of annual mine reports and final reports on exploration work.

Aluminum-Alumina-Bauxite.—In 1980, Brazil was the major producer of primary aluminum in Latin America and had one of the major world reserves of bauxite. Discoveries of large reserves of bauxite in the Amazon Basin in the recent past have increased reserve estimates to about 4.5 billion tons giving Brazil third rank in bauxite reserves after Guinea and Australia.

Despite remarkable success in increasing production of primary aluminum from 56,000 tons in 1970 to an estimated 260,000 tons in 1980, Brazil continued to import sizable amounts of aluminum, which in 1979 was 104,000 tons valued at $177 million.

Brazil's four major producers were expanding aluminum capacity from 278,000 to 470,000 tons in 1985 at plants in Sao Paulo, Minas Gerais, and Bahia. New projects planned in Rio de Janeiro, Pernambuco, Maranhão, and Pará would increase aluminum capacity by 540,000 tons in 1985 giving Brazil a total capacity of 1,010,000 tons. The supply-demand projections indicate that in 1985 Brazil would eliminate its dependency on foreign supply and become an exporter of aluminum, for the first time, of about 350,000 tons.[6]

DNPM estimates that by 1990 Brazil will produce 17 million tons of bauxite, 4.35 million tons of alumina, and 1.4 million tons of aluminum.

Valenorte Aluminio Ltda., a subsidiary of CVRD, acted as the holding company for CVRD's investments in Aluminio Brasileiro S.A. (ALBRAS), Alumina do Norte do Brasil S.A. (ALUNORTE), and Mineração Vera Cruz S.A. (MVC). MVC's 86,000-ton-per-year aluminum plant at Santa Cruz, Rio de Janeiro State, was 65% complete and scheduled for startup in early 1982.

Basic engineering was in progress for the 320,000-ton-per-year ALBRAS aluminum smelter to be constructed at Vila do Conde in Pará south of Belém. Drainage work and the construction of a paved road system were in progress and expected to be completed in 1981. The construction of the Bacarena Velha shipping pier was completed as well as the road link to the smelter site.

The $1.3 billion ALBRAS project is being financed by CVRD and a Japanese consortium, Nippon Amazon Aluminum (Nalco). According to the agreement made in June 1980, Nalco is to finance the entire first stage of 80,000 tons per year capacity due onstream in 1984, as well as the additional 80,000-ton-per-year capacity due in July 1985. CVRD will finance the third stage due in 1987 and the fourth stage in 1988. The entire aluminum output of ALBRAS will be exported.

At the Vila do Conde site, ALUNORTE was building its 800,000-ton-per-year alumina refinery for completion in 1985.

After obtaining Government approval, Alcoa Aluminio S.A., owned 68% by the Aluminum Co. of America (Alcoa) and 32% by Hanna Mining Corp. of Cleveland, Ohio, initiated work in August on the $1 billion complex comprising a 100,000-ton-per-year aluminum smelter and a 500,000-ton-per-year alumina refinery. The refinery and smelter were scheduled for startup in 1983 and 1984, respectively. The complex is sited at São Luis, Maranhão State, near the terminus of the railway link to Carajás.

Bauxite for the ALUNORTE and Alcoa projects will be supplied from the Trombetas operation.

Mineração Rio do Norte S.A. (MRN), a consortium of domestic and foreign companies led by CVRD, completed its first full year of operation of the Trombetas bauxite project in the Amazon Basin in Pará, west

of Belém. Output of bauxite from Trombetas in 1980 was 2.9 million tons, of which 2.8 million tons were exported. With the startup of Trombetas in mid-1979, Brazil became a significant exporter of bauxite, for the first time, of about 516,000 tons. Bauxite exports were estimated at 3.0 million tons and 3.3 million tons for 1980 and 1981, respectively.

In Brazil, production of aluminum has been growing at a rate of 15% per year since 1970, while apparent consumption has been growing at a rate of 13% per year.

Beryllium.—Brazil is the largest producer of beryl ore in Latin America and apparently has one of the largest reserves in the world. Brazil's reserves are located mostly in Galiléia, Minas Gerais, and Anagé, Bahia.

Brazil is the second most important world producer after the U.S.S.R. Brazil's beryl output has been in a steep decline since 1969 when 3,600 tons of beryl concentrate was produced. Practically all of the output is produced by small prospectors (garimpeiros), in connection with gem production. All of the recent output has been exported to the United States except in 1974 when a small amount went to Japan. During 1976-79, Brazil accounted for 48% of U.S. imports of beryl concentrate.

Chromium.—Cia de Ferro-Ligas da Bahia S.A. (FERBASA), a privately owned operation at Campo Formoso in Bahia State, continued as Brazil's major producer of chromite ore and the sole producer of ferrochromium. FERBASA's production of ferrochromium has been in a strong uptrend, as shown in table 4 in metric tons. In 1979, total exports of ferrochromium were valued at $19.6 million and was Brazil's second most valuable ferroalloy export after ferrocolumbium.

FERBASA was installing a new furnace to increase its capacity to produce high-carbon ferrochromium, which was scheduled for operation in early 1981.

In January a consortium of Japanese companies sold its 48% interest in the chromite mine of Mineração Serra da Jacobina S.A.. The Japanese withdrew from the joint venture with FERBASA because of heavy losses since the joint venture was initiated in 1972. The mine opened in 1976.

Table 4.—Brazil: Production and exports of ferrochromium by FERBASA

(Metric tons)

	Production			Exports		
	1978	1979	1980	1978	1979	1980
Ferrochromium, high-carbon	56,326	74,435	79,894	42,370	48,200	45,871
Ferrochromium, low-carbon	5,844	10,079	13,549	--	--	--
Ferrosilicochromium	4,698	7,239	8,086	--	--	--
Total	66,868	91,753	101,529	42,370	48,200	45,871

Columbium (Niobium).—Brazil has the world's largest reserves of columbium minerals (pyrochlore) located mostly in Araxá and Tapira in Minas Gerais. As Brazil expanded its production of ferrocolumbium, exports of pyrochlore concentrate continued to decline. In 1979, exports of concentrate, valued at $5.4 million, represented 6% of total concentrate output compared with a 20% share exported in 1977. On the other hand, exports of ferrocolumbium continued to expand, increasing in volume and value. Exports of ferrocolumbium were valued at $83 million in 1979 and represented Brazil's most valuable ferroalloy export. Most of Brazil's export in 1980 went to the United States, Italy, Sweden, and Japan.

Table 5 shows the output by Brazil's two producers of ferrocolumbium. Catalão initiated production in 1977 and exports 90% of its output. DNPM projections indicate that domestic demand for ferrocolumbium will grow moderately until 1989 and Brazil will continue to have a substantial surplus for export.

Companhia Brasileira de Metalurgia e Mineração (CBMM), which has been mining about 2,500 tons per day of pyrochlore ore on a two-shift basis for an annual ore production of 875,000 tons, progressed with its expansion program for ore treatment facilities. Nominal capacity of these facilities to treat 800,000 tons per year of ore containing an average of 3% Cb_2O_5 to produce 27,600 tons per year of concentrate with 60% Cb_2O_5 was being increased to

44,000 tons per year of concentrate in 1981 and 60,000 tons per year in 1982.

CBMM moved further into provision of only upgraded forms of columbium by inaugurating commercial shipments of technical-grade (98% minimum Cb_2O_5) columbium oxide in January and by ending exports of concentrate as of yearend 1980. The company was reported to be considering future production of columbium metal.

Table 5.—Brazil: Production and exports of ferrocolumbium

(Metric tons)

[e]Estimated.

Source: ABRAFE Yearbook 1981.

Copper.—Brazil continued to rely entirely on imports to meet its demand for primary copper. According to DNPM projections contained in Brazil's mineral balance,[7] demand for copper is expected to grow 11% per year until 1989 when total domestic demand is expected to reach 647,000 tons. At that time new mine, smelter, and refinery projects are expected to contribute 300,000 tons. Together with production of secondary copper from scrap, Brazil's dependency on foreign sources would be reduced to 29% of domestic demand.

In Bahia, the $783 million mine, smelter, and refinery project of Caraiba Metais S.A., Industria e Comercio, controlled by Insumo Básicos, Financiamentos e Participações S.A. (FIBASE) a subsidiary of the Banco Nacional do Desenvolvimento (BNDE), was nearing completion. In the first stage, scheduled to be completed in 1982, a capacity of 65,000 tons per year of copper would be available to be expanded to 150,000 tons per year after 1983.

The copper refinery under construction in Rio Grande do Sul by a joint venture of Eluma S.A. and Noranda Mines Ltd. was rescheduled for completion in 1985 with a capacity of 60,000 tons per year in the first stage. The second stage capacity of 150,000 tons per year would be obtained in 1987. Noranda will supply technology and 60% of the imports of copper concentrate required.

The Government included copper development in its 10-year investment program to exploit the several minerals in the Carajás Mineral Province. The large copper deposits discovered in the vicinity of the deposits of iron ore, manganese, and bauxite would be exploited on the basis of energy, railway, and port facilities put in place to produce iron ore in the first phase.

Gold.—The sharp rise in the price of gold in 1979-80, and the discovery of an apparently large deposit at Serra Pelada, created intense interest in gold exploration in Brazil. This was manifested by the large number of exploration licenses granted by DNPM in the last 2 years for exploration in the States of Amazonas, Bahia, Goiás, Maranhão, Mato Grosso, Minas Gerais, Rio Grande do Sul, and Pará.

Geologic studies on the Serra Pelada deposit located in the southern part of the Carajás Mineral Province, Pará State, were undertaken by Rio Doce Geologia e Mineração S.A., the exploration subsidiary of CVRD. Preliminary studies of Serra Pelada indicate gold reserves of 33,000 tons, substantially above current reserve estimates for all of Brazil. As of the end of 1979, DNPM reported total measured reserves for Brazil at 195 tons located primarily in the municipalities of Mariana and Nova Lima in Minas Gerais.

In the latest available minerals report DNPM stated 1979 gold output at 4.46 tons, of which 3.33 tons were from mine operations by Morro Velho Mineração S.A. and Mineração Tejucana S.A., and 1.13 tons were from many garimpeiros. DNPM noted that the output of the garimpeiros represents only the amount purchased by local agencies of the Federal Government. In its report, "Gold 1981," Consolidated Gold Fields Ltd. estimated Brazil's 1979 and 1980 gold production at 25 tons and 35 tons, respectively. Bureau of Mines estimates in

table 1 are conservative.

The major mine producer, Morro Velho, operated an underground mine at its complex near Belo Horizonte, Minas Gerais. Tejucana operated dredges on Rio Jequitinhonha and Rio das Velhas, and the aluvial deposit at Ribeirão do Carmos in Mariana, Minas Gerais. The garimpeiros operated primarily in the Amazon Basin, the region of Tapajós and Rio Madeira in Rondonia, in Lourenço and Calçoene in Amapá, Serra Pelada in Pará, the region of Rio Guaporé (Vila Bela) in Mato Grosso do Norte, and the region of Rio Maués in Amazonas State.

Brazil's apparent demand for gold, mostly for jewelry, was 16 tons in 1978 and 22 tons in 1979. In 1979, about 80% of domestic demand for gold was imported at a cost of $72 million, most of which was gold ore from Canada and the Federal Republic of Germany.

Iron Ore.—The outstanding event in 1980 was the decision of the Government in October to give priority status to the execution of the Carajás iron ore project in Pará State. The $4.9 billion project is part of the $61 billion comprehensive development program for the Carajás region for the decade ending 1990. The Carajás iron ore deposits of about 18 billion tons of ore has an average grade of 66% iron. Of total reserves at Carajás, 2.4 billion tons of iron ore are measured reserves. The deposit was discovered in 1967 by a subsidiary of United States Steel Corp. This company sold its 49.1% interest to CVRD in 1977 and withdrew its involvement in the Carajás project.

CVRD was implementing the Carajás project through its subsidiary Amazonia Mineração S.A. (AMZA). AMZA, formed in 1970 with United States Steel, was expected to be incorporated into CVRD in early 1981. At that time the project will be controlled within CVRD by the Superintendencia de Implementaçáo do Projeto Carajás, which reports to the Director of Planning.

New infrastructure will be required to support the Carajás iron ore project. Because of its remote location in the Amazon Basin, the project comprises in addition to the open pit mine proper, an 890-kilometer railroad to the Atlantic coast and a deep water port at Ponta da Madeira located between Itaqui and São Luis in Maranhão State. By yearend 1980, detailed engineering was nearing completion for the project.

Development of the open pit mine at Carajás is estimated to cost $515 million, representing 16% of the total base cost of the project of $3.27 billion. (The $4.9 billion estimate given above includes contingencies and interest during construction.) The mine is designed for an output of 35 million tons per year of beneficiated ore with eventual capacity of 50 million tons per year. Initial output scheduled for 1985 will be at the 15-million-ton-per-year rate and consist of 90% sinter feed and 10% natural pellets. The capacity of 35 million tons per year was programed for 1987. Initial mining operations will take place on the N4E deposit, one of the main iron ore bodies in the Carajás area, with 1.2 billion tons of measured reserves of high-grade ore. The proposed open pit mine will employ 2 large-hole rotary drills, 16-yard electric shovels, and 154-ton dump trucks.

A pilot beneficiation plant was completed at the Carajás mine site and trial beneficiation tests were planned for March 1981 to determine the final processing flowsheet. Beneficiation facilities will consist of three stages of crushing-screening, one rodmill stage, a solids recovery stage and a final dewatering stage. Belt conveyors will transport the beneficiated ore to the 1.6-million-ton storage yard.

The Carajás railroad will be used to transport iron ore from the N4E mine site to the Port of Ponta da Madeira for export. The railroad comprises 890 kilometers of single-track line, 11.1 kilometers of bridges including a long 2.3-kilometer bridge over the Tocantins River, and 8 small yards along the line. By yearend 1980, subgrade construction of the first 540 kilometers of the railroad was in progress. About 38% of the earthmoving work and 25% of the bridges and viaducts under contract were completed.

The proposed port for the Carajás project will be located in a sheltered bay about 10 kilometers from São Luis and 1 kilometer north of the existing Port of Itaqui. Adequate natural depth of water for 280,000-deadweight-ton ships is available alongside the proposed berth. Shipping facilities include two car dumpers and a 16,000-ton-per-hour linear shiploader. By yearend 1980, the relocation of the access highway to Itaqui was completed with 85% of the railroad access completed. Construction of two breakwaters to protect the future marine terminal was initiated during 1980 with about 10% completion by yearend.

Overall, by the end of 1980, CVRD had expended $308 million on the Carajás proj-

ect with $438 million budgeted for 1981. According to the Carajás financial plan, CVRD would contribute 48% of the requirements with the balance coming from Brazilian credit institutions and external sources. CVRD was negotiating with the International Bank for Reconstruction and Development (World Bank) for a $350 million loan.

As for market prospects, CVRD forecast a small deficit in iron ore supply in 1985 in worldwide markets taking into account Brazil's own new capacity of 61 million tons per year of iron ore (including Carajás) as well as the capacity increases by Australia, Guinea, Venezuela, the Republic of South Africa, and Peru. CVRD was aggressively negotiating long-term supply contracts with buyers in Japan, Italy, the Federal Republic of Germany, and South Korea, which by yearend 1980 amounted to about 22 million tons per year.

CVRD and other large iron ore producers were also expanding iron ore capacity in the iron quadrangle in Minas Gerais, Brazil's traditional iron ore source. Mineração Brasileiros Reunidos S.A. (MBR), Brazil's second largest iron ore producer was expanding capacity from 15.1 million tons per year in 1980 to 31 million tons per year in 1985-86. CVRD also participated in the Capanema project of Minas da Serra Geral S.A. that completed 20% of its 11.5-million-ton-per-year project scheduled for startup in 1982.

In 1980, Brazil continued as the second world producer of iron ore after the U.S.S.R. and the world's major exporter. CVRD was the world's largest producer and exporter of iron ore. Table 6 provides data on iron ore shipments during 1980 by some of Brazil's leading producers.

In its 1980 annual report, CVRD reported sustained growth in sales despite the slump in the world steel industry. CVRD reported that its total iron ore production increased 18% to 67.6 million tons of which 4.6 million tons were iron ore pellets. Exports of iron ore and pellets in 1980 by CVRD generated foreign exchange earnings of $792 million, a gain of 5% over 1979 despite a 7% decline in volume.

Brazil's total iron ore exports in 1980 of 78.9 million tons were composed of 49.0 million tons of fines, 17.3 million tons of pellets, and 12.6 million tons of lump ore. Iron ore pellets were produced by CVRD, Cía Nipo-Brasileira de Pelotização (NIBRASCO), Cía Italo-Brasileira de Pelotização (ITABRASCO), Cía Hispano-Brasileira de Pelotização (HISPANOBRAS), and Samarco Mineração S.A. (SAMARCO). The shipping ports used were Tubarão-Vitoria, Ponta do Ubu, Sepetiba, and Rio de Janeiro. In 1979, the United States imported only 3.1 million tons from Brazil; shipped by CVRD, SAMARCO, and MBR.

Table 6.—Brazil: Iron ore and pellet shipments by leading producers during 1980

(Thousand metric tons)

[1]Of the total, Japan received 38% and Europe received 50%. The United States received 1,100,000 tons and Argentina received 800,000 tons.

Iron and Steel.—Strong expansion of the iron and steel industry continued, reflecting the priority that the Brazilian Government has given to developing this sector to support industrialization of the country. Production of crude steel grew 10.3% in 1980 to 15.3 million tons compared with the 14.8% growth in 1979. A study made by the Instituto Brasilerio de Siderurgia projects that by 1986 Brazil will produce 25 million tons and that this figure will reach 35 million tons by 1990. These projections are based on an annual GDP growth rate of 6.6%.

During the past decade, Brazil's steel production has increased at an average annual rate of 11%. Per capita steel consumption increased from 61 to 115 kilograms. Steel output from oxygen and electrical furnaces increased from 57% in 1970 to 88% in 1979, thus reducing production from open hearth furnaces. In the same period, steel production from continuous casting increased from 2% to 28% of the total. Employment in the iron and steel industry rose from 81,000 jobs in 1970 to 142,000 jobs in 1979, an annual growth rate of 6.4%.

Since the founding of the Government steel holding company in 1973, Siderúrgica Brasileira S.A., steel output from the majority-owned Government companies has grown to 63% of the country's total steel output.

Since 1973 the Brazilian steel industry has actively pursued the objective of reducing the consumption of imported energy. During 1974-79 the kilograms of fuel oil required to produce 1 metric ton of steel decreased 40% from 142 to 85 kilograms. In 1979, imported energy in the form of coal and fuel oil represented 52% of the energy consumed by the sector. Of the different energy sources, charcoal contributed 13% of the total. In 1979, pig iron made from charcoal was 38% of the total. In the same year, sponge iron output increased 12% to 324,000 tons.

rRevised.

Source: Associação Brasileira dos Produtores de ferroligas, ABRAFE Yearbook 1980, pp. 21, 39.

Ferroalloys.—As shown in metric tons in the table above, Brazil's diverse production and trade in ferroalloys has grown impressively over the past decade.

In 1980, the leading ferroalloy export on a volume basis was ferrochromium followed by ferrosilcomanganese, and ferromanganese (high carbon); whereas on a value basis, the leader was ferrocolumbium followed by ferrochromium and ferrosilicomanganese. Exports were 32% of total ferroalloy output. The value of exports has grown from $68 million in 1976 to $189 million in 1980.

In its 1981 annual report, the Associação Brasileiro dos Produtores de Ferro-Ligas (ABRAFE) reported that 21 companies were active as ferroalloy producers, of which 10 companies were engaged in expansion programs—notably in ferrocolumbium, ferrosilicon, ferrosilicomanganese, and silicon metal.

Outstanding progress was made in 1980 in the output of silicon-base alloys as a result of expansion programs involving the installation of five new electric furnaces. During 1980, domestic consumption of ferroalloys increased 15% to 327,116 tons, of which 82% was consumed by steel plants and 18% by foundries.

Manganese.—Brazil is the leading producer of manganese ore in Latin America and a significant world exporter of beneficiated ore and pellets. As of yearend 1979, DNPM reported a 12% increase in measured reserves of manganese ore to 55.5 million tons with a metallic content of 20 million tons. Total ore reserves were reported at 202 million tons.

According to projections by DNPM, output of beneficiated ore is expected to grow gradually to 2.7 million tons by 1989. However, as Brazil expands its steel industry at a rapid rate, the amount of surplus available for export is expected to decrease from 1,200,000 tons in 1980 to 275,000 tons in 1989.

Industria e Comercio de Minerios S.A., Brazil's largest producer, shipped 1,230,200 tons of manganese ore, including pellets, in 1980 from its Serra do Navio operations in Amapá Territory. Shipments from Porto de Santana went to Europe, 793,000 tons; Japan, 138,000 tons; North America, 73,000 tons, and to South America other than Brazil, 22,000 tons.

Urucum Mineração S.A., 33% owned by CVRD, produced 112,800 tons of manganese ore in the Urucum area of Mato Grosso State near Corumbá. Manganese ore sales amounted to 67,700 tons, of which 38,700 tons were exported and 29,000 tons were

sold in the domestic market.

It is estimated that the Carajás Mineral Province contains 60 million tons of manganese ore with an average grade of 43% manganese in the deposits of Azul, Buritirama, and Sereno. Future development of the manganese would make use of the power, rail, and port infrastructure constructed for the priority iron ore operations. Manganese mining is proposed at a level of 150,000 tons per year.

Tin.—Mostly as a result of discoveries in the Carajás Mineral Province and the increase in reserves at Porto Velho, Rondonia Territory, DNPM reported a 30% increase in the country's measured reserves of tin as detailed below in thousand metric tons:

State or territory	Municipality	Measured reserves[1]	Tin content	1979 production
Rondonia	Porto Velho	44,066	26,440	7,522
Pará	São Felix do Xingú	9,815	6,833	1,306
Mato Grosso	Aripuanã	8,966	4,752	1,366
Amazonas	Novo Aripuanã	3,918	2,062	751
Goiás	Monte Alegre	2,146	1,288	521
Others	--	24,297	13,499	435
Total		93,208	54,874	11,901

[1]Concentrate of cassiterite.

In 1979, the Rondonia tin district accounted for 63% of national output. The principal tin mining operator was a holding company, Paranapanema S.A. Mineração, Industria e Construção operating through a subsidiary, Mineração Taboca S.A. In 1979, Paranapanema produced cassiterite concentrate with a tin content of 2,013 tons. Next in importance were Mineração Brumadinho S.A., Mineração Brasiliense S.A., and Mineração e Prospeccoes Minerais S.A. (BRASCAN Group).

Although output of tin concentrate has been increasing, it has not been adequate to meet the demand of Brazil's smelters. In 1979, Brazil imported 7,542 tons of cassiterite valued at $55 million from Bolivia (74%) and Singapore (26%).

According to DNPM projections, Brazil will become self-sufficient in tin concentrate in 1983 when 15,500 tons will be produced. In 1980, Brazil had an estimated surplus of 5,050 tons of tin metal for export. This tin surplus was projected to increase to 12,960 tons in 1989 when total output by the smelters will be 25,800 tons.

Titanium.—Production of concentrate of ilmenite and rutile is not adequate to meet domestic demand. The sole producer was Nuclebras de Monazita (NUCLEMON) that produced concentrate from ilmeno-monazitic sands. Output has rebounded since 1975 when NUCLEMON assumed control of operations from the Comissao Nacional de Energia Nuclear.

Output of titanium pigment has grown steadily since operations were initiated in 1970. The only producer, Titanio do Brasil (TIBRAS), was expanding capacity from 22,000 to 50,000 tons per year of titanium dioxide to be available during the first half of 1982.

Full capacity would be reached in 1983. TIBRAS had preliminary plans to expand capacity to 70,000 tons per year. DNPM estimated that Brazil's domestic demand in 1980 was 56,000 tons requiring imports of 28,000 tons valued at $34 million. Demand was projected to grow to 88,000 tons by 1989 when imports would increase to 38,000 tons.

Brazil had three producers of ferrotitanium alloy: Electrometalur S.A., Indústria e Comércio in Minas Gerais, Produtos Metalúrgicas S.A. in São Paulo, and Termoligas Metalúrgicas S.A. in Bahia State. Brazilian production during 1967-79 increased almost 350% at an average rate of 16% per year.

Zinc.—While mine output of zinc concentrate and production of primary zinc has been increasing, Brazil remained dependent on foreign sources to meet 23% of domestic demand that in 1980 was about 137,000 tons. In 1979, Brazil's rising trend in imports of refined zinc was reversed and declined 9%. In that year imports of refined zinc amounted to $41 million and came mostly from Mexico (33%), Canada (31%), and Peru (28%).

Output of beneficiated ore increased markedly in 1979, by 80% to 375,900 tons. Utilizing integrated operations at Vazante, Minas Gerais, involving mine, beneficiation, and metallurgical plants, refined zinc was produced by Companhia Industrial

e Mercantil Inga S.A. and Companhia Mineira de Metais S.A. In 1980, Companhia Paraibuna de Metais initiated its metallurgical operations and was expected to produce 21,000 tons of refined zinc. The Praibuna plant processed a small amount of concentrate from Mineração BOQUIRA/COBRAC, a lead producer, and the balance of concentrate was imported.

On the basis of expansion plans by the three refined zinc producers, Brazil was expected to gradually decrease imports of refined zinc and achieve a surplus of 7,000 tons in 1985, at which time total output of primary and secondary zinc would be 187,000 tons.

NONMETALS

As of yearend 1979, DNPM reported substantial increases in the measured reserves of potassic minerals, 523%; diamond, 70%; mica, 67%; natural graphite, 62%; phosphate rock, 53%; leucite, 42%; agalmatolite, 32%; rock salt, 18%; talc, 16%; and magnesite, 15%.

Barite.—Brazil became self-sufficient in barite (barium sulfate) and since that time increasing output has exceeded domestic demand. The surplus available for export in 1980 was estimated at 24,000 tons, while internal demand was estimated at 72,000 tons. Substantial exports of barite were initiated in 1978 to Trinidad and Tobago (82%) and Venezuela (18%).

Brazil's barite reserves are located mostly in Araxá, Minas Gerais, and Camamu and Ibitiara in Bahia, but production has come chiefly from the latter State.

Cement.—Brazil is the largest producer of cement in Latin America and ranks in ninth place worldwide after Spain. Capacity in 1980 was 27 million tons from 56 plants dispersed among the major population centers.

The major cement producer, S.A. Indústrias Votorantim, accounted for 33% of national output. The Votorantim Group operated through 15 cement companies located in 12 States controlling 19 of the 56 plants. As an extensive holding company and Brazil's second largest entity in the minerals sector after CVRD, Votorantim was also an important producer of aluminum through Companhia Brasilera de Alumínio, of nickel through Companhia Niquel Tocantins, and of zinc through Cia Mineira de Metais.

At yearend 1980, Brazil's Votorantim Group began operating Brazil's first underground limestone mine at Santa Helena, State of São Paulo, the site of Latin America's largest cement plant. The $70 million project was completed from studies and with technical assistance of Outokumpu Oy of Finland. The open pit mining in the area has become uneconomical because of the cost of removing overburden.

The second largest cement producer, Grupo João Santos, operated seven plants and accounted for 11% of Brazil's total output. All plants have expansion plans which, together with five new plants programed, would give the João Santos Group a capacity of 7.5 million tons of cement per year by 1985.

Diamond.—In Latin America, Brazil is the second most important producer of natural diamond after Venezuela.

Brazil's total apparent consumption of diamond has grown rapidly from 480,000 carats in 1970 to 3.4 million carats in 1979 at the rate of 22% per year. To meet growing demand for diamond by Brazil's rapid industrialization, imports have risen from 47% to 84% of domestic demand. In 1979, Brazil's demand was comprised of synthetic diamond, 45%; industrial diamond, 25%; and gem-quality diamond, 30%.

The major part of Brazil's production came from garimpeiros, which made it difficult for DNPM to collect precise data. DNPM's conservative estimate is that garimpeiros produce 120,000 carats per year only in the State of Mato Grosso. In 1979, Mineração Tejucana S.A. produced 64,860 carats in the region of Rio Jequitinhonha. Operators in Brazil's diamond industry consider the country's true output to be closer to 800,000 carats per year. Brazil's output consists of 50% industrial-grade and 50% gem-quality diamond.

St. Joe Minerals Corp. reported that it was investigating two promising alluvial diamond properties. At the Alto Coite project, detailed bulk sampling was in progress, to be followed by a feasibility study for a dredging operation. The potentially much larger Araguaia project was in an earlier state of investigation. Discussions were proceeding with potential Brazilian partners for development of these projects should they prove economically viable.

Graphite (Natural).—After Mexico, Brazil ranked second in Latin America as a producer of natural graphite. Brazil's output has increased sharply since 1970 when only 2,500 tons were produced. The main area of commercial importance is Itapecerica in Minas Gerais, where it is estimated that 15 million tons of flake graphite ore occur. Companhia Nacional de Grafite Ltda. is a major producer in Itapecerica, mining

by open pit methods. The company also operates a processing facility that produces flake graphite concentrate that ranges from 60% to 99% carbon, which will be expanded for the widening export market. Chemical beneficiation techniques are employed to produce the grades with the highest carbon content.

Fertilizer Materials.—Brazil has been very successful in closing the gap between demand for phosphatic fertilizers and domestic output. In 1974 Brazil was 85% dependent on imports, whereas in 1980 it was only 40% dependent. In 1980, when domestic demand was 1.57 million tons of phosphatic fertilizers in P_2O_5 content, imports cost $98 million, while in 1979 imports cost $373 million. This improvement resulted from an almost 60% increase in production of phosphate rock in 1980.

According to DNPM projections, the phosphate deficit is expected to decrease markedly until 1985 when imports of 270,000 tons of P_2O_5 will still be required, but then increase again as growing demand outstrips installed capacity.[8]

Local and imported phosphate rock was utilized by Brazil to produce phosphoric acid, 25%; fertilizers, 70%; and other purposes, 5%. Table 7 shows the existing and programed operations for producing phosphate rock concentrate in four States of Brazil. In 1980, Fertilizantes Fosfatados S.A. (FOSFERTIL) was the major producer of phosphate rock from open pit mines in Tapira and Patos de Minas in Minas Gerais. Output was 1,285,000 tons of concentrate, including the merged operations of Mineração Vale do Paranaiba S.A. (VALEP).

CPRM reported a phosphate discovery along the coast of the State of Paraiba between João Pessoa and Rio Tinto. Reserves were estimated at 100 million tons grading 22% P_2O_5.

Table 7.—Brazil: Phosphate projects

(Thousand metric tons)

Company and ownership	Location	Measured reserves	Capacity of P_2O_5 concentrate	Content of P_2O_5	Start-up date
Araxá S.A. Fertilizantes e Produtos Quimicos (ARAFERTIL)[1]	Araxá, Minas Gerais.	273,000	600	210	1977

NA Not available.
[1]Owned 40% by Serrana S.A. de Mineração, 40% by the Itau group, and 20% by FIBASE.
[2]VALEP, a subsidiary of CVRD, was merged into FOSFERTIL in 1980.
[3]Merged company is held 34.1% by CVRD; balance by PETROBRAS and BNDE.

Potassium.—Brazil's demand for potassic fertilizers continued to increase up to the level of 1.3 million tons of K_2O in 1980 and was met entirely by imports valued at $152 million. The large increase in potash reserves announced by DNPM amounts to 12.5 billion tons of mineral and is located primarily at Carmópolis in Sergipe State.

The Taquari-Vassouras potassium project in Sergipe was under construction by PETROBRAS Mineração S.A. (PETROMISA), a subsidiary of PETROBRAS. Startup was set for 1983 with a capacity of 500,000 tons of potassium chloride per year by 1989. This would satisfy only a fraction of demand, which was projected to grow to more than 3 million tons of K_2O in 1989.

Sulfur.—Although output of sulfur has increased greatly since 1974, domestic sources account for only 15% of Brazil's growing demand which in 1980 amounted to 841,000 tons. The small domestic output came from Irati oil shale processed at São Mateus do Sul and mostly PETROBRAS refinery operations. Brazil's demand was projected by DNPM to grow to 1.4 million tons of sulfur in 1989, when the country's dependency on imports would decrease to

70%. Sulfur imports in 1979 were valued at $56 million.

PETROMISA completed evaluation of sulfur reserves of 3 million tons at Castanhal, Sergipe. The project is the first for the production of sulfur in Brazil from domestic raw materials.

MINERAL FUELS

In 1980 the Ministry of Mines and Energy issued its annual National Energy Balance prepared by the Comité do Balanco Energetico Nacional. According to this updated study of Brazil's energy situation, in 1979 the country's energy consumption of petroleum, natural gas, and coal was 45% of the total. Considering Brazil's dependency on oil and coal imports for the steel industry, this meant a 37% dependency on external energy sources.

The report offers a national energy model and provides energy supply-demand projections until 1985. The model is based not only on increased domestic oil output from 171,100 barrels per day in 1979 to 500,000 barrels per day in 1985, but also on the development of alternate energy sources and opportunities for conservation.

The report notes that only 12%, of Brazil's estimated hydraulic power potential of 213,000 megawatts is currently utilized, and gives the following projections for installed electric generating capacity in megawatts.

Source	1980	Percent share	1985	Percent share
Hydro	27,263	86.0	43,485	88.8
Thermal	4,377	14.0	4,851	9.9
Nuclear[1]	--	0	626	1.3
Total	31,640	100.0	48,962	100.0

[1]Initial nuclear capacity scheduled for 1981.

Coal.—Brazil in 1980 replaced Colombia as the leading coal producer in Latin America. Despite this success in increasing production, Brazil remained dependent on imports to meet the steel industry's demand for metallurgical coal. Of 5.1 million tons of such coal consumed in 1979, 3.9 million tons was imported. The value of coal imports that year was $314 million, and coke imports cost $41 million. While Brazil's consumption of a metallurgical coal grew from 2.4 million tons in 1969 to 5.1 million tons in 1979, consumption of local charcoal grew from 1.9 to 4.7 million tons.

Steam coal output has doubled since 1974, with domestic supply exceeding demand. Since 1974 use of steam coal by the steel, cement, and paper industries has grown in addition to the traditional use by thermal electrical plants. According to DNPM projections, supply and demand for steam coal will be in balance in 1982 and remain in balance until 1985 when demand for steam coal will grow to 24.6 million tons.[9]

DNPM reported a 74% increase in measured reserves of coal to 1.8 billion tons mostly in the southern States of Santa Catarina and Rio Grande do Sul. The increases occurred chiefly in Lauro Muller and Criciuma in Santa Catarina; and Bagé, Triunfo, and Cachoeira do Sul in Rio Grande do Sul.

In 1980, DNPM published the second edition of its new publication "Informativo Anual da Industria Carbonifera" with data on coal reserves and production of individual coal companies and their operating mines in 1980. The report covers 11 companies in Santa Catarina, 3 in Rio Grande do Sul, and 2 in Parana. Personnel employed in the coal industry totaled 11,700 in 1980.

Natural Gas.—The consumption of natural gas in 1979 accounted for only 0.4% of the country's consumption of primary energy compared with the 40.7% share for petroleum and the 28.3% share for hydropower. Production of natural gas increased 16% in 1980 to record levels. Onshore fields produced 55%, and offshore fields produced 45% of total gas output. Only 21% was not associated with crude oil production.

In the upper Amazon region, substantial gas deposits were found in the Juruá area and positive results were expected in other areas with similar geological features. Gas was also discovered onshore at Miranga, Bahia. Off the coast of Sergipe, a deep well in the Robalo Field produced gas. Brazil's reserves of natural gas have almost doubled since 1975. At yearend, reserves increased to 52.54 billion cubic meters (1.86 trillion cubic feet), a 17% change compared with 1979.

Petroleum.—As a result of intensified exploration and development activities, PETROBRAS increased Brazil's crude oil output by almost 10%. Output increased from an average of 171,100 barrels per day in 1979 to 182,000 barrels per day in 1980. Table 8 provides a breakdown on the producing areas in 1980.

During 1980, PETROBRAS gave priority to its exploration activities which accounted for 71% of its investment program. The intensity of exploration was indicated by the fact that 88 drilling rigs were used during the year, 79 by PETROBRAS and 9 by risk contract operators. Oil reserves increased 6% to 212.8 million cubic meters or 1.34 billion barrels.

Table 8.—Brazil: Crude oil production by PETROBRAS

(Thousand 42-gallon barrels)

Area	1980 production	Share (percent)	
		1979	1980
Bahia	28,958	51.5	43.6
Sergipe	17,014	27.3	25.6
Rio de Janeiro	10,460	9.7	15.7
Rio Grande do Norte	4,894	6.2	7.4
Espírito Santo	2,848	3.5	4.3
Alagoas	1,183	1.8	1.8
Ceará	1,076	--	1.6
Total	66,433	100.0	100.0
Onshore	39,098	65.6	58.9
Offshore	27,365	34.4	41.2

Source: Annual Report of PETROBRAS, 1980.

By yearend, PETROBRAS had signed 80 risk contracts relating to the first four rounds of bidding; the fifth round was being negotiated. The five rounds cover half of the area targeted for such bids, which covers 83% of Brazil's sedimentary basins. In accordance with the Government's policy to accelerate the evaluation of the country's oil potential, to increase the interest of foreign oil companies, and to stimulate the participation of domestic companies in exploration, certain changes were made in the risk contract conditions.

During the year, the average price of petroleum products increased 113%. The price of gasoline increased 126% (an average of $3.10 per gallon for the year) while the price of fuel oil increased almost 400% as a result of the elimination of the Government subsidy and with a view to making its substitution by coal viable and to rationalizing its consumption. The increase in the price of diesel oil was held to only 67% because of its essential use in agriculture and transport.

Gasoline for automobilies, excluding those using fuel alcohol, accounted for 17% of the total consumption of petroleum fuel, a decrease of 15% from 1979 despite the increased number of cars on the road. About 20% of the demand for petroleum fuel was derived from domestic sources. Domestic crude production provided 80% and fuel alcohol provided 20% of the total.

Alcohol Fuel Program.—According to projections in the 1981 National Energy Balance, use of alcohol fuel is to grow from 2.4% of total primary energy consumed in 1980 to 4.1% in 1985. Brazil continued to make progress towards its goal of a 20% mixture of anhydrous alcohol with gasoline. In 1976, 86 liters of gasoline were used for 1 liter of anhydrous alcohol, this ratio fell to 22 liters in 1977, to 7 liters in 1979, and to 5 liters in 1980. Use of hydrated alcohol was initiated in 1978. By 1985, use of hydrated alcohol was projected to be double the use of anhydrous alcohol.

In 1980 alcohol production was 3.4 billion liters. Brazil's alcohol program aims at an annual production capacity of 10.7 billion liters by 1985.

Shale Oil.—Synthetic oil from shale oil deposits in southern Brazil was scheduled to become available in 1985. The prototype unit for processing oil shale at Irati operated practically without interruption in 1980, producing 19,300 thousand cubic meters of oil and 1,833 tons of sulfur. In the Irati formation, detailed studies were made in the Papanduva/Tres Barras area of Santa Catarina and exploratory investigations were made in the Ivai/São Jeronimo area of Paraná.

During 1980, engineering designs were completed for the São Mateus industrial shale oil plant in Paraná State. Designs included mineral treatment, retorting, gas treatment, transfer, and storage. The conceptual plan for the hydrotreatment of shale oil by PETROBRAS' Research and Development Center was also completed.

Uranium-Nuclear Energy.—Brazil has the largest discovered uranium reserves in Latin America and ranks fifth worldwide. There was no change in the reserves of 215,300 tons of yellow cake reported in 1979. In late 1981 or early 1982, the uranium mine at Poços de Cladas, Minas Gerais, was scheduled to begin production at the rate of 2,500 tons of ore per day.

Angra I, Brazil's first commercial nuclear reactor, was scheduled to begin operations in September 1981. The 626-megawatt pressurized water reactor is located in the State of Rio de Janeiro. Work continued on the 1,245-megawatt Angra II unit scheduled for completion in 1987.

The Mineral Industry of Bulgaria

By Tatiana Karpinsky[1]

Performance of the Bulgarian economy in 1980 showed decreased growth rates in the major economic sectors. According to Bulgarian sources, industrial production and national income increased respectively, 4.1% and 5.7%, well below the initially planned figures of 6.3% and 7.2%.[2]

In 1980, however, the original planned target of 7.2% was revised to 5.7%. The national income generated in 1980 exceeded leva (L) 20 billion.[3]

In 1980, industry accounted for about 58% to 60% of the national income. Capital investments increased from $7.3 billion in 1979 to $8.23 billion in 1980. More than 63% of capital investments was spent for renovation and expansion of existing production facilities in 1980. Labor productivity increased 2.6% and accounted for about 70% of the increase in industrial production.

Major projects put into operation in 1980 included the third turbine of the Maritsa-Istok 3 thermoelectric powerplant; the third 440-megawatt reactor of the Kozloduy nuclear powerplant; the benzine production facility at the petrochemical combine in Burgas; the plant for steel wire and cables in Roman; the first expansion of the U.S.S.R.-Bulgaria gas pipeline; and the first and second lines at the V. Kolarov State cement plant in Temelkovo. In 1979, the number of industrial workers and employees in state enterprises totaled 1,243,768. The number of workers and employees in state mineral and energy enterprises by branch follow:

Branch	Workers and employees (thousands)
Fuel industry	52.0
Ferrous metallurgy (including ore mining)	33.2
Production of electricity and steam and heat power	23.8

Reportedly, the seventh 5-year plan (1976-80) was not fulfilled in all sectors. During 1976-80, the national income of the country increased 40% (planned 48% to 52%). The gross industrial production increased 35% (planned 55% to 60%) and machine-building increased 56.2% (planned about 100%). Cargo transported during the seventh 5-year plan increased by 32% (planned 40%). During the 1976-80 5-year plan, Bulgaria's foreign trade increased 100% (planned 60% to 65%).

Government Policies and Programs.—The targets set for the eighth 5-year plan (1981-85) appear to be scaled down from those of the seventh 5-year plan (1976-80). According to the eighth 5-year plan (1981-85), approved by the 12th National Party Congress, national income is to increase by 25% to 30%, gross industrial output by 30% to 35%, and labor productivity by 36% to 38%. The amount of capital investment is to increase to about L38 billion during the eighth 5-year period. A large part of capital investment is planned for renovation and modernization of existing plants. Heavy

industry is confirmed as the foundation of the economy but more emphasis is to be put on the consumer sector during the 1980-85 period.

In the energy and mineral sectors more emphasis is to be given to increase utilization of local resources and materials. Special stress is to be placed on the production of special steels. The plan also points to the need for increased local production of nonferrous metals, particularly copper. The relative share of electric energy from atomic power is expected to increase from 20% in 1980 to 26% by 1985.

Production of lignite, the main indigenous fuel, is to be increased mainly by developing the important Maritsa-Istok lignite and power generating complex. The exploration of coal in the Dobrudja coal basin is to receive particular attention. Foreign trade is planned to increase 40%, which would be a slowing of the pace set during the seventh 5-year plan (1976-80), when it increased 100%. On improving the management of the economy, the New Economic Mechanism must be fully implemented throughout the entire economy, which is an attempt to partially decentralize the economic planning.

In 1980, Bulgaria created an agency, the Council for Raw Materials and Energy Problems, attached directly to the Council of Ministers. Bulgaria also established a Mineral Bank, the purpose of which is to facilitate receipt of foreign credits for exploitation of Bulgaria's energy and raw materials resources. The bank has vast powers to enter into business arrangements with foreign creditors. Bulgaria's main interest in trade with the west is the import of technology including technology for development of energy and mineral resources including coal.

The national income in the country is to increase 5.1% in 1981 and 5.0% in 1982. Labor productivity is to rise 4.8% in each year. Industrial output is to increase 5.6% in 1981 and 6.0% in 1982. The production of electric power and heating supply is to increase 7.2% in 1981 and 7.4% in 1982 (through the development of atomic energy and thermoelectric plants, based on the local coal supply). Coal mining is expected to develop at an accelerated rate. The plan ensures an increase in the volume of production of ferrous metallurgy; 10% in 1981 and an additional 5.4% in 1982. The production of the chemical industry is to increase 11% in 1981 and 9.5% in 1982. A rapid growth is ensured in the production of ammonia and nitric fertilizers. The volume of transported cargo is to increase 3.6% in 1981 and 3.7% in 1982.[4]

The relative share of machine-building, chemical, metallurgy, and energy in industrial development is planned to increase from 53.2% in 1980 and to 55.2% in 1982.

PRODUCTION

In 1980, the value of industrial output reached L28,578 million, exceeding the 1979 level by L1,130 million. In 1980, industrial production by basic ministries increased over that of 1979 as follows:

Ministry of Power Supply	9.6
Ministry of Chemical Industry	9.7
Ministry of Machine Building	4.5
Ministry of Metallurgy and Mineral Resources	2.4
Ministry of Construction and Construction Materials	3.3

In 1980, the fuel industry fulfilled its plan, 105.6%; the chemical industry, 111%; and machine-building and metal processing industries, 106.3%. In comparison with 1979, the production output increased in coal, steel, nitrogen fertilizers, and the power industries. Ferrous metallurgy also realized slightly higher results in the production of pig iron and rolled steel products. In 1980, zinc production increased slightly in spite of the decline in the metal content of the ore. Production of cement, calcinated soda, and phosphatic fertilizers was lower than in 1979.

In 1980, 34.3 billion kilowatt-hours (kWh) of electric energy was produced or 2.4 billion kWh more than in 1979. Hydroelectric powerplants generated approximately 4.5 billion kWh of electric energy or about 13% of the country's annual output. The Kosloduy nuclear powerplant generated about 7 billion kWh or 20% of the country's annual output. In 1980, the total capacity of the Kozloduy nuclear powerplant was 1,320 megawatts. The share of electric energy produced by nuclear plants is expected to be 30% in 1985 and 50% at the end of the century.[5] Electric energy consumption reached 39 billion kWh in 1980 or 10 billion kWh more than in 1975.

Reportedly, the plan for lowering the use of raw materials and other outlays was fulfilled in 1980. Greater increase in the net industrial output was achieved as a result of savings of raw materials, fuels and energy, and higher labor productivity.

Table 1.—Bulgaria: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity[2]	1976	1977	1978	1979[p]	1980[e]

[e]Estimated. [p]Preliminary. [r]Revised.

[1]Table includes data available through Sept. 30, 1981.

[2]In addition to the commodities listed, bismuth, chromite, gold, palladium, platinum, tellurium, uranium, barite, fluorspar, magnesite, and a variety of crude construction materials (common clays, sand and gravel, dimension stone, and crushed stone) are produced, but available information is inadequate to make reliable estimates of output levels.

[3]Reported figure.

TRADE

In 1980, Bulgaria's foreign trade turnover (exports plus imports) increased 14.1% compared with that of 1979.[6]

The value of exports was L8,918 million, an increase of 16.3% and the value of imports was L8,227 million, an increase of 11.7%.

In 1980, imports of machinery and equipment accounted for about 36% of the total value of Bulgaria's imports; fuels, minerals, and metals accounted for about 43%; chemical products 6%; and building materials less than 1%.

Exports of machinery and equipment comprised about 45% of the value of total exports in 1980; fuels, minerals, and metals about 15%; chemical products 4%; and building materials about 2%.

In 1980, imports of fuels, minerals, and metals increased 16% over that of 1979, these increases were as follows: Bituminous coal, 6.8%; pig iron, 16%; iron ore, 5.6%; coke, 24%; steel, 1.6%; and superphosphate, 22%. In 1980, exports of calcinated soda decreased 1.5% and exports of nitrogenous fertilizer decreased 6%, compared with those of 1979. Trade with the U.S.S.R. accounted for 58.6% of Bulgaria's total foreign trade in 1980.

The U.S.S.R and Bulgaria have signed an agreement on trade for the 1981-85 period and for 1981. The value of trade between the U.S.S.R. and Bulgaria is to amount to 40 billion rubles in the 1981-85 period. During the 1976-80 period, their mutual trade was 28 billion rubles. The Soviet Union is to supply Bulgaria with mining machinery and equipment, iron ore, ferrous and nonferrous metals, natural gas, crude oil and oil products, coal, and electric energy. Bulgaria is to export to the Soviet Union machinery and equipment, food, and chemicals, including soda ash and other commodities.[7]

In 1980, over 13,000 Bulgarian workers were engaged in the construction of various projects in the U.S.S.R. Bulgaria's assistance in developing the fuel and raw material complexes on Soviet territory ensures the country supplies of extra quantities of iron ore concentrate, asbestos, natural gas, and ferroalloys in the next 10 to 12 years.

Trade between Bulgaria and the Democratic People's Republic of Korea in 1981-85 is to increase 75% compared with the 1976-80 period. Bulgaria is to export machinery and equipment, soda ash, and urea in exchange for machinery and equipment, high-grade steel, and cement.[8] Economic cooperation between Bulgaria and Mexico is also to increase considerably. Bulgaria is to supply Mexico with soda ash, fertilizers, machinery, and equipment for various raw materials.

The Deputy Minister of Bulgaria's foreign trade reported that a long-term trade agreement signed by Bulgaria and the other centrally planned economy countries provides for an average growth of trade in the eighth 5-year plan period (1981-85) equal to 43% at 1980 prices, compared with the achievement in the 1976-80 period.

Table 2.—Bulgaria: Apparent exports of mineral commodities[1 2]

(Metric tons unless otherwise specified)

Commodity	1978	1979	Principal destinations, 1979
METALS			
Aluminum:			
Oxides and hydroxides	--	165	All to Italy.
Metal including alloys:			
Scrap	--	384	West Germany 212; Italy 101; Sweden 61.
Unwrought	4,629	5,066	Japan 2,661; West Germany 991; Yugoslavia 800.
Semimanufactures	--	4	All to Thailand.
Bismuth metal including alloys, all forms	3	23	West Germany 15; United States 8.
Cadmium metal including alloys, all forms	133	65	West Germany 56.
Cobalt oxides and hydroxides	2	--	
Copper:			
Sulfate[3]	5	30	All to Vietnam.
Metal including alloys:			
Scrap	293	836	West Germany 686.
Unwrought	2,368	1,201	West Germany 665; Italy 322.
Semimanufactures	256	398	Morocco 209; Turkey 87.
Iron and steel metal:			
Scrap	[4]167,000	[4]130,000	Italy 90.606; Austria 37,584.
Pig iron	[5]47,500	[5]12,300	Italy 8,000; Jordan 404.
Ferroalloys	[4]24,000	[4]22,000	Poland 5,767; West Germany 3,743.

See footnotes at end of table.

Caustic soda	[5]1,400	[5]2,100	Tunisia 62; Costa Rica 21.
Caustic potash	10	135	Turkey 110.
Soda ash[3] thousand tons	959	1,125	U.S.S.R. 445; Hungary 113; West Germany 85.

See footnotes at end of table.

Table 2.—Bulgaria: Apparent exports of mineral commodities[1 2] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Principal destinations, 1979
NONMETALS —Continued			
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked	1,241	1,654	Greece 965; Italy 316; Belgium-Luxembourg 125.
Worked	5	14,370	Pakistan 7,513; West Germany 2,483; Saudi Arabia 1,463.
Gravel and crushed rock	5,545	3,961	All to Hungary.
Quartz and quartzite	42	2	All to Japan.
Sand excluding metal-bearing	5,535	4,443	All to Greece.
Sulfur: Sulfuric acid, oleum[3]	7,237	2,284	Romania 1,885.
Talc, steatite, soapstone	431	--	
Other:			
Crude	8,620	9,249	Hungary 8,668.
Slag, dross, and similar waste, not metal-bearing	--	23	All to Spain.
Halogens	--	4,978	All to Yugoslavia.
MINERAL FUELS AND RELATED MATERIALS			
Carbon black	25	7	All to United Kingdom.
Coal and briquets:			
Anthracite and bituminous coal	[5]184,000	[5]13,600	NA.
Lignite including briquets	--	102	All to Italy.
Coke and semicoke	--	39	All to Greece.
Peat including briquets and litter	--	35	All to Italy.
Petroleum refinery products:			
Gasoline, thousand 42-gallon barrels	549	698	Netherlands 384; West Germany 314.
Kerosine, do.	4	322	Spain 313.
Distillate fuel oil, do.	685	1,519	Turkey 1,299; France 141.
Residual fuel oil, do.	1,513	5,260	Italy 3,447; Yugoslavia 781; Greece 533.
Lubricants, do.	75	199	Yugoslavia 75; Spain 48; Belgium-Luxembourg 33.
Other:			
Liquefied petroleum gas, do.	322	398	Yugoslavia 393.
Mineral jelly and wax, do.	15	23	Italy 16; Yugoslavia 4.
Nonlubricating oils, do.	--	305	All to Spain.
Bitumen and other residues, do.	1	36	All to Yugoslavia.
Unspecified, do.	155	181	All to Poland.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	6,663	3,888	Yugoslavia 1,812; Italy 1,200; France 436.

[r]Revised. NA Not available.

[1]Owing to the lack of official trade data published by Bulgaria, this table should not be taken as a complete presentation of this country's mineral exports. These data have been compiled from various sources which include United Nations information, data published by the partner trade countries, and partial official trade sources of Bulgaria.

[2]Unless otherwise specified, data are compiled from official statistics of individual trading partners.

[3]Official trade statistics of Bulgaria.

COMMODITY REVIEW

METALS

Aluminum.—A plant, producing 30,000 tons of aluminum shapes per year, operated at full capacity at the town of Shumen in 1980. The plant's output almost completely satisfied Bulgaria's demand for aluminum products.[9]

The raw materials for the plant were supplied by the U.S.S.R. and Yugoslavia.

In the near future, production of the metal from a nonbauxite mineral, named bulgarite, is to begin. Bulgarite contains 60% silicon, about 20% alumina, 8% potassium, and some sodium oxide. The country's resources of bulgarite are estimated at 1,000 million tons. Attempts were also made to obtain aluminum from certain types of clay.

Copper.—The Medet open pit, near Pazardzhik, with an output capacity of 8 million tons per year of copper ore, continued to be the main source of copper ore in 1980. The ore was low-grade with an average copper content of 0.34% and molybdenum content of 0.008%. The most abundant copper sulfide mineral was chalcopyrite. Pyrite was also abundant in places.

In 1979, Bulgaria started development of the Assarel copper deposit, which is located near the Medet Mine. The Assarel Mine was considered as one of the major projects of the 1981-85 5-year plan. In 1980, the Elatsite open pit, with a planned annual capacity of 10,000 tons of ore, was another large development. Copper content in the ore is about 0.45%. The Elatsite ore-dressing plant, located near Korlovo, provided approximately 22% of Bulgaria's copper concentrate needs in 1980. A second stage of the plant is expected to be completed in 1982. After completion, the Elatsite plant is to provide all of Bulgaria's needs in copper concentrates.

In addition, the plant is to extract molybdenum and pyrites from the ore. It took 4 years to build a 6.5-kilometer tunnel at the site to enable the Bulgarians to mine the ore high up in the mountains and then transport it down to the ore-dressing plant located below.

Reportedly, the U.S.S.R. was the largest supplier of equipment and machinery for the Elatsite dressing plant. The Federal Republic of Germany, Sweden, and Japan have also supplied equipment for the plant. The Elatsite Mine was designed with Soviet cooperation and L240 million was invested in its development. It is planned to extract up to 87% of the metal content in the ore. In 1980, one of the country's biggest copper ore deposits, the Prokhorovo, was under exploration. Further renovation was underway at the Georgi Damyanov copper plant in 1980. Under an agreement signed in 1979 between Bulgaria and Finland, two Finnish firms, Autokumpu Ahlstvom and Rauma-Repola, were to deliver and install equipment for the Outokumpu flash copper smelter at the Georgi Damyanov copper plant in 1981-82. The planned annual capacity of the plant is 120,000 tons of copper.

Iron and Steel.—Bulgaria's domestic output of iron ore is not large and only partly meets the needs of the Bulgarian industry. The U.S.S.R. has for many years been the main source of iron ore for Bulgaria. Principal iron ore deposits in Bulgaria are located in Kremikovtsi, Krumovo, and Martinovo.

The Krumovo and Martinovo ores contain magnetite and the Kremikovtsi ore contains 70% limonite, 18% to 20% siderite, and 10% to 12% hematite. Iron ore reserves in Bulgaria are estimated at 300 million to 400 million tons with an average iron content of about 30%. Planned production for 1980 was about 1.8 million tons of pig iron, 2.9 million tons of crude steel, and 3.4 million tons of rolled steel products. The output of pig iron, crude steel, and rolled steel products was below the planned targets in 1980. The ferrous metals group held one of the leading positions in foreign trade. In 1980, it accounted for an estimated 4% of Bulgaria's industrial exports and an estimated 10% of total industrial imports. Steel consumption in 1980 was about 3.9 million tons, an increase of about 2% over that of 1979. Two large metallurgical complexes, the Lenin metallurgical complex at Pernik and the Kremikovtsi complex, continued to be under renovation in 1980.

The development program of the Pernik metallurgical complex started in 1972 and is to be completed by 1985. An electric furnace plant, with four 100-ton arc furnaces and a continuous casting plant, was under construction in 1980. The four electric steel furnaces, with a capacity of 1 million tons per year, are expected to be commissioned in 1981. After renovation, the Lenin plant's annual capacity is expected to be 1.5 million tons of steel and about 1 million tons of rolled products. High-quality steel is to make up 80% of the output.

In 1980, the Kremikovtsi iron and steel complex produced more than 80 types of steel and ferrous alloys and more than 1,200 rolled sections. The complex meets about 80% of the national demand in rolled steel. About 30% of the complex's production was exported in 1980. During the 1981-85 period, the Kremikovtsi iron and steel complex is to increase production of pig iron by 20%, steel by 22%, and rolled products by 20%. The increases are to be achieved mainly through improved efficiency.

A metallurgical plant, to be built near the City of Burgas, is to produce 1 million tons of different types of steel per year. During the first stage, which is to be completed by 1985, a rolling mill plant with a planned annual production capacity of 640,000 tons is to be built. Iron ore for the new plant is to come from the U.S.S.R.[10]

In 1985, a small casting shop is to be put into service at the Ikhtiman iron plant to increase the enterprise's annual production to 100,000 tons from its capacity of 62,000 tons in 1980.

Lead and Zinc.—Bulgaria's industry fully met the country's needs for lead and zinc and for over 90% of the consumption of shaped, heavy nonferrous metals and alloys in 1980. Total consumption of zinc was approximately three-fourths of the total zinc production in 1980.

Lead and zinc ore deposits occur in the Rhodopes, Lozen, and Osogovo Mountains in southern Bulgaria. Bulgaria has several mining enterprises for lead and zinc production: Gorubso, Osogovo, Madjarovo, and a few others. The main lead and zinc production is concentrated at the Gorubso Mining Administration which operates the Rudozem, Madan, Ustrem, Erema River, and Lekite beneficiation plants and about 40 mines. Reportedly, in 1980, Gorubso enterprise accounted for about 80% of total lead-zinc production. In 1980, the new Rouen lead-zinc mine at the Osogovo Administration went into operation and in the same year construction of the Osogovo ore concentrator started.

Reportedly, the Bulgarian lead-zinc industry was successful in 1980 regarding utilization of ores, semiproducts, and in the application of a number of new effective technological processes.

NONMETALS

Cement.—The Ministry of Construction and Building Materials approved the plan of the Institute of Kharkov (U.S.S.R.) for the development of the Bulgarian cement industry up to 1990. According to the plan, the production of cement, which was 5.4 million tons in 1980, is expected to increase considerably in the new decade (1980-90). Planned production for cement was 6.6 million tons in 1980. During the coming 5-year plan (1981-85), more funds have been allocated for the construction of a second technological production line at the V. Kolarov State cement plant in Temelkovo with a 600,000-ton capacity, and for a seventh technological line at the V. Pik State cement plant in Vratsa.

Fertilizer Materials.—Bulgaria is self-sufficient in nitrogenous fertilizers and exported 242,000 tons (nutrient content) in 1980. In 1980, Bulgaria had two nitrogen plants under construction at Povelianovo in the Varna district and at Vratsa. Completion of the plants is scheduled for 1981. These plants are to expand the size of Bulgaria's nitrogen industry by an esti-

mated 30% in 1985 compared with the 1980 level. The Stara Zagora nitrogen complex was converted to run on Soviet natural gas in late 1979. In 1980, Bulgaria offered India a guaranteed supply of 1 million tons of fertilizers at 0.2 million tons per year over the next 5 years.[11]

Bulgaria is a large-scale importer of phosphate fertilizers. Imports of phosphatic fertilizers (P_2O_5content) increased from 183,000 tons in 1979 to 223,000 tons in 1980.[12]

Fertilizer plant capacities are planned to be continually enlarged to meet domestic requirements. Expansion in production of the Dmitrovgrad complex was recently reported. According to the plan, capacity of the phosphoric acid plant at the complex is to increase from 110,000 tons per year in 1980 to 140,000 tons per year in 1982 and the new sulfuric acid plant, with a capacity of 180,000 tons per year, is to go onstream by the end of 1982. Other facilities at the complex, which are planned to go into operation in 1982, include the new triple superphosphate plant with a capacity of 160,000 tons per year. In 1980, the total annual capacity of the three existing sulfuric acid plants was 400,000 tons and capacity of the triple superphosphate plant was 150,000 tons. Completion of the facilities for the production of 760,000 tons per year of nitrogen fertilizer at the Dmitrovgrad complex is planned for 1984.

MINERAL FUELS

Estimated production of primary energy derived from fossil fuels and hydroelectric and nuclear generation in Bulgaria was 17.9 million tons of standard coal equivalent (SCE) in 1980 compared with 16.0 million tons of SCE in 1979. In 1980, the estimated share of coal (lignite, brown, and bituminous) in total primary energy production was 89%; the share of crude oil, 1.6%; natural gas, 1.1%; hydroelectric power, 3.3%; and nuclear energy, 5.0%. The total consumption of primary energy increased from 50.7 million tons of SCE in 1979 to an estimated 52.8 million tons of SCE in 1980. In 1980, coal provided an estimated 43.3% of the total consumption, while oil represented 37.5%; hydroelectric energy, 1.1%; nuclear energy, 1.7%; and imports of energy, 0.9%.

Table 4.—Bulgaria: Total primary energy balance for 1979 and 1980

(Million tons of standard coal equivalent)[1]

	Total primary energy	Coal (bituminous, brown, and lignite) and coke	Crude oil and petroleum products	Natural gas	Hydroelectric power	Nuclear power	Other sources of energy
1979:[r]							
Production	16.0	14.3	.3	.2	.4	.8	--
Imports	34.8	6.7	19.5	8.0	--	--	.6
Exports	.1	--	--	--	--	--	.1
Apparent consumption	50.7	21.0	19.8	8.2	.4	.8	.5
1980:[e]							
Production	17.9	15.9	0.3	0.2	0.6	0.9	--
Imports	35.0	6.9	19.5	8.0	--	--	0.6
Exports	.1	--	--	--	--	--	.1
Apparent consumption	52.8	22.8	19.8	8.2	.6	.9	.5

[e]Estimated. [r]Revised.

[1]One ton of standard coal equivalent (SCE)=7,000,000 kilocalories. Conversion factors used are as follows: Hard coal 1.0; brown coal and lignite, 0.5; crude oil, 1.47; natural gas (1,000 cubic meters), 1.33; hydroelectric and nuclear power (1,000 kWh), 0.125.

Coal.—In 1980, coal and lignite production increased over the 1979 level. However, it did not reach the original planned target of 37 million to 38 million tons. Coal production is planned to reach 46 million tons in 1985 and 60 million tons in 1990. Lignite production is planned to be 37.4 million tons in 1985 and brown coal production is planned to be 8.3 million tons. Deep-mined production is to increase from 6.45 million tons in 1980 to 10.64 million tons in 1985. Coal imports amounted to about 6 million tons in 1980.[13]

In 1980, East Maritsa Basin's surface output of lignite accounted for about 60% of the total coal production in Bulgaria and Bobov Dol brown coal basin accounted for 10%. The Bobov Dol Basin produced 40% of total brown coal production in 1980. The plan foresees the development of the Bobov Dol complex, which is to increase brown coal production over the 1979 levels as follows: 1981, 44%; 1983, 56%; and 1985, 61%.[14]

In 1980, Bulgaria continued to undertake efforts to expand bituminous and lignite output in order to ensure the maximum degree of self-sufficiency in national energy consumption. Many mines were under development and renovation with the assistance of the U.S.S.R. Among the mines that came into operation in the 1976-80 period were: Amalgamated Bobov Dol, Troyanovo-South (first stage), and Oranovo (Pirin Basin).

The projected capacity of the Troyanovo-South open pit in the East Maritsa Basin is 26 million tons per year and for the Troyanovo-North Basin it is 19.5 million tons. Zdravets Mine in the West Maritsa Basin is to be the country's largest underground coal mine. It's annual capacity is planned to be 2 million tons per year. A beneficiation plant with 4 million tons of raw coal capacity is to receive coal from other mines as well. The Zdravets Mine is to go into operation in 1985.

Natural Gas.—Natural gas deliveries from the U.S.S.R. are to be increased from 6 billion cubic meters in 1980 to 10 billion cubic meters in 1985. The Soviet Union began exporting natural gas to Bulgaria in 1974 via a pipeline running from the southern Ukraine along the Black Sea coast through Romania to the Varna Devnya area, then west to Pleven, Vratsa, and Sofia.

In 1980, work was continued on the southern branch also terminating at Sofia. The first stage of the Devnya-Burgas-Stara Zagora-Dmitrovgrad-Plovdiv-Sofia southern branch was near completion in 1980. Operation of this line is expected to start in May 1981.

Soviet gas has considerably cut the cost of the Bulgarian production of steel, ammonia, fertilizers, and other commodities. Existing indigenous reserves of gas are limited and insufficient to meet the country's needs. Recently, gas deposits were discovered near Dolni Lucovit, Burdarski, Gevan, and Pisarev.

In 1980, gas and petroleum prospecting with the assistance of the U.S.S.R. continued in the Black Sea on the Bulgarian Shelf.

Petroleum.—The 1980 domestic output of crude oil, compared with estimated oil imports of 11 million to 13 million tons, was relatively unimportant. The U.S.S.R. was Bulgaria's main oil supplier. The prospects for future Soviet oil deliveries are less favorable because Soviet production growth rates have slowed down. In 1980, about 8% of total crude oil imports came from Libya. Domestic oil production came from the small oilfields in the northwest part of the country. Additional fields are thought to be located on the Black Sea Shelf and exploratory drilling is planned to start shortly.

Reportedly, discussions were held with Occidental Petroleum of the United States concerning a plan for joint oil exploration in Bulgaria, both onshore and offshore. The Neftochim petrochemical complex, located about 15 miles outside of Burgas, processed 80% of Bulgaria's crude oil imports into fuels and chemicals. All of the oil used in the complex came from the U.S.S.R. In 1980, about L300 million worth of new facilities were put into operation at the complex. The catalytic cracking complex is due to begin operations by June 1, 1981. Additional quantities of high-octane gasoline, diesel fuel, and raw materials for the chemical industry are expected to be produced at the plant. However, construction of facilities was hampered by the delay in deliveries of imported technological equipment and lack of skilled labor. The benzine unit at this complex was designed for 140,000 tons per year of production capacity.

The Mineral Industry of Burma

By Gordon L. Kinney[1]

Burma's most significant mineral production included lead, zinc, tin, tungsten, barite, jadeite, and petroleum. By far the most valuable product was petroleum, its dollar worth being several times the combined value of all of the nonfuel minerals produced during the year. The petroleum production had the added advantage of making Burma one of the few Southeast Asian countries that was self-sufficient in energy needs. Burma's current mineral output is small by world standards, although it was a major producer of lead before World War II. It is still considered to have a good potential for expansion. Detailed geologic exploration is needed in several areas believed favorable for mineral occurrences.

The unstable security situation, however, has been a detrimental factor for a number of years. Detailed ground surveys and drilling needed for deposit evaluations have been delayed or canceled in some remote areas.

About 68,000 persons, or 0.5% of the active labor force, were employed in mining activities during 1979. During 1980, the mining sector probably accounted for about 2% of the net output of goods and services. Burma's mineral industry was managed primarily by four government-owned corporations. The No. 1 Mining Corp. controlled the lead, zinc, and silver output, which came mostly from the historic Bawdwin mining operations. The No. 1 Mining Corp. will also run the Monywa copper enterprise. The No. 2 Mining Corp. ran all the major tin and tungsten operations and the Heinze dredging project. The No. 3 Mining Corp. mainly was in charge of the Kalewa and Namma coal mines, the Moulmein and Loikaw antimony mines, and the planned direct-reduction steel plant. Industrial minerals such as barite, limestone, and gypsum were managed by the No. 4 Mining Corp.

The Burmese press reported that the fiscal year 1980-81 State budget showed that of a total planned investment of $832 million, $95 million, or 11.0% was allocated to the mining sector. In addition, $270 million was to go to the industrial sector, some of which would involve mineral-related projects. The $56 million earmarked for the electric power sector would also indirectly benefit some of the mineral sectors.

According to government statistics, the economic growth for fiscal year 1979-80 was good, with gross domestic product (GDP) growing by 5.6% in constant 1970 prices. At current prices, it grew at 11.2% to approximately $5.3 billion. Prices were rising somewhat, but the inflation rate for the year was expected to remain below 10%.

This was the fourth consecutive year in which the country achieved an increase in its rate of growth. Another important indicator, the ratio of fixed capital investment to GDP, reached 15.6% in 1979, compared with 7% in 1974. It appeared that the Burmese economy had overcome the stagnation of the late sixties and early seventies and was on the path to steady, sustained growth. Observers attributed the turnaround primarily to the policy changes since 1975-76, which have included the commercialization of State-run corporations, the introduction of a new bonus system for workers, and an effective tax reform.[2]

All sectors of the economy contributed to the growth in the GDP in fiscal year 1979-80. Agriculture accounted for 51% of the GDP and showed a real growth of 4.8%. The highest growth was in the construction

industry, which recorded a 24.1% increase. The mining sector also had an impressive growth rate of 17.6%.

In the fiscal year 1980-81 plan, the targeted real growth in GDP was set at 6.9% by the Government, a difficult but not unreasonable goal. The plan's breakdown by sector showed that the value of mining output was to increase by 17.2%, the highest of any sector. The next largest planned increase was 13.8% in the industrial sector.

In addition to the foreign assistance that it was receiving for the Bawdwin Mine and the Monywa copper project, Burma has also accepted foreign aid in several projects that benefit the entire economy and one that will benefit the overall mineral industry. The mineral-related project is to be a metallurgical research and development center at Ela in Lewe Township, 325 kilometers north of Rangoon. The Japanese International Cooperation Agency reportedly will finance the $8.4 million project.[3]

The Chinese have signed a protocol with Burma on economic and technical cooperation, whereby mainland China will provide financing amounting to 100 million yuan for eight unidentified projects. The Chinese have been helping Burma develop its electric power network for the past several years. A recently completed segment of the work was the installation of two 6,000-kilowatt generator sets and related infrastructure at the port of Moulmein at the mouth of the Salween River.

A number of other electric power projects are either underway or ready to be started. These consist of hydroelectric, gas turbine, or steam generator plants at several locations. A number of international agencies and several countries are reported to be helping both technically and financially.

Mostly as a result of foreign assistance, Burma's installed capacity for electric power generation has increased from about 250,000 kilowatts in 1970 to 435,800 kilowatts in 1980.[4] Total power generated in 1979 was just over 1 billion kilowatt-hours, of which 70% was hydroelectric, 21% was by natural-gas-fueled gas turbine, and the remainder by diesel and steam power.

PRODUCTION

By value, the principal mineral commodities produced in Burma were petroleum, lead, silver, tin, tungsten, and zinc. Crude oil production was the most valuable mineral output in 1980, as well as in 1979, primarily resulting from the increases in world petroleum prices and secondly from a moderate increase in output.[5] Under the Third 4-year plan (fiscal year 1978-79 through fiscal year 1981-82), the main objectives for the minerals sector were to increase production and to develop industrial self-sufficiency. During the first year of the current economic plan, a major metallogenic geologic survey and exploration project was completed delineating the country's existing resources and new mineral occurrences. Additionally, Burma's mining industry, which was invested under the control of four governmental corporations, succeeded in obtaining foreign assistance either through financing or technology and equipment. Since 1978, output by lead-zinc operations and associated byproduct silver were showing annual increases. Similarly, the tin-tungsten sector also reported annual increases in output. However, the output in minerals production was partly attributed to better control and reduced activities in smuggling.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through June 30, 1981.

[2]In addition to the commodities listed, pottery clay, common sand, glass sand, other varieties of crude construction stone, and other varieties of gem stones are produced, but available information is inadequate to make reliable estimates of output levels.

[3]Data are for fiscal years beginning Apr. 1 of that stated.

[4]Includes fire clay powder.

[5]Data exclude products used as fuel in refineries.

TRADE

Detailed trade figures were not available for 1979 or 1980. The mining industry normally ranks third in value of exports after agriculture and forest products. In view of the increased production in the mining sector during fiscal year 1979-80, it is likely that mining increased its share of the total export value. Burma generally exports nearly all of its metallic mineral output, which is insignificant by world standards. Principal exports of Burma's mineral commodities include base metals and ores, sil-

ver, and cement.[6] Mineral fuels were consumed domestically, except for a small amount of petroleum exported. Crude oil export was necessitated not by a lack of internal demand, but rather by a lack of storage and refining capacity. Refined products have actually been in short supply during the last few years. A new refinery is under construction at Mann Oilfield to nearly double domestic refining capacity, and when it is completed in 1982 or 1983, it will utilize all of the excess crude oil available from the presently operating oilfields.

The overall export targets for the recent years were set at $273 million in fiscal year 1978-79, $380 million in fiscal year 1979-80, and $491 million for 1980-81. It was believed that actual export trade fell somewhat below the goal for fiscal year 1979-80.

In addition to the normal trade channels, there was reportedly a brisk trade of uncut precious and semiprecious gem stones, tin and tungsten concentrate, and nonmineral raw materials. This smuggling black market, or illicit trade, as it has been variously described, is apparently unofficially condoned by the Government. The smuggled material is bartered for scarce consumer goods which are in short supply in Burma. This trading or smuggling was estimated in the press to total a large proportion of the official foreign trade.[7]

COMMODITY REVIEW

METALS

Copper.—Construction was reported to have begun on the Monywa copper project. Design and technology for the concentrator and mines was being supplied by RTB Bor of Yugoslavia. The Yugoslavians will build and assist the Burmese in the early stages, but Burmese officials will be in charge of management and operation. Concentrate will be exported. Ore will come from the Kyesintaung and Sabetaung deposits, just west of the Chindwin River, opposite the railhead town of Monywa.

In March 1980, Burma and Finland signed an agreement concerning a feasibility study for the construction of a copper smelter and refinery. The Finnish firm of Outokumpu will conduct the study.[8]

Iron and Steel.—It was believed that the country's first direct-reduction steel plant was under construction at Anisakan in Maymyo Township. The turnkey contract for a Kinglor Metor process plant was signed in July 1979. The plant will be the first of its type outside of Italy. The process uses noncoking coal as a reductant and natural gas as the major fuel. Planned capacity was 20,000 tons per year of metal. A 15- to 17-ton electric arc furnace will smelt the iron into steel.

Lead, Zinc, and Silver.—Two feasibility studies financed by the Federal Republic of Germany were underway during 1980 at the Bawdwin Mine in Namtu. The first was to examine the possibility of producing zinc oxide from the lead smelter slag. The zinc-rich slag and tailings have been accumulating for over 65 years. The second study was to examine the possibility of leaching silver from the tailings of the lead-zinc flotation plant. The studies were scheduled for completion by yearend 1980.

Production of refined lead has increased annually since 1975, reaching close to 6,000 tons in fiscal year 1979-80. However, annual output of zinc concentrate during the same period has been erratic, but averaged around 4,700 tons per year, compared to a reported production of 6,400 tons in fiscal year 1979-80. Refined silver output increased proportionately as a byproduct function of lead refining. Increased output by the lead-zinc industry probably reflects the acquisition of new equipment and rehabilitation of plant facilities completed around yearend 1979.

Tin and Tungsten.—Tungsten resources are associated with tin occurrences in Burma. Both tin concentrates and tungsten concentrates are produced, as well as mixed tin and tungsten concentrates, which presently constitute the final form in which they are exported. Currently, the ratio of tin, tungsten, and mixed tin-tungsten output is 2 to 1 to 4, respectively.

Exploitation of the tin-tungsten deposits along the Tenasserim Coast in southern Burma was to begin at yearend 1980 with delivery of a new dredge. The dredge departed from Singapore, where it was built, in October and was scheduled to begin working as soon as possible.

A further study of the Tenasserim Div. tin resources was to be conducted under Asian Development Bank financing. The study is to develop a feasibility plan for exploiting some of the known onshore deposits.

In February 1980, Burma announced plans to construct a small tin smelter in

Syriam under an economic and technical cooperation agreement signed with North Korea. Although Burma reported output of 1,233 tons of tin in concentrate in 1979, it was believed that much more was actually produced and the excess smuggled out of the country. It is possible that when the smelter is built, it will furnish a more readily accessible market for the concentrate and hence cut down on at least some of the widespread smuggling.

NONMETALS

Burma's nonmetallic mineral production was generally oriented toward domestic consumption. Nonmetallic minerals were not produced in sufficient quantity to be significant in the world market, except certain gem minerals. Barite was probably the most valuable industrial mineral marketed. The Government was trying to increase production and had a ready export market for any barite not used in its own oil and gas well-drilling program. Bentonite, various other types of clays, feldspar, graphite, gypsum, jadeite and other gem stones, iron pigments, salt, and limestone were also produced during the year. Three cement kilns were believed operating at Thayetmyo on the west bank of the Irrawaddy River. Their combined capacity was about 1,000 tons per day. A new cement plant is now operating at Kyangin. An increase in cement production was planned for 1980 to support increased construction activity. Brick production increased over 20% during the first 6 months of 1980.

MINERAL FUELS

Petroleum.—During recent years, Burma has maintained a firm policy of not importing petroleum. This has led to shortages that have dampened plans for industrial and mineral development. However, annual crude production has increased steadily since fiscal year 1975-76, and according to government statistics, it continued the trend with a 6% increase during the first third of 1980. The Burmese set a production goal of 14 million barrels of crude oil for fiscal year 1981.

Crude production surpassed the country's ability to refine it in 1979, and the small surplus was exported to furnish much needed foreign exchange. Three steps were undertaken to eliminate the refined product shortages, two completed in 1980. The first was the addition of a 6,000-barrel-per-day crude topping unit at the Syriam refinery near Rangoon, completed in August; the second was a 2,000-barrel-per-day refinery at Malun, 20 miles south of the Mann Oilfield, completed in October; the third, and most important step, was a new 25,000-barrel-per-day refinery which was being built near the Mann Oilfield with a loan from the Japanese Government. The refinery should meet almost all of Burma's petroleum product needs for several years to come if completed as planned in late 1981 or early 1982.[9]

The Burmese Government, through its own exploration crews and several contracts with foreign survey experts, has been conducting an active search for further oil and gas reserves. Twenty-nine drilling rigs were involved in the onshore exploration, and indications of hydrocarbons reportedly were found in many of 72 test wells drilled in the first half of 1980. Considerable evaluation work will be needed to determine the commercial viability of these tests.

Natural Gas.—Flaring of associated natural gas was essentially stopped in 1975. Gas is now used for electric power generation, fertilizer manufacture, and powering industrial plants, or is reinjected to pressurize the oilfields. Gas production jumped over 600% in the last decade.

Gas strikes were reported at Kyaiklat in the Irrawaddy Delta and in the Indaw area of the upper Chindwin Valley. The Indaw strike reportedly contained substantial reserves, but unfavorable terrain conditions would make development very difficult.

The Mineral Industry of Canada[1]

By Charlie Wyche[2]

In 1980, the Canadian economy was characterized by slow growth in most major industrial sectors. Problems of inflation and unemployment, resulting from high energy costs and record high interest rates, were present throughout the year. However, the overall mineral industry continued to show strong growth. Both the mining and mineral processing industries reached record highs in terms of operating revenues and net profits, even though the volume of output dropped for a number of major metals. Prices increased significantly for oil, natural gas, coal, and such metal commodities as gold, silver, nickel, and uranium. There were approximately 129,000 persons employed directly in mining during 1980, and many more jobs were dependent on mining activity. The industry accounted for an estimated 645,000 jobs, directly and indirectly, or 6% of the Canadian employed work force.

A mixed level of activity described the Canadian fuel industry during 1980. Whereas the number of exploratory wells increased 62%, production of crude oil and natural gas liquids decreased. Sales of natural gas from both domestic and export sources declined in 1980. However, revenue from the sale of crude oil and natural gas increased significantly over that for 1979. Expenditures for exploration and development projects increased about 15%. Prices for coal and uranium remained strong; both industries grew and prepared for future expansion.

In October 1980, the Canadian Government introduced the National Energy Program (NEP). The NEP is intended to restructure the country's energy system on the basis of three general principles: Security, opportunity, and fairness. First, the Government wants to move Canada toward energy self-sufficiency by 1990 by reducing the demand for oil to 10% of total energy consumption in the residential, commercial, and industrial sectors. It intends to do so by offering incentives to encourage conservation and to shift consumption away from oil to natural gas and electricity. Second, the program intends to achieve at least 50% Canadian ownership of oil and gas production by 1990, and Canadian control of a significant number of the larger firms. Third, the Government seeks a more equitable distribution of energy costs and benefits among regions and consumers.

PRODUCTION

According to the Canadian Department of Energy, Mines, and Resources, the total value of Canada's mineral production reached $27.66 billion[3] in 1980. This figure represents 11.4% of the $243 billion gross national product (GNP) value. The value of nonfuel mineral output increased 22% over that of 1979 with the nonmetallic sector showing the greatest increase. The fuel production value, including coal, natural gas, and petroleum, increased 26%. Although the volume of output for both gold and silver declined, the value of output increased 73% and 71%, respectively. Nickel showed a 54% increase in volume and a 102% increase in value. Of the major nonmetals and structural materials, only clay products declined in value. The value of fuel production reached a record $18.5 billion in 1980. The growth of the Canadian oil and gas industry remained stable in 1980 as discoveries made in 1979 were proven up. Production, consumption, and export of coal increased, and a number of new contracts were signed. Activity accelerated at several locations in western Canada as existing mines prepared to expand capacity and new mines prepared for production in early 1981.

Value of mineral output increased in 8 of the 10 Provinces and in 1 of the 2 Territories. The Province of Alberta alone, with its large oil and gas output, accounted for approximately 52% of Canada's total mineral value in 1980. Production values of the Provinces and Territories follow:

Province or Territory	Value, billion dollars	
	1979	1980
Alberta	11.0	14.3
Ontario	2.8	4.0
British Columbia	2.3	2.4
Quebec	1.9	2.1
Saskatchewan	1.5	2.0
Newfoundland Labrador	.94	.92
Manitoba	.50	.70
New Brunswick	.45	.34
Northwest Territories	.35	.33
Yukon Territory	.26	.26
Nova Scotia	.17	.22
Prince Edward Island	(1)	(1)
Total	22.17	27.57

[1]Less than 1/2 unit.

In 1980, Canada was the world's largest producer of asbestos, nickel, and zinc; the second largest producer of potash, gypsum, silver, molybdenum, and sulfur; and a leading producer of uranium, titanium, aluminum, cobalt, gold, lead, copper, iron ore, and platinum. More than 60 commodities were produced from mining activities conducted in every region of the country. There were 16 smelters, 15 refineries, and more than 250 mills operating throughout the country.

Unspecified ——— do	8,757	7,217	3,711	5,440	5,310
Refinery fuel and losses ——— do	31,283	31,697	33,742	34,491	32,035
Total ——— do	624,562	659,003	664,015	711,827	693,629

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Sept. 16, 1981.

[2]Sb content of antimonial lead alloys, flue dust, and doré slag estimated on the basis of reported gross production.

[3]Refined metal and bullion from domestic ores plus recoverable Bi content of exported concentrates.

[4]Refined metal from domestic ores plus recoverable Cd content of exported ores and concentrates.

[5]Actual output not reported. Data represent Co content of all products derived from ores of Canadian origin, including nickel oxide sinter shipped to the United Kingdom and nickel-copper-cobalt matte shipped to Norway for further processing.

[6]Actual output not reported. Data represent the output within Canada of metallic cobalt from ores of both Canadian and non-Canadian origin.

[7]Blister copper from domestic ores plus recoverable Cu content of exported matte and concentrates.

[8]Series revised to reflect actual mine production rather than sales, which were reported as production in previous editions. Sales figures, on a gross weight basis, in thousand metric tons, follow: 1976—55,416; 1977—53,621; 1978—42,931; 1979—59,617; 1980—50,866.

[9]Includes shipments of ingots from primary plants for rolling elsewhere.

[10]Refined nickel from domestic ores plus Ni content of oxide produced and recoverable Ni content of exported matte.

[11]From all sources, including imports and secondary sources.

[12]Cement shipped and/or used by producers.

[13]Includes bentonite products from common clay, stoneware clay, fire clay, and other clays.

[14]Crushed, building, ornamental, paving, and similar stone.

[15]Including synthetic crude (from oil shale and/or tar sands).

TRADE

In 1980, Canada exported about 45% of its crude mineral production to more than 90 countries. Export values of crude and fabricated mineral products were estimated at $21.6 billion, or 35% of Canada's total commodity exports. Some producers faced fierce competition in export markets as economic decline reduced consumption to record low levels. This was reflected in trade figures for crude ferrous metals, where exports declined 11.5% compared with those of 1979. In crude nonferrous, nonmetallic minerals, and fuels, exports increased substantially. Total crude mineral exports (ores, concentrates, and mattes) reached $1.9 billion.

Import values totaled $8.6 billion, of which fuels and metallic mineral products accounted for $8.3 billion. Crude petroleum alone accounted for $5.9 billion, or 69% of total mineral imports. Principal sources of oil imports were Venezuela and Saudi Arabia. Imports of coal, valued at $643 million, were from the United States. Other major mineral imports were bauxite, alumina, and aluminum scrap ($286 million), iron ore and iron and steel scrap ($292 million), and phosphate rock ($115 million).

Table 2.—Canada: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)

COMMODITY REVIEW

METALS

Exploration expenditures, which began to increase in 1978, continued to rise throughout 1980. All areas of the country benefited, and there was a particular resurgence in exploration work on known gold deposits and prospects. Also, capital investment in metal mining was exceptionally strong despite a sharp reduction in spending on iron ore. Many producers that had cut back on exploration during the late 1970's, in the face of stagnant prices and escalating production costs, resumed work in 1980 and in many cases took out options on adjacent properties.

The most intense development activity was in British Columbia, where projects costing almost $1 billion were underway or recently completed. In addition to new mines, these projects include expansion and modernization of processing facilities. By the end of 1981, the volume of potential copper production was expected to increase by almost one-third, and the increase in molybdenum mine capacity could be even larger. Sharp increases were also expected in production of gold and silver. A large silver mine began production in September 1980 at the Sam Goosly silver-copper property of Equity Silver Mines Ltd., near Houston, British Columbia. At full production, Equity is expected to be one of the major silver producers in Canada. Annual mine output has been estimated at 177,000 kilograms of silver, 6,400 tons of copper, and 1,700 tons of antimony.

In the Northwest Territories, construction started at a major zinc-lead mine in the High Arctic and at an important gold mine east of Great Bear Lake. In the Yukon Territory, there was activity in both gold and silver operations. Cyprus Anvil Mining Corp. was carrying out a $240 million expansion program at its lead-zinc-silver properties near Faro.

Silver and gold were also the focus of much activity in Ontario and Quebec. Ontario was again the leading silver-producing Province in Canada, with output in 1980 accounting for about 43% of the country's total production. At the Kid Creek property of Texasgulf Canada Ltd., work was continuing on the $140 million mine-mill expansion and the $280 million copper smelter and refinery complex. Both projects were scheduled to be completed in 1981. In Quebec, large development projects were underway at the Noranda and Grande Baie areas. Noranda Mines Ltd. announced a $35 million program that includes the construction of a 350- to 450-ton-per-day oxygen plant, and modifications to improve efficiency, working conditions, and environment through a reduction in dust emissions. Alcan Aluminum Ltd. completed the first stage of its $500 million aluminum smelter complex at Grande Baie with the startup of 26 pots (57,000 tons). Two additional potlines of the same size were planned for 1981 and 1982.

The Atlantic Provinces' metal mining industry will be further diversified when work on a new tungsten-molybdenum mine is completed. Construction of the Mount Pleasant tungsten-molybdenum mine, being developed under a joint venture between Brunswick Tin Mines Ltd. and Billiton Canada Ltd., is scheduled to begin production in early 1982. At its Lake George antimony mine, Consolidated Durham Mines & Resources Ltd. announced discovery of an extension of its ore body, which will significantly increase the life of the mine.

NONMETALS

In the asbestos industry, shipments of asbestos fiber in 1980 were lower than in 1979, as demand for all grades, particularly the shortest lengths, declined. Private negotiations between the Quebec Crown Corp., La Société Nationale de l'Amiante, and General Dynamics Corp. (GDC) of St. Louis, Mo., remained at an impasse over establishing a satisfactory purchase price. The Quebec Superior Court ruled in May 1980 that legislation designed to expropriate GDC's assets was constitutional. In the potash industry, prices during 1980 were very firm, particularly on the export markets. New production records and a total-revenue record of close to $1 billion were achieved. The Province of Saskatchewan is the largest exporter of potash in the world, and increased output is planned. The Potash Corp. of Saskatchewan controls about 40% of the industry.

Faced with high interest rates and an economic slump, the cement industry declined in 1980. Also, for the first time in many years, some plants stopped producing clinker for a number of weeks while inven-

tories were reduced. Sulfur output decreased about 16% from that of 1979, but Canada remained the world's largest exporter of sulfur. Gypsum production declined from the 1979 level, reflecting the slowdown in activity in the building industry.

MINERAL FUELS

In 1980, the Canadian coal industry received considerable attention from Governments, prospective customers, and producers. Production, consumption, and export of coal increased over those of 1979, and a number of new contracts were signed. In western Canada, several existing mines prepared to expand capacity, and new mines prepared for production. Provincial government institutions and universities increased their coal-related research on coal liquefaction, coal-oil mixture, new combustion processes, and other topics. Canadian forecasts predict the coal industry will increase output in both the domestic and the export sectors.

The record level of activity achieved by the petroleum industry in 1979 was surpassed in 1980. About 8,800 wells were completed to an aggregate depth of more than 11 million meters. This represents an increase of 1,200 wells completed and a depth increase of 2.3 million meters. The number of exploratory wells was expected to increase by some 60% because of greater activity in the Western Provinces and Ontario. In oil sand projects, the Alsands Project Group announced possible delays in its operation because of the lack of Provincial approvals. Expenditures for exploration and development were about $13.5 billion, some $3.0 billion more than in 1979.

Exports of crude oil and refined products in 1980 averaged 468,700 barrels per day, a decrease of 10% from 1979. Shipments to the United States of crude, refined products, and liquid petroleum gas amounted to 212,500 barrels per day and 137,500 barrels per day, respectively.

In Canada, uranium exploration and development activity remained high, with the focus on Saskatchewan, where one new facility commenced production, an important discovery was made, and two additional projects were in the planning stage. Important expansion programs continued in Ontario's Elliot Lake area, and new production projects were being considered in British Columbia and Newfoundland. The summary session of the Saskatchewan Key Lake Board of Inquiry was completed in October, and recommendations regarding the conditions under which the Key Lake Mine and mill development could proceed were expected in early 1981. Also of significance was the commencement, in Calgary, of Canada's first commercial recovery of uranium as a byproduct of the production of phosphoric acid.

Although several expansion projects proceeded on schedule in the Elliot Lake area of Ontario, a major fire destroyed the new mill facility of Denison Mines Ltd., located there. In Labrador (Newfoundland), development of the Kitts-Michelin project was deferred pending improved market conditions and further consideration of the environmental implications of the development. In British Columbia, the Provincial government imposed a 7-year moratorium on all uranium exploration and development activity.

---

[1]For more detailed information on the mineral industry of Canada, see the Canadian Minerals Yearbooks for 1978 and 1979 and the Canadian Mineral Surveys for 1978 and 1979, both of which were prepared by the Mineral Development Sector, Department of Energy, Mines and Resources, Ottawa. The U.S. Department of the Interior, Bureau of Mines has arranged to have these Canadian publications placed in libraries in each of the 50 States and Puerto Rico as follows: University of Alabama, Tuscaloosa; E. E. Rasmuson Library, University of Alaska, Fairbanks; University of Arizona, Tuscon; University of Arkansas, Fayetteville; California State Library, Sacramento; A. Lakes Library, Colorado School of Mines, Golden; Wilbur Cross Library, University of Connecticut, Storrs; H.M. Morris Library, University of Delaware, Newark; Strozier Library, Florida State University, Tallahassee; P. Gilbert Memorial Library, Georgia Institute of Technology, Atlanta; University of Hawaii, Hilo; University of Idaho, Moscow; Morris Library, Southern Illinois University, Carbondale; Indiana University, Bloomington; Iowa State University of Science and Technology, Ames; Watson Library, University of Kansas, Lawrence; M. L. King Library, University of Kentucky, Lexington; University of Southwestern Louisiana, Lafayette; R. H. [3]Where necessary, values have been converted from Canadian dollars (CAN$) to U.S. dollars at the rate of Can$1.17=US$1.00, the average exchange rate for the year.

Does not include the value of uranium production, which is not available.

The Mineral Industry of Chile

By Pablo Velasco[1]

In 1980, Chile maintained its position as the second largest market economy producer of copper after the United States. Chile has the largest share of the world's known and probable copper reserves, estimated at 97.0 million tons or 20%. It also ranks second in output of molybdenum with 24% of the world's reserves after the United States and third in iodine production after the United States and Japan. In addition, Chile is a significant producer of vanadium, rhenium, selenium, and lithium. According to Chile's Oficina de Planificación Nacional (ODEPLAN), the real gross domestic product (GDP)[2] continued to expand, increasing to 6.5% in 1980, compared with the 5.3% average for Latin America and the 1.5% average growth of developed countries. Measured in 1977 dollars, the GDP grew from $15.6 billion in 1979 to $16.7 billion in 1980. Inflation declined to 31% in 1980. Exports of $4.8 billion represented an increase of 28% over the previous year's value. The relative importance of copper, Chile's major export, has been declining as a percentage of the total exports, dropping to 46% in 1980 compared with 82% in 1973, indicating diversification of the export sector.

Revenues from the mining sector, mainly copper, will continue to be the country's single most important long-term source of foreign exchange earnings. Mining sector revenues are expected to steadily decline as new forms of export production enter the scene.

Since the enactment of Chile's Foreign Investment Law in July of 1974, 655 individual investment projects have been authorized, and 554 projects entailing $4.1 billion in direct foreign investment are still in planning or have already materialized. American interests account for 151 of these projects representing 83.3% of the authorized total value. Only 23 of the 554 projects involve the mining sector. Investment in three copper projects, The Anaconda Company in Los Pelambres, Exxon Minerals Corp. in Disputada de Las Condes, and Falconbridge Nickel Mines Ltd. in Quebrada Blanca, is estimated to total $3.2 billion. There are currently 12 prospecting projects being carried out by 15 foreign companies, which are exploring for copper, gold, zinc, lead, barite, coal, silver, and tin. Although the amount of capital invested is small, these projects could open future opportunities for large-scale mining.

As of the end of 1980, firms representing 40 different countries had either made direct investments or had them pending. The largest investor was the United States, with almost $3.3 billion or 80.0% of the approved total, followed by Canada with $259.9 million or 6.4%; Panama, 2.9%; Great Britain, 2.6%; the Federal Republic of Germany, 1.8%; and Japan, 1.4%.

A disappointing development in the mining sector in 1980 was Noranda Mines Ltd.'s decision not to go ahead with the Andocollo project. This decision cut potential investment by $400 million and made it unlikely that Chilean annual copper production will exceed 1.5 million metric tons during this decade.

Government Policies and Programs.—The Chilean Government still exercises widespread control over the mining industry through the State copper mining company, Corporación Nacional del Cobre de Chile (CODELCO-Chile), and the State industrial holding company, Corporación de Fomento de la Producción (CORFO), which controls various relatively small enterprises. Six large State-owned enterprises dominate the Chile mineral industries: (1) CODELCO produces 85% of the country's copper; (2) Empresa Nacional de Minería (ENAMI) manages a number of medium- and small-

size mines and smelters; (3) Cía. de Acero del Pacífico S.A. (CAP) operates the country's largest iron ore mines and its only major steel refinery; (4) Empresa Nacional del Carbón S.A. (ENACAR) is the main producer of coal in Chile; (5) Empresa Nacional del Petróleo (ENAP) controls all exploration and production of oil and natural gas; and (6) Sociedad Química y Minera de Chile (SOQUIMICH), the parent organization of all of Chile's significant nitrate mines and refineries, also produces iodine, lithium, sodium, and potassium sulfate.

The economic policies currently in effect in Chile have encouraged development of the private sector economy. Direct private foreign investment is of central importance to current Government economic policy and plans. Accordingly, regulations have been streamlined and liberalized, and foreign and domestic investments have been placed on a more equal footing. Except for those sectors already occupied by State corporation monopolies, foreign investment is permissible and welcome. Foreign investors are waiting for the final wording of the new mining code, which is expected to be announced in June or July 1981.

In the minerals field, the State remains the principal producer, and the country's new constitution specifically exempts mineral resources from normal private property rights, reserving the country's mineral wealth as the exclusive patrimony of the State. The constitution, however, does envision a mineral concession regime for private sector mineral exploitation. This is to be defined in the new mining code. A draft has been submitted to the President. The new mining code will not cover lithium, petroleum, rhenium, thorium, or uranium, which are already governed by special regulations.[3]

PRODUCTION

Copper production stayed close to the 1979 level. Production rose from 1,060,600 metric tons in 1979 to 1,067,700 metric tons in 1980, although blister copper production declined by 17%. CODELCO-Chile is the principal producer, and the private sector currently accounts for some 200,000 metric tons per year. Owing to El Indio, St. Joe Mineral Corp.'s copper mine, gold production jumped 100% in 1980 and should increase in 1981. El Indio will also produce copper and silver. Production declined in iron, zinc, barite, sodium nitrate, salts, and marble, but increased in all other mineral products. Production of molybdenum in 1980 rose to 13,668 metric tons of fine molybdenite and 100.5 metric tons of metal doré.

Chile produces vanadium from magnetite iron ore as a byproduct from the slag from the steel production. Iron ore production increased 12% to 8.6 million metric tons compared with that of 1979, while steel production increased 8% to 695,000 metric tons compared with 1979 output. Domestic consumption reached 72% of the total output, and the remainder was exported.

Molybdenos y Metales S.A. (Molymet) began extracting rhenium in the later half of 1980, and CODELCO now markets rhenium as an individual product. Production was 80 to 100 kilograms per month. Selenium production at Chuquicamata and ENAMI's refinery accounted for 17,000 kilograms in 1980, of which 9,600 kilograms were exported to the United States. Cement production increased 14% to 1.8 million metric tons compared with 1979 output. Coal production declined 19% to 778,000 metric tons in 1980 compared with 1979 output. Crude petroleum output increased 58% to 12 million gallons in 1980 compared with 1979 production.

Chile's largest worker strike since the 1973 military coup continued at El Teniente copper mine as more than 10,000 mine workers stayed away from their jobs. The strike, which began midnight April 21 and continued to the middle of July 1981, involved eight mine workers' unions protesting poor wages. Government officials estimated that the work stoppage is costing $1 million per day and has cut mine production by about 25%. Under current labor laws drafted by the military in 1979, Government-owned companies could begin hiring temporary workers after 30 days and could permanently replace striking workers after 59 days. Record copper production during the first quarter should limit the strike's effect on supplies or price.

Table 1.—Chile: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity[2]	1976	1977	1978	1979	1980[p]

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through July 15, 1981.

[2]In addition to the commodities listed, pyrite is also produced, but available information is inadequate to make reliable estimates of output levels.

[3]Figures are the nonduplicative copper content of ores, concentrates, precipitate, metal, and other copper-bearing products measured at the last stage of processing as reported in available sources.

[4]Figures are total blister and equivalent copper output including that blister subsequently refined in Chile and copper produced by electrowinning.

[5]Figures are total refined copper distributed into two classes according to method of refining.

[6]Excludes castings.

[7]Estimated on the basis of reported vanadium content of vanadiferous slags imported by the United States from Chile.

[8]Includes natural sodium sulfate and anhydrous sodium sulfate, coproducts of the nitrate industry.

[9]Included in "Unspecified."

TRADE

Chile's current account balance of payments has been in deficit for several years. In 1980, the current account deficit was $1.6 billion; the increase over that of 1979, much more than $400 million, was attributable to rapidly rising consumer good imports. The Central Bank of Chile projects the current account deficit to rise to $2.24 billion in 1981. The 1980 foreign trade figures continued to reflect the upward trend evident since 1975. Exports reached $4.82 billion, up 28.0% over 1979 value. Exports from every sector of the economy increased, especially those from the nontraditional mining and traditional industrial areas. Imports reached $5.82 billion compared with $4.2 billion in 1979, a growth rate of 38.0%. Although the 33.3% rise in the combined total of Chile's international trade reflected a slowdown over the nominal rate of growth experience in 1979, combined export and import trade with the United States grew more than twice as rapidly as in 1979 and accounted for 20.4% of Chile's total merchandise trade.

The share of copper in total value exports

declined from about 82.2% in 1973 to 45.7% in 1980. In value terms, copper exports increased 22.3%, partly as a result of world prices rising 10%. The value of other traditional exports (iron ore, nitrates, iodine, molybdenum, etc.) increased 32.8%. Major items contributing to this favorable performance were nontraditional minerals, which as a class rose 164.3% in value to $243 million, including a $102.6 million increase in precious metals.

In the mining sector, the volatile, now weak, copper price is the key determinant of the nominal value of exports. Pending investment projects, however, demonstrate the potential for enormous increases in mineral exports later in the decade. As an economic category, imports have probably been the most affected by Chile's free market policy, owing to the reduction to 10% of its tariff barriers. In spite of the increase in international oil prices, crude oil imports increased only $3.5 million, from $811.2 million to $814.7 million. The 60.4% increase in domestic production permitted a 20.7% reduction in volume of imported crude oil. Foreign trade was maintained with more than 105 countries; over 3,000 products were exported. The principal countries importing Chilean goods were the Federal Republic of Germany (12.3%), the United States (12.2%), Japan (10.4%), and Brazil (9.3%). Fording Coal Ltd. of Calgary, Canada, has agreed to supply CAP, the Chilean State-owned steelmaker, with 1.5 million metric tons of metallurgical coal over the next 8 years. The shipments will begin this year. Fording's contract is said to be worth in excess of $2.6 million in 1981 terms. Fording is 60% owned by Canadian Pacific Enterprises Ltd. and 40% by Vancouver's Cominco Ltd.

Chile's high rate of unemployment is declining. Higher oil prices are also part of the Chile economic problem. Moreover, Chile is fortunate in that the cost of petroleum imports represents a less serious resource drain. Petroleum consumption rose less than 1% during 1980. In addition, petroleum self-sufficiency averaged 36.3% of consumption, up from 24% in 1979, thus limiting oil imports to $814.7 million, a negligible 0.4% increase, despite a 31% rise in unit value.

Copper production maintained its 1979 level, approximately 1.07 million metric tons, while average sale prices rose 10.4%. Output of molybdenum, gold, silver, and other minerals increased considerably because of new investments and higher international prices. In the energy field, oil production increased by 60.4%, while that of natural gas production decreased slightly. Coal production declined 18.7% as a result of the streamlining of operation by ENACAR. In 1980, Empresa Nacional de Electricidad, S.A. (ENDESA), continued development of the 300-megawatt Antuco hydroelectric plant and the Colbún Machicura 490-megawatt first-stage plant, which is scheduled to come online in 1985.

Copper remains the major Chilean export by far, but has been declining as a percentage of the total. The value of other traditional exports (iron ore, nitrates, iodine, and molybdenum) increased 32.8%.

COMMODITY REVIEW

METALS

Copper.—The production of copper in Chile in 1980 rose to 1.07 million tons compared with 1.06 million in 1979, a 1.0% increase. The large-scale mines showed a 0.6% decrease in production between 1979 and 1980. The medium- and small-scale mines, on the contrary, showed a 11.5% increase in production in the same period. Chile's copper output during 1981 is expected to rise to 1.08 million tons, according to the country's officials. The increase will result from production at Las Cascadas and Manto Verde Mines of Pudahuel Mining Co., El Indio, and Mantos Blanco's new expansion, as all three mines have recently come onstream. CODELCO-Chile, which accounts for 84% of the country's total output, reported earnings of $401 million in 1980 compared with $467 million for 1979.

In 1980, CODELCO-Chile produced 904,513 tons of fine copper. The Chuquicamata Div. produced 56.5% of the total, El Teniente 29.4%, El Salvador 8.3%, and Andina 5.8%.[4] CODELCO-Chile recently announced a capital investment program of $1.84 billion for the next 5 years, compared with $1.04 billion between 1974-80. This expenditure is to be divided among the four divisions of the company (Chuquicamata, El Teniente, Andina, and El Salvador) for the expansion of ore treatment capacity and maintenance of current production, administrative, and other projects. Present production level maintenance will receive the most part of the investment owing to the declining copper content of mined ore, which now averages 1.7% but is being forecast to fall to 1.0% in the next 25 years. CODELCO-Chile expects to maintain production at an average of 940,000 tons of fine copper per year for the next 5 years.

Another problem that these investments are expected to overcome is the increasing hardness of the mined ore. Emphasis is being placed on an energy-saving technology that will allow production at lower costs, on the substitution of alternative fuels for petroleum, and on environmental control.

Chuquicamata's investments planned for the next 5 years amount to $877 million distributed as follows: 1981 primary crushing plant ($68.3 million), new tailings dam construction (first stage, $18.4 million), development of the first phase of a smelter ($45.5 million), the Tocopilla Generating Unit No. 12, ($46.6 million), and the conversion of Tocopilla energy production from petroleum to coal ($80.6 million). These investments are expected in the near future because of the decline in copper content of mined ore from the present 2.21% to 1.66% in 1985. Production levels are expected to be maintained at 510,000 tons of fine copper each year throughout the 1980's.

El Teniente, producing 260,000 tons of fine copper per year, is expected to have an investment of at least $734 million to maintain the same production through 1986. As the copper content of the ore decreases to 1.44% from the current 1.54% and being faced with harder ore, CODELCO-Chile is studying the feasibility of increasing production from 62,000 to 80,000 tons per day by 1986, and to 110,000 tons by 1990. The most important investments to be made by 1985 are as follows: Construction of infrastructure to mine areas that contain about 220 million tons of reserves ($36.1 million); purchase and installation of new equipment to develop, mine, and transport the ore from these new areas ($14 million); construction of new infrastructure and purchase of new equipment for processing ore extracted from the primary crushing plant at level Teniente 6 with a capacity of 25,000 tons per day ($31.7 million); the continuation of the Colihues dam project for tailings discharge ($24 million); and the construction of a new ore processing plant located at Barahona ($216 million). At Andina, which has a copper content that is expected to remain at 1.2% over the next 5 years, an investment of $99 million is planned to stabilize copper production at the current 53,000 tons of fine copper per year through 1985. The most important investments to be made are the expansion of production capacity of the mine and processing plant from 14,000 to 20,000 tons of ore per day ($43 million), construction of new infrastructure for the exploitation of the second production level ($13.6 million), and the construction of Los Leones tailings dam ($13.7 million).

El Salvador investments planned are expected to reach $130 million, maintaining production at the current 77,000 tons of fine copper per year through 1985, with a copper content of the ore decreasing to 0.99% from the present 1.22%. The investments planned for this mine are 30% expansion in ore

processing plant capacity ($18.5 million), of which $12 million is programed between 1980 to 1985. Foreign companies have also stepped up investment in Chilean copper deposits that are expected to be brought onstream in the mid-1980's. Exxon Minerals Co. in Disputada de Las Condes, The Anaconda Company in Los Pelambres, and Falconbridge Nickel Mines in Quebrada Blanca, have all made sizable investments for exploratory studies and construction of ancillary facilities.

Another mine, Lo Aguirre owned by the Chilean firm Sociedad Minera Pudahuel S.A., began operations in 1980. It is expected to produce 17,000 tons of copper per year. Lo Aguirre is not the only venture of Sociedad Minera Pudahuel. Last July the company acquired the Sagasca Mines for $37 million (previously owned by Continental Copper Corp.). The Sagasca operation was renamed Las Cascadas and is expected to produce 23,000 metric tons per year of copper concentrate. In addition, Minera Pudahuel bought a 50% interest in Compañía Minera Manto Verde, a Chilean-owned copper deposit. A $60 million investment to develop this copper oxide ore body near Chañaral is now under way. This operation could also produce 50,000 pounds per year of uranium oxide (yellow cake). It was reported that Minera Pudahuel is negotiating with the U.S. firm AMAX Inc. for the purpose of a joint venture grass-roots, base-metal exploration effort. A disappointing development in the mining sector in 1980 was Noranda's decision not to go ahead with the Andacollo copper project. That decision has reduced the potential investment in mining by $400 million and cut deeply into plans for future national production levels. There is a good possibility that Andacollo will be offered for sale to the private sector sometime after the issuance of the new mining code. Chilean companies have bought 55% of the shares in the El Toqui mining company from the West German Metallgesellschaft group. El Toqui is spending $17 million to develop its Aisen Mine in southern Chile, where ore reserves amount to more than 800 million metric tons of 2.5% copper, 13% zinc, and 0.22 ounce of gold per metric ton.

Iron Ore.—During 1980, CAP decreased its shipments from the higher tonnages of the past 2 years to a total (iron ore and pellet) of 8.6 million metric tons, of which 3.2 million tons were pellets.

CAP iron mines are located in the Copiapó, Vallenar, and Coquimbo zones of northern Chile and currently have an iron ore capacity of some 11.0 million metric tons per year. The production from these mines is exported to other countries and is consumed in Chile, principally at CAP Huachipato steel plant in Region VIII (Concepción) in the south. CAP's major source of iron ore comes from the Santa Fé, Algarrobo, and El Romeral Mines.

Chile has 900 million metric tons of proven iron ore reserves and an additional 2 billion metric tons of probable reserves with 62% average iron content. The ore contains substantial sulfur and phosphorous impurities.

Iron ore is shipped from CAP's own mines, principally from the El Romeral Mine (which formerly belonged to Bethlehem Steel Corp.) but also from CAP's new pellet plant at Huasco. Around 1 million metric tons per year of this is shipped to the Huachipato steel plant, and the remainder (about one-third of which is pellet) is shipped to export markets in Japan, the United States, Argentina, and Europe. There are plans to expand raw materials unloading and handling facilities at the plants. Investments on the order of $60 million are expected by 1983. Projected appropriations include $15 to $20 million in the El Romeral Mine, $7 to $10 million in Los Colorados Mine, and $30 million for new technology.[5]

Iron and Steel.—The 35-year-old CAP, Chile's principal steel producer, owns the Huachipato steel plant and the Huasco pellet plant. The steel plant has two blast furnaces with 750,000 metric tons per year raw steel capacity, which will be increased to 1.1 million metric tons per year by 1984. The pellet plant has a capacity of 3.5 million metric tons per year of self-fluxed pellets. Plans are to expand the complex to 3.8 or 3.9 million metric tons per year by 1983 using an energy-saving Allis Chalmers heat recovery system that uses coal instead of oil and exchanges lime hydrate for cheaper varieties. CAP was transformed into a holding company divided into seven wholly owned subsidiaries. These companies will each be completely independent. These seven subsidiaries include three that had already been created plus four new ones. The three older divisions are Compañía de Acero de Rengo, which operates the smaller Rengo steel plant in Region VI (Rancagua); Manganesos Atacama S.A., producer of ferrous manganese; and Pacific Ores and Trading Co., marketer of CAP's iron ore and pellet production. The two largest subsidiaries of the four new divisions are Sociedad Anónima Siderúrgica, which produces steel at the Huachipato plant in Region VIII (Concepción), and Sociedad Anónima Minera, which mines iron ore and operates the Huasco pellet plant in Region III (Copiapó). The other two are Sociedad Anónima Commercial, which will market steel output, and Sociedad Anónima Abastecedora, which will act as purchasing agent, on a commission basis, for the other divisions. The Huachipato work's location is very favorable from the point of view of raw material supplies. It is only 30 to 40 kilometers from Chile's largest coal reserves—the Lota and Schwager Mines in the Arauco coalfields, which provide 60% of the work's needs. The remainder comes from the United States.

Manganese.—Manganese mining in Chile dates back to the turn of the century. Current production is approximately 28,000 metric tons per year in concentrates, basically from one small enterprise, Manganesos Atacama S.A. The primary use of the manganese produced is in domestic steel production. No significant changes in the current level of production are foreseen. In 1979, Manganesos Atacama's plant at Guayacán processed 11,500 metric tons of ore and obtained 4,593 metric tons of ferromanganese and 102 metric tons of manganese dioxide. Production of manganese mainly

from Atacama, in northern Chile, increased 10% in 1980 while the average grade dropped from 34.5% to 32.6%.

Molybdenum.—During 1980, molybdenum production reached 13,668 metric tons, slightly higher than the 13,559 metric tons produced in 1979. CODELCO-Chile is the only producer of molybdenum in the country and continues to be the third largest producer in the world. CODELCO's molybdenum production sources are distributed as follows: Chuquicamata Div. was responsible for 68% of total molybdenum production; El Teniente Div., 17%; El Salvador Div., 10%; and Andina Div., 5%. Molybdenum shipments for 1980 totaled 14,841 metric tons, a 24% increase compared with that of 1979, valued at $331.4 million, a decrease in value from the $334.2 million registered in 1979. The molybdenum shipments increased 30.4%, but the product yielded lower returns because the price of molybdenum dropped sharply. By contrast, the metal doré and other byproducts showed an increase both in prices and shipments, which resulted in higher income amounting to $32.5 million. CODELCO's El Salvador Div. is concentrating its efforts on molybdenum as its copper ore grade declines. In the future, however, new producers may emerge, since there is significant molybdenum potential in at least three of the new projects planned for the near future—Los Pelambres (Anaconda), Quebrada Blanca (Falconbridge and Superior), and Andacollo (formerly Noranda). According to Chilean sources, molybdenum byproducts from CODELCO's copper mines are decreasing steadily, and copper ore grades will force a sharp downturn in molybdenum production between now and 1985. CODELCO is building a 6,000-metric-ton-per-year molybdenum roaster at Chuquicamata, which will be ready for startup by mid-1982 and will process all of CODELCO's molybdenum output. CODELCO currently has a toll conversion contract with Molymet in Chile where about 42% of its production is processed, and the remaining concentrates are sent abroad for processing.

Table 5.—Chile: CODELCO-Chile output of byproducts

(Metric tons)

Byproduct	1976	1977	1978	1979	1980

Precious Metals.—Chile's gold and silver production comes not only from gold mines but also as byproducts of copper mining and refining. The spectacular production of gold in 1980 at El Indio Mine by Cía. Minera San José, a subsidiary of St. Joe Minerals Corp. of the United States, coincided with a period of record gold prices.

During 1980, high-grade ore (11.5 ounces of gold and 4.6 ounces of silver per metric ton, and 2.63% copper) from St. Joe's El Indio Mine, containing approximately 93,000 troy ounces of gold was shipped directly to ASARCO Incorporated in the United States, Norddeutsche Affinerie in the Federal Republic of Germany, and Société Générale des Minerais in Belgium without further processing at the mine. Profits from this mine were exceptionally high because of the selective mining of high-grade ore. Development of the mine and mill complex will proceed toward its schedule to startup in the third quarter of 1981. Meanwhile, a shipment of gold-bearing ore, which requires no processing at the mine, will continue. The shipments are expected to contain in excess of 100,000 troy ounces of gold. Proven reserves at yearend 1980 were sufficient to permit more than 1 year of gold-bearing ore shipments. El Indio mill will have an estimated daily capacity of 1,400 tons of ore. In 1982, the operation should yield over 175,000 troy ounces of gold, 1.5 million troy ounces of silver, and 13,000 tons of copper. St. Joe intends to form ventures with other international mining companies, as well as Chileans, to explore and possibly develop other prospects. In December 1980, St. Joe reached an agreement with Preussag A.G. of the Federal Republic of Germany and Chilean companies Empresa Pesquera Eperva S.A. and Pesquera Indio S.A. to form the first of these ventures. After final agreements are reached, this group will proceed with drilling and underground exploration to

evaluate further the Sancarrón prospect, which is located about 12 kilometers north of El Indio. St. Joe, Preussag, and the Chilean companies will each hold a 20.95% interest in the venture, and the remainder will be held by other private investors.

CODELCO produces gold as a byproduct of copper metal doré and anode slimes. Production in 1980 was 26,500 troy ounces compared with 24,400 troy ounces in 1979. Chile's total gold production in 1980 was 219,773 troy ounces, an increase of 97% over that of 1979.

Uranium.—According to Decree Law 2886 of November 1979, the responsibility for development, exploration, exploitation, and processing of natural radioactive minerals falls under the Comisión Chilena de Energía Nuclear (CCEN). Uranium is not mined anywhere in the country, although prospecting is carried out, particularly in northern Chile. In view of the availability of coal, oil, and hydroelectric power, nuclear energy is unlikely to form a major source of power for Chile in the foreseeable future. However, as part of the CCEN energy development program, a 600-megawatt nuclear powerplant is under study with assistance of the Empresa Nacional de Electricidad S.A. and Compañía Chilena de Electricidad. Chile is planning a uranium recovery plant for its Chuquicamata copper mine. Production is being estimated at 40 to 60 tons per year of uranium oxide. CCEN is waiting for permission from Chuquicamata before building the plant.

A spokesperson for Minera Pudahuel said that the new Las Cascadas copper mine in Chile will start production of uranium oxide at the rate of 50,000 pounds per year. The Las Cascadas Mine has an annual output capacity of 23,000 metric tons of copper per year and was purchased 3 months ago by its owners from Empresa Sagasca for $37 million.

NONMETALS

Cement.—Chile's cement production in 1980 rose 14% to 1.6 million metric tons compared with 1.4 million metric tons in 1979, of which 96% was domestically consumed leaving only 4% for export mainly to Bolivia and Ecuador. There are four cement plants in Chile: The British-owned Fábrica de Cemento El Melón S.A., a subsidiary of Blue Circle Industries Ltd.; Cemento Cerro Blanco de Polpaico S.A. plant, in which the main shareholder is Holderbank of Switzerland; Cementos Bio-Bio S.A., Chilean owned; and Industria Nacional de Cemento S.A., 82% owned by Blue Circle Industries Ltd. and 18% private. The first two plants are in the process of doubling their capacity by 1983 to 1.3 million metric tons per year to meet the rising demand for cement by housing and industrial expansion and the Colbún hydroelectric project. Cement export will be either minimal or nonexistent for a long time to come.

Iodine.—Chile maintained its position as the third largest iodine producer in the market economy countries after the United States and Japan. Iodine production in Chile is tied to nitrate production (although income from iodine is now as large as income from nitrates). Iodine output in 1980 increased 8% to 2,600 metric tons over 1979 production. SOQUIMICH has exclusive rights to mine nitrates and their byproducts in the country (mainly in the desert areas in northern Chile). In November 1979, SOQUIMICH closed its Victoria Mine in Region I (Arica and Iquique Provinces) and reduced its activities to the Pedro de Valdivia and María Elena Mines in Region II (Tocopilla, Antofagasta, and El Loa Provinces) and the new iodine plant Coya Sur located at María Elena. The new technology and plants being installed and designed by Saline Processors, a U.S. consulting firm, will also help reduce the SOQUIMICH deficit. SOQUIMICH will begin production in mid-1981 at a new facility that will increase iodine production by 500 metric tons per year. Exports of iodine in 1980 were valued at $30.4 million, a 43% increase over the 1979 value of $17.4 million. Iodine exports in 1980 went mainly to Europe (65%), the United States (19%), and Latin America (16%).

Lithium.—Chile has an estimated 4.0 million metric tons of metallic lithium, 40% of the world's identified reserves, contained in brines located in the Salar de Atacama and Salar de Pedernales areas of the Atacama Desert. CORFO (the State-owned Chilean development corporation) and the Foote Mineral Co., a subsidiary of Newmont Mining Corp. of the United States, signed a 30-year contract forming a joint venture, Sociedad Chilena de Litio Ltda., to exploit the lithium content of the brine deposit located beneath the 16,700 hectares of the Salar de Atacama, near Antofagasta (Region II). CORFO owns 45% and Foote Mineral, 55%. The extraction plant is expected to produce up to 1,000 metric tons of metallic lithium per year. The investment necessary to develop this operation is estimated to be about

$30 million. Yearly revenues from this operation are expected to reach $14 million at present lithium prices. SCL estimated that the plant will start production in 1984, at the rate of 5,500 metric tons of lithium carbonate per year. Any additional minerals recovered in the processing (magnesium oxide, potassium chloride, etc.) will belong to the Government, which is also considering a possible joint venture with Union Oil Co. for recovery of 400,000 metric tons per year of potassium oxide from the Salar de Pedernales.

Nitrates.—The production of nitrates held fairly steady in 1980, while output of nitrate byproduct rose slightly. Mining of sodium and potassium nitrates, the major product in this sector, decreased 0.2% to 620,400 metric tons.

Sodium sulfate production increased 2.0% to 70,100 metric tons. The value of nitrate exports was up 21% to $55.8 million in 1980 over $44.4 million in 1979. Nitrate exports in 1980 went to Europe (31%), the United States and Canada (35%), Latin America (25%), and Asia (9%).

Other Nonmetals.—One of the highest mines in the world is producing sulfur at the 6,000-meter (19,700 feet) altitude in Chile, on the upper slopes of the dormant volcano of Aucanquilcha, locally known as The Devil's Hill (near the Town of Amincha close to the Bolivian border). The ore is reported to contain 50% to 60% sulfur. After refining, the sulfur is used to manufacture sulfuric acid for the vast copper mine at Chuquicamata. Front-end loaders load the ore into trucks; the ore is then transported down to the Angulo railroad station at 5,200 meters (17,000 feet) by an aerial tramway. The mine was originally developed in 1913 for the extraction of sodium nitrate for saltpetre manufacture.

CORFO, through the Committee for Mixed Salts, has a second project for recovery of boron from the salts of the Salar de Atacama. International tenders will be sought in 1981. Reserves in an area known as the nucleus of the Salar de Atacama amount to 4 million metric tons of lithium and 11 million metric tons of boric acid together with 57 million metric tons of potassium and 26 million metric tons of magnesium.

MINERAL FUELS

Coal.—Coal production declined 18.7% in 1980 to 778,000 metric tons following the trend begun in 1974. The principal cause was over exploitation of the old mines worked by ENACAR, which has been closing its less efficient operations. Production began to rise to previous levels at the end of 1980. In 1981, the total coal mined is expected to duplicate the amount registered in 1979. Preliminary studies placed resources of subbituminous coal in the Magallanes Region XII at over 4 billion metric tons.

This broad assessment encouraged CORFO to form the Subbituminous Coal Committee to carry out closer prospecting and feasibility studies to pinpoint those parts of the prospect for possible exploitation. It was concluded that the Pecket deposit, the Riesco, and the Dorotea-Natales sectors were the most promising areas. At the beginning of 1980, the prospecting functions of ENACAR were transferred to the Subbituminous Coal Committee. Reportedly, the Comisión Nacional de Energía has engaged the services of Société Francaise d'Etudes Minières of France to carry out further technical and economic feasibility studies on the most favorable locations. The Pecket coal occurrences, not far from Punta Arenas in Chile's far south near the Straits of Magellan, are the most promising. A preliminary study indicates that for an initial investment estimated at some $100 million, the two seams can yield about 2 million metric tons per year of coal over 25 years (or more). Compañía de Petróleos de Chile S.A. (COPEC) presented a $3.5 million offer for CORFO's Pecket coal deposit in Magallanes. The $3.5 million offer, according to COPEC officials, will compensate the Government for costs incurred by CORFO and the National Energy Commission.

Pecket will be exploited by Compañía de Carbón de Chile, a newly created consortium consisting of COPEC, Northern Strip Mining Ltd., Davy McKee Corp., and K. Wardell and Partners. Before mining can begin, support infrastructure will have to be built, including roads, buildings, electric energy generating plants, and a port capable of handling 40,000-metric-ton vessels. An initial investment of $50 to $60 million over the first 4 to 5 years is expected. Exploitation of the deposit will provide employment for 200 to 350 workers. Coal obtained from the Pecket deposit (4,500 calories), with an extraction cost of $30 per ton, compares favorably with the cost of importing coal, $75 per metric ton with a 6,000-calorie content. The Pecket deposit will be Chile's first open pit coal mine,

although it will also be exploited by underground methods. Chilean current coal production is 1 million metric tons per year. ENACAR has announced that there were no takers when the Schwager Coalfield was put up for auction to local and foreign bidders. ENACAR now has to decide what to do with the coalfields, which are excessively costly to operate. The work force had fallen from 15,000 in 1973 to 1,600 at the beginning of 1980.

Petroleum and Natural Gas.—In 1980, production of crude oil increased to 1.9 million cubic meters (12 million 42-gallon barrels), a 58% increase over 1979's output and equivalent to 34% of total domestic consumption. New production was obtained from offshore wells that came onstream during 1979 and 1980. ENAP has been building offshore facilities to handle the larger output of crude oil and petroleum products, thus making further production increases possible. Consumption of fuel oil decreased 0.06% in 1980 owing to the greater efficiency of consumer installations and the substitution of coal for fuel oil.

Chile is expected to produce 41% of its national petroleum consumption requirements in 1981 and 45% in 1982. Domestic production had not been slated to reach this level until 1983. Exploratory drilling programs by ENAP and foreign companies began in 1980 at additional locations. A $50 million offshore oil exploration program will be carried out by ENAP, starting in December 1980 in an area that extends seaward between the mouths of the Maule and Bio-Bio Rivers. The exploration zone is about 12,000 square kilometers. ENAP expressed optimism on finding oil in this region based on the thickness of the sedimentary basin in the Pacific offshore. Oil and natural gas is expected to be found not very deep and will be explored by the General, a semisubmergible platform under contract from the Diamond M Corp. of the United States. Atlantic Richfield Co.-ARCO Petróleos Chile and Amerada Hess Petróleo Chile will renew offshore exploration after breaking off the program in March 1980 for the winter season. A renewal program of exploration will begin in November 1980 with the arrival of a dynamically positioned drill ship leased from IDELCO. ARCO intends to drill exploratory wells off Chiloé Island and further south. The first of these exploratory wells, Chepu No. 1, will be drilled in 148 meters (390 feet) of water to an expected depth of 1.707 meters (5,630 feet) by the Ben Ocean Lancer. Other offshore developments included the addition of a fixed platform at Spiteful Field, which will add nine new wells for petroleum production. The offshore program of oil production in Magallanes presently includes Ostión with one fixed platform and Spiteful with two fixed platforms and comprises 57% of total production in Magallanes or about 18,000 barrels daily.

Production of natural gas totaled 240,000 million cubic feet in 1980, decreasing slightly from that of 1979. The volume of gas reinjected amounted to 97,716 million cubic feet, up 4% from 94,043 million cubic feet per year earlier. A $400 million liquid natural gas project at Cabo Negro in the Magallanes area (Region XII) is in the final planning stage. The projected production is exclusively for export and the project is expected to come onstream during the 1980's. Current estimates are for a plant capacity to liquefy 7 million cubic meters (250 million cubic feet) of gas daily. Once the design is completed, the plant will take at least 3 years to be installed. Two Japanese companies, Mitsubishi Corp. and Nichimen Corp., are in negotiation with Gas de Chile, Ltda., for the purchase of the entire output planned for the Magallanes' Cabo Negro project.

Natural gas is also the subject of exploration that has yielded positive results. ENAP has undertaken a program that will eventually permit the export of surplus natural gas in significant quantities after domestic market requirements have been satisfied.

Other.— CORFO continues developing El Tatío geothermal field. A 30-megawatt geothermal powerplant is being planned at El Tatío, located in Loa Province (Region II) at 4,300 meters (14,000 feet) elevation. The $42 million plant, which will operate on natural energy produced by geysers, will supply power to the Chuquicamata copper mine located 120 kilometers (74.6 miles) away. A United Nations financed feasibility study was completed by Electro Consult, an Italian firm.

During 1980, CORFO updated its studies on the capacity of El Tatío geothermal field and the installations necessary to produce a minimum potential of 15,000 kilowatts. Definite plans for working this geothermal field will be available in 1982 and work can begin 30 days after a public concession document is accepted. It will take 4 years to complete the project, which will generate energy for use in Chile's large-scale mining sector.[6]

In the energy sector, a series of plans and programs have been laid out to minimize domestic dependence on foreign supplies. Petroleum products, the largest import item, which had reached as much as one-third of total imports, fell to less than 19% in 1980 and can be expected to continue to decline as offshore drilling yields greater production and as other types of energy, such as coal or hydroelectric power, are used as replacements. Demand for energy has increased by an annual average of 4.6% over the last 4 years, creating the need to develop greater productive capacity.

The National Energy Commission is coordinating the planning effort to meet projected demand. Increased emphasis has been placed on the production of hydroelectric power since only 7.9% of the country's capacity for this type of energy has been tapped to date. Consumption of electric power has increased by an annual average of 7% during the last 6 years. Several projects have been announced by ENDESA and a consortium of private companies to meet demand, which is expected to grow by more than 6% per year over the next decade. The most important projects are the completion of the 300-megawatt Antuco plant, which is expected to become operational in 1981, and Colbún-Machicura, which will have a first-stage generating capacity of 490 megawatts and is scheduled to come on line in 1985. Studies are underway for two major plants, Neltume and Pehuenche, which will have a combined capacity almost equal to that of the Antuco and Colbún-Machicura facilities.

The Mineral Industry of China

By Edmond Chin[1]

In the early seventies, the principles of China's economic development were readjustment, restructuring, consolidation, and improvement. The modernization program—encompassing agriculture, industry, science and technology, and defense—was to bring the country into the ranks of the advanced and industrialized nations of the world by the year 2000. This ambitious program, composed of 120 major projects, was embodied in China's 10-year plan for 1976-85. After introspection and examination, the primary concern of the Chinese was readjustment; a readjustment in policy by Government planners in 1978 to a more realistic, albeit a slower, development program and one structured on market socialism. A new program, the sixth 5-year plan, replaced the existing 10-year plan, which was to become actually a part of a new 10-year economic plan for 1981-90 and was to emphasize investment priorities in light industry and agriculture.[2]

The main tasks for 1980-81 were to accelerate growth of agriculture and light industry to supply consumer goods commensurate to a rise in purchasing power; increase energy supplies; improve communications service and the construction industry; and readjust production in the metallurgical, chemical, and other heavy industries to support the output in agriculture and light industry and to serve the economy as a whole. The State expounded six guidelines to ensure the success of the 1980-81 objectives. First, in agriculture, the autonomy in decisionmaking by the production unit was to be respected, each unit was to proceed from existing conditions, and responsibility was to be assigned to smaller groups. Second, nationwide attention would be given to light industry to broaden sources of raw materials so as to increase production. Third, equal stress was to be placed on exploiting energy sources and energy conservation. Fourth, further readjustments in heavy industry would be made, as needed, especially in the machine-building industry. Fifth, although higher education will continue to develop, a number of middle schools would be converted into professional and technical training schools. Sixth, experiments in restructuring economic management were to be expedited, and the autonomy of State-owned industries was to be expanded. The main economic targets for 1981 in million tons were steel, 35; cement, 78; coal, 620; and crude oil, 106. Electric power generation was to increase 4% to 312 billion kilowatt-hours. Total industry output value was to increase 6% over 1980, and the total agricultural output value was to increase 4%. Domestic retail trade was to reach 220 billion yuan compared with 55.9 billion yuan for foreign trade.[3]

According to preliminary data released by the State Statistical Bureau, China's total industrial output value in 1980 was 497 billion yuan, 8.4% more than in 1979. The national electric power output was 297 billion kilowatt-hours, an increase of 5.4% over that of 1979. The planned 1980 targets for 83 major industrial products were fulfilled or overfulfilled. Quotas for steel, pig iron, rolled steel, and nonferrous metals were surpassed. All targets for 18 major chemical products, including fertilizers, sulphuric acid, soda ash, and caustic soda, were fulfilled; fertilizer output, for instance, was 17.5% more in 1980 than in 1979. However, China's outputs of crude oil and raw coal were 0.2% and 4.7% less, respectively, than

in the previous year.

During 1979-80, China's industries underwent restructuring and amalgamation to attain full potential and move faster toward production specialization, regardless of locality and ownership. By the end of 1980, 19,300 enterprises were amalgamated into 1,900 specialized companies or plants. Some enterprises also had begun to set up, on a trial basis, national specialized companies. In Liaoning Province, for example, 2,098 enterprises were reorganized under the management of 122 specialized companies and 65 general plants. The combined output values of the new management system accounted for about one-fifth of the Province's total industrial and transportation enterprises. In addition, 953 small units were merged into various joint ventures, thereby increasing their combined output value and profits. After 30 years, China had reportedly built 400,000 industrial and transport enterprises, with a total asset of 800 billion yuan.

Annual per capita gross national product increased from $155 in 1975, to $162 in 1976, $171 in 1977, $208 in 1979, and to around $240 in 1979.[4] [5] No estimate was reported for 1980. The average annual per capita income in State-run enterprises was 781 yuan in 1980, and per capita income of each working family was 395 yuan. Between 1977 and 1980, 26.6 million young people and other jobless persons found employment. The average per capita peasant income in 1980 was around 170 yuan. China's population growth rate was 1.17% in 1979 and was expected to drop to 1% in 1980. Total population was estimated at 970 million in 1980.[6]

Government revenue in 1979 was 110 billion yuan, and expenditure was 127 billion yuan. The deficit of 17 billion yuan was a result of higher State purchase prices for major farm products and the reduction or remittance of the agricultural tax in poor areas; increase in wages and in the number of new jobs; retention of a percentage of profits by localities and enterprises; increase in investments in agriculture and light industry; increase in national defense expenditure; and payment of back salaries and financial aid to people injured as a result of the Cultural Revolution. Surplus accumulation from previous years (8.0 billion yuan) and an overdraft (9.0 billion yuan from the People's Bank of China) covered the deficit in 1979. The budget deficit in 1980 was 12 billion yuan for which the bank issued 7.6 billion yuan in banknotes.

China's total trade in 1980 was 56 billion yuan[7] and was expected to be around 60 billion yuan in 1981. Japan, the United States, and the Federal Republic of Germany, in that order, were China's largest trade partners. To promote international financial transactions, the State Council established the State Administrative Commission on Import and Export Affairs and the Foreign Investment Commission. The former organization was to supervise overall foreign trade, and the latter was created to oversee foreign investments in China. In addition, the State General Administration of Exchange Control was established to exercise control over foreign exchange, and the China International Trust and Investment Corp. was created to handle joint ventures with foreign investors. The Bank of China was restructured and placed directly under the leadership of the State Council. Domestic branch offices were increased to 114 by yearend 1980, and overseas offices were increased to 207, with 196 in Xianggang (Ying Shan) and Aomen, 6 in Singapore, 3 in the United Kingdom, and 1 in Luxembourg. A representative office was established in Tokyo, and preparations were made to set up a branch in New York City and a representative office in Paris.

The Bank of China has also established correspondent relations with 2,735 branches of 1,033 banks in 144 countries. China's representation in the International Monetary Fund and the World Bank was restored in 1980.

During 1980, the Government promulgated a law on individual income tax and a law on joint-venture income tax. The latter law covers income derived from production, business, and other sources by any joint venture with Chinese and foreign investment in China. The income tax rate on joint ventures was to be 30%, with an additional local surtax of 10% of the assessed income tax to be levied. The income tax rates on joint ventures for petroleum, natural gas, and other resources were to be stipulated separately. Upon appropriate approval, a newly established joint venture, scheduled to operate for a period of 10 years or more, may be exempt from income tax in the first profitmaking year and allowed a 50% reduction in the second and third years. Joint ventures in low-profit operations and in remote, economically undeveloped outlying areas may be allowed a 15% to 30% reduction in income tax for a period of 10 years, following the expiration of the term for ex-

emptions and reduction mentioned earlier.

According to the Foreign Investments Commission of the Foreign Investment Council, 20 joint venture contracts for projects within China were approved in 1980, the country's first year with joint ventures, amounting to $177 million, of which the Chinese invested $35 million. In addition, 33 joint-venture projects were formed by Chinese ($38.4 million) and foreign parties ($44.4 million) to operate in other countries. Between $600 and $700 million was invested by foreigners in cooperative production ventures; the foreign party provides all the necessary capital, and the Chinese provide land and labor. Cooperative production ventures are turned over to the Chinese after 10 or 20 years. Agreements were signed with French and Japanese oil companies in 1980 to develop China's offshore oil. Foreign parties were to contribute $500 million (Chinese were to contribute $300 million) and were to be repaid in oil. In 1980, 5,400 compensation trade contracts were signed, under which foreign participants were to provide equipment valued at $112 million and were to be repaid with finished products. In 1979, the China International Trust and Investment Corp. was established to attract foreign investments for various Chinese projects. To date, $14 million has been invested in mining projects, including molybdenum and phosphorus, in four Provinces.

The Capital Construction Commission reported that 60 integrated projects and 183 disparate projects were completed and began operations in 1980. These included new coal operations, with a combined annual capacity of 7 million tons; new oil well development; new annual cement capacity of 1.5 million tons; and the installation of a generating capacity of 2.5 million kilowatts of electricity. Annual freight-handling capacity of ports increased by 7 million tons, and 900 kilometers of new railway were opened to traffic.

Because of growing financial commitments in the national budget, a wider trade deficit because of imports of whole plant purchases and technology-intensive equipment, and domestic inflation, the Government planned cuts in expenditures, and delays, or even curtailment, of some major projects. There was talk of delays or suspension of large industrial projects, which if true would be costly and problematic to foreign investors mostly from Japan, the United States, and the Federal Republic of Germany. The project most criticized for poor planning by the Chinese was the new integrated steelworks at Baoshan. Chinese officials were also to decide the fate of several proposed petrochemical plants,[8] as well as several mining ventures. However, it was expected that work on coal and oil exploration and development would continue. The Government announced also that China would not be able to honor oil export commitments through 1985 and that the country's oil potential had been exaggerated. Moreover, the Government announced that it expected rational domestic use of energy by its industry, and exhorted energy-conservation measures.

The Ministry of Geology continued to announce significant finds of minerals throughout the year.[9] [10] [11] Significant reserves of 132 minerals have been found. Wolfram deposits are three times those in the rest of the world. Rare-earths minerals make up 70%, and antimony makes up 44% of the world's total. Deposits of iron, copper, bauxite, lead, zinc, tin, coal, phosphorus, gypsum, and salt rank among the largest in the world. Some minerals are not being fully extracted, resulting in serious waste. The quantities of chromite, platinum, potassium, and diamonds now mined cannot meet economic needs. Although a considerable number of reserves of important minerals are known, there are not many large reserves. There are quite a lot of mixed-mineral deposits with small reserves.[12] A map delineating the country's mineral deposits, reproduced from an article by Hsu Chieh, in the April 1981 edition of China Reconstructs (V. 30, No. 4) is shown in figure 1.

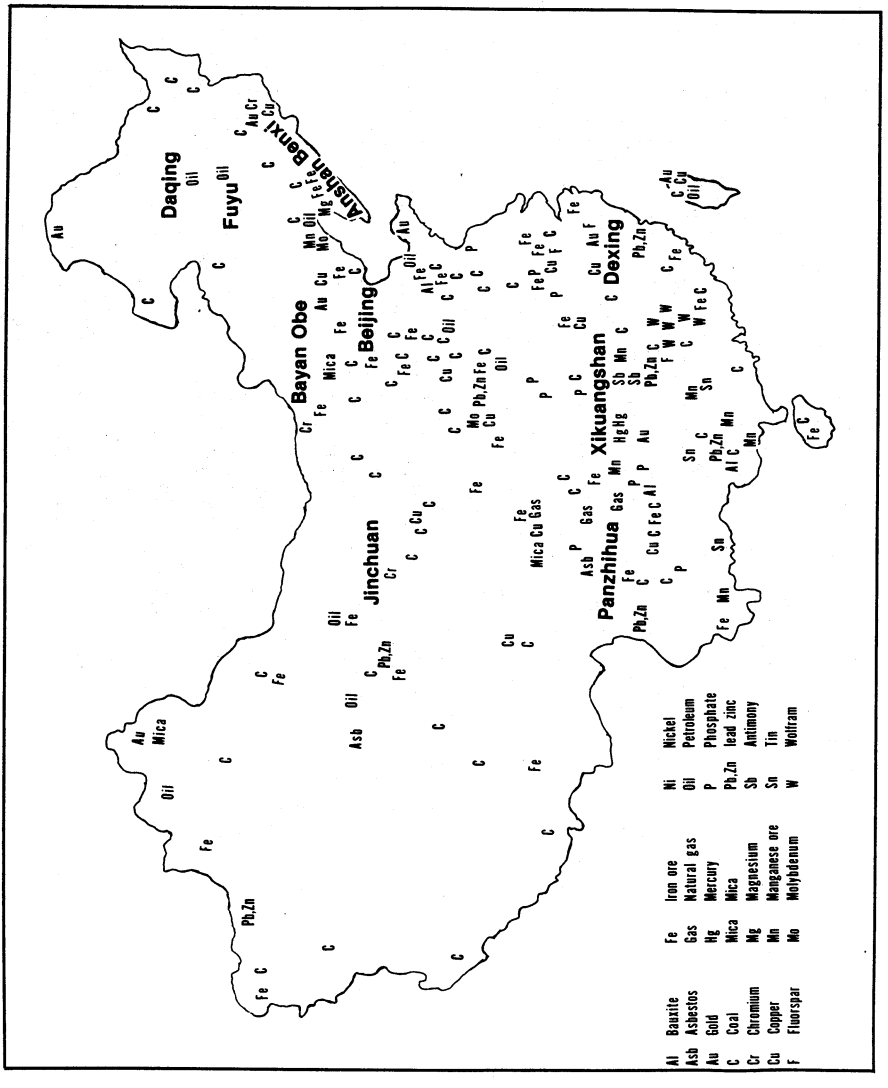

Figure 1.—Geographical distribution of China's mineral deposits.

The Ministry of Geology was devoting more attention to research on basic geologic theory and to the development of expertise in prospecting engineering (remote sensing, physical and chemical prospecting). Greater use of electronic computers was to be encouraged, and technical exchanges and cooperation with foreign countries were to increase. For example, China and France began research on the geological structure of the Himalayas. China and the Federal Republic of Germany were conducting a joint survey and prospecting for molybdenum, columbite, and tin in Hunan Province. A number of countries were cooperating in oil exploration.

PRODUCTION

Since June of 1979, China's State Statistical Bureau (SSB) has been publishing numeric data on select national aggregates. According to SSB, the country's value of gross industrial output (GIO) grew from 373 billion yuan in 1977 to 423 billion yuan in 1978, 459 billion yuan in 1979, and 498 billion yuan in 1980. The average annual growth in GIO during the period was 10.1% compared with 8.4% for the 1980 output. In 1979, the Government announced its decision to emphasize the development of light industries. Reflecting this change in policy, the value of GIO by the light industry sector rose from 198 billion yuan in 1979 to 232 billion yuan in 1980, but the output by the heavy industry sector increased only from 261 billion yuan to 265 billion yuan.

SSB thus far has only reported annual production of the following mineral-related commodities: Fuels—coal, coke, crude oil, and natural gas; metals—pig iron, crude steel, and rolled steel; nonmetallics—caustic soda, cement, salt (for human consumption), soda ash, and sulfuric acid.[13] In addition, output of fertilizers was given for 1977-79. SSB also reported that the output of copper ore, zinc ore, and pyrite, as well as eight other products were not fulfilled under the 1979 economic plan. Output of 10 nonferrous metals, however, was said to have surpassed 1 million tons in 1979, a 12.8% increase over that of 1978. Although only aluminum, copper, tin, and tungsten were specifically noted in the communique as among the 10 metals, lead and zinc presumably must be included.

Although official data are lacking, China is a significant world producer of antimony, barite, fluorspar, graphite, magnesite, tin, and tungsten. In addition to the aforementioned, China is believed to be an important producer, also by world standards, of rare-earth elements, tantalum, and vanadium, as well as a potential significant producer of cobalt, chromium, gold, molybdenum, nickel, platinum-group metals, titanium, and uranium.

The Ministry of Geology, in a concerted effort with its provincial and local counterparts, encouraged surveying of existing mining areas and prospecting for undiscovered mineral deposits. The Government also was to award bonuses for new finds that could be developed. In 1980, various geological departments completed 29 reports on the prospecting of a number of areas. Included in these reports were surveys on diamond, graphite, gypsum, lead-zinc, mercury, and tin. One of the most active minerals reconnaissance programs encouraged by the State was for precious metals.

Refinery products do	548,000	650,000	600,000	620,000	620,000

[p]Preliminary. [r]Revised.

[1]Except those figures specifically footnoted as reported.

[2]Table includes data available through July 1, 1981.

[3]In addition to the commodities listed for which quantitative estimates of output have been made, China is known or believed to have produced the following commodities for which no estimates, even of order of magnitude, have been prepared, owing to a paucity of general information upon which to base an estimate: Arsenic, chromite, titanium minerals, uranium, boron minerals, various clays (including kaolin), feldspar, lime, mica, sand, various industrial and dimension stones, and carbon black. Other unlisted commodities also may be produced.

[4]Diasporic bauxite; includes an estimated 165,000 metric tons per year of production for refractory applications.

[5]In terms of 50% Fe ore.

[6]Reported figure.

TRADE

China's total two-way trade was estimated at $34 billion in 1980 compared with $30 billion in 1979.[14] [15] Exports in 1980 were $15 billion; about two-thirds of the country's exports are composed of light industrial and textile products, and agricultural and sideline products. Imports in 1980 were valued at $19 billion. Principal imports were heavy machinery and equipment to support the country's modernizations program. China's major trading partners were the United States, Japan, and member countries of the European Communities.[16]

By March 1980, China displaced the U.S.S.R. as the leading United States trade partner among the centrally-planned economies. To promote further trade, a Chinese trade exhibit toured the United States in 1980, and a U.S. trade exhibition was held in Beijing on November 17-28. The five main themes of the United States show in China were petroleum exploration and extraction equipment, power generation and distribution, agricultural machinery, transportation, and light industrial machinery.

Since the latter half of 1979, the foreign trade structure of China has been undergoing reform. First, the structure and scope of national trade corporations under the Ministry of Foreign Trade were readjusted. Some headquarter offices no longer were engaged in direct export, while others handled only a few important commodities. For instance, trade of antimony, tin, and tungsten was controlled by the head office of the China National Metals & Mineral Import & Export Corp. (Minmetals). Items such as aluminum, lead, and zinc ingot, and ferrotungsten could be handled by the head office of Minmetals or by the Ministry of Metallurgical Industry. Items such as bismuth; cadmium; chromium; ferrochrome, -manganese, -molybdenum, -silicon, -titanium, and -vanadium; manganese; molybdenum; rare earths; and titanium could be handled locally or centrally. Second, foreign trade corporations were established in three municipalities (Beijing, Shanghai, and Tianjin); in four Provinces (Guangdong, Fujian, Hebei, and Liaoning); and in one autonomous region (Guangxi). Third, trade corporations were established under the relevant ministry as well as the Chinese Academy of Science to engage in joint ventures, coproduction, compensatory trade, material processing, and assembly. Fourth, transregional joint enterprises were to be set up among production departments. And lastly, some industrial plants, mines, farms, and grassroot enterprises, with approval by the appropriate authority, were to control exports directly.

China has trade relations with about 170 countries, and the variety of export commodities number about 50,000 items.

Table 2.—China: Apparent exports of selected mineral commodities[1 2]

(Metric tons unless otherwise specified)

Commodity	1978	1979	Principal destinations, 1979
METALS			
Aluminum:			
Bauxite	86,522	209,181	Italy 74,971; Japan 36,659; West Germany 24,444; United States 23,839.
Oxide and hydroxide	10,398	13,642	Thailand 6,850; Singapore 1,838; Hong Kong 1,382.
Metal including alloys:			
Unwrought	--	2,721	France 2,074; Thailand 647.
Semimanufactures	r1,334	2,019	Hong Kong 1,748; Sri Lanka 48; Indonesia 45.
Antimony:			
Ore and concentrate	249	3,395	Yugoslavia 2,015; France 856; West Germany 307.
Metal including alloys, all forms	4,980	5,412	Japan 2,895; United States 1,234; France 665.
Arsenic:			
Natural sulfides	10	13	Thailand 8; Macau 5.
Trioxide, pentoxide, acids	253	214	Thailand 78; Greece 50; Japan 50.
Chromium:			
Chromite	80	--	
Oxide and hydroxide	40	76	Indonesia 50; Hong Kong 26.
Cobalt:			
Oxide and hydroxide	--	4	All to Japan.
Metal including alloys, all forms	--	3	All to West Germany.
Copper:			
Ore and concentrate	--	1	All to United Kingdom.
Sulfate	105	231	Japan 215.
Metal including alloys:			
Scrap	--	820	All to Hong Kong.
Unwrought	455	35	Italy 30.
Semimanufactures	1,495	2,761	Hong Kong 2,368; Pakistan 159; Singapore 113.
Iron and steel:			
Ore and concentrate	38	196	Pakistan 97; United States 57.
Metal including alloys:			
Scrap	177	440	Japan 263; Saudi Arabia 172.
Pig iron	6,475	28,079	Pakistan 14,278; Hong Kong 8,742; Singapore 4,100.
Ferroalloys	277	766	Sweden 411; Venezuela 154; Yugoslavia 115.
Steel, primary forms	NA	46,347	Pakistan 31,602; Hong Kong 11,409.
Semimanufactures:			
Bars, rods, angles, shapes, sections	143,000	170,961	Hong Kong 132,226; Saudi Arabia 16,594.
Plates and sheets	6,529	10,744	Hong Kong 5,303; Nigeria 2,857.
Hoop and strip	431	715	Pakistan 178; Indonesia 177; Hong Kong 161; Thailand 155.
Rails and accessories	--	4	All to Cameroon.
Wire	25,369	33,570	Hong Kong 13,879; Singapore 6,332; Thailand 4,840.
Tubes, pipes, fittings	10,125	22,756	Hong Kong 13,711; Saudi Arabia 5,164; Pakistan 1,038.
Castings and forgings, rough	1,219	2,294	Saudi Arabia 987; Japan 646; West Germany 271.
Lead:			
Ore and concentrate	1,500	1,100	All to Thailand.
Oxide	403	751	Japan 424; Hong Kong 105; Thailand 101.
Metal including alloys:			
Unwrought	r128	20	All to Indonesia.
Semimanufactures	r10	7	Saudi Arabia 6.
Magnesium metal including alloys, all forms	1	--	
Manganese:			
Ore and concentrate	46,346	45,961	Japan 43,419; Italy 1,060.
Oxide	1,609	1,516	Hong Kong 903; Singapore 312; Italy 200.
Metal including alloys, all forms	25	39	All to West Germany.
Mercury 76-pound flasks	r6,632	8,584	Hong Kong 1,943; United States 1,392; Italy 986; West Germany 957.
Molybdenum ore and concentrate	60	494	Japan 412; West Germany 67.
Nickel metal including alloys:			
Unwrought	--	19	All to United Kingdom.
Semimanufactures	4	4	All to Trinidad and Tobago.
Niobium ore and concentrate	--	29	All to Japan.
Silver:[3]			
Ore and concentrate, value, thousands	--	$3	All to Pakistan.
Waste and sweepings, do.	--	$62	All to West Germany.
Metal including alloys, unworked or partly worked, do.	$4	--	
Tin metal including alloys:			
Unwrought	5,060	3,170	Yugoslavia 1,156; Netherlands 805; Japan 270; France 255.
Semimanufactures	108	124	Hong Kong 78; Singapore 42.

Table 2.—China: Apparent exports of selected mineral commodities[1] [2] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Principal destinations, 1979
METALS —Continued			
Titanium:			
Ore and concentrate	569	--	
Oxide	1,225	1,588	Japan 559; Hong Kong 423; United Kingdom 301.
Metal including alloys, all forms	NA	222	West Germany 127; France 50; United States 45.
Tungsten:			
Ore and concentrate	3,227	6,674	West Germany 1,726; Austria 1,423; Poland 859; United States 849.
Metal including alloys, all forms	7	9	Mainly to Yugoslavia.
Zinc:			
Oxide	914	935	Japan 562; United Kingdom 140.
Metal including alloys:			
Blue powder	--	12	Japan 5; Hong Kong 5.
Unwrought	r10,569	6,802	Hong Kong 2,994; Japan 1,838; Thailand 958.
Semimanufactures	28	123	Saudi Arabia 64; Pakistan 50.
Zirconium metal including alloys, all forms kilograms	--	50	All to Japan.
Other:			
Ores and concentrates	2,455	1,675	Italy 540; United States 369; Belgium-Luxembourg 368.
Ash and residue containing nonferrous metals	427	447	Hong Kong 440.
Oxides, hydroxides, peroxides, n.e.s	295	6,536	Pakistan 3,472; United States 1,675; Netherlands 265.
Metalloids	16	84	Hong Kong 67.
Alkali and rare-earth metals	NA	10	All to Sweden.
Base metals including alloys, all forms, n.e.s	1,724	1,368	Hong Kong 543; Japan 361; United Kingdom 71.
NONMETALS			
Abrasives:			
Pumice, emery, natural corundum	325	274	All to Japan.
Dust and powder of natural or synthetic precious and semiprecious stones value, thousands	--	$4	Hong Kong $3.
Grinding and polishing wheels and stones	r730	1,289	Hong Kong 561; Indonesia 380; Thailand 175.
Asbestos	6,026	9,556	Thailand 5,308; Hong Kong 1,734; Indonesia 1,620.
Barite and witherite	r151,550	360,990	United States 211,910; Netherlands 76,351; West Germany 43,217.
Boron oxide and acid	141	212	Egypt 150; Thailand 25; Hong Kong 20.
Cement thousand tons	718	808	Hong Kong 725; Macau 77.
Chalk	30	23	Venezuela 20.
Clays and clay products:			
Crude clay	84,484	145,437	Japan 102,912; Hong Kong 28,543.
Products:			
Refractory	6,210	5,638	Indonesia 3,539; Pakistan 741.
Nonrefractory	23,544	29,940	Hong Kong 27,504; Singapore 1,405.
Cryolite and chiolite, natural	433	540	United States 535.
Diamond:			
Gem, not set or strung value, thousands	$2,002	$2,873	Hong Kong $1,242; Japan $1,162.
Industrial do	$1,035	$2,022	All to Belgium-Luxembourg.
Diatomite and other infusorial earth	11	21	Japan 20.
Feldspar and fluorspar	170,383	250,773	Japan 208,548; Australia 13,781; Hong Kong 12,878.
Fertilizer materials:			
Crude:			
Nitrogenous	480	60	All to Indonesia.
Phosphatic	115	845	Singapore 490; Indonesia 250.
Manufactured:			
Nitrogenous	--	31,102	Sri Lanka 30,900.
Phosphatic	--	260	All to Japan.
Potassic	--	225	Thailand 200.
Other including mixed	10	2	All to Singapore.
Ammonia	12	29	All to Hong Kong.
Graphite, natural	12,237	26,067	Japan 11,267; West Germany 6,181; United States 2,615.
Gypsum and plasters	3,420	54,817	Hong Kong 52,275; Indonesia 1,545; Singapore 610.
Iodine	--	17	All to France.
Lime	29,148	43,427	Hong Kong 43,074.
Magnesite	59,893	95,185	Japan 37,897; West Germany 19,546; United Kingdom 11,671.
Mica:			
Crude including waste	5,585	7,957	United Kingdom 6,110; West Germany 970; Japan 467.
Worked	12	19	Spain 6; United Kingdom 4; France 4.

See footnotes at end of table.

Table 2.—China: Apparent exports of selected mineral commodities[1] [2] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Principal destinations, 1979
NONMETALS —Continued			
Pigments, mineral:			
Natural, crude	2,661	1,675	Hungary 1,395; Hong Kong 250.
Iron oxides, processed	2,599	2,730	Indonesia 780; Hong Kong 746; Singapore 607.
Precious and semiprecious stones:			
Natural value, thousands	$5,795	$5,809	Japan $1,482; France $1,431; United States $931.
Synthetic do.	$2	$103	Saudi Arabia $59; Switzerland $30.
Pyrite, unroasted	--	21	All to Saudi Arabia.
Salt and brine	165,286	184,704	Japan 143,807; Hong Kong 40,510.
Sodium and potassium compounds, n.e.s.:			
Caustic soda	15,656	8,445	Hong Kong 7,749; Egypt 514.
Caustic potash	18	59	Jordan 50.
Soda ash	4,100	3,254	Hong Kong 2,815; Indonesia 266.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked	35,586	46,668	Japan 44,541; Hong Kong 1,139.
Worked	18,115	21,937	Indonesia 6,309; Hong Kong 6,120; Japan 4,094.
Dolomite	--	500	All to France.
Gravel and crushed rock	58,159	14,804	Hong Kong 7,203; Japan 5,073.
Limestone	23,353	25,644	Hong Kong 25,194.
Quartz and quartzite	25,666	23,894	Japan 21,662.
Sand, excluding metal-bearing thousand tons	991	1,291	Hong Kong 1,239.
Sulfur:			
Elemental:			
Colloidal	NA	10	All to Sri Lanka.
Other than colloidal	28	1,100	All to United Kingdom.
Sulfuric acid	99	89	Hong Kong 85.
Talc	291,580	355,995	Japan 310,869; United Kingdom 10,738; Hong Kong 10,215.
Other:			
Crude	10,114	20,750	Hong Kong 9,940; Japan 3,793.
Slag, dross, and similar waste	22,846	3,707	Japan 3,000; Hong Kong 705.
Oxides of magnesium, strontium, barium	165	260	United States 108; Canada 72; Japan 40.
Halogens	NA	7	Trinidad and Tobago 5.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	r150	NA	NA.
Carbon black	155	270	Thailand 210; Hong Kong 20; Japan 20.
Coal including briquets:			
Anthracite and bituminous coal thousand tons	797	1,814	Japan 1,407; West Germany 132; France 71.
Briquets of anthracite and bituminous coal	--	509	All to Hong Kong.
Lignite and lignite briquets	1,219	649	All to Japan.
Coke and semicoke	--	12	Pakistan 10.
Peat and peat briquets	--	51	All to United States.
Petroleum:			
Crude and partly refined thousand 42-gallon barrels	r67,758	71,915	Japan 53,498; Thailand 5,691; Brazil 5,059.
Refinery products:			
Gasoline do.	159	1,471	United States 711; Hong Kong 298; Japan 257.
Kerosine do.	1,902	2,914	Hong Kong 2,398; Japan 406.
Distillate fuel oil do.	6,658	11,069	Hong Kong 6,073; Thailand 2,578; Japan 1,665.
Residual fuel oil do.	1,672	2,909	Hong Kong 2,225; Singapore 569.
Lubricants do.	75	137	Hong Kong 97; Indonesia 18; Singapore 16.
Other:			
Mineral jelly and wax do.	r199	186	Pakistan 49; Thailand 44; Singapore 26.
Nonlubricating oils do.	31	137	Thailand 84; Indonesia 48.
Petroleum coke do.	979	1,362	All to Japan.
Bitumen and other residues do.	NA	8	Sudan 7.
Bituminous mixture do.	NA	17	Hong Kong 16.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	1,074	40,575	Japan 39,807; Hong Kong 621.

rRevised. NA Not available.

[1]Owing to the lack of official trade data published by China, this table should not be taken as a complete presentation of this country's mineral exports. These data have been compiled from various sources, which include United Nations information and data published by the partner trade countries.

[2]Data are compiled from official trade statistics of individual trading partners.

[3]May include some platinum or other platinum-group metals.

Table 3.—China: Apparent imports of selected mineral commodities[1 2]

COMMODITY REVIEW

METALS

Aluminum.—China's largest aluminum plant is a 100,000-ton-per-year smelter at Fushun, Liaoning. Smaller plants are believed to be located at Hefei, Anhui; Lanzhou, Gansu; Jiaozuo, Sanmenxia, and Zhengzhou, Henan; Wuhan, Hubei; Changsha, Hunan; Changchun, Jilin; Baotou, Nei Monggol; Nanding and Qingdao, Shandong; Taiyuan, Shanxi; and Kunming, Yunnan. In late 1979, Nippon Light Metal (NLM), Tokyo Bussan Co., Ltd., and C. Itoh and Co., Ltd., received a $150 million order for an aluminum plant and technology. Construction of the 80,000-ton-per-year smelter began on February 1, 1980, at Guiyang, Guizhou. Plant construction was under the technical guidance of NLM and was scheduled for completion in September 1981. The Government was considering a 600,000-ton-per-year plant in Guangxi and had approached the Aluminum Co. of America and Pechiney S.A. to provide technical assistance for this project, which was to cost $866 million.

Proven reserves of bauxite as reported by the Chinese were 1.1 billion tons of contained metal in deposits distributed in the east, southeast, and south-central China. Thirty-one bauxite deposits have been discovered in Shansi, which have an average alumina content of 65%.[17] Bauxite in Xiaoyi County reportedly contains as much as 73% alumina. An opencut mine, with an annual output capacity of 550,000 tons, was being constructed in the county. Bauxite deposits in the Province account for 26% of the total reserves in China.

In August 1980, a preliminary agreement was signed by the China International Trust and Investment Corp. and Minermet S.A. of Milan for the construction of a bauxite calcining plant in Henan Province.[18] Two rotary kilns will calcine bauxite from nearby Zhengzhou. The first kiln was to be delivered at the end of 1981, fired during the second half of 1982, and be in full production by yearend 1982. The second kiln was to go into production toward the end of 1983. Total output of refractory-grade bauxite was to be around 200,000 tons per year from both kilns.

Antimony.—China has large reserves of antimony and traditionally has been ranked as one of the three top world producers, along with the Republic of South Africa and Bolivia. The mines at Xikuangshan in Hunan are the largest producers in China. Antimony is also mined in Guangdong Province. A deposit in Sunyand County, in the Qinling Mountain Range, was reported to have reserves of antimony totaling 17,000 tons. Large antimony finds, which were described as of excellent quality, were reported in Qinghai, Sichuan, Tibet, and Yunnan.

Copper.—Reserves of copper in China were estimated at 50 million tons of contained metal. Notwithstanding, total annual production capacity was only 300,000 tons. Copper capacity of the smelter at Kunming was 45,000 tons per year and was to be expanded to 100,000 tons per year; at Shenyang, 50,000 tons per year; smelters No. 1 and No. 2 at Tongling, 60,000 tons per year (combined); and Zhu-Zhou, 10,000 tons per year.

Because of the increasing need for copper, China negotiated with Fluor Corp. to develop the copper at Dexing, Jiangxi. Sumitomo Metal Mining Co. was to build an integrated copper smelter at Guixi, also in Jiangxi, probably linked to the Dexing development. Work on the Guixi copper smelter reportedly began on July 30, 1980. First-stage construction consists of site preparation, infrastructure, and installation of whole equipment for the 90,000-ton-per-year smelter.[19] The Japanese were also to evaluate the expansion of the Tungshankou Mine near Tayeh, Hubei, and evaluate the Anjing Mine in Anhui. Three porphyry ore bodies were being developed or expanded at Yuangu, Shansi. A porphyry deposit containing 6.4 million tons of copper was reportedly found in eastern Xizong. In addition, there was a nickel-copper open pit prospect in Jinchang; copper-gold from Zhaoye in Shandong; and copper occurrences in Anhui.

Gold and Silver.—The Government reported that gold production in China hit an alltime high in 1981, registering a 14.3% increase over that of 1979.[20] There was increased output in all major gold-producing areas—Hebei, Heilongjiang, Nei Monggol, and Shandong. On March 1, the Government reportedly raised the price of gold purchased by State banks from 3.04 yuan per gram to 13 yuan per gram to encourage production and increase Govern-

ment holdings to finance capital investment for modernization.[21] Moreover, the Ministry of Geology was offering cash rewards for new finds. There were unconfirmed reports of racketeering and purchases by unauthorized persons, and smuggling because gold commanded a higher price on the international market.

Wright Engineers Ltd. of Vancouver was studying the feasibility of opening a gold mine and mill in Shandong to produce 500 tons of ore per day. The San Mateo office of Davy McKee Corp. was preparing a feasibility study to expand the Chio and Hsian Hsen gold mines near Wei Feng, overlooking the Yellow Sea in Shandong. The Davy McKee study included building one or two bullion plants, and a possible solution for the problem of proper backfilling. Less than 5 tons of gold per year could be produced from the Wei Feng mines.

Two gold mines, described as large, were opened and started operations in Shandong—Xincheng Mine and Jiaojia Mine. Three ore-dressing plants, with ore-processing capacities of 500 tons per day, and several small dressing plants were also in operation in the area.

Construction continued on one mine and three ore-dressing plants in Henan to produce 100,000 ounces of gold per year. The largest deposit contained reserves estimated at more than 30 tons of gold. A large placer gold deposit was reported in the valley along the Yuehhe River in Shaanxi. Gold in this deposit was associated with ilmenite and garnet.

A large silver deposit was discovered in Henan. The silver content was reported to be 300 grams per ton of ore. A silver lode with reserves of 250 tons was discovered in the Miyun Mountain area, northeast of Beijing. Chinese silver output is obtained mainly as a byproduct in the processing of lead and tin.

Iron and Steel.—China's total annual capacity to produce steel was around 37 million tons.[22] Anshan and Benqi iron and steel complexes are in the northeast. The integrated facility at Anshan produces about one-fifth of the national output. In north China, there are iron and steel works at Beijing, Tianjin, Tanggu, Taiyuan, and Baotou. In east China, there is Shanghai and Maanshan. In south-central China, there is Wuhan, and in the southwest, Panzhihua. Combined, these iron and steel enterprises account for about 86% of China's annual steel production. With the exception of Shanghai, all the major complexes are located near indigenous supplies of coal and iron ore. Singularly, Shanghai is the only plant with a coastal location.

Additionally, smaller iron and steel plants exist in every Province and autonomous region, with the exception of Xizang. These smaller units have collectively an annual production capacity of 11 million tons of iron; and 6 to 8 million tons of steel and steel products. The Chinese estimated that the combined output capacity of the smaller units could be increased by 3 million tons through innovation and improvement. By increasing efficiency, the major enterprises could also collectively increase annual output by 10 to 12 million tons. On the basis of practical improvements and the inclusion of the projected new capacity for the Baoshan integrated complex (6 million tons per year), China's production potential is 55 to 58 million tons.

During 1979, Chinese planners were assessing and reevaluating the country's modernization program. Industrial productivity and output levels were examined critically. By late 1979, veiled pronouncements were being made on emphasizing readjustment in the four modernization keywords. Finally, the Government announced that agriculture and light industry were to be the prime sectors for development. Inflation and lack of foreign currency presumably caused the retrenchment from developing heavy industry—capital intensive—to light industry. The latter required less monies to produce volume exports to gain earnings. Development of energy resources—coal, petroleum, and natural gas, however, retained high priority.

Iron and steel, and other heavy industry, were to support agriculture and the light industry sectors. Capital investment retrenchment in the iron and steel industry was deemed necessary. Although China had large reserves of iron ore (44 billion tons), this was inadequate in light of the low grade. Among the large iron and steel bases, only about 40% of the capacity could be self-sufficient without relying on ore imports. China imports iron ore principally from Australia and North Korea for blending to upgrade domestic ores. Moreover, the critique continued, many of the smaller iron and steel industries could not be self-sufficient. Domestic mining was characterized as difficult and slow in yielding result and return on investment as well as requiring more efficient technology, better mining

equipment, larger investment capital, and long construction periods.

The technology and equipment for steel rolling was described as quite backward as well as insufficient to meet demand. Additionally, the flexibility to regulate mill varieties was also very limited, and output lines failed to meet product specifications. Rather than increase steel output, steel-rolling output capacity and technology should be improved. Furthermore, metal scrap utilization should be enlarged if possible to lower pig iron consumption, and to reduce energy consumption.

During the past 20 years, total investments in the iron and steel industry reached 53 billion yuan or 8.9% of total domestic investment in capital construction. This was far higher than the 5.4% for light industry. Results were deemed quite poor, particularly during the second 5-year plan, when investments in heavy industry rose to 14%.

Energy consumption by China's iron and steel industry was more than double the average world consumption. Because of the present shortage of coal and electricity, a number of Chinese enterprises were criticized and many could not maintain operations. For the production of 1 ton of steel, China needs about 2.5 tons of standard fuel, compared with 0.8 tons for Japan, 0.9 tons for the Federal Republic of Germany, 1.0 tons for the United States, and 1.2 tons for the U.S.S.R. The utilization of residual heat was very low. Additional criticisms involved irrational selection of sites, no seriated enterprises, but rather discrete competitive enterprises, and increased costs as a result of poor integration.

The Baoshan iron and steel project originally was to be completed in two stages—capacity of 3 million tons to be completed in 1982, and the remaining 3 million tons to be completed in 1985. In November 1980, the Government announced the suspension or delay for implementing construction on the second phase. By yearend, there were doubts whether the first stage of construction was to continue. Work, however, was to continue on the coal-fired powerplant at the site. Baoshan is located outside of Shanghai on the Chiang Jiang River, and access by road is difficult. To secure the foundations, it was necessary to drive 100,000 piles into marshy ground. Bulk material will have to be transported by river to service the site; however, 100,000-ton bulk carriers cannot navigate the channel to Baoshan. A new port was to be built near Ningbo, south of Shanghai, in Zhijiang. At Ningbo, ore would be transferred to smaller vessels for the 130-mile distance to Baoshan where a new receiving port was to be built. Another problem was potential movement of a large sandbar north of the port and potential problems with heavy silting. In light of the shortcomings and the readjustments in the modernization program, China was expected to announce in early 1981 a decision on the viability of the Baoshan project.

Lead and Zinc.—In 1980, the Beijing Central Engineering and Research Institute for Nonferrous Metallurgical Industry reported that the proven reserves for lead ore was 20 million tons of contained lead, and for zinc ore, 53 million tons of contained zinc.[23] The lead and zinc ores were widely distributed and were notably in the southwest, south, central, and northwest. The country's primary refined lead and zinc production capacity were each approximately 250,000 to 300,000 tons per year.[24] The rated annual capacity of the smelter at Shaoguan was 12,000 tons; Shenyang, 50,000 tons; and Zhu-Zhou, 50,000 tons. For the principal zinc smelters, the capacities were Huludao, 60,000 tons; Shaoguan, 30,000 tons; Shenyang, 20,000 tons; and Zhu-Zhou, 100,000 tons.

The largest lead-zinc mine is at Fankou, Guangdong; reserves are estimated at 30 million tons of combined lead-zinc. Metal recovery was to be expanded to 150,000 tons annually by 1981. Current output was around 1,500 tons per day of ore or less. Some lead ore is produced at Shuikoushan in Hunan and at a mine not far from Liencheng in Liaoning. There were a number of small mines in Liaoning, and some lead and zinc is mined at Sidin in Guangxi. A multimetal mine and extraction plant was being constructed at Changpo, Guangxi. In addition to tin and antimony, annual zinc output would be 20,000 tons, and lead, 5,000 tons. There were also plans to develop a mine at Houdong near the Yunnan border and construct a 100,000-ton-per-year zinc refinery.

A high-grade ore discovery was found in Gansu, with proven reserves of 7 million tons of lead-zinc. Announcements of other significant deposits included lead (associated with tin) in Guangxi; zinc deposits in Guangxi, Xizang, and Yunnan; and lead-zinc in Gansu, Sichuan, and Yunnan.

Nickel.—Jiuquan in northern Gansu was the largest nickel-producing center in

China.[25] The nickel mine was described by the Chinese to be the second largest deposit (after Canada) of nickel sulfide in the world. Jinchang began producing electrolytic nickel in 1964; the industrial center has a population of 50,000 which is supported by mining, smelting, power and construction industries, and research facilities for science and technology. In addition to nickel, Jinchang produces gold, silver, copper, and cobalt.

Rare-Earth Minerals.—Based on a Chinese geologic survey completed in the early 1950's, China purportedly had more than one-half of the world's reserves of rare-earth minerals. As noted in *Rare Earths*, a 1978 publication of the Ministry of Metallurgy, China has vast reserves of rare-earth minerals, 98% of which are in Nei Monggol.[26] Large occurrences are found also in more than one-half of China's Provinces and autonomous regions. China also has the world's greatest variety of rare-earth-bearing minerals, some of which are unknown elsewhere; these minerals contain nearly every important rare-earth element.

The Bayan Obo Mine in Nei Monggol is the country's major producer of rare earths. Yttrium is produced, as well as some scandium.[27] The Bayan Obo Mine has been decribed as probably the largest samarium mine in the world.

Southern Jiangxi has rich rare-earth resources. Ganzhou prefecture has seven proven deposits of good-quality rare earths in tracts large enough to be strip mined.

China began producing rare-earth products in 1958 and now manufactures more than 200 products. Chinese exports of rare earths began in 1978.

Tin.—China's total tin metal production in 1980 was reported to be 14,600 tons.[28] The Kokiu smelter (south of Kunming) of the Yunnan Tin Corp. is the largest tin smelter in China, with a rated annual capacity of 20,000 tons. The smelter is about 70 years old and currently produces around 10,000 tons per year of four grades of metal. Local ore is concentrated to 43% tin by several concentrators within a 30-kilometer radius of Kokiu, and then transported by truck to the smelter. There are seven reverberatory furnaces used for smelting and slag treatment. Two modern furnaces are fired with powdered coal burners and the other by burning coal on fixed fire grates.

The Linchou smelter in Guangxi was put into operation in 1953 and currently produces 2,000 tons of metal annually. Incoming tin concentrates assaying 45% to 50% tin come mainly from the Da Chang Mine. The Guangghou smelter in Guangdong and the Ping Gui smelter in Guangxi each produce about 1,000 tons of metal annually. Concentrates used by the Guangzhou smelter are high in sulfur and arsenic and require roasting before charging by two electric furnaces. Crude tin is cast into anode for electrolytic refining. Ping Gui smelter lacks roasting equipment and also uses concentrates which are high in sulfur and arsenic (between 1% and 3% each).

There are two small smelters in Guangxi. Limo smelter produces 400 tons of tin per year from concentrates high in tungsten, tantalum, and columbium. The Kandro smelter, also in Guangxi, and the Hingyang smelter in Hunan, each produce 100 tons of metal per year as a byproduct of other metal refining. Construction of a 6,000-ton-per-year smelter was proposed for Leipin County, Guangxi.

Tin mine output in Yunnan was from six alluvial deposits and five underground mines. Tin mineralization in Liaoning is in skarn deposits. Output in Fuhochung, Guangxi, is from placer deposits. The first stage of construction of a tin-mining/ore-dressing complex in Hichih, Guangxi, was reportedly completed. This placer operation was expected to produce 4,000 tons per year of tin, as well as significant quantities of zinc, lead, antimony, and some precious metals.

Tungsten.—China's most significant tungsten occurrences are wolframite mineralization in the Nan Ling Range in Jianjsi. Mining is currently from Dajishan, Gueimeishan, Pankushan, and Xihuashan. However, scheelite deposits in Hunan were becoming more important. Significant deposits also occur in Guangdong, Fujian, and particularly Guangxi. Because of large reserves, tungsten in Guangxi was designated to be a key project of the metallurgical industry. Presently, output from tungsten mining at Donxing, Lingma, and Mashan was used for export. There have been numerous citations for new tungsten finds in China, notably in Guangxi, Tianji, Xizang, and Yunnan.

Uranium.—Although China has demonstrated nuclear capability, it was believed that present technology was limited in uranium enrichment. Neither the production level nor total reserves are known. However, one Western source placed annual uranium production at 1,000 tons of 0.125% ore.[29]

More than 10 uranium deposits have been developed and mined in northern Guang-

dong.[30] A large uranium concentration occurs in a fracture stratum of Mesozoic granite.[31] The radioactive belts were in the Huagang Crag stratum, Tan Mutao, in the Nan Ling Mountains. The Yenshan granites showed pronounced differentiation in uranium content, and the uranium was gradually enriched from the older to the younger rock. In the most recent fine-grained binary granite, the uranium content is six times higher than in the oldest granite.

Uranium was reportedly found in northeast Liaoning, occurring in geologic formations that date back 2 million years. Technical data from this find were being used to prospect other uranium occurrences in similar formations.[32]

The Marine Resources Chemical Research Institute of Shanghai Normal University was continuing its research in uranium extraction from seawater.[33] The institute was cited in 1970 for extracting 30 grams of uranium from seawater. Later, it won a prize at the 1978 National Scientific and Technology Conference for its achievements in uranium extraction.

Other Metals.—The Ministry of Geology reported that China had a large variety of minerals, as well as sufficient reserves of important minerals, for the country's economic development in the 1980's.[34] However, much of China's reserves were contained in associated mineralization in complex ores, especially in Nei Monggol. There was significant recovery of vanadium from the titaniferous magnetite in Panzhihua; vanadium was also being recovered from coal tailings. Large quantities of vanadium were exported, principally to the United States, and in 1980, 88,184 pounds of vanadium pentoxide was shipped to the United States. China was also producing titanium sponge, and in 1980 both sponge and ingot were available for export. Arsenic, molybdenum, and cobalt were recovered as byproducts in copper-nickel smelting and refining. Magnesium metal is produced electrolytically and by the thermic process; small quantities of beryl were shipped to the United States, and high-purity silicon was available for export. The country is a well-known producer of mercury. China is also known to produce tantalum and columbium. Following the ratification of a raw materials exploration agreement, investigators from the Federal Republic of Germany were to conduct a tantalite-columbite exploration in Hunan. Other metals produced in China included gallium, germanium, indium, lithium, and zirconium.

NONMETALS

Barite.—Notwithstanding the increasing domestic consumption of barite for oil and gas drilling, China's output of barite increased sufficiently enough to permit a larger volume of exports. Apparent exports in 1978 were around 150,000 tons, more than double in 1979, and over 500,000 tons in 1980. Principal destinations were the United States, Japan, Netherlands, and the Federal Republic of Germany. In 1980, United States receipts of Chinese barite were 469,000 tons.

K.C.A. Feoso (KCAF), a joint venture of K.C.A. International and Feoso Oil Ltd., signed an agreement with China National Metals and Minerals Import and Export Corp. in which KCAF would finance, design, and build a $3.5 million barite processing plant in Guangxi.[35] The proposed plant will have two 11-ton-per-hour mills. KCAF agreed to buy 140,000 tons of barite before the plant goes onstream in 1981 and will acquire first purchasing rights for barite produced over a 10-year period. The company will use the barite in its existing oil operations in the United Kingdom, Venezuela, and the Far East, and will sell any surplus on the open market.

Reserves of barite in Hubei were estimated at approximately 20 million tons.[36] The deposits were scattered throughout seven counties.

Cement.—On January 1, 1980, China officially adopted new cement standards which were formulated by the country's National Bureau of Standards.[37] Research and formulation for revising standards for portland cement, blast furnace slag cement, pozzolan cement, and fly-ash cement began in 1972. A total of 75 cement concerns from 24 Provinces, municipalities, and regions participated in the task force.

There were seven principal revisions in the cement standards. First, clinker cement and portland fly-ash cement were added to the existing classification. Second, in slag cement, slag blend was revised to 20% to 70% from 20% to 85%. Either pozzolan or fly ash, or a mixture thereof, was permitted to be substituted for the slag—substitution not to exceed one-third of the total amount of the material added or 15% of the total volume of water. The limits for fly ash in fly-ash cement was to be between 20% and 40%. In both pozzolan and fly-ash cement, up to one-third of the total volume of material blended may be slag. Third, the plastic-mortar method was to replace the

earth-drying method for testing cement strength. Fourth, the amount of magnesia in clinker has been revised not to exceed 6% from 4.5%. When between 5% and 6%, autoclave soundness testing must be conducted. Fifth, sulfur trioxide content in cement was revised from 3% to 3.5%. For slag cement, it was not to exceed 4%. Sixth, in addition to the dry-sieve method, the water-sieve method was added for testing fineness. Seventh, sand from Pingtan in Fujian Province was to be the standard sand. Ignition loss was revised from 0.3% to less than 0.4%; silt-carrying capacity was revised from less than 1.0% to 0.2%; and fineness was to range 0.25 to 0.65 millimeters.

About 66% of the country's annual production capacity was comprised of 3,400 plants which are not part of the unified State distribution system.[38] Most of these plants use vertical kilns. About 120 of the 3,400 plants have annual capacities in excess of 80,000 tons; 280 with 40,000 to 80,000 tons; and the remainder, less than 40,000 tons. About 1,000 plants, run by communes and brigades, have an average annual production capacity of about 2,000 tons. Forty-nine plants comprise the remaining third of China's cement output capacity. During 1980, 25 cement works, with a combined annual capacity of 9.6 million tons, were reported under construction by the Ministry of Building Materials. These included the Baimashan cement works in Anhui Province (500,000 tons per year); Changxing cement works in Zhejiang (450,000 tons per year); Litang cement works in Guangxi (500,000 tons per year); and Qujiang cement works in Sichuan (460,000 tons per year). In addition, there were two whole plant imports from Japan (each with a total annual capacity of 1.5 million tons) and one from Romania (1 million tons). Most plants were to be completed and operational in 1983.

Coal accounts for about 88% of the energy supply for China's cement industry, and oil and natural gas account for the remainder. In order to conserve energy, efforts were being made to develop and use large rotary kilns with cyclone preheaters or precalcining burners.

Fertilizers.—Despite the imports of chemical fertilizer plant installations since 1973, China continued to be a large importer of fertilizers. Nitrogenous fertilizers were imported from Italy, Japan, Morocco, and the United States; phosphatic fertilizers from Morocco, Tunisia, and the United States; and potassium fertilizers from Canada and the Federal Republic of Germany. Domestic production included nearly 10 million tons of nitrogenous fertilizers, 2.3 million tons of phosphatic fertilizers, and only 20,000 tons of potash. The varieties of chemical fertilizers produced include single sulfate of ammonia, urea, ammonium nitrate, ammonium bicarbonate, ammonium chloride, lime, nitrogen, calcium phosphate, and calcium magnesium phosphate. Also, there is small-scale production of ammonium phosphate; potassium nitrate; and potassium, borate, molybdic, and copper microelement fertilizers. Jacobs International of Dublin was negotiating the construction of a large fertilizer plant at Qarhan Lake in Qinghai Province.[39] The dry lake basin covers an area 100 miles long by 40 miles wide and was estimated to have 200 million tons of potassium-rich salt reserves.

Fluorspar.—China has been an important producer and exporter of fluorspar for several decades. The leading producing Provinces were Fujian, Hunan, Liaoning, Shanxi, and Zhijiang, with some from Guangdong and Shangdong. In the 1960's, large tonnages were exported to the U.S.S.R. and Japan, and more recently only to Japan which imported close to 225,000 tons in 1980. Reportedly, only small quantities of very high-grade lump fluorspar were shipped to U.S. producers recently on a trial basis for testing, and in 1980, exports to the United States totaled 24,660 tons. Chinese fluorspar, in lumps or fines, were available in specifications from 70% to 95% minimum calcium fluoride, with maximum silica ranging from 4.5% to 29%.

Gem Stones.—The Ministry of Geology reported that 30 varieties of jade and other precious and semiprecious stones were found during 1980 at 165 locations in 10 Provinces. Preliminary surveys showed that some deposits of sapphires, aquamarine, amethyst, amber, tourmaline, and topaz may be workable. Malachite, agate, and other precious stones were found in a dozen localities in Xinjiang. Sapphire was found in a 300-square-kilometer area in Fujian. In 1979, the Ministry had trained more than 100 people to look for gem stones.[40]

Magnesite.—Most of the magnesite mined in China is from Da Shih-Qiao, Liaoning Province. At Da Shih-Qiao there are two mining sites, a mechanical shaft kiln, and a rotary kiln plant. Mine site No. 1 has an annual capacity of 1 million metric tons,

and mine No. 2 has a capacity of 2 million metric tons, compared to current output of 600,000 to 700,000 tons and 1 million tons, respectively. After blasting, magnesite chunks measuring 4 to 5 feet in size are crushed by a jaw crusher to a 1- to 4-inch size. The ore going for rotary kiln calcining is further crushed in a dry pan to 1 inch and finer. Crushed ore is stored in silos at the mine site, and later moved about 6 miles by railroad to the calcining plant. Upgrading before calcining is unnecessary because of the purity and consistency of the magnesite. Both shaft kilns and rotary kilns at the calcining plant are used for dead-burning the magnesite. There are five steel vertical shaft kilns, each producing 80 tons of dead-burned magnesite per day. In addition, there are two 198-foot-long rotary kilns, with 12-foot internal diameter; each kiln produces 200 tons of dead-burned magnesite per day.[41]

Salt.—Production of salt in China has averaged 17 million tons annually since 1977, but this probably does not include salt production used in the production of industrial chemicals. Liaoning Province is one of the country's major salt producers and has more than 60,000 hectares of saltfields along the Yellow and Boahi Seas. China's largest saltfield is at Tanggu near Tientsin. Other major salt-producing areas were in Shandong, Jiangsu, Guangdong, Sichuan, and Hainan. Most of the country's output was from solar evaporation ponds and evaporites in dry salt lake beds.

The largest salt deposit in China was reported in the Qaidam Basin in Qinghai, with reserves sufficient to satisfy the entire population for 10,000 years.[42] The most famous salt-producing areas in China historically were along the Hai He which runs through Anhui, Henan, and Hunan Provinces.[43] The salterns in Huaibei (translates as the north banks of the Hai He) are protected by a 200-kilometer-long dike. Six chemical plants were built in the area to utilize waste brines of the salt-producing process to recover potassium chloride, magnesium chloride, bromine, anhydrous mirabilite, and magnesium metal. The plants also produce compounds for chemical fertilizers.

In the Ih Ju Meng area of Nei Monggol, two-thirds of the Hanggin Qi salt lakes were being covered over with sand. This deposit, opened to mining in 1951, was estimated to contain 5 million tons of salt and 30 million tons of saltpeter. Because of sand intrusion, annual production of salt decreased from 24,000 tons in 1974 to 4,200 tons in 1977, and was expected to become a wasteland unless prompt and effective measures were used to save the field.[44]

At the saltfields along the shores of the Yellow and Bohai Seas, about 1.2 million cubic meters of bittern was produced annually. In the effort to increase product quality for salt and minimize pollution, mine plants (including the newly expanded Piziwo plant) in the area were processing about 55% of the bittern generated from salt production. Compounds recovered from the bitterns included potassium chloride, magnesium chloride, and bromine.[45]

The Japan Soda Industry Association reported that China could become a reliable supply of salt raw materials and has sufficient capacity to export 1 million tons of salt annually.[46] Moreover, the quality of the salt from Huaibei has improved. However, with the exception of Tianjin, salt exports were hampered by inadequate transportation and harbor facilities. The Chinese felt that these hindrances could be overcome on the condition that a large export market existed and was stable.

Other Nonmetals.—Prior to 1950, only a few nonmetal ores such as pyrites and phosphates were mined. To date, however, China has claimed 80 deposits of sufficient reserves for nonmetal minerals. Aside from magnesite, dolomite, limestone, and salt, the most abundant were alum, arsenic, gypsum, phosphate, and pyrites. Phosphate occurrences were found in almost every Province, with three-fourths of the reserves concentrated in Guizhou, Hubei, Hunan, Sichuan, and Yunnan. The second-order minerals—which were present in important amounts—included barite, bentonite, diatomite, graphite, kaolin, mirabilite, perlite, talc, and zeolite. High-quality asbestos occurs in Shaanxi and Sichuan. Graphite[47] is found in Xinjiang, Heilongjiang, and Shandong, as well as Hubei, Jilin, and Shanxi. Kaolin occurs in Jiangsu, and kyanite in Shanxi. Sodium bentonite occurs in Julin, Xingjiang, and Zhijiang, and a new deposit was found in Sichuan. Seventy percent of China's mica reserves are reportedly in Xinjiang. There are four active mines and three processing plants in the area, with a total output of 1,140 tons. China also has large quantities of high-quality marble. While there are vast resources in dry lakes, potassium production is small. Similarly, diamond mining is small scale. China's

largest boron mine went into operation midyear 1980.[48] The open pit mine, located in Yingkou, Liaoning, has high-grade ore and was expected to have an annual output of 100,000 tons of boron.

MINERAL FUELS

China's principal energy resource was coal which accounts for about 71% of its energy resources. Petroleum and natural gas account for 21%, and hydropower accounts for about 3%. Government planners anticipated little change in the country's energy supply configuration for the next 20 years. Under an energy program, newly formulated coal and hydropower development will occupy a priority position. However, petroleum and natural gas will naturally not be excepted.

China's confirmed hydropower resource was estimated at 677 million kilowatts. Within the next decade or two, the key hydropower developments are to include 10 large-scale projects on and along the upper reaches of the Changjiang and Huanghe, and the Yaliongjiang. Construction in progress during 1980, with a total capacity of 9,200 kilowatts, included plants at Lubuge (600 kilowatts) and Tianshenggiao (800 kilowatts) on the Hongshishe on the upper reaches of the Zhujiang; at Longyangxia (1,500 kilowatts) on the upper reaches of the Huanghe; at Wuqiangxi (1,750 kilowatts) in western Hunan; and at Gezhouba (2,710 kilowatts) on the Changjiang. Those planned to be built during the sixth 5-year plan have a combined capacity of 20,000 kilowatts, and those to be built in the seventh 5-year plan have a combined capacity of 40,000 kilowatts.

Coal-fired thermal plants were to be built by constructing clusters of power stations near coal mining districts. During the next decade or two, 10 thermal power bases were to be constructed in various mining districts, including Helanshan, Helinhe, Lianghui, Liupanshui, Lunan, Mengnan, Shanxi, Shuzhou, Weibei, Yimin, and Yuxi. Projects under construction in 1980 included Datong No. 2 (1,200 kilowatts) and Shuxian (1,350 kilowatts) in Shanxi; Huibei (750 kilowatts) and Huinan (600 kilowatts) in the Lianghui area; Shilicuan (500 kilowatts) in Lunan; Pindingshan (1,800 kilowatts) in Yuxi; and Qingling (800 kilowatts) in Weibei. Preliminary plans for the 1990's include construction projects totaling a capacity of 70,000 kilowatts.

Around 1990, two nuclear powerplants were envisioned in the southeast. Concomitantly, energy conservation and the elimination of energy waste was extremely important to ease fuel and power shortages and to guarantee continued growth of industry.[49]

The use of biogas (methane from organic matter) is extensive throughout rural China. It was estimated that there were 17,000 production brigades in 21 counties in the country which produce methane from biogas digesters. In Sichuan alone, there were 5 million methane-generating ponds, 500 methane gas power stations (total power capacity of 5,500 horsepower), and 300 electric power generating stations using methane gas (total generating capacity of 1,500 kilowatts).[50]

Coal.—China's resources of coal were estimated at 1.5 trillion tons, of which 600 billion tons are confirmed reserves. China ranks third, behind the U.S.S.R. and the United States, in terms of overall resources.

Since 1978, China's annual output has averaged close to 625 million tons. Mining bureaus with an annual production of more than 10 million tons were Datong, Fengfeng, Fushun, Fuxin, Hegang, Huaibei, Jixi, Kailan, Pingdingshan, Xuzhou, and Yangchuan. Annual production at Datong, Fushun, and Fixin is each probably around 20 million tons. Bureaus with an annual output of 5 to 10 million tons were Huainan, Jiaozuo, Shihuijing, Shuangyashan, Tongchuan, Tonghua, Xinwen, Xishan, and Zaozhuang.[51]

Most of the coal mined is north of the Changjiang River in the central, north, and northeast regions of the country. About one-half of the national output is produced in the north and northeast. Shanxi alone accounts for about one-sixth of the total annual production. The central Provinces of Anhui, Henan, Jiangsu, and Shandong contribute about one-fifth of the national production.

China's newly formulated energy program emphasized the equal need for energy development and conservation. Conservation was given a priority position for the immediate future, and coal development was a long-term priority. Under the coal development program, existing mines were to be improved and modernized. Mine output was to increase gradually as a result of mine mechanization. County-operated regional mines were to be consolidated to increase efficiency and productivity, and to be technically improved (these mines produced a total of 278 million tons in 1979).

Currently, improvements were being made in 1,200 local mines.

After discussing a long-term plan for developing Shanxi's coal industry, Government planners decided to turn the Province into a major energy base for the country. Coal occurs in 70% of Shanxi's counties, and the Province's large deposits make up one-third of the Nation's total reserve. One-half of the Province's reserves is high-grade coking coal. The reserves are easily accessible, lying 300 to 400 meters underground. Smaller investment was needed for development and extraction because the coal seams were stable, simple structures. Coal transport from Shanxi to neighboring markets outside the Province is relatively convenient. Moreover, Shanxi already had a number of well-equipped coal bases which supplies about one-sixth of the Nation's production.

A pair of shafts, with a designed capacity of 4 million tons per year, was being built at Datong where 23 million tons of coal was produced in 1979. In addition, old pits at Datong were being mechanized. In April 1980, agreement was reached for six Chinese-Japanese joint coal development projects in Shanxi. These were as follows, with annual capacity given in million tons and coal type: Xiqu (3, feitan and coking); Malan (4, feitan and coking); Zhenchengdi (15, feitan and coking); Jining No. 2 (4, steam); Tunlan (4, coking); and Guishigou (3, coking). Construction on Xiqu and Zhenchengdi was to be completed in 1984; on Malan in 1986; no date was set for the others.

The new Huolinhe coal base on the Horqin grassland in Nei Monggol was designed with technical assistance from the Federal Republic of Germany. When completed in 1985, this coal base will produce 20 million tons per year and will become one of China's largest open pit mines. To be automated, Huolinhe will use advanced, continuous mining technology throughout the production process. Japan was to participate in the construction of a mine at Jungar. Proposed output of steam coal for this mine was 10 to 20 million tons annually and was to be completed in 1990.

Large Chinese-made drills were being used in the construction of seven pairs of shafts at the Huainan-Huaibei coal base in Anhui. The total designed capacity for this expansion was 14 million tons per year. A 3-million-ton-per-year steam coal mine at Panji, Anhui, was to be completed in 1985 with Japanese participation.

Construction was being accelerated at Yanzhou in Shandong, and at the Xuzhou base in Jiangsu on the construction of seven pairs of shafts and four coal dressing plants capable of producing 14.7 million tons of coal per year. Japanese assistance was obtained for developing two mines in Shandong. The steam coal mine at Baodian was designed for a 2-million-ton-per-year output and was to be completed in 1984. A 1.5-million-ton-per-year mine at Jiangzhuang for steam coal and feitan was also to be completed by 1984.

The Liupanshui base in Guizhou was being expanded as a major source of coal supply for the steel industry in southwest China. Its present annual capacity is 10 million tons. Two new mines were under construction, with an annual designed capacity of 1.2 million tons and 0.6 million tons, respectively.

Construction of four pairs of shafts, with a total annual capacity of 12 million tons, was nearing completion at Pingdingshan in Henan and Kailuan in Hebei. A 3-million-ton-per-year mine for brown coal was to be developed with Japanese assistance at Yiminhe in Heilongjiang. The mine (coal output was to be used domestically) was scheduled for completion in 1985.[52 53 54]

Petroleum and Natural Gas.—Development of China's petroleum and natural gas resources was still at an early stage. Within China's territorial limits, there is an area of more than 4.2 million square kilometers of sedimentary rock out of 9.6 million square kilometers of the Chinese land mass and more than 1 million square kilometers of the Chinese Continental Shelf with potential oil-bearing prospects. Prospecting has not been done in most areas, or only insufficient studies have been conducted. In places where prospecting has been completed, some authorities feel drilling has not been done to sufficient depths.

There are more than 160 oilfields under exploitation. In 1979, China's crude oil output ranked fifth in the world. Natural gas output amounted to 14.5 billion cubic meters. Production levels for petroleum and natural gas in 1980-81 were to remain substantially at the 1979 level.

Most land prospecting focused on deep wells in eastern China. However, there were plans to intensify oil drilling in the west. Exploratory drilling in the sedimentary pans in Tsaidam, Tarim, Zhunkan, and in the Shaanxi-Gansu-Ningxia area indicated fair prospect for oils.

Offshore developments had more promising prospects. During drilling in the Pearl River Basin on the Continental Shelf off the South China Sea, No. 7 well brought in crude oil. At the South China Sea-Northern Continental Shelf-Fossil Stratum Conference convened in Guangzhou in early 1980, Chinese experts agreed that the South China Sea had potential for oil development.

Between May and July of 1979, China signed agreements with 16 petroleum companies in the United States, the United Kingdom, France, and Italy for seismic surveys. These surveys were contained in eight areas along a line extending 100,000 kilometers in the South China Sea and the southern Yellow Sea, encompassing a total area of 110,000 square kilometers. The surveys were completed in July 1980, and the concerned parties were interpreting and evaluating the seismic data. The Chinese were optimistic about developmental prospects in the area.

There were reports that 20 wells were drilled in the offshore area close to Zhanjiang and that there were gas or oil showings. Oil and natural gas were also believed to have been found in a strike in the Gulf of Tonkin. Other reports concerned large oil and gas finds north of the Yangzi in eastern Jiangsu—26 wells drilled in the southwest Qaidan Basin in Qinghai, 20 of which were reported to have showed oil and gas; a gasfield near Sanshiu in Guangdong; and continued exploration in Ta Li Mu Basin in Zinjiang and gasfields in eastern Sichuan.

Two fields were in the developmental stages. One was along the lower reaches of the Yellow River which produced low sulfur crude, and the other is the Liaohe Field in northeast Liaoning. The Liaohe Field has eight oil-producing districts, with 1,800 wells and 160 stations for collecting, transporting, and measuring oil and gas. Liaohe produces 5 million tons of crude oil and 1.7 billion cubic meters of gas annually.

By mid-1980, China was concluding exploration and development contracts with foreign partners. The first was with Japan-China Oil Development Corp., a subsidiary of the State-owned Japan National Oil Corp. The area included in this contract covered about 25,000 square kilometers of the western and southern parts of Bohai Gulf and may include some onshore area. The other partner was the Société Nationale Elf Aquitaine, which was granted a 9,000-square-kilometer area in the central and eastern section of Bohai; Compagnie Francaise de Pétroles was granted a 10,000-square-kilometer area in Beibu Gulf.[55]

The Mineral Industry of Colombia

By Doris M. Hyde[1]

Colombia experienced somewhat slower economic growth in 1980 than in previous years. The gross national product (GNP), estimated at $32.2 billion[2] at current prices, grew in real terms by 4.5% in 1980 compared with a 5.4% growth rate in 1979. The rate of inflation fell from almost 29% in 1979 to below 26% in 1980. The peso devaluation increased to about 16% in 1980, reducing somewhat its cumulative overvaluation, as well as helping to maintain the competitiveness of minor and nontraditional exports.

The mineral industry remained dominated by the production of mineral fuels and the precious metals, gold and platinum. Natural gas production increased in 1980, with production averaging an estimated 7% above that of 1979. The late 1979 completion of a pipeline linking Texaco Oil Co.'s offshore Chichupa Field and the main line to Cartagena contributed to the increased production and consumption of natural gas. Petroleum production showed a slight gain in 1980, and although it is probably too soon to presume a complete reversal of Colombia's gradual production decline, it at least indicates that the persistent downtrend has been stemmed. Gold production in 1980 was estimated to have increased 87% over that of 1979. As a result, Colombia has regained its rank as the second largest gold producer in Latin America after having dropped to the third position when full-scale gold mining began in the Dominican Republic in 1976.

With respect to major mineral development plans, during 1980 construction was under way at the Cerro Matoso nickel mining project, and a final agreement for the El Cerrejón coal deposit was concluded and construction of infrastructure at the mining site began. Through the Empresa Colombiana de Petróleos (ECOPETROL), Colombia continued its intense efforts to increase crude oil and natural gas production and reserves. Additional association contracts with foreign oil companies were signed, and exploration results have been promising. In 1980, domestic crude oil production was estimated to have provided for about 83% of national demand.

Mining as a whole represented only 1% of the GNP, but the Plan of National Integration (PIN) set the development of energy and mining among the major national goals. PIN advocated a program of public investment in selected high-priority sectors and the provision of direct incentives to encourage private and foreign investment in these areas. A portion of the public investment visualized by PIN was to come from foreign loans. National budget investments in mining and energy increased by 240% between 1978 and 1980, and foreign investment in mining (not including petroleum) increased from $53.7 million in the 1975-77 period to almost $1.4 billion in the 1978-80 period.

The demand for electric energy has been increasing at a rate of over 10% per year. Colombia's Caribbean region, where power is generated by thermal units, was unaffected by the electricity shortages caused by exceptionally light rainfall in the rest of the country which is dependent on hydroelectric generation. During 1980, only residential consumers in the interior were subjected to electricity cutoffs, but industrial users were asked to voluntarily restrict consumption by 10%. Government officials have suggested that the 1980 restrictions may not be sufficient for 1981. By mid-1982, a transmission line linking the national

power network to the Caribbean coast, plus a 15% increase in electric power generation, will help reduce power shortages. Power projects involving over 2,200 megawatts are under construction, with completion planned by 1988.

In December 1979, Nicaragua extended its maritime limit to 200 miles and rejected the 1928 and 1972 agreements which assigned to Colombia ownership of some islands lying within the new maritime jurisidiction. Nicaragua claimed ownership of the Colombian islands of San Andrés and Providencia, and the cays of Roncador, Quita Sueño, and Serrana. The decree establishing the maritime limit specifically mentioned Nicaraguan ownership of natural resources within the zone. Nicaragua indicated it would pursue its claim by legal means. In October 1980, Nicaragua published a new map which showed the disputed islands and cays as part of Nicaraguan territory.

Another jurisdictional dispute has peripheral mineral resource implications. The question of the exact maritime boundary between Colombia and Venezuela has been under negotiation for over a decade. In October 1980, a draft agreement was published by the two countries, but it evoked internal opposition on both sides and formal signing was delayed. The main issues have been Venezuela's claim that the Gulf of Venezuela is an "internal sea" over which it should have absolute sovereignty, and Colombia's insistence that the Los Monjes Islands are the territory of Colombia. In the proposed agreement, Colombia cedes its right to the Los Monjes, and Venezuela recognizes limited Colombian rights in the Gulf. Among other things, the draft deals with the issue of sharing and/or ownership of hydrocarbons. Although there has been no drilling in the Gulf, it is believed that the area contains considerable potential for crude oil and natural gas.

Colombia has several mineral projects in various stages of exploration (copper, molybdenum, uranium, bauxite), feasibility study (phosphate), or development (coal, nickel), which by the mid-1980's should visibly impact on the mining sector's contribution to the economy.

PRODUCTION

Colombia's production of mineral commodities was estimated to have remained fairly stable in 1980, as shown in table 1.

In 1980, precious-metal production increased significantly and was estimated to have ended the year with volumes of gold, in particular, showing a significant 87% gain over the 1979 production level. Gains in silver (52%) and platinum (11%) were more modest. In 1980, production began from Colombia's first asbestos mine.

After a marked decline in 1979, steel production in 1980 was estimated to have increased 12%, surpassing the level produced in 1978. Of the mineral fuels, coal and natural gas were estimated to have shown some increases over 1979 production. The production of crude oil was also slightly higher than in 1979, an encouraging factor in that the steady decline experienced during the last decade may be leveling off.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Oct. 21, 1981.

[2]In addition to the commodities listed, coal briquets are also produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

[3]Revised to zero.

[4]Reported figure.

[5]U.S. imports, largely moralla and gangue, but also including some gem-quality emerald.

[6]Data represent total Colombian exports.

[7]Includes "industrial benzine" (white gasoline).

TRADE

Minerals and mineral-related commodities continued to occupy a minor position in Colombia's overall international trade. Mineral exports were not expected to show a significant growth until the Cerro Matoso nickel project comes onstream in 1982 and the El Cerrejón coal project starts up about 1986.

Excluding coffee, which accounted for about 57% of the $3.4 billion value of 1979 exports, mineral-related exports and petroleum products each contributed about 10% to the value of exports.

In 1979, crude oil and refined product imports were valued at $571 million, representing a 135% increase over the 1978 cost. The volume of imported crude oil in 1979 was approximately 9 million barrels, a 2% increase over that of 1978. Refined petroleum product volumes increased to 10.3 million barrels, a 33% increase over that of 1978. Petroleum imports represented 12% of total registered import costs in 1979. In 1980, about 7.3 million barrels of crude oil were imported at a cost of $220 million, while 13 million barrels of refined products were imported at a cost of $491 million.

For 1980, it was estimated that all petroleum purchases represented about 13% of the estimated $5.4 billion total import cost and that fuel oil sales represented 17% of registered exports of goods other than coffee.

COMMODITY REVIEW

METALS

Bauxite.—Exploration work continued on the Morales-Cajibío bauxite deposits located in Cauca Department and the San Antonio deposits in Valle de Cauca Department. Reserves are estimated to be about 375 million tons grading 40% Al_2O_3. If warranted by exploration results and ongoing density and chemical studies being conducted in the United States and Belgium, a $1.8 million feasibility study may be conducted. The possibility of a 240,000-ton-per-year aluminum plant estimated to cost $1 billion has been proposed.

Copper.—The Government continued its studies on several copper deposits. Exploration of the Alisales deposit in Nariño Department continued, and consideration was being given to a possible joint development project with Texas Petroleum Co., which originally discovered the prospect in 1968. Ore reserves at Alisales were estimated at 400,000 tons, averaging 3% to 10% copper, along with some molybdenum.

The Mocoa copper-molybdenum deposits in the Department of Putumayo near the Ecuadorian border were under development study by the Institute of Geological and Mineral Investigations (INGEOMINAS) in a joint venture with the United Nations Development Program. INGEOMINAS has reportedly invested $2 million in this study, which is expected to be completed in mid-1981. Ore reserves were estimated at about 100 million tons, although earlier reports indicated a considerably higher tonnage.

Colombia has so far committed almost $2 million toward the exploration of the Los Pantanos-Pegadorcito copper-molybdenum deposits in the Department of Antioquia. Potential ore reserves are estimated at 420 million tons. Tentative estimates indicate that with an investment of $1 billion, production could amount to 120,000 tons of copper per year for a period of 20 years.

Gold.—According to preliminary estimates, gold production in 1980 rose 87% above the 1979 level. Colombia now ranks second only to Brazil in Latin American gold production. Over 80% of production comes from one mine and many alluvial operations in Antioquia Department.

In November 1980, direct administration of the gold mines in Marmato (Department of Caldas), located about 300 kilometers northeast of Bogotá, was assigned to State-owned Empresa Colombiana de Minas (ECOMINAS) and the mines were declared a natural resource. The area is divided into

two zones. In the uppermost, Zone A, approximately $120,000 was invested during 1980, with an additional $200,000 investment planned for 1981. By the end of 1980, Zone A had been determined to contain about 6 million tons of ore averaging 0.225 ounce to 0.322 ounce of gold per ton. Reserves are thought to be sufficient to justify the construction of a $5 million plant which could process 250 tons of ore per day. Zone B, the lowermost zone, contains estimated potential reserves of 3 million tons, which average the same gold content as Zone A. The development of Zone B would probably require an additional $5 million investment.

Iron Ore.—In May 1980, after over 20 years of contested ownership, a presidential decree assigned ownership of the Belencito iron ore deposits exploited by Acerías Paz del Río, S.A. (APR), in Boyacá Department to ECOMINAS. The decree also decided ownership of the coal deposits mined by APR to the State-owned company Carbones de Colombia (CARBOCOL). Since its founding in the early 1950's, APR's ownership has changed from less than 1% private to over 96% private. The Government maintained that this shift in company ownership, from majority Government-owned to majority privately owned, also did not change the legal position of the mineral resources used by the company from that of publicly owned resources.

The decree reaffirmed State ownership of the minerals, but did not affect a company's right to exploit them by means of permits, licenses, or concession contracts. APR was given preferential rights to mine the deposits. Royalty payments were to be made to the Instituto de Desarrollo del Departamento de Boyacá (IDEBOY), the Boyacá departmental development agency. APR estimated these iron ore reserves in Boyacá Department to be 73 million tons.

In Córdoba Department, a study was under way on the iron deposits at Cerro Matoso where the nickel and iron ores overlay one another. Metallurgical and concentration tests were being conducted in Colombia, the United States, and Belgium to determine whether a feasibility study is warranted. Present estimates of iron ore reserves at Cerro Matoso are about 15.7 million tons averaging 46% iron. It was reported that any feasibility study undertaken would include the possible installation of a sponge iron reduction plant to take advantage of natural gas to be transported to the area.

Nickel.—If construction does not fall behind schedule, Cerro Matoso, S.A., planned to initiate its first ferronickel shipments to Billiton Metals and Ores International Ltd. by mid-1982 from the plant at Montelibano to the Port of Cartegena.

Energy needs are to be supplied from the San Carlos hydroelectric project in Antioquia Department, from the Carbones de Caribe's new coal mine located 30 miles from the mine, and from natural gas piped from the Jobo Tablón Fields in the Guajira Peninsula. The vital importance of cheap domestic energy can be demonstrated by the financial problems Falconbridge Dominicana S.A. has endured in the Dominican Republic where the ferronickel company is entirely dependent on imported oil and was forced to close down for an extended period in 1980 because of the combined effects of high operating costs and depressed world markets.

When operating at the planned full plant capacity of about 60,000 tons of ferronickel, yielding 50 million pounds of nickel per year, Cerro Matoso would account for approximately 35% of present Latin American nickel capacity, excluding Cuba, and perhaps 3% of total world output. Colombia's ferronickel production in 1982 was projected at about 20,000 tons. Full production may be attainable in 1985.

The 25-year mining concession granted by the Government provided for an 8% royalty payable in kind which, at nickel prices averaging $3.00 per pound on the free market, could yield the Government $12 million in revenue, as well as add $150 million to Colombia's foreign exchange earnings.

NONMETALS

Asbestos.—In 1980, Minera Las Brisas, S.A., opened Colombia's first asbestos mine in Antioquia Department. Full capacity of the mine was planned to be 20,000 tons per year of No. 4 and No. 6 fiber. The reserves have been estimated as sufficient to yield almost 390,000 tons of asbestos fiber over the life of mine.

Cement.—Colombia's 1980 installed portland cement production capacity from 16 plants was 5.5 million tons. New construction in the central region and other expansion projects are expected to increase total capacity to 6.3 million tons by yearend 1981 and to 6.8 million tons by 1983. Domestic demand has been about 3 million tons per

year which allows a substantial amount for export markets.

Regional cement shortages have occurred, particularly in the central area near Bogotá. Two new cement plants are planned for the central region. One, located at Paz del Río, will utilize blast furnace slag from the nearby steel complex, and is scheduled to come onstream by yearend 1981. This plant will further diversify from Colombia's primarily gray portland cement production because the slag cement is suited for use in heavy construction work, such as dams and highways. Output from four asbestos cement plants at Bogotá, Cali, and Barranquilla are primarily exported.

Emeralds.—Royalty payments from emerald mining continued to provide ECOMINAS with assured cash income for use in other mineral development projects. The main mines located at Muzo, Cozcuez, and Peñas Blancas in Boyacá Department accounted for the major share of official production.

By preliminary estimates, 1980 legal emerald exports were valued at $64.6 million. Japan, the United States, and Taiwan accounted for about 92% of these exports. By some estimates, the legal export of emeralds actually represents only 40% of the real amount exported, the remainder is smuggled out of the country illegally.

It was reported that the private companies, which pay fixed amounts plus royalty to the Government for their mining concessions, consider these amounts too high in relation to actual production, and they have suggested a renegotiation of terms.

Fertilizer Materials.—*Phosphate Rock.*—The preliminary feasibility study initiated by ECOMINAS in late 1979 on the Pesca (Boyacá Department) and Sardinata (Notre de Santander Department) phosphate rock reserves was broadened in 1980 and scheduled for completion in late 1982. At an additional estimated cost of $3.8 million, the expanded study will include reserve evaluations, as well as suitable mining, processing, and marketing alternatives. The total cost of the study is now estimated at $6.9 million. Tentative estimates assign Pesca reserves of over 29 million tons containing 20% P_2O_5, while Sardinata may have about 9 million tons of reserves containing 31% P_2O_5. If the preliminary study is favorable, further studies could also involve the feasibility of constructing downstream processing plants.

MINERAL FUELS

Colombia derives 54% of its total energy needs from petroleum, 22% from coal, less than 17% from natural gas, and less than 8% from hydroelectricity. There have been some regional energy shortages because of droughts experienced in areas dependent upon hydroelectric power sources. Especially affected have been the industrialized cities of the interior region. New thermal electric plants in the Caribbean coastal area are being adapted for the use of both natural gas and coal as fuel sources. By 1982, Colombia plans to complete transmission lines linking the coastal area and the industrial area of the interior. If construction schedules are maintained, power projects, mostly hydroelectric, will add over 2,200 megawatts to capacity by 1988. Planning has been based on a 80-20 ratio of hydropower to thermal electric plants.

Coal.—The disputed ownership of the coal deposits mined by APR in Boyacá Department was settled in May 1980 when a presidential decree assigned limited ownership to CARBOCOL. The disposition did not restrict mining by private companies, with APR receiving priority mining contract rights, but it did reassert that the coal is a national resource with undisputed State ownership. APR has estimated the volume of coal involved in the dispute amounts to about 58 million tons. APR will pay a royalty to IDEBOY, the Boyacá Departmental Development Agency.

In September 1980, International Colombia Resources Corp. (INTERCOR), an Exxon Corp. subsidiary, and CARBOCOL, signed a contract to proceed with the development of the northern zone (Block B) of the El Cerrejón coal deposits located in the south-central area of the Guajira Peninsula. The north block development area contains an estimated 1.6 billion tons of coal reserves of the total 3.5 billion tons in the El Cerrejón area.

Originally projected to cost $1 billion, this amount has now escalated to $3 billion. Development includes two opencast mines with excavation down to 200 meters, a new port and other infrastructure at Bahía de Portete on the Caribbean Sea, a 150-kilometer railroad linking the mining area and the port, and a complete town with necessary social infrastructure. The construction phase of the project could employ 8,000 workers, with the operating phase decreasing direct employment to 4,000 or

5,000. However, with auxiliary employment opportunities, the project could provide as many as 15,000 jobs.

The joint agreement extends for 23 years, starting with the first production from the mine, expected to occur in 1986. INTERCOR agreed to pay CARBOCOL a royalty of 15% of its 50% share of production at the mine-head, either in cash or kind. The percent royalty paid is scheduled to increase as production exceeds projected levels. After taxes, royalty, and other payments, INTERCOR's net share of profits are expected to be about 17%. All production has been targeted for export to Europe and the Far East.

Production at El Cerrejón is expected to reach 15 million tons per year during its first phase, but if demand warrants, this could be expanded to 25 million tons per year by 1990. In any case, only about one-fourth of the total Block B reserves are expected to be extracted by the expiration date of the contract.

Available analyses show that the El Cerrejón deposit is a low-sulfur steam coal averaging about 0.5% sulfur content, 4% ash content, 38% to 42% volatile matter, 54% to 56% fixed carbon, and has a calorific value of 13,500 Btu's per pound.

CARBOCOL reportedly has begun preparations to mine the 10,000-hectare Central Block of the El Cerrejón deposits. A partner has not yet been selected for this project, but mining is expected to commence in 1982 at a rate of about 300,000 tons per year, increasing to 1.5 million tons per year by 1984. The major part of output is scheduled to be used by a new steam generating plant to be constructed at the mouth of the Cañas River on the Guajira coast. The remainder of production may be used by various cement and other industrial users.

At Puerto Libertada in Córdoba Department, a Cementos del Caribe subsidiary, Carbones del Caribe S.A., was developing a steam prospect for use at the Cerro Matoso ferronickel project and coastal cement plants. Other coal development projects were under way near La Loma and La Jagua in central César Department, located to the south of La Guajira Department.

Brazil, Romania, Spain, and Colombia have been conducting studies on the development of metallurgical coal in three areas near Bogotá in Cundinamarca Department.

There are some small-scale gasification projects in Medellín undertaken by local industries, but given the abundance of available natural gas, serious large-scale projects do not enter into Government's near- or medium-term planning. Coal liquefaction is also not comtemplated for this century unless crude oil production falls short of expectations and import costs and supply factors present a compelling need.

Present and projected uses of coal by type have been estimated in the PIN national development plan and are shown in the following table, in million metric tons:

Type and use	1979	1980	1981	1985	1990
Thermal coal:					
Power generation	.7	.8	1.0	4.0	6.5
Cement production	.6	.6	.8	1.2	1.5
Other users	2.6	2.8	3.3	4.3	5.3
Export potential	--	--	--	1.0	16.1
Total	3.9	4.2	5.1	10.5	29.4
Metallurgical coal:					
Steel industry	.9	.9	.9	1.2	1.9
Exports	.3	.4	.5	.5	1.0
Total metallurgical	1.2	1.3	1.4	1.7	2.9
Total demand	5.1	5.5	6.5	12.2	32.3

Natural Gas.—There were several encouraging gas discoveries during 1980. In January, Mobile Oil Co. made a discovery at Las Estrellas off the Guajira Peninsula which apparently indicated a small but significant field. In February, International Petroleum announced that a test in Sucre Department indicated the presence of about 10 million barrels of oil and had a producing potential of as much as 60 million cubic feet of natural gas per day. Further testing was planned.

Also in the Guajira area, south of Ríohacha, Texas Petroleum Co. and its joint partner ECOPETROL revealed a gas strike which tested gas at two intervals, both greater than 8,000 feet in depth.

Colombia has known gas reserves of about 4.7 trillion cubic feet, of which about 76% are located at onshore and offshore locations of the Guajira Peninsula, mostly in the Chuchupa, Ríohacha, and Ballenas Fields. The Middle Magdalena Valley contains another 15% of natural gas reserves, and the remainder is in the Putumayo and the Upper and Lower Magdalena Basins.

The productive capacity of the Guajira

Fields is about 200 million cubic feet per day, but production had traditionally been about one-half of that amount due to limited demand and transportation facilities. The completion of a pipeline linking the offshore Chuchupa Field and the main line to Cartagena was mainly responsible for the increased production in 1980. It has been estimated that capacity could be doubled to 400 million cubic feet per day from the Guajira Peninsula.

Even though a 1979 study was not entirely favorable, a liquefied natural gas project in cooperation with El Paso Natural Gas Co. remained under consideration to utilize the Guajiro natural gas for export to the United States. A petrochemical complex is also under consideration which would utilize about 60 million cubic feet per day of Guajiro natural gas to produce 430,000 tons per year of urea.

Colombia's current and projected uses for recovered natural gas, in millions of cubic feet per day, is shown below:

Use	1980	1981	1982
Power generation	149	160	161
Cement production	28	29	30
Other industrial	130	138	161
Other users	1	2	2
Total	308	329	354

Petroleum.—Production of crude petroleum in 1979 averaged about 124,100 barrels per day, compared with the 1978 average of about 130,800 barrels per day. Petroleum production rose slightly in 1980 to an estimated 125,600 barrels per day. In 1979, output came from 30 fields and the largest of these, Mares, averaged 24,900 barrels per day, a slight increase over 1978 production. In the Orito Field, 1979 production averaged 19,800 barrels per day, a 13% decline from that of 1978. In 1980, production from this field averaged 17,400 barrels per day. In 1979, petroleum was produced by ECOPETROL directly (20%), by concessionaires (67%), and through ECOPETROL association contracts (13%).

Table 4.—Colombia: Crude oil production, by company

(Thousand 42-gallon barrels)

Company	1977	1978	1979	1980	Change percent

[1]Operated the Orito Field-Putumayo, owned 50% by Texaco and 50% by Petrolera del Río Panamá S.A. (Petrorio). Petrorio in turn is owned 50% by ECOPETROL and 50% by Cayman International Corp. Texaco sold its share in late 1979.

[2]Exxon Corp. affiliate.

[3]Purchased in early 1980 from Petróleos Colombo Brasileros S.A. Houston Oil Colombiana S.A. is a subsidiary of Houston Oil International, Inc., which is owned by Tenneco, Inc.

[4]Cities Service, ECOPETROL, Amoco, and ARCO each own 25%.

[5]Condensate.

In May 1980, the Government changed its pricing policy on "old" oil from developed sources and agreed to increase the amount it was paying oil companies for the oil. It was anticipated that this action would result in a greater production from some concession fields.

Domestic consumption of petroleum products and natural gas equivalents rose 4% in 1979 and averaged 182,000 barrels per day. In 1980, consumption increased 2.8% and averaged 187,000 barrels per day. In both years over 38% of domestic use was in the form of motor gasoline. Between December 1978 and October 1980, the Government has increased gasoline prices by 175% and transportation fares by 130%. ECOPETROL continued to subsidize the retail sale of motor gasoline and diesel fuel. In October 1980, both regular gasoline and diesel fuel cost about $0.90 per gallon. It was estimated that gasoline would need to be increased to $1.10 per gallon to bring it into line with cost factors.

It has been estimated that only about 25% of Colombia's sedimentary basins have undergone any exploration, and investor interest has been high. Colombia encourages participation contracts between ECOPETROL and foreign investors. These contracts typically specify that the associated company will bear the exploration risk, while ECOPETROL shares 50% of all development and operating expenses and receives 60% of production (which includes a 20% royalty). In 1980, ECOPETROL signed about 18 association contracts with 9 companies. At the end of 1980, there were 29 companies holding 41 association contracts.

As exploration activity increased, there were some promising discoveries during 1980 in the Magdalena Valley region, in the eastern Llanos region near the Venezuelan border, and in the northern border area near Saravena. The size of new discoveries could not be estimated on the basis of the wildcat successes, and further exploration was underway to better define the fields.

Wells in the Llanos region have penetrated over 20,000 feet, and discoveries have been mostly heavy crudes for which Colombia does not have adequate processing facilities at this time.

ECOPETROL postponed the planned construction of a 40,000-barrel-per-day refinery in the Llanos Orientales region. The company plans, however, to build a pipeline from this area to the Barrancabermeja refinery. An expansion of the Barrancabermeja refinery was completed in mid-1980, and Colombia's total refining capacity was 196,000 barrels per day.

Uranium.—The Italian State oil company Azienda Generale Italiani Petroli S.p.A. (AGIP) has acquired a 40% interest in the French company Minatome S.A., which has been conducting uranium exploration in Colombia under contract with the Instituto de Asuntos Nucleares de Colombia through the State entity Empresa Colombiana de Uranio (COLURANIO). COLURANIO's exploration contracts with MINATOME includes the eastern slope of the Eastern Range between Cundinamarca and Huila Departments. AGIP will do exploratory drilling in Berlin, Department of Caldas. Compagnie Générale des Matières Nucléaires of France and the Empresa National del Uranio S.A. (ENUSA) of Spain are working in areas in Boyacá, Santander, Meta, Guainía, and Vaupés Departments. Working alone, COLURANIO has initiated exploration in Bolívar, Córdoba, and Santander Departments. Positive indications of uranium were reported in the Department of Guainía where ENUSA's feasibility study should be completed in 1986.

[2]Where necessary, values have been converted from Colombian pesos (Col$) to U.S. dollars at the average exchange rate for December 1979 of Col$44.00=US$1.00. In 1980, the Colombian peso fell from Col$44.41=US$1.00 in January to Col$50.60=US$1.00 in December.

The Mineral Industry of Cyprus

By E. Shekarchi [1]

The Island of Cyprus remained divided into a northern sector controlled by the Federated Turkish Cypriots and a southern sector controlled by the Government of Cyprus. The information in this chapter reflects primarily the southern sector since no information was available on the northern sector.

The economy of Cyprus continued to surge forward during 1980. The mineral industry contributed approximately 13% of the gross domestic product valued at $1.5 billion.[2] The Geological Survey Department (GSD) was preoccupied with the question of the future of mineral resources in Cyprus, especially after the substantial decrease of cupriferous pyrite reserves. For this reason the GSD, in parallel with its efforts to locate new massive sulfide deposits, initiated a detailed exploration program to investigate the economic potential of industrial nonmetallic minerals such as bentonite clays suitable for ceramics and bricks, limestone, umber, and strontium minerals. The Senior Mines Office, in its annual report, summarized the exploration activities of Cyprus by stating that 62 licenses were issued covering copper, chromite, clays, silicon sands, and gypsum.

In 1980, there were some amendments both to the mines and quarries regulations of 1958 and to the explosive substance regulations of 1940, whereby the rent and fee was to be increased to conform to the present conditions.

The Cyprus Electricity Authority was undertaking a feasibility study into the practicability of using coal in the second phase of the Dhekelia power station, which was to be built in mid-1985. The two 60-megawatt units built in early 1980 were oil-fired. The study was to determine whether dual-source fueling arrangements would be possible. The study was a prerequisite of the $16 million to be provided by the World Bank.

The Bureau de Recherches Géologiques et Minières (BRGM) of France carried out a considerable amount of exploration under the mining leases of Kampia Mines Ltd. as a result of an agreement between the two organizations. During the year, BRGM's activity included basic geological mapping and drilling of 1,100 meters in 14 holes. No results of these activities were available by the yearend.

PRODUCTION AND TRADE

The pattern of mineral output in Cyprus in 1980 was generally similar to that of 1979. Production of chromite, asbestos, and clay minerals remained similar to those of previous years, whereas the output of cement showed a considerable increase. Mineral production statistics are given in table 1.

Cyprus' mineral trade imbalance, which was double that of 1979, continued into 1980 because of low prices for copper and higher prices for petroleum in the world market. Major mineral export earners were cement, asbestos, copper concentrates, chromite, and mineral pigments. The United Kingdom remained the major trading partner, whereas the European Economic Community was the largest supplier of imports.

COMMODITY REVIEW

METALS

Chromite.—Production of chromite by Hellenic Mining Co. Ltd., the sole producer, was from two mines; Kannoures chrome mine and Kokkinorotsos Mine, which were located in the Troodos Mountains. Shipments of hard lumpy chrome ore amounted to about 6,000 tons, and of chrome concentrates approximately 16,000 tons, which represented 80% of the rated capacity of the concentrator located at Aylos Nikolaos. The recipients of Cyprus chromite during the year were Spain, Austria, Poland, and Italy. Cyprus produced both refractory-grade and metallurgical-grade ore during the year. Italy received most of the refractory-grade shipments. Although chromite mine capacity was given at 40,000 tons per year, Cyprus was unable to achieve this production level because of limited concentrator capacity and other infrastructure problems such as transportation on the island.

NONMETALS

Asbestos.—Cyprus Asbestos Mines Ltd. remained the sole asbestos producer in Cyprus during 1980. Combined production of short- and long-fiber asbestos was about 34,000 tons, of which about 20,000 tons were long-fiber. Approximately 95% of production was exported to Western European nations, leading with Denmark, Greece, Italy, and Belgium. Construction of a new plant at Limassol remained at the planning stage because of difficulties with financial arrangements. Total work force in the asbestos industry was about 500 people during 1980, of which approximately 100 were paid monthly and the remaining were paid daily.

Cement.—Cyprus produced over 1.2 million tons of both cement and clinker in 1980. This output was nearly the full rated capacity of Vassiliko Cement Works Ltd., which used 990,000 tons of limestone, 1,600 tons of marl, 280,000 tons of clay, and about 25,000 tons of gypsum. Approximately 380 people were employed in cement manufacturing, of which 280 were paid daily and the remaining were monthly employees.

Clays.—Cyprus produced a variety of clays in 1980, some for domestic consumption and others for export to overseas markets. Bendex Minerals Co. Ltd. produced about 5,000 tons of bentonite, which was processed and activated in the company's plant for export. Because of the strong vitalization of the building industry on the island, there was a shortage of some quarried materials including bricks, sand and gravel, and aggregates. To overcome the shortage, several new quarries came into production to replace the production lost since the Turkish occupation of the north in 1974.

Fertilizer Material.—Cyprus continued to be an importer of fertilizer materials during 1980. The planned Hellenic Chemical Industries Ltd.'s new fertilizer plant continued to be under construction and was expected to go into operation in 1982. Annual production capacity of the facility will be 180,000 tons of sulfuric acid, 150,000 tons of complex fertilizer material, and 40,000 tons of phosphoric acid. Imports of fertilizer material to Cyprus exceeded $10 million during 1980.

Gypsum.—Total gypsum production was about 100,000 tons, shared among United Gypsum Ltd., Peletico Ltd., and Limassol Chemical Products Ltd. There was also some production by small private producers that was difficult to estimate because of seasonal work and unreported production figures. United Gypsum Ltd. operated Psematismenos quarry, which had a mining capacity of 40,000 tons; Peletico Ltd. operated a quarry near Larance with a 30,000-ton capacity; and Limassol operated several small quarries with a total capacity of 30,000 tons. About 25,000 tons of gypsum was used in cement manufacturing and, aside from a few thousand tons that were exported to Middle Eastern countries, the remaining production was consumed domestically in the building industry.

MINERAL FUELS

Petroleum.—The only refinery on the island, Cyprus Petroleum Refinery Ltd., operated at less than its capacity of 16,000 barrels per day. The refinery, owned by Shell Oil Co. (25.5%), British Petroleum Co. Ltd. (25.5%), Mobil Oil Co. (34%), and the Cyprus Government (15%), imported most of the crude oil for the refinery's feedstock from Algeria, Libya, and Saudi Arabia. Algerian crude used by the refinery lacked the high heavy fuel components; therefore, the refinery did not produce substantial

amounts of heavy fuel and the Government was forced to purchase this grade of refinery product from the Soviet Union. However, because of conditions of the trade agreements with the Soviets, the Cyprus Government was obliged to pay higher prices for heavy fuel oil during 1980.

The Mineral Industry of Czechoslovakia

By Tatiana Karpinsky[1]

Czechoslovakia is one of the most industrially advanced countries in East Europe; however, the country is not self-sufficient in raw materials and fuels.

The growth rate of Czechoslovakia's economy was considerably slower in 1980 than in 1979. The planned targets were unfulfilled in several sectors of the industry. According to Czechoslovakia's sources, in 1980 national income increased 3% (planned 3.7%) over that of 1979, reaching 453.6 billion korunas (Kcs).[2] The gross industrial production increased 3.2% (planned 3.5%) over that of 1979.[3] In 1979, the value of total industrial output was Kcs617 billion. Capital investment in the economy increased 1.2% in 1980, while the planned increase for 1980 was 2%.

Important projects completed in 1980 included the second unit of the nuclear powerplant at Jaslowske Bohunice, the 500-megawatt set at the Melnik-3 thermal power station, and an additional section of the transit gas pipeline.

In 1979, mining and quarrying contributed 4.3% of the total industrial production in Czechoslovakia, of which the share of coal was 3.2%; crude oil, 0.1%; metallic ore, 0.5%; and other mining, 0.5%.[4] In 1979, production of petroleum refinery contributed 3.9% to the total industrial output, the iron and steel industry contributed 9.4%, the nonferrous industry contributed 2.5%, and production of the nonmetallic mineral industry was 2.7%. Contribution of mining and quarrying to the total industrial production in 1980 was approximately the same as in 1979.

The number of industrial workers employed in state enterprises in Czechoslovakia totaled 2,896,000 in 1979, and the number of employees totaled 2,008,000.[5] The number of workers and employees in state mineral and energy enterprises by branch (in thousands) follows:

Branch	Workers	Employees	Number of enterprises
Fuel extraction and processing industry	175	136	55
Power and heat generation	56	37	27
Ferrous metallurgy (including ore mining)	168	124	14
Nonferrous metallurgy (including ore mining)	42	30	20

According to Czechoslovakia's sources, during the 5-year plan period (1976-80) the national income of the country increased 20% and industrial production increased 25%.[6]

The original 5-year plan (1976-80) called for a 29% increase in national income and a 34% increase in gross industrial output. Capital investment yielded a considerable increase in basic assets, which were estimated at Kcs628 billion for the entire 5-year plan. New capacities went into operation for the extraction of 13 million tons of coal, for the production of 245,000 tons of steel pipes, for powerplants with total generating capacity of 4,500 megawatts, and for production of other commodities.

The sixth 5-year plan (1976-80) was not implemented. Nonfulfillment of the plan started at the end of 1979 in the strip mines of the North Bohemian brown coal basin at Most and also in the several sectors of the metallurgical industry where supplies of iron ore, raw materials, and metallurgical coke were smaller than expected. During the period of 1976-80, results were inadequate in saving or more effective utilization

of energy, raw materials, and semifinished products.

Government Policies and Programs.— The targets for the seventh 5-year plan (1981-85) were approved by the 16th Congress of the Communistic Party of Czechoslovakia in April 1981.

In the seventh 5-year plan the national income is to increase 14% to 16%. About 90% to 95% of the growth in national income is to be achieved by increased labor productivity. The plan also calls for an 18% to 20% increase in gross industrial output. The basic economic policy target for the seventh 5-year plan is the improvement of the quality and efficiency of industrial output and to make substantially better use of all kinds of fuels and energy, raw materials, capital assets, and labor. The new 5-year plan calls for increasing Czechoslovakia's participation in the Council for Mutual Economic Assistance (CMEA) country division of labor, particularly with the U.S.S.R.

According to the plan outlined at the 16th Party Congress for 1985, the brown coal and lignite output is to be 99 to 100 million tons, and bituminous coal is to be 27 to 28 million tons; electric energy production is planned to be 80,000 million to 83,000 million kilowatt-hours, including 15,000 million kilowatt-hours generated at nuclear powerplants. Steel production is to reach about 16 million tons by 1985. During the 5-year plan period a special effort is to be put on the production of equipment for nuclear, thermal, and hydroelectric powerplants.

The 1981 annual plan foresees an increase in national income of 2.8%. The plan calls for a 2.7% increase in gross industrial output with a 0.7% growth in the coal industry, 1.1% in electric energy, about 3% in the steel industry, 2.7% in rolled ferrous products, and 5.6% in the cement industry.

New production facilities coming onstream in 1981 include a new high-capacity, medium-gage rolling mill at NHKG Kunice, with an annual production capacity of 600,000 tons, and a new blooming and billet mill at SONP Kladno, with an annual production capacity of 900,000 tons. Greater utilization of metal waste and scrap and considerably better organization of collection of waste and scrap metals remains an urgent task. The plan calls for achieving relative savings of not less than 4% in consumption of ferrous metals and a 0.5% decrease in consumption of fuel and energy. Consumption of copper, zinc, and aluminum per unit of product is to decrease more substantially.

PRODUCTION

In Czechoslovakia there are reserves of coal, lignite, antimony, magnesite, mercury, uranium, graphite, kaolin and other clays, sand, limestone, and building materials, but the country remains deficient in oil, natural gas, iron ore, and nonferrous ores.

The state plan of bituminous coal extraction was fulfilled in 1980, but brown coal and lignite mining fell by 1.5% below the plan. There were problems in meeting planned extraction goals in the North Bohemian lignite mines at Most. In 1980, overall production in the metallurgical industry increased 1.2% over that of 1979, while production of nonferrous metals remained approximately at the 1979 level. Oil refining production and nitrogenous fertilizer production slightly increased in 1980. Labor productivity in industry increased by only 2.5% compared with a 2.9% increase in 1979. Despite a certain improvement, the efficiency of the economy was not increasing as fast as planned; there was no distinct reduction on the consumption of raw materials and energy. Electrical energy was increased by the higher output of nuclear power and hydroelectric plants. Nuclear power generated 4.5 billion kilowatt-hours, 2.4 billion kilowatt-hours more than in 1979, and hydroelectric energy increased by 14%.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Aug. 24, 1981.

[2]In addition to the commodities listed, arsenic, gold, uranium, feldspar, graphite, and a variety of other petroleum products are produced, but information is inadequate to make reliable estimates of output levels.

[3]This material, although reported as manganese ore, is believed to be manganiferous iron ore with an Mn content of about 17% and as such is not equivalent to material ordinarily reported as manganese ore, which generally contains 25% or more manganese.

[4]Includes gas produced from coal mines. Gross output of natural gas is not reported, but it is believed to exceed reported marketed output by a relatively inconsequential amount.

[5]Data presented are for those products reported in official Czechoslovak sources and in United Nations publications; no estimates have been included for other products or for refinery fuel and losses.

TRADE

In 1980, the value of total foreign trade turnover increased by 11% compared with that of 1979. The structure of Czechoslovakia's foreign trade for 1980 follows:

Country group	Exports		Imports	
	Million korunas	Percent	Million korunas	Percent
CMEA and other centrally planned economy countries	55,974	69.6	57,214	70.2
Developed countries	17,442	21.7	19,868	24.4
Developing countries	7,017	8.7	4,458	5.4
Total	80,433	100.0	81,540	100.0

Balance of Trade

Country group	Value of trade
CMEA and other centrally planned economy countries	-1,240
Developed countries	-2,426
Developing countries	+2,559
Total	-1,107

In 1980, the trade turnover increased at a faster rate with market economy countries than with centrally planned economy countries. The share of centrally planned economy countries in the total foreign turnover remained very high, at 69.9%. In 1980, Czechoslovakia's exports to market economy countries increased faster than imports. Czechoslovakia's participation in world trade dropped from 1.5% in 1965 to 0.9% in 1980, and its share of trade between CMEA countries decreased from 13% to 9.5% during the same period.

In 1979, exports of fuels, mineral raw materials, and metals contributed 16.9% to the total exports value and the share of this group of commodities in total imports accounted for 30.9%.

In 1980, almost 70% of all imports of fuels and raw materials, in terms of value, came from the centrally planned economy countries, especially from the U.S.S.R.

In 1980, the Soviet Union supplied Czechoslovakia with 18.8 million tons of oil, 7.7 billion cubic meters of natural gas, 1 million tons of cast iron, 3.2 million tons of bituminous coal, 2.2 billion kilowatt-hours of electric energy, and 89,000 tons of nonferrous metals, as well as chemical fertilizers and other commodities.

A large part of the deliveries of these products was supplied on the basis of credits granted Czechoslovakia for its participation in the enlargement of the facilities and the construction of new projects on the territory of the U.S.S.R. and in some other centrally planned economy countries. The surface mining, transportation, and processing equipment supplied by Czechoslovakia on credit made it possible to enlarge the capacity of the U.S.S.R. mining and metallurgical industry. The U.S.S.R. has been repaying the credit in annual deliveries of 20,000 tons of aluminum, 15,000 tons of copper, 9,000 tons of lead, 6,000 tons of zinc, and 1.8 million tons of iron ore concentrate.[7]

Czechoslovakia's participation in the construction of the Soyuz gas pipeline secured annual supplies of 2.8 billion cubic meters of gas for 20 years.

In 1980, Czechoslovakia continued to participate in the construction of a nuclear powerplant in Khmelnitsky in the Ukraine, which will supply it with 3,600 million kilowatt-hours of electric energy annually after completion. The Soviet Union is to export to Czechoslovakia 8.7 billion cubic meters of natural gas in 1981. The contract was signed in Prague by representatives of Metalimex of Czechoslovakia and Soyuzgasexport of the U.S.S.R.[8]

Ferromet and the Soviet foreign trade organization Promsyryoexport signed contracts for 1981 for the delivery to the U.S.S.R. of about 300,000 tons of pipes made in Czechoslovakia, of which 184,000 tons are to be used for oil and gas.

In 1980, a large amount of alloy steel made by Poldi-SONP Kladno National Enterprise in Czechoslovakia, was exported to the French automobile industry.

The agreement for 1981-85 between Czechoslovakia and Cuba envisages an increase of 55% in the value of trade. Czechoslovakia is to take part in the construction of a nickel and cobalt enterprise at Los Camariocas, in the first Cuban nuclear power station at Cienfulgos, and also in two 250-megawatt thermal power stations.

A protocol on commodity exchanges and payments for 1981 between North Korea and Czechoslovakia was signed in October 1980. Czechoslovakia will mainly supply machinery and equipment and import zinc and other commodities from Korea.

In June 1980, Czechoslovakia and Vietnam signed a protocol on the exchange of goods and services for 1981-85 in Prague. The volume of mutual trade will be doubled compared with the 1976-80 period. Czechoslovakia is to supply rolled steel and machinery and import zinc, lead, tin, and other commodities from Vietnam.

A protocol on coordination of national economic plans of Czechoslovakia and Mongolia for 1981-85 was signed in Prague on June 19, 1980. Czechoslovakia will further participate in the development of Mongolian raw material resources and their processing. Mongolia is to export to Czechoslovakia metal concentrates from their new deposits.

Table 2.—Czechoslovakia: Apparent exports of mineral commodities[1 2]

(Metric tons unless otherwise specified)

Commodity	1978	1979	Principal destinations, 1979
METALS			
Aluminum:			
Bauxite	215	--	
Oxide and hydroxide	61	60	All to Sweden.
Metal including alloys:			
Scrap	4,995	3,485	West Germany 2,177; France 656; Austria 495.
Unwrought	18,815	18,168	Japan 15,473; Hungary 1,663.

COMMODITY REVIEW

METALS

Antimony.—In 1980, antimony was mined at Dubrava (Central Slovak region) and at Pezinok near Bratislava (West Slovak region). Antimony ores were also investigated at the Krasna Hora deposits in Bohemia. The extraction of antimony ore is expected to be increased at Dubrava and Pezinok after 1985. The recycling of the Pezinok antimony was found to be particularly promising since remarkable quantities of gold and silver could be acquired from the dumps of Pezinok.[9]

Copper.—Production of copper in Czechoslovakia continued its growth during 1980 and total output of refined copper was slightly higher than that of 1979. In 1980, extraction of copper ore was concentrated in the stratiform types of Bohemian deposits—Zlate Hory and Tisova—as well as in the Banska Stiavnica and other deposits in Slovakia. In Zlate Hory reserves of ore are estimated at 3.5 million tons with metal content more than 1%. The deposit also contains lead, zinc, and gold. Copper in tetrahedrite and chalcopyrite were mined in Rudnany and Roznova deposits. Rudnany ores contain siderite-barite-copper-mercury mineralization.

In 1980, imports of copper metals from the U.S.S.R. and Poland supplied the main requirements of Czechoslovakian industry. Consumption of copper in Czechoslovakia increased 8% during the last 10 years (1970-80).[10]

Gold.—The rich deposits of gold in Czechoslovakia have been depleted. The remaining gold deposits located in Central Bohemia and in the Slovak Ore Mountains are of little economic significance; however, after discontinuing for 10 years, the extraction of gold-bearing ore in Slovakia is to continue in the Kremnice area. In 1980, it was decided to develop a new mine near Sturec. It is expected that in 1982 about 10,000 tons of gold-bearing ore will be extracted from this mine and in 1984 about

20,000 tons.

Estimated output of gold from the new deposits is expected to be 50 to 70 kilograms per year. Possibilities of renewing gold extraction were also studied in the Jeseniky Mountains.[11]

The Valcovny Div. of the Skoda Concern of Plzen started building a rolling mill for precious metals, which will be installed in the Safina works at Vestec near Prague. The rolling mill called "Kvarto 200" will be used to roll strips and foils from pure silver, silver and gold alloys, brass, and copper. The whole equipment for the mill weighs 69 tons and deliveries are to be completed in 1982.[12]

Iron and Steel.—In 1980, iron ore was mainly extracted from the Rudnany Mines, located in Slovakia. Domestic production supplies about 5.4% of the country's requirement of iron ore and 79.1% of the ore was imported from the U.S.S.R. The remaining 15.5% was imported from Brazil, Sweden, India, and Algeria.

Under a long-term agreement Czechoslovakia participated in the development of the Soviet Union's iron ore projects to cover increasing iron ore imports. In 1980, steel production slightly increased compared with the 1979 level and was below the originally planned level of 16.3 million tons. Steel production in 1981 is expected to be about 15.7 million tons and production of rolled steel is expected to be about 11.1 million tons. In 1980, about 60% of steel produced in Czechoslovakia came from charges of pig iron and alloys and the remainder from scrap.

In 1980, the modernization of Czechoslovakia's steel industry and further improvements in its structure continued. The new medium section mill at Czechoslovakia's New Klement Gottwald Metallurgical Works in Ostrava began trial operation in December 1980. The plant has a capacity of 900,000 tons per year, and is to reach full capacity in 1981. Czechoslovakia's plans for the steel industry were to reduce the open-hearth production and to increase the oxygen converter output; however, the share of oxygen converter steel output in 1980 was approximately the same as in 1978 (25.9%). The share of steel continuously cast increased from 0.38% in 1978 to 1.49% in 1980. Total investment in the iron and steel industry in 1980 was estimated at Kcs5.4 billion.

Lead and Zinc.—In 1980, lead-zinc ores were mined at Banska Stiavnica (Slovakia) and also at deep levels of mines at Pribram (Central Bohemian region) and Kutna Hora (eastern part of the Central Bohemian region). Ore production was approximately 0.6 million tons. The lead-zinc ore produced at Banska Stiavnica Mines was exported to market economy countries in the form of concentrate with gold and silver content because Czechoslovakia did not have the facility to separate gold, silver, zinc, and lead from each other.[13]

Benefication and metallurgical facilities in Czechoslovakia continued to experience poor metal recovery, particularly from mixed ores. Czechoslovakia is planning development of lead-zinc deposits at Banska Stiavnica-Hodrusa. Reserves of lead and zinc ore in the new recently discovered deposits near Banska Stiavnica are estimated at approximately 50 million tons.

In 1980, Czechoslovakia imported lead and zinc mostly from the U.S.S.R. and Yugoslavia. The development plan anticipated large investigations for a new lead-zinc deposit in the Horny Benesov area (North Moravia).

Mercury.—In 1980, mercury was extracted from vein deposits at Rudnany (Slovakia). New deposits of mercury ore were discovered in the vicinity of Malachov near Banska Bystrica in Slovakia. Plans are to develop new deposits and to extract 20,000 tons of mercury ore at Malachov in 1984.

Tin.—Tin continued to be mined in the Cinavec (North Bohemian region) and at the Horni Slovak (West Bohemian region) in 1980. Tin mining is expected to increase in the future. Plans are to develop new cassiterite deposits discovered in Slovakia near Medvedi Brook in the vicinity of the Hnilec Village. The tin industry experienced domestic raw material shortages. In 1980, tin was mainly imported from the United Kingdom, Bolivia, and India. Consumption of tin in 1980 increased about 20% over that of 1970.[14]

Uranium.—Czechoslovakia has significant uranium ore deposits. Reportedly the Czechoslovakia uranium industry achieved all planned production tasks for 1980.

In the last few years the Czechoslovak uranium industry concentrated its attention on the Hamar area in the Ceska Lipa district (North Bohemian region) and on the Pribram area (Central Bohemian region). A new uranium dressing plant was put into operation in the Ceska Lipa district in 1979. In 1980, further mining and dressing facilities were under development in the Ceska Lipa district. On September 5, 1980, the

concern enterprise "Pribram Uranium Mines" was renamed the "Czechoslovak Soviet Friendship Enterprise." The U.S.S.R. has total control of the exploration and production of uranium in Czechoslovakia.

NONMETALS

Cement.—The new cement plant at Prachovice in Eastern Bohemia, 100 kilometers from Prague, with a capacity of 1.2 million tons of cement per year, went into operation in 1980. Construction of this plant started in 1974 and the cost was estimated at Kcs2.0 billion. Desposits of calcite in this area were estimated to be sufficient for about 50 years. Reportedly, production of cement at the Prachovice plant is automatic and controlled by computer. Fly ash and waste gases are to be retained and processed into fertilizers. The cement at the Prachovice is made by dry technology.

The large-capacity cement plant Zahorie II at Rohoznic (West Slovak region) was also recently completed. Czechoslovakia is expected to remain an importer of cement for the near future. In 1980, cement was imported mostly from the U.S.S.R., Romania, and the German Democratic Republic.

Prerov Machinery of Czechoslovakia, a monopoly producer of cement, brick, and ceramic plants in the country, exports three-quarters of its output through Pragoinvest, a foreign trade organization.

Reportedly in 1980, Prerov Machinery completed a brick plant and a ceramic plant in Iraq, a cement plant with an output of 2,800 tons of clinker per day in Capao Bonito, Brazil, and facilities for cement production in the Amazon River Valley. In 1980, Brazil contracted for construction of three more cement plants.

Fertilizer Materials.—In 1980, Czechoslovakia continued to make an urea-ammonium nitrate solution, DAM-390, at the new plant at Dusla National Enterprise at Sala (West Slovak region) at the rate of an estimated 100,000 tons per year. The output is to reach 600,000 tons in 1987. Nitrogenous fertilizer was also produced at the Lovosice-Zaluzi chemical complex (North Bohemian region) and at the chemical complex at Strazske (East Slovak region).

In 1980, consumption of fertilizer per hectare of agricultural land was 253 kilograms in nutrient content. Czechoslovakia's production of nitrogenous and phosphate fertilizers provided approximately 60% to 70% of the country's consumption. Nitrogenous fertilizer continued to be imported from the U.S.S.R., potassium fertilizers from the German Democratic Republic and the U.S.S.R., and phosphates from the U.S.S.R. and African countries. Czechoslovakian geologists are to undertake an extensive survey of phosphate deposits in southwest Nigeria, in an area only a few kilometers from the Beni border.

Fluorspar.—Production of fluorite is concentrated in the Ore Mountains (North Bohemia). Czechoslovakia has only one mining enterprise for the production of fluorite concentrate, Sobedruhy. The flotation plant at Sobedruhy, near Teplice, produces concentrate with 95% fluorite (CaF_2). Recently discovered fluorspar deposits in the Ore Mountains are to help make Czechoslovakia self-sufficient in fluorite after 1985.

All deposits of fluorites in Czechoslovakia belong to the hydrothermal type. In the Ore Mountains fluorite is associated with barite, quartz, sulfides, and carbonates. Fluorspar deposits of less significance are located in the South Bohemian region. Under an agreement between Czechoslovakia and mainland China, signed in Prague on May 11, 1981, fluorite is to be imported from China.

Kaolin.—In 1980, production of kaolin fully covered the consumption of this raw material in Czechoslovakia and 380,000 tons was exported. Czechoslovakia is the world's fourth producer of kaolin after the United States, British Columbia, Canada, and the U.S.S.R. In 1980, exports of kaolin went mainly to the Federal Republic of Germany, Poland, and Austria. Kaolin deposits occur in the Karlovy Vary area, and near Plzen, Podborany, and Znojmo. All kaolin deposits in Czechoslovakia belong to the weathering type, which are characterized by reduced intensity of kaolinization at depth. The principal deposits are in Karlovy Vary, where the highest quality type of kaolin is processed at Bozicany. The kaolin for the paper industry is processed at Kuznejov.

In 1980, preparations were made for production of bleached kaolin by electromagnetic separation, a new method developed in Czechoslovakia that makes it possible to obtain a higher degree of whiteness.

Magnesite.—Czechoslovakia has substantial magnesite deposits and is an exporter of magnesite. Magnesite production slightly increased in 1980 compared with the 1979 level.

Total exports of magnesite in 1980 were estimated at 380,000 tons. Magnesite was exported to Hungary, Poland, the German Democratic Republic, Romania, and the

Federal Republic of Germany. Magnesite was produced from six deposits in Slovakia. The largest deposit in the Dubrovsky massive is 400 meters thick and covers an area of 3.2 million square meters; the ore contains about 30% to 40% MgO.

The country is making an attempt to increase production capacity of the larger mines and to close the small mines.

Perlite.—Reportedly, during the sixth 5-year plan about 5 million to 8 million tons of high-grade perlite ore was discovered in Jastraba near Kremnica (Slovakia), which is to replace imports of that raw material from Hungary.

MINERAL FUELS

Total energy production derived from fossil fuels and from hydroelectric and nuclear power generation was estimated at 87.2 million tons standard coal equivalent (SCE) in 1980 (1 million tons below that of 1979) with coal, including lignite, supplying 97.4%.

Total consumption of primary energy was 127.2 million tons SCE with coal providing about 67%; oil, 22%; gas, 9.5%; and hydroelectric power, nuclear power and imported electric power, about 0.5% each. The primary energy balance of Czechoslovakia for 1979 and 1980 is shown in table 4.

Table 4.—Czechoslovakia: Total primary energy balance

(Million tons of standard coal equivalent)[1]

	Total primary energy	Coal (bituminous, brown, lignite) and coke	Crude oil and petroleum products	Natural gas	Hydroelectric power	Nuclear power	Turnover of electric energy
1979:							
Production	r88.2	r86.1	0.2	1.1	0.5	0.3	--
Imports	r45.2	r5.8	r29.1	r9.7	--	--	r0.6
Exports	r7.3	r6.1	r1.1	--	--	--	.1
Apparent consumption	r126.1	r85.8	r28.2	r10.8	.5	.3	r.5
1980:[e]							
Production	87.2	84.9	.1	1.0	.6	.6	--

Exports	6.8	5.9	.8	--	--	--	.1
Apparent consumption	127.2	84.9	28.5	12.1	.6	.6	.5

[e]Estimated. [r]Revised.

[1]One ton of standard coal equivalent (SCE)=7,000,000 kilocalories. Conversion factors used are as follows: Hard coal, 1.0; brown coal and lignite, 0.6; crude oil, 1.47; natural gas (per 1,000 cubic meters), 1.33; and hydroelectric and nuclear power (per 1,000 kilowatt-hours), 0.125.

Sources: Statistical Yearbook of Czechoslovakia, Prague, 1980; Statisticke Prehledy (Statistic Summary), Prague. No. 3, 1981, p. 66.

Coal.—Except for the North Bohemian brown coal basin, all coal basins fulfilled their quotas in 1980. The shortfall in production at the North Bohemian lignite region amounted to 1.8 million tons. The situation was caused by the long-term failure to fulfill the target for the removal of overburden.

The bulk of the country's bituminous coal output came from the Ostrava-Karvina Basin. Ostrava-Karvina Fields supplied more than 24 million tons of bituminous coal in 1980. Planned targets for 1980 were met only with extra ordinary efforts, including Saturday and Sunday work shifts. In the seventh 5-year plan period (1981-85) it is expected that bituminous coal production from this area will remain steady at 24.5 million tons per year and account for about 85% to 87% of bituminous coal output. The mines in the Ostrava-Karvina Basin are the only producers of coking coal. They comprise 16 mining enterprises in the Ostrava, Karvina, Frydek-Mistek, and Opava districts.

In 1980, bituminous coal in the Ostrava-Karvina Basin continued to be mined under increasingly more difficult conditions. The Darkov Mine with a projected annual capacity of 5 million tons was under development in the Ostrava-Karvina coal basin in 1980. Coal extraction at this mine is planned to begin in the 1980's.

In the last few years two new bituminous coal deposits were prepared for extraction in Frenstat-West near the southern edge of the Ostrava-Karvina coal basin and Slany in Central Bohemia. Development of the Slany deposits started in 1979 and continued in 1980; coal extraction is planned to

begin in 1996. Discovered bituminous coal reserves at Slany were estimated to contain 150 million tons at 800 to 1,300 meters below ground. In 1980, survey drilling to a depth of 6,000 meters at Jakunka in the Beskydy Mountains in Northern Moravia has revealed a deposit of coal which is a continuation of the Ostrava coalfield.

A new deposit of bituminous coal was discovered near Radnice in the Rokycany district in West Bohemia. The deposit covers an area of about 12 hectares between Radnice and Privetice and reserves are estimated at about 1 million tons. The seams of the new Ovcin mine in this district are between 1 and 5 meters thick.

In the seventh 5-year plan period (1981-85) exploration of bituminous coal deposits is to be concentrated on the Celadne-Krasne area in the Ostrava-Karvina coal basin and in the Mseno Basin near Melnik. The country's bituminous coal reserves are sufficient for the next 50 to 60 years at the present rate of extraction.

Czechoslovakia's brown coal deposits have been mined principally by the opencast method; only 15% are mined underground. Futher increases in output are to be derived exclusively from opencast mines, while underground production is to decline. In 1980, about 74% of brown coal came from the North Bohemian Basin and the remainder came from the Sokolow, Kandlova, and Mody Kamen Basins. The 1980 production target for brown coal was underfullfilled primarily at the Maxim Gorkiy large mine and the Czechoslovak Army Mine. Brown coal and lignite output is planned to reach 99 to 100 million tons in 1985 and 111 million tons in 1990, but there are already serious concerns about the declining calorific value of the coal.

The North Bohemian brown coal basin, the largest in Czechoslavakia, covers an area of 850 square kilometers and contains 6.5 billion tons of coal, of which 4.6 billion tons are recoverable.

In 1980, a large opencast lignite mine was under development at Vrsany near Most. The area is planned to be 6 square kilometers. Development of the mine is to cost about Kcs5 billion. The Vrsany Mine, with 7 million tons per year projected capacity, is scheduled to come into operation in 1982 and is to supply coal to the Pocerdany electric powerplant. A new opencast mine in the Socolov lignite field came into operation in June 1980; the deposits total about 9 million tons. The mine is expected to remain in operation until 1988. The development of a new brown coal mine at Miculcice near Hodonin (South Moravia) continued in 1980. The mine is to reach full production capacity of 5 million tons in 1983.

On September 20, 1980, mining operations started at the first opencast lignite mine in Slovakia, located in Lehota near Novaky. The mine is expected to produce 1.3 million tons of brown coal; about 36,000 tons of brown coal was produced at this mine in 1980.

Czechoslovak Premier L. Strougal reported in late 1978 that capital investment in the energy sector for the 5-year plan (1981-85) is to reach Kcs55 billion, and coal is to represent more than one-third of all investment for fuel and power on an annual basis. However, this proposed figure may go higher owing to rising costs, both domestically and worldwide.

Czechoslovakia's total consumption of bituminous and brown coal listed by consumer groups for 1979, in percent, follows:

Consumption	Bituminous coal	Brown coal
Coke plants	49.0	--
Electric powerplants	21.8	50.1
Steam for heating and industrial use	18.9	23.9
Coal gas plants	--	2.7
Railroads	.4	.2
Households	4.3	8.4
Other	5.6	14.7
Total	100.0	100.0

Source: Statisticka Rocenka Ceskoslovenska Socialisticke Republiky (Statistical Annual of the Czechoslovak Socialistic Republic), Prague, 1980, p. 367.

Natural Gas.—In 1980, a new field of natural gas was put into operation in Czechoslovakia, in Dolni Durajovice, where reserves are estimated at 1.6 million cubic meters; other gas deposits were discovered in the Hodonin, Senice, and Michalove districts. However, the production of natural gas from local deposits was relatively insignificant. The U.S.S.R. supplied all of Czechoslovakia's gas imports in 1980. The transit gas pipeline, whose construction began in the early seventies, reached an annual capacity of 37 billion cubic meters in 1980 and this is to be expanded to 53 billion cubic meters by 1984. Soviet natural gas is carried by the Czechoslovak gas pipeline system to Western Europe (the Federal Republic of Germany, France, Austria, and

Italy) and to the German Democratic Republic and Yugoslavia, while the system also supplies natural gas for Czechoslovakia's own needs.

Czechoslovakia is compensated by the U.S.S.R. with natural gas deliveries for its participation in the building of the gas pipeline and for the transit of the gas across Czechoslovakia territory. In the 1981-85 5-year plan period, the transit gas pipeline is to transport 210 to 230 billion cubic meters of gas, of which 40 billion cubic meters are to be for Czechoslovakia's economy.

The gas generated in Czechoslovakia's own Sokolov brown coal basin near Zaluzi is carried by a 350 to 500 millimeter pipeline to Prague, Brno, and Central Slovakia. From Vresova it is carried to Brno and from Usti nad Labem to Ostrava.

Petroleum.—The Friendship pipeline, which went into operation in 1962, carried 18.8 million tons of crude oil from the U.S.S.R. to Czechoslovakia in 1980. About 0.5 million tons of crude oil was imported from nations of the Organization of Petroleum Exporting Countries (OPEC). Annual deliveries of Soviet oil, which provides most of Czechoslovak needs, are slated to remain at the 1980 level of 18.8 million tons under the trade agreement for exchange of goods between the two countries. Czechoslovakia participated in the construction of the Adria oil pipeline (together with Yugoslavia and Hungary) leading from Rijeka in Yugoslavia over Sisak and the territory of Hungary to the Czechoslovak border at Tupa where it is linked to the Druzba pipeline. The Adria pipeline was put into operation at the end of 1979 and is to be used for crude oil coming from OPEC to Czechoslovakia and other countries. Indigenous crude oil was produced mainly in the southeastern part of the South Mountain region and in the West Slovak region, and was relatively insignificant.

In September 1980, the second petrochemical complex was completed at Litvinov in North Bohemia. The enterprise will soon achieve production capacity of 450,000 tons per year ethylene, 270,000 tons per year propylene, and 170,000 tons per year benzene.

The Mineral Industry of Denmark and Greenland

By Joseph B. Huvos[1]

Denmark and Greenland have few mineral resources and must import most fuels and minerals. Production includes some crude oil in the North Sea, some industrial minerals in Denmark, and lead and zinc in Greenland.

During 1980, the Denmark and Greenland economy slid into recession, which deepened in the second half of the year. The gross national product (GNP) was down 1% in real terms from the 1979 level. At current prices it was almost $55 billion.[2]

The Government's anti-inflationary program reducing real earnings (by 5%) and halting the growth in public budgets has been pursued with determination. Inflation was 12.3% and unemployment was 6.7%. The contribution of the principal sectors of the mineral industry to the GNP, in million dollars and average employment, are shown in the following tabulation:

Sector	Contribution to GNP (millions)		Average 1979 employment (thousand persons)
	1978	1979	
Iron, steel, base metals	$392	$459	7,827
Nonmetals	1,024	1,110	24,006
Oil refining	819	1,257	589
Fertilizers	116	124	1,336
Total	2,351	2,950	33,758

DENMARK

Some of the important events in the mineral industry of Denmark and Greenland included successful efforts by the Danish Government to change the allocation and ownership of oil rights, by concluding an agreement for this purpose with A. P. Möller, and efforts by the Det Danske Staalvalsevaerk Co. (DDS) to secure a loan of $100 million for restructuring the company.

Table 1.—Denmark: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

COMMODITY REVIEW

Metals.—*Iron and Steel.*—DDS, Denmark's only steelmaker, was reportedly trying to raise about $100 million as part of a 5-year restructuring. The company lost $22 million in 1980, compared with $18 million the year before, and 18 foreign (creditor) banks were asked to write off part of their debts. The Danish Government was expected to contribute the bulk of the money required, and the plan was put before the European Steel Commission for approval. DDS did not foresee any reorganization of production; it felt that its plant was among the most modern in Europe, but prices had not been high enough to achieve profitability.

The production capacity of DDS was about 1.5 million tons of crude steel per year. The company was an all electric steelmaker, using scrap as the only raw material at its Frederiksvaerk plant, located north of Copenhagen, after the company's four open hearth furnaces and blooming mill were phased out in favor of two electric arc furnaces and a new billet casting plant.

Nonmetals.—*Ammonia.*—Domestic production of ammonia at Superfos AS Fredericia plant in Jutland was less than 10,000 tons per year, making the country largely dependent on imports from the Federal Republic of Germany and the Soviet Union. The Danish compound fertilizer manufacturer, Superfos AS, holds a 40% share in the 450,000-ton-per-year (nitrogen) Brunsbüttel ammonia plant, located in the Federal Republic of Germany on the Elbe River estuary, where the Chemische Werke Hüls is the major shareholder. Superfos will eventually take its annual share of ammonia of about 180,000 tons of nitrogen from this source.

Industrial Minerals.—A number of industrial minerals were produced in Denmark in 1980. While sand was dredged in shallow inshore waters and in the North Sea west of Ejsberg, granite, sandstone, and slate were produced on Bornholm Island, from about 14 quarries, where kaolin was also mined for ceramic purposes. The Danish Salt Co. produced salt by solution mining from a salt dome at Hvornum in northeastern Jutland. Moler, a clayey diatomaceous earth, was mined by several companies on Fur and Mors Islands in northern Jutland.

Lime.—In 1980, AS Faxe Kalkbrud of Copenhagen remained the only producer of burnt lime. Faxe Kalkbrud had the capacity to produce up to 125,000 tons per year from its principal operation at Fakse on Zealand Island; the company operated two rotary kilns at this location, and capacity to produce 15,000 tons per year of hydrated lime. At its other operation at Rödvig, a single rotary hearth calcining kiln has a capacity of 60,000 tons per year. At both locations coral limestone is burnt to produce lime with 94% to 94.5% CaO content for mortar, water purification, sewage treatment, and others.

Mineral Fuels.—According to the annual review by the Energy Administration of Denmark, 1980 was the first year after the 1973-74 oil crisis that showed a great reduction in energy consumption. Oil imports were 11% lower and solid fuel imports were 7% lower than foreseen. Total energy consumption decreased 8%.

Coal.—During recent years Denmark has succeeded in increasing the proportion of coal-fired powerplants of the country to 80% of the total by converting oil-fired powerplants to coal. Poland, a major supplier of coal to Denmark, with about 40% of the total in the past, discontinued deliveries in 1980, and like the U.S.S.R., has not committed itself to supplying coal in 1981. The Republic of South Africa, formerly a supplier, was eliminated for political reasons, leaving the United States as a main supplier, with 800,000 tons in 1980 and about 2 million tons in 1981. Australia, the United Kingdom, and mainland China are the remaining suppliers.

Petroleum and Natural Gas.—In December, the Danish Government announced that it will nationalize all or part of the North Sea interests of the shipping company, Möller, holder of a 50-year concession for Denmark's offshore oil and gas granted in 1962 and operated through the Dansk Undergrunds Consortium (DUC) comprising Möller, Shell Oil Co., Chevron Oil Co., and Texaco Oil Co. The move followed a breakdown of negotiations initiated by the Government in 1980, through which it sought to increase the state tax receipts from oil production and to win back all unexplored acreage for relicensing on tougher terms. Legislation was to be put before the Folketing (Parliament) in 1981. Previously Möller had resisted the demand of the Government that it should relinquish 50% of its unex-

plored territory in 1982 and the remainder in 1985, and had made a counter offer of its own. Finally, Möller has reached an agreement with the Government over the relinquishment of exclusive rights to the Danish offshore, thus averting scheduled legislation to expropriate most of the territory, probably with an ensuing battle over compensation. The Government intended to offer most of Möller's former concessions for preliminary seismic work in 1981, with exploration licenses being granted from 1983 onward, although Möller won some concessions. Möller also offered to boost its exploration program, envisaging the use of five rigs from 1982 to the end of 1984.

Möller is to be allowed to retain all of its existing finds, together with an area comprising eight or nine blocs in the southwestern concession, about 1,200 square kilometers of Denmark's most promising acreage. Tougher financial terms are to apply to the retained acreage, with relinquishment beginning in 2000. Of the acreage Möller is not able to retain, 50% is to be relinquished in 1982, a further 25% in 1984, and the remainder in 1986. Möller had to agree to send the state's share of its oil production ashore through a Government-owned pipeline, for which a 5% transit fee will be payable, and has conceded to the state's Dansk Olie og Naturgas AS the right to buy 40% of all Möller-produced oil.

Crude oil production continued at a very modest pace from the North Sea Shelf at the Dan Field, Denmark's first, about 200 kilometers west of Ejsberg. Output in 1980 was about 298,000 tons. Gorm, Denmark's second oilfield, came onstream in May 1981, at a rate of about 800,000 tons per year and was scheduled to increase in 1982 to 2 million tons per year. Reserves were estimated at 15 to 20 million tons. An additional five wells are to be brought into production at the Gorm wellhead platform A. A second wellhead, platform B, was being drilled.

Two further projects, the Tyra and Roar Gasfields were to be developed, with processing facilities to be sited in the Gorm Field. A pipeline was to be laid from Gorm to a landfall in Jutland. DUC has applied for permission to develop its Skjöld Field beginning in 1982. The field is located between the Dan and Gorm Fields.

Denmark's oil refining capacity remained unchanged at about 12 million tons per year. Gulf Refining Co., Dansk Esso AS, and AS Dansk Shell had refineries at Stignaes and Kalundborg, both on Zealand Island and at Fredericia in Jutland, in that order.

GREENLAND

PRODUCTION AND TRADE

Greenland's mineral production for 1976 through 1980 is shown in table 5. Greenland's foreign trade for 1978 and 1979 are detailed in tables 6 and 7.

Table 5.—Greenland: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity[2]	1976	1977	1978	1979	1980[p]
Lead, mine output, metal content	27,000	28,800	30,600	31,900	30,100
Silver, mine output, metal content thousand troy ounces	479	521	559	765	547
Zinc, mine output, metal content	81,000	76,600	82,400	87,300	92,100

[p]Preliminary.

[1]Table includes data available through Oct. 12, 1981.

[2]In addition to the commodities listed, a variety of crude construction materials (common clays, sand and gravel, and stone) are undoubtedly produced, but output is not reported and available information is inadequate to make reliable estimates of output levels. Also, chromite apparently was produced in 1979 for metallurgical purposes.

COMMODITY REVIEW

Coal.—The Geological Survey of Greenland, under contract with the Danish Energy Ministry, carried out a minor drilling program on the Nugssuaq Peninsula near Jakobshavn and identified a series of exploitable seams of Cretaceous coal. Prefeasibility studies and treatment tests were in progress.

Cryolite.—Raw cryolite stockpiles at Ivigtut, south Greenland, were the basis for a refining operation run by AS Kryolitselskabet Øresund at Copenhagen, Denmark, which exported 20,705 tons of refined cryolite in 1980.

Lead and Zinc.—In 1980, mine production of lead-zinc ore at the Black Angel Mine, located at Marmorilik, west Greenland, was 648,000 tons, containing 13.4% zinc, 5.3% lead, and 37 grams of silver per ton. The mine, Greenland's only lead-zinc mine, was operated by Greenex AS, a subsidiary of Cominco Ltd. of Canada. Concentrates produced included 152,000 tons of zinc concentrate and 42,000 tons of lead concentrate, both exported to various Western European smelters, except for part of the zinc concentrate that was tolled on contract and then sold as zinc metal.

About $2 million was spent in 1980 on exploring for new ores, maintaining reserves at 3.2 million tons. Costs of exploration have risen during the last 6 years because of the need to explore further and the increased thickness of the inland ice. Environmental aspects of mining at Marmorilik received much attention. In 1980, a new tailings system was installed; tailings had already been chemically treated since 1977.

Petroleum.—The Geological Survey of Greenland carried out a series of seismic and magnetic surveys in East Greenland waters, under a contract with the European Economic Community and the Danish Energy Ministry. In 1981, negotiations are planned for oil exploration in Jameson Land by the concessionary, Nordisk Mineselskab, in cooperation with Arco Greenland.

Uranium.—In 1980, about 4,200 tons of uranium ore was mined for experimental purposes at Kvanefjeld near Narassaq, South Greenland. The ore was shipped for leaching to the Danish atomic energy research establishment at Risö, west of Copenhagen. Further field activities for development of the low-grade uranium ore deposits

in South Greenland were hampered by environmental concerns among the Greenland population, whose main source of income was fishing in coastal waters.

The Mineral Industry of Egypt

By Peter J. Clarke[1]

Increased petroleum production continued to drive Egypt's economy, providing an estimated real growth rate in the gross domestic product (GDP) of between 8% and 9%. The major mineral industries, besides petroleum, were fertilizer production, phosphate, iron and steel, and aluminum. Revenues from the petroleum sector increased from $1.8 billion[2] in 1979 to an estimated $2.9 billion in 1980, accounting for over 12% of the total gross national product (GNP) of $23.4 billion. These increased revenues from petroleum helped to offset Egypt's import bill, which increased 16% over the 1979 level. Increased revenues from tourism, the Suez Canal, and worker remittances also aided in substantially reducing Egypt's current account deficit, and with higher net capital inflows, Egypt registered a considerable balance-of-payments surplus.

Despite strong growth in the economy overall, several internal problems remained. The population was increasing nearly 3% per year, and unemployment remained high. The public sector accounted for around 70% of total industrial production (nonoil) and operated inefficiently. The Government continued the expensive subsidy system for basic commodities to protect lower income groups from Egypt's high rate of price inflation, which ran at over 20% during the year. This subsidy system has caused persistent budgetary deficits over recent years.

As part of the peace treaty concluded in 1979 between Egypt and Israel, a large portion of the Sinai Peninsula was returned to Egyptian sovereignty during 1980. In April, much of this area was opened up for oil exploration and several concession agreements were signed with companies such as Continental Oil Co. (Conoco), British Petroleum (BP), Ente Nazionale Idrocarburi (ENI), and Compagnie Francaise des Petrole (CFP)-Total. The Sinai was also considered to be a potential source of manganese, coal, kaolin, and gypsum, and studies were initiated by the Egyptian Geological Survey Organization to investigate opening or reopening mining operations in these areas.

The first phase of deepening and widening of the Suez Canal was completed in 1980, enabling ships of up to 150,000 tons, laden, to transit the canal. The second stage was to allow the passage of ships of up to 260,000 tons, laden, and was to be completed by 1985. Revenues from the Suez Canal increased 20% in 1980, to $710 million. Annual revenues are expected to reach $1 billion when the expansion programs are completed.

Egypt continued to negotiate for the supply of two nuclear power stations in their long-term plan for the use of nuclear energy for peaceful purposes. A nuclear cooperation protocol was signed between Egypt and France for the supply of two nuclear power stations, worth over $2 billion. The two reactors were to be 1,000-megawatt pressurized water reactors built by Framatome (France) under license from Westinghouse Corp. (United States). The protocol also included the supply of nuclear fuel. Egypt was scheduled to sign the nuclear nonproliferation treaty in March 1981 to clear the way for the purchase of the reactors.

Egypt also continued investigating the feasibility of constructing a hydroelectric generating plant at the Qattara depression using water from the Mediterranean Sea. The project entailed digging a 76-kilometers channel from the Mediterranean Sea to the Qattara depression, whose base is 135 meters below sea level, and using the flow of water to generate electricity at the rim of

the depression. Lahmeyer International (Federal Republic of Germany) conducted the initial feasibility studies, which were tentatively rejected because of their method of excavation—nuclear explosives. The Swedish Consulting Group began studying the project in late 1980. Pending results of the study, construction was scheduled for as early as the spring of 1981.

Law 43 continued to have a substantial impact on Egypt's economy. Since 1974, when the "Open Door" policy towards foreign private investment first went into effect, the private sector's share in gross fixed investment has risen from 10% to 16%. Oil companies have been the major benefactors, operating production-sharing ventures on favorable terms, but law 43 has also stimulated the private sector in Egypt. Private foreign exchange earnings now finance nearly one-fifth of Egypt's total imports, and their share in the market continues to grow. New emphasis was also placed on decentralizing public sector enterprises in the 1980's in an attempt to streamline their efficiency.

Egypt's 1980-84 5-Year Development Plan was announced in 1980. Public sector investment priorities over the plan period emphasized infrastructure improvements, housing, and food production. The plan would require high import levels for industrial raw materials, equipment, and machinery.

The Government of Egypt, with the financial assistance of the U.S. Agency for International Development (AID), undertook a $37 million petroleum and ground water assessment program to improve their data on mineral and petroleum resources, as well as ground water necessary for the development of such resources. The project was to include new areas of potential mineral and petroleum resources and possibly an atlas of Landsat imagery of the entire country. The program was scheduled for completion in 1983.

PRODUCTION AND TRADE

Production of most of Egypt's mineral commodities increased in 1980, led by new capacity in the petroleum, fertilizer, iron and steel, and phosphate industries. Petroleum production averaged about 590,000 barrels per day in 1980, nearly 20% greater than that of 1979, and export revenues reached $2.9 billion. Egypt planned to produce 1 million barrels of crude oil per day by 1983. Several new discoveries were made during the year, and 36 new exploration concessions were granted.

Egypt became the largest nitrogenous fertilizer producer in the Arab world when the Talkha II fertilizer plant came onstream late in 1980. Annual production of nitrogenous fertilizer was expected to reach 1.7 million tons when Talkha II operates near capacity in 1981. Phosphate production also increased steadily, mainly from the Hamrawein and West Sabaya deposits. Production in 1980 was 20% above 1979 levels. Phosphate rock was used in Egypt's three single superphosphate fertilizer plants and new capacity was being studied to supply a triple superphosphate and phosphoric acid plant at Abu Zaabal.

Iron ore production from the Bahariya Oasis deposits continued to increase in 1980. Steel production also increased from the Helwan iron and steel complex, as the plant switched to higher grade Bahariya ore and natural gas-fired furnaces. The Egyptian Government continued to place high priority on developing the mineral resources of the country. Mineral production in Egypt is shown in table 1.

Egypt's balance-of-trade deficit of $4 billion in 1979 did not improve in 1980, despite the higher level of exports of oil and cotton. The level of imports increased in line with the higher exports. Egypt's principal mineral exports were petroleum, phosphate rock, aluminum, iron and steel, and salt. Petroleum was exported to Italy (70%), Greece (11%), the United States (7%), France (3%), Yugoslavia (2%), Belgium, the Federal Republic of Germany, Sudan, the People's Democratic Republic of Yemen, and Switzerland (the remaining 7%). Egypt exported most of its mineral and nonmineral commodities to Western European and Middle Eastern countries, but the United States remained its largest single trading partner, supplying $1.8 billion worth of goods, or nearly one-fifth of the total imports in 1980, and received about one-seventh of its exports. The United States also remained the largest single aid donor to Egypt, averaging around $1 billion per year over the last 6 years. Official aid for 1980 was in the area of $1.2 billion.

No detailed statistics on Egyptian foreign trade are available for years following 1977; these data appeared in the 1978-79 edition of Minerals Yearbook, Volume III.

COMMODITY REVIEW

METALS

Aluminum.—Aluminum production capacity from the State-owned Aluminum Co. of Egypt was scheduled to increase from 133,000 tons per year to 166,000 tons per year when two new potlines come onstream early in 1981. The plant, located at Nag Hammadi, 500 kilometers south of Cairo, produced aluminum ingots, billets, slabs, and rods from eight operating potlines. Alumina was imported from Australia through the Red Sea Port of Safaga, and trucked to Nag Hammadi on the west bank of the Nile River.

Approximately 70% of the output from Nag Hammadi was exported, mainly to Western Europe and Japan. The Port of Safaga was the export terminal for shipments to Japan, and Nag Hammadi and Alexandria were used for exports to Europe.

Aluminum pellets from Nag Hammadi were used in the aluminum extrusion plant at Ismailia, which began production in 1977. Plans also continued for construction of a joint venture aluminum and zinc smelting operation. The State-owned General Co. for Metals and Krupp A.G. (Federal Republic of Germany) planned to produce 24,000 tons per year of zinc plates and strips, and rolled aluminum. The venture was capitalized at $37 million.

Copper.—The Egyptian Geological Survey Organization continued its investigation into copper deposits in the Eastern Desert. Deposits at Um Samiuki contained reserves of 150,000 tons of ore containing 1% to 1.15% copper, 15.2% zinc, 1.1% lead, and 50 grams per ton of silver. Copper-nickel deposits at Gebel Homs and El Ghariba also contained an estimated 70,000 tons of 0.95% copper ore. No decision had been made to work any of the deposits.

Iron and Steel.—Production of iron ore continued to increase in 1980 to approximately 1.5 million tons, as mining operations expanded at the Bahariya Oasis deposits, 500 kilometers southwest of Helwan. Iron ore at Bahariya Oasis occurs in four localities: Gharabi, El Horra, Nasser, and El Gedida. Mining operations were limited to El Gedida, however, where reserves were estimated at 129 million tons, averaging 54% iron. Total reserves at all the deposits were in excess of 250 million tons, and when brought into production, total output was expected to be 3.5 million tons per year. Smaller amounts of iron ore were also mined at Aswan, but operations were being phased out because of the low grade and high silica content of the ore.

Iron ore from the open pit operations of El Gedida was shipped by rail to the State-owned Egyptian Iron and Steel Co.'s steelworks at Helwan. After opening a fourth blast furnace in 1979 and equipping the older furnaces for sintered feed from Bahariya instead of lumpy ore from Aswan, steel output was expected to reach 1 million tons per year in the mid-1980's. Natural gas from the Abu Gharadig Field was used to fuel the new furnaces, reducing the consumption of coking coal previously imported from Poland and the Soviet Union.

Facilities at Helwan included an 80,000-ton-per-year heavy section mill, an 80,000-ton-per-year merchant bar mill, a 110,000-ton-per-year hot strip mill, and a 300,000-ton-per-year cold reduction mill. Nearly 90% of Helwan's production was sold domestically under the "Hadisold" brand, but Egypt remained a net importer of steel. Around 70,000 tons of steel was exported to other countries in the Middle East, and no change in sales patterns were envisioned by the company.

Three other steelmaking facilities also operated in Egypt, all of which produced reinforcing rods for the domestic market. The 110,000-ton-per-year Copper Works was located in Alexandria, and the 250,000-ton-per-year Abu Zaabal works was located in Abu Zaabal. National Metal Industries Co., in Cairo, expanded operations late in 1979, from 80,000 tons per year to 125,000 tons per year with the addition of an open-hearth furnace from Poland and a rolling mill from the German Democratic Republic.

A joint venture company was set up in October 1980 to build a $520 million steelworks at El Dekheila, near Alexandria. The direct reduction plant had a planned capacity of 800,000 tons per year, and was scheduled to begin production in 1984. The company was to be owned 86% by the Egyptian Government; 10% by a Japanese consortium including Nippon Kokan (NKK), Kobe Steel, and Tomen Co. Ltd.; and 4% by the International Finance Corp. (IFC). Financing was to be provided by the Japanese Government ($80 million loan), the World Bank ($100 million loan), and the IFC ($50 million loan).

In June 1980, Egypt and Romania signed a protocol for cooperation on the construction of two plants, one for cement and the other for steel reinforcing bars. The rebar plant was to have an annual production

capacity of 400,000 tons, at a cost of around $100 million.

Manganese.—Manganese production from the Wadi Mesalik deposits located in the Eastern Desert near the Sudanese border ceased in 1979, due to the high cost of transporting relatively small amounts of ore. Feasibility studies were being conducted on reopening the manganese mines at Abu Zeneima on the Sinai Peninsula, which were closed after the 6-day war in 1967. Reserves at Abu Zeneima were estimated at 2 million tons of 21% manganese ore. Kaiser Engineering and Contractors Inc. (United States) was awarded the contract for the study by the Sinai Manganese Co. of Egypt. The study was also to investigate the technical and economic feasibility of reopening the 10,000-ton-per-year ferromanganese smelter at Abu Zeneima, which also operated prior to 1967. Pending the results from Kaiser, the Egyptians planned to invest $100 million in rebuilding the facility.

Uranium.—Egypt's first uranium mine opened in January 1980. The mine was located in the Muskat area of the Eastern Desert. Two other mines, in the same area, were scheduled to open in 1981. Production from the mine was between 30 and 50 tons of U_3O_8 for 1980. The Eastern Desert mines were part of a 5-year research project which is to conclude in 1984, when production is scheduled to reach 100 tons per year.

Analysis of the black sands along the Mediterranean coast continued in 1980. Monzonite from the sands was shown to contain 5.2% thorium and 0.38% uranium. The phosphate deposits at Abu Tartur were also estimated to contain 100,000 tons of uranium.

NONMETALS

Clays.—Kaolin production from the Kalabsha deposits, 105 kilometers southwest of Aswan, registered a slight increase in 1980. Reserves were estimated at 16 million tons of kaolin with a 38% alumina content. The Geological Survey Organization continued its evaluation of the Kalabsha deposit, and also deposits of nepheline syenite in the Abou Khroug area of the Eastern Desert, for possible use in the production of aluminum. New deposits of unspecified clays were discovered in the Nile Valley, south of Suez, and in the Western Sinai. Kaolin deposits in the Sinai Peninsula had been mined at the rate of 30,000 tons per year in 1966-67 but had ceased after the war. Studies were in progress concerning resuming mining operations there.

Fertilizer Materials.—Egypt's production capacity for nitrogenous fertilizer was expected to reach 1.7 million tons per year when the Talkha II ammonia-urea complex came online at the end of 1980. Egypt's nitrogen industry became the largest in Africa and the Arab world. Capacity for production of phosphatic fertilizers was also undergoing expansion, through the addition of a triple superphosphate plant at the Abu Zaabal fertilizer complex. Total phosphatic fertilizer capacity was expected to reach 685,000 tons per year by 1981, when Abu Zaabal was scheduled to come onstream. Additional capacity was expected to make Egypt self-sufficient in fertilizer production, and also provide limited export revenues. Egypt's operating and planned fertilizer plants are listed in the following tabulation.

Location	Operating company	Primary product	Start-up date	Capacity (thousand tons per year)
Suez	Société el Nasr d' Engrais et d' Industries Chimiques.	Calcium nitrate.	1951	275
Talkha I	do	Calcium ammonium nitrate.	1975	365
Talkha II	do	Ammonia-urea	1980	1,000
Abu Qir	do	do	1979	900
Do	do	Ammonium nitrate.	1984	50
Helwan	El Nasr Co. for Manufacturing Coke and Chemicals.	Calcium ammonium nitrate.	1964	140
Kafr-el-Zaiyat	Société Financiere et Industrielle d' Egypte S.A.	Single superphosphate.	1937	200
Assiut	do	do	1969	200
Kosseir	Kosseir Phosphate Co	do	1958	50
Abu Zaabal	Abu Zaabal Fertilizer and Chemical Co.	do	1948	200
Do	do	Triple superphosphate.	1981	175
Do	do	Phosphoric acid	1981	200

The new nitrogenous fertilizer facilities at Talkha were built by Foster Wheeler Italiana utilizing synthesis loop technology in the ammonia plant, and Stamicarbon's process in the urea plant. Natural gas feedstock was piped from the Abu Madi Field in the Nile Delta, which produced around 30 million cubic feet per day. Plans were to increase natural gas production to over 100 million cubic feet per day to support further industrial development. Talkha II had a daily production capacity of 1,200 tons of ammonia, 1,700 tons of urea, and 180 tons of ammonium nitrate.

The Abu Qir fertilizer complex, completed in 1979, also embarked on a program to expand its nitrogenous fertilizer production. The company planned to install a 150,000-ton-per-year fertilizer-grade ammonium nitrate plant to absorb excess ammonia, and a 135,000-ton-per-year nitric acid facility by 1983 or 1984. The Abu Qir plant currently operates a 1,000-ton-per-day ammonia unit and a 1,500-ton-per-day urea plant, both built by Uhde-Mannesmann of the Federal Republic of Germany.

Three phosphatic fertilizer plants in Egypt produced single superphosphate from phosphate rock and sulfuric acid. The triple superphosphate plant at Abu Zaabal was scheduled to produce 175,000 tons of triple superphosphate and 200,000 tons of phosphoric acid per year when fully onstream sometime in 1981. The triple superphosphate unit was completed in 1979 by Bradley Pulverizer (United Kingdom). Lurgi (Federal Republic of Germany) and Babcock-Moxley (United Kingdom) were contracted for construction of the phosphoric acid plant and handling facilities. The Abu Zaabal complex consisted of two single superphosphate plants and two sulfuric acid plants. In addition to the triple superphosphate and phosphoric acid units under construction, a third sulfuric acid plant was to be added to the Abu Zaabal complex. Krebs of Paris (France) was awarded the contract for the design, engineering, and equipment supply for the plant. Design capacity was 215,000 tons per year of sulfuric acid, and 100,000 tons per year of 65% oleum.

Phosphate.—Plans were underway in 1980 for expansion and development of Egypt's two major phosphate deposits, West Sabaya and Abu Tartur. Phosphate deposits in the Eastern Desert, at Safaga and El Kosseir were nearly depleted, while production at Hamrawein, also in the Eastern Desert, increased substantially.

Overall phosphate production increased almost 20% in 1980 over 1979 levels. Production continued from the Red Sea coast, at Kosseir and Safaga, where reserves were estimated at 150 million tons, and from the Nile Valley area, at West Sabaya and Mahamid, where reserves were estimated at 400 million tons.

The expansion of the West Sabaya Mine, 31 kilometers north of Idfu on the Nile River, was postponed early in 1980 when a $27 million grant from the United Kingdom's Ministry of Overseas Development Administration was withheld following the United Kingdom Government's cutback on expenditure. The expanded mine and beneficiation plant were intended to supply the new phosphoric acid and triple superphosphate plant at Abu Zaabal. Egypt continued to seek development aid for the project.

Action was taken in 1980 on developing Egypt's largest phosphate deposit at Abu Tartur in the Western Desert. Reserves at Abu Tartur were estimated at 1 billion tons of phosphate rock with an average P_2O_5 content of 25.6%. The deposit had been examined for several years, without any development plans, due mainly to problems in beneficiation and separation of finely disseminated pyrite, and the high cost of associated infrastructure. In 1980, Occidental Petroleum Co. (United States) drew up a $1.5 billion plan to develop the deposit. In 1978, the World Bank approved an $11 million loan to set up a 500,000-ton-per-year pilot plant and mine, and construction was carried out by Sofremines (France) and Alusuisse (Switzerland). The pilot plant operation was encouraging enough to draw Occidental's attention toward developing the deposit. Should Occidental proceed with their plan, total capacity of Abu Tartur would exceed 4 million tons per year of ore, processed to produce 175,000 tons per year of triple superphosphate and 350,000 tons per year of phosphoric acid. Infrastructure development was to include building an entire town, construction of a 480-kilometer railroad from Abu Tartur to the Port of Safaga, and expansion of handling facilities at Safaga.

Salt.—Egypt was planning a major project to produce salt, magnesia, and sodium sulfate from a new facility to be located at Lake Quarun. With a $25 million aid grant from the United States, Egypt planned to produce 200,000 tons per year of high-grade (99% NaCl) salt, 21,000 tons per year of magnesia, and 7,500 tons per year of sodium

sulfate. The salt was to be marketed for consumption domestically and for export, while the sodium sulfate was to be used in the domestic detergent industry. Magnesium oxide was expected to be used in the developing refractories industry in Egypt. Feasibility studies regarding production process and plants for the Lake Quarun facility were carried out by DSS Engineers (United States) and White Consultants (United Kingdom).

Sulfur.—Feasibility studies continued on the sulfur deposits in the Siwa Oasis area of northwest Egypt at Taaweeny. Egypt remained under pressure to develop its sulfur deposits after Iraq banned all exports to Egypt in 1979. Egypt had been a major customer of the Iraqi sulfur industry before the Camp David agreements and the Arab boycott. Construction of four sulfur grinding plants was nearing completion in 1980. The plants were to grind 20,000 tons per year of sulfur rock into sulfur powder. The plants were being constructed by Klockner A.G. (Federal Republic of Germany) under contract from the Chama Sulfur Co. of Egypt.

Trona.—Egypt's production of natural sodium carbonate remained constant during 1980. The major source was the trona deposits of Wadi Natrun, northwest of Cairo. The entire output of the mine was used in the Misr Chemical Manufacturing Co. plant near Alexandria. The plant used imported and domestic sodium carbonate in the production of 45,000 tons of caustic soda, 5,000 tons of sodium bicarbonate, and 82,000 tons of heavy sodium carbonate per year.

MINERAL FUELS

Coal.—Egypt regained control in 1980 of a significant coal deposit in the north-central Sinai Pennisula. The Maghara coal deposit was first discovered in 1959, and mined until the June war of 1967. The Maghara deposit contained 27.5 million tons of proved reserves, with an additional 11 million tons of probable reserves. The Egyptian Government allocated $21 million in 1980 for complete plans to renew mining activity of Maghara. The annual output, once operations begin, is expected to be 800,000 tons. The coal was to be combined with imported Polish coal to produce coke for the Helwan steel plant.

Natural Gas.—Egypt marketed around 60 billion cubic feet of natural gas during 1980, most of which was directed toward power generation, fertilizer production, and industrial uses. Nonassociated gas was produced from three fields: Abu Madi, Abu Qir, and Abu Gharadig, where total reserves were estimated at 5 trillion cubic feet. About 300 million cubic feet per day of associated gas was also produced at the Gulf of Suez oilfields, most of which was flared. In 1979, the World Bank's International Bank for Reconstruction and Development granted the Egyptian General Petroleum Authority (EGPA) a $75 million loan to partly finance a project to gather, process, and transport the associated gas. The project was to include three gas-gathering stations; a liquefied petroleum gas (LPG) and condensate recovery plant; compression facilities; a pipeline; and engineering, technical, and training services. The initial phase of the project was to collect up to 40 million cubic feet of gas per day from a gas-gathering station at Ras Bakr and transport it by a 16-inch pipeline to a processing and compression station south of Ras Shukair. The total cost of the venture was $167 million, and was to be completed by 1982.

Production from the gasfields at Abu Madi was scheduled to increase fivefold by the mid-1980's as new wells come onstream. Natural gas from Abu Madi was used to support industrial development in the area, and provide feedstock for the Talkha I and II fertilizer complexes.

Production from the Abu Gharadig Field averaged around 60 million cubic feet per day. Gas from Abu Gharadig was supplied to cement plants at Helwan and Turah, as well as the iron and steel plant at Helwan.

Production from the offshore Mediterranean Abu Qir Field began in 1979 at around 100 million cubic feet per day and was scheduled to reach 200 million cubic feet per day by the mid-1980's. The gas was used in the Abu Qir fertilizer plant, nearby power-generating facilities, and industrial plants in Kafr al-Dawar and Demanhur. EGPA also drew up a plan in 1980 to utilize natural gas instead of bottle gas in residences around Cairo. Tenders were issued for the construction of a natural gas distribution system in the Cairo area. The project was scheduled for completion in 1982.

The Elf-Aquitane group (France) made a substantial gas discovery 20 kilometers northeast of Alexandria in their offshore Mediterranean concession. Initial reports indicated that the field was at least as large as the nearby Abu Qir Field, and possibly much larger. Elf planned to continue drilling in the area to evaluate the actual size of the discovery. The group also submitted proposals to the Egyptian Oil Minister for

the construction of a $950 million gas liquefaction plant onshore at Abu Qir. No decision was made by the ministry during the year.

Petroleum.—*Production.*—Egypt's oil production increased nearly 20% in 1980 over 1979 levels, due mostly to the new producing wells in the Gulf of Suez and the recovery of oilfields lost as a result of the June war of 1967. Egypt planned to attain a production target of 1 million barrels per day by 1985. Production for 1980 averaged 590,000 barrels per day. With new discoveries in 1980, Egyptian petroleum reserves stood at 2.3 billion barrels. The EGPA supervised all exploration, production, refining, and marketing of crude and refined petroleum. The spot price of Egypt's Gulf of Suez blend reached $40 per barrel at the end of 1980, while the official price was raised to $36 per barrel in December of 1980.

The Gulf of Suez continued to be the major oil-producing area in Egypt during 1980. The increase in production during the year was largely brought about by increased drilling in existing oilfields, and not by new discoveries, which were still under evaluation. The major fields in the Suez were operated by the Gulf of Suez Petroleum Co. (GUPCO), a joint venture of Amoco Egypt Oil Co. and EGPA. The July, El Morgan, and Ramadan Fields all averaged near 100,000 barrels per day in 1980. Production from the Gulf of Suez fields was slightly reduced midway through 1980 in an attempt to conserve reserves. Egypt's total oil production for the second half of 1980 averaged around 545,000 barrels per day as a result of reduced output from these fields. Production from the Shi'ab Ali (formerly Alma) Field, returned to Egypt in 1979, was reduced from 40,000 to 15,000 barrels per day to prevent damage to the field.

Production from oilfields in the Sinai also increased during 1980. The major field in the Sinai, Abu Rudeis, increased production from 50,000 barrels per day in 1979 to an average 90,000 barrels per day in 1980. The Abu Rudeis Field was operated by Cie. Orientale des Petroles d'Egypte (COPE), a joint venture of EGPA and ENI (Italy). Nearly two-thirds of the Sinai was returned to Egypt in January 1980, as part of the Egypt-Israel Peace Treaty, much of which was opened up for exploration during the year.

The General Petroleum Co. (GPC), owned totally by the Egyptian Government, produced oil from seven fields in the Eastern Desert. The Egyptian Petroleum Development Co. (Epedeco) group of Japan started production from the West Bakr onshore field in the Eastern Desert. The field came onstream in June 1980 at 3,400 barrels per day. Other oil companies operating in Egypt were the Western Desert Petroleum Co. (WEPCO), a joint Phillips Petroleum Co.-EGPA venture; Fayum Petroleum Co. (FAPCO), a joint venture of Amoco and the EGPA; and the Nile Valley Petroleum Co. (NIPCO), another Amoco-EGPA company.

Exploration.—In recent years, Egypt has attempted to attract the major oil companies into oil exploration and joint venture concessions. During the 1970's, 75% of the cost of developing the country's oil reserves came from EGPA's foreign partners, and EGPA's management emphasized that new agreements would be liberal and negotiable. Favorable terms and large unexplored areas prompted 36 concession agreements to be signed during 1980, 15 of which were with U.S. companies. Exploration capital committed by these agreements alone was in excess of $500 million.

Exploration in the Gulf of Suez continued to be the most profitable, with several new discoveries. Amoco, Deminex, Petrobel, CFP-Total and Mobil Oil Corp. all had commercially viable discoveries during 1980. Details of these discoveries are listed in the following tabulation.

Location	Company	Initial flow (barrels per day)	API gravity
Gulf of Suez	Amoco	8,720	28.2
Northwest Gulf of Suez	do	9,300	13.6
Gulf of Suez	do	6,790	40
Do	do	2,900	30
Do	Deminex	2,045	29.7
Do	do	1,900	15
Do	do	1,753	30
Do	do	1,860	Condensates
Feiron-onshore	Petrobel	1,080	23
South Rudeis-onshore	do	770	17.5
Gulf of Shugair	CFP-Total	3,280	35
Gulf of Suez-Red Sea	Mobil	2,948	23

Most interesting was Mobil's strike in the Red Sea. The area had not been considered to have great potential for oil, but the new discovery was likely to prompt more thorough exploration efforts. New exploration agreements in the Gulf of Suez were also signed by CFP-Total, Petrofina, and Conoco.

As a result of the 1979 Peace Treaty between Egypt and Israel, nearly two-thirds of the Sinai Peninsula was returned to Egypt in 1980. The Sinai coast, or the "oil corridor," and offshore areas in the Mediterranean Sea were considered as having good potential for oil reserves. The EGPA signed production-sharing agreements for concessions in both areas—with Conoco for a 1,600-square-kilometer tract in Ras Muhammad, South Sinai, committing $113 million over 3 years; with BP for a 1,200-square-kilometer tract in the Mediterranean-North Sinai Area; with the International Egyptian Oil Co., an affiliate of Italy's ENI, for a 1,200-square-kilometer tract in the same area; and with CFP-Total for a 1,200-square-kilometer offshore Mediterranean concession. Terms offered by the EGPA allowed the companies to recover their costs out of 30% of production for onshore areas, and 40% for offshore areas.

Contracts and agreements were also signed in other areas in Egypt. Agypetco (Switzerland-Federal Republic of Germany) signed an agreement with EGPA for an 1,800-square-kilometer concession in the Razzak West Area of the Western Desert, and a 5,800-square-kilometer concession in the Qattara depression in the Northwest Desert was awarded to Shell Winning N.V. (Netherlands). Other companies who signed production-sharing agreements during the year with EGPA include Gulfstream Resources Ltd. (Canada), Medoil-Mediterranean Oil and Gas Co., L.K. Exploration, Brinco Group (Canada), and Polar Bear Co. (Canada).

Refining.—Around 45% to 48% of Egypt's crude petroleum production was refined within the country in six refineries operated by three public companies. A small amount of petroleum products was imported in 1980, mainly from Western Europe. Egypt planned to increase refinery output from 85 million barrels per year to 110 million barrels per year to keep pace with the increase in domestic consumption. Egypt's refinery capacities were as follows in thousand barrels per year:

Company	Location	Capacity
Suez Petroleum Co	Suez	10,000
	Musturud	25,000
	Tanta	10,000
El Nasr Petroleum Co	Suez	7,000
	Ameriyah	15,000
Alexandria Petroleum Co	Alexandria	15,000

Construction continued on the $100 million lube oil complex at the Alexandria Petroleum Co.'s refinery. The unit was scheduled to produce 54,000 tons per year of lube oil, 16,000 tons per year of cylinder oil, 100,000 tons per year of asphalt, and 11,000 tons per year of micro wax.

Work began in 1980 on Egypt's first petrochemical complex, to be located at Ameriyah, near Alexandria. The complex is scheduled to come onstream in 1982 with an annual production capacity of 80,000 tons of polyvinyl chloride, 90,000 tons of low-density polyethylene, and 50,000 tons of high-density polyethylene. Ethylene feedstock was to be imported from Montedision of Italy, and in return, Egypt was to supply Montedison with sufficient naphtha to produce the ethylene needed. The complex was owned 75% by EGPA and 25% by Montedison. Total cost of the complex was estimated at $550 million.

Pipelines.—The second line of the Sumed pipeline began operating in September 1979. Total capacity of the line was 590 million barrels per year. The pipeline, which runs between Suez on the Red Sea, and Alexandria on the Mediterranean, operated at the rate of 1.6 million barrels per day in 1979-80. Around 50% of the pipeline's capacity was reserved by seven major oil companies. Saudi Arabia continued to investigate the possibility of using the Sumed pipeline in conjunction with its Abqaiq-Yanbu transpeninsular line to facilitate shipping Saudi crude to Western Europe. Saudi Arabia would put through up to 1 million barrels per day starting in 1982, but these plans appeared less likely since the Arab boycott was imposed on Egypt after signing the peace treaty in 1979.

The Mineral Industry of Finland

By Joseph B. Huvos[1]

In 1980, Finland, which is a modest producer of mineral commodities, sustained a continued strong growth of the economy, with unemployment down to about 4.7% and inflation on the rise at about 13.5%. The gross national product (GNP) was about $50 billion.[2] The contribution of mining and quarrying remained minor, but manufacturing, mining, and quarrying together contributed about 27% of the GNP. There were several noteworthy events in the Finnish mineral industry in 1980. Plant commissionings included the starting of a nuclear powerplant, and of a ladle injection steel plant. Work was started to raise the capacity of several existing plants, including the country's sole ferrochrome plant, the only electrolytical copper refinery, copper smelter, and steel billet treatment plant. Work started on the construction of a sulfuric acid plant. Exploration for mineral deposits continued in many areas, including the Talvivaara copper-nickel-cobalt-zinc deposit and the Luikonlahti talc deposit. Agreements were reached to expand domestic apatite production and also to expand an iron ore pellet project in the Soviet Union near the Finnish border.

PRODUCTION

Production of mineral commodities in 1980 and the 4 previous years is shown in table 1.

Volume indices (1975=100) for the production of the country's mineral industry and its industry as a whole are shown in the following tabulation:

Sector	1979	1980[p]
Mining and quarrying	126	129
Nonmetallic mineral processing	103	104
Iron and steel	168	166
Nonferrous metals	147	150
Petroleum refining	154	162
Industrial chemicals	113	111
All industry	118	125

TRADE

Since 1975, exports had fueled the Finnish economy, but in 1979 a downturn started in the trade balance; in 1980 the current account deficit was projected at $1.5 billion. Finland's mineral commodity trade in 1978 and 1979 are shown in tables 2 and 3.

Table 2.—Finland: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS				
Aluminum metal including alloys:				
Scrap	644	(1)	--	(1)
Unwrought	2,652	1,337	--	Sweden 909; Japan 256.
Semimanufactures	38,580	23,277	NA	West Germany 5,377; Denmark 3,763; United Kingdom 3,464.
Cadmium metal including alloys, all forms	507	(2)	(2)	(2)
Chromium: Chromite	364,461	308,847	8,508	Sweden 264,223; France 14,715.
Cobalt metal including alloys, all forms	853	(2)	(2)	NA.
Copper metal including alloys:				
Scrap	218	521	--	Mainly to Denmark.
Unwrought	17,542	16,893	92	East Germany 5,472; Spain 3,777; West Germany 2,899.
Semimanufactures	26,865	29,158	2,105	United Kingdom 7,023; Sweden 4,547; France 3,748.
Gold metal, including alloys, unwrought and wrought troy ounces	4,710	NA	NA	NA.
Iron and steel:				
Ore and concentrate	13,302	NA	NA	NA.

Elemental, all forms	8	NA	NA	NA.
Sulfuric acid	113,128	NA	NA	NA.
Talc and steatite, soapstone, pyrophyllite	27,609	(5)	NA	NA.
Other:				
Crude	6,254	5122,354	NA	Sweden 39,353; United Kingdom 36,693; West Germany 14,485.
Slag, dross, and similar waste, not metal-bearing:				
From iron and steel manufacture	30	NA	NA	NA.
Other	13	NA	NA	NA.
Building materials of asphalt, asbestos and fiber cements, and unfired nonmetals	4,622	5,768	--	U.S.S.R. 2,453; Norway 1,417; Sweden 1,020.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	436	NA	NA	NA.
Carbon black	11	NA	NA	NA.
Coke and semicoke	612	2,080	--	Mainly to Norway.
Hydrogen, helium, rare gases kilograms	1,400	NA	NA	NA.
Peat including briquets and litter	17,241	30,028	NA	Netherlands 9,808; United Kingdom 5,884.
Petroleum refinery products:				
Gasoline thousand 42-gallon barrels	4,923	4,342	205	Sweden 3,290; Netherlands 523; United Kingdom 207.
Kerosine ____ do	r154	82	--	Mainly to Denmark.
White spirit ____ do	471	NA	NA	NA.
Jet fuel ____ do	154	NA	NA	NA.
Distillate fuel oil ____ do	3,950	1,150	--	Sweden 1,067; U.S.S.R. 82.
Residual fuel oil ____ do	3,459	2,818	--	Sweden 2,078; West Germany 319; United Kingdom 259.
Lubricants ____ do	124	113	NA	U.S.S.R. 55; Nigeria 45.
Other:				
Liquefied petroleum gas ____ do	64	20	NA	Mainly to Cuba.
Mineral jelly and wax ____ do	12	NA	NA	NA.
Nonlubricating oils ____ do	4	NA	NA	NA.
Petroleum coke, bitumen, bituminous mixtures ____ do	28	25	--	U.S.S.R. 22; Sweden 2.

rRevised. NA Not available.

[1] Aluminum scrap, if any, is included in "Other: Ash and residue containing nonferrous metals."

[2] Exports, if any, of metallic cadmium, cobalt, and tin in any form (except tin scrap) are included in "Other: Base metals including alloys, all forms."

[3] Quantity not available; exports valued at $389,000, mainly to West Germany and the United Kingdom.

[4] Quantity not available; exports valued at $4,932,000, mainly to Sweden and West Germany.

[5] Exports, if any, of chalk, crude clays, diatomite, feldspar, leucite, nepheline syenite, limestone, quartz, talc, steatite, soapstone, and pyrophyllite, are included in "Other: Crude."

[6] Quantity not available; exports valued at $499,000, mainly to the United Kingdom and West Germany.

[7] Quantity not available; exports valued at $569,000, mainly to the United States.

rRevised. NA Not available.

[1]Imports, if any, of metallic antimony, beryllium, cadmium, cobalt, magnesium, molybdenum, and tungsten are included in "Other: Base metals including alloys, all forms."

[2]Quantity not available; imports valued at $697,000, mainly from the United Kingdom and Sweden.

[3]Quantity not available; imports valued at $6,785,000, mainly from the United Kingdom, Sweden, and West Germany.

[4]Less than 1/2 unit.

[5]Imports, if any, of barite, witherite, crude natural borates, chalk, crude clays, cryolite, chiolite, feldspar, leucite, nepheline syenite, fluorspar, graphite, magnesite, crude mica, dolomite, limestone, quartz, quartzite, talc, steatite, soapstone, and pyrophyllite are included in "Other: Crude."

[6]Quantity not available; imports valued at $6,069,000, mainly from Belgium-Luxembourg, the United Kingdom, and Switzerland.

[7]Quantity not available; imports valued at $175,000.

[8]Quantity not available; imports valued at $351,000, mainly from Switzerland and West Germany.

[9]Quantity not available; imports valued at $449,000, mainly from the United States and Switzerland.

COMMODITY REVIEW

METALS

Chromite.—Work started in 1980 to raise from 50,000 tons per year to 60,000 tons per year, the production capacity of the ferrochrome plant at Outokumpu Oy's Tornio works, located at the head of the Gulf of Bothnia. Construction is to be completed by the end of 1981. The quantity of ferrochrome available for sale is to decline, because of the increased demand in the stainless steel works. Company plans called for a doubling of stainless steel output in the 1980's from the present 140,000 tons per year. In 1980, preliminary figures for ferrochrome production were about 52,000 tons, and for rolled speciality steels, 76,000 tons.

In 1980, Outokumpu Oy remained the country's only chromite producer, with mines located at Kemi at the head of the Gulf of Bothnia. Under exploitation were the Viia ore body and the Elijärvi open pit. The company's ferrochrome plant and stainless steel plant were nearby at Tornio.

Cobalt and Molybdenum.—Outokumpu Oy decided to raise cobalt output at its Kokkola works on the west coast to 1,350 tons in 1981; 1980 production was about 1,200 tons. The increase was a result of an 8-year contract to buy residues from the Democratic Republic of Germany's Mansfeld copper smelter, which contain cobalt and molybdenum among other metals. Most of the cobalt product is to be exported, half of it to the United States. Finland's domestic consumption of cobalt was only 10 tons per year.

Copper, Nickel, Lead, and Zinc.—Exploration and process development work was started by Outokumpu Oy at the Talvivaara copper, nickel, cobalt, and zinc deposit near Sotkamo, near the center of the

country. Other major investment goals of the company were centered on the Pori plant on the west coast and the converting section of the Harjavalta smelter nearby. In Pori, capacity of the electrolytical copper refinery is to be expanded from 45,000 to 56,000 tons per year, the quantity of drawn products (wire) is to be expanded from 28,000 to 43,000 tons per year, rolling capacity is to be expanded from 16,000 to 20,000 tons per year.

In 1980, Outokumpu Oy's production of copper cathodes was about 41,000 tons, and the total of copper semiproducts was 51,500 tons. Production of nickel cathodes was about 12,800 tons, and zinc production was 146,000 tons.

In 1980, Myllikoski Oy, a paper manufacturing company, continued to produce copper ore at its Luikonlahti Mine, located near the Outokumpu Mine near the southeast border. The company increased prospecting activities for copper ores during the year. The Suomen Talkki Co. produced 4,400 tons of nickel concentrate during 1980, as a byproduct of the company's talc production.

Iron Ore.—In November 1980, an agreement was reached on the second and third stages of the Kostamus cooperative project in the U.S.S.R., signed during President Kekkonen's trip to Moscow. Stage 1, signed earlier, was to be completed in 1982. The agreement is to have a significant impact on Finnish-Soviet bilateral trade, and is to involve a value of $750 million and approximately 3,500 Finnish workers. The capacity of the mining industry complex will be expanded from 3 million to 9 million tons of iron ore pellets per year, and a town for 9,000 inhabitants will be built. The Finnish contractor, Finn-Stroi Oy, expected the final agreement with its Soviet counterpart, V. O. Promashimport, early in 1981. Indirectly the project employed 20,000 people in Finland, because 90% of the contract was covered by Finnish raw materials, machinery, and equipment. The Kostamus project, located 60 miles from the Finnish border town of Kainuu, was also important to Finland in alleviating the high unemployment (14%) in this area, because workers could commute across the border to their jobs. The unemployment rate was expected to fall to 11% during the life of the project.

Production of iron ore at Rautaruukki Oy's Rautavaara Mine in the north did not change significantly in 1980 and was 288,000 tons, but the Otanmäki Mine in central Finland increased production by approximately 15% to 522,000 tons. The company continued its 3-year-old project for mapping the country's iron ore deposits, which is being conducted in cooperation with the Finnish Geological Survey and Soviet experts.

Iron and Steel.—Ovako Oy decided to raise the share of special steel billets from 20% of its output to 30% of output by 1982. Speciality steel produced included high carbon and welding quality steels, cold heading grades (containing boron), and spring steels, mainly silicomanganese, as well as heat treatment steels for the engineering industry. As part of the expansion, the company has completed a ladle injection plant, and is to increase capacity of its billet treatment facilities.

Outokumpu Oy, the country's principal stainless steel producer, a Government-owned company, took over Oy Ja-Ro AB, formerly part of Oy Wilh. Schauman AB. Ja-Ro's activities are said to be unaffected by the takeover, and the company is to remain a separate company. The company bought most of its steel from Outokumpu Oy's Tornio works in northern Finland, and produced longitudinally welded stainless pipes and fittings, as well as vessels and tanks. Outokumpu Oy also bought the Gothenburg, Sweden-based steel importer, trader, and stockholder, Lennart Sjöstedt AB, and will rename it Outokumpu Svenska AB. The company has offices in Oslo and Paris.

NONMETALS

Apatite.—In 1980, Rautaruukki Oy continued prospecting and pilot-plant work at its Sokli apatite deposit in Kuopio Province. According to the company, evaluation of the project was making good progress.

Contracts were signed between two Government-owned companies, Outokumpu Oy and Kemira Oy, for the delivery of pyrite. Outokumpu's Pyhäsalmi Mine, in central Finland, was to supply 5 million tons of pyrite concentrate over a period of 15 years, which will be used for the production of sulfuric acid at Kemira's Siilinjärvi fertilizer plant, where the company's sulfuric acid capacity is to be raised from 300,000 to 500,000 tons per year. Until completion of the Siilinjärvi sulfuric acid plant expansion, the balance of sulfuric acid used is to be produced by the existing Kokkola plant on the west coast. According to the contract, phosphate rock mining operations at

Kuopio, central Finland, are to be expanded. Production of apatite concentrate is to be increased from the current level of 210,000 tons per year to around 500,000 tons per year. At present, the concentrate containing 36% P_2O_5 is produced from 2 million tons of ore containing 4% P_2O_5.

Industrial Minerals.—In 1980, Oy Lohja AB produced 1.2 million tons of dolomite limestone, 78,000 tons of burnt lime, and 604,000 tons of cement. Oy Partek AB produced 3 million tons of dolomite limestone, mainly for cement and lime, at six locations: Pargas, Villmanstrand, Kolari, Vimpeli, Siikainen, and Ankele. Kemira Oy produced 10,000 tons of calcite concentrate as a byproduct of its apatite process. Myllikoski Oy produced a byproduct talc concentrate at its Luikonlahti copper mine which is used by the company as a paper filler. Rauma-Repola Oy produced 200,000 tons of dolomite and 20,000 tons of quartzite.

Paraisten Kalkki Oy remained the country's largest cement producer, with three cement plants with a total capacity of 1.85 million tons. The plants were located at Pargas, south coast, Lappeeranta in south east, and Kolari in Finnish Lappland.

MINERAL FUELS

In 1980, Finland remained about 85% dependent on imported fuels, mostly crude oil, natural gas, nuclear fuel, coal, and coke. A major share of the crude oil and all natural gas was imported from the Soviet Union. Domestic fuel production was mainly hydroelectric power, peat, fuelwood, and industrial waste.

Nuclear Power.—Operations started at the second 660-megawatt electrical unit of the nuclear powerplant of Teollisuuden Voima Oy, located on the west coast at Olkiluoto Island, 13 kilometers north of Rauma. The plant was built by the AB Asea-Atom (Sweden) and the Työyhtymä Jukola Consortium (Finland).

Construction continued at the second 440-megawatt electrical unit of the nuclear powerplant of Imatran Voima Osakeythiö (IVO), located at Loviisa, about 80 kilometers east of Helsinki.

IVO has plans to build a third nuclear powerplant of 1,000 megawatt electrical of the Soviet VIS Atomenergoexport type in the general area of Helsinki. The plant would also provide about 1,000 megawatt of heat for long-distance space heating in the area.

Peat.—Vapo, the Finnish State Fuel Center, reported that production of peat in 1980 exceeded 6 million cubic meters. The peat bogs in production this year exceeded 23,000 hectares, while individuals owned and exploited 3,000 acres. The goal is to produce eventually 20 million cubic meters of peat. The Haukineva peat-coke plant, in southwest Finland, resumed operation at the rate of 100 tons of briquettes daily, for supplying private consumers.

Petroleum and Natural Gas.—Neste Oy, the Government-owned oil company, agreed to continue refining crude oil for Sweden during 1981 and 1982, at the rate of 1.5 million tons per year. Neste Oy had a total oil refining capacity of 15 million tons, located at Naantali on the west coast and at Porvoo on the south coast. Most of the country's oil imports and all its gas imports came from the Soviet Union pipeline. During the past 2 years, the price of oil was said to have increased well over twofold, but industrial exports to the Soviet Union could balance most of Finland's trade debts.

The Mineral Industry of France

By Roman V. Sondermayer[1]

France produced moderate quantities of minerals and was also an important processor of imported crude mineral commodities, including petroleum, during 1980. In some regions the mineral industry was a significant economic factor that provided employment and was essential for the well-being of the population. Some mines in France remained operational for social reasons during 1980.

The most prominent minerals and metals produced in France during 1980, with production expressed as approximate percentage of the world totals, were arsenic, 18.3; gypsum, 8.0; fluorspar, 5.9; and diatomite, 3.2. With the reorganization of France's Government agencies dealing with minerals and energy completed in 1979, the Government started to implement its policy more forcefully than in the past.

There were four basic ingredients in this policy: (1) To develop domestic resources, starting with a thorough inventory to develop information on known resources and to locate new deposits; (2) to improve recovery and utilization of materials; (3) to increase the security of foreign supplies by encouraging French involvement, both governmental and private, in foreign production, and by diversifying sources; and (4) to establish and maintain a raw materials stockpile. The policy is administered by the Ministry of Industry through its General Direction for Energy and Raw Materials, which comprises a number of operating agencies, notably the Bureau de Recherches Géologiques et Minières (BRGM).

In 1975, the Ministry of Industry put into practice a plan to inventory French domestic resources of nonferrous metals and other minerals. Its Comite de l'Inventaire du Territoire Metropolitain spent 142 million francs on this in 1975-79, and in Guyana about 38 million francs were spent for a similar purpose by the overseas section of the Counseil General des Mines. A forerunner of the plan was the so-called Copper Plan, started in 1973, which was the Government's first strong interest in minerals supply.

Since 1975, a number of programs have been implemented to economize on the use of raw materials (not only metals), to promote new and more economical products, and to improve primary and secondary recovery of metals. These programs include some of the steps taken under the Copper Plan and other metals plans.

France tries to ensure supplies of minerals from abroad by direct investment in foreign minerals industries; by political support of French minerals interests abroad; by rendering various services, such as exploration mapping and technical assistance; by education of foreigners in French educational institutions; and by providing easy credit terms for purchase of French know-how and equipment. Both BRGM and private companies act as instruments of this policy.

In 1975, a start was also made on a minerals stockpile. A provision was inserted in the budget to provide 250 million francs (about US$50 million) to provide an average of a 2-month supply to supplement industrial stocks. No details of actual stockpile materials were released, but it was reported that most important were silver, platinum, diamonds, phosphate, zirconium, titanium, and cobalt.

In 1980, the Caisse Francaise des Matieres Premieres (CFMP) was constituted to finance a national precautionary stockpile (stock national de precaution). About 1.6

billion francs were to be spent by the end of 1981. The CFMP retains control, but financing comes from the existing Caisse Nationale de l'Energie, and physical management of the stockpile is by the Groupement d' Importation des Metaux, an industry association.

It is important to note that the French stockpile is conceived primarily as a peacetime instrument, to ensure continuous supplies at regular prices to French consumers. It is of course intended as a defense stockpile in wartime.

Principal events in the mineral industry during 1980 included the discovery of two possible antimony deposits, the preparation for opening a small antimony mine in Finisterre, the discovery of a deposit of complex sulfide ores in Morbihan, the commissioning of two oxygen converter plants by Usinor, the beginning of tungsten and tin production in the Ille-et-Vilaine, and the startup of a new plant for beneficiation of andalusite in Glomel.

PRODUCTION

Table 1 shows the latest figures on French mineral production. Both private companies and the Government, through state-owned corporations, produced minerals at home and abroad. BRGM was an important instrument of the Government in ensuring raw materials for the French economy by exploration and ventures abroad.

Kerosine do	866	770	705	884	1,054
Distillate fuel oil do	309,401	303,920	302,436	326,710	267,655
Residual fuel oil do	243,617	240,783	239,820	246,540	215,723
Lubricants do	8,909	9,364	10,276	10,427	10,860
Other:					
Liquefied petroleum gas do	33,811	34,785	33,860	33,489	36,048
Bitumen do	21,743	20,268	19,956	20,150	19,453
Unspecified do	49,096	32,348	82,755	[e]87,950	[e]79,250
Refinery fuel and losses do	53,793	52,689	50,771	54,691	56,832
Total do	902,197	873,504	927,689	978,051	881,291

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Oct. 5, 1981.

[2]Although output reported is at the smelter stage of production rather than at the mine stage and thus could include metal contained in ores mined in other countries, it is believed that any such production derived from ores from other countries is not duplicative to any significant extent of mine production reported for other countries.

[3]Revised to none.

[4]Series revised to include blast furnace ferroalloys and silicon metal, both hitherto counted separately.

[5]Includes smectic clay.

[6]Includes material for both the glass industry and the ceramics industry.

[7]Excludes bituminous material produced by oil refineries.

TRADE

Tables 2 and 3 show details on foreign trade in minerals of France.

Table 2.—France: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite	17,437	12,471	NA	Sweden 8,069; West Germany 1,026.
Oxide and hydroxide	[r]303,031	326,901	12,093	Netherlands 85,473; Spain 83,478; Norway 82,989.
Metal including alloys:				
Scrap	33,967	39,790	NA	Italy 16,797; West Germany 13,876; Belgium-Luxembourg 7,141.
Unwrought	166,418	157,598	NA	Italy 40,133; West Germany 35,126; Belgium-Luxembourg 25,670.
Semimanufactures	217,291	260,798	12,822	West Germany 76,398; Italy 23,525; United Kingdom 21,275.
Antimony:				
Ore and concentrate	7	770	--	Belgium-Luxembourg 365; Czechoslovakia 290; Spain 115.
Metal including alloys, all forms	392	126	NA	Belgium-Luxembourg 47; Italy 30; West Germany 18.
Arsenic metal including alloys, all forms	146	41	NA	NA.
Beryllium metal including alloys, all forms value, thousands	$41	$22	NA	NA.

See footnotes at end of table.

Table 2.—France: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS —Continued				
Bismuth metal including alloys, all forms	7	49	NA	Netherlands 32; United Kingdom 5.
Cadmium metal including alloys, all forms	219	478	92	Belgium-Luxembourg 158; West Germany 144; Netherlands 54.
Chromium:				
Chromite	983	1,379	NA	Italy 793; West Germany 340.
Oxide and hydroxide	171	280	NA	Italy 123; Belgium-Luxembourg 47; West Germany 33.
Metal including alloys, all forms	611	720	245	West Germany 155; Italy 74; Sweden 74.
Cobalt:				
Oxide and hydroxide	192	118	NA	West Germany 40; United Kingdom 35; Belgium-Luxembourg 19.
Metal including alloys, all forms	1,100	797	272	West Germany 186; Italy 83; United Kingdom 56.
Columbium and tantalum:				
Ore and concentrate	--	12	NA	NA.
Metals including alloys, all forms:				
Columbium value, thousands	$14	$21	NA	NA.
Tantalum	12	22	5	West Germany 7.
Copper:				
Ore and concentrate	(1)	564	NA	Spain 346; West Germany 217.
Matte	504	1,181	NA	Spain 978; Belgium-Luxembourg 159.
Sulfate	11,245	12,549	NA	West Germany 5,062; Netherlands 1,460; United Kingdom 1,159.
Metal including alloys:				
Scrap	r98,204	104,933	226	West Germany 45,884; Belgium-Luxembourg 23,345; Italy 21,415.
Unwrought:				
Blister and other unrefined	3,665	5,790	NA	Belgium-Luxembourg 3,990; West Germany 1,775.
Refined	21,249	21,756	733	Italy 7,325; Belgium-Luxembourg 5,070; West Germany 3,469.
Masteralloys	342	257	NA	Italy 79; West Germany 54; Spain 17.
Semimanufactures	117,679	161,090	9,505	West Germany 43,380; Italy 34,708; United Kingdom 20,552.
Gold:				
Ash and sweepings value, thousands	$54,128	$43,910	NA	Spain $42,719; Switzerland $398.
Metal including alloys, unwrought and partly wrought:				
Of domestic origin troy ounces	r733,454	1,080,553	NA	Belgium-Luxembourg 427,283; French Polynesia 287,299.
Temporary imports do.	158,117	171,556	--	Algeria 51,666; Netherlands 46,811; Switzerland 31,990.
Iron and steel:				
Ore and concentrate thousand tons	11,371	10,220	NA	Belgium-Luxembourg 8,328; West Germany 1,890.
Metal:				
Scrap do.	3,662	3,526	2	Italy 2,722; Spain 410; Belgium-Luxembourg 193.
Pig iron including cast iron[2] do.	128	362	26	Italy 158; Belgium-Luxembourg 60; Romania 49.
Sponge iron, powder, shot do.	36	40	NA	West Germany 17; Italy 9.
Ferroalloys do.	501	602	198	West Germany 140; Italy 89; Belgium-Luxembourg 59.
Steel, primary forms do.	2,200	2,333	551	Italy 672; West Germany 154; Greece 126.
Semimanufactures:				
Bars, rods, angles, shapes, sections do.	2,327	2,359	209	West Germany 434; Belgium-Luxembourg 279; China, mainland 187.
Universals, plates, sheets do.	3,486	3,134	311	West Germany 570; Italy 467; Belgium-Luxembourg 141.
Hoop and strip do.	449	452	4	West Germany 154; Belgium-Luxembourg 82; Italy 61.
Rails and accessories do.	231	254	15	Italy 58; Belgium Luxembourg 33; Netherlands 20.
Wire do.	154	164	40	West Germany 33; Belgium-Luxembourg 13; Italy 8.

See footnotes at end of table.

Table 2.—France: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
NONMETALS —Continued				
Precious and semiprecious stones except diamond:				
Natural ____ value, thousands__	$19,860	$26,963	$758	Switzerland $17,503; United Kingdom $2,218.
Manufactured _____do____	$11,043	$13,094	$1,402	Switzerland $7,809; Mexico $582; U.S.S.R. $509.
Pyrite (gross weight)_____	87	36	NA	NA.
Salt and brines _____	167,728	230,393	NA	West Germany 149,488; Belgium-Luxembourg 32,465.
Sodium and potassium compounds, n.e.s.:				
Caustic soda_____	52,564	82,202	NA	Egypt 9,546; Indonesia 8,950; Tunisia 8,605.
Caustic potash, sodic and potassic peroxides _____	r11,022	15,121	NA	Netherlands 5,093; Switzerland 1,911.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked:				
Calcareous _____	17,996	18,479	NA	Belgium-Luxembourg 5,120; Switzerland 4,580; West Germany 3,735.
Slate_____	51,926	66,157	NA	Netherlands 30,929; West Germany 16,461; Belgium-Luxembourg 12,350.
Other _____	58,808	58,093	NA	Belgium-Luxembourg 41,092; West Germany 4,330; Switzerland 3,574.
Worked:				
Slate_____	5,105	5,417	NA	Belgium-Luxembourg 1,873; United Kingdom 1,345; West Germany 1,287.
Paving stone and flagstone__	7,443	11,612	NA	Belgium-Luxembourg 5,910; West Germany 3,267.
Other _____	30,938	34,938	276	Belgium-Luxembourg 12,814; West Germany 11,504; Saudi Arabia 4,165.
Dolomite, chiefly refractory grade __	51,755	51,512	NA	Belgium-Luxembourg 13,693; West Germany 9,750; Switzerland 6,407.
Gravel and crushed rock thousand tons__	10,624	10,912	5	West Germany 7,450; Switzerland 1,279; Belgium-Luxembourg 1,057.
Limestone except dimension _____	157,068	208,036	NA	West Germany 163,656; Belgium-Luxembourg 41,295.
Quartz and quartzite_____	2,308	1,536	NA	United Kingdom 280; West Germany 204.
Sand, excluding metal-bearing thousand tons__	4,342	4,596	NA	West Germany 2,555; Switzerland 931; Italy 792.
Sulfur:				
Elemental, all forms_____do____	1,159	1,249	NA	United Kingdom 369; Tunisia 168; Netherlands 160.
Sulfuric acid, oleum _____	139,057	213,517	NA	Belgium-Luxembourg 116,646; Spain 38,805; West Germany 22,161.
Talc, steatite, soapstone, pyrophyllite __	77,310	75,159	3,601	West Germay 26,178; United Kingdom 9,218; Belgium-Luxembourg 7,864.
Other:				
Crude_____ thousand tons__	1,255	1,206	NA	Belgium-Luxembourg 1,023; Switzerland 165.
Slag, dross, and similar waste, not metal-bearing:				
From iron and steel manufacture thousand tons__	2,383	2,408	15	West Germany 1,103; Belgium-Luxembourg 957; Netherlands 272.
Unspecified _____	253,859	309,427	NA	Mainly to West Germany.
Oxides, hydroxides, peroxides of strontium, magnesium, barium _____	4,978	9,426	3,319	U.S.S.R. 3,571; West Germany 1,062.
Fluorine, elemental _____	1	25	NA	NA.
Building materials of asphalt, asbestos and fiber cements, and unfired nonmetals_____	126,366	139,173	870	West Germany 28,939; Netherlands 16,624; Italy 16,055.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural _____	10,379	7,248	NA	United Kingdom 4,500; Morocco 384; Comoros 340.
Carbon black and gas carbon:				
Carbon black _____	56,246	72,664	NA	West Germany 21,676; Italy 17,616; Spain 12,981.
Gas carbon _____	--	1	NA	NA.

See footnotes at end of table.

Table 2.—France: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
MINERAL FUELS AND RELATED MATERIALS —Continued				
Coal and briquets:				
Anthracite and bituminous coal	531,749	569,554	--	West Germany 323,095; Belgium-Luxembourg 83,831; Norway 60,836.
Briquets of anthracite and bituminous coal	27,786	41,312	--	United Kingdom 36,478; West Germany 2,195; Switzerland 2,022.
Lignite including briquets	6,370	6,908	NA	Mainly to Spain.
Coke and semicoke thousand tons	766	1,570	389	West Germany 290; Romania 238; Belgium-Luxembourg 145.
Gas, hydrocarbon, natural thousand cubic feet	6,250	5,854	NA	Switzerland 3,175; Belgium-Luxembourg 2,649.
Hydrogen, helium, rare gases	3,469	6,205	NA	Italy 4,430; Netherlands 371; Switzerland 364.
Peat including briquets and litter	2,075	2,145	NA	NA.
Petroleum and refinery products:				
Crude and partly refined thousand 42-gallon barrels	194	1	NA	Mainly to Austria.
Refinery products:				
Gasoline[3] do	21,970	25,736	303	Netherlands 6,928; West Germany 4,773; Switzerland 4,176.
Kerosine[4] do	8,151	9,509	148	Switzerland 2,433; Greece 1,075; Denmark 926.
Distillate fuel oil do	35,430	35,683	561	Switzerland 11,730; West Germany 8,451; Greece 3,789.
Residual fuel oil do	26,557	42,243	5,507	United Kingdom 6,188; Italy 5,344; West Germany 5,058.
Lubricants do	r4,424	5,235	124	Belgium-Luxembourg 949; United Kingdom 621; West Germany 535.
Mineral jelly and wax do	738	585	NA	United Kingdom 241; West Germany 164; Netherlands 67.
Liquefied petroleum gas do	6,256	8,745	135	Spain 4,182; West Germany 958; Portugal 760.
Petroleum coke, bitumen, other residues do	2,451	1,962	NA	West Germany 868; Switzerland 678; Belgium-Luxembourg 271.
Bituminous mixtures do	335	337	NA	Algeria 141; Belgium-Luxembourg 56; Sweden 37.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	194,478	375,952	NA	West Germany 136,243; Netherlands 106,240; Italy 61,156.

rRevised. NA Not available.
[1]Value only reported at $6,000.
[2]Includes spiegeleisen.
[3]Includes motor and aviation gasoline, other light oils for similar uses, and white spirit.
[4]Includes other medium oils.

METALS —Continued				
Arsenic metal including alloys, all forms	60	113	6	Sweden 31; Netherlands 29.
Beryllium metal including alloys, all forms	18	9	8	U.S.S.R. 1.
Bismuth metal including alloys, all forms	346	322	NA	Bolivia 104; Belgium-Luxembourg 79; West Germany 55.
Cadmium metal including alloys, all forms	609	735	NA	Belgium-Luxembourg 193; Netherlands 147; Japan 140.
Chromium:				
Chromite	242,480	261,701	NA	Republic of South Africa 105,781; Turkey 56,750; Madagascar 37,852.
Oxide and hydroxide	5,241	5,821	55	West Germany 2,924; Italy 1,434; United Kingdom 755.
Metal including alloys, all forms	64	246	21	Japan 95; Belgium-Luxembourg 92.
Cobalt:				
Intermediate metallurgical products	9,727	7,684	NA	Mainly from Morocco.
Oxide and hydroxide	293	267	17	Belgium-Luxembourg 229; United Kingdom 12.
Metal including alloys, all forms	994	897	127	Belgium-Luxembourg 325; West Germany 137.
Columbium and tantalum metals including alloys, all forms:				
Columbium	11	5	NA	Mainly from West Germany.
Tantalum	30	52	31	West Germany 11.
Copper:				
Ore and concentrate	1	4	NA	NA.
Matte	522	45	NA	NA.
Sulfate	2,540	2,758	NA	Italy 829; U.S.S.R. 622; Belgium-Luxembourg 539.
Metal including alloys:				
Scrap	r19,086	24,870	89	West Germany 7,412; Belgium-Luxembourg 5,827; United Kingdom 2,603.
Unwrought:				
Blister and other unrefined, unalloyed	22,734	21,258	NA	Zaire 16,431; Belgium-Luxembourg 1,596; Chile 1,351.
Refined, unalloyed	282,691	347,731	14,081	Zambia 107,637; Belgium-Luxembourg 105,884; Chile 41,844.
Master alloys	789	305	NA	Belgium-Luxembourg 149; Spain 107; West Germany 39.
Semimanufactures	213,502	206,220	3,213	Belgium-Luxembourg 110,088; West Germany 39,901; Italy 23,463.
Germanium metal including alloys, all forms, value, thousands	$795	$755	$222	Belgium-Luxembourg $413.
Gold:				
Waste and sweepings, do.	$4,575	$7,454	NA	Switzerland $5,037; United Kingdom $661; West Germany $591.
Metal including alloys, unwrought and partly wrought:				
For domestic use, thousand troy ounces	1,666	2,804	8	West Germany 1,932; Netherlands 328; Italy 248.
Temporary imports, do.	629	591	72	Netherlands 236; Switzerland 176; United Kingdom 53.
Iron and steel:				
Ore and concentrate except roasted pyrite, thousand tons	14,604	17,345	NA	Brazil 4,398; Sweden 3,000; Mauritania 2,868.
Roasted pyrite	92,272	87,452	NA	Italy 56,332; West Germany 18,927; Spain 12,115.
Metal:				
Scrap	393,803	422,289	321	Belgium-Luxembourg 201,389; West Germany 102,894; United Kingdom 55,269.
Pig iron including cast iron[1]	407,438	446,457	NA	West Germany 417,646; Canada 12,608.
Sponge iron, powder, shot	19,335	29,342	5	Sweden 14,649; West Germany 7,770; Venezuela 2,497.
Ferroalloys	178,554	318,117	395	New Caledonia 142,095; Belgium-Luxembourg 38,836.
Steel, primary forms, thousand tons	2,272	2,664	(2)	Belgium-Luxembourg 1,473; West Germany 785; Netherlands 132.
Semimanufactures:				
Bars, rods, angles, shapes, sections, do.	1,871	1,988	(2)	Belgium-Luxembourg 611; West Germany 583; Italy 534.

rRevised. NA Not available.
[1]Including spiegeleisen.
[2]Less than 1/2 unit.
[3]Includes oxides of germanium, if any.
[4]Includes matte of zinc.
[5]Includes motor and aviation gasoline, other light oils for similar uses, and white spirit.
[6]Includes other medium oils.

COMMODITY REVIEW

METALS

Aluminum.—Aluminium Pechiney, Union des Bauxites, Société Anonyme des Bauxites et Alumines de Provence, Société Alusuisse France, Etablissement Sabulard, and Etablissement Rondani produced bauxite in France during 1980 from mines located in Var, Herault, Bouches-de Rhone, and Ariege Departments. Roughly two-thirds of French consumption was domestic

bauxite, but the general trend of bauxite production was downward, caused by exhaustion of reserves. About 800 persons were employed in bauxite mines.

Pechiney Ugine Kuhlmann (PUK) produced alumina in three plants in France with a total capacity of 1,390,000 tons per year. The largest, with a capacity of 745,000 tons of alumina per year, was located at Gardanne, Bouches-du-Rhone. Aluminum metal was produced in 10 plants situated in the Alps and Pyrenees; the plant at Nogueres, Pyrenees-Atlantiques was the largest, accounting for about one-third of the total French aluminum output. Approximately 7,000 persons worked in aluminum-producing facilities. France also operated 40 plants with a capacity of 520,000 tons of semimanufactured aluminum products per year. Employment in these plants was 14,000 persons.

Antimony.—During 1980, exploration of the deposit of Ty Gardien at Quimper, Finisterre, confirmed the existence of a small deposit of antimony with reserves of about 2,800 tons of contained metal. Exploitation was planned for 1981 and the deposit should be exhausted by 1983. In addition, indications of possible antimony deposits were discovered at Rosnoen in Finisterre and Coefferies in Ile-et-Vilaine.

Société Industrielle et Chimique de l'Aisne, situated in Chauny and owned by the Hochschild Group, produced antimony chemicals; Société Nouvelle des Mines de la Lucette operated an antimony smelter and a plant for production of antimony chemicals. Both companies operated on imported raw materials.

Copper.—Preliminary results of exploration carried out by the BRGM indicated possible copper, lead, zinc, and silver complex ore deposits at Rosemellec Stival and Telhaie in Morbihan. In addition, metallurgical work continued on samples from the Bodennec and Porte aux Moins deposits of complex lead, zinc, and copper ores.

During 1980, France had only one large 45,000-ton-per-year electrolytic copper plant, situated at Palais, Haute-Vienne, in operation. This plant operated on imported blister or anodes and on scrap. A small refinery was operated by Afficuivre. Afficuivre was acquired by the Compagnie Francaise de Ferrailles during 1980. Furthermore, another plant located near Toulouse and owned by the Affinerie du Sud-Oest was a producer of fire-refined copper.

About 50 plants with an annual capacity of 600,000 tons of copper semimanufactured products, employing 17,000 persons, were in operation during 1980 in France.

Gold.—Exploration for gold continued at Saint Yrieix, Haute Vienne, conducted by the BRGM and Penarroya.

The only producer of gold in France was the Salsigne Mine in the Department of Aude. This mine, owned by Canadian interests, was purchased by Coframines, a subsidiary of the BRGM, at the beginning of 1980.

Iron and Steel.—The iron ore producing sector of France had an uneventful year. East Basin was by far the largest area of iron ore production in the country during 1980.

The steel producing sector, after going through a drastic intervention by the Government during 1979, started to show slight signs of improvement. Two new oxygen converters, 125 tons each, went onstream at the Neuves-Maison steelworks operated by Usinor; another two oxygen converters, 85 tons each, started production at the Rehon steelworks also operated by Usinor. At the Seremange plant owned by Sollac, a new continuous caster was commissioned.

Lead and Zinc.—Possible new lead and zinc deposits were discovered in the complex sulfide mineralization near Rosmellec, Stival, and La Telhaie in Morbihan. The Bodennec and Porte aux Moins deposits were explored and metallurgical research was underway to resolve complex problems faced during flotation of these ores.

In France, lead and zinc ores and lead and zinc concentrates were produced at the Largentiere, Ardeche, and Malines, Gard, Mines, owned by the Société Minière et Metallurgique de Penarroya. In addition, at the La Farges Mine, Correze, owned by the Société Minière de Correze, lead concentrates and barites were produced; at the Noailhac-Saint-Salvy Mine, Tarn, only zinc concentrates were produced and germanium was a byproduct. Primary lead was produced in an Imperial smelter plant at Noyelles-Godault, Pas-de-Calais, with a capacity of 150,000 tons per year of lead; in addition, a lead refinery was part of the operation. Both facilities were part of a metallurgical complex operated by Penarroya.

Primary zinc was produced in three smelters. Compagnie Royale Asturienne des Mines, Asturienne, operated one electrolytic zinc plant located at Auby-les-Douai, Nord, with a capacity of 115,000

tons of zinc per year. A second electrolytic zinc plant was operated by the Société des Mines et Fonderies de Zinc de la Vieille Montagne, at Viviez, Aveyron, with a capacity of 110,000 tons of zinc per year. In addition, Vieille Montagne operated a thermal zinc refinery, with a capacity of 30,000 tons of extra pure zinc, located at Creil, Oise. Imported concentrates for Vieille Montagne were roasted in a roasting plant at Calais, Pas-de-Calais, before being sent to various European smelters. The third French zinc smelter was the Imperial smelter at Noyelles-Godault, Pas-de-Calais, with a capacity of 110,000 tons of zinc per year, operated by Penarroya.

Nickel.—After closure in 1979 because of a fire, the nickel plant located at Sandouville near Le Havre started up again in 1980. The plant capacity was reported at 20,000 tons per year of nickel products, of which 16,000 tons were nickel cathodes (99.98% nickel), as well as about 600 tons of cobalt.

Tungsten.—The Société des Mines de Montbellaux (SMM) started production of tungsten and tin from the Luitre deposit in Ille-et-Vilaine. Reports indicated reserves of 3 million tons of 0.25% WO_3 ore. The Société Industrielle et Chimique de l'Aisne (SICA) owned about three-fourths of SMM, and SICA was controlled by the Panamanian company Corona S.A., reportedly the principal company of the Hochschild Group.

Salau Mine in Ariege, owned by the Société Minière d'Anglade, was the major producer of tungsten in France during 1980.

The significant drop in tungsten production resulted from closure of the Enguiales Mine in Aveyron in the latter part of 1979.

NONMETALS

Andalusite.—During 1980, Demain-Azin-Mineraux (DAM) produced andalusite from its operations at Glomel, Cote-du-Nord, in northern Brittany. The reserves of the deposit were reported at 4 to 5 million tons. A new 25,000-ton-per-year beneficiation plant became fully operational at Glomel during 1980, bringing total plant capacity in the area to 50,000 tons per year.

The mine at Glomel was open cast, with 10- to 15-meter benches. Blasting was necessary. The ore was crushed to minus 1.6 millimeters to plus 0.6 millimeters. An electromagnetic separator removed most of the black chlorite and mica. The andalusite-quartz concentrate was separated into its two components in a double circuit, heavy media separation unit. DAM produced two grades of products that are sold under the commercial name "Kerphalite," named after a local village. Chemical composition of the two products was as follows:

Percent	Kerphalite KA	Kerphalite KB
SiO	37.5 -38.6	44.3 -44.8
Al_2O_3	59.0 -59.5	52.0 -53.0
Fe_2O_3	.9 - 1.1	.9 - 1.1
CaO	.15- .3	.12- .27
MgO	.09- .15	.12- .17
TiO_2	.2 - .28	.25- .31
Na_2O	.08- .10	.15- .25
K_2O	.15- .35	.25- .40

Barite.—During 1980, France remained an important producer of barite. The largest barite producer in the country (about 60% of the total) was the Société Barytine de Chaillac, with mines located about 50 kilometers southwest of Chateauroux in the northern part of the Massif Central. During 1980, the company engaged in research on treatment of tailings aimed at making pellets for use as backfill. During the year, dewatering techniques for this purpose were tested.

At the Lacan Mine, Aveyron, operated by the Société des Produits Chimiques de Viviez, a new access road was completed. Construction of a new plant for gravimetric preconcentration was near completion at yearend, with startup expected early in 1981. In addition to the two companies already mentioned, barite was produced by the following companies: Société des Couleurs Zinciques with mines at Pesseus, near Rodez, Aveyron, in the southern part of the Massif Central; Société Minière de Correz with Farges Mine near the town of Ussel; and Société de Mines de Garrot at Parres, near Les Arcs, Var. Barite was also recovered at the Rossignol fluorspar mine near Chaillac, Indre, operated by the Société Industrielle du Centre, as a byproduct of fluorspar production.

Cement.—About three-fourths of the 40 million tons per year of cement capacity in France was operated by the Société des Ciments Francais (SCF), Ciments Lafarge, France (CLF), and Ciments Vicats. Of the of 20 plants owned by SCF, 3 had a capacity of over 1 million tons: Airvault, 1.12 million tons, in Deux-Sevres Department; Rombas, 1.16 million tons, Moselle Department; and Couvrot 1.6 million tons, Department of the Marne. CLF operated 21 plants, but only 1 at Saint Pierre-la-Cour, Mayenne Department, had a capacity over 1 million tons. Ciment Vicat operated nine plants. Three had capacities over 1 million tons: Grave de

Paille, in Alpes Maritimes Department; Montalieu, at Verieu, Isere; and Xeuille, in Meurth et Moselle Department.

Clays.—Clays for refractories and ceramics were produced in almost all parts of France during 1980. In the Charente Basin, in the Charente Maritime Department in southwestern France, production of chamotte (burnt refractory clay) was dominated by the following companies: Argiles et Mineraux S.A., which operated quarries at Fountbuillant, Grand Liot, and Saint Georges and plants at Clerac and Bernet, all near Montguyon; and by the Société des Argiles Refractaires at Ceramiques d' Aquitaine, which produced clay from a quarry at Condeon in the northern part of the Charente Basin and processed it in a plant near Oriolles. In the Provins Basin, about 80 kilometers southeast of Paris near the town of Provins, DAM was the largest producer of chamottes with eight quarries, two underground mines, and one processing plant. A subsidiary of DAM, Terres Refractaires du Centre, produced clay for sanitary and tile products from the Damperre quarry near Beaulon, Allier. A subsidiary of Watts, Blake, Bearne and Co. Ltd. (WBB) of the United Kingdom, WBB of France produced clay from a property at Tournon-Saint-Martin near Chatelleraux.

Diatomite.—Riom-les Montagnes Mine in Cantal and Saint Bazil Mine in Ardeche operated by the Carbonisation et Charbon Actif S.A. remained principal producers of diatomite in France during 1980. In addition, Johns-Manville Corp. of the United States operated the Murtal Mine, also in Cantal.

Dolomite.—The leading dolomite producers in France were: La Dolomie Francaise S.A., with installations at Neau, near Mayenne, at Voisey in Haute-Marne, and at Ferriere-la-Grande in the north of France; Magnesie et Dolomie de France with mines at Elinghem-Ferques, Pas-de-Calais; Blanc Mineraux de Paris S.A., with a mine at Saint-Martin-Lys, Aude, was the major producer of filler-grade dolomite. Another producer of filler-grade dolomite was the mine at Saint Colombe-sur-Guette operated by Sopramine S.A., a subsidiary of Saint Gobin S.A. Société d' Exploitation de Sables et Mineraux S.A. produced dolomite at Chanac, Lozer, and Septemes in Bouche du Rhone, largely for production of glass. In addition, Chaux et Dolomies du Boulonnais S.A. produced calcined dolomite at Locquinghem-Rety. Crude dolomite for sale was produced by Randin S.A. at Elinghem-Ferques, Carrieres du Basin de Sambre at Dourlers, and Ara et Co. at Asap-Arros.

Fluorspar.—During 1980, France was an important producer and a net exporter of fluorspar, although imports of acidspar from South Africa in 1980 increased four times compared with 1979 imports.

The French fluorspar production was dominated by subsidiaries of PUK. The Société d' Enterprises, Carrieres et Mines de l'Esterel (SECME) completed deepening the main shaft at its mine at Fontsante, Var, in the first half of the year and managed to produce over 100,000 tons of acidspar during the year in review. At the Fontsante Mine sellaite (MgF_2) was produced and used for use in PUK's hydrofluoric acid plant near Lyon. The Fontsante Mine was the only mine operated by SECME after the closure of the Langeac Mine near Puy in Haute-Loire during 1979.

The Société General de Recherches et d'Exploitation Minières (SOGREM) increased capacity of its plant located near an opencast mine at Montroc, Tarn, to over 50,000 tons per year of concentrates. In addition to the Montroc Mine, SOGREM operated an underground mine, Le Bourg, near Albin in Tarn.

DAM produced fluorspar ore from an opencast mine based on the deposit at Escarro on Mount Canigou, about 50 kilometers southwest of Perpignan. The Escarro Mine has proven reserves reported at about 1.5 million tons of fluorspar. Compagnie Francaise de Mokta, formerly the Compagnie Francaise des Minerais d'Uranium, operated two mines, at Reclesne in Saone and at d'Argentolle in Loire.

The Société Industrielle du Centre produced fluorspar at its Rossignol Mine near Chaillac in Indre. Société des Mines du Haut du Them produced less than 5,000 tons of metspar from a mine at Mexaconchamp in the Vosges.

Gypsum.—France was the largest producer of gypsum in Europe during 1980. The major producing areas were the Paris Basin, the Rhone Basin, Alsace-Lorraine, the Atlantic Pyrenees, the Jura, the French Alps, Provence, and Charente.

The most important gypsum operations of the Société Anonyme de Material de Construction (SAMC) were at Taverny, Penchard, and Vaujours in the Paris Basin, at several mines in Alsace-Lorraine, and at Pouillon in the Atlantic Pyrenees. The

Taverny Mine, rated 1.1 million tons per year and located northwest of Paris, was an underground mine, using a room and pillar mining method. The gypsum bed was 8 to 12 meters thick and reportedly extended over an area of 1,500 hectares. Reserves were reported at 150 million tons of 97% to 98% gypsum with very small quantities of calcium carbonate. To the east of Paris, the Penchard underground mine produced about 400,000 tons of gypsum per year. Reserves at Penchard were reported at 10 million tons of 96% gypsum, in a 15-meter-thick bed. At the Vaujours deposit an opencast mine produced about 800,000 tons of gypsum per year.

In Alsace-Lorraine, two underground mines produced about 400,000 tons of gypsum per year. The operator was the Société Anonyme Anhydrite Lorraine, a subsidiary of SAMC and Knauf of the Federal Republic of Germany.

Lambert Industries, a joint subsidiary of Lambert Freres & Co. and Rhone-Poulenc S.A., operated two opencast mines, at Billeparisis near Vaujours and at Cormeilles west of Paris in the Paris Basin. Each mine can produce about 600,000 tons of gypsum per year. At Villaparisis production comes from two gypsum seams 17 meters and 8 meters thick.

Platrieres de France, a part of the Lafarge Group, produced gypsum from mines at Vazan, in Vaucluse, Auriol; Tarascon in the vicinity of the Rhone River; Portel to the north of Perpignan, Aude; St. Pierre de Martigues, Carresse, in the Atlantic Pyrenees; and Lontosque in the Maritime Alps in the southeast of France. In addition, smaller amounts of gypsum were produced by Platrieres de Grozon, Etablissements Boutaz, and Garandeau.

MINERAL FUELS

During 1980, the French Government continued to pursue its energy policy of reducing dependence on imported fuels and diversifying sources of imported energy. The Government continued to control imports and domestic prices of most products, inducing foreign oil companies to send the lowest priced crude to France in order to keep the market and maximize profits.

Two French companies, Total S.A. and Elf Aquitaine S.A., benefited from the Government's policy of negotiating agreements with producing countries. The Government, with interest in both firms, helped the companies in increasing their international stature and assisted them by underwriting their investments in France and abroad. Furthermore, the Government intended to help the companies in getting access to 111 million metric tons of crude by 1990. During 1980, bilateral oil agreements were signed with Mexico, Saudi Arabia, Iraq, and the U.S.S.R. In addition, an earlier oil agreement with Kuwait gave France direct access to Kuwait oil for the first time. Negotiations with Venezuela for an agreement for cooperation in investments for the processing of Orinco heavy oils continued during 1980, but no agreement was made public by yearend.

In the fall, the Government changed its energy balance for 1985 as follows, in million tons of oil equivalent:

Estimated energy consumption, 1985

	Revised estimate	Previous estimate	Actual 1979
Coal	30	29	33.9
Natural gas	36	36	23.2
Petroleum	101	106	108.2
Hydroelectric	14	14	15.8
Solar-geothermal	1	--	--
Total	182	185	189.1

During 1980, promotion and development of French nuclear power remained the most dynamic part of the French effort to reduce dependence on imported liquid hydrocarbons and resolve energy shortages. Although the program was effectively managed, construction was slowed down by strikes and delays in obtaining site authorizations.

Coal.—According to preliminary reports the downtrend in coal production continued during 1980, although output of lignite remained at the same level as in 1979.

To illustrate the drop of coal production, the following tabulation shows production of coal in France by basins for 1959 and 1979.

Basins	1959	1979
Nord: Pas-de Calais	29,248	5,386
Lorrain	15,142	9,595
Center Midi	14,332	5,155
Subtotal	58,722	20,136
Others	1,058	929
Total	59,780	21,065

Mine productivity reached 3,171 kilograms per shift during 1979.

At the beginning of 1980, the capacity of 26 washeries totaled 13,872 tons per hour of

raw coal. Roughly 19 washeries with a capacity of 10,520 tons per hour could treat fines and grain; 4 installations with a capacity of 1,312 tons per hour treated only grains, and 3 installations with an hourly capacity of 970 tons could treat only fines.

The consortium Groupe d'Etude de la Gazeification Souterraine announced success in its pilot program at Bruay to fracture the coal seams with water. Two wells were drilled a few dozen meters apart, water was injected at pressures up to 800 atmospheres, seams were fractured and communication was established between the wells. A second phase will include ignition of the coal and injecting oxygen in one well and recovering gases at the other. The collected gas is later transformed into methane. About 2 billion tons of coal reserves in France are not amenable to economic and safe production because of difficult geological conditions including gas, water, and thin seams but could be used for underground gasification.

Natural Gas.—As in the past, France was dependent on imported natural gas. Domestic production covered one third of the country's demand during 1980. The gasfield et Lacq remained by far the major producer. According to incomplete reports, it appeared that the construction of the natural gas vaporization plant was completed at the methane terminal at Montoir de Bretagne. Reported capacity of the facility was 1,200 cubic meters of liquefied natural gas per hour. At Fos, a seaport in southern France, an 80,000-cubic-meter underground gas storage space was completed.

In February, the first direct deliveries to France of gas from the U.S.S.R. started, under an agreement for the delivery of 4 billion cubic meters annually. In addition, France was negotiating with the U.S.S.R. to participate in construction of a gasline between the U.S.S.R. and Western Europe, but an agreement was concluded during 1980.

Petroleum.—France remained dependent on imported crude to meet its demand. About 99% of crude processed in France was foreign.

Two offshore wells drilled in the Iroise Sea and one in the Gulf of Lion were dry. During 1980, the first phase of the development of the oil deposit Vic Birh, Lacq, in southern France was completed. An additional six wells were needed to assess the deposit, which is very complex. Elf Aquitaine expected production from Vic Birh to reach 200,000 tons per year from 12 wells during 1981. In the Paris Basin, the well in the Chateaurenard Field started using territory methods for production by injecting microemulsions-polymers.

At the beginning of 1980, 22 petroleum refineries were operational in France, with an annual capacity of about 167 million tons. During 1980, refineries operated at about 76% capacity. At the Esso SAF refinery, at Port Jerome, construction of a dewaxing unit with a capacity of 367,000 tons of dewaxed lubricants was completed in the late part of 1980.

Supply of refineries with crude oil was mostly done through pipelines. The following tabulations show movement of crude oil for 1978-79 (the latest years for which data were available):

	1978	1979
South European pipeline:		
Movement of crude for France	17,933	17,871
Total movement of oil through pipeline	36,854	39,903
Ile de France pipeline	7,327	8,710
Lorraine refinery pipeline	3,722	3,280
Sarre pipeline	2,110	2,754
Carling	813	713
Donges-Vern	1,079	343
Antifer Le Haure	33,453	34,079
Berre-Monasgne	2,015	2,352
Parentis-Ambes	690	686
Trapil-Vernon	3,224	3,265
Le Harve-Valenciennes	2,689	2,935

Capacity for storage of liquid hydrocarbons at the beginning of 1980 was as follows in million cubic meters:

In refineries	43.5
Underground	12.4
Outside refineries	13.9
Total	69.8

For petroleum transport, France owned and operated a fleet of 72 boats. During 1979, five tankers were scrapped and four new ones were added to the fleet. About 89% of imported crude was moved by tankers flying the French flag.

The French Trade Ministry concluded two contracts with the U.S.S.R. for the sale of equipment for construction of offshore oil drilling platforms. Approximations set the values of both contracts at 500 million francs (about US$100). According to the contract the French companies, Entreprise pour les Petroliers Maritime and Union Industrielle et d'Entreprise, will deliver equipment for the construction of oil drill-

ing platforms at Astrakhan and Baku on the Caspian Sea. The three additional contracts for technical expertise require use of French experts on the construction sites. Deliveries of equipment were scheduled to start in the summer of 1981 and reportedly the platforms would be completed by 1983.

Uranium.—During 1980, the Compagnie General des Matieres Nucleaires (COGEMA) completed development of a uranium mine at Lodeve, Herault. According to reported plans the new mine should produce 800 to 1,000 tons of U_3O_8 annually. In addition, COGEMA announced discovery of a uranium deposit in the area of Contras, Gironde. Reportedly proven reserves were 20,000 tons of U_3O_8.

Development of nuclear powerplants continued to ensure a share of 50% in the total power-generating capacity of France by 1985. The most significant event was the beginning of operation of the Agence National Pour la Gestion des Dechets Radioactifs (ANDRA; National Agency for the Management of Radioactive Wastes). Although nuclear waste questions have been managed by groups within the Commissariat a l'Energie Atomique (CEA), the Government recognized that as the production of nuclear wastes increased with the rapidly expanding French nuclear program, the overall management of short- and long-term radioactive wastes must be handled by an industrial organization. While ANDRA reports to the CEA, it will have an independent budget (about $23 million in 1980) and coordinate with appropriate Government agencies in the management of short-term waste storage areas at Cap de la Hague and the establishment of new facilities for long-term waste storage.

The Eurodif uranium enrichment facility, which is to provide enriched fuel for the French nuclear program and for sale to others, began operation in late 1979 with the output of 2.6 million separative work units expected by the end of the year. With full plant operation expected in 1981, enrichment capacity should be 10.8 million separative work units per year.

Construction was proceeding on the 1,200-megawatt-electrical Super Phenix fast breeder reactor (FBR), with operation now scheduled for 1984, according to a Ministry of Industry report. This indicates a slippage of 1 year from the formerly scheduled 1983 date. In line with its commitment to pursue FBR's, the Government has just announced plans to order two additional reactors similar to Super Phenix but with a power level of 1,500 megawatts electrical each. Reports indicate the two new reactors would also be constructed at the Super Phenix site, with work to begin in 1985 and operation expected in 1990.

The Mineral Industry of Gabon

By Peter J. Clarke[1]

The economic recovery that began in 1979 continued throughout 1980, maintained by higher prices for Gabon's principal exports, petroleum and manganese, and strictly controlled levels of imports. The nominal gross domestic product (GDP) increased 27% from $2.85 billion in 1979 to $3.62 billion[2] in 1980, which represents around 15% real growth. Around 71% of the total GDP growth was due to higher petroleum prices. Other sectors of the economy that showed significant growth rates were transportation (24%), industrial (22%), retail sales (19%), and other services such as banking, real estate, medical, insurance, and advertising (24%). The mining sector's contribution to the GDP declined 12% in 1980. The petroleum sector accounted for about 50% of the GDP, while mining contributed 5% to the total.

Despite a decrease in its contribution to the country's economy, the mineral sector was important in terms of world supply of critical minerals. Gabon remained the world's fourth largest producer of manganese and a leading supplier of uranium. Manganese production provided about 7% of Gabon's export earnings, while uranium supplied about 5% of the total. Petroleum provided about 75% of the country's export earnings, and over 55% of the Government's total receipts.

The minerals sector was preparing to make a much larger contribution to the country's overall development, pending the completion of the Trans-Gabon Railroad. The railroad was the country's top development priority. It was to provide a vital link between the resources of the country and the ports from which they would be exported.

The railroad was to run from the coastal Port of Santa Clara inland through Owendo and Ndjole and then to Booue. At Booue, the rail was to split into two lines. One was to go northeast to Mekambo, where the Belinga iron ore deposits are located, and the other was to head southeast to Franceville to link the Mounana uranium deposits and the Moanda manganese mines. The only section of the railroad that was operating in 1980 was the 182-kilometer link between Owendo and Ndjole. Another 500 kilometers of track was necessary to complete the project. The roadbed and track was being laid from Franceville, but the link to Booue was not expected to be completed until 1985. Completion of the whole project was revised for sometime in 1987. Over $1 billion had already been invested in the project.

While further mineral development was awaiting completion of the Trans-Gabon Railroad, a major exploration effort was underway in the petroleum sector. Essence et Lubrificants de France (ELF)-Gabon, the country's largest oil company, along with other companies from the United States, the United Kingdom, Finland, and Austria were exploring in Gabon's offshore waters for additional petroleum reserves. Through its attractive joint-concession offers, the Government hoped to attract other oil companies and possibly stop the continuing decline in crude oil production.

PRODUCTION

Production of Gabon's major mineral commodities remained fairly stable, with declines in both petroleum and gold production. Most of the country's nonoil resources were being extracted at full operating capacity, and no expansion plans were being implemented until the transportation system could accommodate the increase. However, the value of production remained fairly stable for all commodities. Petroleum was the major currency earner with production valued at about $2.0 billion, an 11% increase over the 1979 value, despite the 9% drop in actual production. Manganese was second, with production valued at approximately $145 million, followed by uranium ($110 million), cement ($14 million), and gold ($200,000).

Petroleum was expected to remain the major currency-earning mineral commodity for several years, despite a continuing decline in production. Both petroleum and gold production was expected to continue their trend toward lower production levels, owing to depletion of reserves. Production levels for manganese and uranium were expected to significantly increase when the Trans-Gabon Railroad reaches the mining areas, allowing a greater capacity route to ports.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.
[1]Table includes data available through Aug. 25, 1981.
[2]In addition to the commodities listed, a variety of crude construction materials (clays, sand and gravel, and stone) is also produced, as well as diamond from artisan works, but output is not reported and available information is inadequate to make reliable estimates of output levels.

TRADE

Gabon's balance-of-payments situation continued to improve in 1980. Preliminary figures indicated a merchandise trade surplus of about $1.7 billion. The value of imports increased 21% in 1980 over that of 1979, while the value of exports increased 37%, owing largely to price increases for petroleum and wood products. Gabon's current accounts balance showed a surplus of $610 million and, with a capital account deficit of $551 million, the overall balance of payments showed a surplus of about $60 million. The country's major exports in order of decreasing value were: Petroleum, manganese, wood, and uranium. While France remained Gabon's largest single trading partner, the United States purchased the largest share of Gabonese oil (about 22%), followed by the Latin American and Caribbean countries and then France and other European countries. Gabon's manganese went primarily to France (25%), Norway (13%), Italy (10%), and the United States (7%). All of Gabon's uranium was exported to France, under contract with the French Commissariat à l'Énergie Atomique (CEA).

Table 2.—Gabon: Exports of mineral commodities

Commodity	1976	1977	Destinations, 1977	
			United States	Other (principal)
Manganese ore concentrate thousand metric tons	2,217	2,162	243	Canada 620; France 357; Japan 252.

COMMODITY REVIEW

METALS

Gold.—Gold production in Gabon has declined unevenly from the early 1960's when output was over 30,000 troy ounces, to 1980 when production totaled 553 troy ounces. Most of the mines were abandoned gradually after reserves were mostly depleted, and operations were no longer economic. The recent high price of gold had some officials contemplating returning to a systematic exploitation of the old mines, but no action was taken during the year. Gold was produced primarily in the Eteke region and used mostly in jewelrymaking within the country, which made inventory of production difficult. Gold output, valued at approximately $200,000, was sold by the Société Gabonaise de Recherche et d'Exploitation Minière (SOGAREM). Some gold was also mined from the Lastoursville, Makokou, and Ndjole regions, all by small workers. Despite the higher price of gold and the Government's interest in reactivating old mines, gold output was expected to remain low unless significant new discoveries were made.

A gold discovery in the Mont Bouet District held some promise for increased production in the future, although information regarding the deposit was limited. Gold was apparently discovered by workers remodeling and expanding the Mont Bouet market. Initial estimates indicated a large deposit, but no reserve figure was available.[3]

Iron Ore.—Development plans for the Belinga iron ore deposit remained at a standstill, awaiting completion of the 250-kilometer Booue to Belinga leg of the Trans-Gabon Railway. Reserves at Belinga, located in northeast Gabon, were estimated at 910 million tons of between 60% and 68% iron content, of which 188 million tons was low in phosphorus. The deposit was to be developed by the Société des Mines de Fer de Mekambo (SOMIFER), which was owned by the Gabonese Government (41%), Bethlehem Steel Corp. (United States) (20%), Exploration Bergbau (Federal Republic of Germany) (10%), Industrialexport (Romania) (5%), Finsider (Italy) (3.5%), the Bureau de Recherches Géologiques et Minières (BRGM) (France) (3%), Solmer (2.4%), Banque de Paris et de Pays-Bas (1%), Hoogovens (Netherlands) (0.5%), and a Japanese group (13.6%). Belinga was to be mined by open pit methods and produce between 7.5 and 10 million tons per year of ore. Development was expected to cost about $100 million.

Linking the deposit in Belinga to Booue and to the already operating segment from Ndjole to Owendo and then to Santa Clara was the only factor holding up the development of the project. The mine, located near Mekambo, was in the eastern-most portion of the country, near the Congolese border. Under the revised schedule for completing that leg of the railroad, the earliest movement of ore would be 1986. The shareholders in the project have limited their investments until the fate of the railroad was clear, and a decision to start development work on the deposit was postponed until 1982.

Manganese.—In 1980, Gabon remained the fourth largest producer of manganese ore and the world's largest producer from a single mine. For the past 2 years, output has been above 2 million tons from the Moanda Mine in the far southeastern portion of the country. Gabon supplied about 8% of world manganese output, behind the U.S.S.R., which produces about 38% of the total, the Republic of South Africa which supplied about 21% of world output, and Brazil which also supplied about 8%.

The manganese deposits at Moanda were operated by the Compagnie Minière de l'Ogooue S.A. (COMILOG), the capital participation in which was BRGM (France) (22%), Compagnie de Mokta (14%), Société Auxiliare du Manganese de Franceville (SAMAF)— Minière del Oubanghi Oriental—Banque de Paris et des Pays-Bas (15%), and United States Steel Corp. (49%). The mine and transportation network began operation in 1972.

The ore bodies at Moanda consist of the cappings on the tops of five adjacent plateaus, the Bangombe, the Okouma-Bafoula, the Yeye, the Messando, and the Boouba. The three western-most plateaus, Bangombe, Okouma-Bafoula, and Messando, have been fully explored, but ore occurs over the entire area in a more or less horizontal bed from 3 to 7 meters in thickness. The manganese minerals are essentially oxides. As of 1980, only the Bangombe was being exploited. Mining is by open pit methods using walking draglines for stripping and excavating. The ore is beneficiated by simple crushing, washing, and screening.

Salable ore represents about 60% to 70% of the total run-of-mine.

Reserves on the three explored plateaus were estimated at 450 million tons of ore, from which 200 million tons of salable product could be extracted. The richest zones, on the Bangombe and Okouma-Bafoula plateaus, cover 8.5 square kilometers and contain 75 million tons of salable product.

The transportation system was the limiting factor in ore extraction. The current method is to load the ore onto an aerial cableway 78 kilometers over mountainous forested country from Moanda to Mbinda on the Congolese side of the border. The ore is then loaded onto COMILOG's own railways for 285 kilometers to Mont-Belo, where the company railway connects with Chemin de Fer Congo-Ocean, which is the main rail line between Brazzaville and Pointe Noire on the Congo coast. COMILOG also constructed loading, storage, and reclamation facilities at Ponte Noire. Maximum capacity of the transport system was about 2.5 million tons per year. The Trans-Gabon Railroad was scheduled to reach Moanda by 1985, after which the mine capacity could be expanded to a planned 4 million tons per year. The railroad was to terminate at a new port at Cape Santa Clara, 25 kilometers north of Libreville. The terminus was to handle manganese from COMILOG and also iron ore from Belinga. Two berths were to be constructed at Santa Clara, one to handle vessels up to 280,000 dead-weight tons and load from stockpiles at 10,000 tons per hour. The other was to handle up to 60,000 dead-weight tons and load at 4,000 tons per hour.

High-grade manganese ore was also produced at Moanda. About 102,700 tons of 83% MnO_2 was produced for sale as battery-grade ore for the dry cell industry. Batteries were produced by Société Gabonaise des Piles (SOGAPIL), which was owned 20% by the Government, 20% by COMILOG, and 20% by Wonder Inc., with the remaining shares in private hands. Production capacity at the plant was 12 million 1.5-volt batteries per year. Gabon was the largest producer of battery-grade manganese in the world. Around 5% of the run-of-mine ore was separable as battery grade.

Uranium.—Not far from the manganese deposits at Moanda, a major uranium deposit was centered around the Mounana region. Three deposits have been delineated at Oklo, Boyindzi, and Okelobondo, but only the Oklo Mine was producing uranium. Infrastructure development for the Boyindzi deposit began in 1979, but exploitation was not scheduled until the middle of the decade.

Ore from the Oklo Mine was excavated by both open pit and underground methods. Underground exploitation began in 1978, thereby raising production capacity of the operation to about 1,200 to 1,500 tons per year of uranium metal. The mine was operated by Compagnie des Mines d'Uranium de Franceville (COMUF), which was owned jointly by the Gabonese Government (25%), Cie. de Mokta (28%), the French CEA (15%), Minatome S.A. (France) (13.2%), Compagnie Française des Minerais d'Uranium (7.5%), Cie. des Mines d'Huaron (3.75%), and Compagnie de Gestion d'Investissements Internationaux (7.5%).

Ore from Oklo was processed to yellowcake at a plant in Mounana that began operating in 1978. The run-of-mine ore contained an average of 5% U_3O_8. The first processing plant enriched the ore to between 35% and 55% U_3O_8. The throughput capacity of the plant was 240,000 tons of ore. The yellowcake plant produced a 70% to 75% uranium concentrate. Capacity of the plant was 1,000 tons per year of contained uranium metal. All of Gabon's uranium concentrate was sold under contract to the French CEA.

Speichim S.A. (Empian Schneider Group) (France) and Techminemet S.A. (Imetal Group) (France) were awarded a joint contract worth $50 million to construct a uranium ore processing plant at Mounana. The plant was designed to produce 1,500 tons of uranium per year as magnesia uranate. The project was to be completed in 1982.

Uranium exploration was continuing in Gabon, concentrated in the region between Mounana and Lastoursville to the northeast. In January 1980, an agreement was signed by the Korean Electric Co., COGEMA of France, and the Gabon Government for exploration of the Lastoursville region, an area previously under concession to COGEMA alone. The Korean company was to commit $12 million in exploration capital over a 1-year period.

NONMETALS

Barite.—Barite was first discovered in Gabon in 1960, by the BRGM. The deposit, which was estimated to contain about 1 million tons of ore with a barite content of 47%, was located at Dourakiki in the Nyanga region, 110 kilometers north of Mayum-

ba. A joint company composed of the BRGM, COMILOG, ELF-Gabon, and the Gabonese Government, was formed to exploit the deposit. The initial project was to start exploitation of a 25,000- to 50,000-ton reserve base. Benefication by gravitational methods was to provide about 80% of the run-of-mine as salable product. Output was to be sold domestically, with the remainder being exported to Cameroon and the Congo. Zaire, Angola, and the Ivory Coast also expressed interest in Gabon's barite. No startup date for the project was available.

Cement.—Cement production remained below capacity at Gabon's only operating plant. The clinker-grinding plant, operated by Société des Ciments d'Owendo, had an annual production capacity of 270,000 tons. Principal shareholders in the plant were the Gabonese Government (20%) and Ciments Lafarge S.A. (France) (71.3%).

Two new cement plants were under construction in 1980. Both plants were being built under contract by Cruesot Loire Enterprises and Lafarge Conseils et Etudes, both of France. The first plant, located near Ntoum, about 40 kilometers from Libreville, was to produce 350,000 tons of cement per year, utilizing local raw materials. The second plant was to be constructed at Franceville. The plant was to have a 100,000-ton-per-year grinding capacity. With all three plants onstream in the early 1980's, Gabon was expected to satisfy its domestic requirements for cement and have some surplus available for export. Annual consumption of cement was about 220,000 tons in 1980, but was expected to increase as the economic situation improved. The two new plants were to be operated by Société des Ciments de Gabon (which was owned by the Government) (51%), ELF-Gabon (19%), Ciments Lafarge (15%), and Société des Ciments d'Owendo (15%).

Talc.—The Gabonese Government, in association with BRGM, was continuing its investigation of talc deposits in the N'dende-Tchibanga region. The Government considered exploitation of the deposits as feasible, and was investigating the infrastructure requirements for talc extraction and exports. Involved in the investigation project were the Gabonese Government, the BRGM, and another French company, Société du Talc de Luzenac. Earliest possible exploitation of the deposit was set at 1983. A group of Japanese businessmen from C. Itoh and Co. discussed conducting a feasibility study for a talc processing plant in 1980, but no definite plans were made.

MINERAL FUELS

Natural Gas.—Production of natural gas in Gabon declined slightly in accordance with the decline in crude oil output. All of Gabon's natural gas was associated gas. About 95% of the country's gas production was flared in 1980. The remainder was used for power generation. Reserves of natural gas remained stable, at about 70 billion cubic meters.

Petroleum.—*Production.*—Gabon's crude oil production, mostly from offshore fields, continued to decline in 1980. Production during the year averaged just under 180,000 barrels per day compared with a peak of about 224,000 barrels per day in 1976. An intensive exploration effort was underway during the year, attempting to halt the decline, and several new discoveries were put into production in 1980.

Oil production began in Gabon in 1957, around the Port Gentil area. Development and production has centered around this region ever since and only recently expanded to the southern part of the country's offshore region. ELF-Gabon was the dominant company in the country, producing about 80% of the country's crude oil. ELF-Gabon was owned 25% by the Government, and 75% by Essence et Lubrificants de France-Enterprise de Recherches et d'Activités Pétroliès (ELF-ERAP). ELF-Gabon operated 14 fields by itself and 14 others in conjunction with other companies. Its major fields and levels of production were: Grondin (10,500 barrels per day), Gamba (4,170 barrels per day), Torpille (3,475 barrels per day), Girelle (2,900 barrels per day), Breme (2,500 barrels per day), and Madaros (2,360 barrels per day). Over 84% of the total production from ELF fields was from offshore. All of ELF-Gabon's fields were linked into a three-pipeline network, which connects with a single tanker loading terminal at Cap Lopez.

Shell Gabon, a subsidiary of U.S. Shell, was the country's second largest producer. The Gabonese Government also held a 25% share in Shell Gabon. Shell's major fields, which were shared with ELF-Gabon, were the Gamba and Lucina Fields. Production from the Gamba Field continued to decline, and Shell was in the midst of a major exploration drive to increase its output in the near future.

Other foreign companies also operate in Gabon, mostly in joint ventures with ELF-

Gabon. Gulf-Gabon, a subsidiary of Gulf Oil Corp. (United States), shared production with ELF from the Lucina and Olende Fields. Mobil Oil Corp. also operated a share in the Batanga offshore fields. Other companies, their production levels and shares in total production in 1980, were as follows:

Company	Production (barrels per day)	Percent of total
ELF-Gabon	121,938	69.1
Société Nationale Elf-Aquitane	28,551	16.2
Shell Gabon	13,669	7.7
Ocean Drilling and Exploration Co. (United States)	4,185	2.4
Ocean	4,185	2.4
Gulf Oil Corp	2,495	1.3
Mitsubishi Petroleum Development Co. (Japan)	648	.4
Murphy	330	.2
Mobil Oil Corp. (United States)	193	.1
Hispanoil (Spain)	182	.1
Ensearch	180	.1

In 1979, the Gabonese Government set up a state-owned oil company, the Société Nationale des Pètroles Gabonaise (PETROGAB), and required equity participation in all oil companies of 25%. The private companies were then required to deliver 25% of their crude oil output to the state company. PETROGAB sold most of its allocated output on the spot market in 1980, with the remainder through short-term contracts. New exploration contracts could only be obtained as production-sharing ventures with the state company.

Exploration.—ELF-Gabon and Shell-Gabon, along with several other international and small private companies, have joined a major exploration effort in Gabon. The effort was begun late in 1979 when the economy began to show signs of improvement. Development work was still centered around the Port Gentil area, but several small discoveries have been made in the southern waters near the Congo border. In addition to the companies already operating, Acorn Petroleum, a subsidiary of Nigeria's Lawson Group, Neste Oy (Finland State Oil Co.), Burmah Oil (United Kingdom), Hudbay Oil (Canada), Norcen Oil and Gas Co. (Canada), and OMV Aktiengesellschaft (Austria) have joined together to undertake exploration on a 6,000-square-kilometer tract offshore Gabon. Acorn, which originally held the concession, was to retain a 44% share, with the other operators taking 11% shares.

Meanwhile, ELF-Gabon continued to concentrate exploration and development around its already established fields. Six drilling rigs were carrying out development work for ELF-Gabon at the end of 1980. Shell was exploring a 14,000-square-kilometer free zone, and also renewed its exploration permits in the Gamba South offshore, Cap Lopez offshore, and Grand Large areas.

Mitsubishi Petroleum Development Co., in conjunction with ELF-Gabon, recently started production from the new Baliste Field. Production began at about 1,500 barrels per day and was to build up to 7,000 to 8,000 barrels per day by the middle of 1981. In the southern waters off Gabon's coast, Gulf discovered the Mayumba structure and subsequently installed three wells that were producing 3,150 barrels per day by yearend. Also, Wed Gabon Oil Co., a company composed of Japan National Oil Co. (50%), World Energy Development (28.6%), and C. Itoh Energy Development (21.4%), in a joint concession with ELF-Gabon, discovered oil in the North Concession. Oil was discovered in the Batanga stone at a depth of 2,259 meters. Initial flow was 1,082 barrels per day.

These discoveries, and others sure to come, hold the potential of slowing, if not halting altogether, the steady decline in Gabon's crude oil output. Most industry sources expect output to stabilize at between 160,000 and 180,00 barrels per day, given Gabon's proven reserves of only 500 million barrels.[4]

Refining.—Two refineries were operating in Gabon in 1980. The Société Gabonaise de Raffinage (SOGARA) refinery at Port Gentil had an annual capacity of 12 million barrels of crude oil. The refinery was supplied crude oil from Madji Isle by an 18-kilometer pipeline. SOGARA was owned 51% by the Government, 18.75% by ELF-Gabon, 18.75% by Compagnie Française des Pètroles (CFP), and 11.5% by a group of petroleum marketing companies. Output from the refinery in 1980 was 794,363 tons of petroleum products, which represents about 60% of capacity. Petroleum products from the SOGARA refinery were sold mostly on the domestic market, with some gasoline and fuel oil being exported to Cameroon and the Congo.

Gabon's second refinery, also located in Port Gentil, came onstream in 1977. The

refinery was operated by the Compagnie Gabonaise-Elf de Raffinage (COGER), and was owned 30% by the Government and 70% by ELF-Gabon. Production capacity of the refinery was 40,000 barrels per day. Total production from the refinery in 1980 was about 500,000 tons of butane, naphtha, gas oil, and fuel oil. Exports from the COGER refinery were destined for France, the Federal Republic of Germany, Brazil, Italy, and the Netherlands.

The Mineral Industry of the German Democratic Republic

By Richard Levine[1]

The German Democratic Republic (GDR) in 1980 continued to experience economic growth despite the increased burden of rising energy and raw materials costs. Reportedly, in 1980, the net national income of the GDR increased by 4.2% compared with a 4% increase in 1979. The gross industrial product grew by 4.7%, fulfilling the plan, but slightly down from the 4.8% growth registered in 1979. Although investment in the industrial ministries increased by 4% in 1980, total investment (including industrial investment and investment in the CMEA[2] countries) grew by only 2%. Over one-third of total investment was for energy and raw materials, and over 60% of industrial investment was used to increase the energy supply or to expand the raw materials base.

Rising energy and raw materials costs are significant in shaping the development of the economy and particularly the mineral industry. The GDR is engaged in a major effort to conserve and make more effective use of minerals. This is necessitated by the rising cost of imported minerals coupled with the large expenditure required to expand the domestic raw materials base. In addition, there will be the naturally increasing demand for energy and minerals. Insuring future supplies will become more difficult both through imports and from domestic supply as even minerals such as lignite, which the GDR has in abundance, become more expensive to produce, and eventually become scarce.

In an effort to stimulate savings on energy and raw materials, the GDR has introduced as basic economic indicators net industrial production and basic materials costs per 100 marks of gross industrial output. Gross industrial output alone has the undesirable effect of including inputs purchased outside the enterprise as part of industrial output, thus allowing increased energy and raw materials expenditures to be recorded as production. Net industrial output, on the other hand, excludes raw materials and energy purchased outside the enterprise. In 1980, net industrial production rose by 5.5%, exceeding gross industrial production, while savings on basic materials cost per 100 marks of gross industrial output exceeded the plan. This indicates that the GDR has been effectively implementing its energy and raw materials cost reduction program. An important component of this program is to conserve energy and raw materials through improved production methods and increased use of secondary materials. The country is presently able to provide approximately 10% of its industrial raw materials requirement using secondary materials.

The GDR is not richly endowed in most mineral resources except lignite and potash for which it is a leading world producer. For practically all ferrous and nonferrous metals, mine production is either insufficient or nonexistent. There is practically no mining of precious metals which are produced primarily from secondary materials. The GDR does produce enough building sand, gravel, salt, fluorspar, and kaolin along with certain other construction, cement, glass, and ceramic raw materials to meet its needs and for export. However, the country produces insufficient quantities of some nonmetals, such as pyrites and special clays and has no production of other nonmetals such as asbestos and magnesite.

The GDR relies heavily on its lignite production as a primary energy resource and in the future plans to replace petroleum with lignite for fuel and chemical pur-

poses. In 1980, the GDR remained the world's leading lignite producer with approximately 28% of the world's output. Although the GDR has been seriously affected by rising petroleum prices, owing to its large lignite production, it is less dependent on imported petroleum than many industrial countries. The country also produces some natural gas and very small amounts of crude oil, neither of which is sufficient for the needs of the economy.

Because of its poor raw materials base, the GDR relies heavily on imports for a large percentage of its minerals and is particularly dependent on the Soviet Union as its chief supplier. However, during the next 5-year period, 1981-85, the GDR will have to seek additional suppliers as Soviet imports of most essential minerals will not increase over their 1980 level.

PRODUCTION

Mineral production is administered by several ministries with each ministry responsible for specific minerals. The main ministries for minerals are the Ministry of Ore Mining, Metallurgy, and Potash; the Ministry of Coal and Energy; and the Ministry of the Glass and Ceramics Industry. The Ministry of Ore Mining, Metallurgy, and Potash administers the production of ferrous and nonferrous metals and the production of potash, rock salt, and spar. Approximately 143,000 workers are engaged in ferrous and nonferrous mining and metallurgy, 22,000 workers in the production of potash, and the remaining 10,000 workers in the production of rock salt, spar, and other enterprise activities. Subordinate to the Ministry are firms (Kombinat) that administer mining and metallurgical production at their subordinate enterprises. The Ministry also administers foreign and domestic trade along with technical schools, research facilities, and recycling activities. Within the other ministries, there have been reported estimates of 28,000 workers engaged in coal mining and 2,000 workers engaged in the silicate mining industry.

In 1980, production of most mineral commodities either increased or remained at their current level. Many of the figures reported in table 1 are estimates because the GDR does not officially report production of many mineral commodities. In addition, the country is 1 to 2 years behind in publishing many of the statistics that it does report. Current estimates will be revised after the official figures are published.

[e]Estimated. [p]Preliminary. [r]Revised.

[1]Table includes data available through June 23, 1981.

[2]In addition to the commodities listed, magnesium, peat, and a variety of crude construction materials are produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[3]Source indicates that data include "roasted ore," presumably roasted pyrite.

[4]Reported figure.

[5]Figures represent the sum of estimates for silicon metal production (3,000 tons in 1976 and 1977 and 4,000 tons in 1978 and 1979) and reported figures for production of all other ferroalloys (1980 estimated).

[6]Total of listed products only; no estimates have been made for unreported products or refinery fuel and losses.

TRADE

The GDR must depend on imports to cover a large percentage of its raw material needs; therefore, foreign trade plays a large role in the economy. The GDR reports that in 1980, foreign trade turnover increased by 10% over the 1979 figure of 109 billion VM (valuta marks).[3] Approximately 65% of this trade turnover is with CMEA countries.

The Soviet Union is the GDR's largest trading partner upon which the GDR is heavily dependent for exports of raw materials. In 1980, the GDR imported the following commodities from the Soviet Union: 19 million tons of petroleum; 6.5 billion cubic meters of natural gas; 1.7 million tons of iron ore (iron content); 3.2 million tons of rolled steel; 130,000 tons of aluminum; 42,000 tons of copper; and 430,000 tons of apatite concentrates. There were some increases in deliveries of commodities such as petroleum and rolled steel, and a substantial increase in the delivery of natural gas. The GDR also imports other minerals such as zinc, nickel, manganese, and lead from the Soviet Union, but figures are not reported.

During the 1981-85 planning period, the GDR is scheduled to import from the Soviet Union 95 million tons of petroleum, 32.5 billion cubic meters of natural gas, 8.5 million tons of iron ore (iron content), 4.8 million tons of pig iron, 650,000 tons of aluminum, 211,500 tons of copper, 6.5 million tons of coke, and 21 million tons of hard coal. Although these trade figures are impressive and are proclaimed as such, the reality is that Soviet deliveries of petroleum, natural gas, iron ore, aluminum, and copper will remain at their 1980 levels during 1981-85, and the GDR will have to meet increased demand for these products from other sources.

The other CMEA countries will not be able to substantially supply the GDR with raw materials, although the GDR does import some significant raw materials from other CMEA countries. These materials include bauxite, alumina, and aluminum from Hungary, and hard coal from Czechoslovakia and Poland. The GDR in turn is able to supply the CMEA countries with lignite briquets, potash, salt, and building materials. The labor unrest in Poland has caused Polish exports of hard coal to drop sharply below the expected levels. To compensate, the GDR is trying to makeup some of the difference through increased imports from the Federal Republic of Germany (FRG) and is, in addition, trying to convert its furnaces to lower Btu domestic lignite.

The GDR is engaged in mutual ventures with the Soviet Union and the other CMEA countries to obtain energy and raw materials. These projects include the exploration for petroleum off the Baltic Coast and the construction of the Kiyembay Asbestos complex. In regard to the latter project, the GDR supplied the Soviet Union with structural metals, cables, cement, cranes, pumps, and locomotives, and in return is to receive 20,000 tons of asbestos in 1980, increasing to 40,000 tons in 1991.

Because U.S.S.R. petroleum exports to the GDR will remain at 19 million tons annually through 1985, the GDR is actively seeking other sources of petroleum and is cultivating relations with Iraq and Algeria, both of which exported petroleum to the GDR in 1980. The GDR is also developing relations with Mexico, Angola, and Iran, which in 1980 did not export petroleum to the GDR, although Iran previously did. In the past, the GDR also obtained petroleum from Syria and Libya, and it is uncertain whether these shipments are continuing.

The GDR would prefer to obtain its petroleum through other than hard currency payments, such as the now-canceled barter agreement which the GDR concluded with the Shah's Government in Iran. It now appears that nonbloc exporting countries will demand payment in hard currency. If the GDR is not able to obtain a stable supply of petroleum from outside the Soviet Union, the Soviet Union will be under pressure to increase its petroleum exports to the GDR.

Regarding trade with developed countries, in the first 6 months of 1980, exports rose almost one-third, and imports also rose. The GDR publishes no data on foreign indebtedness and estimates vary. The U.S. Department of Commerce estimates the GDR's hard currency deficit for end-year 1979 at 10.1 billion dollars and its 1979 debt servicing ratio at 51%.[4]

Trade between the GDR and the FRG comprises a significant portion of the GDR's trade with the Western countries. The GDR is recording increased exports to the FRG in part because of the sharp increase in the price of refined petroleum products that the GDR exports to the FRG. This exchange is based on a trade agreement whereby the GDR imports crude oil from the FRG and in

return exports refinery products to the FRG, particularly to West Berlin. In 1979, this trade agreement was set on a long-term basis. Trade between the GDR and FRG is expected to continue to increase. In 1980, the GDR and the FRG negotiated a 5-year skeleton trade agreement whereby the GDR will export annually 1.25 million tons of lignite briquets to the FRG, with an additional FRG option of 0.25 million tons. This does not include lignite deliveries to West Berlin, which are to be separately negotiated. As part of this agreement, the FRG will ship the GDR lignite-processing machines in which the coal is pulverized and better suited for use in certain industries. In addition, the GDR is an importer of bituminous coal from the FRG. According to a 1979 skeleton trade agreement, the GDR will purchase DM250 million worth of bituminous coal annually for a 6-year period from 1980 to 1985. The GDR might try to increase this amount because of shortages in supply from Poland.

Table 2.—German Democratic Republic: Apparent exports of mineral commodities[1] [2]

(Metric tons unless otherwise specified)

Commodity	1978	1979	Principal destinations, 1979
METALS			
Aluminum metal including alloys:			
Scrap	2,997	2,272	France 1,321; Austria 608.
Unwrought	24,080	15,579	West Germany 12,565;[3] Japan 1,116;[4] United Kingdom 902.
Semimanufactures	7,344	6,584	Hungary 3,476; Poland 2,608.
Arsenic trioxide, pentoxide, acids	--	3	All to Greece.
Bismuth metal including alloys, all forms	--	2	All to Spain.
Chromium oxide and hydroxide	--	26	Greece 21.
Cobalt metal including alloys, all forms	5	--	
Copper:			
Sulfate	--	48	All to Greece.
Metal including alloys:			
Scrap	92	1,252	Netherlands 687; France 314; Belgium-Luxembourg 230.
Unwrought	14,708	15,352	West Germany 6,345;[3] Belgium-Luxembourg 5,419.
Semimanufactures	173	315	United Kingdom 182; Austria 94.
Iron and steel metal including alloys:			
Scrap	13,708	1,540	Thailand 1,278; Japan 224.
Pig iron	58,124	47,620	Philippines 19,961; Yugoslavia 16,783; Sweden 6,293; Austria 3,850.
Ferroalloys[5]	1,000	7,000	NA.
Steel, primary forms[5] thousand tons	374	296	Italy 152; Belgium-Luxembourg 15.
Semimanufactures:[5]			
Bars, rods, angles, shapes, sections do	604	688	Poland 54; Bulgaria 29; Yugoslavia 18.
Plates and sheets do	286	350	Poland 59; West Germany 41;[6] Italy 41.
Hoop and strip do	124	242	Italy 10; France 6.
Rails and accessories do	11	17	NA.
Wire do	68	63	NA.
Tubes, pipes, fittings do	105	118	Poland 30; Yugoslavia 17; France 13; Hungary 13.
Castings and forgings, rough do	25	62	Poland 12.
Lead:			
Oxides	637	799	Sweden 286; Italy 220; Yugoslavia 220.
Metal including alloys:			
Scrap	100	23	All to Sweden.
Unwrought	2,317	1,246	Austria 699; Netherlands 547.
Manganese oxides	4	9	Sweden 6; Ethiopia 3.
Molybdenum metal including alloys, all forms	3	--	
Nickel:			
Matte and speiss	10	--	
Metal including alloys:			
Unwrought	218	90	Netherlands 60; United Kingdom 19.
Semimanufactures	11	33	Canada 31.
Platinum-group and silver metals including alloys:			
Waste and sweepings value, thousands	--	$55	All to Switzerland.
Worked or partly worked:			
Platinum-group do	$12	$84	All to Netherlands.
Silver do	$38,649	$73,962	All to United Kingdom.
Tin metal including alloys, unwrought	7	27	Netherlands 20; Belgium-Luxembourg 5.
Tungsten metal including alloys, all forms kilograms	10	--	
Zinc:			
Ore and concentrate	--	363	All to Belgium-Luxembourg.
Oxide and peroxide	2,259	17	All to Sweden.
Metal including alloys, semimanufactures	10	5	All to Greece.
Other:			
Ores and concentrates, n.e.s	6	--	
Ash and residue containing nonferrous metals	14,370	13,975	Austria 12,625.
Oxides, hydroxides, peroxides, n.e.s	--	4	France 2; Pakistan 2.
Metals including alloys:			
Metalloids	15	3	All to Belgium-Luxembourg.
Base metals including alloys, all forms, n.e.s	6	21	All to United Kingdom.

See footnotes at end of table.

Table 2.—German Democratic Republic: Apparent exports of mineral commodities[1 2] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Principal destinations, 1979
NONMETALS			
Abrasives, n.e.s.:			
Pumice, emery, natural corundum, etc	2	--	
Dust and powder of natural and synthetic precious and semiprecious stones value, thousands	--	$5	All to Spain.
Grinding and polishing wheels and stones	154	173	Pakistan 38; United Kingdom 38; Italy 37; Greece 35.
Corundum, artificial	NA	22	All to Spain.
Barite and witherite	9,887	45	Belgium-Luxembourg 25; United Kingdom 20.
Boron materials: Crude natural borates	--	41	All to Italy.
Cement[7] thousand tons	1,131	1,183	Hungary 220; Czechoslovakia 77.
Chalk[6]	36,747	28,054	NA.
Clays and clay products:			
Crude:			
Fire clay	2,078	3,149	All to Poland.
Fuller's earth and chamotte	2,276	--	
Kaolin[6]	87,413	106,356	Poland 15,260; Hungary 12,790; Yugoslavia 12,685.
Other	7,019	6,314	All to Hungary.
Products:			
Refractory (including nonclay brick)	12,460	7,796	Hungary 4,078; Poland 1,617; Sweden 1,218.
Nonrefractory	4,597	7,425	Morocco 975; Belgium-Luxembourg 948; Yugoslavia 915.
Diamond:			
Gem, not set or strung value, thousands	$243	--	
Industrial do	$305	$2,390	Belgium-Luxembourg $2,230.
Feldspar and fluorspar	30,417	44,714	Poland 19,491; Netherlands 12,537; Austria 8,845.
Fertilizer materials:			
Crude:			
Nitrogenous	--	60	All to Sweden.
Phosphatic	797	968	Hungary 918.
Potassic	24,370	29,973	United Kingdom 14,831; United States 13,924.
Manufactured:			
Nitrogenous	15,040	65,834	Brazil 25,489; Portugal 12,448.
Phosphatic	--	4,860	All to Netherlands.
Potassic, K_2O content[6] thousand tons	2,744	2,745	Czechoslovakia 482; Poland 292; Brazil 220; Hungary 208.
Other, including mixed	3,256	655	Sweden 540.
Ammonia	14,308	4,864	Poland 4,194.
Graphite, natural	350	240	Yugoslavia 200.
Gypsum, calcined[6]	68,681	80,353	Hungary 43,851; Czechoslovakia 24,000.
Lime	10,354	10,210	All to Hungary.
Mica, worked	2	2	All to Belgium-Luxembourg.
Pigments, mineral: Processed iron oxides	r2	--	
Precious and semiprecious stones:			
Natural value, thousands	--	$14	All to United States.
Synthetic do	r$35	$15	All to Turkey.
Salt including rock salt[6] thousand tons	1,213	1,232	Sweden 95; Finland 67.
Sodium and potassium compounds, n.e.s.:			
Caustic soda[7]	11,700	77,600	Sweden 20,509; Netherlands 18,609.
Caustic potash	1,412	1,691	Hungary 1,335; Egypt 229.
Soda ash[6]	274,800	295,500	Czechoslovakia 65,000; Sweden 26,956; Finland 22,146.[6]
Stone, sand and gravel:			
Dimension stone:			
Crude or partly worked	r2,080	814	Norway 709; Belgium-Luxembourg 69.
Worked	r681	266	Netherlands 79; Belgium-Luxembourg 74; Norway 68.
Gravel and crushed rock[6]	267,881	296,918	NA.
Sand thousand tons	2,476	2,539	West Germany 2,472;[8] Austria 30; Yugoslavia 21.
Sulfur:			
Elemental other than colloidal	986	--	
Sulfuric acid[6]	41,208	34,522	NA.
Talc	--	24	All to Netherlands.
Other:			
Crude	10,886	13,001	United Kingdom 8,144; Hungary 4,709.
Slag, dross, and similar waste, not metal-bearing	--	728	Netherlands 608.
Oxides of magnesium, strontium, barium	1,279	1,049	Sweden 756; United Kingdom 158.
Halogens	--	460	Switzerland 278; Italy 182.

See footnotes at end of table.

Table 2.—German Democratic Republic: Apparent exports of mineral commodities[1 2] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Principal destinations, 1979
MINERAL FUELS AND RELATED MATERIALS			
Carbon black	3,487	2,438	Bulgaria 679; United Kingdom 614.
Coal and briquets:			
Anthracite and bituminous coal, thousand tons	315	285	All to Poland.
Briquets of anthracite and bituminous coal, do.	r500	462	All to Hungary.
Lignite and lignite briquets[6], do.	2,211	1,806	West Germany 690; Czechoslovakia 343; Austria 164.
Coke and semicoke, do.	31	42	Spain 25; Austria 9.
Gas, manufactured, million cubic feet	[6]456	[6]343	Mainly to Netherlands.
Peat and peat briquets	218	166	France 105; Italy 61.
Petroleum refinery products:			
Gasoline[6], thousand 42-gallon barrels	3,270	3,340	NA.
Kerosine, do.	35	57	Hungary 56.
Distillate fuel oil[6], do.	7,341	6,932	Sweden 1,089.
Residual fuel oil[7], do.	2,631	4,562	Austria 1,062; Sweden 737.
Lubricants[7], do.	27	31	Austria 29.
Other:			
Mineral jelly and wax, do.	71	87	West Germany 24;[8] United States 13; Netherlands 11; Austria 10.
Bitumen and other residues, do.	1	1	All to Austria.
Unspecified, do.	430	255	All to Poland.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	1,500	2,496	Switzerland 998; Czechoslovakia 832.

rRevised. NA Not available.

[1]Owing to the lack of trade data published by the German Democratic Republic, this table should not be taken as a complete presentation of the German Democratic Republic's mineral exports. These data have been compiled from various sources which include United Nations information, data published by the trading partners, and partial official trade statistics of the German Democratic Republic.

[2]Unless otherwise specified, data are compiled from the official trade statistics of individual trading partners.

[1]Owing to the lack of official trade data published by the German Democratic Republic, this table should not be taken as a complete presentation of the German Democratic Republic's mineral imports. These data have been compiled from various sources which include United Nations information, data published by the trading partners, and partial official trade sources of the German Democratic Republic.

[2]Unless otherwise specified, data are compiled from the offical trade statistics of individual trading partners.

[3]Unless otherwise specified, data for West Germany are from official trade statistics of the Federal Republic of Germany, for January-September 1979 only.

[4]Official trade statistics of the German Democratic Republic.

[5]World Bureau of Metal Statistics, World Metal Statistics, London.

[6]United Nations. Quarterly Bulletin of Steel Statistics for Europe, New York.

[7]Data incomplete; tonnage not available for all sources.

[8]Statistical Yearbook of the Member States of the Council for Mutual Economic Assistance, Moscow.

[9]As reported in the Federal Republic of Germany's trade statistics, it is unclear how this grouping fits into the "Sand" and "Gravel and crushed rock" categories reported above, so it has been reported separately.

COMMODITY REVIEW

METALS

The GDR does not have adequate resources of most metals. The country has economic reserves of metals such as copper, nickel, and tin, but does not have sufficient quantities to cover domestic needs. For metals such as lead, zinc, tungsten, antimony, and iron ore, the mines are depleted, and the metals can only be recovered at high costs. For a number of other metals such as cobalt, chrome, and manganese, the GDR lacks reserves and does not expect to discover any.

Due to its poor resource base, the GDR is attempting to utilize all means to increase its production of metals. A large campaign is underway to recycle metals and to recover metals wasted in production processes. For example, at the Mansfeld firm's Hettstedt Copper-Silver smelter, between 1981 and 1985, plans are to produce annually 600 tons of zinc, 250 tons of lead, 50 tons of copper, and 30 tons of tin from previously unused flue dust. Secondary materials are an important source for the production of ferrous and nonferrous metals and for practically all precious metals. Furthermore, the GDR is conducting geological explorations to expand its base of copper, tin, zinc, and tungsten.

In 1980, the GDR increased its production of crude steel, while its output of most nonferrous metals either increased slightly or remained at the previous level, except for cadmium for which production declined. Because the GDR does not report production for nonferrous metals, production figures are estimates. Occasionally, however, the GDR publishes some types of information regarding nonferrous metals production. For example, the GDR reported that in 1978 it produced the following amounts of semimanufactures: Aluminum—173,250 tons; copper—70,035 tons; tin—1,487 tons; and zinc—20,552 tons.

Aluminum.—In 1980, aluminum production remained at the same level. The GDR is entirely dependent upon imported bauxite which it obtains mainly from Hungary and Yugoslavia. Because of the energy-intensive nature of aluminum production, the GDR is attempting to minimize the use of aluminum in materials used in construction, although aluminum is still being substituted for copper in the production of electric wire and cables. At present, 65% of electric wire and cable is made from aluminum.

In 1980, installation was completed at the VEB Aluminum Foil Rolling enterprise in Merseburg of an aluminum foil rolling mill

purchased from the French Secim Co. The Merseburg enterprise receives wide aluminum strips from the Nachterstedt Light Metals plant, which it can roll to a thickness of 0.007 millimeter for use in the production of condensers. The new equipment will enable the Merseburg plant to produce 1,600-millimeter-wide foil at a rate of 2,000 meters per minute. To make better use of secondary materials, the GDR constructed a new treatment plant in Rackwitz for household aluminum waste.

Copper.—In 1980, copper output remained the same although mining conditions are increasingly more difficult. The VEB Wilhelm Pieck firm in Mansfeld administers all copper industry enterprises. The Mansfeld firm is one of the main concerns administering nonferrous mining and metallurgy. It employs approximately 46,000 workers, and produces copper, aluminum, and other nonferrous metals.

The Mansfeld firm has not conducted mining at the Eisleben or Mansfeld Mines for many years, and copper is now mined at the Allstedt and Sangerhausen Mines. The former mines have been turned into various types of enterprises. For example, the former Thaelman Mine now contains a division of the Mansfeld firm developing means for the rationalization of production.

In the summer of 1980, the Mansfeld firm put into operation a copper wire mill at the Hettstedt Copper-Silver smelter that can cast wire directly from molten copper. In addition, the Soviet Union is scheduled to supply the Hettstedt smelter with a press with a force of 3,150 tons for the manufacture of copper blanks.

Iron and Steel.—Crude steel output rose again in 1980. However, the GDR's reserves of iron ore are almost depleted, and there have not been advances in the production of iron ore and pig iron similar to those for steel. The GDR is continuing to expand its steel industry although demand is still exceeding production. The country was able to supply 74% of its demand for rolled steel, while the remainder was imported mainly from the Soviet Union. Demand for rolled steel increased in 1980 to 11 million tons.

There have been a number of improvements in steel production capabilities. In September 1979, a pipe extrusion facility began continuous operations at Zeithain near Riesa, with an annual capacity of 190,000 tons per year. This new facility manufactures seamless low-alloy or alloy-less pipes, with an external diameter of 20 to 89 millimeters and a wall thickness of 2 to 6.5 millimeters. The new pipe extrusion facility should reach full capacity in 1981. Yugoslavian and Czechoslovakian enterprises participated in building and equipping this facility.

At the VEB Qualitaet und Edelstahl firm in Brandenburg, a new electrosteel works began operations with two electric arc furnaces and continuous billet casting. The new works has a capacity of 550,000 tons per year, and was constructed by the Italian firm Danieli C. S.p.A. There are additional plans to startup a new continuous wire mill at the Brandenburg firm in 1981.

Other new projects underway include a plate mill ordered for the Ilsenburg Enterprise from Austria's Voest-Alpine AG as consortium leader, in conjunction with the FRG's Schloemann-Siemag AG. A new section mill to be installed at Saalfeld was ordered by the VEB Maxhuette Unterwellenborn from a consortium led by the Belgium steelmaker Cockerill S.A. Japan's Nissho-Iwai Co., Ltd., and Komatsu Ltd. have contracted to supply the GDR with a new steel foundry, with a capacity of 15,400 tons of castings per year for the coal mining industry. The foundry will be located in Bosdorf, north of Berlin, and the estimated value of the contract is $32 million. At the VEB Bandstahlkombinat Eisenhuettenstadt Ost, Austria's Voest-Alpine AG expects to start construction of a 2.5-million-ton-per-year melting shop with continuous casting for blooms and slabs. Construction is to begin after the scheduled contract signing in 1981 and is to take 3 1/2 years. Voest-Alpine AG will subcontract some of the work to the FRG's Friedrich Krupp-Huettenwerke and the Salzgitter AG.

In the way of advanced technology, the GDR has in operation two plasma furnaces at the VEB Edelstahlwerk in Freital which produce stainless steel from scrap. The plasma system generates temperatures of more than 15,000° C and is said to offer high recovery rates of alloys with iron losses below 2%. Voest-Alpine AG is newly licensed to make and market these furnaces.

Lead and Zinc.—Although the mining of lead and zinc has almost ceased, the GDR is able to maintain production or achieve increases in its metal production. The country is attempting to reduce its heavy dependence on imports by increasing output

from secondary materials. Perspective development depends on increasing the recovery of lead along with precious metals from scrap and on increasing the production of lead from battery scrap.

To increase secondary production of lead, a rotary furnace and a new lead remelting complex, with a capacity of 100,000 tons per year, will be constructed at the Muldenhuetten site of the VEB Bergbau und Huettenkombinat Albert Funk in Freiberg. The Italian Snam Progetti S.p.A. subsidiary of Ente Nazionale Idrocarburi (ENI) has a $90 million contract for the construction of the remelting complex, and the British firm Imperial Smelting Processes Ltd. is subcontracting for planning the smelting and refining sections. The Freiberg firm's present lead smelter is the only lead smelter in the GDR. It smelts secondary materials and has a capacity of 40,000 tons per year.

The GDR reported increased production of zinc for the first half of 1980. From 1981 through 1985, the country plans to produce 600 additional tons of zinc annually from flue dust at the Hettstedt smelter of the Mansfeld firm.

Nickel.—Nickel production in 1980 remained the same. Although the GDR has some economic reserves of nickel, it must rely on imports to meet its domestic needs.

Silver.—Silver production did not change significantly in 1980. Silver is obtained as a byproduct of other nonferrous operations or is recovered from secondary materials.

Tin.—The GDR has shown a significant increase in the production of tin during the past 5 years, but indications are that tin production did not increase in 1980. Although the GDR is still importing tin, it is attempting to become self-sufficient. The GDR claims it has large reserves of tin ore, but the majority of this ore is in a fine coalesced form and is difficult to concentrate using the usual "wet mechanical" processes. A new concentration technology has been developed that is being used on tin ore from the Altenberg Mine and is enabling the GDR to increase output. In addition, new smelting installations have been put into operation, and plans call for an intensification of smelting processes at the Freiberg firm.

NONMETALS

The GDR produces a variety of nonmetallic minerals for agricultural, industrial, construction, and other uses. It also produces some nonmetals such as potash, limestone, gravel, building sand, fluorspar, kaolin, and salt in quantities great enough to provide for its domestic needs and for export. However, the GDR produces insufficient quantities of other nonmetals such as pyrites and special clays, and is almost entirely dependent on imports for other important nonmetals such as phosphate raw materials and asbestos.

Practically all building materials are extracted from surface mines. There are more than 1,000 of these surface mines that range in production from 1,000 tons per year for some small grit mines to 4 to 6 million tons per year for mines for the cement industry. An important source of nonmetals that is not being adequately exploited is the overburden from lignite mines. Gravel, sand, and kaolin are found in large quantities in this overburden, and future plans are to increase the percentage of all minerals recovered from overburden. The most significant nonmetallic mineral produced is potash, which is one of the GDR's major exports.

Clays.—A number of clay deposits are becoming depleted or more difficult to mine. Even kaolin, which is produced in considerable quantity, is now being mined under more difficult conditions and is of a lesser quality.[5] Some clay deposits which have special properties have been depleted. For example, up until 1979 a special clay was being mined south of Osterfeld in the Zeits region (Kreis) that was the most valuable domestic raw material for the red or "flaming" slabs produced at the VEB Kurt Buerger Slab Enterprise. This clay must now be imported from Poland.

Fluorspar.—The country produces sufficient quantities of fluorspar to supply its needs and for export. Fluorspar production is administered by the VEB Potash (Kali) firm which contains plants producing fluorspar and barite. The existence is reported of four fluorspar and barite plants that employ 2,500 workers.

Gravel and Sand.—The production of gravel and building sand has been continually increasing. The GDR exports large amounts of gravel and sand. The Halle district (Bezirk) is the largest gravel and sand producing district. It contains over 90 gravel and sand deposits that supply approximately 14% of the gravel and sand in the GDR. The GDR has sufficient gravel and sand for supplying the construction industry and other uses beyond the year

2000.

Lime and Dead-Burned Dolomite.—The GDR has been experiencing an increasing demand for lime and dead-burned dolomite. Lime is among the few mineral commodities for which the GDR is an exporter. Plans are to increase yearly production of limestone mines to 4 to 6 million tons per year. New equipment is being used to increase production. For example, the Caaschwitz surface mine near Gera has begun using a Soviet shovel, with a bucket capacity of 10 cubic meters, to mine magnesian limestone to produce dolomite. The magnesian limestone from this mine is sent to the Wuenschendorf plant where it is made into sinter dolomite for use as refractory material for steel mills and foundries.

Potash.—In 1980, potash production again increased. The VEB Potash firm (VEB Kombinat Kali) administers the entire GDR production of potash, rock salt, and spar. This firm, which contains seven enterprises with their subordinate mines and plants, employs approximately 32,000 workers, of which approximately 22,000 are engaged in the production of potash. VEB Potash's fixed assets are valued at approximately M5 billion. The production of potash is concentrated at the Sued-Harz, Werra, and Zeilitz enterprises, while the other enterprises produce primarily salt products, fluorspar, and barite.

The GDR is the world's third largest producer of potash following the U.S.S.R. and Canada and is the world's second largest exporter of potash after Canada. Approximately 85% of GDR potash production is exported. Exports go to over 50 countries, including all the CMEA countries, except the U.S.S.R. Hungary, Czechoslovakia, and Poland are particularly large importers among the centrally planned economy countries.

The Minister for Mining, Metallurgy, and Potash, Dr. Kurt Singhuber, stated that present potash reserves are sufficient through the year 2010. Mining conditions, however, are becoming more difficult and costly. Large increases in production are not foreseen in the near future. During the first half of 1979, and also in 1980, additional capacities were put into operation at the Werra enterprise's Merkers plant. In 1981, a new compaction unit is to be put into operation at the Zeilitz enterprise, which will provide customers with a wider range of grades.

Rock Salt.—The production of rock salt has been steadily increasing, and the GDR is an exporter of rock salt. Practically all rock salt is produced at the Bernburg Rock Salt plant which is subordinate to the VEB Potash.

MINERAL FUELS

The GDR produces small amounts of natural gas, a very small amount of petroleum, and has discontinued mining of bituminous coal. The major mineral energy resource that the GDR has in abundance is lignite. Owing to the increased cost of petroleum and the uncertainty of increased supply, the country is planning to rely even more heavily on domestic lignite as a primary energy resource. The GDR is planning to substitute lignite for petroleum wherever possible as a fuel and in petrochemical production.

Despite the fact that the country has been seriously affected by the increase in petroleum prices, it is not as dependent on petroleum as some other industrial countries. In 1980, petroleum comprised approximately 21% of the GDR's primary energy balance, while lignite comprised approximately 58%. (See table 4.) Thus the GDR's lignite production, along with its production of other energy sources such as natural gas, makes it less dependent on imports than, for example, the FRG, which supplied only 40% of its primary energy needs from domestic production.

In 1980, reliance on natural gas as a primary energy source increased as imports from the Soviet Union rose sharply. Natural gas in 1980 comprised approximately 14% of primary energy consumption. Because imports of natural gas from the Soviet Union will not increase during 1981-85, and the GDR's own production of natural gas has stabilized, the GDR's reliance on natural gas should not rise much over the 1980 level, barring any significant discoveries.

Although lignite is to be the principle energy resource for electric power production, the GDR is also promoting its nuclear power program as quickly as possible. Lignite fuel is the source for approximately 80% of the electric energy produced, while nuclear power comprised approximately 11% in 1980. The Minister for Coal and Energy, Wolfgang Mitzinger, stated that solar, wind, and water power will not play a role in electric power generation due to the GDR's geographic location.[6]

Lignite will continue to be the primary

fuel for electric power generation. New lignite-fired powerplants will be opened, and capacities will be increased at existing plants. In 1980, construction on the Jaenschwalde powerplant was conducted. It is to be supplied with lignite fuel from expanded mining operations in the Cottbus district (Bezirk).

Table 4.—German Democratic Republic: Primary energy balance for 1979 and 1980

(Million tons of standard coal equivalent)[1]

Year	Total primary energy	Coal (lignite, brown, bituminous)	Crude oil and petroleum products	Natural and associated gas	Hydroelectric power	Nuclear power
1979:[r]						
Production[2]	97.2	84.5	0.1	11.4	0.2	1.0
Exports	.8	.7	--	--	.1	--
Imports	46.1	9.7	30.4	5.8	.2	--
Apparent consumption	142.5	93.5	30.5	17.2	.3	1.0
1980:						
Production[2]	98.1	85.3	.1	11.4	.2	1.1
Exports	.8	.7	--	--	.1	--
Imports	49.8	9.7	31.2	8.7	.2	--
Apparent consumption	147.1	94.3	31.3	20.1	.3	1.1

[r]Revised.

[1]One ton standard coal equivalent (SCE)=7,000,000 kilocalories. Conversion factors used follow: Hard coal, 1.0; lignite and brown coal, 0.33; crude oil, 1.47; natural gas, 1.33 (per 1,000 cubic meters); and hydroelectric and nuclear power, 0.123 (per 1,000 kilowatt-hours).

[2]Production is taken from production table.

Coal.—In 1980, production of lignite increased to approximately 258 million tons, and plans call for production to reach 261.1 million tons in 1981. Long-term plans call for lignite production to reach 300 million tons by 1990. According to 1980 GDR reports, the country is extracting lignite from 28 surface mines.[7] In 1979, the GDR reported that lignite was being extracted from 32 surface mines, 3 of which were in the running-down and 2 of which were in the starting-up stages. Indications are that mines have not opened up at a rate greater than they are closing down, although production is increasing. During the 1980's, 11 surface mines will be depleted, and 16 are scheduled to commence operation, although earlier reports stated that 21 new mines were to commence operations in the 1980's.[8]

In 1975, lignite resources were estimated at 47.6 billion tons. Of these, 18 to 20 billion tons are economic reserves.[9] Approximately 45% of the economic reserves are in fields containing more than 250 million tons, while 55% are in smaller fields, of which there are 77 fields with less than 100 million tons. In the future, the GDR will have to depend more on smaller fields despite the negative economic effects. There are also a number of deeper lignite seams not classified as economic reserves that the GDR will have to resort to after the year 2000.

During the first half of 1980, additional mining facilities were put into operation at the Groitsches-Dreieck and the Delitzsch-Suedwest surface mines in the Leipzig district. These new mining facilities can make-up in some measure for production shortages at the Borna coal mining enterprise in the Leipzig district. The Borna enterprise, which supplied approximately 112,000 tons daily in 1980, did not meet its production goals, especially at Borna's large Espenhain surface mine. The largest lignite mine in the GDR is the Nochten surface mine in the Cottbus district, which supplies lignite primarily to the newly expanded Boxberg powerplant. It also supplies the VEB Schwarze Pumpe Gaskombinat (Gas Manufacturing complex) and a number of briquet plants. The Nochten Mine in 1980 produced a record output of 24 million tons and has sufficient reserves until approximately the year 2020.

The GDR plans to equip its new surface mines with high-capacity machinery. This is to include mobile haulage bridge assemblies with an output of 450,000 cubic meters per day and rotary excavators, with a capacity of 150,000 to 200,000 cubic meters per day. These machines, along with belt conveyors, are to predominate beyond the year 1990.

Although the supply of lignite briquets is continuing to increase, it is not increasing

at a rate adequate to meet demand. It will be necessary for the GDR to expand its lignite briquet production facilities. Lignite briquets are now being used by a number of industries as a substitute for hard coal, the mining of which has stopped because of the depletion of existing mines. The country now depends entirely on imports for hard coal. The demand for high-temperature lignite coke has continued to increase. Production of high-temperature lignite coke has expanded with the addition of a new oven unit, with a capacity of 700,000 tons at the Schwarze Pumpe Gaskombinat in the Cottbus district. A large percentage of the production of high-temperature lignite coke, hard coke, and lignite briquets occurs at the Schwarze Pumpe complex which produces approximately 65% of the hard coal coke, 50% of the high-temperature lignite coke, and 20% of the lignite briquets in the GDR.

Because of the shortage of lignite briquets, coke, and bituminous coal, ways are being sought to replace these products with raw lignite wherever possible.

Natural Gas and Petroleum.—The increased supply of natural gas from the Soviet Union, along with the GDR's own production of natural gas, has somewhat alleviated the energy supply situation. Since the GDR's production of natural gas has stabilized, and imports from the Soviet Union are planned to remain at their 1980 level of 6.5 billion cubic meters annually, consumption of natural gas should not greatly increase. The GDR plans to more effectively utilize gas for domestic purposes and in industry, and to increase its gas storage capacity.

In addition, the GDR has been increasing its production of manufactured gas. This is in keeping with the GDR's long-term strategy of relying on domestic lignite. There are 14 gas manufacturing plants in the GDR, 4 of which produce 90% of the total output. The largest of these, the VEB Schwarze Pumpe Gaskombinat, produces 75% of the total output.

As part of its effort to conserve petroleum, the GDR plans to better utilize petroleum through more efficient cracking. At present, 40% of petroleum is utilized in fuel uses for which lignite can be substituted. In accordance with these plans to change the refinery mix, the petroleum refinery at the Schwedt Petrochemical complex is adding a large amount of equipment to produce the more valuable petroleum components. Improvements in petroleum refining to upgrade the product mix are occurring at the VEB Walter Ulbricht Leuna enterprise and are to be completed in the mid-1980's.

Nuclear Power.—The GDR, with Soviet assistance, has developed its nuclear power industry, and with Soviet assistance is planning to construct a nuclear powerplant at Stendal, approximately 100 kilometers from Berlin in the Magdeburg district. The GDR originally intended by 1985 to double its nuclear power capacity which is under the administration of the Bruno Leuschner Nuclear Powerfirm based in Greifswald. However, plans have been revised to have nuclear power increased from its current 11% of electric power generation to only 12% to 14% by 1985.

The GDR produces uranium with which it can expand its nuclear power generation. However, the uranium is produced by the joint Soviet-GDR stock company, SDAG Wismut, and must first be delivered to the Soviet Union. The Soviet Union then supplies the GDR with enriched uranium rods, which the Soviet Union later repossesses for reprocessing.[10]

[2]CMEA is the Council for Mutual Economic Assistance. It is comprised of Bulgaria, Cuba, Czechoslovakia, German Democratic Republic, Hungary, Mongolia, Poland, Romania, the U.S.S.R., and Vietnam. Yugoslavia has associate status with limited participation, but is normally not included for statistical purposes.

[3]The GDR mark (M) is a nonconvertible currency officially pegged at 1:1 with the Federal Republic of Germany's mark (DM). The GDR mark's relation to the dollar fluctuates with the dollar/DM exchange rate. Foreign trade figures are denoted in an accounting unit known as the valuta mark (VM). The rate of dollars to valuta marks is US$1.00=3.11VM.

The Mineral Industry of the Federal Republic of Germany

By Joseph B. Huvos[1]

In 1980, the Federal Republic of Germany (FRG) remained one of the world's major processors and consumers of minerals, most of which were imported. There was, however, a plentiful supply of domestic coal, potash, and salt. National efforts were focused on securing and expanding raw material supply by encouraging development of domestic resources, concluding diversified trade agreements, and encouraging foreign exploration, development, and operations. Private industry was assisted by Government guarantees, loans, and favorable tax rates.

In mid-1980, the FRG economy reached a cyclical turning point. Following a strong expansion that lasted for 2 years, the economy turned sharply downward in the second quarter and remained stagnant past the end of the year. The growth of the economy in real terms was only about 2%. In 1980, FRG's gross national product was about $759 billion.[2] Contribution of the individual sectors of the mining and minerals-processing industry to the gross national product and employment in 1979 and 1980 are shown in the following tabulation:

	Contribution to gross national product (million dollars)[1]		Employment at end of 1980 (thousand persons)
	1979	1980[p]	
Coal mining	11,818	12,709	207
Stones and earths	15,033	15,808	193
Iron and steel	24,164	25,093	284
Nonferrous metals	11,262	13,399	80
Chemicals including petroleum	66,670	66,911	568
Total	128,947	133,920	1,332

[p]Preliminary.
[1]Does not include value added tax.

Source: Adapted from Statistisches Bundesamt, Wiesbaden. Wirtschaft und Statistik, No. 2, 1981, p. 87.

Several events were noted in 1980 in the minerals industry. Significant new plants commissioned included the first stage of the Töging aluminum plant of the Vereinigte Aluminium Werke AG (VAW), a ministeelworks of the Thyssen Niederrhein AG at Oberhausen, and a direct-reduction steel plant of the Norddeutsche Ferrowerke in Hamburg. All forging activities of the Krupp Group were consolidated in Essen and Bochum. Grafitwerk Kropfmühl expanded the capacity of its Kropfmühl Mine in Bavaria.

PRODUCTION

In 1980, there was a modest increase in the production of mineral commodities in the FRG. Production for the last 5 years, including 1980, is shown in table 1.

Table 1.—Federal Republic of Germany: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1976	1977	1978	1979	1980[p]
METALS					
Aluminum:					
Bauxite, gross weight	221	28	280	349	--
Alumina thousand tons	1,333	1,454	1,410	1,352	1,422
Metal:					
Primary do	697	742	740	741	731
Secondary:					
Alloyed do	305	347	368	381	368
Unalloyed do	42	45	47	45	40
Bismuth:					
Ore and concentrate[e]	11	11	9	10	10
Metal, smelter	500	700	600	661	NA
Cadmium metal, smelter	1,275	1,336	1,182	1,266	1,194
Cobalt metal, smelter	384	400	350	385	400
Copper:					
Mine output, metal content	1,613	1,210	821	861	1,274
Metal:					
Blister and anodes:					
Primary	193,695	r189,600	165,800	158,200	165,800
Secondary	50,805	58,407	55,700	92,500	92,000
Total	244,500	248,007	221,500	250,700	257,800
Refined, including secondary:					
Electrolytic	285,581	r340,709	318,551	303,122	302,516
Fire refined	161,000	r99,451	84,881	79,396	71,261
Total	446,581	440,160	403,432	382,518	373,777
Gold:					
Mine output, metal content troy ounces	2,456	2,392	2,119	2,357	e2,400
Metal, including secondary do	346,874	319,803	336,264	293,857	298,873
Iron and steel:					
Iron ore and concentrate:					
Gross weight thousand tons	2,256	2,470	1,597	1,649	1,948
Iron content do	750	816	510	526	597
Metal:					
Pig iron do	31,538	r28,697	29,861	34,855	33,609
Blast furnace ferromanganese and spiegeleisen do	220	175	209	233	200
Blast furnace ferrosilicon do	91	87	78	79	64
Electric furnace ferroalloys do	239	210	139	195	182
Steel ingots and castings do	42,415	38,985	41,253	46,040	43,838
Semimanufactures do	29,793	28,758	30,198	32,813	31,661
Lead:					
Mine output, metal content	r30,733	r30,468	23,181	25,227	23,063
Metal:					
Primary	r186,300	r182,900	189,900	194,800	191,109
Secondary	r151,100	r190,600	179,100	178,500	159,200
Total	337,400	373,500	369,000	373,300	350,309
Magnesium metal including alloys:					
Unwrought (secondary only)[e]	500	600	600	600	600
Castings	r17,699	r16,360	16,359	15,999	15,102

(Metric tons unless otherwise specified)

Commodity	1976	1977	1978	1979	1980[p]
NONMETALS —Continued					
Clays:					
Fire clay (exclusive of klebsand) _ thousand tons__	5,056	5,276	5,224	5,635	[e]5,600
Kaolin, marketable _____ do____	[r]442	[r]500	521	556	[e]600
Bleaching _____ do____	628	642	621	639	[e]600
Other (schieferton) _____ do____	108	129	128	124	[e]120
Diatomite and similar earth, marketable _____	52,948	49,457	47,600	43,271	[e]40,000
Feldspar, marketable _____	419,976	393,793	385,590	372,754	[e]370,000
Fluorspar, marketable:					
Acid-grade[e] _____	57,789	75,375	68,150	56,855	[e]56,700
Metallurgical-grade[e] _____	6,421	8,375	[r]7,572	6,317	[e]6,300
Total _____	64,210	83,750	75,722	63,172	[e]63,000
Graphite:					
Crude _____	19,101	16,653	12,763	7,342	[e]7,200
Marketable[e 3] _____	[r]9,551	[r]8,326	[r]6,381	3,671	3,600
Gypsum and anhydrite, marketable _ thousand tons__	[r]2,100	[r]2,218	2,238	2,251	[e]2,340
Lime (hydrated), quicklime, dead-burned dolomite do____	9,426	8,770	8,990	9,230	9,000
Nitrogen, N content of ammonia _____ do____	1,863	1,989	1,955	2,161	2,044
Phosphates:					
Phosphate rock (including apatite), gross weight do____	86	80	__	__	__
Thomas slag-based fertilizer, P_2O_5 content _do____	167	134	150	145	161
Pigments, mineral, natural _____	22,840	26,421	21,475	28,561	[e]28,000
Potash, K_2O equivalent:					
Crude, marketable _____ thousand tons__	70	76	72	74	76
Chemically processed _____ do____	1,966	2,265	2,398	2,542	2,661
Total _____ do____	2,036	2,341	2,470	2,616	2,737
Pumice:					
Crude and washed _____ do____	3,689	3,137	3,552	2,640	2,102
Marketable _____ do____	2,197	1,749	2,087	1,432	807
Pyrite, marketable concentrate, gross weight _do____	523	531	502	460	[e]450
Quartz, quartzite, glass sand:					
Quartzite _____ do____	372	425	411	426	426
Quartz sand, ground _____ do____	418	407	421	454	453
Quartz sand, unground and glass sand____ do____	6,111	6,737	7,026	7,417	7,475
Salt, marketable:					
Rock _____ do____	6,375	7,131	6,846	8,960	[e]6,900
Marine and other _____ do____	4,942	5,192	5,812	6,130	[e]6,100
Sodium compounds, n.e.s.:					
Sodium carbonate _____	1,363,528	1,350,543	1,229,722	1,400,922	1,411,110
Sodium sulfate _____	256,677	242,247	211,000	210,664	[e]201,000
Stone, sand and gravel, n.e.s.:					
Dimension stone _____ thousand cubic meters__	194	215	307	311	264
Limestone, industrial _____ thousand tons__	52,615	48,953	50,995	54,521	53,477
Crushed and broken stone _____ do____	102,215	110,718	118,096	126,463	117,610
Slate[4] _____ do____	2	2	3	4	4
Basalt lava and lava sand _____ do____	5,922	6,623	7,047	8,056	NA
Calcite _____ do____	4	9	12	8	NA
Grinding stone _____ cubic meters__	48	63	238	71	43
Tuff _____ thousand tons__	3	2	3	3	NA
Sand and gravel _____ do____	155,010	170,425	184,786	198,637	190,255
Sulfur:					
S content of pyrite _____ do____	233	235	221	203	[e]198
Byproduct:					
Of metallurgy _____ do____	390	385	380	450	[e]450
Of natural gas _____ do____	460	631	650	903	[e]900
Of petroleum _____ do____	119	186	190		
Unspecified _____ do____	161	165	160	93	[e]93
Total _____ do____	1,363	1,602	1,601	1,649	[e]1,641
Talc including talc schist _____ do____	18	16	15	15	[e]15
MINERAL FUELS AND RELATED MATERIALS					
Carbon black _____	292,322	301,678	297,509	340,629	353,568
Coal:					
Anthracite _____ thousand tons__	6,628	6,067	6,942	7,018	87,146
Bituminous coal _____ do____	82,641	78,773	76,994	79,301	

See footnotes at end of table.

Of anthracite and bituminous coal do	1,357	1,305	1,453	1,673	1,455
Of lignite do	4,390	4,104	3,889	4,752	4,446
Gas:					
Manufactured (excluding that from petroleum refineries):[5]					
Blast furnace million cubic feet	201,399	174,312	179,857	212,629	199,456
Coke oven[6] do	263,517	223,294	205,848	214,324	226,366
Other do	76,915	70,735	72,818	52,760	[e]53,000
Total do	541,831	468,341	458,523	479,713	478,822
Natural:					
Gross do	665,537	678,565	738,002	743,900	671,223
Marketable do	658,050	637,578	707,156	[e]725,000	[e]665,000
Peat:					
Agricultural use thousand tons	1,707	1,911	2,047	1,849	1,734
Fuel use do	227	221	228	230	279
Petroleum:					
Crude thousand 42-gallon barrels	39,902	39,021	36,541	34,482	33,450
Refinery products:					
Gasoline, motor do	147,439	123,479	127,069	182,800	182,296
Jet fuel (including aviation gasoline) do	10,799	10,099	10,620	10,345	10,506
Kerosine do	378	456	334	523	315
Distillate fuel oil do	301,929	293,903	292,020	345,621	311,192
Residual fuel oil do	158,397	143,004	160,047	146,333	128,509
Lubricants do	9,081	6,763	6,653	9,660	9,080
Other:					
Liquefied petroleum gas do	32,680	38,741	37,932	36,669	30,938
Bitumen do	23,063	22,421	22,866	23,756	20,406
Unspecified do	98,534	86,999	[e]76,555	97,846	89,758
Refinery fuel and losses do	38,230	46,253	54,362	99,807	91,557
Total do	820,530	772,118	788,458	953,360	874,557

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Aug. 3, 1981.

[2]Primary nickel and nickel contained in ferronickel, Monel metal, and nickel oxide directly used by the steel industry.

[3]Series revised to reflect estimated marketable output from ores of West German origin. Total output of marketable graphite, including production from imported crude graphite, is reported as follows in metric tons: 1976—14,026; 1977—13,456; 1978—11,927; 1979—10,282; and 1980—not available.

[4]Exclusive of slate recovered from mine dumps.

[5]Natural gas equivalent is 240 kilocalories per cubic foot (8,400 kilocalories per cubic meter).

[6]Includes water gas and generator gas from coke ovens.

TRADE

In 1980, members of the European Communities remained the FRG's principal trading partners, but member countries of the Organization of Petroleum Exporting Countries were of growing importance. Considerable concern was expressed about the mounting deficit in the balance of payments, which was expected to be in the $12 billion range and was mainly a result of reliance on foreign oil and minerals.

In the U.S.-FRG trade relationship, a $2.3 billion surplus was recorded in favor of the United States, the highest ever. U.S. deliveries amounted to $14.1 billion, while the FRG exports to the United States amounted to $11.8 billion. Automobiles were the largest single item in the FRG deliveries, while machinery dominated U.S. deliveries. The FRG's mineral commodity trade in 1978-79 is shown in tables 2 and 3.

Table 2.—Federal Republic of Germany: Exports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite	12,260	21,621	--	Belgium-Luxembourg 7,196; France 5,828; Switzerland 3,448.
Alumina	344,606	223,954	3,748	Austria 70,557; Canada 58,368; U.S.S.R. 23,499.
Aluminum hydroxides	120,544	155,077	9,065	Sweden 44,816; Netherlands 23,187; France 19,654.
Metal including alloys:				
Scrap	52,982	51,974	--	Italy 18,756; Netherlands 13,916; France 13,267.
Unwrought	271,610	247,866	2,454	Italy 80,294; France 56,295; Netherlands 45,389.
Semimanufactures	343,982	354,116	5,819	France 74,675; United Kingdom 50,419; Netherlands 41,728.
Antimony:				
Oxides and hydroxides	319	344	--	Taiwan 51; Austria 34; Italy 30.
Metal including alloys, all forms	20	16	NA	NA.
Arsenic trioxide, pentoxide acids	82	166	NA	NA.
Beryllium metal including alloys, all forms kilograms	15	17	NA	NA.
Bismuth metal including alloys, all forms	517	407	81	United Kingdom 132; Spain 20.
Cadmium:				
Oxide and hydroxide	18	22	--	Portugal 5.
Metal including alloys, all forms	313	494	NA	NA.
Chromium:				
Chromite	3,212	8,807	--	Romania 2,924; Spain 2,042; Austria 1,360.
Oxides and hydroxides[2]	47,668	55,688	NA	NA.
Metal including alloys, all forms	125	224	47	Belgium-Luxembourg 52; Italy 29; France 20; Netherlands 20.
Cobalt:				
Oxides and hydroxides	86	45	--	Netherlands 13; Italy 10; Czechoslovakia 6.
Metal including alloys, all forms	796	847	NA	NA.
Columbium and tantalum metals including alloys, all forms:				
Columbium kilograms	19,109	41,659	--	Belgium-Luxembourg 836; Poland 198; Czechoslovakia 126.
Tantalum do.	47,122	81,307	320	United Kingdom 873; Hungary 435; Yugoslavia 278.
Copper:				
Ore and concentrate	(3)	--		
Matte	300	96	--	Sweden 52.
Sulfate	1,861	1,446	NA	NA.
Oxides and hydroxides	2,455	2,814	76	Netherlands 595; Norway 285; United Kingdom 277.
Metal including alloys:				
Scrap	53,956	54,820	90	Italy 20,794; Belgium-Luxembourg 7,291; Netherlands 6,924.
Unwrought:				
Smelter	29,589	22,384	--	United Kingdom 19,106; Belgium-Luxembourg 3,059; Iran 150.
Refined:				
Alloyed	8,064	11,152	--	Italy 4,398; France 1,659; Austria 1,299.
Unalloyed	112,695	86,686	3,925	Belgium-Luxembourg 14,983; Italy 12,631; United Kingdom 11,313.
Master alloys	1,283	1,068	--	Belgium-Luxembourg 623; France 199; Sweden 85.
Semimanufactures	319,822	357,086	33,299	Netherlands 42,941; France 40,987; Switzerland 36,023.
Gallium metal including alloys, all forms kilograms	5,600	5,400	700	Japan 2,300; Netherlands 1,000.
Germanium metal including alloys, all forms do.	400	1,300	--	United Kingdom 600; Romania 500.
Gold:				
Ash and waste value	$6,970	$1,637	NA	NA.
Scrap and sweepings do.	$164,791	$700,529	NA	Spain $670,522.
Metal including alloys:				
Unwrought thousand troy ounces	r1,423	739	2	Israel 162; Italy 120; Switzerland 75.
Partly wrought troy ounces	194,531	136,544	1,704	United Kingdom 64,494; Italy 10,224; France 9,967.
Iron and steel:				
Ore and concentrate	5,855	3,438	--	Italy 904; United Kingdom 620; Austria 546.

See footnotes at end of table.

Tubes, pipes, fittings do	3,691	3,532	71	China, mainland 477; Netherlands 340; Czechoslovakia 187.
Castings and forgings, rough do	113	113	9	Belgium-Luxembourg 19; Netherlands 14; France 12.
Lead:				
Ore and concentrate	10	2,577	--	Bulgaria 1,380; Romania 1,196.
Oxides	11,508	10,635	127	Netherlands 5,467; Sweden 1,044; U.S.S.R. 572.
Metal including alloys:				
Scrap	16,801	18,414	--	Italy 7,315; Netherlands 6,711; Denmark 1,814.
Unwrought	106,810	107,031	1,376	Italy 43,042; France 13,602; Austria 13,545.
Semimanufactures	11,626	4,974	70	Denmark 2,162; Switzerland 1,263; Sweden 989.
Lithium:				
Oxide and hydroxide	557	717	--	France 209; Italy 195; Belgium-Luxembourg 117.
Metal, all forms	16	12	--	Switzerland 6; France 3.
Magnesium:				
Oxide, hydroxide, peroxide	599	445	--	Denmark 125; Colombia 100.
Metal including alloys:				
Scrap	2,620	1,964	262	Italy 894; Netherlands 564.
Unwrought	179	200	--	Austria 116; Brazil 30; France 25.
Semimanufactures	409	482	--	Republic of South Africa 87; Sweden 64; France 50.
Manganese:				
Ore and concentrate	2,088	1,946	--	Netherlands 936; France 598; Denmark 175.
Oxides	3,527	5,171	--	Austria 117; France 107.
Metal including alloys, all forms	31	59	--	Italy 15.
Mercury 76-pound flasks	2,205	2,344	--	Netherlands 908; Switzerland 296; Egypt 174.

See footnotes at end of table.

Table 2.—Federal Republic of Germany: Exports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS —Continued				
Molybdenum:				
Ore and concentrate	1,117	6,668	1,546	Belgium-Luxembourg 1,586; United Kingdom 810; Sweden 672.
Oxides and hydroxides[4]	5,976	2,748	NA	NA.
Metal including alloys, all forms	237	391	NA	NA.
Nickel:				
Matte, speiss, similar materials	7	1,332	--	Netherlands 500; Spain 464; Italy 305.
Oxides and hydroxides	290	147	--	Netherlands 45; Italy 33.
Metal including alloys:				
Scrap	7,150	8,380	363	Sweden 6,188; Austria 843.
Unwrought	5,175	11,337	456	France 4,352; Netherlands 3,757.
Semimanufactures	8,882	10,159	3,102	United Kingdom 1,448; France 659; Belgium-Luxembourg 533.
Platinum-group metals:				
Platinum:				
Ash and waste value	$57,752	$54,558	--	All to Belgium-Luxembourg.
Scrap and sweepings do	$658,668	$658,519	NA	Netherlands $503,574; Sweden $123,848.
Metal including alloys, unwrought and partly wrought troy ounces	r252,476	288,034	7,988	Switzerland 69,160; Netherlands 38,157; France 35,629; Japan 31,867.
Palladium metal including alloys, unwrought and partly wrought do	110,918	130,757	868	Netherlands 54,881; Switzerland 22,538; Japan 16,397.
Other metal including alloys, unwrought and partly wrought do	80,967	114,585	2,249	Japan 20,768; Republic of South Africa 13,923; Bulgaria 12,348.
Silicon metal	1,678	1,496	271	France 385; Netherlands 281; Belgium-Luxembourg 131.
Silver:				
Ash and waste value, thousands	$20,448	$3,213	--	France $1,510; Belgium-Luxembourg $1,378; Switzerland $312.
Scrap and sweepings do	$220	$1,071	--	Spain $445; Switzerland $394; Netherlands $158.
Metal including alloys, unwrought and partly wrought thousand troy ounces	39,192	33,508	322	Italy 4,070; Switzerland 3,976; Sweden 3,084.
Tin:				
Ore and concentrate	r500	100	NA	NA.
Metal including alloys:				
Scrap	88	52	--	Netherlands 36.
Unwrought	4,813	5,784	--	Netherlands 3,968; France 479.
Semimanufactures	741	781	--	Switzerland 94; Austria 93; Netherlands 38.
Titanium:				
Ore and concentrate	6,195	5,602	55	Netherlands 1,265; Bulgaria 1,046; Switzerland 973.
Oxides	48,073	48,018	7,775	Italy 5,105; Netherlands 3,290; France 2,650.
Metal including alloys, all forms	1,904	1,864	217	United Kingdom 481; Italy 324; France 269.
Tungsten:				
Ore and concentrate	87	174	--	Austria 111; Italy 36; Netherlands 18.
Metal including alloys, all forms	542	608	(3)	NA.
Uranium and thorium:				
Oxides including rare-earth oxides	1,212	1,923	1,421	Japan 208.
Metals including alloys, all forms kilograms	6,700	9,900	--	Italy 6,900; U.S.S.R. 2,400.
Vanadium metal including alloys, all forms	55	108	--	United Kingdom 85; Japan 18.
Zinc:				
Ore and concentrate	72,495	70,592	--	Netherlands 32,123; Belgium-Luxembourg 22,315; France 7,993.
Matte	4,514	5,609	--	Italy 2,025; Belgium-Luxembourg 1,418; France 1,309.
Oxides	12,033	15,166	NA	NA.
Metal including alloys:				
Scrap	7,254	8,824	--	Netherlands 6,344; Italy 1,263.
Blue powder	6,539	4,588	18	Netherlands 1,492; Romania 1,060; Spain 523.

See footnotes at end of table.

Table 2.—Federal Republic of Germany: Exports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS —Continued				
Zinc —Continued				
Metal including alloys —Continued				
Unwrought	87,538	97,031	20,612	Netherlands 14,402; United Kingdom 8,234; Belgium-Luxembourg 6,206.
Semimanufactures	13,526	15,012	21	NA.
Zirconium:				
Ore and concentrate	6,885	8,205	--	France 2,170; Netherlands 1,334; United Kingdom 682.
Metal including alloys, all forms	97	127	23	France 52; Japan 20.
Other:				
Ores and concentrates:				
Of columbium, tantalum, vanadium	1,040	1,276	1,074	Belgium-Luxembourg 90; Japan 76.
Of base metals, n.e.s	5	2	--	Netherlands 1.
Ash and residue containing nonferrous metals	168,640	187,752	6,522	Belgium-Luxembourg 61,428; Netherlands 46,685; Sweden 20,680.
Oxides, hydroxides, peroxides	17,106	8,108	3	Italy 291; Brazil 288.
Metals:				
Metalloids:				
Arsenic and tellurium	2	10	--	France 2; Spain 1.
Selenium and phosphorus[5]	7,629	11,784	NA	NA.
Alkali, alkaline-earth, rare-earth metals	264	167	NA	NA.
Pyrophoric alloys	r62	39	--	Kuwait 6; United Kingdom 6; Hong Kong 5.
Base metals including alloys, all forms	615	960	175	France 344; Canada 136; Japan 106.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	1,619,101	426,761	34	Netherlands 373,412; Belgium-Luxembourg 37,358.
Artificial:				
Corundum	45,234	52,035	2,444	Italy 7,296; France 5,640; Sweden 4,592.
Silicon carbide	24,444	28,480	NA	NA.
Dust and powder of precious and semiprecious stones kilograms	385	414	69	Brazil 106; Greece 100; Austria 67.
Grinding and polishing wheels and stones	11,440	11,797	617	France 1,643; Netherlands 1,156; Belgium-Luxembourg 856.
Asbestos, crude	43,314	65,366	NA	NA.
Barite and witherite	38,178	38,720	--	Netherlands 9,623; France 7,118; Sweden 5,404.
Boron materials:				
Crude natural borates	11,966	11,589	--	Sweden 4,024; Italy 2,908; Norway 1,600.
Oxides, acid, borates, perborates	46,648	41,489	--	Switzerland 19,662.
Bromine	112	13	NA	NA.
Cement thousand tons	2,644	2,397	183	Netherlands 1,538; Nigeria 263; Belgium-Luxembourg 149.
Chalk	18,064	22,538	--	Denmark 7,135; Sweden 5,362; Finland 5,347.
Clays and clay products:				
Crude clays:				
Andalusite and kyanite	6,199	9,512	--	Italy 3,366; Austria 2,335; France 1,202.
Bentonite	25,014	26,250	--	France 12,182; Netherlands 5,220; Belgium-Luxembourg 3,530.
Ceramic clay	691,412	776,003	--	Italy 248,440; Netherlands 193,910; Belgium-Luxembourg 158,465.
Chamotte	36,473	45,618	--	Netherlands 20,319; Italy 5,739; Switzerland 5,465.
Dinas earth	39,401	60,770	--	France 24,989; Italy 9,123; Switzerland 7,652.
Fire clay	294,199	283,985	--	Netherlands 92,337; Italy 85,233; Belgium-Luxembourg 36,051.
Fuller's earth	1,086	3,157	--	Netherlands 1,801; France 768.
Kaolin	102,599	114,578	--	Italy 33,687; Austria 23,679; France 14,334.
Other	218,441	235,133	--	Netherlands 194,772; Italy 13,938; France 12,273.

See footnotes at end of table.

Table 2.—Federal Republic of Germany: Exports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
NONMETALS —Continued				
Clays and clay products —Continued				
Products:				
Refractory including nonclay brick	622,672	639,466	16,996	Belgium-Luxembourg 104,802; France 90,242; Netherlands 44,014.
Nonrefractory	943,170	846,593	9,600	France 238,760; Belgium-Luxembourg 161,456; Netherlands 146,420.
Cryolite and chiolite	17	58	--	Italy 56.
Diamond:				
Crude, set or strung thousand carats	146	113	2	Belgium-Luxembourg 42; Switzerland 30; Hong Kong 7.
Industrial do	360	296	13	Ireland 122; Belgium-Luxembourg 43; Netherlands 35.
Diatomite and other infusorial earth	3,999	4,153	--	Netherlands 2,172; United Kingdom 524; Austria 414.
Feldspar, leucite, nepheline, nepheline syenite	18,759	17,802	--	France 5,928; Italy 3,290; Belgium-Luxembourg 2,014.
Fertilizer materials:				
Crude:				
Phosphatic	1,230	952	--	NA.
Potassic	32,279	49,296	--	Belgium-Luxembourg 25,810; United Kingdom 12,896; Netherlands 9,694.
Manufactured:				
Nitrogenous thousand tons	1,232	1,619	66	Belgium-Luxembourg 546; India 141; Brazil 140.
Phosphatic do	46	54	--	France 26; Austria 14.
Potassic do	2,378	2,433	31	Belgium-Luxembourg 709; India 214; Brazil 166; Ireland 166.
Other including mixed do	962	892	(3)	Belgium-Luxembourg 134; France 119; Austria 111.
Ammonia, anhydrous do	221	242	--	Denmark 111; France 57; United Kingdom 34.
Fluorspar	14,789	16,609	--	Austria 5,926; Netherlands 3,472; Czechoslovakia 1,358.
Graphite, natural	7,927	6,860	854	Italy 2,097; France 807; Spain 346.
Gypsum and plasters	355,983	356,918	--	Netherlands 210,794; Belgium-Luxembourg 43,946; Switzerland 38,749.
Iodine	31	45	--	Italy 14; France 9; Netherlands 5.
Lime	580,035	573,377	--	Netherlands 457,695; France 58,956.
Magnesite	21,693	20,445	281	France 5,443; Belgium-Luxembourg 3,158; Netherlands 2,570.
Mica:				
Crude including splittings and waste	777	642	--	Austria 150; Yugoslavia 139.
Worked including agglomerated splittings	427	332	--	United Kingdom 120; Yugoslavia 21; Australia 17.
Pigments, mineral:				
Natural, crude	84	22	NA	NA.
Iron oxides, processed	158,898	170,421	23,107	France 22,098; United Kingdom 14,776; Italy 13,029.
Precious and semiprecious stones except diamond:				
Natural kilograms	166,716	169,038	7,059	Hong Kong 10,218; Japan 9,691; Switzerland 8,367.
Synthetic do	19,728	26,380	3,147	Japan 13,176; Netherlands 3,896; Italy 3,295.
Pyrite (gross weight)	1,361	1,238	NA	NA.
Salt thousand tons	1,985	2,499	(3)	Belgium-Luxembourg 1,419; Sweden 254; Netherlands 206.
Sodium and potassium compounds, n.e.s.:				
Caustic soda do	1,176	1,379	40	Netherlands 200; Sweden 50; Canada 47.
Caustic potash do	15	14	NA	NA.
Soda ash	87,172	218,582	--	Belgium-Luxembourg 89,042; Saudi Arabia 22,926.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked:				
Calcareous	3,286	5,230	--	Italy 1,744; Austria 1,278.

See footnotes at end of table.

Dimension stone —Continued				
Crude and partly worked — Continued				
Slate	11,170	12,556	--	Denmark 4,077; Belgium-Luxembourg 4,075; Netherlands 3,561.
Other	405,232	628,720	--	Netherlands 530,886; Switzerland 78,041; Austria 11,799.
Worked:				
Slate	1,616	1,139	--	Netherlands 636; Belgium-Luxembourg 165; France 112.
Paving and flagstone	24,284	14,917	--	Denmark 6,157; Belgium-Luxembourg 3,297; Netherlands 2,570.
Other	22,310	21,881	56	Belgium-Luxembourg 5,770; Austria 5,596; Switzerland 3,258.
Dolomite, chiefly refractory-grade	230,987	279,055	265	France 134,241; Netherlands 106,889.
Gravel and crushed rock thousand tons	9,646	9,264	--	Netherlands 7,198; Switzerland 844; Belgium-Luxembourg 716.
Limestone except dimension	66,562	80,157	--	Netherlands 58,662; Belgium-Luxembourg 165.
Quartz and quartzite	161,466	121,887	390	Belgium-Luxembourg 57,400; Netherlands 13,323; Austria 13,090.
Sand excluding metal-bearing thousand tons	8,350	8,093	--	Netherlands 6,688; Belgium-Luxembourg 877.
Sulfates, natural: Magnesium sulfate (kieserite)	536,386	512,916	18,922	Singapore 103,653; Norway 85,462; France 66,752.
Sulfur:				
Elemental:				
Other than colloidal	304,693	356,669	--	Netherlands 94,012; Denmark 74,575; Switzerland 51,181.
Colloidal	1,568	1,238	79	Italy 648; Belgium-Luxembourg 69; Yugoslavia 56.
Sulfur dioxide	11,871	8,744	--	Belgium-Luxembourg 4,397; Austria 1,831.
Sulfuric acid, oleum	625,406	802,738	--	Netherlands 213,811; Belgium-Luxembourg 112,676; Spain 84,298.
Talc, steatite, soapstone, pyrophyllite	7,949	5,607	--	Yugoslavia 1,644; Belgium-Luxembourg 616; Denmark 362.
Other:				
Crude:				
Pottery, broken	31,184	38,504	--	Netherlands 15,667; Belgium-Luxembourg 6,604: Switzerland 6,337.
Vermiculite, perlite, chlorite	2,767	4,403	--	Belgium-Luxembourg 3,046; Netherlands 500.
Unspecified thousand tons	1,657	1,289	--	Netherlands 1,188; Belgium-Luxembourg 26.
Slag, dross, and similar waste, not metal-bearing:				
From iron and steel manufacture do	2,993	2,658	--	Netherlands 2,533.
Other do	715	702	--	Netherlands 564; France 90.
Oxides and hydroxides of strontium and barium	2,547	3,633	1,323	France 793; Belgium-Luxembourg 407; Italy 337.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	1,941	6,552	--	Netherlands 4,323; Austria 1,327.
Carbon black	94,688	107,982	594	France 23,572; Austria 14,040; Belgium-Luxembourg 11,646.
Coal and briquets:				
Anthracite and bituminous coal thousand tons	18,656	15,225	--	France 6,763; Belgium-Luxembourg 3,375; Italy 1,967.
Briquets of anthracite and bituminous coal do	382	391	--	France 159; Belgium-Luxembourg 133; Austria 38.
Lignite and lignite briquets do	509	718	--	France 207; Austria 178; Netherlands 167.

See footnotes at end of table.

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
MINERAL FUELS AND RELATED MATERIALS —Continued				
Coke and semicoke thousand tons	9,124	10,958	--	Belgium-Luxembourg 3,214; France 2,041; Romania 1,118.
Gas:				
Natural million cubic feet	239,511	217,289	NA	NA.
Manufactured do	--	39	--	All to Switzerland.
Hydrogen, helium, rare gases	23,030	21,974	--	Italy 8,158; France 3,838; Austria 2,882.
Peat including peat briquets and litter	494,921	497,431	374	Netherlands 320,309; France 60,586; Switzerland 50,857.
Petroleum and refinery products:				
Crude thousand 42-gallon barrels	224	318	--	NA.
Refinery products:				
Gasoline:				
Aviation[6] do	21	35	--	United Kingdom 12.
Motor do	r5,889	6,250	9	Austria 2,229; Switzerland 1,937; Netherlands 778.
Kerosine do	r29	168	--	Netherlands 135; Austria 18.
Jet fuel[7] do	9,958	10,022	--	Sweden 488; Switzerland 368.
Distillate fuel oil[8] do	r3,324	3,144	--	Switzerland 627; Austria 540.
Residual fuel oil[9] do	r20,771	19,391	167	Austria 2,853; United Kingdom 1,822; France 1,484.
Lubricants do	r222	255	1	Denmark 128; Poland 28; Netherlands 16; Switzerland 11.
Other:				
Mineral jelly and wax do	r1,102	1,103	30	Italy 127; Netherlands 101; Austria 70; Belgium-Luxembourg 67.
Nonlubricating oils do	7,671	8,333	9	France 3,669; Netherlands 1,650; Belgium-Luxembourg 1,325.
Liquefied petroleum gas do	r3,668	4,303	--	Netherlands 1,206; Belgium-Luxembourg 718; United Kingdom 584.
Petroleum coke do	2,134	2,140	--	Netherlands 667; France 460; Switzerland 260.
Bitumen and other residues do	1,963	2,126	--	Austria 799; Denmark 410; Switzerland 319.
Bituminous mixtures do	380	457	--	Netherlands 340.
Unspecified do	r896	796	(3)	Netherlands 191; Belgium-Luxembourg 111; Switzerland 104.

rRevised. NA Not available.
[1]This table does not include exports to the German Democratic Republic.
[2]May include a small quantity of tin.
[3]Less than 1/2 unit.
[4]May include a small quantity of tungsten.
[5]Includes elemental sodium and potassium.
[6]Includes 15,183 barrels of bunker in 1978 and 16,296 barrels in 1979.
[7]Includes 8,831,216 barrels of bunker in 1978 and 8,744,192 barrels in 1979.
[8]Includes 1,840,695 barrels of bunker in 1978 and 1,434,931 barrels in 1979.
[9]Includes 26,627 barrels of bunker in 1978 and 40,786 barrels in 1979.

Ore and concentrate	3,040	3,126	--	Thailand 1,063; Bolivia 316; China, mainland 306.
Oxides and hydroxides	3,406	3,896	26	France 1,540; Belgium-Luxembourg 1,393.
Metal including alloys, all forms	748	567	--	Belgium-Luxembourg 208; China, mainland 161.
Arsenic trioxide, pentoxide acids	r647	825	NA	Belgium-Luxembourg 376; France 119; Sweden 102.
Beryllium metal including alloys, all forms kilograms	815	1,233	1,005	NA.
Bismuth metal including alloys, all forms	112	211	--	United Kingdom 94; Bulgaria 15.
Cadmium:				
Oxide and hydroxide	428	539	--	Belgium-Luxembourg 372; United Kingdom 157.
Metal including alloys, all forms	994	1,126	18	Belgium-Luxembourg 256; Japan 199; France 121.
Chromium:				
Chromite	371,738	546,786	--	Republic of South Africa 263,890; Albania 182,420; U.S.S.R. 20,998.
Oxides and hydroxides	1,453	1,407	166	U.S.S.R. 806; United Kingdom 166; Netherlands 94.
Metal including alloys, all forms	698	883	26	Belgium-Luxembourg 292; Japan 214; France 197.
Cobalt:				
Oxides and hydroxides	603	483	74	Belgium-Luxembourg 164; Japan 84; United Kingdom 56.
Metal including alloys, all forms	2,059	1,848	103	Belgium-Luxembourg 520; Zaire 464; France 125.
Columbium and tantalum metals including alloys, all forms:				
Columbium kilograms	10,743	22,078	18,557	Belgium-Luxembourg 3,000.
Tantalum do	251,247	252,425	186,539	United Kingdom 18,183; Japan 12,688.
Copper:				
Ore and concentrate	531,355	483,740	14,764	Papua-New Guinea 185,036; Republic of South Africa 72,001; Norway 64,047.
Matte	7,561	12,249	2,814	Canada 2,727; Yugoslavia 1,530; Australia 1,508.
Oxides and hydroxides	165	216	--	Italy 183.
Sulfate	8,575	12,477	--	France 6,245; Belgium-Luxembourg 2,870; U.S.S.R. 1,909.
Metal including alloys:				
Scrap	137,562	168,822	9,801	France 42,581; United Kingdom 28,764; Netherlands 27,579.
Unwrought:				
Smelter	109,225	62,785	80	Chile 29,072; Republic of South Africa 23,353; Norway 5,696.
Refined:				
Alloyed	46,399	53,358	252	United Kingdom 13,924; Romania 5,313; Switzerland 3,824; Hungary 3,680.
Unalloyed	428,794	449,995	10,860	Chile 136,634; Belgium-Luxembourg 71,150; Poland 68,731.
Master alloys	1,551	1,752	(2)	United Kingdom 905; Belgium-Luxembourg 637.
Semimanufactures	163,940	194,689	6,791	Belgium-Luxembourg 68,856; France 43,672; Italy 16,860.
Gallium metal including alloys, all forms kilograms	1,700	3,500	800	France 800; United Kingdom 800.
Gold:				
Ash and waste value, thousands	$2,408	$6,099	$1,948	Switzerland $1,896; Israel $635; Denmark $582.
Scrap and sweepings do	$3,106	$9,765	$46	Sweden $2,505; Switzerland $1,462; Israel $1,421.
Metal including alloys:				
Unwrought thousand troy ounces	3,600	3,377	438	Switzerland 1,799; U.S.S.R. 431.

See footnotes at end of table.

Table 3.—Federal Republic of Germany: Imports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Sources, 1979	
			United States	Other (principal)
METALS —Continued				
Gold —Continued				
Metal including alloys —Continued				
Partly wrought thousand troy ounces	61	68	11	Republic of South Africa 19; Switzerland 13; Netherlands 10.
Hafnium metal including alloys, all forms kilograms	r200	100	NA	NA.
Iron and steel:				
Ore and concentrate thousand tons	42,133	51,703	--	Brazil 11,985; Liberia 7,591; Sweden 6,831; Canada 6,802.
Roasted pyrite do	533	626	--	Spain 409; Belgium-Luxembourg 152.
Metal:				
Scrap do	1,548	1,608	50	Netherlands 616; Belgium-Luxembourg 225; France 190.
Pig iron, including cast iron do	293	229	--	Brazil 67; Canada 57; Norway 33; Finland 16.
Sponge iron, powder, shot do	45	69	2	Venezuela 20; France 18; Sweden 16.
Spiegeleisen	37	17	--	NA.
Ferroalloys:				
Ferrochrome thousand tons	194	230	1	Republic of South Africa 126; Sweden 44; Turkey 15.
Ferromanganese do	160	152	3	Norway 56; France 47; Belgium-Luxembourg 14.
Ferronickel do	61	71	(2)	Greece 36; New Caledonia 31.
Ferrosilicon do	159	187	--	Norway 87; France 42; Spain 27.
Ferrosilicochrome do	6	11	1	Republic of South Africa 5; Sweden 4.
Ferrosilico-manganese do	101	116	--	Norway 54; Spain 18; Republic of South Africa 17.
Other do	17	18	4	France 5; Belgium-Luxembourg 3; United Kingdom 2.
Steel, primary forms do	2,571	2,518	--	Belgium-Luxembourg 703; Netherlands 481; Austria 271.
Semimanufactures:				
Bars, rods, angles, shapes, sections do	4,020	3,963	1	Italy 625; France 535; Spain 304.
Universals, plates, sheets do	3,684	4,152	5	France 690; Austria 334; Netherlands 258.
Hoop and strip do	623	715	2	Belgium-Luxembourg 321; France 185; Netherlands 75.
Rails and accessories do	34	42	--	Netherlands 16; Canada 12; Sweden 4.
Wire do	236	256	(2)	Belgium-Luxembourg 99; France 50; Austria 17.
Tubes, pipes, fittings do	811	908	2	France 208; Italy 168; Netherlands 126.
Castings and forgings, rough do	36	43	(2)	France 8; Poland 6; Netherlands 5.
Lead:				
Ore and concentrate	170,055	191,179	--	Canada 47,232; Sweden 46,668; Morocco 24,260.
Oxides	6,455	6,111	133	France 2,086; Belgium-Luxembourg 1,682; Mexico 570.
Metal including alloys:				
Scrap	45,621	62,566	4,904	Netherlands 19,957; Canada 12,580; United Kingdom 10,538.
Unwrought	131,102	129,034	88	United Kingdom 41,098; Sweden 21,459; Belgium-Luxembourg 19,015.
Semimanufactures	2,822	4,054	--	Belgium-Luxembourg 2,245; Yugoslavia 767; France 739.
Lithium:				
Oxide and hydroxide	469	464	297	Netherlands 96.
Metal including alloys, all forms	17	9	8	NA.
Magnesium:				
Oxide, hydroxide, peroxide	r3,246	459	--	France 343; Italy 38.
Metal including alloys:				
Scrap	825	1,032	--	Netherlands 304; Denmark 163; Italy 108.
Unwrought	29,244	32,340	7,303	Norway 15,157; Italy 4,584; France 2,290.
Semimanufactures	359	500	189	Norway 142; Austria 122.
Manganese:				
Ore and concentrate thousand tons	673	717	--	Republic of South Africa 432; Australia 124; Brazil 76.

See footnotes at end of table.

Table 3.—Federal Republic of Germany: Imports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Sources, 1979	
			United States	Other (principal)
METALS —Continued				
Manganese —Continued				
Oxides	2,625	5,462	--	Belgium-Luxembourg 3,162; Greece 905; Ireland 880.
Metal including alloys, all forms	5,438	5,848	991	Republic of South Africa 3,084; Netherlands 436; France 402.
Mercury 76-pound flasks	12,592	13,373	--	Algeria 3,568; Italy 2,466; Spain 1,682.
Molybdenum:				
Ore and concentrate	19,203	22,065	12,110	Canada 2,214; Netherlands 1,882; Chile 1,559.
Oxides and hydroxides	456	515	91	Netherlands 252; United Kingdom 54; Australia 40.
Metal including alloys, all forms	638	797	172	Austria 411.
Nickel:				
Ore and concentrate	10	34	--	U.S.S.R. 25.
Matte, speiss, similar materials	16,464	15,746	69	Australia 8,297; Canada 4,910.
Oxides and hydroxides	595	612	42	Canada 319; Netherlands 93; France 80.
Metal including alloys:				
Scrap	4,002	6,505	1,332	France 2,283; Netherlands 869; United Kingdom 594.
Unwrought	38,880	47,708	6,714	U.S.S.R. 8,330; Republic of South Africa 7,066; Norway 6,426.
Semimanufactures	5,280	6,325	1,295	France 2,321; United Kingdom 1,610.
Platinum-group metals:				
Platinum:				
Ash and waste value, thousands	$2,951	$2,580	$448	Italy $1,220; Netherlands $378; Switzerland $168.
Scrap and sweepings do	$19,060	$30,034	$2,624	Netherlands $5,848; Hungary $5,154; Belgium-Luxembourg $2,206.
Metal including alloys, unwrought and partly wrought thousand troy ounces	r301	510	84	United Kingdom 151; Switzerland 136; U.S.S.R. 51.
Palladium metal including alloys, unwrought and partly wrought do	431	382	50	U.S.S.R. 163; United Kingdom 80; Belgium-Luxembourg 35.
Other including alloys, unwrought and partly wrought do	128	114	53	United Kingdom 34; Republic of South Africa 15; U.S.S.R. 8.
Rare-earth metals:				
Oxides and other compounds	977	1,196	356	France 369; United Kingdom 240; Austria 187.
Metals, all forms	110	107	NA	NA.
Silicon metal including alloys, all forms	49,570	59,236	NA	France 19,766; Norway 11,042; Switzerland 5,425.
Silver:				
Ash and waste value, thousands	$20,448	$20,752	$10,991	Sweden $2,106; Switzerland $1,942; Norway $1,772.
Scrap and sweepings do	$6,424	$20,602	$2,180	United Kingdom $9,385; Netherlands $2,285; Hong Kong $1,976.
Metal including alloys, unwrought and partly wrought thousand troy ounces	43,904	42,489	3,326	Switzerland 9,413; United Kingdom 5,041; Sweden 4,372; Poland 3,818.
Tin:				
Ore and concentrate	7,989	7,158	--	United Kingdom 3,192; Bolivia 1,867; Republic of South Africa 1,703.
Oxides	20	30	--	France 15; Japan 10.
Metal including alloys:				
Scrap	624	340	--	Netherlands 127; Yugoslavia 79; Switzerland 59.
Unwrought	15,481	17,098	--	Indonesia 5,260; Thailand 4,746, Malaysia 2,718.
Semimanufactures	1,572	1,684	--	Netherlands 1,580.
Titanium:				
Ore and concentrate	519,562	574,005	1,880	Norway 378,508; Canada 116,629; Australia 45,490.
Oxides	17,586	21,916	454	Belgium-Luxembourg 13,044; France 2,554; United Kingdom 1,939.
Metal including alloys, all forms	3,871	3,836	602	Japan 1,991; U.S.S.R. 608; United Kingdom 208.
Tungsten:				
Ore and concentrate	3,422	4,097	72	China, mainland 1,726; Australia 526; Canada 244.

See footnotes at end of table.

Table 3.—Federal Republic of Germany: Imports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Sources, 1979	
			United States	Other (principal)
METALS —Continued				
Tungsten —Continued				
Oxides and hydroxides	428	294	--	Australia 285.
Metal including alloys, all forms	1,149	831	76	Austria 348; United Kingdom 77; Netherlands 58.
Uranium and thorium:				
Oxides	229	416	--	U.S.S.R. 382; France 24.
Metals including alloys, all forms	16	2	--	Mainly from France.
Vanadium:				
Oxides	1,850	710	--	NA.
Metal including alloys, all forms	27	42	42	
Zinc:				
Ore and concentrate	498,930	502,951	--	Canada 193,567; Sweden 70,139; Greenland 58,401.
Matte	5,783	4,231	--	Netherlands 1,539; Czechoslovakia 764; Belgium-Luxembourg 536.
Oxide and peroxide	6,673	6,853	--	France 2,540; Netherlands 2,074; Italy 740.
Metal including alloys:				
Scrap	9,637	12,369	1,160	France 2,317; Netherlands 1,910; United Kingdom 1,794; Denmark 1,519.
Blue powder	11,676	12,705	--	Belgium-Luxembourg 9,844; France 1,210; Netherlands 924.
Unwrought	152,294	156,138	--	Belgium-Luxembourg 74,539; Netherlands 33,779; France 6,545.
Semimanufactures	23,227	24,014	--	France 2,505; Netherlands 2,085; Yugoslavia 1,197.
Zirconium:				
Ore and concentrate	36,817	50,185	1,882	Australia 33,022; Republic of South Africa 10,970.
Metal including alloys, all forms	348	218	117	France 74.
Other:				
Ores and concentrates:				
Of columbium, tantalum, vanadium	870	1,458	51	Brazil 996; Thailand 118; Canada 100.
Of base metals	2,836	5,319	--	Chile 3,330; Australia 1,903.
Ash and residue containing nonferrous metals	302,408	402,496	18,337	Canada 107,690; Belgium-Luxembourg 32,499; United Kingdom 29,250.
Oxides, hydroxides, peroxides	6,869	2,001	187	France 699; United Kingdom 398.
Metals:				
Metalloids:				
Arsenic and tellurium	56	54	--	Belgium-Luxembourg 12; U.S.S.R. 12; Sweden 9.
Selenium and phosphorus	30,234	28,873	NA	NA.
Alkali, alkaline-earth, rare-earth metals	322	443	--	France 287.
Pyrophoric alloys	r67	37	NA	NA.
Base metals including alloys, all forms	680	691	124	Sweden 246; United Kingdom 48.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	43,787	66,202	1,581	Greece 50,581; Italy 4,424.
Artificial:				
Corundum	33,587	40,011	969	Netherlands 16,639; Hungary 6,000; Austria 4,982.
Silicon carbide	61,884	66,711	238	Norway 10,571; Italy 4,917; Poland 2,864.
Dust and powder of precious and semi-precious stones kilograms	1,856	2,205	1,422	Ireland 531; Switzerland 123.
Grinding and polishing wheels and stones	7,210	7,100	198	Austria 3,302; Italy 1,195; France 881; Spain 807.
Asbestos, crude	345,817	386,383	657	Canada 305,300; Republic of South Africa 31,612.
Barite and witherite	196,465	197,658	--	France 94,071; China, mainland 43,281; Spain 35,593.
Boron materials:				
Crude natural borates	124,564	143,862	72,997	Turkey 65,187; Belgium-Luxembourg 4,343.
Oxide, acid, borates, perborates	76,929	90,114	17,506	Belgium-Luxembourg 38,751; France 14,119; Turkey 7,559.
Bromine	1,871	2,922	--	Israel 2,290; United Kingdom 3.
Cement thousand tons	1,193	1,288	3	France 470; Belgium-Luxembourg 463; Netherlands 186.

See footnotes at end of table.

Table 3.—Federal Republic of Germany: Imports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Sources, 1979	
			United States	Other (principal)
NONMETALS —Continued				
Chalk	89,658	104,237	--	France 88,211; Belgium-Luxembourg 14,133.
Clays and clay products:				
Crude clays:				
Andalusite and kyanite	57,258	65,312	40,445	Republic of South Africa 16,872.
Bentonite	45,879	66,841	45,104	Greece 11,982; Belgium-Luxembourg 4,817.
Ceramic clay	96,548	91,421	--	France 32,414; Netherlands 26,410; United Kingdom 18,334.
Chamotte	70,037	90,398	989	France 34,635; Czechoslovakia 32,751; United Kingdom 12,675.
Dinas earth	4,964	6,550	--	Belgium-Luxembourg 6,449.
Fire clay	123,230	134,053	11,485	France 43,932; Czechoslovakia 43,634; United Kingdom 13,861.
Fuller's earth	6,785	5,282	3,250	Spain 1,256.
Kaolin	716,891	800,113	108,354	United Kingdom 471,070; Czechoslovakia 125,725.
Other	168,149	161,764	27,892	Czechoslovakia 52,153; France 45,163.
Products:				
Refractory including nonclay brick thousand tons	204	249	2	Austria 30; Czechoslovakia 30; France 25.
Nonrefractory do	1,560	1,795	--	Italy 649; Netherlands 593; France 223.
Cryolite and chiolite	1,244	2,724	--	Mainly from Greenland.
Diamond:				
Crude:				
Not set or strung thousand carats	3	--		
Other do	678	520	3	Belgium-Luxembourg 260; Israel 112; India 46.
Industrial do	1,165	1,057	75	Belgium-Luxembourg 363; Republic of South Africa 331; United Kingdom 102.
Diatomite and other infusorial earth	39,100	40,190	8,162	Denmark 23,763; France 6,910.
Feldspar, leucite, nepheline, nepheline syenite	126,080	120,150	--	Norway 86,411; Italy 15,318.
Fertilizer materials:				
Crude:				
Nitrogenous	867	2,631	--	All from Chile.
Phosphatic thousand tons	2,441	2,584	1,483	Morocco 384; U.S.S.R. 195; Senegal 180.
Manufactured:				
Nitrogenous do	1,319	1,466	26	Belgium-Luxembourg 461; Netherlands 375; Austria 205.
Phosphatic do	785	740	--	Belgium-Luxembourg 581; Netherlands 53; Tunisia 36.
Potassic do	94	88	--	France 85.
Other including mixed do	840	1,037	67	Belgium-Luxembourg 274; Austria 215; France 113.
Ammonia, anhydrous do	107	196	--	France 105; Austria 56.
Fluorspar	240,385	248,690	--	Republic of South Africa 53,456; Spain 33,910; Morocco 16,840.
Graphite, natural	28,583	26,062	97	China, mainland 6,180; Austria 5,768; Norway 2,612.
Gypsum and plasters	374,263	572,093	46	France 313,989; Austria 206,986.
Iodine	791	871	--	Japan 510; Chile 341.
Lime	111,191	153,558	--	France 124,482; Denmark 13,934.
Magnesite	322,409	386,152	26,589	Greece 113,667; Austria 42,821; North Korea 41,145.
Mica:				
Crude including splittings and waste	9,729	8,631	276	India 2,667; Argentina 1,779; China, mainland 970.
Worked including agglomerated splittings	579	611	--	France 268; Belgium-Luxembourg 197.
Pigments, mineral:				
Natural, crude	2,083	2,174	--	Austria 1,897; France 164.
Iron oxides, processed	5,499	6,152	440	Netherlands 2,181; France 1,390; Belgium-Luxembourg 902.
Precious and semiprecious stones except diamond:				
Natural kilograms	1,479,756	1,635,635	221,556	Brazil 1,012,548; Republic of South Africa 105,007.
Synthetic do	22,220	25,587	6,766	Switzerland 12,712; Japan 3,848.
Pyrite (gross weight)	116,669	98,943	--	U.S.S.R. 89,227; Spain 8,029.
Salt	700,421	914,848	--	Netherlands 547,381; Italy 202,985; France 150,096.

See footnotes at end of table.

Table 3.—Federal Republic of Germany: Imports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Sources, 1979	
			United States	Other (principal)
NONMETALS —Continued				
Sodium and potassium compounds, n.e.s.:				
Caustic soda	200,812	167,119	--	Belgium-Luxembourg 36,673; Poland 22,920.
Caustic potash	2,868	3,253	--	Spain 966; Belgium-Luxembourg 697; France 449.
Soda ash	178,012	197,422	1,553	Poland 43,369; France 34,075; Switzerland 22,416.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked:				
Calcareous	148,547	124,036	--	Austria 50,753; Italy 38,272.
Slate	22,988	33,756	--	France 14,196; United Kingdom 7,742; Portugal 5,283.
Other	287,620	367,446	--	Sweden 82,409; Denmark 56,137; Republic of South Africa 42,861.
Worked:

COMMODITY REVIEW

METALS

Aluminum.—In 1980, the Government-owned VAW member of the Vereinigte Industrie-Unternehmungen AG (VIAG) concern, a holding company, commissioned the first half of its newly built aluminum smelter at Töging, Bavaria, replacing its old pre-1914 smelter at the same location. The second half is due for commissioning in 1982. The completion of the smelter is to raise capacity of the plant from 55,000 to 75,000 tons per year, with a line of 120 pots. The plant is expected to be 20% to 25% more energy efficient and to have improved pollution control. Hydropower is to be purchased as previously from VIAG's Innwerk. Construction costs are estimated at about $100 million.

VAW was planning the construction of a secondary aluminum smelter in West Berlin at a cost of $6 million. Smelted West Berlin scrap and some primary aluminum will also be extruded there at the rate of 15,000 tons per year.

It was reported that no plans existed to build new additional primary capacity in the FRG aluminum industry because of the high level of construction and other costs. The FRG index of electricity prices has risen to 172; labor costs have risen to 186; and oil prices to 442 (all 1972=100). In the meantime, VAW's list price for aluminum ingot has risen only 50% since 1970. The company was therefore considering building smelters abroad in countries with low-energy cost; it was negotiating the construction of a 220,000-ton-per-year smelter in Brazil, and also had under consideration projects for aluminum smelters in Australia and Canada. In 1980, the FRG's smelter output declined slightly. The country's total

primary capacity remained basically unchanged at 762,000 tons per year in 10 plants operated by 6 companies. Alumina capacity remained at approximately 1,730,000 tons per year in five alumina plants controlled by four companies. Some of the alumina and all of the bauxite used was imported.

Cadmium.—The FRG's Internal Affairs Minister announced plans to tighten the country's controls on production and use of cadmium for environmental reasons. The FRG has two of Europe's three largest producers of cadmium—Preussag AG and Metallgesellschaft AG—as well as some of Europe's largest consumers, among chemical companies such as BASF, Bayer, and Bärlocher.

Iron Ore.—In 1980, the FRG produced 1,948,000 tons of iron ore (iron content, 596,000 tons) in 10 mines operated by 4 domestic companies. The total was slightly up from that of the previous year, mainly because of the increased use of new modern equipment. A total of 803 people were employed in iron ore mines. Domestic production supplied less than 4% of the iron ore used by the iron and steel industry. The remainder of the supply, amounting to more than 50 million tons, was imported from various countries including Sweden, Norway, and France in Europe; Liberia and the Republic of South Africa in Africa; Brazil and Canada in the Americas; and Australia.

Iron and Steel.—In 1980, Thyssen Niederrhein AG Hütten-und Walzwerke, a member of the Thyssen Group, commissioned a new ministeelworks at Oberhausen in the Ruhr. This event marked the completion of the company's transition from an integrated steelmaker producing both flat-rolled and long products to an electric furnace operator mainly making rebars and wire rod. Concurrently, the company's last open-hearth furnace in Oberhausen (where a century earlier open-hearth steelmaking was introduced) was closed down.

The Krupp Group has consolidated all of its forging activities into one company. Forging activities of the Krupp Metall und Schmiedewerke in Essen and those of Friedrich Krupp Hüttenwerke AG in Bochum were united under the name of Friedrich Krupp Stahlschmiede. The new company had 3,500 employees and was expected to generate a turnover of $200 million.

Norddeutsche Ferrowerke, a subsidiary of Korf Industrie und Handel GmbH & Co. KG, and of Sydvaranger AS of Norway, was completing construction of its direct-reduction steel plant in Emden based on Norwegian natural gas. The $210 million plant, due for completion in 1981, has two Midrex-type furnaces with total capacity of 880,000 tons per year. Shipments of Norwegian and Swedish iron ore pellets (from Svappavaara) started in 1980 to fill the 280,000-ton ore storage space. The plant is said to be the first in the FRG to produce sponge iron for sale to other steel plants. The sponge iron is treated to protect it against oxidation by the company's special proprietary process.

Several other steel companies also had plans to modernize their plants. AG der Dillinger Hüttenwerke was planning to build a 3.15-million-ton-per-year sinter machine at its Killingen plant in the Saar for $35 million. Hoesch Hüttenwerke AG of Dortmund was planning to build a 2-million-ton-per-year oxygen steel mill and a continuous-casting machine at its Westfalenhütte plant for $25 million. Thyssen Edelstahlwerke AG was planning to build a 300,000-ton casting plant at its Krefeld works at a cost of $40 million. The plant is expected to be completed by the end of 1981. Thyssen Edelstahlwerke was planning construction of a new 110-ton arc furnace at its Witten works in the Ruhr with a capacity of about 480,000 tons per year, at a cost of $16 million. The furnace is mainly to replace an open-hearth steel plant at the same location.

In November, the Mannesmann Group voted to incorporate the Mannesmann AG Hüttenwerke (Steelworks) into Mannesmannröhren-Werke AG (Pipe Works), and thereby give up steel company status to avoid the special codetermination laws that apply to the coal and steel industries. In those industries, the labor representatives exert greater power in deciding tie votes than do union representatives on the supervisory board of nonsteel companies. However, a compromise was worked out by the Bonn Government postponing the Mannesmann merger until 1987.

The FRG Government, always a strong supporter of the free enterprise system, participated reluctantly in the European Communities' steel production quotas during 1980. By yearend, the FRG was considering countervailing duties if the Communities would not prohibit subsidies by other governments to their respective steel indus-

tries. A deadline to eliminate all such subsidies was set by the FRG Government for June 31, 1981.

In 1980, total raw steel production of the FRG declined somewhat to 43.8 million tons, although it was still the largest among West European countries. Pig iron production declined also to about 33.9 million tons. Top crude steel producers in 1979 (output in million tons) were the Thyssen Group (12.2), Hoesch-Estel Group (11.5), Krupp Group (5.2), Klöckner Group (5.1), Peine-Salzgitter Group (4.4), and Mannesmann Group (4.3).

More than 48 companies produced stainless and alloy steels in the FRG; the most important producers, representing about 60% of the national output, were, in decreasing order of output, the Edelstahlwerke Buderus AG at Wetzlar; Klöckner Werke AG in Osnabrück; Friedrich Krupp Hüttenwerke AG in Bochum; Stahlwerke Röchling Burbach GmbH (Arbed) of Völklingen in the Saar; Stahlwerke Südwestfalen AG in Siegen; and Thyssen Edelstahlwerke in Krefeld.

Lead, Zinc, and Copper.—Falling metal content in the remaining ore reserves and persistent low prices could make necessary the shutdown of the 100-year-old lead-zinc mine at Meggen, North Rhine Westphalia, according to the owner, Metallgesellschaft AG, but there were no immediate plans to do so. One-quarter of the 940 employees of the mine were already working in a new mining service enterprise for third parties.

A new fill process, adapted during the previous year, was used at the Bad Grund (Lower Saxony) lead-zinc-copper mine. Tailings are pumped back in water suspension, mixed with 3% cement, giving good stability and increased safety at reduced cost.

Only three metal mines in the FRG were left in 1980: Meggen (lead-zinc), operated by Metallgesellschaft's Sachtleben Bergbau GmbH; and Bad Grund (lead-zinc) and Rammelsberg (lead-zinc-copper), both located in Lower Saxony, and both operated by Preussag AG Metall. The FRG smelting and refining capacity remained approximately unchanged at 395,000 tons per year of lead, 435,000 tons per year of zinc, and 260,000 tons per year of copper. Domestic mines provided only about 1% of the copper and less than a quarter of the lead and zinc.

NONMETALS

Graphite.—Mining at the Kropfmühl graphite mine near Passau, west of the Austrian border, was extended by nearly a mile of new tunnels at the Erhard shaft. The mine was operated by Graphitwerk Kropfmühl AG.

Artificial graphite was produced in the FRG by the Sigri Group, the second largest producer after Union Carbide Corp. of the United States. Sigri is owned jointly by Hoechst AG of Frankfurt and Plania-Beteiligungs GmbH of Munich, the latter two-thirds owned by Rüttgerswerke AG. The group controlled five graphite producers operating seven plants located throughout Europe. The largest of them was Sigri Elektrographit GmbH, which had two plants, one at Meitingen near Augsburg and another at Griesheim near Frankfurt.

Limestone.—Burnt limestone production in the FRG was fairly constant, around 9 to 10 million tons during the last decade. The principal area of production was the State of North Rhine Westphalia, with about 60% of the total. About 35% of the burnt lime is used for iron and steel, 22% for building materials, 15% in the construction industry, and 10% in the chemical industry. Although a large number of companies produce burnt lime in the country, only two companies account for half of the production. The largest producer is the Rheinische Kalksteinwerke GmbH, part of the large Wulfrath Group, 75% owned by the Thyssen Group and 25% by Friedrich Krupp GmbH. Although plants are in various places, principal operations are located northeast of Düsseldorf, with total burnt lime capacity about 2.6 million tons per year. The second most significant producer is Rheinisch Westfälische Kalkwerke AG, with about 2 million tons of burnt lime capacity. Other significant producers are Fels-Werke Peine-Salzgitter GmbH (capacity of 500,000 tons of burnt lime) and Johann Schaefer Kalkwerke (capacity of around 300,000 tons of burnt lime).

Potash and Salt.—In 1980, a persistently high level of demand led to increased potash production. More than 29 million tons of raw ore was produced with a K_2O equivalent of 3.3 million tons; gross weight of product produced was 8.1 million tons and sales (expressed as K_2O) were 2.737 million tons. A substantial decrease in salt production from that of 1979 was probably owing to slack demand because of milder weather.

The FRG's potash output was controlled mainly by two companies. Kali und Salz AG controlled nine mines with approximately 90% of domestic production. Funds earmarked for investment in potash produc-

tion by the company in 1980 were $60 million, and employees numbered about 8,800 persons. Kali Chemie AG controlled one mine with about 10% of domestic production.

Sodium Carbonate.—The FRG sodium carbonate production in 1980 increased to about 1.4 million tons. The largest producer was a subsidiary of the Solvay Group with an operating capacity of about 1.3 million tons per year, including the Deutsche Solvay Werke plant at Rheinberg in the Ruhr, and the Kali Chemie plant in Heilbronn, north of Stuttgart. The second largest producer was the Chemische Fabrik Kalk GmbH, a subsidiary of Kali und Salz, operating a 280,000-ton-per-year plant located at Köln-Kalk.

MINERAL FUELS

In 1980, domestic coal, lignite, natural gas, and crude oil supplied about one-third of the FRG's energy consumption. Imported oil accounted for almost one-half of all primary energy used, amounting to 182 million tons of standard coal equivalent (SCE) or 47.8% of all energy used. Bituminous coal used was 77 million tons of SCE or 19.7%; natural gas used was 64.5 million tons of SCE or 16.5%; lignite was 38.5 million tons of SCE or 9.9%; nuclear energy was 14.0 million tons of SCE or 3.6%; waterpower and imported electricity was 7.5 million tons of SCE or 1.9%; and the remainder including fuelwood was 2.5 million tons of SCE or 0.6%.

Coal, Coke, and Lignite.—In 1980, the FRG's bituminous coal production increased for the second consecutive year, reaching almost 88 million tons; consumption closely equaled production.

Stocks of coal at yearend were about 30 million tons including reserves of coke, consisting of 9 million tons of producers' stocks, 10 million tons of consumers' stocks, and 10 million tons in the national coal reserves. This should be sufficient for supplying the country for about 120 days. At yearend, 186,800 persons were employed by the bituminous coal industry, an increase of 4,500 during 1980. The number of employees underground was 99,800.

The FRG's lignite production in 1980 was slightly under 130 million tons. Lignite briquette production decreased to under 4.5 million tons.

To diversify sources of supply, import restrictions on non-European Community coal were relaxed resulting in an increase of imports. There were also official discussions with Poland and mainland China. Private FRG banks were planning to grant Poland a $600 million loan, one-third of which was to go for developing new Polish coal mines, and this part of the loan was to be repaid by additional coal shipments on the order of 1 million tons per year starting in 1985. In 1979, Poland was the FRG's single largest coal supplier with shipments of about 2.4 million tons of coal and 70,000 tons of coke. In 1979, the FRG imports of U.S. coal increased also, from 585,000 tons (plus 325,000 tons of coke) in 1978 to 1,200,000 tons (plus 330,000 tons of coke).

The FRG coking coal has been subsidized since 1967 to offset the difference between FRG prices and world market prices. This difference, which was Deutsche mark (DM) 7 per ton in 1967, reached about DM55.80 per ton in the fourth quarter of 1979 when the world market price was DM115.20 per ton and the domestic price was DM171 per ton. The Federal Government and the Government of North Rhine Westphalia (NRW), together paid DM45 per ton of the 1979 fourth quarter subsidy, two-thirds by the Federal Government. Coal suppliers and coal users (such as steel mills) contributed DM5.40 per ton each. In the case of coal exports to the Common Market, coal users made no contribution, but the FRG received compensation from a European Economic Council fund. The Government subsidy for 1980 was set at DM53 per ton and for 1981 at DM45 per ton. In 1980, NRW contributions totaled over DM0.5 million.

In 1980, the FRG had 40 coal and 17 lignite mines, 21 coking plants, 5 briquetting plants, and 29 mine-mouth powerplants. The bituminous coal industry was controlled mainly by seven companies: Three in the Ruhr, two in the Aachen area, and one each in the Saarland and Lower Saxony. The largest coal industry group was the Ruhrkohle AG, controlling about three-quarters of the country's bituminous coal output.

In 1980, the FRG's lignite industry was dominated by the Rheinische Braunkohlenwerke AG, which accounted for nearly four-fifth's of the country's output; the remaining production came from two medium-sized and four smaller companies.

Nuclear Power.—Esso AG of Hamburg was planning to invest $100 million to develop a uranium ore mine in the vicinity of Wunsiedel, on the southeast slopes of the Fichtel Mountains, east of Bayreuth. There

were no data on grade of ore or reserves. About 35 people were engaged in exploration work on the site. When commissioned, the mine was to be the first commercial uranium mine in the FRG.

In 1980, the FRG operated 15 commercial nuclear powerplants, belonging mostly to local utilities, with a total nominal capacity of 8,767 megawatts. In 1980, the plants consumed nuclear fuel at the rate of 14 million tons of standard coal equivalent, slightly more than that of 1979. The plants generated 43.7 billion kilowatt-hours, which is 1.4 billion kilowatt-hours more than in 1979. Another 11 nuclear powerplants were under construction, with a total nominal capacity of over 13,000 megawatts. Experiments continued for storing radioactive waste materials at the Asse salt mine south of Hannover. In the meantime, test drilling continued at the Gorleben salt dome in Lower Saxony to prepare a waste storage facility there.

Petroleum and Natural Gas.—In 1980, crude oil and natural gas production decreased slightly to about 4.6 million tons, and 18.7 billion cubic meters, respectively. Crude oil imports decreased significantly to 97.9 million tons, while natural gas imports increased to 47 billion cubic meters. Refinery output also decreased significantly to 98.6 million tons. Crude capacity (throughput) of the FRG's refineries was 150.4 million tons per year. Refining capacity was owned by about 21 companies controlling 39 oil refineries. Five refineries were under construction. The FRG refineries continued to extend their conversion capacities during the year including catalytic crackers, hydrocrackers, and thermal cracking units.

In 1980, the FRG imported more natural gas than any country in the world, amounting to about one-fifth of all world exports. Two-thirds of consumption came from imports, mainly from the Netherlands and Norway. An internationally controversial subject was the FRG's plan to participate in building a natural gas pipeline from the Soviet Union to Europe, which would deliver to the FRG 10 billion cubic meters of natural gas per year or about one-sixth of the country's consumption.

The Mineral Industry of Ghana

By George A. Morgan[1]

In 1980, the mineral industry in Ghana experienced continued stagnation in terms of production of several major commodities. The industry as a whole was adversely affected by many of the problems that affected other sectors in the economy, such as the loss of experienced personnel, insufficient food, and persistent shortages of parts and equipment. A number of commodities, including cacao and diamond, were selling at less than the cost of production. The country also suffered from work stoppages in critical industries. The Government raised the minimum wage by 300%, which affected employees in the more than 100 semiautonomous State bodies, including the State Gold Mining Corp (SGMC). The cost of public sector wages made up 40% of total Government expenditures. A new directive specified the dismissal of public corporation employees who engaged in work stoppages. Thus, striking officers and officials of the Black Star Line, the Government-owned transportation company, were replaced with foreign specialists.

Public corporations were to show a profit prior to consideration of worker requests. Inflation, which had declined from 117% in 1977 to 40% by early 1980, rose to 50.1% by yearend 1980. High expenditures resulted in 83% of the Central Bank's total net assets and 62% of commercial bank assets being borrowed by the Government, leaving little for the private sector. The extreme shortage of foreign exchange, of which one-third was required for the purchase of imported oil, also affected the private sector to the extent that it was functioning at only 25% to 30% of capacity. The Ashanti Goldfields Corp., the country's leading gold producer with about 67% of total output, operated at only two-thirds of capacity during a period of record gold prices. Problems within both the public and private sectors were exacerbated by price controls and a deteriorating transportation system. Price controls had the effect of limiting return to the producers, who subseqently reduced output. Large quantities of imported fertilizer purchased with scarce foreign exchange remained at ports because of the lack of transport. Smuggling of many commodities increased, particularly diamond and gold.[2]

The Government's efforts to alleviate the failing economy were directed at a 2-year period of rehabilitation of basic industries and infrastructure, and by conserving and increasing foreign exchange through the exploitation of local resources. About $900 million in international aid was estimated to be required for the program.[3] The World Bank granted a $33 million loan for overhauling the 1,300-kilometer-long railroad system. The Federal Republic of Germany granted loans totaling $40 million for developing the Volta Lake transportation system. A cooperative agreement was also concluded with Romania for the reopening of old mines and exploration of potential ore bodies.

An Investment Code bill incorporating all existing legislation, including the 1973 Capital Investments Decree and the 1975 Investment Policy Decree, has been proposed.

PRODUCTION AND TRADE

Output of mineral commodities remained relatively unchanged, excluding production of aluminum metal from imported alumina which increased to a record high. Shortages of foreign exchange, spare parts, and equipment continued to stagnate the industry. In the case of diamond and manganese ore, declining ore grade and decreased reserves also were limiting factors in maintaining production capacity. Evaluation of manganese carbonate reserves continued, with the aim of supplanting the country's nearly exhausted manganese oxide reserves.

A proposal was made to expand gold output. Attention was drawn to Ghana's gold industry because of the metal's high price, making it a significant source of foreign exchange revenue.

Oil production was estimated to have expanded in 1980 despite mechanical problems at the Saltpond Oilfield. Although output was insignificant, additional finds will help to offset the large fuel import bill currently being experienced. The major portion of oil imports was from Nigeria.

A trade agreement with Romania provided for the exchange of cacao and timber in return for mining equipment and exploration assistance. The Government began the approval of import licenses on the basis of need, rather than on the basis of available foreign exchange.

Table 1.—Ghana: Production of mineral commodities[1]

Commodity[2] and unit of measure	1976	1977	1978	1979	1980[p]

[e]Estimated. [p]Preliminary. NA Not available.
[1]Table includes data available through Sept. 3, 1981.
[2]In addition to the commodities listed, a variety of crude construction materials (clays, sand and gravel, and stone) is produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

COMMODITY REVIEW

METALS

Aluminum.—A bauxite development company was to be established to exploit deposits in the Kibi area.[4] Nigeria and Ghana held preliminary negotiations regarding a possible joint venture to mine the deposit which had 182 million tons of ore. Inadequately operating rail transport from the country's only operating bauxite mine at Awaso to the Port of Takoradi continued to hinder production. The mine was operating at less than one-half of the 500,000-ton-per-year rated capacity.

The Government was seeking to renegotiate the terms of the contract under which the Volta Aluminum Co. (VALCO) originally was granted electric power for its 198,000-ton-per-year aluminum smelter at Tema. The electricity rates were part of a long-term contract between Kaiser Aluminum & Chemical Corp., which built both the smelter and Volta River hydroelectric plant, and the Ghanaian Government.

Columbite-Tantalite.—Ashanti Goldfields Corp. commenced prospecting for columbite-tantalite mineralization near Winneba. The company had originally spent 3 years prospecting in the area, but suspended its search in 1962.

Gold.—The high price of gold in 1980 resulted in considerable attention being drawn to deficiencies in the gold mining industry of Ghana. The mines of the Government-owned SGMC were unable to maximize revenue from the production and sale of gold. Black-market operations have reportedly increased because of the disarray of the industry. Numerous reasons for the decline in output from a level of about 700,000 troy ounces per year in 1973 to the current level of about 400,000 troy ounces per year were reported by a committee appointed to study the problems of the industry. The committee noted that there had been no new gold mining ventures since 1938, with only four mines currently operational. Exploration, both at existing mines and at new sites, has been inadequate.

The generally negative growth in all economic sectors, coupled with scarcities of essential commodities and equipment, were compounded by the Government's lack of a consistent mineral policy. In the past 5 years, the gold industry has been subject to numerous taxes which undermined profitability. Such taxes included a 6.5% royalty on the gross value of minerals, a mineral duty of 5% to 10%, an import duty of 35%, and a foreign exchange tax of 33% to 75%, as well as other taxes.[5]

Tarkwa Goldfields Ltd., 100% controlled by SGMC, had a design capacity of 740,000 tons per year of ore yielding approximately 170,000 troy ounces of gold. However, actual output in 1980 was only about 250,000 tons yielding 41,000 troy ounces. Ashanti Goldfields Corp., 55% controlled by SGMC and 45% by Lonrho Ltd., was the country's principal producer accounting for 67% of total production in 1980. Output by the company was up 5% or 12,000 troy ounces over that of 1979. The Konongo Mine was forced to shut down because of depletion of minable ore, despite continued Government attempts to forestall closure to avoid exacerbating the unemployment situation.

Reserves of exploitable gold were reported at about 1.3 billion troy ounces. The technical committee, assisted by the United Nations Development Program (UNDP), recommended the rehabilitation and expansion of the existing mines and the establishment of several others. A Gold Promotion Council has been set up by the Government to coordinate Government activities for developing the gold industry. Gold sales made up about 10% of export earnings, and if high gold prices continue, may supplant aluminum as the second highest exchange earner after cacao.

NONMETALS

Diamond.—Despite a slight increase in output of diamond in 1980, prospects appeared poor for continued viability of the industry which accounted for about 4% of world output in 1979. Current deposits, which were declining in grade, were estimated to provide only about 2 more years of productive life. The major portion of output was from Ghana Consolidated Diamonds Ltd. (GCD), which employed about 2,000 people. GCD has suffered a severe loss of experienced managerial personnel, and was also losing trained artisans, mainly to higher paying positions outside the country. In addition, old equipment, lack of spare parts, and high local costs may result in a loss of about $7 million for the year ending June 30, 1981.

GCD was 55% controlled by the Government of Ghana and 45% by Consolidated African Selection Trust Ltd., which manages the company. Actual diamond output was sold through the Diamond Marketing Co., usually at three auctions per year. All output was sold overseas, with 12.5% of exports reserved at the option of mainland China under a bilateral commercial agreement. The value of exports in 1980 was estimated at about $11.8 million. The Diamond Industry Commission was established in March 1980 to conduct hearings both on the industry itself and GCD in particular. GCD was seeking about $40 million to purchase draglines and other equipment to expand its plant at Akwatia.[6] The United Nations continued assistance to diamond

prospecting on the Birim River. The first phase of the program was to be completed in 1982.

Limestone.—Work commenced on a $12.4 million limestone project at Buipe in the northern region. Hydrated lime was to be produced both for local consumption and for export, with full production planned for 1982. Output was to be at the rate of 40,000 tons of lime per year, and 200 Ghanaians were to be employed. The project was a joint venture of Ceramica Cordiere S.A. of Italy, the Bank of Housing and Construction, and the Northern Regional Housing Corp. A $15 million loan was advanced by the Italian Government for machinery and equipment for the undertaking.

MINERAL FUELS

Petroleum.—Output from Ghana's only producing oilfield at Saltpond by Agri-Petco Co. averaged 1,522 barrels per day in 1979 and nearly 1,800 barrels per day in 1980. No gas production was reported.

Phillips Petroleum Co. reported the discovery of oil at Half Hassini. Further drilling was planned to complete an evaluation of the find. The company has invested $60 million thus far in its operations in Ghana and expected to spend another $10 million in its search for oil and gas. Another company was awarded an onshore concession covering 1,220 square miles in the Keta Basin in southeast Ghana.

Limited production from the Saltpond Oilfield had little effect on the country's importation of crude oil. About 35% of Ghana's foreign exchange revenue was spent for imported fuel. Rationing of gasoline was considered the only method available to reduce consumption; by midyear, a 20% decline in demand from the Tema refinery, the country's sole refinery, was reported.

The Mineral Industry of Greece

By Roman V. Sondermayer[1]

Greece continued its efforts to develop the mineral industry during 1980. However, the European economic crisis adversely affected output of minerals for export, and consequently, the results of the industry were mixed. Bauxite and various nonmetals remained the major minerals produced in the country. The share of the industry in the gross national product was around 7%, the same level as in previous years. As in the past, the Government of Greece participated in the activities of the mineral industry; it dominated activities in crude oil, lignite, chromite, asbestos, in exploration for all minerals, and in financing new projects.

The major events in the mineral industry during 1980 were as follows: Expansion of alumina plant at Distomon; development of the ferrochrome industry; development and construction of an asbestos mine and plant near Kozáni; decision to build a lead-zinc smelter; and development of an offshore oilfield near the Island of Thassos.

PRODUCTION

The Greek mineral industry was owned both by the Government and by the private sector. The Government acted through publicly owned corporations, of which the ones of principal interest to the mineral industry were Public Power Corp. (PPC); Hellenic Industrial & Mining Co. (HIMIC); the Public Petroleum Co. (DEP); Project Studies and Mining Development Corp., S.A.; the Institute of Geological and Mining Research (IGME); and, for financing, the Hellenic Industrial Development Bank (ETVA). In the private sector, the major mining companies were the Bodossakis Group (nickel, sulfide ores and concentrates, fertilizers, etc.); the Eliopoulou-Kyriacopoulou Group (bauxite, perlite, expanded perlite, bentonite, barite, and kaolin); the Scalistiri Group (magnesite, refractories bauxite, and chromite); Aluminium de Grece S.A. (aluminum); Grecian Magnesite (magnesite); Mykobar S.A. (barite, bentonite); and four companies that shared Greece's cement output, Heracles (known also as General), Titan, Chalkis, and Halyps.

COMMODITY REVIEW

METALS

Aluminum.—No major developments were made public in the bauxite producing sector of the mineral industry of Greece. Bauxites Parnasse Mining Co. S.A. remained the leading producer and, during the year, continued to expand its underground mines in the Parnassos-Ghion area. The second largest bauxite producer was Eleusis Bauxite Mines, Mining-Industrial & Shipping Inc., which operated mines near Eleusis, Lamia Itea, and Kymi.

Aluminium de Grece S.A. (AG) started preparing for expansion of its alumina plant at Distomon, Boeotia, from an annual capacity of 500,000 to an annual capacity of 600,000 tons. However, some difficulties created by high prices that the Government of Greece intended to charge for additional power delivered to Distomon were not resolved at the yearend. Attempts of Greek authorities to find a partner for another alumina plant in Greece were not successful during 1980. After a visit by a Greek Government delegation to Moscow, the Greek and Soviet negotiators reached agreement on another feasibility study for the new alumina plant.

Chromite.—Hellenic Ferro-Alloy S.A., a subsidiary of HIMIC, continued with preparations for construction of a 30,000-ton-per-year ferrochrome plant. During 1980, plant equipment was ordered and some preliminary construction work started on the plant site near Volos. The principal contractor for plant know-how was Outokumpu Oy of Finland. While the ferrochrome project was underway, HIMIC was preparing feasibility studies for development of stainless steel producing facilities that will use ferrochrome produced at Volos.

The ore base for plant operations was chromite deposits on Vourinos Mountain, near Kozáni. Hellenic Ferro-Alloys S.A. owned about 80% of the concession area. The major producer of chromite in the area was the Xeralivado Mine, located 1,000 meters above sea level southwest of the town of Kozáni. Mining was underground, using sublevel caving and shrinkage stoping in areas where the ore is subvertical, and room and pillar in near vertical lenses. During 1980, development of the deeper section of the mine continued. A new adit was being driven on the 700-meter level to enable construction of shafts for haulage, ventilation, and dewatering. In the central section of the mine, plans called for construction of a spiral ramp to link levels at 868 meters and 850 meters.

The nearby mill processed about 180 to 200 tons of ore per day with an average of 16% Cr_2O_3. Output of the mill was 45 tons of concentrates containing about 52% Cr_2O_3. The recent introduction of heavy media separation has improved the performance of the concentrator. Expansion of the plant was planned during 1980 to a capacity of 600 tons of ore per day.

Gold.—After 5 years of exploration by the geologists of IGME in northern Greece, an alluvial gold deposit discovered in the area apparently warranted construction of a pilot plant near Nigrita, Serrai. Reserves of the area were reported to be about 12 tons of gold. Mining for gold in Greece has a long history. Archaeological works have identified about 21 old gold mining sites in Greece, mostly in areas of Mount Panagion, the Krousia Range, the Gallikos River, Anagista, the Vermion and Pieria Mountains, and on the Island of Thassos.

Iron and Steel.—Halyvourgiki S.A., the only integrated steel producer in the country, placed an order with Danieli for a new bar-and-rod mill for its plant at Eleusis. The capacity of the mill was reported at 230,000 tons per year of 120-square-millimeter continuously cast billets, 8- to 26-millimeter-diameter round bars, and 5.5- to 12-millimeter-diameter wire rods.

Lead and Zinc.—Greece decided to implement its plan to build a lead-zinc smelter located in northern Greece. A feasibility study was prepared by Stolberg Zinc Co. of the Federal Republic of Germany and Imperial Smelting Processes Ltd. of the United Kingdom. The project calls for an Imperial smelter with an annual capacity of 60,000 tons of zinc, 30,000 tons of lead, plus by-product silver and gold. A 600,000-ton-per-year sulfuric acid plant was included in the project. Total investments were reported at US$300 million. ETVA's subsidiary, Hellenic Metals S.A., organized in the spring of 1980, should carry out construction and should operate the facility after completion.

During 1980, the largest producers of lead and zinc concentrates remained the Kassandra lead and zinc mines on the Chalkidiki Peninsula, operated by Hellenic Chemical Products and Fertilizers. The mines were located near the coast on the Gulf of Ierissos. The main concentrator and the ship-loading facilities were located at Stratonion. One of Kassandra's mines, Olimpia, was

being modernized, and it is expected that the modernization, when completed in 1983, will increase mine capacity to 800,000 tons per year.

Nickel.—The world economic conditions affected Larco S.A.'s nickel operations during 1980. Production of ore was down and exports were lower than in recent years.

NONMETALS

Asbestos.—Development of an asbestos mine and construction of a 100,000-ton-per-year asbestos processing plant continued at Zidani, south of Kozáni, a town in north-central Greece. The property was discovered in 1936 and after being owned by the Kennecott Copper Corp. and Cerro Corp., both of the United States, was taken over by the Greek Government through its company, Asbestos Mines of Northern Greece, Mining S.A. (MABE). Reportedly production should start early in 1981.

The asbestos deposit on which the operation of the mine and the plant is based is large by European standards. Proven reserves were reported at 90 million tons with an average fiber content of 2.63%; about 40 million tons of ores with an average content of fiber of 3% were known to exist below level 500. Some cores from exploratory holes drilled below level 450 indicated the existence of zones of mineralization with higher content of fiber than in more shallow zones.

The mine will be open cast, with vertical benches 10 meters high. Blasting is necessary and 7-inch holes will be drilled on a 10-meter by 10-meter grid. Ammonium nitrate and fuel oil was planned as the blasting agent. For drilling blasting holes Schram C-64-C drills were purchased; two Caterpillar wheel loaders 992 C with 10-cubic-meter buckets and two hydraulic O and K power shovels RH 75 equipped with 7.6-cubic-meter shovels will be used for loading, and five 80-metric-ton Caterpillar 777 trucks will be used for moving ore and overburden.

Magnesite.—During 1980, Greece remained a net exporter of magnesite and magnesite refractories, but activities of the sector were adversely affected by the slump in economic activities in general, and in particular by difficulties faced by steel producers in Europe.

Grecian Magnesite Ltd. S.A. and Ore Sorters of Canada, a subsidiary of the Rio Tinto Ore Sorters Group, signed a contract for the supply of three Model 16/80 photometric sorters. The new machines will be used in the existing sorter installations at Gerakini Mines in northern Greece.

Perlite.—Based on a possibility of expanded exports to the Middle East, Silver and Barites Ores Mining Co. decided to expand its perlite mining capacities, on the islands of Milos and Kos, from 125,000 tons per year to 180,000 tons per year at a cost of US$2.5 million.

MINERAL FUELS

Lignite.—The only fuel produced in Greece remained lignite. Most of the lignite was mined at Aliveri (Euboea), Ptolemais (near Kozáni), and Megalopolis (central Peleponnesus), and used by the PPC to fuel nearby power stations.

In 1980 PPC continued work on opening the Ptolemais south field. Plans called for the field to produce sufficient lignite to supply seven 300-megawatt power units in the area. In addition, work was underway to construct a pilot plant to test making cement with the lignite ash.

During 1980, no major discoveries were made public in the joint exploration for lignite conducted by PPC and IGME.

Petroleum and Natural Gas.—Greece was not a producer of natural gas and crude oil. However, development of the offshore oil and gas fields of Prinos and Kavalla near the Island of Thassos in the north Aegean Sea were close to completion, and consequently Greece should become a producer of crude petroleum and natural gas during 1981.

During 1980, development of the Prinos offshore oilfield continued. Two of the three planned shore production platforms were in place. The net pay totaled 500 feet (about 150 meters) and expected production was estimated to be between 20,000 and 25,000 barrels per day of 28° API oil. The undersea pipeline from the Prinos Field to Kavalla on the mainland was also completed, and construction started on a crude oil storage facility with a capacity of 250,000 barrels (about 40,000 cubic meters). Reserves in the Prinos Field were estimated to be between 70 million barrels and 140 million barrels and the life of the field was set between 10 and 15 years. Development costs were reported at US$500 million with unit costs amounting to almost double that of the North Sea.

The Kavalla South Gasfield was expected to produce about 18 million cubic feet per day and 1,000 barrels of condensate per day.

The fields were operated by North Ae-

gean Petroleum, acting for a consortium of the following companies: Denison Mines, 68.8%; Hellenic Oil, a subsidiary of Fluor, 14%; Wintershall, 12.5%; and White Shields, 4.7%. The concession was renegotiated, and the new agreement gives the state an enhanced 65% share of net profits from production after recovery of development costs.

While the private consortium was preparing for production, the state-owned petroleum company, DEP, continued exploration for oil and gas on its own account, mostly by using contractors. In addition, DEP was planning future exploration, chiefly in areas away from the disputed central and eastern Aegean Sea, reported to be as follows: (1) Northwestern Peloponnese (onshore) and Gulf of Patras (offshore). (2) Plain of Thessaloniki-Katerini (Macedonia). (3) Strimon River Valley (Macedonia). (4) Gulf of Kyparissia (onshore and offshore), western Peloponnese. (5) Offshore of the islands of Zakinthos and Keffalinia, Ionian Sea. (6) Offshore western Epirus, Ionian Sea. (7) Offshore to the northwest of the Island of Corfu, Ionian Sea. (8) From Grevena to Meteora, in the interior of north-central Greece. (9) River Evros estuary (Thrace), close to the border with Turkey.

Uranium.—During 1980, geologists and geophysicists from the Democritus Research Center continued to explore for uranium in Macedonia and Thrace. In addition, IGME continued uranium exploration in Epirus with cooperation from scientists at Democritus. Apparently no major uranium discoveries were made during the year.

COMMODITY REVIEW

METALS

Hungary has limited economic reserves of ore for a number of metals. These include aluminum, copper, gallium, iron, lead, manganese, molybdenum, vanadium, and a few other rare metals. Production of many metals is not sufficient for domestic needs, and Hungary must rely on imports. Although prospecting for nonferrous metals was conducted in 1980, no significant finds were reported.[7]

Despite increased efforts to economize on the use of raw materials, the metallurgical industry is not endowed technologically for maximum processing of scrap, and therefore Hungary exports large amounts of high-quality aluminum, copper, steel, and other metallic scrap.

Aluminum.—Hungarian bauxite production ranks third in Europe and eighth in the world. Bauxite reserves are reportedly estimated at 200 million tons of 52% Al_2O_3, and are located in five regions at a depth of 100 to 300 meters. Of bauxite production, 80% is processed domestically, and 20% is exported.

Hungary occupies the 6th place in Europe and the 12th in the world in alumina production. However, in aluminum output Hungary is neither a European nor a world leader because metal producing electrolysis capacity is low and the pots are obsolete. Aluminum production methods are not efficient and have been termed environmentally objectionable. Also, metal refining technology is not advanced, and semimanufactures rank near the bottom of world market specifications.[8]

Regarding new development, construction was completed of the Ajka alumina plant and the Deaki Mine. The Ajka plant was the aluminum industry's biggest investment project and is to increase the production of alumina by 80,000 tons annually. This goal is being gradually achieved. The Deaki Mine has an annual capacity of approximately 600,000 tons of bauxite.

It was announced that the development of a new bauxite mine at Fenyofo is underway. The mine is to produce 1 million tons per year, and development time is expected to be 5 years. The mine is projected to reach its design capacity by 1988. In 1980, it was reported that Hungary purchased a fully automatic computer-controlled rolling mill installation from Japan's Nissho-Iwai Co. Ltd. for the Szekesfehervar light metal works. The contract was valued at $11 million, and the installation is scheduled to go into operation in 1981. Payment is to be made in part by delivery of 40,000 tons of aluminum products. Japanese engineers are to supervise the erection and test runs.

As part of an administrative reorganization, three enterprises (Hodmezovasarhely, Balassagyarmat, and Zalaegerszeg), formerly under local control, were put under the administration of the Hungarian Aluminium Corp., Magyar Aluminiumipari Troszt (MAT).

Hungary has only one secondary aluminum smelter, the Qualital smelter, that produces approximately 20,000 tons of secondary aluminum. Current scrap collection brings in approximately 25,000 tons per year, much of which is exported. A new shredder is to be installed at the Qualital smelter to improve performance. Exports of scrap are to be replaced by exports of alloy and foundry ingots. The sixth 5-year plan envisages a rise in the amount of aluminum scrap processed to 27,500 tons per year by 1985.

Future plans also call for a 40% to 50% increase in bauxite exploration drilling. New bauxite mines are to be opened to meet production targets. The newly explored deposits at Nagyegyhaza, Bakonyoszlop, Iharkut, and Nyirad, containing high-grade bauxite, have substantial potential reserves.

Casting capacity is to be increased by 3,000 tons per year upon the 1982 scheduled completion of the foundry at the Ajka plant. Construction is planned for a new aluminum smelter with a capacity of 100,000 tons per year. Discussions are being conducted with U.S., Japanese, and French firms concerning the construction of the new smelter.

Copper.—The Hungarian copper industry uses primarily imported raw materials. However, it is claimed that the Recsk copper deposit discovered in 1972 is one of the world's largest. In 1980, prospecting at the Recsk deposit was declared almost complete. The ore body is more than 3,000 feet below the surface, and the copper content is about 1%. Plans are to develop mining, concentrating, and smelting facilities, and negotiations are being conducted with foreign firms to establish cooperative ventures for this development. Initial processing capacity is planned to be approximately 2.5 million tons of ore annually with eventual capacity to reach 5 million tons.

Copper content of collected copper and copper alloy scrap amounts to approximate-

ly 15,000 tons per year. Processed scrap that is not exported is used by the Csepel metallurgical works except for about 1,000 tons that goes to a foundry at Mosonmagyarovar. There has been an increase in foreign trade activity to provide for domestic copper requirements because of the closing in 1978, for stated environmental reasons, of a shaft furnace treating copper scrap at the Metallochemia plant, a part of the Csepel works.

Gallium.—In 1980, gallium output was to increase at the newly reconstructed Ajka alumina plant. Exports were predicted to be 1.5 tons.

Gold.—Hungary's only gold mine at Recsk is being depleted. Plans are to increase production of metal from scrap. It was announced that a process has been patented in Hungary for obtaining gold from scrap. Using this process, it is said to be possible to recover 6 grams of gold from 1 kilogram of scrap, and to recover gold of 95% purity from complex alloys. Also, the Rubbish Collection Trust announced that one of its enterprises is to begin production of gold bars.

Iron and Steel.—In 1980, production of iron ore, total pig iron, crude steel, and steel semimanufactures declined compared with the 1979 level. In 1980, labor productivity in the steel industry was quite low, being one-seventh of that in Japan.[9]

In 1980, foreign trade turnover in steel declined by 17.5% with exports falling 17% and imports by 18.1%. The domestic price of iron and steel products rose by 28% to 29% for the year. The number of workers in the steel industry declined to 76,351. The Csepel metallurgical works reported a serious labor shortage with an 18% vacancy rate that jeopardized production.[10]

Domestic raw materials supply only a fraction of ferrous metallurgy requirements. Imports provide all of the ferromanganese, almost all of the iron ore, and the majority of the coke. In 1980, the Martin process accounted for over 90% of steel production, and electric, the bulk of the remainder. Owing to insufficient production of high-quality steel, the machine building industry is forced to use imported steel even though the ferrous metallurgy industry exports 30% of its products. Despite its need for advanced technology and equipment to upgrade the ferrous industry, Hungary is limited in what it can afford and must be highly selective in its development policy.[11]

The Rudabanya Mine supplies all of Hungary's iron ore in the form of limonite and siderite. Ore is treated near the mine using magnetic separation and sintering. In an effort to boost iron ore production, techniques are being examined to recover the iron from bauxite. Consideration is also being given to other domestic iron ores neglected in the past because of their low iron content.

During 1980, construction of the oxygen converter shops continued at the Lenin metallurgical works in Diosgyor and at the Danube ironworks in Dunaujvaros. The first converter at the Lenin works was commissioned in 1980. It is an 80-ton converter and has a rated annual capacity of 700,000 tons. The converter at the Danube works is scheduled for commissioning in the second half of 1981. Also, finishing facilities are to be installed at the Lenin and Danube works. Two Japanese firms, Kobe Steel Ltd. and Nippon Kokan, K.K., have contracted to supply the Lenin works with an electric arc furnace with a rated output of 220,000 tons per year, and with a continuous casting machine with a 350,000-ton-per-year capacity.

The present blast furnaces and steelmaking facilities at the Lenin works are not considered modern. The blast furnaces are small and obsolete and the open-hearth plant has been termed "uneconomical, obsolete, and hazardous." As part of a renovation program, blast furnace No. 2 was rebuilt in 1980. Renovation of blast furnace No. 3, supplying approximately 55% of total output, was scheduled to begin in July 1980. Blast furnace No. 3 is to be expanded to provide 70% to 75% of plant output, and is to supply predominantly the new oxygen converter plant.[12]

At the Danube works a third continuous casting unit is to be built, and plans are to modernize the existing casting plant. A coking facility at the Danube works is scheduled for completion by 1985.

Other development plans for the sixth 5-year plan call for the modernization of two blast furnaces at the Ozd metallurgical works and the construction of a new pipe mill at the Csepel metallurgical works.

By 1985, crude steel production is projected to reach 4.3 to 4.5 million tons per year, and rolled steel, 3.4 to 3.6 million tons per year. Investment in ferrous metallurgy is to be greater than during the fifth 5-year plan. Problems procuring coke and alloying materials are expected to persist into the sixth 5-year plan.

Lead and Zinc.—The mine output of lead and zinc rose slightly in 1980 as did concentrate production. Production of lead concentrate equaled 2,081 tons, and zinc concentrate, 5,443 tons.

In 1980, Hungary's only major lead-zinc mine at Gyongyosoroszi in the Matra Mountains supplied 145,000 tons of lead and zinc ore. Lead and zinc production can increase because the copper deposits under development at Recsk contain economically recoverable quantities of lead and zinc.

At present, large metal imports are required to meet lead and zinc consumption needs. Annual lead consumption is approximately 20,000 tons. The battery industry consumes about 60% of the lead supply and is also the major supplier of secondary lead. In conjunction with the campaign to increase secondary recovery, complaints were raised that automobile owners are still discarding their old batteries, and a trade-in system is to be established. Under optimum conditions it is estimated that 13,000 tons of lead in battery scrap could be collected annually.

The major problem in scrap processing is the lack of a smelting facility. When the shaft furnace at the Metallochemia plant of the Csepel works was closed in 1978 for claimed environmental reasons, production of lead from battery scrap virtually ceased. The lead scrap is now exported. In 1980, approximately 10,000 tons of lead scrap was exported, 40% of which Hungary exported to the German Democratic Republic under an arrangement to have it smelted there. Besides the German Democratic Republic, Italy is a major European importer of Hungarian lead scrap. The problem of processing battery scrap in the future is to be solved by either setting up a new smelting facility or by making further arrangements for processing abroad.

Also, owing to low production and a subsequent lack of processing facilities, Hungary exports zinc concentrates and zinc scrap and meets consumption needs with imported metal.

Manganese.—Hungary has substantial reserves of manganese ore, the majority of which is carbonated and a smaller percentage oxidized. Carbonated manganese ore reserves are estimated at 100 million tons, but owing to a lack of processing capacity it can be extracted only in small quantities. Reserves of oxidized manganese ore are estimated at 25 to 30 million tons. This amount is deemed sufficient beyond the year 2000. Despite production of oxidized manganese ore, Hungary, at present, produces no ferromanganese. Annual consumption of ferromanganese is approximately 50,000 tons, which is imported from both the non-market-economy countries and the market-economy countries.

NONMETALS

The demand for a number of nonmetallic minerals is satisfied by domestic production, and several of these minerals are exported. Industrially important deposits of nonmetallic minerals (bentonite, diatomite, illite, kaolin, perlite, zeolite, etc.), are concentrated in the Tokaji Mountain area where 12 mines supply 13 types of minerals. In 1980, there were recorded production increases for bentonite and perlite and decreases for cement, kaolin, and lime.

Cement.—Cement production declined in 1980 after years of steadily increasing production. It was reported that the Labatlan reinforced concrete works was enlarged, and production is expected to greatly increase.

In conjunction with the policy of energy conservation, the cement plant under construction in Belapatfalva is to use the dry processing method.

Diatomite.—The new diatomaceous earth calcination plant that was put into operation in mid-1979 at Erdobenye in the Tokaji Mountain region is reported producing 20,000 tons per year.

Fertilizer Materials.—Less fertilizer was consumed in 1980 than in 1979, and there was not always the desired selection. Demand for granular rather than powder form potassic and phosphatic fertilizers exceeded supply. It was stated that during the sixth 5-year plan there is no need for additional production capacities for nitrogenous fertilizers because demand for additional fertilizer is to be provided by imports from the Soviet Union through the framework of a broadened agrochemical agreement.[13] However, it has been deemed advisable to modernize outdated superphosphate plants and to increase the selection of specialized fertilizers. Demand is emerging for liquid chemical fertilizers, but conversion to liquid fertilizers has to be gradual because neither industry nor agriculture possesses the necessary equipment for production or application.

The Pet nitrogen works is currently producing over half of Hungary's fertilizer production, including almost three-fourths

of the country's nitrogen fertilizer production. Approximately 4,500 persons are employed at the Pet works. During the sixth 5-year plan, it is planned to construct an argon plant at the Pet nitrogen works that will make use of waste gases from the Pet works. By improving efficiency at the Pet works, urea production is expected to double, and there is to be a significant increase in fertilizer production.

Limestone.—Limestone is one of the nonmetallic minerals that Hungary is able to produce in quantities sufficient for domestic consumption and for export. Limestone quarrying has been conducted in the Transdanubian Uplands, and the Mecsek, Cserhat, and Bukk Mountain regions since ancient times. The "red marble" limestone of the Gerecse Mountain region is a popular decorative building material. Freshwater limestone is quarried around Budapest as well as in the Gerecse Mountain region.

Sand.—Almost all sand for Hungarian glassworks comes from the Fehervarcsurgo operation in the Transdanubian Uplands, and in 1980, there was a reported increase in glass sand production. Sand suitable for foundry use is in deposits in the Pannonian Basin. Sand and gravel for the construction industry is obtained from alluvial fans, river sediment, flood plains, and terraces. A significant amount is obtained from dredging existing river channels.

Zeolite.—Total zeolite resources are estimated at 100 million tons. A new zeolite plant with a production capacity of 10,000 to 15,000 tons per year was recently built as part of the Mad enterprise.

MINERAL FUELS

Hungary's short supply of energy and the continuous rise in energy prices are considered permanent facts. The country depends on imports of oil, natural gas, and electric power for over half of its energy needs. Coal is the only energy resource available in large quantities, and it is composed mainly of brown coal of low calorific value. Owing to the lowland nature of the country and the absence of fast rivers, possibilities for utilizing hydroelectric power are limited. During the 1980's, increasing electric energy requirements are to be met in part by the new nuclear powerplant at Paks, by electric energy imports, and by expansion of brown coal output.

The expansion of brown coal output is planned to meet the fuel requirements of thermal powerplants. However, the putting into operation of the Bicske thermal powerplant that is to be supplied by the new mining operation at Many is to be delayed until the end of the 1980's. This delay is attributed to the reduced growth in energy needs because of the slowing down of economic growth.

During the fifth 5-year plan, 32% of industrial investment was for projects in the energy sector (production of coal, hydrocarbons, and electric energy, processing of oil and gas, development of the distribution network, etc.). During the sixth 5-year plan, there is to be continued heavy investment to exploit the extensive, but generally low-quality coal deposits, to complete the nuclear power program, and to acquire technology and equipment for deep drilling and secondary recovery techniques for the limited oil and natural gas deposits.

During the sixth 5-year plan, total energy use is to increase by 2% annually in comparison with the 3.3% rate of the last plan period, and electric energy consumption is to increase by 3.5% annually instead of the previous 4.9%. The projected growth in energy consumption is to be 0.6% to 0.7% for each 1% growth in the gross national product. The energy savings program for the sixth 5-year plan calls for substituting imported crude oil and petroleum products with domestic coal and natural gas. Owing to its participation in the construction of the Khmelnitskiy nuclear powerplant in the Soviet Union, Hungary is to begin receiving imports of electricity from this cooperative venture.

Along with imports and fuel substitution, the energy savings program is to include modernizing technological processess in metallurgy to save coke, increasing motor vehicle inspections, individually metering dwelling units, improving building insulation, making more energy efficient appliances, etc. In addition, ways are being sought to make greater use of nonconventional energy sources such as solar, geothermal waters, waste heat, and forest deadfall.

The total energy balance for 1979 and 1980 is shown in table 4.

Table 4.—Hungary: Primary energy balance for 1979 and 1980

(Million tons of standard coal equivalent[1])

Year	Total primary energy	Coal (lignite, anthracite, bituminous), coke, and briquets	Crude oil and petroleum products	Natural and associated gas	Fuelwood	Hydroelectric and other power
1980:						
Production	26.4	14.5	3.0	8.2	0.7	--
Exports	3.1	.05	3.0	.01	--	--
Imports	23.8	2.9	14.5	5.4	--	1.0
Apparent consumption	47.1	17.3	14.5	13.6	.7	1.0
1979:						
Production	26.8	14.4	3.0	8.7	.7	--
Exports	2.6	.05	2.5	.01	--	--
Imports	24.6	2.8	17.5	3.6	--	.7
Apparent consumption	48.8	17.1	18.0	12.3	.7	.7

[1]One ton of standard coal equivalent (SCE)=7,000,000 kilocalories. Conversion factors used are hard coal, 1.0; lignite and brown coal, 0.5; briquets 0.67; coke, 0.9; crude oil, 1.47; refinery products, 1.53; natural gas, 1.33 (per thousand cubic meters); manufactured gas, 0.6; and hydroelectric power, 0.125 (per thousand kilowatt-hours).

Coal.—The coal mining industry reported overfulfillment of its targets for the 1976-1980 planning period. In the area of geological exploration, there were reported significant discoveries of bituminous and brown coal.

Four new mines are to be developed under the Eocene program; Hungary's large-scale program to reduce foreign energy dependency by developing domestic brown coal reserves. Two mines are to be opened in 1981, 1 year ahead of schedule. These are the Nagyegyhaza Mine, an estimated 55-million-ton brown coal field scheduled to produce approximately 1.7 million tons of coal per year by 1985, and the Markus-Hegy Mine, proclaimed as Hungary's most modern coal mine with an eventual capacity of 8,000 tons per day. The Markus-Hegy Mine, the first to begin production, is expected to produce 300,000 tons of brown coal in 1981 and 800,000 tons in 1982. At the largest new mining site at Many, with an approximate 100-million-ton deposit, the scheduled start of production has been delayed an additional year. Production at Many from the seams closest to the surface is to begin in 1983. At the fourth new mine, the Lencse-Hegy II Mine, a revised plan has been enacted to begin production in 1982 instead of 1985. The Eocene program also calls for the renovation of the Balinka and Dudar Mines.

In addition to development and renovation, attention is being given to the expansion of existing mines. For example, new benches are being brought into production at the Thorez surface mine, Hungary's largest coal mine. It is also planned to establish brown-coal-based coke and briquet manufacturing.

The increasing cost of imported coking coal is said to impose an unbearable burden on domestic metallurgy, which relies on imports for a large percentage of its needs. The Lias program calls for the exploration of new liassic bituminous coal deposits. It is designed to increase domestic coking coal production in the Mecsek area, containing Hungary's only bituminous coal reserves. Coking coal production is planned to increase to 670,000 tons per year by 1986 and to 900,000 tons per year by 1990. The Lias program is closely connected to supplying coking coal for the planned expansion of the Danube metallurgical works. Even with increased deliveries from the Lias program, the Danube works will require large amounts of imported coking coal.

In 1980, personnel in coal mining decreased to 78,000 workers. A labor problem exists because it is difficult to attract young people to this profession, and there is a high rate of attrition for workers. Absenteeism is also a problem at mines. This has forced coal miners to put in extra days to achieve targeted production.[14]

In 1981, the Coal Mining Trust is to be abolished and the enterprises are to be declared independent. The Trust's functions are to be assumed by the Coal Mining Coordination Center and the Coal Mining Management Council. The Coordination Center, among its other duties, is to assist in technical development and standardization. Enterprises operating under the Coordination Center include the Dorog, Mecsek, Borsod, Matraalja, Veszprem, Oroszlany, Tatabanya, and Nograd coal mining enterprises, and the Mining Supply enterprise.

The other new organization, the Management Council, is to assume some of the

managerial responsibilities of the Trust. The Management Council, which is to be headed by a chairman, is to contain the directors of the coal mining enterprises and is to include the chairman of the Coordination Center, who is to have advisory rights. The Management Council is to be given the responsibility for coordinating at the sector level all long-term, medium-term, and annual plans for the coal mining industry.

Natural Gas.—Efforts are to be made during the sixth 5-year plan to maintain natural gas production at the 1980 level. As of January 1, 1980, natural gas reserves were estimated at 115 billion cubic meters. Although Hungary's position regarding natural gas production is more favorable than it is for crude oil, the country is still dependent on imports. The Soviet Union is the major supplier with deliveries in 1980 of approximately 3.8 billion cubic meters. Hungary also receives 200 million cubic meters of natural gas annually from Romania under the provisions of a long-term contract that expires in 1983.

Maintaining current production levels will become more difficult as present reserves become depleted. In 1981, production of natural gas is projected to decline at Hungary's largest producing Algyo Field. Increased efforts are being made to use natural gas reserves rich in inert gas of which there is a substantial volume. Starting in 1983, production is to begin of an additional 500 million cubic meters of natural gas with high inert gas content for use in the Tisza thermal powerplant.

In order to accommodate imports and to avert shortages during peak usage periods, more storage capacity must be made available. Underground gas storage facilities at Hajduszoboszlo and Kardoskut were scheduled to begin operation by 1980. There is also a need for increased domestic gas transport capacity.

Regarding international gas transport, plans are to increase the capacity of the Brotherhood pipeline to enable the U.S.S.R. to ship gas directly to Yugoslavia. At present, Hungary delivers gas from its own fields to Yugoslavia and is then compensated for these deliveries by the U.S.S.R.

Nonconventional Energy.—Nonconventional energy production is being introduced. Hungary has abundant geothermal waters that are considered an energy source for auxiliary usages. In 1979, nonelectric uses for geothermal waters were estimated at 300 thermal megawatts for space heating and 370 thermal megawatts in agriculture. In Szeged, 10,000 apartments are heated by thermal water that is then pumped back into the wells to prevent exhaustion of the deposits.

Wind power is also being used. Hungary's largest wind-powered well was put into operation at the Mezofalva agricultural complex. It yields 40 liters of water per minute and has a reserve to hold water for 4 to 5 windless days. The Mezofalva complex has set up a plant to manufacture this wind-powered equipment. Solar power is not planned to play a significant role until better technical and economic solutions are developed.

Nuclear Power.—Nuclear power is stated to be a necessity owing to a lack of other alternatives. Also, domestic uranium ore deposits present favorable conditions for nuclear energy development. The first nuclear powerplant at Paks is to be equipped with four 440-megawatt reactors. The first 440-megawatt reactor is scheduled to go into operation in 1981, and the three others are to be installed by the mid-1980's. Equipment for the Paks nuclear powerplant is being supplied primarily by the Soviet Union along with other CMEA countries. Following the installation of the four 440-megawatt reactors, plans are to install several 1,000-megawatt reactors.

Claims are being made that the safety measures included in the design of the Paks nuclear powerplant will preclude any accidents. Also, Hungary has developed a process for waste disposal that it states can greatly reduce transport and storage costs.

In addition to developing domestic nuclear power, Hungary is participating in the construction of the Khmelnitskiy nuclear powerplant in the Soviet Union. The Khmelnitskiy powerplant is to begin supplying Hungary with electricity by the mid-1980's.

Reportedly, Hungary mines uranium in quantities large enough to serve industrial purposes. Uranium ore mined in the Mecsek region is described as primarily pitchblende and uranite with other secondary uranium ores. Regarding future production, in an article published in Hungary's national daily newspaper "Nepszabadsag," on January 18, 1981, the State Secretary for the Ministry of Industry, Laszlo Kapolyi, stated that uranium ore production cannot

be increased.[15]

Petroleum.—During 1980, crude oil production increased slightly, and efforts are to be made during the sixth 5-year plan to maintain crude oil production at its 1980 level. Intensive exploration is needed to accomplish this as current reserves are becoming depleted. In 1981, there is to be an expected decrease in crude oil output at the Algyo Fields of approximately 64,000 tons.[16] Pressure in the wells is dropping, and there is an increasing amount of water. The Algyo Fields currently account for approximately 75% of domestic crude oil production and in 1985 are to still account for 65%. At present, 1,600 persons are employed in the Algyo Fields in the production of oil and natural gas. In an effort to utilize all hydrocarbon resources, in 1980 detailed exploration was conducted to determine future use of oil shale deposits discovered in Transdanubia in 1972.

In 1980, construction was completed of the first phase of the Tisza oil refinery with a capacity of three million tons per year. During the sixth 5-year plan, construction is planned of a 1-million-ton-per-year catalytic cracking plant at the Szazhalombatta refinery. Production is scheduled to begin in 1984. A $50 million contract for this project has been awarded to France's Procofrance S.A. Construction of this plant is part of a strategy to replace fuel oil with coal and to instead produce the lighter petroleum products.

In 1980, a 40.4-mile long, 6-inch diameter crude line from Kiskunhalas to Baja was scheduled for completion. Oil transport and storage capacity are considered sufficient, and during the sixth 5-year plan, no additional oil pipeline construction is envisaged. Oil storage capacity, which increased from a 25-day supply in 1975 to a 28-day supply in 1980, is now considered adequate to satisfy seasonal demand.

Approximately 20% of Hungary's crude oil requirements are met by domestic production. The Soviet Union is Hungary's chief oil supplier and in 1980 was scheduled to deliver 7.5 million tons of crude oil. In negotiations with the Soviet Union, Hungary's aim is to maintain and, if possible, to expand imports. Imports of oil from the market-economy countries are to be held to the necessary minimum.

---

[2]The commercial and noncommercial rates of exchange for the Hungarian forint (Ft) have been undergoing periodic reevaluations. These rates have been adjusted monthly although more frequent changes are envisaged. Hungary states its future goal is to have a unified exchange rate. The exchange rate for the forint as of Aug. 28, 1981, quoted by the National Bank of Hungary was, noncommercial—Ft32.63=US$1 (buying), Ft32.70=US$1 (selling);. commercial—Ft35.57=US$1 (buying) Ft35.64=US$1 (selling).

The Mineral Industry of Iceland

By Joseph B. Huvos[1]

Although Iceland has no significant mineral resources, there is an abundance of hydroelectric and geothermal power that supports energy-intensive industries for the processing of imported raw materials. The mineral and mineral-related industries' chief contributions to the national economy continued to be inexpensive hydroelectric power, geothermal energy, aluminum, ferroalloys, and some nonmetallic minerals.

In 1980, the Icelandic economy had both a low rate of growth (1%) and a high rate of inflation (48%); consequently, on January 1, 1981, a new krona, the unit of currency, was introduced, its value being equal to 100 old kronas. The gross national product was $2.7 billion.[2] Average unemployment for the year was only 0.4%.

Noteworthy events included the commissioning of Icelandic Alloys Ltd.'s second ferrosilicon furnace; a shortage of electric power due to a lack of rain and snow; an eruption of a volcano, causing disruption in diatomite production; and completion of feasibility studies for a third ferroalloy furnace, a magnesium plant, and an oil refinery.

PRODUCTION

Production of mineral commodities for the years 1976-80 is shown in table 1.

Table 1.—Iceland: Production of mineral commodities[1]

Commodity and unit of measure	1976	1977	1978	1979	1980[p]
Aluminum metal, primary metric tons	65,300	74,245	73,800	72,145	73,111

TRADE

In 1978 and 1979 there was no significant change in Iceland's modest foreign mineral trade. Iceland's mineral trade in 1978 and 1979 is shown in tables 2 and 3.

COMMODITY REVIEW

METALS

Aluminum.—According to an allegation by the Icelandic Government, Swiss Aluminium Ltd. (Alusuisse) has over a period of 7 years withheld profits amounting to $60 million from its subsidiary, Icelandic Aluminum Co. Ltd. (ISAL), which would otherwise have been subject to a tax by the Icelandic authorities. This was done, the statement alleged, by Alusuisse's selling alumina to the ISAL smelter from the Gove deposit in Australia (which is owned by Alusuisse) at excessive prices. Alusuisse claimed the allegations were the result of a misunderstanding, and discussions were initiated to settle the differences. Another point of difference between the two parties was the price of electricity supplied on contract by Icelandic authorities to the aluminum smelter.

Iceland's only aluminum smelter, located at Straumsvik, south of Reykjavik, was operated by ISAL, a wholly owned subsidiary of Alusuisse. The 75,000-ton plant was supplied with power by the National Power Co. of Iceland, jointly owned by the Government and the city of Reykjavik. Production of aluminum increased slightly, from 72,000 tons in 1979 to 73,000 tons in 1980.

Ferroalloys.—In 1980, Icelandic Alloys Ltd. continued production at its first ferrosilicon furnace, completed the previous year in Grundartangi, north of Reykjavik. Although there were temporary shortages of electric power and cooling water, 25,309 tons of ferrosilicon was produced.

A contract was concluded to sell the plant's flue dust to the State cement plant to be used as an additive in cement. In 1980, 4,400 tons of silica dust pellets was sold.

A feasibility study was completed for a third ferrosilicon furnace at Grundartangi. However, in view of the power situation, the company's board of directors decided to postpone the project for at least 1 year. Icelandic Alloys Ltd. is jointly owned by the Icelandic Government (55%) and Elkem Spigerverket AS of Norway (45%). At present, the equipment consists of two 30-megawatt semiopen rotary Elkem furnaces.

Magnesium.—It was reported that Iceland's Ministry of Energy and Industry was completing a feasibility study to build a magnesium smelter based on seawater and domestic hydropower. Such an industry would be completely independent of foreign raw materials.

NONMETALS

Diatomite.—An alert was ordered at the Lake Myvatn diatomite plant at Lake My-

vatn when, for the third time in 1980, lava erupted in the area, near Krafla, not far from the plant. The diatomite plant, the only one in the world to be operated by geothermal steam, was not damaged by the eruption. Diatomite is recovered from Lake Myvatn. The plant is a joint enterprise of the Icelandic Government and of Johns-Manville Corp. of the United States.

Pumice.—In 1980, Jardefnaidnadur, a south Iceland enterprise, shipped about 36,000 tons of pumice to Denmark. In 1981, exports are to be increased substantially. Pumice, used mainly as an additive for lightweight concrete, is recovered on the slopes of the volcano Mount Hekla, where it has accumulated by repeated eruptions of the volcano. Production during the warm season from March to fall is stored in Thorlákshöfn, a small fishing port southeast of Reykjavik.

MINERAL FUELS

Hydroelectric Power.—In September the Minister of Energy and Industry inaugurated a newly finished 160-kilometer-long power supply line connecting Arnafjördur (northwest-Iceland) to Hrutarfjördur (southeast of Arnafjördur), and to the central area of southern Iceland where the large hydropower plants are located. This will eliminate use of diesel powerplants in the Arnafjördur region, where geothermal heat is scarce.

During 1980, there was a 36% shortage of electric power due to a lack of precipitation. Power-intensive industries such as aluminum, ferroalloys, and diatomite had to curtail production. However by yearend, it was reported that the water level in Lake Thorisvatn, the main reservoir of the National Power Co. in the south, was nearing normal.

Petroleum.—A study was sponsored by Iceland's Fish Industries Fund on the feasibility of an oil refinery in Iceland. The refinery could have a throughput of up to 100,000 tons per year. Conclusions of the study were not released.

Iceland has no oil refinery and imports petroleum products, mostly from the Soviet Union.

The Mineral Industry of India

By Gordon L. Kinney[1] and Francis E. Shafer[2]

The Indian economy had a rather good year overall despite continuing problems in the energy and transportation sectors. Gross national product (GNP) recorded an 8% increase during fiscal year 1980-81[3] (at constant 1970 prices). GNP at current prices was $165 billion[4] compared with $135 billion in fiscal year 1979-80. The improvement was mainly because the critically important Indian agricultural sector made a strong recovery in 1980-81 from the effects of one of the century's worst monsoons the previous year.

Industrial production, which declined 1.4% in fiscal year 1979-80, increased 3% during the year. Most of the growth came after July 1980 following modest improvements in the coal, electric power, and transportation sectors. The planned industrial increase of 8% set in the sixth 5-year plan was not met. Major industries registering production declines during fiscal year 1980-81 included aluminum, cement, nitrogenous fertilizer, steel, and zinc.[5]

Although India was an important producer and consumer of many mineral products, its per capita consumption, because of its large population, was one of the lowest of any major nation. Per capita steel consumption, for instance, was about 14 kilograms compared with the world average of around 165 kilograms per year. The Indian per capita energy consumption was 200 kilograms of coal equivalent compared with the world average of 2,050 kilograms and the U.S. usage of nearly 12,000 kilograms per year. Value of mineral production has increased at a rate of 5% per year since 1970.

After a 5-year period of stagnation at around 100 million tons, coal production rose encouragingly and in turn stimulated thermal power output. The monsoon also helped the hydroelectric output after the drought conditions had curtailed that sector's output in fiscal year 1979-80. Other industries that registered improved performance were electronics, automotive equipment, machine tools, tractors, paper, cotton textiles, and railroad rolling stock. Most industries, however, continue to be afflicted by labor problems, power shortages, and transportation constraints, as well as difficulties associated with obsolete plants and equipment. The poor performance of the Indian railroad system was a serious impediment to all industries.

The labor situation improved a great deal during 1980 but was still a major factor in the industrial economy. Employee-days lost as a result of labor disputes declined from about 44 million in 1979 to 13 million in 1980. However, labor unrest—slowdowns, work-to-rule, and similar actions—continued to be a major hindrance to industrial production, particularly affecting key sectors such as railways, coal, power, petroleum, and banking. With no relief from inflation in sight in 1981, worker demands for higher wages will continue.

Much of India's heavy industry was owned by the Central Government. Performance of these Central Government public sector corporations continued to deteriorate, with losses almost doubling to $93 million in fiscal year 1979-80 as against $50 million the previous year. Overall performance statistics were not available for fiscal year 1980-81. However, the Indian press indicated that the Steel Authority of India Ltd. (SAIL) alone would suffer its heaviest ever loss in 1980-81, possibly more than the whole public sector loss in 1979-80.[6]

Power generation increased about 6% in 1980-81 as against a 2% increase the previous year, but serious power shortages continued in several States. The overall national supply-demand gap rose 2% to about 14% in 1980-81. Rajasthan and Tamil Nadu face the most serious shortages, and marginal power cuts continued in Maharashtra,

Gujarat, Karnataka, Madhya Pradesh, Haryana, and Punjab. There was recent improvement in power supplies to heavily industrial West Bengal and Bihar, but these States continued to operate under chronic shortages. A reliable power supply will be a key factor in the improving performance of the coal and steel sectors.

Thermal power capacity utilization, which declined from 56% in fiscal year 1976-77 to 45% in 1979-80, has reportedly improved to 48% in 1980-81. The India Government planned to invest $90 billion in the electric power industry during the next 15 years. Generating capacity reportedly was to be increased from the present 30,000 megawatts to 100,000 megawatts by 1995. It remains to be seen if such an ambitious construction program can be accomplished, even with concessional loans from foreign countries and international financial organizations.

PRODUCTION

India was a major world producer of a number of important minerals. Of the market economy countries, it was the principal producer of sheet mica; second only to the United States in ammonia for nitrogen fertilizer; third in garnet, kyanite, and the rare earths; and fourth in barite and zirconium. In addition, India was in the top nine producers of several other minerals including iron ore, chromite, manganese, cement, and magnesite.

The output of chromite and iron ore, key inputs into India's steel industry as well as major export commodities registered only marginal gains in 1980. Barite production declined significantly, and manganese ore dropped owing largely to a fall in export demand. Steel production, with strong support from the mini-steel plants, just managed to exceed the 1979 output. Despite chronic shortages of power, aluminum manufactures managed a slight increase in overall production with most of the gain coming in the fourth quarter of 1980. Production of the other nonferrous industries was mixed. Lead and blister copper made sound increases. Zinc suffered severely from the power constraints and labor problems that held capacity utilization to about 50%.

The total value of mineral production during 1979 was $2.12 billion and was estimated at $2.68 billion, an alltime high, in 1980. The minehead value of nonfuel mineral production in 1980 was $450 million, slightly lower than the $463 million recorded in 1979.

Mineral output in India can be quite seasonal owing to the monsoon condition's effect on manual mining operations and on the transportation system. In the good weather months of February and March 1980, the combined value of mineral production was $448 million. Solid fuels accounted for 69%; petroleum and natural gas, 15%; metallic minerals, 10%; and nonmetallic minerals, 6% of the total value.

Of India's 30 States and territories, Bihar occupied the leading position with 34% of total value, followed by Madhya Pradesh 17%, West Bengal 13%, Gujarat 6%, Andhra Pradesh 4.8%, and Orissa 4.2%. Value of petroleum from the offshore Bombay High has been climbing steadily since 1977 to a solid fourth place after West Bengal with 9.6% of the total January and February value. Continuing development of the offshore area for oil and natural gas will probably put Bombay High (BH) first in economic importance within 5 years.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Sept. 30, 1981.

[2]In addition to the commodities listed, other clays (bentonite, fuller's earth, and common clays), other gem stones (aquamarine, ruby, and spinel), and uranium are also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels. In 1975, production of 6,514 tons of uranium ore containing about 3 tons of U_3O_8 was reported from two mines, which was only a part of total national production. Moreover, reported production of stone, sand and gravel are clearly only partial figures, and exclude a number of types of stone; the amounts reported are inadequate to provide sufficient aggregate for production of concrete from domestically produced and consumed cement, nor do they provide for other supplies of aggregate for road metal and other construction uses.

[3]Data are for fiscal year beginning Apr. 1 of that stated.

[4]Partial figures; for details see footnote 2.

[5]Includes reinjected gas.

TRADE

India's external trade continued its recent upward trend by increasing an estimated 25% in 1980. Exports were estimated at $9 billion during fiscal year 1980-81 compared with $8.1 billion in fiscal year 1979-80. The cost of imports rose even faster during the same period, from $11.1 billion to around $15 billion. The trade deficit nearly doubled to $6 billion largely because of increased crude oil prices and increased petroleum product volume. After a period of relative price stability and growing international reserves, India was faced with reemerging chronic inflation and balance of payments problem.

India was a major exporter of several minerals. Valuewise, cut and polished gem stones and jewelry were the top export

category of the mineral-related commodities, earning $808 million in fiscal year 1980-81, an 8% increase over the $730 million (revised) earned in fiscal year 1979-80. About 93% of this value was from diamonds, mostly 1/2 carat or less in size. The source of the diamonds ($500 million worth of imported uncut diamonds) was from Belgium and the United Kingdom. Other major exports were iron ore, $411 million; mica, $28 million; manganese, $18 million; and chromite, $14.5 million.[7]

Petroleum was by far the most important mineral import in 1980 as it has been the last several years. The proportion of petroleum to total imports increased again, going from 35% in fiscal year 1979-80 to 47% in fiscal year 1980-81. According to preliminary trade data, the cost of petroleum imports in fiscal year 1980-81 rose to $6.46 billion from $4.02 billion in the previous year. Other sources put the figure at close to $7.0 billion. The petroleum import bill used up over 70% of the country's export earnings. With the resumption of production in the northeast States coupled with higher offshore production from Bombay High, India's fiscal year 1981-82 petroleum import bill was expected to decline at least $1 billion and possibly more.

Another major mineral-based import was fertilizer. During fiscal year 1980-81, imports recorded a 38% rise to 2.76 million tons valued at $1.16 billion. All types of fertilizer materials were imported by India, which remained totally dependent on imports for its supply of potassium fertilizers. Imports were projected to continue rising during the 1981 to 1985 period.

rRevised. NA Not available.
[1]Less than 1/2 unit.
[2]Includes blue powder.
[3]Incomplete figure; excludes data for January-March.
[4]Value only reported at $37,719.
[5]Data are from the International Petroleum Annuals, 1977 and 1978. Official trade statistics do not report petroleum refinery products under the categories listed. Instead, all products are listed in three categories as follows, with quantities given in metric tons: 1977—light distillates 524,061, middle distillates 1,492,543, other 351,298; 1978—light distillates 383,586, middle distillates 2,629,185, other 865,908.

COMMODITY REVIEW

METALS

Bauxite, Alumina, and Aluminum.—The aluminum industry[6] continued to have problems of low capacity utilization during a period of increasing demand. Production of metal during fiscal year 1980-81 averaged about 58% of the currently installed and operable aluminum smelting capacity. Total production by the end of fiscal year 1980-81 showed a small decline for the second straight year after hitting a high of 214,000 tons of primary metal in 1978.

Persistent power shortages and the high cost of raw material input such as caustic soda, fuel oil, aluminum fluoride, etc., hampered the performance of the industry throughout fiscal year 1980-81. Actual requirements for aluminum in 1980 were estimated at 300,000 tons, calling for imports on the order of 100,000 tons.

India's aluminum smelter capacity, as reported by the Ministry of Steel and Mines, was as follows, in tons per year:

Name	Location	Existing capacity	Proposed expansion
Public sector:			
Barat Aluminium Co., Ltd	Korba, Madhya Pradesh	100,000	--
National Aluminium Co., Ltd	Talcher, Orissa	--	218,000
Private sector:			
Indian Aluminium Co., Ltd	Hirakund, Orissa	20,320	4,150
Do	Alwaye, Kerala	15,850	--
Do	Belgaum, Karnataka	60,000	--
Hindustan Aluminium Co., Ltd	Renukoot, Uttar Pradesh	100,000	20,000
Madras Aluminium Co., Ltd	Mettur, Tamil Nadu	25,000	--
Total		321,170	242,150

The 9,000-ton-per-year smelter at Jaykaynagar in West Bengal has been closed for several years.

There was considerable controversy during the year about the price of aluminum, which was controlled by the Government. According to industry sources, the increasing costs for raw materials, if not compensated by higher prices, could lead to further cuts in production. Reportedly, producers were losing on the average about $312 per ton of metal output. The Ministry of Steel and Mines recommended a $312 to $375 per ton increase in price. The Ministry of Energy, however, vigorously opposed the increase on the grounds that it would jeopardize its ambitious program for expanding electric power generating capacity and the rural electric power distribution network. Some suggested that aluminum producers would not benefit in the medium term by a price increase, since although they could charge more for their aluminum they might face further power cuts due to delays in the electric power program.

Unlike the consumption pattern for the United States or Western Europe, where the electric cable industry accounts for about 11% of aluminum produced, this sector in India accounted for nearly 60% of the metal consumed.

The controversy was settled at the end of fiscal year 1980-81 with the announcement of a $346-per-ton increase effective March 27, 1981. The increase brought the price of electric conductor-grade aluminum to $2,330 per ton.

Provisional bauxite production figures showed a decline in 1980 reflecting the lowered demand from the aluminum smelters. Maharashtra, Madhya Pradesh, Bihar, and Gujarat produced over 90% of India's bauxite, the great majority being consumed by the aluminum industry. The remainder was used by the chemical, refractory, abrasives, cement, and steel industries.

During 1980, a major new bauxite deposit was reported on the Gandhamardan plateau in the Bolangir-Sambolpur District. Reserves were not yet determined. Both Bharat Aluminium Co. (BALCO) and Orissa Mining Corp. expressed interest in the deposit.

India ranked about fifth in the world in bauxite reserves, with about 76% being located along the east coast of Orissa and Andhra Pradesh. As exploration and more detailed examination continued, the total reserves of 2.3 billion tons of all grades were expected to increase considerably.

The much publicized Orissa bauxite and aluminum complex was approved for construction during the year. A separate, Government-owned corporation named National Aluminium Co. Ltd. (NALCO) was set up to implement the project, which will cost over $1.5 billion when completed. The project will be heavily aided by the French Government and the Aluminum Pechiney Co. of France. The French Government agreed to loan $400 million, and $680 million will be loaned by a syndicate of 48 banks in Europe, guaranteed by the Government of India. The remainder will be furnished by Indian Government funding.

Three Orissa bauxite deposits were examined in detail to determine which would be the most economical to develop for the project. The Panchpatmali deposit contained 377 million tons of ore at 40% Al_2O_3 cutoff. Average grade was 47% Al_2O_3 and 2.1% silica. The other two deposits, Gandhamardhan and Pottangi, contained 231 million tons and 92 million tons, respectively, also with good ore composition. The central ore block of the Panchpatmali deposit was chosen as the site for the mining operation. It was located near the Andhra Pradesh border and about 110 kilometers from the coast. The deposit caps a hill about 450 meters above the adjoining plain and is 12 to 14 meters thick with 1 to 3 meters of overburden.

The mine at Panchpatmali will be fully mechanized and developed in two stages of 1.2 million tons per year each. Standard open pit equipment will be used—4.6-cubic-meter electric shovels loading 32-ton rear dumpers. The mine is to employ 900 workers.

The alumina plant will be at Damonjodi 23 kilometers from Koraput (18°49'N, 82°43'E) and have two production lines of 400,000 tons per year each. About 450,000 tons per year would be utilized for conversion to metal and the balance of 350,000 tons per year would be exported to France on a buy-back agreement to pay off the loan. The alumina plant would employ 1,800 people. The alumina will be transported via railroad either to Visakhapatnam for export or to the site of the new smelter near Talcher (20°57'N, 85°13'E). The smelter will have two 240-cell potlines of 109,000 tons per year capacity each. Design power consumption is to be 13,540 kilowatt-hours per ton of metal. All cells will have fume hoods and the latest environmental controls. The

smelter and anode plant will employ a total of 2,040 persons.

The choice of Talcher for the smelter site was governed by the need for a reliable source of electric power. A 700- to 800-megawatt thermal powerplant will be built for the exclusive use of the smelter. Smelter and powerplant will be located close to a new, captive 3.5-million-ton-per-year coal mine and a coal washing plant.

Plans for the U.S.S.R.-backed export-oriented Andhra Pradesh bauxite and alumina project did not progress much during 1980. The Soviet feasibility report estimated cost of a 600,000-ton-per-year alumina plant, including infrastructure, at $548 million, or a 800,000-ton-per-year plant at $663 million.

The initial Soviet report called for an 80% import component, which was entirely unacceptable to the Government of India. In later discussions, the Soviets were willing to finance only 15% of the cost with the balance to be funded by India. India was reluctant to furnish the funding and did not have a long-term alumina customer lined up. It was very unlikely that the U.S.S.R. would accept more than 50% of the plant output. India had reportedly already ruled out export of bauxite to the U.S.S.R. in place of alumina.

In light of the Soviets' hesitancy to finance the majority of the cost, there was a good possibility that the project would be further delayed.

Exploration for additional bauxite in the Kutch District of Gujarat continued during 1980. A deposit of 10 million tons of high-grade bauxite was added to the known reserves bringing the total to 85 million tons. The Gujarat Government planned to establish a joint sector alumina project using the Kutch ores. A technical collaborator was being sought at yearend.

BALCO's proposal for bringing its alumina production line at Korba up to design capacity of 200,000 tons per year was approved by the Government. The achievable operating capacity was 150,000 tons per year. In addition to the alumina plant upgrading, the electrical-grade wire rodmill was also under expansion to meet the growing demand for electric cable. Both projects were scheduled for completion during 1981.

The third and fourth potlines at the BALCO smelter were not started as planned during fiscal year 1980-81 and the prospect for their startup in fiscal year 1981-82 remained poor. The two 25,000-ton-per-year potlines were ready for commissioning in December 1977 and August 1978 but were never energized because of nonavailability of electric power.

The Geological Survey of India is to carry out reassessment and exploration for new occurrences of bauxite of the leasehold of Madras Aluminium Co. in the Shevaroy hills in Tamil Nadu. The company is facing a shortage of metallurgical-grade bauxite for its plant at Mettur.

India's demand for imported aluminum could be as high as 130,000 tons in fiscal year 1980-81. Supplies of electric conductor grade were particularly tight during the year. Minerals and Metals Trading Corp. (MMTC) reportedly had over 25,000 tons of electric conductor ingot in warehouses, which could not be released because of problems over payment of import duty. The Government had waived the aluminum import duty in April 1980 in order to encourage imports to fill the domestic shortage. The duty waiver was canceled in September 1980. Reimposition of the duty caused problems for dealers who had ordered metal after April but were not able to receive delivery before September. Slow distribution and delivery of metal to the consumers also caused further problems during the year.

Chromite.—There was a marginal increase in chromite production during the year, but mine value dropped slightly to $15.8 million in 1980 compared with $16.8 million in 1979.

Much of the Indian chromite production was for the export market. The Government's export quota was changed from 266,000 tons in 1979 to 300,000 tons in 1980, although the quota for high-grade ore, included in this figure, was lowered from 160,000 tons to 137,000 tons. The price of high-grade ore bought by Japan, India's major customer, was $110 per ton for the 1980 contract, an increase of $2 per ton over the 1979 price.

Test drilling for additional chromite reserves was under way by the Geological Survey of India and the Mineral Exploration Corp. (MEC) in several locations. A test boring at Kimsibura, Singhbhum District, Bihar, encountered an encouraging vein of chromite. Work in the adjacent Jamliuli, Ranjrakocha, and Janao areas was continuing. Mapping and surface evaluation was underway in the Krishna, Khammam, and West Godavari Districts of Andhra Pradesh, and in Hassan District of Karnataka.

As a result of the continuing exploration program, the reserve picture for chromite was much more favorable than a few years ago. Officially quoted at 60 million tons of over 30% Cr_2O_3 ore, the figure could go over 100 million tons in the next few years. A large part of the total increase in recent years was from changing technologies that allowed for the redefining as ore, certain lower grade deposits, deposits with lower Cr:Fe ratios, and friable deposits formerly considered unusable.

Based on the improved reserve picture in Orissa and the feasibility of using lower grade chromite fines, three export-oriented charge chrome plants were planned. The Orissa Mining Corp. was to build the first 50,000-ton-per-year plant at a cost of around $35 million. Outo Kumpu Oy of Finland was to provide technical expertise and Voest Alpine A.G. of Austria was to supply the equipment. The plant will have an electric arc furnace using a sinter pellet feed. Furnace waste gases will be used to preheat the pellets, saving an estimated 30% in electric power consumption.

Ferroalloy Corp. was also issued a letter of intent for a similar plant to be built at Baudpur in Balasore District of Orissa at a cost of $25 million. The company will also expand the production from its Boula chromite mine and construct a 450-ton-per-day beneficiation plant. The mine has been an open pit operation, but the workings will be extended underground as well.[9]

The Indian Metals and Ferroalloys Ltd., which already operates a ferrosilicon plant in Orissa, has proposed a third 50,000-ton-per-year charge chrome plant.

Copper.—The Indian copper industry continued to have serious problems of under utilization of designed smelter and refinery capacity during 1980. The Khetri copper complex of Hindustan Copper Ltd. (HCL) with a design capacity of 31,000 tons of copper metal per year was particularly hard hit. Mine development, mine production, and ore milling suffered from frequent power outages and cutbacks of up to 50% of its operational needs. With the power restrictions, the smelter and refinery were given priority and the mining operations as well as the byproduct fertilizer plant suffered as a result.

HCL was having feasibility reports prepared to examine the expansion of Khetri's smelter and refinery up to 45,000 tons per year. HCL felt the increase was necessary to handle anticipated increases in local ore production and the copper concentrate that will be available from Malanjkhand. HCL has ordered two 3,500-kilowatt diesel generator sets for the Khetri complex to augment the standby power capacity and ensure that essential mining and plant operations can continue during a shutdown caused by power outages. The often unannounced power outages have caused damage to equipment in the past.

Excavation and equipping were completed on the new deep shaft at the Kolihan Mine, one of the main sources of copper ore for the Khetri complex. Installation of the underground crusher was underway. Completion of this deep mine development will eliminate long underground ore hauls that contribute to ore handling bottlenecks in the mine. The new shaft will permit a production increase from the present capacity of 1,500 tons per day to 2,500 tons per day.[10]

At the Ghatsila copper complex in Bihar, power shortages during fiscal year 1979-80 caused a considerable loss of ore production and the liquidation of the concentrate stockpile.

A mine expansion was underway at the Mosaboni Mine, one of the main ore suppliers to the Ghatsila complex. The project, which would increase monthly ore production from 50,000 tons to 80,000 tons, ran into power problems, and progress was adversely affected during 1980. HCL has proposed an expansion of its Ghatsila refinery capacity from 16,500 tons per year to 20,000 tons per year. Mitsubishi Metal Corp. of Japan has reportedly been selected to supply the electrolytic technology.

Development of the Malanjkhand copper project in Balaghat District of Madhya Pradesh continued during the year. Overburden removal totaled 1.2 million cubic meters during fiscal year 1979-80 and was estimated at 2.57 million cubic meters during fiscal year 1980-81. Work on the ore concentration plant proceeded generally on schedule.

This project will be the country's first large-scale open pit copper mine. The mine will be designed to produce 2 million tons per year of ore (23,000 tons copper equivalent) and the concentrator scaled accordingly. The first phase of the program will produce 1 million tons per year of ore and was scheduled for startup in July 1982. The Government of India's estimated cost of the project has been revised from $107 million up to $115 million with a 10% foreign

exchange component. The Malanjkhand ore body contains an estimated 117 million tons of ore averaging 1.13% copper, or roughly one-quarter of the country's known copper reserves. Rio Tinto Zinc of the United Kingdom was the prime consultant on the project. A prototype test leaching facility was set up to recover oxydized and low sulfide ore. Copper concentrates will be shipped to the Khetri smelter where they will supplement the concentrates available from HCL's local mines.

Gold.—Gold was produced in modest amounts from the old Kolar Goldfield and from Hutti Gold Mines Co., Ltd., both in Karnataka, and from HCL's precious metal byproduct plant at the Ghatsila copper complex. In addition, a byproduct recovery plant, under construction at the Debari smelter in Rajasthan, will recover silver and about 10 kilograms of gold per year from the zinc concentrate. The recovery plant was scheduled for completion in late 1982.

The miners at the Kolar Goldfield celebrated the 100th anniversary of active mining in 1980. The mines were among the deepest active workings in the world. Past production totaled 785 tons of gold from 46 million tons of ore. However, unstable ground, fire, water problems, and low-grade ore were contributing to the high mining costs and low economic return.

The Geological Survey of India has been actively exploring for additional reserves at both Kolar and Hutti and in a number of other States where low-grade deposits were being reexamined in light of the current high price of gold.

Bharat Gold Mines Ltd., the public sector company that operates the Kolar Mines, planned to reopen the Yeppamana Mine near Anantapur (14°41'N, 77°36'E) in Andhra Pradesh. The mine was one in the old Ramagiri Goldfield run by the former John Taylor and Sons Co. of Great Britain. The mines have been closed since 1929 when costs exceeded the value of production. The Geological Survey of India reportedly reopened the old shaft, and exploration work was underway during 1980. Production was projected to begin within 2-1/2 years of an investment decision. The mine would operate at a rate of 250 tons per day from proved reserves of 300,000 tons of 5.5-gram-per-ton ore.

Iron Ore.—Iron ore[11] production rose marginally in 1980, with the mines in the Goa area contributing one-third of the total. Lump ore accounted for about 54% of the total. In 1979, the latest available data, there were 358 reporting iron ore mines with the largest number located in Goa where mining was predominantly in the private sector. Madhya Pradesh, Orissa, Bihar, and Karnataka together produced about 63% of the iron ore, mostly from public sector mines.

The public sector National Mineral Development Corp. (NMDC), which operated highly mechanized, export-oriented mines at Bailadila in Madhya Pradesh and Donimalai in Karnataka continued to be the largest producer of non-Goan iron ore. In 1980, NMDC's production was 7 million tons with roughly 85% consisting of lump ore. In contrast, nearly 90% of the Goan ore consisted of fines. Meanwhile, the stockpile of fines at Bailadila continued to grow to an estimated 15 million tons. Efforts to promote the export of these fines have met with limited success, with Romania, Japan, and Yugoslavia buying a total of 4 million tons in 1980. A proposed pelletization plant at Bailadila was further delayed by priority being given to establishing a pellet plant at Mangalore to increase the salability of Kudremukh iron ore concentrate.

One of the major iron ore developments during 1980 was the completion in August, ahead of schedule, of the $630 million Kudremukh iron ore project. The output from this project, which was to reach 7.5 million tons per year in the third year of operation, was initially earmarked for Iran. Project financing was also to come from Iran, but owing to internal political problems exacerbated by the Iranian-Iraqi war, Iran advanced only $255 million toward the project cost. One of the two planned Iranian steel plants that was to use the Kudremukh concentrate has been canceled and construction on the other, at Ahwaz, has been delayed at least 3 years. Physical status of the Ahwaz plant, which was located in a reported combat area, was not determined at yearend 1980. Iran's inability to lift any of the concentrate has created a number of operational and financial problems for the Kudremukh Iron Ore Co. Ltd. (KIOCL). It was unclear at yearend if Iran was going to continue financing the project, attempt to negotiate a new contract, or try to recover its investment.

Meanwhile, the Government has been negotiating with several countries including Bahrain, Indonesia, Malaysia, Romania,

and others for the sale of the concentrate. Romania has accepted a trial shipment of 40,000 tons and reportedly has agreed to lift 1 million tons per year over the next 3 years as part of a buy-back arrangement involving a contract to build a 3-million-ton-per-year pellet plant at Mangalore. Lurgi of the Federal Republic of Germany would provide the pelletization technology. Romania's offer was reportedly the lowest of five international bids submitted and contained the ore purchase agreement as well. The Arab Iron and Steel Co. of Bahrain has reportedly agreed to buy 1.5 to 2.0 million tons of concentrate annually at a price to be determined.

In 1980, there were three relatively small pellet plants in India. These were the 0.5-million-ton-per-year captive Tata Iron and Steel Co. (TISCO) plant, and two export-oriented plants in Goa, a 1.0-million-ton-per-year plant operated by Chowgule Co. Pvt., Ltd., and a 1.8-million-ton-per-year joint Chowgule-NMDC plant also in Goa. High fuel oil costs were making it very difficult to operate the Goan plants at a profit. They were subject to temporary closure if the costs could not be passed on to the Japanese consumer. Both plants had plans to make modifications that would lower operating costs.

The Bailadila-14, Bailadila-5, and the Donimalai Mines operated at well under design capacity during 1980 because of lack of demand, railroad transportation bottlenecks, and the electric power shortages.

Exploration and development work continued on the most promising iron deposits. Of the eight main ore bodies at Bailadila, the detailed study of the 11-B deposit was scheduled for completion in March 1981 and the 11-C deposit was chosen for development to supplement the output of the operating Bailadila-14 Mine. In 1980, the NMDC completed field investigations or feasibility studies on the Bababudan and Kumaraswamy deposits in Karnataka, the Ongole magnetite deposit in Andhra Pradesh, and the Malangtoli deposit in Orissa.

Despite the depressed outlook for the steel industry worldwide particularly in Japan, Indian production of iron ore in fiscal year 1981-82 was expected to remain close to the fiscal year 1980-81 level because of the anticipated increased domestic demand and diversified overseas sales. The 6-year plan target called for a production of 60 million tons by fiscal year 1984-85. Indian iron ore consumption should amount to about 16 million tons in fiscal year 1981-82, rising to 23 million tons in fiscal year 1984-85, and to 30 million tons by fiscal year 1989-90.

Export earnings from the sale of iron ore and pellets in fiscal year 1980-81 rose to an estimated $411 million compared with $351 million in fiscal year 1979-80. Japan remained India's most important iron ore customer accounting for 60% of the total exports. Romania was the second largest buyer of Indian ore. U.S.S.R. for the first time imported Indian ore amounting to 2 million tons. Seven other countries bought at least 100,000 tons each in both fiscal year 1979-80 and fiscal year 1980-81.

Direct sales of iron ore by Goan producers last year declined by more than 2.5 million tons to about 8.5 million tons. This was attributed to reduced liftings by Japan, a strike by the inland bargemen who move most of the Goan ore to Mormugoa port for export, and other labor problems. The Goan mining companies also sold nearly 3.5 million tons of iron ore to MMTC for export. Total Goan mine production was 1 million tons more than the output in fiscal year 1979-80.

Steel.—Total Indian salable steel production during fiscal year 1980-81 rose slightly with the country's six integrated steel plants accounting for 6.12 million tons and the balance coming from 146 operating mini-steel plants. The small improvement fell short of meeting the demand of approximately 9.3 million tons. The near stagnation in production during 1980 was attributed to chronic shortages of power and coking coal as well as labor unrest. Average capacity utilization of the five public sector integrated plants was 63.5% while the private sector TISCO plant operated at 101.7% of its design capacity during the same period.

Steel production from the mini-steel plants continued to increase in fiscal year 1980-81. Major steps were being taken to promote the production from these plants. These included (1) allowing direct import of scrap metal, (2) import of about 30,000 tons of sponge iron from Indonesia on an experimental basis, and (3) exemption of excise duty on products made from indigenous sponge iron. India was also negotiating for the supply of up to 200,000 tons per year of sponge iron from Indonesia.

Output of crude steel declined in 1980 primarily because of a 600,000-ton stockpile accumulated by the public sector plants and, to a lesser degree, of shortages of power

and coking coal. Some of the inventory was carried over from the previous year when the power shortage in the rolling mills adversely affected the conversion of the crude steel to salable steel. Crude steel target for fiscal year 1981-82 was 9.15 million tons of which about 7.20 million were to come from SAIL plants. Chronic transportation bottlenecks, however, could make it a difficult goal to attain. Nevertheless, salable steel output was expected to pick up in fiscal year 1981-82 to as much as 9.0 million tons.

During fiscal year 1980-81, steel imports were valued at $625 million compared with $563 million in fiscal year 1979-80. Major suppliers were the United Kingdom, Japan, and the Federal Republic of Germany. In light of the persistent shortages, imports were likely to remain around 1 million tons over the next several years.

The Government had a continuing expansion program underway that would greatly increase India's steel production capacity by 1990. Current programs underway or approved were projected to raise the country's crude steel capacity from the present 14.7 million tons including mini-steel plants to nearly 19 million by yearend 1984. According to the Government's annual plan, expenditure for the steel sector in fiscal year 1981-82 was put at $950 million, with over half of that for expansion of Bokaro and Bhilai steel from 2.5 million tons to 4.0 million tons each by the end of 1982. Total sixth plan outlay for Bokaro and Bhilai was $1.01 billion and $1.14 billion, respectively. The Bokaro expenditure was to include the construction of a three 60-megawatt turbogenerator unit captive thermal powerplant. The mill has suffered serious power shortages in the past 2 years and operated at 40% to 43% of installed capacity during that period. The 6-year plan outlay of $528 million including $101 million in fiscal year 1981-82 was scheduled for the Rourkela plant, which included a silicon steel project to be completed by January 1982, captive powerplants, and other modifications. The Durgapur plant was allocated $70 million for a captive electric powerplant.

Work was nearing completion on the first stage of the Salem stainless steel plant in Tamil Nadu estimated to cost $175 million. The plant will have a capacity of 32,000 tons per year of cold-rolled stainless steel sheets and strips from imported feedstock. Plans call for doubling of the capacity.

The Government has allocated $163 million in fiscal year 1981-82 for the 3.4-million-ton Soviet Union aided Visakhapatnam steel plant. The first 1.15 million tons of capacity was scheduled for completion by fiscal year 1984-85 at a cost of $1.31 billion. Total cost of all stages was estimated at more than $3.24 billion. The Soviet Union has offered credit of $313 million for the first stage and an equal amount for the second. Site preparation and infrastructure construction was underway during 1980.

TISCO's plans called for a $425 million modernization program over the 1980-85 period. The TISCO integrated steel plant, oldest in the country, consisted of the 1.5-million-ton-per-year salable steel plant at Jamshedpur in Bihar; captive collieries at Sijua, Jamadoba, and West Bokaro; and the iron ore mine at Noamundi. The West Bokaro Colliery was being expanded and a coal washing plant was under construction. Half of the 50-year-old steelmaking capacity was to be replaced with a new oxygen-based steel converter shop. A 300,000-ton-per-year continuous casting line and vacuum arc degassing equipment will also be installed. The company estimated that nearly $9 million will be saved annually on fuel costs from the new melt shop. The new equipment will allow salable steel output to increase to about 1.75 million tons per year.

India's long-term program called for a crude steel capacity of 24 million tons by fiscal year 1989-90. The increase was to be achieved by commissioning the second stage of the Visakhapatnam steel plant and by building a 3.0-million-ton-per-year steel plant at the port city of Paradip (20°17'N, 86°42'E). Negotiations for a contractor were underway at yearend 1980. Financing of the project and technology being offered were the prime consideration in the choice of contractor.

The 30,000-ton-per-year sponge iron (direct reduction) demonstration plant became operational in July 1980. The plant operated by Sponge Iron India, Ltd., a government-owned company at Kothagudam, Andhra Pradesh, was set up with United Nations assistance using Lurgi's coal-based direct reduction process. The plant operated successfully through yearend, and plans were being made to double its capacity.

India's only commercially designed direct reduction plant, under the corporate name of Orissa Sponge Iron, Ltd., was nearing completion. Allis Chalmers Co. (United

States), which has provided the process know-how and equipment at a cost of $10.6 million, holds a 10% equity in the project. Trial runs of the $30 million, 150,000-ton-per-year coal-based plant were set for September 1981. Plans called for doubling the capacity of this plant also, if it operates as a commercial success.

TISCO has reportedly received approval to set up a plant in Orissa based on its own technology. Mini-steel plants were expected to buy most of the sponge iron output as a substitute for scarce and expensive ferrous scrap.

Lead and Zinc.—Power outages during most of February and March 1980 at the Debari lead-zinc complex in Rajasthan reportedly caused a production loss of around 1,200 tons of lead and 9,000 tons of zinc. Despite the problem, production of lead concentrates increased marginally for the year but zinc production dropped significantly.[12]

The Mochia and Balaria Mines and associated concentrator of the Zawar group of mines near Udipur, Rajasthan, continued to be the major source of lead-zinc ore and concentrate. The mining out of the upper level ore reserves at Mochia necessitated extending the workings to a greater depth. Construction was underway on two main shafts—Mochia and Balaria— and on an auxiliary shaft for Mochia. The auxiliary shaft was due for completion in 1981, and the main shafts, in 1982. Lower level development of the ore bodies will begin after completion of the shafts.

The Government sanctioned a $13 million expenditure for setting up a leach residue treatment plant at the Debari zinc smelter using a process and technical aid from Outokumpu Oy of Finland. When completed, the leach plant would add 4,000 tons per year capacity to the present 45,000 tons per year capacity. A silver and gold byproduct recovery plant using Mitsubishi process technology was also approved for the smelter. The plant would, for the first time, enable recovery of silver and gold values from the zinc concentrates. In addition to current production, the stockpiled residue of the past 11 years of operations at the smelter will also be treated. The planned annual recovery capacity will be about 10 kilograms of gold and 8,500 kilograms of silver. It was believed that the silver would be refined at the Visakhapatnam zinc smelter.

Construction continued on the Rajpura-Dariba lead-zinc mine and concentrator near Chittor, Rajasthan. Installation of the hoisting system was behind schedule by about 6 months. A tailings disposal plant was also ordered in 1980 for the treatment of concentrator tailings. The plant will deslime the tailings, then mix the sands with cement, and pump the mixture back to the mine for use in backfilling the worked-out stopes. Design output of the new mine will be 3,000 tons of ore per day.

Work continued on the $15 million Sargipalli lead mine in Orissa, which was being developed to reach a production of 500 tons of ore per day by late 1983. Construction on the concentration plant was to begin early in 1981. The Sargipalli project was designed for an annual yield of about 10,000 tons of 63% lead concentrate for the Visakhapatnam smelter. Proved reserves were 2.6 million tons of 6.7% lead ore.

At the Agnigundala lead mine in Guntur District, Andhra Pradesh, work on expanding the milling capacity from 100 to 200 tons per day of ore was completed except for installation of an additional crusher, which was underway. Doubling of the mining capacity to 240 tons of ore per day was also in progress.

The Rajasthan Government has granted a mining lease for the Rampura-Agucha lead-zinc deposit in Bhilwara District. A detailed investigation has been sanctioned. The property was the largest single lead-zinc deposit in India and had 30 million tons of proved reserves grading over 10% combined metal content. In view of the continuing need to import both lead and zinc, the Government was anxious to begin mining the deposit as soon as the economic viability of the project could be assured. The deposit was reportedly suitable for open pit exploitation. Also planned in conjunction with this deposit was a new smelter with a capacity of 100,000 tons per year of zinc and 35,000 tons per year of lead.

A proposal to expand the Visakhapatnam lead smelter from 10,000 tons per year to 22,000 tons per year was approved by the Government. Hindustan Zinc, Ltd. (HZL), has dropped its plans for expanding the 8,000-ton-per-year Tundoo smelter.

HZL's zinc smelter at Visakhapatnam was reportedly operating at 75% to 80% capacity on imported concentrate and was producing the majority of the country's zinc during the power shortage at Debari. A prolonged strike at Cominco Binani Zinc Co.'s 17,000-ton-per-year smelter near Al-

waye in Kerala had cut production there considerably during 1980. The labor problems were settled around yearend and operations were likely to resume in April 1981.

The status of lead-zinc ore reserves has been steadily improving as the Indian exploration programs added to total reserves and upgraded the classification of many reserves. As of January 1981, 29 distinct ore blocks have been evaluated and cataloged. Total ore reserves were 229 million tons averaging 4.72% zinc and 1.76% lead. Of the total, 148 million tons were classified as proved or probable. Estimated metal content of the proved and probable classes came to 7.5 million tons of zinc and 3.0 million tons of lead.

Manganese.—Production of manganese ore was valued at $29.0 million at the minehead in 1980, marginally higher than in 1979 because of a price increase. Orissa was the leading supplier, followed by Karnataka, Madhya Pradesh, and Maharashtra. According to the latest count, there were 278 operating manganese mines in 1979.

Production by the public sector Manganese Ore India, Ltd. (MOIL), the leading Indian producer of high-grade ore, rose 3% to 450,000 tons in fiscal year 1980-81. A major share of the company's ore was consumed by the ferromanganese and steel industries. To increase production and improve recovery of manganese, plans have been made to construct beneficiation and agglomeration plants near MOIL's Balaghat and Ukwa Mines. Ore samples have been sent overseas for testing. A 60,000-ton-per-year ferromanganese plant was also proposed for Balaghat. MOIL has contracted with domestic consultants to prepare feasibility reports for an electrolytic manganese dioxide plant and an electrolytic manganese metal plant. MOIL has begun manganese exploration in Orissa where efforts were being made to locate high-grade low-phosphorous ore. Such ore would be used to blend with low-grade high-phosphorous ore in an effort to stretch existing reserves. The fiscal year 1981-82 budget was to provide $16.25 million for MOIL's development programs.

The domestic requirement for manganese ore was in the neighborhood of 1 million tons annually, 60% of which was high-grade ore (plus 48% Mn content). The major consumers were ferromanganese, 47%, and steel industries, 35%. Requirements of steel plants were expected to rise from about 0.4 million tons in fiscal year 1980-81 to 0.75 million tons in fiscal year 1984-85 and to 1.0 million tons by the end of the decade following expansion of the indigenous steelmaking capacity. By then, total domestic demand for manganese ore was projected to reach 2.0 million tons, or double the present level.

With the domestic demand anticipated to rise and reserves presently estimated at about 80 million tons, the Government has cautiously restricted exports to low-grade ore. In fiscal year 1980-81 exports of manganese ore were 653,000 tons worth $18.1 million compared with 672,000 tons worth $17.4 million exported in fiscal year 1979-80. The fall in exports was due mainly to reduced liftings by Japan, which remained India's principal customer (75% of total).

Other Metals.—The Government announced the production of crude tellurium for the first time in India from a 20-kilogram-per-month pilot plant at HCL's Ghatsila smelter in Bihar. Tellurium was being recovered from anode slimes generated during the copper refining process. The crude metal will be refined at the Department of Atomic Energy's Special Materials plant at Bhaba Atomic Research Center. Based on the pilot plant operation, HCL has prepared a feasibility report for a commercial-scale 1,500-kilogram-per-year plant to be installed at Ghatsila.[13]

Part of the Centennial celebration of the Kolar Goldfield consisted of the inauguration of a scheelite recovery plant at the mines. Tungsten concentrate will be obtained from both the run-of-mine gold ore and the sizable reserve of old tailing sands. The plant will produce a 63% WO_3 concentrate with a rather low recovery of 32% of the tungsten present. Hutti Gold Mines Co., Ltd., was also investigating the possibility of recovering the scheelite values from its ores.

Most of India's small tungsten production has come from the Degana wolframite deposit in Nagour District of Rajasthan where mining and sorting were done manually. The deposit was being studied in detail with a view toward increasing output.

In addition, the Government was evaluating wolframite deposits in Sirohi (24°53'N, 72°52'E), Rajasthan; Agargaon (21°06'N, 79°29'E), Maharashtra; and Almora, Uttar Pradesh. Indian press reports state that the Sirohi deposit was very promising but reserves were not yet totaled.

A minable deposit of vanadium mineralization at Khursipur (21°23'N, 90°18'E), Ma-

harashtra, containing an estimated 6.3 million tons of 0.9% to 1.0% V_2O_5 was being investigated for the possibility of supporting a ferrovanadium plant. The size of the plant would probably be around 500 tons per year of ferrovanadium with a byproduct production of 50,000 tons per year of pig iron. Most of the output would be for export.

Meanwhile, the proposed ferrovanadium plant for Orissa remained in the planning stage. The latest proposal was by the Finnish firm Outokumpu Oy to set up a 400- to 500-ton ferrovanadium plant at Rairangpur, Mayurbhanj District, based on minable ore reserves (1.0% V_2O_5 cutoff) of 1.2 million tons at Kumardhubi (22°17'N, 86°19'E) and 0.8 million at Betjharan (22°16'N, 86°19'E).

NONMETALS

Barite.—Production, keyed primarily to exports, declined significantly in 1980. Minehead value was placed at $2.5 million. Cuddapah District of Andhra Pradesh, with around 65 million tons of reserves, accounted for over 90% of the country's production. India ranked fourth in world production in 1980.

Despite a worldwide increase in oil exploration and drilling, exports of Indian barite, both lump and powder, dropped from 340,000 tons in fiscal year 1979-80 to about 284,000 tons in fiscal year 1980-81. The decline was attributed to disruption in shipments to Iraq resulting from the Iraqi-Iranian conflict, Indian port congestion, and the uncertainty among foreign buyers regarding India's future barite export policy. On May 17, 1980, the Government announced that the private sector could undertake once again the export of barite, which had been restricted exclusively to the MMTC since April 1979. Exports to Mexico and Iraq, which were on a government-to-government basis, continued to be handled solely by MMTC. The United States, which imported about 90,000 tons, was the largest buyer; Mexico received 50,000 tons; and the Persian Gulf countries, primarily the United Arab Emirates and Saudi Arabia, got a total of 80,000 tons.

The Government revised floor prices for drilling-grade barite effective January 1, 1981, and valid through June 30, 1981. Barite powder was fixed at $67 per ton, a $2-per-ton increase, and $42 per ton for lump ore, a $2-per-ton decrease. Paint-grade prices were set at $138 to $162 per ton depending on the whiteness.

The Andhra Pradesh Mining Corp. principal mine at Mangampet can produce about 560 tons per day. Plans called for this to be increased to 1,000 tons per day within the next 2 years. About 70% to 80% of the run-of-mine production was marketable ore with the remainder being stockpiled until the company management can economically justify installing beneficiation facilities. The operation was being studied with this in mind.

Cement.—Despite an ambitious program of plant expansions and new construction, the supply of cement fell far short of the Indian requirements during 1980. Indian production rose modestly in fiscal year 1980-81 after a serious drop in fiscal year 1979-80 caused by acute shortages of coal and electric power. Unlike many of India's more important mineral based industries, the cement industry was mostly in the private sector, 85% of the total capacity. Owing largely to continuing coal shortages, capacity utilization declined to 67% in fiscal year 1980-81 compared with nearly 73% in the previous year. Cement plants in the south, especially in Karnataka, were most severely affected.[14]

The cement shortfall was met by high-priced imports. During fiscal year 1980-81, imports rose by 500,000 tons and were valued at about $150 million. Principal suppliers included the Republic of Korea, the Philippines, Indonesia, and North Korea. Imports were projected to reach 2 million tons valued at $188 million in fiscal year 1981-82 and rise to around 2.5 million tons in fiscal year 1982-83.

Because of the sizable gap between supply and demand, steps were being taken to increase output as well as the quality of cement. An interministerial working group reportedly has recommended liberalized licensing of new capacity, adoption of better technology—conversion to dry process or precalcination—provision for special foreign exchange allocation for imports of critical components, and improving power and coal supplies.

In addition, public sector units have been assigned a major program of utilizing slag from steel plants. The Uttar Pradesh Cement Corp. proposed a 1.68-million-ton-per-year plant at Chunar based on slag from the Bokaro steel plant. SAIL was also setting up a 2-million-ton-per-year cement plant at Chilahati based on Rourkela and Bhilai slag.

Total installed capacity of the cement industry in March 1980 was listed as 24.29 million tons from 57 units. The anticipated

growth in production capacity from cement plants both planned and under construction is shown as follows, in million tons:

Fiscal year	Capacity at start of year	Capacity added		
		Public sector	Private sector	Total
1980-81	24.29	2.24	[1]1.32	3.56
1981-82	27.85	.84	2.29	3.13
1982-83	30.98	.55	4.76	5.31
1983-84	36.29	1.40	2.65	4.05
1984-85	40.34	2.40	3.54	5.94
Total		7.43	14.56	21.99

[1]Includes 0.26 ton from joint ownership.

Successful completion of the ambitious expansion program will require a huge influx of capital funds plus substantial additional investment in the infrastructure to assure a smooth flow of cement to the consumer.

Expected demand for cement at the end of fiscal year 1984-85 was put at about 38 million tons. If the projected plant capacity produced at the planned 85% utilization factor, the new construction would be sufficient to put India into a position of slight cement surplus during 1985.

Diamond and Gem Stones.—Fiscal year 1980-81 export earnings from diamonds and jewelry rose 8% to $808 million from $749 million in the previous year. About 93% of this value was represented by cut and polished diamonds. The industry was helped by an increased demand for small diamonds (1/2 carat or less) from the United States where the import duty on small diamonds was withdrawn. Diamond exports were targeted at about $963 million for fiscal year 1981-82.

The export trade remained dependent on imports of rough diamonds, which cost India about $500 million in fiscal year 1980-81, up from $475 million in fiscal year 1979-80. Belgium and the United Kingdom supplied over 90% of the rough stones in 1980. The MMTC has been attempting to procure rough stones on a government-to-government basis from Ghana, Zaire, Central Africa, and Sierra Leone.

Domestic production of diamonds remained relatively insignificant. During 1980, over 14,000 carats were recovered from the Majhgawan Mine in Panna District of Madhya Pradesh. About 50% of the output was classed as gem quality. Workings at India's only other diamond mine, Ramkheri, were closed down during 1980 but processing of gravel stockpiles continued through July 1980.

The Government has drawn up a 3-year diamond exploration program for the Kalyandurg-Wajrakarus-Jonnagiri belt in Andhra Pradesh, the Panna diamond belt in Madhya Pradesh, and the Jungel area of Uttar Pradesh. The main purpose of the $31 million program was to establish the incidence of diamonds in different host rocks, to locate primary sources of diamonds and to evaluate the commercial viability of these occurrences. The Geological Survey of India was to act as coordinating agency with MEC and NMDC assisting in excavation and treatment of material.

The Geological Survey of India was studying the schists and pegmatites in the Teckhi-Khera area, Udaipur District, Rajasthan, for occurrences of emerald-bearing zones. It was also proposed to initiate investigation for semiprecious stones in Kanyakumari District, Tamil Nadu, and for agate in Kutch District, Gujart.[15]

Fertilizer.—To augment a steadily declining phosphate rock production, India was forced to import about 1.35 million tons in 1980, primarily from Jordan, the United States, Morocco, and Senegal. Production of rock phosphate by Rajasthan State Mines and Minerals, Ltd., at its Jamar Kotra deposit (65 million tons of reserves) was around 300,000 tons of more than 31% P_2O_5 in fiscal year 1980-81. The production was unlikely to change in fiscal year 1981-82, but plans called for raising the output of this mine to 1.0 million tons in the next 4 or 5 years. A 200-ton-per-day pilot plant for beneficiating 14% to 20% P_2O_5 content ore to 35% was to be commissioned in July 1981. By January 1982, if the pilot plant performs as designed, a 4,000-ton-per-day commercial-scale plant will be built.

Phosphate fertilizer production (P_2O_5 content) rose over 10% to 841,000 tons in fiscal year 1980-81. Improved operation of the Tuticorin plant, the addition of two new single superphosphate plants in the private sector, and a slight overall improvement in capacity utilization contributed to the higher output. In contrast, production of nitrogenous fertilizer during fiscal year 1980-81 declined marginally despite a 22% increase in the annual capacity to 4.73 million tons (nitrogen content). At the same time, capacity utilization also fell to 45% in fiscal year 1980-81 from 57% in the previous year. A shortage of naphtha feedstock, student and labor problems, and the chronic electric

power shortage were the main causes of the poor performance.

Two coal-based nitrogen fertilizer plants, Ramagundam in Andhra Pradesh and Talcher in Orissa, each with a capacity of 900 tons of ammonia and 1,500 tons of urea per day, began commercial production in November 1980. The plants reportedly cost $280 million each. Early reports indicated they had not achieved a very high level of efficiency by March 1981.

According to the Government, Haldia and Trombay V projects in the public sector, Gujart Narmada Valley Fertilizers Co. and Kanpur expansion in the private sector, and Kandla expansion in the co-op sector were expected to commence operating in fiscal year 1981-82. The country's total annual capacity would then be 5.3 million tons of nitrogen and 1.5 million tons of P_2O_5 by yearend 1981.

Fertilizer consumption during fiscal year 1980-81 increased over 6% to 5.58 million tons and was projected to rise to 6.6 million tons in fiscal year 1981-82 comprising 4.40 million tons of nitrogen, 1.47 million tons of P_2O_5, and 0.73 million tons of K_2O. This projected demand compared with an anticipated production of 3.0 million tons of nitrogen and 0.925 million tons of P_2O_5. There was no K_2O production in India. The shortfalls on each type would be met by imports.

The sixth 5-year plan (1980-85) proposed an outlay of $2.63 billion for setting up 8 new nitrogen and 11 new P_2O_5 plants. The eight nitrogen plants were in addition to the two natural gas based projects scheduled for Thal-Vaishet near Bombay and Hazira in Gujarat. Six of the eight are to be based on the natural gas from the Bassein Field, and one each on naphtha and coal. Of the 11 planned phosphatic fertilizer plants, an expansion of the Tuticorin plant was already underway and a new plant at Paradip costing $238 million was expected to be started in 1981.

Planning and financing for the new ammonia plants at Hazira and Thal-Vaishet continued during 1980. Preliminary development of infrastructure and site preparation also got underway in 1980. These plants will be the first based on the large offshore reserves of the Bassein Gasfield.

Hazira project was estimated to cost over $1.2 billion and would produce 2,700 tons per day of ammonia from two similar production lines. Downstream urea facilities will have an output of 4,400 tons per day from four 1,100-ton-per-day production lines. Pullman Kellogg of the United Kingdom was to provide the ammonia technology and Snam Progetti SpA of Italy the urea know-how.

An ammonia plant of similar capacity was also taking shape in 1980 at Thal-Vaishet. Project delays on this plant have been costly to the Indian Government. Since the original estimates in 1978, costs have nearly doubled to $1.1 billion. Haldor Topsoe of Denmark was to supply the ammonia technology. Snam Progetti will install three urea production lines of 1,500 tons per day each.

Limestone.—Limestone production in India dropped slightly during 1980 owing to less offtake by user industries. Limestone accounted for nearly one-half of the total value of output of nonmetallic minerals, about $84 million in 1980. Andhra Pradesh, Bihar, Gujart, Karnataka, Madhya Pradesh, and Tamil Nadu, which possess most of the country's reserves, accounted for over 70% of the production. Current reserves are in the neighborhood of 70,000 million tons with 6,300 million tons proved, 4,500 million tons indicated, and 59,200 million tons inferred. Roughly three-fourths of these reserves were cement grade and were widely dispersed. Over 60% of the production originated at captive mines of cement plants. The concentration of the cement industry in southern and western India was a reflection of plants being set up near the most suitable limestone deposits. The Government's recent policy of encouraging the construction of large new cement plants and the establishment of numerous mini cement plants throughout the country was going to increase overall limestone production considerably and expand the exploitation of smaller deposits of cement-grade limestone.

Chemical-grade limestone reserves were confined to Gujarat State and flux-grade limestone, to Orissa and Madhya Pradesh. In addition to cement, industrial users of limestone included those producing iron and steel, fertilizers, refractories, asbestos, ferromanganese, and sugar. Almost all of India's production of limestone was consumed within the country. Only small quantities were exported to the neighboring countries of Bangladesh, Nepal, and Sri Lanka.

Mica.—The increased demand for fabricated mica or mica-based products has spurred a new official policy of encouraging the development of value added mica-based

products. Accordingly, the Government's Mica Trading Corp. (MITCO) was planning to set up (1) a micronized mica powder plant at a cost of $0.5 million to produce 3,000 tons per year of mica powder, (2) a mica paper plant involving investment of $27.5 million for producing 1,200 tons of paper with 50% based on the mechanized disintegration process and 50% on the thermochemical process, (3) a mica paper-based products plant with capital outlay of $4.5 million, (4) a wet ground mica powder plant at a cost of $1.6 million to produce 1,200 tons per year, and(5) a glass bonded mica plant at a cost of $1.5 million. Final arrangments for technical collaboration were yet to be made for some of the above plants. Most of the plants would require foreign know-how to some extent.

In addition, a mica capacitor plant was to be set up in the joint sector with the public sector Bihar State Electronics Development Corp. having a 26% share in the $662,000 cost. The entire output of the plant was to be exported. Negotiations were reportedly going on with some U.S. firms for a technical collaboration.

The declining trend in the production of mica that set in a decade ago continued into 1980. The official statistics, however, were lower than the actual production as substantial quantities come from existing stockpiles or are simply unreported to avoid taxation and royalties. Regardless of the production trend, India was by far the major producer of natural sheet mica, accounting for nearly 85% of the world's total in 1980.

Mica mining, almost entirely in the private sector, continued to be a traditional cottage-type industry operating mostly in Bihar, Andhra Pradesh, and Rajasthan. Bihar produced 60% of the production by value and had 151 of the 251 reporting mica mines in 1979.

Despite the private ownership, the Government extended considerable control over the industry and through MITCO controlled prices and shared with the private sector all exports of crude and processed mica on an equal 50:50 basis. Mica export earnings increased from $23.4 million in 1979 to $28.1 million in 1980. By far the greatest proportion of the exports were in the form of relatively low value scrap mica. The block mica accounted for only 6% of total export tonnage but made up 68% of the total value.

Mineral Sands.—Production of titanium and heavy beach sand minerals by the public sector Indian Rare Earths, Ltd., (IREL), registered some impressive gains during 1980. Value of production, however, remained at around $11 million for the year. Most of the monazite production, which contains about 10% ThO_2, came from IREL's mineral sands project at Manavalakurichi, Tamil Nadu. The installation of a preconcentrator at Manavalakurichi and the modernization of IREL's Chavara plant near Quilon, Kerala, was reflected in the higher production statistics and in higher production targets for 1981. In addition to the monazite, these beach sands yield ilmenite, rutile, zircon, garnet, and sillimanite. Processing of the monazite yields exportable amounts of rare-earth chloride, fluoride, and oxide and trisodium phosphate. The thorium hydroxide was stockpiled for possible future use. Through its research efforts, IREL has been able to recover samarium, gadolinium, and yttrium, which could be added to the export list as production improves.

Completion of the $100 million (first phase) Orissa mineral sands complex was set for yearend 1982 following several delays and reschedulings. The plant will have an annual capacity of 220,000 tons of ilmenite (50% TiO_2) to be processed into 100,000 tons of synthetic rutile (90% TiO_2), 30,000 tons of sillimanite, 2,000 tons of zircon, 4,000 tons of monazite, and 10,000 tons of natural rutile (95% to 97% TiO_2). Based on this planned output, IREL was looking for foreign collaboration in setting up a titanium sponge plant or titanium pigment plant.

IREL's Chavara plant was scheduled to receive magnetic separation equipment to further improve its ore recovery operation. To meet shortages of titanium dioxide pigment in India, Kerala Minerals and Metals, Ltd., was going to set up a 25,000-ton-per-year plant near Quilon, which was to be completed in late 1982. Kerr McKee Co. of the United States was reportedly providing the process technology.[16]

MINERAL FUELS

Coal.—Indian coal reserves at 112 billion tons are the fifth largest in the world (based on maximum depth of 1,200 meters and minimum thickness of 1/2 meter). About one-eighth of these reserves is considered to be of metallurgical grade. Owing to the high ash and moisture content, most Indian coal is considered poor in quality. Nevertheless, in view of the vast coal reserves and rising petroleum import bill, which exceeded $6.5 billion in 1980-81, coal remained the coun-

try's primary energy resource.

The Geological Survey of India and MEC continued their exploration programs to upgrade existing reserves and establish new ones. Press reports indicated major new finds in the north Karanpura coal belt under Central Coalfields, Ltd.

Based on recent geophysical and core drilling activities, Gujarat State has established coal reserves of over 60 billion tons at depths between 1,300 and 1,800 meters. Random testing indicated that compared with most other Indian coal, the deposits were of unusually good quality—2% to 3% ash, 4% to 5% moisture, 50% volatiles, 42% to 50% fixed carbon, and 6,500 kilocalories per kilogram heating value. Because of the excessive depth and presence of several high-pressure gas- and oil-bearing horizons (present source of oil and gas production) overlying these coalbeds, the State Government was investigating the possible application of in situ coal gasification technology to exploit these reserves. It would be extremely difficult to exploit these deposits economically using conventional mining methods. Exploration of these deposits was continuing.

Following 5 years of relatively little change in coal output, fiscal year 1980-81 production reached a record level. Production of Coal India Ltd.'s (CIL), five subsidiaries came to nearly 101 million tons, or nearly 88% of India's total coal output. The other coal producers also increased their output during the year.

The major increase in production came from mechanized open pit mines, which accounted for 35% of production, up from 28% in 1979-80. CIL's share from open pit mines was reported to be even higher. Output per employee shift, which had been nearly static for the last 5 years at 0.66 ton, rose to 0.71 ton in fiscal year 1980-81.

The sharp increase in total coal production resulted in raising pithead coal stocks by 4.5 million tons to 18.5 million tons in fiscal year 1980-81. Inadequate supply of high-quality coal and railroad transport bottlenecks, however, continued to affect production of many major industries including fertilizer, cement, and paper. Continued shortages of metallurgical coal also restricted steel production as coking coal output increased only marginally. India was forced to continue importing high-grade coking coal to blend with the domestic output. The continued overall inferior quality of coal being delivered hampered boiler efficiency and created maintenance problems for end users and the added burden of higher handling and freight costs.

Despite higher costs, movement of coal by road transport since 1977-78 has risen by 73%, whereas the movement by rail during the same period declined by 9%. Rail transport reportedly picked up sharply during the fourth quarter of fiscal year 1980-81.

In light of the continuing problems relating to the coal sector, several proposals were being considered by the Government of India to improve decision making and increase coal output. Reorganization of CIL was being considered but no decision had been reached by yearend 1980.

New technologies to increase production as well as to eliminate wasteful mining practices were under review. In addition to modernizing production methods, several captive electric powerplants were planned for the mining areas. In recent years, one of the main production constraints in the underground mines was the shortage of electric power, which caused severe mine dewatering and ventilation problems.

A major component of the development strategy was a gradual shift to more open pit mining. Fiscal year 1984-85 open pit operations were expected to account for 71 million tons or about 43% of coal produced and raise to over 50% by fiscal year 1989-90 compared with the present 35% share.

By fiscal year 1984-85, longwall mining was to contribute 10 to 13 million tons, compared with the present 2.5 million tons. Only about 20% of Indian coal was estimated to be recoverable by open pit mining; therefore, development of longwall and other modern underground mining technology was critical in the long-term overall coal production plan.

Research and development efforts were being stepped up to improve the quality of coal shipped to consumers. Construction of five new coal washeries with a throughput capacity of nearly 9 million tons of raw coal was planned. These would expand the present washery capacity from 27.8 million tons to 36.5 million tons by fiscal year 1984-85 at a reported cost of $31 million. Introduction of simple methods of upgrading noncoking coal to ensure a consistent quality of feed to powerplants was being considered. The Central Coal Research Institute was engaged in developing fluid-bed combustion technology to offset the rising ash content of Indian coal.

In an effort to offset the $144 million financial loss of CIL in fiscal year 1979-80, the price of coal was increased an average of $2.50 per ton in February 1981. CIL's mine-head coal prices, after the increase, ranged from $12 to $17 depending on location and grade. CIL's financial position for fiscal year 1980-81 was not available.[17]

Lignite.—Neyveli Lignite Corp. in Tamil Nadu mined about 4.6 million tons of lignite in fiscal year 1980-81 and was by far the major producer in India. The company's plan was to raise lignite production at its first open pit mine cut to 5.8 million tons in fiscal year 1981-82, to 6.5 million tons in fiscal year 1982-83, and ultimately to 8.5 million tons per year. Proposed expenditures for fiscal year 1981-82 were put at $140 million. Work was progressing on the second mine cut, which would initially produce 4.7 million tons of lignite per year. The Federal Republic of Germany was helping to finance the development work.

Virtually all of the lignite goes to the generation of electric power or the production of nitrogen fertilizer. Output of the second mine cut will feed a 630-megawatt onsite powerplant. Ultimate capacity of the second mine would be 10 million tons per year and power a 1,470-megawatt plant still on the drawing boards. The feasibility of a third mine cut, to produce 10.5 million tons per year to support a 1,500-megawatt powerplant by 1995, was also being studied.

Aside from Tamil Nadu, lignite resources were also being developed in Gujarat to help meet the State's massive electric power expansion program. Expansion of present lignite mining operations were called for by the Gujarat Mineral Development Corp. to meet the demand of 2,000 tons per day in support of a 110-megawatt powerplant being set up by the State Electricity Board. The goal was to eventually produce 4,000 to 5,000 tons of lignite per day. The possible production of lignite in Rajasthan was also being studied.

Natural Gas.—Overall gas production declined substantially because much of the flow originates as associated gas from the Assam crude oil production. A major increase in production came from offshore BH which increased production from 386 million cubic meters in fiscal year 1978-79 to 673 million cubic meters in fiscal year 1980-81.

Plans called for the eventual doubling of the Uran gas fractionation plant capacity as natural gas production increases. First phase development of the 300-billion-cubic-meter (10.5-trillion-cubic-foot) Bassein South Gasfield was about to get underway. Under Phase I, gas production was to reach 10 million cubic meters per day by the end of 1984. This would be raised to 18 to 20 million cubic meters per day in the Phase II development. Two well platforms would be needed plus a 236-kilometer subsea pipeline to link the field with onshore processing facilities in Gujarat. The gas processing yielded about 150,000 tons per year of liquefied petroleum gas (LPG) plus a small amount of heavier condensate. The Government Oil and Natural Gas Commission (ONGC) was also considering exploiting a smaller gasfield discovered on the Tapti structure in the Gulf of Cambay. The recent discoveries of gas off Porto Novo and the Andaman Islands have not been sufficiently drilled to define whether they could be economically developed.

Oil.—Despite an increase in offshore crude oil production during fiscal year 1980-81, India's crude oil output fell substantially. This decline was attributed to prolonged student agitation in northeast India, which crippled petroleum operations in that region. The result was higher imports of refined products that, coupled with increased crude oil prices, produced a record POL import bill estimated at close to $7 billion in contrast to $4 billion in fiscal year 1979-80. Imports in fiscal year 1980-81 included 16.25 million tons of crude oil and 7.05 million tons of refined products compared with 16.12 million tons of crude and 4.78 million tons of refined products in the previous year. Despite some disruption in supplies as a result of the Iraqi-Iranian hostilities, these countries plus Saudi Arabia, the United Arab Emirates, and the U.S.S.R. remained India's principal crude oil suppliers in 1980.[18]

India firmed up its crude oil requirements for 1981 on a government-to-government basis. These arrangements called for 17 to 18 million tons, which should provide some surplus as well as some built-in flexibility. Several nontraditional suppliers including Algeria, Mexico, Libya, and Venezuela have offered crude for the first time in 1981. However, unless some swapping arrangement could be worked out, India was likely to reject most of these offers owing to the high freight costs and difficulty of refining crude from these countries.

In order to lower petroleum imports, the costs of which are causing an increasingly

serious burden on the entire Indian economy, the Government has undertaken an urgent program to step up oil exploration and development with emphasis on the more promising offshore areas. The sixth 5-year plan has earmarked $3.6 billion for oil exploration and development but this figure now appears to be unrealistically low. Estimates for developing the full potential of the Bombay High and satellite fields and expanding refinery, petrochemical, and fertilizer facilities come to nearly $8 billion.

ONGC deployed onshore 32 seismic parties, 12 geological field parties, and 5 gravity-magnetic survey parties during 1980. About 32 drilling rigs deployed mainly in the eastern and western regions completed 47 exploratory and 36 development wells in 1980 for a total of 155,000 meters. The drilling level was below target because of the student agitation in Assam. Eight new structures were drilled during the year resulting in the discovery of new oil reserves and a new gas structure at Dehej in Ankleswar Oilfield in Gujarat.

ONGC's onshore drilling program in fiscal year 1981-82 called for completion of 102 wells totaling 238,000 meters and covering both the eastern and western regions. Under an Indian-Soviet agreement, the Soviets were to explore and develop one or two onshore oil and gas deposits on a turn-key basis in Tripura and West Bengal. They will also help in secondary recovery operations in the northeast oilfields. A Canadian group was to assist in improving production from some of the Gujarat wells in western India.

ONGC's offshore survey work totaled 22,600 line kilometers in the 1980 survey season, and another 21,000 line kilometers were scheduled for 1982.

Offshore drilling work in fiscal year 1980-81 totaled 14 exploratory and 20 development wells conducted by 6 rigs. One was the Indian-owned jackup Sagar Samrat, and the remainder were on charter from the United States and Norway. India was to take delivery of its second jackup rig, the Sagar Vikas, from Japan in March 1981. The French-built Sagar Pragati was scheduled for delivery shortly thereafter, and two more jackups were under construction in Singapore. Additional purchases were being made or planned.

During 1980, five new offshore structures were drilled leading to discovery of hydrocarbons at Godavari, Ratnagiri, the Andaman Islands, and Porto Novo. Except for Ratnagiri, the discoveries were found on the east coast for the first time. As of March 1981, ONGC had drilled a total of 91 offshore exploratory and assessment wells of which only 35 have proven to be dry, reflecting a remarkably high rate of success.

The ONGC planned to drill 20 exploratory and 39 development wells during fiscal year 1981-82. Further exploration was called for in the Krishna-Godavari Basin where there are numerous structures with at least eight located in water depths beyond the 200-meter shelf limit. Owing to physical conditions in the Godavari Basin such as relatively strong surface currents, a soft sea bottom, and greater depths, the deeper areas may now be turned over to foreign companies on a production sharing basis for exploration if contract conditions can be agreed on. During 1980 three wells were drilled in this basin but all had to be abandoned following loss of two blowout-preventers and some casing.

Oil India Limited (OIL), a joint 50:50 venture by the Government of India and Burmah Oil, Ltd., of the United Kingdom, until recently confined its operations to onshore exploration in the northeastern States. During 1980, OIL drilled 12 onshore wells and for the first time 2 offshore wells off the coast of Orissa. Five of the 12 onshore wells were drilled in the Kharsang area of Arunachal Pradesh and yielded new oil discoveries. The find was considered very promising and will probably be put into commercial production. Oil was also found in the Bagapani area of Assam. Thirty more exploration wells were planned for the next 3 years on the basis of these discoveries.

In addition to its onshore drilling, OIL spudded two offshore wells in the Mahanadi Basin that were judged noncommercial. Additional wells were planned when a drill rig becomes available.

OIL's crude production was severely curtailed by unrest in Assam but was returning to normal after the situation quieted. Natural gas production was scheduled to nearly double during 1981. OIL was having a 60,000-ton-per-year LPG plant built in Assam that will also produce 12,000 tons of condensate per year. The project would annually save over $19 million in foreign exchange by replacing 70,000 tons per year of kerosine imports. Scheduled completion was for 1982.

Negotiations for the 100% takeover of OIL by the Indian Government continued, with indications that an agreement would be reached in 1981. India was also expected

to take over the Assam Oil Co. in the near future.

Crude oil production from offshore BH oilfield continued to show improvement in 1980 averaging nearly 100,000 barrels per day from 19 platforms, 11 of which were installed during 1980. The rate of production was to be stepped up to 180,000 barrels per day by October 1981 and later to 225,000 barrels per day. These production increases will call for 10 more well platforms as part of Phase IV and V development made possible by the recent installation of the $90 million, 180,000-barrel-per-day processing-pumping platform installed by J. Ray McDermott and Co. of the United States. A second 180,000-barrel-per-day processing-pumping platform was scheduled for BH by mid-1982. This $190 million project will serve the southern part of BH. Other fields near BH will also be developed as funding and equipment permit. By 1985, with the development of several satellite structures, offshore crude oil production could possibly exceed 400,000 barrels per day (20 million tons per year).

Consumption of refined products increased 3.6% to 31 million tons in fiscal year 1980-81. This compared with a 4.6% rise in fiscal year 1979-80 and 10.6% in fiscal year 1978-79. This deceleration in the consumption growth rate was attributed largely to retail price increases levied in June 1980 and January 1981 to offset the sharp increase in the cost of imported petroleum. Indian pattern of consumption in recent years was as follows in thousands of tons:

Product	1978-79	1979-80	1980-81
Diesel oil	9,854	10,940	10,326
Furnace oil	4,395	4,582	5,336
Kerosine	3,952	3,867	4,200
LPG	408	405	394
Gasoline	1,499	1,480	1,521
Naphtha	2,515	2,429	2,324
ATF	1,154	1,140	1,128
Bitumen	943	1,072	1,081
Petroleum coke	155	173	100

Based on the April 1, 1981, commissioning of a gas fractionation plant for production of 150,000 tons per year of LPG at Uran, two refineries in Bombay have already built bottling plants for LPG distribution. Once the Uran plant is operating, consumption of kerosine should decline as consumers switch to LPG. Over the next 30 months, gas connections for about 3 million new customers were likely to be approved. This should further lower the kerosine consumption.

The Indian Government's projected consumption of refined products for fiscal year 1981-82 was between 33 million and 35 million tons, 45.5 million in 1985, and 62 million by 1990. Even if the estimates are on the high side, such demands would be beyond India's financial capabilities. The Government was thus examining various options and methods of conservation, conversion, and pricing mechanisms to lower the rate of consumption increase.

Refining was almost entirely in the public sector. The one exception was the 0.5-million-ton-per-year Digboi refinery operated by Assam Oil Co., which was owned by Burmah Oil of the United Kingdom. Refinery throughput in 1980 declined because of the intermittent closing of the refineries in the northeast due to the student unrest. The fiscal year 1981-82 crude throughput target was set at 32.25 million tons, a nearly 25% increase over that of 1980. The target was feasible with the normal functioning of the northeast refineries and the commissioning of part of the 6-million-ton capacity of the Mathura refinery.

To meet the anticipated growth in consumption of refined products, the country was embarking on a major refinery expansion program that will raise India's refining capacity from 31.8 million tons per year to around 45 million tons per year by 1985, including (1) doubling the annual capacity of Madras refinery to 5.6 million tons, (2) expanding Visakhapatnam refinery from 1.5 million to 4.5 million tons per year, and (3) upgrading the Cochin refinery from 200,000 tons to 3.5 million tons per year. Also under consideration was a 6-million-ton-per-year plant at Mangalore and a 3-million-ton-per-year plant at Karnal (29°41'N, 76°59'E) in Haryana. Secondary processing facilities to increase the output of middle distillates were also proposed for a number of refineries.

The Government was developing pipelines for petroleum distribution to reduce the burden on the railroad system. A 532-kilometer product pipeline was under construction in two segments, Mathura-Delhi and Delhi-Ambala-Jullunder. The first section was scheduled for completion by August 1981 and the second by April 1982. Several other projects including modernization and looping of existing lines will help to upgrade the overall distribution system.

The Mineral Industry of Indonesia

By John C. Wu[1]

In 1980, the second year of the 5-year development plan (1979-84), there was a significant improvement in Indonesia's real economic growth. In 1980, Indonesia's growth in real gross domestic product (GDP) was about 7.1% compared with 4.9% in 1979. The level of inflation came down to about 17.1% in 1980 from 30% in 1979. Indonesia's GDP in current price was $67,022 million in 1980 compared with $48,961 million (revised) in 1979.[2] A record high rice crop and favorable prices and production of crude oil, liquefied natural gas (LNG), tin, rubber, and timber were the major contributing factors to the overall growth of Indonesia's GDP in 1980. By sector, components of GDP during 1979-80 were[3] agriculture, 31%; industry (manufacturing), 10%; energy, mining and quarrying, 18%; construction, 5%; transportation and communication, 5%; and services and other, 31%.

The oil and gas sector continued to remain the most important industry. Indonesia was the world's 10th largest oil exporter in 1980. The industry's export earnings accounted for 73% of the estimated $23.3 billion of overall merchandise export earnings in 1980. This revenue from oil provides for about two-thirds of Government development expenditure. There was a new wave of oil and gas exploration as a result of an attractive new joint-venture contract and arrangement. Exploration was also intensified by a series of hikes in the price of oil and gas. More than 200 exploratory wells were drilled in 1980, numerous onshore and offshore oil and gas wells were discovered, a total of 11 oil and gas production-sharing contracts were signed, and a record high $591 million for oil exploration was committed by eight foreign oil companies. However, Indonesia's oil output continued to drop by 2% because of a noticeable slowdown in oil exploration activities during the 1975-77 period and the depletion of some old wells. Production of LNG by five liquefaction trains, which utilized natural gas from Arun Field of North Sumatra and Badak Field of East Kalimantan was at full capacity. A record high production of LNG was reached in 1980. Two LNG plants were scheduled to be completed by 1983, doubling the country's existing capacity. Indonesia's coal production continued to increase, and the expansion project of Bukit Asam was moving on schedule. A coal preparation plant for Ombilin Mine was scheduled to come onstream in 1981.

The nonfuel minerals sector remained as the fourth largest export earner after oil and gas, timber and wood products, and rubber. The continuing high price of tin and the operation of two new large offshore dredges (Bangka II and Bima) helped the country's tin production to reach a new record high since 1954. Indonesia was the world's fourth largest producer of tin in 1980. The $101.5 million expansion program of Freeport's Ertsberg East underground copper mine in Irian Jaya was ahead of schedule. A new manganese ore deposit in the Bima area of West Nusa Tenggara Island began production in 1980. Sarae Bure Port was being constructed to handle the exports of manganese ore to Taiwan and other countries. Work on P.T. Aneka Tambang's nickel operation on Gebe Island continued to progress. P.T. Inco had resolved problems at its Soroako plant to achieve 93% of planned nickel output for 1980. The $2 billion Asahan aluminum project was proceeding on schedule. The overall construction of the aluminum smelter and

two gigantic hydroelectric powerplants was about 50% completed. However, construction of an alumina plant, using the bauxite in the Tayan region of West Kalimantan remained uncertain.

Indonesia's cement industry continued to expand. In 1980, two new cement plants (Padang II and Tonassa II) were inaugurated. Indonesia's total cement capacity was increased to 7 million tons per year. However, owing to rapidly increasing demand for cement caused by the construction boom, net imports of cement totaled about 100,000 tons in 1980. In 1980, P.T. Pupuk Kujan's new urea plant in Java was inaugurated.

PRODUCTION

Production of oil and natural gas remained the dominant sector of Indonesia's mineral industry. In 1980, output of crude oil dropped slightly from 1.59 million barrels per day in 1979 to 1.56 million barrels per day in 1980. Output of natural gas remained at about 1 trillion cubic feet. Production of LNG increased substantially and reached over 8 million tons by yearend. Coal production increased moderately, and reached over the 300,000-ton level.

Output of tin reached a 25-year high of 32,527 tons in 1980, as a result of two additional, new large offshore dredges operating around Bangka and Tudju Islands. Bauxite production in 1980 was at a higher level than production of 1979. Nickel and copper production decreased slightly. Manganese ore production from the Java area remained at about 6,000 tons. A new manganese mine in Bima, with an estimated ore reserve of about 50 million tons, started production in 1980. About 15,000 tons of ore were produced by yearend for export to Taiwan, Japan, and the Republic of Korea. Gold and silver production in 1980 reversed the downward trend of the 1977-79 period as a result of increased mine output induced by higher prices.

The cement industry had expanded its total annual capacity from 5.9 million tons in 1979 to 7.0 million tons in 1980. A construction boom in Indonesia resulted in cement shortages in many areas of the country. Total industry capacity to produce chemical fertilizers was more than 2.8 million tons per year, most of which was nitrogenous fertilizer. Indonesia manufactures about 500,000 tons of phosphate and complex fertilizer using imported raw materials.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through July 30, 1981.

[2]Includes Au content of copper ore and output by Government-controlled operations. Gold output by operators of so-called People's mines is not available but may be as much as 30,000 troy ounces per year.

[3]Includes a small amount of cobalt which is not recovered separately.

[4]Data represent limestone used for cement production. Excludes considerable amounts of limestone produced by enterprises under local jurisdictions for building materials, for crushed rock to be used as aggregate, and to burn for lime.

[5]Sulfur produced by other than the Frasch process.

[6]Less than 1/2 unit.

TRADE

Crude oil, LNG, rubber, and tin, along with timber and wood products remained the major export earners of Indonesia.

In 1980, exports of crude oil and LNG alone were estimated at $17 billion, about two-thirds of overall export earnings. Japan and the United States remained Indonesia's two biggest customers in 1980. Of a total of 378.5 million barrels of oil exported in 1980, Japan purchased a total of 206 million barrels, accounting for 54%, and the United States, purchased 113 million barrels, accounting for about 30%. Indonesia exported most of its LNG to Japan (7.5 million tons valued at over $1.5 billion in 1980) and to the United States. Nonoil minerals remained the fourth largest export earner. Export earnings of tin, up 23% to $461 million in

1980, accounted for about two-thirds of total nonoil mineral exports. Exports of bauxite, copper concentrate, and nickel ore and concentrate were mainly to Japan and the Federal Republic of Germany.

Indonesia imported about $15 billion of merchandise in 1980. Imports of machinery and electrical equipment, base metals, vegetable products, mineral products, chemical and allied products, and vehicles and transport equipment remained the top six import groups. Principal suppliers were Japan, the United States, and the European Communities.

Because of the sharp increase in export earnings, mainly from oil and gas, Indonesia's foreign exchange position improved greatly with more than $8 billion overall trade surplus.

Table 2.—Indonesia: Exports of mineral commodities

COMMODITY REVIEW

METALS

Aluminum and Bauxite.—Production of bauxite by P.T. Aneka Tambang from its open pit mines on Bintan Island and the nearby islets of Angkut, Dendang, Kelong, and Tembeling totaled about 1.1 million tons in 1980. Japan continued to import most of the Indonesian bauxite; and in 1979, 91% went to Japan, and the remainder was shipped to the Netherlands. High-grade trihydrate bauxite normally requires less energy than the monohydrate to produce alumina.

During 1980, the feasibility studies for developing a bauxite mine and an alumina production facility in Indonesia were completed by a Japanese consortium composed of Showa Aluminum Industries K.K., Nippon Light Metal Co. Ltd., Sumitomo Aluminum Smelting Co. Ltd., Mitsubishi Light Metal Industry Ltd., and Mitsui Aluminum Co. Ltd. A final report, which includes site recommendation and cost of the alumina plant, was submitted to the Indonesian Government. The final decision for the alumina project was to be officially announced in early 1981. According to the feasibility studies, an Indonesia-Japan joint venture firm would be established to mine the below export-grade bauxite in the Tayan region of West Kalimantan, with a mining capacity of 3 million tons per year, and a 600,000-ton-per-year capacity alumina plant would be built in Sumatra. Seventy-five percent of the total alumina production would be shipped to the forthcoming Asahan smelter at Kuala Tanjung in North Sumatra, and the remaining 150,000 tons of alumina would be exported.[4]

The Asahan aluminum project, carried out and owned by P.T. Indonesia Asahan Aluminum (IN-ALUM), was in its third year of construction. Work on the aluminum smelter and the two hydroelectric power stations was proceeding according to schedule.

Construction work at both power stations was the most difficult part of the whole project. The first 286-megawatt power station at Sigura-gura would have an intake dam standing 48.5 meters high at an elevation of 500 meters above sea level, while the powerplant was 200 meters below the earth's surface. The second 317-megawatt power station at Tangga would have an intake dam standing 73 meters high; however, the power station was at ground level.

Construction work at the smelter site, Kuala Tanjung, about 50 miles southeast of Medan, was about 50% completed. At

Kuala Tanjung, which covers an area of 200 hectares, a 510-cell reduction plant equipped with a gas cleaning system; a carbon plant consisting of a green carbon plant, anode baking plant, and rodding plant; a casting shop; and maintenance shop were to be built. A new port at Kuala Tanjung was about 80% to 90% complete. Other infrastructures including a company town and camp facilities, roads, water, and electricity were about 50% complete.

The first-stage production capacity would be 75,000 tons per year in 1982; the second-stage production capacity would be 150,000 tons per year in 1983; and the third-stage production capacity would be 225,000 tons per year in 1984.[5] If the plan for a 600,000-ton-per-year alumina refinery in Sumatra had not materialized by 1982, Indonesia would be forced to import large quantities of alumina annually to provide feedstock for the Asahan aluminum smelter. In 1980, a contract between IN-ALUM and three Japanese alumina producers was reportedly signed for the Asahan smelter to import alumina from Japan—100,000 tons in 1981, 245,000 tons in 1982, and 340,000 tons in 1983.[6]

IN-ALUM is owned 75% by Nippon Asahan Aluminum Co. (invested 50% by the Overseas Economic Cooperation Fund of Japan, 32.5% by five Japanese aluminum smelting companies headed by Sumitomo Aluminum Smelting Co. Ltd., and 17.5% by seven integrated trading firms headed by Mitsubishi Corp.), and 25% by the Indonesian Government. Of the estimated Asahan's total project cost of $2.1 billion, $460 million, or 22.2%, would be equity capital of the company and the remaining $1.6 billion, or 77.8%, was to be funded by borrowing (30% from Indonesia and 70% from Japan).

The proposal to develop the below export-grade bauxite on Bintan Island was dropped, mainly because of the high silica content.

Copper.—Copper production of Indonesia was by P.T. Freeport Indonesia, Inc., which operates an open pit mine and concentrator at Gunung Bijih, Tambagapura (Ertsberg) of Irian Jaya. Output of copper ore in 1980 remained at about the same level as that of 1979, but the average copper content of the ore in 1980 declined to about 2% from 2.1% in 1979. The concentrator was operating at 83% to 84% of its 225,000-ton-per-year capacity.

The $101.5 million expansion program of the new underground mine at Ertsberg East, near its existing open pit mine, was ahead of schedule. Ore production from this underground block caving mine was planned to begin at 4,500 tons of ore per day before the end of 1980. The annual output of the existing open pit mine and new underground mine was expected to increase to 135 million pounds of copper in 1981 from 126 million pounds produced in 1980. Upon completion of the project in 1983, Ertsberg East underground mine was expected to operate at 9,500 tons of ore per day. By 1983, the combined annual output of Freeport was projected to be 180 million pounds of copper, 72,000 ounces of gold, and 1.2 million ounces of silver. The copper reserves at Ertsberg East were estimated to have 45 million tons of ore averaging 2.64% to 2.75% copper content, plus unspecified gold and silver values.

For the past 7 years since Freeport began operating, all its copper output (in the form of concentrates, averaging 31% Cu) was exported to Japan (70%) and the Federal Republic of Germany (30%). In June 1980, the long-term sales contract between Freeport and Norddeutsche Affinerie (NA) of the Federal Republic of Germany (has 3.5% interest in Freeport) expired. It was reported that Freeport had replaced its contract with NA by "an international trader" to take 25% of Freeport's copper output from Ertsberg East for the 1980-91 period. For the next 10 years the remaining 65% to 75% of output would be exported to Japan, based on the renewed long-term sales contracts between Freeport and two Japanese smelter and refineries.

P.T. Tropic Endeavor Indonesia, a joint venture firm of Endeavor Resources Ltd. of Australia and Utah Exploration Inc. of the United States, reportedly was acquired by Utah Exploration Inc. in mid-1980. According to the agreement, Utah paid Endeavor $1.1 million at the signing of the agreement, and was to pay $5.5 million by September 1, 1981. Additionally, Utah will pay Endeavor a 1.5% royalty from the future output value of the property at Kayubulan Ridge. Utah Exploration Inc., a wholly owned subsidiary of Utah International, Inc., of the United States, continued the exploration activities at the Kayubulan Ridge porphyry copper prospect, located in the Motomboto-Tombuililato region of Sulawesi. An additional $3.3 million was expected to be spent on exploration in the area for the 1980-81 period. Based on earlier drilling by Endeavor, the Kayubulan Ridge

porphyry copper deposit contains 196 million tons of ore, averaging 0.74% copper and 0.1 troy ounces of gold per ton of ore.[7]

Gold and Silver.—Gold and silver production in Indonesia were mainly by P.T. Aneka Tambang and by P.T. Freeport Indonesia, Inc. In 1980, gold and silver production by Aneka Tambang from its Cikotok Mine, about 5 miles north of Bayah in South Banten, West Java, totaled 247 kilograms of gold and 2,189 kilograms of silver, compared with 170 kilograms of gold and 1,645 kilograms of silver produced in 1979. The increase was due to additional mine output from Cirotan, Hatemi, Labak Sembada, and Cierang in the South Banten area. Output of gold and silver as byproducts of Freeport's copper project at Ertsberg in Irian Jaya reportedly had shipments of 52,000 troy ounces of gold and 608,000 troy ounces of silver. The gold and silver recovered by the Freeport copper operation was averaging 0.31 troy ounces of gold and 4.11 troy ounces of silver per ton of concentrate.

Endeavor Resources Ltd. of Australia started a feasibility study on development of alluvial gold deposits near Marisa in North Sulawesi. The study was expected to be completed early in 1981. Utah Exploration, Inc., reportedly would also participate on the investigation of the gold deposits in Marisa hinterland held by Endeavor.

Iron Sands.—In 1980, there were two iron sand mines operated by the state-owned P.T. Aneka Tambang; the Cilacap Mine in Central Java, and the Palabuhanrata Mine in West Java. In 1980, output of the Palabuhanrata Mine remained at the same level as that of 1979 at about 44,000 tons of iron sand concentrates. The output of iron sand concentrate from the Cilacap Mine continued to drop because of a dispute over export price and quantity with the Japanese buyer, Nippon Kokan Kabushiki Kaisha. Most of the iron sand was consumed by the domestic cement industry, and only a small portion of iron sands (55% to 56% Fe, 8% to 10% TiO_2) was exported to Japanese Kanematsu Gosho Ltd.

Manganese.—Production of manganese ore in Indonesia was by the state-owned P.D. Pertambangan Jawa Barat and two private firms; P.T. Panca Ubaya Paksi and P.T. Kiswoyo Jaya. Recovery of manganese ore was by washing and hand sorting, mainly in Karangnunggal, Southern Tasikmalaya, West Java, and the special Province of Yogyakarta. Annual output of the ore from these areas remained at about 6,000 tons since 1977.

In 1980, a new manganese ore deposit was being mined in the Bima area of the West Nusa Tenggara Islands by P.T. Miga Lima. Based on surveys conducted by the company, ore reserves on this 4,000-hectare site in Bima, Sumbawa, West Nusa Tenggara were estimated at 50 million tons of manganese ore and 40 million tons of perlite. By mid-1980, about 15,000 tons of manganese ore was being produced from this area. A special seaport called Sarae Bure, about 22 miles west of Bima, was being constructed at Waworada Bay to handle the ore exports, and a 9-mile road to link the port and the manganese mining site at Pela Simpasai was also being built. The cost of the new port was estimated at $3.2 million, and was expected to be completed by 1981. It was reported that the first 7,000 tons of manganese ore, under a 360,000-ton contract, were shipped to Taiwan in late 1980. The 3-year contract calls for shipment of 120,000 tons of manganese ore to Taiwan annually.[8]

Nickel.—Indonesia remained one of the world's important nickel producers. In 1979, the country's nickel mine output accounted for about 4% of the world's total nickel mine production. Nickel ore mining and smelting were by the state-owned P.T. Aneka Tambang and P.T. International Nickel Indonesia.

P.T. Aneka Tambang operated nickel mines in the Pomalaa area of southeast Sulawesi, and at Oeboelie deposit in Moluccas on Gebe Island, as well as a ferronickel smelter at Pomalaa in Sulawesi. The smelter received annually about 350,000 to 400,000 tons of wet ore containing 2.5% (Ni+Co) from the Pomalaa Mine, and produces about 20,000 tons of ferronickel (high carbon and low carbon) ingots annually. In an effort to boost nickel ore exports, the Government began a feasibility study on developing new mines around Buli Bay in North Moluccas on Gebe. Nickel ore output in 1979 from the Oeboelie deposit was 402,076 tons. Output of nickel ore and ferronickel by the company was exported mainly to Japan.

P.T. International Nickel Indonesia, a subsidiary of International Nickel Co., Ltd., of Canada, operated a large nickel mine and refining facility at Soroako in South Sulawesi. In 1980, most of the production problems had reportedly been resolved by blending the less acidic low-grade nickel ore with more acidic high-grade nickel ore for

the process plant and by adding the cooling devices to the furnaces. Output of nickel in matte from the Soroako operation increased from 8,620 tons in 1979 to 19,500 tons in 1980.[9]

Tin.—In 1980, Indonesia became the world's fourth largest tin producer as the country's output of tin-in-concentrate reached over the 32,000-ton-level for the first time since 1954. The continuing high price of tin and the operation of two new large offshore dredges (Bangka II of P.T. Tambang Timah and Bima of P.T. Riau Tin Mining) were the two contributing factors to the increase in tin output of Indonesia in 1980. Indonesia's tin export earnings climbed 23% to $461 million in 1980 from $376 million recorded in 1979.

Production of tin in Indonesia was by the state-owned P.T. Tambang Timah, and three joint venture companies, P.T. Koba Tin, P.T. Broken Hill Proprietary Indonesia, and P.T. Riau Tin Mining, under a contract-of-work agreement with the Indonesian Government. The country's tin industry employed a total of 29,700 persons in 1980. Over 90% of the total labor force was working in various tin mining areas concentrated on Bangka Island, Belitung Island, and at the Mentok tin processing plant.

P.T. Tambang Timah operated 30 bucketline dredges and 125 hydraulic mines around Bangkinang on Sumatra and Bangka Island, Belitung Island, and the islands of Singkep, Kundur, and Karimum. The firm produced about 85% of the country's total tin production in 1979. About 74% of the firm's tin output was from Bangka; 21% was from Belitung; and the remainder was from Singkep, Kundur, and Karimum. In an effort to increase tin production, as well as replacing the aging dredge fleet (about two-thirds of dredges are 40 years old), the firm's second new large dredge Belitung I, was being built by Mining and Transportation Engineering N.V. of Amsterdam and P.T. McDermott Co. of the United States on Batam Island in Indonesia. The $27 million Belitung I will be able to dredge tin ore up to a depth of 164 feet compared with a depth of 150 feet for Bangka II. Belitung I was scheduled to be completed by April 1981, and would be operating in the Kelapa Kampit area of Belitung. A third new dredge, to be named Singkep I, with the same capacity as Belitung I, would be built during 1981-83 and would be operating in the Kundur and Karimum Island region.[10]

P.T. Koba Tin, a subsidiary of Kajuara Mining Corp. Pty. Ltd. of Australia, operated in the Koba district of Bangka Island. The firm's tin production in 1980 had increased more than four times over production in 1976, and accounted for about 13% of the country's total tin production in 1979.

P.T. Broken Hill Proprietary Indonesia, a subsidiary of the Broken Hill Proprietary Co., Ltd., of Australia, operated an underground tin mine at Kalapa Kampit on Belitung. Its tin production was 469 tons in 1979.

P.T. Riau Tin Mining, a subsidiary of Royal Dutch/Shell Group of the Netherlands, began operating the world's largest dredge in late 1979, offshore Cebia Island and around Tujuh Islands between Bangka and Singkep Islands. The $33 million dredge, Bima, is capable of producing 2,500 tons of tin per year. However, the company produced only 95 tons of tin in 1979 and averaged only 100 tons per month of tin during 1980, because of technical problems and delays.

Production of tin metal in Indonesia was by Peltim, a production unit of P.T. Tambang Timah, at Mentok on Bangka Island. The smelter produced 27,790 tons of tin metal in 1979.

Uranium.—In mid-1980, large uranium deposits were reportedly discovered in a 200-square kilometer area of Ngada district on Flores Island.

An agreement on joint exploration and development of uranium resources in southern Sumatra was expected to be formalized between Indonesia and Japan by the end of 1980. Under the agreement, Japan would provide an estimated $3 million for a 3-year survey, using its technological knowhow and equipment.

The National Atomic Energy Institute of Indonesia decided to suspend investigations in Devel's Hill on Timor Island because of poor prospects for uranium development.

NONMETALS

Cement.—Despite the spectacular growth of Indonesia's cement industry during the 1977-79 period, the country reversed its export position in 1980 to import about 100,000 tons of cement from Japan, the Republic of Korea, and the Philippines to meet the shortage of cement in West Irian, Sulawesi, and North Sumatra areas. The development of the cement shortage in 1980 was caused by a drastic increase in demand for cement because of the construction boom in the country, and a reduction of supply because of the overhaul of two ce-

ment plants. Despite the continuing growth of demand for cement, Indonesia was expected to be a net exporter during the 1981-84 period, and to be in a balance position by 1985. Based on the projection made by Indonesia Cement Association, the country's projected supply and demand for cement was as follows, in thousand tons:

Year	Production	Consumption	Exports
1981	8,400	7,200	1,200
1982	10,130	8,650	1,480
1983	11,810	10,380	1,430
1984	12,726	12,456	1,270
1985	14,947	14,947	--

Total demand for cement in Indonesia was estimated at 6 to 6.3 million tons in 1980. Cement production by company in 1979 and projected capacity by company in 1980-81 were as follows, in thousand tons:

Company	Location	Production 1979	Capacity 1980	Capacity 1981
P.T. Semen Gresik	Gresik, East Java	1,177.4	1,500	1,500
P.T. Semen Cibinong	Narogong, West Java	1,043.8	1,200	1,200
P.T. Indocement	Citeureup, West Java	1,300.3	2,000	2,000
P.T. Semen Nasantara	Cilacap, Central Java	684.4	750	750
P.T. Semen Padang	Indarung, Sumatra	361.5	[1]930	930
P.T. Semen Tonassa	Ujung Pandang, South Sulawesi	128.6	[2]620	620
P.T. Baturaja	Baturaja, South Sumatra	--	--	500
Total		4,696	7,000	7,500

[1]Includes Padang I, 338,000 tons per year; Padang II 600,000 tons per year, which was scheduled for completion during 1980.

[2]Includes Tonassa I, 120,000 tons per year; Tonassa II, 500,000 tons per year, which was scheduled for completion during 1980.

By 1985, three other cement plants were expected to be built at Lhoknga in Aceh, Kupang in Timov, and Bahorok in North Sumatra. P.T. Semen Andalas awarded a $115 million contract to a Japanese Consortium composed of Mitsubishi Corp. and Kobe Steel Ltd. in August 1980. The consortium was to construct a 1-million-ton-per-year capacity cement plant, on a full turnkey basis, at Lhoknga in Aceh on the northern tip of Sumatra. The contract calls for Kobe Steel Ltd. to provide engineering, supply of equipment, and field construction of the plant, including harbor facilities at Lhoknga, and construction of a packing plant in Belawan.[11]

Fertilizer.—Indonesia's fertilizer industry continued to grow in 1980. The industry produced nitrogen, phosphate, and complex fertilizer. Production of nitrogen fertilizers was by two state-owned fertilizer companies, P.T. Pupuk Sriwijaya (Pusri) and P.T. Pupuk Kujan. Production of phosphate and complex fertilizer was by the third state-owned company, P.T. Petrokimia Gresik. Fertilizer production and capacity in 1980 by company and product were as follows, in thousand tons:

Company	Location	Production	Annual capacity	Product
P.T. Pupuk Sriwijaya (Pusri I, II, III, and IV).	Palembang, South Sumatra.	1,400	1,620	Urea.
P.T. Pupuk Kujan	Tjikampak, Java	456	570	Do.
P.T. Petrokimia Gresik	Gresik, East Java	NA	330	Triple superphosphate.
		NA	80	Diammonium phosphate.
		NA	50	Nitrogen, phosphate, and potassium.
	Surabaja, East Java	NA	45	Urea.
		NA	150	Ammonium sulfate.
Total			2,845	

NA Not available.

During the 1976-78 period, about 160,000 to 200,000 tons of nitrogen fertilizer was exported annually to India, the Philippines, Malaysia, Pakistan, and Bangladesh. Despite the continuing growth of the country's nitrogen fertilizer capacity, the exports of urea were cut back substantially in 1980. First, there was a shortage of natural gas feedstock caused by difficulty with equipment in the South Sumatra Gasfield which provides gas to the Palembang fertilizer complex. Second, the domestic demand for the nitrogen fertilizer was rising at a rapid rate, stimulated by various Government price support policies. To keep up with the domestic consumption of nitrogen fertilizer, it was expected that Indonesia would import fertilizer in 1981. Data on three new fertilizer projects, scheduled to be completed by the end of the third 5-year plan, are as follows:

Company	Location	Annual capacity (thousand tons)	Product	Completion date
P.T. Pupuk Kaltim	Bontang, East Kalimantan	258	Urea	1982
P.T. Asean-Aceh Fertilizer	Lhokseumane, Aceh, North Sumatra.	570	do	1984
P.T. Petrokimia Gresik	Tjilatjap, Java	184	Triple, superphosphate.	1985
		12.6	Aluminum fluoride	

P.T. Pupuk Kaltim's project at Bontang involved the installation of a 406,000-ton-per-year N ammonia unit in the urea plant; total project cost was estimated at $240 million, with $150 million foreign financing from West European sources.

P.T. Asean-Aceh fertilizer project, an Asean-sponsored project, reportedly had revised the total development cost to $403 million (was $313 million in 1977), with a $309 million loan from two Japanese Government financial institutions (the Overseas Economic Corporation Fund and the Export-Import Bank of Japan); and the remainder by Indonesia (60%); Malaysia, the Philippines, and Thailand (13% each); and Singapore (1%).

Under an agreement signed in December 1980, Toyo Engineering Corp. of Japan was to supply the fertilizer plant.

P.T. Petrokimia awarded a contract to Sim-Chen Ltd., a member of the Simon Engineering Ltd. group of the United Kingdom, as the technical adviser for the expansion of its fertilizer complex in East Java. The two-stage construction project was to start in 1982 and be completed by 1985. Upon completion of phase 1, a 184,000-ton-per-year triple superphosphate plant would be added to the existing 330,000-ton-per-year plant at Gresik. In phase 2, a 162,000-ton-per-year phosphoric acid plant, a 500,000-ton-per-year sulfuric acid plant, and units for the production of ammonium sulfate and aluminum fluoride were to be added. The total cost of the expansion project was estimated at $250 million.

Other Nonmetals.—Granite production in Indonesia was by P.T. Karimum Granite on Karimun Island and by small operators in many localities. About 32% of the output was consumed domestically, and 68% was exported to neighboring countries (mainly to Singapore).

Iodine was produced by P.T. Kimia Farma, at Watudakon, Mojokerto, East Java, from brines. Output of iodine varied greatly each year. In 1979, about 14,700 kilograms of iodine was exported to Australia (6,800 kilograms), the United States (6,000 kilograms), Taiwan (1,000 kilograms), and New Zealand (900 kilograms).

Kaolin production in Indonesia was by 19 companies operated on Belitung and Bangka Islands, and in North Suluwesi. In 1979, about 74% of the total output was from Belitung Island, and 25% was from Bangka Island. Most of the kaolin output was consumed by the domestic ceramic industry, paint manufacturing, rubber, and cosmetic industries.

Quartz sand and silica stones were produced on Bangka and Belitung Islands, and in Central and East Java. Marble production was by P.T. Industri Marmar Indonesia Tulungagung. Most of the output of marble slabs was shipped to Jakarta and Java Timur to make ornamental stone.

MINERAL FUELS

Coal.—P.N. Tambang Bartubara Bukit Asam, the state-owned company, operates open pit Bukit Asam Mine in South Sumatra (accounting for two-thirds of out-

put), and the underground Ombilin Mine in Sawahlunto, West Sumatra (accounting for one-third of output). In 1979, domestic consumption of coal totaled 188,403 tons; 59,595 tons of coal was exported mainly to Malaysia (40%), Taiwan (28%), and Thailand (15%). The configuration of domestic coal consumption in 1979 by end use was as follows, in tons:

Railroad, state-owned company-PJKA	26,125
Tin smelting, state-owned company-P.T. Timah	26,225
Nickel smelting, state-owned company-P.T. Aneka Tambang	12,002
Cement plant, state-owned company-P.T. Semen Padang	56,896
Coal mines	57,815
Other	9,340
Total	188,403

P.N. Tambang Batubara reportedly was to purchase five bucket-wheel excavators from Rheinbraun of Cologne of the Federal Republic of Germany. Rheinbraun was to be placed in charge of mine site development at Bukit Asam. A Canadian consortium (Montreal Engineering, Swan Wooster, and Canadian Pacific) completed a study on coal transportation and an upgraded railway system to a new port on the southern tip of South Sumatra. The study reportedly had been submitted to the Government of Indonesia in October 1979. Alternative routes (eastern route and southern route) were proposed by the consortium, and the Government had decided in favor of the southern route. This route would have a longer rail haul, which would run across South Sumatra to open up the agriculture of Lampung Province, as well as to assist cement transport from the forthcoming Baturaja cement plant to West Java. Total capital investment, including interest during construction, was estimated at $830 million. The financing of the project would be sponsored by the World Bank. In June 1980, the Federal Republic of Germany reportedly would extend a loan of 120 million deutsche marks to Indonesia, and a portion of this loan would be allocated to the mine development and expansion of Bukit Asam.

An agreement between Indonesia and the French Government was signed in mid-1980 for building a 100-megawatt coal-fired powerplant in the Bukit Asam mining area. About one-half of the plant's generating capacity would be utilized for coal production, and the remaining surplus electricity would be for general distribution in the South Sumatra area. Construction of the powerplant was expected to begin in 1981 with aid of approximately 420 million francs from the French Government and technical assistance in design by a French consulting firm, Sofrelec. Babcock & Wilcox Canada Ltd. and Marubeni Corp. of Japan were awarded a contract worth more than $150 million to supply a 800-megawatt coal-fired powerplant at Suralaya in West Java. The powerplant was scheduled to be operational in 1984 and to supply electricity to Jakarta and Central Java.[12]

A coal preparation plant, with an hourly capacity of 150 tons, was being built at Ombilin with a $4 million Australian Government loan. The preparation plant was scheduled to be completed in 1981.

Based on the latest Government figures, coal reserves at Bukit Asam were estimated at 223 million tons of subbituminous coal. Heat value ranged between 5,000 and 6,500 calories per gram, and the coal contained up to 3% ash and less than 0.5% sulfur. Coal reserves at Ombilin were estimated at 95 million tons of coal, with heat value averaging 7,000 calories per gram, up to 7% ash and averaging 0.5% sulfur. Most of the coal from the mines is suitable for fuel in electric powerplants and as industrial fuel, such as for coal-fired cement plants.

Petroleum and Natural Gas.—Indonesia's crude oil production continued its decline throughout 1980, and output averaged 1.56 million barrels per day. The total output of crude oil for 1980 represented an 11% drop from output of 1979. Beginning in 1981, oil output was expected to be about 1.64 million barrels per day and gradually increase to 1.83 million barrels per day by 1983.

P.T. Caltex Pacific Indonesia (CPI), the largest single crude oil producer in Indonesia, started oil production at its seven new fields in Central Sumatra on March 3, 1980. Beruk Oilfield, located about 36 miles east-southeast of CPI's Minas Field (north of Pakanbaru), was producing 23,000 barrels per day from 10 wells in 1980. Six new oilfields—Tanjung Medan, Buaya, Kerang, Jorang, Rokiri, and Topi (all located northwest of the Minas Field)—were producing at a combined total of 19,000 barrels per day. The total 42,000-barrel-per-day output of oil from these seven new fields helped CPI to maintain its 750,000-barrel-per-day output in 1980. The Beruk Oilfield is only part of CPI's Beruk-Zamrud project, that includ-

ed Beruk, Northeast Beruk, Bamgus, and Zamrud. The entire Beruk-Zamrud project was expected to be completed with a peak production rate of 80,000 barrels per day of oil in 1983. The total project cost was estimated at $87.2 million.[13] CPI (50% owned by Texaco Inc. and 50% by Standard Oil Co. of California) operates as a contractor to Indonesia's state-owned oil company, Pertamina; CPI produced about 48% of the country's total oil output in 1980.

Independent Indonesia American Petroleum Co. (Iiapco), the fifth largest crude oil producer in Indonesia, began production at the newly discovered Krisna Oilfield in December 1980. The Krisna Field, located offshore southeast of Southeastern Sumatra, was discovered in 1976 near the company's Cinta-Rama oil production complex. By June 1980, 10 development wells were sunk. The field's first production platform came onstream with an initial production of 36,000 barrels per day of oil in December 1980. The second platform was scheduled to come onstream with an output of 20,000 barrels per day of oil in February 1981. The combined total output of 55,000 to 56,000 barrels per day of oil could be stabilized to about 40,000 barrels per day by 1981.[14] Iiapco, a division of Natomas International Co. of San Francisco (United States) operating as a contractor to Pertamina, produced about 5% of the country's total crude oil in 1980.

During 1980, numerous new oil and gas wells were discovered in Indonesia. The following summarizes only the significant discoveries by seven companies (flow data for oil given in barrels per day and for gas, million cubic feet):

Company and well name	1980	Location	Well	Flow oil (barrels per day) gas (million ft³)
Atlantic Richfield Indonesia:				
ETA	July	Offshore north of West Java	Oil	4,700
UV	do	do	Oil	3,400
UX	do	do	Oil	3,200
Bangkudulis-1	March	Onshore East Kalimantan	Oil	6,000
SW Sembankung-1	do	Onshore Northeast Kalimantan.	Oil	2,500
PSI UY-1	September	Offshore Southeast Sumatra.	Oil	3,000
Union Oil of Indonesia:				
Attaka 16	February	Offshore East Kalimantan	Oil	2,286
Attaka 18	August	do	Oil	11,385
Hudbay Oil (Malacca Strait):				
MUS-2	do	Offshore Northeast Sumatra.	Oil	7,092
Total Indonesie (CEP):				
N Tambora-1	May	Onshore East Kalimantan	Oil	2,360
Serban-1	March	Offshore East Kalimantan	Gas	19
Marathon Petroleum Indonesia:				
KH-IX	September	Offshore Natuna-Kakap	Oil	7,246
Mobil Oil Indonesia:				
S Lhok Sukon-A3	February	Onshore North Sumatra	Oil	188
			Gas	19.3
P.T. Caltex Pacific Indonesia:				
Pancake-1	June	Onshore South Sumatra	Oil	864
			Gas	7.1

Under attractive contractual environment for the new joint venture arrangements, oil exploration activities in Indonesia continued to increase in 1980. Based on Indonesian Government statistics, more than 200 exploratory wells were drilled in 1980 compared with 130 wells in 1979. During 1980, a total of 11 new production-sharing contracts were signed.[15]

Contractor	1980	Contract area (square kilometers)
Phillips	January	Irian Java-Kamura (22,305).
Amoco	do	Irian Java-Waipona (15,250).
Esso Exploration and Production Natuna.	May	Natuna Sea Block D-Alpha (5,700).
Union Texas	do	Tomori Block (5,700).
Conoco	June	Central Sumatra (6,500).
	November	Java Sea-Karimum Block (17,000).
Total Indonesie	June	Natuna, Block D-III (5,125).
	do	E. Kalimantan, Spasu Block (905).
Union	November	Java Sea-Madura (17,340).
Atlantic Richfield	do	Java Sea-Kangean Island (18,305).
AGIP/Ina Naftaplin	do	Java Sea-North of Bali (16,925).

The Government of Indonesia awarded a $950 million contract in February 1980 to two Spanish companies, Técnicas Reunidas and Centurnón (TRC) to build a hydrocracker unit for the Dumai oil refinery in Central Sumatra. Union Oil Products, Inc., of the United States was appointed as a licensee and the designer of the nine process units, utilities, and offsite facilities. Indonesia reportedly would finance the entire expansion project of the Dumai refinery itself. Upon completion of the Dumai refinery expansion in 1983, a daily output of 85,000 barrels would be added to the current capacity of 100,000 barrels per day.

In late 1980, the Government of Indonesia signed contracts with Bechtel Great Britain Ltd. for refinery expansion at Balikpapan in East Kalimantan. Fluor Engineers and Contractors of the United States was chosen for the refinery expansion project at Cilacap in Central Java. An additional 200,000-barrel-per-day capacity was to be added to each existing refinery by 1983. The total cost of both projects was estimated at more than $1.7 billion. In late 1980, the Japanese Government reportedly was prepared to provide $500 million of credit assistance to Indonesia for the expansion of both oil refineries.

Indonesia's natural gas production for 1980 remained at about the same level as that of 1979. The main use for the country's natural gas was by two state-owned LNG plants. The larger LNG complex at Arun, Aceh, was operating at full capacity (4.8 million tons per year) with three trains, and the LNG plant at Bontang, East Kalimantan, was also operating near full capacity (3.2 million tons per year) with two trains.

In order to increase LNG exports to Japan, Indonesia planned to double the existing capacity (8 million tons per year) of two LNG plants by 1983. Bechtel of the United States was to be awarded a $850 million contract as a major contractor for doubling the annual LNG capacity to 6.4 million tons per year at the Bontang plant in East Kalimantan. Construction was to start in early 1981 and to be completed by 1983. Financing of this LNG expansion project would be from four Japanese utilities, with an $800 million cash advance. In mid-1980, Pertamina and the Government of Japan were negotiating the financing of expanding the Arun LNG plant in North Sumatra from the current annual capacity of 4.5 million tons to 7.5 million tons by 1983. An agreement was finally reached in November 1980 between Indonesia and Japan for the construction of two additional production units under a Japanese loan.

Indonesia was ranked the 10th largest oil exporter in the world. Although the tonnage of crude oil exports declined in 1980, export earnings from crude oil increased about 50%, from $8.6 billion in 1979 to $13 billion in 1980.

Indonesian exports of LNG from Arun and Bontang earned over $1.5 billion in foreign exchange for 1980.

The Mineral Industry of Iran

By George A. Morgan[1]

The disruptions in the Iranian economy, brought on by the revolution that began in 1978 and continued through 1979, worsened in 1980. Major changes were affected in the position of Iran as a significant petroleum producer and in the development of its mineral industry. Exports of crude oil and refined products were nearly brought to a halt in April when the United States, the major trading partner, broke diplomatic relations and initiated economic sanctions for what it termed were breeches of international law by Iran. Subsequent support for the position by the members of the European Economic Community and Japan resulted in the loss of established export markets for the country's principal products. Military skirmishes with Iraq over border disputes in early 1980 erupted into open warfare in September. With the country in a state of war, the already meager amount of information on the country's mineral industry was further reduced. There were persistent reports of unavailability of parts and skilled labor. Rationing became commonplace as the impairment or complete destruction of oil and natural gas facilities forced the country to purchase supplies for which it had formally been self-sufficient, such as kerosine and jet fuel. Numerous reorganizations of Government agencies and private industry occurred as the Government attempted to follow up on its policy of nationalization and emphasis on domestic markets. A Ministry of Mines and Metallurgy was to be created to achieve greater control over mining and smelting operations.

PRODUCTION AND TRADE

At yearend 1980, a number of major oilfields in Khuzestan Province, such as Marun, Gach Saran, and Aghajari, appeared jeopardized due to fighting between Iran and Iraq. Kharg Island, the export terminal through which was shipped most of the crude oil produced in Khuzestan, was heavily damaged, while insurance rates for tankers sailing the Persian Gulf increased 300%. Crude oil continued to be exported through the Lavan Island and Sirri terminals, with capacities of 100,000 and 40,000 barrels per day, respectively. Some crude was also reported for sale at Kharg Island in late December for $28 per barrel, $7 below the official price, to compensate for increased insurance rates.

Although imports of iron and steel from the Federal Republic of Germany and France have been reduced significantly, the country imported large quantities of steel products in mid-1980, mainly from Belgium and Japan. The National Trading Co. had announced that it planned the import of considerably more iron and steel in 1980 than in 1979. Between April and June imports from Japan were at the rate of 130,000 to 150,000 tons per month.

Table 1.—Iran: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity[2]	1976	1977	1978	1979[p]	1980[e]

[e]Estimated. [p]Preliminary. NA Not available.

[1]Data are for years beginning Mar. 21 of that stated, except those for natural gas, natural gas liquids, and petroleum, which are for regular calendar years. Table includes data available through June 15, 1981.

[2]In addition to the commodities listed, other types of crude construction materials (such as common clays, sand and gravel, and other varieties of stone) are produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[3]Excludes petroleum reinjected into fields.

COMMODITY REVIEW

METALS

Chromite.—The decline in output of chromite in recent years is substantial from a high of over 230,000 tons in 1977. The major portion of production has been derived from the southern area of Iran. Exports of a significant portion of production have gen-

erally been to Japan and Eastern Europe. In 1980, approximately 20,000 tons were reported exported to the U.S.S.R.[2]

Copper.—Iran's major copper development project at Sar Cheshmeh continued to be stalled. Begun in 1973, and estimated to cost $1.4 billion, the operation entailed development of a deposit estimated to contain 450 million tons of ore grading 1.13% copper. Most of the complex infrastructure requirement for the remote region was completed by yearend 1978, and ore production had begun, but work was suspended following withdrawal of foreign personnel because of the revolution. The Government reported that production would be 145,000 tons per year, with output destined solely for the domestic market.[3] Reliance was being placed on local industry to furnish equipment and service for the smelter, as well as for construction of the refinery.

Shipments of concentrates from the Minakan Mine in eastern Khorassan Province, mainly to Japan, were resumed in early 1980 following their interruption during the height of the revolution. Total production was 14,000 tons per year of concentrate.[4]

Iron Ore.—The extent of Iranian participation in the iron ore project at Kundremukh, India, continues to be uncertain, despite commitment of $630 million and the near startup of ore production. Output was originally slated for the Iranian iron and steel industry. However, other alternatives for marketing a portion of the ore are being explored as Iran has declared it intends to purchase only 4.5 million tons per year instead of the 7.5 million tons per year originally contracted.

Iron and Steel.—The Aryamehr Steel Plant of the National Iranian Steel Corp. (NISC) at Isfahan has a reported capacity of 1.5 million tons per year of crude steel. The plant was built with conventional technology under Soviet supervision. Production was less than half of capacity because of coal supply problems.[5]

The most recent plans for construction of a $1.5 billion steelworks near Isfahan by Italimpianti remain intact following renegotiation of the original contract. Source of iron for the plant is to be the deposit at Kudremukh, India, under joint development by both countries. However, ore from the Gol-e-Gowhar deposit in the Kerman area was also reported to be a possible source.[6]

NONMETALS

Phosphate Rock.—The French Bureau de Récherches Géologiques et Miniéres and its Iranian partner GEOMETAL continued work on a major contract for the National Petrochemical Co. The project involved detailed exploration of two specific areas in central Elburz and northeastern Zagros, as well as a technical-economic study of deposits already detected in southern Iran.

MINERAL FUELS

Coal.—Efforts were made to increase the supply of locally produced coal, particularly in the Kerman region, for use in the Isfahan Steel Plant of NISC. The Kerman Province deposit has been a good source of coking coal and, if blended with coal from other mines, may extend the supply of acceptable coking coals.

Natural Gas.—The new Government continued to emphasize development of ongoing natural gas projects primarily for domestic needs rather than for the export market. The Gevarzin Gas Processing Plant at Qeshm Island began operations in May with a capacity of 75 million cubic feet per day. A 12-inch gas pipeline extending 70 kilometers to Bandar Abbas to supply a 320-megawatt power station was also placed in operation.

Repair work neared completion in the Pars Field following an underground blowout that occurred in September 1977. Reserves of the natural gasfield were put at 54 trillion cubic feet.[7]

Exports of natural gas to the U.S.S.R. in early 1980 were reported at only 15% of the 10 billion cubic feet per year contracted. Associated gas from the Khuzestan Oilfields was shipped to the U.S.S.R. through the Iranian Gas Truckline (IGAT-1) pipeline. The two countries were renegotiating the price for the gas as well as the amount shipped. Iran claimed its gas requirements were increasing, particularly for reinjection to maintain pressure in the Khuzestan Oilfields. However, a landslide reportedly cut the pipeline in March and by April exports of gas to the U.S.S.R. were officially terminated, with all supply to be used internally.[8] By October, military operations between Iran and Iraq in the Khuzestan area jeopardized production from many of the major oilfields.

Petrochemicals.—Work was reported to again be underway on the long delayed petrochemical complex at Bandar Kho-

meini.[9] The project by the Iran Japan Petrochemical Co. was begun in 1973 at a cost of $500 million. Present cost for the complex is now put at $3.3 billion including $750 million in excess interest payments incurred during the revolution. In early 1980, delays reportedly were adding about $420,000 per day in interest payments and wages. The plant is to use flared gas from the Ahwaz and Marun Oilfields. Output is planned at 1.9 million tons of liquefied petroleum gas (LPG) plus 1 million tons of other products.

The Raze chemical complex increased production of urea to 19,150 tons in June. Output of 950 tons per day of sulfur and 800 tons per day of ammonia was also reported. Phosphorus production was expected to resume shortly using Moroccan phosphate rock in place of the U.S. supply.

Petroleum.—Production and exports of crude petroleum stabilized for a brief period in early 1980 following nearly a 50% reduction between 1978 and 1979. In late March insurgent action cut the supply of 15,000 barrels per day of crude oil to the Kermanshah refinery as well as severing seven oil and gas pipelines supplying the Abadan refinery. Output at the refinery was cut from 580,000 barrels per day to 395,000 barrels per day. Military clashes with Iraq occurred sporadically during this time. Losses of traditional export markets for Iranian crude and refined products following the imposition of economic sanctions by the United States and other countries resulted in major changes in production policy and severe inbalances in fuel supply. Storage tanks were filled with unusable residual fuel while lighter fuels were used internally. In late September, open conflict with Iraq placed the country in a state of war, with many petroleum and gas installations and pipelines being damaged or destroyed. By mid-October both the Abadan and Tabriz refineries with capacities of 700,000 and 80,000 barrels per day, respectively, were considered totally inoperative. The Abadan refinery accounted for 70% of all product output for Iran. The Kermanshah refinery also was inoperative. The recently completed Isfahan refinery with a capacity of 100,000 barrels per day and the Shiraz refinery with a throughput of 40,000 barrels per day were believed still operational at yearend. The Teheran refinery was reported damaged and operating below its 275,000-barrel-per-day capacity.[10] Offloading facilities at Kharg Island were severely damaged, but at yearend Iran was offering crude at the terminal at reduced rates.[11]

The Mineral Industry of Iraq

By Suzann C. Ambrosio[1]

The petroleum sector continued to dominate the mineral industry in Iraq. Despite the interruptions caused by the Iran-Iraq war, Iraq remained the second largest Middle East crude oil producer and exporter after Saudi Arabia. Iraqi crude oil output of roughly 3.2 million barrels per day, represented approximately 4% of the world's total production during 1980. Crude oil exports reached approximately 2.2 million barrels per day and represented nearly 8% of the 1980 oil exports of the market-economy countries.

Petroleum accounted for over 99% of Iraq's total export bill during 1980. Oil revenues were estimated to approach $30 billion, and the total import bill was estimated at $14.6 billion.[2] The country's overall trade balance increased nearly 30% over the 1979 balance to approximately $15 billion.

Iraq's gross national product was projected to grow at an average annual rate of 16.6% over the period (1976-80) of the 5-year plan. When oil exports were halted late in the year, Government officials announced that the economy could be sustained for an entire year without oil revenues, utilizing gold and foreign exchange reserves. The country's reserves were estimated to exceed $20 billion by yearend 1980. The strength of the economy lies primarily with petroleum reserves; however, the growing agricultural and industrial sectors have made increasing contributions. Major obstacles which have impeded economic development included lack of a skilled workforce and insufficient infrastructure. Economic growth stagnated during the war because most of the million expatriate technicians departed.

The war also delayed oil exploration and drilling projects. Mobil Corp. was conducting advanced seismic tests just west of Baghdad during 1980. The analyses indicated the presence of a huge oil reservoir, which could potentially double Iraq's production capacity by 1990. Mobil, Exxon Corp., and two French oil companies were expected to resume their investigations early in 1981.

The Iraqi Government continued to get involved in all phases of the petroleum industry. Plans were underway to develop the Majnoon, Nahr Umr, Halfayah, Ghart al-Qurnah, and Baghdad oilfields. In December 1979, Iraq's National Oil Co. (INOC) acquired Braspetro's (Brazil) holdings of the first two fields, thereby acquiring control over all the country's operating and most promising petroleum fields.

In July of 1980, the Iraqi Revolutionary Command Council (RCC) organized a Supreme Technical Authority to supervise all phases of new oil development projects. In addition, a Projects Development Department was created within INOC and was given ultimate delegation and implementation authorities over the new oilfields. The RCC set up the General Establishment for Liquefied Petroleum Gas, affiliated to Iraq's State Corp. for Oil Projects (SCOP), which is expected to operate and manage the refineries and associated facilities for the Northern and Southern gas projects.

Iraq declared force majeure late in September 1980, thereby legally excusing the country from previously signed contracts. The Iran-Iraq war escalated from the cancellation of the 1975 Shatt al Arab border accord with Iran, to heavy ground force movements in the southern two-thirds of the border and air raids in the mountainous northern border between the two countries. Iraq's oilfields near Kirkuk, Mosul, and Basrah were repeatedly attacked. Kirkuk pumping stations and the Kirkuk-Dortyol

pipeline were damaged. Oil export terminals on the Persian Gulf at Fao, Mina al-Bakr, and Khor al-Amaya were reported to be heavily damaged. The Basrah and Daura petroleum refineries were also attacked. War damages were assessed in November 1980, and repair costs were estimated at $3 to $4 billion. Most of Iraq's petroleum exports were halted by yearend 1980. Trade patterns were changed, and the Jordanian Port of Aqaba became Iraq's vital link to the rest of the world.

PRODUCTION AND TRADE

Crude oil output declined by approximately 25% during 1980; however, the value of exports increased by approximately 23% over exports of the previous year. Production capacities were increased for natural gas facilities and other crude petroleum refineries. Iraq's domestic market required nearly 10% of the oil produced and 100% of the refined products. Contracts were signed to expand petroleum products for domestic consumption and export markets. Natural gas refining and petrochemical industries were expected to play an increasing role in Iraq's trade.

In the nonfuel mineral sector, production and exports increased in the sulfur and fertilizer industries. Expanded facilities and the achievement of greater production efficiences were largely responsible for the growth in output. Production of cement and steel was increased, and therefore less imports were required to meet domestic needs. These trends were expected to continue, and the Government set objectives to triple cement and quadruple steel output.

The volume of trade between the United States and Iraq, although relatively small, continued to increase. The value of U.S. exports increased by 34% in 1979 and were projected to exceed that level during 1980. The renewed oil supply contracts fixed the volume, and prices were deemed subject to change. The U.S. trade deficit with Iraq was projected to reach approximately $500 million by yearend 1980.

Table 1.—Iraq: Production of mineral commodities[1]

Commodity[2] and unit of measure	1976	1977	1978	1979[p]	1980[e]
Cement, hydraulic thousand metric tons	2,728	3,170	4,600	5,100	5,300
Gas, natural:					
Gross million cubic feet	380,000	[e] [3]370,802	[e] [3]388,460	560,000	430,000
Marketed[4] do.	74,408	56,502	60,035	78,751	79,000

Byproduct[e] do.	40	40	40	70	60
Total do.	622	660	640	620	660

[e]Estimated. [p]Preliminary. NA Not available.

[1]Includes data available through July 16, 1981.

[2]In addition to the commodities listed, lime and a variety of crude construction materials (clays, stone, and sand and gravel) are also produced, but output is not reported, and available information is inadequate to make reliable estimates of output levels. In addition, limited, unreported quantities of phosphate rock may have been produced for test purposes prior to inauguration of commercial production at the Al-Qaim chemical complex.

[3]Reported as estimated.

[4]Includes reinjected, if any.

COMMODITY REVIEW

METALS

Iron and Steel.—The Khor Al Zubair steelworks operated near capacity of 400,000 tons per year during 1980. Creusot Loire (France) was nearing the completion of the semi-integrated steelworks and it expanded installations by yearend 1980. The steel complex was to include two HyL direct-reduction units, with capacities of 1,467 tons per day and 2,500 tons per day, respectively, a melting shop with four UHP electric-arc furnaces feeding 80% sponge iron and 20% scrap, and two 6-strand curved-mold continuous casters. The total carbon steel production capacity was designed at 440,000 tons per year. Billets were to be cast at 80, 100, 120, and 150 millimeters. The rolling mills consisted of two walking beam reheating furnaces with average capacities of 50 tons per hour, a 17-strand merchant bar mill, and a 4-strand medium section mill.[3] A raw materials handling installation was constructed for iron imports. The berth located at Um Kasr was designed to accommodate bulk carriers with a maximum of 100,000 tons.

NONMETALS

Cement.—Iraq's cement industry set a production capacity goal at 9 million tons per year for 1980. Although approximately a 7-million-ton-per-year capacity was achieved, contracts were signed to add another 3 million tons during the year. Two Japanese companies, Kawasaki Heavy Industries and Marubeni Corp., won contracts worth $230 million to construct cement factories at Al Tamin and Hit, near Baghdad. The cement plants were expected to produce approximately 2 million tons per year by yearend 1982. Fives-Cail Babcock, a French construction company, was expected to build a dry-process cement production line for the existing Badoosh plant near Mosul. The facility was expected to add 3,200 tons per day to production capacity by 1983, at a cost of $150 million.

Fertilizer Materials.—*Nitrogenous.*— The Khor Al Zubair fertilizer complex was comprised of two main units for the production of 2,000 tons per day of ammonia, 3,200 tons per day of urea, and 419,000 cubic meters of carbon dioxide. The first phase of the complex was completed late in 1979. The second phase was expected to be completed within the decade and add two more ammonia and urea processing units.

Iraq's State Organization for Minerals (SOM) considered constructing an ammonia plant for the Al Qaim fertilizer complex, which would require ammonia for ammonium phosphate and other complex fertilizers. A small, 150-ton-per-day skid-mounted ammonia facility was expected to be installed downstream from the Al Qaim plant. Natural gas for the ammonia production was expected to be supplied by Kirkuk. The entire complex was slated for completion by 1983.

Phosphorous.—The Akashat phosphate rock mine and the Al Qaim fertilizer complex with production capacities of 3.4 million tons per year and 1.1 million tons per year respectively, were nearing completion by yearend 1980. Syndicate Belge d'Enterprises a l'Etrange, 44% owned by Belgium and 56% owned by SOM, continued construction on the complex. The facility was designed to produce phosphoric acid, sulfuric acid, triple superphosphoric acid, and fertilizer products.

Salt.—The construction of a salt production complex in southern Iraq continued through 1980. The project was expected to supply 525,000 tons per year of industrial salt and 75,000 tons per year of packaged table salt for domestic consumption by yearend 1981.

Sulfur.—Sulfur was produced at an average 70% capacity from the Mishraq mines, and at an average 35% capacity from the Kirkuk natural gas desulfurization units during 1980. Despite the war and subsequent declines in output, production continued to exceed domestic demands. Increased consumption was expected to occur when the Basrah petrochemical refinery and as the Akashat-Qaim fertilizer complex were completed. Over the next 2 years, sulfur exports were expected to decline because roughly 500,000 tons of sulfuric acid would be diverted into fertilizer and petrochemical production.

In 1980, SOM signed a $49 million contract with a Japanese firm to construct a sulfur recovery unit near the Kirkuk refinery and a sulfuric acid plant at Mishraq. Contaminated sulfur from Mishraq's sulfur extraction process was expected to be refined by a recovery unit with a 150,000-ton-per-year capacity. The sulfuric acid plant was expected to have a capacity of 60,000 tons per year. The Mishraq Mine was in the process of becoming an integrated sulfur complex through the expansion of products,

to sulfuric acid, powdered sulfur, and alum.

MINERAL FUELS

Natural Gas.—Iraq continued to flare approximately 80% of the natural gas produced in association with crude petroleum. Small quantities of petroleum were refined into butane and propane, and marketed as liquefied petroleum gases (LPG). Total LPG plant capacity was approximately 4.3 billion barrels per year in 1979. The Oil Refineries Administration (ORA) and SCOP continued to operate refining facilities at Zubair, Basrah, and Kirkuk. During 1980, LPG units were added to the Daura refinery, and a $120 million gas liquefaction plant was completed at Zubair. In addition, a natural gas liquids (NGL) plant, which recovers the gas from various processing, pipeline, and dehydration plants, was completed at Rumaila.

Contracts continued to be awarded, and construction was initiated for the large gas-gathering and production schemes in the northern and southern regions of Iraq. The two natural gas projects undergoing construction during 1980 were targeted for different markets—domestic consumption in the north, and fertilizer production and exports in the south.

Mitsubishi Corp. and Mitsubishi Heavy Industries (Japan) won a $214 million turnkey contract for the Northern Gas Project. Compressors and fractionator facilities were expected to be provided with capacities of 2.8 million cubic feet per day. Ingeco Laing (Switzerland) subcontracted $16.5 million worth for distillation and ancilliary equipment. Toyo Engineering (Japan) was preparing the overall engineering design, and India's Dodsal was expected to lay 400 kilometers of gas-gathering and transmission lines for the project. Approximately 15 million barrels per year of LPG were expected to be processed in Kirkuk and distributed to Baghdad and other northern Iraqi cities.

Rapid development of the Rumaila oilfields allowed for a 30% expansion of the original Southern Gas Project contract that was signed in 1978. The new plant was expected to produce approximately 4 million tons per year of propane and butane and 1.5 million tons per year of condensate. Snamprogetti (Italy) was expected to handle the basic engineering design. Technip (France) was expected to construct a $240 million gas liquefaction plant at Zubair near Basrah. Nuovo Pigone (Italy) was awarded a $200 million contract for the construction of a gas-processing plant at Basrah and associated gas-gathering centers. Chiyoda and Mitsubishi (Japan) were awarded a $138 million turnkey contract to construct the NGL fractionator plant in Baiji. Toyo Engineering (Japan) was expected to build the LPG export terminal at Khor al-Zubair at a cost of $72 million. The entire southern gas project was expected to be completed in 1982.

Petroleum.—Proven oil reserves were estimated at 30 billion barrels in 1980. Crude oil production capacity was rated at over 4 million barrels per day, and the total oil refinery capacity was projected to reach 200,000 barrels per day. Actual crude oil output was reported between 3 and 3.5 million barrels per day through August 1980. There were approximately 250 producing wells for most of the year. Iraq's major operating and projected oilfields are shown in the following tabulation:

Table 2.—Major oilfields in Iraq, 1980[1]

Oilfield	Capacity[e] (millions of barrels per day)	Discovery date[2]	API gravity	Depth (feet)
Kirkuk	1.45	1927	36.0	2,800-4,200
Northern Rumaila and Rumaila.	.90	1958 (1972)	34.0	10,000-10,800
Zubair	.55	1949	34.2	11,000
Laheis	.51	(1978)	NA	NA
Bai Hasen		1953	34.0	4,800-5,400
Jambur	.30	1954	38.0	5,500-12,500
Abu Ghurab:				
Buzurgan and Jabal Faugui.	.20	(1976)	27.7	NA
Majnoon:				
Phase 1	.35	(1982)	NA	NA
Phase 2	.75	(1983)	NA	NA

[e]Estimated. NA Not available.
[1]Based on published figures prior to the Iran-Iraq war.
[2]Startup date is in parentheses.

Refining.—Prior to the war in 1980, ORA operated seven refineries. The total distillation capacity was approximately 170,000 barrels per day. Compared with the other oil-producing Middle East countries, Iraq represented a small fraction equivalent to 4% of the area's combined refining capacities. Plans were made to expand the refineries in order to supply domestic transport and the growing demands of commercial industries for middle distillates.

Construction continued on the Baiji plant, which was expected to add 220,000 barrels per day to existing capacity. Phase 1 of the Baiji project was expected to contribute 70,000 barrels per day by 1981. Snamprogetti won the contract for the engineering design and Czechoslovavia's Technoexport and Chemoprojekt were contracted for phase 1. Mitsubishi and Chiyoda won the $283 million contract for Baiji phase 2, which was expected to add 150,000 barrels per day by mid-1983. Another contract was signed during 1980 between SCOP and Snamprogetti for a 4,800-barrel-per-day lubricating oil plant at Baiji. The same company was nearing the completion of a $138 million, 1,900-barrel-per-day lubricating oil plant at Basrah.

Petrochemicals.—Lummus (Netherlands) won the contract for a $1 billion, 700,000 ton-per-year petrochemical complex in Basrah. The plant was expected to produce 150,000 tons per year of polyvinyl chloride, 135,000 tons per year of ethylene, 40,000 tons per year of caustic soda, and small amounts of other assorted organic chemicals.

Iraq's Ministry of Mines, Industry of Minerals, signed a technical assistance agreement with Norway's Saga Petrokjemi during 1980. The contract called for Iraqi technicians to be trained at Saga's Bamble petrochemical plant in Norway. The initial group of Iraq technicians were expected to supply a skilled workforce for the Basrah complex. Startup for the Basrah petrochemical facility was projected for 1981; however, the plant site was heavily bombed in September 1980.

Pipelines.—Iraq had a network of oil and gas pipelines connecting the major oil producing areas of Kirkuk, Zubair, and Bai Hasan. Because Iraq had approximately 50 miles of navigable coastline and therefore limited access to the Persian Gulf, pipelines were built to link the Kirkuk fields to the Mediterranean across Syria, and from the Port of Fao in southern Iraq to the Mediterranean, via Turkey. Iraq's pipeline system included a two-way, reversible flow, north-south pipeline which was designed to deliver up to 1 million barrels per day of Kirkuk crude southwards to the gulf terminals or approximately 900,000 barrels per day of Basrah crude northwards to the Mediterranean export terminals. An alternative route to the Mediterranean was provided with the commissioning of the newest line in 1978, from Kirkuk to Turkey's Port of Ceyhan.

Prior to the damages incurred by the Iran-Iraq war, throughput via the trans-Turkey pipelines was near capacity at 650,000 barrels per day. The trans-Syrian pipeline, with a designed capacity of 1.4 million barrels per day, was closed in 1976 because of transit fee disputes. However, the pipeline was briefly reopened in 1980 to accommodate Iraq's oil exports. During brief periods in November and December 1980, an estimated maximum of 1.2 million barrels per day could be exported through the Mediterranean ports. Oil exports through the gulf had ceased altogether during the initial weeks of the war.

The Mineral Industry of Ireland

By William F. Keyes[1]

The Irish economy was affected by the general economic slowdown in its major trading partners, and the gross national product was expected to reach only about $16 billion, or a 1% growth over 1979, allowing for inflation of about 15%. Mining and mineral production grew faster than the economy, however, as a major zinc-lead mine came into full production, and expansion continued in peat, natural gas, and the small coal industry. Difficulties, largely consisting of labor disputes, continued to plague the aluminum, nitrogen, and other industries.

The Minerals Development Act, 1979, was passed late in 1979, repealing certain sections of the Minerals Development Act, 1940. The purpose of the new act was to eliminate the deterrent posed to new exploration by uncertainties over mineral rights.

The major feature of the 1979 act was the vesting, in the Minister for Industry, Commerce, and Energy, of the "exclusive right of working minerals." (Hydrocarbons are excluded and are covered by the Petroleum and Other Minerals Development Act, 1960, which vests petroleum—liquid and gaseous hydrocarbons—in the Minister.) The act does not mention the controversial problem of ownership and does not apply to persons who were lawfully working mines prior to December 15, 1978. Provisions were made for these parties to register their minerals as "excepted." Such registration may be canceled if deposits are underworked or not worked at all. If the Minister does not exercise his right to work a mineral deposit covered by the act, he is empowered to grant a license to work it to another party. In such cases, the Minister must give advance public notice of his intention and take into account the views of interested individuals. When the Government exercises its rights under the new act, the Minister is obliged to publicly notify persons entitled to compensation and to pay such compensation. The act provides an appeal process in case of disputes, as well as general guidelines for assessing fair compensation.

In practice, almost all mining in Ireland has been done by private corporations, including a number of non-Irish corporations. Hydrocarbon exploration has been conducted by a number of non-Irish firms, including an American firm that found the only commercially exploitable natural gasfield yet discovered; several American firms were currently searching for oil in Irish offshore waters.

PRODUCTION

Production of minerals in 1978, 1979, and 1980 is given in table 1.

Table 1.—Ireland: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity[2]	1976	1977	1978	1979	1980[p]

eEstimated. pPreliminary. rRevised. NA Not available.

[1]Table includes data available through Aug. 24, 1981.

[2]In addition to the commodities listed, substantial quantities of stone and sand and gravel are produced by local authorities and road contractors. In 1976, the latest year for which such data are available, this output included 418,650 tons of sand and gravel, 193,779 tons of limestone, and 260,788 tons of various other stones. Ireland also produces significant quantities of manufactured diamond, but output is not quantitatively reported, and available general information is inadequate to make reliable estimates of output levels.

[3]Excludes output by local authorities.

[4]Figures given as reported in source; includes granite, marble, silica rock, sand, calcspar, fire clay, and slate and clays for cement production.

[5]Includes production by farmers and by Bord Na Mona.

[6]Includes milled peat used for briquet production.

[7]Produced from milled peat shown separately.

TRADE

Irish trade in minerals for the 2 most recent years is given in tables 2 and 3. As a member of the European Communities (EC), Ireland has an active mineral trade with other EC members and the United States. This trade consists, to a large extent, of imports of finished products, and exports of concentrates and semifinished minerals.

Table 2.—Ireland: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS				
Aluminum:				
Hydroxide	1,752	1,577	--	United Kingdom 385; France 311.
Metal including alloys:				
Waste and scrap	840	2,151	--	United Kingdom 1,417; Netherlands 299.
Unwrought	2,325	2,523	--	United Kingdom 2,146.
Semimanufactures	1,407	2,099	--	United Kingdom 1,165.
Copper:				
Ore and concentrate	25,002	17,703	--	Spain 7,391; Belgium-Luxembourg 4,260.
Metal including alloys:				
Waste and scrap	5,869	5,910	--	United Kingdom 1,641; Belgium-Luxembourg 1,310; West Germany 1,290.
Unwrought	359	253	NA	NA.
Semimanufactures	1,827	2,569	458	United Kingdom 1,014.
Iron and steel:				
Ore and concentrate	r37,352	31,160	NA	NA.
Metal:				
Waste and scrap	54,100	40,991	--	United Kingdom 16,206; Spain 10,605; Denmark 5,930.
Pig iron, ferroalloys, similar materials	115	95	NA	NA.
Steel, primary forms	3,678	437	--	United Kingdom 103.
Semimanufactures	56,374	25,281	--	United Kingdom 19,046.
Lead:				
Ore concentrate	69,175	115,276	--	France 44,656; West Germany 23,595; Belgium-Luxembourg 20,637.
Oxides	7	NA	NA	NA.
Metal including alloys:				
Waste and scrap	1,976	954	--	Belgium-Luxembourg 194.
Unwrought	3,231	3,196	--	United Kingdom 3,161.
Semimanufactures	1,007	1,438	--	United Kingdom 1,342.

rRevised. NA Not available.
[1]Including 33 tons of lignite.

COMMODITY REVIEW

METALS

Aluminum.—Another strike, this time resulting in a 7-week shutdown in May and June, delayed construction at the new alumina plant on Aughinish Island in the Shannon estuary. The strike by members of the Irish Transport and General Workers Union was over negotiations on previously agreed bonus payments; it was only 1 of about 12 disputes during the previous 12 months between the management, Alumina Contractors Ltd., representing the owners (Alcan, Billiton, and The Anaconda Company), and the 12 unions at the site. Cost estimates were consequently raised during the year to the $750 million[2] to $1 billion range, and the completion date was delayed to at least early in 1983. The plant was to process bauxite from Guinea and Brazil, largely for Alcan's European and North American aluminum smelters.

Copper.—Avoca Mines Ltd., operator of Ireland's only copper mine at Avoca, County Wicklow, granted Government assistance of £4.35 million to clear its debts and to reequip the mine.

Iron and Steel.—The modernization and expansion program of Irish Steel Ltd. (IS), formerly Irish Steel Holdings Ltd., was delayed considerably by failure of the manufacturer in England to deliver the new rolling mill on time. The plant, scheduled for commissioning in June, was now expected to be operational early in 1981.

In addition to the Ferrco-designed rolling mill, which was to produce sections up to 8 by 5-1/2 inches, new equipment included a three-strand Concast bloom caster, which started up in October, and a 90-ton Tagliaferri arc furnace, which began operating early in 1981.

IS suffered a loss of £6.4 million in the financial year to June 30, 1980, partly because of delays in commissioning the new plant and partly because of a somnolent market, according to IS's chairman. Output reached only 59,000 tons, with strong price competition from imports, compared with a nominal capacity of 150,000 tons per year, and a capacity of 300,000 tons per year after expansion is completed.

Lead-Zinc.—The Tynagh Mine, the original major lead-zinc producer in Ireland, which started up in 1965, was closed at the end of July. Modifications, however, were made in the surface plant for treating a stockpile of about 110,000 tons of ore, averaging about 7.5 ounces of silver per ton. Tynagh had been operated by Northgate Exporation and Development Ltd., of Toron-

to, Canada.

The application by Bula Ltd. for permission to mine its deposit near Navan, in County Meath, was rejected by the National Planning Appeals Board early in 1981, on the grounds that the opencast mine proposed was too close to residential properties and would pose polluton problems. An underground operation was being considered.

Tara Exploraton and Development Co. Ltd., at Navan, which attained almost full production by the beginning of the year, was just breaking even financially, because of a steep rise in operating costs, high interest rates, and a decline in metal prices. Profit for the year was only $108,000, compared with $9.05 million in 1979. Production of zinc in concentrates was 191,641 tons, and production of lead in concentrates was 30,000 tons. Capital investment, in view of the company's financial difficulties, was being limited to about $3 million per year, chiefly for the maintenance of long-term term production.

Plans to build a zinc smelter at Ballylongford, on the Shannon estuary, in western Ireland, were reportedly scrapped by the Irish Government in view of low zinc prices and rising construction costs.

NONMETALS

Barite.—The Glencarbury barite mine of Sligo Bay Barytes Ltd., a subsidiary of Imco Inc. (Halliburton) of the United States, at Ballintrillick (Ballaghnatrillick), County Sligo, ceased producton early in the year, apparently because of the low contract price of barite for North Sea drilling operations. The other major mines, Dresser Magcobar's Silvermines (about 270,000 tons per year), Milchem Inc.'s operations at the defunct Tynagh lead-zinc mine (60,000 tons per year), and the recently reopened Lady's Well Mine near Clonakilty, County Cork (50,000 tons per year), continued in operation.

Diamond.—The General Electric Co. (GE) of the United States announced that it had chosen Dublin as the locaton of a new industrial diamond plant, having been persuaded to change from its original choice, Livingston New Town in Scotland, by a direct grant of £17 million from the Irish Industrial Development Authority and by various tax concessions on its export profits. The factory, already under construction, was expected to create about 500 new jobs over the next 5 years.

The plant will be the second of its type in Ireland. The first, established by De Beers Ltd. of South Africa, in the early 1960's, is Ultra High Pressure Units (Ireland) Ltd., near the Shannon Airport. The new plant should increase GE's share of the estimated present world market of 100 million carats annually to almost equal that of De Beers.

Nitrogen.—The 366,000-ton-per-year (nitrogen content) ammonia plant near Cork, completed in 1979 for Nitrigin Eireann Teoranta (NET), the state-owned fertilizer company, ran into difficulties soon after commissioning. Profit on imports of ammonia was £5 million, but, overall, there was a loss of about £12 million, due to last-minute delays, a prolonged strike by employees early in 1980, and high financing costs.

MINERAL FUELS

Ireland supplied close to 20% of its total energy requirements from indigenous sources in 1980. The traditional and still important fuel was peat, which generated about one-quarter of the electricity used; hydropower also contributed to some extent, and there was a small production of coal. The construction of a nuclear powerplant at Carnsore Point, the extreme southeast point of Ireland, was still under discussion.

In January, a new Department of Energy was set up within the Irish Government, which assumed the responsibilities for formulation of an energy policy, formerly under the Department of Industry, Commerce, and Energy. A separate division dealing solely with energy conservation was set up within the department.

Coal.—The new Kealy Mine in the County Tipperary Coalfield (presumably in the Slieve Ardagh region) was expected to reach its planned output of 50,000 tons per year. A second mine in the Leinster (Castlecomer) Field nearby was opened. Coal in this area is anthracitic. In the Connaught semibituminous coalfield at Arigna, expansion was also under way on the local high-ash coals. It was estimated that a 25-year supply of coal is available there, and a 40-megawatt powerplant was being built to test fluidized bed combustion.

Natural Gas.—Production of the Kinsale Head Gasfield off the southern coast reached the planned rate of 125 million cubic feet per day during the year. Production from the field, which has reserves of over 1 trillion cubic feet, is sold to the state-owned Bord Gais Eireann, which in turn sells it the semi-state Electricity Supply

Board for electricity generation in the Cork area (69 million cubic feet per day), to NET for ammonia production near Cork (52 million cubic feet per day) and to the Cork Gas Co. for local use (4 million cubic feet per day).

The Irish Government was studying the feasibility of building a gasline to introduce Kinsale natural gas to the Dublin City gas system, which was currently supplied with expensive naphtha-based town gas. In addition to an 18-inch, 140-mile pipeline from Cork to Dublin, branches were being considered to other cities in Ireland, including Belfast in Northern Ireland. The pipeline was expected to cost £70 million to £100 million, and another £70 million would be required for improvements and extensions in the Dublin distribution system.

Peat.—The European Investment Bank, the long-term finance institution of the European Economic Commmunity, granted a loan of 4.5 million units of account (about £3 million or $6 million) to the Bord na Mona (Peat Board) to help develop the production of peat for fuel. The loan will go toward the sum needed (about 20 million pounds) to develop 7,000 acres of bogland in central Ireland, plus the construction of a factory at Littleton, County Tipperary, to convert the peat into briquettes at the rate of 130,000 tons of product annually by 1984.

Petroleum.—The Irish Energy Minister, reacting to press reports, said reserves in the British Petroleum (BP) discovery offshore in the Porcupine Basin, made in 1979, were not as high as rumored and most likely would be in the region of 100 million barrels. The site is in very deep water (1,200 to 1,400 feet) and rather rough seas, about 100 miles off the southwest coast.

BP confirmed in September the completion of a second successful well, 26/28-2, toward the complex western edge of the same structure as that tested in 1979 by its discovery well, 26/28-1. The second well, in 1,230 feet of water, flowed 39° to 41° API oil at rates of 1,120 and 370 barrels per day from two separate intervals. The earlier well had tested at rates of between 3,093 and 579 barrels per day. In addition to BP (38.5% of the equity), the group included Aran Energy (16.7%), Amerada Hess Corp. (20.0%), and Getty Oil International (Ireland) Ltd. (10.0%); the remainder of the equity was held by a group comprising Phillips Petroleum Co. (55%), Fina (35%), and Century Power and Light of Ireland (10%).

Phillips Petroleum was also continuing drilling in its area of the Porcupine Basin, where its original discovery was made, also in 1979, and the Elf Aquitaine group intended to test the western edge of the Porcupine Trough as well.

The Irish Government in November announced a second round of offshore petroleum licensing. For the previous 5 years, applications for exploration licenses had been accepted on an "open door" basis. The new policy was adopted to attract new companies and encourage greater competition, and hence more favorable terms for Ireland.

Under terms of the second round, bids were invited on 108 blocks in 5 areas. Forty-six are in the deeper part of the Porcupine Basin; 45 are in the Celtic Sea, south of Ireland, where the only producing field, the Kinsale Head Gasfield, is located; 6 are in the Donegal Basin northwest of Ireland; 4 are in the Kish Basin east of Dublin; and the remaining 7 blocks are in the Slyne Trough, a new area northeast of the Porcupine Basin and off the Mayo coast. Applications were to be accepted from November 16, 1981, to January 29, 1982. Awards were promised for early 1982.

The Government's fledgling Irish National Petroleum Corp., which was established in 1979, concluded two Government-to-Government contracts for the supply of petroleum from the Middle East. The first, with the Iraqi National Oil Co. late in 1979, was for 10,000 barrels per day; this subsequently became inactive because of the Iraq-Iran war. The second contract, for a similar amount from Saudi Arabia, started late in 1980. Each of these contracts would supply about 8% of Ireland's current consumption (122,000 barrels per day). Oil from both contracts was being refined in the United Kingdom because Ireland's one refinery could not handle additional supplies.

Uranium.—Munster Base Metals Ltd., a subsidiary of Anglo United Development Corp. Ltd. of Canada, continued to obtain good results in the exploration being carried out in the Fintown area of central Donegal. Drilling increased the known strike length to more than 520 meters, and additional drilling was to be undertaken on 2 targets to the east which showed strong induced polarization responses.

The Mineral Industry of Israel

By Suzann C. Ambrosio[1]

Israel's mineral industry, consisting primarily of nonmetal chemicals, cement, fertilizer, and polished diamonds, continued to be highly export oriented. Israel Chemicals Ltd. (ICL), the Government holding company for all nonmetal mineral production, estimated the 1980 sales value of the potash, phosphate rock, bromine, and periclase at $225 million.[2] The overall economy grew at the projected rate of 4.2% with the total gross national product (GNP) estimated at $17 billion. Israel's chemical and fertilizer products, approximately 1.5% of the GNP, contributed 12% of total foreign export sales. Nearly 40% by weight of the world production of gem-quality diamonds were polished in Israel. The total value of diamond sales was approximately $1.6 billion. Diamond sales represent 10% of GNP and contributed 32% of export sales.

Despite the growth in some sectors of the economy, there was an increase in the number of unemployed and a continued spiral in inflation pressure causing a decline in domestic demand of products and a diminution overall in investments. The jobless rate during the first half of 1980 was 4.4% as compared with 2.8% in 1979. The unemployed tended to move into those developing areas where sophisticated technology and other production-oriented industries were expanding. Over 50% of those hired during the second half of 1980 were absorbed by these export industries.[3] Inflation was estimated at 133% in 1980 and continued to be driven up by the increases in oil import bills.

Economic policies implemented during 1980 included monetary and fiscal policy restraints and currency devaluation. The Israeli pound was renamed the shekel in February; 1 shekel equaled 10 Israeli pounds. The shekel was devalued in 1980 for a total reduction of 114% against the dollar and 106% against a basket of currencies belonging to Israel's major trading partners.[4] The Bank of Israel's policy attempted to keep devaluation equal to the differences between the domestic rate of inflation and inflation "imported" from abroad. Other Government financial policies focused on reducing the Government budget, revising the linkage system through a possible wage and price freeze, and promoting export industries.

There was a significant improvement in Israel's 1980 trade balance, primarily owing to increased export earnings and diminished growth of import expenditures (other than oil). Total exports grew 6% in real terms during 1980. The trend to support export industries through various credit incentives continued to increase. An import deposit scheme was in effect during 1980 that required a 10% import deposit where customs duties were required. The trade deficit declined 13% over that of the previous year to approximately $2.6 billion.

Exports of mineral, chemical, and metal industries exceeded the value from the food and textile industries for the first time. The change in export composition signifies the shift from light to heavy industries. The greatest growth in export revenues was attributed to the nearly 80% growth in nonmetallic products. Phosphate rock, potash, and polished diamond export revenues surpassed all other industrial products.

The country's transportation situation improved since the signing of the 1979 peace treaty with Egypt. The Suez Canal has been open to traffic from the Israeli Red Sea port of Eilat. Mine transport costs have declined owing to the elimination of lengthy trucking of products to Israel's Mediterranean ports. A new export depot at the cargo terminal at Ben-Gurion International Airport was inaugurated in September 1980.

Improvements in transportation and water facilities were planned for Samaria, other west bank development areas, and the eastern Negev. Construction on the east section of the Israel-Samaria road began in November in an effort to strengthen commerce between the settlements and the rest of the country. Work on the Negev water pipeline was renewed in 1980 after a 4-year work stoppage. The pipeline capacity was designed to reach 7,600 cubic meters per hour and was expected to facilitate increased water supplies to Beersheba.

Oil consumption remained stable at approximately 8 million tons during 1980. Israel is 98% dependent on oil for energy requirements and spends approximately 15% of GNP on petroleum imports. Steadily increasing oil expenditures and decreasing accessibility to markets have induced research and applications of alternative energy sources. The development of the Mediterranean-Dead Sea linkage in addition to coal, solar, and nuclear alternatives were among Israel's major national priorities. Near-term projects included the increased use of coal power and exploitation of Israeli-occupied oil and gasfields. Long-range projects, including hydroelectric, solar, and oil shale proposals, have been initiated through feasibility studies and pilot plants. A discovery of oil shale in the southern Negev nearly doubled known reserves to 4 billion tons.

PRODUCTION AND TRADE

Nonmetals continued to dominate Israel's mineral production. Expansion of the sector's production capacity and export potential was expected to continue to offset the high costs of importing required fuels and metals. Because Negev phosphate rock and Dead Sea potash and bromine production have grown to near capacity over the past 4 years, ICL targeted $65 million per year over the next 4 years for various expansion projects. ICL invested in transportation facilities and has subsequently focused on improving marketing infrastructure for chemical and fertilizer products.

The value of Israel's mineral exports showed marked increases in 1980. Mining, quarrying, and nonmetallic mineral products (excluding diamonds) increased 48.5% to approximately $156 million. Chemicals, rubber, and plastics grew 36.5% to approximately $757 million. Of total industrial exports (less diamonds), the shares of the two sectors, (1) mining, quarrying, and nonmetallic mineral products and (2) chemicals, rubber, and plastics, remained relatively stable at 5% and 27%, respectively.[5] Diamond export values increased to approximately $1.4 billion. Reported uncut and polished diamond imports grew by 11% (carats) and 43% (dollar value), and exports increased by 8% (carats) and 22% (dollar value).[6]

Although growth in the diamond export industry was reported during 1980, the published figures included large quantities of stones that were exported on consignment. It is doubtful whether many of these diamonds sold, since the world demand for diamonds has dramatically declined over the past 2 years. Israel's diamond industry was estimated to be set back by 10 years. By yearend 1980, nearly 40% of the workshops closed operations and approximately one-half of the 17,000 workers were let go. The major problem facing the industry was reducing supplies of rough diamonds for investments and polished diamonds that were hard to sell. The total debt of the industry to Israeli banks reached $1.2 billion in 1980.

Israel's balance of trade with the European Economic Community (EEC) was favorable in 1980. Exports to the EEC increased 45% overall; Italy's purchases increased 100% and France, Netherlands, and Federal Republic of Germany imports increased by 50%. The growth was indicative of the increase in both the volume of Israeli exports and the variety of exported products. Israel has maintained relatively small trade relationships with Eastern Europe and Africa. However, exports to Africa increased 66% in 1980. Less than 1% of South Africa's trade was shared by Israel, although Israel imports most of the uncut diamonds produced in the Republic of South Africa. Israel exported mostly fertilizers, chemicals, construction, materials and electrical equipment to Africa in return for metals, iron, steel products, and mineral fuels.

The balance of United States-Israeli trade remained fairly constant over the past 2 years. Israeli exports in 1979 were approximately $750 million and imports were $1.5 billion. Imports of capital equipment exceeded agricultural purchases for the first time. The emphasis on expanding Israeli export industries was reflected by a 45% increase in the purchase of machinery and equipment.

COMMODITY REVIEW

METALS

Copper.—Timna copper mines, just north of Eilat in the Negev Desert, had approximately 21 million tons of proven copper ore reserves. Owing to depressed world copper prices, the mines were closed from March 1976 until October 1980. The decision to reopen the mines was based in part on increased world copper demands, rising prices, and new extraction technologies. Timna researchers have proposed an extraction method that will produce various copper and manganese chemicals from the ore. Cement copper in the form of precipitates will still be produced but at lower output levels. Peak production of cement copper was 10,000 tons in 1975, and renewed levels were expected to reach 4,000 tons.

Magnesium Compounds.—Dead Sea Periclase Ltd. (DSP), jointly owned by Israel Chemicals (71.5%) and General Refractors (U.S.-owned Austrian company), produced periclase, a form of refractory magnesia. Residual Dead Sea brines were processed for the production of 99.4% pure magnesium oxide and hydrochloric acid. All of the manufactured periclase was exported to Europe. The hydrochloric acid was sold to Negev Phosphates and used in the production of phosphoric acid. Magnesium compounds production in 1979-80 was near full capacity of 50,000 tons. Recent increases in periclase prices and wider market applications encouraged DSP to expand production. DSP reported plans to increase production by 15% over the next 5 years.

NONMETALS

Bromine.—The Dead Sea Bromine (DSB) group, a subsidiary of Dead Sea Works (DSW), was composed of Dead Sea Bromine Co. Ltd. (DBC), Bromine Compounds Ltd. (BCL), Eurobrom B.V., and Broomchemie B.V., Netherlands. The company estimated reserves of 1 billion tons of recoverable Dead Sea bromide salts. Elemental bromine was extracted from Dead Sea brines at DSW's Sedom plant. Roughly one-third of the bromine was sent for processing in the Netherlands, and two-thirds was locally processed at the Beersheba and Ramat Hovev plants.

DSB was the world's largest single exporter of bromine compounds and was second only to the United States in production. DSB's extraction plant was projected to increase current capacity of 40,000 tons per year to 70,000 tons per year.

Cement.—Nesher Cement Co., Israel's only cement producer, owned five quarries and three plants in Haifa, Ramle, and Har Tuv. The plants produced portland cement (roughly equivalent to American Portland Type 1) from 95% clinker and 5% gypsum. Approximately 10% of the clinker was imported from various Mediterranean countries to meet domestic demand. To meet the projected 14% increase in 1981 cement consumption (2.5 million tons), Nesher has invested in a new quarry at Tamra and a grinding mill at Har Tuv. The plant was scheduled for completion in January 1981 and will raise Nesher's grinding capacity to 2.5 million tons annually. A fourth plant, to be located at Tel Yeshua pending environmental approval, would add approximately 500,000 tons of clinker output per year.

Fertilizer Materials.—*Phosphorous.*—Negev Phosphates Ltd. (NPL) estimated that 350 million tons of minable phosphate rock existed in the Negev Desert. NPL produced varying qualities of 20% to 30% P_2O_5 at four processing plants. These were located at Oron (calcinated rock and defluorinated phosphate ore), Arad (phosphoric acid and rock phosphate), Makhtesh (rock for superphosphate), and Zin (washed phosphate). During 1980, the plants averaged 80% of their production capacities.

Oron Mine, the oldest phosphate mine in Israel, utilized an energy- intensive calcination process to produce 73% to 75% BPL (bone, phosphate, and lime) grade phosphate rock. Plant capacity in 1980 was 500,000 metric tons per year. Owing to increased fuel costs, alternative production of semicalcined phosphate was undergoing trial production. Transportation difficulties at the Makhtesh Mine were expected to cause operations to cease within 5 years. The newest operation, Zin Mine, produced low chloride 70% to 72% BPL washed rock with a plant capacity of 2 million tons per year. The Zin plants located in the Hor Hahar Field were operating at 85% capacity in 1979-80. Slight modifications may potentially increase the plants' capacity to 3 million tons per year.

Completion of the Mishor Rotem fertilizer plant by Rotem Fertilizers Ltd. was scheduled for 1981. An improvement in Arad's

high-grade phosphate rock sales was expected. The opencast mining expansion of the low-grade upper beds for Rotem's fertilizer feedstock should ultimately allow greater mining of the high-grade lower phosphate beds.

Construction of Rotem Fertilizers Ltd. phosphoric and sulfuric acid plants in Arad were proceeding on schedule. Monsanto Industrial Chemicals Co. designed the sulfuric acid plant, and a French company was building the phosphoric acid plant. Both plants were expected to be completed by the second half of 1981. All aspects of phosphate rock supply from rock mining through processing and delivery were controlled by NPL. The value of phosphate rock exports in 1979-80 increased by approximately 40% over 1978-79 levels, while production of phosphate rock increased only 18%. Output of phosphate rock in 1981 was expected to increase another 50% over 1980 production levels. Exports of phosphoric acid were projected to increase sixfold to 150,000 tons per year in 1981.

Potassium.—DSW produced five grades of muriate of potash and the coproducts magnesium chloride, industrial salt, and table salt. Almost all of DSW's potash was exported directly as potassium chloride and indirectly as potassium nitrate and potassium sulfate. Although potash production slightly increased between 1975-80, current sales have doubled 1975-76 levels. World demand was expected to increase 5% per year, and DSW planned to increase potash production capacity by 15% per year between 1980-85. Israel was the fifth largest producer and contributed 3% of the global potash requirements during 1980. The expansion plans were expected to add 900,000 tons in a two-phase construction project. DSW's 2.1-million-ton production capacity expected in 1985 represents 7% of the world's projected demand.

Trans Pacific Resource Inc., a subsidiary of Estech General Chemicals Ltd. of Chicago, acquired 20% of Haifa Chemicals Ltd. The Israeli company was the world's single largest producer of potassium nitrate fertilizer and manufactures a variety of phosphate-based chemicals. Haifa Chemicals 1979 annual report showed a 30% increase in exports over those of the previous year. Estech's large marketing potential and the two firm's complementary products would allow further expansions in Haifa Chemical's export markets.

MINERAL FUELS

Energy.—The expansion of natural gas output from the Sinai fields were expected to continue. New wells in the gasfield near Sadot Moshav were projected to boost production by 40% to about 40 million cubic feet per day. The fields will be returned to Egypt in 1981 as part of the Israeli-Egyptian peace treaty. A gradual Israeli defense force withdrawal from the eastern section was scheduled through April 1982.

The Israeli Government put into motion the first of a series of feasibility studies for the Mediterranean-Dead Sea canal and tunnel linkage. The project was intended to replenish the water level of the Dead Sea and power a 600-megawatt hydroelectric plant. A 1-year feasibility study during 1981 was to involve drilling, mapping, and seismic testing.

The 150-kilowatt pilot solar-electric power station at Ein Bokek on the west bank of the Dead Sea has demonstrated Israel's solar potential. The continuous generating system based on the Ormat Organic Rankine Cycle and a solar pond utilized water, salt, and solar energy. Another 5,000-kilowatt solar power station was expected to be operational by 1981. The plants were part of a 2,000-megawatt Dead Sea solar complex.

Coal.—The Israel Electric Corp. (IEC) was in the process of shifting the supply source of Israel's electricity generation from oil to imported coal. Construction of the Hadera coal complex with four 350-megawatt generating units continued in 1980. Design features have been built into the complex to accommodate alternative firing by bunker "C" fuel oil or crude oil. Construction of the first two generating units neared completion by yearend 1980. The rescheduled start-up date for the first unit was 1981, and the second unit was expected to come online in 1982.

IEC had contracted Trinacria Lavoria Maritimi (Italy) to build the world's largest offshore unloading terminal near Ashdod. The first section of the 2,000-meter trestle and pier was scheduled for completion by March 1981. When finished there will be two stationary 225-ton-capacity cranes and two 150-centimeter-wide conveyor belts to carry the coal. The present mooring space can accommodate ships carrying up to 130,000 tons of coal. This may be extended for the next generation of ships with capaci-

ties up to 170,000 tons. Total unloading capacity may reach 9 million tons per year.

Coal supply agreements have been signed between the IEC and the Republic of South Africa, the United States, and Australia. Nearly half of the Hadera plant's coal requirements were expected to be imported from South Africa during the next 6 years. The United States was expected to supply 1 million tons of coal for 30 consecutive years. The remaining coal supplies were expected to be imported from Australia. Long-range electric generation plans included another coal-powered plant in Ziqim to be constructed in 1987.

Petroleum.—Small quantities of crude oil continued to be produced in the Heletz Fields near Ashquelon. Extensive oil exploration carried out during 1980 in Sedom and the Dead Sea area was expected to continue in 1981. Two studies estimated oil reserves of 500 million and 2 billion barrels for Israel. Hanah, the Government oil investment company, planned to conduct seismic surveys of all potential oil- and gas-bearing sites. The Ministry of Energy and Infrastructure reported that there were no restrictions whatsoever for U.S. citizens to own or control any interest in companies seeking oil and gas exploration rights in Israel.

The Mineral Industry of Italy

By Roman V. Sondermayer[1]

As in the past, Italy was a significant processor of imported raw minerals and crude petroleum during 1980. In addition to construction materials, major minerals mined in the country included ornamental stone, pumice, feldspar, pyrite, fluorspar, barite, asbestos, and zinc. The mining and minerals processing industry of Italy contributed an estimated 11% in the country's gross national product.

The indexes for the mineral industry's activities for the latest 5 years are shown in the following tabulation:

	1976	1977	1978	1979	1980
All industry	122	123	126	134	142
Extractive industry	98	94	94	101	97
Mining of metals	66	49	45	39	39
Mining of nonmetals	102	99	100	107	104

Employment in the mineral industry has declined during recent years. The following tabulation shows the latest data on such employment:

	1976	1977	1978	1979	1980
Mining of metals	6,705	5,198	4,285	3,725	NA
Mining of nonmetals	9,268	8,061	7,104	7,001	NA
Total	15,973	13,259	11,389	10,726	9,671

NA Not available.

The declining state of the mineral industry was caused by various factors; most frequently mentioned were lack of a firm mineral policy; scarcity of capital, because mining was considered too risky a venture; a sharp decline in grades of ores mined in certain mines; and exhaustion of some deposits.

In January 1980, the Council of Ministers approved and submitted to Parliament a draft law regulating all activities of the mineral industry. The proposed law made provisions to assure supply of raw materials; improve recovery of minerals in mines, beneficiation plants, and smelters; and stimulate conservation and regulate operations of marginal ventures, which are kept active for social reasons. Reports indicated Parliament may enact the law during 1981 but its final form was difficult to foresee. The three major political parties in Italy have diverging views on the new mining law and major changes are possible.

The major events in the mineral industry of Italy during 1980 included reorganization of the state-owned steel group Finsider; startup of a new steel plant near Brescia; closure of the Salafossa lead-zinc mine in the Province of Belluno; temporary closure of the potash mine at Racalmuto, Sicily; continuation of work for reopening the Sulcis coal mines in Sardinia; discovery of a gasfield near Ravenna; and placement under extraordinary administration of the largest Italian independent petroleum group owned by Attilio Monti.

PRODUCTION

During 1980, the mineral industry of Italy, including processing and mineral fuels, showed mixed results. Extractive industry, mostly metals, declined. Table 1 shows production trends for the latest 5 years.

The mining and processing sectors were owned by public and private companies. The Government, with Ente Nazionale Idrocarburi (ENI) and its affiliates Societa per Azioni Minero-Metallurgiche (SAMIM) and Azienda Generali Italiana Petroli S.p.A. (AGIP); Finsider, with its subsidiary Italsider; and the Government-owned potash mines, controlled most of the sector. Societa Mineraria e Metalurgica di Pertusola S.A. (Pertusola) in lead-zinc, Acciaierie Ferriere Lombarde Falck (Falck) in steel, and major foreign oil and gas companies were the principal privately owned companies of the sector.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.
[1]Table includes data available through Sept. 28, 1981.
[2]Excludes pelletized iron oxide derived from pyrite.
[3]Included with other if any was produced.
[4]Serpentine output for dimension stone applications (if any) is included with crushed and broken stone.
[5]Less than 1/2 unit.

TRADE

The supply position of Italy did not change during 1980, and Italy remained dependent on imports of large quantities of raw materials and fuels. Tables 2 and 3 show details of Italy's foreign trade in minerals.

Table 2.—Italy: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite and concentrate	12,240	27,565	--	Greece 6,710; France 6,236; West Germany 4,863.
Oxide and hydroxide	327,599	417,897	--	Netherlands 144,317; Norway 114,085; United Kingdom 48,760.

NONMETALS —Continued				
Asbestos, crude	68,923	74,478	--	West Germany 23,794; Japan 7,916; Israel 7,050.
Barite and witherite	73,863	88,736	--	Algeria 41,200; Nigeria 9,650; Netherlands 6,540.
Boron materials:				
Crude natural borates	155	1,998	--	France 1,194; Yugoslavia 514.
Oxide and acid	4,444	6,300	2,357	West Germany 2,065; France 658; Austria 362.
Cement—thousands tons	1,585	1,695	--	Israel 265; Saudi Arabia 243; Libya 229.
Chalk	574	567	--	Zaire 59.
Clays and clay products:				
Crude clays:				
Bentonite	20,205	31,246	--	Libya 9,528; France 9,504.
Kaolin	42,546	29,490	--	France 22,128.
Other	7,725	9,485	--	Tunisia 2,771; West Germany 734.
Products:				
Refractory including nonclay brick	105,508	99,942	--	West Germany 15,475; Egypt 12,883; Romania 5,943.
Nonrefractory—thousand tons	2,365	2,878	136	West Germany 671; France 566; Saudi Arabia 109.
Cryolite and chiolite	2	(2)	NA	NA.
Diamond:				
Gem, not set or strung—carats	237	3 1,186	--	Venezuela 460.
Industrial—do	2,980	82,808	--	Netherlands 1,997.
Diatomite and other infusorial earths	1,185	1,866	--	U.S.S.R. 1,064.
Feldspar	28,808	37,601	--	West Germany 15,159; Greece 3,958; Algeria 3,929.
Fertilizer materials:				
Crude	7,836	6,797	--	France 3,679; Austria 1,582.
Manufactured:				
Nitrogenous—thousand tons	1,199	1,458	--	China, mainland 401; India 258; Turkey 256.
Phosphatic—do	7	2	--	Switzerland 1.
Potassic—do	107	105	--	Algeria 33; Greece 16; Turkey 15.
Other including mixed—do	385	335	--	West Germany 55; France 45; China, mainland 39.
Ammonia	47,208	16,927	--	Israel 9,462; Greece 3,841; Spain 2,819.
Fluorspar	60,952	55,080	36,255	Norway 7,600; Romania 3,000.
Graphite, natural	2,823	3,854	--	France 2,728; West Germany 438.
Gypsum and plaster	11,153	11,931	--	Switzerland 7,819.
Lime	124,561	96,437	--	Saudi Arabia 50,708; Switzerland 29,484.
Magnesite	131,459	151,740	--	West Germany 31,075; Austria 29,190; United Kingdom 20,953.
Mica:				
Crude including splittings and waste	800	661	--	West Germany 136.
Worked including agglomerated splittings	54	11	NA	NA.
Pigments, mineral including processed iron oxides	1,034	2,936	--	France 1,282; Spain 273; West Germany 250.
Precious and semiprecious stones except diamond:				
Natural—kilograms	r3,623	11,457	NA	NA.
Manufactured—do	442	548	--	France 19.
Pyrite (gross weight)	3,189	3,375	--	West Germany 1,689; France 556; Austria 501.
Salt, all forms	497,316	1,241,023	21,000	United Kingdom 672,595; Netherlands 200,896; West Germany 107,046.
Sodium and potassium compounds, n.e.s.:				
Caustic soda	326,877	175,384	--	Yugoslavia 73,855; U.S.S.R. 15,150; Iraq 7,457.
Caustic potash	8	8	NA	NA.
Soda ash	15,934	20,190	NA	Algeria 11,862; Israel 4,008; Spain 3,296.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked:				
Calcareous	337,475	372,621	--	Spain 56,500; Saudi Arabia 34,560; Lebanon 32,981.
Slate	3,168	3,320	NA	NA.
Other	108,667	118,988	57	West Germany 44,984; Austria 15,904; France 15,680.

See footnotes at end of table.

Table 2.—Italy: Exports of mineral commodities —Continued

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
NONMETALS —Continued				
Stone, sand and gravel —Continued				
Dimension stone —Continued				
Worked:				
Slate	35,154	40,244	24,587	Austria 2,631; West Germany 922; Canada 850.
Paving and flagstone	95,775	131,317	--	West Germany 60,834; Switzerland 37,759.
Other	955,829	1,121,106	63,102	West Germany 454,180; Saudi Arabia 179,616; France 99,178.
Dolomite, chiefly refractory grade	29,670	47,317	--	France 15,546; Switzerland 4,646; West Germany 4,258.
Gravel and crushed rock	643,828	620,069	--	West Germany 109,304; Switzerland 95,857; Kuwait 81,145.
Limestone except dimension	72	10,995	NA	NA.
Quartz and quartzite:				
Piezoelectric crystal kilograms	30			
Other	37,798	36,220	--	Switzerland 18,383; France 12,376.
Sand excluding metal-bearing	434,043	420,108	--	Switzerland 369,621; Yugoslavia 30,626.
Sulfur:				
Elemental, all forms	3,797	190	NA	NA.
Sulfuric acid, oleum	81,097	36,043	--	Turkey 13,797; Greece 10,639.
Talc, steatite, soapstone	56,591	55,181	10,765	West Germany 9,989; United Kingdom 8,540; France 7,423.
Other:				
Crude	87,542	51,289	215	United Kingdom 25,115; Ireland 8,951; Switzerland 4,053.
Slag, dross, and similar waste, not metal-bearing	307,019	354,707	--	Yugoslavia 313,368.
Oxides, hydroxides, and peroxides of strontium, magnesium, barium	2,396	2,099	604	France 337; Iraq 240; Denmark 100.
Building materials of asphalt, asbestos and fiber cements, and unfired nonmetals	141,317	152,787	616	France 61,288; West Germany 12,466.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	6,018	2,385	NA	NA.
Carbon black and gas carbon	39,493	44,989	--	Yugoslavia 13,796; Austria 9,900; France 9,729.
Coal, all grades, including briquets	5,554	13,074	--	France 6,288; Switzerland 5,126.
Coke and semicoke	625,167	645,114	89,846	Romania 152,690; Algeria 118,914; Spain 73,146.
Gas, natural thousand cubic feet	502	1,426	NA	NA.
Peat including briquets and litter	730	644	NA	NA.
Petroleum refinery products:				
Gasoline thousand 42-gallon barrels	66,590	59,882	2,672	Netherlands 17,113; France 7,888; United Kingdom 5,833.
Kerosine do	22,310	22,951	926	Netherlands 3,600; Greece 2,122; United Kingdom 2,078.
Distillate fuel oil do	49,721	47,197	--	Netherlands 13,412; Syria 4,040; Switzerland 2,869.
Residual fuel oil do	57,550	49,311	4,514	Netherlands 4,886; Turkey 4,809; France 3,059.
Lubricants do	3,298	3,648	1	Belgium-Luxembourg 494; West Germany 345; Algeria 293.
Other:				
Liquefied petroleum gas do	5,461	4,544	--	Egypt 824; Algeria 747; Portugal 454.
Mineral jelly and wax do	18	25	--	Vietnam 9; West Germany 4.
Bitumen and other residues do	1,228	904	--	Austria 403; Tunisia 175; Switzerland 121.
Bituminous mixtures do	46	42	--	Sudan 9; Tunisia 6.
Petroleum coke do	r180	234	--	Egypt 188; Spain 13.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	r79,029	62,587	--	France 38,033; West Germany 8,599; Yugoslavia 5,845.

rRevised. NA Not available.
[1]Less than 1/2 unit.
[2]Unreported quantity valued at $1,388.
[3]Excludes an unreported quantity valued at $1,384.

Table 3.—Italy: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Sources, 1979	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite and concentrate thousand tons	1,645	2,287	--	Australia 1,670; Guinea 389.
Ash and residue containing aluminum	61,782	62,260	--	Austria 44,536; France 7,367.
Oxide and hydroxide	166,841	179,690	370	Guinea 114,382; France 17,076.
Metal including alloys:				
Scrap	41,448	57,754	7,308	West Germany 13,917; Switzerland 10,360; France 9,209.
Unwrought	231,849	276,281	1,499	West Germay 81,885; France 46,213; Netherlands 23,213.
Semimanufactures	62,312	92,114	7,706	West Germany 34,549; France 22,002; Belgium-Luxembourg 13,073.
Antimony metal including alloys, all forms	152	121	--	Belgium-Luxembourg 56.
Arsenic trioxide, pentoxide, acid	r785	820	--	Belgium-Luxembourg 396; France 340.
Beryllium metal including alloys, all forms kilograms	1,700	1,400	NA	NA.
Bismuth metal including alloys, all forms	61	55	--	United Kingdom 11.
Cadmium metal including alloys, all forms	179	85	--	West Germany 30.
Chromium:				
Chromite	140,186	232,445	--	Turkey 104,960; Republic of South Africa 51,474; Albania 40,374.
Oxide and hydroxide	1,357	2,202	--	West Germany 1,642; Hungary 255.
Metal including alloys, all forms	206	206	--	West Germany 64; France 37; United Kingdom 33.
Cobalt:				
Oxide and hydroxide	214	189	--	Belgium-Luxembourg 149; France 30.
Metal including alloys, all forms	369	338	23	Belgium-Luxembourg 126; France 77.
Columbium and tantalum metals including alloys, all forms	9	26	4	West Germany 2.
Copper:				
Ore and concentrate	16	10	NA	NA.
Cement copper kilograms	54,100	400	NA	NA.
Sulfate	3,213	3,063	--	Austria 780; Czechoslovakia 730; France 597; Yugoslavia 500.
Ash and residue containing copper	227	670	NA	NA.
Metal including alloys:				
Scrap	69,579	76,310	--	West Germany 22,045; France 21,050; United Kingdom 18,309.
Unwrought:				
Blister	4,654	6,802	100	Chile 5,440; Yugoslavia 472.
Refined, unalloyed	351,646	338,464	--	Chile 89,178; Zambia 63,061; Belgium-Luxembourg 31,947.
Alloys	14,447	17,067	366	Yugoslavia 4,592; West Germany 4,370; United Kingdom 2,620.
Semimanufactures	69,492	107,552	522	France 32,162; West Germany 30,828; Belgium-Luxembourg 10,974.
Gallium, indium, thallium metals including alloys, all forms kilograms	1,000	1,200	--	Canada 500; Belgium-Luxembourg 300.
Germanium metal including alloys, all forms do	100	200	--	Belgium-Luxembourg 100.
Iron and steel:				
Ore and concentrate thousand tons	16,297	17,318	212	Brazil 4,006; Canada 2,381; Liberia 2,234.
Roasted pyrite	173	2,800	NA	NA.
Metal:				
Scrap thousand tons	6,566	6,891	871	France 2,651; West Germany 2,092.
Pig iron, cast iron, spiegeleisen do	347	517	--	France 140; West Germany 112; Sweden 82.
Sponge iron, powder, shot do	68	119	--	Canada 46; Venezuela 31; Sweden 17.
Ferroalloys:				
Ferromanganese do	106	122	--	Republic of South Africa 45; France 45; West Germany 13.
Other do	187	220	1	France 32; Norway 26; Yugoslavia 20.
Steel, primary forms do	2,210	3,061	(1)	France 648; Belgium-Luxembourg 480; West Germany 296.
Semimanufactures:				
Bars, rods, angles, shapes, sections do	584	768	1	France 260; West Germany 130; Austria 84.
Universals, plates, sheets do	1,255	1,822	77	France 516; Belgium-Luxembourg 318; West Germany 220.
Hoop and strip do	165	209	1	France 72; West Germany 67; Belgium-Luxembourg 26.

See footnotes at end of table.

Rails and accessories thousand tons	139	139	--	France 37; West Germany 26; Belgium-Luxembourg 17.
Wire ---------- do	54	66	(1)	Belgium-Luxembourg 27; France 13; West Germany 11.
Tubes, pipes, fittings do	169	282	2	West Germany 107; France 96; Sweden 12.
Castings and forgings, rough do	5	8	--	West Germany 4; France 2.
Lead:				
Ore and concentrate	18,589	45,365	--	Canada 23,613; Morocco 10,528; Greece 8,060.
Ash and residue containing lead	8,555	4,038	--	West Germany 1,706; Netherlands 644; Belgium-Luxembourg 424.
Oxide and hydroxide	3,671	4,829	--	Netherlands 3,667; West Germany 569.
Metal including alloys:				
Scrap	38,275	48,707	--	France 21,670; United Kingdom 8,491.
Unwrought	138,318	151,411	871	West Germany 42,088; Australia 17,917; Republic of South Africa 16,234.
Semimanufactures	974	1,538	--	Yugoslavia 1,065.
Magnesium metal including alloys:				
Scrap	2,251	1,746	--	West Germany 766; Netherlands 316; Austria 240.
Unwrought	1,032	1,649	392	Netherlands 626; Norway 476.
Semimanufactures	327	263	181	United Kingdom 28; Switzerland 24.
Manganese:				
Ore and concentrate	284,319	424,230	--	Republic of South Africa 181,483; Gabon 179,582; Brazil 38,974.
Oxide and hydroxide	2,850	3,219	--	Belgium-Luxembourg 1,054; Greece 921; France 548.
Metal including alloys, all forms	1,165	1,886	--	Republic of South Africa 957; France 791.
Mercury ---------- 76-pound flasks	1,297	2,321	--	Algeria 1,021.
Molybdenum:				
Ore and concentrate	5,637	5,866	807	Netherlands 4,069; Belgium-Luxembourg 511; Canada 351.
Metal including alloys, all forms	176	240	64	Austria 81; Netherlands 56.
Nickel:				
Matte, speiss, similar materials	7,537	5,727	--	Canada 2,960; Cuba 1,804.
Metal including alloys:				
Scrap	299	314	9	Norway 174; Republic of South Africa 50.
Unwrought	11,912	16,595	4,000	Republic of South Africa 3,527; Netherlands 2,042; Australia 1,834.
Semimanufactures	2,313	2,811	239	United Kingdom 868; West Germany 832; France 188.
Platinum-group metals including alloys, unwrought and partly wrought thousand troy ounces	455	580	3	Republic of South Africa 299; West Germany 159; United Kingdom 47.
Rare-earth metals:				
Oxides and other compounds value, thousands	$795	$966	--	France $784; Austria $155.
Metals, all forms	122	117	--	West Germany 76; Brazil 10; United Kingdom 10.
Selenium, elemental	21	39	6	Canada 7; Japan 7.
Silicon, elemental	5,579	17,701	--	Yugoslavia 8,459; France 2,320.
Silver metal including alloys, unwrought and partly wrought thousand troy ounces	31,768	25,068	6,257	United Kingdom 6,990; West Germany 3,385; Switzerland 1,707.
Tellurium and arsenic metals	78	63	14	Sweden 47.
Thorium:				
Ore and concentrate	20	NA	NA	NA.
Thoria ---------- value	$7,486	$9,857	NA	NA.
Tin:				
Ore and concentrate	--	508	--	All from Austria.
Metal including alloys:				
Scrap ---------- kilograms	--	900	NA	NA.
Unwrought	6,426	7,107	--	Indonesia 2,601; Malaysia 2,547; Thailand 726.
Semimanufactures	214	410	--	West Germany 192; United Kingdom 67.

See footnotes at end of table.

Table 3.—Italy: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Sources, 1979	
			United States	Other (principal)
METALS —Continued				
Titanium:				
Ore and concentrate	126,428	82,166	--	Australia 59,968; Norway 18,367.
Oxide and hydroxide	44,716	43,552	3,459	West Germany 15,825; France 9,911.
Metal including alloys, all forms	2,769	2,856	690	Austria 1,075; West Germany 325.
Tungsten:				
Ore and concentrate	126	181	--	Canada 126; China, mainland 35.
Metal including alloys, all forms	124	144	6	West Germany 57; United Kingdom 26.
Uranium metal including alloys, all forms kilograms	300	1,800	NA	NA.
Vanadium:				
Ore and concentrate	1,798	449	NA	NA.
Oxide and hydroxide	1,009	864	95	Austria 556; Republic of South Africa 134.
Metal including alloys, all forms kilograms	2,000	300	NA	NA.
Zinc:				
Ore and concentrate	206,600	232,587	--	Canada 64,070; Peru 49,412; Ireland 39,243.
Matte, ash, residue containing zinc	6,665	13,706	2,054	West Germany 6,720; Switzerland 2,584.
Oxide and hydroxide	2,248	2,525	--	Netherlands 986; France 778; West Germany 426.
Metal including alloys:				
Scrap	1,710	4,022	--	France 1,234; West Germany 1,150; Switzerland 778.
Blue powder	444	332	--	Norway 130.
Unwrought	54,043	56,496	--	West Germany 15,165; Belgium-Luxembourg 11,258; Netherlands 7,304.
Semimanufactures	2,038	3,047	--	West Germany 1,618; France 724; Belgium-Luxembourg 529.
Zirconium:				
Ore and concentrate	42,209	67,273	--	Australia 57,325; Republic of South Africa 4,560.
Metal including alloys, all forms kilograms	24,200	12,000	1,500	NA.
Other:				
Ores and concentrates	508	858	--	Australia 180.
Ash and residue containing nonferrous metals	15,417	34,090	--	Republic of South Africa 18,255; West Germany 1,324; France 1,685.
Oxides, hydroxides, peroxides	7,725	8,680	37	Cuba 2,914; West Germany 1,864; France 755.
Metals:				
Metalloids	1	45	NA	NA.
Alkali, alkaline-earth, rare-earth metals	6,573	4,862	--	West Germany 3,648.
Base metals including alloys, all forms	5	68	--	West Germany 41.
NONMETALS				
Abrasives, natural, n.e.s.:				
Natural: Pumice, emery, corundum, etc	3,551	2,138	--	West Germany 316; Yugoslavia 245.
Dust and powder of precious and semiprecious stones kilograms	1,111	1,421	757	Ireland 514.
Grinding and polishing wheels and stones	3,689	4,463	115	Austria 1,946; West Germany 556; United Kingdom 541.
Asbestos, crude	47,189	77,151	--	Republic of South Africa 38,935; Canada 25,044.
Barite and witherite	13,871	13,634	36	Spain 5,923; France 5,625.
Boron materials:				
Crude and natural borates	186,803	172,792	20,972	Turkey 131,264.
Oxide and acid	843	1,622	426	Turkey 700; U.S.S.R. 199.
Cement	67,729	73,158	--	France 16,087; Libya 14,871; Algeria 11,549.
Chalk	15,235	14,958	--	France 14,517.

See footnotes at end of table.

COMMODITY REVIEW

METALS

Aluminum.—Although without any significant production of bauxite, Italy was an important producer of alumina and aluminum metal during 1980.

Planning for the expansion of the large alumina plant at Porto Scuso in Sardinia, owned by Euroalumina, slowed down; reportedly the idea of expansion was abandoned during the last part of the year.

The Societa Aluminio Veneto per Azioni and Lavorazione Leghe Leggere decided to merge. It will be known as Sava-Aluminio-Veneto. The new company will operate two primary aluminum smelters (Fusina and Porto Marghera), with a total annual capacity of 60,000 tons, and plants near Milan for production of 100,000 tons per year of aluminum semimanufactured products, 10,000 tons per year of aluminum foil, and 7,000 tons per year of "rolbond." The total work force should be 3,200 persons and annual value of sales should reach an equivalent of US$270 million.

A small output of bauxite came from mines at Palmarigi, Otranto, and Poggiardo in the Puglia region owned by the Societa Mineraria Montevergine. Most of the domestic bauxite was used by the cement industry.

Iron and Steel.—Italsider Mines on the Island of Elba continued production during 1980. In the Ginevro Mine the northern part of the deposit was exhausted. Rumors regarding planned shutdown of mines on Elba caused strong protest from both local authorities and trade unions. In response, the Italsider group confirmed that the mining will continue up to the expiration of its concession at the end of 1981.

A proposal for reorganization of Italy's state-owned steel group, Finsider, was made public at the end of 1980. The plan aims to form three groups of operating companies, Italsider, Piombino, and Societa Italiana Acciai Speciali (SAIS). Italsider would be considerably slimmed down and would be essentially a flat rolled steel producer, with perhaps a change of name. Piombino would take over two plants operated by Italsider (the San Giovanni Valdarno and Marghera works), thus becoming the largest producers of rails and sections in Italy. The SAIS, Finsider's sales agency, was scheduled to take over ownership and operations of the special steelworks of Breda and Cogne. Approval from the authorities for this reorganization was expected sometime in 1981.

At San Zeno Naviglio, south of the city of Brescia, north Italy, the Seta S.p.A., an affiliate of Pietra Acciaierie Ferriere Tubifici S.p.A., started operation of a 500,000-ton-per-year electric arc and continuous caster for rounds of 200 to 450 millimeters.

At Italsider's Cornigliano plant, near Genoa, a new continuous slab caster went into operation in the second half of 1980. The new unit had a capacity of 1.2 million tons per year of slabs 4 to 8 meters long. In addition, at Cornigliano, in the second quarter of the year, the modernization and rebuilding of the coke oven battery No. 1 was completed. The 30-oven battery was fully onstream at the end of May. Furthermore, at Cornigliano, reconstruction of the No. 2 blast furnace was completed in the first half of 1980. Reportedly, after reconstruction, consumption of energy at blast furnace No. 2 was lower than it was before remodeling. The No. 2 furnace has an 8.6-meter hearth diameter and has a daily capacity of about 3,000 tons.

The leading private sector steel producer, Falck, decided to build a continuous casting installation based on technology developed by the Société des Etudes de Centrifugation, a subsidiary of the French steel producers, Creusot-Loire and Vallourec. The new four-strand caster should produce 180,000 to 200,000 tons per year of steel rounds of various sizes. Startup was planned for the latter part of 1981.

Lead and Zinc.—During 1980, lower mine production of lead and zinc resulted from the closure of several mines and drop in grade of mined ores. The Salafossa Mine, owned by Pertusola, located near Santo Pieto di Cadore, Province of Belluno, was closed in August because a large landslide destroyed the mine's flotation plant. At yearend the mine remained closed. At Monteponi Mine, owned by SAMIM, located near Inglesia, Province of Cagliari, Sardinia, production from the low-grade ore body was reduced and preparation for dewatering the 200-meter level was underway during 1980. In addition, reconstruction of the mine's flotation plant had begun, but details were withheld.

The Fontana Ramirosa Mine, owned by

SAMIM and located in Sardinia, was closed for ecological reasons. A new flotation plant, with technology that will offer better protection to the environment, was under construction during 1980. Preparatory work for opening a new mine in the area continued. Montevecchio Mine, owned by SAMIM, located at Guspini, Province of Cagliari, Sardinia, was closed during the year to evaluate the results of experiments in mining with cement slurry back filling.

The Arenas Mine, owned by the Piombo Zinzifera Sarda S.p.A., located in Sardinia, was closed for 4 months because of a major repair of the flotation plant.

A decision was made to start modernization and expansion of the zinc plant at Porto Vesme in Sardinia, to a capacity of 75,000 tons of metal per year. Three obsolete smelters, Ponte Rosa, Porto Marghera, and Monteponi, were not closed during 1980, but reports indicated all of them may be converted to producers of secondary metal.

SAMIM announced future production goals. By 1983, SAMIM plans to produce 95,000 tons of lead and zinc concentrates, as well as 160,000 tons of smelter zinc, and 130,000 tons of smelter lead per year.

Titanium.—The Societa Amiantifera del Balangero of Turin and Societa Mineraria Italiana have obtained a concession to develop a titanium deposit at Pian Paludo, near Novara, which according to reports, is of high commercial value. No other details on the deposit were made public.

No development has taken place on the large titanium ore deposit on Mount Beigua, near Varazze west of Genoa. The Beigua deposit is rutile with a titanium metal content of up to 7%. Reserves were estimated at 50 million tons, from which 2.5 million tons of rutile may be recovered. Ecological problems have delayed development since its discovery in 1977. The deposit is located in an untouched area of the Liguria coast and mining might mean destruction of one of the country's few remaining natural landscapes. Opposition to mining was strong but the consortium stated that with advanced, but costly, technology both conservation and mining of minerals can be achieved.

NONMETALS

Barite.—Bariosarda Co., a state-owned entity, and Edem Co. and Mineraria Baritina S.p.A., both private, controlled the country's barite output during 1980. Exploration programs were underway in the Arcu Sa Cruzi, Sa Bagatu, Seddorgia Barega, and Mont'Ega Mines in Sardinia, all operated by Bariosarda Co., leading to the discovery of some additional reserves. Bariosarda has increased its capacities for desliming and crushing barite to 1,000 tons per day at the Barega and Mont'Ega Mines.

Fluorspar.—Fluorspar was mined by two private companies, Mineraria Silius and Fluoramine in northern Italy, Sardinia, and Latium. Mineraria Silius, with mines at Gennas, Tres Montes, and Miscandroxiu in Sardinia, was by far the largest producer of fluorspar and accounted for approximately two-thirds of the country's output; in the area of the Silus mines in Sardinia, work on a central shaft for several mines continued and conversion to full mechanization was underway during 1980.

The completion of the Pianciano fluorspar mine and plant located in the Province of Lazio, about 34 kilometers northwest of Rome, was delayed because of slow delivery of equipment. The operator, Soucom S.p.A., a fully owned subsidiary of Southland Mining Ltd. of Australia, expected start of production in 1981.

Magnesium.—Societa Italiana per il Magnesio e Leghe di Magnesio, which operated a 12,000-ton-per-year magnesium plant at Bolzano, announced the possibility of stopping production. High costs for power and lower demand for magnesium made the operations uneconomic. The future of the plant depended on the results of continuing power tariff negotiations.

Potash.—Reduced potash production in Sicily resulted from lower output of the San-Cataldo-Palo Mine, where reserves were near exhaustion, and from closure of the Racalmuto Mine for repair of the main shaft.

At the Milena Mine, development work continued. About 300 meters of inclined truck ramp as well as buildings for powerplants, offices, warehouses, and repair shops were completed. Reportedly, the new mine would become operational some time during 1982 or 1983. Exploration by drilling continued to determine whether the Milena Mine is connected with the Vallone potassium-salts bearing basin. If the connection exists, a third plant for the conversion of the kainite ore to potasium sulfate may be built. All ore mined in Sicily was principally kainite.

Pyrite.—At a Campiano mine (Grosseto), operated by Solmine S.p.A., a service ramp for trucks that joins the 240 level below the sea level with the surface was completed. During 1980, Solmine S.p.A. produced all of the pyrite in Italy. Pyrite was consumed in

a sulfuric acid plant and pyrite cinder was used in a plant for production of iron pellets. Both plants were operated by Solmine.

MINERAL FUELS

In the fall of 1980, the revision of the National Energy Plan was completed. The draft of the plan was sent to the Council of Ministers for approval but was withdrawn for further study before yearend. It was expected that the Parliament would act on the energy plan during 1981.

Italy was dependent on imports of high-rank coals, crude oil, and natural gas to meet its energy demand. The major domestic source of energy was natural gas, followed by hydropower and a modest output of lignite, but even natural gas imports amounted to 53% of the country's consumption.

Coal.—Exploration around the Santa Barbara lignite mine near Arezzo confirmed the existence of an additional 2 million tons of lignite in the area.

The Italian Government, Carbosulcis (owned by the Sardinian Regional Government), and SAMIM continued to work on reopening of the Sulcis Coalfield in Sardinia. The authorities were planning a two-prong approach to reopening the Sulcis Mine. At first the old mine will be reopened and the coal will be used in power-generating installations in Sardinia. To minimize pollution, the high-sulfur Sulcis coal will probably be mixed with low sulfur imported coal before it is used in powerplants. Over the long term, the Government and ENI were exploring technologies that could be used to gasify and liquefy Sulcis coal. Imports of coal were essential to meet the country's energy demand. During the past 3 years, use of coal in Italy was increasing, reflecting efforts by the Government to lower the use of imported and expensive crude oil.

Natural Gas.—Although natural gas was the largest primary energy source produced in the country, Italy was chiefly dependent on imports to meet demand during 1980. Construction of the Trans-Mediterranean gas pipeline from Rassi R'mel in Algeria to Minerbio near Bologna in Italy continued. The first of the three underwater pipelines between Algeria and Sicily, Italy, were laid down. The first flow of gas was planned for 1981, providing agreement is reached on the price.

A new onshore gasfield was discovered near Ravenna by ENI. ENI expects to discover wells that produce 300 million cubic meters of gas per year. Near Ravenna, ENI also has 15 offshore platforms with 118 wells in operation.

Another deposit of natural gas was discovered offshore Gyevi, near San Benedetto del Tronto, a port on the Adriatic Sea. Tests on the first well indicated a possible daily production of about 0.25 million cubic meters. At yearend, further drilling was underway to determine the size and economic potential of the deposit.

In addition, Societa Viscosa announced a natural gas strike at Biccari near Foggia (Puglia). Preliminary reports indicated dry gas (99% methane) at pressures up to 200 atmospheres. Depth of the pay zone was 2,400 meters.

Petroleum.—During 1980, exploration for petroleum continued but no major discoveries were announced. The number of exploration permits decreased compared with those of previous years. However, the apparent decline in these activities does not reflect the interests of domestic and foreign companies in exploration in Italy because they do not include permits granted in offshore Zone F. AGIP and Texaco Inc. jointly requested 16 oil exploration permits covering 1.1 million hectares, including all of the Puglia region and parts of Zone F. AGIP started exploration offshore in an area located between Marsala, Sicily, and Pantellaria Islands, and plans were made to explore the Sicilian mainland as soon as necessary permits were granted by the regional government.

With a total output of 97 million tons, Italian refineries had a low rate of utilization during 1980, probably about 60%; a major reason, in addition to low demand, was the imposition of Government regulations requiring export licensing for reexport of products, which made processing of crude less advantageous in Italy than in other European processing centers.

Mediterranea Raffineria Petroli S.p.A. of Messina, a subsidiary of the largest Italian independent oil group, owned by Attilio Monti, became insolvent and the Ministry of Industry appointed a commission to find a solution to its problems. One measure taken was to revoke the operating permits of the company's four refineries, which had an annual capacity of 37 million tons. In addition ENI, after negotiations, took over the group's SAROM company, with a refinery at Ravenna. At yearend, ENI was negotiating to take over the rest of the group.

---

The Mineral Industry of Japan

By John C. Wu[1]

Despite the sluggish domestic demand and the continuing rise in oil prices in 1980, Japan's economy successfully achieved a 4.2% growth in real gross national product (GNP). According to the Economic Planning Agency, Japan's real GNP in 1975 constant yen, increased from 181,740.8 million yen in 1979 to 189,431.4 million yen in 1980. An increased investment on plant and equipment by industry and a high rate of export earnings were cited as the major contributing factors to the growth of Japan's GNP in 1980. During the 1979-80 period, the wholesale price index rose by 17.8%, and the consumer price index increased by 8.0%. However, the unemployment rate was kept at 2.0% of the 56.5 million labor force throughout 1980.

Since the 1973 energy crisis, Japan has been investing heavily in plant and equipment designed mainly for energy- and labor-saving purposes. Investment in machinery and equipment, consistently accounting for 15% of Japan's GNP during the 1975-78 period, rose 16% to 17% of the GNP during the 1979-80 period. As a result, labor productivity of the Japanese industry has increased rapidly during the past 4 years. An increase in labor productivity has strengthened the Japanese industry's competitive position in the world market, as well as sustained a high rate of export earnings.

According to Japan's Productivity Research Institute, labor productivity indexes for all industries, as well as selected mining- and mineral-related manufacturing industries for the 1977-80 period, with 1975 as a base year, were as follows:

	1977	1978	1979	1980
Industry	117.6	126.9	141.9	154.6
Mining	112.6	123.0	125.1	124.9
Coal	102.6	106.3	106.1	112.3
Metal	117.9	130.0	136.2	143.1
Nonmetal	124.2	149.6	160.6	148.3
Crude petroleum and natural gas	112.8	113.5	102.9	100.1
Manufacturing	118.0	127.4	142.8	156.0
Iron and steel	114.1	121.4	140.1	145.9
Nonferrous metal	132.1	148.3	161.4	162.4
Stone, clay, glass products	119.7	131.2	144.7	150.2
Chemical	120.5	136.9	153.2	157.7

In stabilizing prices, Japan has successfully controlled the growth in labor productivity in excess of the growth in wage cost.

According to the Metal Mining Agency of Japan, the number of mines under operation and the number of employees for metal and nonmetal mining in 1973, 1975, 1977, and 1979 were as follows:

Year as of April 1	Number of mines		Number of employees	
	Metal	Nonmetal	Metal	Nonmetal
1973	139	898	22,913	23,318
1975	107	828	19,037	22,224
1977	96	754	16,914	20,168
1979	79	730	12,551	18,967

Scarce resources, declining ore grades, high labor costs, and rigid Government environmental restrictions were the major factors for the decline of the Japanese mining industry over the past 7 years. However, the limestone mining industry of Japan remained one of the world's largest in 1980. Japan continued to be a significant

producer of lead and zinc in the world. However, Japan's coal mining industry, despite a moderate gain in labor productivity, was unable to expand and achieve its 20-million-ton-per-year goal.

Japan continued to be among the world's significant producers of cement, iron and steel, ferroalloys, fertilizer, nonferrous metals, and petroleum products. However, Japan is dependent on overseas sources for most of its major minerals. For example, dependency of iron ore on imports was about 98.5% in 1980; copper ore, 97.5%; bauxite, 100%; coking coal, 89%; phosphate rock, 100%; and crude petroleum, 99.8%. To secure stable sources of imports, most of Japan's major minerals were imported under a long-term contract or received through overseas minerals development by investment (equity participation) and by technological assistance in exploration.

During 1980, a multimillion-dollar Amazon aluminum project was signed with Brazil, a joint venture project agreement was reached with China for development of a major copper mine near Tongling in Anhui Province, and a joint venture company was established with Peru for exploration of lead and zinc in central Peru. Major long-term coal contracts were signed in 1980 with Australia and Canada. Japan also signed two major joint venture agreements; one with Australia and the other with China to develop steam coal mines. In oil exploration and development, Japan signed two major contracts with China to develop the oil resources in Bo Hai Bay. Japan also signed an agreement with Canada to develop the oil deposits of Beaufort Sea in the Arctic. In addition to the existing overseas sources of its liquefied natural gas (LNG), Japan secured two 20-year supply contracts from Canada and the Soviet Union. A major long-term uranium purchase contract was also signed by Japan and Australia.

Japan's direct overseas investment in fiscal year (FY) 1979 totaled $4,995 million, according to the Ministry of Finance. The figure represented an 8.6% increase over the previous fiscal year, and was about 0.5% of the country's GNP. Since FY 1951, Japan's cumulative direct overseas investments were $31,804 million by FY 1979. The share of investments in North America, Latin America, and Oceania increased from 49.8% of the outstanding balance for 1951-79 to 64.6% of the overseas investments for FY 1979, while the share of Asia, the Middle East, and Africa decreased from 37.9% to 25.5%. Other new characteristics of Japan's overseas investments for FY 1979 were a sharp increase in the form of credit acquisitions and a significant increase in investments in natural resources.

Japan's overall foreign economic assistance in FY 1979 totaled $7.6 billion, down 29% from $10.7 billion recorded in 1978, according to the Ministry of International Trade and Industry (MITI). However, the Japanese Official Development Assistance (ODA) in FY 1979 totaled $2.6 billion, representing a 19.1% increase over the previous year. ODA funds were distributed as follows: $560.2 million was for financial grants and technical assistance, $1,361 million was for development lending and capital, and the remainder was for contributions to multilateral institutions. According to a MITI white paper released in late 1980, Japan would provide economic assistance to the developing nations because of its need in securing a stable supply of oil and other energy resources.

During the past 5 years, exports of chemicals and heavy industry products (such as machinery, electric power machinery and equipment, and motor vehicles) have been rising in terms of quantity as well as unit value. Concomitantly, exports of light industry products (such as textiles, wood products, and foodstuffs) were on the decline. Imports of intermediates (such as fabrics, refined metals, and alloys) have been rising faster than imports of raw materials (such as raw textile materials and metal ores). A significant technological advance in chemicals and heavy industries and high energy costs of processing the raw materials were the principal factors for the change in the Japanese trade structure. In 1980, Japan's total exports were valued at $129.8 billion,[2] a 26% increase over that of 1979. Increased exports of automobiles and machinery and equipment contributed most to the increase in exports. Japan's total imports also rose by 27% to $140.5 billion. Increased imports of mineral fuels contributed most to the increase in imports, despite a decline in volume of crude oil imports in 1980. The merchandise trade deficit in 1980 was valued at $10.7 billion.

During 1978-80, Japan's export earnings and import expenditures of selected major mineral-related groups were summarized as follows, in million U.S. dollars:

	1978	1979	1980
Exports:			
Chemicals	5,102	6,100	6,766
Chemical fertilizers	282	328	376
Nonmetallic mineral products	1,378	1,547	1,862
Metal and metal products	16,041	18,378	21,318
Iron and steel	11,854	14,113	15,454
Imports:			
Chemicals	3,763	5,178	6,202
Metal, ore and scrap	4,836	6,850	8,429
Iron ore	2,453	2,999	3,448
Nonferrous metal ore	1,754	2,879	3,730
Mineral fuels	31,336	45,286	69,991
Petroleum, crude and partly refined	23,432	33,470	52,762
Petroleum products	2,273	4,499	5,087

In its report to the Ministerial Conference for Enforcing Comprehensive Energy Policies in 1980, MITI stressed that securing a steady supply of energy is the utmost priority for Japan. It was recommended that the Government should press ahead with policies designed to secure a steady supply of oil, to promote energy conservation pursuant to the Law for Rationalization of Energy Use, to push forward comprehensive measures for the development and introduction of nonoil energy sources (atomic power, coal, LNG, etc.), pursuant to the Alternative Energy Law, to deepen the understanding of the communities adjacent to proposed sites for power stations, to simplify the procedures for the development of sites for power stations, and to implement the laws concerning power source developments.

In 1980, MITI announced that it would seek an appropriation of 2.1 billion yen in FY 1981 for the research and development of a satellite and equipment program to launch a natural resources exploration project. MITI planned to launch the satellite into a 560-kilometer earth orbit to conduct exploration from space for oil, uranium, iron ore, and other natural resources in 1986. The estimated total project cost was about 80 billion yen.

PRODUCTION

Japan's mine production of copper, gold, lead, manganese, tin, and tungsten declined in 1980, while production of iron ore and most of the nonmetallic minerals including clays, dolomite, limestone, pyrophyllite, and silica stone and sand, were at a higher level in 1980 than in 1979. Domestic crude oil and natural gas production continued to decline in 1980. However, coal production in 1980 increased slightly over that of 1979 owing to an increase in labor productivity.

Production of metals through processing of domestically produced and imported raw materials in 1980 was at a higher level for aluminum, cobalt, copper, tin, and titanium reflecting either increased exports or strong domestic demand for the metals. Production of gold, iron and steel, lead, primary magnesium, nickel, silver, and zinc decreased slightly owing to the sluggish domestic demand and reduced exports. Japan became the world's second largest producer of steel in 1980. In metal output of aluminum, copper, and zinc, Japan remained among the world's top 10 producing countries. Japan's production of titanium sponge increased by 46% to 19,000 tons, surpassing the output of the United States and making Japan the world's second largest producer following the U.S.S.R. in 1980.

Production of cement by processing domestic raw materials reached another record high in 1980, while output of fertilizer continued to decline owing to increased prices of raw materials and declining exports. Japan remained a major producer of refined oil and petrochemicals in 1980.

Table 1.—Japan: Production of mineral commodities[1]

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Sept. 8, 1981.

[2]For reasons not evident in sources, these figures are reported as negative numbers. (See also footnote 3.)

[3]Sum of listed detail as reported, but adding quantity bearing footnote 2 as positive numbers. Japanese sources provide the following totals for ferroalloy output in the years indicated: 1978, 1,512,791; 1979, 1,900,974; and1980, 1,866,423. These totals represent the sum of listed detail using the quantities bearing footnote 2 as negative numbers, thereby not only omitting the footnoted numbers, but actually subtracting them from the sum of all other alloys. The reason for this procedure in source publications is not explained.

[4]Includes a small amount of natural coke.

[5]Includes output from gas mines and coal mines.

[6]May include some additional unfinished oils.

TRADE

In 1980, Japan's total value of two-way merchandise trade reached $270.3 billion, with values of exports and imports amounting to $129.8 billion and $140.5 billion, respectively. The record high trade deficit of over $10 billion represented a 40.3% increase over that of 1979. The increased deficit in 1980 was primarily because of a 54.6% increase in the import bills of crude oil and a 23% increase in the prices of imported mineral ores and metals.

The top seven foreign exchange earners were export of motor vehicles, valued at $23.3 billion and accounting for 18% of the total export earnings; iron and steel, $15.5 billion (12%); vessels, $4.7 billion (3.6%); scientific and optical equipment, $4.5 billion (3.5%); metal products, $3.9 billion (3.0%); tape recorders, $3.3 billion (2.5%); and radio receivers, $3 billion (2.3%). The seven principal imports were petroleum (crude and partly refined), valued at $52.8 billion,

which accounted for 37.6% of the total imports; wood, $6.9 billion (4.9%); petroleum products, $5.1 billion (3,6%); nonferrous metals, $4.5 billion (3.2%); coal, $4.5 billion (3.2%); nonferrous metal ores, $3.7 billion (2.6%); and iron ore, $3.5 billion (2.5%).

Of Japan's total exports, the United States remained the principal customer for total exports, accounting for about 24%, followed by the Federal Republic of Germany, 4.4%; the Republic of Korea, 4.1%; Taiwan, 4.0%; China, 3.9%; Hong Kong, 3.7%; and Saudi Arabia, 3.7%. The United States was the main buyer of Japan's motor vehicles, iron and steel, metal products, machinery and equipment (other than motor vehicles), and nonmetallic mineral products.

The United States also remained the major supplier of total imports, accounting for about 17%, followed by Saudi Arabia, 14%; Indonesia, 9.4%; Australia, 5.0%; Canada, 3.4%; Iraq, 3.1%; and China, 3.1%. The United States was the main supplier of Japan's chemicals, coal, equipment and machinery, foodstuffs, metal ores and scrap, and wood.

During 1980, the top seven trading partners of Japan, based on the value of two-way trade, were the United States with total trade valued at $55.8 billion; Saudi Arabia, $24.4 billion; Indonesia, $16.6 billion; Australia, $10.4 billion; China, $9.4 billion; the Republic of Korea, $8.4 billion; and Taiwan, $7.4 billion.

Table 2.—Japan: Exports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)

Metal including alloys:				
Scrap	1,097	292	--	Republic of Korea 137; Taiwan 113.
Unwrought	54,594	7,946	1	Philippines 3,094; Republic of Korea 1,714.
Semimanufactures	149,185	98,959	39,025	Republic of Korea 11,082; Taiwan 6,699; Hong Kong 6,580.
Arsenic trioxide, pentoxide, acid	6	NA	NA	NA.
Beryllium metal including alloys, all forms kilograms	237	6	--	Singapore 5.
Bismuth metal including alloys, all forms	288	182	71	Netherlands 52.
Cadmium metal including alloys, all forms	111	151	--	Netherlands 94; United Kingdom 23; India 20.
Chromium:				
Chromite	1,636	1,786	--	All to Republic of Korea.
Oxides and hydroxides	1,562	1,965	612	Taiwan 616; Republic of Korea 370.
Cobalt oxides and hydroxides	87	41	2	Netherlands 8; West Germany 6; Taiwan 6.
Columbium and tantalum: Tantalum metal including alloys, all forms	41	30	16	West Germany 9; Austria 5.
Copper:				
Sulfate	325	246	--	Taiwan 177; Indonesia 20.
Metal including alloys:				
Waste and scrap	51,411	47,233	18,387	Taiwan 24,125.
Unwrought	4,530	5,535	650	Republic of Korea 4,792.
Semimanufactures	164,324	175,974	30,124	Hong Kong 28,700; Taiwan 24,898; Singapore 12,994.
Iron and steel:				
Ore and concentrate	18	49	--	Taiwan 35; Hong Kong 14.
Metal:				
Scrap	164,395	150,562	97	Republic of Korea 78,125; Hong Kong 46,646.
Pig iron, including cast iron	32,678	50,225	--	Republic of Korea 28,183; Bangladesh 16,500.
Sponge iron, powder, shot	10,585	10,537	1,341	Australia 2,337; Republic of Korea 2,047; Taiwan 1,193.
Ferroalloys:				
Ferromanganese thousand tons	37,147	92,886	30,927	China, mainland 23,290; Australia 10,294.
Other do	r33,153	39,559	5,885	Netherlands 23,097; China, mainland 4,002; Republic of Korea 2,132.
Steel, primary forms do	4,428	4,568	575	Republic of Korea 1,154; Taiwan 503; Philippines 289.

See footnotes at end of table.

Table 2.—Japan: Exports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS —Continued				
Iron and steel —Continued				
Metal —Continued				
Semimanufactures:				
Bars, rods, angles, shapes, sections thousand tons	6,166	7,202	1,351	China, mainland 1,379; Saudi Arabia 929; Iraq 568.
Universals, plates, sheets:				
Uncoated do	10,372	6,019	972	China, mainland 1,595; Taiwan 638; Republic of Korea 361.
Tinned do	815	834	189	China, mainland 104; Philippines 93; Singapore 56.
Other, coated do	2,315	2,381	1,092	Saudi Arabia 110.
Hoop and strip do	812	633	62	China, mainland 152; Indonesia 58; Taiwan 34.
Rails and accessories do	193	139	37	China, mainland 33.
Wire do	367	302	115	China, mainland 24.
Tubes, pipes, fittings do	6,280	6,630	1,375	U.S.S.R. 1,242; China, mainland 770.
Castings and forgings, rough do	31	26	14	Iraq 2; Taiwan 2.
Lead:				
Ore and concentrate	9,312	8,266	--	All to U.S.S.R.
Oxides	1,021	243	--	Taiwan 123; Burma 79.
Metal including alloys, all forms	9,587	15,627	2	Taiwan 6,602; Republic of Korea 5,596.
Magnesium metal including alloys, all forms	313	108	--	Republic of Korea 40; Taiwan 24; Singapore 17.
Manganese:				
Ore and concentrate	4,831	6,230	--	Republic of Korea 3,442; Indonesia 962.
Oxides	21,946	19,436	3,401	Republic of Korea 2,329; Indonesia 2,135; Philippines 1,570.
Mercury 76-pound flasks	6,929	15,662	9,273	Netherlands 1,261; Taiwan 1,200; Indonesia 1,082.
Molybdenum metal including alloys, all forms	39	71	18	Hungary 18.
Nickel:				
Ore and concentrate	--	40	--	All to Sweden.
Metal including alloys, all forms	5,242	2,623	1,232	Taiwan 205; Republic of Korea 162.
Phosphorus, elemental (red)	148	91	2	Taiwan 30; Vietnam 25; Philippines 15.
Platinum-group metals including alloys, unwrought and partly wrought thousand troy ounces	123	137	14	Taiwan 68; Netherlands 22; Republic of Korea 15.
Selenium, elemental	264	313	39	Netherlands 98; United Kingdom 71.
Silver:				
Waste and scrap	15	24	--	Mainly to Republic of Korea.
Metal including alloys, unwrought and partly wrought thousand troy ounces	3,015	4,155	883	Taiwan 942; Republic of Korea 813; United Kingdom 767.
Tin:				
Oxides	11	35	17	Netherlands 4; Republic of Korea 4.
Metal including alloys, all forms	r488	1,405	2	Burma 439; Taiwan 435; Mozambique 120.
Titanium:				
Oxides	10,503	13,818	2,875	Taiwan 3,916; Republic of Korea 2,554; China, mainland 1,202.
Metal including alloys, all forms	4,176	4,887	2,164	Netherlands 1,382; United Kingdom 1,055.
Tungsten metal including alloys, all forms	172	209	43	U.S.S.R. 58; Taiwan 25.
Zinc:				
Ore and concentrate	458	798	--	All to Canada.
Oxides	1,322	690	(2)	Republic of Korea 313; Thailand 123; Taiwan 108.
Metal including alloys, all forms	67,181	42,642	12,005	Republic of Korea 9,320; Taiwan 5,572; Thailand 4,071.
Other:				
Ores and concentrates:				
Of molybdenum, tantalum, titanium, vanadium, zirconium	1,398	844	29	Republic of Korea 632; Vietnam 100.
Of other base metals	153	2	--	Malaysia 1; People's Democratic Republic of Yemen 1.
Ash and residue containing nonferrous metals	5,123	10,898	3,314	Belgium 1,608; United Kingdom 1,531; West Germany 1,240.
Oxides, hydroxides, peroxides	2,164	1,592	156	Republic of Korea 457; Taiwan 276; Iraq 200.
Metals:				
Metalloids	149	NA	NA	NA.

See footnotes at end of table.

Table 2.—Japan: Exports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS —Continued				
Other —Continued				
Metals —Continued				
Alkali, alkaline earth, rare-earth metals	688	861	100	Taiwan 554; France 58.
Pyrophoric alloys	81	76	12	France 30; Hong Kong 9.
Base metals including alloys, all forms	7,236	5,841	2,004	West Germany 617; Australia 506; Netherlands 425.
NONMETALS				
Abrasives, n.e.s.:				
Natural:				
Emery	1,429	1,340	--	Taiwan 400; Republic of Korea 304; Hong Kong 171.
Other	416	506	1	Taiwan 243; Republic of Korea 242.
Dust and powder of precious and semi-precious stones -- thousand carats	1,168	934	685	Taiwan 138; Republic of Korea 83.
Grinding and polishing wheels and stones	4,868	6,215	976	Thailand 784; Hong Kong 707; Singapore 677.
Asbestos	756	147	--	Taiwan 50; Republic of Korea 40; India 26.
Barite and witherite	2,894	1,002	--	U.S.S.R. 1,000.
Boron materials:				
Crude natural borates	285	381	--	All to Republic of Korea.
Oxide and acid	120	150	(2)	Republic of Korea 101; Taiwan 35.
Cement thousand tons	8,624	10,814	1,468	Saudi Arabia 2,594; Kuwait 1,965; Singapore 1,290.
Chalk	50	13	--	All to Republic of Korea.
Clays and clay products:				
Crude clays	64,171	79,267	20	Taiwan 50,865; Republic of Korea 14,372.
Products:				
Refractory including nonclay brick	167,655	196,270	8,580	Republic of Korea 47,164; Taiwan 20,804; Brazil 20,766.
Nonrefractory[3]	48,442	44,896	16,090	Singapore 10,514; Hong Kong 6,337.
Diamond:				
Gem, not set or strung carats	232	1,031	--	Republic of Korea 539; Hong Kong 484.
Industrial do	1,185	1,286	--	Romania 478; North Korea 225; Republic of Korea 219.
Diatomite and other infusorial earth	1,298	1,277	15	Taiwan 392; Cuba 192; U.S.S.R. 180.
Feldspar	15,157	23,630	6	Taiwan 22,219.
Fertilizer materials:				
Manufactured:				
Nitrogenous thousand tons	2,030	1,816	(2)	China, mainland 1,268.
Phosphatic	10,726	26,243	--	Burma 18,414; Taiwan 4,510.
Potassic	4,153	2,006	--	Republic of Korea 2,003.
Other including mixed	64,182	141,185	499	Thailand 88,546; Philippines 21,100.
Ammonia	201,108	169,675	--	Philippines 156,368.
Fluorspar, leucite, nepheline, nepheline syenite	532	115	--	Taiwan 71; Indonesia 36.
Graphite, natural	1,406	1,554	217	Republic of South Africa 650; Taiwan 412.
Gypsum and plasters	6,172	6,157	22	Taiwan 2,524; Republic of Korea 1,392; Indonesia 822.
Kyanite and related materials	16,470	22,721	--	Taiwan 16,362; Republic of Korea 2,816; Thailand 2,170.
Lime	33,290	28,581	--	Papua New Guinea 22,562.
Magnesium materials:				
Magnesite and magnesia clinker	144,796	133,832	24,676	Australia 22,815; Taiwan 13,670; Republic of Korea 12,488.
Oxides	NA	4,467	780	West Germany 1,019; Taiwan 511; U.S.S.R. 350.
Mica, all forms	783	714	39	Hong Kong 308; Taiwan 210.
Pigments, mineral including processed iron oxides	15,589	16,731	3,169	Taiwan 7,159; Mexico 1,250; Republic of Korea 1,080.
Precious and semiprecious stones except diamond:				
Natural kilograms	75,753	50,044	2,388	Republic of Korea 29,340; Taiwan 11,617.
Manufactured do	24,108	29,934	839	Republic of Korea 12,197; West Germany 6,830; Malaysia 3,297.
Salt and brine	2,934	2,774	1,850	North Korea 338; Papua New Guinea 174.
Sodium and potassium compounds, n.e.s.:				
Caustic soda	146,385	243,413	15	Australia 192,962; Republic of Korea 27,179; Thailand 20,491.
Caustic potash, sodic and potassic peroxides	5,501	5,268	55	Taiwan 1,217; Australia 1,149; Republic of Korea 1,025.

See footnotes at end of table.

Table 2.—Japan: Exports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
NONMETALS —Continued				
Sodium and potassium compounds, n.e.s. — Continued				
Soda ash	110,487	114,598	13	Indonesia 43,371; Philippines 22,958; Republic of Korea 13,357.
Stone, sand and gravel:				
Dimension stone	1,507	1,010	50	Republic of Korea 417; Saudi Arabia 194.
Dolomite, chiefly refractory-grade	5,399	8,470	--	Philippines 5,350; Indonesia 2,060.
Gravel and crushed rock	19,541	213,617	14	Australia 138,520; Republic of Korea 73,834.
Limestone except dimension thousand tons	1,339	1,427	(2)	Australia 1,280.
Quartz and quartzite	568	1,209	43	Saudi Arabia 350; Taiwan 336; Republic of Korea 232.
Sand excluding metal-bearing	6,956	4,667	--	United Arab Emirates 1,020; Taiwan 959; Republic of Korea 778.
Sulfur:				
Elemental:				
Other than colloidal	320,986	414,884	--	Republic of Korea 312,762; Taiwan 86,609.
Colloidal	220	221	--	North Korea 132; Cuba 40; Iraq 32.
Sulfur dioxide	66	[4]33	--	Taiwan 31.
Sulfuric acid	325,195	362,387	--	Turkey 140,312; Peru 87,039; Philippines 75,745.
Talc, steatite, soapstone	1,803	1,145	--	Taiwan 352; Republic of Korea 235; Philippines 176.
Other:				
Crude	10,112	12,335	19	Republic of Korea 4,991; Taiwan 2,669; Argentina 766.
Slag, dross, and similar waste, not metal-bearing	[r]517,185	528,972	--	Republic of Korea 237,571; Philippines 156,051.
Oxides, hydroxides, peroxides of strontium and barium	[5]4,340	27,019	253	Poland 18,254; Thailand 2,561; Republic of South Africa 2,000.
Bromine, iodine, fluorine	6,020	5,524	2,217	United Kingdom 734; France 650; West Germany 609.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	7	3	--	Republic of Korea 2.
Carbon black and gas carbon:				
Carbon black	30,856	26,883	16	China, mainland 14,076; Indonesia 2,625; Singapore 1,461.
Gas carbon	26	--		
Coal, all grades, including briquets	47,740	59,563	--	Republic of Korea 40,862; North Korea 15,400.
Coke and semicoke	896	2,081	1,012	Philippines 222; Peru 149; Republic of Korea 138.
Hydrogen, helium, rare gases	1,156	1,008	11	Taiwan 351; Republic of Korea 155; Saudi Arabia 127.
Petroleum refinery products:				
Gasoline thousand 42-gallon barrels	83	62	--	Taiwan 51.
Kerosine do.	1,508	56	40	Australia 7.
Distillate fuel oil do.	503	(2)	--	NA.
Residual fuel oil do.	233	452	50	Taiwan 203; Republic of Korea 198.
Lubricants do.	2,350	1,889	150	Republic of Korea 740; Taiwan 297; Indonesia 255.
Other:				
Liquefied petroleum gas do.	282	367	--	Republic of Korea 143; Philippines 140; Hong Kong 63.
Mineral jelly and wax do.	565	554	17	Republic of South Africa 148; Republic of Korea 93; India 52.
Petroleum coke do.	33	37	--	Italy 31.
Bitumen do.	6	7	--	NA.
Unspecified do.	101	101	--	Republic of Korea 50; Taiwan 19; India 16.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	149,461	163,991	8,733	U.S.S.R. 78,900; Republic of Korea 38,189; Taiwan 23,205.

[r]Revised. NA Not available.

[1]Excludes exports under the Japanese-United States Mutual Defense Agreement or for account of the U.S. military forces.

[2]Less than 1/2 unit.

[3]Excludes mosaic tiles valued at $83,370,000 in 1978 and $82,918,000 in 1979.

[4]May contain some arsenic trioxide and pentoxide.

[5]Includes oxides of magnesium.

Table 3.—Japan: Imports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1978	1979	Sources, 1979	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite and concentrate thousand tons	4,743	4,597	2	Australia 3,204; Indonesia 1,012.
Oxide and hydroxide do	759	761	2	Australia 741.
Fused alumina (artificial corundum)	5,769	10,875	259	India 4,717; Brazil 4,464.
Metal including alloys:				
Scrap	139,612	181,531	143,705	Canada 11,560.
Unwrought	740,204	748,438	104,270	New Zealand 110,132; Canada 108,811.
Semimanufactures	25,889	33,055	5,815	Romania 10,856; France 3,494; Venezuela 1,904.
Antimony:				
Ore and concentrate	6,553	6,702	56	Bolivia 5,603; Republic of South Africa 536; Thailand 335.
Metal including alloys, all forms	1,611	3,202	--	China, mainland 2,895; Bolivia 83; Spain 69.
Arsenic:				
Natural sulfides	10	30	--	All from China, mainland.
Trioxide, pentoxide, acids	755	999	--	France 666; Mexico 180.
Beryllium:				
Oxides	33	75	75	
Metal including alloys, all forms kilograms	1,674	2,197	2,197	
Chromium:				
Ore and concentrate	669,987	962,251	--	[e] Republic of South Africa 443,340; Philippines 183,553; India 156,133.
Oxide and hydroxide	3,505	2,977	1,191	West Germany 987; U.S.S.R. 650.
Cobalt:				
Oxide and hydroxide	615	651	23	Belgium 582; Canada 31.
Metal including alloys, all forms	1,351	197	75	United Kingdom 56; Netherlands 31; Canada 25.
Columbium and tantalum:				
Columbium (niobium) ore and concentrate	1,858	1,659	--	Canada 883; Brazil 600.
Tantalum:				
Ore and concentrate	128	304	--	Malaysia 142; West Germany 75.
Metal including alloys, all forms	46	61	54	West Germany 5.
Copper:				
Ore and concentrate thousand tons	2,818	2,969	172	Philippines 888; Canada 776; Papua-New Guinea 379.
Sulfate	553	730	(2)	China, mainland 215; Taiwan 154; Peru 120.
Metal including alloys:				
Scrap	55,049	50,158	24,556	Hong Kong 11,100; Taiwan 8,479.
Unwrought	[r]333,073	395,062	8,716	Zambia 158,889; Chile 78,040.
Semimanufactures	1,359	3,295	1,701	West Germany 447; Belgium 270.
Germanium:				
Dioxide	12	15	(2)	West Germany 10; Belgium 3.
Metal including alloys, all forms kilograms	1	9	--	All from Belgium.
Gold metal including alloys, unwrought and partly wrought thousand troy ounces	3,167	2,022	12	Switzerland 880; United Kingdom 871.
Indium metal including alloys, all forms kilograms	[r]2,868	6,572	1,631	Canada 1,980; United Kingdom 693; Peru 558.
Iron and steel:				
Ore and concentrate except roasted pyrite thousand tons	114,645	130,268	--	Australia 55,297; Brazil 26,136; India 17,088.
Roasted pyrite	2,891	1,495	--	[e] All from Philippines.
Metal:				
Scrap thousand tons	3,229	3,346	2,727	Australia 314.
Pig iron including cast iron do	640	551	1	Australia 171; Brazil 149; Mexico 76.
Sponge iron, powder, shot	6,389	13,054	141	Sweden 7,794; Indonesia 4,117.
Ferroalloys	361,189	503,796	7,246	Republic of South Africa 251,577; Brazil 45,874; Norway 39,567.
Steel, primary forms	149,397	648,629	3,626	Taiwan 166,137; Republic of Korea 147,844; Sweden 103,159.
Semimanufactures	23,590	37,203	4,517	Republic of Korea 19,893; Italy 3,080; Sweden 2,600.
Lead:				
Ore and concentrate	222,447	218,544	--	Canada 143,680; Peru 44,233; Australia 14,703.
Oxides	766	1,492	86	Mexico 881; China, mainland 424; Bulgaria 100.

See footnotes at end of table.

[1]Excludes imports under Japanese-United States Mutual Defense Agreement or for account of U.S. military forces.
[2]Less than 1/2 unit.
[3]Includes oxides of magnesium.

COMMODITY REVIEW

METALS

Aluminum.—After a quick recovery sustained by reduced output and increased demand in 1979, Japan's ailing aluminum industry suffered again in 1980 from a sharp fall in aluminum prices on the world market, a weak domestic demand for aluminum, and a continuing high cost of production. As a result, the imports of low-priced aluminum increased by 21% to an alltime high of 841,372 tons in 1980 and the aluminum stocks at producers plants rose from the 89,619-ton level at the end of 1979 to 231,491 tons at the end of 1980. Aluminum production was cut back substantially in the second half of 1980. For 1980 as a whole, Japan's aluminum smelting industry utilized its 1.64-million-ton-per-year capacity at only about a 67% rate.

Imports of aluminum ingots (including high and regular grades) and alloyed ingots in 1980 were mainly from the United States (34%), Venezuela (14%), and Canada (13%). Foreign aluminum was lower in price largely owing to a soft world market condition, significantly lower cost of production, and considerable appreciation of the Japanese yen. These factors were cited by an official at the MITI as the main contributing factors to the substantial increase of imports of aluminum ingots in 1980.

Japan's domestic demand for primary aluminum metal fell from 1.80 million tons in 1979 to 1.64 million tons in 1980. A drop in new housing starts and construction work reduced demand for aluminum sashes and related housing materials. An unusual-

ly cold summer and the general business slump adversely reduced sales of air-conditioners and beverage cans, which use aluminum sheets and plates. An overbooking of aluminum materials by consumers in anticipation of higher prices and metal shortages during 1979 was another main factor contributing to the downturn of the domestic demand for aluminum.

The long-term problem of high energy cost had forced the world's second largest aluminum smelting industry to scrap or freeze about 33% of its capacity in 1980. It was expected that more of the old and inefficient potlines would have to be shut down during the next few years. Based on the industry's estimate, the total production cost of Japan's aluminum was about $1.08 per pound, of which power costs alone averaged 50 to 57 cents per pound of aluminum, compared with about 15 cents per pound in the United States.[3] In an effort to reduce the high energy cost of aluminum production in Japan (about 72% of Japan's smelting capacity uses oil-fired generated electricity), the industry had either shut down uneconomical facilities or planned to convert to energy sources other than oil. Nippon Light Metal Co., Ltd., had closed its Niigata plant, which suffered a $23 million loss annually because of the high cost of oil-generated electricity. The company also planned to convert the oil-fired powerplant to coal at its Tomakomai plant in Hokkaido. Sumitomo Aluminum Smelting Co., Ltd., suspended part of its uneconomical smelting units at its Toyama plant and planned to build a 180-megawatt coal-fired powerplant to replace the existing oil-fired powerplant for its smelter at Kikumoto. Mitsui Aluminum Co., Ltd., had converted the powerplant at its Omata plant to coal. Other smelters were trying to develop energy-saving smelting technology and ways of utilizing wasted heat from the smelting and fabrication processes. The president of Japan's Light Metal Association indicated that Japan's aluminum industry must go to nuclear power to survive.

In past years, Japan's aluminum smelters were actively engaged in various overseas joint venture aluminum smelting operations. In addition to the joint venture projects already in operation in Venezuela and New Zealand, the Asahan aluminum project, a joint venture with Indonesia, was moving on schedule in North Sumatra (see Aluminum section of the Mineral Industry of Indonesia, 1980).

An agreement was finally reached in November 1980 between Japanese and Brazilian interests on the Amazon aluminum project. The entire $1,839 million (at 1979 prices) complex project, which includes a $1,278 million project for the Albras smelter and a $561 million project for the Alunorte alumina plant, would be funded 30% by equity capital and 70% by borrowing. On the equity portion, 51% would be owned by Rio Doce, the Brazilian state development and mining firm, and 49% by Nippon Amazon Aluminum Co., which is formed by the Japanese Overseas Economic Cooperation Fund and 31 Japanese companies (including 5 major smelters, 10 trading houses, and 16 users).

The construction work on the smelter at Bancarena near Belem was expected to begin in mid-1981. Upon completion of phase 1 by June 1984, the smelter would have two 80,000-ton-per-year potlines. By May 1985, another 160,000 tons per year of capacity would be added. The construction work for the 800,000-ton-per-year Alunorte alumina plant was scheduled to be completed by October 1984, and reach full capacity by February 1985 to provide feed for the smelter. Bauxite for the alumina plant, to be supplied by Rio Doce, would be mined in the Trombetas area along the Amazon. According to the agreement, the Japanese group would take 80% to 85% of Albras aluminum output in 1984-88, and 49% after that; the price of the aluminum would be based partly on Alcan's international price and partly on the Japanese imported price.

An agreement was reached in August 1980 between Nippon Light Metal Co., Ltd., and the Republic of South Africa's Alusuf Pty., Ltd., for the purchase of Nippon's used aluminum refining equipment from its Niigata plant at a cost between 1 billion to 1.5 billion yen. The shipment of the equipment to the Republic of South Africa was to start in late 1980.

Nippon Light Metal Co. was to resume high-purity metal production in October 1980 at an annual rate of 1,200 tons (the plant was shut down in May 1978). Sumitoma Aluminum Smelting Co. had increased its Kikumoto plant's capacity by 650 tons per year to 5,200 tons per year in 1980 owing to increased demand for super-purity aluminum for high-tension electrolytic condensers in Japan.

Copper.—Production of refined copper reached an alltime high of over 1 million tons in 1980; however, domestic copper ore production continued to decline. Domestic

copper ore supplied only 5% of refined copper production; imported ore and concentrate, 83%; and scrap and others, 12%. Japan's copper mine production was principally from copper-lead-zinc mine operations at Hanaka, Kosaka, Syakanai, and Minami-Furutobe in Akita Prefecture; copper-zinc operations at Shimokawa in Hokkaido; and copper-iron operations at Kamaishi in Iwate Prefecture. During 1980, Japan imported over 3.1 million tons of copper ore and concentrate. Principal suppliers were the Philippines, Canada, the United States, Papua New Guinea, Chile, Indonesia, Australia, Sabah (Malaysia), and Zaire.

Based on a MITI survey, copper smelting and refining capacities by company were as follows in tons.[4]

Company	Location	Annual capacity	
		Smelting	Refining
Nippon Mining Co., Ltd	Hitachi	84,000	192,000
	Saganoseki	240,000	168,000
Mitsubishi Metal Corp	Naoshima	168,000	163,200
Sumitomo Metal Mining Co., Ltd	Toyo	168,000	48,000
	Niihama	--	132,000
Mitsui Mining & Smelting Co., Ltd	Hibi	68,400	--
	Takehara	--	87,600
Dowa Mining Co., Ltd	Kosaka	63,360	48,000
	Okayama	--	12,000
Furukawa Mining Co., Ltd	Ashio	42,000	--
Furukawa Electric Co., Ltd	Nikko	--	48,000
Rasa Industries Co., Ltd	Miyako	31,200	--
Onahama S & R Co., Ltd	Onahama	234,000	234,000
Hibi Kyodo Smelting Co., Ltd	Tamano	132,000	102,000
Total		1,230,960	1,234,800

During 1980, Japan's copper smelting and refining industry was operating at 82% of total capacity.

Japan also imported 227,660 tons of refined copper in 1980; the principal suppliers were Zambia, Chile, Peru, and Zaire.

Japan's consumption of refined copper amounted to about 1,325,500 tons in 1980 compared with 1,330,100 tons in 1979. About 864,000 tons was for the manufacture of wire and cable, and 462,000 tons was for rolling mills and others. Consumption of rolled copper products (including copper and copper alloys, such as brass and bronze) by industry was as follows in tons:

Industry	1977	1979
Textile	254	368
Chemicals and allied products	2,904	2,075
Fabricated metal products	113,057	135,179
Electric machinery, equipment and supplies	171,843	225,281
Transportation equipment	84,181	100,009
Other machinery and equipment	76,834	104,383
Ordnance and accessories	1,198	2,997
Other manufacturing	102,848	97,257
Construction	31,657	44,705
Other	9,206	30,475
Total	593,982	742,729

Japan's exports of refined copper during 1980 was 205,728 tons compared with 46,934 tons in 1979. The major buyers of Japanese refined copper for 1980 were the United States (63%), Taiwan (24%), and China (6%). As a result of strong domestic demand for copper and an export boom in 1980, refined copper stocks at producer plants fell 63% to 53,851 tons at the end of 1980 from 143,973 tons at the end of 1979.

A 7-year contract between The Anaconda Copper Company of the United States and Nippon Mining Co., Ltd., and C. Itoh & Co., Ltd., was signed on December 17, 1980, in Tokyo. The contract calls for Anaconda to supply Nippon Mining, Mitsui Mining and Smelting, Mitsubishi Metal, Sumitomo Metal Mining, Furukawa, Dowa Mining, and Nittetsue Mining with copper ore for processing from Anaconda's mines in Arizona, Montana, and Utah. During 1981-82, the Japanese copper producers would receive 398,000 tons of copper concentrate (averaging 25% copper) annually, and 500,000 tons annually from 1983 through 1987. The contract can be automatically extended for 1 year without advance notice. It was reported that under the contract the Japanese smelters would be allowed to buy copper for their own needs (at least 50% of the refined copper would be bought by the Japanese smelters), and that it would take at least 5 months for the remaining toll-refined copper to be returned to the United States.

The contracted toll refining reportedly would allow Anaconda to remain competitive on a worldwide basis. It was estimated that it costs 45 cents per pound for Anaconda to smelt and refine in the United States, while the cost of smelting and refining in Japan was in the 33- to 35-cents-per-pound range.[5]

A Japanese-Chinese joint venture project for exploration and development of the copper mine at Anquin (Anjing) near Tongling in Anhui Province, China, was expected to start in the spring of 1981. The exploration was expected to take 3 to 4 years to be followed by the development of the copper mine. The Anquin Mine was estimated by the Chinese to have a deposit of 18 million tons of ore with an average copper content of 1.8%. The estimated costs for the exploration were between $4.8 million to $9.5 million. Japan plans to provide funds, technology and exploration equipment. In exchange, China is to provide the labor force and materials.

An agreement between Mitsubishi Corp. and Kennecott Corp. of the United States was expected to be signed by March 1981. Under the agreement, Mitsubishi was to invest about $116 million for a multiyear modernization program, and receive a one-third ownership of Kennecott's Chino Mines Div. (a copper mining and processing facility) near Silver City, N. Mex. Mitsubishi was to have the right to take one-third of the production.

Iron and Steel.—Japan displaced the United States as the world's second largest iron and steel producer in 1980. Output of pig iron was at a higher level, while the production of crude steel remained at about the same level as that of 1979. However, exports of steel dropped slightly in 1980 from that of 1979. Domestic apparent consumption of steel in 1980 increased slightly from that of 1979.

Japan's output of pig iron in 1980 accounted for about 15% of the world's production. Production of pig iron by blast furnace accounted for 99.8% in 1980. By the end of 1980, out of the country's 65 blast furnaces (excluding blown-out blast furnaces), 44 were in operation, and about 50% of the blast furnaces had adopted all-coke operations.

A downturn in demand from Japan's auto industry, the continued slump of the construction industry, and the decline in exports were the factors that caused a rapid decline of crude steel production in the second half of 1980. Production by basic oxygen furnaces (BOF) accounted for 75.5% of crude steel in 1980, and the remaining output was by electric furnaces. Crude steel production in 1980 was comprised of 94.5 million tons of ordinary steel and 16.9 million tons of special steel. Crude steel processed by continuous casting in 1980 was 66.3 million tons (a 59.5% overall continuous casting ratio of ordinary and special steel rollings compared with 52.0% in 1979). Continuous casting ratios for ordinary steel and special steel in 1980 were 63.3% and 38.3%, respectively. As a result of higher continuous casting ratios for 1980, the ratio of semifinished steel products to crude steel increased to over 90% compared with the ratio of about 70% to 80% for the United States and Europe. Japan ranks first in the world in both number of BOF's and continuous-casting machines. By the end of 1979 and 1980, the number of steelmaking furnaces and continuous casting machines were as follows:[6]

Facility	Units at yearend	
	1979	1980
Basic oxygen furnaces	96	94
Electric furnaces	629	627
Continuous casting machines:		
For slabs	36	37
For blooms and billets	101	104

By yearend, Japan's annual steel production capacity was estimated at 136 million tons.

Domestic mine output of iron ore and concentrate and pyrites cinder was negligible. Japan stopped production of iron sands in 1980. Consumption of iron ore, pellets, and iron sands in 1980 was 129.3 million tons, about 5% higher than that of 1979. Japan's dependency on imports of iron ore reached 99% in 1980. During 1980, 116.4 million tons of iron ore and concentrates was imported principally from Australia (57.1 million tons), Brazil (23.0 million tons), and India (15.5 million tons). Japan also imported 17.3 million tons of sinters, pellets, and briquettes primarily from Brazil (5.5 million tons), the Philippines (4 million tons), Chile (3.1 million tons), Australia (2.9 million tons), and India (1 million tons). Consumption of other raw materials by the industry in 1980 includes 64.8 million tons of coking coal (89.4% was imported), 45.5 million tons of coke, 86.7 million tons of pig iron, 43.8 million tons of iron and steel scrap, 1.2 million tons of ferruginous manganese ore (all imported), 1.5 million tons of manganese ore, and 15.8 million tons of limestone. Consumption of fuel oil dropped 34% to 4,769,000 kiloliters in 1980. Consumption of oxygen was 5.3 billion cubic meters and electricity was 67.4 billion kilowatt-hours in 1980.

During 1980, Japan's exports of iron and

steel were 30.3 million tons, a 3.8% drop from 31.5 million tons in 1979. Exports of iron and steel were as follows in thousand tons:

	1979	1980
Pig iron	60.8	14.6
Ferroalloys	132.4	70.5
Ingots	3.3	7.2
Semifinished products	124.2	184.4
Ordinary steel products	28,244.6	27,305.1
Special steel products	1,678.7	1,590.6
Other steel products	394.4	393.1
Cast iron pipe and secondary steel products	857.9	761.7
Total	31,496.3	30,327.2

Exports to the United States were 5.2 million tons, a decline of 16%; China, 3.2 million tons, a decline of 28%; and the U.S.S.R., 1.7 million tons, a 4.4% decline. By region, exports to Southeast Asia (excluding China) showed a 9% improvement (about the 10-million-ton level). Shipments to the European Economic Community were only 633,000 tons, and to other European countries, 1.3 million tons. Exports to the Middle East remained at the 4-million-ton level, exports to Latin America were 2.6 million tons, and exports to Africa were 1.5 million tons. Iron and steel exports for 1980 were valued at $15.5 billion and accounted for about 12% of overall export earnings.

Domestic orders for ordinary and special steel products by end use were as follows in thousand tons:

	Ordinary steel products		Special steel products	
	1979	1980	1979	1980
Construction and repairing	15,283	14,845	433	441
Industrial machinery and equipment	2,215	2,435	1,010	1,079
Electrical machinery and equipment	2,460	2,524	70	73
Home and office appliances	724	752	185	199
Shipbuilding and marine equipment	2,924	3,802	59	73
Automobiles	8,543	9,470	1,376	1,487
Rolling stocks	227	245	63	69
Tanks and containers	2,042	1,841	97	130
Others	368	350	76	85
Conversion and processing	3,754	3,770	2,652	2,797
Steel dealers	15,956	15,084	901	845
Total	54,496	55,118	6,922	7,278

Demand for seamless pipes for oil drilling, as driven by thriving oil development activities, continued to increase in 1980. Demand for heavy steelplate also rose as a result of a strong recovery in orders for new vessels during 1979-80. Demand for special steel continued its 5-year upward trend in 1980, reflecting the continuous expansion of the Japanese auto industry and the industrial machinery and equipment industry.

To cope with the soaring costs of energy, Japan's major integrated steel companies had made efforts to reduce and save energy. During 1978-79, various energy conservation measures were adopted and, as a result, consumption of fuels by the industry (excluding LNG) declined 8% to 83 liters per ton of crude steel produced in 1979, and was to decline further to about 55 to 60 liters in 1980. The energy-saving measures taken by the industry during 1980 were as follows: Nippon Kokan K.K. had made an effort to reduce energy consumption at its Keihin works by recovering waste energy through the use of cold, dry quenching and maximizing energy and resource usage. A waste heat recovery system was installed in the sintering plants at its Ohgishima complex and Fukuyama works. Kawasaki Steel Corp. began to build a $4 million facility in the slag yard at its Chiba works. The facility was to recover heat from blast furnace slag to produce steam and electricity, and was expected to come onstream in the spring of 1981. At the Nippon Steel Corp., in addition to the existing four top-gas driven turbines, three other blast furnaces were to be equipped with turbines to generate electricity for general distribution by 1980. Sumitomo Metal Industries began operation of the freon-gas turbine generator at its Kashima No. 1 steelmaking plant.

Sumitomo also modified its Kashima works to use more coke than fuel in blast furnace operations. Other energy-saving measures taken by the industry include shifting toward sintered ore in pig iron making, installation of continuous casting machines, computerized energy control systems, and utilization of direct-rolling processes.

Technical cooperation between Nippon Steel (the major turnkey contractor) and China for the development of Baoshan steelworks suffered a major setback when the Chinese Government announced to postpone indefinitely the second-stage construction. As a result, Nippon Steel's share in construction of the second stage of Baoshan's steelworks would be reduced substantially. (See Iron and Steel section of the Mineral Industry of China).

In August 1980, two large steel mill joint venture projects were signed between Japan and Mexico. The first project involved building a 290,000-ton-per-year large-diameter steel pipe plant in the Lazaro Cardenas region on the west coast of Mexico. According to the agreement, Sumitoma Metal Industries, Ltd., was to build the plant by setting up a joint venture company called Japan-Mexico Large-Diameter Steel Pipe Corp. The cost of the project was estimated at $157 million, of which $95 million was to be financed by borrowing and $62 million by equity capital. The Japanese interest, led by Sumitomo, would hold 40% of the equity capital. (The Japanese interest was to be shared by Sumitomo, 60%; Overseas Economic Cooperation Fund, 30%; and other Japanese interests, 10%).

The second project involved construction of a casting and forging steel plant by Kobe Steel, Ltd., in the same region, and the setting up of another Japanese-Mexican joint venture company called Japan-Mexico Steel Casting and Forging Corp. The estimated cost of the casting and forging project was $277 million, of which $194 million was to be financed by borrowing, and $83 million by equity capital. The Japanese interests, led by Kobe Steel would hold 33% of the equity. (The Japanese interest was to be shared by Kobe, 60%; Overseas Economic Cooperation Fund, 30%; and other Japanese interests, 10%). The Government of Japan declared both projects to be national projects, therefore, these two projects would be qualified for a low-interest loan from the Japanese Government.[7]

Lead and Zinc.—Japan's mine output of lead was insignificant by world standards. Output of zinc in 1980 accounted for about 4% of the world mine production. Japan remained 1 of the world's top 10 producers of refined lead and zinc in 1980.

Based on the latest survey by the Agency of Natural Resources and Energy, Japan's total ore reserves of lead and zinc were estimated at 61,828,000 tons, averaging 6.6% zinc and 1.1% lead (zinc metal content of 4,022,000 tons, and lead metal content of 682,000 tons). The minable crude ores were estimated at 61,972,000 metric tons, averaging 5.0% zinc and 0.9% lead (with zinc metal content of 3,039,000 tons and lead metal content of 524,000 tons).[8]

Domestic mine production of lead and zinc was principally by Mitsui Mining and Smelting Co., Ltd., at Kamioka Mine in Gifu; Dowa Mining Co., Ltd., at Hanaoka Mine and Kosaka Mine, both in Akita; Syakanai Mining Co., Ltd., at Syakanai Mine also in Akita; Hosokura Mining Co., Ltd., at Hosakura Mine in Miyagi; Toyoha Mining Co., Ltd., at Toyoha Mines in Hokkaido; and Nippon Zinc Mining Co., Ltd., at Nakatatsu Mine in Fukui. Domestic mine output of lead and zinc supplied about 23% of refined lead production and about 32% of refined zinc production in 1980. During 1980, Japan imported 258,634 tons of lead ore and concentrates mainly from Canada, Peru, and Australia (these three countries accounted for 91% of total imports), and 804,851 tons of zinc mainly from Canada, Peru, and Australia (these three countries accounted for 90% of total imports). Japan also imported about 69,000 tons of refined lead principally from North Korea, Mexico, Peru, and Australia, and about 42,000 tons of refined zinc principally from North Korea and the Republic of Korea in 1980.

Production of primary refined lead and zinc in 1980 was at a slightly lower level than that of 1979 owing to the tight supply of concentrates from overseas mines and stagnant domestic demand during the second half of 1980. During 1980, capacity utilization rates at the smelters ranged from 65% to 80%. Utilization rates during the first half of 1980 were generally higher than that of the second half.

Dowa Mining's expansion project of the electrolytic lead refining facility at its Kosaka works was completed in October 1980, and raised its annual capacity to 20,800 tons from 16,800 tons.

Annual production capacity of primary lead and zinc by type of operation was as follows, in tons:

Company	Plant location	Annual capacity	
		Electrolytic	Dry smelting
LEAD			
Toho Zinc Co., Ltd	Chigirishima	72,000	--
Mitsui Mining & Smelting Co., Ltd	Kamioka	33,600	--
	Takehara	43,800	--
Nippon Mining Co., Ltd	Saganoseki	36,000	--
Mitsubishi Metal Corp	Hosokura	21,600	--
Mitsubishi Cominco Smelting Co., Ltd	Naoshima	--	36,000
Dowa Mining Co., Ltd	Kosaka	20,800	--
Rasa Industries Co., Ltd	Miyako	2,640	--
Sumiko ISP Co., Ltd.[1]	Harima	26,400	--
Total		256,840	36,000
		Annual capacity	
ZINC		Electrolytic	Distillation
Mitsui Mining & Smelting Co., Ltd	Kamioka	72,000	5,280
	Hikoshima	84,000	--
	Miike	21,600	116,400
Toho Zinc Co., Ltd	Annaka	139,200	--
	Chigirishima	--	5,160
Mitsubishi Metal Corp	Hosokura	21,600	--
	Akita	105,600	--
Nippon Mining Co., Ltd	Mikkaichi	--	120,000
Nisso Metal Co., Ltd	Aizu	31,200	--
Hachinohe Smelting Co., Ltd	Hachinohe	--	84,000
Sumiko ISP Co., Ltd.[1]	Harima	--	79,200

Total		631,200	410,040

[1]Wholly owned subsidiary of Sumitomo Metal Mining beginning Oct. 1, 1980.

For 1980 as a whole, the industry was operating at 75% of capacity for primary lead and 71% of capacity for primary zinc. Production of secondary lead and zinc in 1980 was at a higher level than that of 1979 owing to a strong domestic demand for the secondary metals by the manufacturers of storage batteries, galvanized sheets, die casting, and brass.

Domestic consumption of primary lead rose 4.4% to 279,000 tons in 1980. By end uses, storage batteries were 45% of the total, inorganic chemical was 23%, lead pipe and sheet were 7.5%, cable sheathing was 9.5%, and others were 15%. Consumption of primary zinc dropped 2.6% to 735,000 tons in 1980. By end uses, sheet galvanizing was 41%; wire, tube, and general galvanizing were 17%; brass and rolled zinc were 18%; and others were 24%.

Stocks at producer plants for primary lead were 13,081 tons at the end of 1980 compared with 12,947 tons for 1979, and for primary zinc, stocks were 108,371 tons at the end of 1980 compared with 96,007 tons for 1979.

During 1980, Japan exported about 5,000 tons of refined lead mainly to the Republic of Korea (2,040 tons) and Cuba (1,313 tons); 41,700 tons of refined zinc was exported mainly to Taiwan (7,861 tons), the Republic of Korea (7,422 tons), the Philippines (6,507 tons), the U.S.S.R. (4,497 tons), Nigeria (3,581 tons), Indonesia (2,417 tons), and Thailand (2,281 tons).

The industry was also facing the problem of high energy costs. The price of electricity used by the industry was raised by 56% in April of 1980. As a result, production was cut back and many smelters had made efforts to reduce energy consumption by increasing the proportion of nighttime electricity use (at lower prices), recycling hot waste gases, and other means. In 1980, about 60% of the production cost was attributable to the power cost of the Japanese smelters.

A joint venture company was established in December 1980 between a Japanese consortium, composed of Mitsubishi Metal and Mitsubishi Corp., and Compañía Mineral Milpo S.A. of Peru, for the exploration of lead and zinc deposits in central Peru. The prospecting work was expected to start early in 1981 in a concession area at San Hilarion (about 459 kilometers from Lima), where the ore reserves were estimated at about 10 million tons containing lead, zinc, and silver. The estimated cost of the prospecting work was about $2 million. Milpo was to own 65% of the equity capital and mining rights of the Hilarion deposits, and

the remaining 35% was to be equally shared by the two Mitsubishi companies.

Magnesium.—Production of primary magnesium was by Furukawa Magnesium Co., Ltd., at Koyama with an installed annual capacity of 6,000 tons, and Ube Industries, Ltd. (Ube Kosan), at Yamagachi with an installed annual capacity of 7,000 tons. Production of primary magnesium metal in 1980 declined 18.6% to under 10,000 tons owing to a drastically reduced demand from light metal rolling and casting and increasingly cheaper imports brought about by the appreciation of the Japanese yen. The industry was operating at about 60% of its installed capacity for 1980.

In 1980, Japan imported 12,476 tons of magnesium ingots principally from the United States (8,673 tons), Norway (1,777 tons), and Canada (1,546 tons).

Total demand for primary magnesium metals in 1980 was 18,270 tons. In addition, 24,820 tons was utilized as a reducing agent for the production of titanium and zirconium. Other main users of the metals were light metal rollings (6,760 tons), aluminum alloys (5,457), nodular cast iron (2,031 tons), and powder (1,129 tons). During 1980, Japan exported about 90 tons of magnesium mainly to the Republic of Korea (53 tons) and North Korea (30 tons).

Manganese.—Domestic mine production of manganese ore continued to decline in 1980. About 75% of total mine output was from three major mining operations at the Ooe Mine and at the Inakunaishi Mine of Hokushin Mining Co., Ltd., and at the Jokoku Mine of Chuugai Mining Co., Ltd.; all are in Hokkaido. Japan's manganese ore reserves were estimated at 3,182,000 tons averaging 20.7% manganese (manganese metal content of 658,600 tons). The minable crude ores were estimated at 3,193,000 tons, averaging 16.6% manganese (manganese metal content of 529,100 tons). Because of the insignificant quantity and low-grade manganese ore of domestic mine output, most of Japan's requirements for manganese were met by imports. During 1980, Japan imported about 1.8 million tons of manganese ore and concentrates (excluding ores and concentrates of manganese dioxide and ferruginous manganese). The main supplying countries were the Republic of South Africa (760,721 tons), Australia (601,762 tons), Gabon (150,427 tons), and Brazil (149,235 tons). Japan also imported about 1.1 million tons of ferruginous manganese ore and concentrates principally from the Republic of South Africa (537,975 tons) and India (515,769 tons) in 1980.

Over 90% of manganese ore was consumed by the iron and steel and ferroalloy industries. The remainder was for the manufacturing of electrolytic manganese for welding rod and chemical use.

During 1980, Japan imported 26,872 tons of manganese dioxide ore and concentrate, mainly from Australia (11,069 tons), Gabon (8,135 tons), and China (3,089 tons), for the production of manganese dioxide.

Production of manganese metal in 1980 was by Chuo Denki Kagyo and Toyo Soda with a combined annual capacity of 9,600 tons. The former sold the metal only in the domestic market through Sumitomo Corp., and the latter sold both in the domestic and the international markets through Mitsui & Co. and Mitsubishi Corp.

Production of manganese dioxide in 1980 was by Toyo Soda Manufacturing Co., Mitsui Mining and Smelting Co., and Daiichi Carbon Co. Toyo Soda has plants at Hinata in Shizuoka Prefecture with an annual capacity of 18,000 tons, and a joint venture company, Tekkosha Hellas A.B.E. in Greece, with an annual capacity of 10,000 tons. Mitsui Mining & Smelting has plants at Takehara in Hiroshima Prefecture with an annual capacity of 19,000 tons, and a joint venture company, Mitsui Denman in Ireland, with an annual capacity of 12,000 tons. Daiichi Carbon has an annual capacity of 4,000 tons. Owing to the rapid growth in demand for the manganese dioxide used in electric cells, a new company, Japan Metals and Chemicals Co., was expected to join the industry. The company was to complete a $14.3 million ore reduction and electrolysis facility at Takaoka and begin operation in early 1981 with an annual capacity of 6,000 tons. In addition, Toyo Soda was expanding its Hinatu's capacity from 18,000 to 24,000 tons per year by April 1981. Toyo Soda also decided to build a $20 million plant with an annual capacity of 12,000 tons by mid-1983. Mitsui was also expected to raise capacity at its Takehara plant from 19,000 to 25,000 tons per year by August 1981 with an estimated cost of $14.3 million.

Molybdenum.—Domestic production of molybdenum concentrate declined to about the 110-ton level in 1980. Mine output was by Taenaka Mining Co., Ltd., at the Higashiyama Mine and at the Komagi Mine in Shimane Prefecture. Imports of molybdenum concentrates totaled 20,278 tons for 1980. The major suppliers were the United States (10,530 tons), Canada (6,190 tons),

and Chile (2,525 tons). Japan also imported about 100 tons of molybdenum ore mainly from the United States and the Federal Republic of Germany.

Consumption of molybdenum ore and concentrates was by the manufacturers of molybdenum metal, ferromolybdenum, and other fabricated metal products such as wires, rods, and sheet.

Molybdenum metal production for 1980 was estimated at about 400 tons, while output of ferromolybdenum in 1980 was 4,367 tons.

Nickel.—Production of nickel metal in 1980 was slightly below the level of 1979. Sumitomo Metal Mining and Nippon Mining were the only two producers operating in 1980. Japan's requirements for nickel ore and concentrates of about 4 million tons per year were imported from New Caledonia (51%), Indonesia (33%), and the Philippines (16%). During 1980, Japan also imported about 52,000 tons of nickel matte principally from Indonesia (52%), Australia (38%), and New Caledonia (9%) and about 15,000 tons of refined nickel mainly from Canada (27%), the U.S.S.R. (16%), Australia (15%), Norway (13%), the Philippines (11%), and the Republic of South Africa (8%).

Consumption of nickel metal in 1980 was 36,539 tons, about 5,000 tons higher than that of 1979. The increased demand was due to an increase in the production of nonferrous alloys. By end use, consumption for specialty steel accounted for 37%; nonferrous alloys, 20%; plating, 19%; magnetic materials, 8%; fabricated products, 6%; and others, 10%.

Japan also consumed about 76,000 tons of nickel for the manufacture of ferronickel by the ferroalloy industry, and about 12,000 tons of nickel for the production of nickel oxide in 1980.

Tin.—Mine output of tin concentrates declined in 1980. Production was by Akenobe Mining Co., Ltd., at the Akenobe Mine (a copper-zinc-tin operation) in Hyogo Prefecture. The concentrates were shipped to Mitsubishi Metal Corp. for refining at its Naoshima plant in Kagawa Prefecture. During 1980, Japan imported only 14 tons of tin ore and concentrates from Laos. Japan's output of refined tin in 1980 was 1,319 tons.

During 1980, Japan imported 31,068 tons of refined tin mainly from Malaysia (18,455 tons), Indonesia (6,324 tons), Thailand (6,166 tons), and China (84 tons).

Consumption of tin in Japan was mainly by the manufacturers of tin plate (40%), solder (33%), stabilizer for vinyl chloride (7%), wire and cable (4%), and fabricated copper and casted copper alloy (5%). Other uses of tin were for abrasives and galvanizing.

As of April 1978, estimated tin ore reserves in Japan were 1,147,000 tons averaging 1.08% tin. The minable crude ore was estimated at 1,528,000 tons averaging 0.71% tin.

Titanium.—Japan was the world's second largest titanium sponge producer following the U.S.S.R. In 1980, output of titanium sponge reached another record high at 19,400 tons, as a result of expanded capacity boosted by growing demand for the metal both in domestic and international markets. During 1980, two Japanese producers were operating at nearly full capacity of about 21,000 tons per year.

During 1980, Japan imported 409,080 tons of rutile and ilmenite. The principal supplying countries were Malaysia (including Sabah), accounting for 45%; Australia, 27%; India, 12%; and Sri Lanka, 10%.

About 8,000 tons of the total sponge production in 1980 was exported mainly to the United States (3,332 tons, or equivalent to 72% of the United States' total imports), the United Kingdom (2,451 tons), and the Netherlands (1,870 tons). The remaining titanium sponge was for inventory and domestic consumption by the manufacturers of titanium tubes, pipes, plates, and condensers for nuclear powerplants, chemical and power products, and ferroalloy products.

Osaka Titanium Co., Ltd., completed the construction work for the expansion of titanium production capacity at Amagasaki in Hyogo Prefecture to 12,000 tons per year in November 1980 at a cost of $12 million. The company planned to raise the capacity by 1,200 tons in April 1981. Osaka produced an additional 2,000 tons of titanium sponge in 1980 at Nihongi in Niigata Prefecture under a toll-smelting contract with New Metals Industries Co., a subsidiary of Nippon Soda Co., Ltd. Nippon Soda was expected to expand its annual capacity to 2,500 tons in April 1981. In 1981, Osaka's annual capacity was expected to reach 15,200 tons including that of toll smelting by Nippon Soda, surpassing Titanium Metals Corp. of America of the United States (15,000 tons per year).

Toho Titanium Co., Ltd., has been expanding its capacity at Chigasaki in Kanagawa since June 1980. Upon completion of the expansion by the spring of 1981, Toho was expected to raise its production capaci-

ty from 8,400 to 10,800 tons per year.

During 1980, the two Japanese companies had made an effort to cut down the power requirements for the production of titanium. As a result, approximately 30,000 kilowatt-hours of electricity required for 1 ton of titanium sponge was reduced to about 25,000 kilowatt-hours.

Exports of Japan's titanium sponge to the United States were normally under long-term contracts with prices being renegotiated annually. Based on the new contracts, Japan's titanium sponge would be priced between $7.50 and $8.50 per pound c.i.f. or $8.85 and $10.03 per pound, duty paid, starting in April 1981. In 1981, the duty-paid prices of Japan's titanium sponge under the old contracts were between $7.50 and $8.70 per pound.[9]

Tungsten.—Domestic mine output of tungsten ore and concentrate declined in 1980 owing to the falling quality of ore in various mines. In 1980, the leading producers were Kaneuchi Mining Co., Ltd., which operated the Kaneuchi Mine in Kyoto Prefecture and the Fujigatani Mine in Yamaguchi Prefecture; Awamura Mining Co., Ltd., which operated the Otani Mine in Kyoto Prefecture; Yaguki Mining Co., Ltd., which operated the Yaguki Mine in Fukushima Prefecture; Chitose Mining Co., Ltd., which operated the Takatori Mine in Ibaraki Prefecture; and Tanaka Mining Co., Ltd., which operated the Kuga Mine in Yamaguchi Prefecture. During 1980, Japan imported 3,480 tons of tungsten ore and concentrates mainly from the Republic of Korea (733 tons), Canada (675 tons), Australia (557 tons), Portugal (355 tons), Bolivia (299 tons), and other countries including Peru, Thailand, China, and the United States.

Consumption of tungsten ore in Japan was mainly by the manufacturers of tungsten metal and ferrotungsten. Output of tungsten metal in 1980 was estimated at about 2,000 tons, while output of ferrotungsten was about 240 tons.

In 1980, two tungsten deposits were discovered in the Nishikigawa district of Yamaguchi Prefecture. Seven mineralized veins occur at about 2 kilometers west of the Kuga Mine of Tanaka Mining Co. The ore contains an average of 2% to 3% tungsten. The other site, located 1 kilometer west of the Kichita Mine in the Nishikigawa district, has a thicker vein. The ore contains an average of 3.7% tungsten.[10]

As of April 1, 1979, Japan's tungsten ore reserves were estimated at 3,565,900 tons averaging 0.71% WO_3, and minable crude ores were estimated at 4,551,100 tons averaging 0.46% WO_3.

Other Metals.—Japan's requirements for antimony were all imported from overseas sources. During 1980, about 7,000 tons of antimony ore and concentrates were imported from Bolivia (87%), the Republic of South Africa (6%), Thailand (6%), and Malaysia (Sarawak) (1%). Imports of refined antimony were about 1,560 tons. China alone supplied 95%; the remainder of the imports were from Bolivia and Vietnam. There was a sharp fall in ingot production owing to the reduced demand for antimony alloy battery plate following the continuing success of maintenance-free battery production in Japan. However, production of antimony trioxide increased in 1980, and was mainly used in the manufacture of flame-resistant materials, glass, and enamel.

Production of cadmium declined to about the 2,200-ton level. Cadmium was produced as a byproduct of zinc smelting. Six producers were Mitsui Mining and Smelting Co., Ltd.; Mitsubishi Metal Corp.; Sumitomo Metal Smelting Co.; Nippon Mining Co.; Dowa Mining Co.; and Toho Zinc Co. About half of the total output was consumed domestically by the makers of nickel-cadmium batteries for emergency lights, the manufacturers of fire alarms in building blocks, and for the production of pigments and alloy additives. The remaining 50% was exported mainly to the United Kingdom, the Federal Republic of Germany, the Netherlands, Taiwan, and East European countries. Japan also exported about 230 tons of cadmium alloys to the Netherlands, the United Kingdom, Romania, the Republic of South Africa, Taiwan, and the Southeast Asian countries. The export price of Japanese cadmium in 1980 was based on London Metal Bulletin quotations.

Japan's mine production of chromium ore and concentrates increased slightly in 1980 to about 14,000 tons containing 32% chromium. The two domestic producers were Hirose Mining Co., Ltd., which operated the Hirose Mine, and Nihon Chromium Mining Co., Ltd., which operated the Wakamatsu Mine. Domestic consumption of chromium ore and concentrates by the ferroalloy industry alone totaled 798,066 tons in 1980. Over 95% of Japan's requirements for chromium ore and concentrates were imported. During 1980, Japan imported 950,039 tons of chromium ore and concentrates from the Republic of South Africa (43%), the Philippines (22%), India (18%), the U.S.S.R. (4%),

Madagascar (3%), Turkey (3%), Brazil (2%), and the remaining 5% was from nine other countries. During 1980, Japan also imported 257,157 tons of ferrochromium, of which 201,955 tons was imported from the Republic of South Africa. Chromium metal production was mainly by Toyo Soda in 1980. Consumption of chromium metal was by the manufacturers of superalloys (43%), aluminum and copper alloy (32%), welding rods (23%), and other uses (2%).

In April 1980, Japan withdrew from a joint venture project to exploit the Serjana chromite mine in Brazil. The Japanese consortium reportedly received $1.9 million from Cia. de Ferro-Ligas da Bahia S.A. (Ferbasa) for selling its share to Ferbasa, the largest Brazilian producer of chromite. The high costs of shipping the ore and the planned reduction in the Japanese ferrochromium capacity were cited as the main reasons for the withdrawal.

Japan was the world's fourth largest producer of cobalt metal in 1980. Production of the metal, a byproduct of copper and nickel refining, was 2,867 tons in 1980, of which about 960 tons of toll-refined metal was shipped back to foreign customers. During 1980, Japan imported 1,606 tons of cobalt and cobalt alloy, principally from Zaire and Belgium. Domestic consumption of cobalt metal was 1,914 tons in 1980, of which 385 tons was consumed by the makers of high-speed steel, other alloy steels, and heat-resisting alloys; 668 tons for magnetic materials; 165 tons for cemented carbides; 98 tons for catalysts; and 598 tons for other uses.

Japan's mine output of gold and silver continued to decline. Mine production in 1980 was by Mitsui Kushikino Mining Co., Ltd., at the Kushikino Mine in Kagoshima Prefecture, and Chitose Mining Co., Ltd., at the Chitose Mine in Hokkaido. Other important gold and silver mines were the Kasuga Mine (gold only) of Kasuga Mining Co., Ltd.; the Asahi Mine of U.R.I. Mining Co., Ltd.; the Mochikoshi Mine of Chigai Mining Co., Ltd.; the Sado Mine of Sado Mining Co., Ltd.; and the Nebazawa Mine of Arakawa Mining Co., Ltd. During 1980, Japan imported 889,000 troy ounces of gold mainly from Switzerland (52%), the United Kingdom (37%), the U.S.S.R. (9%), and other countries (2%). Imports of silver totaled 18.1 million troy ounces, of which 64% was from Mexico, 22% from Peru, 9% from Australia, and 5% from other countries.

Japan also obtained substantial amounts of gold and silver by recycling. During FY 1979, 997,000 troy ounces of gold and 4,115,000 troy ounces of silver were recovered. Domestic demand for gold in FY 1979 was estimated at about 4.6 million troy ounces. Consumption was for ornaments (jewelry), 32%; private hoarding, 24%; plating, 14%; electronic communication, 10%; dentistry, 8%; handicrafts, 3%; and other, 9%. Domestic demand for silver in FY 1979 was 71 million troy ounces. About 48% was for silver nitrate sensitive film, 10% for other silver nitrate, 13% for point connectors, 7% for rolled sheet, 7% for silver solder, and 15% for all other uses.

Indium production in 1980 was estimated at about 12 tons. Nippon Mining increased its monthly output from 500 to 750 kilograms in mid-1980. Dowa Mining's monthly output remained at a 300-kilogram level. Mitsui Metal and Sumitomo Metal Mining supplied a total of about 1,000 kilograms of indium by recycling scrap. During 1980, Japan imported 2,811 kilograms of refined indium principally from Canada (1,200 kilograms), Belgium (701 kilograms), China (344 kilograms), and the Federal Republic of Germany (340 kilograms). Indium was used in electronic components, solders, and other alloys.

Mitsui & Co. and Ishizuka Research, Inc., announced a new technology for zirconium sponge production. After 12 years of research at Hiratsuka, east of Tokyo, with an investment of $2.7 million by both companies, a new method of extracting zirconium, known as distillation with differential partial condensation, was developed in mid-1980. The two companies established a joint venture firm and were expected to start with an initial monthly output of 10 to 15 tons of sponge per month in December 1980 and gradually increase to 100 tons per month in 1982. The production cost of zirconium by the new method was estimated at $3.30 per pound compared with about $6 to $7 per pound under the conventional method. During 1980, the market price of zirconium sponge was about $10 per pound.[11]

Japan also produced other metals and compounds of high purity and of significant quality by world standards. These metals included cerium, germanium, germanium oxide, lanthanum oxide, selenium, silicon, tantalum, tellurium, and uranium. Most of the output of these metals was from imported materials.

NONMETALS

Cement.—In 1980, Japan's cement industry consisted of 24 firms operating 60 plants and 202 kilns. The industry's total annual

production capacity was 116 million tons. Japan remained one of the world's leading cement producers in terms of output, technology, and exports.

Onoda Cement Co., Ltd., and Nippon Cement Co., Ltd., were the two oldest and largest cement producers, followed by Sumitomo Cement Co., Ltd.; Mitsubishi Mining and Cement Co., Ltd.; Ube Industries, Ltd.; Chichibu Cement Co., Ltd.; and Osaka Cement Co., Ltd. The industry's labor force was estimated at 11,000 persons compared with 11,800 persons in 1979. Japan ranked first in labor productivity of cement production in the world. In 1980, the industry's annual output per worker was 7,945 tons compared with France (2,751 tons), the United States (2,616 tons), and the Federal Republic of Germany (2,200 tons).[12]

For the past 2 years, varieties of new cement products were successfully introduced into the market by Chichibu Cement Co. The new products included cement that is capable of solidifying in the presence of various deterrents to hardening, that can resist too much water during application, and that can quickly solidify. Creation of a special clinker of the aluminate group was cited as the key to the new products.

Nippon Cement Co. started to operate its newest and largest vertical mill at Kamiiso in 1979. The 2,700-kilowatt raw mill was capable of grinding a harder limestone with a throughput of 350 tons per hour.

Similar to its aluminum industry, Japan's cement industry was also experiencing serious problems of soaring fuel costs. The industry required an average of about 80 liters of "C" type fuel oil to produce each ton of clinker. In 1980, based on the industry's average, energy cost accounted for more than 60% of the production cost. To reduce energy cost, the industry continued its efforts to switch from type C fuel oil to coal. According to an industry source, about 90% of the industry's total fuel consumption was expected to be based on coal by mid-1981. To supplement coal, the industry was successfully utilizing waste tires as fuel for cement production. The technology of utilizing waste tires was jointly developed by the Nippon Cement Co. and the Bridgeston Tire Co. in 1978.

According to the Cement Association of Japan, domestic shipments of cement totaled 82.4 million tons and exports totaled 8.6 million tons in 1980. Of the total demand in 1979, about 58.8% was shipped to the fresh concrete industry composed of more than 4,800 medium- and small-sized operators in the country, and about 13.5% to cement product manufacturers. Domestic cement consumption by other end uses was civil engineering, 2.7%; private buildings, 2.5%; public buildings, 1.1%; roads and bridges, 0.9%; electric powerplants, 0.7%; harbors and airports, 0.4%; railways, 0.2%; for own use, 0.1%; and other, 7.8%. About 11.3% was exported, principally to Saudi Arabia, Kuwait, and other Middle and Near East oil-producing countries, and Singapore and Hong Kong. The distribution of cement in the domestic market and exports of cement to the principal overseas market remained substantially the same in 1980.

Fertilizer Materials.—In 1980, Japan's fertilizer industry was still being considered as one of the world's largest, although the production capacity had been reduced substantially during the past 2 years as recommended by the Industrial Structure Council in May 1978. As a result of price increases in raw materials including naphtha and liquefied petroleum gas (LPG), low level of domestic demand, the deterioration of international competitiveness, self-supply policy of developing countries, and the appreciation of the Japanese yen, Japanese fertilizer production and exports continued to decline in 1980.

During 1980, the annual output capacity of ammonia was reduced from 3.7 million to 3.4 million tons, and was operating at about 70% capacity. During the 1979-80 period, Japan produced 1.9 million tons of ammonium sulfate, of which about 1.2 million tons was for the manufacture of fertilizer, 26,000 tons was for industrial use, and the remaining 700,000 tons was for exports, mainly to China. During 1980, the annual output capacity of urea was also reduced from 2.6 million to 2.3 million tons, and was operating at about 68% of capacity. During the 1979-80 period, total output of urea was about 2 million tons, of which about 400,000 tons was for fertilizer use, about 600,000 tons was for industrial use, and about 1 million tons was for exports, mainly to China.

During 1980, Japan's fertilizer exports to China remained favorable. However, exports to the Philippines, Pakistan, Sri Lanka, and New Zealand decreased sharply because large quantities of urea were offered to these consuming countries by low-cost suppliers such as Iraq, Kuwait, and Saudi Arabia.

In 1980, Japan's ammonia and nitrogen fertilizer industry also produced about 650,000 tons of ammonium chloride. About

40% was for domestic use, 5% was for industrial use, and the remainder was exported. Calcium cyanamide production remained at 181,000 tons; about 93% was for domestic fertilizer use and the remainder was for industrial use. Exports of calcium cyanamide were insignificant at about the 5,000-ton level.

Japan's phosphatic and compound fertilizer industry also suffered from excess output capacity. Based on the Industrial Structure Council's recommendation, about 20% of wet phosphatic fertilizer production equipment was to be scrapped, imports of phosphates were to be restricted, and the system of distribution and pricing were to be rationalized. During 1979, the industry's production facilities were curtailed by 17%. Imports of secondary phosphoric acid products including phosphoric acid liquid, ammonium phosphate, and double superphosphate of lime were reduced because of higher import prices. As a result, the supply and demand situation began to improve in 1980.

Japan's annual output capacity of calcium superphosphate was about 2 million tons. During 1980, the industry was operating at about 25% to 30% of capacity. Fused magnesium phosphate was operating at about 50% of its 1-million-ton capacity.

During the 1979-80 period, Japan produced about 540,000 tons of calcium superphosphate and about 450,000 tons of fused magnesium phosphate. Production of high-analysis compound fertilizer was about 3.2 million tons, of which 3 million tons was consumed domestically. Exports of high-analysis compound fertilizer were about 120,000 tons, mainly to Thailand, Indonesia, and Malaysia. Japan also produced about 690,000 tons of low-analysis compound fertilizer and about 200,000 tons of nitrogen and potassium compounds, mainly for domestic consumption. Japan's requirements for phosphate were 100% dependent on foreign sources. In 1980, Japan imported 2.8 million tons of phosphate rock mainly from the United States (1.9 million tons) and Morocco (645,000 tons). Japan also imported 100% of its potash requirements mainly from Canada (60%) and the U.S.S.R. (20%). Imports of potassium chloride in the 1979-80 period totaled about 642,000 tons (in K_2O). Imports of potassium sulfate totaled about 125,000 tons (in K_2O), mainly from France, the Federal Republic of Germany, and the United States.

Japan's production of potassium sulfate was only about 43,000 tons, compared with annual requirements for potassic fertilizer at about 780,000 tons in the 1979-80 period. The Nippon Kasei Chemical Co., Ltd., began the construction work of a potassium sulfate plant and its Onahama complex in Fukushima Prefecture in mid-1980. The 10,000-ton-per-year-capacity plant was expected to come onstream in March 1981. Plant construction was by Chisso Engineering Co., Ltd. Potassium chloride would be imported, but the sulfuric acid would be supplied by domestic sources.[13]

Gypsum.—Japan stopped mine production of natural gypsum in 1978. According to a recent report published by MITI, the estimated gypsum supply and demand situation in Japan from 1979 to 1983 was summarized as follows, in thousand tons of $CaSO_4 \cdot 2H_2O$:

	1979	1980	1981	1982	1983
Demand					
Cement	2,659	2,595	2,638	2,691	2,745
Boards	2,230	2,286	2,187	2,328	2,479
Plaster	430	395	375	357	338
Calcined gypsum	95	100	105	110	115
Other	241	273	294	309	321
Exports	444	450	400	400	400
Total	6,099	6,099	5,999	6,195	6,398
Supply					
Production byproducts:					
Phosphoric and flue gas desulfurization	5,063	4,837	4,855	5,063	5,310
Titanium	347	388	389	394	394
Hydrofluoric acid	396	419	429	441	450
Mineral water refining	252	243	243	243	243
Other	215	218	221	222	222
Imports	37	43	45	45	45
Total	6,310	6,148	6,182	6,408	6,664

The industry maintained about 1.2 million tons of inventory at the end of 1979. During 1980-83, the inventory was expected to remain at less than the 1-million-ton level.

Iodine.—Japan's iodine production in 1980 remained at about the 6,000-ton level. Total industry installed production capacity in 1980 was 9,700 tons per year. Japan remained the dominant producer of iodine in the world, accounting for about 58% of the world's total output (10,400 tons), followed by Chile (2,000 tons), the United States (1,200) tons, and the U.S.S.R. (1,000 tons). The largest single producer of iodine in Japan was Ise Chemical Industries Co. followed by United Resources Industry Co. and four small producers.

For the past 2 years, the industry has moved to other areas including Okinawa and overseas to expand its production capacity to offset the declining production owing to ground sinking problems in Chiba Prefecture, where most of the Japanese natural brine was concentrated. Ise Chemical Industries Co. recently resumed a long-pending joint venture project in Indonesia. United Resources Industry Co. established Godoe, Inc., in Oklahoma (United States), to produce iodine using salt water purchased from a local producer. United Resources also participated in Okinawa Natural Gas Development Co. (tentative name) jointly with Ryukyu Oil Corp. and Okinawa Gas Co. for the manufacture of iodine in Okinawa. By mid-1983, the joint venture company was expected to produce iodine at an annual rate of about 200 to 250 tons using salt to be purchased from Okinawa Gas Co.

Japan exported about 90% of its total sales, mainly to the United States and Western European countries. Applications of iodine in Japan included synthetic rubber, acetic acid by the methanol process, stabilizers for synthetic fibers, additives for feedstock, pharmaceuticals, and disinfectants.

Limestone.—Japan was the third largest limestone producer in the world in 1979, following the United States and the U.S.S.R. Production of limestone increased at an average annual rate of about 7% during 1975-79. The industry was composed of 246 companies operating 312 quarries with a labor force of about 10,500 workers. The top five producers were Ube Industrial Co., Ltd. (13.4 million tons), operating the Isa Mine; Mitsubishi Mining Cement Co., Ltd. (9.4 million tons), operating the Higashitani Mine; Nittetsu Mining Co., Ltd. (9.3 million tons), operating the Torigatayama Mine; Todaka Mining Co., Ltd. (9.2 million tons), operating the Todaka-Tsukumi Mine; and Onoda Cement Co., Ltd. (8.2 million tons), operating the Onoda-Tsukumi Mine.

Limestone deposits are widely distributed throughout Japan. Good-quality Japanese limestone normally contains 98% $CaCO_3$. According to the Agency of Natural Resources and Energy of Japan, as of April 1977, limestone reserves in Japan were estimated at 53.8 billion tons averaging 54.2% $CaCO_3$, while the minable limestone was estimated at 36.5 billion tons averaging 54.2% $CaCO_3$.

In 1979, about 58% of total output was consumed by the cement industry and about 12% was consumed by the steel industry as flux. Other main uses included aggregate (18%), lime (6%), filler and fertilizer (3%), soda and glass (1%), and all other (2%).

Salt.—Domestic production of salt in 1980 remained at about the 1-million-ton level. However, Japan imported about 88% of its total requirements for salt in 1980. During 1980, Japan's imports of salt, including industrial-use and common salt for retail sales, totaled 7,477,049 tons compared with 6,817,543 tons in 1979. Principal overseas suppliers were Mexico 50%; Australia, 40%; and China, 9%. The average unit value of all imported salt was estimated at $24 per ton compared with about $18 per ton in 1979. The average unit value of Mexican salt in 1980 was the cheapest at $22.90 per ton, Chinese salt was $23.50 per ton, and Australian salt was $26 per ton. Imports of common salt for general use totaled only 3,102 tons and was imported mainly from the United States (2,602 tons) and the Federal Republic of Germany (550 tons).

Consumption of salt in 1980 was estimated at about 8.5 million tons, of which about 6.8 million tons was consumed principally by the chlora-alkali industry. Production of salt for general consumption, including refined, common, ordinary, crushed, raw, and table salt, was estimated at about 1.6 million tons in 1980.

In 1980, production of caustic soda was 3,132,789 tons. About 3.1 million tons was delivered to the domestic market, and about 192,000 tons was exported. Japan also imported 34,000 tons of caustic soda in liquid form (a major portion) mainly from the Dow Chemical Co. of the United States and Dow Chemical Korea. During 1980, Japan's caustic soda industry was operating at about

70% of its 4.5-million-ton-per-year capacity. Production of soda ash totaled about 1.35 million tons. Practically all of the output was delivered to the domestic market.

Since July 1979, an export cartel on caustic soda was being carried out by 15 companies headed by Toyo Soda Manufacturing Co., Ltd., and Asahi Glass Co. under the approval of MITI. By December 1980, seven companies headed by Showa Denko, K.K., and Sumitomo Chemical Co. had joined the cartel.

Sulfur.—Japan's output of sulfur, recovered from petroleum refining, increased from 808,000 tons in 1975 to 1,256,000 tons in 1979 owing to the stepped-up regulations of environmental pollution by the Japanese Government. Output of sulfur by petroleum refining for FY 1980 was estimated at 1,276,000 tons, of which 867,000 tons was delivered mainly to the manufacturers of sulfuric acid and to other users, and about 410,000 tons was exported, mainly to the Republic of Korea (74%). Sulfuric acid production in FY 1980 was down slightly from that of FY 1979. Both domestic demand for sulfuric acid and exports were at about the same level as that of FY 1979.

Production and demand estimates of sulfur and of sulfuric acid for FY 1979 and FY 1980 released by the Japanese Sulfur and Sulfuric Acid Subcommittee of the Mining Industrial Council were as follows, in thousand tons for sulfur and thousand tons of 100% H_2SO_4 for sulfuric acid:

	FY 1979	FY 1980
Sulfur:		
Production	1,256	1,276
Domestic demand	838	867
Sulfuric acid	544	583
Other	294	284
Exports	420	410
Sulfuric acid:		
Production	6,680	6,660
Smelter gas	3,821	3,730
Pyrites (sulfide ore)	926	875
Sulfur	1,641	1,750
Other	292	305
Domestic demand	6,360	6,359
Fertilizer	2,121	2,152
Industrial use	4,239	4,207
Exports	371	268

Inventories of sulfur at the beginning and at the end of FY 1980 were 147,000 tons and 146,000 tons, respectively. Inventories of sulfuric acid at the beginning and at the end of FY 1980 were 132,000 tons and 165,000 tons, respectively.

The annual installed production capacity of Japan's sulfuric acid was about 9.3 million tons. During 1980, the industry was operating at about 70% of its capacity. The industry was composed of 56 plants owned by 43 companies at the end of 1979.

MINERAL FUELS

Japan's primary energy supply in FY 1979 (ending March 31, 1980) was estimated, by the Natural Resources and Energy Agency of MITI, at 4,087.4 trillion kilocalories or 7,473,000 barrels per day of oil equivalent, about 6% higher than FY 1978. In FY 1979, Japan relied on overseas sources for 87% of its primary energy supply and the remaining 13% was supplied by domestic coal, hydropower, nuclear power, and insignificant quantities of domestic crude petroleum and natural gas. Japan's primary energy supply in FY 1979 was summarized as follows:

	Quantity	Billion kilocalories	Oil equivalent (thousand barrels per day)	Percent
Petroleum:				
Domestic crude	551,000 kiloliters	5,180	9	0.13
Imported crude	273,752,000 kiloliters	2,573,270	4,705	62.95
Imported products	23,242,000 kiloliters	212,600	389	5.20
Imported LPG	9,669,000 tons	116,020	212	2.84
Coal:				
Domestic	18,880,000 tons	119,490	219	2.92
Imported	59,385,000 tons	454,740	831	11.13
Hydropower	85,044 million kilowatt-hours	208,360	381	5.10
Nuclear power	70,393 million kilowatt-hours	172,460	315	4.22
Imported LNG	14,858,000 tons	197,610	361	4.83
Natural gas	2,630 million cubic meters	25,270	46	.62
Other		2,380	5	.06
Total		4,087,380	7,473	100.00

Based on a revised long-term energy supply and demand forecast, total primary energy supply was to be increased from 7,473,000 barrels per day of oil equivalent in FY 1979 to 12,100,000 barrels per day in FY 1990. The Japanese Government was aiming to reduce the share of oil imports from 71% in FY 1979 to 50% by FY 1990. Moreover, the share of coal imports including coking and steam coal was to rise from 11% to 15.6%; LNG imports from 4.8% to 9.0%; nuclear power from 4.2% to 10.9%; and all others including domestic crude and natural gas, domestic coal, hydropower, geothermal energy, new energies, and other sources from 9% to 14.5%. In other words, Japan's oil import was to be kept below 366 million kiloliters per year, while imports of steam coal and LNG were to be raised to 535 million and 45 million tons, respectively, and the generation of nuclear power is to be increased to the 53-million-kilowatt level by FY 1990.

In 1979, Japan was the second largest energy-consuming nation of the industrialized world after the United States. Japan's total energy consumption in 1979 was estimated at about 378 million tons of oil equivalent. However, Japan's per capita annual energy consumption was the lowest among advanced industrial nations. Japan's per capita annual energy consumption was estimated at 2.3 tons of oil equivalent compared with the United States at 6.2 tons, Canada at 6.0 tons, the Federal Republic of Germany at 3.3 tons, France at 2.7 tons, and the United Kingdom at 2.6 tons.[14]

Coal.—Japan's domestic coal production in 1980 increased slightly over that of 1979, but was 2 million tons short of the 20-million-ton target set by the Government's national policy on domestic coal mining. During FY 1979, domestic coal production was principally by 9 large coal mining firms (accounting for about 95% of the total output) and 11 small mining firms. As of March 1980, coal production by the top nine producers in FY 1979 by company and by location of colliery was as follows, in thousand tons:

Company	Location of colliery	Production
Mitsui Coal Mining Co., Ltd	Ashibetsu-shi, Hokkaido	1,027
	Kamisunagawa-machi, Hokkaido	1,040
	Omuta-shi, Fukuoka, Kyushu	5,046
Mitsubishi Coal Mining Co., Ltd	Yubari-shi, Hokkaido	940
	Takashima-machi, Nagasaki	671

Total		16,994

Of the total coal produced in FY 1979, about 43% was coking coal and 57% was steam coal. By district, about 61% of the total output was in Hokkaido and 39% was in Kyushu. By method of mine development, about 95% was from underground

mines and about 5% was from open-cut mines. About 73.6% of the total production was mined from depths of over 500 meters from the pit mouth. By mining method, 73.6% was by longwall, 5.1% by open cut, 3.8% by hydraulic, 2.5% by room-and-pillar, and 15% by other methods.

The Japanese coal mining industry employed 18,816 mine workers at the end of March 1980. About 65% of the coal miners were working in the Hokkaido area. The annual working day of the Japanese coal miner remained at about 296 days in FY 1979 and labor productivity was 76.8 tons per month of coal per miner in FY 1979 compared with 74.6 tons per month per miner in FY 1978.

During 1980, Japan imported 68,277,000 tons of coal to meet the 88-million-ton demand. To meet this demand, 1,124,000 tons of anthracite was imported mainly from China (39%), Vietnam (28%), the Republic of South Africa (14%), and North Korea (8%); 5,109,000 tons of steam coal was imported mainly from Australia (67%), China (12%), and the United States (7%); and 62,044,000 tons of coking coal was imported principally from Australia (42%), the United States (31%), Canada (17%), and the Republic of South Africa (4.5%). Japan adopted a quantitative allocation system to import coal from overseas, and no tariffs were imposed on coal imports.

Japan's coal demand by consuming sector and by source of coal for 1979-80 was summarized as follows, in thousand tons:

	1979	1980
Manufacturing:		
Coke	4,195	4,309
Domestic	1,461	1,450
Imported	2,734	2,859
Iron and steel	57,688	64,123
Domestic	5,220	5,461
Imported	52,468	58,662
Cement, ceramics, other	3,372	8,148
Domestic	1,738	2,868
Imported	1,994	5,280
Utilities:		
Electric power	7,142	8,603
Domestic	6,872	7,712
Imported	270	891
Gas	1,591	1,604
Domestic	842	825
Imported	749	779
Other	1,233	1,504
Domestic	1,207	1,461
Imported	26	43

According to Japan's long-term energy supply and demand forecast, coal imports are expected to play an important role as an alternative source of the Japanese energy requirements during the next 10 to 15 years. Japan's coal imports are expected to reach 101 million tons (of which 22 million tons is steam coal) by FY 1985 and 143.5 million tons (of which 53.5 million tons is steam coal) by FY 1990, while domestic coal production is expected to remain at the 20-million-ton level through FY 1990.

In an effort to convert energy sources from oil to coal, the Natural Resources and Energy Agency of Japan was planning to construct a coal complex at Sakito in Nagasaki Prefecture and another at Tomakomai in Hokkaido. Each complex would have a coal center equipped with a transportation system, stockpile facilities, and coal cinder disposal facilities capable of handling 7.5 million tons and storing up to 1.25 million tons of coal per year. Each complex would have a harbor berth capable of handling up to 100,000-ton coal carriers. The construction work was expected to start in FY 1981. The total cost of the construction was estimated at about $381 million, and would be financed by the Japan Development Bank with low-interest loans.

In line with the Japanese long-term energy supply forecast, Japan was actively securing overseas coal either through signing of a long-term contract or participating in the actual development and exploitation of foreign coal resources, particularly in Australia, Canada, and China.

During 1980, Japan signed numerous agreements or contracts with Australia and Canada. Important contracts or agreements were summarized as follows:

Date	Buyer	Supplier	Terms of delivery	Remarks
February 1980	8 major steel companies led by Nippon Steel Corp.	Central Queensland Coal Association, Australia.	9.6 million tons for an unspecified 8-year period.	Coking coal from the Norwick Park coal mine.
April 1980	C. Itoh for Japanese steel mills.	MIM Holdings, Ltd., Australia.	15 million tons, 1984-98.	Coking coal from Collinsville Mine (prices would be $52 to $55 per ton).
July 1980	Onoda Cement Co	Australian Associated Resources, Ltd., a subsidiary of CSR, Ltd., Australia.	2 million tons, 1981-80.	Anthracite from Yarrabee Mine in Central Queensland.
July 1980	Mitsubishi Mining and Cement Corp.	Warkworth Association, Australia.	5.5 million tons, 1981-91.	Steam coal from Warkworth Mine in New South Wales.
August 1980	6 Japanese steel mills led by Nippon K.K.	Crows Nest Resources, Ltd., a subsidiary of Shell Canada Resources, Ltd., Canada.	15 million tons, 1983-97.	Coking coal from Line Creek coal mine.
August 1980	do	Gregg River Resources, Ltd., a subsidiary of Menalta Coal Co., Ltd., Canada.	31.5 million tons, 1983-97.	Coking coal from a new Gress River coal mine in Alberta.
December 1980	Japanese steel mills (unnamed).	Capricorn Coal Development, Australia.	5 million tons, 1982-91.	Coking coal from German Creek Mine in Central Queensland.
December 1980	do	The Queensland State Government, Australia.	47 million tons for an unspecified 14-year period.	Coking coal from Riverside Mine in Central Queensland.

In August 1980, a joint venture agreement was reached between four Japanese companies and the New South Wales Electricity Commission (a state agency) of Australia to develop the Birdsrock steam coal mine in New South Wales. Steam coal production was expected to start in 1984 at an annual rate of about 1 to 3 million tons. During 1984-90, about 70% of the output was expected to be shipped annually to the Japanese utilities, which include the Hokkaido Electric Power Co. The Electricity Commission would hold 51% of the mining rights, and the remainder was to be jointly held by the Japanese group (Taiheiyo Coal Development Co. 25%, Japan Coal Development Co. 14%, and Mitsui Co. and C. Itoh Co. 5% each).

An agreement was also reached in August 1980 between Mitsui Mining Co. and the Chinese Government to develop the Si Xiong Kou Mine and to expand the Xiao Kou Mine, both in the Da Dong Coalfields of Shanxi Province. The Si Xiong Kou Mine was expected to produce about 4 million tons of steam coal annually beginning in 1985, while the Xiao Kou Mine would be expanded from an annual output of 600,000 to 1.2 million tons in a 2- or 3-year period. Mitsui Mining reportedly planned to form a consortium to finance and develop China's coal mines in Shanxi Province.

In September 1980, the Export-Import Bank of Japan signed an agreement with the Bank of China to extend four loans totaling about $200 million for the financing of four coal projects. The projects included development of Qianjiaying coking coal deposits in Hebei Province and the steam coal mines at Sitaigou, Zhenchengdi, and Malan in Shanxi Province. After completion of the projects, Japan was expected to import about 10 million tons of coal annually from China starting in 1985.

For the past 7 years, Mitsui Mining has been involved in a research program on coal liquefaction called the Solvent Refined Coal (SRC) process. In 1974, the Mitsui group signed a joint SRC research contract with Gulf Oil Corp. of the United States, which also signed a similar contract with Ruhr Kohle AG of the Federal Republic of Germany. The trilateral group planned to build a coal liquefaction pilot plant in West Virginia (United States) by 1983-85.

In December 1980, an agreement was signed between the Japanese companies and the Victoria State Government of Australia to build a coal liquefaction pilot plant with a daily capacity of 50 tons (brown coal used) in Victoria. The Japanese companies involved in the project were the Mitsui

group and a new coal liquefaction consortium called Nippon Brown Coal Liquefaction Co. (NBCL) comprised of Kobe Steel, Ltd.; Mitsubishi Chemical Industries Ltd.; Nissho Iwai Corp.; Idemitsu Kosan Co.; and Asia Oil Co. The project was promoted as a national project of the Japanese and Australian Federal Governments. MITI would seek an appropriation of about $27 million in FY 1981 to assist in the financing of the plant. Under the agreement, the Victoria State Government would supply the brown coal free of charge to the pilot plant, and the Japanese firm would build the plant by the end of March 1982. The pilot plant was expected to be operational in 1983. If commercial operation proved to be feasible, then a 5,000-ton-per-day verification plant would be built in the 1986-87 period and a 30,000-ton-per-day commercial plant would be built in the 1988-89 period by NBCL.

Petroleum and Natural Gas.—Domestic production of crude oil continued to decline and remained insignificant, accounting for only 0.13% of Japan's primary energy supply and 0.2% of Japan's total crude oil supply in FY 1979. During 1980, Japan imported 256.8 million kiloliters, or 4.4 million barrels per day of crude oil (including natural gas liquids but excluding petroleum products), to meet about 99.8% of its crude oil requirements. However, Japan's crude oil imports in 1980 represented an 8.4% decline from that of 1979 and was the lowest since 1972 (4.1 million barrels per day). It also represented the first significant configuration in change of the Japanese energy consumption pattern (shifting from oil to other energy sources such as coal or LNG) as a result of Government energy-saving measures and promotion of alternative energy resources development.

In 1980, Japan remained the world's second largest petroleum importing country. The principal sources of Japan's crude oil imports were the Middle East region, (73.2% of the total imports) led by Saudi Arabia (31.6%) and the United Arab Emirates (13.6%), and the Asian region (23.4%) led by Indonesia (14.3%). Because of the Iranian Revolution and the Iran-Iraq war, Japan's crude oil imports supplied by Iran, the Neutral Zone, Oman, Kuwait, and Qatar were substantially reduced in 1980. On the other hand, the Japanese crude oil imported from Latin America and Africa increased dramatically in 1980. Crude oil imported from Venezuela increased about fivefold from 8,000 barrels per day in 1979 to 38,000 barrels per day in 1980, and imports from Algeria increased from 6,000 barrels per day in 1979 to 28,000 barrels per day in 1980. Algeria, Libya, Venezuela, Mexico, and Ecuador emerged as potentially important overseas suppliers of Japan's crude oil.

Crude oil supplied by major international oil companies declined from 56.4% of total crude imports in 1979 to only 44.6% in 1980. The share of imports supplied by oil-producing countries through direct deals and a government-to-government basis increased substantially from 31.7% of the total crude imports in 1979 to 44.9% in 1980.

To secure stable supplies and to diversify crude oil supply sources following a restructuring of its crude oil supplies, Japan signed a 10-year crude oil contract with Mexico on December 11, 1979, on a government-to-government basis, with an initial import volume of 25,000 barrels per day, and was expected to reach 100,000 barrels per day by December 1980. In mid-1980, Japan asked Mexico to increase its crude oil supplies to Japan from 100,000 barrels to 200,000 barrels per day in 1981 and to 300,000 barrels per day in 1982. However, no agreement was reached by yearend 1980.

Japan signed two contracts with China on May 29, 1980, for exploration and development of oil resources in Bo Hai Bay in China. The first contract covers 14,100 square kilometers in southern Bo Hai and 11,400 square kilometers in western Bo Hai. The second contract covers the Chengbei block in the deeper areas of western Bo Hai. The total cost of exploration and development for the two areas was estimated at $1.2 billion, of which Japan was expected to pay $210 million for the exploration and the remaining $1 billion was to be shared by Japan and China in a 49:51 ratio. Japan was expected to import from China 42.5% of the output for 15 years beginning in 1982.

In August 1980, Japan, represented by the Japan National Oil Corp. and a group of Canadian private companies represented by Dome Petroleum, Ltd., signed an agreement to jointly develop oil deposits covering 154,440 square miles in Canada's Beaufort Sea in the Arctic. Japan would provide a 400-million Canadian dollar loan to the Canadian companies for exploration and development. The loan was to be repaid by Dome Petroleum in the form of crude oil to be developed. The production was expected to start in 1985 with an initial output level of 100,000 barrels of oil per day.

During 1980, three overseas oil development projects that were undertaken independently started oil production: Mitsubishi Petroleum Development Co., Ltd., in Baliste Field (a Baudroie concession) off the coast of Gabon; the Egyptian Petroleum Development Co., Ltd., in West Baker Field onshore the Gulf of Suez; and Sumitomo Petroleum Development Co., Ltd., in Sahmah Field, in Oman. Japan was to import oil from these areas under production-sharing contracts.

Japan's domestic production of natural gas was about 2,200 million cubic meters in 1980. About 98% of the output was from natural gasfields and 2% was from oilfields and coalfields. The total output of natural gas contributed only 0.6% of Japan's primary energy supply. Japan imported about 16.8 million tons of LNG in 1980 for consumption by Japan's electric utilities (76.9%), city gas companies (19.5%), and manufacturing (3.6%). Japan's LNG imports, which accounted for about 6% of its primary energy supply, was secured normally by a 20-year contract with foreign governments participating in the LNG projects. During 1980, the major suppliers of Japan's LNG imports were Indonesia, 8.5 million tons; Brunei, 5.5 million tons; Abu Dhabi, 1.9 million tons; and the United States (Alaska), about 859,000 tons. Other future overseas suppliers were Malaysia (Sarawak), Australia, Canada, and the Soviet Union.

On October 27, 1980, a group of five Japanese companies comprised of the Nissho-Iwai Corp., Chubu Electric, Kyushu Electric, Osaka Gas, and Toho Gas reached an agreement with Canada's Dome Petroleum, Ltd., for the purchase of 400 million cubic feet per day of natural gas over a 20-year period starting in 1985. This long-term contract, valued at about $20 billion, would be the first sale of Canadian natural gas in any form to any foreign country other than the United States.

In late 1980, after a series of negotiations, an agreement was reached for the Soviet Union to supply 5 billion cubic meters of natural gas or 3 million tons of LNG per year to Japan over a 20-year period beginning in or after 1986. The natural gas would be produced from the areas offshore northeast of Sakhalin (a Soviet island, north of Japan), where vast natural gas reserves have been confirmed by Sakhalin Oil Development Corp.

Uranium.—In September 1980, the Japan-Australia Uranium Resources Development Co. (JAURD) signed an agreement with Energy Resources of Australia (ERA) to invest 41 million Australian dollars on a 10.1% equity participation in ERA and to purchase about 1,000 short tons per year of U_3O_8 over a 15-year period starting in 1982. Under the agreement, the Japanese firms have the option to double their purchases of U_3O_8 to 2,000 short tons per year, beginning in 1990. JAURD was established on September 12, 1980, with an equity of $18 million, which was held by Kansai Electric Power Co. (50%), Kyushu Electric Power Co. (25%), Shikoku Electric Power Co. (15%), and C. Itoh Co. (10%). ERA planned to develop the Ranger uranium mine with proven uranium ore reserves of 120,000 short tons of U_3O_8 and start production at an annual rate of 3,300 short tons of U_3O_8 in 1982. The 400-million-Australian-dollar project would be financed mostly by borrowing from abroad. JAURD, in addition to equity participation, planned to extend a $146 million U.S. loan to ERA from Japan's Export-Import Bank and other domestic financial institutions to help the project.[15]

The Mineral Industry of Kenya

By George A. Morgan[1]

In 1980, the growth of the mining and quarrying sector of Kenya's economy remained relatively unchanged. Although the real gross domestic product (GDP) was up almost 2.4% at $4.2 billion,[2] the mining and quarrying sector again accounted for only about 0.25% of GDP, or $10.7 million. The economy was very vulnerable to energy costs as the country had to import 88% of its total energy for consumption. Imports were up because of a relaxation of the advance import deposit requirement, and a trade deficit of $1,116 million was experienced. The balance of payments reached a record deficit of $880 million. Total energy consumption increased 3.5%, and imported crude petroleum cost $678 million, or about 53% of total export earnings, including petroleum product exports.[3]

The country attempted to expand its energy base which was heavily reliant upon imports. Nearly 18% of its electricity requirements were imported from Uganda in 1980. Both hydroelectric and thermal generating capacity were being increased. A process was implemented to make charcoal from coffee husks, and two alcohol plants using cassava as a raw material were expected to produce the equivalent of 13% of total motor fuel consumed. A geothermal electric plant was to be commissioned in 1981 at Olkaria.

Assessment of the nation's nonfuel mineral resources was undertaken by the Mines and Geological Department (MGD) of the Ministry of Environment and Natural Resources. Geological, geophysical, and geochemical work continued in western and southeastern Kenya following completion of an airborne geophysical survey. The MGD and the Institute of Geological Sciences of the United Kingdom agreed to conduct a 4-year joint geological mapping and mineral exploration program in north-central Kenya. Another agreement was signed with the Finnish Geological Survey for a joint industrial mineral assessment program. The assessment would be countrywide, with the object of initiating mining and processing of deposits, as well as providing specialized services to the private sector.

PRODUCTION AND TRADE

The principal mineral commodities produced continued to be soda ash and fluorspar. Capacity to produce barite was increased with the installation of updated processing facilities because demand was up for drilling muds. The possibility of further expansion of barite production from deposits in Coast Province was considered. Most other mineral production was on a low-volume basis, with local markets predominating as the primary users. Cement capacity was increased as demand was up in the major cities. Negotiations were concluded for the establishment of a fertilizer facility at Mombasa. Imported ammonia and phosphoric acid would be feed material to the enterprise. Government and quasi-Government institutions approved 110 projects in 1980, valued at $45 million. However, these were aimed primarily at the manufacturing and agricultural sectors. Additional funds were provided to the cement industry for increasing capacity, while upgrading of the railroad was under way to satisfy new

haulage requirements.

Total freight handled at the Port of Mombasa was up 20% to 7.4 million tons. The major portion of Kenya's imports was from the European Communities (EC) and the Near East. Exports were predominately to the EC and Africa. Exports of soda ash, fluorspar, and cement were valued at $56 million in 1980, while exports of refined petroleum products were valued at almost $400 million.

[1]Table includes data available through Sept. 15, 1981.

[2]Less than 1/2 unit.

[3]Quality (gem or industrial) not specified.

[4]Coral for cement manufacture apparently has been included with limestone for cement manufacture.

[5]Probably an incomplete figure.

[6]Including some fuel oil described also as unfinished oil.

COMMODITY REVIEW

METALS

Production of metallic minerals in Kenya was virtually nil. About 15,000 tons per year of magnetite was produced, mainly for the cement industry. Production of lead and byproduct silver from Coast Province ceased with the exhaustion of minable material.

NONMETALS

Asbestos.—Asbestos cement products consisting mainly of sheeting material and pipes manufactured from chrysotile asbestos imported from Swaziland and Australia were produced at Bamburi by the Kenya Asbestos Cement Co. No asbestiform minerals of suitable quality to meet accepted standards have been found in Kenya. Tests made on anthophyllite asbestos from local deposits, for example, at Makinyambu, about 180 kilometers northwest of Mombasa, indicated the fiber to be too brittle and difficult to combine with cement.[4]

Barite.—Economically significant occurrences of barite were located in Coast Province at Mrima Hill and Vitengeni. Production at Vitengeni was from the reworking of old lead mine dumps. Mineral Mining Corp. Ltd. was the principal barite producer. Exploration was under way to determine additional resources, while increased output was provided by the installation of a screening and washing plant.

Cement.—Two cement plants were operated in 1980; the Bamburi plant of the Bamburi Cement Co. near Mombasa, with a capacity of 1.25 million tons per year, and the Athi River plant of the East African Cement Co. near Nairobi, with a capacity of 450,000 tons per year. A third plant was being considered for western Kenya, provided sufficient raw materials proved to be available. Overall national consumption was 62,000 tons per month, of which about 32,000 tons was supplied by Bamburi Cement Co. and the remainder by the East African Cement Co. The remaining portion of production, about 530,000 tons in 1980, was exported.

The principal producer continued to experience transportation problems because of a shortage of railroad cars. The shortage has persisted for several years following recently expanded production capacity at the two cement plants in order to meet increased demand. Most of the supply was destined for construction in Nairobi. Approximately 12,000 tons per month of the 32,000 tons per month normally shipped to Nairobi by Bamburi Cement Co. was backlogged. The Kenya Railway was to provide 60 haulage cars per day instead of the 40 being used in order to move the backlogged material and bring daily shipments to more normal levels.

Modifications at the Bamburi plant were planned to utilize coal imported from Swaziland in order to replace oil. A reduction of 50% of production costs was believed achievable as a result of the changeover in energy source. The Commonwealth Development Corp. provided aid to further expand the cement industry.

Diatomite.—A number of deposits of diatomite have been located in the Rift Valley, the most significant being Kariandus and Soysambu near Gilgil. Reserves at Soysambu were 1.5 million tons, of which 0.3 million tons were suitable for the manufacture of filter aids. Production was by the East African Diatomite Industries Ltd. About 1,600 tons of marketable product was obtained from 3,000 tons of mined ore. The diatomite was calcined in a rotary kiln, crushed, and then graded on the basis of particle size. Four grades of filter aid, as well as six filler and insulating grades, were produced.

Fertilizer Materials.—An agreement was made with a Dutch company by National Agricultural Chemicals & Fertilizers of Kenya Ltd. for the design and construction of Kenya's first nitrogen fertilizer project. A previous plan to erect a 54,000-ton-per-year ammonia synthesis plant using naphtha feedstock was abandoned. Capacity of product plants to be included in the fertilizer project at Mombasa include 75,000 tons per year of nitric acid, 99,000 tons per year of combined product calcium ammonium nitrate and nitrophosphate, and 130,000 tons per year of monoammonium and diammonium phosphate. Port facilities would be built to handle imports of ammonia and phosphoric acid. Commissioning of the facility was scheduled for late 1981. Imports have supplied the fertilizer market in Kenya with consumption at only about 25,000 tons per year of contained nitrogen. Supply to the local market has been restricted by Government price controls which prevented sufficient financial return to importers.[5]

Magnesium based fertilizers were produced locally by the Lokhani Group from magnesite and dolomite operations.

Soda Ash.—The Magadi Soda Co., a subsidiary of Imperial Chemical Industries, Inc., of the United Kingdom, produced soda ash at Lake Magadi. Capacity was 250,000 tons per year. Expansion plans called for a total capacity of 500,000 tons per year by 1983. Soda ash (Trona) was dredged and crushed by a pontoon-mounted dredge, which then pumped the material in slurry form via a flexible pipe to a treatment plant at the site. Treatment included washing, screening, dewatering, and calcination to yield a product having a total alkalinity as Na_2CO_3 of 97.4%. Shipment from Lake Magadi was by way of a 146-kilometer branch line to the Kenya-Uganda Railroad at Konza. Warehouses and a deepwater pier for bulk handling of soda ash were owned and operated by Magadi Soda Co. at Kilindini Harbor. The principal recipient countries have been Thailand, Indonesia, Malaysia, and Singapore.

Vermiculite.—Several deposits were worked for vermiculite, with most production exported. Local consumption was used in production of lightweight concrete products and acoustic plaster.

The deposit at Kenze, 200 kilometers east of Nairobi, had reserves of 500,000 tons and was mined opencast. Crude vermiculite, crushed and screened at the mine site, was shipped to Nairobi for use in the building and construction industry. Other small deposits located in the vicinity of Ndolo provided a product with bulk densities of 8.4 to 9.2 pounds per cubic foot upon exfoliation. Output was also shipped to Nairobi.

The Wasini Mine near Lodosoit was the principal vermiculite mining operation. Reserves were not quantified, but were considered substantial. Production was by the Iwatani-Lonata Vermiculite Co. of Kenya, Ltd. Output was geared to specific customer requirements. Reduction in the cost of transportation could lead to substantially increased production levels.

MINERAL FUELS

Petroleum.—Kenya was dependent upon imports of crude oil for the major portion of total energy consumed. Only about 12% of energy consumption was derived internally, all of which was from hydroelectric powerplant generation. About 4% of total energy consumption was in the form of electricity imported from Uganda. The country's sole oil refinery at Mombasa had a throughput of 3,038,000 tons of crude oil in 1980. About 53% of refinery production was used locally, the remainder was exported. Several major oil firms shared an exploration permit for a 12,420-square-kilometer area covering both onshore and continental shelf zones north of Mombasa.

The Mombasa-Nairobi product pipeline, commissioned in February 1978 and operated by Kenya Pipeline Co., had a throughput of 1.5 million cubic meters in 1980, up 7% from 1979. Road tankers were used at Nairobi for further distribution.

The Mineral Industry of North Korea

By Edmond Chin[1]

Total expenditure of the 1980 budget of the Democratic People's Republic of Korea was estimated at $10.5 billion. Expenditures for the people's economy (includes basic construction; mining; electricity; metal, chemical, and construction material industry; technical development; and other sectors) was $6.3 billion, or about 60% of the total. The remainder was for social welfare, military, and administration and management. Estimated national income and revenue in 1979 were $9.7 and $9.5 billion, respectively. About 8% of the national income in 1979 was from Provincial governments, an increase of 24% over that in 1978. Revenues of local governments increased by 10.1% in 1979.[2]

In the early 1970's, North Korea began a large-scale modernization program by importing technology primarily for its heavy industrial sectors.[3] Subsequently, with the increase in oil prices and a drop in the nonferrous metals market, a prime foreign currency earner for the country, North Korea became delinquent in debt payments to creditor countries including Austria, the Federal Republic of Germany, France, Japan, Sweden, and the United Kingdom. Because of ballooning debt problems, North Korea was not able to meet interest payments, and in some instances, defaulted on payments. By 1977, North Korea was indebted to at least 17 Western Nations for $1.4 billion and at least $1 billion to its centrally planned economy trading partners. Japan's claim against North Korea alone was nearly 80 billion yen (about $10.4 million). By 1979, however, a debt repayment agreement was reached with Japan, and negotiations and agreements were being conducted or concluded with other creditors.

To stabilize the country's economy, President Kim Il-sung exhorted the country to meet planned targets for national output and to increase industrial productivity. Priorities in 1979 were revised for 1980. Highest priority in 1980 was again given to mining, especially to increase coal output. The second highest priority was given to the transportation sector for improvement and modernization. The third highest was for trade, that is, output of export products was to be given preference over all other industries. Although Government statements on meeting the target of the current second 7-year plan claim fulfillment and overfulfillment, some sectors of the economy continued to stagnate due to economic isolation as a result of its "chuche" (economic self-reliance) policy and a national budget which favors military defense expenditures.

PRODUCTION

Geologically, North Korea has predominantly the best mineralization for commercial exploitation of the Korean Peninsula. The leading mineral commodity produced is coal, mostly anthracite with some lignite.[4] There is, however, no known commercial production of oil and natural gas. The leading metal ore is magnetite, mined mainly from four provinces. North Korea is also a significant producer of lead and zinc in the Orient. Copper, gold, and silver are mined along with lesser quantities of cobalt, chromium, manganese, molybdenum, nickel, and tungsten. Mine production of magnesite is of world significance. Because the country was overextended in redemption of its foreign debts, the Government exhorted the mining and metals sector to fulfill annual targets to gain foreign exchange through export sales. The central Government does not publish minerals and metals production data, and hence no official statistics are available.

Table 1.—North Korea: Estimated production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity[2]	1976	1977	1978	1979	1980[p]
METALS

[p]Preliminary. [r]Revised.

[1]Table includes data available through June 16, 1981.

[2]In addition to the commodities listed, a number of other commodities apparently are produced, but available information is inadequate to make reliable estimates of output levels. These include (but are not limited to) antimony, arsenic (in arsenopyrite), asbestos, beryl, bismuth, boracite, chromium, cobalt, columbite, germanium, indium, kaolin (china clay), lithium minerals (lepidolite), manganese ore, mica (phlogopite), molybdenite, monazite, nickel and/or ferronickel, selenium, tellurium, titanium minerals (ilmenite and rutile), zircon, a variety of crude construction materials (including miscellaneous clays, glass sand, building sand, crushed and dimension stone, and gravel), and refined petroleum.

[3]Includes granulated iron.

TRADE

The Government of North Korea does not publish trade transaction data for foreign dissemination. However, North Korea's main trading partners were China, Japan, and the U.S.S.R., not necessarily in that order.[5] The principal mineral commodity trade with China and the U.S.S.R. was believed to be petroleum for North Korea's crude oil refineries. In addition, trade with the U.S.S.R. included imports of plant machinery and equipment for iron and steel production, oil refining, coke, and coal; and exports of steel and nonferrous metals, magnesia clinker, barite, talc, chemicals, and cement.

Shipments to Japan included zinc ore concentrates, lead and zinc metal ingot, pig iron, silver, magnesia clinker, talc, and anthracite. Receipts from Japan included finished products such as transport equipment, general machinery, electrical apparatus, and textiles, as well as less valued imports of steel and aluminum. North Korea also exported nonferrous metals, primarily lead and zinc, to Belgium, Denmark, France, Italy, Singapore, Switzerland, and the United Kingdom. Moreover, trade agreements were negotiated with several countries which included mineral commodities such as cement, zinc, anthracite, manganese, steel, apatite, crude oil, and refractory brick.

North Korea's main trading companies for the mining and metallurgical industries were as follows:

Name	Remarks
Korea Jeil Equipment Import Corp	Equipment for mining iron and steel, nonferrous, and cement industries.
Korea Jei Equipment Import Corp	Equipment for chemical industry.
Korea Jesam Equipment Import Corp	Do.
Korea Machinery Export Corp	Machinery and equipment for mining, metallurgy, and chemical industries.
Korea Machinery Import Corp	Machinery and equipment for mining, metallurgy, and chemical industries; and equipment for radioactive applications.
Korea Mineral Exports and Import Corp.	Solid fuels; metallic and nonmetallic minerals; construction aggregate; gem stones; and insulation, abrasive, and filtering materials.
Korea Ferrous Metals Export and Import Corp.	Pig iron; ferroalloys; steel; and ferrous manufactures and semimanufactures.
Korea Chemicals Export and Import Corp.	Petroleum and refinery products and chemical fertilizer raw materials.
Korea Building Material Export and Import Corp.	Cement and construction materials.
Korea Light Industries Goods Exports and Import Corp.	Jewelry, and gold and silver goods and products.
Korea Daesong Trading Corp	Metallic and nonmetal minerals and ores; ferrous and nonferrous metal products; and gold and silver.
Korea Pyongang and Trading Co. Ltd	Metallic and nonmetallic materials and ores; ferrous and nonferrous metal ingots; metal manufactures; magnesia.
Korea Ponghwa Trading Corp	Minerals, and metal products.
Korea Maibong Trading Corp	Nonmetallic minerals; nonferrous metal ingots; jewelry; gold and silver; and ferrous manufactures.
Korea Manpung Trading Corp	Equipment and raw materials for the chemical industry.
Korea Senbong Trading Corp	Metallic manufactures.

In addition, the committee for the Promotion of International Trade of the Democratic People's Republic of Korea and the Korea Society for Scientific and Technical Exchange with Foreign Companies were trade promotion groups established by the central Government. The principal banks involved with foreign exchange of currencies and transactions and settlements of foreign accounts were the Foreign Trade Bank of the Democratic People's Republic of Korea and the Kumgang Bank.

Table 2.—North Korea: Apparent exports of mineral commodities[1 2]

(Metric tons unless otherwise specified)

Commodity	1978	1979	Principal destinations, 1979
METALS			
Aluminum metal including alloys, semimanufactures	r1,372	316	All to Saudi Arabia.

Dust and powder of natural and synthetic precious and semiprecious stones do	1	2	All from Japan.
Grinding and polishing wheels and stones	38	12	Japan 10.
Boron materials: Oxide and acid	21	--	

See footnotes at end of table.

Table 3.—North Korea: Apparent imports of mineral commodities[1] [2] —Continued

(Metric tons unless otherwise specified)

Commodity	1978	1979	Principal sources, 1979
NONMETALS —Continued			
Chalk	18	53	All from United Kingdom.
Clays and clay products:			
Crude	5	300	All from Singapore.
Products:			
Refractory	3,074	4,132	Japan 4,082.
Nonrefractory	5	91	Italy 88.
Diamond:			
Gem, not set or strung ____ value, thousands	$20	--	
Industrial ____ do ____	--	$28	All from Japan.
Diatomite and other infusorial earth	--	3	Do.
Fertilizer materials:			
Crude, phosphatic ____ thousand tons	NA	[5]325	Syria 177; Algeria 93; Egypt 55.
Manufactured:			
Nitrogenous	--	100	All from Japan.
Potassic	150,900	83,474	All from U.S.S.R.
Other including mixed	202	--	
Gypsum and plasters	1	--	
Mica, all forms	1	5	All from Japan.
Precious and semiprecious stones except diamond, natural and synthetic ____ value, thousands	$10	$84	France $72; Austria $12.
Salt	317	338	All from Japan.
Sodium and potassium compounds, n.e.s.:			
Caustic soda	5	48	All from Belgium-Luxembourg.
Caustic potash	--	1	All from Japan.
Soda ash	1	2	Do.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked	--	30	All from Italy.
Worked	--	175	Italy 167.
Sand	--	4	All from Japan.
Sulfur:			
Elemental	7	4	Do.
Sulfuric acid	3	3	Do.
Other, crude	--	3	Do.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	401	9	Do.
Carbon black	188	544	Do.
Coal, anthracite and bituminous ___ thousand tons	17	15	Do.
Coke ____ do ____	96	186	Poland 94; Japan 92.
Peat and peat briquets	--	12	All from Canada.
Petroleum refinery products:			
Gasoline ____ thousand 42-gallon barrels	97	--	
Kerosine ____ do ____	--	4	Hungary 3.
Residual fuel oil ____ do ____	[r]388	147	All from Singapore.
Lubricants ____ do ____	11	18	Singapore 17.
Other:			
Liquefied petroleum gas ____ do ____	--	([6])	All from France.
Mineral jelly and wax ____ do ____	2	--	
Bitumen and other residues ____ do ____	2	--	

[r]Revised. NA Not available.

[1]Owing to the lack of official trade data published by North Korea, this table should not be taken as a complete presentation of North Korea's mineral imports. These data have been compiled from various sources which include United Nations information and data published by the trading partners.

[2]Unless otherwise specified, data are compiled from available official trade statistics of individual trading partners.

[3]Partial figure; Japan reports additional exports to North Korea but only in terms of value.

[4]Reported Canadian exports of zinc ore with 4,734 tons metal content.

[5]The British Sulphur Corporation Limited. Statistical Supplement, London.

[6]Less than 1/2 unit.

COMMODITY REVIEW

METALS

Ferrous Metals.—*Iron Ore.*—The main producing areas for iron ore in North Korea are the Provinces of North Hamgyong, South Hwanghae, Kangwon, and South Pyongan. The largest deposit is at Musan which is estimated to contain 1.3 billion tons of magnetite. The Musan Mine has an annual output capacity of 6.5 million tons, and during the second 7-year plan, capacity was to be increased to 10 million tons

annually. The magnetite granules at Musan are described as large and easily separated. The ore dressing plant at Kangdok treats the 40% iron content ore and concentrates it to 59% to 60%. Ore transport to Kangdok is by the electrified Chogjin-Musan Railway and by a slurry pipeline completed in 1975. The Musan Mine is the principal iron ore supplier for Kim Chaek Iron and Steel and is located 98 kilometers from the complex. The iron ore mines at Songnim and Tokyon feed the Hwanghae Steel Refinery complex. Annual mine output at Tokyon was 750,000 tons per year. The major iron ore mines in North Korea were as follows:

Province administrative unit	County	Mine	Remarks
Chongjin City	Musan	Musan	6.5 million tons per year; output for Kim Chaek Iron and Steel.
South Hamgyong	Toksong	Toksong	Undergoing expansion.
Do	Tiwon	Yiwon	
Do	Nochon	Yongwon	
North Hwanghae	Songnim	Songnim	Output for Hwanghae Steel.
South Hwanghae	Chaeryong	Chaeryong	
Do	Unyul	Sohaeri	
Do	Taetan	Taetan	Under development.
Do	Unyul	Unyul	1.2 million tons per year; output for Hwanghae Steel.
North Pyongang	Uiju	Tokyon	750,000 tons per year; output for Hwanghae Steel.

The final-year target for iron ore output for the 6-year plan (1971-77—this plan was extended by 1 year) was 13 million tons per year. In the second 7-year plan (1978-84), the final year target was for a goal of 16 million tons per year.

Iron and Steel.—The Kim Chaek Iron and Steel complex is the largest in North Korea. In addition to 3 or 4 small blast furnaces, the No. 1 and No. 2 blast furnaces at Kim Chaek have an inner volume of 1,000 cubic meters and for No. 3, 1,500 cubic meters. During the 6-year plan (1971-77), a 3-million-ton-per-year continuous sintering furnace was installed; as well as No. 3 and 4 coking ovens and two 100-ton rotary furnaces; and a 1-million-ton-per-year hot-rolling plant (Model 1700 hot roller) was completed with Soviet aid. Under the second 7-year plan, installation of a second slurry pipeline between Musan Mine and the ore dressing plant at Kangdok was proposed; the railway line between Komusan and Musan was to be double tracked; construction of a 400,000-ton-per-year cold-rolling plant was to be completed; and plans for construction of a No. 5 coking oven were reported.

Hwanghae Iron and Steel complex has three 1,000-cubic-meter blast furnaces. Ore from the Unyul Mine is shipped by sea by way of Kumsanpo or by two overland railway routes— Sohaeri-Sugyo/Umpa line and Songnim via the Pyongbu line. A sheet roller was completed in 1963; medium blast furnaces installed in 1964; a 400,000-ton-per-year blooming shop completed in 1964; and the No. 6 open-hearth furnace installed in 1965. During the 6-year plan, the three blast furnaces were enlarged to the present inner volume of 1,000 cubic meters; construction of a granulated iron and reduced lump ore shop was completed; and a sintering plant completed.

North Korea's iron and steel works were as follows:

Name	City	Principal product line
Kim Chaek Iron and Steel.	Chongjin	Pig iron, sponge iron, steel, rolled steel.
Hwanghae Iron and Steel.	Songnim	Pig iron, granulated iron, steel, rolled steel.
Kangson Iron and Steel (includes 13-14 Iron-Works).	Taen	Granulated iron, rolled steel, alloy steel, tool steel, steel wire and rope, seamless steel pipe, castings, blister.
Chongjin Steel Works.	Chongjin	Granulated iron, steel, rolled steel.
Songjin Steel Complex.	Kim Chaek	Rolled steel, alloy steel.
Puryong Metallurgical Works.	Chongjin	Iron alloys, ferrochromium, ferrosilicon.
Pyongyang Steel Factory.	P'yongyang	Cast iron pipe.
Chongjin Cast Iron Pipe Factory.	Chongjin	Cast iron pipe.
Muchon Steel Factory.	Muchon	Castings.

The Pyongyang, Puryong, Chongjin, and Muchon facilities are small casting plants, using open hearths and electric furnaces. In addition, the central Government proposed the construction of an iron works to be located on the lower reaches of the Taedong River and an electric furnace iron works in Sobu.

Other Ferrous Metals.—Nickel was mined from the Pugan area, Chongjin City; manganese in Cholwon County, Kangwon Province; and tungsten from the Kyongsu Mine in Taegung County, South Pyongan Province, and from the Mannyon Mine in Sinpyong County, North Hwanghae Province. Cobalt and molybdenum was also produced, the latter probably as a byproduct of copper mine production.

Nonferrous Metals.—Little information is publicly available on the nonferrous industry in North Korea. Under the second 7-year plan, a production target of 1 million tons per year was set collectively for nonferrous metals, most of which was for lead and zinc, followed by copper.

Copper-lead-zinc.—The most prominent lead-zinc producer in the country is the Komdok Mine in Tanchon County, South Hamgyong Province. In the same Province, lead-zinc is also produced at the Sankok Mine in Kowon County. Other lead-zinc operations include the Kyesong Mine in Chagang Province; Kaun Mine, Muchon, Kangwon Province; and Sungchang Mine in South Pyongan Province.

The country's most significant copper production is from the Huchang Mine in Chagang Province, the Kapsan Mine in Yanggang Province, and the Tanchon Mine in South Hamgyong Province. Other production is from the Hyesan Youth Mine at Haisan City and the Hwapyong Mine in Hwapyong County. Substantial copper mineralization reportedly occurs also in multimetal orefields in South Pyongan and North Hwanghae Provinces.

North Korea's nonferrous smelters were as follows:

Name	City	Product and Remarks
Haeju Smelter	Haeju	Copper and sulfur.
Hungnam Smelter	Hamhung	Electrolytic copper, lead, silver, nickel.
Mumpyong Smelter	Muchon	Copper, electrolytic copper, lead, zinc, chalcopyrite, sulfur.
Nampo Smelter	Nampo	Electrolytic copper, zinc, gold, silver, chalcopyrite, associated fertilizer plants.
Pyongyang Nonferrous Metal Plant	Pyongyang	Electrolytic copper, also refines scrap copper.
Tanchon Smelter	Tanchon	Copper.

The current annual production capacity for lead and zinc is estimated at 200,000 tons and for copper, 100,000 tons. In addition to the primary products, North Korean refineries also recover byproduct molybdenum, and remelt aluminum and tin from scrap or imported material.

Miscellaneous Nonferrous Metals.—According to early source materials, gold production in North Korea has been as high as 31 tons, around 1939. The large gold occurrences are in the Unsan region of North Pyongan Province; other widely scattered occurrences are in North Hwanghae, Kangwon, and South Pyongan Provinces. Nonferrous metal mines reportedly active in the country were as follows:

Commodity	Mine	City and Province
Aluminum (nepheline).	Changsan	Taedong, South Pyongan.
Antimony	Inpyong	Yangdok, South Pyongan.
Gold	Multong	Yonsan, North Hwanghae.
	Suan	Suan, North Hwanghae.
	Sinyon	Sakchu, North Pyongan.
	Taeyudong	Tongchang, North Pyongan.
	Unsan	Unsan, North Pyongan.
Nonferrous, n.e.c.	Hamgyung	Hoechang, South Pyongan.
	Kukok	Ongjin, South Hwanghae.
	Mandok	Hochon, South Hamgyong.
	Nanchon	Pyongsan, South Hwanghae.
	Ongjin	Ongjin, South Hwanghae.
	Pupo	Kangyong, South Hwanghae.
	Pyogsan	Pyongsan, North Hwanghae.
	Sinpung	Kumhwa, Kangwon.
	Sinwon	Sinwon, South Hwanghae.
	Tongbang	Changgang, Chagang.
	Unhung	Unhung, Yanggang.

Most of the country's requirement for tin and aluminum is met by imports. In the 1950's, an aluminum smelter utilizing nepheline was built at Yongampo. However, no information is currently available regarding the status of this smelter.

NONMETALLIC MINERALS

Cement.—By the end of 1978, the Government announced that the annual production capacity for cement had reached 8 million tons. By the end of 1984, annual capacity was expected to be 12 to 13 million tons. Because of the large demand for cement as a result of domestic construction and military requirements, and as an exportable item to earn foreign exhange, North Korea was expected to make a considerable effort to attain the 1984 target. North Korea's annual cement production capacity, estimated by plant, was as follows, in thousand tons:

Plant	City and Province	Capacity
Chonnaeri	Muchon, Kangwon	1,000
Haeju	Haeju, South Hwanghae.	850
Comusan	Chongjin, North Hamgyong.	810
Kujang	Kujang, North Pyongan.	200
Madong	Pongsan, North Hwanghae.	1,350
Puraesan	Kowon, South Hamgyong.	500
Sunchon	Sunchon, South Pyongan.	3,000
Sunghori	Pyongyang	650
All other plants (30).		1,140
Total		9,500

In addition to the major product, portland cement, some plants produced white cement, clinker, slake lime, and fireproofing materials. North Korea exports cement under the "Deer" brand name. Partial specifications of this brand are SO_2 2.5%; MgO 4.5%; fineness, 2,250 cubic centimeters per gram; refractory, 3,400 pounds per square inch after 7 days.

Chemical Fertilizer.—The largest chemical fertilizer producer in North Korea is the Hungnam Combined Fertilizer Enterprise. This facility produces over one-third of the country's total output of fertilizer. North Korea has abundant hydropower, limestone, and apatite, but lacks oil and natural gas for production of nitrogenous fertilizers. Additionally, the quality of domestic apatite reportedly is poor, and the industry has imported up to 1.2 million tons of phosphate rock for feed solely to the Haeju Phosphate Fertilizer Plant. North Korea's chemical fertilizer plants are as follows:

Name	City	Product line and remarks
Aoji Chemical	Undok	Ammonium bicarbonate; phosphate fertilizers; methanol; 50,000-ton-per-year ammonia capacity and coal gasification facilities under construction.
Chongjin Lime Nitrogen Fertilizer Plant	Chongjin	Lime; nitrogen.
Chongnyon Combined Chemical Enterprise	Anju	Urea fertilizer.
Chongsu Chemical Plant	Chongsu	Lime; nitrogen; deliquescent phosphate fertilizer; phosphate fertilizer; microelement nutrients.
Haeju Phosphate Fertilizer Plant	Haeju	Deliquescent phosphate fertilizer.
Haeju Smelter	Haeju	Phosphate fertilizer.
Huichon Lime Nitrogen Fertilizer Plant	Huichon	Lime; nitrogen.
Hungnam Combined Fertilizer Enterprise	Hamhung	Ammonium sulfate; ammonium nitrate; lime; superphosphate of lime; microelement nutrients; urea; agricultural chemicals; 1-million-ton-per-year capacity of nitrogenous fertilizers; 100,000-ton-per-year capacity of calcium superphosphate fertilizer.
Hungnam Smelter	Hamhung	Phosphate fertilizer.
Hwanghae Combined Iron Works	Songnim	Ammonium sulfate.
Kaechon Lime Nitrogen Fertilizer Plant	Kaechon	Lime; nitrogen.
Kanggye Microbe Fertilizer Plant	Kanggye	Nitrogen fixation nutrients.
Kimchaek Combined Iron Works	Chongjin	Ammonium sulfate.
Munpyong Smelter	Muchon	Phosphate fertilizer; microelement nutrients.
Nampo Smelter	Nampo	
Sandung Chemical Plant	Kangdon	Microelement nutrients.
Sinchon Lime Nirogen Fertilizer Plant	Sinchon	Lime; nitrogen.
Sinwon Calcium Hydroxide Plant	Sinwon	Lime.

Under the last economic plan, the target for the final year was 3 million tons of chemical fertilizers, of which 1 million tons was for phosphatic fertilizers. Under the current plan, annual production for total fertilizer output was to be 5 million tons by 1984.

Magnesite.—North Korea is believed to have one of the world's largest magnesite operations. Reserves at Yongyang Mine in Tanchon County in South Hamgyong Province are estimated at 3.6 billion tons. Magnesite ore is transported by the electrified Hamnan railway line to the Tanchon Magnesia Plant in Tanchon and to the Songjin Fireproof Materials Plant in Kim Chaek, where the magnesite is calcined into clinker. Refractory bricks and products are manufactured by the Songjin Plant and by Kangdok Fireproof Material Plant in Chongjin. In 1977, a large rotary oven was installed at the Songjim Plant; and in 1979, two 110-meter rotary ovens were installed at the Tanchon Plant. Construction of a large magnesite ore dressing plant was proposed for construction during the second 7-year plan.

Other Nonmetals.—In addition to aggregates and dolomite, active nonmetal mining operations included the following:

Commodity	Mine	City and Province
Clay (refractory)	Saenggiryong	Chongjin, North Hamgyong.
Graphite	Pakchon	Pakchon, North Pyongan.
	Tongbang	Changgang, Chagang.
Limestone	Munmuri	Sohung, North Hwanghae.
	Puraesan	Kowon, South Hamgyong.
	Sindok	Sinwon, South Hwanghae.
	Songsan	Sunchon, South Pyongan.
	Tongan	Tanchon, South Hamgyong.
	Unsan	Sunchan, South Pyongan.
Marble	Panmun	Kaesong.
Phosphate (apatite)	Nagyon	Changyon, South Hwanghae.
	Pongman	Pyonggang, Kangwon.
	Pungnyon	Tonchang, North Pyongan.
	Pungyon	Sakju, North Pyongan.
	Sinpung	Pyonggang, Kangwon.
	Yongyu	Pyongwon, South Pyongan.
Silica	Monggumpo	Changyon, South Hwanghae.
	Myonggan	Myonggan, North Hamgyong.

Nampo Glass Factory, the largest user of domestic silica, is the leading producer of flat glass and other glass in the country. Barite and talc are also locally mined, parts of which are domestically consumed, as well as exported.

FUELS

Anthracite.—Total reserves in North Korea were estimated at 8 billion tons in 1963, but as a result of exploration, the estimated reserves should exceed this amount. The ratio of anthracite and lignite is about 2 to 1. Up to 90% of the anthracite is fines, while most of the soft coal is lignite. Deposits of bituminous coal are small. Over 90% of the anthracite deposits occur widely in South Pyongan Province on the west coast while over 90% of the lignite occurs throughout North Hamgyong on the east coast. North Korea's coalfields are characterized as follows:

District	Coalfield and Province	Principal mines
West coast	Northern, South Pyongan.	Choyang, Hyongbong Shinchang, Tokchon, Yongmun, Yongtung.
	Southern, Pyongan and environs.	Hukyong, Kandgong, Kampo, Samsin.
	Western, South Pyongan and North Hwanghae.	Anju, Sariwon.
East coast	North Hamgyong.	Aoji, Hamyon, Kokonwon, Onsong.
	Kowon, South Hamgyong.	Kooham, Yongan Chonnae, Kowon.

The Northern Coalfield is the largest anthracite deposit in the country. The Kowon Coalfield on the east coast is based on anthracite occurrences, as is the Hyesan Mine in Yanggang Province. About 70% of the lignite is contained in the coalfields of North Hamgyong Province. Other lignite production is from Naju, Kocham, Sariwon, Tongchon (in Kangwon Province), and Yongam.

During the 6-year plan, the central Government announced that the country's coal production capacity reached 50 million tons in late August 1975. Under the second 7-year plan, the target was to increase production to 70 to 80 million tons per year by 1984.

Petroleum and Natural Gas.—There is no commercial production of oil and natural gas in North Korea. According to the Ministry of Resource Development, there are oil deposits in the lower estuary of the Chongchon River Basin. Furthermore, North Korea reportedly recovered very small quantities from offshore oil deposits in the Yellow Sea but no confirmation of the occurrence is available.

All the country's requirements for petroleum are met by imports. The Sungni Chemical Plant is a crude petroleum refinery located in Unggi, completed during the middle of the 6-year plan. The 2-million-ton-per-year refinery uses light crude oil supplied by the U.S.S.R. The crude is unloaded at the Najin port and is transported about 4 kilometers by pipeline to the Sungni refinery.

With Chinese aid, construction of a second petroleum refinery was completed in 1978 at Paengma-ri, Pihyon County, in North Pyongan Province. This refinery, Ponghwa Chemical Plant, uses Chinese crude oil transported by two pipelines installed between China and Sinuihi.

North Korea also receives crude oil from Algeria and other countries in the Middle East. Aside from the crude refineries, the Chongnyon Combined Chemical Enterprise, a petrochemical plant, was completed in 1976. Another petrochemical plant was proposed for Nampo, but construction was reportedly not yet under way.

The Mineral Industry of the Republic of Korea

By Edmond Chin[1]

After the assassination of President Park Chung-Lee on the night of October 26, 1979, Premier Choi Kyu-hah became acting President and was subsequently elected 10th President on December 6, 1979, by the National Conference for Unification. In his inaugural address, Choi defined his Presidency as a "crisis management" administration[2] and announced plans to hold elections as soon as possible following the enactment of a new constitution. In August 1980, General Chun Doo-huan was elected President under the terms of the Yushin Constitution ratified in 1972.

Under the current 5-year economic development plan, the country's gross national product (GNP) was to grow at a projected annual rate of 9.2% between 1977 and 1981. In addition to the drastic political changes in 1979-80, the Korean economy was buffeted with inflation, increasing foreign deficit, weak domestic demand for goods, low employment, and a poor rice harvest. GNP in current prices[3] was $57.6 billion in 1980 compared with $60.1 billion in 1979. In constant (1975) prices, GNP in 1980 was $28.8 billion ($30.5 billion in 1979), a decline in real terms of 5.7%.[4] Real growth in GNP in 1978 and 1979 were 11.6% and 6.4%, respectively. By sectors, the largest inputs to GNP in current dollars were manufacturing, $16.9 billion; wholesale and retail trade, $9.8 billion; agriculture and fishing, $9.7 billion; construction, $5.4 billion; and transport, storage, and communication, $3.6 billion. The mining and quarrying sector provided only $715 million to GNP in 1980.

Total personal income decreased from $46.2 billion in 1979 to $44.1 billion in 1980, while the average index (1975=100) for labor productivity increased from 151.5 in 1979 to 165.1 in 1980, industrial production declined from 213.5 to 211.4, respectively. The index for wholesale prices increased from 162.1 in 1979 to 225.2 in 1980, while the consumer price index went from 171.9 to 221.2, and the average industrial wage increased from 305.5 to 384.9 in 1980. The labor force increased by 308,000 to 14.5 million in 1980. However, the unemployment rate also increased from 3.8% in 1979 to 5.0% in 1980. Employment in the mining sector was estimated at 124,000 in 1980 compared with 111,000 in 1979.

Between 1974 and 1979, the Korean currency (won) was pegged to U.S. currency at the rate of 484 won to $1.00. In January 1980, the Korean currency was devalued by 20% to 580 won and allowed to float with its value determined by special drawing rights and a trade-weighted currency valuation. Between February and May, the won lost ground, and the Bank of Korea posted monthly devaluations. By June, the won reached the 600 mark, and at yearend 1980, the won conversion was 659.90.

Because of the economic slump, the Government planned to stimulate investment by providing incentives and accelerate the implementation of public works projects. Five major areas were selected for policy emphasis: Realizing the country's growth potential; promoting exports and strengthening the balance of payments position; controlling inflation; redressing income inequities and expanding social services; and undertaking institutional reforms for continued growth through greater economic efficiency.[5]
