lion barrels of crude oil during 1975 and produced 29.1 million barrels of petroleum products. In millions of barrels, the output was: Distillate blending stock, 2.7; fuel oil (high sulfur), 19.9; fuel oil (low sulfur), 2.4; and naphtha, 4.1.[11] During 1974 Aminoil processed 30.2 million barrels of crude oil, and output totaled 29.4 million barrels of petroleum products: Distillate blending stock, 2.2 million barrels; fuel oil (high sulfur), 17.2 million barrels; fuel oil (low sulfur), 5.4 million barrels; and naphtha, 4.6 million barrels. Two fires damaged the Aminoil refinery during the month of December. The first inflicted only minor damage to the plant, but an extensive fire on December 27 caused damages estimated to exceed $1.7 million to the refinery's desulfurization unit.

No wells were reported completed in Kuwait during the year, although a Spanish company was drilling one well under contract with KOC. That well was projected to be drilled to a depth of nearly 4,000 meters. KOC planned to begin drilling a 6,000-meter well in 1976, the deepest ever for Kuwait, hoping to discover hydrocarbons believed to underlie the Burgan oilfield.

Drilling declined in the partitioned Neutral Zone; 12 wells were completed in 1975 (10 oil and 2 service), compared with 20 drilled in 1974. AOC had three offshore rigs operating under contract during the year, and the drilling totaled 23,160 meters in 1975, 10,300 meters less than that of 1974. Onshore, Aminoil did not drill any wells during 1975, but planned to drill three exploratory wells in 1976.[12] The company carried out a marine seismic survey covering 570 kilometers in the offshore territorial waters of the partitioned Neutral Zone.

Aminoil crews performed well workovers during the year and brought the South Fuwaris, South Umm Gudair, and Wafra oilfields up to full production. The company installed nine new field pumping units in 1975, and planned to add 17 more during 1976.

Crude oil reserves for Kuwait were estimated at 70.2 billion barrels at yearend 1975, sufficient for 96 years of production at the average rate of 2 million barrels per day. The total crude oil reserves of the partitioned Neutral Zone were estimated at 6.6 billion barrels at yearend 1975, including reserves in offshore fields.

SAUDI ARABIA

Saudi Arabia maintained its position as the leading producer-exporter member of OPEC. Its estimated proved crude oil reserves were set at 107,857 million barrels at yearend 1975, an increase of 4,377 million barrels or 4.0% over that of yearend 1974.

The Ministry of Petroleum and Mineral Resources revealed plans to conduct a 5-year study of all minerals in the country. The study will locate and delineate all known mineral deposits, and it will report on the economic feasibility of exploitation of those minerals. The Saudis awarded a 4-year contract valued at $675,000[13] to a Canadian firm to recruit 12 geologists for the Government's program to gradually take over all mineral exploration in the country. Saudi Arabia also negotiated an agreement with Sudan for jointly exploring the Red Sea for minerals. The Government and British Petroleum Corp. (BP) began negotiations during the year concerning the establishment of a protein-from-oil project in Saudi Arabia using BP technology. A study group will investigate the feasibility of constructing and operating a protein plant rated at 100,000 tons per year, as well as a paraffin extraction plant and downstream facilities for turning the protein into animal feed. UOP Inc. of the United States will carry out a detailed feasibility study for the development of mineral resources in Saudi Arabia, according to an agreement signed by the company and the General Petroleum and Mineral Organization (Petromin).[14] Petromin also renewed a cooperative agreement for 2 years beginning in July 1975 with the French Bureau of Recherches Géologiques et Minières. The original agreement was signed in 1964.

Early in the year, Petromin announced a development program for the period

1975–80 that involved investments totaling nearly $13 billion in a number of projects, including establishing aluminum and steel industries as well as petroleum industry developments.[15] About $5 billion will be spent developing natural gas gathering, transmission, and treatment projects; $3 billion developing petroleum refineries; $4 billion for petrochemical plants; and the remainder will be utilized on other industrial projects.

Saudi Arabia launched its second 5-year (1975–80) development plan that would see some $140 billion invested in the industrial, power, transportation, and other economic sectors. It reflected the Government's desire to achieve economic independence by extensive investment in nonpetroleum industrial projects. Water desalination plants will be constructed along the Persian Gulf and Red Sea coasts, and associated facilities will raise the country's electric power generating capacity 3,300 megawatts under the 5-year plan. Over the next 5 years, the Saudis will spend $7 billion to $8 billion on desalting and power-generating facilities at 25 sites. The highway network and seaports will be enlarged, the international airports at Juddah and Ar Riyad will be extended, and as many as nine new domestic airfields may be constructed. The Government will establish manpower training centers to enable large numbers of the nonskilled labor force to become productive in the industrial sector of the economy; however, the development projects will require the continuing services of a large number of skilled foreign workers.

Transportation projects approved during the year included constructing a new $46 million airport, developing port facilities on both coasts, and building several cross-country pipelines. The new airport will be built at Abha in the southwest part of the country. The Government also issued a $12.8 million contract to a Republic of Korea firm to build a petroleum storage and distribution center at Qīzan on the Red Sea; the depot was scheduled to be completed within 15 months. Contracts valued at $413 million were awarded to a group of Dutch companies to construct port facilities in the Persian Gulf to serve the projected industrial center at Al Jubayl.

The Saudi Arabian Saline Water Conversion Corp. awarded a $91 million contract to Sanderson and Porter, Inc., of the United States to be the consultants for the construction of an electric power generating and water desalination complex at Al Jubayl. The plant, possibly largest of its kind in the world, will produce up to 175 million gallons of fresh water per day and 1,750,000 kilowatts of electricity per day to serve nearby communities and industries. The Ministry of Agriculture and Water awarded a similar contract to the same U.S. firm to design and supervise the construction of a smaller complex, to be rated at 30 million gallons of fresh water per day and 300,000 kilowatts of electric power per day, and also slated to serve the Al Jubayl area. The Arabian American Oil Co. (Aramco) and the Government developed plans for a new integrated electric power system for eastern Saudi Arabia that would serve the oil company, other industries, and the inhabitants of the region.

The Government transferred the responsibility for petroleum, natural gas, and minerals projects from Petromin to the Ministry of Industry and Electricity. Petromin's responsibilities will be in refining, distribution, marketing, and transportation. The firm will also supervise the operations of the Arabian Drilling Co., Arabian Geophysical and Surveying Co., and the Arabian Marine Petroleum Construction Co.

During 1975, Saudi Arabia negotiated an agreement with Abu Dhabi to define the border between the two countries. Iraq and Saudi Arabia also signed an agreement providing for the partition of the Neutral Zone located between those two countries and to the west of Kuwait by dividing the zone into two equal areas that would be annexed into the respective States; and the two countries signed an agreement defining their 760-kilometer common border. During the year under review, Saudi Arabia also reached a tentative agreement with Kuwait that may settle a long-standing dispute regarding offshore boundaries.

The Saudis negotiated 5-year economic and technical cooperation agreements with several foreign countries during 1975. Italy negotiated such an agreement that called for a working group to identify specific joint projects. The Italians envisaged participation in a number of development projects in Saudi Arabia that included civil engineering, mining, petrochemicals, and

[15] Arab Oil and Gas. Petromin's Board Approves a $12.7 Billion Development Program for 1975–80. V. 4, No. 81, Feb. 1, 1975, p. 17.

transportation. A Japanese-Saudi agreement provided for increased Japanese investments in Saudi Arabia in petrochemical projects and in providing vocational training for Saudi workers.

Kuwait and Saudi Arabia concluded a number of economic agreements, and agreed to study the feasibility of developing the use of atomic energy for the desalination of sea water and for the generation of electricity. The Saudis held preliminary talks with France concerning the possible construction of two nuclear reactors in the country.[16]

Saudi Arabia tied its currency to the Special Drawing Rights (SDR) and severed its currency links with the U.S. dollar. The exchange rates of the Saudi riyal and U.S. currency will be adjusted daily in relation to the SDR value. SDRs will be based on the values of 16 foreign currencies, including the U.S. dollar.

The petroleum industry dominated the Saudi economy, and government oil revenues soared to $25.7 billion in 1975 from an estimated $22.6 billion in 1974 and $4.3 billion in 1973.

PRODUCTION

Saudi Arabia was the most important oil producer in the Middle East and the third largest in the world during 1975. About 96% of the country's oil production came from Aramco's fields in Saudi Arabia, and the remaining 4% was the country's share of the oil produced in the partitioned Neutral Zone.

The output from Aramco's wells fluctuated from 5.6 million to 8.1 million barrels of oil per day in 1975, and reached its peak monthly rate of production during September. The company's oil output averaged 6.8 million barrels per day during the year, a decline of 16.8% from 1974. Aramco's declining output was in response to a worldwide slump in the demand for petroleum, and the company's rate of production during 1975 was only about 68% of the installed production capacity.

Processing and handling facilities were expanded at the Ra's at Tannūrah petroleum refinery, but the output of refined petroleum products fell 36 million barrels to 180.8 million barrels (averaging 495,300 barrels per day) during 1975. The throughput at the Ra's at Tannūrah plant averaged 376,934 barrels per day of crude oil and 137,163 barrels per day of natural gas liquids (NGL) during 1975, compared with 482,211 barrels per day of crude oil and 132,121 barrels per day of NGL during 1974.

[3] Naphtha apparently included in gasoline.
[4] Revised from none.

TRADE

State-owned Petromin marketed 149.2 million barrels of crude oil during 1975, compared with its direct sales of crude oil totaling 142.8 million barrels during 1974 and 88.2 million barrels during 1973. More than 90% of Saudi Arabia's petroleum output was exported. Aramco loaded 3,831 ships with a total of 2.4 million barrels of petroleum during the year, and more than 75% of the shipments were purchased by oil importers in Asia and Europe.

Table 3.—Saudi Arabia: Aramco ships loaded at gulf terminals

(Thousand barrels)

Negotiations between France and Saudi Arabia included future trade relations between the two countries, and France reportedly discussed with the Saudis the possibility of building an export petroleum refinery in Saudi Arabia. Trade relations between Saudi Arabia and neighboring Jordan and Lebanon deteriorated during the year because of unresolved differences over pipeline deliveries of Saudi oil to those countries. A bilateral trade agreement between Lebanon and Saudi Arabia expired and was not renewed.

Petromin developed plans to market refined petroleum products in Europe beginning in 1976 at the rate of 100,000 barrels per day, and later to Japan and the United States.[17] During the year, the Saudis held talks with trade groups from the United Kingdom, and the two parties agreed to increase trade and to broaden economic and industrial cooperation.

Numerous tanker companies were formed in Saudi Arabia during 1975. The new firms were apparently established to take advantage of the Government's announced policy to give preference for oil exports to Saudi-owned tanker companies.

COMMODITY REVIEW

Metals.— *Aluminum.*—Government planners reviewed plans for the construction of an aluminum smelter in Saudi Arabia that would produce up to 200,000 tons per year of aluminum ingots from imported alumina.

Iron Ore.—Although it had substantial deposits of ore with an iron content rated at between 32% and 50%, government studies have reported that enormous expense would be entailed in exploiting and transporting the ore from isolated areas in the country and recommended that Saudi Arabia import iron ore from abroad, namely Brazil.

Iron and Steel.—Petromin planned to expand the capacity of its steel rolling mill at Juddah from 45,000 tons per year to about 300,000 tons per year by 1978 or 1979. The pellets for the mill will be shipped from the projected joint venture steel plant to be built by Petromin and the Marcona Group at Al Jubayl, which will have a capacity to produce pellets at the rate of 3.5 million tons per year.[18]

Saudi Arabia will hold a 51% interest in a project with Sumitomo Metal Industries, Ltd., and Sumitomo Shoji Kaisha, Ltd., both of Japan, to build a plant at Ad Dammam in eastern Saudi Arabia to produce steel pipes at the initial rate of 20,000 tons per year, starting early in 1977.[19]

Nonmetals.— *Cement.*—Saudi Arabia had three cement plants in operation during 1975 with a combined output rated at 1.1 million tons per year. The Government contracted with a French firm to build a

[18] Middle East Economic Survey (Beirut, Lebanon). Petromin to Expand Juddah Steel Mill Capacity to 300,000 Tons by 1978–79. V. 18, No. 44, Aug. 22, 1975, p. 3.

[19] Metal Bulletin. Saudi Pipe Mill Progress. No. 5,994, May 30, 1975, p. 39.

new plant with a capacity of 2,000 tons per day in Buraydah,[20] near Ar Riyad. In addition to its domestic production, during 1975 Saudi Arabia scheduled imports of cement from Taiwan totaling 240,000 tons and from Japan totaling 500,000 tons. The Saudis also issued a contract to a Norwegian company to study plans for establishing a cement plant in the southern area of the country. The industry's future plans called for raising the country's cement production capacity to 10 million tons per year by adding five new plants and increasing the capacity of existing plants. The new facilities will be located at Al Jubayl, Al Hufūf, Tabūk, Yanbu', and in the Southern Province.

Fertilizer Materials.—Saudi Arabia and Taiwan negotiated an agreement during the year under which a fertilizer plant will be built in Saudi Arabia with Chinese assistance. The facility will produce up to 1,000 tons of liquid ammonia per day, sufficient for the production of up to 1,600 tons of urea per day.

Saudi Arabia reportedly agreed to extend an interest-free loan of $320 million to Syria to finance several projects, including the construction of an ammonia/urea complex at Homs, Syria, and the Saudi Government agreed to help Pakistan finance the construction of a fertilizer plant near Sukkur, Pakistan. Saudi Arabia will provide most of the foreign exchange financing required for purchasing the equipment for the $193 million Pakistani plant.

Other Minerals.—A $3.6 million plant will be constructed near Ad Dammam that will produce up to 8,400 tons per year of oil well drilling mud additives. The plant's capacity will be set at 2,400 tons per year of barite-base and 6,000 tons per year of bentonite-base additives.

Mineral Fuels.—*Natural Gas.*—The Government requested Aramco to plan, construct, and operate an extensive project to gather and process associated gas from the company's operations and to develop nonassociated gas production in the country. The total cost of the program may exceed $10 billion.[21] The project would be capable of processing up to 5.5 billion cubic feet of natural gas per day. Wet gas is to be treated at six plants in Saudi Arabia to remove sulfur and other contaminants. The processed dry gas then will be made available to industry. The Government project calls for the recovery of ethane (to be used as feedstock for petrochemical plants), hydrogen sulfide (to be converted into elemental sulfur), and NGL. The output of NGL from the project will be as much as 900,000 barrels per day. The NGL will include butanes, propanes, and natural gasoline. Pipelines will be built from the eastern producing areas to Yanbu', on the Red Sea, where the ethane and NGL will be processed. Aramco placed an order valued at $70 million with a U.S. company for 90 centrifugal compressors to be used in the gas development program, and Fluor Intercontinental Inc. will provide engineering and procurement services for the extensive gas project. During 1975 the Saudis also studied a proposal to pipe natural gas across the country to Yanbu', where it would be liquefied and loaded aboard tankers for export.

Another proposal under consideration was that of establishing a plant in Saudi Arabia to produce 2,500 tons per day of methanol for export to be used as chemical feedstock. Earlier, plans were considered to build a methanol fuel plant in the country to produce up to 12,500 tons per day to be exported.

In 1975 a natural gas treating plant was completed near Jaww al 'Uḍaylīyah to desulfurize gas used in gaslift water injection operations for the Ghawar oilfield.

Petroleum.—The U.S. shareholders in Aramco (Exxon Corp., Mobil Oil Corp., Standard Oil Co. of California, and Texaco, Inc.) conceded the principle of 100% takeover of their Saudi Arabian operations by the Saudi Government, and negotiations were held during the year concerning compensation for the transaction and the future role of the U.S. companies in Saudi Arabia. Mobil reached an agreement with the other U.S. shareholders in Aramco to increase the Mobil interest in Aramco from 10% to 15% over the next 5 years. The action will not affect the Saudi Government's interest in Aramco or its proposed takeover of the Saudi operation. Mobil's share in Aramco will increase 1% per year, reaching 15% in 1979, while the interest of the other U.S. shareholders will drop

[20] Middle East Economic Survey (Beirut, Lebanon). Saudi Arabia Initials Contract for $93 Million Cement Plant. V. 18, No. 29, May 9, 1975, p. 7.

[21] Middle East Economic Survey (Beirut, Lebanon). Cost of Saudi Arabia's Gas Project Escalates to $10 Billion. V. 19, No. 8, Dec. 12, 1975, pp. 1–4.

progressively to 28.3% each over the 5-year period. Aramco will remain a U.S. corporation wholly-owned by the four U.S. companies. The Saudi participation and proposed takeover affects only Aramco's operations in Saudi Arabia. Saudi Arabia and Kuwait reached an agreement during 1975 to cooperate in the takeover of the foreign oil company operations in the partitioned Neutral Zone.

In January 1975, the Saudi Arabian Government notified Getty Oil Co. that royalty rates and income taxes were being increased retroactively. Royalty rates were increased to 14.5% effective July 1, 1974, to 16.67% effective October 1, 1974, and to 20% effective November 1, 1974. Income tax rates were increased to 65.66% effective October 1, 1974, and to 85% effective November 1, 1974.

Concerned with the possible continuation of economic and political problems in transporting its crude oil through foreign countries to the Trans-Arabian Pipeline Co. (TAPline) export terminal on the Mediterranean Sea, Saudi Arabia studied plans to construct a pipeline from its oilfields to the Red Sea, bypassing Jordan, Lebanon, and Syria. One proposal called for rerouting the trunklines of TAPline to Red Sea and raising its overall capacity to 1 million barrels of oil per day; the alternate plan was for the construction of a 1,300-kilometer, 122-centimeter-diameter pipeline at a cost of about $1 billion from eastern Saudi Arabia to Yanbu' on the Red Sea. Future Saudi oil exports could then be switched from the Mediterranean and Persian Gulf outlet to the Red Sea. Owing to the sharply reduced demand for Mediterranean liftings and a dispute with Jordan and Lebanon over the prices of crude oil deliveries to refineries in those countries, TAPline's oil deliveries to Mediterranean consumers and export terminals dwindled during 1974 and were terminated by the pipeline company in February 1975. The Saudis resumed pumping oil to Jordan's Zerqa refinery and Lebanon's Zahrani refinery during the second quarter of 1975, following a request by the Saudi Arabian Government. During the latter part of the year, Lebanon made payments totaling $35 million to TAPline against outstanding debts for crude oil deliveries.

The Saudi Arabian Saline Water Conversion Corp. issued a contract to a United Kingdom firm to design and build a 45-kilometer petroleum products pipeline from the Juddah petroleum refinery to a seawater desalination and electric power generating plant nearby. The $6.7 million pipeline will utilize one pumping station at the refinery and will have a throughput capacity of 50,000 barrels of petroleum products per day.

A 100-kilometer pipeline was under construction from Buqayq to Ra's at Tannūrah that will transport NGL to the company's refining and export terminal on the coast. Additional storage and processing units will be added at Ra's at Tannūrah to handle the NGL. The company also added a second crude oil pipeline from the Al Qaṭīf pipeline junction to the Ju'aymah export terminal. Plans were reportedly approved during the year to build a 1,330-kilometer pipeline across Saudi Arabia to transport NGL to Yanbu' for petrochemical feedstock and for export.

Petromin reviewed plans to build four large export petroleum refineries, each with an initial capacity of 250,000 barrels of oil per day and capable of being expanded to 500,000 barrels per day; or three export plants with a combined capacity of 750,000 barrels per day and rising ultimately to 1.5 million barrels per day.[22] Negotiations continued during the year between Petromin and the Mobil Oil Corp. for construction of one of the 250,000-barrel-per-day facilities. The Mobil-Petromin petroleum refinery and petrochemical plant will be built at Yanbu' on the Red Sea, and the plant will be supplied with crude oil from the eastern oilfields by an 1,300-kilometer pipeline. The refinery-petrochemical complex will be jointly owned by Mobil and Petromin, and the Government will be the sole owner of the long-distance crude oil supply line.[23] Output from the Yanbu' refinery will be marketed chiefly in the United States and Western Europe.

Petromin also approved a project to construct a large petroleum refinery and petrochemical plant at Al Jubayl in eastern Saudi Arabia, in collaboration with the Royal Dutch/Shell Group. The plant will cost $1.2 billion to construct and will begin production in 1980 with an initial throughput capacity of 250,000 barrels of

[22] Middle East Economic Survey (Beirut, Lebanon). Saudi Arabia Petromin Embarks on $13-Billion Development Plan. V. 18, No. 30, May 16, 1975, pp. 1–3.

[23] Wall Street Journal. Mobil Says Saudis Clear Building of Big Refinery. V. 186, No. 40, Aug. 26, 1975, p. 2.

oil per day. The petrochemical complex will use NGL feedstocks and will produce a wide range of ethylene-based chemicals. A substantial proportion of the output will be exported. Petromin also signed a letter of intent with the Gulf Oil Corp. for the construction of a jointly-owned, $1.5 billion petroleum refinery and petrochemical complex. The project called for the refinery to initially process 250,000 barrels of crude oil per day; the petrochemical plant would produce 330,000 tons per year of ethylene-based chemicals. However, late in the year, Gulf and Petromin reevaluated and cancelled the project.

Petromin's small Ar Riyad petroleum refinery completed its first year of operation, and the company added an atmospheric vacuum distillation unit rated at 32,925 barrels of oil per stream day at the Juddah refinery. Aramco awarded a $50 million contract to the Fluor Corp. to design and construct a 25,000-barrel-per-day fixed bed naphtha reformer at the Ra's at Tannūrah petroleum refinery. The project was scheduled for completion during 1977.

Petromin finalized an agreement with Mobil for a $100 million lubricating oil production project under which the Government will hold 70% of the investment and Mobil, the remaining 30%. To be built at Juddah, the plant will have an annual capacity of 1 million barrels of lubricating oil base stocks. Part of the output will be processed by the Petrolube plant at Juddah.

The Dow Chemical Co. received Petromin's approval in principle for a project to build an $800 million petrochemical complex at Al Jubayl. The Dow plant would use associated natural gas as feedstock, and the initial plans called for the complex to include an ethane cracker, ethylene glycol unit, and a low-density polyethylene plant. Several other petrochemical projects were also under consideration in Saudi Arabia during 1975, including ammonia, methanol, and urea plants.

A major expansion project was carried out at the Ju'aymah deepwater tanker terminal, north of Ra's at Tannūrah, increasing the loading capacity there to 2 million barrels of oil per day. A third single-buoy mooring and tanks raising the crude oil storage capacity to 16.5 million barrels were also completed at the Ju'aymah terminal. A 900,000-barrel-capacity, 88-meter-diameter storage tank for propane was under construction at Ra's at Tannūrah and scheduled for completion during 1976. Two more tanks of the same size, one for butane and one for propane, will be built nearby during 1976 and 1977.

Seismograph crews were active in the central and eastern regions of the country, and an active program of exploratory drilling was carried out. Three new oilfields were discovered in 1975. Two of them (Lawhah and Ribyan) were found in the Persian Gulf and the third (Ad Dibdibah) in the northwest corner of Retained Area 1 of the Aramco concession.[24]

Three other previously discovered fields, Bakr and Ramlah onshore and Al Qurayyin offshore, were confirmed by drilling and testing. Drilling operations were active dur-1975, although 45 fewer wells were completed than in 1974. Aramco crews drilled 255 wells in 1975, of which 101 were for oil production; 109 pressure maintenance, exploratory, and field delineation; and 45 wells for observation and water. In 1975 the company operated 18 onshore and 5 offshore drilling rigs and drilled a total of 452,800 meters, compared with 639,900 meters during 1974.

The Mineral Industry of Liberia

By Janice L. W. Jolly [1]

The mineral industry of Liberia consisted of the production of iron ore, diamonds, gold, cement, and refined petroleum products in 1975. Despite an 18.2% increase in gross domestic product (GDP) from $565.5 million [2] in 1974 to an estimated $668 million in 1975, Liberia's economy was influenced by depressed market demand in the rest of the world. Total value of mineral exports decreased in 1975. Earnings from mineral exports fell because of reduced sales and lower market prices. Slackened demand resulted in growing iron ore stockpiles at ports. Diamond mining activities continued the decline that was evident in 1974 as the downward trend of the world diamond market reached even greater proportions by 1975. The iron ore industry was hit by a worldwide decline in production of steel and a slight lowering of price. In some cases, companies were obliged to stockpile ore to maintain full employment. Only companies with long-term contracts were able to continue production at full capacity. The Liberian Bureau of Mines again reported [3] that the resurgence of interest in gold mining experienced in 1974 continued to grow in 1975.

In May 1975, 15 West African countries put into force a treaty on cooperation and created the Economic Community of West African States (ECOWAS). In addition to Liberia, signators included Benin, Gambia, Ghana, Guinea, Guinea Bissau, Ivory Coast, Mali, Mauritania, Niger, Nigeria, Senegal, Sierra Leone, Togo, and Upper Volta. This agreement aims at eliminating obstacles to the free movement of goods, capital, and people, and accelerating and sustaining economic development in the subregion.

New markets were opened through signing of the Lome Convention with the European Economic Community (EEC), which already participates in 65% of Liberia's trade. The most noticeable change that the Lome Convention will make in Liberia's trade will be the lifting of tariff barriers on some products. Tariff discrimination by EEC arose from the previous Yaounde and Lagos agreements. Liberia was also eligible for increased trade benefits under the U.S. Trade Act of 1974.

A contract by the United Nations Industrial Development Organization (UNIDO) with Alexander Gibb and Partners of the United Kingdom for a study of the feasibility of a Liberian industrial free zone (IFZ) was completed. The report recommended establishment of an IFZ with 71 industrial plots, each with 1 acre at the port of Monrovia. A law establishing the IFZ Authority has already been promulgated. Foreign financing was sought. The IFZ was scheduled to become operational by mid-1978. The report recommended that the IFZ be developed in two stages over a 15-year period at an estimated cost of $32 million. Infrastructure construction would start in 1977.[4]

New development loans included $15 million from the World Bank for financing the Mesurado Bridge and Port Access Roads, the Ganta-Tototo Highway, and an integrated rural development program in Lofa County. The World Bank was also considering studies for increased hydro-

electric generation facilities necessary for the exploitation of ores from the Putu, Gbie, and Wologisi deposits.[5] The African Development Bank (ADB) made available $5.4 million for the road link between Sierra Leone and Liberia, and for other development projects of the Liberian Bank for Development and Investment (LBDI). Liberia also obtained $1.8 million from the Arab League's Arab Loan Fund for Africa. This is said to represent 50% of Liberia's total allocation from the fund. This the first known assistance from this source since the energy crisis, although a $100 million loan-investment proposal by the Flower Group of the United Kingdom and Gulf Development Co. (Persian Gulf) was still under consideration. The total allocation of $3.6 million from the Arab League for Liberia is less than 10% of the cost to Liberia for the oil price increase experienced in 1974. Other loans include $60.8 million from Japan for telecommunications and $9 million from the U.S. Agency for International Development (AID) for rural development and road construction.[6]

The Liberian Geological Survey formulated a mineral evaluation program for locating new mineral commodities to augment those presently exploited. A 5-year Mineral Evaluation Program was established coincident with the Government's 5-year development program; priority was given to gold evaluation, exploration, and quantification. A preliminary starting date was set for January 1975, with a termination date of December 30, 1980. However, funds to implement the project were still being awaited in 1975 from the Development Budget of the Ministry of Planning and Economic Affairs,[7] causing a delay in the planned project dates. The Liberian Cartographic Service launched a 5-year development plan in geodesy and cartography to meet the increased demands for maps and other geographic data by all sectors involved in the economic and municipal development projects.

PRODUCTION AND TRADE

Liberia's export earnings, valued at $405.6 million in 1975, were dependent upon two principal mineral commodities, iron ore (75%) and diamonds (5%). Although the rate of iron ore production was maintained throughout 1975, production was expected to decrease early in 1976. Consumers had begun to defer and cancel orders late in 1975 causing mining companies to stockpile unsold ore and exports to decline. In 1975, 18.4 million tons of iron ore was exported by four companies, of which about 3.1 million tons was in the form of pellets. The comparative figures in 1974 were 25.6 and 3.6 million tons, respectively. Bong Mining Co., Ltd. (BMC) increased production of pellets, but exported one-third less than in 1974.[8] Liberia's list of iron ore export recipients in 1975 included West Germany (25%), Italy (16%), the Netherlands (15%), the United States (11%), France (10%), and Belgium (7%).

Diamond exports for 1975 decreased 32.9% in quantity and 38.2% in value. For the period January 1 to December 15, 1975, diamond exports were valued at $17.8 million compared with $28.8 million for the same 1974 period. No accurate production figures can be given for the gold mined. All gold recovered was sold at mining sites either to jewelers or other interested buyers, who take their product to neighboring countries for better prices. This practice was expected to cease following issuance of a press release in May 1975 by the National Bank of Liberia that removed restrictions on the sale of gold.

COMMODITY REVIEW

METALS

Gold.—The National Bank of Liberia announced on May 5, 1975, that it would buy gold from financial institutions at $42.00 per fine troy ounce, but would not place any restriction on public buying, selling, or dealing in gold above that price. The Government's gold evaluation and exploration program created sufficient interest among the local population to produce a 42% increase in gold mining licenses issued in 1975 compared with those of 1974. A total of 69 prospecting and 56 gold mining licenses were issued for claims in all counties except Bong County.[9]

The following companies applied to the Government for mineral-concession rights for gold: Hydrocarbon Industries, Ltd., Bruce Clayman and Associates, Trico Mining Corporation, and Azuza Mining Corporation. African Mining Partners continued exploration in the Weaju, Jenne Wonde, and Gondoja areas of Grand Cape Mount County until the end of March, when it abandoned the Butterhill area and transferred all exploration to Grand Gedeh County.

The Liberian Geological Survey continued to implement a 3-year quantification program of all gold-bearing areas in the country. Areas investigated since 1974 were the Todee District (Montserrado County), Bentol-Mount Coffee area, Webbo/Karloke area, and Grand Gedeh County. Results were encouraging. A total of 252 placer gold samples from the eastern and western regions were processed and evaluated. Many were too low to warrant further investigation at that time.

Heavy Minerals.—An initial investigation covering a cross sample of 7% (45 kilometers) of the Liberian coast disclosed reserves of 700,000 tons containing an average of 40% heavy minerals, including a concentration of 192,000 tons of ilmen-

[9] Page H of work cited in footnote 3.

ite, 33,000 tons of zircon, 12,000 tons of rutile, and 4,000 tons of monazite.[10] Large areas of yellow, unconsolidated beach sand with a 50% heavy-mineral concentration occur at depths of 6 to 9 meters, in addition to those previously described in sands at the sediment surface.

Liberian Beach Sands Exploitation Company (LIBSEC), a Netherlands syndicate under a 25-year concession, will exploit the heavy minerals between the Cestos and Cavalla Rivers. No new exploration activities were executed by LIBSEC in 1975. The 20-ton bulk sample collected in 1974 consumed considerably more time and money in testing and shipping than anticipated. Readings of Limore, an Australian company, received the sample in February 1975. An economic feasibility study was being executed by V. G. Bennet and Associates Pty., Ltd., beach sand mining consultants from Brisbane, Australia. Two engineers of Bennet spent 2 weeks in Liberia in June. No final decision from LIBSEC was expected before sometime in 1976. It was anticipated that extra chemical treatment of the zircon to remove iron will be necessary before it is salable. Total expenditure by LIBSEC for 1975 was $134,428.

The Liberian Geological Survey evaluated 406 heavy-mineral concentrations for economic potential. Minerals of possible economic significance include the following:[11]

Chrysoberyl.—Several grains had been recognized in the washed gravels from Lofa River near Yangaya Town, Lofa County. Plans were being made to make a survey of the pegmatites in this area.

Chromite.—The source is the several ultramafic rocks that exist in western Liberia. Detailed geophysical and geochemical studies were planned to determine the potential of these bodies.

Ruby Corundum.—Corundum occurs as a major mineral associated with the diamond placers in Liberia. Most is of the gray variety, but occasionally pink grains (less than 1% of the total) are also found. Large grains of gem quality can be obtained as a byproduct of gold and diamond mining. Gray corundum can be used as an abrasive. Large quantities are reportedly available and presently are regarded as waste.

Monazite and Xenotime.—Both have been recognized in all mineral samples and occur in almost every proportion. Monazite is the most common heavy mineral except for ilmenite and zircon.

Rutile.—Like monazite, rutile is recognized in nearly all heavy-mineral concentrates. Coarse-grained rutile is common in the Tawalata area. A columbium-bearing variety has also been identified.

Iron Ore.—Technical studies were completed on Liberian Iron and Steel Corp.'s (LISCO) Wologisi iron ore project. An investment decision was to be made in 1976 with expected costs to be in excess of $700 million.

BMC was planning a second pelletizing plant of 2.4 million tons per year. Startup was scheduled for 1977. This would bring the total annual production to 7.5 million tons, consisting of 4.8 million tons of pellets and 2.7 million tons of concentrates. BMC has been studying the second plant for more than 2 years. An important consideration in planning was the increasing demand for pellets as the most suitable furnace feed. Also, the increasing ultrafines content of the BMC concentrate reduces its suitability as sinter feed. The following new facilities were required: Additional mining equipment to provide more crude ore, expansion of grinding capacity of the concentrator because of increasing hardness of the ore, erection of an 11th concentrating line to raise the concentrate production 10%, and process improvements to increase iron recovery and adjust for the decreasing grain size of the ore. Final beneficiation to 66% iron and a constant silica content of 5% to 6% will be achieved by indirect flotation after regrinding to pellet fineness. Because of the increase in the production capacity, other facilities will also require expansion. The powerplant capacity will be increased from 68 to 95 megawatts, and the harbor and railroad will be extended. The entire expansion program was estimated to require a $120 million investment.[12] Allis-Chalmers Corp. has signed a license agreement with the West German Thyssen Rheinstahl Technik GmbH to supply the facilities for the BMC pelletizing plant. Thyssen will be responsible for management, engineering, and equipment. The equipment will be manufactured under

[10] Page 22 of work cited in footnote 4.
[11] Pages 34–36 of work cited in footnote 3.
[12] Skillings' Mining Review (Duluth, Minn.). Bong Plans to Construct Second Pellet Plant in Liberia. V. 64, No. 32, Aug. 9, 1975, p. 22.

license according to Allis-Chalmers specification.

BMC continued to explore and study deposits in the Putu Range. A recent agreement was made between BMC and a consortia of German and Japanese interests to finance feasibility and technical studies for the Putu deposits. Reserves were estimated at 350 million tons with 38% iron. Construction of pelletizing plants with a capacity of 8 million tons per year were anticipated. The Japanese companies include Nippon Steel Corporation, Nippon Kokan K.K., Sumitomo Metal Industries Ltd., and two trading companies, Sumitomo Shoji Kaisha, Ltd., and Nichimen Co., Ltd. The West German firm was Exploration and Bergbau GmbH (a joint exploration company owned by August Thyssen-Hütte AG, Friedr Krupp Hüttenwerke AG, Rheinstahl AG, and ESTEL N.V.). The German group reportedly had completed a survey of the initial phase. The Japanese will provide $1.5 million to finance the second-phase survey. Negotiations with the Liberian Government of development and production terms were in progress. The United Workers Congress of Liberia (UWC) and BMC signed a contract on September 30, 1975, making UWC the leading mine labor union in Liberia.

Sensing an easing of demand, Liberian American-Swedish Minerals Company (LAMCO) continued high production in the first half of 1975 to build stockpiles but, on July 1, cut its production work week to 5½ days and its production rate to 9 million to 10 million tons per year. LAMCO is continuing to explore other deposits near its Nimba operation and is planning a $140 million expansion at its Tokadeh operation. Although LAMCO's ore shipments were lower in 1975 than in 1974, the company's earnings were higher. Improvements were attributable to price increases negotiated during the latter part of 1974. Shipments from the LAMCO mine in the first 6 months of 1975 were approximately 4.3 million tons, down from 5.2 million tons during the same 1974 period. LAMCO was negotiating with Guinea for possible ore shipment from deposits of the Guinean Iron Mining Co. (MIFERGUI) on the LAMCO railroad. LAMCO was investigating the possibility of electrifying its railroad to increase transport efficiency.

The Liberia Mining Co., Ltd. (LMC) Bomi Hills mine was gradually phasing out operations. LMC will continue to operate as long as old equipment and the limited iron ore supply last. LMC's ore reserves are reportedly being extended every 3 to 4 months and upgraded by using selective mining to blend high-grade material with low-grade ore to produce a salable product. LMC was expected to continue operations through 1976, but at a decreasing production rate. LMC is also continuing to explore at Bie Mountain near the Sierra Leone border.

Production at the Mano River mine of National Iron Ore Co., Ltd. (NIOC), increased in the first half of 1975 to 1,561,637 tons from 1,230,137 tons produced in the first half of 1974. The increase was primarily due to solving some of its production problems. Problems confronting NIOC included poor quality of ore (compared with that of other Liberian firms), high content of waste, fine-grained ore texture, and complex geological structures. Some major mining problems have included beneficiation, maintenance of adequate tailings storage and all-weather roads, contamination of water, and acquisition of special equipment. Disposal of tailings is a continuous challenge to the operation of Mano and its efforts in environmental control. NIOC suffered financial losses in development of the Mano Two project, caused by miscalculations and faulty equipment. Of a total $10 million for Mano Two invested on new equipment, $2 million to $3 million were spent on faulty equipment.[13] The labor force employed was larger than required, and management fees were high. A new General Manager was appointed early in 1975 as part of an effort to solve some of the problems.

Erection of an integrated West African steel mill at Buchanan was being considered by the Liberian Government. The Economic Commission for Africa (ECA) was studying arrangements for cooperation of countries of the West African subregions in this project.[14]

NONMETALS

Barite.—The Lofa Construction Company, Inc., in 1975 applied for mineral-

[13] Pages 14–16 of work cited in footnote 3.
[14] Page 20 of work cited in footnote 4.

concession rights for barite. A concession was granted to Universal Mineral and Oil Co., Ltd., which was carrying out extensive exploration in an area where 13 veins had been reported.

Diamond.—A total of 438 mining licenses for diamonds was issued by the Liberian Bureau of Mines along with 290 prospector's licenses and and 21 broker's licenses. Globex Minerals (Liberia) Inc. continued exploration around the Lake Piso area. Diamond production by Globex was 1,336.4 carats valued at $51,212 in 1975. The company was now in its third year of operation. Gold was also found to be an important constituent in the Lofa River diamond gravels and was made part of Globex's exploration program. Konte Mining Trading Corp. and Bulaco Corp. made application for mineral-concession rights for diamonds in 1975.

The Mineral Industry of Libya

By John L. Albright [1]

Petroleum and natural gas continued to be the most important mineral commodities in the Libyan economy, but 1975 was unrestful for these hydrocarbon industries as Government actions adversely affected production and marketing of both commodities. In 1974 the Government had called for a significant increase in the export price of liquefied natural gas (LNG) by Esso Standard Libya, Inc. The company's production and exports of LNG fell during the latter part of 1974 and early part of 1975, while the firm negotiated new sales agreements with its European customers; Esso's oil production was also curtailed during this period, as the Government refused to allow flaring of associated gas normally processed into LNG for export. BP Exploration Company (Libya) Ltd. withdrew its claims against the Government that previously had been publicized because of the 1971 Libyan nationalization of BP's interest in the prolific Sarir oilfield. The Nelson Bunker Hunt Petroleum Co. reached final settlement with Libya for the 1973 nationalization of its share of the Sarir oilfield.[2] An altercation took place during the year between Occidental of Libya, Inc., and the Government that adversely affected Occidental's operations in Libya.[3]

Concerned with reduced sales of crude oil during the previous year that had been attributed in part to high prices, Libya lowered its price of 37-degree gravity crude oil in January 1975 to $11.86[4] per barrel from $12.50 per barrel and lifted its embargo on exports of crude oil to the United States and several other Western countries. Prices for the 37-degree gravity oil were further reduced three more times during the first half of 1975. The June 1, 1975 price was set at $11.10 per barrel.[5]

Libya's development budget for 1975 was set at approximately $3,752 million, of which about $283 million or 7.5% was designated for projects in the petroleum sector of the economy. Contracts were awarded for the construction of extensive facilities at Marsá al Burayqah (Brega) to produce petrochemicals. The new complex, scheduled to be completed in 1978, will produce ammonia (rated at 2,000 tons per day), ethylene (rated at 1,000 tons per day), methanol (rated at 1,000 tons per day), and urea (rated at 2,700 tons per day).[6]

India and Libya held discussions during the year on numerous petroleum industry-related projects. India proposed participating in oil exploration in Libya, and the two countries agreed to form a joint company to service oil wells in Libya. The Indians will also supply petroleum industry training facilities to Libya. Indian and Libyan delegations also discussed the possibility of joint petrochemical projects. The output would be marketed mainly in India, which may assist Libya in building a 400-kilometer crude oil pipeline from the Western Desert to the Mediterranean Sea. Libya and Pakistan held talks during the year concerning several joint projects that may be undertaken in Pakistan, including

the establishment of a fertilizer plant, an investment company, and a maritime shipping company. Libya also discussed several petroleum industry development projects with Romania, and the Romanians plan to explore for oil in Libya. Under the terms of an economic agreement signed during the year, the Austrian Government will provide Libya with assistance in developing its petroleum industry and transportation systems, and Libya pledged to step up deliveries of crude oil to Austria in the future. Argentina and Libya signed an agreement in 1975 for cooperation in the field of atomic energy, whereby the South Americans would assist Libya in exploring for radioactive ores.

PRODUCTION

Oil output decreased for the fifth consecutive year and totaled only 551 million barrels in 1975, less than one-half of Libya's record output of 1,209 million barrels recorded in 1970 and down 4.1 million barrels or about 1% from 1974. Ten petroleum companies were engaged in producing crude oil. Despite the declining rate of output, Libya maintained its position as the second largest oil producer after Nigeria in Africa. During 1975, the average daily rate of crude oil production sunk to an 11-year low of 912,100 barrels in February, increased steadily during the second quarter of the year after several substantial price reductions, and reached the year's highest rate of production at 2.1 million barrels per day in July. In September the Government ordered cuts in production, and the total oil output fell by 302,200 barrels per day during the month.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the commodities listed, construction material such as sand, gravel, crushed stone, brick and tile are produced but information is inadequate to make reliable estimates of output levels. Natural gas liquids are also produced, but are blended with crude oil and are reported as a part of that total.

[2] Includes gas reinjected to reservoirs, if any.

TRADE

Libya's mineral trade was dominated by exports of crude oil and natural gas. The Libyan National Oil Corp. (LINOCO) was the largest exporter. Libyan crude oil was loaded onto tankers for export at five terminals: Az Zuwaytīnah, Brega, As Sidr, Ra's al Unūf, and Ṭubruq. Trade agreements were negotiated with several foreign countries during the year. The Italian company Ente Nazionale Idrocarburi (ENI) signed a trade agreement with Libya for the purchase of up to 91 million barrels of crude oil per year. Two-thirds of ENI's liftings will be from the Bu Attifel oilfield and one-third from other Libyan oilfields. Libya agreed to use part of the income from the oil deliveries to ENI for the purchase of Italian goods and services to be utilized in the petroleum industry. Under terms of an agreement reached with Turkey, Libya is to supply that nation in 1975 with nearly 23 million barrels of crude oil and 2 million barrels of refined petroleum products at favorable prices. The Libyan-Turkish talks included future deliveries of petroleum and natural gas to Turkey, the formation of a joint tanker fleet, and the construction of a petrochemical complex in Turkey. Spain concluded the purchase of nearly 198 million barrels of Libyan crude oil to be delivered from 1975 to 1980. According to the agreement, Spain would receive 3.8 million barrels of oil in 1975; 34.3 million barrels in 1976; 38 million barrels each during 1977, 1978, and 1979; and 45.7 million barrels in 1980. The trade talks between Libya and Yugoslavia included future Libyan oil exports and cooperation by the two countries in petrochemical projects.

COMMODITY REVIEW

METALS

Aluminum.—Libya held preliminary discussions with Yugoslavia concerning the establishment of an alumina facility in Yugoslavia and an aluminum smelter in Libya. The two countries did not reveal the proposed output capacities or sites for the plants.

NONMETALS

Cement.—Contracts totaling an estimated $110 million were awarded to two West German firms for the construction of a cement plant near Banghāzī with an annual production capacity of 1 million tons,[7] and further expansions to the industry will raise Libya's cement production to 5 million tons in 1980.

MINERAL FUELS

Natural Gas.—During the fourth quarter of 1974 and the first quarter of 1975, Esso encountered interruptions in marketing its LNG from the Brega plant because of a dispute with its European customers over an increase in the price of the LNG. Esso continued shipments to Spain during the dispute, but deliveries to Italy, Esso's primary customer, were halted in October 1974 and did not resume until early in 1975.[8]

Yearend 1975 reserves of natural gas were estimated to total 28.5 billion cubic feet, a decrease of approximately 0.7% from the yearend 1974 reserves. Libya's natural gas reserves were the third largest in Africa, after those of Algeria and Nigeria.

Petroleum.—Petroleum industry drilling activities fell sharply from those of 1974, when 72 wells were drilled. According to the Libyan official news agency, only 14 wells were drilled during 1975, of which 8 produced oil and the remainder were dry holes. A discovery well in the Sirtica Basin was tested by Occidental at a rate of 2,400 barrels of oil per day. Under the terms of Occidental's agreement with LINOCO, any oil and gas produced from the area will be shared 19% by Occidental and 81% by the Government. Aquitaine Libye brought one well in its El Meheiriga oilfield into production during 1975 at an average rate of 8,900 barrels of oil per day, and a second well was tested at the field. Under the terms of the agreement concluded in 1974 between the company and the Government, production will be shared 85% to 15%, with the Government obtaining the larger share.

In 1975 representatives of several foreign companies discussed petroleum exploration arrangements with Libya. The Italian firm ENI concluded an agreement to explore nine tracts of land covering nearly 60,000 square miles, with the stipulation that any commercial production from the area would be shared 51% to 49%, with the Government acquiring the larger share. Libya and India held talks during the year concerning the possibility of India's Oil and Natural Gas Commission exploring for oil in Libya, and Libya reportedly negotiated an agreement with Romania for oil exploration and well drilling in Libya. Details of the agreement were not released.

Libyan crude oil reserves maintained their position as Africa's largest, and at yearend 1975 they were estimated to total 24 billion barrels, an increase of 1 million barrels or 4.3% from 1974.

A dispute took place during 1975 between Occidental and the Government concerning the oil company's marketing and its payments to Libya. The Minister of Petroleum ordered Occidental to cut oil production in September to 196,000 barrels per day, and during the fourth quarter of 1975 the Government suspended the company's crude oil liftings from the Zuetina terminal when Occidental suspended payments to the Government. In December, negotiations resulted in new agreements, and Occidental resumed its crude oil exports and payments to the Government. The new agreements permit the oil company to produce up to 300,000 barrels of oil per day for a period of 5 years; the output level would then be lowered to not less than 275,000 barrels per day during the next 3 years and to not less than 250,000 barrels per day during

the following 2 years. Occidental will have the right to buy back the Government's share of the company's oil production.[9]

Operating problems were encountered at the Az Zāwiyah petroleum refinery on the western coast near the border with Tunisia, but the plant's output reached the designed capacity level of 60,000 barrels per day during the year. Output included fuel oil, jet fuel, kerosine, liquefied petroleum gas (LPG), lubricating oil, and motor gasoline. The Italian firm Snam Progetti S.p.A. was engaged in expanding the Az Zāwiyah refinery; when the facility is completed, it will have a crude oil throughput capacity of 120,000 barrels per day. LINOCO contracted Snam Progetti to supervise the construction of a 220,000-barrel-per-day petroleum refinery at Ţubruq on the eastern coast near the border with Egypt. Libya also developed plans during the year for building refineries at Mişrātah (near Ţarābulua) and Az Zuwaytīnah (near Banghāzī) but dropped them because of the uncertain world demand for petroleum products.[10]

The capacity of the Mişrātah plant would have been the same as that of the Ţubruq refinery, and the capacity of the Az Zuwaytīnah refinery was to be set at 400,000 barrels per day, Africa's largest. The Libyan Petroleum Institute planned to establish a petroleum refinery simulator at Qarqārish to be used in training petroleum industry personnel. Simulated equipment at the training facility will include control gauges and valves, a control room (which will utilize a computer), processing units, storage tanks, and other equipment that would be encountered in a petroleum refinery.[11] LINOCO and the Yugoslavian firm Servina signed an agreement to establish a joint petroleum refinery at Koper, Yugoslavia. In 1974 the two firms discussed the project and set the throughput capacity for the Koper refinery at 160,000 barrels of oil per day. LINOCO also held discussions with the Italian firm ENI concerning possible Libyan participation in Italian refining operations.

The Mineral Industry of Malaysia

By E. Chin [1]

The Malaysian gross national product (GNP) in 1975 was $8.7 billion in current dollars [2] compared with $8.8 billion in 1974. In terms of 1970 constant dollars, the real growth in GNP was 2.5% in 1975 and 8.4% in 1974. The gross domestic product (GDP) in 1975 was $6.1 billion in 1970 dollars and was distributed by sectors as follows, in billion dollars: Agriculture, forestry, and fishing, 1.8; manufacturing, 0.9; wholesale and retail trade, 0.8; transport, storage, and communications. 0.4; construction, 0.3; mining and quarrying, 0.2; electricity and water, 0.2; and other, 1.5. The value of production by the mining and quarrying sectors was down only 1.1% from that of 1974. The increase in oil production nearly offset the decline in quantity of tin-in concentrate and bauxite produced in 1975.

Tin production in Malaysia accounted for almost 29% of the total world production in 1975. Moreover, Malaysian tin mine output was more than twice the output of the next largest tin producing country. At one time, production of tin and rubber were the basis of the Malaysian economy. Because of the growth of the palm oil industry, tin has fallen to third place and was likely to surrender that position in the economy to the petroleum and copper industries, and perhaps even to timber. The Government stated that the tin industry was likely to grow slowly unless new commercial ore deposits were found. Because of the worldwide decrease in demand for tin in 1975, fluctuations in prices, and export controls, 94 small, marginal mines were reportedly closed during the year.

Under the terms of the Petroleum Development Act, the Government set up Petroleum Nasional Berhad (Petronas), which was empowered to acquire effective control of foreign companies through the issuance of management shares. Pending resolution of negotiations with Petronas by foreign companies, new exploration was at a virtual standstill during 1975. The companies affected were Esso Production Malaysia, Inc. (Esso), Picten Malaysia Co., Sabah Shell Petroleum Co., and Sarawak Shell Berhad. The key points being negotiated were increased cost-recovery allowances, a 70%–30% after-cost profit split before taxes (70% going to the Government), and production-sharing rights for a sufficient time to allow investment recovery and an adequate return on investment.

The Government established guidelines to regulate acquisitions, mergers, and takeovers of companies and businesses.[3] The primary objectives of guidelines were to discourage those forms of foreign investment that confer no visible benefits to the national economy and would perpetrate the present imbalances that exist in the pattern and structure of ownership and control of companies and businesses. Private investments which would contribute to the development of the country, consistent with the Government's economic policy, would be welcomed and encouraged.

The acquisition, merger, and takeover of companies and businesses by foreign or Malaysian interests should: (1) Result directly or indirectly in a more balanced Malaysian participation in ownership and control; (2) lead directly or indirectly to net economic benefits in relation to such

---

matters as the extent of Malaysian participation, ownership, and management; income distribution; growth; employment; exports; quality and range of products and services; economic diversification; processing and upgrading of local raw materials; training; efficiency; and research and development; and (3) not have adverse consequences in terms of national policies in such matters as defense, environmental protection, or regional development. Moreover, proof that the proposed acquisition, merger, or takeover is not against the objectives of the Government's economic policy rests with the acquiring party.

PRODUCTION

The principal, commercially exploited mineral resources of Malaysia, in addition to mineral fuels, in order of value, were placer tin, heavy mineral deposits (beach sands), bauxite, and iron ore. In the mining and quarrying sector, tin was the country's largest foreign exchange earner. In 1975, a total of 64,363 tons of tin-in-concentrate was produced, valued at $0.41 billion. The value of production of ilmenite, zircon, monazite, wolfram, columbite, scheelite, and xenotime from heavy mineral sands was $6.28 million of which zircon and ilmenite accounted for 40% and 32%, respectively. Production of bauxite was 703,561 tons, down 26% from the 1974 output level. The decrease in production was attributed more to the gradual depletion of deposits rather than to a decline in demand for aluminum raw materials. Production of iron ore was 348,200 tons, down 28% from the 1974 output. The production decline was due to lower tenor of the ore deposits and to reduced demand by Japan, the major export destination. Production of manganese ore increased by 48,046 tons, reaching 133,308 tons in 1975, valued at $3.12 million. Output of mine gold was mostly from West Malaysia and the remainder from Sarawak. Copper production was about 14,000 tons, all from the Mamut area in Sabah.

The most notable prospect in the mineral industry was Malaysia's potential in petroleum production. Crude oil production in 1975 was 35,774,000 barrels, an increase of 21% over the 1974 level. Output was expected to increase another 60% in 1976 so that petroleum exports would become the second major export earner after rubber, overtaking tin and palm oil.

e Estimate. p Preliminary. r Revised.

[1] All production is from West Malaysia unless otherwise indicated.

[2] In addition to the commodities listed, a variety of crude construction materials (clays, sand, gravel, and stone), salt and fertilizer is produced, but production is not reported and available information is inadequate for the formulation of reliable estimates of output levels.

[3] Estimates based on exports of copper concentrates.

[4] Based on export figures.

[5] Includes small production of tin from smelter in Singapore.

[6] Includes production from Sarawak and West Malaysia.

TRADE

Total Malaysian exports in 1975 were valued at $3,688 billion. Principal destinations were Southeast Asian countries, Europe, the United States, Japan, and others, in that order. Exports of major commodities were as follows in million dollars: Rubber, 810; palm oil, 527; tin and tin-in-concentrates, 482; crude petroleum, 344; and lumber, 268. In addition to shipments of crude oil, exports of petroleum products in 1975 totaled 342,000 tons and were valued at $41.6 million.

Tin, third after rubber and palm oil as a major foreign exchange earner, was the leading export among mineral commodities. Exports of tin, primarily to the United States and Japan, totaled about 78,000 tons, down 9.1% from shipments in the previous year. The average unit value of tin and tin-in-concentrates exported in 1975 was $6,170.40 per ton compared with the high unit value received in, 1974 of $7,046.40.

Imports in 1975 totaled $3,402 billion and, in order of value, were chiefly from Europe, Japan, Southeast Asian countries, the United States, and Australia. By industrial classification, imports were distributed by value as follows, in percent: Machinery and transport equipment, 33%; consumer durable and nondurable goods, 21%; food, beverages, and tobacco, 18%; mineral fuels, 12%; chemicals, 8%; and other, 8%.

COMMODITY REVIEW

METALS

Aluminum.—Three mines in the State of Johore in Peninsular Malaysia accounted for the total production of 703,561 tons of bauxite in 1975. Output of bauxite was down 26% due to lower grade ore and lack of export demand. As in previous years, most of Malaysia's bauxite production was shipped to Japan.

Copper.—In May 1975, the Overseas Mineral Resources Development (OMRD) Sabah Bhd, a joint venture between OMRD Tokyo (51%) and Malaysian interests (49%) began test production at the Sabah mine, located in northwest Sabah, about 65 kilometers east of Kota Kinabalu.[4] The ore body was estimated to contain 80 million to 100 million tons of copper ore. The total annual output was to be shipped to Japan, and the ore and concentrates would be allocated to the smelters according to the investment ratio by the seven Japanese companies which comprise OMRD Tokyo. About $93 million has been spent on the project since 1973 to cover development costs of the mine and construction of port facilities, roads, and other infrastructure. The bulk of the funds was from the Japan Export-Import Bank and the Japan International Cooperation Agency.

Commercial production from Mamut was rescheduled for late 1975. Technical problems associated with heavy perennial rainfall delayed initial production, due to the difficulty of separating mud from the porphyry ore. By yearend, 7,000 tons of copper concentrate was ready for shipment to Japan.

Iron Ore.—Output of iron ore has declined annually since the late 1960's; production in 1975 was 348,200 tons compared with 5,234,000 tons in 1969. Mine production was from Perak, Johore, Kedah, and Pahang States, with Pahang producing about one-half of the total output. Most of the iron ore and concentrate was exported to Japan.

Tin.—Mine output (metal content) and smelter output declined 6% and 2%, respectively, in 1975 primarily because of export controls. However, Malaysia remained the world's largest producer of tin-in-concentrate and refined metal, as well as the world's largest exporter of tin. At yearend, there were 55 tin dredges, 810 gravel pump mines, and 45 opencast, underground, and unspecified mines in operation. Production of tin metal by the Butterworth and Penang smelter totaled 78,978 tons.

Production of tin-in-concentrate by type of operation was as follows: Gravel pump, 55%; dredging, 32%; opencast, 4%; underground, 3%; and other sources, not identified, 6%. Between May 1 and yearend, export controls and low prices forced the closure of 94 marginal gravel pump mines. However, the Government established a hardship quota pool to assist producing mines during the period of imposed export restrictions. Additional production was allowed for some mines to permit higher output, thereby reducing operating costs.

Berjuntai Tin Dredging Bhd. (Berjuntai) was the largest tin producing company in Malaysia. Berjuntai operated seven dredges at extensive mining leases in Kuala Selangor and accounted for about 6% of the total output of tin-in-concentrate. Dredge No. 8 was being constructed at a cost of about $7 million and was to replace Berjuntai's No. 1 dredge when placed in operation in mid-1976.

London Tin Corp., Ltd. was the world's largest tin investment group and the largest holder of Malaysian tin mines. London Tin had 38 alluvial dredges operating under the management of Anglo Oriental (Malaysia) Sdn. Bhd., of which 32 dredges were stationed in Malaysia. Through a series of proposed stock transactions, Pernas Securities, a subsidiary of Perbadanan Nasional Bhd., was to acquire 39.7% of the share capital of Har Par Brothers International. In turn, Har Par would gain 50.35% of the issued capital of London Tin. While the takeover offer had been approved in principle, final consent had not been received from the Exchange Control and Revenue Authority.

In 1975, other producers of tin concentrates in Malaysia included Kamunting which had dredging operations near Taiping; Malayan Tin near Kampong Gajah in Perak; Southern Kinta Consolidated, Ltd. at the Rasa Section in Selangor; Southern Malayan Tin in Kinta and Batang

---

[4] Mining Magazine. V. 132, No. 4, April 1975, p. 252.

Padang; Kinta Kellas, Pengkalen, and Tanjong Tin, each operating in the Kinta Valley region of Perak; Petaling Tin Bhd. in southwest Selangor; Tronoh Mines Ltd. in Perak; and Ayer Hitam in Selangor. In addition, Sungei Besi had opencast mining operations approximately 10 miles south of Kuala Lumpur; Idris Hydraulic had opencast and gravel pumping operations in Ipoh; and Pahang Consolidated operated the only underground lode mine in Malaysia in Pahang on the east coast of Peninsular Malaysia.

Titanium.—Production of ilmenite concentrate, all from West Malaysia, totaled 112,248 tons and was derived principally from tailings of dredging operations. The bulk of the ilmenite produced was exported to Japan. Currently, a synthetic rutile plant utilizing ilmenite as feed material was in operation in Lahat near Ipoh for the production of titania pigment. Sakai Trading Co., Klöckner Werke A.G., and Malaysian interests were reportedly forming a company to develop ilmenite occurrences in northeast Malaysia. Malaysian Titanium Corp., composed of Straits Trading Co., Ltd. (30%), and Malaysian interests (70%), announced the construction of a 50,000-ton-per-year synthetic rutile plant near Ipoh, Perak State. Ilmenite, available from tin tailings, would be upgraded to a synthetic rutile for the production of titania. Trial operations were planned for 1976.

Other Metals.—During the year, about 250 tons of antimony ore was mined in Sarawak. Output of gold was around 3,700 troy ounces; close to 70% was from mine output in West Malaysia, and the remaining 30% from Sarawak. Mine output of tungsten was 194 tons. Recovery of metals from tailings of dredging operations were as follows, in tons: Columbite, 50; monazite, 3,285; wolfram, 194; and xenotime, 53. Output of manganese ore was up 64% and totaled 133,308 tons in 1975.

NONMETALS

Cement.—Production of cement in 1975 was about 1.5 million tons. Total output was by five firms with seven plants. Associated Pan Malaysian Cement Sdn. Berhad, with a total capacity of 750,000 tons per year, has plants in Chemor, Perak, and Rawang. Tasek Cement, Ltd., has a 520,000-ton-per-year capacity plant at Ipoh. Malaya Industrial and Mining Corp. Berhad operated a 60,000-ton-per-year plant at Batu Caves, Selangor. In late 1974, Cement Industries of Malaysia Sdn. Berhad completed construction of its 400,000-ton-per-year plant and initial production began in early 1975. Construction of a cement plant with an output of 20,000 tons per month was completed in late 1975. The plant, a joint venture between the Perlis State Government and private interests, was expected to be in full production in 1976.

Fertilizer Materials.—Total production of crude and manufactured fertilizers in 1975 was estimated at 246,000 tons, compared with domestic consumption of 675,000 tons. To meet domestic requirements, about 400,000 tons of potassium fertilizers; urea; composite, complex, and compound fertilizers; and natural phosphate were imported during 1975 from Canada, the Christmas Islands, West Germany, Japan, and the United States. Petronas formulated plans to set up a nitrogeneous fertilizer plant to serve domestic needs and the area market. An ammonia-urea plant, planned for startup in 1981, would make use of local natural gas as feedstock.

MINERAL FUELS

Natural Gas.—As a result of the increase in crude oil production, output of associated natural gas was estimated at 96 billion cubic feet per day in 1975. While nonassociated natural gasfields have been discovered offshore Sarawak and on Peninsular Malaysia, no commercial production has occurred. Petronas was negotiating with undisclosed parties to build and operate a plant to liquefy natural gas from Central Luconia Province in Sarawak. A plant to be constructed in Bintulu by 1981 would have a capacity of 6.4 million tons per year of liquefied natural gas (LNG). Petronas estimated that gas reserves were sufficient to feed the plant for 20 years. The LNG produced would be exported probably to Japan.

Petroleum.—The production of crude oil in 1975 increased 21% over that of 1974 to average about 98,000 barrels per day. The entire output of crude came from offshore fields in Sabah and Sarawak. Commercial oil deposits have been discovered off Peninsular Malaysia. Production from these fields has not commenced because negotiations were still in progress between Petronas and Esso on a production-sharing agreement.

The biggest single producing company in Malaysia was Sarawak Shell which operated offshore fields in West Lutong and Baram, close to the rich deposits of Brunei. Sarawak Shell produced close to 75% of the country's total output of crude oil. The bulk of the remainder was produced by Sabah Shell from three platforms in the Samarang Field off the southwestern coast of Sabah. Esso produced only between 3,000 to 5,000 barrels per day from the Tembungo Field off Sabah. Construction of Esso's two offshore platforms in the Tembungo concession was halted in May 1975 pending the outcome of Esso's negotiation of production arrangements with Petronas.

Only about 20% of the total crude oil production was locally consumed; the rest was exported. Malaysia's oilfields produce low-sulfur light crude which commands a higher price compared with the heavier West Asia crude, which is imported for refining. Moreover, the yield of local crude does not fit the domestic demand, particularly for kerosine. Additionally, Malaysian refineries were designated basically to use heavy crude as a feedstock.

In 1975, the intake of crude oil by the three refineries in Malaysia (two at Port Dickson in Peninsular Malaysia and one at Lutong in Sarawak) averaged about 83,200 barrels per day. The Shell and Esso refineries at Port Dickson had capacities to process 90,000 and 35,500 barrels per day, respectively, while the Shell refinery at Lutong had a 40,000-barrel-per-day capacity. The total output of finished petroleum was estimated at 80,100 barrels per day in 1975 by the three Malaysian refineries.

The Mineral Industry of Mexico

By Roland W. Merwin [1]

Mexico's gross domestic product (GDP) at current prices was $78,690 million,[2] an increase of 21% over that of 1974, with the increase being largely accounted for by an inflation rate of 16% in 1975. The mining sector contributed 0.8% in 1975 as compared with 1.0% in 1974 while the petroleum sector accounted for 4.8% in 1975 as compared with 4.5% in 1974.

The mining and petroleum sectors were key elements in efforts by the Mexican Government to industrialize its economy and were receiving priority consideration by government planning organizations. There was a continuing trend toward complete government ownership or control of the mineral extractive industries, as well as greater government participation in the industrial sectors utilizing minerals and fuels for the manufacture of finished products.

Late in 1975 the Government formally approved a new mining law which in effect fundamentally changed the mining law of 1961 as it related to nonfuel minerals. The basic intent of the new law was to give the Government an even greater control over mining activities in Mexico. One section of the law provides a legal basis for the establishment of government-owned firms to carry on large-scale mining exploration and development programs. Another section gives the Government virtually an exclusive right in exploration and exploitation of phosphate, potassium, sulfur, iron ore, and coal with the provision that this exclusive right could be expanded upon by the Ministry of National Patrimony. The Government was also authorized to take over unworked mining concessions and operate them directly or assign their development to other companies within the industry. Additionally, concessions would no longer be issued on an indefinite basis but would be subject to future periodic renewals.

The new law came in for immediate criticism from private mining companies in Mexico. One objection was that the reforms could eventually result in a complete phasing out of private sector participation in the mining industries as well as tend to limit short-term private investment interest in mining. It was also claimed that the reforms contained retroactive clauses that could greatly affect operations of presently active privately owned companies including those which are 100% Mexicanized as concerns full equity capital and administration.

Notwithstanding the objections from the private sector, the reforms were strongly supported by government agencies, which stated that the reforms would put an end to the problem of unworked or abandoned mining concessions and would also promote a full pledged program of national exploration for new mineral deposits. These programs would be financed primarily by the Government or its specialized agencies such as the Mining Development Commission and the Council of Non-Renewable Resources. It was also maintained that the reform would promote much greater activity by small miners who could under certain circumstances be exempt from many of the regulations cov-

[1] Supervisory physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from Mexican pesos (Mex$), to U.S. dollars at the rate of Mex$1 = US$0.08.

ering exploitation and development programs which the major mining companies would be subject to under the new reforms.

The new mining law was expected to lead to an increasing participation by the Government in mining activity in Mexico either on a direct investment basis or by joint ventures with national and/or foreign investors from the private sector. This participation has been definitely increasing in recent years. In 1970 mining companies with a strong government equity position accounted for approximately 15% of national mining production, but by 1975 their production had increased to about 35%.

PRODUCTION

Mexico's mining industry, exclusive of construction materials, is largely based on the production of copper, lead, zinc, silver, fluorspar, and sulfur.

After 2 years of sustained growth both the metallic and nonmetallic sectors of the mining industry were adversely affected by depressed world demand. With the exception of a few individual commodities, production decreased in both quantity and value as compared with 1974. On the basis of preliminary data covering 18 metallic and 21 nonmetallic minerals it was estimated that the production value of Mexico's mining industry decreased by 8% from $1,053 million in 1974 to $968 million in 1975.

In contrast to the mining industry, Mexico's petroleum industry registered strong gains in both production and value of sales. Crude petroleum production increased 262 million barrels in 1975 as compared with 210 million barrels in 1974, an increase of 25%. The value of sales, including exports, increased by 21% from $2,328 million in 1974 to $2,806 million in 1975.

Data on mineral production are shown in table 1.

[3] For export.
[4] Calculated from reported iron content based on grade 66.67% iron.
[5] Calculated on the basis of ore containing 36% manganese, from reported metal content of mine production.
[6] Estimate by the International Tin Council.
[7] Excluding that for cement production.

TRADE

The principal nonfuel mineral exports by value were blister copper, zinc concentrates and metal, lead metal, refined silver, metallurgical- and acid-grade fluorspar, and crude sulfur. As in the past, the principal destinations of these exports were to the United States.

Because of lower world prices, the export value of nonfuel minerals was substantially below that of 1974. Based on preliminary statistics, the value of metallic and nonmetallic mineral exports in 1975 amounted to only $434 million as compared with $529 million in 1974, a decrease of 18%.

Mexico became a net exporter of petroleum and petroleum products for the first time since 1969. The export value of these products was $465 million in 1975 as compared with imports of $278 million for a favorable balance of trade of $187 million. By contrast, exports of these products in 1974 were valued at only $124 million against imports of $351 million for a trade deficit of $227 million.

Available data on mineral exports and imports are shown in tables 2 and 3.

Table 2.—Mexico: Exports of mineral commodities
(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal destinations, 1974
METALS			
Aluminum:			
Oxide (alumina) ----	25	6	All to Costa Rica.
Metal including alloys, all forms ----	822	1,378	Chile 481; Colombia 303; United States 137.
Antimony:			
Ore and concentrate, gross weight --	6,266	6,587	All to United States.
Metal including alloys, all forms ---	100	98	United States 76; Brazil 10.
Arsenic:			
Oxide, gross weight:			
White ----	5,269	5,328	United States 5,275.
Black ----	82	(1)	Mainly to Ecuador.
Speiss and similar materials, oxide content ----	--	72	All to United States.
Bismuth metal including alloys, all forms ----	675	838	United States 431; United Kingdom 268.

See footnotes at end of table.

(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal destinations, 1974
METALS—Continued			
Cadmium:			
Concentrate and speiss, gross weight	23	660	All to United States.
Flue dust, metal content	253	462	Do.
Metal	151	441	Brazil 221; United States 202.
Copper:			
Ore and concentrate, gross weight	16,126	4,774	Belgium-Luxembourg 3,147; United States 1,627.
Copper sulfate	964	1,343	Brazil 1,140.
Metal including alloys:			
Scrap	2,045	--	
Unwrought and semimanufactures	28,901	14,551	United States 8,874; Japan 1,660.
Iron and steel:			
Ore and concentrate, gross weight	--	4	Mainly to United States.
Metal including alloys:			
Scrap	3,617	327	All to United States.
Ferroalloys:			
Ferrosilicomanganese	3,862	--	
Other	400	1,777	United States 1,421; Colombia 336.
Steel, primary forms	([1])	2	All to United States.
Semimanufactures	135,371	106,358	United States 81,985.
Lead:			
Ore and concentrate, gross weight	3,224	17,263	All to United States.
Oxides:			
Litharge	40,269	40,819	Italy 11,008; United States 8,324.
Red lead	2,423	3,377	United States 783; Colombia 504; Italy 475.
Metal including alloys:			
Scrap	4	--	
Unwrought:			
Antimonial and other bars	8,064	5,348	Netherlands 3,549; United States 730.
Refined	56,013	108,104	Italy 37,750; United States 22,972; Netherlands 15,297.
Semimanufactures	891	75	United States 38; Venezuela 15; Netherlands 10.
Manganese ore and concentrate, gross weight	195,863	264,695	Japan 119,041; United States 110,536; France 27,058.
Mercury ---- 76-pound flasks	21,646	29,342	United States 16,613; Brazil 3,312.
Nickel metal including alloys, all forms	3	6	Costa Rica 4.
Selenium:			
Elemental	35	20	United States 10; United Kingdom 7.
Matte, speiss, anode slimes, smelter residues	--	50	All to United States.
Silver [2] ---- thousand troy ounces	466,120	632,482	United States 623,413.
Tin metal including alloys, all forms	18	17	United States 12.
Tungsten ore and concentrate, gross weight	522	349	United States 204; West Germany 71; France 38.
Zinc:			
Ore and concentrate, gross weight	241,351	292,092	United States 122,006; Italy 42,400; Spain 40,545.
Oxide, white	9,333	11,606	United States 10,598.
Sulfate	4,672	7,351	United States 7,063.
Metal including alloys:			
Powder	924	2,105	United States 1,412; Argentina 692.
Unwrought	12,076	73,711	United States 34,882; United Kingdom 15,626.
Semimanufactures	1	348	Brazil 332.
Other nonferrous base metals:			
Ores, concentrates, metallurgical residues, except scrap	2,118	3,489	All to United States.
Metal, all forms	140	83	United States 82.
NONMETALS			
Abrasives, natural, n.e.s.:			
Emery	1	2	El Salvador 1.
Pumice	98	20	All to United States.
Asbestos	16	7	Guatemala 5.
Barite and witherite	132,565	148,351	United States 148,250.
Cement	170,400	187,679	United States 185,566.
Clays and clay products:			
Crude clays, n.e.s.:			
Bentonite	23	43	Guatemala 30; El Salvador 8.
Fuller's earth and other earth	11,586	28,039	West Germany 11,777; Brazil 4,191; Syria 4,080.
Kaolin (china clay)	259	5	All to Colombia.
Other	179	263	Peru 77; Ecuador 72; Guatemala 64.

See footnotes at end of table.

Clays and clay products—Continued			
Products:			
Refractory	20	302	Guatemala 88; Dominican Republic 52; Nicaragua 50.
Nonrefractory	173,406	161,955	United States 158,681.
Diamond, industrial ---- carats	5,000	30,000	United States 25,000; West Germany 5,000.
Diatomite and other infusorial earth	9,081	15,505	Argentina 4,513; Brazil 2,982.
Feldspar	--	709	Nicaragua 301; Venezuela 261; Costa Rica 100.
Fertilizer materials:			
Crude, phosphatic	1,973	5,239	All to United States.
Manufactured:			
Nitrogenous, including urea	77,899	31,076	Nicaragua 9,499; Peru 7,350; El Salvador 4,700.
Phosphatic	98,754	65,248	United States 25,096; Bermuda 18,384; West Germany 10,530.
Potassic	289	943	Guatemala 942.
Other including mixed	446	729	United States 514; Brazil 104.
Ammonia	3,466	4,525	Costa Rica 4,000; Guatemala 504.
Fluorspar:			
Acid grade	382,810	546,097	United States 512,913.
Metallurgical grade	635,537	531,049	United States 455,084; Canada 74,106.
Graphite, natural	57,228	58,429	United States 58,404.
Gypsum:			
Crude ---- thousand tons	1,187	1,227	United States 1,159.
Calcined ---- do	53	11	All to United States.
Lime	1,205	591	United States 233; Belize 165; El Salvador 101.
Perlite	1,183	2,614	Colombia 715; Cuba 416; Brazil 285.
Precious and semiprecious stones, except diamond ---- kilograms	3,050	358	United States 165; Japan 76; Canada 64.
Salt ---- thousand tons	3,929	4,470	Japan 3,324; United States 865.
Sodium and potassium compounds:			
Sodium compounds:			
Sodium carbonate	797	599	Chile 500; Venezuela 71.
Sodium hydroxide	5,060	5,949	West Germany 2,703; Argentina 2,373.
Sodium sulfate	65,785	85,946	Brazil 57,283; Venezuela 14,139.
Potassium compounds	28	5	Peru 2; Ecuador 1.
Stone, sand and gravel:			
Dimension stone	15,210	10,236	United States 10,111.
Crushed rock	25,504	18,805	United States 18,646.
Limestone, dolomite, calcite	4,403	1,967	United States 1,449; U.S.S.R. 354.
Quartz and quartzite	5,735	4,407	United States 4,404.
Sand:			
Construction	3,371	3,546	All to United States.
Glass	28,074	23,979	Guatemala 23,694.
Strontium minerals	21,358	27,164	Mainly to United States.
Sulfur:			
Elemental, all forms thousand tons	843	1,906	United States 981.
Sulfuric acid	3,906	62	Costa Rica 21; Ecuador 21; Panama 20.
Talc, steatite, soapstone, pyrohyllite	542	--	
Wollastonite	2,102	1,727	All to United States.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural (including gilsonite)	37	65	United States 50; Israel 10.
Carbon black	789	1,950	Brazil 935; Costa Rica 661; Guatemala 354.
Coal and coke	2	5	All to United Kingdom.
Gas, natural ---- million cubic feet	1,971	438	All to United States.
Petroleum:			
Crude thousand 42-gallon barrels	--	1,924	Netherlands Antilles 1,384; Uruguay 410.
Refinery products:			
Gasoline ---- do	158	359	United States 216; Colombia 142.
Kerosine ---- do	109	--	
Distillate fuel oil ---- do	192	2,295	West Germany 1,265; United States 572; Netherlands 153.
Residual fuel oil ---- do	4,826	7,757	United States 2,301; West Germany 1,287; Bahamas 888.
Lubricants ---- do	1	1	Mainly to United States.

[1] Includes free trade materials in totals but excluded in principal sources.
[2] Does not include ingots of high carbon and alloy steel.
[3] Uranium oxide.
[4] May include a small quantity of manufactured materials.
[5] Less than ½ unit.
[6] Includes that derived from natural gas plants.

COMMODITY REVIEW

METALS

Aluminum.—Final agreement has been reached on the establishment of a binational aluminum complex that will utilize Jamaican bauxite to produce aluminum metal in Mexico. It will include an alumina plant in Southern Jamaica and an aluminum smelter at Coatzacoalcos, Veracruz, Mexico. The Jamaican Government will own 51% of the alumina plant; the Mexican Government, 29%; and Kaiser Aluminum & Chemical Corp., 20%. The Mexican Government will own 51% of the smelter; the Jamaican Government, 29%; and Kaiser, 20%. The initial capacity of the smelter will be approximately 120,00 tons per year of aluminum ingot.

Alumínio, S.A. de C.V., with a smelter near Veracruz, was Mexico's only existing primary aluminum producer in 1975. It was proceeding with plans to increase the capacity of the smelter from 40,000 tons per year of aluminum metal to 90,000 tons per year, with completion of the expansion scheduled for 1977.

Copper.—Major mine, smelter, and refinery projects underway were designed to make Mexico a major exporter of copper.

Cía. Minera de Cananea, S.A., the nation's largest producer, planned to increase capacity from its present 40,000 tons of blister copper per year to 70,000 tons per year by 1976 and 140,000 tons per year by 1982.

Cia. Mexicana de Cobre, S.A., continued work on its mine, mill, and smelter complex at the La Caridad deposit at Nacozari, Sonora, with initial operations scheduled for late 1976 at a rate of 140,000 tons of copper per year. It is planned to increase the capacity to 250,000 tons per year by 1980. Ore reserves have been estimated at 700 million tons grading 0.7% copper and 0.02% molybdenum. This is the largest project of this type ever initiated in Mexico and will require an initial investment of approximately $500 million.

Cobre de Sonora, S.A., continued with initial exploration and development programs at the Santa Rosa and Pilares mines in Mocorito, Sonora. These mines have reported copper ore reserve totaling 130 million tons. Plans have been made to bring these properties into production at a rate of 37,000 tons of copper per year.

Cía. Minera Cuprífera la Verde, S.A., was in the initial stages of developing a promising copper deposit in the State of Michoacan. Plans called for an initial production of 30,000 tons of copper per year. Ore reserves were reported to exceed 50 million tons with a grade of 0.7% copper.

Expansions in electrolytic copper refining capacities were planned so that Mexico would be able to export both electrolytic copper and finished copper products. Industria Minera Mexico, S.A., was to build an electrolytic copper plant in San Luis Potosí, S.L.P., with an annual capacity of 110,000 tons. Additionally, Mexicana de Cobre was to construct an electrolytic copper plant at Guaymas, Sonora, in conjunction with the development of the La Caridad copper complex with a capacity of 140,000 tons per year. Both projects are to be completed by mid-1978.

Iron and Steel.—In an effort to obtain self-sufficiency in iron and steel production by 1977, Mexico was accelerating the development of iron ore reserves and adding additional steelmaking capacity to its industry.

Operation began at the important Peña Colorada iron ore deposit in Colima, with estimated reserves of more than 100 million tons. Operated by Consorcio Minero Benito Juarez, Peña Colorada is a joint venture of the Federal Government and Mexico's four largest steel companies. It will produce approximately 1.5 million tons per year of 65% grade iron ore pellets. Plans were completed to double the capacity to 3 million tons per year by 1978.

Altos Hornos de Mexico, S.A., was in the midst of a large-scale expansion program at its El Anteojo iron ore deposits in Chihuahua, which contain estimated reserves of approximately 100 million tons.

Fundidora Monterrey, S.A., announced facility expansions that will increase its present steelmaking capacity of 900,000 tons per year to 1.5 million tons per year by yearend 1976. The program will include the construction of a concentrate plant and an iron ore pelletizing plant as the expansion of blast furnace and steel plate rolling facilities.

El Grupo Acero, an affiliate of Hojalata y Lamina, S.A. (HYLSA) announced plans for the construction of a sponge iron plant at Xeoxtla, Pueblo, to produce 700,000 tons per year by 1976 for the purpose of supplying the country's small- and medium-sized steel industries with a substitute for imports of scrap iron.

The major contributor to Mexico's steel developing program is the fully integrated iron ore to steel Las Truchas complex under construction on the Pacific Coast by the Government-owned Cía. Siderúrgica Lázaro Cárdenas-Las Truchas, S.A. (SICARTSA). Backed by nearby ore reserves, the complex will include pelletizing plants, blast furnaces, basic oxygen furnaces (BOF) and continuous casting systems. Construction of this complex will advance through four stages, culminating in 11 million tons of steel ingot capacity by 1995. Stage 1, which will provide a capacity of 1.3 million tons of steel ingot per year, is now under construction and scheduled for startup in August 1976. When completed, the SICARTSA project will be one of the largest steel complexes in Latin America. It is one of the largest construction endeavors ever attempted in Mexico and represents an initial investment of $1.1 billion.

The Government established the Mexican Steel Research Institute, a decentralized Federal Government agency that is to carry out technological and development programs for the country's steel industry. One of its primary aims is to develop a national steel technology as well as to check and analyze all technological processes now imported by local steel companies whether state-owned or privately operated.

Lead and Zinc.—A number of expansions in the lead and zinc industries, in which silver is an important byproduct, were either completed or in the planning stages in 1975.

Industria Minera Mexico S.A. expanded its mine operations at San Martín, Zac., Charcas, S.L.P., and in the State of Chihuahua. At Taxco, Gro., it made major additions to facilities including a new central hoisting shaft and a 2,200-ton-per-day flotation mill. Additionally, it completed initial engineering design for a new electrolytic zinc refining complex in San Luis Potosí, S.L.P. It will have a planned capacity of 115,000 tons per year of zinc metal and is expected to be operational in 1977.

Industria Peñoles, S.A., was continuing with the construction of a new lead smelter and refinery at Torreón, Coahuila, which will have an annual capacity of 190,000 tons of lead per year.

Zincamex, S.A., the Government-owned zinc refining complex at Saltillo, planned the construction of a 15,000-ton-per-year electrolytic zinc refinery that would complement its present 30,000-ton-per-year retort zinc plant.

Manganese.—Cía. Minera Autlan, S.A. de C.V., was in the process of expanding its mine production capacity at its Molango, Hidalgo, mines 30% by 1976. Additionally, Autlan was constructing a new plant in Tomás, Veracruz, for producing high-carbon ferromanganese that will increase its production of ferroalloys by 150% when completed in early 1976.

Silver.—Three important projects were under way during 1975 which when fully operational should insure Mexico's ability to regain world leadership in silver production, a position it has not held since 1963. The Cía. Minera Lampaso mine in Sonora placed its first unit in operation in 1975 with an annual capacity of 2 million troy ounces. Full-scale operations were expected by 1976 at a rate of 12 million troy ounces of silver per year.

Cía. Minera Las Torres, S.A., a joint venture headed by Industrias Peñoles, S.A., was developing four mining properties in the State of Guanajuato. First stage plans called for the production of 7 million troy ounces of silver per year as well as 50,000 troy ounces of gold.

A third project involved development of silver mining properties near Real de Angeles, Gto., by a joint venture involving the Banco de Comercio and the Placer Group of Canada with a proposed production of 5 million troy ounces of silver per year.

Additionally, the Government-owned Cía. de Real del Monte y Pachuca, S.A., increased its milling capacity substantially and planned to begin commercial exploitation of several new potentially highly productive silver veins in the State of Hidalgo.

NONMETALS

Cement.—The cement industry in 1975 was basically comprised of 7 operating groups which among them operated 23 of the country's 28 plants. Together the 4 largest groups with 17 plants accounted for 73% of the sales.

The following tabulation shows the distribution of sales in 1975:

Cement group	Number of plants	Percent of market
Tolteca	8	25.5
Mexicanos/Maya	5	17.8
Anahuac	2	18.0
Cruz Azul	2	12.0
Guadalajara	2	7.9
Apasco	2	9.5
Chihuahua	2	2.6
Others	5	6.7
Total	28	100.0

The cement industry has been expanding very rapidly. At yearend 1975 the industry had a total installed capacity of approximately 13.5 million tons compared with 7.9 million tons at yearend 1970. Expansion programs underway in the project stage are expected to increase the installed capacity by 27%. In several cases the expansion programs will enable the companies involved to have a very definite export capability.

Fertilizer Materials.—A Government-owned holding company, Productos Básicos para Fertilizantes, S.A. (PROFERSA), was formed that in effect joined six established and newly formed state-owned corporations which produce a wide range of minerals used to produce fertilizers such as sulfur, potassium, and phosphate rock. PROFERSA will hold a minimum of 51% of the shares of such companies, which include all of the basic producers of these minerals. The country's only domestic producer of fertilizer products, the Government-owned Guanos y Fertilizantes de Mexico, S.A. (GUANOMEX), has not as yet become incorporated into the PROFERSA holding company, although it is expected that it would be at least partially absorbed during 1976.

GUANOMEX announced a major expansion program to be completed over a 4-year period. It will involve the construction and/or expansion of 10 plants to be partially financed by a $50 million loan from the World Bank. It is expected that these new projects will make Mexico self-sufficient in finished fertilizer production by the end of the decade.

Nitrogen.—Petróleos Mexicanos (PEMEX), the nation's largest producer of anyhydrous ammonia, completed the first year's operation at near capacity of a 900-ton-per-day plant at Cosoleacaque, Veracruz. PEMEX was continuing with engineering and construction on three other new anhydrous ammonia plants with a combined production capacity of 2,900 tons per day.

Phosphate Rock.—A new corporation, Roca Fosfórica Mexicana, S.A. (ROFOMEX), was formed to explore and develop the promising deposits of phosphate rock in an area north of La Paz, Baja California. The company is 51% Government-owned and will be a part of the PROFERSA group. The deposits were extensively explored during 1975 with indications that approximately 150 million tons of ore had been delineated grading between 12% and 25% P_2O_5 with the geologic probability of much greater reserves in the area. At yearend 1975 bulk sampling was in progress for the purpose of metallurgical testing. If these results are promising it will be followed up by a 1,000-ton-per-day pilot plant.

Fluorspar.—Mexico's export oriented industry was further expanded during 1975. Industria Minera Mexico, S.A., announced plans for a new fluorspar flotation mill in Santa Bárbara, Chihuahua, with a monthly production capacity of 15,000 tons. Cía. Florita del Río Verde, S.A., a subsidiary of Industrias Peñoles, was undertaking to double its metallurgical acid-grade fluorspar capacity. Minera Frisco completed its first year of operations at its new installation at San Francisco del Oro, Chihuahua, which will have an annual capacity of 75,000 tons of acid-grade fluorspar concentrate.

Mexico moved toward the upgrading of fluorspar output as opposed to its export as metallurgical- or acid-grade products, with the initiation of hydrofluoric acid production at the new Matamoros, Tamps., plant of Química Fluor, S.A. de C.V., at its rated capacity of 70,000 tons per year of hydrofluoric acid. Most of the firm's hydrofluoric acid production will be exported.

The Mexican Fluorspar Institute, of which almost all fluorspar producers of the country are members, became fully operative in 1975. The Institute, specializing in promotion and marketing, will attempt to develop and coordinate medium- and long-range programs for fluorspar exports and export prices and promote fluorspar uses.

Sulfur.—As in past years, Mexico's sulfur industry was primarily based on the Frasch-type operations of the Government-controlled Azafrera Pan Americana, S.A., and Cía. Exploradora del Istmo, S.A. with large operations in the Tehuantepec region. The industry continued to be largely export oriented. These companies were also absorbed into the PROFERSA group.

MINERAL FUELS

Petroleum.—Petróleos Mexicanos, S.A. (PEMEX), is the Government-owned organization having exclusive control over the Mexican petroleum industry from crude oil production through marketing. Additionally, it is the sole authorized producer of basic petrochemicals.

The year 1975 was a very successful one for PEMEX. Not only did production increase substantially but the potential production was much larger than current or projected demand. Unless a political decision to the contrary is made, Mexico should soon become a major exporter of crude and refined petroleum products. The rapid expansion of Mexico's petroleum industry had been due largely to the discovery in 1972, and the subsequent rapid development, of a major highly productive petroleum Province situated in the States of Chiapas and Tabasco in southern Mexico. The area as a whole is commonly referred to as the Reforma trend.

Production in the Reforma area in 1972 amounted to only 0.4 million barrels, increasing to 11 million barrels in 1973 and 62 million barrels in 1974. In 1975, production amounted to 118 million barrels, or an average of 234,000 barrels per day. At yearend 1975, 7 distinct fields in the region, with 81 wells, were producing at the rate of 440,000 barrels per day. PEMEX projects that production in the Reforma area will exceed 500,000 barrels per day at yearend 1976.

The extent of the productive area in the Reforma trend has not been fully delineated. Exploration efforts seemed to indicate that the fields extend northeast into the Gulf of Campeche, eastward toward the Guatemalan border, south toward to Tuxtla Gutierrez, and west as far as Minatitlan.

PEMEX had been reluctant to release the full extent of reserves in the Reforma trend pending a complete evaluation. Officially, hydrocarbon reserves in Mexico were set at 6.3 billion barrels at yearend 1975 as compared with 5.8 billion barrels at yearend 1974. Unofficially, it has been estimated that reserves, including those in the Reforma region, might reasonably amount to more than double this quantity.

With the Reforma trend having established an expanded production base, PEMEX moved forward rapidly with the construction of extensive new downstream facilities. These included the building of new pipelines, expansion of terminal facilities, acquisition of new tankships, and the construction of new refineries. Additionally, desulfurization and petrochemical facilities were being expanded.

In 1975, PEMEX completed construction on 205 miles of oil pipelines, 78 miles of natural gas pipelines, and 1,506 miles of product pipelines. An additional 1,420 miles of pipelines of various types were in the design or construction stages at yearend.

The delivery of a new tankship during 1975 increased PEMEX's tanker fleet to 26 ships totaling 480,900 deadweight tons and having a load capacity of 3.7 million barrels. In 1975 PEMEX moved 99 million barrels in its own bottoms and 71 million barrels in leased vessels.

Installed primary distillation refining capacity at the six PEMEX refineries in operation at yearend 1975 was 785,000 barrels per day as compared with 590,000 barrels per day of installed capacity at yearend 1971. PEMEX had four new refineries under design or construction at yearend that would increase its refinery capacity by an additional 650,000 barrels per day by 1980.

Although Mexico has the potential for becoming a major U.S. supplier of crude and refined products, the impact on U.S. markets in 1975 was only minor. In 1975 Mexico exported 38.3 million barrels of crude petroleum, including 25.6 million barrels to the United States and 2.5 million barrels to Puerto Rico. By comparison, total U.S. imports of crude petroleum in 1975 amounted to 1.5 billion barrels. Also in 1975, U.S. exports of refined products to Mexico amounted to 15.4 million barrels while U.S. imports of refined products from Mexico were only 269,000 barrels.

The Mineral Industry of Morocco

By David G. Willard [1]

At the beginning of 1975, Morocco's mining industry was stimulated by quadrupled phosphate rock prices and continued strong demand, but by yearend, production and exports were decreasing. Weather, price resistance, and competition combined to curtail phosphate sales and erode posted prices, while rising petroleum costs hindered world industrial growth and undermined additional export markets. Aided by an expansionary government policy and its basically strong position, however, the industry was weathering the decrease and awaiting an improvement in conditions.

Exports of phosphate rock fell 30%, although late 1974 price gains held the decline in revenues to 14%, and output had a corresponding drop of 28%. At the same time, exports of most metals decreased, and the total value of metals exports slumped 42%. Production of metals decreased 8% in total tonnage, but individual commodities showed a mixture of gains and losses. Revenues from mineral exports declined 16% from 1974 to 1975.

The decline in mineral exports, coupled with a similar downturn in nonmineral exports and a continued rise in import expenditures for food and capital equipment, caused the trade deficit to swell in excess of $1 billion.[2] Morocco's economy suffered less damage than might have been expected, because of loans from the International Monetary Fund and the oil-producing countries. However, no signs had appeared of the recovery that was anticipated because weather and competition continued to depress phosphate prices.

Government policy showed no basic change from its previous viewpoint that the economy could ride out this troubled period and be in a position to take advantage of expanding markets when recovery occurred. Government programs assisted private companies to maintain production, employment, and prices—even at the expense of considerable stockpiling. About 1 million tons (7% of production) of phosphate rock went into stockpiles, along with about 30% of lead production, 60% of copper production, 45% of iron ore production, and 15% of the manganese mined. At yearend the Government boldly announced an expansionary budget for 1976 that included a 57% increase in investment expenditures. Predicated on recovery of phosphate and metals markets and the availability of large-scale external financing, the budget sought both to prevent current problems from delaying the country's development and to stimulate a budding recovery of private investment, which had been lagging ever since imposition of the Moroccanization laws in 1973. Major projects in the budget included the new port at Jorf Lasfar and its related phosphate and petrochemicals facilities, the Nador steel mill, a major expansion of the Mohammedia oil refinery, and construction of several new cement plants.[3]

In the crucial area of energy, efforts were being pushed in several directions at once. Morocco lacks significant oil and gas reserves, and its deteriorating relations with neighboring Algeria threatened to close off the principal source of new

---

[2] Where necessary values have been converted from Moroccan dirhams (DH) to U.S. dollars at the rate of DH4.40=US$1.00 in 1974 and DH4.00 =US$1.00 in 1975.

[3] U.S. Embassy, Rabat, Morocco. State Department Airgrams A-15, Jan. 30, 1976, and A-68, June 17, 1976.

natural gas supplies. The Government-owned Bureau de Recherches et de Participation Minières (BRPM) was accelerating its onshore search for minerals. A new agreement was signed with a consortium headed by Phillips Petroleum Co. for offshore oil exploration, and research and drilling were being carried out on the half dozen concessions already awarded off the country's coasts. Studies were being conducted in the U.S.S.R., the United States, Canada, and Brazil with BRPM funding in the hope of devising a technology for exploiting the extensive oil shale deposits near Timahdit and Tarfaya. Also, research into the possibility of obtaining uranium as a phosphate byproduct was being discussed with a U.S. company.

A major addition to the country's actual and potential mineral supply was acquired late in the year when the former colony of Spanish Sahara was partitioned between Morocco and Mauritania. Morocco's portion includes the rich Bu Craa phosphate mine and known but unexplored resources of several metals and oil shale. Government policy concerning the new territory, which was renamed "Western Sahara," was still undetermined, but indications were that it would follow the pattern established in the rest of the country; namely, a government monopoly of the phosphate industry (with the exception of Bu Craa, for which a joint venture was negotiated with Spain) and freedom for private prospecting and production of other minerals, with government assistance and investment where necessary. Foreign participation was also being encouraged.

PRODUCTION

Mineral production in Morocco declined in 1975. Output of phosphate rock was down 31% from 19.7 million tons in 1974 to 13.5 million tons in 1975. Production of minerals other than phosphate showed mixed results. Output of the more important metals was below 1974 levels. Lead production was down 26% to 104,000 tons in 1975 from 141,000 tons in 1974, and production of manganese declined 25%. Metal mining industries in which production increased included copper, which increased 9%; zinc, up 32%; cobalt, a gain of 12%; and iron ore, a small increase of 4%.

Among the nonmetallic minerals, production of pyrite and pyrrhotite, all of which is consumed in phosphate processing, decreased 60%. Output of fluorspar from the new El Hammam mine was more than double that of its initial year in 1974.

In the fuels sector, production of coal, natural gas, and crude petroleum increased. Coal production was 14% greater in 1975 than in 1974. Natural gas output was up 20%, and production of crude petroleum increased 60%.

Total value of all crude mineral production declined 38% to $701 million in 1975 from $1,132 million in 1974. Reduced output and lower prices for phosphate were responsible for almost the entire drop. The value of mined phosphate rock was down $431 million to $602 million in 1975 from $1,033 million in 1974, a decline of 42%. Total value of minerals other than phosphate remained virtually unchanged, amounting to $99 million in 1974 and $100 million in 1975. (These figures may not total exactly because of differences caused by rounding). The phosphate industry's proportion of total mineral value declined to 86% in 1975 from 91% in 1974. Other minerals experiencing a significant change in value included lead, which was down 34% to $25 million in 1975 from $38 million in 1974, and coal, which gained $9 million and was more than double its 1974 value.

e Estimate. p Preliminary. r Revised.

[1] In addition to the commodities listed, Morocco also produces manufactured phosphatic fertilizers and a variety of crude construction materials, but available information is inadequate to make reliable estimates of output levels.

TRADE

Rapidly rising prices of phosphate rock and other mineral commodities enabled Morocco's export revenues to keep pace with the higher costs of imported goods in 1974. A fourfold increase in phosphate rock prices was responsible for most of a 111% increase in total export revenues. Higher prices also raised the values of other mineral exports, particularly metals. However, equally rapid uptrends in the costs of imported mineral and nonmineral commodities canceled those gains and left the country's overall balance of trade slightly on the deficit side, little changed from 1973.

Morocco's trade position worsened appreciably in 1975. Phosphate exports fell 30%, and recession in world industrial markets caused a drop in exports of metals. These two factors brought about a 14% decline in the country's export revenues. Meanwhile, import expenditures continued to rise, fueled by increased food imports due to crop failures, capital equipment investments, and inflation; the balance of trade deficit soared above $1 billion.

Balances of mineral and nonmineral trade in 1973 through 1975 are shown in the tabulation below, in million dollars:

	1973	1974	1975
Exports:			
Minerals	266	1,152	971
Nonmineral	595	663	588
Total	861	1,815	1,559
Imports:			
Minerals	188	518	536
Nonmineral	889	1,504	2,062
Total	1,077	2,022	2,598
Balance of trade:			
Minerals	78	634	435
Nonmineral	−294	−841	−1,474
Total	−216	−207	−1,039

COMMODITY REVIEW

METALS

Copper.—Production increased in 1975 as a result of the expansion program included in the 1973–77 5-year plan, but more than one-half had to be stockpiled. Output was up 9%, from 16,504 tons in 1974 to 17,970 tons in 1975. At the same time, prices plummeted from $2,877 per ton in 1974 to $1,222 per ton by yearend 1975. The total value of copper produced gained only 17%, from $6 million in 1974 to $7 million in 1975. Exports fell to 8,870 tons in 1975 from 19,019 tons in

1974. As with other minerals, the Government's policy was to maintain production and employment by stockpiling the excess output.

The new Ouansimi mine, opened in 1974, contributed 11,919 tons to the production total, up from 8,614 tons in 1974. Development of other elements of the expansion plan, which was designed to triple copper output by 1977, were postponed. These elements included new mines at Talat Nouame, Bini Mellal, and Bleida, washing plants at Ouansimi and Tazallaght, and a foundry at Safi.

Iron Ore.—Production of iron ore at the mine of BRPM's subsidiary Société d'Exploitation des Mines du Rif (SEFERIF) near Nador increased slightly during 1975. Output was 554,000 tons in 1975, up 4% from the 531,000 tons produced in 1974. Total value of iron ore production also increased slightly, from $13 million in 1974 to $14 million in 1975, a gain of 8%. Nearly one-half had to be stockpiled because exports fell to 301,000 tons, down 44% from the 538,000 tons shipped in 1974. Those stocks were not being held for future export, however, because they were slated for consumption in the $1 billion steel mill to be built near Nador. A call was issued by the Government for preselection of firms to bid on construction of the plant, and bids were expected to be taken beginning in August 1976. Plans called for the plant to begin operation in 1980 or 1981 and reach full capacity of 850,000 tons by 1985. A variety of steel shapes and products will be manufactured, all for domestic consumption. Raw material inputs for the plant will include the entire SEFERIF production along with imported iron ore. Coke or coking coal will also be imported, since reducing anthracite coal from the nearby Jerada mine to coke would involve higher costs. Plans to use a direct reduction process fueled by natural gas had been considered but were dropped in favor of a coke operation because of the possibility that the necessary natural gas supplies from Algeria would not be available. Ownership of the plant will be vested in Société Nationale de Sidérurgie (SONASID). Sources remained to be found to supply the major part of the financing for the mill.[4]

Lead.—The industrial recession also caused lead demand and prices to drop, and the production level in Morocco followed suit. Production declined 26% to 104,000 tons in 1975 from 141,000 tons in 1974, and the value of production slumped 34% to $25 million from $38 million in 1974. Exports were off 40%, from 126,000 tons in 1974 to 75,000 tons in 1975. Quantities shipped to major consuming countries fell by the greatest percent, exports to France were down 72%; to Tunisia, down 69%; to Spain, down 48%; and to Belgium-Luxembourg, down 36%. Reduced world prices and currency devaluations together caused a drop in value to producers of approximately 50%. High production costs forced the Aouli mine near Midelt to close. The foundry at Oued el Heimer reopened after completion of a modernization program, and Morocco was once again able to process its own ore, which had to be exported in concentrate form in 1972–74.

New facilities included a mine at Bediane, near Touissit, with a capacity of 50,000 tons per year when fully developed, a smelter under construction at Zaida, and the discovery of additional deposits by BRPM. BRPM continued its exploration work in the Upper Moulouya area.[5]

Manganese.—Manganese output fell victim to industrial recession in the same manner as other metals and slipped 25% to 131,000 tons in 1975 from 175,000 tons in 1974. Exports declined even more sharply, implying some degree of stockpiling. All production continued to be from the Imini mine operated jointly by BRPM and Société Anonyme Chérifienne de'Études Minières (SACEM). Availability of proven reserves of 1.5 million tons will enable a large increase in production to take place once market conditions improve.

Zinc.—Zinc fared somewhat better on world markets than many other metals in 1975. Exports in 1975 totaled 30,655 tons, down 17% from the 1974 level of 36,792 tons, although the value of exports slipped 25% to $6 million from $8 million in 1974. Production rose to 36,000 tons from 27,000 tons in 1974. However, reserves of zinc were reported to be nearing depletion. La Société des Mines de Zellidja was investigating a process for deriving

[5] U.S. Embassy, Rabat, Morocco. State Department Airgram A-68, June 17, 1976, p. 6; and State Department Telegram 2396, May 1975, p. 2.

zinc oxide from a 15-million-ton mine dump at the Boubeker mine in the Touissit area.

Other Metals.—The Office Chérifien des Phosphates (OCP), Morocco's official phosphate monopoly, continued its investigation into the possibility of extracting uranium as a byproduct of phosphate rock processing. Given the country's deficiency in energy resources, such a development would be of significant value to the economy. Discussions on the technical and economic feasibility of such an operation were being held during the year with a U.S. company that has conducted research on this type of process.[6]

Morocco was seeking assistance from U.S. and European mining interests in exploring and developing the newly acquired mineral deposits in the Western Sahara. Investigations by the United Nations and others have indicated the presence of iron ore, uranium, vanadium, titanium, cobalt; and oil shale in the territory.[7]

NONMETALS

Fluorspar.—Production at the El Hamman mine, which began operation in 1974, increased considerably in 1975. Output totaled 47,000 tons, more than double the 19,000 tons produced in 1974. Total exports also were up strongly, rising to 29,000 tons from 5,500 tons in 1974. Production capacity of the mine was given as 80,000 tons of 50% ore and 60,000 tons of 98% ore annually. The reserve was estimated at 5 million tons.

Phosphate Rock.—A drastic weakening of phosphate demand resulting from a combination of factors forced OCP to retreat from its stated objective of maintaining the production and price levels set at the outset of 1975. Price resistance and stockpiling by consumers as a reaction to the unprecedented price increases of 1973–74, late spring rains in western Europe that delayed planting and reduced fertilizer use, and the balance of payments difficulties experienced by many countries as the result of soaring petroleum costs all combined to depress fertilizer demand, particularly in the western European market. At the same time, the $68-per-ton price level, which was set early in 1975, stimulated a rapid rise in competitive production and exports, particularly from the United States. Price discounting and production cutbacks inevitably followed, dropping Morocco's output 28% to 14.1 million tons in 1975. The average unit value was lowered from $52.36 per ton in 1974 to $42.61 per ton in 1975, and exports of phosphate rock and fertilizers were cut 30% to 13.2 million tons in 1975. Revenues earned by phosphate exports slipped to $884 million from $1,028 million and represented $12.5% of the gross national product in 1975 as compared with 15.0% in 1974.

Little change had occurred in the overall geographic distribution of phosphate rock sales as of 1974. Western Europe remained the major customer, taking 60% of the shipments, down slightly from 63% in 1973. Eastern Europe increased its share from 19% to 24%, and a smaller share went to the rest of the world, 16% in 1974 as compared with 18% in 1973.

It had been anticipated that depletion of consumer stockpiles and a general economic recovery would allow phosphate demand and prices to regain their former levels by 1977. However, continued unfavorable farming weather in western Europe and competing production caused the downtrend in prices to continue. As a result, postponements of some parts of OCP's expansion program were considered likely.

The drying facilities under construction in the Khouribga area were being completed to enable production to reach the 20-million-ton-per-year goal targeted for the late 1970's. Output from the Sidi Hajjaj mine, beginning in 1980 or 1981, was expected to supplement this amount by 5 million tons per year. In the Youssoufia area, the Ben Guerir 1 mine was under construction in 1974 and slated to produce 2.65 million tons annually by 1981. Contracts worth $20 million were signed to provide equipment for the Ben Guerir 2 mine, which was scheduled to begin producing in 1981 and to reach its 9.75-million-ton-per-year capacity in 1990.

The Maroc Phosphore II processing plant, which is to consume the output of the Ben Guerir 1 mine, was nearing completion at Safi. The plant will be able to convert 495,000 tons of phosphate rock

Engineering and Mining Journal. Morocco Seeks Exploration Knowhow for Sahara. V. 177, No. 5, May 1976, p. 47.

per year, contained P_2O_5 basis, into phosphoric acid and triple superphosphate. Planning was continued for its successors, Maroc Phosphore III and IV, but their time schedules were set back because of the current market weakness and the resulting loss of revenues. Maroc Phosphore III and IV processing plants are to be part of an industrial center planned for the new port of Jorf Lasfar, which will also include a petrochemical complex. The port and petrochemical complex will be a joint project with Abu Dhabi, which will supply oil for refining and petrochemicals production. Loan agreements were signed with Kuwait, West Germany, and the World Bank during the year to help finance the various phosphate processing projects. Lockwood Greene Co. and the Badger Corp. were among the U.S. companies that had won design contracts for the port and petrochemicals complex.

The phosphate processing facilities at Jorf Lasfar will have a combined capacity of 2.9 million tons per year, P_2O_5 basis, and will handle the output of the Sidi Hajjaj and Ben Guerir mines. By 1985 Morocco expects to be capable of mining over 40 million tons per year of phosphate rock and plans to process about 30% of its output into higher valued manufactured products. In order to have a phosphoric acid shipping capacity, OCP, Compagnie Marociane de Navigation (COMANAV), and Gazocean S.A. of France formed an ocean shipping company, Marphocean, and ordered four 10,500-deadweight-ton vessels, which were being constructed at Le Havre, France. One vessel was received in early 1975, and the other three were scheduled to begin operation in 1977–78.[8]

The U.S.S.R. participation in the development of the Meskala deposit was postponed indefinitely by OCP. Soviet mining equipment and technology were to be provided in return for phosphate shipments of up to 10 million tons per year in a deal having an estimated value of $1 billion. However, one door had no sooner shut when another opened. Plans for a joint venture with Spain, a major phosphate customer, were under study at yearend.

The year's major event was Morocco's annexation of the Western Sahara. The territory contains a rich phosphate deposit at Bu Craa with an estimated 10-billion-ton reserve of ore averaging 31% to 33% P_2O_5. Negotiations with the Spanish company that was developing the mine, Fosfatos de Bu-Craa S.A., resulted in a joint venture of the same name in which Morocco holds a 65% interest and Spain a 35% interest. Former mine personnel were retained. Damage to the conveyor belt that carries the ore from the mine to the port at El Aaiun, a distance of 62 miles, caused production to be halted temporarily. Operation was later resumed with a fleet of trucks hauling the ore. Output was expected to total approximately 4.5 million tons in 1976. OCP planned to increase the mine's capacity to 10 million tons per year by expansion of the open pit operation and the construction of additional washing units. Long-range plans announced by OCP included a phosphoric acid plant and a fertilizer plant at El Aaiun.[9]

Salt.—Production from existing salt mines increased from 36,000 tons in 1974 to 60,000 tons in 1975.

A rock salt mine was under development in the Berrechid Basin near Mohammedia. The salt deposit, which was discovered during an exploration program for potash, covers an area of approximately 15 square kilometers with an average thickness of 80 meters. The total reserve was estimated at 3 billion tons, and the bottom 7 meters has an average grade of 99% NaCl. Mine output was projected at 900,000 tons of salt per year.

A chemical complex based on the salt mine was under development concurrently. The complex includes three plants. One is to produce 25,000 tons per year of chlorine and 28,000 tons per year of caustic soda. A second is to produce 25,000 tons per year of polyvinyl chloride, using the chlorine along with ethylene as inputs. The third plant is to manufacture 500,000 tons per year of soda ash. The manufactured products are to supply the requirements of domestic industry and provide export earnings, and salt will be produced

Works cited in footnote 7.

for the domestic market. A Moroccan company, Société Nationale d'Electrolyse et de Petrochemic, is to manage the operation. Contracts totaling about $170 million were signed with French, Spanish, and Italian companies for construction of the mine and plants. Mining is to begin in 1976, and completion of the project is scheduled for 1977.[10]

Other Nonmetals.—Pyrrhotite production at the Kettara mine was expected to terminate as soon as arrangements could be made to absorb the displaced workers. The mine produced a high-sulfur-content pyrrhotite used to produce sulfuric acid for the Maroc Chimie fertilizer plant. Reduced world sulfur prices have made imported sulfur a less expensive source of acid than pyrrhotite. Production fell to 204,000 tons in 1975 from 509,000 tons in 1974.

Recent increases in world potassium prices have reawakened interest in low-grade deposits located near Khemisset. BRPM commissioned a feasibility study to determine the economic and technical conditions under which mining could take place.[11]

MINERAL FUELS

Coal.—Coal production at the Jerada mine rose 14% to 652,000 tons in 1975 from 574,000 tons in 1974. Exports of coal slipped to 19,000 tons in 1975 from 34,000 tons in 1974, but higher prices held the decline in value to a more modest 18%, from $1.7 million in 1974 to $1.4 million in 1975.

Work continued during the year on a modernization program at the Jerada mine that is expected to increase the production to 830,000 tons annually. Included in the program were a new gallery, a new crushing and screening station, and a new conveyor system. Much of the additional production is slated for export, to offset part of the cost of imported coal for the Nador steel mill. Coal from the Jerada mine will not be used at Nador because its cost exceeds that of imported coking coal. Jerada coal will also continue to fuel the adjacent powerplant and cement and sugar industries and to provide home heating.

A deposit of lignite was discovered in the Sais Basin southwest of Fez. The Government released no details concerning its size, grade, or production prospects.[12]

Natural Gas.—Production from the Essaouira and Gharb gasfields increased 20% in 1975 compared with 1974 output. A natural gas pipeline from the Gharb fields to Kenitra presumably was completed in 1975 as scheduled, although confirmation of its completion was not received. Completion of the pipeline would allow the exploitation of new fields in the Gharb to tap a reserve estimated at 750 million cubic meters. However, these relatively small reserves, along with a diminished prospect of importing natural gas from Algeria, did not permit that fuel to figure highly in Morocco's future energy plans.

Oil Shale.—Research continued in an attempt to find an economically feasible method for exploiting the country's extensive oil shale resources. The two major deposits at Timahdit and Tarfaya constitute Morocco's only known sizable domestic source of petroleum, and the effort to develop them was given high priority by the Government. The Timahdit deposit was estimated at 5 billion to 7 billion tons of rock containing 10% oil, while reserve estimates at Tarfaya had not been given. Geological studies of the two sites were being conducted by BRPM, and ore samples from Timahdit were being tested in Europe and the United States. A Moroccan team visited the United States and Brazil, both of which have similar oil shale deposits, and concluded that essentially the same technical approach had been adopted in both countries. A contract was signed with the Oil Shale Corp. (TOSCO) of the United States for experimental processing of shale samples at TOSCO's Colorado pilot plant. A mission of 12 Soviet oil shale experts visited Morocco to discuss cooperative research, but the results of those meetings had not been announced.[13]

Petroleum.—Output of the oilfields operated by Société Chérifienne des Pétroles (SCP) declined in 1975, totaling 306,000 barrels in 1975 as compared with 191,000 barrels in 1974. Crude oil imports were up slightly to 19.6 million barrels from 19.2 million barrels in 1974, but their total

value dropped a small amount, from $241 million in 1974 to $224 million in 1975.

A petroleum discovery was announced by BRPM near Essaouira in 1975, but no information on its size or quality had been given by yearend. Interest in the area was stimulated, however, and exploration teams continued to work there. Also, BRPM was engaged in a series of basic geologic studies in search of petroleum covering two-thirds of the country.

Exploration for petroleum was in progress off most sections of Morocco's coast. Concessions granted to Burmah Oil Co., Ltd., Sun Oil Co., and a combine of EXXON and Shell Oil Co. blanketed most of the Atlantic coast of Morocco, while Tidelands Oil Co. held a concession covering an area in the Atlantic farther offshore. Other concessions granted to Tidelands, Shell, and a combine headed by Chevron (Standard Oil Co. of California) covered various portions of Mediterranean water. A new concession agreement for a deep water Atlantic area was signed with a consortium consisting of Phillips Petroleum Co., Agip S.p.A. and Getty Oil Co.

The pace of offshore exploration picked up in 1975, but no successes were reported. Sun drilled one well off Sidi Ifni and had plans for another. Tidelands completed a seismic research project in its deep water Mediterranean concession and was carrying out another in its Atlantic area. Two of the companies holding concessions in the Mediterranean were expecting to drill in 1976 or 1977. However, unsuccessful drilling caused Burmah to close down operations in its area, which lies offshore between Tangier and Rabat.

Société Anonyme Marocaine-Italienne de Raffinage (SAMIR), the larger of Morocco's two oil refining companies, announced a $200 million project involving expansion of its refinery at Mohammedia and the addition of a small complex of plants to manufacture lubricating oil and fertilizer. Petrofrance, a subsidiary of United Oil Products, is consultant on the project. The project had been under consideration for several years, but domestic demand had previously been too small to justify it. Refinery capacity was to be enlarged from 2.5 million to 5.7 million tons per year (approximately 18 million to 42 million barrels per year). This expansion was to give the country a total refinery capacity of about 7.3 million tons (54 million barrels) per year.

Other parts of the complex included a 100,000-ton-per-day ammonia plant and a 200-ton-per-day urea plant. The two plants would be owned by a new company, Nitromar, a joint venture of SAMIR, U.S., and Swiss interests. Auxiliary facilities were to include a new pier at the harbor in Mohammedia to improve handling for vessels up to 100,000 deadweight tons and a crude oil pipeline to the country's other refinery at Sidi Kacem (both refineries are wholly or partly Government-owned).

The complex, which will be the first of its kind in Morocco, is scheduled for completion in 1977. It will serve the domestic market and will consume excess naphtha and fuel oil from the refinery. Still under consideration is an ethylene plant that would consume propane to make butane, a product in growing domestic demand.[14]

The Mineral Industry of Mozambique

By David E. Morse [1]

The mineral industry of Mozambique was a minor contributor to the economy of the country in 1975. Production remained at about the 1974 level which was down compared with that of 1973. Coal production increased 34% and was the only mineral commodity to show a significant increase during the year. Output of cement fell nearly 31% and limestone production was down over 12%. Tantalite production was estimated to be in the order of 40 tons. Petroleum refinery output was estimated to be at 50% of capacity due to the exodus of technicians and reduced imports caused by lack of foreign exchange.

Prospecting and mine output were temporarily affected by the political changes that took place in Mozambique in 1975. The country began the year under a transition Government and gained independence from Portugal on June 25, 1975. The incoming Government immediately claimed ownership of all mineral rights and to all the land in the country. During the tenure of the transition Government a large portion of the trained administrators and technicians exited the country which left a vacuum in several areas of the economy that was not easily filled by local people.

The estimated government budget was $524 million in 1975 and the gross domestic product (GDP) was estimated at $3.1 billion.[2] Mozambique's external debt was expected to be over $650 million and the balance of payments deficit about $60 million in 1975.

Prior to 1975, Mozambique's system of railroads, roads and harbors contributed significantly to the country's foreign exchange earnings as a large volume of import-export traffic generated in Zambia, Rhodesia, Republic of South Africa, Swaziland, and Malawi passed through the major Mozambique ports of Maputo (formerly Lourenço Marques), Beira, and Nacala. During 1975, South African traffic through Mozambique dropped nearly 60% after independence as part of the exports normally handled at Maputo were shipped via Durban or other South African ports. Delays and loss of trained dock workers at Maputo prompted South African shippers to seek other routes for their exports. Traffic through Mozambique from Rhodesia and Swaziland also decreased but to a lesser degree. The total tonnage handled at Maputo was about 10.9 million tons in 1975, an 18% decrease compared with 1974 tonnage and 23% below that of 1973. The port of Beira on the central coast handled over 3 million tons in 1975, a 1% increase over 1973 tonnage and 3% above that of 1974. The port of Nacala which could handle the largest vessels but was the least accessable of the three major ports in terms of land transportation because of its position in the north, handled 758,000 tons in 1975, a 6% drop from the 1974 tonnage and 5% below that of 1973.

Upgrading of the ports of Maputo and Beira continued in 1975. Maputo received new loading and railway equipment and began preliminary work on the Porta Dobela facility. Plans for Porta Dobela included dry bulk storage space for 1.2 million tons, liquid storage of 800,000 tons, and facilities to offload crude oil to an inland tank farm. Improvements at Beira included dredging of the access channel and construction of a new wharf.

Improvements of the rail system between Moatize in the Tete District and Beira were designed to accommodate planned

[1] Physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from Mozambique escudos (M. Esc) to U.S. dollars at the rate M.Esc1=US$0.0367589.

increases in coal exports from Tete's coal basins as well as Zambian copper. The road system from Moatize to Zambia was improved with a section Tarmaced so that Zambian shipments could be effectively transported to the improved railyard at Moatize. These shipments were generally routed to the port of Nacala rather than to Beira because Nacala has facilities for larger vessels. Impounding of water by the Cabora Bassa dam began in December 1974 and it was expected to take about 2 years for the reservoir to fill. The reservoir would allow navigation on the upper Zambezi River in Mozambique so that waterborne ore shipments from areas in western Tete could be easily shipped to the rail connection at Moatize.

A stock company, Hidro-Electrica de Cahora Bassa S.A.R.L., was formed in June 1975 to operate the Cabora Bassa hydroelectric complex. Major subscribers were Soc. Fin. Portugesa, State of Portugal, State of Mozambique, Banco de Formento Nacional, and Coxia Gerl de Deps. Complete division of stock was not known, but the organization of the company was such that the State of Mozambique would eventually acquire the company and its holdings. The Cabora Bassa hydroelectric complex began power production from 450-megawatt generators in the south power station early in 1975. When the complex is completed, its total output was expected to be 3,600 megawatts, making it the largest hydroelectric producer in Africa. The Republic of South Africa had contracted to use 1,470 megawatts of the dam's production by yearend 1979.

An estimated 100,000 Mozambique nationals were working in South African mines in 1975 and generated about $120 million in foreign exchange earnings for the Mozambique Government. Another 85,000 nationals were estimated to be working in Rhodesia and Zambia, half in mining-related activities.

PRODUCTION AND TRADE

The available data on mineral production and trade are given in the following tables:

Table 1.—Mozambique: Production of mineral commodities
(Metric tons unless otherwise specified)

Commodity [1]	1973	1974	1975 [p]
METALS			
Aluminum, bauxite, gross weight	[r] 5,594	2,405	[e] 2,000

COMMODITY REVIEW

METALS

Bauxite.—The Alumen mine near Manica in the Villa Perry District continued to produce slightly over 2,000 tons per year with an average grade of about 62% Al_2O_3. Reserves of the deposit were reported to be over 60 million tons averaging 44% Al_2O_3. Other known bauxite deposits occurred in the Zambézia District at Milange and south of Lake Chirua near Malawi's eastern border. The extent and grade of these deposits were being studied during the year.

Copper.—The only copper mine in Mozambique was the Edmundian Mine located in the Manica area of Villa Perry near the Rhodesian border. The mine's 1975 production of copper ore and concentrate was valued at about $400,000. This was a 60% drop from 1974 due to reduced exports, lower world copper prices, and the restricting of the mine's activities to prospecting and evaluation of the ore body. Copper deposits had been found in the Tete District near Camitala, Concia, Chidua, Luzina, Mepanda-Unkua, and Tumba. The Chidua deposit had been studied in detail and was considered for possible economic development.

Gold.—The Bragana and Monque gold mines in the Manica area were reported as being reopened. The director of the Mozambique Bureau of Mines pointed out that gold bearing terrain had been located in other parts of the country but remained unworked because of internal civil disorder.

Iron.—There were numerous occurrences of iron-bearing mineral deposits in Mozambique, according to the Mozambique Geological Services report in 1974.[3]

Titano-magnetite deposits which occur in the Precambrian gabbro anorthosite crystalline complex of the Tete District, were known at Caldas Xavier, Doa, Inhantipissa, Machidua, Massamba and Txizita. The chemical composition of the ore varied little between localities and generally contained 47% Fe and 13% TiO_2 with the rest consisting of silicate minerals. Known reserves at Massamba were 4.5 million tons; at Inhantipissa, 3 million tons; and at Caldas Xavier, 2 million tons. The deposit at Doa was estimated to contain reserves of 18 million tons.

Iron-bearing deposits that occurred in Precambrian limestones near Fingoa were estimated to have reserves of over 10.5 million tons containing an average of 65% Fe.

[3] Direccao Dos Servicos De Geologia e Minas, (Lourenço Marques). Carta De Jazigos e Ocorrencias Minerais (Map of Deposits and Mineral Occurrences). Imprensa Nacional de Moçambique, 1974, 60 pp.

Sedimentary deposits included banded ironstones of the Macaqueca formation in the Villa Perry District and taconites in the Tete, Zambézia and Moçambique Districts. Reserves were estimated to be over 20 million tons containing an average of 30% Fe.

Information was not available as to the progress of construction on the steel mills at Tete and Beira. Construction on the foundry at Nampula began in 1975 before the change in Government.

Titanium.—Dense mineral layers were contained in the coastal beach dunes between Maganja de Costa and Moma along the north central coast. These layers comprised up to 30% of total dune material and had an average composition of 78% ilmenite, 13% zircon, 5% monazite, 2% rutile, and minor amounts of quartz, and garnet. The destruction of the coastal dunes by the sea during high energy events had resulted in effecting the removal of these denser layers in some coastal areas. During low energy conditions reconstruction of the beach had preferentially used the less dense materials, leaving the more dense materials in underwater deposits. Deposits of this nature were found during 1973 by the West German Preussag Exploration group in 30 meters of water near Pebane. Dense minerals comprised 70% to 80% of the material in these underwater concentrations. The known underwater deposits were estimated to contain 30 million tons of ilmenite, 3 million tons of zircon, and 2 million tons of rutile. Preussag applied for concessionary rights to prospect and exploit these deposits in the Pebane area.

NONMETALS

Cement.—The total annual capacity of Mozambique's three major cement plants at Matola, Dondo, and Nacala was 990,000 tons. The plants were all controlled by Companhia de Cementos de Moçambique, S.A.R.L. Production for 1975 was estimated to be in the order of 300,000 tons which was short of the 1973 record of 611,000 tons. Problems including loss of technicians, inadequate regular supplies of limestone and coal, lack of spare parts, and decreased worker productivity were cited as causing the marked decrease in production. Planned expansion to produce 1.89 million tons of cement annually remained uncertain due to the change in Government.

Clays.—Kaolin from the Tete deposits replaced imported Brazilian kaolin at the Maputo ceramics factory. Montmorillonitic clay production increased 25% over that of 1974. Large montmorillonite deposits existed in the Lourenço Marques District between Namaacha and Maputo and exceeded 15 million tons in resources.

Fluorite.—Fluorite deposits occurred in several areas, notably Djanguire and Lupata in the Tete District and at Canxine and Dejarlie in the Villa Perry District. The Djanguire deposit had an estimated 600,000 tons of 62% average grade fluorite. Total reserves of lower grade, 16% to 26% fluorite, were estimated at 60 million tons.

Other Minerals.—In the pegmatite areas of Zambézia, Niassa, and Moçambique the small-scale mines produced beryl (aquamarine and emerald), tourmaline, topaz, amazonite, morganite, rose quartz, rare kunsite and hiddenite crystals, and colombotantalite ore. Quality garnets were mined in the Nova Freixo area of the Niassa District.

MINERAL FUELS

Coal.—Companhia Carbonifera de Moçambique S.A.R.L. (CCM), the only company mining coal in Mozambique, produced over 575,000 tons of bituminous coal in 1975. CCM's production came from its Moatize mine which was part of a concession area of about 31 square kilometers in the Moatize-Minjova Basin. The mine was located about 30 kilometers east of Tete and had a proven reserve of over 400 million tons of coal. Expansion was planned for the Moatize mine to produce 4 million tons annually in the early 1980's with 1 million tons projected for the 1978 output. These expansion plans included using power generated by the Cabora Bassa hydroelectric complex for a system of electric trains in the underground and open pit operations. Most of the expanded capacity was to be exported through the ports of Beira and Nacala to Portugal, West Germany, and Japan. About 60% of the coal produced at the Moatize Mine was of coking coal quality.

The Zambezi valley contained other large coal deposits notably those near Chicoa and near Muncanha. The Tete

District was expected to produce 8 million tons of coal per year for export when expansion and development is completed in the early 1980's. Coal deposits found in the Niassa District near Manicamba and in the Catur area were being evaluated for possible development. Coal deposits also occurred near Macio southwest of Espungabera close to the Rhodesian border in the Villa Perry District.

Petroleum and Natural Gas.—Natural gasfields at Temane and Pande in the Inhambane District and at Buzi in the Beira District were estimated to contain 121 billion cubic meters of gas but were not being exploited in 1975. The Government proposed a petrochemical complex for the manufacture of synthetic fertilizer and synthetic gasoline using the natural gas from the Pande Field. Hunt International Petroleum held the only exploration permit for petroleum in an offshore concession near Pande at the beginning of 1975. Interest in petroleum exploration was expressed by other oil companies but uncertainties remained in the Government's policies concerning the granting of concessions. An estimated 3 million barrels of crude oil was imported for the Maputo oil refinery in 1975. Almost all of the oil refinery's production was consumed domestically in 1975.

The Mineral Industry of the Netherlands

By William F. Keyes [1]

The worst postwar recession in the Netherlands' economy reached its low point in July 1975, but by yearend there were signs of recovery. Gross national product (GNP) at constant prices declined 2%, although it rose from \$74 billion to \$80 billion [2] at current prices; the index of industrial production declined from 121 in 1974 to 115 in 1975 (1970=100); and the unemployment rate rose from 4% to 5.4% during the course of the year. Added to usual cyclical problems was the heavy burden that government expenditures continued to place on the private sector. Public expenditures as a share of the gross domestic product (GDP) were the highest in the Organization for Economic Cooperation and Development (OECD), and they took more than 50% of the wage earner's income. Business conditions in the major minerals industries of the Netherlands generally followed the economy.

By world standards the only important primary mineral produced in the Netherlands was natural gas—about 6% of the world total. Nonmetallic minerals, such as building materials, are only locally important. The country is, however, a moderately important processor of imported ores and concentrates. It produced about 1.6% of the world's primary aluminum metal from imported alumina and almost 1% each of the world's pig iron and steel.

The year 1975 saw the announcement of forthcoming expansion at one of the country's two aluminum smelters; application for a concession for solution mining of magnesium and potash; and discovery of additional natural gas reserves.

Natural gas production and exports continued to increase, as the Netherlands remained the leading supplier of this product to other European countries. Abandonment of the coal industry in 1974 left unemployment high in the southeast. Demand for petroleum continued low, and refineries operated at not much more than one-half their capacity.

PRODUCTION

Production of virtually all primary minerals and metals declined in the Netherlands in 1975, but the declines were in general modest. Exceptions were petroleum products which were down to not much more than half of refinery capacity and natural gas production which continued to grow strongly on the basis of large proven onshore and offshore reserves. Pig iron, crude steel, lead, salt, and sand production declined, but new zinc capacity led to a significant increase in production of that commodity in 1975.

[1] Supervisory physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from the Netherlands guilders (Hfl) to U.S. dollars at the rate of Hfl2.53=US\$1.00, the annual exchange rate for 1975.

e Estimate. p Preliminary. r Revised.
[1] In addition to the commodities listed, the Netherlands presumably produces a variety of crude construction materials (clays, sand, gravel, and stone), but production is not reported and available information is inadequate to make reliable estimates of output levels.
[2] Coke oven and blast furnace gas only.

TRADE

The Netherlands imported alumina, iron ore, and zinc concentrates for processing. Other imports were usually in a more advanced state of processing or were ready for consumption. Coal and coke were imported from the United States and West Germany, and crude petroleum for the Netherlands refineries was imported from the Middle East. Exports of primary forms and semimanufactures of steel were significant, as well as nonmetallics such as sand and gravel. The market for the Netherlands minerals and metals exports consisted primarily of nearby members of the European Economic Community (EEC), especially West Germany.

[2] Includes spiegeleisen, sponge iron, shot, grit, and pellets.
[3] Imports of bentonite from Belgium-Luxembourg are included in other clays.
[4] Less than ½ unit.
[5] Includes bunkers.

COMMODITY REVIEW

METALS

Aluminum.—Plans were announced to expand the Vlissingen smelter to a capacity of 280,000 tons per year, at an estimated cost of $114 million. Construction was scheduled to start in 1977.

Two producers accounted for all of the Netherlands production of primary aluminum, from imported alumina. Aluminium Delfzijl N.V., at Delfzijl, northeast Netherlands, a member of the Billiton (Royal Dutch/Shell) group, had a capacity of 106,000 tons of aluminum ingots per year. The other producer, Péchiney–Nederland N.V. at Vlissingen (Flushing) in the southwest, with a capacity of 187,000 tons per year, was owned by the Péchiney Ugine Kuhlmann group (85%), with the remainder held by Hunter Douglas N.V. and Alcan Aluminium Ltd.

Iron and Steel.—Start of construction on the ore pelletizing plant in the Europoort outer harbor at Rotterdam had not occurred by the end of 1975, because of delays in obtaining numerous environmental and local clearances. The plant, to be constructed by three West German steel producers—August Thyssen–Hüettenwerke AG, Mannesmann AG, and Friedr. Krupp GmbH, would supply the German blast furnaces of these companies. It would produce 4 million tons of pellets per year from imported ores and employ 190 persons. The latest cost estimate was over $158 million.

The only producer of pig iron and the largest producer of steel in the Netherlands was Hoogovens IJmuiden B.V., a subsidiary of ESTEL N.V., which in turn is controlled by the two steel companies, Koninklijke Nederlandsche Hoogovens en Staalfabrieken N.V. (KNHS) of the Netherlands and Hoesch AG of West Germany. Steel is also produced at Alblasserdam, near Rotterdam, by NKF Staal B.V., which is controlled by the NKF Groep B.V. and in which Thyssen has a minority interest; and at Utrecht, by N.V. Staalgietwerk SMDK, a subsidiary of Hoogovens IJmuiden B.V.

Magnesium.—Billiton Delfstoffen B.V. applied for a concession for the solution mining of potassium and magnesium salts in the provinces of Groningen and Drente, near Veendam. Agreement was reached with Norsk Hydro A.S. for a joint venture; 70 million to 80 million guilders would be invested by Billiton in a magnesium oxide plant and 1 million guilders by Norsk Hydro in a refinery for purification of magnesium and potassium chloride. Yearly processing capacity of salt solution (15% to 20% magnesium chloride) would be approximately 1 million tons by the Billiton plant and 700,000 tons by the Norsk Hydro refinery. Estimated output of the Billiton plant would be 100,000 of magnesium oxide per year; Norsk Hydro would process its product to magnesium metal in Norway. A final decision on the entire project, dependent on final test drillings, was to be made in 1976, allowing a possible startup in 1978.

Zinc.—The Netherlands' only primary zinc producer was Kempensche Zink Maatschappij B.V. at Budel on the Belgian border, which was jointly owned by Billiton Maatschappij B.V., a subsidiary of Royal Dutch/Shell, and Australian Mining and Smelting Europe, a subsidiary of two Australian zinc producers. Output of the recently expanded electrolytic zinc plant (capacity 150,000 tons per year) was increasing rapidly. Billiton acquired an 11.25% interest in Nanisivik Mines on Baffin Island, Canada, and the mine was to supply 50,000 tons of concentrate per year to Budel starting in 1976.

NONMETALS

Potash.—Potash would be solution-mined near Veendam, along with magnesium, if a project under study by Billiton Delfstoffen is carried out (see section on magnesium).

MINERAL FUELS

Energy.—Total consumption of energy in the Netherlands increased almost three times between 1960 and 1974, according to figures published by the Centraal Bureau voor de Statistiek. In the period the contribution made by coal declined from over 50% to under 5% of the total, while that of natural gas increased from 1% to 54%. Figures for 6 months of 1975 showed a continuation of these trends: Coal provided 4% of all energy and natural gas 61%; the remaining energy was provided in each year almost entirely by petroleum. The energy balance for the years 1973 and

1974, given in table 4, is the gross balance, including conversion losses and excluding stock changes. In 1974 the Netherlands was for the first time a net energy exporter because of the continued growth in natural gas production and exports.

Table 4.—Netherlands: Supply and apparent consumption of energy-producing materials for 1973 and 1974
(In million tons of standard coal equivalent) [1]

	Total energy	Coal and coke	Petroleum and refinery products	Natural gas	Nuclear power
1973:					
Production	98.4	1.7	2.3	94.3	0.1
Imports	117.7	4.5	113.2	--	--
Exports	117.7	2.4	70.9	44.3	.1
Apparent consumption	[2] 98.4	3.8	[2] 44.6	50.0	--
1974:					
Production	114.9	.8	2.2	111.5	.4
Imports	107.4	5.0	102.4	--	--
Exports	123.4	1.7	63.5	58.0	.2
Apparent consumption	[2] 98.9	4.1	[2] 41.1	53.5	.2

[1] 1 ton standard coal equivalent (SCE) = 7,000,000 kilocalories.
[2] Includes refinery fuel and losses.

Source: Adapted from United Nations, World Energy Supplies 1950–1974, Statistical Papers, ser. J, No. 19, 1976, 825 pp.

Coal and Coke.—The last two Dutch coal mines closed down late in 1974. No plans were advanced during 1975 to reopen any mine. Most of the 40,000 mineworkers whose jobs had been eliminated in the 10 years prior to the closing retired, were retrained, or found jobs elsewhere, but unemployment in the former mining area of Limburg remained high.

Natural Gas.—Two major additional gasfields were discovered in the Dutch sector of the Continental Shelf by the Shell-Esso exploration partnership—Nederlandse Aardolie Maatschappij. The first field, announced in October, was located off Ameland Island on the north coast; reserves were estimated at 50 billion cubic meters of gas. The second field, announced less than a month later, was located about 36 miles northwest of the Dutch naval base of Den Helder, north of Amsterdam; it was reported to contain possibly as much as 40 billion cubic meters.

Natural gas resources in the Netherlands, both onshore and offshore on the Continental Shelf, were estimated by official sources as follows, as of October 1, 1975, in billions of cubic meters:

	Proven	Probable
Slochteren (Groningen) Field	1,620	190
Other onshore fields	120	180
Continental Shelf	60	170
Total	1,800	540

The above figures do not include the 90 billion cubic meters announced subsequently in the Ameland Island and Den Helder offshore areas. The Slochteren reserves reportedly constituted the world's largest producing natural gasfield and provided one-half of West European requirements.

Nitrogen.—An application for planning permission was submitted by DSM for increasing the ammonia capacity of its subsidiary, Unie van Kunstmestfabrieken (UKF), at Geleen, Limburg, by 440,000 tons of ammonia per year. Construction was expected to start early in 1976.

Total ammonia production capacity in the Netherlands was estimated in 1975 as follows:

Company and location	Capacity (thousand tons per year)	Startup date
Esso Chemie:		
Rotterdam-Europoort	371	1969
Possible additional	(11)	1974
Nederlandse Stickstoff:		
Sluiskil	298	1965–66
Unie van Kunstmestfabrieken (UKF):		
Geleen	272	1971
Do	108	1965
Do	108	1966
Do	108	1967
Do	365	NA
Pernis (Rotterdam)	250	1966
Ijmuiden	250	NA
Total	2,130	
Possible additional	(11)	

NA Not available.

Petroleum.—The Netherlands refineries operated at only 50% to 60% of capacity in 1975, and unit costs increased substantially. After completion of the Total refinery in Vlissingen in 1974, total crude oil refining capacity was reported as follows:

Refinery	Location	Capacity (million tons per year)
B.P. Raffinaderij Nederland N.V	Rotterdam	24.5
B.V. Smid & Hollander	Amsterdam	.3
Compagnie Française des Petroles (Total)	Vlissingen-Oost	7.2
Chevron Petroleum Maatschappij Nederland N.V	Rotterdam (Pernis)	15.0
Esso Nederland B.V	Rotterdam	16.2

The Mineral Industry of New Zealand

By Walter C. Woodmansee[1]

New Zealand's mineral industry showed little change during 1975, a period of mild economic recession when demand for its mineral products was slack in the export market. Output of most of the limited number of mineral commodities produced was at about the same level or was lower than that of 1974. However, production of two valuable commodities—natural gas and ironsand concentrate—was higher in 1975.

Exploration, which was relatively costly owing to New Zealand's remoteness and difficult land transportation, was increasing onshore and offshore from both islands, with some favorable indications. Principal exploration activity was for base metals, gold, coal, oil, and gas. For oil and gas, a semisubmersible drill rig and a drilling vessel arrived in New Zealand waters and drilled several offshore wells during the year.

PRODUCTION

Total value of mine and quarry output (metals and nonmetals), exclusive of the mineral fuels, was $70.2 million,[2] compared with $74.3 million in 1974. This loss in output value was in part attributed to a 15% devaluation of the New Zealand dollar in August 1975. Value was $13.7 million in the metals sector and $56.5 million in the nonmetals sector. Principal commodities in these sectors in 1974 and 1975 were as follows, in thousand dollars (1974 values converted at the 1975 rate for comparability):

	1974	1975
Sand and gravel	$43,598	$41,983
Ironsand concentrate	11,671	13,264
Stone (principally limestone)	11,178	11,979
Clays	859	1,126
Silica (glass sand)	588	647
Gold	531	389

Data were not available on output values for other metal products, cement, and the mineral fuels, but estimated values are as follows: Steel billets, $23 million; nonferrous metals and alloy castings (principally copper and aluminum), $6 million; cement, $30 million; coal, $25 million; coke, $0.5 million; natural gas, $4.0 million; and natural gas liquids, $17 million. On this basis, total mineral output value was estimated at nearly $176 million, or 1.7% of the gross national product estimated at $10,051 million for 1975 (current prices).

Coal production was down slightly, but the industry was undergoing mechanization and expansion to provide increased fuel supplies for domestic power and the export market. Output of natural gas and liquids was higher as new wells were brought into production in the Kapuni gasfield, and development continued at the large, offshore Kaui gasfield. Plans proceeded for expansion at New Zealand's only petroleum refinery, where output was down because of rising prices and energy conservation practices.

[1] Contained in zinc concentrate.
[2] Contained in lead-copper concentrate.
[3] Includes that contained in lead-copper concentrate.
[4] Average 60% iron.
[5] Crushed rock for building aggregate, roads and ballast is included with sand, and gravel.
[6] Excludes carbon dioxide component of natural gas, which is reported separately.

Among the metals, expansion continued at New Zealand's one aluminum reduction plant, which was scheduled for completion in 1976, and in ironsand concentrate production, which provided raw materials for the domestic iron and steel industry and was an important export commodity. Previously announced expansion plans for iron and steel capacity were deferred because of lagging domestic and foreign demand for steel.

TRADE

New Zealand's principal trading partners for mineral commodities were Australia and Japan. The principal mineral export was ironsand concentrate, which went wholly to Japan. The Mineral Resource Council took steps to expand export sales for ironsand and for coal, clays, and ilmenite. Principal mineral imports were crude petroleum and petroleum refinery products which, according to the Department of Statistics at Wellington, were valued at $334 million ($179 million in 1974). Total import value for all commodities was $2,610 million ($1,977 million in 1974).

COMMODITY REVIEW

METALS

Aluminum.—New Zealand Aluminium Smelters Ltd., comprising government interests, Comalco Industries (Pty.) Ltd. (Australia), Showa Denko KK (Japan), and Sumitomo Chemical Co. Ltd. (Japan), continued an expansion program at its reduction plant on Tiwai Point, near Bluff. Annual capacity of 110,000 tons, based on alumina imported from Australia, was to be increased to 150,000 tons.

A proposal by Otago Metal Industries Ltd. to establish New Zealand's second aluminum smelter, at Aramoana in Otago Harbor, was rejected by the Government. The metal would be produced for the export market, and government authorities rejected export of an energy-intensive resource for insufficient financial returns.

Copper-Lead-Zinc.—Base metal exploration was underway in several districts, but no significant discoveries were reported. Otter Minerals Exploration Ltd. conducted a regional stream sampling program in the Baton River catchment area, Nelson District, South Island, and Minerals Exploration Ltd. was drilling in the same area. Prospecting activity was also underway on Coromandel Peninsula, near Auckland. Pennzoil of Australia Ltd. was also sampling stream sediments in the headwaters area of the Anatoki and Slate Rivers, Nelson District.

The Department of Scientific and Industrial Research (DSIR) developed a process for removal of most of the mercury content in base metal ores from the Tui mine at Te Aroha, where operations ended in 1973 when a supply contract for delivery of concentrate to Japan was terminated. The mercury content of the concentrate had been unacceptable under Japanese regulations.

Gold.—Activity was limited, and production from dredging operations decreased compared with that of 1974. Kanieri Gold Dredging Ltd., which had the only operating dredge, produced 1,859 troy ounces of gold at the lower end of, and downstream from, its license area on the Taramakau River, west coast, South Island. Operational time was lost when the dredge was reconditioned. The dredge was also working back through tailings, which also contributed to production losses. Kanieri sought government funds for moving from the Taramakau River to the Grey River, 48 kilometers to the north, but the move was deferred.

Mineral Resources (New Zealand) Ltd. recovered a small quantity of gold by retreating tailings material from old mine sites.

About 10 of 61 current claims were operated intermittently, when weather permitted, in the Southern District, South Island. Carpentaria Exploration Co. Pty. Ltd. and Lime and Marble Ltd. were drilling alluvium along the west coast, South Island. Investigations were also underway on alluvial materials in the Otago goldfields in the southern part of the South Island.

Ironsands.—For the year ended March 31, 1976, New Zealand Steel Mining Ltd. produced 1,274,442 tons of titanium-iron (ilmenite-magnetite) concentrate containing 56% to 60% iron for domestic steelmaking and for shipment to Japan. This concentrate was produced by magnetic separation from raised beach and dune black ironsands at Taharoa and the Waikato North Head area, along the west coast of the North Island. The Taharoa concentrate was exported and the Waikato concentrate was shipped to the company's iron reduction plant at Glenbrook.

Waipipi Ironsands Ltd. shipped 1,019,049 tons of concentrate from Waipipi Point, near Waverly, also on the North Island, to Japan. For this operation, Marcona Corp. (United States) had joined with Europa Oil (New Zealand) Ltd. to adapt the Marconaflo system for transporting a concentrate slurry through an underwater pipeline to an offshore loading buoy. Waipipi made plans to expand concentrate capacity from 1.2 million to 2 million tons per year with a second dredging unit. The pipeline also was to be extended to deeper water to accommodate vessels of 150,000 deadweight tons (currently 65,000 deadweight tons), and a new mooring/loading buoy was to be installed.[3]

Ironsand resources on both the North Island and the South Island had been esti-

---

[3] Iron and Steel International. Development of New Zealand's Iron Sands. V. 49, No. 1, February 1976, pp. 45–49.

mated to be as much as 5 billion tons, and titanomagnetite resources had been estimated at 800 million tons, largely on the North Island. The DSIR estimated resources of ilmenite concentrate of 50 million tons from black sands south of Westport on the west coast of the South Island.

Iron and Steel.—New Zealand Steel Mining reported production at its Glenbrook Steelworks, 58 kilometers south of Auckland, for the year ended Mar. 31, 1976, as follows, in tons:

Sponge iron	113,135
Billets	106,127
Galvanized flat products	92,727
Pipe and hollow sections	18,189

Designed direct reduction and billet capacity was 150,000 tons per year, and pipe and tube capacity was 40,000 tons per year. A planned $400 million expansion was deferred owing to poor economic conditions and depressed demand for steel. This plan would have provided an integrated operation by 1980, including a threefold increase in iron reduction and steelmaking capacity with one new kiln, an 800,000-ton-per-year hot-rolling mill, and an expanded galvanizing line. The Government was to take a 35% stock interest and guarantee overseas loans. The proposed expansion would have provided 75% national self-sufficiency in steel and would have saved an estimated $150 million in foreign exchange from reduced imports of foreign steel.

Titanium.—McLaughlin and Associates Ltd. sent black sand concentrates from Taurango on the east coast of the North Island to Australia for metallurgical testing.

Tungsten.—Small-scale scheelite mining continued at Glenorchy and Macrae's Flats in the southern part of the South Island, although no shipments were reported for the year. Production costs were high because of small, broken veins and difficult access and transportation.

NONMETALS

Asbestos.—Markets were sought for the very short fiber variety, which comprised a high proportion of deposits in the Upper Takaka area, Nelson District, at the northern end of the South Island.

Cassiar Asbestos Corp. Ltd. of Canada had withdrawn from the Pyke River-Little Red Hill area, Otago District, in the southern part of the South Island, but a new joint venture to continue investigations appeared probable.

Cement.—Production by Golden Bay Cement Co. Ltd. at Tarakohe, South Island, was down slightly, but New Zealand Cement Holdings Ltd. increased output by 6% at Cape Foulwind, also on the South Island, where a new kiln went into operation in July.

Clays.—A new grade of bentonite for use in oil well drilling was produced at Coalgate, South Island. Bentonite was also exported to Tasmania and Japan for use in iron ore pelletization.

Peat Wax.—The DSIR conducted research on solvent systems and extraction technology for montax wax from moorland peat beds on the Chatham Islands and from lignites in the central Otago area, South Island.

Phosphate.—Sea floor deposits of phosphorite nodules, 300 to 500 meters deep, were prospected in the Chatham Rise area, offshore west of the Chatham Islands.

Sand and Gravel.—Quarrying of sand and gravel for concrete aggregate, other industrial uses, roads, and ballast was New Zealand's principal mineral activity. Demand for aggregate was high, particularly for roads. Locally, existing quarries were depleted of good-quality aggregate materials. Quarrying efficiency was improved with new methods, new explosives, and new facilities. Secondary blasting was being replaced by drop hammers, the use of which reduced explosives consumption. In the Wellington area, new water recovery and re-use facilities were installed at quarries. Landsea Minerals Ltd. was granted prospecting rights to six areas offshore from the northern peninsula, North Island.

Stone.—Winstone Ltd. closed a large quarry at Whangarei, North Island, and reopened a nearby stone quarry (graywacke) at Otaika. Downer and Co. Ltd. was preparing a basalt quarry for production at Wiri and was phasing out a quarry at Roscommon.

Greenstone.—Recent production of greenstone for ornamental uses and the export market came from boulders in Olderog Creek, a tributary of the Arahura River, west coast, South Island. The boulders were reduced in size by diamond saw and transported by helicopter to processing areas.

Good quality greenstone was in short supply because of reduced gold-sluicing operations, which had been a major source.

Sulfur.—A separation process was under development at a sulfur-pumice deposit at Rotorau, North Island. Small production was derived from a pilot plant test operation.

MINERAL FUELS

In 1975 New Zealand imported 61% of the total energy it consumed. An energy conservation program, proposed by the Minister of Energy Resources in April, would reduce these imports to 20% to 30% by 1985, based on increased use of domestic coal and natural gas. The program also provided for interest-free loans for insulation, plans for improved insulation in government buildings, stricter insulation standards for new construction, 10-year loan financing to industry for costs of conversion from oil to coal-firing, increased use of public transportation, and reduced lighting and heating levels in government buildings. Shares of energy consumption, by consuming sector, were as follows: Industry, 39.1%; transport, 34.8%; residential and commercial, 24.6%; and nonenergy uses, 1.5%. Petroleum was the principal energy source, comprising 60.3% of total fuel consumption, followed by hydroelectric and geothermal (for electricity generation) (22.1%), solid fuels, mainly coal (14.7%), and natural gas (2.9%).

The Government acted to assume 50% State participation in any future energy resource development. Hydropower accounted for 85% of total electrical generation, although this source had substantial undeveloped potential. The Wairakei geothermal power scheme was capable of producing 130 megawatts, and the Broadlands Field had a generating potential of about 100 megawatts.

According to a report prepared by the Planning Committee on Electric Power Development, which forecast demand for electric power during 1975–90, growth in this demand cannot be met by existing conventional power sources, and nuclear power would probably be needed. The Committee recommended two 600-megawatt nuclear plants, the first of which would be operable by 1988, requiring a decision by 1978. Six possible sites on the North Island and one on the South Island were under consideration.

Coal.—Output, down 6% from 1974, was as follows, by type, in tons:

	Quantity
Bituminous	457,414
Subbituminous	1,818,530
Lignite	136,449
Total	2,412,393

There were 67 operating mines (71 in 1974), including 38 underground and 29 surface. About three-fourths of the mines were Crown operations; the remainder were small private operations. A number of mines were closed for various reasons—depleted reserves, safety, uneconomic—and new mines were opened.

Exploration drilling and trenching were underway in several districts. Most of the known coal reserves were in the Waikato-Taranaki District, North Island, the chief source of subbituminous coal. Large-scale exploration and development drilling were underway in the Waikato Valley to provide fuel for planned thermal power stations. The west coast, South Island, was essentially the only source of bituminous coal. The largest reserves of lignite were in the Otago-Southland District, South Island.

Productivity was increasing at the larger mines with increased mechanization and hydraulic mining. However, mining costs remained high, averaging $11.45 per long ton for underground mining and $5.60 per long ton for surface mining. Since investments in coal mine development had totaled only $25 million, a $27 million expansion program initiated in 1974, was a major boost to the industry. Production from Crown mines in the Huntly District, Waikato Valley, was expected to triple to more than 2 million tons per year, with three new mines (two underground, one surface). Underground development started in 1975. The mines will be fully mechanized, with continuous mining equipment and conveyor belt haulage to the Huntly power station, which was one of four large coal-fired thermal units planned on the North Island. The Huntly station, under construction in the new Huntly coalfield, will consume 500,000 tons of coal per year on one boiler in 1978 and more than 1 million tons per year by 1985. On the west coast of the South Island, a new coal-fired power station was also scheduled for operation in 1983.

In 1974, Ataki and Co. Ltd. (Japan), which had conducted coal exploration in New Zealand for several years, submitted a proposal for development and export of coking coal at Mount Davey, Greymouth area, South Island. In June 1975, the Government announced agreement in principle to a $17.7 million project for mining and shipment to Japan of 500,000 tons per year for a minimum of 15 years, subject to agreement on price, royalty, and other considerations. The coal would be hauled by conveyor belt system and rail to stockpiling and slurry shiploading facilities at Lyttleton, near Christchurch on the east coast. West Coast Resources Ltd. (Ataki 50%, New Zealand interests 50%) was established as the operating company.

Natural Gas.—Production continued to increase, with four new producing wells going into operation in the Kapuni gasfield, North Island. The Kapuni gas-processing plant was undergoing expansion. Kapuni gas consumption was mainly residential; small quantities were consumed by industry. Reserves were considered sufficient for 25 years.

The large, offshore Kaui gasfield, discovered 32 kilometers off the Taranaki coast, near Kapuni, in 1969, was under development to provide fuel for three power stations, under government contract starting in 1978. Condensate from the field was expected to supply 10% to 15% of the feedstock at the Marsden Point oil refinery. Natural gas reserves at Kaui were estimated at 5 trillion cubic feet of high-quality methane. In the $300 million first stage, the Shell Oil (New Zealand) Ltd.–Todd Oil Services Ltd. consortium, which had been developing the Maui Field since 1973, planned a production platform to deliver 600 million cubic feet per day and was laying gas and condensate pipelines. For the second stage, 1979–83, a second platform for 300 million cubic feet per day and additional pipelines were scheduled.

In October, the Minister of Energy Resources announced a more flexible gas-use policy, which would divert more Maui gas to domestic, commercial, and other industrial uses rather than unlimited use for electrical power generation. The National Gas Corp. was required to annually prepare a 5-year as well as a long-term development and marketing program.

Petroleum.—No crude petroleum was produced, but condensate production at the

Kapuni gasfield was substantially higher than that of 1974.

According to the Ministry of Mines, 61 petroleum prospecting licenses, comprising 622,311 square kilometers, both onshore and offshore, were operative at yearend. Geological and geophysical exploration was in progress in a number of areas, and drilling activity was increasing. For offshore drilling, two new rigs arrived in New Zealand waters during the year. Hunt International Petroleum Co. started drilling from the semisubmersible rig *Penrod 74* in February and planned a 2-year stay, including hiring by other exploration companies. Two wells were drilled for the Shell-BP-Todd consortium, 18 kilometers offshore from Taranaki, North Island, and in the Foveaux Strait, off the southern end of the South Island, near Stewart Island. The latter was in progress at yearend.

The offshore drill ship *Glomar Tasman,* owned by Global Marine Inc. of the United States, planned a stay of 1 to 1½ years after arriving at midyear. It completed dry wells offshore from Canterbury, east coast, South Island, and offshore from the Taranaki coast, North Island, and was drilling near Rugged Point, Stewart Island, at yearend. These wells were also drilled for the Shell–BP–Todd consortium.

Onshore, Republic Petroleum Corp. (New Zealand) Ltd., announced the purchase of a drill rig, which arrived at New Plymouth, North Island, in June and drilled two shallow wells in its Taranaki concession, which showed oil and gas indications.

The Petroleum Amendment Act of 1975, which rewrote and amended Part I of the Petroleum Act, became effective in September. It provided for greater government control over exploration and development, government participation in these and production operations, and stricter licensing procedures.

In March, the Minister of Energy Resources announced a plan to proceed with expansion of the Marsden Point refinery, New Zealand's only oil refinery, located on the east coast, northern peninsula, North Island, but details were not available at yearend. Ownership was divided as follows: Mobil Oil New Zealand Ltd. 19.2%, Shell Oil New Zealand Ltd. 17.1%, BP New Zealand Ltd. 15.1%, Caltex Oil (New Zealand) Ltd. 8.6%, Europa Oil (New Zealand) Ltd. 8.6%, and New Zealand public shares 31.4%.

The Mineral Industry of Nigeria

By Janice L. W. Jolly [1]

The importance of petroleum to Nigeria's economy in 1975 is revealed by the statistics: 92.8% of export value and about 47% of the 1975 gross domestic product, estimated at $25 billion.[2] Lower petroleum production in 1975, however, meant revenues fell short of the fund requirements previously projected for the development plan in 1975. The fall in production was attributed to declining world demand. Soaring labor costs, which added about 30% to the wage bill, a shortage and high cost of spare parts, and reduced metal prices all contributed to a difficult year for the mining industry. The shortage of spare parts was largely due to extreme port congestion, which reached a critical state toward yearend. By September 1975, 420 ships were waiting to enter Lagos port including a large number of cement vessels. The jam at Lagos harbor grew out of the purchase of 20 million tons of cement—at a cost of about $1 billion—with delivery stipulated to take place within a year. The tonnage was far in excess of port handling capacity. Inflation approached 50% in 1975 and continued at a similar rate through the first part of 1976. Inflationary pressures were traced to short supply of locally produced and imported goods, high prices of imports due to high foreign prices, higher freight rates, surcharges arising from port congestion, and domestic wage increases combined with low productivity.

Plans were being implemented to expand the industrial sector, requiring an outlay of nearly $10 billion to be allocated during the third development plan period (1975–80). Flaring of over 2 billion cubic feet of natural gas per day was to end with the construction over the next 5 years of two liquefied natural gas (LNG) and liquefied petroleum gas (LPG) facilities at Bonny and Escravos, costing together over $3.4 billion, by The Shell-British Petroleum Development Co. of Nigeria Ltd. (Shell-BP) and Phillips Oil Co. of Nigeria Ltd. and Nigerian AGIP Oil Co. Ltd. The Government was to hold a 55% equity in the two plants. Two new oil refineries were to be built for local use, each with 100,000 barrels per day capacity, one at Warri by Ente Nazionale Idrocarburi (ENI) and one at Kaduna. Capacity of the existing Port Harcourt refinery was to be expanded from 60,000 to 75,000 barrels per day, and two additional export-oriented refineries were to be built with a capacity of 300,000 barrels per day each. Other industrial projects already underway or planned included a $500 million petrochemicals complex at Port Harcourt; a $110 million nitrogenous fertilizer plant; a blast furnace complex at Ajaokuta; new or expanded power stations or generating units at Sapele, Afam, Delta, Eket, Kainji, Shiroro, Jebba, Gongola, and Ikom; expansion of cement plants at Ukpilla, Sokoto, and Calabar; expansion of the Enugu coal mine; and salt and superphosphates projects.

Mining activity of the third plan was heavily weighted toward petroleum. Approximately $3.2 billion was appropriated for petroleum out of the total $4.4 billion. Private mineral investment, estimated at nearly $2 billion, was also mostly petroleum oriented. With $118 million added for coal development, fossil fuel extraction was to consume nearly 97% of all allocations to the mining sector. Nonferrous mining and minerals development was expected to command more than $380 million in capital spending. Iron and steel development was slated for five times this investment level,

[1] Physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from Nigerian naria (N) to U.S. dollars at the rate of N1.00=US$1.62.

but was progressing more slowly. About $1.7 billion was earmarked in the plan for iron and steel projects.

Port development expenditures were expected to exceed the $350 million earmarked in the third plan. Port congestion loomed as the most severe transportation bottleneck threatening development progress. Port expansion was planned for Lagos/Apapa, Warri, Calabar, Port Harcourt, and Koko. More than one-fifth of all public outlays ($12 billion) was allotted for transportation improvements. The highway system was to get the greatest emphasis. The Federal and State Governments together were to undertake more than $7 billion in highway construction, with most of the activity scheduled in the first half of the plan period.

During 1975, the Federal Government awarded three airborne geophysical survey contracts. The areas to be covered were the Sokoto and Middle Niger region, the Chad Basin, and the Niger Delta and adjoining offshore areas. The three areas totaled about 396,000 square kilometers. Airborne magnetometers and airborne gamma ray spectrometers were to be employed during the survey. A report on a 144,500-square-kilometer survey of the north-central part of Nigeria completed by Hunting Geology and Geophysics of England was expected in early 1976. The area covered extended from the Niger border south towards Benue River and included the towns of Kano, Kaduna, Jos, and Zaria. Part of Hunting's contract included the training of Nigerian Geological Survey scientists in all aspects of airborne geophysics. The surveys were begun in late 1973. Complete coverage of Nigeria was the ultimate objective. The Geological Survey of Nigeria was calling for tenders for geochemical reconnaissance of certain parts of Nigeria. The Nigerian Mining Corp. (NMC) was investigating the Kigom molybdenite deposit, the Kogo tin-sphalerite lode, the Abakaliki lead-zinc deposit, and the Ilesha gold deposit.

PRODUCTION AND TRADE

Oil production declined from an average of 2.3 million barrels per day in 1974 to less than 1.5 million barrels per day by May 1975. Production had improved in the third quarter of 1975, and demand had improved sufficiently by the fourth quarter to enable Nigeria to successfully impose a price increase of more than the 10% agreed upon by the Organization of Petroleum Exporting Countries (OPEC). Crude oil production was 652.5 million barrels in 1975, down 20.9% compared with 823 million barrels produced in 1974.

Crude petroleum processed by Nigeria's only refinery, located at Alesa-Eleme near Port Harcourt, was about 19 million barrels in 1975. The Nigerian Petroleum Refining Co., Ltd. (NPRC), which operated the refinery, was owned 60% by Nigerian National Oil Co. (NNOC) and 40% by Shell-BP. NPRC accepted and processed crude on a fee basis from seven marketing companies including AGIP, BP, Esso Standard Nigeria, Ltd., Mobil Oil Nigeria, Ltd., Texaco Overseas (Nigeria) Petroleum Company, Total Oil Co. of Nigeria and the National Oil Marketing Co. (NOMCO) (formerly Shell Nigeria). The Government acquired a 60% interest in the Shell marketing company in April 1975 and the company's name was changed to NOMCO.

Tin and coal were Nigeria's principal mineral products after petroleum, but production of both declined in 1975. Nigerian tin production continued to decline for the seventh consecutive year, reaching the lowest level in 1975 since 1933. Total coal production for 1975 was 314,000 tons, about 13% more than in 1974. Slight production increases were recorded for cement, marble, and gold in 1975, but kaolin and columbite (a coproduct of tin mining) production decreased. Columbite production was 17% less than in 1974. Whereas tin prices weakened, columbite prices became firmer.

Total exports for 1975 were valued at $8.1 billion, compared with $9.4 billion in 1974. Petroleum exports were valued at $7.5 billion and tin exports at $28 million in 1975, compared with $8.9 billion (petroleum) and $29 million (tin) in 1974. Total imports (c.i.f.) for 1975 were valued at $6 billion. Nigeria and the German Democratic Republic signed a trade agreement on October 15, 1974, in which Germany was to buy crude oil and other minerals. On August 28, 1975, NNOC agreed to supply Senegal with 18.4 million barrels of crude annually. The 15-year contract was to begin January 1978.

The United States was taking a progressively higher proportion of Nigerian crude and less was being exported to Europe in 1975; demand in both areas was lower than in 1974. This shift in emphasis from European to U.S. markets for Nigerian crude was expected to continue because light low-sulfur, Nigerian crude commands a premium price at U.S. refineries designed to produce a high yield of gasoline.

COMMODITY REVIEW

METALS

Columbium and Tantalum.—With lower tin production, output of columbium concentrates, a coproduct of tin mining, fell to about 990 tons. Although tin prices weakened, columbite prices became firmer, $2 per pound of pentoxide for the first time in many years. The principal sources of columbite output were Bisichi-Jantar, Vectis Mines, and Amalgamated Tin Mines of Nigeria Ltd. (ATMN), with 381, 356, and 174 tons, respectively. Supplies to users were further obstructed by shipping congestion at Lagos, which reduced shipments to almost nil by yearend.

Gold.—Toward yearend 1975, arrangements were finalized for a geochemical survey to determine the presence of gold in the Ilesha area of Western State. Starting in January 1976, the initial survey was to be geochemical, followed by pitting and drilling. Exploration was to cover 382,000 square kilometers and extend to Birnin, Bwari, and Osi in North Central, North Western, and Kano States, respectively. Gold was not found in appreciable quantity in Nigeria, although small amounts were recovered from streams. Formerly the most important producing areas were in Niger, Zaria, and Sokoto areas, but the major part of output in 1975 came from the Ilesha and Oyo areas where stream sediment panning had been fairly extensive.

Iron and Steel.—The Government announced that the planned Nigerian iron industry would start production in 1985 with technical aid from the Soviet Union. The first meeting was held in March 1975 to discuss the Soviet preliminary report for the iron and steel project. Representatives of the Soviet export-import organization for steel industry construction projects, members of the French consulting firm SOFRASID, and Nigerian officials discussed the Soviet report. The Soviet recommendation for completion of all geological surveys before starting detailed plant design was rejected, and it was suggested that plant capacity be increased from the original 1 million tons per year planned, since current needs and the expected consumption growth rate were to require far more by 1985, the suggested year of startup. The blast furnace complex was to be erected in Ajaokuta in the Kwara State and was to initially produce 1 million tons of steel per year. Two direct reduction plants with a total capacity of about 1 million tons sponge iron per year were also to be constructed during the 1975–80 national development plan using abundant natural gas. Sites had not yet been selected. Nigerian planners estimated the country could absorb 3.2 million tons of steel annually by 1985—almost 2 million more than the blast furnace capacity.

The Nigerian Steel Development Authority announced that some 200 million tons of iron ore had been discovered in the Itakpe Hill area of Kwara State. The ore contains 37% to 41% iron as magnetite and hematite in a quartz gangue. Deposits with average iron content of 40% and 50% were also discovered at Agbaja near the confluence of the Niger and Benue Rivers, and at Enugu. Reserves of these ores were estimated at 30 million tons and 45 million tons, respectively.

Two Japanese companies were forming a joint venture with Nigerian and British interests for production of small-diameter welded pipes in Lagos. The company, called Standard Industrial Development, was to be capitalized for $17 million with 17% held by Mitsubishi Corporation and 10% by Kobe Steel, Ltd. The remaining 73% was held by Nigerian and British companies. The plant was to start up in 1977; the 1,000- to 1,200-ton monthly production of pipe was to be used in gas and municipal water supply projects. A scrap metal processing plant was to be established by the Lagos State Government, costing $4 million. The Nigersteel factory at Emene, in East Central State, which was destroyed during the civil war, was fully reactivated at a cost of $6.5 million. The annual output of the factory was estimated at 15,000 tons. An expansion scheme estimated to cost $64.8 million was to be started by Bendel Steel Structures Ltd., Warri, Midwestern State. The Nigerianization of existing foreign-controlled steel companies began. Pioneer Metal Products, a producer of galvanized sheets and largely owned by Japan's Marubeni Corp., agreed to increase local holdings to 40% and accept Nigerians as executives. Galvanized Industry, in which Yodogawa Steel Works, Ltd. and C. Itoh & Co., Ltd. of Japan had holdings, was to take in 20% Nigerian capital, later to be expanded to 40%.

Lead and Zinc.—Lead-zinc mineralization extends discontinuously for about 563 kilometers in a narrow belt in Ishiagu and Bende in East Central State and also in Bauchi Province in North Eastern State. The most important deposits were found in Abakaliki, where NMC had been exploring. As an incentive to miners, the Federal Government declared the mining of lead-zinc by underground methods to be a pioneer industry, thereby providing generous tax-free periods.

Tin.—Tin export control was in force throughout the year, but this had no effect on Nigeria's output because production did not reach the country's quota. Poor demand for tin on the world market was compounded by rising labor costs, labor scarcity, and rising power and production costs. A wage compromise arrangement was concluded between the Employers Association and the Trade Unions, enabling operators in the tin industry to stay in business. It was estimated that the increase in the wage bill during the year was $256,000 to ATMN after introduction of the Udoji wages award at the beginning of 1975. Nigeria's Makeri tin smelter was at a standstill early in 1975 as a result of a strike called in support of a 200% pay rise, following a management offer of 30%. Makeri Smelting Company Limited had 17,700 tons per year capacity.

A government organization, the NMC, continued its search for minerals throughout 1975 and explored the possibility of participation with established companies such as ATMN and the Makeri Smelting Co. A new 22-story headquarters building was being constructed for NMC, scheduled for occupation by mid-1978. NMC arrived at a settlement with Gold & Base Metals Mines of Nigeria Ltd. (GBMM) on the development of the Liruie lode in Kano State. The NMC was to be the largest shareholder in the new company, Ririwar Mines Ltd., with GBMM holding 20% interest. Mine development was to cost about $32 million, including a treatment plant for 900 tons of ore per day. During 1975, GBMM produced 383 tons of cassiterite and 9 tons of columbite. The latest ore reserve estimates for Liruie follow: Measured, 351,000 tons; indicated, 2,478,000 tons; and inferred, 3 million tons.

ATMN produced 2,604 tons of cassiterite during 1975 and 174 tons of columbite. The company purchased two bucket wheel excavators and about 2 miles of conveyor system costing more than $1.6 million. Delivery of the excavators was delayed by the backlog of ships at Nigeria's main port. Both excavators were to work tin deposits in the Sabon Gida area, about 150 feet deep, in conjunction with draglines to remove the overburden. The first tin ore from these operations was to be recovered by mid-1976. The operation would be the deepest opencast mining venture on the Jos Plateau.

United Tin Areas announced proved reserves on their plateau areas at only 40 tons of cassiterite, scarcely adequate for 6 months' production. The company disposed of more than half of its mining leases to Vectis Mines and ceased columbite production.

NONMETALS

Cement.—Nigeria had six cement factories: The Calabar Cement Co. at Calabar in South Eastern State; the West African Portland Cement Co. (WAPC) at Ewekoro in Western State; Lagos Cement Works; the Cement Co. of Northern Nigeria Ltd. at Sokoto; Nigerian Cement Co. Ltd. at Nkalagu in East Central State; and a plant at Ukpill in Mid-Western State. Their entire production did not exceed 1.4 million tons, including 750,000 to 800,000 tons from Ewekoro and 500,000 tons from Nkalagu. Extensions for the plants at Sokoto and Calabar were in progress and were to enable them to attain total production of about 1 million tons for both by 1978. The Nigerian Cement Co. at Nkalagu awarded a $9.7 million contract to Costain West Africa Ltd. for an extension to the plant there. This was part of a $43.7 million expansion planned by the company to step up its present production by 50% to 750,000 tons annually. New cement plants planned or started also included one at Ashaba with WAPC; one at Yandei with the Swiss group Cementia; and one at Shegamu with the Industrial investment and Credit Corp., the Government of Western State, and WAPC. The whole of these operations was to provide supplemental production of 1.8 million tons to Nigeria, each with a capacity of 600,000 tons per year. The foundation stone for the $96 million cement plant at Shagamu was laid in July 1975. The cement complex was situated at Kilometer 64 on the Lagos-Shagamu road. Production was to start in

1977 with about 1,500 people employed. An asbestos cement plant with 30,000 tons annual capacity was inaugurated in March 1975 in Oron, South Eastern State, by the Italian firm Technimpianti.

The Government had ordered 20 million tons of cement in 1975 to be delivered within 12 months. At a rate of 1.6 million tons per month, the import shipments proved to be more than twice the unloading capacity of all of Nigeria's ports combined. The massive orders led to an armada of ships anchored off Lagos; by September 1975 more than 420 freighters were waiting. Some ships waited for 8 months to a year. The cement lost its binding quality after 6 months and became worthless for construction; even so, millions of tons of the ruined cement found its way to small contractors. Estimates were that as much as half the cement went bad. It was widely speculated that in 2 or 3 years buildings might collapse as a consequence. Ironically, by 1976, shortages of cement were reported and the price rose 30%. The economic repercussions of clogging at the ports were severe in closing down factories that could not get parts, in preventing vital exports, and in feeding the inflation rate.

Clays.—About 2.7 million tons of clay was discovered at Awkunanaw near Enugu in March 1974.[3]

Fertilizer Materials. — *Phosphate.* — A study was to be made of the phosphate deposits of southwestern Nigeria, which are an extension of the Togo phosphates. The total cost of all exploration programs to be undertaken by the Nigerian Government and specialist groups was estimated at $15 million. Hunting Geology and Geophysics and Polservice (Pologne) were to participate in geophysical studies. In 1975, Nigeria had no fertilizer production facilities of its own, but an 18,000-ton-per-year P_2O_5 single-superphosphate plant was nearing completion at Kaduna in Central North State. The plant was being financed and built with Japanese aid and was to utilize phosphate rock from Togo. Fertilizers were heavily subsidized by the Nigerian Government, up to 70% of the total cost, but supply was restricting consumption. Fertilizers were procured by the State Governments, and the poor distribution system within the country was probably the major problem hindering efficient supply.

Stone.—*Limestone.*—A reserve of about 32 million tons of limestone was reported in the Lokoja area of Kwara State.

MINERAL FUELS

Coal.—The main coal mines were at Enugu in East Central State, but a new mine was opened in Okabba in Kwara State in 1974. The Nigerian Coal Corp. (NCC), a Government organization responsible for the mining and distribution of coal, announced the possibility of a new coalfield near Lafia in Benue Plateau State. It was reported that the estimated reserves near Lafia were in excess of 100 million tons. The coal had a relatively high sulfur and ash content and would require considerable dressing before coking. The main consumers of coal were the Railway Corporation, the Electricity Corporation of Niger, the Nigerian Ports Authority, cement companies, and firms operating river boat fleets. An $8 million contract for the sale of 2.5 million tons of coal for export was signed in July 1974 between the NCC and an indigenous company, the United National Co., Nigeria Ltd., Lagos.[4]

Coal reserves were estimated at about 245 million tons. Consideration was being given to establishing a chemical industry based on coal or lignite. Carbonization tests have revealed a high yield of tars and oils. Promising lignite for development occurs on both sides of the River Niger between Okpanam in the Benin area and Nnewi in the Onitsha area. Reserves of 71 million tons were indicated in Benin by drilling.

Petroleum.—Only OPEC's African members Algeria, Libya, and Nigeria showed a decrease in per-barrel revenues in 1975. Estimated Nigerian Government oil revenue was approximately $6.6 billion for 1975, compared with $8.9 billion for 1974, a decrease of 26%.[5] The fall in petroleum production experienced in 1975 was attributed to declining world demand and to a policy of production conservation. It was also argued that Nigerian crude was overpriced in relation to other OPEC oil of similar quality. Demand had so improved by the fourth quarter of 1975 that Nigeria felt confident in raising its price by more than the 10% agreed upon by OPEC in Oc-

[3] Daily Times of Nigeria Ltd. (Apapa, Nigeria). Nigeria Yearbook 1975, November 1973 to October 1974, p. 21.
[4] Page 36 of work cited in footnote 3.
[5] Petroleum Economist (London). Estimated Oil Exports and Revenues of Main OPEC Countries. V. 43, No. 9, September 1976, p. 338.

tober. The Government's across-the-board price for its 55% of Nigerian oil production (buy-back oil) reached $12.75 per barrel, the highest in OPEC for that grade of oil. Earlier in 1975, troubled by persistent decline in crude oil production and exports, and the consequent erosion in oil revenues, the Nigerian Government had moved to make its crude more competitive by reducing its direct sale (to buyers who did not produce oil in Nigeria) and buy-back prices by 20 cents to $11.40 per barrel for 34° gravity crude. The income tax rate on equity crude (producers' remaining 45% of production) was also raised to 85% from the previous 65.7%, while the royalty rate was increased to 20% from 16-2/3% in April 1975. By yearend 1975, in two separate moves, the Government had increased oil revenues, pushing up the average buy-back price by about 38 cents per barrel. By increasing selling and posted prices, the Government reduced company profit margins from 50 cents to 30 cents per barrel, bringing them closer to Middle East levels. Producing companies claimed that the increases would bring cash-flow problems, pointing out that the investment per barrel of production is higher in Nigeria than in the Middle East. The posted price for the first quarter of 1976 was to be $13.709, raised from $13.071 per barrel for 34° gravity crude. The Government also imposed restrictions on credit terms extended to oil producing companies, which had a 90-day credit on buy-back oil. The companies were being given 60 days' credit from the date of loading and asked to pay an additional 10 cents per barrel should they require a further 30 days' credit.

While the Government was successful in raising the price in late 1975, the producing companies considered the margin allowed per barrel too low in the face of inflated capital costs to justify large new investments and substantially reduced their exploration activities. Drilling rigs in operation declined gradually but steadily all year from 27 at the beginning of 1975, and many were taken out of the country by yearend. By 1976, drilling rigs in operation were down to 15, and Japan Petroleum Co. (Nigeria), Ltd., canceled one rig in spite of stiff penalty payment clauses. Occidental Petroleum Nigeria's entire investment in Nigeria was written off in 1975. After a number of unsuccessful attempts to negotiate an arrangement whereby the firm's discovery on oil prospecting license 90 could be economically developed, Occidental relinquished interest in this block and wrote off the remaining oil investment of approximately $33.3 million. Three other Nigerian offshore exploratory blocks had been relinquished in 1974.

All exploration rights not already allocated were reserved for NNOC, giving it almost a third of offshore concessions. NNOC was also entitled to drill in deep water outside existing concession areas and owned some onshore rights. Including NNOC, 14 companies were prospecting for oil. The others were Nigerian Agip Oil Company, Limited; Gulf Oil Company (Nigeria) Limited; Mobil Producing Nigeria, Phillips Oil Company (Nigeria) Ltd.; Safrap (Nigeria); Shell-BP Petroleum Development Co. of Nigeria Ltd.; Tenneco Oil Company of Nigeria; Ashland Oil Co. (Nigeria); Deminex (Nigeria) Ltd.; Japan Petroleum Company (Nigeria) Ltd.; Pan Ocean Oil Co., Ltd.; Texaco Overseas (Nigeria) Petroleum Company Ltd.; and Henry Stephens and Sons Ltd. (owned by Chief Fajemirokun). Some were in partnership: Phillips was in partnership with Agip; Pan Ocean with Delta; Texaco with Tenneco; and Ashland with NNOC. In January 1975, a petroleum deposit of apparently high quality was discovered in West Central State by the Mobil-Tenneco-Sun Oil consortium. An onshore strike in midwestern Nigeria was also reported by Pan Ocean. The well, Ogharefe No. 3, tested 14,674 barrels of oil and 16.5 million cubic feet of gas per day from three separate zones between 9,830 and 10,350 feet. The gravity of the oil ranged from 43° to 45° API with a negligible sulfur content. The well was located 32 kilometers south of Benin City in Mid-West State.

Through NNOC, the Government held a 55% share in the Nigerian operations of Shell-BP, Gulf, Mobil, Agip-Phillips, Essence et Lubrifiant de France (ELF) and Texaco, the main producer companies. Ashland Oil, which began production in June 1975, was the only company operating under a production-sharing contract with NNOC, representing the startup of NNOC's "own" oil production. Ashland began production from its onshore Izombe oilfield at an initial rate of 10,000 barrels per day and had a target of 20,000 barrels per day by the end of 1975. Ashland was to recover costs from a portion of production, and the remaining production up to 50,000 barrels per day was to be split 65%–35% in favor of NNOC. The split was to increase to 70%–30% on production over 50,000 barrels per day. The field was found in early 1974, located in Block OPL 118 in the Oguta division of East Central State. Oil from Izombe was produced from six wells through a flow station into the 10-inch Izombe-Ebocha pipeline to the Brass River coastal terminal. Ashland was drilling a wildcat in an offshore production contract area. Texaco increased production sharply to 9,210 barrels per day in November 1975. Texaco/Chevron's offshore fields were suspended from production of Government orders in May 1974, pending outcome of negotiations which were held through much of 1975 to give a 55% participation to the Government. The company expected to be producing 20,000 barrels per day by yearend 1975 and to reach 50,000 barrels per day in 1976.

Seven foreign-owned oil companies marketed all refined petroleum products consumed locally except for LPG. An agreement giving the Government majority interest (60%) in Shell Nigeria was negotiated. The new company was called National Oil Marketing Co. and had legal authority to market petroleum. The only refinery in Nigeria was owned and operated by Nigerian Petroleum Refining Co. Ltd., which was owned 60% by the Government, 20% by BP, and 20% by Shell. The Government has determined that future refineries will be 100% Government-owned, although others may operate them.

Nigerian gasoline consumption soared almost 30% in 1974 to 20,000 barrels per day. Gasoline shortages have become a chronic problem. Notable disruption of petroleum supplies occurred throughout the country over much of 1975. Domestic marketing of oil products was chaotic despite efforts by the marketing companies and some emergency actions by Government. Striking truck drivers caused a shortage of petroleum products in mid-January, and Nigeria's only refinery was shut down for maintenance throughout February. The problem of supply was compounded by smuggling (since the controlled price in Nigeria was lower than in neighboring countries), hoarding, and profiteering. Transport fares and haulage prices also soared. The Government outlined immediate short-term measures to arrest the shortages and commissioned a team of experts to find the cause or causes of frequent fuel shortages. Minirefineries, able to handle 5,000 barrels of oil per day, were to be set up, and oil storage facilities were to be built throughout the country. A $6 million contract was signed with Norway's Det Norsek Oljeselskap (Texas subsidiary, Val Verde Corp.) for two portable minirefineries to go into operation by mid-1976. The capacity of the Port Harcourt refinery was to be expanded to 75,000 barrels per day by the installation of a skid-mounted mobile distillation unit capable of refining 20,000 barrels of crude per day. Other measures included the construction of new jetties and the expansion of existing ones to handle the offloading of larger quantities of imported petroleum products and an increase in the fleet of road tankers. There were also indications of other refining and pipeline contracts being privately negotiated on a crash basis to accelerate projects to solve the distribution problem.

The Government approved establishment of two LNG/LPG gas plants with capacity of 1 billion cubic feet per day each; they were expected to cost over $2 billion each. These were first introduced during the second development plan, but were expected to be implemented during the third plan. One would be built at Bonny (Rivers State) and would have Shell/BP as the Government's partner. The other would be built either on the southern bank of Escravos River in Mid-West State or in some other more suitable locality and would incorporate an ethylene complex with Phillips and AGIP as partner. The Federal Government would have 60% participation in each plant and 50% in the LNG tanker fleet. The Government would establish, own, and operate an integrated gas-gathering company to serve all gas projects.

The third development plan included a $486 million investment in a petrochemical complex near Port Harcourt. The following capacities were tentatively recommended,[6] pending negotiations: Ethylene 100,000 tons per year; caustic soda, 40,000 tons per year; vinyl chloride, 40,000 tons

[6] European Chemical News (London). ECN New Projects. V. 27, No. 691, June 20, 1975, p. 18.

per year; PVC, 40,000 tons per year, and polyethylene, 40,000 tons per year. The ethylene plant was planned for expansion in the future to 250,000 tons per year. It was also recommended that a 1,400-ton-per-day ammonia plant and a 10,500-ton-per-day methyl fuel plant be incorporated into the complex. Production was expected to begin by 1978. A nitrogenous fertilizer facility was also planned utilizing gas. Plans called for producing 450,000 tons per year of ammonia and 260,000 tons per year of urea. These plants were to be situated near the Port Harcourt complex and were to utilize tail gas to supplement the natural gas feedstock. A completion date of 1977 was hoped for project completion. Scientific Design of the United Kingdom signed a contract to act as consultant, and approximately $113 million was to be spent on the two projects. Two new oil refineries were to be established at Warri and Kaduna with capacities of 100,000 barrels per day and 70,000 barrels per day, respectively. The Warri refinery was to include catalytic cracking facilities and an aromatics separation unit. In addition, two export-oriented refineries each with 250,000 barrels per day capacity were to be built.

The Mineral Industry of Norway

By Joseph B. Huvos [1]

In 1975, Norway, with its sizable hydroelectric resources, continued as one of the world's major producers of aluminum, magnesium, and ferroalloys. Owing to recent North Sea discoveries, Norway was also on its way to becoming one of Europe's major oil producers. The most important mineral products of the country, with approximate percentages of world totals, were as follows: Ilmenite (20), magnesium (16), nickel (6), cobalt (4), aluminum (5), and pyrite (3). Production of other metals, minerals, and fuels, important only to the national economy, included copper, pig iron, steel, lead and zinc, vanadium, sand and gravel, cement, feldspar, fertilizer materials, nepheline syenite, quartzite, sulfuric acid, and some coal and peat.

In 1975, Norway's gross national product (GNP) was about $27 billion.[2] Of this total, the oil and coal industries contributed about $1 billion; the iron, steel, and ferroalloy industries, $850 million; nonferrous metals, $1.2 billion; and nonmetallic minerals, $500 million. Out of a total mining and industry employment of about 400,000 persons in 1975, the iron, steel, and ferroalloy industries employed about 16,000; the nonferrous metal industry, 13,000; the mineral-product industry, 9,000; and the petroleum and coal industries, about 2,000.

Norwegian mining companies have been affected to varying degrees by the current international recession and higher oil prices, depending on the commodities produced. Most affected by market conditions were production of cupriferous pyrites and ilmenite. Iron ore and pellet production have profited from recent price rises. Most other mineral products were subject to little change. On balance, the mining industry production index increased about 1%.

The bulk of Norway's mining production is exported to West European countries. Main import items were bauxite and alumina, mostly from Surinam and Guinea; nickel matte from Canada; coal and coke from various sources; and crude oil or products from the Middle East and West European countries.

There were a number of significant developments in 1975. New mining capacity came onstream at Titania A/S, Hauge I Dalane ilmenite mine in the north of the country. Work also continued on the expansion of the company's Frederikstad pigment plant on Oslo Fjord. In the petroleum industry, production started at the 4-million-ton-per-year Mongstad refinery in Karmøy, West Norway. The 350-kilometer pipeline from Ekofisk to Teeside, England, started to carry oil. Development drilling began in the West Ekofisk area. Norway also became a net exporter of oil and petroleum products in 1975.

Norwegian oil policy aims at increasing state control and intervention in all phases of petroleum activity; following this policy, the Government concluded an agreement to purchase British Petroleum's Norsk Braendselolje A/S, a production and distribution subsidiary, in 1975 and carried out a number of other minor purchases.

The Government also purchased the DNN Aluminium A/S, 25,000-ton-per-year Tyssedal reduction plant and approved a 25% excess profit tax on oil and gas products.

[2] Where necessary, values in Norwegian kroner (NKr) were converted to U.S. dollars at the rate of NKr5.2269=US$1.00 for 1975 and NKr5.542=US$1.00 for 1974. Source of conversion rate for 1974 and 1975 was International Monetary Fund.

PRODUCTION

The following tabulation shows preliminary indices of production for various sectors of the mineral industry:

Industry sector	(1970=100)	
	1974	1975
Mining and quarrying:		
Coal mines	94	84
Metal mines	106	111
Other mining and quarrying [1]	108	117
Manufacturing:		
Iron, steel, ferroalloys	120	122
Nonferrous metals	125	110
Ceramics, glass, glassware	118	105
Chemical raw materials	119	108
Refining of petroleum and coal	112	130
Electric power	133	133

[1] Includes production of crude oil and natural gas.

[1] Excludes nepheline syenite.
[2] Excludes a quantity of stone only reported volumetrically as: 1973—4,722,646 cubic meters; 1974—4,525,996 cubic meters; and 1975—NA.

TRADE

In 1975, Norway continued to run a trade deficit. However, the increasing Norwegian production of crude oil is expected to generate a trade surplus in 1976.

Nonferrous metals (mainly aluminum and nickel), ferroalloys, rolled steel, and liquid fuels were again major export items in 1975 and accounted for about three-quarters of the total value of all mineral commodity exports. Imports of liquid fuels, iron and steel, basic chemicals (mainly alumina and aluminum hydrate), and metallic ores (mainly nickel-copper matte) accounted for approximately four-fifths of the mineral commodity imports in 1975.

Trade in mineral commodities in 1973 and 1974 is detailed in tables 2 and 3.

Table 2.—Norway: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal destinations, 1974
METALS			
Aluminum:			
Alumina	100	9	Mainly to Switzerland.
Metals including alloys:			
Scrap	8,941	12,805	West Germany 6,137; Sweden 2,083; Netherlands 1,235.
Unwrought	576,131	554,513	West Germany 129,871; United Kingdom 127,629; Netherlands 53,846.
Semimanufactures	54,937	40,688	Sweden 11,079; United Kingdom 8,467; Denmark 7,702; Finland 4,079.

Arsenic	(1)	--	
Cadmium	80	59	NA.
Chromium oxide and hydroxide	1	1	NA.
Cobalt	723	1,172	NA.
Copper:			
Ore and concentrate	63,841	52,964	West Germany 25,284; Sweden 15,905; Finland 6,165.
Oxide and hydroxide	2,166	2,173	Taiwan 34; Finland 20.
Copper sulfate	--	--	
Metal including alloys:			
Scrap	1,076	2,152	Belgium-Luxembourg 766; West Germany 749; Sweden 263; United Kingdom 224.
Unwrought:			
Unrefined	7,633	6,290	West Germany 5,520; East Germany 720.
Refined	26,796	25,777	Sweden 4,104.
Semimanufactures	3,186	1,955	Sweden 1,008.
Gold metal, unworked or partly worked troy ounces	3,569	2,154	Denmark 1,157; West Germany 418; United Kingdom 386.
Iron and steel:			
Ore and concentrate, except roasted pyrite thousand tons	2,988	2,657	West Germany 1,217; United Kingdom 873; Poland 281.
Roasted pyrite	174,524	152,508	West Germany 134,518.
Metal:			
Scrap	24,538	34,446	Spain 20,140; West Germany 7,825; Sweden 6,460.
Pig iron including cast iron	140,167	121,301	United Kingdom 41,129; West Germany 21,860.
Ferroalloys:			
Ferromanganese	225,254	309,365	United Kingdom 74,534; West Germany 58,854; Sweden 41,642.
Other	472,169	527,408	West Germany 140,072; United Kingdom 109,793; Belgium-Luxembourg 46,085.
Steel, primary forms	231,248	212,460	Netherlands 140,684; Denmark 40,396; West Germany 19,971.
Semimanufactures:			
Bars, rods, angles, shapes, sections	244,030	193,475	Sweden 42,227; United Kingdom 42,204.
Universals, plates, sheets	102,061	129,461	Sweden 64,689; Denmark 19,122.
Hoop and strip	3,563	8,463	Sweden 5,023; Denmark 3,290.
Rails and accessories	1,259	975	Spain 600; Sweden 213; Finland 144.
Wire	10,947	8,769	United Kingdom 1,398; Portugal 1,205; Switzerland 775; Iran 746.
Tubes, pipes, fittings	36,599	33,244	Sweden 1,151.
Castings and forgings, rough	12,763	14,002	Sweden 10,649; Denmark 1,847; Liberia 1,406.
Total	411,222	388,389	
Lead:			
Ore and concentrate	6,533	6,015	Netherlands 5,648.
Oxides	12	26	Libya 10; Japan 10; Thailand 6.
Metal including alloys:			
Scrap	4,554	4,748	Denmark 2,748; Sweden 1,558.
Unwrought	520	366	Sweden 121; France 100; Denmark 75.
Semimanufactures	212	164	Mainly to Sweden.

See footnotes at end of table.

Table 2.—Norway: Exports of mineral commodities—Continued
(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal destinations, 1974
METALS—Continued			
Magnesium metal including alloys:			
Unwrought ---- value, thousands --	$31,502	$45,311	NA.
Wrought	196	260	Netherlands 143; Sweden 108.
Manganese ore and concentrate	3,030	1,831	Sweden 1,020; United Kingdom 811.
Mercury ---- 76-pound flasks --	464	58	Mainly to Denmark.
Molybdenum:			
Ore and concentrate	218	--	
Metal including alloys, all forms	(1)	1	Mainly to Austria.
Nickel:			
Ore and concentrate	11,535	13,515	All to Finland.
Matte, speiss, and similar materials	2	--	
Metal including alloys:			
Scrap	240	309	West Germany 247; United Kingdom 27.
Unwrought	43,254	43,810	United States 15,807; West Germany 6,657.
Semimanufactures	1	13	United States 8; Denmark 3.
Platinum-group metals and silver:			
Waste and sweepings - kilograms --	52,421	57,051	West Germany 39,104; United Kingdom 13,875; Sweden 8,358.
Metal including alloys:			
Platinum-group metals troy ounces --	38,742	30,833	United States 17,329; Netherlands 6,302; West Germany 3,151.
Silver ---- do ----	668,188	862,443	Sweden 663,337; Denmark 166,187.
Rare-earth metals:			
Oxides	4	8	Mainly to United States.
Metals including alloys, all forms ---- value --	$172	--	
Silicon, elemental	55,742	63,931	United Kingdom 15,888; U.S.S.R. 14,533; West Germany 13,997; United States 7,471.
Tin metal including alloys:			
Scrap	39	54	United Kingdom 34; Denmark 20.
Unwrought	223	284	Sweden 237; Finland 39.
Semimanufactures	7	8	Finland 6.
Titanium:			
Ore and concentrate (ilmenite)	684,660	776,814	NA.
Oxides	1,226	900	Sweden 623; Denmark 191.
Tungsten metal including alloys, all forms ---- value --	$1,548	$3,339	Mainly to West Germany.
Uranium and thorium metal including alloys, all forms ---- do ----	$19,608	$28,882	Mainly to Denmark.
Zinc:			
Ore and concentrate	14,888	20,488	Poland 8,362; Netherlands 7,352; Belgium-Luxembourg 4,774.
Oxide	923	560	Sweden 317; Denmark 205.
Metal including alloys:			
Scrap	133	371	Sweden 125; West Germany 116; France 91.
Blue powder	2,899	459	NA.
Unwrought	67,387	55,238	Sweden 22,062; United Kingdom 16,702; West Germany 6,868; France 4,848.
Semimanufactures	597	873	Sweden 317; Netherlands 102; Denmark 91; West Germany 88.
Other:			
Ash and residue containing nonferrous metals	6,691	22,932	West Germany 11,145; United Kingdom 3,351.
Oxides, hydroxides and peroxides of metal, n.e.s	21	2	NA.
Metal including alloys:			
Metalloids, n.e.s	11	10	United States 7.
Pyrophoric alloys, value, thousands --	$2	$3	NA.
Base metals including alloys, all forms, n.e.s	33	23	West Germany 8.
NONMETALS			
Abrasives, natural, n.e.s., grinding and polishing wheels and stones	1,079	1,140	Sweden 238; Poland 209; Finland 206; Iran 63.
Asbestos	1	73	Mainly to Sweden.
Barite and witherite	52	75	Do.

See footnotes at end of table.

COMMODITY REVIEW

METALS

Aluminum.—In 1975, five companies smelted mainly imported alumina in eight primary aluminum reduction plants with a total capacity of about 690,000 tons per year:

1. A/S Årdal og Sunndal Verk (ÅSV), owned 75% by the Norwegian State and 25% by Alcan Aluminium Ltd., Canada, operated a 175,000-ton-per-year plant at Årdal, on the Sognefjord; a 120,000-ton-per-year plant at Sunndalsøra, southeast of Kristiansand; and a 30,000-ton-per-year plant at Hoyanger, also on the Sognefjord.
2. Norsk Hydro A/S, Oslo, owned 51% by the Norwegian State and 49% by diverse other companies, operated a 120,000-ton-per-year plant at Karmøy, south of Haugesund.
3. Mosal Aluminium A/S, owned in equal parts by Elkem-Spiegerverket A/S, Oslo, and the Aluminum Co. of America (Alcoa), operated a 100,000-ton-per-year plant at Hosjoen, near Frederikstad, and a 50,000-ton-per-year plant at Lista, west of Mandal.
4. Sør Norge Aluminium A/S operated a 70,000-ton-per-year plant at Husnes, near Skanevik.
5. DNN Aluminium, owned in equal parts by Alcoa and British Aluminium Ltd., operated the 25,000-ton-per-year Tyssedal plant.[3]

In 1975, the Norwegian parliament approved the purchase of DNN Aluminium by the Norwegian State for $35 million from its present owners. Rights to hydroelectric power for the plant were also purchased.

The Norwegian Government was moving ahead with plans to use North Sea oil revenue to restructure the country's aluminum industry, with the emphasis placed on producing prefabricated and processed products rather than exporting primary metal. A 10-year diversification program was developed by the Ministry of Industry, providing for heavy capital investments in both production and marketing facilities by the three state-controlled aluminum companies of Norway.[4]

Copper, Lead, and Zinc.—In 1975, 9 companies operated 10 major mines producing complex sulfide ores. Lately a surplus of pyrite concentrates has caused a change in ore-dressing trends and, in 1975, most copper was produced as copper concentrate instead of cupriferous pyrite.

Much of the copper concentrate produced was exported to West European countries; only a small share of the total was fire-refined or converted to cathodes at the Kristiansand refinery of Falconbridge Nikkelverk A/S.

According to the Norwegian Ministry of Commerce, export restrictions on nonferrous metal scrap and waste, excluding lead and zinc, remained in effect in 1975. Licenses were not granted if there was a domestic buyer at the prevailing market price.

Iron Ore.—In 1975, four companies operated one iron ore mine each. Norway's known reserves of iron ore, with an Fe content exceeding 30%, are estimated officially at 800 million to 1,000 million tons, of which about 300 million tons are accessible by surface mining.[5]

Among the individual companies involved in iron ore mining was A/S Sydvaranger, holder of the Bjørnevatn mine, the largest in the country. The mine, located 5 miles south of Kirkenes, accounted for 14 million tons of ore and rock excavated. The ore was processed into 2.3 million tons of iron ore pellets. However, the pellet plant's capacity exceeds mining capacity at the mine. Therefore, the company plans to increase its mining capacity in the next 4 to 5 years to cover pellet capacity. In the meantime, there are plans to import a total of 300,000 tons per year of iron concentrate from the U.S.S.R. (shipped via Murmansk), if an earlier trial shipment of 10,000 tons proves suitable for pelletizing.

Sydvaranger has applied to the Norwegian Ministry of Industry for an allocation of natural gas from the Ekofisk gasfield in the North Sea to supply a direct-reduction plant it plans to set up at Emden, West Germany. The 1.5-million-ton-per-year plant, to become operational by 1980, is to cost $35 million. Korf Industrie und Handel and Sydvaranger

---

[3] Aluminium (Düsseldorf). V. 51, Nov. 12, 1975, p. 806. Engineering and Mining Journal. November 1973, p. 130.

[4] American Metal Market. Oct. 31, 1975.

[5] U.S. Embassy, Oslo, Norway. State Department Airgram A-201, Nov. 12, 1974, p. 1.

have joined forces for this project. At another project, Sydvaranger has applied to the Ministry of Industry for supplies of 350 million cubic meters of natural gas from the Frigg gasfield, to be landed at Karmøy Island, West Norway, for eventual direct reduction of one-half of Sydvaranger's iron ore production into prereduced pellets with an Fe content of 92% to 93%. For this purpose, Sydvaranger has taken over production facilities and land holdings of Vignes Kobberverk near the planned landing site for Frigg gas on Karmøy.

Elsewhere, A/S Norsk Jernverk, a wholly-owned subsidiary of the Norwegian State, operated the nation's second-largest iron ore mine at Rana near Mo. About 2.3 million tons of hematite and magnetite ore was produced; total material mined, including overburden, was about 10 million tons. Work continued also at Rana on the Ortfjell ore body. Open pit production from Ortfjell is scheduled to begin in 1976 and is to provide the bulk of Rana ore by 1980. Proven reserves were estimated at 150 million tons averaging 32% Fe (including 4% in the form of magnetite).

Other Norwegian iron ore production included 100,000 tons of magnetite concentrate at the Elkem-Spigerverket A/S Rødsand mine, and 1.1 million tons of ore yielding 500,000 tons of magnetite concentrate and 5,000 tons of flotation pyrites from a 1,170-meter-deep shaft at the Fosdalens Berkwerks-AB Malm mine located on the Trondheimsfjord.

Iron and Steel.—In 1975, Norway had three major steelmaking companies. The state-owned A/S Norsk Jernverk operated the Mo-I-Rana plant, the largest in the country. Pig iron capacity was 600,000 tons per year, to be increased to 650,000 tons per year; steel capacity was 800,000 tons per year. There were six electric ironmaking furnaces, two 40-ton oxygen converters, three 80-ton electric arc furnaces, and a steel rolling mill. Raw material was domestic iron ore.

Norway's second-largest steelmaker was the Hydalen plant of Elkem-Spigerverket. The minimill-type operation uses mainly local scrap fed preheated into two arc furnaces. Capacity was 175,000 to 185,000 tons per year, mostly low alloy or carbon steels. Elkem-Spigerverket also operated four smaller plants including those of Stalogttau in Tønsberg, Mandal, and Stavanger, and that of Sinterco in Larvik.

Ferroalloy production was a major part of the Norwegian metals industry. There were 14 ferroalloy-producing units in the country, 8 for ferrosilicon, and the rest for ferromanganese and other special alloys. A typical example of a ferrosilicon-production unit is the Salten Verk of Elkem-Spigerverket, near Bodø, north of the Arctic Circle. The plant produces 80,000 tons per year of 75% ferrosilicon. Power supply is by a private 110-megawatt hydroelectric station.

Magnesium.—Norway's entire magnesium output came from the Norsk Hydro A/S plant, Porksgrunn Fabrikker, at Herøya in Telemark. Capacity of the plant was about 38,500 tons per year of primary metal from seawater and magnesite. Work continued at Herøya on construction of a new anhydrous magnesium chloride plant providing raw material for the production of 15,000 tons of magnesium. Construction continued at Sørford, Nordland, on a 200,000-ton-per-year magnesia plant based on local magnesite. Both plants are to be completed by 1977.

Nickel, Cobalt, and Platinum-Group Metals.—The Kristiansand refinery of the Falconbridge Nikkelverk continued to account for all Norwegian production of refined nickel, cobalt, and platinum-group metals as well as all refined copper. Production was based principally on nickel-copper matte imported from Canada and small amounts of sulfide concentrate produced as a byproduct of processing ilmenite ore at Tellnes, West Norway. The operating rate at the refinery at Kristiansand was reduced in August because of a strike at the Sudbury, Canada, operations and was maintained at about two-thirds normal capacity for the remainder of the year in response to lower demand.

Titanium.—Titania A/S, a subsidiary of N. L. Industries, Inc., U.S., accounted for over 99% of Norwegian production of ilmenite. Substantial additional capacity came onstream at the Hauge I Dalane ilmenite mines in the north of the country in 1974, allowing for an increased ilmenite output potential after 1975. Titanium-pigment production capacity at the Frederikstad pigment plant was in the process of being expanded from 20,000 tons to 25,000 tons per year. However, about four-fifths of the ilmenite concentrate produced in the country was exported.

NONMETALS

Cement.—In 1975, A/S Norcem, the only producer, operated three cement plants and employed about 3,000 persons. Two plants were located at Brevik and Slemmestad in the south of the country near large markets, and there was a small plant at Kjøpsvik in the north. Products included oil well cement, for which demand has been growing because of North Sea oil developments. Norway's cement exports went mainly to the United States and West Africa. Norcem built silos for 33,000 tons of cement in New York City, and has encouraged the building of special bulk carriers for transporting cement.

Other Nonmetallic Minerals.—A/S Olivin, Åheim, produced 150,000 tons of olivine, a magnesium iron silicate, at a West Coast location. Norddal Olivin A/S & Co. produced crushed olivine in Norddal, Sogn og Fjordane County. Norsk Nefelin, division of Elkem-Spigerverk mined nepheline syenite at Sternøy, on the Altafjord in Finnmark County, and operated an ore-dressing plant that produced 213,000 tons of glass and ceramic-grade material. Norfloat A/S, Lillesand, on the south shore, quarried 500,000 tons of pegmatite granite, obtaining 12,000 tons of flotation products, including alkali feldspar and quartz. A/S Norwegian Talc, Bergen, operated a grinding plant that produced 600,000 tons of dolomite, talc, mica, and other minerals. Elkem-Spigerverket A/S, Salten, produced 200,000 tons of quartzite in Gildeskal near Bodø. A/S Skaland Grafitwerk produced 9,375 tons of graphite flotation concentrate from an ore mined on Senja Island, Finnmark, in the north of the country.

Fertilizer Materials.—Norsk Hydro continued to account for the bulk of Norway's production and trade of fertilizer materials; its present ammonia capacity is 830,000 tons per year.

Gazocean Norsk A/S, Oslo, has awarded Norwegian shipbuilders an order for four 15,000-ton vessels. The ships are to transport phosphoric acid from the Republic of South Africa to Norway.

Pyrite and Sulfur.—Production of pyrite at principal mines in 1974 and 1975 is shown in the following tabulation, in tons:

Mine	1974	1975 p
Tverfjellet	260,311	294,783
Lokken	93,148	--
Skorovas	152,570	--
Sulitjelma	58,903	138,420
Fosdalens	24,238	--
Bleikvassli	19,300	24,352
Mofjellet	9,000	15,380
Killingdal	4,500	--
Total	621,970	472,935

p Preliminary.

The decrease in production was from cutbacks owing to further weakening of the pyrite export markets. Increased use was made of selective flotation for separating a copper concentrate from the bulk pyrite concentrate.

MINERAL FUELS

Norway has adequate supplies of hydroelectric power and has discovered large offshore oil deposits, which placed it among the oil-exporting countries in 1975. More than one-half of the country's energy requirement came from crude oil and oil products, four-tenths came from hydroelectric energy, and the rest from coal. The Norwegian Government controlled much of the country's oil industry, set the petroleum product prices, and was maintaining a go-slow policy on oil development. The Government has also controlled the Svalbard coal mining operations in recent years.

Higher oil prices and strict economy measures helped to lower the country's energy demand temporarily in 1974, but the level of consumption again reached previous highs in 1975. Norway's supply of energy and apparent consumption in 1973, 1974, and 1975 are shown in table 4. As will be seen, Norway was self-sufficient and a net exporter of energy for the first time in 1975.

Table 4.—Norway: Primary energy balance for 1973, 1974, and 1975
(Million tons of standard coal equivalent)[1]

Year	Total primary energy	Coal	Crude oil and petroleum products	Hydro-electric-power[2]
1973:				
Production	11.7	0.4	2.2	9.1
Imports	18.2	1.0	17.2	--
Exports	7.3	.1	6.5	.7

Coal and Coke.—The Norwegian Government took full control of the Store Norske Spitzbergen Kulkompani A/S. The company's Longyearbyen mine, Spitzbergen Island, is to reduce output to 400,000 tons per year of coal to stretch operations for another 20 years. A $90 million development continued at the Svea coalfield near Van Mijenfjorden, 33 miles south of Longyearbyen. Production is expected to start in 1978–79 with an initial capacity of 800,000 tons per year, to be increased later to 1.2 million tons or more. Seams up to 5 meters thick make efficient mechanization of the mining possible.

The Soviet Trust Artikugol mining company also operated two mines on Spitzbergen, one near the town of Barentsburg and the other at Pyramiden. Their total annual production of about 450,000 tons was shipped to the U.S.S.R.

Petroleum and Natural Gas.—*Exploration.*—Drilling activity was slow in the Norwegian sector of the North Sea at the beginning of the year with only three semisubmersible drilling rigs operating; by September, however, the number of rigs had increased to seven. In 1975, recoverable petroleum reserves were estimated at about 940 million tons of oil and 700 billion to 880 billion cubic meters of natural gas, but this is believed to be only a small part of probable reserves.

The official Norwegian estimate of total resources south of the 62d parallel was 3 billion to 4 billion tons of oil equivalent (oil and gas) in 1975. At the end of August, a total of 128 wells had been drilled in the area, but only about 3% of Norway's Continental Shelf had been allocated for drilling.[6]

North of the 62d parallel, the Norwegian Government has not yet permitted any drilling, but it is expected to start on a modest scale off the northern coast in 1977.

Exploration was concentrated mainly in the area between the 61st and 62d parallels, around Statfjord, the largest oilfield discovered in the North Sea. Statfjord, in which the Norwegian Government has exercised its 50% option through the national oil company, Statoil, contains recoverable reserves estimated at 400 million tons of oil and 123 billion cubic meters of natural gas.[7] No final decision has been made, but there are plans to transport the oil by pipeline to the west coast of Norway and the gas to West Germany.

Several other important structures are known to be located in the area, some of them in yet unallocated blocs nearer to the Norwegian coast.

Production.—The first oilfield to come into commercial operation in the Norwegian sector of the North Sea was the Ekofisk Field. Ekofisk is developed by the

[6] U.S. Embassy, Oslo, Norway. State Department Airgram A-176, Sept. 26, 1975, pp. 5–6.
[7] Work cited in footnote 6.

Phillips Norway Group, with Phillips Petroeum Co. Norway as the operator. It consists of Phillips Petroleum Co. Norway (39.96%), Norske Fina A/S (30%), Norsk Agip A/S (13.04%), Norsk Hydro (6.7%), Elf Norge A/S (5.396%), Total Marine Norge, A/S (4.047%), Aquitaine Norge A/S (2.698%), Eurafrep Norge A/S (0.456%), Coparex Norge A/S (0.399%), and Cofranord A/S (0.304%). Crude oil production built up throughout the year in the Norwegian sector of the North Sea. The initial 30-well Ekofisk Field development drilling program was nearing completion. Development drilling began in West Ekofisk, one of the six fields in the area to be linked by pipeline to the Ekofisk production complex. In mid-October the 350-kilometer crude oil pipeline to the Teeside terminal in England started transporting oil, eliminating interruptions in the production process caused by winter storms. The production rate exceeded 16 million tons per year from 23 wells until November 1, when a fire temporarily suspended operations at one of three platforms. The platform was expected to be back in operation in March 1976. For 1975 as a whole, Ekofisk production totaled 9.5 millions tons [8] from an average of 16 wells.

Construction of the 440-kilometer natural gas pipeline from the Ekofisk complex to Emden, West Germany, and a natural gas distribution center there were completed. Operation will start in 1977 with completion of related facilities at the Ekofisk complex and the Teeside terminal.

A new contract was signed for sale of Norwegian North Sea gas to the European gas distribution consortium; four Ekofisk area fields are involved. Deliveries are to begin in 1978 and are to reach, under the present and an earlier contract, 22 billion cubic meters per year.

The development of the Frigg Field, one of the world's largest offshore natural gas deposits, estimated to contain total reserves of about 300 billion cubic meters of gas in its main gasfield, has experienced some setbacks from technical difficulties and delays in platform deliveries.[9] The gas is to be transported by two pipelines to St. Fergus, Scotland, starting in 1977. The Petronord group, which controls the Norwegian part of this Norwegian-British gasfield, has committed itself to build and operate a 3-billion-cubic-meter-per-year pipeline to Karmøy in West Norway, but Norwegian authorities have not yet concurred in the scheme.

The Norwegian Government is deliberately moderating the exploitation of Norway's offshore petroleum resources to extend the lifetime of the petroleum resources. The state petroleum directorate predicts yearly production of 90 million tons in the early 1980s and, if no new reserves are found, production will fall off gradually thereafter.

Trade, Refining, and Consumption.— Increasing production from the Ekofisk oilfield resulted in increased exports of crude oil and petroleum products, and the country became a net exporter in spite of substantial crude oil and product imports.

Production started officially at the $230 million, 4-million-ton-per-year Mongstad refinery in Karmøy, West Norway, which will bring the country's refining capacity to about 12.6 million tons per year. Other refineries included A/S Norske Esso's 5.5-million-ton-per-year Slagen, the 200,000-ton-per-year Valloy refineries, and A/S Norske Shell's 2.75-million-ton-per-year Sola and 150,000-ton-per-year Valloy refineries.

Norwegian oil policy is aimed at increased state control in all phases of the petroleum industry. The Government negotiated a contract for the takeover of Norsk Braendselolje A/S, British Petroleum's Norwegian subsidiary. The $180 million deal includes a countrywide system of 1,300 gas stations and a 40% interest in the Mongstad refinery. The remaining 60% in the refinery's stock is owned by Norsk Hydro, in which the Norwegian Government has majority interest. The Government was also negotiating a takeover of A/S Norske Oljekonsum, a smaller petroleum distribution system owned by Norwegian and Swedish consumers' cooperatives.

Inland consumption of refinery products in 1974 was as follows, in thousand tons:

	1974
Aviation fuels	254
Gasoline	1,049
Kerosine	294
Gas and diesel oil	2,569
Residual fuel oil	1,869
Other	1,034
Total	7,069

The Mineral Industry of Pakistan

By David G. Willard [1]

The future looked better than the present for Pakistan's mining industry in 1975. Production and exports of mineral commodities remained almost stationary, while the cost of mineral imports increased by over 80%, plunging the country's balance of trade deep into deficit. Little improvement in the picture is expected in the next year or two, but long-term plans were being made to increase the utilization of domestic resources and reduce costly dependence on foreign supplies.

Marketed production of natural gas, Pakistan's most valuable mineral commodity, dropped slightly, and the output of crushed stone fell sharply. Production of cement, the country's only important mineral export, decreased and that of chromite, its principal metal ore, increased. Crude petroleum output declined and supplied less than 10% of domestic requirements, whereas the oil import bill, inflated by climbing world prices, was more than double that of 1974. A wide variety of other mineral production took place but remained minor in quantity and value.

Under the impact of higher petroleum costs, the country's balance of mineral trade fell steeply into the red. The value of mineral exports, chiefly cement, gained 15%, while expenditures for petroleum, metals, fertilizers, and other mineral imports soared 83% above the 1974 level, swelling the deficit in mineral trade by 91%. Mineral export earnings covered 6% of mineral import expenses in 1975, down from 10% in 1974.

Government plans to improve the mineral economy involved a multitude of activities. An increased rate of crude oil production and further development of the natural gas and fertilizer industries were scheduled in an attempt to gain relief from the escalating costs of imported petroleum and fertilizers. Construction of new cement plants and modernization of marble quarries and salt mines were planned in the hope of augmenting foreign-exchange earnings. In the longer term, several major projects including the country's first steel mill, development of a copper mine, and increased utilization of domestic uranium for nuclear power were designed to accelerate development of the country's mineral potential and bolster its sagging foreign trade position.

Other long-range government programs included developing the mineral potential of economically depressed Baluchistān Province and continuing the geological and mineral surveys in the country. Among the numerous mineral prospects being investigated in Baluchistān were copper, iron, magnesite, fluorspar, and sulfur. Major projects or proposals included a copper mine at Saindak, a ferrochrome plant, two cement plants, and a ministeel mill. Other mineral survey programs were concentrating on the relatively unexplored northern mountain districts of Azad Kashmin, Chitrāl, Gilgit, and Swāt in efforts to evaluate and develop their resources of gold and other metals, graphite, and gem stones.

No changes were made in the organization of government mineral-related activities. Two agencies formed in 1974, the Pakistan Mineral Development Corp. (PMDC) and the Resource Development Corp. (RDC), defined their objectives and initiated operations. RDC was concerned exclusively with the Saindak copper development and PMDC covered all mineral fields except Saindak copper, nuclear materials, and oil and gas. Specialized agencies in charge of energy materials were the

[1] Economist, Division of Nonmetallic Minerals.

Pakistan Atomic Energy Commission (PAEC) and the Oil and Gas Development Corp. (OGDC), the latter operating under the Ministry of Fuel, Power, and Natural Resources. In addition, the Geological Survey of Pakistan conducted geologic studies and nonpetroleum mineral exploration. Three provincial governmental bodies, the Baluchistān Devolpment Authority (BDA), the Punjab Mineral Development Corp., and the Sarhad Development Board (of the Northwest Frontier Province), performed similar nonpetroleum exploration and development functions within their regions, often through outside contractors.

Domestic private industry's role in the mining sector continued to be limited by both government policy and investor caution. New investment in heavy industry, aside from petroleum exploration and refining, was limited almost exclusively to the public sector. Government policy was to maintain control of those industries considered essential to the economy, except where foreign technology and/or capital were required, leaving most areas of medium and small industry to private enterprise. No further nationalizations had occurred since early 1974, but growth of private investment remained slow and was concentrated in such nonsensitive areas as farm improvement, transportation, residential construction, and small industry. Foreign private investment continued to be welcome as long as it could provide advanced technology, large capital inputs, or new export markets.[2]

PRODUCTION

Pakistan's mineral output exhibited minor changes in 1975, but the overall results remained similar to those of 1974. Production of natural gas from the Sui and Mari Fields was slightly lower, and crude petroleum output decreased in 1975 after a small gain in 1974. Recorded coal production decreased, as did production of marine salt. Dimension stone increased, as crushed stone output fell drastically, probably reflecting completion of the major portion of Tarbela Dam.

In addition to these major commodities, Pakistan produced relatively small amounts of a wide variety of minerals. The major metal ore was chromite, output of which was up 4%. Among the numerous nonmetals, those of some importance included barite, refractory clays, china clay, other clays, magnesite, rock salt, sand and gravel, soapstone, and sulfur. Production of some of these may be increased substantially in the future if development programs being carried out, mostly by the Government, prove successful.

Processed mineral commodities are of considerable importance to the economy. Although cement is the country's only significant mineral industry export, domestic production of chemical fertilizers and petroleum refinery products reduced the need for costly mineral imports.

[2] Data are for urea and ammonium sulfate for all years, and figures for last half of 1974 and all of 1975 also include ammonium nitrate; total output listed for each year distributed as follows in metric tons: 1973: urea—592,865 and ammonium sulfate—74,942; 1974: urea—554,662; ammonium sulfate—94,544; and ammonium nitrate—32,370 (last half of year only); 1975: urea—626,496; ammonium sulfate—97,463; and ammonium nitrate—59,191.

[3] As reported by North-West Frontier Province only; no details on the nature of this sand are available.

[4] Punjab and Sind Provinces only; additional quantities may be produced in other provinces.

[5] Punjab, Sind, and North-West Provinces only; additional quantities may be produced in other provinces.

[6] Produced in Baluchistān Province only; type of sulfur not reported.

TRADE

Recession in Pakistan's export markets and sharp increases in the prices of many of its major imports caused a drastic deterioration in the country's balance of trade in the 1974–75 fiscal year. Value of exports increased only 4% to $1,057 million, but value of imports increased 54% to $2,088 million, causing a tripling of the trade deficit from $333 million in 1973–74 to $1,031 million in 1974–75. Mineral trade constituted an important part of the deficit, for while mineral exports gained 15% to $45 million, imports of mineral commodities increased 83% to $728 million, raising the mineral trade deficit 91% to $683 million. Principal mineral imports were iron and steel, crude petroleum, petroleum refinery products, and manufactured fertilizers. Iron and steel, crude petroleum and petroleum refinery products accounted for most of the increase in value of imports. Higher prices, particularly for petroleum, were responsible for a large share of that growth. Cement continued to be the most important mineral product exported, and was the only export that showed a significant gain in value; the gain was partly offset by declines in petroleum refinery products and nonmetallic building materials.

Balances of mineral and nonmineral trade for the last 3 fiscal years are shown in the following tabulation, in million dollars:

	1972–73	1973–74	1974–75
Exports and reexports:			
Mineral	30	41	47
Nonmineral	934	980	1,010
Total	964	1,021	1,057
Imports:			
Mineral	247	397	728
Nonmineral	692	957	1,360
Total	939	1,354	2,088
Balance of trade:			
Mineral	−217	−356	−681
Nonmineral	242	23	−350
Total	25	−333	−1,031

Aside from raising import taxes on 25 classes of luxury goods, Pakistan has imposed no additional restrictions on trade despite its balance of payments difficulty. Increased foreign aid, especially from the Organization of Petroleum Exporting Countries (OPEC), covered most of the trade deficit, and should continue to do so in 1975–76. Improvement in mineral trade seemed unlikely in 1975–76 since there were no major new mineral export possibilities and the country continued to be dependent on foreign sources of petroleum, petroleum-related products such as fertilizers, and metals. However, improved world economic conditions and agricultural recovery from the 1974 drought were expected to reduce the overall trade deficit slightly. Within the next few years, increased domestic fertilizer-production capacity and greater cement exports may narrow the mineral trade gap.

The following tabulations list the value of Pakistan's mineral exports and imports by major class.

Commodity or commodity group	Value of exports and reexports (million dollars)	
	1973–74	1974–75
Chromite	(1)	1.0
Other metallic ores	(1)	(1)
Metals including scrap	r 1.7	.5
Cement	r 16.1	28.2

r Revised.

COMMODITY REVIEW

METALS

Bauxite.—A 3-year exploration program for the bauxite deposits in the Khushab and Kāla Chitta areas and aluminous clays near Campbellpur has been prepared by the PMDC. One possible use for these bauxite and aluminous ores may be in refractories for the Karāchi steel mill.[3] Iran has agreed to purchase alumina from Pakistan under the Regional Cooperation Development Program.[4]

Chromite.—Production increased 4% to 9,961 tons in 1975 from 9,537 tons in 1974 but remained well below the 25,000-ton annual level of the late 1960's. Most of the production was exported. Transportation costs, labor problems, and the high iron content of the ore have made it increasingly difficult for domestic mines to compete in world markets and have been responsible for the long-term decline in output.

Because of the high and varying iron content (iron-to-chromium ratio of between 1:2.5 and 1:3.6), a study of the feasibility of setting up a ferrochrome plant was underway. The plant, to be built with West German assistance, would be located at either Muslimbagh or Quetta. Cost of the 15,000-ton-per-year plant was estimated at about $7 million. The scheduled completion date of 1977 for the plant may prove overly optimistic.[5]

Copper.—The Geological Survey of Pakistan expected to complete core drilling of the Saindak copper deposit in the Chagai Hills of Baluchistān by mid- to late 1976. RDC was seeking assistance from the United Nations and international mining companies in preparing a feasibility study. Some U.S. firms had expressed interest in the project, but none had yet indicated an intention to participate. Remote location and inadequate transportation and water supplies continued to be the principal problems inhibiting exploitation of the resource.[6]

Iron and Steel.—Construction of the country's first integrated steel mill, which was being built with Soviet aid, was in progress at Pipri, east of Karāchi. The 1.1-million-ton-capacity plant will utilize Australian iron ore because domestic deposits, though large, are too low in grade. Construction of the first blast furnace began. Engineering services were being provided by Société Française Siderurgie (SOFRASID). Operation of the first blast furnace was expected in 1978, with full capacity to be attained by 1980.[7]

An aeromagnetic survey has indicated that there may be 5 million tons of iron ore in Baluchistān Province. PMDC was conducting ground surveys in an attempt to prove out a reserve of at least that amount in the Pachi Koh area to make feasible a ministeel mill there. Plans called for the mill, which actually would be a pig iron plant, to use a direct-reduction method in order to take advantage of readily available natural gas. Technical and financial assistance for the project was being provided by the People's Republic of China.[8]

Uranium.—Pakistan's Atomic Energy Commission proposed ambitious plans for nuclear power development based on the uranium resources in the Dera Ghazi Khan area of Punjab Province. Construction of eight nuclear powerplants was scheduled during the 1980's, beginning with the 600-megawatt unit at Chashma Barrage, which was to come onstream in 1982. In addition, a plutonium separation plant was to be built with French assistance to reprocess spent nuclear fuel, along with a technical training center at Karāchi. The commission based its proposal on the country's inadequate petroleum and coal resources and its desire to reserve natural gas for domestic heating and raw material uses. However, the availability of foreign sources of financing required for these projects remained uncertain.[9]

Other Metals.—Austromineral, a subsidiary of VOEST-Alpine AG of Austria under contract to PMDC, was investigating the feasibility of large-scale placer mining for gold in the Indus River Valley of Gilgit District in the Northwest Frontier Province. The mineral potential of this mountainous region has been little explored owing to its remote location and lack of infrastructure. Activities planned during 1975 included geologic mapping, trenching, drilling, and analysis of gold-bearing samples. If a deposit of at least 25 million tons containing 0.3 grams of gold per ton could be proven, PMDC planned to establish a 5,000-ton-per-day operation.

Under a contract with the Sarhad Development Authority of the Northwest Frontier Province, Austromineral was also examining deposits of antimony, gold, iron ore, molybdenum, and tungsten in the Chitral District, another high mountain area whose mineral potential was largely unknown and undeveloped.

Deposits of manganese were located in the course of exploration for iron ore in the Las Bela–Khuzdar region of Baluchistān Province. Canada's International Development Agency planned to carry out an aeromagnetic survey of the area in order to determine its full mineral potential.[10]

NONMETALS

Barite.—Production declined to 4,600 tons in 1975 after an increase to nearly 5,200 tons in 1974, thus reverting to the previous downward trend. Production from small mines in the Northwest Frontier Province has been declining for several years despite the upturn in petroleum exploration activity. Plans for reversing this trend rest on development of the deposit near Khuzdar in Baluchistān, which was estimated to contain at least 1.3 million tons of ore. The barite-crushing plant at Khuzdar, a joint project of Pakistan Petroleum Ltd. (PPL), and the Government of Baluchistān, was expected to begin operation in the early part of 1976. Cost of the plant will be about $800,000. Its initial capacity will be 25,000 tons per year, with planned expansion to 70,000 tons per year in 5 years. Most of the production will be exported.[11]

Cement.—Output totaled 3.1 million tons in 1975, slightly lower than the 3.5 million tons produced in 1974. Earlier plans had called for doubling the country's cement production by 1977 by expanding four of the nine existing plants to add a total of 1.2 million tons annual capacity, and constructing three new plants with an aggregate capacity of 2.5 million tons per year. Total cost of the new plants was estimated at $120 million, and an additional $50 million would be required for the expansions. Recent economic and balance-of-payments difficulties may have forced some delay in implementing these plans. They will probably be completed in the near future, however, because the cement serves both domestic needs and is the country's principal mineral source of foreign exchange.

Fertilizer Materials.—Domestic chemical fertilizer production satisfied about 70% of Pakistan's fertilizer requirements; the remainder had to be imported at rapidly rising costs, which exceeded $100 million in the 1974–75 fiscal year. In order to eliminate this large foreign-exchange drain, the Government planned to build four additional fertilizer plants by 1979: The Pak-Arab plant at Multan, the Hazāra complex at Haripur (near Abbottābād), the Pak-Saudi plant at Mirpur Mathelo (near Sukkur), and the Fauji Foundation plant at Machi Goth (near Bahawalpur).

The Hazara project involved mining a phosphate deposit located near Abbottābād in the Northwest Frontier Province. Powell-Duffryn Co. of the United Kingdom was carrying out a survey of the deposit and preparing a feasibility report on the project. The area had previously been estimated to contain 2.5 million tons of phosphate ore in three deposits. One of the deposits reportedly contained approximately 700,000 tons of marketable rock, averaging 32% P_2O_5. To test the ore, 20 tons per day was being mined and processed at the Lyallpur-Jaranwala plant, with plans to increase the rate to 120 tons per day by July 1976. In April 1975, the Government placed orders with Simon Carves, Ltd., of the United Kingdom for the ammonium phosphate and urea plants. The $247 million project, which would also include an ammonia plant, was expected to produce 700,000 tons per year (approximately 2,100 tons per day)

of superphosphate, diammonium phosphate, and phosphoric acid on its completion in late 1978 or early 1979.

The Pak-Arab plant, a joint project of the Pakistan Government and the Abu Dhabi National Oil Co., was expected to be the first of the four plants to come onstream, in 1977 or 1978. It was to produce 1,200 tons per day of ammonium nitrate and 1,500 tons per day of calcium ammonium nitrate.

The Mirpur Mathelo project was to consist of a 1,000-ton-per-day ammonia plant and a 1,740-ton-per-day urea plant. Its natural gas supply would come from the nearby Mari Field. The estimated $196 million cost would be financed by a $50 million loan from the Government of Saudi Arabia a $30 million loan from the Saudi Fund for Development, a $50 million loan from the Asian Development Bank, and the remainder from the Government. Operation was scheduled to begin in early 1978.[12]

Salt.—Rock salt output remained at approximately 400,000 tons, where it has been for the last several years. Although Pakistan has large reserves of rock salt in the Salt Range of Punjab Province and an export market, obsolete equipment at the mines and transportation costs have kept a ceiling on production. Marine salt output decreased to 131,000 tons, 2% less than the 134,000 tons produced in 1974.

Modernization of the three major rock salt mines was planned by PMDC. Machinery dating from the 1930's was to be replaced and modern extraction methods adopted. A 50% increase in production was anticipated.[13]

Stone.—Production of marble and other types of dimension stone were up substantially to 33,219 tons in 1975 from 23,597 tons in 1974, but exports of marble declined sharply in value from $286,000 in 1974 to $47,000 in 1975. Recession in the construction industry in Italy was believed to have caused most of the drop. Good-quality travertine marble has been one of the country's more important mineral exports, and ample deposits are available. An opportunity was believed to exist for increased exports to Pakistan's oil-producing neighbors.[14]

Other Nonmetals.—Two projects designed to boost Pakistan's production of refractory materials were undertaken by the Pakistan Industrial Development Corp. (PIDC). A plant was opened in Karāchi that will make 6,000 tons per year of fire clay brick and 4,000 tons per year of high-alumina brick. Fire clay is mined locally, but the alumina must be imported because the country has as yet no alumina production and only a small output of bauxite. General Refractories Ltd., will operate the plant.

A deposit of magnesite at Kumber, near Abbottābād, was being investigated by PIDC with the People's Republic of China's assistance. A reserve of 1.5 million tons has been proven, and total resources may be considerably more. Analysis of the ore has shown it to be suitable for the manufacture of refractories, and a plant producing 15,000 tons per year of magnesite and magnesite-chrome bricks has been proposed. Present plans call for construction to begin in 1977 or 1978, with the plant coming onstream in 1980.[15]

A proposal to use the kaolin produced in the Swāt District to make fine china was under discussion. The material presently goes into the manufacture of tiles and sanitary fixtures.

Included among the Government's plans to improve the economy of Baluchistān were projects to investigate the sulfur and fluorite resources of that province under the joint direction of PMDC and BDA. A small production of sulfur was taking place at Koh-i-Sultan in the Chagai Hills, where an estimated 644,000 tons of ore containing 50% to 65% sulfur are located. There are other surface signs of sulfur in the area, and PMDC and BDA together with private interests formed the Baluchistān Sulphur Enterprise to develop the deposits and establish a 3,000-ton-per-year refining plant near Quetta. The project was expected to take several years.

Fluorite deposits in the province were being examined with an eye to their pos-

sible use in the steel mill to be built at Karāchi.

An official gem stone buying agency came into being following the disclosure that emeralds worth many millions of dollars had been smuggled out of the country over the last several years. Police raids recovered a large cache of the precious stone and appeared to implicate a number of local officials in the district of Swāt where the mines are located. In an attempt to forestall further smuggling, the Government setup an organization to buy, process, and export the gem stones. In addition, a training institute in gem cutting and polishing and a gem cutting center, both in Peshawar, were planned. These facilities were to be part of a Lapidary Pilot Project approved by the Government in 1974.[16]

Studies were also being conducted of the graphite resources located in Azad Kashmir Province, which are estimated at more than 50,000 tons and would be sufficient to supply the country's needs for many years. An investigation of the deposits was scheduled for the summer of 1975. Upgrading the existing processing plant was planned, but no date was given.

A number of other mineral deposits in various parts of Pakistan were being examined by PMDC and the three provincial mining agencies. Included were bentonite near Kohat, fuller's earth and gypsum near Dera Ghazi Khan, graphite and kaolin in Dir District, corundum near Abbottābād, potash in the Salt Range and in brine deposits near Jhelum, dolomite near Mianwali and at other locations (for possible fluxing use in the Karāchi steel mill), and marble in Buner District.[17]

MINERAL FUELS

Although Pakistan fared better than many countries during the world energy crisis of 1974–75, assuring a sufficient future supply of energy continued to be a major Government concern. Common religious ties with the oil-producing nations secured the country's petroleum supply in 1975, but the oil import bill was assuming serious proportions. Imports of crude oil and petroleum refinery products cost $337 million in the 1974–75 fiscal year, 120% more than in 1973–74, and accounted for 16% of total 1974–75 import expenditures. Domestic petroleum production met less than 10% of the country's requirements. Other domestic conventional energy sources, principally natural gas and undeveloped hydroelectric power, were not large or, in the case of coal, were of low quality. Barring major petroleum discoveries, the Government planned to depend more heavily on nuclear power based on domestic uranium resources, possibly supplemented by unconventional sources such as bio-gas converters and solar energy.

Coal.—Reported production of coal decreased to 1.0 million tons in 1975 from 1.5 million tons in 1974. Total coal production was not known because a sizable proportion, mined by brick producers for their own use, was unreported. An additional $8.3 million of coal and coke were imported, a 60% increase in cost from the $5.2 million purchased in 1974. Brick kilns consumed 95% of domestic coal production, powerplants consumed 4%, and 1% went to domestic uses.

Rising petroleum prices and a desire to reserve natural gas for raw materials purposes has caused greater attention to be focused on the country's extensive but low-grade coal resources. Two major coal-utilization projects were in the planning stage: The Lakhra coal-fired powerplant and the Sharigh coal-washing project.

At the Lakhra coalfield in the Indus River Valley north of Hyderabad, PMDC was establishing the reserves, which had been estimated at 250 million tons. Tentative plans called for production of 4,000 tons per day, the entire output to be consumed in a 240-megawatt powerplant. Development work was scheduled to begin in early 1977. No date was given for completion of the project.

The Sharigh coal-washing project is intended to provide part of the fuel supply for the Karāchi steel mill, reducing the need for imported coal. Production from the low-grade Sharigh Field, east of Quetta in Baluchistān Province, will be upgraded by washing, transported to Karāchi, and blended with high-quality imported coal for use in the mill. Funding for the project will come partly from a Canadian International Development Agency loan.

Page 5 of work cited in footnote 4.

[17] Industrial Minerals. Pakistan, Joint Venture Exploits Baluchistān Minerals. No. 100, January 1976, p. 9.
Work cited in footnote 5.

The Government also planned to install modern equipment at the Makerwal mine in Punjab Province, the country's largest, and at three smaller mines in Baluchistān in order to reach proven coal reserves below those currently being exploited.

In addition to these projects, the Government planned to establish a Fuel Research Laboratory that would investigate ways to utilize domestic coal resources.[18]

Natural Gas.—Sales from the Sui and Mari Fields totaled 149.6 billion cubic feet in 1975, down slightly from the 1974 figure of 152.0 billion cubic feet. Minor production may also have taken place at the Potwar plateau oilfields and at several small gasfields in Sind Province. There were no imports of natural gas, but a small amount of liquefied natural gas was exported. Gas from Sui served a large number of customers in northern Pakistan and in the Karāchi area. Mari gas was consumed entirely in the Esso Pakistan Fertilizer Co. Ltd., plant near Sukkur.

Revised figures reduced the country's total estimated reserve to 14.33 trillion cubic feet from the 17.43 trillion cubic feet reported earlier. Reserves in the Sui Field were estimated at 7.9 trillion cubic feet and those in the Mari Field at 4.1 trillion cubic feet, with the oilfields and minor gasfields accounting for the remainder.

An agreement was reached in principle between the Government and Esso that would open the way to further development of the Mari Field. The Government would purchase Esso's oil product-distribution system and its interest in a refinery, and Esso would use the money from that sale to develop Mari. Details and timing of the scheme remained to be worked out.

Construction was in progress on the second pipeline from the Sui Field to Karāchi, scheduled for completion by the end of 1976. It would relieve a shortage of industrial gas in the Karāchi area.

Another gas pipeline expansion was underway in northern Pakistan where Sui Northern Gas Pipelines, Ltd., was preparing to build 65 miles of new pipeline and 116 miles of looping. The expansion would provide gas supplies from Sui to four new cities. Financing for the project was to be provided by the World Bank.[19]

Petroleum.—Domestic crude oil output from the Potwar plateau fields declined sharply in 1975 to 2.2 million barrels (300,000 tons) from 2.9 million barrels (400,000 tons) in 1974. More than 90% of the country's petroleum requirements had to be imported at a cost that reached $337 million in the 1974–75 fiscal year, including $118 million of refinery products. Saudi Arabia and the United Arab Emirates were the main sources of supply. Pakistan's three refineries produced 23.8 million barrels of refinery products, a decrease of 6% from the 1974 output of 25.4 million barrels.

The Government planned to reduce the drain on foreign exchange by raising the rate of production from the existing oilfields to a level sufficient to meet 15% to 20% of the country's annual petroleum needs. The higher production rate would require an increase in the ratio of gas to oil and would result in a more rapid depletion of the underground gas pressure that moved the crude oil into the wells. As a result, the increased output rate would hasten the time when secondary recovery methods would be needed if the fields were to remain in production.

Six oil companies and OGDC were actively exploring for petroleum during the year, but the finds were modest. Pakistan Oilfields, Ltd. (POL), discovered one oil producer in the Meyal Field, bringing the total number of successes in that field to three and adding between 500 and 2,000 barrels per day to the nation's production. OGDC brought in three gas producers in various locations. A total of seven exploration wells were begun during the year, five onshore and two offshore. Both offshore wells came up dry: One by Marathon Oil Co. and one by Wintershall A.G., and both companies deferred further drilling in favor of additional studies. American Oil Co. (AMOCO) had one dry hole in its old concession area and began to conduct seismic surveys in its new concession south of the Kandkhot gasfield. POL and OGDC each had wells in progress at yearend. The year's

unsuccessful efforts were expected to bring a reduction of exploration activity in 1976.[20]

Construction work continued on the Pak-Arab refinery at Multan. Contract bidding was to begin for the pipelines, pumping stations, and terminals serving the refinery. Construction programs were also underway at two of the country's existing refineries. Additional crude naphtha hydrotreating capacity and new units for catalytic reforming and distillate hydrodesulfurization were being installed at the National Refinery Ltd. in a project expected to be completed in early to mid-1976. Total capacity would be raised to 43,760 barrels per day from 31,190 barrels per day. At the Pakistan Refinery Ltd., new visbreaking and distillate hydrodesulfurization units were being added, with the expected completion date in 1977. Total refinery capacity would be unchanged. Another set of projects involved the construction of a specialty asphalt plant, a specialty oils plant, and a wax-refining plant, all of which would be located adjacent to the National Refinery and would take their feedstocks from it. Work on the specialty asphalt plant began in early 1975, and all three plants were expected to be finished within the next 2 years. Their production would replace imported supplies.[21]

Other Energy Sources.—In related energy developments, the Government planned to setup a series of nontraditional energy sources in rural areas on an experimental basis. A total of 100 small bio-gas plants had been installed in various locations, and 10,000 more were programed for installation during the next 5 years. The University of Peshawar had been distributing solar stoves and planned to have 25,000 in operation within 5 years. Another Government program involved the installation of solar water pumps for irrigation use in remote areas. These programs might reduce the need for expensive petroleum imports and make energy sources available to sparsely populated regions of the country.[22]

The Mineral Industry of Peru

By Orlando Martino [1]

The Peruvian economy experienced a lower rate of growth during 1975. The rate of growth of the gross domestic product (GDP) declined in 1975 to 4% for the year, compared with an average annual rate of growth of almost 6% during 1972–74. The rate of inflation was a record high, increasing to 24% compared with the 10.6% average annual increase for the 10 preceding years.

Peru's mineral production declined 10.4% in 1975 and accounted for 7% of the estimated GDP of $12.2 billion [2] at current prices, compared with 8.2% of the GDP in 1970. Mineral exports valued at $560 million accounted for 45% of Peru's export earnings in 1975.

Peru's export-oriented mineral industry was dominated by the copper, lead, zinc, silver, and iron ore sectors. Together they accounted for 97% of mineral exports value in 1975. Other mineral production, including bismuth, indium, molybdenum, rhenium, selenium, tellurium, and tungsten comprised the remaining 3%. The United States received a substantial portion of Peru's mineral exports.

Government Policies and Programs.— The year 1975 marked the beginning of the Second Development Plan (1975–78), which was to concentrate on channeling investment into basic industrial sectors and bring into operation in 1977 and 1978 the large projects undertaken in oil and copper.

The investment program for 1975–76 for the mining sector included the Cuajone copper project, the Cerro Verde copper mine, the Lima zinc and Ilo copper refineries, and the Bayovar phosphate project. Principal investments in the petroleum industry for the same biennial included completion of the Trans-Andean oil pipeline, continuation of oil and gas exploration, and the expansion of the Pampilla oil refinery.

By Decree Law No. 21094 of February 4, 1975, the Government of Peru promulgated a new organic law for the energy and mines sectors of the economy and to govern the basic structure and functions of the Ministry of Energy and Mines. This law also provided that the public enterprises and institutions operating in these sectors will abide by the general policies formulated by this Ministry. The public enterprises included were as follows:

Empresa Minera del Perú (Minero Perú),
Petroleos del Perú (PETROPERU),
Electricidad del Perú (ELECTROPERU);

and the public institutions included were as follows:

Instituto Peruano de Energia Nuclear
Instituto Cientifico y Tecnologico Minero (INCITEMI),
Instituto de Investigaciones Energeticas y Servicios de Ingenieria Electrica,
Instituto de Geologia y Mineria (INGEOMIN), and
Registro Publico de Mineria.

Minero Perú, PETROPERU, and ELECTROPERU were Government enterprises in the fields of mining, petroleum, and electricity operating under their own bylaws and statutes. INCITEMI was in charge of mining research and INGEOMIN was in charge of planning, directing, and executing all the activities related to geo-

[1] Physical scientist, International Data and Analysis.
[2] Where necessary, values have been converted from Peruvian Soles (S/) to U.S. dollars at the rate of S/45.0=US$1.00.

logical studies in Peru, as well as the exploration, appraisal, and inventory of the country's mineral resources. The Registro Público de Mineria was responsible for recording all mining concessions and rights granted by the State. This new organic law replaced Decree Law 17527 of March 1969.

In September, Peru and Canada signed two loan agreements totaling $8 million; the first loan was for use by the Banco Minero to finance the Polymetallic Development Program within the medium mines sector, and the second for Corporación Financiera de Desarrollo (COFIDE), the Government development corporation.

In July, the assets of Marcona Mining Co. were nationalized by Decree Law 21228. This company was Peru's sole iron ore producer and exporter and had been in operation since 1953.

In late August, General Morales Bermudez assumed the presidency of Peru. A new junta was appointed including Army General Luis La Vera Velarde as Minister of Energy and Mines. Subsequently, on September 26, 1975, the sol was devalued 16% and a program of economic austerity was under preparation.

By Decree Law 21297 of October 1975, the Government reserved for the State the exclusive right to explore, exploit, and refine radioactive substances found in Peru. Any radioactive substance obtained as a byproduct of the processing of other substances would be under the control of the Peruvian Nuclear Energy Institute.

PRODUCTION

Mineral production declined 10.4%, in 1975 owing in part to strike-related work stoppages at the principal copper mines. In addition, high costs closed some of the smaller mines. Iron ore production suffered the greatest reduction, declining 19%. Other production declines in commodities of significance were copper (9%) and crude oil (6%). Silver production, on the other hand, increased almost 8% and zinc production increased about 2%. The copper output did not reflect the production potential of the Cuajone project which was in its final stages of development. The sharp drop in crude oil production from the Continental Shelf was not compensated by new production in the Amazon areas. Production of refined products increased 4.8%.

During 1975, a total of 77,900 were employed in the mining sector, exclusive of fuels, 71,000 of which were in metallics and 6,900 in nonmetallics or employees of contractors.[3] This represented a 7% increase in employment over 1974. The Department of Junin, east of Lima, had the largest number active in mining at 13,144.

Data on mineral production are shown in table 1.

[1] Includes crushed marble.
[2] Includes hexane.

TRADE

The total value of mineral exports from Peru was $560 million, a 30% decrease from that of 1974. The mineral export figure for 1974 was revised to $800 million. Mineral exports in 1975 represented 45% of total export earnings. The Peruvian Mining Society reported the following data for 1975 for Peru's leading mineral commodity exports:

Commodity	Quantity	Value, f.o.b. (million dollars)	Share of value (percent)
Copper ____ metric tons__	156,500	161	29
Iron ____ do____	3,025,900	52	9
Lead ____ do____	128,100	41	7
Silver ____ thousand troy ounces__	34,200	140	25
Zinc ____ metric tons__	405,500	149	27
Other minerals ____ do____	NA	17	3
Total ____	XX	560	100

NA Not available. XX Not applicable.

The United States, Europe, and Japan were the major markets for Peruvian mineral exports. In 1975, Peru started to export crude oil from the new Amazon fields to Brazil and a small quantity to Argentina. Exports of refined products decreased 73% to 1.6 million barrels.

Crude oil imports increased over 53% from 11.2 million barrels in 1974 to 17.1 million barrels in 1975. Imports of refined petroleum products increased.

The Eighth Annual Conference of Ministers of the Conseil Intergouvernemental des Pays Exportateur de Cuivre (CIPEC) held in Lima, November 17–20, 1975, was attended by Ministers of the four member countries—Chile, Zaire, Zambia, and Peru. Indonesia was formally admitted as a new full member and Australia and Papua New Guinea were given nonvoting associate member status. At the conclusion of the conference, it was announced that CIPEC countries would continue their 15% export production cutback until June 30, 1976, in order to correct the world supply and demand imbalance. It was also stated that CIPEC will initiate a dialogue between producing and consuming countries with a view to negotiating a copper price stabilization agreement.

Shortly after nationalization of the Marcona Mining Co., Peru joined the Association of Iron Ore Exporting Countries, together with Venezuela, Algeria, Chile, India, Australia, and Mauritania.

COMMODITY REVIEW

METALS

Bismuth.—Peru continued to be one of the world's largest producers of bismuth. Refined bismuth was produced as a byproduct of lead at the La Oroya smelting and refinery complex of Empresa Minera del Centro del Perú (CENTROMIN). On the basis of CENTROMIN's preliminary figures, output decreased about 19% in 1975.

Copper.—In 1975, Peru ranked 10th in world mine production and 4th in estimated reserves. Copper production declined 9% chiefly because of strikes at the large copper mines. High costs forced certain smaller mines to close.

Southern Peru Copper Corp. (SPCC), a consortium of four U.S. companies, suffered a decline in copper production at its open pit mine at Toquepala because of labor strikes covering 71 calendar days compared with 27 days lost in 1974. SPCC was Peru's largest copper producer and accounted for 56% of the country's total output in 1975. On July 1, 1975, SPCC entered into a commercialization agreement with Minero Perú Comercial (MINPECO) under which this government agency will take title to and market all production from the Toquepala mine. CENTROMIN was the second largest producer of copper contributing about 23% of Peru's total production with about 36,000 tons.

The most important event concerning new projects in 1975 was the completion of financial arrangements to develop the Cuajone project of SPCC in the Department of Moquegua, south of Arequipa, 16 kilometers from Toquepala. Financing, totaling $404 million for the $620 million project, involved 54 different lending institutions in several countries. In mid-1969, costs were estimated at $355 million. By yearend 1975, $560 million had been invested and 85% of the construction completed. Twenty-seven kilometers of tunnels on the railroad extension to haul concentrates from Cuajone to the SPCC Ilo smelter was completed. The smelter was being expanded to treat Cuajone's output.

When the Cuajone open pit project enters production in the second half of 1976, it will have a mine production of 40,000 tons of ore per day and about 154,000 tons of blister copper per year, making SPCC the operator of one of the world's largest mining-metallurgical complexes. Cuajone's output will increase Peru's copper production 80%. The Cuajone ore body was estimated to contain 430 million tons of sulfide ore averaging 1% copper and 0.02% molybdenum.

CENTROMIN made plans on a priority basis to expand its mine and concentrator at Cobriza, east of Lima in the Department of Huancavelica. A feasibility study to expand production from 2,000 to 7,000 tons of ore per day was carried out by R. M. Parsons Co. On the basis of this study, CENTROMIN and a World Bank mission made an economic evaluation of the plans and recommended expansion to 10,000 tons per day. The expansion, estimated to cost $161 million, was expected to be financed by the World Bank, Inter-American Development Bank, and COFIDE.

Development work was underway by Minero Perú on the superjacent Cerro Verde/Santa Rosa deposits located in the Department of Arequipa. In stage 1, the Cerro Verde deposit, of which half is oxide ore, was being developed first. By yearend, most of the infrastructure work, access roads, and water installations had been completed. Work continued on the solvent-extraction, electrowinning, and anode plants. Cost of stage 1 was estimated at $189 million, $87 million of which was invested by yearend. The balance will be invested in the first half of 1976 when stage 1 is scheduled to be in operation, producing 33,000 tons of copper per year. Stage 2 development involved the Santa Rosa sulfide deposit. The engineering-economic feasibility study for stage 2 was completed and Minero Perú was seeking financing for the project estimated to cost $1.3 billion. When completed in 1980, stage 2 would add about 150,000 tons per year to copper capacity and include a smelter-refinery complex, to be built at Matarani.

A feasibility study was completed during 1975 by the Michiquillay Copper Corp. of Japan of the Michiquillay porphyry copper deposit located in northern Peru, northeast of Cajamarca. Over $700 million will be required to exploit ore reserves estimated to be over 544 million tons grading 0.69% sulfide copper. The Japanese consortium of five copper smelters was awaiting the Peruvian Government's decision with respect to financing the infrastructure for exploitation of the mine, as well as the formation of the Michiquillay Special Mining Co. on a 51%–49% equity basis with Minero Perú.

During 1975, planning continued by CENTROMIN to develop its open pit project at Toromocho, located in Morococha, 160 kilometers east of Lima. By yearend, the fourth drilling program was almost completed. In addition to the open pit mine, the $491 million project will include a concentrator, smelter, and refinery to produce 108,000 tons of refined copper per year.

The new copper refinery at Ilo, located on the coast of southern Peru to handle the present and future output from Toquepala and Cuajone, came onstream in October. The $57 million plant of Minero Perú was constructed by Mitsui Mining & Smelting Co. Ltd. and Furukawa Mining Co. Ltd., and had a rated capacity of 150,000 tons of copper per year. In August, the Government approved a technical-economic feasibility study for the $76 million stage 2 expansion of the Ilo refinery to 300,000 tons per year. This study will also be made by the Mitsui-Furukawa group. Expanded refinery production is to be primarily exported, since domestic demand for refined copper is small.

In August, Seltrust Engineering Ltd. of London completed a feasibility study for the rehabilitation and expansion of the copper circuit at CENTROMIN's La Oroya complex. Output of refined copper was to be increased from 39,000 to 73,000 tons per year. Total cost of the project was estimated at $141 million.

Gold.—Gold metal production decreased 15% compared with that of 1974. CENTROMIN, with 31,046 troy ounces produced as a byproduct in its La Oroya smelter, continued to be Peru's major producer, followed by Cia. Minera Ocona in the Department of Arequipa with 14,300 troy ounces, which was the only major lode gold mine operator.

The increase in gold prices in 1974 prompted a major investigation of the country's gold mining potential. The main gold project under consideration by Minero Perú was the San Antonio de Poto project located in the Ananea District in the Department of Puno, which was expected to produce 39,000 troy ounces of gold per year by 1978.

Iron Ore.—There was a marked decrease in production of iron ore in 1975 and a moderate reduction in exports, from 10.5 million tons in 1974 to about 9.4 million tons in 1975.

By Decree Law 21228 of July 24, 1975, the assets of Marcona Mining Co., a wholly-owned subsidiary of Marcona Corp. based in San Francisco, were nationalized. The Marcona Mining Co., Peru's sole iron ore producer, had been in operation since 1953. The Marcona Corp. noted that its Peruvian subsidiary had been conducting negotiations since the fall of 1974 for the sale of its net assets, but no agreement had been reached. The decree specified that the Marcona assets would be administered by a new autonomous State entity called Empresa Minera de Hierro del Perú (HIERRO PERU). In August, a multisectoral commission was established by the Peruvian Government to determine the assets of the company that were subject to expropriation. Subsequent to the expropriation action, a new president assumed control in Peru and Marcona's management was invited to resume discussion with Peruvian officials regarding just compensation. By yearend these negotiations had not been concluded.

In September, HIERRO PERU first announced that since August 1 it had temporarily reduced its iron ore production 30% as a strategic measure while the world markets made certain adjustments. It was also mentioned that MINPECO was contacting Marcona's former clients to secure sales for HIERRO-PERU.

Decree Law 21234 of August 5, 1975 was published, by which the Peruvian Government approved the agreements reached to establish the Association of Iron Ore Exporting Countries, involving Chile, Venezuela, India, Algeria, Mauritania, and Australia.

Iron and Steel.—In 1975, there was a small decrease in production of raw steel. The only major steel plant, operated by the Government-owned Empresa Siderúrgica del Peru (SIDERPERU) at Chimbote, was undergoing expansion from a yearly output of 425,000 tons to 700,000 tons of raw steel, scheduled for yearend 1975. Mitsubishi Heavy Industries was constructing a tinplating plant at Chimbote on a turnkey basis.

Peru was planning two additional expansion projects, one involving SIDERPERU's existing steelworks at Chimbote, north of Lima, and an entirely new project at San Nicolas on the coast south of Lima, referred to as the Nazca project, and which was being planned by Industrias del Perú (INDUPERU). Although the proposed Nazca project would be less than 32 kilometers from the former Marcona iron ore facilities, complete infrastructure, including a port and water pipeline, would have to be built. At yearend, a decision had not been reached on the Nazca expansion. INDUPERU contracted for two independent feasibility studies on the Nazca project. The first, prepared by the U.S.S.R., was submitted to INDUPERU in December 1974; the other was being prepared by Arthur G. McKee & Co. of the United States.

In October, it was reported that the Ministry of Industry had approved the first stage of a major expansion at the Chimbote works at an estimated cost of $1 billion. Annual production capacity is to be increased to 1.4 million tons per year of ingot steel in the first stage, and to 2.3 million tons in the second stage by 1981.

The feasibility study on this project was prepared by a French firm.

Lead.—There was a 7% increase in lead production during the year. CENTROMIN continued to be the country's major refined lead producer at the La Oroya complex. Other important lead producers were Cia. Minera Atacocha, Cia. Minera Milpo, Cie. des Mines de Huaron, and Cia. Minera Raura. In November 1975, CENTROMIN signed a contract with Kaiser Engineers of Oakland, Calif., for a basic engineering study of a new $26.6 million lead sintering plant at La Oroya.

Worldwide, Peru ranked fifth in mine production and fifth in reserves, which were estimated at 4 million tons of lead.

Silver.—Peru was among the world's largest silver producers. Production of silver in 1975 increased almost 8%. Silver continued as an important mineral export, ranking third after copper and zinc in value. Silver export earnings in 1975 were $140 million, with 43% going to the United States, the main market. The largest silver producer continued to be CENTROMIN, which produced it as a byproduct from the smelting and refining of copper, lead, and zinc.

Of Peru's total production in 1974, 49% was in the form of refined silver, 2% in sterling, 11% in copper bars, and 38% in ores and concentrates.

INCITEMI was planning to build a silver refinery with a production capacity of 3.5 million troy ounces per year near the Ilo copper refinery.

Zinc.—In 1975, Peru ranked fourth in mine production of zinc. After copper, zinc was the second most valuable Peruvian export in 1975. CENTROMIN continued to be the major producer with 45% of national output.

As one of its priority projects, CENTROMIN was planning to expand its zinc refinery at La Oroya from 70,000 to 90,000 tons per year. The feasibility study was completed in April 1975. In November, CENTROMIN signed a contract with the consulting firm Surveyer, Nenninger and Chenevert of Montreal to prepare the basic engineering studies.

In November, the Peruvian Government approved a $77.5 million contract between Minero Perú and the Syndicat Belge d'Enterprises S.A. (SYBETRA) for the construction of a 75,000-ton-per-year zinc refinery to be located at Cajamarquilla, 38 kilometers east of the port of Callao. Input for the new refinery was to be supplied by mines in the central Andean region producing about 200,000 tons of zinc concentrates, which were being exported unrefined. Completion was expected in 1978.

NONMETALS

Cement.—Production of portland cement has almost quadrupled since 1960 when output was about 600,000 tons. In February 1975, the Minister of Industry stated that Fabrica Cementos Lima in Lima, Fabrica de Cemento Pacasmayo in La Libertad, and Fabrica Cemento Yura in Arequipa will be expanded so that Peru can remain self-sufficient and would have a surplus to export by 1978, when total output is planned to be 3.5 million tons.

Fertilizer Materials.—Minero Perú completed a feasibility study for the development of the phosphate rock deposits in the Sechura Desert of northern Peru, as a part of the Government program to establish a fertilizer and petrochemical complex at Bayovar.

The Talara fertilizer complex built for PETROPERU by Toyo Engineering of Japan began commercial production in April. The design capacity was 168,000 tons per year of nitrogenous fertilizer materials. During 1975, 48,000 tons of urea was produced.

MINERAL FUELS

Coal.—The combined production of anthracite and bituminous coal has been decreasing since 1969 when total production was 161,800 tons. Production in 1975 was insignificant.

KOPEX of Poland and Universal Engineering of Switzerland were negotiating with ELECTROPERU and Minero Perú for a detailed technical-economic feasibility study of the proposed Alto Chicama coal mining-energy complex. A preliminary feasibility study of the Alto Chicama anthracite coal deposit, north of Trujillo, was completed by KOPEX in 1974. Based on their findings, KOPEX recommended development of a mine followed by construction of a thermo-electric powerplant. The proposed 480-megawatt plant would supply energy for the Michiquillay copper project and the fertilizer-petrochemical complex at Bayovar.

KOPEX completed its study of the Oyon deposits, east of Huacho in the Department of Lima, reported to contain coal suitable for blending with coking coals. Further evaluations by an independent consultant indicated that the infrastructure costs alone would be too high for exploitation in the near future.

Petroleum. — The Government-owned PETROPERU continued to be responsible for all aspects of the industry from exploration through marketing. In addition to its own extensive operations, seven foreign companies continued to carry out exploration and production service contracts for PETROPERU.

As of January 1, 1975, the Maquia concession, with a production of 1,000 barrels per day, was taken over by PETROPERU. This action completed the termination of the old concession system in accord with government guidelines that called for the abolition of oil concessions.

There was a 6% decline in the production of crude oil compared with that of 1974. A 25% decrease in production on the Continental Shelf was not offset by increased production in the Amazon area. Crude oil production during 1975 was from the northwestern coastal area (49%), the Continental Shelf (40%), and the Amazon jungle area (11%). The country's consumption rate was approximately 113,000 barrels per day compared with a production rate of 65,000 barrels per day. The deficit of 48,000 barrels per day was covered by imports from Colombia, Ecuador, and Venezuela. Total imports of petroleum and petroleum products in 1975 were valued at $227 million.

In March, oil production began in the Shiviyacu Field in the Amazon Basin within the contract area of Occidental del Peru Petroleum Co. By yearend, production from Shiviyacu was averaging 8,000 barrels per day and production facilities were expanded to allow an output of 10,000 barrels per day. The oil was pumped through a pipeline to a storage terminal on the Tigre River and then shipped by barge 720 kilometers to the port of Iquitos on the Amazon River. Occidental's 50% share of production was sold to Petróleo Brasileiro S.A., the Brazilian State oil company.

At yearend, construction was completed on one-half of the 853-kilometer, 24- and 36-inch Trans-Andean pipeline project of PETROPERU to run from San Jose de Saramuro west to the Pacific port of Bayovar. This project, which began in the fall of 1974, was originally estimated to cost $250 million and was expected to be completed by mid-1976. By yearend 1975, it became apparent that the 200,000-barrel-per-day pipeline would not be completed until late 1976 or early 1977 and that the cost of the project would be about $650 million.

Occidental was negotiating a contract with PETROPERU under which the latter would construct and finance a 250-kilometer spur pipeline to the Trans-Andean pipeline from Occidental's contract area. The 16-inch-diameter spur will have a capacity of 80,000 barrels per day and was estimated to cost $115 million. Completion of the spur pipeline was expected in late 1976 or early 1977.

It became evident in 1975 that the optimistic projections made in 1973 for an output of 500,000 barrels per day of crude oil from the Peruvian Amazon Basin would not be realized. The maximum output from the Amazon fields already discovered was estimated at 130,500 barrels per day by 1980. PETROPERU indicated in late 1975 that proved reserves of 11 productive structures amounted to 546 million barrels in the Amazon area, not including additional probable reserves which could amount to 204 million barrels. At yearend, total proven reserves of petroleum in Peru were estimated at 770 million barrels.

At yearend 1975, total refinery capacity in Peru was 113,000 barrels per day. PETROPERU planned to build two new refineries—a 150,000- to 300,000-barrel-per-day unit at the Bayovar terminal, and a 12,000-barrel-per-day refinery near pumping station No. 5 on the Maranon River across from Borja. Additionally, PETROPERU's La Pampilla refinery was to be expanded from a capacity of 37,000 to 100,000 barrels per day by yearend 1976.

The Andean Pact program for the petrochemical sector was approved on August 29, 1975. Twenty products were assigned to Peru. The investments proposed for Peru totaled $420 million. For new projects, feasibility studies would have to be completed within 2½ years and production initiated by yearend 1982. A provision in the agreement permits the establishment of petrochemical plants for non-Andean markets.

The Mineral Industry of the Philippines

By E. Chin [1]

The Philippine economy continued to grow in 1975 in spite of worldwide inflation and falling export demand due to recessions in major markets.[2] At current prices, the gross national product (GNP) reached $15,388 million [3] in 1975, compared with $13,864 million in 1974. In terms of constant 1967 prices, GNP was $5,986 million, showing a real growth of 5.9%, compared with 5.7% in 1974. The net domestic product in 1975 was $4,703 million in 1967 prices; contribution by origin follows: Agriculture, fishery, and forestry, 34%; manufacturing, 25%; services, 17%; commerce, 15%; construction, 3%; mining and quarrying, 2%; and other, 4%.

Output of ores and concentrates containing chromium, copper, gold, iron, nickel, silver, and zinc comprised 71% of the mineral production value.[4] All except nickel were exported for smelting overseas. Copper continued to dominate the mineral industry, providing 42% of the total mineral output value, which was estimated to be around $542 million in 1975 at current prices. The indices of physical volume of production for mining and mineral-related industries in the manufacturing sector were as follows (1965=100):

Sector	1974	1975
Mining:		
Coal	56.7	48.5
Iron	118.4	97.6
Chromium	95.7	98.2
Copper	630.5	815.9
Gold	127.8	106.3
Other	91.4	162.2
Manufacturing:		
Chemical products	119.3	138.1
Petroleum and coal	146.4	173.3
Nonmetallic minerals	134.9	130.2
Basic metals	534.4	411.5
Metal products	179.5	149.5

In 1975, the Philippines traded with 133 countries. The country's largest trading partners were Saudi Arabia, Kuwait, the Netherlands, the United States, Australia, West Germany, Malaysia, Canada, Indonesia, and the United Kingdom, in that order. Petroleum and petroleum products were the principal imported materials by value, while the top three export items were sugar, coconut oil, and copper concentrate.

By yearend 1975, 18 million hectares had been covered by reconnaissance surveys out of a total land area of 30 million hectares targeted for geological survey. Of the 18 million hectares, only 1.4 million hectares were covered by detailed and semidetailed geological surveys. The 1.4 million hectares were estimated to contain 12 billion tons of metallic mineral ore reserves. The amount of Philippine ore reserves contained in this area follows: Gold (primary ore), 0.6 million tons; gold (byproduct ore), 0.2 million tons; copper ore, 650 million tons; iron ore, 1.0 billion tons; nickel ore, 1.1 billion tons; and 225 million tons of other mineral ores including chromite, mercury, zinc, molybdenum, and platinum-group metals. In addition, the country had various other minerals which have not been inventoried such as pyrite, limestone, shale, gypsum, kaolin, feldspar, silica sand, magnesite, dolomite, asbestos, talc, coal, and sulfur.

PRODUCTION

The value of mineral production in 1975, excluding petroleum products, decreased 13% to $542 million. Copper production dominated the mineral sector, comprising 42% of the mineral output value, followed by gold, 15%; chromium, 3%; iron, 2%; silver, 1%; and zinc, 0.8%. Output of portland cement, second to copper in value, dominated nonmetallic mineral production and accounted for 22% of the country's total mineral output value. Output values of other nonmetallic minerals of importance were: Construction materials (principally sand and gravel), $17 million; fertilizers, $6 million; salt, $3 million; gypsum, $2 million; and silica sand, $1.4 million. Output of coal, about double the 1974 production, was valued at $1.8 million. Production of residual fuel oil led total output of petroleum refinery products, followed by gasoline, distillate fuel oil, kerosine, and jet fuel, in that order.

TRADE

Total trade in 1975 was $5,754 million, down 2% from the 1974 figure.[5] Exports decreased from $2,725 million in 1974 to $2,295 million in 1975. However, imports increased 10% to $3,459 million in 1975. The largest import items were mechanical and electrical machinery, apparatus, and appliances, 23.4%; mineral fuels, lubricants, and related materials, 22.3%; transport equipment, 8.7%; foodstuffs, 6.9%; base metals, 6.2%; and chemicals, 4.4%. By value, shipments from Japan accounted for 28% of the Philippines' total imports, followed by the United States, 22%; member nations of the Organization of Petroleum Exporting Countries, 17%; countries of the European Economic Community (EEC), 12%; and others, 21%.

Food products, principally sugar, coconut oil, desiccated coconut, bananas, and pineapple, constituted 41% of total exports, or $94.3 million, followed by plant fibers, 9.6%; lumber products, 9.4%; copper concentrates, 9.2%; gold ore, 3.3%; and others, 27.5%. Principal export destinations were Japan, the United States, EEC, and others, in that order. In 1975, the value of mineral and metal products represented 17% of all exports. Table 2 indicates the quantity and value of major mineral products exported during 1975.

COMMODITY REVIEW

METALS

Aluminum.—West Pacific Alumina Corp., an eight-member consortium, was considering the construction of an alumina plant at Mindanao using bauxite imported from Weipa, Australia. The feasibility study called for an 800,000-ton-per-year alumina plant to be completed by 1980, which would later be expanded to 4 million tons per year.

In 1974, Reynolds International, Inc., signed an agreement of intent to construct a 100,000-ton-per-year aluminum smelter at Ormoc, Leyte Province. A smelter, designed to use indigenous aluminous clays, was being considered. The project was held at abeyance pending the economic availability of power. Swiss Aluminium Ltd. reportedly was considering a 10,000-ton-per-year aluminum smelter at Mindanao.

Chromite.—The bulk of the refractory-grade chromite was mined in Masiloc, Zambales, by Benguet Consolidated, Inc., for Consolidated Mines, Inc. The remainder of the output, 761 tons, was by Superior Mining and Industrial Corp., a new company which began production in January 1975. Three companies produced metallurgical-grade chromite. Acoje Mining Co. Inc., accounted for 98% of the output. Cecilia Estanislao and New Frontier Mines, Inc., new producers of lump ore in 1975, accounted for the remainder. At yearend 1975, the estimated reserves of refractory-grade chromite ore in the Philippines were 6.65 million tons; reserves of metallurgical-grade chromite ore were 1.47 million tons.

Table 5.—Philippines: Production and exports of chromite, 1975

Total exports	486,766	20,085

Copper.—Production of copper ores and concentrates in 1975 totaled 840,991 tons and was by 11 companies from 12 mines. Apex Exploration & Mining Co., Inc., Consolidated Mines, Inc., and Eastern Rizal Copper Corp., ceased production at yearend 1974, and no mine output was reported for 1975. Output of byproduct copper concentrates totaled 2,319 tons, valued at $316,835, and was by Benguet Exploration Co. (694 tons), Itogon-Suyoc Mines Inc. (508 tons), La Suerte Gold Mining Corp. (157 tons), and Zambales Base Metals, Inc. (960 tons).

Atlas Consolidated Mining & Development Corp. (Atlas), with the largest copper mine in the Philippines, accounted for 41% of the total domestic production in 1975. Installation of a third concentrator at its Carmen ore body was scheduled for completion in 1978, thereby adding 32,000 tons of milling capacity to bring Atlas' total concentrate capacity to 94,000 tons per day. A 130,000-ton-per-year copper smelter, designed to treat the output of the three concentrators, was planned for construction on Bataan, Luzon Island, or Cebu Island, at an estimated cost of $300 million. However, the Government requested Atlas to defer the smelter project until the establishment of a Government-supported copper project, Copper Smelter Corp. of the Philippines (CSCP). The CSCP smelter with an annual output of 84,000 tons of copper was to be sited on Negros Island. Although CSCP is a joint venture of the Government and copper producers, foreign investors were to be invited to participate to the extent of 40% of equity.

Marcopper Mining Corp., the second largest producer of copper, completed expansion of its concentrator throughput capacity to 24,600 tons per day. Philex Mining Corp (Philex), the third-ranking copper producer, completed the expansion of its concentrator from 14,000 tons per day to 24,000 tons per day in July 1975. Under Philex management, the Santo Nino mine of Baguio Gold Mining Co. was expanding the capacity of its concentrator to 7,500 tons per day, to be operational in early 1976. Expansion of the Sipalay mill of Marinduque Mining &

Industrial Corp. was completed during the year. Western Minolco Corp. planned to expand its milling capacity from 15,000 to 22,000 tons per day by mid-1976; a second-stage expansion to 30,000 tons per day was also proposed.

Benguet Consolidated, Inc., conducted geologic testing of several porphyry copper prospects. Indicated ore reserves were estimated at 92 million tons of 0.42% copper for the Dizon prospect, 112.6 million tons of 0.42% copper for the Tayson prospect, and 155 million tons of 0.393% copper for the Tawi-Tawi prospect. Development of the underground mine and the construction of a 20,000-ton-per-day concentrator at Tayson, Luzon, was underway. Estimated cost for the project was $24 million. Benguet Consolidated also planned to develop the Tawi-Tawi prospect and to install a 30,000-ton-per-day mill at the site.

Table 6.—Philippines: Production and exports of copper concentrates, 1975

	Quantity (metric tons)	Value (thousands)
Production by company:		
Acoje Mining Co., Inc	6,513	$818
Atlas Consolidated Mining & Development Corp	343,894	103,631

Marcopper Mining Corp	131,834	32,021
Marinduque Mining & Industrial Corp.:		
Bagacay project [1]	47,183	4,748
Sipalay project	96,411	22,147
Philex Mining Corp	102,092	30,408
Philippine Iron Mines Inc	1,405	287
Western Minolco Corp	34,541	7,258
Total	840,991	225,958
Exports by country of destination:		
China, People's Republic of	28,194	9,497
Greece	19,903	4,847
India	13,579	3,286
Japan [2]	665,313	171,500
Taiwan	9,512	2,496
United States	43,180	18,328
Total	779,681	209,954

[1] Includes 21,503 tons of direct-shipping-grade ore, valued at $1,153,470.
[2] Includes 17,253 tons of direct-shipping-grade ore, valued at $1,136,871.

Gold.—Total output of gold in 1975 was 501,808 troy ounces, valued at $79 million. Production by primary producers follows, in troy ounces: Atok-Big Wedge, 3,215; Benguet Consolidated, 127,413; Benguet Exploration, 13,310; Itogon Suyoc Mines, 28,614; La Suerte Gold Mining Corp., 3,922; Manila Mining Corp., 4,115; and Northern Surigao Mining Corp., 482. Gold recovered as a valued byproduct of copper processing totaled 320,703 troy ounces. Principal producers of byproduct gold were Philex Mining Corp., 134,422 troy ounces; Atlas, 79,669 troy ounces; and Lepanto Consolidated Mining Co., 40,478 troy ounces. The remainder of the production was by Marcopper Mining Corp., Western Minolco Corp., Marinduque Mining & Industrial Corp. (Sipalay and Bagacay copper project), and Black Mountain, Inc., in order of output.

The Central Bank of the Philippines contracted with Johnson-Matthey for a gold-silver refinery to be located in Quezon City. The refinery capacity, reportedly sufficient to process domestic concentrates for all of the country's gold-silver bullion production, would be about 610,000 troy ounces of gold and about 450,000 troy ounces of silver. Completion date for the project was scheduled for 1976–77.

Iron Ore.—Inco Mining Corp., the largest iron ore company in the country, produced 722,324 tons of magnetite in 1975; 83% of the output was from its Leyte operation, and the remainder from its Negros operation. During the year, Inco concluded an agreement with Nippon Steel

Corporation of Japan for the purchase of 1 million tons per year of magnetite for 10 years commencing in 1978.

Filmag (Philippines), Inc., produced 595,476 tons of magnetite from beach sands located along the west coast of northern Luzon Island. Filmag announced a $32 million project to establish an iron smelter in the Philippines to produce 75,000 tons of ductile pig iron to be used in the manufacture of specially cast products and specialty steels. This project was expected to be operational by 1977–78.

Philippine Iron Mines accounted for the remainder of iron ore production. Three small operations, Anglo-Philippines Oil and Manufacturing Corp., Atlas, and Long Beach Mining Co., ceased mine production in 1974.

Table 7.—Philippines: Production and exports of iron ore concentrate, 1975

	Quantity (metric tons)	Value (thousands)
Production by company:		
Filmag (Philippines), Inc	595,476	$5,394
Inco Mining Corp	722,324	6,517
Philippine Iron Mines Inc	33,646	600
Total	1,351,446	12,511
Exports by country of destination:		
Japan	1,473,315	13,296
United States	38,495	666
Total	1,511,810	13,962

Nickel.—Mine output of nickel was 9,500 tons in 1975 and was by Marinduque Mining & Industrial Corp. (9,364 tons) and Acoje Mining (136 tons). Production by Acoje Mining was nickel contained in nickel-cobalt sulfide concentrate which was shipped to Japan for smelting. The Nonoc mine and refinery of Marinduque Mining was commissioned in 1974. This operation, based on the Sherritt-Gordon hydrometallurgical process, has a rated capacity to produce 31,000 tons of nickel metal and 4,500 tons of mixed nickel-cobalt concentrate from lateritic ores. The Nonoc refinery, however, had startup difficulties, and plant production reportedly averaged 27.5% of the designed capacity for the whole year.

Rio Tuba Nickel Mining Corp., in a joint venture with Pacific Metals Co. Ltd., a Japanese firm, began the development of a nickel mine and concentrator complex on Palawan Island. Design mine output was 500,000 tons per year of nickel ore with initial production targeted at around 350,000 tons, to be onstream in 1976. Total output was scheduled for export to Japan for ferronickel production. The $34 million project was scheduled for completion in 1978.

Atlas postponed the development of its mine and concentrator project on Palawan Island and the construction of a nickel refinery at Mindanao owing to the high cost of fuel oil. The company, however, was conducting studies to determine the feasibility of using coal in place of oil.

Other Metals.—In 1975, production of silver by 16 companies totaled 1.62 million troy ounces, valued at $7 million. Most of the silver was contained in copper concentrates, which were shipped to Japan for smelting. The gross weight of zinc mine output was 19,113 tons, valued at $4.5 million. Production was by Benguet Exploration (10,801 tons), La Suerte Gold Mining Corp. (17 tons), and Zambales Base Metals, Inc. (8,295 tons). In addition, small amounts of cadmium, cobalt, lead, mercury, molybdenum, manganese, platinum, and palladium were produced; total value of output was estimated at $2.1 million.

NONMETALS

Cement.—Output of cement in 1975 by 15 plants totaled 4.3 million tons, valued at $121 million. Marinduque Mining's Island Cement Corp. produced 565,582 tons, followed by Northern Cement

Corp., 563,652 tons, Republic Cement Corp., 445,382 tons, and Bacnotan Construction Industry Corp., 438,374 tons. The remainder of the production, in order of output, was by Floro Cement Corp., Fortune Cement Corp., Filipinas Cement Corp., Iligan Cement Corp., Hi-Cement Corp., Rizal Cement Co., Inc., Mindanao Portland Cement, Continental Cement Corp., Pacific Cement Corp., Luzon Cement Corp., and Apo Cement Corp. Universal Cement Corp. ceased production in December 1974.

During the year, about 690,000 tons was exported, principally to Indonesia (199,838 tons), Bangladesh (192,333 tons), Saudi Arabia (77,103 tons), Iran (49,002 tons), and Brunei (48,417 tons). The remainder of the cement shipments were to 12 countries in Southeast Asia and the Middle East.

Fertilizer Materials.—Output of guano increased from 13,552 tons in 1974 to 125,813 tons in 1975. Production of phosphate rock on the other hand decreased 80% to 5,401 tons. Production of sulfur remained at the 160,000-ton-level. Most of the output of sulfur was recovered as a byproduct of copper ore flotation and was converted to ammonium sulfate by domestic fertilizer producers. Close to 16,000 tons of limestone production was consumed locally in agricultural uses.

Other Nonmetals.—Clay production in 1975 totaled 470,444 tons. Initial production from the 45,000-ton-per-year bentonite mine and processing plant of Lepanto Exploration, Inc., and Filmag, Inc., was only 661 tons.

Gypsum production decreased 6.5% to 117,983 tons. About 6% of the output was mined; the rest was recovered as a byproduct of phosphate rock processing.

Lime production continued to decline and was 35,728 tons in 1975. Limestone production was 5.8 million tons, of which 98% was consumed locally in the manufacture of cement.

Production of sand and gravel totaled 5.3 million cubic meters. Output of other construction materials, including broken adobe, crushed coral and stone, rock aggregate, stone, cobbles, and boulders, totaled 942,131 cubic meters. Production of unprocessed marble was 11,805 tons; production of processed marble was valued at $1.3 million.

Production of marine salt declined to 70,625 tons from 213,644 tons in 1974. Output value of other nonmetals during 1975 follows: Barite, $106,000; feldspar, $81,000; perlite, $29,000; and talc, $50,000.

MINERAL FUELS

Coal.—Production of coal in 1975 was double the 1974 output and totaled 105,128 tons, valued at $1.8 million. Output by 15 establishments in Cebu Province was 90,847 tons. The remainder was by one mine in Zamboanga del Sur. All production was consumed domestically.

Petroleum.—The Philippines continued to meet its oil demands by imports, primarily from the Middle East. Imports of crude oil in 1975 totaled 9,137,000 tons and were provided as follows, in thousand tons: Saudi Arabia, 4,807; Kuwait, 1,859; Indonesia, 698; Malaysia, 553; People's Republic of China, 414; Iran, 373, Iraq, 336; and other, 97.

By presidential decree of August 25, 1975, all activities relating to the discovery, development, and production of indigenous petroleum resources were placed under a single governmental authority. The powers and duties formerly vested in the Secretary of National Resources were transferred to the Petroleum Board created under Presidential Decree No. 87. The functions of the Petroleum Division of the Petroleum Technical Committee in the Bureau of Mines, together with applicable appropriations, records, equipment, and property, were likewise transferred to the Petroleum Board.

The decree provided that "all holders of valid and subsisting petroleum exploration concessions or published petroleum exploration concession applications under the Petroleum Act of 1949, as amended, shall convert their concession or concession application to a service contract under the terms and provisions of Presidential Decree No. 87, either alone or with any local or foreign oil company or companies within a period of one year from the effective date of this Decree. Any concession or concession application not so converted for any cause within the said one year period, shall be deemed automatically cancelled and the area covered thereby shall become part of the National Reserve Area."

The Philippine National Oil Co.

(PNOC), an arm of the Petroleum Board, mapped out an extensive program to spur exploration. Forty-eight concessions covering 26,000 square miles offshore had been converted to contracts between 1972 and 1975. Concessions covering an area of 45,200 square miles, of which 60% was in offshore areas, remained to be converted; about 50 companies were involved in this conversion process. The companies were encouraged to pool resources and were free to select foreign partners. PNOC's objective was to place exploration rights with companies or groups of companies that have the financial and technological capability to carry out sound and active exploration programs.

The Government forbids any company to make public announcements on drilling operations, and reserves this prerogative for itself; no government announcements were made in 1975. While some oil shows have been reported, no commercial finds have been confirmed. At least seven holes were known to have been drilled offshore Palawan and in the Sulu Sea in 1975 by Amoco Philippines, Inc., Sun Oil Co. (two holes), Champlin Philippines, Inc., Cities Service International Inc., and Phillips Petroleum International, Inc. (two holes).

PNOC budgeted $2.78 million for geological and geophysical surveys in the Cagayan Valley and in central Luzon for 1976. The Chinese Petroleum Corporation (Taiwan) carried out an active drilling program on Cebu Island for several years without success. The company, under contract with Philippine firms, was committed to drill three wildcats in the range of 15,000 to 16,000 feet.

The Mineral Industry of Poland

By Tatiana Karpinsky [1]

In 1975, Poland continued to be the world's 10th largest industrial nation with 2.3% of total world industrial output and about 8% of the total industrial output of CMEA[2] member countries. The country accounted for approximately 7.2% of world coal output, 5% of the production of lignite, 2.5% of the copper, 2.2% of the steel, and 13% of the sulfur.

There are large reserves of coal, lignite, sulfur, copper, salt, and construction materials in Poland, but the country remains deficient in oil, natural gas, iron ore, phosphates, nickel, manganese, tungsten, chrome, and rare earths.

In 1975, Poland was the world's 4th largest producer of bituminous coal and 5th in the production of lignite, 8th in copper ore, 8th in zinc and lead ore, 3d in elemental sulfur, and 12th in salt. Mining contributed about 6% of the country's total industrial output, accounted for 10% of the employment in industry, and 4% of the national labor force.[3] Development of the mining industry accounted for about 14% of annual investment allocated to industrial expansion. In 1975, the Polish mining industry produced over 446 million tons of mineral raw materials, representing a growth of 8.3% compared with the 1974 level.

According to Polish sources, the national income of Poland in 1975 increased about 8% compared with the 1974 level. The value of gross industrial production (in current prices) increased 12%. In agriculture, the value of net production declined 2.6% below the level of 1974. Capital investment in the economy totaled approximately Zl484 billion in 1975,[4] an increase of about Zl60 billion, or 14%, over that of 1974.

Government Policies and Programs.—The final targets of the sixth 5-year plan (1976–80) were approved by the Seventh Congress of the Polish United Workers' Party and ratified by the Polish Sejm in 1976. The new 5-year plan foresees a 42% increase in national income. The plan calls for a 50% increase in gross industrial output and a 17% rise in agricultural production. The basic task of the new 5-year plan is the better utilization of existing production facilities and the achievement of higher technical and quality levels.

Accelerated development was planned for energy and mineral fuel commodities. Extraction of hard coal in 1980 is to increase more than 17% over the 1975 level, and is to reach a total of more than 200 million tons. The generation of electric power in 1980 is to reach 132 billion kilowatt-hours. The goal is to make Poland a net exporter of energy by 1980.

The metallurgical industry is to be expanded and modernized. Production of steel in 1980 is to increase about 40% and is to reach 20 million to 22 million tons. Output of rolled products is to increase 30%; that of steel pipe, almost 30%; and that of cold-rolled sheet metal, 50%. Targets for 1980 call for the production of 425,000 tons of copper, 120,000 tons of lead, 140,000 tons of aluminum, and 260,000 tons of zinc. Production of the electrical engineering in-

[4] Where necessary values have been converted from Polish Zloty (Zl) to U.S. dollars at the official exchange rate of Zl3.32=US$1.00 (basic rate), special commercial rate, Zl19.92=US$1.00.

dustry is to expand 67% and that of the chemical industry about 70% with marked increases in the production of petrochemicals, fertilizers, sulfur, and salt.

All branches of industry are to be developed for the export market. The plan calls for a 15% increase in exports per year during the 1976–80 period. Capital investments in Poland for the next 5 years are to be increased 37% to 40% to about Zl2,600 billion. Of this amount, Zl700 billion is to be used for completion of projects already underway and Zl1,900 billion will be invested in new productive capacity.

PRODUCTION

Among the minerals and fuels in the Polish economy, coal is considered the most important because it is the major fuel and because of its significance in the development of the national economy. About 95% of Poland's power generation is based on coal and lignite. The increase in production of hard coal in 1975 was 9.6 million tons, or 5.9%, compared with production in 1974. Lignite production was 39.9 million tons, nearly the same as in 1974. In 1975, there were 68 hard coal mines; 2 underground mines and 7 open pits produced lignite. Of the 340,300 employees in the coal industry, 219,800 were employed at deep mines. Longwall mining of hard coal accounted for about 87% of production in 1975, practically unchanged from 1974.

In December 1975, the Piast mine at Nowy Bierun (south of Katowice) was commissioned. Its target output was set at 24,000 tons per day by 1982. In January 1975, the final decision was made to develop a complex of underground coal mines in the Lublin region. It was assumed that the whole complex of mines in Lublin Basin will produce about 25 million tons per year in 1990. It was planned to develop new coking coal mines in the Rybnik area and to continue the development of a fuel-power complex in the Belchatow region. It was assumed that open pits in the Belchatow region will produce 40 million tons of brown coal per year in the future. There were plans to expand 25 mines, among which were Halemba, Jankowice, Makoszowy, Sosnica, and Ziemowit. The plans also called for the development of two commercial plants for gasifying coal with further processing facilities for chemical products.

Polish output of iron ore decreased from 1.3 million tons in 1974 to 1.2 million tons in 1975. To meet the raw material requirements of rapidly increasing iron and steel production, Poland has been importing iron ore from the U.S.S.R., Sweden, Brazil, and other countries. In 1975, 16.4 million tons of iron ores were imported, an increase of 5.1% in comparison with 1974. In 1975, production of pig iron totaled 7.6 million tons and that of crude steel 15.0 million tons (an increase of 0.4 million tons of steel over the 1974 level).

Imports of pig iron reached 1.8 million tons. Poland's main targets in 1975 were to continue modernization of existing metallurgical plants and to develop the Katowice steelworks. The entirely new Katowice plant is to have two of the largest blast furnaces in Poland (each with a capacity of 3,200 cubic meters), three sinter units, and two 350-ton oxygen converters. The plant is to supply 4.5 million tons of raw steel per year during the first phase of operation, and 9 million tons in the second phase. Production at the plant was expected to start in October 1976.[5] The total cost of construction was estimated at Zl34 billion.

Development of the copper industry continued in the Legnica-Glogow copper region. In 1975, copper ore output amounted to 17.0 million tons, an increase of 3.2 million tons, or 23%, over that of 1974. Production of electrolytic copper amounted to 249,000 tons, an increase of 27.7% over the 1974 level. The growth in mine production of copper was derived from the greater application of mechanized mining methods. Poland will continue modernization of copper mines and processing plants. A new smelter is planned for the Legnica-Glogow complex.

In 1975, lead-zinc ore production reached 4.6 million tons, an increase of 10% over the 1974 level. Production of refined lead increased from 71,600 tons in 1974 to 76,200 tons in 1975, and that of refined zinc from 233,000 to 243,000 tons. To increase production of lead and zinc, a new Imperial Smelting Furnace (ISF) is scheduled to start operation in 1977 at the Huta Cynku

[5] Zolnierz Wolnosci (Soldier of Freedom), Warsaw. May 1976, p. 5.

Miasteczko Slaskie works. Imports of zinc concentrate continued in 1975.

In 1975, production of crude petroleum amounted to 553,000 tons. This was far from meeting national demand, and about 13.3 million tons of crude oil was imported from the U.S.S.R. Poland processed about 13.5 million tons of crude oil in 1975. The Plock plant expansion and activation of the Gdansk plant should enable Polish refineries to meet all domestic petroleum product needs.

Output of natural gas was 5.96 billion cubic meters, and imports of Soviet gas amounted to 2.51 billion cubic meters in 1975. Poland needs gas not only as a fuel, but also for its chemical industry. It was estimated that a complex for fertilizers and other products at Police, near Stettin, will require up to 50% of all the gas now used in Poland.[6]

In 1975, the three sulfur mines produced 4.8 million tons of sulfur, and 3.1 million tons of sulfur was exported.

In 1975, production of different varieties of salt totaled about 3.5 million tons from deposits having total reserves of 46 billion tons. Poland's salt production supplies all of the domestic demand and allows for an export of approximately 200,000 tons annually. Klodawa and Inowroclaw are the two major salt-producing areas in the country.[7]

The total output of construction materials was over 215 million tons in 1975. Fire clays, burnt slate, gypsum slabs, slaked lime, and granite were exported from Poland.

Production of electric energy was 97.2 billion kilowatt-hours, an increase of 6.1% over that of 1974. In 1975, the country exported 2.9 billion kilowatt-hours and imported 2.4 billion kilowatt-hours.

The 1975 production plan for many mineral commodities was met, but natural gas, crude steel, rolled products, petroleum products, and cement production failed to meet the growth rate set for 1975. The year 1975 marked the end of the sixth 5-year plan, 1971–75. According to Polish sources, in this 5-year period, the national income of the country increased more than 50%. The following increases compared with 1970 figures have been reported, in million tons: Raw hard coal, 32; raw lignite, 7; copper ore, over 10; sulfur, over 2; zinc and lead ore, over 1.

e Estimate. p Preliminary. r Revised.

[1] In addition to the commodities listed, antimony, cobalt, germanium, gold, a variety of crude nonmetallic construction materials, and carbon black are also produced in Poland, but information is inadequate to make reliable estimates of output levels. Poland may also produce alumina in small quantities, but details on such an operation, if it exists, are not available.

[2] Includes content of multigradient fertilizers.

[3] Total of listed commodities only, excluding products not reported individually in official sources, as well as refinery fuel and losses.

TRADE

In 1975, Polish foreign trade turnover amounted to Zl75.8 billion, an increase of Zl13.4 billion, or 21.5%, over that of 1974. In 1975, total exports were valued at Zl34.2 billion, an increase of Zl6.6 billion, or 23.9%, over that of 1974, and the value of imports rose to Zl41.7 billion, an increase of Zl6.9 billion, or 19.8%, compared with the 1974 level. The trade balance showed that the deficit increased from Zl7.2 billion in 1974 to Zl7.5 billion in 1975, or 4.2%. Most of the deficit was incurred in trade with non-CMEA countries.

The value of total commodity trade with various groups of countries in 1975 follows:

Country group	Exports		Imports	
	Million zlotys	Percent	Million zlotys	Percent
CMEA and other [1] centrally planned economy countries	20,472	60	19,087	46
EEC [2]	6,289	18	11,610	28
EFTA [3]	1,973	6	4,870	12
Other developed countries	2,506	7	4,059	9
Developing countries	2,921	9	2,025	5
Total	34,161	100	41,651	100

[1] People's Republic of China, Yugoslavia, North Vietnam, and North Korea.

[2] European Economic Community comprising the following countries: Belgium-Luxembourg, Denmark, France, Ireland, Italy, the Netherlands, the United Kingdom, and West Germany.

[3] European Free Trade Association comprising the following countries: Austria, Finland, Iceland, Norway, Portugal, Sweden, and Switzerland.

In 1975, more than one-half of Poland's foreign trade was transacted with the centrally planned economy countries, primarily the U.S.S.R. (31.5% of the total exports and 25.3% of the total imports), East Germany (9.2% exports, 7.5% imports), and Czechoslovakia (8% exports, 5.4% imports). West Germany was the developed country with the largest trade turnover (5.2% exports and 8.1% imports), followed by the United Kingdom, Italy, the United States, France, and Austria.

Among branches of the Polish industry, the electrical and manufacturing sector were the most important in production and trade. In 1975, exports of the electrical and manufacturing industry contributed about 41% of Poland's total exports; coal, coke, and electrical power, 20%; chemical products, 9%; steel products, 7%; and products of remaining industries, about 23%. Of the total value of imports, engineering and manufactures accounted for 41%, steel products 18%, chemical 12%, and petroleum and power 6%.

In 1975, the most significant increases in Poland's exports, compared with those of 1974, were 56% in copper, 36% in petroleum products, 16% in sulfur, and 5% in coke. Decreases in exports were noted for lignite (35%) and hard coal (4%). Substantial increases in Poland's imports included 26% in petroleum, 18.4% in gas, 5.1% in iron ore, and 3.4% in alumina. Imports of steel products decreased 26% in 1975, compared with 1974 figures.

In response to the situation confronting the Polish economy, action was being taken to reduce imports, increase exports, and borrow enough money to overcome what is seen as a short-term foreign exchange scarcity. New investment proposals were being studied with great care. Projects requiring a net foreign exchange expenditure during the next few years being delayed or abandoned, unless they had a particularly high priority in addition to economic viability. Ministries have been assigned targets of foreign exchange balances, and their progress toward these balances is reviewed regularly by the Ministry of Foreign Trade, whose role has been greatly strengthened. If import levels appear too far out of line with export earnings, the Ministry may be deprived of its right to import.

COMMODITY REVIEW

METALS

Aluminum.—Production of aluminum amounted to 103,000 tons in 1975,[8] an increase of about 1.0% over the 1974 level. The aluminum industry experienced severe domestic raw material shortages and depended on imports of bauxite and alumina.

In 1975, alumina imports from Yugoslavia, the United States, Hungary, and West Germany totaled 272,000 tons, an increase of 9,000 tons, or 3.4%, over the 1974 level.

Production of primary aluminum began at the Skawina plant, near Krakow, in 1954. Equipment for this plant was imported from the U.S.S.R. In 1966, a second plant started production of metal, and in 1967 Poland's output of aluminum had reached 92,000 tons. It is estimated that aluminum production may reach 140,000 tons in 1980.

Construction of the first Polish alumina plant, with an annual capacity of 78,000 tons, at Nowiny near Kielce, continued in 1975. It was reported that the plant may be completed in 1978. The thin aluminum strip section of the Konin aluminum works was estimated to have had an annual capacity of 6,000 tons in 1975. Poland's first aluminum mill, to produce 0.1- to 0.2-millimeter foil, was to start operating in the beginning of 1976. In the second quarter of 1976, a production of 370 tons of aluminum foil was planned.

Copper.—The annual economic plan provided for 235,000 tons of electrolytic copper to be produced in 1975, but the output was actually 249,000 tons, a 28% increase over that of 1974.[9] Electrolytic copper production was planned to reach 285,000 tons in 1976, rising to 425,000 tons by 1980 and to 800,000 tons by 1990.[10]

Production of copper ores totaled 17.0 million tons in 1975, an increase of 3.2 million tons, or 23%, over that of 1974. The 1980 goal was 30 million tons.[11] In 1975, Poland exported 90,300 tons of unwrought copper, 32,300 tons more than in 1974, an increase of 56%. It is planned to increase the export of copper products in the future. In 1975, approximately 75% of the export copper was sent to non-CMEA countries.

In 1975, copper ore was extracted from the Lubin, Polkowice, and Rudna mines (with small output from the old Groditz mine, now called Konrad). The Lubin mine started production in 1968, Polkowice in 1972, and Rudna in 1974. The fourth largest mine, the Choroschowice, was under development in 1975. The Lubin and Polkowice mines each had an annual produc-

[10] Kurier Polski (Polish Courier), Warsaw. December 1975, pp. 1-8.
[11] Journal of Commerce. New York. July 7, 1976, p. 5.

tion capacity of about 5 million tons of ore. The Rudna mine was larger with a projected annual capacity of 7.5 million tons. At the Rudna mine, work was in progress on a new ore concentration plant and a second extraction shaft 1,000 meters deep. The fourth production line of the concentrator, with an annual capacity of 2.5 million tons of ore, was to be put in operation in April 1976. The shaft was to start operation in the third quarter of 1976. The room-and-pillar mining system was the main mining system in use, although shortwall and longwall mining was practiced in some areas.

Two main smelters, one at Legnica and one at Glogow, each a completely integrated plant with smelting and electrolytic refining, were in operation in 1975. The third smelter, at Szopienice, was equipped with an electrolytic refinery and fire-refining furnace for secondary copper. The Szopienice plant also produced Poland's silver, cadmium, and nickel.

Construction of several copper smelters over the 1975–85 decade was planned. The Glogow I plant was completed, and the second stage expansion was to bring its capacity to 160,000 tons of electrolytic copper yearly. The new Glogow II plant, with an annual capacity of 150,000 tons, under a U.S. contract (Textron), was to operate by yearend 1976.[12] Projected capital investment for copper mining and processing during the next 5 years has been set at a level of Zl44 billion.[13]

In the copper mining industry, foreign machinery and equipment were used. The application of new machinery and equipment has resulted in increasing productivity at copper mines.

The Legnica-Glogow copper deposits are located in the Lubin area of Lower Silesia, about 40 miles northwest of Wroclaw. Copper deposits are relatively small and lie at depths of 600 to 1,000 meters. The average copper content is about 1.5%, and proved reserves grading more than 1% of copper were estimated at 1.5 billion tons.[14] The ore deposits lie below water-bearing Tertiary and Quaternary formations, and all shafts had to be sunk using freezing techniques. Rock temperatures in the ore zone range from 28° to 42°C, making heavy demands on ventilation.

Iron and Steel.—In 1975, Poland produced 1.2 million tons of iron ore, a decrease of 104,000 tons, or 8%, from that of 1974, and a decrease of 1.4 million tons, or 53%, from that of 1970. Extraction of iron ore was mainly from mines in the Czestochowa region. Output of iron ore is not large and only partly meets the needs of the Polish industry. The Polish steel industry is almost entirely dependent on imported iron ore, of which 16.4 million tons were purchased in 1975. Imports of iron ore increased in 1975 by 0.8 million tons, or 5.1%, in comparison with those of 1974.

The Soviet Union has for many years been the chief source of iron ore imports. In 1975, approximately 85% of iron ore was imported from the U.S.S.R. and 15% from Sweden, Brazil, and other countries. Under a contract signed at Katowice by Stalexport for Poland and its Soviet counterpart Soyuzpromeksport, the Soviet Union was to supply Poland with 13 million tons of iron, manganese, and chromium ores in 1976.

In 1975, production of pig iron totaled 7.6 million tons, approximately the same as in 1974. Imports of pig iron reached 1.8 million tons and rose 6% as compared with the 1974 level.

In 1975, Poland produced 15.0 million tons of crude steel, an increase of 0.4 million tons, or 3%, over that of 1974. Steel production was expected to reach 16.2 million tons in 1976 and 22 million tons by 1980. In 1975, consumption of steel in Poland was about 19.0 million tons; in 1976, it was expected to total about 20 million tons. The annual increase for steel consumption ranges from 1.0 million to 1.3 million tons.

Output of rolled steel products rose 527,000 tons (5%) over the 1974 level and that of steel pipe rose 45,000 tons (4.1%). Exports of rolled products amounted to 1.3 million tons. Steel products were also an important part of Polish imports. In 1975, imports of rolled products decreased to 1.7 million tons from 2.3 million tons in 1974.[15] Polish steel imports consisted mainly of ingots, thin sheets, and light sections.

In 1975, the main increases in steel demand by industry sector were as follows: Shipbuilding, 50%; agricultural machinery, 22%; automobile industry, 21%; manufacture of metalworking machinery, 11%.

[15] Page 191 of work cited in footnote 8.

The Lenin Steel Works, near Krakow, produced over 40% of Poland's steel output and was the only Polish producer of special steelplate. Products of this plant were galvanized and tinplate, car body plate, thin cold-rolled sheet, cold-bent sections, electroweld pipe, and ship construction plate. In 1975, the Lenin Steel Works produced 6.8 million tons of steel and employed 38,000 people. Long-range plans call for output of more than 10 million tons per year.[16]

The output of the Lenin Steel Works as a percent of total Polish steel industry output follows:

Item	1970	1975
Coke	23.5	22.9
Pig iron	50.7	47.7
Steel	37.2	36.2
Rolled products	35.4	34.9
Steel pipe	16.5	27.3
Cold-bent sections	92.6	98.6

In 1975, there were five blast furnaces in operation at this plant, including a 2,000-cubic-meter-capacity unit, the largest in the Polish metallurgical industry, three modern converters; one tandem-type open hearth furnace; and an ordinary open hearth furnace. The auto plate rolling mill was put into operation in 1975 and was to produce some 350,000 tons of sheet metal in 1976. Decisions have been made to build a sixth blast furnace with a 2,000-cubic-meter capacity.

Production of silicon steel is expected to start in the beginning of 1976. Silicon steel is to be the 50th steel product to be produced at Lenin Steel Works. In 1975, Poland relied on the Soviet Union for supplies of ferroalloys.[17]

At the Laziska plant, the furnace section was being modernized and transportation and loading operations were being fully mechanized.

The Nowotko Steel Works at Ostrowice was to receive Poland's first continuous steel-casting unit from France in 1976. The works was to produce 300,000 tons of high-grade steel in 1976, to be sent for further processing to plants in Warsaw, Florina, Bobrek, and Dzierzynsk. The Florina Steel Works has been modernized and supplies industry with galvanized and plastic-coated sheet metal.

The Institute for Iron Metallurgy at Gliwice was working on steels with greater corrosion resistance and coordinated all metallurgical research in the country in 1975.

The Katowice metallurgical plant at Losien was to supply its first steel at year-end 1976. In that year, the following units were to start production: The agglomerating plant, blast and steel furnaces, and a rolling mill. The total capacity in 1976 was planned to be 4.5 million tons of steel per year. Construction of rolling mill for finished products at this plant was expected to be completed in 1977. Nearly 30,000 workers were employed at the Katowice construction site in 1975. After 1980, the Katowice metallurgical plant was to produce 9 million tons of steel annually.[18]

In 1975, the following installations were brought into operation: (1) Two coke oven batteries with a capacity of 1.6 million tons per year each at Zaklady Koksowricze Zdzieszowice; (2) three 140-ton electric arc furnaces at the Zawiercie Steel Works; (3) one 140-ton electric arc furnace at the Nowotko Steel Works; (4) the first stage of the cold-rolled sheet mill with a capacity of 350,000 tons per year at the Lenin Steel Works.

In 1976, the following installations were expected to be put into operation: (1) Two coke oven batteries at Zaklady Koksowricze Zdzieszowice coke plant; (2) a blast furnace of 3,200-cubic-meter volume, two oxygen converters of 300 tons each, and a blooming mill with continuous casting at Katowice Steel Works, (3) three electric arc furnaces; (4) a mill for production of cold-rolled transformer steel at Lenin Steel Works; (5) a zinc-galvanizing line with cold forming and plastic coating at Florina Steel Works.[19]

Lead and Zinc.—Lead-zinc ore production reached 4.6 million tons in 1975, an increase of 10% over the 1974 level. Extraction of lead-zinc ore was developing in the Olkusz region, which has the largest reserves. The new Pomorzany underground lead-zinc mine started production in 1974.

In 1975, Poland produced 243,000 tons of refined zinc and 76,200 tons of refined lead. Production of lead increased 6.4%, and zinc output increased 4%. Export of zinc and

[16] Kurier Polski (Polish Courier), Warsaw. Sept. 16, 1975, p. 2.
[17] Metal Bulletin, London. Sept. 23, 1975.

[19] United Nations Economic and Social Council (New York). Steel. WP.1/R.4/Add 2, Mar. 24, 1976.

zinc-rolled products (excluding alloys) amounted to 91,700 tons, an increase of 800 tons or about 0.8% over that of 1974. In 1975, the import of zinc concentrate increased to 137,000 tons from 95,200 tons in 1974.

In 1975 a new production line for continuous casting of zinc and zinc alloy strip was commissioned at the Silesia Zinc Works in Katowice. The strip, produced directly from molten metal, is used in the production of gutters, pipes, window sills, and batteries. Poland awarded a contract to Lurgi (West Germany) to construct a plant for the processing of lead and zinc sulfide ores. The contract includes an associated sulfuric acid unit using sulfur dioxide offgases as feedstock. These plants were to form part of the expansion of an already existing zinc smelter at Miasteczko Skaskic, near Katowice, scheduled to start up by 1977–78.

NONMETALS

Fertilizer Materials.—The Polish chemical industry produced 1.5 million tons of nitrogen and 0.93 million tons of phosphatic fertilizers in 1975 (in terms of nutrient content). Production of nitrogen fertilizers increased 4.8% compared with 1974 output, and phosphatic fertilizer increased 13.4%. The goals for 1980 were 2.2 million and 1.3 million tons, respectively. The 1975 volume of annual fertilizer production fully covered domestic requirements. Reportedly, consumption of mineral fertilizers increased from 173.6 kilograms per hectare in 1974 to 182.3 kilograms in 1975. About 905,000 tons of nitrogen fertilizers was exported in 1975.[20] East Germany was one of the main importers and in exchange, Poland purchased potash salts from East Germany. Polish fertilizers were also purchased by Pakistan, India, and Indonesia.

There was a shortage of phosphate ores in Poland. In 1975, in terms of nutrient content, 3.3 million tons of phosphorites and apatites were imported, an increase of about 15% compared with the 1974 level.

The fivefold increase in phosphate prices over the past few years has convinced Poland to resume phosphate production and thus reduce imports. The known deposits in the areas lying in a belt from Annopol to Przytyk (west of Radom) contain only 13% to 22% phosphorus pentoxide and lie at great depths. The Poles in 1975 were prospecting for new phosphate deposits between Przytyk and Ilza and in an area north of Lublin.[21] Phosphate fertilizers were produced at Worclaw, Kracow, Szezecin, Ubocz, Bogus, Zowize, Tornobrzey, and Gdansk.

There were five main nitrogen fertilizer plants in operation in 1975—the Chorzow, Tarnow, Kedzierzyn, Pulawy, and Wlockeawek plants. The nitrogen plants at Pulawy and Police converted to the production of high-concentrate and multicomponent fertilizers prior to 1975. Pulawy was Poland's largest ammonia-producing plant, with a capacity of 1 million tons per year.

In 1975, work began on the new melamine plant at the Pulawy nitrogen fertilizer complex. The 32,000-ton-per-year unit was due to start up in 1977. During the process, byproduct ammonia was to be produced. Poland's largest methanol plant came onstream at the P. Finder chemical combine in Chorzow. It had a design capacity of 100,000 tons per year.[22] The nitrogen plant in Tarnow planned to increase production in 1976 by 6.2% by improving labor productivity and management of materials. A large fertilizer plant was to be built next to the existing plants at Police near Szezecin. The plant was to produce nitrogen, phosphorus, potassium fertilizers, ammonia, urea, sulfuric acid, phosphoric acid, and other products.[23] The complex of facilities, worth $385 million was to be built in cooperation with France. The contract was awarded by Cekop to a West European consortium headed by Creusot-Loire Entreprises. The contract called for construction of two ammonia units, each with a capacity of 750 tons per day, a 1,200-ton-per-day urea plant, and a 2,600-ton-per-day complex-fertilizer unit using the Fisons (United Kingdom) process.[24] The first production of fertilizers from the Police complex was to be delivered in the second half of 1980.[25]

The Poles announced plans to build their own seaport on the River Oder at Police by yearend 1980, to ship fertilizers by inexpensive water transport to the interior of Poland.

Sulfur.—About 90% of sulfur in Poland was extracted by the Frasch process. Poland's sulfur output totaled 4.8 million tons in 1975, a 16.7% increase over that of 1974. It was anticipated that the output of sulfur would increase to about 7 million tons in 1980. Poland had become the world's second largest exporter of sulfur, with 1975 exports reaching a volume of about 3.1 million tons, almost one-third of the total world sulfur exports. The new 1976–80 plan called for annual exports of 5 million tons by 1980. In 1975, about 50% of Poland's sulfur was exported to CMEA countries. The U.S.S.R. imported over 1.5 million tons. Imports of Polish sulfur into market economy countries in 1975 totaled over 1.5 million tons, 23% less than in 1974. Almost all of Poland's market economy customers reduced their purchases of Polish sulfur. The United Kingdom, France, and West Germany, the three biggest, cut purchases 20%, 13%, and 31%, respectively, a total reduction of 225,000 tons. Exports to Finland, the Netherlands, and Norway slightly increased in 1975. The Soviet Union and Czechoslovakia, the most important CMEA purchasers of Polish sulfur, increased their imports by 60% and 46%, respectively, over those of 1974. Polish sulfur was exported in both liquid and granular form. The major export terminal is located at Gdansk.

The geological resources of sulfur in the Tarnobrzeg, Piaseczno, and Grybow area totaled 150 million tons.

Production of sulfuric acid in Poland increased from 3.3 million tons in 1974 to 3.4 million tons in 1975. The lower rate of increase for sulfuric acid production was due to the depressed level of the West European market.[26] In 1975, installed capacity for sulfuric acid production in Poland totaled 3.7 million tons per year. An increase of 300,000 tons per year was expected in 1976 with commissioning of the Gdansk sulfuric acid plant.

MINERAL FUELS

For many years, coal including lignite has been the major source of primary energy in Poland.

Total production of primary energy derived from fossil fuels, fuelwood, and hydroelectric generation rose from 185.1 million tons in standard coal equivalent in 1974 to 195.2 million tons in 1975. In 1975, the share of coal (lignite, anthracite, and bituminous) in the total primary energy production was about 94%; crude oil comprised 0.4%; natural gas, 4.1%; and others (peat, wood, and hydropower), 1.5%. Approximately the same distribution of primary energy production was observed in 1974.

Total consumption of all types of primary energy in Poland increased from 163.1 million tons in standard coal equivalent in 1974 to 179.2 in 1975.

Coal in 1975 produced about 80% of the energy consumed in Poland, compared with 12% for petroleum, 6% for natural gas, and about 2% for peat, wood and hydropower.

The total primary energy balance for 1974 and 1975 is shown in table 4.

In 1975, Poland produced 97.2 billion kilowatt-hours of electricity, up from 91.6 billion kilowatt-hours in 1974, an increase of 6.1%. The installed capacity of electric powerplants was 20,057 megawatts in 1975, an increase of 4.8%. During 1975, about 2.92 billion kilowatt-hours of electricity was exported and 2.41 billion kilowatt-hours imported.[27] The generation of electricity is to be based mainly on hard coal until 1980 and on lignite thereafter. According to Polish sources, nuclear power will supply 13% of Poland's energy needs by 1990. By 2000, the share of nuclear energy is to increase to 40%.[28]

Field studies for Poland's first nuclear power station on Lake Zarnowieckie confirmed the site. The station is to have a final capacity of 1,600 megawatts and is to be linked with a 680-megawatt pumped storage station on the lake. The first stage of the station is to become operational in 1984.

Coal.—During 1975, Poland produced a total of 171.6 million tons of hard coal, an increase of 9.6 million tons, or 5.9%, over that of 1974.[29] Coal production was expected to reach 177 million tons in 1976, 200 million to 210 million tons by 1980, and approximately 250 million tons by 1990.[30] The average daily output achieved by hard coal mines was 8,125 net tons; 23 mines achieved output over 9,000 tons per day.

Table 4.—Poland: Total primary energy balance for 1974 and 1975
(Million tons of standard coal equivalent) [1]

	Total primary energy	Coal (lignite, anthracite, bituminous) and coke	Crude oil and petroleum products	Natural gas	Other (peat, wood, hydropower)
1974:					
Production	185.1	173.9	0.8	7.6	2.8
Exports	46.2	44.4	1.8	--	--
Imports	24.2	1.2	20.2	2.8	--
Apparent consumption	163.1	130.7	19.2	10.4	2.8
1975:					
Production	195.2	183.6	.8	7.9	2.9
Exports	44.8	42.3	2.5	--	--
Imports	28.8	1.1	24.4	3.3	--
Apparent consumption	179.2	142.4	22.7	11.2	2.9

[1] 1 ton of standard coal equivalent (SCE) = 7,000,000 kilocalories. Conversion factors used are from the United Nations as follows: Hard coal, 1.0; brown coal, 0.3; coke, 0.9; crude oil, 1.47; petroleum products 1.54; natural gas (1,000 cubic meters), 1.33; hydroelectric power (1,000 kilowatt-hours), 0.125.

Source: Concise Statistical Yearbook of Poland, Warsaw, 1976.

About 23% of the total hard coal production was exported in 1975, but total exports of hard coal decreased from 40.1 million tons in 1974 to 38.5 million tons in 1975, a decrease of 1.6 million tons, or 4%, resulting from decreased demand for coal from the European Economic Community (EEC) countries. Poland was the second largest exporter of coal in the world. In 1975, exports of Polish coal accounted for 21% of total world coal exports and about 15% of Poland's overall exports. In 1975, about 62% of the country's hard coal exports went to Western Europe; all non-CMEA countries imported about 23.8 million tons of coal from Poland, and CMEA countries took 14.7 million tons.

In Western Europe, the largest importers of Polish hard coal in million tons were France (3.8), Denmark (3.4), Finland (3.3), and Italy (3.0), followed by West Germany, Spain, and Belgium. Of the overseas countries, Japan was the largest importer, with 1.1 million tons, and Brazil followed with 810,000 tons; other importers included Argentina, the United States, Uruguay, Egypt, Canada, and others. Among the CMEA countries, the U.S.S.R. was the largest importer of Polish hard coal, with a total of 9.7 million tons, followed by Czechoslovakia (2.4 million), East Germany (770,000), Hungary (741,000), Romania, Bulgaria, and Yugoslavia.

Poland was an important producer of brown coal (lignite). In 1975, the country produced 39.9 million tons of brown coal, approximately the same amount as in 1974. Brown coal production was expected to reach 42 million tons in 1980, compared with 32.8 million tons in 1970.[31]

In 1975, about 3.4 million tons of brown coal was exported, a decrease of 1.8 million tons, or 35%, from the 5.2 million tons exported during 1974. The main importers of brown coal were Bulgaria, Yugoslavia, India, East Germany, and Romania. The main brown coal deposits are located in the Wroclaw, Zielenogora, Poznan, and Lodz regions.

Production of coke reached 18.3 million tons in 1975, a 1.1% increase over that of 1974. In 1975, about 83% of Poland's 3.1-million-ton coke exports went to CMEA countries and 17% to the market economy countries. Poland's largest importers of coke among CMEA countries were the Soviet Union and East Germany. Among Western European countries, Austria imported the largest amount of Polish coke, followed by West Germany, Finland, and Switzerland.

In 1975, about 62% of total coal exports was shipped through seaports. Coal and coke loadings at Polish seaports, in thousand tons, are shown in the following tabulation:[32]

[31] Polish Coal Review, Weglokoks, (Katowice). Sole Exporters of Polish Coal and Coke Economic Department 1975. V. 13, No. 10–12/149–151, p. 7.

[32] Polish Coal Review, Weglokoks, (Katowice). Sole Exporters of Polish Coal and Coke Economic Department 1976. V. 14, No. 4/155, p. 4.

Port	Loading in 1975
North Port	6,706
Szezecin	6,475
Swinoujscie	4,091
Gdynia	3,671
Gdansk	2,741

The tabulation shows that the North Port, which commenced operation in 1974, is the most important port for coal shipments.

A new hard coal mine, the Piast, at Nowy Bierun (south of Katowice) was commissioned in December 1975. Its target output is 24,000 tons of coal per day in 1982.[33]

In January 1975, plans for the development of the Lublin hard coal basin were approved by the Polish Political Bureau and the Executive Council of Government.[34] The first mine is to be located in the village of Bogdanka, near Lublin. The whole complex of mines in the Lublin Basin is to produce about 25 million tons per year by 1990. The first shafts at the Bogdanka mine were scheduled to be sunk at yearend 1977, and coal production should begin in 1980.

The other big coal development underway in 1975 was at Belchatow, where opencast operations were to provide 40 million tons of brown coal per year. The Belchatow open pit was to go into operation in 1980 and was planned to reach its target output by 1985. It was planned to develop the Szczercowo mine immediately after completing the Belchatow mine and for it to commence operations in 1985, with planned output of 40 million tons per year.

The newly discovered deposits of hard coal in Lublin Province are estimated at 40 billion tons. Reserves of brown coal at the Belchatow coalfield amounted to 2 billion tons.[35]

Poland has been experimenting with fuel conversion since 1967. The first commercial plant producing liquid fuels from coal was expected to be built in the mid-1980's. Poland participated in coordinated coal research programs with the United States, the United Kingdom, West Germany, and other countries.

Natural Gas.—Gas production in 1975 was 5.96 billion cubic meters, an increase of 0.2 billion cubic meters, or about 3.8%, over the 5.74 billion cubic meters produced in 1974. In addition, about 212 million cubic meters came from draining gaseous hard coal mines, mainly in the Rybnic region. Natural gas deposits in Poland were too small to supply the national demand. Imports of natural gas from the U.S.S.R. totaled 2.51 billion cubic meters, an 18.4% increase compared with 1974. Poland was to receive an additional 2.8 billion cubic meters of gas per year from the U.S.S.R. via the Orenburg pipeline by 1980.

In May 1975, an agreement was signed between CMEA countries and the Soviet Union concerning the construction of the Orenburg gas pipeline to bring Soviet natural gas from the Urals to Eastern Europe. The Polish sector is to be 556 kilometers long, extending from Orenburg (in the southern Ural Mountains) to Alexandrow Gai (at the northern end of Kazakhstan, U.S.S.R.). The total length of the gas pipeline is to be 2,750 kilometers. The Polish section is to be completed in the third quarter of 1978.

Polish-owned gas comes from Carpathian foothill lowland deposits. Poland, the U.S.S.R., and East Germany announced plans for joint exploration of the Baltic Sea shelf.

Petroleum.—In 1975, production of crude oil in Poland amounted to 553,000 tons, an increase of 3,000 tons, or 0.5%, over that of 1974. About 13.3 million tons of crude oil was imported in 1975, an increase of 26%. The Soviet Union supplied Poland with about 90% of its imports of crude oil. About 10% came from the Middle East (mainly Kuwait, Libya, and Iran).[36]

In 1976, the Soviet Union was to deliver to Poland 11.7 million tons of crude oil, and over the succeeding 5 years deliveries to reach 50 million tons of crude oil and 6.5 million tons of petroleum products. At the same time, Polish oil imports from the Middle East were to increase in order to supply the new 3-million-ton-per-year-capacity Gdansk refinery.[37]

In 1975, 13.52 million tons of crude oil was processed in Poland, an increase of 2.11 million tons over 1974 level. In 1976, about 15.5 million tons of crude oil, mainly from

[33] National Coal Board, (London). British Mining Delegation in Poland, Official Report. Coal and Energy Quarterly, No. 8, Spring 1976, p. 21.
[34] Zycie Gospodarcze (Economic Life), Warsaw. Feb. 28, 1975, p. 2.
[35] Page 26 of work cited in footnote 30.

[37] East-West Markets (New York). Oct. 20, 1975, p. 8.

the U.S.S.R., was to be refined.[38] Plans for the petrochemical industry call for the processing of about 20 million tons of crude oil by Polish refineries in 1980.[39]

In 1975, Poland exported 1.6 million tons of petroleum products and synthetic fuels, which is about 36% more than in 1974. Imports of petroleum products increased by 0.11 million tons, from 3.02 million tons in 1974 to 3.13 million tons in 1975.

Poland's foreign trade in petroleum products (including synthetic fuels) for selected years is shown, in thousand tons, in the following tabulation:

Year	Export	Import
1960	223	1,789
1970	1,316	2,424
1974	1,177	3,019
1975	1,601	3,133

Exports of petroleum products showed a stronger rate of growth than imports. Petroleum products were exported to West European countries, especially to Scandinavia.[40] Some petroleum products were imported from the U.S.S.R. (about 30% to 35%), the United Kingdom, Belgium, Albania, Hungary, and the Netherlands.

At the end of November 1975, the first production unit of the Gdansk refinery (Poland's eighth), started operations; the second unit was to be put into operation in the second half of 1976. During the initial phase of operation, the refinery was to process 3.16 million tons of crude oil per year, and this output was to double after completion of the expansion program. The refinery will supply primarily various types of motor fuels, heating fuel, lubricants, and hydrocarbons for petrochemicals, especially the synthesis of polymers.

The Plock refinery, the largest in Poland, (northwest of Warsaw), according to a Polish source, was processing 240,000 barrels per day of crude oil in spring 1975 and increased its capacity to 300,000 barrels per day in July.

Poland planned to explore its Baltic seabed for oil and gas; to establish a Research Institute of Baltic Geology, and to open a Department of Marine Prospecting at Gdansk University.

The Mineral Industry of Portugal

By Roman V. Sondermayer [1]

During 1975 Portugal remained a modest producer of many minerals and related products. However, its tungsten output accounted for about 4% of the world's total. In addition, coal, tin, gold, copper, iron and steel, feldspar, and cement were the main minerals produced in the country. Their output was only of domestic significance. The mineral industry of Portugal accounted for about 5% of the gross national product (GNP) and employed about 49,500 persons, or 3% of the employed labor force.

There were few significant developments during 1975. Expansion was completed on the petroleum refinery of the Sociedade Anónima Concessionária da Refinação en Portugal S.A.R.L. (SACOR), near Oporto. Construction also continued on a 6-million-ton-per-year refinery located 60 miles south of Lisbon.

The unsettled political climate of the country in 1975 affected its minerals industry and new development and expansion were delayed. However, most existing facilities operated during 1975 without major or costly disruptions.

PRODUCTION

Except for petroleum refining and stone production, most of the activities of the mining industry were modest by European standards. Table 1 shows production statistics of Portugal for 1973, 1974, and 1975.

[2] Revised to none.

TRADE

The pattern of foreign trade did not change significantly in 1975. The high cost of petroleum caused a continuing deficit in Portugal's minerals trade. The principal minerals exported were petroleum refinery products, pyrites, fertilizers, and stone. West European countries were the principal purchasers. Imports were diversified and included a large variety of commodities (mostly in modest quantities by U.S. standards) from numerous countries. Iron and steel from Japan, the United States, and Western Europe and petroleum from Iraq and Saudi Arabia were the principal imports.

Table 2.—Portugal: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal destinations, 1974
METALS—Continued			
Iron and steel—Continued			
Semimanufactures:			
Bars, rods, angles, shapes, sections	10,015	3,936	Angola 1,640; Cape Verde Islands 488; Guinea Bissau 421.
Universals, plates, sheets	7,932	5,130	Brazil 3,037; Guinea Bissau 1,210; Angola 657.
Hoop and strip	882	1,357	Angola 991.
Rails and accessories	100	1,741	Thailand 1,700.
Wire	1,788	828	Angola 342; Mozambique 293.
Tubes, pipes, fittings	5,073	5,341	Angola 819; Italy 642; Lebanon 547.
Castings and forgings, rough	1,819	2,295	Sweden 598; United States 433; United Kingdom 171.
Lead:			
Ore and concentrate	1,335	--	
Oxides	54	71	Angola 33; Canada 30; Mozambique 7.
Metal including alloys, all forms	175	164	Angola 142; Mozambique 18.
Magnesium metal including alloys, all forms	7	(1)	Mainly to United Kingdom and Belgium-Luxembourg.
Manganese:			
Ore and concentrate	3,386	3,680	All to Spain.
Oxides	(1)	(1)	All to Mozambique.
Mercury — 76-pound flasks	(2)	(1)	Mainly to Angola.
Molybdenum ore and concentrate	--	4	All to Belgium-Luxembourg.
Nickel metal including alloys, all forms	193	402	Spain 324; Netherlands 37; United Kingdom 30.
Platinum-group metals and silver:			
Waste and sweepings — thousand troy ounces	2,362	--	
Metals including alloys:			
Platinum group — troy ounces	1,905	2,842	West Germany 2,025; France 611; United Kingdom 206.
Silver — do	5,942	466	United States 257; Cape Verde Islands 161; Angola 48.
Tin metal including alloys, all forms	190	115	Netherlands 25; United States 24; Switzerland 16.
Tungsten:			
Ore and concentrate	r 1,809	3,195	United States 1,230; United Kingdom 793; Japan 485.
Metal including alloys, all forms	21	1	Mainly to Switzerland.
Zinc:			
Ore and concentrate	2,150	--	
Oxide	223	2,069	West Germany 850; Netherlands 443; Belgium-Luxembourg 220.
Metal including alloys, all forms	366	236	Belgium-Luxembourg 160; Italy 42; Spain 22.
Other:			
Ore and concentrate:			
Of titanium, vanadium, zirconium	618	500	All to Italy.
Of base metals, n.e.s	49	152	West Germany 133; Brazil 10; United States 9.
Ash and residue containing nonferrous metals	393	754	Belgium-Luxembourg 501; West Germany 114; Japan 68.
Oxides, hydroxides, peroxides of metals, n.e.s	1	(1)	Mainly to Angola.
Base metals, including alloys, all forms, n.e.s	25	21	United Kingdom 20; Belgium-Luxembourg 1.
NONMETALS			
Abrasives natural, n.e.s.:			
Pumice, emery, natural corundum, etc	29	23	Angola 11; United Kingdom 10.
Grinding and polishing wheels and stones	166	139	Angola 48; United States 30; Mozambique 14.
Asbestos	2	(1)	Mainly to Angola.
Barite and witherite	21	26	All to Angola.
Cement	89,834	66,610	Israel 29,630; Cape Verde Islands 17,583; Gibraltar 6,700.

See footnotes at end of table.

Table 2.—Portugal: Exports of mineral commodities—Continued
(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal destinations, 1974
NONMETALS—Continued			
Chalk	144	119	Angola 81; Mozambique 30.
Clays and clay products (including all refractory brick):			
Crude clays, n.e.s.:			
Kaolin	266	535	Morocco 400; Angola 110; Italy 20.
Other	1,465	994	Spain 831; Angola 66.
Products:			
Refractory (including nonclays bricks)	747	985	Angola 855; Guinea 58; Belgium-Luxembourg 37.
Nonrefractory	28,782	19,345	Spain 6,935; Cape Verde Islands 3,607; Mozambique 1,878.
Diamond:			
Gem, not set or strung thousand carats	r 1,492	1,439	United Kingdom 1,410; Belgium-Luxembourg 29.
Industrial do	662	563	All to United Kingdom.
Diatomite and other infusorial earth	77	64	Venezuela 20; Mozambique 20; Angola 11.
Feldspar, leucite, nepheline, etc	9,140	7,800	Italy 4,000; France 2,290; United Kingdom 1,340.
Fertilizer materials, natural, manufactured:			
Nitrogenous	90,401	190,479	Brazil 137,705; Republic of South Africa 23,977; West Germany 23,400.
Phosphatic	51,239	71,485	Brazil 37,500; Salvador 19,425; Guatemala 3,150.
Potassic	1,706	442	Angola 398; United States 34.
Other including mixed	34,516	4,022	Angola 3,600; West Germany 396.
Ammonia	56,378	49,449	United Kingdom 13,809; Greece 12,458; Spain 9,015.
Graphite, natural	9	6	Angola 4; Mozambique 2.
Gypsum and plasters	260	125	Angola 62; Mozambique 43; Cape Verde Islands 9.
Lime	941	620	Mozambique 444; Cape Verde Islands 81; United States 81.
Magnesite	(1)	(1)	Mainly to Cape Verde Islands.
Mica, all forms	(1)	--	
Pigments, mineral:			
Natural, crude	70	86	Angola 30; Republic of South Africa 30; Mozambique 17.
Iron oxides, processed	52	67	Spain 24; Angola 12; Norway 10.
Pyrite (gross weight)	76,340	94,426	All to Belgium-Luxembourg.
Salt	359	466	Finland 310; Angola 101; Guinea 21.
Sodium and potassium compounds, n.e.s.:			
Caustic soda	1,288	4,404	Spain 2,273; Angola 1,740; Mozambique 199.
Caustic potash, sodic, potassic peroxides	11	4	Cape Verde Islands 3.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked:			
Marble and other calcareous	138,564	132,510	Italy 43,733; Spain 31,420; Belgium-Luxembourg 20,988.
Slate	9,828	8,141	Belgium-Luxembourg 2,359; West Germany 1,441; Denmark 1,342.
Granite and other	10,496	17,605	Italy 13,978; Japan 1,984; Spain 875.
Worked:			
Slate	6,095	8,014	Belgium-Luxembourg 2,681; Netherlands 2,624; United States 709.
Paving and flagstone	147,560	133,036	West Germany 78,379; United Kingdom 16,979; Denmark 14,478.
Marble and other	20,664	23,277	West Germany 11,126; France 3,237; United Kingdom 2,212.
Dolomite, chiefly refractory grade	4	--	
Gravel and crushed rock	12,855	12,277	Gibraltar 9,507; Italy 1,900; Netherlands 400.
Limestone (except dimension)	242	95	United States 59; Cape Verde Islands 9; Guinea 8.
Quartz and quartzite	134,809	97,553	Norway 74,150; Italy 17,480; Sweden 3,002.
Sand excluding metal bearing	47,031	64,123	Italy 32,420; Gibraltar 24,790; Morocco 3,410.

See footnotes at end of table.

Table 2.—Portugal: Exports of mineral commodities—Continued
(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal destinations, 1974
NONMETALS—Continued			
Sulfur:			
Elemental, all forms	r 50	4	Angola 3.
Sulfuric acid	41,790	27,806	Brazil 19,767; Turkey 4,830; Spain 2,080.
Talc, steatite, soapstone, pyrophyllite	r 179	71	Angola 61; Mozambique 9.
Other nonmetals, n.e.s.:			
Slag, dross and similar waste, not metal bearing from iron and steel manufacture	6	10	All to West Germany.
Oxides and hydroxides of magnesium, strontium and barium	5	--	
Bromine, iodine, fluorine	1	1	Mainly to Angola.
Building materials of asphalt, asbestos, fiber cement, unfired nonmetals, n.e.s	4,274	2,475	Cape Verde Islands 1,343; West Germany 328; Sweden 117.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	1,896	874	Guinea 818; Cape Verde Islands 51.
Carbon black	7	8	Angola 7; Mozambique 1.
Coal, all grades including briquets	162	99	Cape Verde Islands 27; Angola 25; Spain 23.
Coke and semicoke	15,654	15,079	Netherlands 15,027; Angola 52.
Hydrogen and rare gases	(1)	(1)	Mainly to Guinea and Angola.
Petroleum refinery products:			
Bunker deliveries:			
Gasoline, aviation thousand 42-gallon barrels	9	6	Foreign flag vessels and aircraft.
Kerosine do	(1)	(1)	Do.
Jet fuel do	721	1,126	Do.
Distillate fuel oil do	166	364	Do.
Residual fuel oil do	472	339	Do.
Lubricants do	18	33	Do.
Total do	1,386	1,868	
Non-Bunker deliveries:			
Gasoline:			
Aviation do	44	44	Guinea 30; Guinea Bissau. 6
Motor do	85	230	West Germany 155; Guinea 50; Cape Verde Islands 9.
Kerosine do	743	56	Cape Verde Islands 23; Angola 16.
Jet fuel do	4	4	Netherlands 1; Brazil 1; United States 1.
Distillate fuel oil do	358	815	Angola 380; France 134; Belgium-Luxembourg 125.
Residual fuel oil do	--	772	United States 406; Sweden 224; Norway 129.
Lubricants do	321	209	United Kingdom 86; Spain 56; Sweden 14.
Other:			
Liquefied petroleum gas do	19	14	Cape Verde Islands 6; Guinea 5; Guinea Bissau 2.
Mineral jelly and wax do	20	33	West Germany 13; Spain 11.
Unspecified do	2	6	Spain 4; Angola 1.
Grand total do	2,982	4,051	

r Revised.
1 Less than ½ unit.
2 Value only reported at $1,337.

Table 3.—Portugal: Imports of mineral commodities
(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal sources, 1974
METALS			
Aluminum:			
Bauxite and concentrate	617	20	All from Netherlands.
Metal including alloys, all forms:			
Scrap	115	640	Canada 284; Norway 146; Spain 111.
Unwrought	4,295	6,619	Norway 1,878; Spain 1,823; France 935.
Semimanufactures	18,127	26,154	Canada 6,142; Belgium-Luxembourg 4,331; Switzerland 2,460.

Table 3.—Portugal: Imports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal sources, 1974
METALS—Continued			
Beryllium:			
Beryl ore and concentrate	311	27,772	Brazil 23,617; Spain 3,821.
Metal including alloys, all forms	--	(1)	Mainly from France.
Chromium:			
Chromite	327	556	Republic of South Africa 202; Netherlands 158.
Oxide and hydroxide	280	215	West Germany 181; Spain 19.
Cobalt oxide and hydroxide	57	13	Belgium-Luxembourg 7; West Germany 3; United States 2.
Copper:			
Ore	--	5	All from Netherlands.
Copper sulfate solution	885	1,031	United Kingdom 879; France 143.
Metal including alloys:			
Scrap	394	337	Spain 100; Guinea 53; Guinea Bissau 27.
Unwrought:			
Blister	1,599	1,520	Angola 750; Zambia 675; Belgium-Luxembourg 75.
Refined, unalloyed	6,334	6,851	Canada 3,159; Belgium-Luxembourg 2,594; United Kingdom 999.
Other	2,114	1,433	United Kingdom 792; Denmark 373; West Germany 226.
Semimanufactures	8,931	13,414	United Kingdom 3,286; France 2,540; West Germany 2,086.
Gold metal, unworked or partly worked troy ounces	1,129	4,598	West Germany 1,926; Belgium-Luxembourg 1,520; Switzerland 1,003.
Iron and steel:			
Ore and concentrate	491,717	[2] 417,841	Angola 192,000; Republic of South Africa 92,092; Brazil 90,744.
Metal:			
Scrap	6,288	8,113	Lebanon 835; United Kingdom 621.
Pig iron, ferroalloys, similar materials	39,832	45,060	Spain 32,933; Canada 2,940; Belgium-Luxembourg 1,990.
Steel, primary forms	191,339	274,656	United States 70,091; West Germany 34,028; Spain 32,149.
Semimanufactures:			
Bars, rods, angles, shapes, sections	99,832	173,804	Belgium-Luxembourg 58,692; West Germany 39,400; Netherlands 17,403.
Universals, plates, sheets	187,267	249,874	West Germany 76,674; France 49,355; Belgium-Luxembourg 42,692.
Hoop and strip	29,076	53,240	Belgium-Luxembourg 29,831; West Germany 16,023.
Rails and accessories	15,620	32,025	Belgium-Luxembourg 20,014; France 10,134.
Wire	11,150	18,272	West Germany 4,848; Belgium-Luxembourg 3,362; United Kingdom 3,085.
Tubes, pipes, fittings	23,664	31,412	West Germany 16,758; France 4,524.
Castings and forgings, rough	767	908	West Germany 340; France 219.
Lead:			
Oxides	77	302	West Germany 212; United Kingdom 64; United States 19.
Metal including alloys:			
Scrap	309	263	Malta 100; United Kingdom 63; Gibraltar 60.
Unwrought	10,074	14,086	Mexico 6,226; United Kingdom 4,055; Australia 1,807.
Semimanufactures	234	359	West Germany 157; United Kingdom 48; France 44.
Magnesium metal including alloys, all forms	9	9	United Kingdom 6; France 1.
Manganese:			
Ore and concentrate	123	508	Spain 505.
Metal including alloys, all forms	444	538	United Kingdom 266; Spain 77; Belgium-Luxembourg 76.
Mercury 76-pound flasks	319	580	Yugoslavia 299; Spain 223; United States 52.

See footnotes at end of table.

'ortugal: Imports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal sources, 1974
METALS—Continued			
Molybdenum:			
Ore and concentrate -- kilograms --	--	20,000	All from Finland.
Metal including alloys, all forms do ----	1,600	1,900	Spain 500; Netherlands 500; United Kingdom 400.
Nickel metal including alloys:			
Scrap	100	47	Canada 32; Norway 6.
Unwrought	65	80	Finland 30; United Kingdom 20; Norway 11.
Semimanufactures	465	560	United Kingdom 235; West Germany 180; Finland 64.
Platinum-group metals and silver:			
Waste and sweepings troy ounces --	--	64	All from Saudi Arabia.
Metals including alloys:			
Platinum group do ----	3,526	5,541	France 2,559; West Germany 1,504; United Kingdom 1,433.
Silver - thousand troy ounces --	1,812	1,407	United Kingdom 633; West Germany 524; Switzerland 158.
Rare-earth metals:			
Oxides	10	12	Spain 4; West Germany 3; United Kingdom 2.
Metals including alloys kilograms --	200	11,000	France 6,700; United Kingdom 4,300.
Tin:			
Oxides	13	14	West Germany 11; United Kingdom 2.
Metal including alloys:			
Scrap	--	(1)	Mainly from United Kingdom.
Unwrought	318	481	United Kingdom 221; Belgium-Luxembourg 120; Malaysia 120.
Semimanufactures	47	60	West Germany 13; Netherlands 11; Japan 8.
Titanium:			
Ore and concentrate, rutile	268	259	All from Australia.
Oxides	6,014	5,531	United Kingdom 1,714; West Germany 1,495; Finland 877.
Tungsten metal including alloys, all forms	6	(1)	All from United States and West Germany.
Zinc:			
Ore and concentrate	4	10	All from United Kingdom.
Oxide	296	342	United Kingdom 135; West Germany 95; Italy 33.
Metal including alloys:			
Scrap	131	145	Belgium-Luxembourg 52; France 50; West Germany 16.
Blue powder	148	151	Norway 83; United Kingdom 37; West Germany 30.
Unwrought	11,488	11,463	Belgium-Luxembourg 5,212; Netherlands 1,310; United Kingdom 1,033.
Semimanufactures	1,094	1,385	West Germany 762; United Kingdom 264; Belgium-Luxembourg 244.
Other:			
Ore and concentrate:			
Of titanium, vanadium, zirconium	474	1,069	Australia 621; United Kingdom 286; Spain 81.
Of base metals, n.e.s	742	176	United Kingdom 125; Australia 50.
Oxides, hydroxides and peroxides of metals, n.e.s	1,961	2,320	United Kingdom 1,783; Spain 280; West Germany 117.
Metals including alloys, all forms:			
Metalloids	67	413	Spain 288; Sweden 52; United Kingdom 43.
Alkali, alkaline earth, rare-earth metals --------- kilograms --	200	12,400	West Germany 12,200.
Pyrophoric alloys	4	4	Austria 3; United Kingdom 1.
Base metals including alloys, all forms, n.e.s	95	113	People's Republic of China 28; United Kingdom 26; Belgium-Luxembourg 16.

See footnotes at end of table.

Table 3.—Portugal: Imports of mineral commodities—Continued
(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal sources, 1974
NONMETALS			
Abrasives:			
Natural, n.e.s.:			
Pumice, emery, natural corundum, etc	475	530	Italy 220; Netherlands 186; Greece 52.
Dust and powder of precious and semiprecious stones (including diamond) kilograms	113	30	United Kingdom 20; Denmark 4; United States 4.
Grinding and polishing wheels and stones	518	569	United Kingdom 160; West Germany 103; Italy 97.
Artificial corundum	651	935	West Germany 357; France 250; Spain 168.
Asbestos	8,701	9,653	Canada 3,950; Republic of South Africa 2,103; West Germany 962.
Barite and witherite	840	1,702	United States 926; Netherlands 632; West Germany 68.
Boron materials:			
Crude natural borates	817	1,358	United Kingdom 1,100; France 213; Spain 205.
Oxide and acid	187	259	France 115; Netherlands 62; Turkey 35.
Cement	46,827	12,063	Sweden 9,162; France 1,891; United States 659.
Chalk	6,658	6,344	France 3,034; Spain 1,522; Belgium-Luxembourg 905.
Clays and clay products (including all refractory brick):			
Crude clays, n.e.s:			
Bentonite	7,194	9,548	Spain 4,827; United States 1,481; Algeria 1,333.
Kaolin	5,827	7,406	United Kingdom 5,701; France 1,280.
Other	3,560	7,518	United Kingdom 2,259; Spain 1,305; Mozambique 575.
Products:			
Refractory (including nonclay bricks)	7,269	9,154	West Germany 2,711; Italy 1,915; France 986.
Nonrefractory	3,678	6,774	Spain 4,280; Italy 2,143.
Cryolite and chiolite	73	80	Denmark 68; Spain 12.
Diamond, except powder and dust:			
Gem, not set or strung thousand carats	7	6	Belgium-Luxembourg 5.
Industrial do	11	2	Mainly from Belgium-Luxembourg.
Unclassified do	1,942	2,186	All from Angola.
Diatomite and other infusorial earth	3,272	3,847	Spain 1,658; United States 959; West Germany 517.
Feldspar, leucite, nepheline, etc	1,521	1,543	United Kingdom 1,100; France 213; Spain 205.
Fertilizer materials:			
Crude:			
Nitrogenous	1,420	1,537	Chile 1,500.
Phosphatic	298,354	308,100	Morocco 307,704.
Manufactured:			
Nitrogenous	13,515	3,753	Netherlands 1,440; Belgium-Luxembourg 1,125.
Phosphatic	8,276	8,826	Belgium-Luxembourg 6,729; France 1,998.
Potassic	41,916	53,247	Spain 53,094.
Other including mixed	45,856	9,293	Belgium-Luxembourg 2,643; Spain 2,594; United Kingdom 2,102.
Graphite, natural	322	286	United Kingdom 207; Italy 35; West Germany 22.
Gypsum and plasters	33,549	24,411	Morocco 22,682; France 915; Spain 748.
Iodine	6	5	Japan 4.
Lime, hydraulic	(1)	16	France 10; West Germany 6.
Magnesite	472	618	Italy 286; Netherlands 176; Austria 73.
Mica:			
Crude including splittings and waste	391	294	Norway 196; United Kingdom 72; Republic of South Africa 10.
Worked including agglomerated splittings	10	16	Sweden 7; Belgium-Luxembourg 3; Spain 2.

See footnotes at end of table.

Table 3.—Portugal: Imports of mineral commodities—Continued
(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal sources, 1974
NONMETALS—Continued			
Pigment, mineral:			
Natural, crude	61	56	Spain 46; France 6.
Iron oxides, processed	1,789	2,101	West Germany 852; Spain 707; United Kingdom 241.
Salt and brine	53,469	48,326	Italy 31,585; Netherlands 11,815; Cape Verde Islands 2,940.
Sodium and potassium compounds, n.e.s.:			
Caustic soda	31	82	United States 27; Italy 20; Sweden 13.
Caustic potash, sodic and potassic peroxides	455	204	France 104; Italy 37; West Germany 31.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked	2,238	2,562	Angola 2,524.
Worked	188	231	Spain 156; Italy 58; Belgium-Luxembourg 13.
Dolomite, chiefly refractory grade	5,512	4,443	Italy 3,251; Norway 772; Spain 351.
Gravel and crushed rock	334	136	Denmark 72; France 30; Italy 17.
Quartz and quartzite	149	288	Sweden 129; West Germany 78; Belgium-Luxembourg 77.
Sand excluding metal bearing	7,201	9,332	Belgium-Luxembourg 5,896; Spain 2,788; France 323.
Sulfur:			
Elemental:			
Other than colloidal	23,262	30,078	France 28,349; Spain 1,470.
Colloidal	265	169	France 90; West Germany 72.
Sulfur dioxide	253	289	West Germany 149; Netherlands 64; Spain 49.
Sulfuric acid	21,073	28,472	West Germany 13,946; United Kingdom 7,509; Poland 4,343.
Talc, steatite, soapstone, pyrophyllite	3,981	3,399	France 1,694; Norway 530; Austria 376.
Other nonmetals, n.e.s:			
Crude:			
Meerschaum, amber, jet	1	(1)	All from West Germany and United States.

COMMODITY REVIEW

METALS

During 1975, there was little change in the variety of metal-bearing minerals and metals produced in Portugal. Tungsten, iron and steel, copper, tin, and gold remained the principal metals produced in the country.

Iron and Steel.—There were one iron ore and one manganese mine in operation in Portugal during 1975; Siderurgia Nacional S.A.R.L., with a plant at Seixal, was the major iron and steel producer in the country.

Tungsten.—Tungsten ores remained the most significant mineral produced in Portugal. Most of the tungsten mines were situated in the northern and central northern part of the country. There were nine tungsten mines, the largest of which was Panasqueira, situated about 300 miles northeast of Lisbon, near the locality of Fundão, operated by Beralt Tin & Wolfram Ltd.

NONMETALS

Construction materials, mostly cement and ornamental stone, feldspar, clays, salt, and manufactured fertilizers were produced in the country during 1975. Nonmetals production was significant only to Portugal.

Cement.—Five cement plants with 16 kilns (total annual kiln capacity, 3.5 million tons) were in operation in Portugal during 1975. Compania Cimento Tejo S.A.R.L. and Compania Geral de Coil e Cimento S.A.R.L. (SECIL), both headquartered in Lisbon, were the two largest producers, accounting for about 50% of the total cement output.

Fertilizer Materials.—Amoniaco Português will have a 51% interest in two companies that will operate facilities based on a 1,500-ton-per-day ammonia plant. The new fertilizer project will be located at Sines, south of Lisbon, and was scheduled for production in 1980.

Stone.—Approximately 390 producers of stone operated various stone quarries in the country. Ornamental stone (marble and granite) remained the most important activity and large quantities were exported to Italy for further processing. The area around Vila Viçosa-Borba-Estremoz was the major producing region, accounting for about 70% of the total output.

MINERAL FUELS

During 1975, imported petroleum and refinery products remained the principal sources of energy in the country. In addition, high-rank coal and coke had to be imported to meet the demand. Coal, mostly anthracite, remained the principal source of energy produced domestically. Table 4 shows supply and apparent consumption of energy for 1973 and 1974.

Coal.—The only mineral fuel produced in Portugal remained coal—anthracite. During 1975 the only anthracite mine in production was located near Oporto in the northern part of Portugal.

Natural Gas and Petroleum.—There was no production of natural gas and petroleum in Portugal. Consequently imported liquefied natural gas and crude oil were processed in domestic plants and refineries. During 1975, two petroleum refineries at Lisbon and Oporto were in operation with an annual capacity of 9.5 million tons of crude per year. Expansion was completed on the largest refinery, the SACOR Refinery, located at Oporto. Annual capacity was increased from 3.5 million tons to 7.5 million tons of crude oil. Crude oil storage capacity was increased to about 805,000 cubic meters. Construction continued on the Sines Petroleum Refinery, located 60 miles south of Lisbon. Sociedade Portegesa de Refinação de Petroleo (Petrosol) is expected to operate the new refinery, which is rated at 6 million tons of crude per year. However, if a projected merger of the three petroleum companies (Petrosol, Sines, and SACOR) becomes reality, a new Government-owned company, Petrogal, would operate the refinery.

Table 4.—Supply and apparent consumption of energy for 1973 and 1974 [1]
(Million tons of standard coal equivalent) [2]

	Total energy	Coal and coke	Petroleum and refinery products	Natural gas	Peat, fuelwood and other fuels	Hydroelectric power
1973:

The Mineral Industry of Romania

By Nikita Wells [1]

The Romanian economy continued to expand at a relatively high rate despite difficulties caused in 1975 by the world economic slowdown and raw materials price increases. According to Romanian sources, the 1971–75 industrial production plan was fulfilled, but many of the goals in the 1975 annual plan were not reached. National income increased 9.8% instead of the 14.0% called for in the 1975 plan. Labor productivity in industry increased 7.1% over that of 1974, compared with a planned 10.3%. Foreign trade also lagged far behind the plan, increasing 6.6% compared with the planned 21.8%. Overall industrial production increased 12.4% over that of 1974. The metal processing, machine building, and chemical industries were developed on a top priority basis in 1975 and represented 54.8% of the overall industrial output.

Romania carried out an extensive geological prospecting program during the last 5-year plan in order to discover and delineate new reserves of minerals needed for expansion of its raw materials and energy base. The extraction of raw materials was considerably more intense in 1975 compared with 1970. Production of copper ores increased 73.9%; complex ores, 31.7%; bauxite, 13.4%; and salt 33.9% during this period. New methods were introduced in crude oil drilling and extraction. Mining of lignite was expanded and increased 36.4%. In ferrous metallurgy, production increased by 70% during the last 5-year plan. The output of finished rolled products increased 51%; that of medium and light rolled products, 34%; heavy and medium plate, 160%; steel sheet, 130%; and steel pipe, 50%. Additional installed capacity of electric powerplants during this period totaled 4.3 million kilowatts. Romania's total electric generating capacity had reached 11.5 million kilowatts in 1975.[2]

Government Policies and Programs.—The Romanian Grand National Assembly adopted the 5-year plan for 1976–80 in July 1976.[3] By yearend 1980, the plan calls for an annual production of 75 billion to 78.8 billion kilowatt-hours of electric power, 53 million to 56.6 million tons of coal, 15.5 million tons of crude oil, 26.8 billion cubic meters of natural gas, 16.6 million to 17.3 million tons of crude steel, 255,000 to 260,000 tons of aluminum and aluminum alloys, and 19 million to 20 million tons of cement.

According to the 1976–80 plan, the average annual growth rate of industrial production is to range between 10.2% and 11.2%. Ferrous and nonferrous metallurgical production is to increase 73% to 81% in 1980 as compared with 1975. The output of fuels in 1980 is to increase 38% to 45%, while chemical output is to increase 103% to 115% over that of 1975. The average annual growth rate of foreign trade is to be between 13.7% and 15%. The total volume of investments in the national economy in the period 1976–80 is to amount to 1 trillion lei,[4] of which 580.5 billion lei is to be allocated to the industrial branch.

[3] Scînteia (Bucharest). July 3, 1976, pp. 2–3.
[4] Values have not been converted from Romanian currency units (lei) to U.S. dollars because of the wide variation between the official exchange rate and the rate actually used for some transactions. The exchange rate for 1975 was 4.97 lei=US$1.00 (official), and 12.00 lei=US$1.00 (tourist rate).

PRODUCTION

In 1975, Romania's iron and steel industry continued to expand and nearly met the goals of the last 5-year plan. Crude steel production, in 1975 increased 8.0%, pig iron, 8.6%, and steel rolled products, 8.9% as compared with 1974. New production capacities were commissioned at many steel plants during 1975. In the nonferrous metals sector, primary aluminum production increased 9.1% owing to a higher output from the aluminum plant at Slatina. Copper ore production increased and new deposits were discovered in the Moldova Nouă and Raşia Poieni areas.

In the nonmetals sector, mineral fertilizers showed a rapid growth with an increase of 23% over that of 1974. Cement production increased only 2.9% and fell considerably short of its plan. Except for natural gas, which showed a 9.4% increase, the production of domestic minerals fuels showed a small increase in 1975 as compared with 1974. Romania's electric power generating capacity increased 8.5% in 1975 over that of 1974.

Romania does not report production statistics on many of its mineral commodities, and therefore much of the data presented in table 1 were estimated.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the commodities listed, antimony, asbestos, gypsum, mica, and natural gas liquids, as well as a variety of crude construction materials, are produced, but output is unreported and available general information is inadequate to permit formulation of reliable estimates of output levels.

[2] Romanian sources do not indicate whether refinery fuels are reported as a part of the listed product yields or not. Moreover, additional minor products may be produced but are not listed in official sources.

TRADE

In 1975 the total volume of foreign trade turnover (exports plus imports) reached 53.1 billion lei, demonstrating an average annual growth rate during the 1971–75 plan of 18.4%. However, the total turnover in 1975 showed only a 6.6% increase over that of 1974, while the plan called for a 21.8% increase, requiring the total volume to reach 60.6 billion lei. The total values of Romanian exports and imports were balanced in 1975, each totaling about 26.5 billion lei.[5]

In 1975, Romania's most important imports consisted of raw materials including crude oil, coking coal and coke, iron ore, bauxite, apatite, and copper. Romanian exports consisted mainly of petroleum products and other processed raw materials. In 1974 and 1975, trade by major commodity groups was as follows:[6]

[5] Revista Economica (Bucharest). No. 13, Apr. 2, 1976, pp. 13–16.

[6] Anuarul Statistic al Republicii Socialiste România 1976 (Annual Statistics of the Socialist Republic of Romania 1976). Bucharest, 1976, pp. 384–387.

	Value (million lei)		Percent of total	
	1974	1975	1974	1975
Exports:				
Building materials	723.2	772.0	3.0	2.9
Chemicals, fertilizers, rubber	2,714.5	2,857.0	11.2	10.8
Fuels, minerals, metals	5,308.0	5,911.9	21.9	22.3
Imports:				
Building materials	237.5	296.4	1.0	1.1
Chemicals, fertilizers, rubber	2,586.7	1,721.1	10.1	6.5
Fuels, minerals, metals	8,209.5	10,153.2	32.1	38.2

Romania's principal trading partners in 1974 and 1975 were as follows:

	Total trade (million lei)		Percent of total	
	1974	1975	1974	1975
U.S.S.R	7,842	9,858	15.8	18.6
Germany, West	6,271	5,039	12.6	9.5
Germany, East	2,850	2,909	5.7	5.5
United Kingdom	2,646	1,503	5.3	2.8
Czechoslovakia	2,231	2,447	4.5	4.6
Italy	2,157	2,273	4.3	4.3
Switzerland	1,832	2,068	3.7	3.9
Poland	1,828	2,073	3.7	3.9
People's Republic of China	1,738	2,164	3.5	4.1

The proportion of Romania's trade with centrally planned economy countries was 41.2% in 1974 and 44% in 1975, while developing market economy countries accounted for 13% in 1974 and 19% in 1975.[7]

In August 1975 the United States granted Romania "most favored nation" status for trade agreements, creating favorable conditions for trade between the two countries.

COMMODITY REVIEW

METALS

Aluminum.—In 1975, Romania's primary aluminum production, including aluminum alloys, reached 204,000 tons, an increase of 9.1% over that of 1974. The single Romanian aluminum plant, located at Slatina, has surpassed its production capacity objective of 200,000 tons per year under the 1971–75 5-year plan. The Slatina plant has been under continuous expansion for the past 10 years and thus has paced the dramatic growth in Romania's modest aluminum industry. By 1980, Romania is planning to produce 255,000 to 260,000 tons of aluminum and aluminum alloys.

Bauxite for Romania's aluminum industry is surface-mined near Dobreşti in the vicinity of Oradea. However, a large part of the bauxite has to be imported. Bauxite is converted to alumina at two alumina plants, each of which has an annual capacity of 250,000 tons. One plant is located near Tulcea in the Danube Delta, and the other near the Oradea bauxite mines.

A new foil-rolling mill at the Slatina aluminum plant, with an annual capacity of 6,500 tons, is to start operation in the near future. The installation will produce various types of aluminum foil of thicknesses ranging between 5 and 200 micrometers, which will be used for fine packaging.

Copper.—Romania's production of copper in 1975 was estimated at 37,000 tons. New deposits of copper ore were discovered in the Moldova Nouă and Roșia Poieni areas. Reportedly, two new copper mines are to be developed there with a combined capacity of 20 million tons of ore per year. In 1975, production of copper ores increased 73.9% over that of 1970.[8]

The most important Romanian copper mines are located at Baia Mare, including Baia Sprie and Cavnic, and the areas of Roşia Montana, Moldova Nouă, Borşa, Bălan, and Leşul Ursului.

Iron and Steel.—Romanian crude steel production for 1975 reached 9.55 million tons, slightly below the planned figure of 10 million tons as outlined in the 1971–75 plan. This production figure showed an increase of 8.0% over that of 1974. Romania's total crude steel production is to reach 11.0 million tons by yearend 1976.

Expansion of the steel industry was a major goal of the 1971–75 5-year plan. In 1975, new production capacities were commissioned at the Galați integrated iron and steel works. The No. 2 unit at the Linz-Donawitz (LD) steelmaking facility began to operate and eventually is to reach a capacity of 3.5 million tons per year. The 1,700-cubic-meter-volume blast furnace No. 4 underwent initial checkout tests. This new furnace incorporates a number of technological advancements over the three installed blast furnaces. It is to contribute significantly to the increase in productive capacity and to cut down coke consumption. A continuous-casting plant, with an annual capacity of 750,000 tons, and a galvanizing shop, with a capacity of 100,000 tons per year, were also commissioned in 1975. At the Hunedoară integrated iron and steel works, a wire mill with a capacity of 280,000 tons per year was put into operation. A medium- and light-product rolling mill with a capacity of 250,000 tons per year was commissioned at the Tîrgovişte special steel complex. The production of welded pipe of various diameters began at the Iasi iron and steel works. Total annual capacity there was reportedly 331,000 tons.

During 1975, work continued at the Galați works on the construction of the 2,700-cubic-meter-volume blast furnace (No. 5) and the 600,000-ton-annual-capacity coke battery (No. 6). At the Reşita integrated iron and steel works, construction proceeded on the blooming mill, having a capacity of 1.3 million tons per year. At the Tîrgovişte special steel complex, a blooming mill of 800,000 tons annual capacity and a strip shop with a capacity of 100,000 tons per year were being installed. A continuous-casting installation, having an annual capacity of 300,000 tons, and an electric furnace shop were also being constructed at the Otelul Roşu iron and steel works during 1975.[9]

In 1975, the share of steel produced by LD converters and electric furnaces was 47%, while the rest was produced by the open hearth method. By 1980, however, 70.3% of the steel in Romania is planned to be produced by LD converters and electric furnaces. This change in steel technology is to reduce fuel consumption by 20%.[10] Medium and thick steel plates continued to account for the bulk of exports in 1975. Exports of sections, wire rod, wire products, and welded pipe increased as a result of the commissioning of new production capacities. Fifteen new types of steel products began to be produced in 1975 at the Galați iron and steel works. Among these were high-resistance shipbuilding steel plates, special steel for automobile bodies, and other steel for the machine-building industry.[11]

By 1980, Romania is to produce 16.6 million to 17.3 million tons of crude steel per year. This figure is to be achieved mainly by the expansion of the Galați works and the operation of the new steel complex being erected at Călăraşi on the Danube. The planned expansion at Galați is to increase the plant's capacity to 10 million tons per year.

Wean United Inc., a U.S. metal equipment manufacterer, has received a contract for over $30 million from Romania for the delivery of five rolling mills for steel plate to be installed at the Galați steelworks.

NONMETALS

Cement.—Total cement production in 1975 was 11.5 million tons, a 2.9% increase over that of 1974. This figure, however, was 15.3% less than the 13.6 million tons set by the 1975 plan. By 1980, Romania plans to produce 19 million to 20 million tons of cement annually. In 1975, total cement exports were 2.8 million tons.

In 1975, construction began on the biggest and most technologically advanced cement plant in Romania, located in Tașca in the district of Neamț. The first production line is to go into operation in 1977. The new plant is to produce high-quality cement employing the dry method.[12] A new type of cement was recently put into production at the binders and asbestos-cement combine of Bicaz. The manufacture of this cement, labeled RIM–A, is based on the partial replacement of clinker with slag, thereby reducing the amount of costly raw material. The resistance and grinding fineness of the cement is unaffected. This cement is to be used particularly in the production of prefabricated building materials.[13]

A new cement production line, with an annual capacity of 320,000 tons, has been commissioned at the Tîrgu Jiu building materials combine.

Fertilizer Materials.—The Romanian fertilizer industry continued its rapid growth in 1975 but fell short of the planned production levels of the 1971–75 national plan. Total fertilizer production in 1975 was 1.7 million tons, an increase of 23% over that of 1974, but representing only 64% of the amount planned for 1975.

During the 1971–75 5-year plan, Romania had been building up its mineral fertilizer capacities by the construction and planning of a number of new facilities. During this time, the fertilizer industry reportedly received 18% of the total national appropriation for investment. When all the new facilities reach capacity operation, Romania will have a total annual productive capacity of over 5 million tons of fertilizers per year, including complex fertilizers, urea, ammonium nitrate, and ammonium sulfate. Romania is planning to export nitrogen fertilizers, urea, and ammonium nitrate primarily to West Germany, France, North Africa, and Latin America.

Two of the 891,000-ton-per-year-complex fertilizer plants went into operation in 1975. These are located at Tîrgu Mures and Craiova. Two more identical plants were scheduled to be commissioned at Arad and Turnu Măgurele in mid-1976. The supply and basic engineering for all four plants was carried out by Davy Powergas, Inc., while the detailed engineering was done in conjunction with the State-owned engineering company, Iprochim. At the Tîrgu Mures complex, bulk storage facilities for 80,000 tons of fertilizer and feedstock have been built. The third ammonia plant at Tîrgu Mures started operating in 1975 and reached designed capacity of 300,000 tons per year. The plant was designed by M. W. Kellogg Co. and constructed by Iprochim for the Combinatul De Ingrasominte Azotase.[14]

The nitrogen and compound fertilizer plant to be constructed at Tecuci was relocated and is to be established at Bacău, in the eastern part of the country some 80 kilometers northwest of the original location.[15] The new complex is to consist of a 300,000-ton-per-year ammonia plant constructed by Kellogg, a 420-ton-per-year urea plant constructed by Coppée-Rust Co., a 480,000-ton-per-year nitric acid plant using the technology supplied by Grande Paroisse (a duplication of the unit already located at Arad), and a 891,000-ton-per-year complex fertilizer plant with units identical to those used at Norway's Norsk Hydro plants. The entire complex is scheduled to be completed in 1978.

The Azot No. 4 unit of the chemical fertilizer combine at Piatra Neamț began operating at full capacity of about 140,000 tons of nitrogen fertilizers and in 1975 produced its first batch of 1,000 tons of urea, which was to be exported. A 20,000-ton-per-year phosphoric acid unit has been installed at the Navodari chemical combine. This

[15] Nitrogen (London). No. 100, March–April 1976.

combine produced single and triple superphosphates and had a capacity of approximately 600,000 tons per year.[16]

Lime.—The production of lime in 1975 was 3.1 million tons. A new kiln was commissioned in 1975 at the Bicaz binders and asbestos cement combine, which was to double lime production there and reduce fuel consumption.[17] A modern plant has been commissioned at Tîrâveni for crushing and preparing lime used for the manufacture of carbide.

Sulfur.—The production of sulfuric acid reached 1.4 million tons in 1975, a 6.6% increase over that of 1974. A unit was to be constructed to utilize the pyrite cinders recovered as waste from the sulfuric acid plant located at the Turnu Măgurele complex, where annual sulfuric acid production capacity was 300,000 tons per year, using the Lurgi process. This unit was to produce granules of 55% iron and other byproducts.[18]

MINERAL FUELS

Romania's total primary energy consumption in 1975 reached an estimated 83.3 million tons of standard coal equivalent, an increase of 7.6% over that of 1974. Natural gas provided 52.8% of the total primary energy, while coal represented 22.1%, oil 23.8%, and hydroelectric power 1.3%.

Romania has been giving particular attention to development of its domestic primary energy resources in order to meet its steadily increasing fuel and energy requirements. Increased emphasis was placed on use of solid fuels for the generation of electrical power in order to save hydrocarbons for the petrochemical industry. Marketable coal production increased from 20.5 million tons in 1970 to 27.1 million tons in 1975, and is expected to reach 56 million tons in 1980 and 72 million to 78 million tons by 1990. The share of electric energy generated through the use of solid fuels is to increase from 23.9% in 1975 to 44% in 1980. This is to be achieved by an increase in lignite production, which is expected to rise from 13.5 million tons in 1970 to 47 million tons in 1980 and 60 million to 65 million tons by 1990. The production of electrical energy during 1976–80 is to be increased with the construction of additional thermal electric powerplants (capacity 5.4 million kilowatts to 5.7 million kilowatts).

Production of primary energy derived from fossil fuels and hydroelectric generation increased from 77.0 million tons of standard coal equivalent in 1974 to 81.1 million tons in 1975. The total primary energy balances for Romania for 1974 and 1975 are shown in table 4.

[16] Phosphorous and Potassium (London). No. 80, November–December 1975, p. 15.
[17] Page 28 of work cited in footnote 11.
[18] Sulphur (London). No. 116, January–February 1975, p. 14.

Table 4.—Romania: Total primary energy balance for 1974 and 1975
(Million tons of standard coal equivalent) [1]

Year	Total primary energy	Coal and coke	Crude oil petroleum products	Natural gas	Hydroelectric power
1974: [2]					
Production	77.0	14.1	21.3	40.5	1.1
Imports	10.7	3.6	6.7	--	.4
Exports	10.3	--	9.6	.3	.4
Apparent consumption	77.4	17.7	18.4	40.2	1.1
1975: [3]					
Production	81.1	14.3	21.4	44.3	1.1
Imports	12.0	4.1	7.5	--	.4
Exports	9.8	--	9.1	.3	.4
Apparent consumption	83.3	18.4	19.8	44.0	1.1

[1] 1 ton of standard coal equivalent (SCE) = 7,000,000 kilocalories. Conversion factors used are: Hard coal, 1.0; lignite and brown coal, 0.33; crude oil, 1.47; natural gas, 1.33 (per 1,000 cubic meters); hydroelectric power, 0.125 (per 1,000 kilowatt-hours).
Source: United Nations (New York). World Energy Supplies, Statistical Papers, Series J, No. 18, 1975.
[2] Production data for 1974 were taken from the Statistical Yearbook of the Socialist Republic of Romania (Bucharest), 1975; trade data came from Foreign Trade of the Socialist Republic of Romania (Bucharest), 1974.
[3] Production data reported in Scînteia (Bucharest) Feb. 4, 1976, and in other Romanian sources.

The total electric power produced in Romania in 1975 was 53.7 billion kilowatt-hours and fell short of the 56.6 billion kilowatt-hours planned. At yearend 1975, total capacity of the country's electric powerplants reached 11.5 million kilowatts, an increase of 8.5% over that of 1974 but falling short of the 13.0-million-kilowatt goal of the 1971–75 5-year plan.

During 1971–75, newly installed electric power generating capacity totaled 4.3 million kilowatts, of which 0.7 million kilowatts represented thermal electric powerplants using solid fuel and 1.4 million kilowatts was hydroelectric powerplants.[19] The remaining capacity was fueled by oil.

The electric power plan for 1971–80 had been drastically amended because of postponements in construction of nuclear powerplants which were to have a capacity of 1.8 million kilowatts to 2.4 million kilowatts by yearend 1980. Construction of these plants has been rescheduled to start in 1981. Thus, the figures for the 1976–80 plan had to be revised downward, and a larger amount of fuel oil, gas, and coal is to be utilized for the anticipated electricity requirements.[20]

Coal.—In 1975, Romania produced a total of 29.4 million tons of run-of-mine coal, a slight increase over the 1974 output and considerably below the planned production of 29.8 million tons. The total marketable coal production in 1975 was 27.1 million tons.

Approximately 30% of Romania's 1975 coal production was anthracite and bituminous and came mostly from the Valea Jiului coalfield. The remainder was lignite, from deposits located mostly south of the Carpathian Mountains in the neighborhood of Tîrgu Jiu but with some smaller deposits near Brasov. Total Romanian lignite reserves are estimated at 3 billion tons.

Romania is expected to launch a drive to increase coal production 16% during the 1976–80 5-year plan. Total coal production is to reach 56 million tons by yearend 1980. To meet the coal requirements, new mines, with a total productive capacity of approximately 27 million tons of lignite, are to be brought into operation during 1976–80. Surface mining is to provide 72% of this amount. All of the lignite production increase up to 1985 is to come from new mines. In 1985–90, however, the new production capacity will have to be obtained from underground mines. Romania is planning to increase automation and the use of more productive machinery and equipment in its surface and underground mines.

The development of five new underground mines was started in 1975 in the Jilt lignite basin.[21]

A preliminary agreement was signed on July 1, 1975, between a private U.S. coal mining company and a Romanian State enterprise to develop an underground mine in Buchanan County, Va. The mine, which is to be called Virginia Pocahontas No. 6, is to have a capacity of more than 1 million tons of high-grade coal per year and is to be operated by the U.S. company. The development of the mine will require an investment of over $50 million.[22]

Natural Gas.—Romania's total natural gas production reached 33.3 billion cubic meters in 1975, a 9.4% increase over that of 1974. The nonassociated gas production included in this total was 27 billion cubic meters in 1975.

Romania's natural gas reserves are estimated at 280 billion cubic meters and are largely centered in the Transylvanian Basin around Tîrgu Mures, Turda, Copsa Mică, and Făgăras.

Romania signed a cooperative agreement with the U.S.S.R. to participate in construction of the Orenburg natural gas pipeline. Romania is to finance purchases of Western equipment, pipe, and materials required for the development of the gasfield and the construction of gas-drying and sulfur-removal installation within the Orenburg complex.[23] In return, Romania is to receive 1.5 billion cubic meters of Soviet natural gas per year upon completion of the pipeline late in 1978. The pipeline, construction of which began in the spring of 1975, links the large condensate deposits of the Orenburg region, south of the Urals, with the western border of the U.S.S.R. at Uzhgorod. This 2,750-kilometer pipeline will allow the participating countries to

draw up to 15.5 billion cubic meters of natural gas annually.[24]

The natural gas pipeline from the Soviet Union to Hungary, running across Romania, was completed in 1975. Romania, however, has no rights to use any of this gas without further negotiations with the Soviet Union.

Another gas pipeline, which connects the Romanian gasfields to Hungary, is used to export 200 million cubic meters of Romanian natural gas per year.

Oil Shale.—To conserve oil and gas supplies, Romania started construction in 1975 on the nation's first electric powerplant designed to use oil shale as fuel. The powerplant is located at Oraviţa, in western Romania near the Yugoslav border, and will have a capacity of 990 megawatts. In was patterned after two large U.S.S.R. powerplants in Estonia near the Baltic Sea. The plant is to use more than 12 million tons of oil shale per year, which is to be extracted from nearby surface mines.

Petroleum.—Crude oil production in Romania has leveled off, reaching the planned target of 14.6 million tons in 1975, an increase of less than 1% over that of 1974. Romania currently imports approximately 6 million tons of crude oil per year from Saudi Arabia, Iran, Iraq, Libya, and Venezuela, and is the only COMECON [25] country which does not import crude petroleum from the Soviet Union. By 1980, total Romanian crude oil production is to reach 15.5 million tons. Romania was a major exporter of refined petroleum products and operated 11 refineries with an estimated total crude oil processing capacity of 23 million tons per year.

One of Romania's major investment projects during the coming 5-year plan is to be the construction of a large petrochemical complex on the Black Sea, between Navodari and Cape Midia, north of Constanţa. The complex is to include an oil refinery, rubber and synthetic fiber plants, and a special port facility. The total cost of the project will be approximately $1 billion, of which approximately half will be provided by Kuwait. The additional refining capacity will require increased imports of crude oil from the Middle East, probably from Kuwait.

In 1975, Romania continued exploratory and developmental drilling in the Ploieşti-Facsani oil and gas district. Although drilling was extended to greater depths, no significant reserves were located.

Offshore drilling in the Black Sea has become the major effort for future oil exploration. Romania has built its first offshore floating drilling rig (Gloria I), which was launched by the Galaţi shipyard in October 1975.[26] It was provided with ice breakers, bow and stern propellers for increased mobility, and four 122-meter legs that support the rig on the seabed where it can drill to a maximum depth of 6,000 meters.[27]

According to an agreement signed in June 1975, Romania is to provide assistance to Bulgaria in the drilling of deep wells on Bulgarian territory and off the Bulgarian coast in the Black Sea.

Reportedly, the "First of May" petroleum equipment plant at Ploieşti has begun producing a new type of onshore deep drilling rig, identified as F–500, which can reach a maximum depth of 10,000 meters and is highly automated. A hydrorefining installation has been put into operation at the Ploieşti-Sud refinery. The plant has reached capacity operation in the production of high-quality products. The plant has been designed by the Ploieşti Refineries Research and Design Institute and built by T.C.I. Ploieşti.[28]

Nuclear Power.—The first 10-year electrification plan (1966–75) called for two 0.5 million kilowatt to 0.6 million kilowatt nuclear powerplants to be built during this period. The second plan (1971–80) required an installed nuclear powerplant capacity of 1.8 million kilowatts to 2.4 million kilowatts by yearend 1980. The share of nuclear power in the total power production was to amount to 1.2% in 1970, 3.4% in 1975, and 8.5% in 1980. However, the nuclear power program has been delayed, and the first nuclear powerplant was rescheduled to go into operation in 1981. By 1990, Romania plans to have approximately 20% of its electric power generated by nuclear powerplants.

The Mineral Industry of Sierra Leone

By Janice L. W. Jolly [1]

Sierra Leone's mineral industry experienced a difficult year in 1975. Like most other diamond producers, Sierra Leone had its worst year in recent memory as the world diamond market continued its downward trend that began late in 1973. Iron mining had a setback with liquidation of the Sierra Leone Development Co., Ltd. (DELCO). DELCO had accounted for 11% of the nation's exports in 1975. Repercussions were felt throughout the economy. When the Sierra Leone Petroleum Refining Co., Ltd., lost DELCO as its biggest customer for heavy oil and gas, the company was left with a surplus on its hands. A brighter picture was painted, however, for bauxite mining at Mokanji by the Sierra Leone Ore and Metal Co., Ltd. (SIEROMCO) as expansions were being planned and production maintained.

With the signing of the rutile mining agreement during 1975, the foreign investment climate was interpreted as easing and becoming more favorable. Pressures on the economy from higher prices for petroleum and imported foodstuffs have impressed the Government of the need to increase exports and to adopt a more realistic attitude towards foreign investment including the mining sector. The Government would like to attract investments for domestic processing of Sierra Leone's agricultural and mineral exports. Sierra Leone's new 5-year (1974–79) plan clearly recognizes the need for foreign capital and technology.

The chromite deposits of Sierra Leone received a flurry of attention from several U.S. companies during 1975 as a result of a visit from the Overseas Private Investment Corporation (OPIC). OPIC officials visited several West African countries in April 1975, including Sierra Leone, to determine new investment possibilities. Several mining companies indicated an interest in looking for gold in Sierra Leone. One U.S. company, Diamond Distributors Inc. of New York, acquired a prospecting license for both gold and diamonds.

In May 1975, Sierra Leone joined with 14 other West African countries to form the Economic Community of West African States (ECOWAS). Liberia, Benin, Gambia, Ghana, Guinea, Guinea Bissau, Ivory Coast, Mali, Mauritania, Nigeria, Niger, Senegal, Togo, and Upper Volta were also signatories to this treaty. Sierra Leone was also a beneficiary of the U.S. Trade Act of 1974 and a signatory to the Lome Convention, affording special rights of access to the markets of the European Communities (EC). Sierra Leone joined the 11 member Iron ore Exporters Association in April 1975.

Libya and Sierra Leone signed an agreement for joint cooperation on a number of technical, cultural, and agricultural projects on November 21, 1975. Loans included $10.5 million from West Germany for road building; $7.3 million for schools from the U.S. International Development Association (IDA); and $30 million from the Electricité de France (EDF) for other development schemes.[2]

---

[2] Africa Report. Loans, Grants and Credits. March–April 1976, v. 21, No. 2, p. 36.

PRODUCTION AND TRADE

Mineral commodities produced by Sierra Leone were valued at an estimated $93 million[3] in 1975 (not including petroleum refinery products) compared with $103 million in 1974. Mineral production figures are shown in table 1. Minerals formed 71% of total export earnings in 1975. Diamond exports were valued at $77.7 million in 1975 compared with $87.4 million in 1974, and iron ore exports were valued at an estimated $14.6 million in 1975. Nearly 87% of Sierra Leone's exports went to the United Kingdom in 1974, with most of the remainder going to the United States (8%), Japan (7%), and West Germany (6%). Imports came from the United Kingdom (46.7%), Japan (20.8%), the United States (19.6%) and West Germany (14.6%). The recommencement of rutile mining is expected to result in greatly increased exports to the United States. If other potential U.S. investments such as those in iron ore materialize, exports to the United States may increase even further. The United States has long been the recipient of a large share of Sierra Leone's rough diamonds.

The latest available statistics on foreign trade in selected mineral commodities are given in the 1974 Minerals Yearbook.

Table 1.—Sierra Leone: Production of mineral commodities

Commodity [1]	1973	1974	1975 [p]
Aluminum, bauxite, gross weight thousand metric tons	603	672	655
Diamond:			
Gem thousand carats	646	670	[e] 560
Industrial do	758	1,000	[e] 840
Total do	1,404	1,670	[e] 1,400
Iron ore, gross weight thousand metric tons	2,405	2,014	1,454
Petroleum refinery products:			
Gasoline thousand 42-gallon barrels	350	369	797
Jet fuel do	119	144	201
Kerosine do	144	153	56
Distillate fuel oil do	496	469	304
Residual fuel oil do	846	536	--
Other do	87	12	61
Refinery fuel and losses do	204	68	--
Total do	2,246	1,751	1,419

[e] Estimate. [p] Preliminary.
[1] In addition to the commodities listed, a variety of crude construction materials (clays, sand, gravel, and stone) is produced, but quantities are not reported and available general information is inadequate for the formulation of reliable estimates of output levels. Also a very limited production of gold may occur but again data are not available and no basis is available for reliably estimating this production. In addition, Sierra Leone annually refines 4,000 to 10,000 metric tons of salt from imported crude marine salt, but this is not included in the body of the table because it would represent a double counting of material credited to the country where the salt was originally collected.

COMMODITY REVIEW

METALS

Chromite.—Renewed interest was being shown in chromite following a visit to Sierra Leone by OPIC officials early in 1975. Chromite occurrences have been traced along a belt 70 miles long. The approximate center of this belt is located near Kenema on a railway. The belt extends northeast to the Gori Hills and southwest to Pujehun. The deposit at Ngelehun was the only one mined and was reported as occurring as lenses in serpentine and talc (altered dunite) over a wide area in the Kambui Hills. These chromite bodies have not been mined since 1963 when the company, Sierra Leone Chrome Mines Ltd., experienced production, transportation, and marketing difficulties and was forced to close down. There were three areas of ore at the Ngelehun

[3] Where necessary, values have been converted from Leones (Le) to U.S. dollars at the rate of Le1=US$1.11.

deposit being mined with three different grades called Amba, Benda, and Waku. The dip of the ore bodies was nearly vertical, the deposit was highly sheared, and the ore was broken into numerous small lenses. The Amba ore averaged 45% Cr_2O_3 and was the best grade. The chrome ratio was reported as varying between 3:1 and 2:1 (Cr:Fe). Over 330,000 tons was extracted and sold between 1973 and 1963. The largest shipment in any one year was 24,000 tons. The lump ore averaged 39% Cr_2O_3. The grade of ore, marketed as refractory-grade chrome, was unsuitable for the ferrochrome and chemical industries. In 1939, the Sierra Leone Government gave the company assistance in the form of a 25-year monopoly and a freight subsidy on the railway. Production diminished after 1959 because of a fall in world prices. The end of the railway subsidy was a contributory cause to the company's decision to cease operations.[4] Reserves were estimated in 1959 to be about 326,386 tons of chromite with an average grade of 38% Cr_2O_3 in the area around the mine itself. Reserves of minable ore were apparently difficult to estimate. Several U.S. companies were reported as taking out prospecting licenses for chromite in 1975.

Gold.—A U.S. mining company, Diamond Distributors Inc., was to prospect for gold in the Valunia area. The company was reportedly[5] known previously as the Diamond Export Co. Valunia Chiefdom was selected by the Government for the company's operation because gold mining in the chiefdom was once very successful. Royalties and taxes were to go towards the development of the chiefdom. A special exclusive prospecting license was also granted to Diamond Distributors Exploration Inc. to prospect for gold and diamonds in an area covering 57.80 square miles in Baomahun area of the Bo District.

Iron Ore.—Iron ore mining operations of DELCO ceased at yearend 1975 as the company was placed into voluntary liquidation following continued heavy losses. Substantial Government loans had been made (totaling nearly $5 million) over the last 2 years in an effort to continue mining despite problems encountered. In November 1974, the Sierra Leone Government loaned DELCO approximately $2 million at 9% repayable over 3 to 5 years. In July 1975, a further loan of $2 million was also made. Finally, a subsidy of $500,000 was made in September 1975. One purpose of the Government support was to enable negotiations with Bethlehem Steel Corp. of the United States to continue. Against a background of a worldwide declining activity in the steel industry, however, no acceptable agreement could be reached although negotiations were apparently continuing. Ceasing operations will bring to close a 40-year period of activity. William Baird and Co.'s share of DELCO (95%) was estimated at a book value of approximately $4 million.[6] The Sierra Leone Government was the largest creditor. The Government was seeking another company to manage operations. These include running of the rail link between the mine and the Port of Pepel, which was also owned by the company. The Government was also interested in attracting foreign investment for the Tonkolili iron deposits.

Titanium Minerals.—The Sierra Leone Government and Sierra Rutile Ltd. (SRL) officials signed the final agreement for mining the Gbangbama rutile deposits on May 23, 1975. The Sierra Leone Parliament approved the SRL rutile agreement on July 3, 1975. A recent estimate puts reserves at 187 million tons of alluvium containing 3 million tons of rutile. The investment was expected to total about $28 million, of which Bethlehem Steel International Corporation, which owns 85% of SRL, would provide $19 million. The U.S. Export-Import Bank was to provide $9 million. An agreement was arranged between Nord Resources Inc., a U.S. company and Bethlehem for Nord's share of the financing. Bethlehem will advance or otherwise provide on behalf of Nord, all phase III costs in respect to Nord's 15% equity interest and pay $1.75 million to Nord. For consideration of these payments, Nord transferred 5% of the former 20% interest in SRL and relinquished its option right and obligation to purchase an additional interest. Nord thus retained a 15% equity interest in SRL. Nord was responsible for the man-

agement of phases I and II of the project which determined the ore reserves and feasibility studies. A 24-cubic-foot bucket ladder dredge will be used in the mining. Production of rutile at rates of 100,000 to 125,000 tons per year, were planned to start by late 1977. The Bayer-Preussag Mining Group currently holds two special exclusive prospecting licenses for 560 square miles in the Moyamba District. Forty-six persons were employed in 1975. Prospecting operations were suspended early in 1975. Erection of a pilot plant was being planned for 1976. It was also reported that the Sierra Leone Ore and Metal Company, Ltd. (SIEROMCO), would start rutile prospecting in the Bo area.

NONMETALS

Diamond.—Exports of diamonds are restricted by a variety of methods linked with the marketing services of the Central Selling Organization (CSO) cartel. Restrictions vary between the two major producing systems, the National Diamond Mining Co. (DIMINCO) and the Alluvial Diamond Mining Scheme (ADS). DIMINCO's rate of production and exploration of new areas may be limited. The export license may be also limited for DIMINCO production to about five buying firms. Two of these are U.S. firms that are obligated to buy fixed percentages. Fifty percent of DIMINCO production goes to the Diamond Corporation of West Africa Ltd. (DICORWAF) and is subject to 7½% ad valorem export tax. Restrictions on exports under the ADS scheme, which consists of thousands of small-scale licensed diggers, is accomplished by licensing. To help curb smuggling, the Government licensed four new firms in 1974 to buy and export ADS diamonds in competition wth the Government Diamond Office (GDO). The same 7½% ad valorem export tax applies to ADS diamonds.

In 1975, DIMINCO, which is 51% state owned and the rest owned and managed by Selection Trust Ltd., saw its production drop from the 1974 level by almost 7% to 738,000 carats. For the first time, the company dropped the planned production rate. Over the past 2 years, costs have risen 17.5% while diamond prices rose in 1975 by only 4.5%. Drastic modifications to the scale of operations were contemplated in order to remain viable. DIMINCO accounts for approximately 53% of total diamond exports, which form 84% of the total value for all minerals produced and 60% of the total national export value for 1975. Negotiations were being held between the Government and Sierra Leone's Selection Trust over management of DIMINCO. Production from individual alluvial miners also worsened as heavy rains affected their workings. In March 1975, a total of 14,204 persons were engaged under the Alluvial Diamond Mining scheme. Alluvial mining slumped from 917,000 carats in 1974 to 645,000 carats in 1975. Smuggling of Sierra Leone diamonds through Liberia and Guinea had also dropped to the lowest levels in recent times.

Marine Salt.—A new salt factory was opened at Suein in the Ribbi Chiefdom, Moyamba Province. The factory created jobs for 150 Sierra Leoneans and was to produce salt from marine water with solar energy.

MINERAL FUELS

Petroleum.—A request was approved by the Sierra Leone Government for seismic testing along the Sierra Leone coast by an international exploration group composed of several European oil companies. Most previous exploration licenses have expired. In the first 6 months of 1975, petroleum imports were 250,473 barrels of crude oil and 47,607 barrels of distillate fuel oil. Nigeria, Congo Brazzaville, and Trinidad and Tobago were the principal sources of crude.

The Mineral Industry of the Republic of South Africa

By Miller W. Ellis [1] and Charles W. Sweetwood [2]

The mineral industry was the most important single factor in the economy of the Republic of South Africa during 1975, and accounted for nearly 17% of the country's gross domestic product. The quantity of mineral production increased 8% over the record output of 1974. Quantity and value of local sales increased 6% and 3%, respectively, and exports increased 14% in quantity and 3% in value. Imports of mineral commodities, excluding petroleum, were held to a 3% increase in quantity and their value decreased 23% to produce a more favorable balance of trade and improve the country's foreign exchange credit.

For the first time, the value of mineral products exceeded 4 billion rand(R), reaching a total of R4.27 billion ($5.83 billion)[3] compared with R3.95 billion ($5.81 billion) in 1974. The 8% increase in terms of domestic currency was equivalent to a 0.35% increase in terms of U.S. dollars as a result of the rand's devaluation to R1=US$1.15 in September 1975. Because of commitments of capital to major projects for expansion of the mineral industry, neither the Government nor the private sector embarked on significant new ventures in a year of general recession, but a number of construction programs remained on or ahead of schedule. Construction of the railway line for the transport of iron ore from Sishen to Saldanha Bay was almost completed, and equipping of port facilities there for loading 350,000-deadweight-ton ore carriers at a rate of 7,500 tons per hour was expected by late 1976. Commissioning of coal loading facilities at Richards Bay was scheduled for early 1976. The South African Iron and Steel Industrial Corp. Ltd. (ISCOR) commenced active production at its new open pit mine at Sishen in November, utilizing 9.2-cubic-meter P and H shovels and 150-ton Wabco Haulpak rear-dump trucks, some of the largest equipment of its type yet imported into the country.

PRODUCTION AND TRADE

The Republic of South Africa continued to lead the world in production of antimony, chromite, gem diamonds, gold, platinum-group metals, and vanadium, and was an important producer of asbestos, coal, fluorspar, iron, manganese, phosphate, uranium, and vermiculite. Production of copper, lead, tin, zinc, cement, salt, and sulfuric acid was adequate to provide a high degree of self-sufficiency for domestic industries. Except for copper, gold, and uranium, the production and/or sales value of all these commodities increased in 1975. Production of copper decreased because of the depressed world market price; this factor, as well as mining of

[1] Physical scientist, International Data and Analysis.

[2] Regional resources officer, U.S. Consulate General, Johannesburg, Republic of South Africa.

[3] Where necessary, values have been converted from South African rand (R) to U.S. dollars at the rate of R1=US$1.3663 (average of 1975 monthly averages as given in v. 30 of International Financial Statistics). The rate for 1974 was R1=US$1.471.

lower grade ore, was also responsible for the decline in production of gold and byproduct uranium.

The mineral industry of the Republic of South Africa was important to the world economy and contributed to the mineral production in neighboring countries. Part of this contribution was the development of transport and port facilities, and part the continued expansion of mineral production and processing plants and of industries producing mining equipment. A large part of the Republic's influence on the world economy was due to its production of gold, platinum, and diamond, but the production of less glamorous metals and minerals was also important. Details of mineral production are shown in table 1, exports in table 2, and imports of mineral commodities in table 3. Table 4 compares the value of domestic sales and exports of major mineral commodities, including ore, concentrate, slag, and other products.

Bituminous do	1,039	1,242	1,122

e Estimate. r Revised.

[1] Because official South African trade statistics provide data only on the total value of exports of each commodity class (no data on quantity and no data on destinations), this table has been compiled chiefly from information appearing in the quarterly publication "Minerals" issued by the Department of Mines of the Republic of South Africa. Figures obtained from supplemental sources and Bureau of Mines estimates are individually footnoted.

[2] World Bureau of Metal Statistics. World Metal Statistics. July 1978, 108 pp.

Table 3.—Republic of South Africa: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal sources, 1974
METALS			
Aluminum:			
Bauxite	20,589	7,188	Mainly from Argentina.
Oxide and hydroxide	[r] 119,845	169,487	Mainly from Australia.
Metal including alloys:			
Scrap	440	202	NA.
Unwrought	878	842	France 300; West Germany 175; Netherlands 168.
Semimanufactures	[r] 8,023	12,086	United States 4,258.
Arsenic:			
Oxides and acids	133	117	Mainly from United Kingdom.
Metal	3	1	NA.
Chromium:			
Chromite	122,703	75,948	NA.
Oxide and hydroxide	94	469	West Germany 250; United States 94; U.S.S.R. 46.
Cobalt, oxide and hydroxide	18	15	West Germany 7; Canada 6.
Copper:			
Ore and concentrate	37,138	76,770	Chile 47,199; Italy 29,571.
Metal including alloys:			
Scrap	278	1,088	United States 319; Hong Kong 255; Canada 117.
Unwrought	[r] 5,915	9,713	NA.
Semimanufactures	[r] 1,927	4,490	United Kingdom 1,570; West Germany 1,348.
Gold metal, unworked or partly worked troy ounces	8,256	11,462	United Kingdom 6,759.
Iron and steel:			
Ore and concentrate	1	10,978	NA.
Metal:			
Scrap	24,846	10,383	United Kingdom 1,486.
Pig iron, ferroalloys, similar materials	[r] 9,523	9,232	Sweden 1,908.
Steel ingots and other primary forms	[r] 27,559	27,574	United Kingdom 8,051; United States 7,600; Italy 6,341.
Semimanufactures:			
Bars and rods	[r] 108,142	160,260	West Germany 52,667; Japan 36,825; Netherlands 18,073.
Angles, shapes, sections	[r] 17,058	63,196	Japan 36,918; Belgium-Luxembourg 10,261.
Plate and sheet	[r] 303,855	705,408	West Germany 242,402; Japan 223,548.
Hoop and strip	[r] 39,816	46,040	Mainly from West Germany.
Rails and accessories	2,463	52,577	Do.
Wire and wire rod	11,877	19,720	West Germany 6,818; Belgium-Luxembourg 3,114.
Tubes, pipes, fittings	[r] 34,725	46,069	Japan 20,855; West Germany 7,625.
Castings and forgings, rough	4,714	3,832	Belgium-Luxembourg 986; France 908; West Germany 684; Australia 530.
Total	[r] 522,650	1,097,102	
Lead:			
Ore and concentrate	10,420	25,508	United States 18,158; New Zealand 7,350.
Oxides	22	31	Mainly from United Kingdom.
Metal including alloys:			
Scrap	2,684	4,665	United States 1,317; Australia 315.
Unwrought	6,129	4,043	Australia 99; Canada 82.
Semimanufactures	[r] 87	28	NA.
Magnesium metal including alloys, all forms	617	519	Mainly from United States.
Manganese:			
Ore and concentrate	606	1,029	United Kingdom 753; Netherlands 150.
Oxides	828	846	Japan 310; United States 248; United Kingdom 152; Belgium-Luxembourg 136.
Mercury 76-pound flasks	1,711	1,825	United Kingdom 379; Japan Kingdom 251.
Molybdenum metal including alloys, all forms	5	8	Mainly from United States.
Nickel metal including alloys, all forms	566	1,390	United Kingdom 379; Japan 119.

See footnotes at end of table.

Table 3.—Republic of South Africa: Imports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal sources, 1974
METALS—Continued			
Platinum-group metals including alloys, all forms ----troy ounces--	1,565	14,254	United States 8,727; United Kingdom 3,321.
Silicon and tellurium ----	226	385	France 208; United Kingdom 71; Canada 54.
Silver:			
Waste and sweepings ---troy ounces--	54,343	581,683	Mainly from United States.
Metal including alloys, all forms do----	1,040,666	1,179,750	United Kingdom 418,660; West Germany 325,100.
Tin:			
Ore and concentrate ----	89	23	NA.
Oxides ----	19	23	United Kingdom 11; West Germany 7.
Metal:			
Scrap ----	r 30	3	NA.
Unwrought and semimanufactures	994	1,177	United States 868; Belgium-Luxembourg 303.
Titanium (ilmenite):			
Ore and concentrate ----	--	17,130	Mainly from Australia.
Oxides ----	546	602	Mainly from Belgium-Luxembourg.
Tungsten:			
Ore and concentrate ----	468	539	Australia 290; Brazil 145; Canada 74.
Metal including alloys, all forms ----	49	71	Netherlands 11; Ireland 7.
Zinc:			
Ore and concentrate ----	16,036	38,077	Canada 21,749; Peru 12,526; Australia 3,800.
Oxides ----	303	400	United Kingdom 183; West Germany 182.
Metal including alloys:			
Scrap including powdered dust---	r 1,154	604	Mainly from Australia.
Unwrought ----	918	4,691	Mexico 601; Japan 477.
Semimanufactures ----	177	384	Mainly from U.S.S.R.
Zirconium ore and concentrate ----	72	41	NA.
Other:			
Ores and concentrates:			
Of molybdenum, tantalum, vanadium ----	271	256	United States 133; Canada 118.
Of base metals n,e..s ----	3,152	5,728	Mainly from Australia.
Ash and residue containing nonferrous metals ----	r 1,344	1,943	United States 708; Australia 255; Spain 240; Canada 222.
Oxides, hydroxides, peroxides of metals, n.e.s ----	212	351	United States 193; West Germany 84.
Elemental boron, phosphorus, and/or selenium ----	69	100	United Kingdom 54; Japan 27.
Metals including alloys, all forms:			
Alkali, alkaline earth, rare-earth metals ----	31	6,869	NA.
Pyrophoric alloys ----	8	6	Austria 1; West Germany 1.
Base metals including alloys, all forms, n.e.s.[1] ----	421	436	Mainly from United Kingdom.
NONMETALS			
Abrasives, natural, n.e.s.:			
Pumice, emery, natural corundum, etc-	2,441	4,956	NA.
Grinding and polishing wheels and stones ----	605	669	West Germany 189; United Kingdom 114.
Asbestos ----	19,388	30,385	NA.
Barite ----	3,211	4,684	Italy 2,216; West Germany 683.
Boron materials:			
Crude natural borates ----	1,862	1,431	United States 876; Netherlands 251; Turkey 250.
Acid ----	r 6,625	8,805	Mainly from Japan.
Bromine ----	13	32	Mainly from Israel.
Cement ----	71,991	84,691	United Kingdom 12,557; France 4,605.
Chalk ----	6,627	9,067	Mainly from Israel.
Clays and clay products:			
Crude clays and refractory minerals--	17,151	29,488	United States 19,240; United Kingdom 4,832.
Products:			
Refractory ----	r 35,188	34,828	West Germany 15,370; Austria 5,932; United Kingdom 5,724.
Nonrefractory ----	5,600	8,682	NA.
Cryolite and chiolite ----	776	1,148	Republic of Korea 500; Denmark 432.

See footnotes at end of table.

Table 3.—Republic of South Africa: Imports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal sources, 1974
NONMETALS—Continued			
Diamond:			
Gem ----carats--	63,000	61,500	United Kingdom 41,000; Belgium-Luxembourg 13,500.
Industrial ----thousand carats--	10,164	7,741	United Kingdom 3,305; Ireland 522.
Diatomite and other infusorial earth ----	6,747	8,805	Mainly from Japan.
Feldspar, leucite, nepheline syenite ----	184	1,159	United States 535; West Germany 250.
Fertilizer materials:			
Crude:			
Nitrogenous ----	42	235	Poland 134.
Phosphatic ----	385	34	NA.
Potassic ----	177,410	309,820	West Germany 65,705; Israel 24,030.
Other ----	4,552	6	NA.
Manufactured:			
Nitrogenous ----	31,133	78,436	Italy 34,652; Portugal 23,978.
Phosphatic:			
Thomas slag ----	5,699	1,795	All from Belgium-Luxembourg.
Other ----	563	8	NA.
Potassic ----	45,053	18,179	Mainly from West Germany.
Other including mixed ----	497	917	Mainly from Belgium-Luxembourg.
Graphite, natural ----	234	557	Mainly from Norway.
Gypsum and plasters ----	7,184	6,179	West Germany 4,174; Spain 1,080.
Lime ----	r 530	5,185	United Kingdom 2,541; United States 1,764.
Lithium minerals, not further described--	437	270	NA.
Magnesite ----	122,256	97,275	Japan 8,879; United Kingdom 6,042.
Mica:			
Crude, including splittings and waste-	469	357	NA.
Worked, including agglomerated splittings ----	48	73	United Kingdom 33; United States 21.
Pigments, mineral:			
Natural, crude ----	811	773	Austria 442; United Kingdom 262.
Iron oxides, processed ----	r 3,289	4,961	West Germany 3,790; United Kingdom 374.
Precious and semiprecious stones, except diamond [2] ----value, thousands--	$2,099	$1,208	Ireland $281; Israel $134.
Pyrite ----	37	34	NA.
Salt ----	1,793	16,594	Mainly from Australia.
Sodium and potassium compounds, n.e.s.:

COMMODITY REVIEW

METALS

Aluminum.—Production of aluminum metal increased slightly at the Richards Bay reduction plant operated by Alusaf (Pty.) Ltd., the Republic's only aluminum producer. Most of the raw material was imported as alumina from the Gove plant in Australia, operated by Swiss Aluminium Ltd. (Alusuisse) which owns 22% of Alusaf. Local sales accounted for more than 53,000 tons of this production, and nearly 15,000 tons was exported. Slightly more than 12,000 tons of manufactured and semimanufactured aluminum products reportedly was imported. In February 1975, Hullets Aluminium Ltd. announced that improvements to its 40,000-ton-per-year cold strip mill at Maritzburg should be completed by March 1977. Costs were estimated at $27 million, and decreased operating costs with better quality control was the primary objective. Small amounts of alumina, as well as calcined and activated bauxite, were imported for the manufacture of chemicals, abrasives, and refractories.

Antimony.—All antimony production came from the Murchison range, northwest of Phalaborwa in northeastern Transvaal. Consolidated Murchison Ltd. (CML) continued operations at its Gravelotte, Monarch, United Jack, Weigel, Free State, and Mulati mines, and commenced hoisting at the newly equipped 50,000-ton-per-month Athens shaft. Ore production was reported at about 637,000 tons, 2.5% higher than in 1974, but the grade declined from slightly above to below 3% antimony content. Local sales of concentrates increased from 122 tons in 1974 to nearly 12,000 tons in 1975, with a corresponding decrease in exports. Antimony Products (Pty.) Ltd., a joint venture of Chemtron Corp. (Chicago), CML, and Johannesburg Consolidated Investment Co., Ltd. (JCI), was responsible for the increase in local sales. Its new plant at Gravelotte extracted the antimony as crude oxide and manufactured a fire retardant, most of which was exported. Exports of antimony concentrates were slack during the first 9 months of 1975, averaging less than 600 tons per month, but increased substantially to an average of nearly 2,300 tons per month during the final quarter of the year. The increase was apparently due to an accelerated demand for antimony-based fire-retardant insulating material needed by U.S. manufacturers to comply with legislation which became effective in September 1975, requiring the use of flameproof material in cabinets of television sets.

CML continued exploration along the Murchison range and reported the discovery of a new ore body in November 1975. Location, size, and grade of this ore body were not revealed.

Chromite.—Production of chromite in 1975 increased 11% to more than 2 million tons, and increases of 32% and 16% were reported for domestic sales and export tonnages, respectively. The rand value of local sales increased 170% to more than R10 million, and the U.S. dollar value of exports increased 79% to almost $28 million. Production of chrome sand increased 26% to more than 500,000 tons. Increased foundry demand was largely responsible for a 31% increase in domestic sales and higher prices accounted for a 92% increase in sales value to nearly R2 million ($2.7 million). Sand exports increased 21% and their value, 78%, to $11.2 million in 1975 compared with $6.3 million in 1974.

In July 1975, the General Mining and Finance Corp. Ltd., which owned some of the country's 15 major chromite producers, announced negotiations with the Frelimo Government of Mozambique for improvements at the port of Maputo (formerly Lourenço Marques). The firm proposed to invest more than $4.5 million in railway improvements, construction of a new ore dock, chromite loading facilities, modern stockpile reclaimers, multiple conveyors, and facilities for harbor dredging so that 60,000-ton ore carriers could be loaded completely instead of having to be "topped up" from barges.

Copper.—The 1975 production of copper ore, concentrates, and metal were at essentially the same levels as those recorded during 1974. Owing to the prevailing low price on world markets, export volumes and sales were down 18% and 34%, respectively, while imports were drastically curtailed, 86% in volume and 93% in value. The tonnage sold domestically increased 3% but its value decreased 36%, reflecting the decline in world copper prices.

Virtually all of the Republic's copper was produced by four companies. Adverse market conditions caused the shutdown of two underground mines and one concentrator operated by the O'okiep Copper Co. Ltd. at its massive sulfide deposits near Springbok in northwestern Cape Province, nearly 500 kilometers north of Cape Town. Massive deposits of complex sulfide ore were extracted by underground methods from underground mines operated by Prieska Copper Mines (Pty.) Ltd. (PCM), about 500 kilometers east of Springbok. Copper, zinc, lead, and pyrite (for sulfuric acid) concentrates were recovered by PCM's mill. Erratically distributed copper sulfide ore bodies in veins were extracted from underground mines near the Southern Rhodesian border in the northern Transvaal by the Messina (Transvaal) Development Co., Ltd. More than 1 million tons of ore was milled and the resulting concentrates produced more than 10,000 tons of copper. A ring complex near the town of Phalaborwa, 170 kilometers southeast of Messina, was the site of an open pit copper mine owned by Palabora Mining Co. Ltd. (PMC). A vermiculite-rich outer ring surrounds an intermediate ring of magnetite-apatite rock, enclosing an inner core of carbonatite which contains copper sulfides disseminated throughout at an average ore grade range of 0.50% to 0.65% copper.

In 1975, PMC continued to increase the capacity of the country's largest single mining complex at Palabora. Heavy equipment moved 56.7 million tons of material from the pit, including 19.5 million tons of ore averaging 0.56% copper, to the concentrator. The smelter produced nearly 92,000 tons of anode copper from Palabora ore, and more than 13,700 tons of anodes from concentrates purchased or treated on a toll basis for smaller producers. Byproducts, including apatite (for phosphate), vermiculite, magnetite, and minerals containing nickel, uranium, zirconium, and precious metals, were also recovered and contributed to the successful operation of the plant during a year of low copper prices.

Proved recoverable copper ore reserves were reestimated as shown in the following tabulation:

Area	Quantity (million metric tons)	Percent copper
O'okiep	27	1.62
Prieska	48	1.74
Messina	5	1.40
Palabora	300	.60
Total and average	380	.83

Exploration and development of cupriferous and multimetal deposits has continued with encouraging results in the northwestern part of the Cape Province. Reportedly, Union Corporation (with O'okiep-Newmont Mining Corporation) has intensified assessment of a 90-million-ton copper-lead-zinc ore body near Gamsberg, about 100 kilometers northeast of Springbok. Nearby, at Phelps Dodge Corp.'s Broken Hill and Black Mountain holdings, sufficient copper-lead-zinc ore has been delineated for feasibility studies. Reserves at Broken Hill reportedly may exceed 79 million tons averaging 0.38% copper, 4.28% lead, 2.32% zinc, and 1.7 troy ounces silver per ton; about 40 million tons would be recoverable by open pit methods. The Black Mountain ore body was stated to include 30 million tons averaging 0.60% copper, 2.30% lead, 0.50% zinc, and 0.73 troy ounce silver per ton. Most of this tonnage was considered as amenable to open pit mining, and an additional 56 million tons might be recoverable by underground methods. JCI was also investigating a copper-zinc find in the same vicinity. Rio Tinto-Zinc Corporation Ltd. has reported the prospect of about 100 million tons of 1.0% copper ore in the Haib River area, northwest of Springbok. Development of these properties was deferred because of depressed world economic conditions, which was also the reason for a second postponement of the 120,000-ton-per-year copper refinery by O'okiep and Tsumeb Corp. Ltd., for construction near Cape Town.

Gold.—The Republic's gold industry recorded a profitable year in 1975. Working revenue increased slightly in terms of the South African rand despite a 6% drop in the grade of ore milled, a slight decrease in the volume of ore milled, and a 27% increase in operating costs (in part due to a general increase in miners' wages effective July 1, 1975). The highest free market gold price in 1975 was $185.50 per troy ounce at the end of February, compared with that of 1974 at $195.50 per troy ounce. The average price of gold for 1975 was $162.25 per troy ounce, an increase of nearly 2% over the $159.62 average price for 1974.

Major gold mines of the Witwatersrand produced 22,497,083 troy ounces; the Barberton mines to the northeast produced 47,133 troy ounces; and 393,634 troy ounces came from small mines or was produced as byproduct from base metal ores. Production for 1974 and 1975 with proven reserves of the various mines or companies are shown in table 5.

The output of some of the country's smaller mines was custom-smelted, but most of the gold mines processed their own ores into bars weighing about 840 troy ounces (26 kilograms). These bars, which contained approximately 88% gold, 10% silver, and 2% base metals, were shipped to the Rand Refinery, Germiston, which had an annual capacity of 1,000 tons of gold and 100 tons of silver. Rand Refinery products included 996-fine gold for coinage, 999-fine gold for industry and the arts, and electrolytically refined silver and platinum-group metals. The refined gold was cast into ingots weighing about 400 troy ounces (12.5 kilograms) which were cleaned, check-weighed, and marked to meet international bullion market specifications. The entire gold output was sold to the South African Government's Reserve Bank on a daily basis. Payments to the producing mines were made immediately following receipt of the bullion, based on the world market price of gold on the day received. The average total elapsed time, mine to Reserve Bank, was 5 days.

Following the December 1974 accord between the United States and France, market economy countries recognized that central banks should be allowed to value their gold holdings at market prices if they so wish. The South African Reserve Bank made no change in its official price of R29.7 per troy ounce of fine gold throughout 1975. Domestic producers received the official price plus additional revenue depending on the world price.

Sales abroad were handled by the International Gold Corporation Ltd. (Intergold), which conducted promotional activities with manufacturers, wholesalers, and retailers of gold products (including jewelry and watches) throughout the world. Intergold also launched a successful advertising campaign for overseas sales of the Krugerrand which contained 1 troy ounce of gold. Sales of this coin were heaviest in the United Kingdom early in the year until a ban on imports of gold coins for resale was imposed by the British Chancellor of the Exchequer on April 15. Subsequently, West Germany became the largest buyer. Total overseas sales of Krugerrands amounted to about 4.7 million coins in 1975, a 56% increase over the 1974 sales of slightly more than 3.0 million coins. Sales of gold R2 coins were resumed toward yearend 1975 and about 108,000 were sold to distributors in West Germany and Switzerland at a higher premium than that commanded by the Krugerrand.

Iron and Steel.—The demand for iron ore and steel products continued to show gains in every category during 1975 although exports of pig iron and steel manufactures declined slightly toward yearend. Construction of ISCOR's 861-kilometer railway from the new open pit mine at Sishen to Saldanha Bay was nearly complete, and commissioning of ore-loading facilities was progressing as scheduled. Shipment of magnetite ore through the Indian Ocean port of Maputo was interrupted and exports of iron ore to Japan (the country's major customer) declined 26% from about 2.2 million tons in 1974 to little more than 1.6 million tons in 1975.

Iron Ore and Concentrate.—Production of hematite ore increased 8.5% from more than 8.6 million tons to nearly 9.4 million tons, but magnetite production remained at about 2.9 million tons. Local sales of hematite increased 17.7% from nearly 6 million tons to more than 7 million tons, and magnetite sales increased nearly 36% from 0.9 million tons to nearly 1.2 million tons. ISCOR continued to be the country's leading producer and consumer of iron ore, with most of its 6.5 million tons extracted from its old Sishen mine in the northern part of Cape Province. The firm's Thabazimbi mine in northern Transvaal Province produced 2.1 million tons of ore and its three steel mills consumed 6.2 million tons of its total production.

Production of magnetite ore by the Highveld Steel and Vanadium Corp. Ltd. increased about 8% from less than 2.2

[1] Fully developed and blocked-out ore only; calculated at January 1, 1976, price of gold and at current operating costs. Additional indicated and inferred (possible) reserves are not included.

million tons to more than 2.3 million tons in 1975. Magnetite production at the Palabora mine was interrupted for 4 months because of rail car shortages and shipping delays at the Mozambique port of Maputo which resulted in a 21% decline in production.

In September 1975, the Anglo-Transvaal Consolidated Investment Co. Ltd. (Anglovaal) announced that its Associated Manganese Mines of South Africa Ltd. (AMM) had signed an agreement to supply 3 million tons per year of iron ore to the United States Steel Corp. from AMM's open pit mine in Northern Cape Province. United States Steel had subscribed to 355,000 shares of Anglovaal stock at a cost of more than $10 million and was to loan AMM about $6 million to finance expansion of iron ore production.

Iron and Steel Products.—All categories of iron and steel products registered gains in 1975. Production of pig iron increased 12%, ingots 13%, iron castings and ferroalloys 17% each, and steel castings 5%. Manufacturing and fabricating industries had a generally productive year as indicated by the 8% increase in sales of steel semimanufactures. Exports remained relatively steady and imports were curtailed. By October 1975 stocks of coil, hot- and cold-rolled sheet, and light plates were reported to be accumulating due to decreased demand for appliances and automobiles.

ISCOR's new open pit mine at Sishen began production in November, the railway to Saldanha was nearing completion, and ore storage and loading facilities at Saldanha were expected to be operational during 1976. Provision was made for increasing the ore export capacity of the port from 7 million tons to 20 million tons per year. Construction of a steel mill at the port was also contemplated. At ISCOR's Newcastle steel plant in Natal, installation was completed on the last of three 150-ton Linz-Donawitz (LD) steel furnaces, a third 40,000-ton-per-month continuous bloom-casting machine, a 45,000-ton-per-month bar mill, a 27,500-ton-per-month rod mill, and a 7,000-ton-per-month wire drawing and galvanizing machine. Under construction were additional coke ovens, a new blast furnace, and a continuous slab-casting machine. Expansion and improvements were also continuing at the firm's Pretoria and Vanderbijlpark works in the Transvaal.

Ferroalloys.—In mid-1975, construction of three electric furnaces at a new plant to produce 120,000 tons of high-carbon ferrochrome per year commenced by Fraser and Chalmers (SA) (Pty.) Ltd. for Tubatse Ferrochrome Ltd. General Mining held 51% of this newly formed company, which was managed by Union Carbide Corp., the minority shareholder. General Mining was to supply the ore from its newly acquired Chrome Mines of South Africa Ltd. The total output from Tubatse was to be exported. Early in 1975, JCI confirmed that a member of the JCI group, Consolidated Metallurgical Industries Ltd., had been given approval to construct a 120,000-ton-per-year ferrochrome plant at Lydenburg in the eastern Transvaal. South African Manganese Amcor Limited (SAMANCOR) (formerly South African Manganese Limited) acquired two mines in the western Transvaal, Grasvally Chrome mine and Union Carbide's Ruighoek Chrome mine, as well as the plant of Ferrometals Ltd. at Witbank in the central Transvaal. The capacity of the two chrome mines was 180,000 tons and was expected to more than double by 1980. SAMANCOR was the country's fourth largest chromite producer in 1975 and, with its new public sector ties, anticipated becoming the country's principal exporter of ferroalloys. Future annual production was estimated to include some ferrovanadium, 150,000 tons each of ferrochrome and ferromanganese, and 45,000 tons of ferrosilicon.

Reported production of ferroalloys is shown in the following tabulation, in tons:

	1974	1975
Ferrochrome	184,398	216,830
Ferromanganese	362,534	425,890
Ferrosilicon	89,068	104,580
Ferrovanadium	200	300
Total	636,200	747,600

Manganese.—The Republic of South Africa was the world's second largest producer of manganese ore (after the U.S.S.R.), and the largest exporter among market economies. The most important deposits were developed some 50 kilometers south and 60 to 100 kilometers north of Sishen in the Cape Province. Large deposits were also exploited west of Johannesburg in the Transvaal. Proved reserves in these areas exceeded 1 billion tons, and resources were estimated at more than 10 billion tons. Total production of all ore grades was nearly 5.8 million tons, 22% more than in 1974. Metallurgical grades accounted for nearly 5.7 million tons. Local sales increased 63% to more than 1.6 million tons and exports increased 16% to more than 3.6 million tons. With an increased price in the world market, manganese ore provided some $140 million in foreign exchange, about 46% more than in 1974.

SAMANCOR continued as the country's leading manganese producer, with nearly 3.8 million tons of ore, or 65% of total output during the year. This company acquired all of Amcor Limited's operating subsidiaries during 1975. Amcor was wholly owned by ISCOR and has become a nonoperational company, holding 45% equity in SAMANCOR. The principal assets acquired from Amcor included the Grasvally Chrome mine and Ferrometals Ltd., a ferrochrome producer at Witbank, Transvaal. SAMANCOR also acquired Union Carbide's Ruighoek Chrome mine (also in the Transvaal). SAMANCOR operated the Wessels mine, the largest underground manganese mine in the world, and three open pits—

Hotazel, Mamatwan, and Lohathla. A second inclined shaft and an increased crushing and sizing plant were expected to double Wessel's production to 500,000 tons per year. SAMANCOR produced ferromanganese and exported more than 2 million tons of ore which was carried by rail to Port Elizabeth, 800 kilometers to the southeast. AMM was the country's second largest manganese producer with nearly 2 million tons of ore in 1975.

Nickel.—All nickel production was a byproduct of the country's platinum mining operations. Ores from the norite zone of the Merensky Reef in the Bushveld Igneous Complex of the northern Transvaal were reported to contain about 0.2% nickel, which was recovered from the refining of nickel-copper matte. Between 55 and 100 troy ounces of platinum-group metals was produced per ton of nickel. Production of nickel during 1975 declined 6% to 20,754 tons. The apparent volume and reported value of local sales declined 40% and 31%, respectively, and exports continued to increase 24% in volume and a reported 53% in value during 1975.

Platinum-group Metals.—The Republic of South Africa remained the world's leading producer of platinum-group metals during 1975. The four platinum producing companies treated nearly 13.4 million tons of ore to produce more than 2.6 million troy ounces of platinum-group metals, a decrease of about 7.5% from the 2.8 million troy ounces reported in 1974. Approximately 1.6 million troy ounces of platinum metal was recovered, compared with more than 1.2 million troy ounces in 1974. The remaining production included osmiridium recovered from gold ores.

Platinum was discovered during 1923 as a minor constituent of a thin layer or zone of pyroxenitic norite with chromite and sulfides in the Bushveld Igneous Complex. This zone, later named the Merensky Reef, had an average thickness of about 0.7 meter (28 inches) but was traceable along a strike length of nearly 500 kilometers around the Complex. The reef dipped at about 9° toward the center of the Complex to a depth of more than 1,000 meters. Platinum-group metals (platinoids) were present in their metallic state and as complex sulfide minerals associated with sulfides of copper, nickel, and iron (chalcopyrite, pentlandite, and pyrrhotite). A narrow band of chromite-rich rock often occurred at the base of the reef, and this mineral, as well as nickel and copper, was recovered as byproduct.

Rustenberg Platinum Mines Ltd. had started a major expansion program which was deferred in 1975 except for the introduction of longwall mining with downdip scraper recovery. This has increased mining speed and recovery, reduced the number of miners required, and introduced better mechanized methods of extraction. Anglovaal announced that its research staff has developed a revolutionary new refining process which reduced refining time and cost by recovering palladium before platinum.

Tin.—The output of tin concentrate during 1975 increased 10% to 5,652 tons, but the metal content was lower, averaging 46.1% tin compared with 48.1% in 1974. Production of tin metal declined from 854 tons in 1974 to 780 tons in 1975.

Uranium.—The uranium oxide mineral uraninite was recovered as a byproduct from the gold ores of the extensive Witwatersrand deposits. Smaller amounts were recovered from the cupriferous carbonatite ore at Palabora. Production of U_3O_8 from gold ores declined about 8% from 3,074 tons in 1974 to 2,809 tons in 1975. Production from Palabora increased from 124 tons to 125 tons. Only 8 of more than 40 Witwatersrand gold mines produced uranium in 1975 but a number of others were prepared for uranium recovery when market conditions improved. West Rand Consolidated planned to produce nearly 500 tons of U_3O_8 from its recommissioned plant during 1976 and subsequent years. Anglo-American's plant at Welkom was nearing completion, and by 1976 was scheduled to re-treat waste products from its West Rand mines for an annual production of about 600 tons of U_3O_8 as well as a substantial amount of pyrite for sulfuric acid. A similar plant was expected to recover about 360 tons of U_3O_8 annually from waste dumps at its East Rand mines.

In November 1975, the Minister of Mines announced that the Government would construct a full-scale uranium enrichment plant based on the new and confidential process developed by the Uranium Enrichment Corp. (UCOR) in 1974. The process was to use uranium hexafluoride gas as feedstock, was reportedly aerodynamic, and was of the same basic type as the jet nozzle process developed in West Germany. The Government announcement noted that while UCOR's pilot uranium plant (at a cost of approximately $105 million) had been successful in every respect, studies to determine the size and site of the proposed 5,000-ton-per-year production plant were continuing. UCOR estimated the cost of the unit to be $1.0 billion to $1.5 billion and that the enrichment of the more highly fissionable U–235 from 0.7% to 3.5% at the expense of U–238 will be 20% cheaper than other known full-scale methods.

Vanadium.—More than half of the vanadium produced by market economy countries was produced by the Republic of South Africa from reserves reported to exceed 232 million tons containing from 1.5% to 2.0% V_2O_5 and calculated to a mining depth of about 30 meters. The principal source was the prolific Bushveld Ingenous Complex near Lydenburg and elsewhere in the northern Transvaal. Concentrations with as much as 2.4% V_2O_5 occurred in titaniferous magnetite ore but the average content of the normal open pit product was between 1.0% and 1.6% V_2O_5. The mined ore was leached to produce ammonium vanadate which was converted to the oxide form. Statistics published by the South African Department of Mines combined the V_2O_5 content of several products—pentoxide, ferrovanadium, metavanadate, and slag—indicating about 19,000 tons in 1975, 31% more than the 14,600 tons reported for 1974.

The country's largest vanadium company (and the leading world producer of this commodity), Highveld Steel and Vanadium Corp., Ltd. (HSV), was operating at an installed capacity reported to be 12,000 tons of vanadium pentoxide per year. HSV's ore originated from the Steelpoort Roosenekal area of the Transvaal and was treated at Witbank. The country's second most important producer, Ucar Minerals Corp. (Union Carbide, S.A., Ltd.), obtained its ore from the Brits area and processed it at Bon Accord near Pretoria (installed capacity 2,000 tons of vanadium pentoxide annually).

A third group entered the South African vanadium scene in 1974—Otavi Mining Co. Ltd. Otavi's output was to have been limited initially to 1,500 tons of vanadium pentoxide per year, though reportedly the firm will expand its operations within a 5-year period if export sales, mainly to Japan's Taiyo Koko company and to West Germany, improve. Otavi's mine (operated by Transvaal Alloys (Pty.), Ltd.) and plant were located at Wapadskloof, about 65 miles northeast of Middelburg (Transvaal).

Zinc.—The Republic of South Africa's zinc was produced by PCM from its operation 50 miles west of Prieska in the east-central part of Cape Province. The PCM concentrator, uprated from 2.6 million tons to 3.7 million tons of ore milled, achieved full capacity in 1975. It produced nearly 128,000 tons of zinc concentrate, 88% more than the 68,000 tons produced in 1974, at a grade of more than 51% zinc. Approximately 100,000 tons of copper concentrate at 25% copper, 5,000 tons of lead concentrate, and, for the first time, 75,000 tons of pyrite concentrate were also produced in 1975. The zinc concentrate was sold to the Zinc Corp. of South Africa (ZINCOR), a subsidiary of Gold Fields of South Africa, Ltd., which produced some 64,000 tons of electrolytically-refined zinc in 1975, despite a rectifier breakdown during the last quarter of the year. With the impending development of copper-lead-zinc ore bodies in the northwestern part of Cape Province and the reported discovery of additional deposits, the country's zinc supply was apparently assured.

NONMETALS

Asbestos.—Production, domestic sales, and exports of asbestos continued to increase during 1975. Production totaled nearly 355,000 tons compared with about 333,000 tons in 1974. Local sales increased from approximately 21,000 tons to more than 30,000 tons, and exports rose 69% to more than 544,000 tons from nearly 322,000 tons reported in 1974. Part of the increased demand for South African asbestos was due to a protracted strike by mineworkers in Canada during 1975. South African stockpiles were reduced and exports exceeded mine output by as much as 56% in terms of Cape Blue crocidolite. Imports of asbestos products declined from more than 30,000 tons in 1974 to about 28,500 tons in 1975 (approximately 9% of production).

Cement and Limestone.—Cement production and sales declined slightly to approximately 7.2 million tons and 6.8 million tons, respectively, in 1975. Imports declined 17% to about 70,000 tons. Shortages of rail cars forced a cutback in plant output so that the industry's extended capacity was not reached. Pretoria Portland Cement Co. Ltd., which supplied nearly half of the domestic requirements, stopped all further plant expansion until local market conditions improved. Anglo-Alpha Cement Ltd. expressed agreement with this policy.

The production of limestone increased marginally to 16.6 million tons, but local sales declined 8% while their value increased 18% in 1975. The increase in price, coupled with diminished demand from the cement industry, resulted in a stockpile increase of 84% from nearly 3.4 million tons to more than 6.2 million tons by yearend 1975. Approximately 14%, or about 2.3 million tons, of the limestone production was converted into nearly 1.3 million tons of lime, an increase of 11% over the amount produced in 1974. Most of the lime was sold to local consumers, but 13,300 tons was exported, an increase of 32% in quantity and 70% in value over the amounts reported in 1974.

Diamond.—Although diamond production in the Republic of South Africa decreased marginally in 1975, the volume and local value of diamond sales increased 13% and 22%, respectively, compared with 1974 levels. Renewed consumer demand for gem diamonds developed early in the year and sales of larger stones had reportedly improved by yearend 1975. Production of diamond in 1975 totaled 7.3 million carats compared with more than 7.5 million carats in 1974. Sales increased to more than 8.0 million carats from nearly 7.1 million carats in 1974. The Finsch mine near Kimberly in the Cape Province and the Premier mine near Pretoria in the Transvaal have each produced more than 2 million carats annually. Some idea of the relative abundance of gem and industrial diamond may be inferred from table 6.

All rough diamond produced in the Republic of South Africa was sold through the industry's Diamond Producers Association to De Beers' Central Selling Organization. Mine operators who were not members of the Diamond Producers Association sold their output under contract to De Beers or an associated company. The Central Selling Organization controlled external sales of South African diamond production and reportedly marketed about 80% of the world's diamond per year.

Fluorspar.—In 1975, acid-grade fluorspar, containing 97% or more CaF_2, accounted for about 172,000 tons or about 85% of the Republic's total production of nearly 203,000 tons. Nearly all of the fluorspar exported was this type. Ceramic-grade fluorspar, with 85% to 96% CaF_2, amounted to 5% of the total output, and metallurgical grades contributed barely 20,000 tons or about 10% of this commodity. Production of metallurgical and chemical grades of beneficiated fluorspar increased 113% and 106%, respectively, above 1974 levels, but output of acid-grade

Table 6.—Republic of South Africa: Diamond sales, by province

Province	1974		1975	
	Sales (metric carats)	Average price (rands per carat)	Sales (metric carats)	Average price (rands per carat)
MINE DIAMOND				
Transvaal	2,456,043	6.24	2,413,380	7.16
Cape Province	3,182,827	15.09	3,771,586	16.55
Orange Free State	327,949	31.27	470,087	28.02
Total	5,966,819	12.34	6,655,053	13.95
ALLUVIAL DIAMOND				
Transvaal	16,760	80.12	12,590	71.78
Cape Province	1,087,737	62.51	1,344,897	59.82
Orange Free State	118	107.84	91	68.41
Total	1,104,615	62.78	1,357,578	59.92
Grand total	7,071,434	20.22	8,012,631	21.74

material declined 11%. Domestic requirements for flux in the iron, steel, and ferroalloy industries and for glass and ceramic glazes accounted for increases of 85% and 101%, respectively, in volumes of local sales during 1975. Local demand for acid-grade fluorspar declined 18%, but exports increased 13% to about 126,000 tons.

The South African Government's Department of Mines listed Marico Fluorspar (Pty.) Ltd. at Zeerust, Transvaal, as one of seven producers of record during 1975. This new subsidiary of United States Steel was scheduled to commence mining by yearend, with full-scale mine and beneficiation plant to operate at an annual capacity of 120,000 tons of acid-grade and 50,000 tons of metallurgical-grade fluorspar concentrates during 1976. All of Marico's output was to be exported to the United States and to consumers in West Europe. Ottoshoop Holdings (Pty.) Ltd. also was listed as a 1975 producer. Its property, also near Zeerust, was purchased in 1973 by Chemspar, Inc., a subsidiary of Phelps Dodge Corp. The plant was rehabilitated and brought into production in 1974 with a rated capacity of 30,000 tons of acid-grade fluorspar per year.

Phosphate.—Production of phosphate ores increased from 7.8 million tons in 1974 to 11.6 million tons in 1975. Virtually all of the ores and concentrates were sold locally for the production of phosphoric acid and superphosphate fertilizers. The P_2O_5 content of concentrates sold locally increased from 1.3 million tons in 1974 to more than 1.5 million tons in 1975 and the value rose from $23.4 million in 1974 to nearly $32.2 million in 1975. Crushed ore from Gold Field's Glendover mine, north of Thabazimbi in the Transvaal, was sold to SAMANCOR. Production was more than 94,000 tons containing 30% P_2O_5, compared with about 79,000 tons of the same grade sold in 1974. The Phosphate Development Corp. Ltd. (FOSKOR) continued open pit mining on the apatite-rich ring surrounding the Palabora carbonatite. The 11.6 million tons of ore reported as production included some apatite-rich overburden removed from the neighboring PMC's open pit, as well as ore from FOSKOR's pit. FOSKOR's concentrator treated part of its own ore but also treated phosphate-rich tailings pumped directly from PMC's copper concentrator. Additional capacity at the FOSKOR concentrator was scheduled for 1976.

Pyrite.—*Sulfuric Acid.*—Iron pyrite concentrate was produced as a byproduct at several South African gold mines and from the PCM copper-zinc-lead mine west of Prieska. Nearly 651,000 tons was produced in 1975, a 14% increase over the 1974 output. The sulfur content of concentrates sold locally amounted to more than 218,000 tons worth about $6.9 million in 1975, compared with over 215,000 tons worth more than $5.6 million in 1974. Recovery of pyrite from waste dumps on the Witwatersrand was increased in order to provide more sulfuric acid for the phosphate fertilizer industry.

Vermiculite.—Byproduct vermiculite production from PMC's open pit at Palabora increased 14% from nearly 183,000 tons in 1974 to more than 207,000 tons in 1975. Local sales increased 17% from nearly 6,000 tons to almost 7,000 tons, and the volume and value of exports rose 24% and 38%, respectively, from about 150,000 tons and almost $5.6 million in 1974 to 186,000 tons and more than $7.7 million in 1975.

MINERAL FUELS

Coal.—Extensive coal deposits provided most of the country's energy requirements, and exports of surplus coal earned about $51 million in foreign exchange during 1975. Production of anthracite coal increased from about 1.4 million tons to 1.6 million tons during 1975 and bituminous coal output rose from 64.6 million tons to 67.8 million tons. Increases recorded in production, local sales, and exports, in thousand tons and thousand dollars, are shown in the following tabulation:

	1974		1975	
	Quantity	Value	Quantity	Value
Coal, all types:				
Production	66,056	NA	69,440	NA
Local sales	62,354	$262,334	66,434	$380,904
Exports	2,277	31,837	2,687	46,933
Bituminous and subbituminous:				
Production	64,621	NA	67,849	NA
Local sales	61,771	254,886	65,732	367,681
Exports	1,242	15,385	1,565	26,186
Anthracite:				
Production	1,435	NA	1,591	NA
Local sales	583	7,448	701	13,223
Exports	1,035	16,452	1,122	24,846

NA Not available.

Bituminous and subbituminous coal accounted for 99% of domestic sales but only 58% of export sales. About 42% of the coal exported consisted of more than 1.1 million tons of Natal anthracite. Of the domestically consumed coal, 37.6 million tons was used to generate electricity, 13% to produce coke, 11% by local industries, 6% for household consumption, 3% (nearly 2 million tons) each to coal gas producers and for the oil-from-coal project, 2% each to other gas producers, for consumption at coal mines, and for transport, and 1% for other mining industries.

On December 5, 1974, the Government announced that the South African Coal, Oil, and Gas Corp. Ltd. (SASOL) was planning the construction of a second and larger oil-from-coal conversion plant, SASOL II, with a U.S. firm, Fluor Corp., as general contractor. By May 1975, the cost of the project was estimated at $1.6 billion, and by yearend the estimate had escalated to $2.2 billion. Controversy over the practicality of the plan had continued since its announcement and at yearend detailed studies were still in progress.

Petroleum.—All of the Republic's oil supply was imported and most of it was refined within the country. Imports of crude oil increased from nearly 94 million barrels in 1974 to more than 122.5 million barrels in 1975.

Exploration for oil was scheduled to continue both onshore and offshore during 1975, under the direction of the Southern Oil Exploration Corp. (Pty.) Ltd. (SOEKOR). Seven wildcat holes with a combined depth of about 37,000 feet were reportedly drilled in 1975, compared with the 14,000 feet completed in five wildcat holes during 1974. A drilling rig operating in the St. Lucia area, 240 kilometers north of Durban, was reported to have encountered troublesome rock but no sign of either gas or oil.

The Mineral Industry of Southern Rhodesia

By Janice L. W. Jolly [1]

Mineral production in Southern Rhodesia contributed about 6.9% to the gross domestic product (GDP) of $3,055 million[2] in 1975 at current prices, compared with 7.2% of the 1974 GDP.[3] The economy recorded a 7.7% growth rate in current dollars during 1975, versus 9.6% in 1974. In the first 10 months of 1975, the rate of inflation averaged 7.8%. The Rhodesian dollar was devalued relative to the U.S. dollar in September 1975. The increases in fuel and freight rates were expected to add further to inflationary trends. With no significant recovery in copper, nickel, iron ore, or chrome prices expected before 1976, foreign exchange remained tight.

The fall in world mineral prices and demand resulted in a reduction in the value of mineral production for the first half of 1975. Mining production recovered during the second half of 1975, however, and increased 39% in the first 2 months of 1976. Southern Rhodesia's fourth nickel mine was opened in October 1975 with production expected to reach full capacity by early 1976. Growth recorded for both mining and agriculture offset a decline in manufacturing production. Southern Rhodesia was making preparations for alternative transport routes in the event of Mozambique border closures. Rhodesian Railways Co. was increasing the capacity of the Rutenga-Beitbridge line to the Republic of South Africa in anticipation of this eventuality.

The fuel ration to the business sector was cut back by a further 20% in July 1975, following a 10% cutback in March, reflecting foreign exchange strain. The 10% surcharge on income tax introduced in 1974 remained, and in April 1975, company tax was fixed at 44% instead of 40%. Higher mineworker wages were being negotiated by the Mineworkers of Rhodesia (AMR) and the Rhodesian Chamber of Mines to alleviate further possible loss of mine labor to the Republic of South Africa. A new 5-year agreement was signed by Southern Rhodesia in early 1975 with Wenela (the official recruiting organization of the Republic of South Africa), giving a minimum of $2.56 per shift for mine workers in South Africa, which was significantly higher than the 68 cents per shift claimed by the AMR for mine workers in Southern Rhodesia. Wenela was not allowed to hire men who had worked in Rhodesian mines for a year previous to their application, nor could recruitment take place in mining areas of the Midlands or in Manica, where it might compete with agricultural manpower requirements.

Electrical energy used by mining and quarrying in 1975 was 1,086 million kilowatt-hours.

PRODUCTION AND TRADE

Mineral production was valued at $271.7 million in 1975, compared with $264.3 million in 1974. Both the mineral unit value index and the volume index (1964=100) increased in 1975 compared with 1974 indices.[4] A fall in world mineral prices and demand resulted in a reduction in value of mineral production for the last half of 1974 and first 6 months of 1975, and was reflected by the low mineral unit value index recorded for those two periods. By the last half of 1975, however, this indicator had increased by 11%. A 2% fall in terms of trade was indicated for 1975 over 1974. (The terms of trade is defined as the unit value of exports divided by the unit value of imports. The fall in terms of trade indicated a fall in export prices relative to import prices.) Unit value indices for both imports and exports increased in 1975 relative to 1974.

Exports remained firm through 1975 even though weaker prices were obtained for some items such as copper. Rhodesian exporters were somewhat wary of using Mozambique ports despite the fact that Mozambique had not yet taken action to implement sanctions and did not until early 1976. Transport problems during 1975 included congestion and workers' strikes at the port of Maputo and numerous disruptions along the rail line from Umtali. The net effect was to almost stop Rhodesian imports and exports through Mozambique during mid-1975. A report on Rhodesian trade published by the United Nations Security Council in May 1975 estimated total Rhodesian exports valued at $1,240 million in 1973.

Since the Unilateral Declaration of Independence (UDI) in 1965, few details have been available on the asbestos industry. Estimates range up to 270,000 tons produced in 1975. Rhodesia had exported 165,000 tons of asbestos in 1973, compared with 80,000 tons in 1972. Most of this was exported to Japan, West Germany, Spain, and Yugoslavia.[5] In 1975 Rhodesian asbestos exports were estimated to be 200,000 tons.

Shipments of both ferrochrome and chrome ore were delayed in 1975, sometimes as much as 30% behind schedule, owing to continuing technical problems with the railroads and the Mozambique ports. U.S. imports of Rhodesian chrome in 1975 were as follows: Chromite (all types), 138,000 tons, valued at $7.2 million; high-carbon ferrochromium, 75,855 tons, valued at $33.2 million; and low-carbon ferrochromium, 5,238 tons, valued at $5.4 million.

Copper production in general increased, but profits fell as world copper prices weakened during 1975. Gold profits increased, despite a lower output and increased working costs, as a result of higher gold prices. Production from the Coronation Syndicate Ltd. mines for the financial year ending in September 1975 (Arcturus, Mazoe, Muriel, and Inyati) was 77,800 troy ounces of gold, 169,700 troy ounces of silver, and 6,900 tons of copper from 696,000 tons of ore processed. A sharp decline in demand for nickel during the first half of 1975 led to a fall in company profits. The Anglo American Trojan and Madziwa mines produced approximately 8,816 tons of nickel (contained metal content) in 1975. Nickel production was expected to reach 2,500 tons for the financial year ending June 30, 1976, at the Shangani nickel mine, which started production in October 1975. The United States imported 2,510 tons (nickel content) from Southern Rhodesia out of the total 147,211 tons of nickel it imported for 1975. The imported nickel was valued at about $2.20 per pound, or $12.2 million for all the imported Rhodesian nickel. The export and domestic price of Rhodesian steel was increased 25% during December 1975.

Coal sales fell 11% to 2,493,108 tons for the financial year ended August 31, 1975. In the same period coke sales rose 9% to 290,076 tons. Despite unpredictable demands for coal, as well as an increased rate of taxation, the company's after-tax profit in 1975 was the highest recorded since 1971. This was due to an increased coal price from March 1, 1975, and to increased export sales of coke and coking coal in the second half of the financial year. Washed coal rose from $8.88 to $12.24 per ton, and coking coal from $10.53 to $14.40 per ton. Wankie coal sales for October, November, and December 1975 were 264,834, 257,612, and 232,178 tons, respectively. Coke sales in November and December were 15,291 and 15,678 tons, respectively.

[1] In addition to the commodities listed, modest quantities of unlisted varieties of crude construction materials (including clays, stone, sand, and gravel) presumably were produced, but output is not reported quantitatively, and available information is inadequate to permit formulation of reliable estimates of output levels. Also, natural corundum, graphite and mica have been produced in the past and output presumably has continued, but no basis for estimates of output levels is available. Through 1965, annual corundum output was at a level of several thousand tons, ranking Southern Rhodesia second only to the U.S.S.R.

[2] Data are for years ending September 30 of that stated.

[3] Includes nickel content of nickel oxide and nickel fonte.

[4] Output of Inyati mine only for years ending September 30 of that stated.

[5] Output of Beardmore mine only for years ending September 30 of that stated.

[6] Data are for years ending September 30 of that stated and denote only an approximate order of magnitude.

[7] Data represent sales for years ending August 31 of that stated.

COMMODITY REVIEW

METALS

Cesium, Rubidium and Lithium.—The Bikita pegmatite, containing cesium, rubidium, and lithium minerals, was described as the largest of a group occurring in the Bikita tinfield, located 65 kilometers northeast of Fort Victoria. It formed a dike striking northeast with a length of over 1,600 meters and width up to 120 meters. The pegmatite was zoned, permitting selective mining. The minerals recovered were, in order of abundance, petalite, lepidolite, spodumene, pollucite, beryl, eucryptite, and amblygonite. Lithium minerals also occurred in pegmatites of the Enterprise area to the east of Salisbury, the Umtali District, the Mtoko District, the Insiza District, the Matolo District, the Mazoe District, and the Fort Rixon area. Deposits were also reported at Shamva, Inyanga, and near Gadzema. At Bikita a conveyor belt sorting system had been used to facilitate sorting. An experimental flotation pilot plant was also devised for flotation of lithium minerals.[6]

Chromite.—Principal chromite producers in Southern Rhodesia included the Rhodesian Vanadium Corp., Consolidated Minerals Ltd., Rio Tinto (Rhodesia), and the Union Carbide subsidiaries—Rhodesia Chrome Mines Ltd., which operated several mines in the Selukwe area and the Prince Mine in Victoria District; African Chrome Mines Ltd., at Mtoroshanga; and Union Carbide Rhomet, which operated a chrome alloy smelter at Que Que and the Lulapanzi Mine in the Gwelo District. Subsidiaries of the U.S.-owned companies came under Rhodesian Government control when sanctions were instituted in 1967. Rhodesian Vanadium Corp. became a member of the Anglo American group in 1973 when the chrome interests of Foote Mineral Co. (United States) were acquired. The mining operations of Rhodesian Vanadium Corp. became part of Rhodesian Alloys Ltd. in November 1975, according to an Anglo American statement. Rhodesian Alloys operated a ferrochrome plant in Gwelo using chrome ore from the Rhodesian Vanadium mines at Mtoroshanga (now Rhodesian Alloys Mining Division (RAMD)). Rio Tinto (Rhodesia) acquired the Frances Chrome Mine, the Rhodesian Mining Enterprises Ltd. properties of the Lomagundi District, and the Great Dyke Chrome Mines Ltd. claims of the Darwendale area in 1972.

Three types of chromite deposits, associated with ultramafics or serpentine and talc schists, are mined in Southern Rhodesia: (1) Lenticular bodies, which range from only a few tons to major ore bodies (Selukwe, Belingwe, Mashaba, and Gwanda); (2) regular chromite seams in layered complexes (the Great Dyke); and (3) eluvial deposits (certain areas of the Great Dyke). The Great Dyke was classified into four complexes from north to south, the Musengesi, Hartley, Selukwe, and Wedza. The most important was considered to be the Hartley complex. Since 1960, the chromite seams of the Great Dyke have been numbered 1 to 11 from the top down after the Worst system, introducing uniformity between mines and making seam recognition simpler. Disseminated ores are also found but are not mined. The disseminated ores can be concentrated to over 40% Cr_2O_3 with a Cr:Fe ratio of more than 2:1, and then pelletized on site. The initial cost of a concentrating plant would be a retarding factor in their development.[7]

RAMD successfully introduced new mining methods at Mtoroshanga in 1975 which were helping to cut costs and to increase production. One method uses a hydraulicking unit, which was developed in cooperation with Aquapower, a South African mining equipment company. RAMD comprises the Caesar, Vanad, and Sutton mines. Reserves were estimated at 1.3 million tons to a depth of 300 meters at the Caesar. Two new potential mining sections developed in 1974–75 were expected to produce 20,000 tons, building up to 40,000 tons, of ore per year. The capital expenditure by RAMD on prospecting was approximately $1.6 million in 1975, while a further $800,000 was spent on rehabilitation. Rio Tinto (Rhodesia) commissioned its new ferrochrome smelter at Gatooma. The smelter was a first step toward a large smelting complex designed to achieve maximum beneficiation of the group's chromite reserves. Plant capacity was not disclosed.

A bill (HR 1287) to end imports of Rhodesian chrome to the United States, as allowed under the Byrd amendment, was subject of congressional debate until September 1975, when the House of Representatives voted 209 to 187 against the bill.

Copper.—Coronation Syndicate Ltd. (a subsidiary of Lonrho Investment Co. Ltd.) reported that earnings for the financial year ending September 30, 1975, were 20% lower than in 1974. This was mostly caused by the substantial decrease in the copper price and the increase in operating costs at the company's Inyati mine. Throughput at Inyati increased from 393,000 tons of copper ore in 1974 to 402,000 tons in 1975, and the output rose from 6,116 tons of contained copper in 1974 to 6,640 tons in 1975. Long-term development at the mine would be affected by the flat-lying, 160-meter-thick dolerite intrusive that was encountered in the Eta No. 2 shaft. The nature of the ore body below the intrusive was to be established. Lonrho Investment also held 50% ownership in the Nyaschere Copper (Pvt.) Ltd. mine.

Messina (Transvaal) Development Co.

[6] Chamber of Mines Journal (Southern Rhodesia). Background to Mining In Rhodesia, Lithium. April 1975, pp. 41–42.

[7] Airey, N. M. A Review of Chromite Mining in the Great Dyke. Chamber of Mines Journal, v. 17, No. 6, June 1975, p. 36.

Ltd. operated the MTD (Mangula) Ltd., Silverside, and Norah mines. Profits for MTD (Mangula) fell from $16.5 million in 1974 to $6.9 million for the financial year ended September 30, 1975, a reduction of 58%. Silverside production from the open pit was adversely affected by a drop in ore grade until March 1975 when underground sulfide ore production was started. This resulted in improvement in both grade and concentrator recovery. Contained copper production at Silverside was 1,674 tons. Norah mine proved and probable ore reserves were increased from 3.5 million tons at 1.37% to 5,246,000 tons at 1.26% copper. The concentrator capacity at Norah was to be doubled, costing $1.3 million and expected to be completed by early 1977. The additional copper production gained thereby was to compensate for closure of the leach plant. The Mangula mine planned to increase production at the Miriam shaft by 14% not later than the middle of 1977 to compensate for an anticipated decline in ore grade. Contained copper output to the end of September 1975 at the Norah mine was 2,757 tons and at the Mangula, 13,540 tons. Messina's Gwai River mine suspended operations on April 1, 1975, and the mine was put on a care and maintenance basis. The mine had produced 486 tons of contained copper in 1975. At Messina's Alaska mine, the tonnage milled decreased from 312,000 tons to 251,000 tons of copper ore, with a contained copper recovery of 1,753 tons. The Shackleton mine recorded satisfactory results with a production of 10,381 tons of contained copper.

Gold.—Development advances were well maintained at the three Coronation Syndicate Ltd., gold mines and total gold ore reserves for the group increased from 946,000 tons at 0.04 troy ounce per ton to 969,000 tons at 0.37 troy ounce per ton as of June 30, 1975. As a result of a major plant breakdown in January 1975, Arcturus mine throughput decreased from 95,000 to 91,000 tons for the year and production fell from 22,891 troy ounces to 22,377 troy ounces of gold. Profits increased despite lower output and increased working costs owing to higher gold prices. The tonnage milled at Mazoe increased following plant improvements made early in the year. In addition 14,000 tons of old tailings was treated. In the Mazoe District, the Bernheim prospect shaft was sunk 92 meters in difficult ground. Plant improvements completed at Muriel in the 1974 financial year operated at better than designed capacity. Production increased from 22,120 troy ounces of gold and 394 tons of copper in 1974 to 22,666 troy ounces of gold and 432 tons of copper in 1975. During 1975, Coronation acquired the entire issued capital of Tatcoll Mining Co. (Pvt.) Ltd., which had claims covering the dormant Ayshire mine. Option agreements over the Uno and Viceroy gold properties were also negotiated during the year. Located about 12 kilometers from the Arcturus mine, the ore was amenable to treatment at the Arcturus plant. At yearend, a 6-year tribute agreement was concluded for working the Mashona Kop mine, a small high-grade gold mine also located near Arcturus. The agreement included an option to purchase the property outright.

Rio Tinto (Rhodesia) purchased the Renco gold mine in 1975, located near Fort Victoria. Underground exploration and development had indicated sufficient ore reserves to justify low-tonnage operation for about 10 years. A number of gold-copper occurrences similar to Renco mineralization were found in the vicinity. Mining operations were to continue at a low level while an intensive exploration program at Renco and the surrounding areas was conducted. Sabi Consolidated Mines was developing a new underground gold mine at Shabani. The Globe and Phoenix Co. underground mine at Que Que was shut down in early 1975. Underground machinery and equipment were being sold, but some gold was expected to be extracted from the tailings dumps even though mining operations had ended. Banket Mine Private Ltd. (a subsidiary of Falconbridge Nickel Mines Ltd.) completed dewatering of the old workings in the Feudal mine, and shaft sinking was started at the bottom of the old shaft. Exploration in old workings in the upper part of the mine added 130,000 tons of ore to reserves. In 1974, Banket Mines milled 161,000 tons of ore, with 22,201 troy ounces of gold produced. The Athens and Falcon claims were acquired by Homestake Mines (Pvt.) Ltd. Reserves at the Athens had been indicated as approximately 270,000 tons containing 0.26 troy ounce per ton of gold, 0.42 troy ounce per ton of silver, and 1.51% copper. Reclamation of the Falcon mine, located west of the Athens, was to be considered once the Athens was established as a full-scale mining operation. The Falcon mine had been previously worked to 17 levels and was subsequently flooded to within 30 meters of the surface. The Chamber of Mines announced that more than 70 new gold mines had come into operation in 1975, encourage' by the high price of gold and by the Government's new policy of easier loans for prospectors.[8]

Iron and Steel.—In early 1975, the United Nations Sanctions Committee asked all nations to ban Rhodesian steel imports after learning of a multinational scheme to finance a 600,000-ton-per-year increase in the steelmaking capacity of Rhodesian Iron and Steel Corp. Ltd. (RISCO) to a 1-million-ton-per-year total capacity. Financing was to be arranged via a South African company and several European and Swiss banks and steel firms. The European Economic Community's (EEC) Technical Research Committee also approved a grant of about $44,000 toward a project that was sponsored by the International Pig Iron Secretariat, of which Southern Rhodesia is a full member. The project concerned development of a new pig-iron-casting process and was to be undertaken jointly by RISCO, the British Pig Iron Group and their counterparts in France, Italy, Finland, Norway, and Sweden.

Rhodesia exported some 214,000 tons of pig iron and 80,000 tons of steel in 1975, before sanctions were imposed. Another 60,000 tons of steel was consumed locally. Estimated iron ore resources at that time included more than 200 million tons of relatively high-grade material with an iron content ranging from 55% to 65%. RISCO was owned by a consortium composed of Anglo American Corp., British South Africa Co., Lancashire Steel Co., Messina (Transvaal) Development Co., Rhodesian Selection Trust Co., Stewarts and Lloyds, and Tanganyika Concessions.[9] Iron ore mining companies in 1975 included RISCO, Africa Strip Mining Co. (Buchwa mine), Belingwe Mining Investments (Pvt.) Ltd., Ingezi Mining Co., (Pvt.) Ltd., and Iron and Mineral Development Co. The Mashonaland Iron and Steel Co., a subsidiary of the More Wear Group, embarked on a $5.1 million expansion program in 1975. The new plant was scheduled to have two ore furnaces that were to provide 500 tons of steel castings per month and 1,000 tons of iron castings. Most production was intended for export. RISCO was also upgrading the Redcliff steelworks and stage II of the development was expected to be complete by 1976.

Nickel.—Johannesburg Consolidated Investment Company Ltd.'s (JCI) (55.2% owned) Shangani Mining Corp., Ltd.'s nickel mine, 12 kilometers northeast of Insiza, started production in October 1975. The initial prospecting program was carried out by Prospects of Rhodesia (Pvt.) Ltd. (POR), wholly-owned subsidiary of JCI. Shangani Mining took over exploration operations in January 1972, and by December 1974 underground development was being done. Nearly 2 million cubic meters of overburden were removed to start open pit operations on two ore bodies, comprising east and west mineralized lobes of serpentinite intruded into older bedded tuffs and metabasalts. Both ore bodies have a continuous strike of 140 meters, but the eastern ore body was presumed to be the larger. Approximately 3.9 million tons, grading 0.81% nickel, were assumed to be amenable to open pit mining; the balance of 15.2 million tons grading 0.77% nickel was expected to be mined by underground operations. Production of 2,500 tons of nickel and 400 tons of copper was forecast for the financial year ending June 30, 1976. The final cost of JCI's Shangani mine development was $34.1 million.

The Rhodesian Nickel Corp.'s Epoch mine was on schedule to start production in January 1976. The cost of bringing the Epoch mine onstream was estimated at $10.1 million. Located near Filabusi, the Epoch mine had a potential of 2.5 million tons per year with an average grade of 0.75% nickel. At Rhodesian Nickel's Trojan mine, a new subvertical shaft was underway for exploitation of the lower levels. The Trojan ore graded 0.65% nickel, and an estimated 900,000 tons of ore was milled during 1975. Rhodesian Nickel's Madziwa mine milled just over 1 million tons, grading 0.94% nickel and 0.31% copper. The electric smelting furnace at Rhodesian Nickel's Bindura Smelting and Refining Co. (BSR) was commissioned in November 1975. A major setback took place a week after the furnace was commissioned when a slag runaway

[8] Chamber of Mines Journal. Gold Hits the Headlines. V. 17, No. 90, October 1975, p. 34.
[9] Journal of Metals (Salisbury). Iron and Steelmaking in Rhodesia. V. 17, No. 4, April 1965, p. 380.

penetrated the main power station, causing a fire. BSR had a 10-year agreement to smelt and refine copper-nickel from Shangani. The $13.9 million expansion to the Bindura plant was launched to treat both Shangani concentrates and the expected production of the Epoch mine. Rhodesian Nickel's profits fell 9% in 1975 to $3.7 million. Profits were good during the last half of 1974, but a sharp decline in demand during the first half of 1975 led to comparatively poor results. Rhodesian Nickel Corp. was owned by Anglo American Corp.

Rio Tinto's Perseverance mine shutdown in 1975 because of metallurgical problems caused by arsenic in the ore. The smelter feed ratio of Perseverance to Empress ore was adjusted to compensate for the high arsenic content. Stockpile ore was expected to last the smelter through 1976 when problems were expected to be solved. Mining was to resume in 1977.

Tin.—The most important tin occurrences in Southern Rhodesia were in the Kamativi tin belt 50 kilometers east of Wankie. All deposits were the pegmatite type, as in the areas of Myagomo, located 20 kilometers east of Kario, and in Bikita, located 60 kilometers east of Fort Victoria. The only underground mine was at Kamativi. Small alluvial deposits were also worked in Rhodesia by panning or simple sluice box. Kamativi Tin Mines, a subsidiary of N.V. Billiton Maatschappy of the Netherlands, had its own treatment, crushing, and milling plant. The company also owned a smelter (Kamativi Smelting and Refining) in which tin and various alloys for solders were produced. Kamativi declared a record profit of $3.5 million for 1974 and was to spend $6 million on deepening the shaft to facilitate underground exploration. Work began in November 1974 and was expected to be completed by September 1975.

Uranium.—During 1975, Gold Fields Prospecting Co. of South Africa was active in uranium prospecting in Southern Rhodesia.

NONMETALS

Asbestos.—The Rhodesian and General Asbestos Corp. (Pvt.) Ltd. (a subsidiary of Turner and Newall Ltd. of the United Kingdom) dominated the industry with its Shabanie mine in the Shabani District and its King and Temeraire mines in the Mashaba District in south-central Southern Rhodesia. Pangani Asbestos Mine (Pvt.) Ltd. controlled the Pangani, Boss, Vanguard, and Rex mines in the Bulawayo—Shabani region. The Kudu Mines (Pvt.) Ltd. asbestos mine located near Essexvale was to boost the milling rate from 200 to 1,000 tons per day, and a new tower dryer was to be constructed. In the past, work had to be halted during the rainy season because the asbestos could not be dried. The milling rate was planned to be more than 360,000 tons of ore containing 6% to 7% short-fiber asbestos within a year. Ore reserves in the main Kudu Mines quarry were estimated at 5 million tons with approximately another 15 million tons beneath the quarry floor. Two additional quarries were under development. The asbestos was to be used mainly in the asbestos cement industry and for water, wine, and scent filters. A new mill was to be constructed to achieve the increased production by mid-1977. Asbestos was to be also extracted from the dump, which runs about 4% asbestos, by a high-speed milling and degritter machine. Other asbestos mining companies included D.S.O. Asbestos (Pvt.) Ltd., Thornwood Asbestos Mines (Pvt.) Ltd. (two mines in the Gwanda District), and Bend Asbestos Ltd.

Diamond.—Intensified prospecting was being carried out by Kimberlitic Searches and Prospecting Ventures Ltd., a subsidiary of DeBeers Consolidated Mines of South Africa, near the border of the Republic of South Africa at Beit Bridge. Kimberlitic Searches had pegged a small area where preliminary work indicated more intensive prospecting. Diamonds mined earlier in the century at Somabula near Gwele were alluvial. It was Kimberlitic Searches, which has been systematically searching for diamonds in Rhodesia from its Bulawayo base for about 10 years, that found the Orapa diamond pipes in Botswana.

Emerald.—A new emerald mine, claimed to be the largest in Southern Rhodesia, started partial production. The mine, situated 75 kilometers northwest of the Rio Tinto Sandawana mine, was owned by a Filabusi miner.[10]

Phosphate.—Phosphate output was from the African Explosive and Chemical Industries Ltd. (AE & CI) mine at Dorowa. The

[10] Barclay's National Review (London). Rhodesia Mining. March 1976, p. 10.

apatite ore, occurring in igneous rocks of a carbonatite complex, contained between 4% and 13% P_2O_5 over a 10-square-kilometer area. The concentrate was shipped to a plant at Msasa on the eastern outskirts of Salisbury. Three other carbonatite complexes were also the subject of investigation: The Katete occurrence in northwest Rhodesia on the Gwai River, the Shawa complex in the Sabi Valley, and the Chishanya complex located 25 kilometers north of Birchenough Bridge and 90 kilometers southeast of Shawa and Dorowa. The Shawa deposits, reportedly superior to the Dorowa deposits were to be developed in the near future.[11] The Katete carbonatite complex did not contain appreciable phosphate minerals. Three mining companies had claims in the Chishanya area. Apatite is largely restricted to narrow intrusive carbonate bands, each up to 3 meters wide, making separation of the apatite from the carbonate host rocks difficult. Carbonate is undesirable in the manufacture of superphosphates. The P_2O_5 content of the Chishanya rocks ranges from less than 3% to over 20% in the iron-rich, calcium-magnesium carbonate rock. An occasional specimen contains about 25% P_2O_5. Consideration was being given to using the finely ground apatite-rich carbonatite directly for pasture improvement and agricultural purposes. A salable product from Chishanya would contain approximately 10% P_2O_5 in mixed calcium, magnesium, and iron carbonate.

MINERAL FUELS

Coal.—An oil-from-coal plant was an important topic for discussion at the energy symposium held in Bulawayo in 1975. Rio Tinto (Rhodesia) Ltd. announced that it could build the plant for Rhodesia and that finance would be no problem. Over 10 years, the plant could be developed at a cost of $384 million, complete with mine, town, and rail and road services. Gold Fields Ltd. was to do a feasibility study on the Bubi coalfield as the latest stage in its recent prospecting program east of Beitbridge. Gold Fields Prospecting Co. (Pty.) Ltd. explored the same area in 1962. Analyses from drill holes showed that the coal had excellent coking quality; calorific value was more than 13,000 Btu per pound and ash content was 10% to 12%. The Bubi Field was believed to contain at least 15 million tons of economic coking coal. Early in 1975, the Government also granted a 3-year prospecting license to Gold Fields for oil, coal, copper, nickel, and zinc over an area covering more than 480 square kilometers in the Bulawayo and Victoria mining districts.

The Mineral Industry of the Territory of South-West Africa

By Candice Stevens [1]

The mineral industry of the Territory of South-West Africa continued to be the dominant factor in the country's economy in 1975. Although statistics were not available, the value of mineral exports was estimated at $320 million,[2] accounting for about 60% of the value of all exports. The production of diamonds, which increased significantly during the year, remained the Territory's foremost mineral activity. Other key minerals, particularly the production of base metals by Tsumeb Corp. Ltd. and of metallic concentrates by the South-West Africa Co. Ltd. (SWACO), showed a general decline. The overall effects on the natural resources of the Territory of South-West Africa, of a United Nations decree prohibiting the export of mineral commodities from the Territory without the prior authorization of the U.N. Council for Namibia had yet to be determined.

Although exploration activity was at a low level in 1975, development of facilities and ongoing projects continued on schedule. Both the Asis Ost copper mine of Tsumeb Corp. and the Otjihase copper mine, a joint venture of Minerts Development (Pty.) Ltd. and Johannesburg Consolidated Investment Co. Ltd. (JCI), came onstream in 1975. SWACO brought its Brandberg West tin-tungsten mine back into production after a 2-year dormant period and initiated production on a trial basis at the Otjivalunda saltpans. Development of the Rössing uranium project, expected to become the world's largest producer when output commences in 1977, progressed during the year, and sales contracts were settled for the marketing of output. However, in the petroleum sector, extensive prospecting for offshore oil and gas failed to locate any commercially viable sources, prompting a number of companies to relinquish their exploration rights during the year.

The most promising new source of power for the Terrority's large mineral industry was the Ruacana Falls hydroelectric scheme on the Cunene River bordering Angola. Construction began in early 1973 under the direction of the South-West Africa Water and Electricity Corp., the agency established by the Industrial Development Corp. (IDC) of the Republic of South Africa for supervision of electric power production. Major construction work was being performed by an Italian consortium, Construzioni Internazionali, at a cost of $307 million. The project comprised a diversion dam immediately above the falls, which channeled the Cunene waters through an open headbay into feeder tunnels which then led to turbines in an underground powerhouse. The regulating dams for the project were at Gove and Calueque in Angola, which were also to divert water for major irrigation projects in Angola and Ovamboland in the northern Territory of South-West Africa.

Upon completion in 1977, initial capacity was to be 160 megawatts, increasing to 320 megawatts by 1982. The annual output of about 1.2 billion kilowatt hours was to be transmitted into the South-West African

[1] Economist, International Data and Analysis.
[2] Where necessary, values have been converted from South African Rand (R) to U.S. dollars at a rate of R1=US$1.3663 (average of monthly averages for 1975 as given in International Financial Statistics).

grid reaching to the main centers of Windhoek, Tsumeb, and Walvis Bay. The expected fivefold increase in the production of electric power was to support new copper mines and the uranium mine, and to provide energy for further industrial development in the Territory of South-West Africa.

PRODUCTION AND TRADE

The South-West Africa Administration, Republic of South Africa, continued its policy of not disclosing mineral production statistics for the Territory of South-West Africa. Most of the statistical data on production were derived from the annual reports of companies operating in the Territory, primarily Tsumeb Corp., Consolidated Diamond Mines of South-West Africa Ltd. (CDM), and SWACO. Although the Territory of South-West Africa traditionally produces a variety of other minerals, particularly nonmetals, output data are not available and these commodities are not listed in table 1.

In general, mining activity in the Territory of South-West Africa in 1975 was adversely affected by falling mineral prices, a deteriorating economic situation, and increased operating costs. Production of cadmium, silver, blister copper, and refined lead by Tsumeb Corp. all declined during fiscal 1975. Output of lead-zinc concentrates at SWACO's Berg Aukas mine was at a reduced level, and overall tin-tungsten production in the Territory fell slightly. Only diamond recovery by CDM evidenced a gain over the 1974 level, due to the installation of modernized equipment and the improvement in diamond grade.

The Territory of South-West Africa's foreign trade in mineral commodities was included in the trade statistics of the Republic of South Africa and was not differentiated. Apart from some tin and zinc, consumed by the Republic of South Africa, and diamonds, marketed by DeBeers Consolidated Mines Ltd., most of the mineral production was shipped to world markets from Walvis Bay, the area's major deepwater port.

Table 1.—Territory of South-West Africa: Production of mineral commodities
(Metric tons unless otherwise specified)

Commodity [1]	1973	1974	1975 [p]

[e] Estimate [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the commodities listed, the Territory of South-West Africa, prior to 1967, produced bismuth concentrates, cesium ore, columbite-tantalite concentrates, gold, manganese ore, molybdenum concentrates, graphite, lime, mica, precious stones, kyanite, sillimanite, and a variety of crude construction materials (clays, stone, sand, and gravel). No official statistics have been published since yearend 1966, and available information is inadequate to ascertain whether production has continued or not, and if so, at what levels.

[2] Data are compiled from operating company reports as follows: Tsumeb Corp. Ltd. (arsenic, mine and refined cadmium, mine and blister copper, mine and refined lead, mine and smelter silver, mine zinc, and pyrite concentrate); South-West Africa Co. Ltd. (mine lead, mine tin, mine tungsten, mine vanadium, and mine zinc); South African Iron and Steel Industrial Corp. Ltd. (ISCOR) for Imcor Zinc (Pty.) Ltd.'s Rosh Pinah mine (mine lead and mine zinc), and for ISCOR's own Uis mine (mine tin); General Mining and Finance Corp. Ltd. for Klein Aub Koper Maatskappy Ltd.'s mine near Rehoboth (mine copper and mine silver); and Falconbridge Nickel Mines Ltd. for Oamites Mining Co. (Pty.) Ltd., Oamites mine (mine copper). Data from Tsumeb Corp. Ltd. and Falconbridge Nickel Mines Ltd. are for calendar years, data from other companies for fiscal years ending June 30 of the year stated.

[3] White arsenic equivalent of all arsenic products reported as being produced.

[4] Figures comprise reported production of Tsumeb Corp. Ltd., and Oamites Mining Co. (Pty.) Ltd., plus an estimate for Klein Aub Koper Maatskappy Ltd. for 1974 and 1975, and an estimate for Johannesburg Consolidated Investment Co. Ltd. (Otjihase copper mine) for 1975.

[5] Figures comprise reported production of Tsumeb Corp. Ltd. plus estimates for Oamites Mining Co. (Pty.) Ltd., and Klein Aub Koper Maatskappy Ltd.

[6] Compiled from operating company reports of Tsumeb Corp. Ltd., South-West Africa Co. Ltd., and ISCOR for Imcor Zinc (Pty.) Ltd.'s Rosh Pinah mine. Data from Tsumeb Corp. Ltd. are for calendar years, data from other companies are for fiscal years ending June 30 of the year stated.

[7] Total figures reported by DeBeers Consolidated Mine Ltd. in company annual reports for calendar years; detail on gem and industrial diamonds are estimates, assuming output to be 95% gem quality.

[8] Output has not been officially reported since 1966, but presumably has continued since a number of countries record imports from "South Africa", which in total quantity considerably exceed reported output of the Republic of South Africa proper, and presumably include shipments from the Territory of South-West Africa. Quantities given represent imports of the United States and the European Community reported as originating in South Africa, but the reader is cautioned that a portion of the material may have been mined in Southern Rhodesia.

COMMODITY REVIEW

METALS

Total metal sales of Tsumeb Corp. Ltd., the principal producer of copper, lead, zinc, silver, cadmium, and arsenic, decreased 24% (in terms of rand) from those of the previous fiscal year. In 1975, Tsumeb Corp.'s revenue from metal sales was approximately $75 million, including $20.5 million from custom material processed in the company's lead and copper smelters. The principal shareholders in Tsumeb Corp. were American Metal Climax Inc. (29.6%), Newmont Mining Corp. (29.6%), and O'okiep Copper Co. of South Africa (9.5%).

Tsumeb's three older mines have traditionally accounted for about 80% of the base metal production in the Territory of South-West Africa. In 1975, the Tsumeb mine, the largest of the three, milled approximately 424,000 tons of ore grading 4.27% copper, 9.73% lead, and 2.47% zinc. The Kombat mine, situated just south of the Tsumeb mine in the northern part of the country, milled about 284,000 tons of ore assaying 1.32% copper and 2.32% lead.

[1] Concentrates from Tsumeb Corp. Ltd.
[2] Production.

The Matchless mine, which came onstream in 1970 about 42 kilometers south of Windhoek, milled 102,000 tons of ore grading 2.72% copper. The Matchless mine also produced pyrite concentrate, which was shipped to Tsumeb for use in lead smelting. The Asis Ost mine, a joint venture between Tsumeb Corp. (75%) and SWACO (25%), began production on a limited scale during the year, the ore being treated at the adjacent Kombat mill. In 1975, production at Asis Ost was approximately 22,000 tons of ore grading 1.26% copper and 0.33% lead.

The smelter production at Tsumeb in 1975 was 36,410 tons of blister copper and 44,300 tons of refined lead, compared with 46,612 tons of blister copper and 64,342 tons of refined lead in 1974. These constituted decreases of 22% and 31%, respectively, and reflected the lower concentrate output from Tsumeb mines and the decreased percentage of custom material. During 1975, a total of 3,384 tons of zinc concentrate was exported from Walvis Bay for overseas smelting and refining.

The expansion of the Tsumeb copper smelter for an additional 127,000 tons per year of custom material, expected to come primarily from the new Otjihase mine, was scheduled for completion in early 1976 at a cost of $14 million. Construction of a new copper refinery at Capetown, Republic of South Africa, a joint venture between Tsumeb Corp. and O'okiep Copper Co. of the Republic of South Africa, was deferred in February 1975.

Tsumeb Corp. continued exploration and development at its four mines during the year. After taking into consideration ore mined during 1975 and after a recalculation of ore reserves based on information from diamond drilling, positive ore reserves decreased from the 1974 levels. Positive ore reserves at the Tsumeb mine decreased 441,062 tons; at the Kombat mine, 225,205 tons; and at the Matchless mine, 149,745 tons. A complete reappraisal of reserves at Asis Ost was also necessitated, resulting in a decrease in positive ore reserves of 202,683 tons and an overall net loss of about 177,000 tons. Ore reserves at yearend 1975 are given in table 3.

In other exploration activity, Tsumeb Corp. placed emphasis on the reevaluation of known prospects within the Otavi Mountains concession area. Diamond drilling at Asis West, situated west of the Kombat mining district, continued with good results, and 897,319 tons of ore grading 7.18% copper and 4.82% lead was delineated by yearend 1975. Of this tonnage, about 199,000 tons was located within the Asis mining district operated by Tsumeb Corp; the remainder was within the prospecting area shared by Tsumeb Corp. and SWACO. Two of Tsumeb Corp.'s other joint prospecting arrangements were terminated in 1975. Due to discouraging results, exploration by Tsumeb Corp. in conjunction with Anglo-Transvaal Consolidated Investment Co. (Anglovaal) ended at yearend 1975, and the joint venture relinquished its rights in the Gamma Mining and Prospecting Co. Exploration results in a joint venture in Botswana managed by United States Steel Corp. were similarly discouraging despite findings of considerable copper mineralization, and Tsumeb Corp. withdrew from further participation in January 1975.

Table 3.—Territory of South-West Africa: Ore reserves of Tsumeb Corp. Ltd.[1]

	Quantity (thousand metric tons)	Grade (percent)

Asis Ost	58	1.21	2.97	--	--

[1] As of Dec. 31, 1975.

Arsenic.—A total of 18,724 tons of reverberatory and converter baghouse dusts, dross skims, and storage material was roasted at the arsenic plant operated by Tsumeb Corp. in 1975. A total of 6,687 tons of arsenic trioxide material of various grades was produced, compared with 6,722 tons in 1974. Approximately 6,770 tons of pyrite concentrate from the Matchless mine was used as roaster flux. Total sales by Tsumeb of arsenic trioxide were 5,138 tons, a 5% decrease from the 1974 level.

Cadmium.—During 1975, Tsumeb Corp. processed 3,071 tons of sinter baghouse dust, producing 100 tons of refined cadmium, 14 tons less than in 1974. The assay of refined cadmium produced continued at 99.98% pure. Total sales of cadmium in 1975 were 124 tons, valued at about $916,000.

Copper.—The other major copper producer in addition to Tsumeb Corp. was Oamites Mining Co. (Pty.) Ltd., a joint venture between Falconbridge Nickel Mines Ltd. (FNM) of Canada and the IDC. The Oamites mine, 55 kilometers south of Windhoek, milled 568,000 tons of ore in 1975, a decrease of 8% from the 1974 level of 617,000 tons. However, owing to improved grade and mining control and higher metallurgical recovery, copper production increased from 6,356 tons in 1974 to 6,852 tons in 1975. Development kept pace with the requirements of mining operations, and installation of a crusher and conveyer belt at the 34th level was near completion at yearend. Production statistics for the Oamites mine for 1974 and 1975 are as follows:

	1974	1975
Ore milled ....tons..	617,000	568,000
Mill head grade ....percent..	1.13	1.31
Mill recovery ......percent..	91.32	93.40
Concentrates produced dry tons..	19,000	19,000
Recoverable copper ...tons..	6,356	6,852

Although Falconbridge Exploration Ltd., a subsidiary of FNM, announced plans in 1974 to develop its copper-zinc sulfide deposit at Elbe, this action was deferred in 1975 owing to low copper prices. Mine development costs had been set at $13 million, with startup at a milling capacity of 35,000 tons per month scheduled for 1976. Drilling at FNM's Swartmodder prospect, located near Elbe at Okahandja, was also suspended.

The mine owned by Klein Aub Koper Maatskappy Ltd., a subsidiary of General Mining and Finance Corp. Ltd. (South Africa), was the third largest operating copper mine in the Territory. Total ore reserves were reported at 8 million tons of copper-silver ore grading 2.5% copper. During 1975, the profitability of the Klein Aub mine was seriously affected by the decrease in copper prices coupled with increased production and smelting costs. Although concentrate output grew from 7,840 tons in 1974 to 8,946 tons in 1975, the company's net income fell from about $1.8 million in 1974 to $735,000 in 1975. However, the program for the improvement of existing facilities was completed during the year, and the company planned an expansion of production at lower costs. A review of the mining potential of the Okasewa copper deposits near Witvlei was also conducted during the year.

The Otjihase copper mine, owned by JCI (52.5%) and Minerts Development (Pty.) Ltd. (47.5%), came onstream in October 1975. Initial production was less than capacity due to technical problems, but normal milling was to begin in the second quarter of 1976. Planned output was an annual rate of 115,000 tons of 22% copper concentrates, which would be smelted at the Tsumeb plant prior to export for refining in Europe. The capital cost of development of the Otjihase mine, situated 27 kilometers northeast of Windhoek, was approximately $48 million. Surface drilling during the year indicated reserves of 23 million tons averaging 2.4% copper.

Lead, Zinc, and Vanadium.—Concentrate production at the Berg Aukas lead-zinc-vanadium mine, operated by SWACO near Grootfontein, declined 18% in fiscal year 1975. Total concentrate output was 41,773 tons in 1975, compared with 50,708 tons in 1974. In an effort to streamline plant operation, milling capacity was reduced to 124,000 tons per year, which resulted in an 8% decrease in ore milled during 1975. In addition, the grade of ore mined and hoisted was adversely affected by a decrease in the quantity of vanadium-rich cavity fill material and by operating difficulties at lower mine levels. These factors resulted in 31% and 23% production decreases in lead-vanadium and zinc-silicate concentrates, respectively. Total combined lead and zinc sulfide production was slightly higher than in 1974. Production statistics for the Berg Aukas mine in fiscal 1975 are as follows:

	Quantity (metric tons)		Grade (percent)		
	1974	1975	V_2O_5	Lead	Zinc
Ore hoisted	172,300	209,600	0.70	4.2	13.8
Ore milled	135,000	123,700	1.10	6.3	21.7
Concentrates:					
Lead vanadates	8,348	5,771	17.37	42.6	18.2
Zinc sulfide	11,436	9,541	--	4.6	54.1
Lead sulfide	1,214	3,551	--	53.0	17.8
Zinc silicates	29,710	22,910	--	4.5	46.7

The company continued development of ore bodies on the 17 and 19 levels. The No. 2 shaft was deepened about 100 meters, and additional shaft-deepening and dewatering operations were scheduled for 1976. Drilling indicated no major new ore discoveries, but sufficient ore was located to replace most of that mined from previously indicated blocks. The ore reserves at the end of fiscal year 1975 at the Berg Aukas mine are as follows:

Locality	Quantity (thousand metric tons)	Grade (percent)		
		V_2O_5	Lead	Zinc
No. 1 shaft	102	0.6	3	21
No. 2 shaft	1,396	.4	5	16
Possible No. 2 shaft	307	.5	3	20
Total mine 1975	1,805	.5	5	17
Total fiscal 1974	1,830	.5	4	17

The other major lead-zinc producer in the Territory was the Rosh Pinah mine of Imcor Zinc (Pty.) Ltd., a subsidiary of the South African Iron and Steel Industrial Corp. (ISCOR). Although zinc concentrate production in 1975 increased 3% to 27,100 tons, lead concentrate production fell 31% to 5,288 tons. The total output of zinc concentrate, which had a zinc metal content of 52.3%, was dispatched to the Republic of South Africa for processing in an electrolytic refinery near Springs; lead concentrate production was marketed in the Territory. Production at the original underground mine at Rosh Pinah, located in the Namib Desert about 27 kilometers north of the Orange River, was discontinued at yearend 1975 owing to the depletion of reserves. Production from the new open pit mine began in 1974 and was scheduled to reach 160,000 tons of mine-head output per month by 1976. Continued exploration for zinc ore was planned by ISCOR in the existing mining area of Rosh Pinah and farther north.

Silver.—Domestic production of silver, a byproduct of copper and lead mining, declined 4%, from 1,904,000 troy ounces in 1974 to 1,823,000 troy ounces in 1975. The largest silver producer continued to be Tsumeb Corp., which recovered 1,205,843 troy ounces in company-produced concentrates compared with 1,325,407 troy ounces in 1974. The balance of silver production was from the Klein Aub copper mine near Rehoboth. Virtually all silver produced in the country was processed by Tsumeb Corp., which exported the silver contained in blister copper and in the form of dore bullion for toll refining elsewhere. In 1975, total sales of silver by Tsumeb Corp., which also custom-smelted imported concentrate, amounted to 1,760,665 troy ounces valued at $7.8 million.

Tin-Tungsten.—The Uis tin mine, operated by ISCOR's wholly-owned subsidiary of Industrial Minerals and Mining Corp. (Pty.) Ltd., continued to be the Territory's major tin producer. In 1975, production was 1,177 tons of tin concentrate with a tin metal content of 64.6%, a slight decrease from the 1974 level. Output from the Uis mine, located northeast of Swakopmund near Brandberg, was shipped to the smelting plant at Vanderbijlpark steelworks in the Republic of South Africa, where it accounted for nearly half of ISCOR's tin requirements.

SWACO brought its Brandberg West tin-tungsten mine back into production in mid-1975 on a trial basis. Operations had been suspended in 1973, but in late 1974 the company commenced overburden stripping of the mine and plant rehabilitation. Exploratory drilling indicated an additional block of some 600,000 tons of ore of better than average grade in the northeast of the quarry, which was to be mined while overburden stripping of the west face continued. Total ore reserves of the mine were estimated at 6.6 million tons grading 0.24% combined tin and tungsten and requiring the removal of approximately 3.7 million tons of overburden.

The only tungsten producer in the Territory in 1975 was Nordex Joint Venture Ltd., owned by Ebco Mining Co. (60%) and Nord Resources Corp. (40%), the latter serving as operator and marketing all output. Annual capacity at the Krantzberg tungsten mine, situated about 160 kilometers south of Windhoek near Omaruru, was approximately 500 tons. However, the plant was reported as operating at about half of capacity, with total output exported to European markets.

Uranium.—Development continued at the uranium deposit owned by Rössing Uranium Ltd., projected to become the world's single largest uranium producer when the mine comes onstream in 1977. Rössing's production target was revealed for the first time in 1975, with output set at 5,000 tons of U_3O_8 per year. The large but low-grade uranium ore body, situated 70 kilometers northeast of Swakopmund, was to be mined by open pit methods. The mining rate of ore and overburden was to start at a capacity of 60,000 tons per day, building up to 120,000 tons per day by 1980. Estimated reserves of uranium oxide exceeded 100,000 tons.

Sales contracts for the major part of production were reportedly finalized during the year. The United Kingdom Atomic Energy Commission contracted to receive 7,500 tons of uranium between 1977 and 1982 at a price just under $13 per pound. The balance of production was to be marketed in Europe and Japan. Shareholders in the Rössing venture included Rio Tinto Zinc Corp. Ltd. (45.2%), IDC, General Mining and Finance Corp. Ltd. of South Africa, Total Compagnie Minière et Nucleaire, and Rio Algom Mines Ltd.

NONMETALS

Diamond.—CDM, a wholly-owned subsidiary of DeBeers Consolidated Mines Ltd., continued to be the largest contributor to the Territory's mineral industry. In 1975, the tonnage treated at Oranjemund increased to 12.2 million tons, and the grade rose sharply from 0.1326 to 0.1427 carat per ton. Final diamond recovery was thus 1.75 million carats, nearly 200,000 carats higher than the 1974 level. Overburden stripping was also increased over 1 million tons to total 46 million tons in 1975.

CDM has mining rights until the year 2010 in an 8,000-square-kilometer area stretching along the coast from the Orange River to Luderitz. Development of the Western Block, an area a few kilometers north of the mouth of the Orange River, has involved extensive overburden removal to expose underlying diamondiferous gravels. The installation of a bucket wheel excavator and conveyer bridge system in 1975 brought capacity to 1,000 cubic meters of overburden per hour. This allowed construction of a seawall, permitting mining 120 meters seaward of the high-water mark and to a depth of 90 meters below mean sea level. On the processing side, the No. 2 conglomerate treatment plant was commissioned in early 1975 and operated throughout the year at the capacity rate of 160,000 tons per month. The 172,000-ton-per-month No. 3 plant was to start up in 1976. Also in operation during 1975 was a new X-ray recovery facility designed to eventually treat concentrates from all four of the major treatment plants.

Salt.—SWACO began production at the Otjivalunda salt pans on a preliminary basis in 1975. Preparation for the mining of natural trona (sodium carbonate) and thenardite (sodium sulfate) commenced in 1974, but excessive rains brought mining and transport operations to a standstill. In 1975, approximately 2,000 tons of trona and 250 tons of thenardite were produced, with the major part of output being transported to Tsumeb for sale. Further development of the salt operations depended on the procurement of markets and the provision of an all-weather road from Otjivalunda to Ondangwa.

MINERAL FUELS

Petroleum.—The overall outlook for oil and gas exploration activity in the Territory was negative in 1975, as a number of oil companies relinquished their rights due to lack of commercial discoveries. The Southern Oil Exploration Corp. (South-West Africa) (Pty.) Ltd., (SWAKOR), the state agency responsible for the coordination of oil exploration, reported that there was no drilling activity in 1975.

Getty Oil Co. announced the termination of exploration activities of a three-company group which held a 34,110-square-kilometer offshore lease. Getty Oil (Walvis Bay) Ltd. (25%), a wholly-owned subsidiary of Getty Oil Co., and subsidiaries of Phillips Petroleum Co. (37.5%) and Continental Oil Co.

(37.5%), had been conducting geological and geophysical surveys in the deepwater area since 1972. Chevron Oil Co. of South-West Africa, a wholly-owned subsidiary of Standard Oil Co. of California, relinquished its offshore tract which it operated in conjunction with Regent Petroleum of the Republic of South Africa. This included an area approximately 180 kilometers west of the mouth of the Orange River where gas was discovered in 1974. Kuda 9A–1 was abandoned at 14,606 feet after gas tested from Lower Cretaceous sands proved noncommercial. The Milford Argosy Corp. (United States) relinquished rights in deepwater areas covering about 27,000 square kilometers.

In other leasing action, Canadian Southern Petroleum Ltd. increased its interest to 10% in a permit covering 13,000 square kilometers near the mouth of the Orange River, which it holds with Damson Oil Co., Aminex Ltd., and Asmera Ltd., all of Canada, and Aracca Petroleum Co. of the United States. The other remaining concessions were two awarded by SWAKOR in 1972 under terms which required an expenditure of $1.2 million in the first year and drilling after the third year. These were a 58,000-square-kilometer area in two blocks held by Aquitaine South-West Africa, and a 50,000-square-kilometer area directly offshore between Walvis Bay and the Cunene River held by B.J.H. duPreez.

The Mineral Industry of Spain

By Roman V. Sondermayer [1]

During 1975, Spain remained among the important producers of nonmetals, metals, and petroleum refinery products in Europe. The more prominent minerals, with production expressed in percentages of the world production, were as follows: Mercury, 20%; pyrite, 10%; fluorspar, 9%; strontium, 9%; gypsum, 7%; magnesite, 3%; lead, 3%; potash, 3%; feldspar, 3%; and zinc, 2%.

Production of other minerals and fuels was of only domestic significance. Domestic output of nonferrous ores, iron ores, and fuels did not meet demand. The mineral industry of Spain produced about 10% of the gross national product (GNP) of $101,050 million [2] at current prices. However, the share of the extractive sector of the mineral industry was less than 1% of the GNP. The general economic situation was characterized by unemployment averaging 5.4% and by an increase in the cost of living of 14.1% during the year.

As a consequence of a long-standing national policy aimed at developing mineral resources, a high rate of investment continued. In 1975, new investment in all mineral industry amounted to $458.7 million. Investment in mining of metallic ore ($200 million) almost doubled compared with that of 1974. Investments in the coal industry amounted to $163 million, $73 million over the 1974 figure, and investments in exploration for crude oil reached $88 million, twice the 1974 figure. The sharp increases in investments in prospecting for energy resources reflected the country's deficit position in energy supply.

The Mining Promotion Law (draft) and the National Fuels Plan were approved by the Government during 1975. The Mining Promotion Law is expected to constitute the basis for future development of the national mining sector. The draft contains several innovations. The most important were as follows: Compulsory preparation of a 4-year National Plan for the supply of minerals; a decision to set up a geological and mining data bank; regulation of activities abroad; financing of mining; and revision of the tax system for mineral industry. The approved 1976 National Fuels Plan (in addition to production targets) includes norms and provisions governing the supply of different fuels: Liquid and gaseous hydrocarbons, coal, and nuclear fuels.

There were a number of significant developments during 1975. Construction began on a 175,000-ton-per-year aluminum plant and on an 800,000-ton-per-year alumina plant near San Ciprian (Province of Lugo). Development continued at the Aznalcollar (Sevilla) mining complex. Discovery of a new iron ore deposit was announced near Granada. Development started on lead and zinc deposits near Rubales, and construction began on a 50,000-ton-per-year lead smelter. The discovery of two offshore oilfields was announced near the Tarraco oilfield. A new 7-million-ton-per-year petroleum refinery at Tarragona became fully operational in March 1975.

PRODUCTION

Spain continued to develop new domestic mineral resources. In addition, renovation of installations and introduction of modern equipment throughout the industry continued. The aim was to increase production of ores and concentrates and, consequently, cut imports of raw materials needed for the growing mineral processing and refining in-

[1] Physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from Spanish pesetas (Ptas) to U.S. dollars at the rate of Ptas68=US$1.00.

dustry. Mine operations were characterized by low levels of mechanization and atomized operations. This situation resulted mostly from difficult geological and mining conditions. However, many metallurgical and petroleum processing plants were of modern design. As table 1 shows, trends in output were mixed. In spite of the recession, outputs of some commodities during 1975 were higher than during 1974.

e Estimate. p Preliminary. r Revised. NA Not available.
[1] Production from Spanish Sahara.
[2] Data presented includes recorded production of salable acid grade fluorspar from both fluorspar mines and lead-zinc-fluorspar mines, plus some salable acid grade fluorspar obtained by beneficiating a portion of total reported salable metallurgical grade output.
[3] Series revised to include byproduct output from potash works, not previously included.
[4] Includes sand obtained from the washing of kaolin in cubic meters as follows: 1973—143,936; 1974—250,246.
[5] Revised to none.

TRADE

During 1974, Spain's balance of foreign trade was negative. Imports of ores, concentrates, and fuels, especially crude oil, contributed largely to the deficit. African and Middle Eastern countries were the largest suppliers of minerals. Value of mineral imports was reported at $5,447 million. Crude oil accounted for 55% of mineral imports. Minerals exports, consisting mostly of various forms of metals, and petroleum refinery products totaled $1,850 million. European countries were the principal purchasers of Spanish mineral industries' products. Tables 2 and 3 show Spanish foreign trade in minerals.

Asbestos	1	16	Morocco 11; Austria 5.
Barite and witherite	82,105	67,534	West Germany 54,916; Italy 8,580; United Kingdom 3,675.
Boron materials, oxides, acid	43	159	France 29; Belgium-Luxembourg 26; West Germany 24.
Cement ---- thousand tons	1,279	1,746	Algeria 979; United States 286; Israel 140.
Chalk	10,145	3,056	Portugal 1,544; Libya 850; France 642.
Clays and clay products (including all refractory brick):			
Crude clays n.e.s.:			
Bentonite	16,452	18,857	Portugal 4,334; France 3,843; West Germany 3,310.
Kaolin (china clay)	62,699	61,973	West Germany 23,006; Italy 19,276; France 9,074.
Other	15,860	15,411	Portugal 5,411; Andorra 4,881; Netherlands 1,357.
Products:			
Refractory, including nonclay brick	6,765	7,939	Cuba 3,534; Brazil 1,840; Algeria 1,042.
Nonrefractory	148,223	178,647	France 34,385; West Germany 33,095.
Diamond, natural and synthetic:			
Gem, not set or strung value, thousands	$38	--	
Industrial including powder do	$36	$78	Mainly to Mexico.
Diatomite and other infusorial earth	1,357	5,656	France 4,256; Portugal 1,000; Lebanon 400.
Feldspar, leucite, nepheline, nepheline syenite	1,346	1	All to Andorra.
Fertilizer materials:			
Crude and manufactured:			
Nitrogenous	170	86,374	Brazil 43,208; Venezuela 11,000; Taiwan 10,602.
Phosphatic	142,234	(1)	All to Australia.
Potassic	310,383	230,813	Norway 80,732; Portugal 51,755; Algeria 33,830.
Other	24,400	135,350	Philippines 37,450; Morocco 31,965; United States 28,093.
Ammonia	2,296	12	Mauritania 11.
Fluorspar	239,705	--	
Graphite, natural	--	1	All to Argentina.
Gypsum and plasters	146,044	211,540	Sweden 100,700; Denmark 57,648.
Iodine	2	2	Portugal 1; Venezuela 1.
Lime	5,239	4,399	Guinea 3,444; Andorra 339.
Magnesite	67,367	72,305	United Kingdom 43,177; West Germany 20,019; France 2,725.
Mica, all forms	183	250	Italy 73; West Germany 68; United Kingdom 28.
Pigments, mineral, including processed iron oxides	11,009	15,503	United Kingdom 1,922; United States 1,597.

See footnote at end of table.

Table 2.—Spain: Exports of mineral commodities—Continued
(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal destinations, 1974
NONMETALS—Continued			
Precious and semiprecious stones, except diamond:			
Natural ________ value, thousands __	$29	$69	Mainly to France.
Manufactured ____________ do ____	$229	$211	Mainly to Switzerland.
Pyrite (gross weight) thousand tons __	308	203	Belgium-Luxembourg 156; Denmark 19.
Salt and brine ______________ do ____	3	2	All to United Kingdom.
Sodium and potassium compounds n.e.s _	8,437	36,606	Brazil 9,987; Argentina 7,471; Egypt 4,805.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked:			
Calcareous ________________	16,701	15,967	Italy 12,125.
Slate ____________________	1,505	1,186	West Germany 943; Andorra 116.
Other ____________________	28,650	44,519	Italy 30,704; France 8,406.
Worked:			
Slate ____________________	64,244	86,234	France 75,348.
Paving and flagstone ______	(1)	40	United Kingdom 16; France 14; Zambia 9.
Other ____________________	18,444	15,909	West Germany 12,137; France 1,715.
Dolomite ______________________	36,870	44,526	United Kingdom 39,848.
Gravel and crushed rock __________	53,234	35,232	Andorra 29,589; Portugal 4,160.
Quartz and quartzite _____________	115,198	167,471	Norway 115,368; Sweden 42,062.
Sand excluding metal bearing ______	49,352	59,959	Andorra 57,249.
Sulfur:			
Elemental, all forms ______________	988	772	France 617; Morocco 145.
Sulfur dioxide __________________	10	24	All to Portugal.
Sulfuric acid ___________________	3,439	70,357	Turkey 34,023; Romania 14,207; Brazil 10,348.
Talc, steatite, soapstone, pyrophyllite ___	140	183	Italy 142; Colombia 18.
Other nonmetals, n.e.s.:			
Crude:			
Meerschaum, amber, jet ________	r 47,410	60,900	France 19,921; United Kingdom 15,566; West Germany 14,589.
Other ______________________	152,739	305,590	France 228,002; Belgium-Luxembourg 37,908.
Slag, dross and similar waste, not metal bearing ______________	3,994	39,793	Portugal 38,570.
Oxides and hydroxides of magnesium, strontium, barium ___	502	852	United States 368; West Germany 332.
Building materials of asphalt, asbestos and fiber cement, and unfired nonmetals, n.e.s _________	29,222	34,475	France 19,759; Cuba 8,583.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural __________	--	(1)	All to Mauritania.
Carbon black and gas carbons __________	6,062	--	
Coal and briquets:			
Anthracite and bituminous coal ____	7,630	70,874	Belgium-Luxembourg 12,154; Liberia 11,665; West Germany 11,045.
Briquets of anthracite and bituminous coal ________________	--	980	All to West Germany.
Lignite and lignite briquets ________	626	122	All to Andorra.
Coke and semicoke ___________________	2,195	15,236	Portugal 12,015; France 2,564.
Hydrogen, helium, rare gases __________	6	9	Portugal 7; Algeria 2.
Peat including peat briquets and litter __	350	112	All to Portugal.
Petroleum:			
Crude and partly refined thousand 42-gallon barrels __	103	1,441	France 787; Italy 391; West Germany 264.
Refinery products:			
Gasoline, including natural do ____	7,436	8,009	West Germany 2,034; United Kingdom 1,057; France 1,028.
Kerosine and jet fuel do ____	407	1,678	Syria 608; United States 326; Zaire 217.
Distillate fuel oil _____ do ____	17,259	19,774	West Germany 7,620; Netherlands 1,907.
Residual ____________ do ____	12,293	4,490	United States 852; Brazil 468.
Lubricants __________ do ____	104	108	Cuba 27; United Kingdom 24; Belgium-Luxembourg 16.
Other:			
Liquefied petroleum gas do ____	237	215	Algeria 127; France 55; Morocco 32.

See footnotes at end of table.

(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal destinations, 1974
MINERAL FUELS AND RELATED MATERIALS—Continued			
Petroleum—Continued			
Refinery products—Continued			
Other—Continued			
Mineral jelly and wax thousand 42-gallon barrels	7	23	Netherlands 10.
Bitumen and other residues do	427	925	Libya 423; Algeria 210; Portugal 110.
Bituminous mixtures, n.e.s do	127	294	Libya 159; Sudan 35; Congo 35.
Pitch and pitch coke do	42	64	France 59.
Unspecified do	83	11	All to Cuba.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	15,991	7,332	Belgium-Luxembourg 3,064; Argentina 1,967; France 854.

[r] Revised.
[1] Less than ½ unit.

Table 3.—Spain: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal sources, 1974
METALS			
Aluminum:			
Bauxite and concentrate	108,839	132,374	Guyana 54,694; Greece 42,053.
Oxide and hydroxide	326,770	399,779	Guinea 158,886; France 84,089; Jamaica 78,933.
Metal including alloys:			
Scrap	3,453	4,439	West Germany 1,803; Portugal 1,293.
Unwrought	25,541	27,443	Norway 12,579; Ghana 4,408.
Semimanufactures	9,123	12,752	West Germany 2,215; Canada 1,836; France 1,286.
Antimony:			
Ore and concentrate	306	1,709	Norway 800; Morocco 750.
Metal including alloys, all forms	367	319	Belgium-Luxembourg 90; Czechoslovakia 83; United States 46.
Arsenic:			
Trioxide, pentoxide, acids	547	421	All from France.
Metal including alloys, all forms	16	7	All from Sweden.
Beryllium metal including alloys, all forms kilograms	5	1	All from West Germany.
Bismuth metal including alloys, all forms	103	81	West Germany 35; Mexico 34; United Kingdom 10.
Cadmium metal including alloys, all forms	1	--	
Chromium:			
Chromite	89,690	84,597	Turkey 52,953; Finland 9,027.
Oxide and hydroxide	357	467	West Germany 140; United States 113; U.S.S.R. 82.
Metal including alloys, all forms	18	55	United Kingdom 38; Japan 16.
Cobalt oxide and hydroxide	148	194	Belgium-Luxembourg 88; United States 37; Canada 36.
Copper:			
Ore and concentrate	115,457	128,689	Australia 62,590; Ireland 27,785.
Matte	14,408	8,417	Israel 4,038; Chile 3,609.
Copper sulfate	908	2,187	France 866; U.S.S.R. 319; Hungary 300.
Metal including alloys:			
Scrap	18,419	11,926	France 4,092; United States 2,185; West Germany 1,401.
Unwrought	50,578	79,687	Chile 10,033; Belgium-Luxembourg 9,003; Zambia 8,677.
Semimanufactures	16,871	14,510	West Germany 2,548; Sweden 2,096; United Kingdom 2,067.
Gold:			
Waste and sweepings kilograms	509	149	All from West Germany.
Metal, worked or partly worked thousand troy ounces	804	198	West Germany 195.

Table 3.—Spain: Imports of mineral commodities—Continued
(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal sources, 1974
METALS—Continued			
Iron and steel:			
Ore and concentrate, excepted roasted pyrite ---- thousand tons --	5,116	5,280	Brazil 1,303; Venezuela 896; Sweden 730.
Roasted pyrite ----	--	(1)	All from France.
Metal:			
Scrap ---- thousand tons --	2,012	1,925	United States 950; United Kingdom 186; France 135.
Pig iron including cast iron do ----	43	24	Norway 1; Switzerland 1.
Sponge iron, powder, shot do ----	8	10	Sweden 7; France 2; West Germany 1.
Ferroalloys ---- do ----	26	23	Republic of South Africa 7; French Oceania 3.
Steel, primary forms -- do ----	173	416	West Germany 93; Greece 66; Belgium-Luxembourg 49.
Semimanufactures:			
Bars, rods, angles, shapes sections ---- do ----	173	157	West Germany 43; France 17; Italy 16.
Universals, plates, sheets ---- do ----	403	248	West Germany 61; France 54; United Kingdom 41.
Hoop and strip --- do ----	74	44	France 17; West Germany 13; Belgium-Luxembourg 5.
Rails, and accessories do ----	3	15	Belgium-Luxembourg 7; West Germany 2; France 2; United States 2.
Wire ---- do ----	15	6	West Germany 2.
Tubes, pipes, fittings ---- do ----	47	43	West Germany 12; France 12; United Kingdom 8.
Castings and forgings, rough ---- do ----	11,178	6	West Germany 2; France 1; Belgium-Luxembourg 1.
Lead:			
Ore and concentrate ----	33,012	41,638	Morocco 26,743; Poland 10,191; Canada 4,704.
Oxides ----	452	704	United Kingdom 360; France 259; Bulgaria 78.
Metal including alloys:			
Scrap ----	984	1,214	United States 938.
Unwrought ----	6,344	22,663	West Germany 8,193; United States 4,272.
Semimanufactures ----	140	100	West Germany 70; France 11.
Magnesium metal including alloys, all forms ----	953	840	United States 567.
Manganese:			
Ore and concentrate ----	331,098	384,103	Republic of South Africa 155,677; Gabon 64,981; Brazil 61,060; Ghana 39,841.
Oxides ----	1,954	1,413	Japan 792; United States 347; People's Republic of China 160.
Metal ----	694	709	France 338; Japan 190; Republic of South Africa 152.
Mercury ---- 76-pound flasks --	15	13	Austria 6; West Germany 4.
Molybdenum metal including alloys, all forms ----	30	34	Austria 9; United States 9; Netherlands 5.
Nickel:			
Ore and concentrate ----	10	16,011	Australia 13,816.
Matte, speiss, similar materials ----	468	150	Canada 108; United Kingdom 24; Finland 17.
Metal, including alloys:			
Scrap ----	116	126	France 51; Italy 28; West Germany 19.
Unwrought ----	4,853	6,010	Canada 2,218; Cuba 1,726; United Kingdom 898.
Semimanufactures ----	2,037	2,571	France 1,049.
Platinum-group metals and silver:			
Ore and concentrate ----	--	6,438	Australia 5,006; United States 606.
Waste and sweepings ----	644	411	United States 355; France 47.
Metal including alloys:			
Platinum group - troy ounces --	(1)	(1)	Mainly from France.

See footnote at end of table.

Metal including alloys—Continued			
Silver _ thousand troy ounces	11,413	8,359	Belgium-Luxembourg 1,951; West Germany 1,768; United Kingdom 1,557.
Rare-earth metals:			
Oxides	160	192	France 124; United Kingdom 63.
Metals including alloys	21	18	France 10; United States 6; Brazil 2.
Selenium, elemental	20	35	Japan 16; Yugoslavia 6; United States 5.
Silicon, elemental	440	311	Yugoslavia 303.
Tellurium, elemental	10	4	U.S.S.R. 3.
Tin:			
Ore and concentrate	5,351	6,156	Zaire 2,724; Bolivia 1,430.
Oxides	117	153	United Kingdom 87; West Germany 64.
Metal including alloys	111	109	United Kingdom 44; West Germany 25.
Titanium:			
Ore and concentrate	43,766	76,596	Norway 76,482.
Oxides	7,205	6,364	West Germany 3,225; France 978.
Tungsten:			
Ore and concentrate	348	11,206	Greece 11,186.
Metal including alloys, all forms	22	17	Austria 5; United Kingdom 4; France 2; Netherlands 2; Singapore 1; United States 1.
Uranium and thorium:			
Ore and concentrate (uranium) kilograms	434	4	France 4.
Oxides	2	14	France 12; United Kingdom 2.
Metal including alloys, all forms kilograms	561	461	Italy 313; United Kingdom 108.
Vanadium:			
Pentoxide do	19	389	Netherlands 100; United States 84.
Metal including alloys, all forms	10	5	United States 5.
Zinc:			
Ore and concentrate	55,830	126,404	Peru 61,026; Mexico 33,431; Canada 16,304.
Oxide and peroxide	906	2,119	Greece 998; France 461; West Germany 445.
Metal including alloys all forms	3,560	2,197	France 514; West Germany 410; Bulgaria 248.
Zirconium metal including alloys, all forms	8	1	All from France.
Other:			
Ore and concentrate:			
Of molybdenum, tantalum, titanium, vanadium, zirconium	15,987	32,449	Australia 18,822.
Of base metals n.e.s	272	588	Australia 320; Sri Lanka 101; United States 71.
Ash and residue containing nonferrous metals	131,682	95,266	Peru 70,278.
Oxides, hydroxides, peroxides of metals	1,518	1,723	West Germany 379; France 372.
Metals including alloys, all forms:			
Alkalai and alkaline earth	72	206	West Germany 198.
Pyrophoric alloys	10	15	West Germany 6; France 5; Austria 2.
Base metals including alloys, all forms, n.e.s	403	428	United States 149; Belgium-Luxembourg 82; France 55.
NONMETALS			
Abrasives, natural, n.e.s.:			
Pumice, emery, natural corundum, etc	809	2,423	Greece 1,524; United States 444; France 232.
Dust and powder of precious and semiprecious stones (except diamond) value thousands	$49	$47	United States $21; Ireland $10.
Grinding and polishing wheels and stones	1,339	1,732	West Germany 293; United Kingdom 266; Austria 255.
Asbestos	109,045	125,971	Republic of South Africa 50,424; Canada 46,846; West Germany 16,592.

Table 3.—Spain: Imports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal sources, 1974
NONMETALS—Continued			
Barite and witherite	1,012	656	France 587.
Boron materials:			
Crude natural borates	58,139	81,110	Turkey 42,712; United States 38,383.
Oxides and acid	2,739	164	France 115; Italy 41.
Bromine	20	15	Israel 9; France 4; United States 1.
Cement	375,388	162,486	United Kingdom 126,179.
Chalk	6,907	7,360	France 5,895.
Clays and clay products including all refractory brick:			
Crude clays, n.e.s.:			
Bentonite	36,227	47,722	Morocco 17,715; Italy 16,006; United States 8,690.
Kaolin (china clay)	106,690	139,804	United Kingdom 101,300; France 16,870; United States 14,915.
Other	57,160	66,817	United Kingdom 31,867; France 15,416; Morocco 8,855.
Products:			
Refractory, including nonclay brick	31,577	27,799	Austria 10,114; West Germany 9,186.
Nonrefractory	32,433	38,050	Italy 20,114; West Germany 6,455; Portugal 5,693.
Cryolite and chiolite	1,520	3,925	Denmark 3,925.
Diamond:			
Natural and synthetic:			
Gem, not set or strung value, thousands	$6,203	$9,636	Mainly from Belgium-Luxembourg.
Industrial including powder do	$5,454	$4,326	Do.
Total do	$11,657	$13,962	
Manufactured industrial do	$4	$62	Mainly from U.S.S.R.
Diatomite and other infusorial earth	3,017	2,863	United States 1,450; France 1,244.
Feldspar, leucite, nepheline, nepheline syenite	14,390	16,448	France 12,970.
Fertilizer materials:			
Crude:			
Nitrogenous	40,617	39,902	All from Chile.
Phosphatic thousand tons	1,941	1,189	Morocco 1,107.
Potassic	1	1	All from France.
Manufactured:			
Nitrogenous	230,903	130,023	Netherlands 37,161; France 29,996.
Phosphatic	42,800	32,117	France 16,009; Belgium-Luxembourg 15,527.
Potassic	15,843	49,613	Congo 22,380; West Germany 17,706.
Other including mixed	27,013	20,221	Poland 9,122; Belgium-Luxembourg 4,311; West Germany 2,220.
Fluorspar	24	17	West Germany 7; Netherlands 6; Belgium-Luxembourg 3.
Graphite, natural	1,430	1,650	West Germany 641; Malagasy Republic 531.
Gypsum and plasters	1,381	2,891	United States 882; Morocco 862; France 661.
Iodine	53	61	Japan 40; Chile 20.
Lime	206	497	Morocco 212; France 162; Austria 100.
Magnesite	37,065	44,380	Greece 13,139; United Kingdom 5,193; Austria 4,130.
Mica, all forms	1,543	1,257	India 384; Norway 211; France 188.
Pigments, minerals, including processed iron oxides	4,164	4,476	West Germany 2,604; France 951.
Precious and semiprecious stones, except diamond:			
Natural:			
Gem value, thousands	$6,042	$8,171	Belgium-Luxembourg $2,921; Thailand $1,202; India $1,088.
Industrial do	$819	--	
Manufactured do	$561	$629	Switzerland $457; India $93.
Pyrite (gross weight)	169	140	Italy 101; United States 28.
Salt and brine	52,484	98,103	France 90,999.
Sodium and potassium compounds, n.e.s	32,717	92,950	France 54,628; Italy 17,554; West Germany 11,360.

COMMODITY REVIEW

METALS

Complex sulfide ores, containing iron, copper, lead, and zinc were the principal sources of nonferrous metals in Spain. The tabulation below shows the number of mines producing a combination of various metals in Spain in 1975:

	Number of mines
Copper-iron-lead	5
Iron-pyrites-copper	13
Lead-zinc	19
Lead-zinc-pyrites	6
Lead-zinc-fluorspar	7
Gold-silver	1
Pyrite-copper	10

During 1975, production of metals was adversely affected by increased cost for power, labor, and transportation. In addition, some metal prices had a ceiling imposed by the Government. All of these factors made the economics of certain operations less profitable than in the past.

Aluminum.—During 1975, construction began on the alumina and aluminum complex at San Ciprian (Province of Lugo). The project called for the annual production of 800,000 tons of alumina and 175,000 tons of aluminum. The investor was Aluminio Español S.A. (formerly Aluminio de Villagarcía S.A.). Empresa Nacional de Aluminio (ENDASA) shared 55%; Aluminio de Galicia S.A. (ALUGASA), 20%; and others, 25%. In addition, ALUGASA announced plans to expand its 15,000-ton-per-year primary aluminum plant at Sabiñánego. However, capacity after expansion was not made public at yearend. Plans also were announced to expand ALUGASA's La Coruna smelter to 106,000 tons per year by 1978. The San Ciprian facility and other projects were part of the large program for expansion of aluminum-producing facilities in Spain from 216,000 tons in 1975 to 411,000 tons per year by 1980.

During 1975, four primary smelters were in operation with a combined capacity of 216,000 tons. The Government-owned company ENDASA was the major producer of aluminum in Spain and operated the country's largest smelter, a 110,000-ton-per-year plant near Aviles. The aluminum industry suffered from the stagnation of the economy; production of aluminum metal increased, but consumption declined. Consequently, stocks increased and reached record levels. Spain, with its modest production of bauxite, remained dependent on imports to meet the demand of domestic refiners.

Copper.—During 1975, development of the Aznalcóllar (Sevilla) mining complex, operated by Andaluza de Piritas S.A. (APIRSA), continued. According to reports, the open pit will be among the largest on the European continent. In addition to the mine, the mining complex includes a beneficiation plant, water supply system, and other auxiliary facilities. Planned production includes about 51,000 tons of copper concentrates, 42,000 tons of lead concentrates, and 98,000 tons of zinc. The proven reserves of the deposit amounted to

78.5 million tons of which approximately 44.5 million tons was complex sulfide ores (average metal content: 0.58% copper, 1.78% lead, 3.33% zinc, and 67 grams per ton of silver) and 34 million tons was pyritic cuprious ores (average metal content: 0.58% copper, 0.40% lead, and 10 grams per ton of silver). The yearly planned targets for the opencast operation were set at 2 million tons of pyrites and 1.5 million tons of copper ore with an overburden-to-ore ratio of 3.2 to 1. The beneficiation will include crushing and milling facilities, differential flotation systems for sulfides, and dewatering installations. The complex is scheduled to start production at yearend 1977 or early 1978. Before any large-scale mining starts, the Argio River will have to be diverted because it flows over a mineralized zone.

During 1975, there were 28 mines producing copper, but Spain remained dependent on imports of concentrates and matte to meet its demand. Five mines produced copper as main products; 10 pyrite mines produced copper as byproduct, and 13 mines produced copper as byproduct of iron output. Most of the copper mines were located in the Province of Huelva. There were four copper smelters and six copper refineries in operation during 1975. The largest smelter and refinery, with an annual capacity of 85,000 tons of copper each, were located in the Province of Huelva and were operated by Rio Tinto Patino, S.A.

Iron Ore.—Exploration was the focal point of the iron-ore-producing industry in Spain during 1975. A new deposit of iron ore was found in the Marquesdado zone of the Province of Granada in southern Spain near the Alquife mines. Reports indicated reserves of about 30 million tons of high-grade ore. The ore will probably be processed by a fourth Spanish integrated iron and steel plant at Sagunto, Valencia. An annual production of 1 million tons was planned for the new mine. In addition, exploration for iron ore was conducted by the Geological and Mining Institute. No new major discoveries were announced, but results confirmed the size of reserves proven in existing mines.

During 1975, about 30 iron ore mines were in operation in Spain. In addition, six nonferrous metal mines produced iron ore as a byproduct of their operations.

Four Provinces—Leon, Teruel, Vizcaya, and Guadalajara—had iron ore production over 500,000 tons per year.

Domestic production of iron ore was sufficient to meet only about 50% of demand.

Iron and Steel.—There were no new major events in the iron and steel industry of Spain during 1975. Empresa Nacional Siderúrgica S.A. (ENSIDESA) remained the principal steel producer in the country. ENSIDESA, with plants located at Aviles, La Felguera, Gijon-Moreda, and Gijon-Verina, accounted for approximately 70% of the country's pig iron production and about 46% of steel output.

There were no installations for direct reduction of iron ore in operation during 1975; however, two plants were planned by ENSIDESA, fundamental characteristics of which are as follows:

One installation will be located in northern Spain near the port of Bilbao. There will be two modules using natural gas as reductant. Capacity will be about 1 million to 1.2 million tons per year. The other facility will be located in the Bay of Algeciras, southern Spain. One module was planned, and the reductant will be manufactured gas. Annual capacity will be 500,000 tons. The exact process to be used in each project had not been determined at yearend 1975. Since projects are included in the new Concerted Action Program for Iron and Steel Metallurgy, they should be completed prior to December 31, 1980.

Lead and Zinc.—Highlights of lead and zinc mining in Spain in 1975 were development of the lead and zinc deposit near Rubiales in the Province of Lugo, expansion of San Juan de Nieva Zinc Smelter, and construction of a new lead smelter. At Rubiales, the underground mine was scheduled for production in 1977. Output of 2,600 tons of ore was planned. This should yield approximately 115,000 tons of zinc concentrates and 15,000 tons of lead concentrates per year. Proven reserves were reported at 7.5 million tons with an average zinc content of 9.9% and lead content of 1.7%. Future zinc concentrates from the new mines were scheduled for shipment to the zinc smelter, San Juan de Nieva, owned by Asturiana de Zinc S.A.; the lead concentrates will be smelted at a lead smelter near Cartagena owned by Société Minera Metalúrgica Peñarroya–España S.A. (Peñarroya). The development was financed by Cominco Ltd., 45%; Union Corporation of South Africa, 27%; and Asturiana de Zinc and Banco Urquijo S.A., 25%. In addition, lead and zinc concentrates will be produced at the new mining operation Aznalcóllar, Sevilla, described in the copper section of this chapter. Expansion continued on the zinc smelter at San Juan de Nieva, owned by Peñarroya. When completed in 1977, the smelter capacity will have been increased from 130,000 tons to 205,000 tons of zinc per year.

A 50,000-ton-per-year lead smelter was under construction near Linares at yearend. Startup was scheduled for 1976. Five companies were participating in the venture (Peñarroya, El Adaro, Los Guindos, Compania La Cruz S.A., and C. AR. M.).

During 1975 there were 19 lead mines, 19 lead and zinc mines, 6 zinc-lead-pyrite mines, and 7 zinc-fluorspar mines operating in Spain. Approximately 50% of the zinc produced in Spain was mined in the northern district near Santander. In addition, about 30% was mined in the district of Cartagena in southern Spain. Two zinc smelters and four lead smelters were operating at yearend 1975. Peñarroya was the largest producer of lead and operated the largest lead smelter in the country, located near Santa Lucia, Cartagena. Asturiana de Zinc was the major zinc producer in the country and operated the largest Spanish zinc plant, the San Juan de Nieva. At yearend, Spain's installed capacity for zinc production totaled 110,000 tons per year; the installed capacity for lead production was 106,000 tons per year. Spain was dependent on imports of lead and zinc raw materials to supplement domestic supply.

Other Metals.—No major events were registered in production of tin (17 mines), tungsten (8 mines), mercury (1 mine), and gold and silver (1 mine) during 1975. Except for mercury, which was produced in one of the largest mercury mines in the world (Almaden), output of all others was only of domestic significance.

NONMETALS

Spain produced a large variety of nonmetals. However, their importance was mostly limited to the domestic economy. The nonmetals contributed about 29% of the value of mining production of the country.

Cement.—Spain was among the world's principal exporters of cement during 1975. The production capacity of the Spanish cement industry, which was 26.8 million tons at yearend 1974, grew by 3.3 million tons by 1975. Plans call for an additional 3.9 million tons of installed capacity by yearend 1976, which will bring the total to 34 million tons. In principle, output of new facilities was not aimed at foreign markets. However, as a result of slowdowns in the construction industry, cement consumption in Spain was down by 6.2% from the 1974 level. Consequently, the surplus was exported, and Spain was among the largest exporters of cement in the world at yearend. The following companies were among the largest producers of cement in Spain during 1975: Cía. General de Asfaltos y Portland Asland S.A., Barcelona (4.2 million tons kiln capacity, seven plants); Portland Vardirrivas S.A., Madrid (2 million tons, two plants); Cementos Uniland S.A., Barcelona (1.9 million tons, two plants); Compania Valenciana de Cementos Portland S.A. (1.9 million tons, three plants).

Fertilizer Materials.—Four potash mines were in production during 1975. Three were located in the province of Barcelona, but one mine in Navarra accounted for about 43% of the output. Minas de Potasa de Suria has plans to increase annual output by 50,000 tons of K_2O and reach production of 200,000 tons per year in 1980. The program included development of a new mine in the Suria area.

Potasas de Navarra has announced plans to start producing from new zones within the potash deposit near Pamplona. Reportedly, capacities for carnalite beneficiation in the area will be increased to 150,000 tons of K_2O by 1978–79. Reserves near the shaft of Beriain were near exhaustion. The shaft will be dismantled in the future.

Other Nonmetals.—Recent trends in output of other nonmetallics are shown in table 1. For selected commodities the number of producing facilities are listed in the following tabulation:

Commodity	Number of facilities	Provinces with largest output and number of facilities
Andalusite	7	Coruna (all)
Barite	29	Cordoba (all)
Bentonite	9	Almeria (8)
Kaolin	123	Valencia (33) Teruel (24)
Feldspar	14	Avila (2) Madrid (2)
Fluorspar	20	Oviedo (10)
Gypsum	348	Jaen (33) Murcia (24) Zagora (22) Alicante (21)
Magnesite	3	Madrid (1) Lugo (1) Navarra (1)
Sand and gravel	526	Barcelona (97) Madrid (45) Burgos (32) Oviedo (27) Baleares (23)

There were no major events in the other nonmetallic facilities. Quarry output—building stone, crushed stone, and sand and gravel—accounted for 43% of the value of nonmetallics.

MINERAL FUELS

Petroleum, mostly imported, remained the principal source of energy in Spain. During 1975, about 81% of Spain's apparent energy consumption was met through imports. Crude oil and petroleum refinery products accounted for about 94% of energy imports. Coal was the principal source of energy produced in the country and provided 15% of apparent energy consumption. However, additional imports of high-rank coals were necessary to meet demand. Table 4 shows supply and apparent consumption of energy-producing materials for 1974 and 1975. Approximately 60,000 persons were employed in the fuel industry of Spain.

Table 4.—Spain: Supply and apparent consumption of energy-producing materials for 1974 and 1975

(Million tons of standard coal equivalent)[1]

	Total energy	Coal and coke	Petroleum and refinery products	Natural gas	Fuelwood	Hydroelectric power
1974:						
Production	19.1	11.8	2.9	(2)	(2)	4.4
Imports	68.8	3.6	65.2	(2)	(2)	(2)
Exports	7.1	.1	7.0	(2)	(2)	(2)
Apparent consumption	80.8	15.3	61.1	(2)	(2)	4.4
1975:						
Production	19.9	12.7	2.6	(2)	(2)	4.6
Imports	66.8	4.3	62.5	(2)	(2)	(2)
Exports	4.0	(2)	4.0	(2)	(2)	(2)
Apparent consumption	82.7	17.0	61.1	(2)	(2)	4.6

[1] 1 ton standard coal equivalent = 7,000,000 kilocalories.
[2] Less than 0.01 million tons of standard coal equivalent.

Coal.—Major activities in the coal industry were related to expansion of output and renovation of coal mines. As a direct result of the petroleum crisis, domestic coal became more attractive as a source of primary energy in Spain. Renewed emphasis was placed on the coal industry. The Government was stimulating developments of the coal industry through tax relief and credit policies. During 1975, a number of firms within the coal-mining sector entered into "Concerted Action Agreements" with the Spanish Government for the purpose of increasing coal production. These agreements call for an output of 33.7 million tons of coal by 1980. During 1975, Spain produced anthracite (69 mines), bituminous coal (39 mines), and lignite (34 mines). The Provinces of Oviedo and Leon were the largest producers of anthracite and bituminous coal. Most of the lignite was produced in the Provinces of Teruel, Barcelona, and Coruna.

Petroleum.—During 1975, domestic output of crude oil and natural gas was modest, and Spain remained almost totally dependent on imported crude oil and natural gas. Exploration, offshore and onshore, and processing remained focal points of the petroleum industry. Toward yearend, Spain's Hydrocarbons Bureau had received bids for seven offshore tracts recently offered for tender, one in the Bay of Biscay and the others in the Mediterranean Sea. The tracts were Mar Cantabrico H tract in the Bay of Biscay, Montanazo B tract in the Ebro

River Basin, Montanazo C & D tracts in the Ebro River Basin, Benicarlo tract off Caltelon Province, and Grumete A, B, & C blocks off Alicante Province.

Two significant discoveries were made offshore from Spain during 1975. The Chevron Group (made up of California Oil Co. of Spain, Pacific Petroleum Ltd., and Cía de Investigacion y Explotaciones Petroliferas S.A.) made a discovery on an offshore wildcat well on a lease located immediately east of Tarraco Field and 35 miles east of Amposta oilfield. The "1-Casablanca," in 132 meters of water, flowed about 147 tons of oil per day (1,074 barrels per day) from two zones at about 2,740 meters and 2,890 meters in depth. The oil is reportedly 31.2° API with low sulfur content.

Further tests indicated the possibility of production from deeper zones. The second discovery, E-1 Tarragona, which appears to be a major one, was made by Union Texas España, a subsidiary of Allied Chemical Corp. and Getty Oil Co. The wildcat well (E-1 Tarragona) was located 45 miles northwest of Shell's offshore Amposta Field, 16 miles from the Spanish shore. Further drilling was planned to determine the extent of the new deposit. To assure crude oil supply, Spain's State-owned Hispanoil was participating in various exploration ventures abroad. In Algeria, offshore Sicily, Peru, and Gabon, Hispanoil was involved in drilling for crude oil.

The new Tarragona refinery, which started production in December 1974, became fully operational in March 1975 with an annual capacity of 7 million tons. This new addition brings Spanish installed refinery capacity to 68.8 million tons (1,376,000 barrels per day).

A large new oil port was under construction near Bilbao, and partial operation started during 1975. The new port will have facilities for berthing ships up to 500,000 deadweight tons. It is expected that this port will change the general flow of crude from the Middle East to Europe by diverting some oil from northern Europe (Antwerp and Rotterdam) to southern Europe. Completion of construction is expected during 1977.

Two oilfields, one near Burgos, the other near Tarragona, (yearly output, 2 million tons) and 11 refineries (installed capacity, 68.8 million tons) were in operation in Spain during 1975. The following tabulation shows refineries with a capicity over 7.5 million tons per year:

Refinery location	Capacity (million tons)	Company
Escombreras	10.5	Empresa Nacional del Petroleo.
Santa Cruz de Tenerife	8.0	Compañía Española de Petroleos S.A. (Enpetrol).
Tarragona	7.8	Empresa Nacional del Petroleo (Enpetrol).
Puertollano	7.5	Empresa Nacional del Petroleo.

Retail prices for petroleum refinery products during 1974 and 1975 are shown below in U.S. cents per gallon except for bunker "C" fuel oil, which is given in U.S. cents per 42-gallon barrel.[3]

[3] U.S. Bureau of Mines. International Petroleum Annual, 1974. 1976, p. 36.

	July 1975	July 1974	Change percent
Motor gasoline:			
Regular	113.6	116.0	−2.1
Premium	129.8	139.0	−6.7
Household kerosine	64.9	60.0	+8.2
Motor lubricating oil	454.1	463.0	−2.0
Distillate fuel oil	34.5	NA	NA
Bunker "C" fuel oil	1,108.6	843.0	+31.5

NA Not available.

The modest domestic output of natural gas was far below the country's demand. Imports of liquefied natural gas were essential for adequate supply. Spain's Empresa Nacional del Gas (ENGAS) has signed a 20-year contract with SONATRACH of Algeria for a supply of up to 435 million cubic feet per day. Deliveries were expected to start in 1976. In addition, construction was underway to expand the Barcelona regasification plant to 240 million cubic feet per day.

Nuclear Energy and Uranium.—Spanish Government policy continued to aim at replacing oil with uranium by 1985–90 as the main fuel used in electric powerplants. Of a total of 37 existing and planned reactors, 3 were in use, 7 under construction, 6 contracted for, 1 licensed, and 20 more for which license applications had been submitted. If all these reactors are constructed, they will represent a total capacity of 34,275 megawatts of electric power by 1990. Table 5 shows details related to nuclear powerplants in Spain at yearend.[4]

Uranium ore reserves and resources are modest. Apparently, imports will be needed to supplement domestic output of U_3O_8 to meet requirements of nuclear powerplants in the future. However, the Government has started a nationwide exploration program for uranium to be carried out by the Spanish Institute of Geology and Mining and the Nuclear Energy Board. The goal was set to assure reserves that will support a production covering 50% of the country's demand at the end of 1985.

Uranium ores were mined and processed in two locations, Anudhar and Saelices el Chico-Ciudad Rodrigo, near Barcelona. Empresa Nacional del Uranio S.A. (ENUSA) managed uranium related activities in Spain. Expansion of the uranium mill at Ciudad Rodrigo continued. When completed in 1976, mill capacity was expected to be 120 tons per year of U_3O_8.

The Mineral Industry of Sweden

By Joseph B. Huvos [1]

In 1975, Sweden was one of the world's major iron ore producers and exporters, and produced substantial amounts of hydroelectric energy and nonferrous metals. Virtually all of the country's fossil fuel needs and a significant proportion of its industrial minerals requirements were imported. The major mineral products of the country and approximate percentages of world totals were as follows: White arsenic, 31%; selenium, 5%; iron ore, 4%; lead, 2.1%; zinc, 2.1%; pyrite, 2%; feldspar, 1.1%; copper, 0.6%; and tungsten, 0.4%.

In 1975, Sweden's gross national product (GNP) was about $69 billion.[2] Mining and quarrying, including stone and clays, contributed only an estimated 1.9%, while employing about 1.7% of the industrial labor force of about 670,000.[3] Iron and steel and metals (exclusive of mining) contributed about 2.2%, and the chemical industry, 3.1%.

The international recession finally reached Sweden in 1975, and was still deepening at yearend. Ore production ran at a low level as a result of marketing difficulties.

There were a number of significant developments in Sweden's mineral industries in 1975. Plants commissioned in 1975 included additions to AB Nynas Petroleum's oil refinery and three nuclear powerplants, two of them operated by Statens Vattenfallsverk and one by Sydsvenska Kraft AB. Construction continued at several projects. Zinc-mining capacity was expanded at the mines of Société des Mines et Fonderies de Zinc de la Vieille Montagne (Vieille Montagne), a Belgian firm. North of the Arctic Circle, Luossavaara-Kirunavaara AB (LKAB) continued to modernize and expand its Kirunavaara iron mining facilities and its transshipment facilities at Narvik, Norway and at Luleå (Gulf of Bothnia). Boliden AB continued construction of a sulfur dioxide gas system at its Rönnskär smelter. Statsforetag AB continued construction of its petroleum refinery at Lysekill on the west coast.

Government measures in 1975 included the scaling-down of Stälwerk 80 (the proposed expansion of the State-owned steel company), enacting a new energy policy limiting Sweden's energy consumption, approving expansion plans of Boliden's Rönnskär smelter, and concluding a Swedish-Norwegian agreement to coordinate the two petroleum industries. These subjects are discussed more fully later in the chapter.

PRODUCTION

In 1975, production of most minerals and related products decreased owing to falling domestic and foreign demand. Production of selected mineral commodities in Sweden in 1973–75 is detailed in table 1.

Table 1.—Sweden: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity [1]	1973	1974	1975p
METALS			
Aluminum, unalloyed:			
Primary	81,399	82,008	76,789
Secondary	260	472	606
Arsenic:			
White, refined	15,200	13,300	10,500
Metallic	1,100	1,050	900
Bismuth, mine output, metal content e	15	15	15
Copper:			
Mine output, metal content	44,819	40,637	40,634
Metal, unrefined	2,420	--	807
Metal, refined:			
Primary	47,863	47,478	49,468
Secondary	11,628	12,430	6,753
Total	59,491	59,908	56,221
Gold:			
Mine output, metal content troy ounces	80,923	68,352	63,176
Metal including alloys do	122,141	118,990	109,923
Iron and steel:			
Iron ore and concentrate, gross weight:			
Direct shipping ore thousand tons	22,107	23,643	18,847
Concentrates do	12,620	12,509	12,020
Total do	34,727	36,152	30,867
Pig iron and sponge iron [2] do	2,759	3,176	3,484
Electric furnace ferroalloys do	226	214	205
Crude steel do	5,664	5,989	5,611
Steel semimanufactures:			
Bars, rods and sections do	1,588	1,621	1,494
Plates and sheets do	2,048	2,125	1,927
Strip do	142	164	115
Rails and accessories do	45	50	57
Pipe and tube stock do	229	266	253
Other, including forgings and castings do	200	247	280
Total do	4,252	4,473	4,126
Lead:			
Mine output, metal content	75,777	73,656	70,383
Metal (refined):			
Primary	46,632	45,185	38,342
Secondary and remelted	18,998	e 18,000	NA
Magnesium metal, secondary	9	e 10	e 10
Nickel metal, unalloyed	4,318	e 4,300	e 4,300
Selenium, elemental (refined)	62	e 50	e 40
Silicon metal	19,381	NA	NA
Silver:			
Mine output, metal content thousand troy ounces	4,739	4,545	4,515
Metal including alloys do	6,303	6,006	7,034
Tungsten, mine output, metal content	338	215	143
Uranium oxide (U_3O_8) e	70	70	70
Zinc:			
Mine output, metal content	118,542	113,699	111,325
Clinker (70% to 75% zinc)	28,200	26,900	25,200
NONMETALS			
Cement, hydraulic thousand tons	r 4,214	3,309	3,121
Chalk	33,816	44,135	33,945
Clays, refractory thousand tons	186	225	225
Diatomite, calcined	444	566	423
Feldspar, salable, crude and ground	27,955	31,964	44,742
Fertilizer materials, manufactured:			
Nitrogenous thousand tons	503	e 500	NA
Phosphatic:			
Thomas slag, gross weight do	143	148	137
Other do	430	NA	NA
Mixed and other do	886	NA	NA

See footnotes at end of table.

Table 1.—Sweden: Production of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity [1]	1973	1974	1975[p]
NONMETALS—Continued			
Fluorspar	4,636	4,074	3,405
Lime (quicklime, hydrated lime, and deadburned dolomite) thousand tons	877	912	805
Pigments, natural mineral	1,578	1,083	1,440
Pyrite and pyrrhotite (including cupreous), gross weight thousand tons	450	425	414
Stone, sand and gravel:			
Dimension stone:			
Unworked:			
Limestone and marble do	45	38	36
Granite and gneiss do	83	72	64
Quartz do	44	47	41
Quartzite do	31	22	22
Micaceous schist do	20	19	18
Sandstone do	50	44	38
Other do	38	36	32
Worked, all types do	115	98	[3] 76
Crushed, broken and other:			
Clay slate do	81	81	68
Dolomite:			
Crude do	260	307	405
Burnt do	36	37	32
Granite and gneiss do	6,464	6,994	7,696
Limestone:			
For cement do	5,682	4,981	4,366
For lime do	1,221	1,221	1,050
For other industrial uses (including lime marl) do	1,571	1,771	2,053
Marble do	149	117	NA
Micaceous schist do	16	16	17
Quartz do	21	22	18
Quartzite do	1,861	1,902	1,932
Sandstone do	304	353	290
Other do	544	534	1,064
Sulfur:			
Content of pyrite do	232	218	211
Byproduct:			
From metallurgy do	139	[e] 140	[e] 140
From other sources do	8	[e] 10	[e] 10
Total do	379	[e] 368	[e] 361
Talc and steatite	28,029	28,404	23,846
Other nonmetals, crude [4]	36,359	13,394	NA
MINERAL FUELS AND RELATED MATERIALS			
Carbon black	28,527	[e] 28,000	[e] 23,600
Coal, all grades [e] thousand tons	10	30	70
Coke, metallurgical do	533	481	820
Oil shale:			
For fuel production use do	126	101	88
For other use do	8	11	10
Peat:			
For agricultural use do	68	73	77
For fuel use do	28	36	34
Petroleum refinery products:			
Gasoline thousand 42-gallon barrels	11,209	9,592	12,989
Jet fuel do	956	950	1,013
Kerosine do	333	101	--
Distillate fuel oil do	24,594	24,933	26,700
Residual fuel oil do	30,010	29,148	33,664
Lubricants do	534	644	294
Other:			
Naphtha do	NA	1,988	491
White spirit do	NA	1,340	101
Unspecified do	2,334	566	3,868
Refinery fuel and losses do	3,812	5,501	2,850
Total do	73,782	74,663	81,970

[e] Estimate. [p] Preliminary. NA Not available.

[1] In addition to the commodities listed, cobalt, nickel (as nickel sulfate), and metallic titanium are also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[2] Production of sponge iron is as follows in thousand tons: 1973–190; 1974–197; 1975–175.

[3] Figure represents material for sale, not produced.

[4] Includes strontium minerals, unspecified minerals, and fragments of ceramic materials. Previously listed incorrectly as strontium minerals only.

TRADE

In 1975, there was no major change in the country's general trade pattern. Sweden traded with about 170 countries, although the bulk of the trade was with the Scandinavian countries and West Europe.

The main mineral commodities exported included iron and steel, iron ore, and nonferrous metals.

In 1974, U.S. imports from Sweden were valued at about $860 million; U.S. exports to Sweden during the same period were about $900 million. Mineral commodities, including iron and steel, nonferrous metals, mineral fuels, ores, and crude nonmetallic minerals accounted for about 8.5% of U.S. imports from Sweden and 6% of U.S. exports to Sweden.

Trade statistics for mineral commodities in 1973 and 1974 are shown in tables 2 and 3.

Table 2.—Sweden:—Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal destinations, 1974
METALS			
Aluminum:			
Alumina	20	5	NA.
Metal including alloys:			
Scrap	2,164	1,796	West Germany 1,188; Netherlands 416.
Unwrought	20,322	11,765	Norway 9,220.
Semimanufactures	r 43,003	50,674	Finland 10,942; Denmark 10,248; Norway 7,667.
Arsenic, oxides and acids value, thousands	$1,594	$11,846	NA.
Chromium, ore and concentrate	66	80	Norway 79.
Cobalt oxide	(1)	(1)	NA.
Copper:			
Ore and concentrate	36,687	33,855	Bulgaria 14,580; East Germany 8,435; Finland 6,463.
Matte	--	220	All to West Germany.
Metal including alloys:			
Scrap	423	353	West Germany 266.
Unwrought	19,011	20,632	United Kingdom 8,105; West Germany 4,690; France 3,093.
Semimanufactures	r 54,107	53,015	Norway 13,748; Denmark 9,704; United States 6,807.
Iron and steel:			
Ore and concentrate, except roasted pyrite thousand tons	32,917	33,105	West Germany 10,013; Belgium-Luxembourg 9,086; United Kingdom 4,171.
Roasted pyrite do	379	418	United Kingdom 284; West Germany 134.
Metal:			
Scrap do	12	11	West Germany 6; Denmark 2.
Pig iron [2] do	r 138	313	Italy 60; Finland 45; People's Republic of China 40.
Ferroalloys do	84	85	United States 33; United Kingdom 22.
Steel, primary forms do	r 89	189	West Germany 79; Poland 34; Denmark 25.
Semimanufactures:			
Bars, rods, angles, shapes, sections do	591	591	United Kingdom 92; Finland 75; Denmark 60.
Universals, plates, sheets do	819	792	West Germany 125; Denmark 117; France 108.
Hoop and strip do	87	92	Denmark 12; United States 9; Norway 8; Finland 8.
Rails and accessories do	18	26	Norway 8; West Germany 6; East Germany 6.
Wire do	74	82	United States 15; West Germany 7; France 6.
Tubes, pipes, fittings do	231	242	West Germany 27; United Kingdom 24; France 21; Finland 20.
Castings and forgings, rough do	3	3	Finland 1; Denmark 1.

See footnotes at end of table.

COMMODITY REVIEW

METALS

Aluminum.—The decline in demand for aluminum products, which began at yearend 1974 and affected mainly semimanufactures, grew still more pronounced in 1975. The only Swedish producer of primary metal, Gränges Aluminium AB, owned 79% by Gränges AB and 21% by Alcan Aluminium Ltd., operated its 85,000-ton-per-year reduction plant at 91% of capacity. The plant is located at Sundsvall on the east coast. To maintain employment, which was about 3,380 persons in 1975, there was a heavy buildup in stocks.[4] Gränges also operated a secondary smelter at Mansbo, about 100 kilometers northwest of Stockholm.

Original plans to expand the Sundsvall reduction plant to 110,000 tons per year in 1977 and 135,000 tons per year in 1978 were shelved because the Government declined to help with financing of the project. In the meantime, the company's available resources were to be rechanneled, mainly into the enlargement of the finished goods manufacturing sector. Potential increases

[4] Gränges A.B. 1975, Annual Report. Pp. 15–16.

in future demand for metal were to be met by purchases on the international market.

Copper, Lead, and Zinc.—There were a number of important events in 1975 in the copper, lead, and zinc industry.

The Swedish Government approved the $150 million expansion of Boliden's Rönnskär smelter located near Skellefteå, on the Gulf of Bothnia. The plan called for copper production capacity to be increased from 60,000 to 85,000 tons per year. Lead capacity was to be raised from 45,000 to 70,000 tons per year; sulfur dioxide capacity, from 30,000 to 70,000 tons per year; and arsenic metal capacity, from 1,300 to 1,600 tons per year. About $40 million of the cost was to be spent on pollution control equipment. This plan represented the first of a two-stage expansion. Final plans for the second stage of the project, to be prepared by 1978, were to include an increase in copper production capacity to 100,000 tons per year.[5]

In 1975, Boliden continued to account for most of the copper and lead produced in Sweden. Stora Kopparbergs Bergslags AB (SKB) produced the rest at its Falun and Tomtebo mines in central Sweden.

Boliden operated about 22 mines, most of them for complex sulfide ores containing copper, lead, zinc, arsenic, gold, and silver. The company's six concentrating plants were located strategically near Boliden's principal mining centers. Sweden's largest copper mine, Aitik, was situated in the Kiruna-Malmberget area. Fourteen mines were in the Skellefteå District, which extends from Boliden in the east to the highlands in the west and along the Norwegian border. The largest of these was at Laisvall, said to be the greatest single source of lead ore in Europe. Seven mines, owned by Boliden, were operated in the Bergslagen mining district in central Sweden. Sweden's proven reserves of sulfide ores amounted to about 250 million tons.[6]

Continued expansion of Boliden's Aitik mine in 1975 was estimated to have raised the mine's capacity to 25,000 tons per year of copper contained in ore.[7]

Boliden planned to start mining the Stekenjokk deposits in 1976. The deposits are located about 65 kilometers north of Gäddede on the Norwegian border and were leased from the Swedish Government. Plans called for mining 400,000 tons per year of ore averaging 1.6% copper and 3.3% zinc.

In an attempt to locate new copper sources to supply the expansion of its smelter, Boliden launched an exploration program on Catanduanes Island in the Philippines in partnership with Swedish Match Co.[8]

Work continued on expanding production capacity at the mines of Vieille Montagne from 300,000 to 600,000 tons per year of zinc ore; the project started in about 1973 and was to be completed in 1976. Thus, Sweden's largest zinc producer and the only foreign-owned mining operation in Sweden, was on the way to becoming the largest zinc producer on the European continent.

Vieille Montagne had mining operations in the Zinkgruvan area, about 15 kilometers north of Motala on the eastern shore of Lake Vättern and centered around the Nygruvan and Knallagruvan mines. There the firm mined zinc-lead ores grading 8% zinc, 1.2% lead, and 35 grams per ton of silver. There was no zinc smelter in Sweden, and domestic zinc concentrates had to be exported for processing.

Iron and Steel.—Stählverk 80 is the proposed expansion of Sweden's State-owned steel company, Norbottens Järnverk A/S (NJA), located at Luleå on the northeast coast. According to the original plans, the project was to produce 4 million tons of blooms, slabs, and billets; new plans call for a trimmed down capacity of 2.5 million tons. The reduced project was estimated to cost about $2 billion compared with $3 billion for the earlier plan. NJA was to build, jointly with SKB, a 1.5-million-ton-per-year rolling mill at Gävle, 15 kilometers north of Stockholm.[9]

Although pig iron production in 1975 was sustained at a high level, the production of crude steel declined even though it had been rising almost continuously during the last decade. The decline in Sweden's steel production in 1975 was blamed mainly on the economic recession prevailing in market economy countries. De-

pressed steel prices, both in Sweden and abroad, plus sharply rising mill operating costs, notably for labor and fuel, cut deeply into the profits of most Swedish steel companies. NJA was hit particularly hard by the downturn in Sweden's construction and shipbuilding industries. The company lost $27.5 million in calendar year 1975.[10]

Special steels, including alloys and high carbon steels, comprised nearly one-third of Sweden's total steel production. About 20 mills could be classified mainly as special-steel producers, although they often turned out a quantity of ordinary steel. The largest special steel manufacturers in Sweden were Avesta Järnverks AB, Fagersta AB, Sandvik AB, and Uddeholm AB. Other leading producers were Hofors and Hellefors (which belong to the SKF Steel Div.), and Söderforswikmanshyttan (belonging to SKB).

Ordinary steel including nonalloyed steel of low carbon content was produced at about 10 Swedish mills. The mills were relatively small compared with steelworks in other countries, and only three of them had an annual crude steel production in the 1-million-ton range. The largest was the Domnarvet Works near Borlänge (owned by SKB), producing about 1.2 million tons of steel per year. This was processed into sheet, plate, bars, sections, wire rod, and strip. Next in size was Gränges Steel's Oxelösund Steelworks, turning out 1 million tons per year of steel that was used entirely to roll plate for shipbuilding and industrial use.

NJA, located at Luleå at the far northern end of the Gulf of Bothnia, produced about 0.8 million tons per year of crude steel, which was used to produce sheet metal. Many steelworks in central Sweden extracted high-quality, low-phosphorus iron ore from their own mines, often located close to the mills, and had complete facilities to produce finished products. Examples of such vertical integration included Gränges, Sandvik, and SKF. All Swedish steelmakers were coowners of the Swedish Ironmasters' Association (Jernkontoret). One of the main tasks of Jernkontoret was to administer the joint research program of the Swedish steel industry.[11] Jernkontoret represented the steel industry in all matters of common interest except labor relations, which were handled by a separate organization called the Swedish Iron and Steel Workers' Association (Järnbruksförbundet).

Iron Ore.—In 1975, LKAB continued planning and construction work at its mines. Development continued at the new 775-meter haulage level in Kirunavaara, including laying out the rail haulage and trackless services. A decision was made to modernize the Kirunavaara pelletizing plant. Plans were prepared to raise capacity of the Svappavaara concentrator and pelletizing plant from 2.2 million to 3 million tons per year. At Malmberget, a complete hematite concentrate drying plant was installed to prevent freezing of the concentrate when it is unloaded in winter.

LKAB also continued work on modernizing ore transshipment facilities at Narvik in Norway and planning expanded facilities to supply ore to Stålverk 80 at Luleå.

Sweden's iron ore production and export shipments dropped steeply during 1975 as a result of the economic recession in Western Europe and the low rate of capacity utilization of its iron and steel industry. The decline in iron ore production would have been even steeper had it not been for the fact that most mines built up ore inventories as a means of sustaining employment. By the end of 1975, these inventories had reached a high of 9.7 million tons.[12] Thus mine production ran at about 85% of capacity and deliveries at about 70%. However, even at the lower rate, Sweden remained one of the world's major producers of iron ore, with almost 4% of world output.

Sweden exported the major share of its iron ore production. In 1975, about one-half of exports was direct-smelting lump ore; the remainder was concentrate, powder, pellets, and sinter. Major recipients of iron ore exports in 1975 remained the West European countries, led by the Federal Republic of Germany, Belgium-Luxembourg, and the United Kingdom, and Poland in East Europe.

Sweden's iron mining industry was controlled mainly by four companies operating 13 major and 10 smaller mines. The largest among them was State-controlled LKAB, employing about 8,000 persons in iron-ore-related operations. LKAB ac-

[10] U.S. Embassy, Stockholm, Sweden. State Department Airgram A-147, June 29, 1976, p. 3.
[11] Swedish Institute. The Swedish Steel Industry. FS 17 JP, January 1976.
[12] Swedish Mineowners Association (Stockholm). As reported by U.S. Embassy, Stockholm. State Department Airgram A-39, Feb. 20, 1976, p. 1.

counted for about 83% of Swedish output with five mines, all located north of the Arctic Circle in Swedish Lapland. Three among these, the Kirunavaara, Malmberget, and Tuollavaara mines, were underground operations; the others were the open pit mines of Svappavaara and Kirunavaara. Of the remaining mines, all situated in central Sweden, Gränges AB operated those at Grängesberg and Strassa; Stora AB operated Dannemora, Risbergsfältet, Håksberg, Blotberget, and Vintjärn; Ställberg AB operated four smaller mines; and there were six independent mines of minor importance.

Proven iron ore reserves in the Kiruna-Malmberget District were estimated at about 3 billion tons. In central Sweden's mining district, known as Bergslagen, iron ore reserves were about 975 million tons in 1975.[13]

Tungsten.—Production of tungsten concentrate declined in 1975 at the country's only tungsten mine at Yxsjöberg in the Berglagen area of central Sweden. The mine was operated by AB Stätsgruvor, a subsidiary of LKAB.

Uranium.—At the beginning of 1975, LKAB assumed responsibility, together with AB Atomenergi and the Swedish State Power Board, for conducting further studies on the extraction of uranium from alum shales in the Billingen shale at Ranstad, southeast of Lake Vänern near Skara in central Sweden. If the necessary permits are secured in 1976, uranium production would start in 1981. Production from 6 million tons of shale was to amount to 1,275 tons per year of U_3O_8. Planning was to cost about $10 million and was subject to a government loan.

NONMETALS

Cement and Other Building Materials.—In 1975, Cementa AB remained Sweden's only cement producer, with its six plants around the country having a total installed capacity of about 4.2 million tons.[14] The three largest plants—Gullhoegan (north of Jönköping), Linhamn (near Malmö), and Slite (on Gotland Island)—had a capacity of 1 million tons per year each. Smaller plants were located at St. Vika, near Stockholm (500,000 tons per year) and Degerhamn on Äland Island (300,000 tons per year). Cementa's Köping plant was recently converted from cement to lime.

Ahsell and Ågren AB was Sweden's leading producer of industrial sand, mainly on the Danish island of Bornholm, and at Baskarp near Jönköping, as well as from dredging off the Swedish coast near Malmö and from a sandstone deposit at Motala.

AB Forshammars Bergverk exploited a quartzite deposit southwest of Lake Vänern in the Dalsland area of central Sweden. Mines were at Vingenäs (65,000 tons per year) and at Annebyn (10,000 tons per year). Svenska Silikaverken was the other main producer of silica, also in the Dalsland area.

Limestone and dolomite were produced by numerous firms, the main ones being Ytong AB, Strabruken AB, and Cementa. Enström Mineral AB mined underground a white crystalline dolomite marble at Glanshammar near Örebro in central Sweden, and also in the Ostergötland District.

Kritbruksbolaget i Malmö AB, Sweden's sole chalk producer, mined white chalk at the Kvarnby pit near Malmö.

Feldspar.—In 1975, AB Forshammars Bergverk, a subsidiary of LKAB, was Sweden's only feldspar producer. The Limberget quarry in Örebro County, about 40 kilometers north of Köping, was based on a white pegmatite consisting mainly of albite, microline, quartz, and muscovite. Proven reserves were estimated at 4 million tons with evidence of additional tonnages. Current capacity of the mine and processing plant was about 55,000 tons per year.[15]

Fertilizer Materials.—With the exception of nitrogenous fertilizers, almost all raw materials for the production of manufactured fertilizers had to be imported. LKAB continued studying the possibility of utilizing the apatite ore associated with the iron ore mined at the company's Kiruna and Malmberget mines in the north of the country.

Boliden produced dicalcium phosphate using its sulfuric acid at its Reymersholme works near Stockholm. At Hälsingborg and at Landskrona in the south, it produced phosphoric acid. All production was from imported phosphate rock.

Sweden produced domestically about one-half of its nitrogenous fertilizer requirements. Four ammonia plants had an annual total capacity of 109,000 tons of nitrogen.

[14] Industrial Minerals. December 1974, p. 26.
[15] Industrial Minerals. Sweden: Real Potential Yet to be Realized. January 1976, p. 17.

Electrokemiska AB operated a 3,000-ton-per-year plant at Bohun on the west coast; Svenska Salpeterverken AB operated a 49,000-ton-per-year plant at Köping and a 54,000-ton-per-year plant at Kvantorp, both in central Sweden; and Uddeholms AB operated a 3,000-ton-per-year plant at Skoghall near Lake Vänern.[16]

Fluorspar.—Production of fluorspar concentrate declined somewhat at the Stollberg mine of AB Statsgruvor in central Sweden, the only producer in the country.

Sulfuric Acid.—In 1975, lessened demand caused cutbacks in Swedish sulfuric acid production. Construction continued at Boliden's Rönnskär smelter on a gas recovery system including a 140,000-ton-per-year sulfur dioxide plant to be completed by 1977.[17]

About 90% of Sweden's pyrites was produced by Boliden from metal mining operations. The remainder was by SKB's Falun lead-zinc-copper mine in central Sweden. Pyrites accounted for 80% of Swedish sulfuric acid production. Boliden produced pyrite-based acid at its Remersholm acid and fertilizer works near Remersholm in the southwest. Some of Boliden's acid was produced at the Rönnskär smelter at Skelleftehamn in the north from smelter gases.

MINERAL FUELS

Energy.—Hydroelectric power and fuelwood were the main sources of primary energy produced in Sweden in 1975. They supplied about one-fifth of all energy needs. All other fuels were imported in the form of crude oil, petroleum products, coal and coke, and enriched uranium fuel.

In 1975, the Swedish Parliament enacted a comprehensive energy policy for Sweden, in accordance with which growth in Sweden's energy consumption would be limited to 2% per year until 1985. Within this total, however, electrical energy consumption was to be permitted to grow at the rate of about 6% per year. The 1975 decision was the result of Sweden's dependence on imported oil as well as the risks and opportunities entailed by nuclear power. Nuclear power and some power generated in oil-fired powerplants is to account for the main part of the increase in production of electrical energy until 1985, when nuclear power capacity is to reach 10,400 megawatts. There was to be further emphasis on economy measures supported by taxation of fuels. About $88 million was allotted for energy research and development for a 3-year period.

Table 4 shows supply and apparent consumption of energy for 1974 and 1975.

Coal and Coke.—In 1975, Sweden continued to import most of the coal, coke, and lignite used in the country. However, about one-third of the country's metallurgical coke requirements were prepared

domestically from imported coking coal and used in the iron and steel industry. Höganäs, AB, the country's only coal producer, produced marginal quantities from the Skäne area north of Lake Vänern.

Hydroelectric Power.—Present installations have a capacity of 12,900 megawatts of hydroelectric power and produced about 58 million megawatt-hours in 1975. Sweden's total possible hydroelectric power potential has been estimated at 95 million megawatt-hours per year. However, official policy limits any further growth in exploitation to 66 million megawatt-hours per year up to 1985 in order to safeguard the scenic and recreational resources of the country.[18]

Nuclear Power.—In 1975, Sweden had five installed nuclear powerplants, three of them completed during the current year. The plants had a cumulative design capacity of 3,180 megawatts and were all located in the densely populated southern part of the country. Plants completed before 1975 included Oskarshamn 1 and 2 on the east coast about 250 kilometers south of Stockholm. Plants completed in 1975 were Barsebäck 1, at Öresund near Malmö, and Ringhals 1 and 2, on the west coast about midway between Göteborg and Varberg. Plants under construction were Barsebäck 2, Ringhals 3 and 4, and Fosmark 1 and 2. The last two plants are near Gävle on the east coast about 150 kilometers north of Stockholm.[19] In 1975, the Swedish Parliament granted permission for the construction of three additional plants with at least one located at Fosmark (No. 3). This will increase the number of powerplants operating in 1985 to 13, with a total capacity of about 10,400 megawatts.[20] Technical data on Swedish nuclear powerplants in 1975 are shown in table 5.

Peat.—In 1975, a development project was underway at an unspecified location to operate a pilot plant for district heating based on the burning of peat. Sweden continued as a modest producer of peat. About two-thirds of it was used for agricultural purposes; the rest as fuel. In 1975, 6 million hectares of Sweden was covered by peat bogs, the fuel content of which was estimated at up to 6 billion tons of standard coal equivalent.[21]

Petroleum.—*Exploration and Production.*—Marginal crude oil production started in June on the Island of Gotland in the Baltic Sea. Oljeprospectering AB (OPAB), a State-controlled exploration company, found minor accumulations of oil and operated four pumped wells. The largest of these, the Hamra 8A located in the south, produced 37 barrels per day of oil. One-third of the 40 holes drilled by mid-1975 in Gotland showed signs of oil. Oil was also found at Hamra's seaward extension and was estimated to have a 2-million-ton-per-year production potential.[22] In 1975, through its subsidiary, Petroswede AB, OPAB continued prospecting for oil abroad including in the North Sea, Egypt, and Tunisia.

Svenska Petroleum AB agreed to assume one-half the share of Santa Fe International Corp.'s development costs in the Thistle Field located in the United King-

dom's sector of the North Sea. In return, the Swedish State-owned oil company is to receive 25% of Santa Fe's interest in the field and an option to buy another 25% of the crude produced.[23]

Refining.—In 1975, Sweden continued to depend on imported oil and petroleum products for about 68% of its energy requirements. About 60% of the oil imported was crude oil used as refinery feedstock in domestic refineries.

Expansion in the petroleum industry included completion of Swedish-owned Nynäs Petroleum's lubricating-oil hydrofinisher at its Nynäshamn refinery located near Stockholm.

Construction continued on State-owned Statsföretag's 7-million-ton-per-year refinery on the west coast at Lysekill. Nynäs Petroleum continued planning its 10-million-ton-per-year refinery.

In 1975, there were six refineries in Sweden with a total throughput capacity of about 20.7 million tons per year.[24] The largest refinery was the 8.3-million-ton-per-year Lysekill plant on the west coast, operated by AB Scanraff; BP Raffinaderi AB operated the 5.5-million-ton-per year Göteborg (west coast) refinery; Koppartrans Olje AB (Shell) operated a 5-million-ton-per-year refinery, also located in Göteborg. Finally, Nynäs Petroleum operated the 1.4-million-ton-per-year Nynäshamn refinery near Stockholm, and the 284,000-ton-per-year Göteborg and 190,000-ton-per-year Malmö refineries on the west coast.

The Swedish and Norwegian Governments concluded an agreement to coordinate the oil industries of the two countries. A joint committee is to explore alternative refinery locations and the distribution of Norwegian oil products in Sweden. Alternatives to be considered include jointly financed expansion of the Norwegian oil refinery at Mongstadt, and expanding the old or building a new refinery at the State-owned Brofjord refinery north of Göteborg in Sweden. The plan for a catalytic cracker at Stenungsund, also north of Göteborg, is to be compared with the possibility of building a plant based on wet gas from the Statfjord Field at Sotra near Bergen in Norway, to supply both countries with petrochemical feedstock.[25]

The Mineral Industry of Switzerland

By Roman V. Sondermayer [1]

During 1975 Switzerland continued to be a modest processor of imported crude oil, alumina, and raw materials for iron and steel production. Imports of metals were vital to the Swiss economy. In addition, Switzerland produced cement, lime, gypsum, salt, stone, sand, and gravel from domestic sources. Most of the country's energy requirements were met by imports of high-rank coals, crude oil, natural gas, nuclear fuels, and some petroleum refinery products. Hydroelectric power and fuelwood were the primary sources of energy produced in the country. The mineral industry of Switzerland was significant only to the domestic economy and contributed only about 2% of the gross national product (GNP) of about $55.3 billion. The inflation rate was 8%, Swiss unemployment remained under 1%, and Switzerland had a balance of payment surplus on current account in 1975. No major events relating to the minerals industry occurred during 1975.

PRODUCTION

Data on domestic production of mineral commodities showed a declining trend during 1975, reflecting a general slowdown of the economy. A large number of the processing facilities were modern and efficient. However, some of the installations for production of gypsum, lime, and stone were less mechanized than those in other parts of Europe. Productivity was rather high among mineral industry workers.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the commodities listed, a variety of crude construction materials (common clay, sand, gravel, and stone) is undoubtedly produced, but output is unreported and available general information is inadequate to make reliable estimates of output levels.

TRADE

During 1975 Switzerland's imports consisted mainly of fuels and raw mineral products for the metal processing industry. Exports included metals, cement, and petroleum refinery products. Tables 2 and 3 show recent foreign trade data of Switzerland. The volume of imports and exports of mineral commodities showed a general downward trend during 1975.

COMMODITY REVIEW

METALS

Aluminum.—Two Swiss Aluminium Ltd. (Alusuisse) plants (one at Chippis, Valais, and the other at Steg, Valais) and one owned by Usine d'Aluminium at Martigny were in production during 1975. Imported alumina from Surinam, Guinea, and Australia was used for feed. Most of the domestic aluminum was consumed in the country; apparent consumption, in thousand tons, is given in the following tabulation:

	Apparent consumption
1970	90.7
1973	111.5
1974	105.0
1975	[e] 90.0

[e] Estimate.

Iron and Steel.—Four steel plants, (with a total capacity of about 700,000 tons per year), located at Bodio, Lucerne, Gerlafingen, and Wöhlen, produced about 400,000 tons of steel during 1975, or 20% of demand. The 1975 output was lower than that in 1974, a result of the general slowdown of the economy. A network of about 1,000 traders distributed domestic and imported steel to consumers. In Switzerland, some of the steel traders have elaborate facilities for decoiling, slitting, guillotining, and other methods for preparing steel to the customers' desired specifications.

Silicon.—Monteforno Acciaerie e Laminator's 8,000-ton-per-year ferrosilicon plant and Gothardwerke für Electrochemische Industrie's 800-ton-per-year ferrosilicon plant remained the only producers of ferrosilicon in the country during 1975. Both plants were located at Bodio in southeastern Switzerland. Imported raw materials from European countries were used as feedstock during 1975, however, data on output were not available.

NONMETALS

Cement.—During 1975, the 15 Swiss cement plants, with 6 million tons per year installed capacity, operated at 60% of capacity. Three of the plants were located in the canton of Argau; the cantons of Bern and Vaud had two each; and one cement plant was in each of the following cantons: Graubünden, St. Gallen, Neuchatel, Schaffhausen, Solothurn, Schwyz, Valais, and Ticino. In addition, four clinker grinding plants were operational. During

1975 there were no major changes in capacity or equipment. Lower production resulted from a slowdown in the building sector of the economy.

Lime and Other Building Materials.—Production and consumption of lime and other construction materials, such as stone, sand, and gravel, followed the generally lower trend of cement.

MINERAL FUELS

The Swiss Federal Office for Energy Policy (L'Office Federal de l'Economie Energetique—OFEE) in its annual report indicated a decline in energy consumption of 2.5% compared with that of 1974. Petroleum remained the principal source of energy. Hydropower and natural gas followed.

Reliance was being placed on nuclear power to lower dependence on imported hydrocarbons. Construction of a nuclear powerplant at Gosgen, north of Brig, proceeded according to schedule, and production was expected in 1977.

Petroleum.—There was no domestic production of petroleum in Switzerland. However, exploration, mostly seismic, was underway in various parts of the country (cantons of Fribourg, Bern, Lucerne, Zug, Schwyz, Glaris, and St. Gallen). Seismic work which started during 1974 was continued. A total of 640 kilometers of seismic profiles was completed at the concession of Petrol Suisse S.A., Zurich, and Petrol de Lucerne, Lucerne. These two companies conducted exploration in the cantons of Zug, Schwyz, and Lucerne. Exploration was related to the Molasse formation of Miocene age, which is composed of Alpine detritus and is extensively developed in northern Switzerland. There was no actual drilling for petroleum in Switzerland during 1975.

The country's three refineries operated at 72% of installed capacity during the year. Two of them processed crude oil and the newest, the Raffinerie Rheintal located in the Rhine Valley and onstream since 1974, processed topped crude oil supplied through the Central Europe Pipeline. The Raffinerie de Sud-Ouest S.A., located at Collombey-Muraz, processed about 2.1 million tons or 27% less than in 1974. The Raffinerie de Cressier S.A., located at Cressier, processed about 2.6 million tons during 1975 or 16% less than during 1974.

Table 4.—Switzerland: Supply and apparent consumption of energy materials in 1973 and 1974
(Million tons of standard coal equivalent) [1]

	Total energy	Coal and coke	Petroleum and refinery products	Natural gas	Fuelwood	Hydro-electric power	Nuclear power
1973:

[2] Less than 0.005 million tons of SCE.

The Mineral Industry of Taiwan

By E. Chin [1]

Taiwan's gross national product (GNP) for 1975 was estimated at $14.4 billion at current prices and at $8.9 billion at 1971 prices, compared with $13.8 billion and $8.7 billion, respectively, for 1974. In absolute values, the growth in GNP for 1975 was 2.8%, compared with 0.6% for 1974 and 11.9% for 1973. The average annual growth rate for 1969–72 was 10.7%. As in many countries, the higher costs for fuels and other raw materials caused economic dislocation, as evidenced by a slowdown in real growth in GNP during 1974–75.

The value of Taiwan's imports and processing activities for minerals and metals overshadowed values of indigenous extraction. The mineral processing sector outweighed the domestic mining sector by 16 to 1 in output value. The total industrial input into the GNP was $4.1 million,[2] and by sector was constituted as follows, in percent: Mining 1.1; manufacturing, 27.0; utilities, 2.6; and construction, 5.6. Agriculture, forestry, fishery, and livestock contributed 16.3% to the GNP, followed by commerce and banking, 15.8%, and transportation and communications, 5.8%. The remainder comprised real estate, Government expenditure, and other services.

The breakdown by value of output for specific mineral-related sectors, in million U.S. dollars, follows:

Economic sector	1974	1975
Overall mining:		
Coal	129	102
Metals	29	25
Oil and natural gas	99	99
Salt evaporation	4	4
Nonmetals and quarrying	24	25
Total	285	255

Economic sector	1974	1975
Manufacturing of mineral and related products:		
Chemical products	1,786	2,076
Oil and coal products	930	1,016
Nonmetallic mineral products	364	422
Basic metals	651	479
Metal products	140	137
Total	3,871	4,130

Coal, natural gas, and limestone (including marble), ranked by value, are the three leading mineral products mined in Taiwan. However, output of these minerals is not significant in terms of the world market. The reserves of the important economic minerals in Taiwan in 1974, as reported by the Industrial Technology Research Institute, follow, in million tons: Asbestos, 0.88; copper ore, 15.1; dolomite, 119.2; gold ore, 7.0; marble, 299,980.0; pyrite, 1.9; sulfur, 2.4; and talc, 2.4. Additionally, reserves of mineral fuels were coal, 222.7 million tons; petroleum, 3.9 kiloliters; and natural gas, 41.4 billion cubic meters.[3]

Despite the sluggish growth of the economy during 1974–75, Taiwan continued the planning and construction of its 10 major development projects.[4] The first project to be started was the North-South Freeway linking Keelung in the north with Kaohsiung in the south. Completion of the 232-mile freeway was expected in late

[1] Physical scientist, International Data and Analysis.

[3] Mineral Resource Development in Taiwan. Mining Research and Service Organization Industrial Technology Research Institute. October 1975. P. 33.

[4] Industry of Free China. The Republic of China Builds for Tomorrow: The Ten Major Development Projects. V. 44, No. 2, August 1975, pp. 18–25.

1978. The highway would also provide high-speed access to the new international airport, another of the major projects, which is being constructed on the west coast near Taoyuan, about 18 miles southwest of Taipei. Completion of the airport was scheduled for 1979.

The railroad on the west coast mainline was being extended from Suao on the northeast coast to Hualien, the principal city at the northern end of the east coast plain. A link will be made with the existing east coast line connecting Hualien with Taitung to the south. Construction of the railroad will end the relative inaccessibility of the Hualien-Taitung area to the rest of Taiwan. The east coast has marble reserves estimated at about 300 million tons, and limestone and dolomite are plentiful. A cement mill currently under construction was scheduled for completion in late 1978.

Another project, the electrification of the west coast mainline railroad from Keelung to Kaohsiung, was scheduled for completion by 1979. Orders were placed for 94 locomotives to service passenger traffic and cargo and freight transport between Keelung and Chunan, Chunan and Changhua, and Changhua and Kaohsiung. Electrification was expected to reduce fuel oil imports in 1977 when the availability of power from nuclear generators would begin.

Construction continued on the first nuclear powerplant in northern Taiwan. Generation from a 636,000-kilowatt unit was expected by early 1977, and a second unit with identical capacity was to be completed by 1978. A second nuclear plant with two 985,000-kilowatt units was also planned for construction on the coast near the first plant site. A third plant with two units of 950,000 kilowatts each was also proposed for this nuclear project. At yearend 1975, Taiwan's 30 hydroelectric plants had a total capacity of about 1.4 million kilowatts. The largest thermal powerplant, at Taling near Kaohsiung, was completed in 1975 and has a capacity of 1.85 million kilowatts.

Two projects involving a new harbor and expansion of an existing port were in progress. A new harbor was being constructed in central Taiwan near Taichung. When completed in 1976, Taichung Harbor will accommodate nearly 3 million tons of cargo annually. Further expansion to 12 million tons per year was scheduled by 1982 and would provide relief from overcrowding at Keelung in the north and Kaohsiung in the south. An industrial district was also planned for Taichung, which would include a power station, a shipyard, and petrochemical plants. Suao, a fishing port on the northeast coast, was being enlarged to increase its capacity to 6.5 million tons of cargo by 1981.

Projects involving the petrochemical industry include expanding the production of basic petrochemical raw materials and the production of intermediate and consumer products. Two naphtha crackers have been constructed. The second, completed in 1975, will produce 230,000 tons of ethylene, and a third plant of equal size was being constructed. During 1975, a 66,000-ton polyacrylonitrile plant was completed for fiber processing. A polyester plant and a caprolactam plant were nearing completion.

China Steel Corp. was constructing an integrated steel mill at Kaohsiung. When completed in 1978, annual production capacity would be 150,000 tons of pig iron, 245,000 tons of steel ingot, and 1 million tons of steel plates, wires, and rods.

China Shipbuilding Corp. continued construction of its shipyard at Kaohsiung, which will have an annual capacity of 1.5 million tons of construction. When completed, the dry dock, which will handle vessels up to 1 million tons, will be 950 meters long and 92 meters wide. A second harbor entrance was included in the Kaohsiung expansion program, whereby port facilities could be enlarged to handle 100 million tons of cargo annually, facilitating the operation of the new shipyard in both shipbuilding and ship repair.

Late in the year, the Economic Planning Council completed the conceptual framework for the 6-year (1976–81) economic development plan for submission and approval by the Executive Yuan. The objectives of this new plan were to improve economic structure, promote economic modernization, expedite development of economic resources, and strengthen the ability of the economy to adapt to change. Ten major development projects were slated for completion duirng the plan period, and new projects were to be introduced. Closer coordination between industrial sectors was to be carried out for the purpose of balanced development and economic growth without hampering the overall economic stability.

During 1975, Taiwan's total supply of energy was estimated at 17.6 million kiloliters expressed in oil equivalence. Domestic production accounted for about 31% of the total; production by sector was as follows: Coal, 13%; hydroelectric power, 8%; natural gas, 9%; and crude oil, 1%. Imports provided the bulk of the country's primary energy supply and were distributed as follows: Crude oil, 49%; petroleum products, 20%; and coal, less than 1%.

Taiwan's industries consumed 15.8 billion kilowatt-hours of electricity in 1975 including 7.2 billion kilowatt-hours in the minerals and related fields. Estimated breakdown within the minerals and related industries was as follows, in million kilowatt-hours: Iron and steel, 1,560; cement, 885; chemical fertilizers, 480; metal products, 443; mining and quarrying, 339; aluminum, 231; basic industrial chemicals, 1,172; and other chemical products, 2,084.

PRODUCTION

By value, coal was the most important mineral commodity mined in Taiwan. Output of bituminous coal increased 7% to 3.1 million tons in 1975. Crude petroleum production was close to 1.4 million 42-gallon barrels, a 2% increase over that of 1974. The principal significance of indigenous oil was as a supplement in the production of refinery products derived from imported crude oil, which overshadowed domestic crude in Taiwan's overall oil supply. Production of natural gas declined slightly to 55.6 billion cubic feet. While output was of little consequence by world standards, natural gas production was important to the domestic economy.

Overall output in iron and steel products showed a general decline owing to decreased demand in both domestic consumption and export shipments. Production of pig iron and crude steel ingot declined 40% and 8%, respectively. Production of primary aluminum metal dropped 10%. The aluminum industry continued to be plagued by higher production costs primarily because of the electrical energy consumed. Output of mine copper decreased substantially, but refined copper metal production decreased 13%.

The production levels for manufactured fertilizer materials were erratic with increases in some items and declines in others. Salt production declined for the fourth consecutive year and was 268,000 tons in 1975 compared with 670,000 tons in 1971. Limestone production, principally for cement manufacture, totaled 9.5 million tons, up 6% over that of 1974. Increased domestic demand for cement absorbed the 10% higher output by the industry.

Table 1.—Taiwan: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1973	1974	1975 p
METALS			
Aluminum:

e Estimate. p Preliminary. r Revised.
[1] From Chinkuashih only.
[2] Excludes sulfur produced by oil refineries.
[3] Largely processed into natural gas liquids.

TRADE

Taiwan's two-way trade in 1975 was \$11.2 billion, down 11% from the previous year. Exports decreased from \$5.6 billion in 1974 to \$5.3 billion in 1975. Similarly, imports decreased from \$7.0 billion to \$5.9 billion. The largest import items were fuels, minerals, and metal products (\$1.5 billion); machinery, mechanical appliances, and electrical equipment (\$1.4 billion); mineral products (\$0.9 billion); agricultural, animal, and food products (\$0.8 billion); chemicals (\$0.6 billion); and textile materials (\$0.4 billion). By value, shipments from Japan accounted for 32% of Taiwan's total imports, followed by the United States, 24%; West Germany, 7%; Kuwait, 6%; Saudi Arabia, 5%; Indonesia, 3%; and the United Kingdom, 2%. The remaining 21% was contributed by a host of countries.

Textile articles and apparel constituted 35% of total exports, or \$1.9 billion, followed by electrical, optical, and transport equipment, \$1.1 billion; and prepared foodstuffs, \$0.8 billion. Principal export destinations were the United States, Japan, West Germany, Canada, Australia, and others, in that order.

In 1975, the value of mineral and metal products represented 25% of all imports, compared with 6% for these categories in total exports, reflecting Taiwan's reliance on imported raw materials and semimanufactures. During the year, mineral exports were valued at \$337 million, a 35% increase over the prior year's shipments, mainly owing to exports of iron and steel and other metal products. Mineral imports were about \$0.3 million less than in 1974, principally because of the decreased volume of petroleum imports. Table 2 shows the principal mineral categories traded during the last 3 years, and table 3 indicates the tonnage and value of major mineral products imported in 1975.

Table 2.—Value of principal mineral exports and imports by Taiwan

COMMODITY REVIEW

METALS

Aluminum.—Taiwan Aluminum Corp. (TALCO) remained the sole producer of primary aluminum in 1975. The capacities of TALCO's alumina plant and smelter facilities at Kaosiung were rated a 76,000 tons per year alumina and 38,000 tons per year aluminum. During the year, 114,433 tons of bauxite was imported; 105,873 tons was shipped from Malaysia, and the remainder was from Hong Kong, India, Japan, and Singapore. In 1975, Taiwan produced 70,000 tons of alumina, 28,111 tons of aluminum ingot (down 3,209 tons from 1974), and about 3,000 tons of secondary aluminum metal. Manufacture of aluminum sheet was 17,705 tons; foil, 1,959 tons; and miscellaneous products, 28,741 tons. TALCO produced all of the primary aluminum ingot, the bulk of the sheet and foil, and a minor portion of the aluminum manufactures. China Wire & Cable Co. and Walsin Electric Wire & Cable Co. accounted for all of the secondary recovery of aluminum and the bulk of the output of extrusions, castings, and semimanufactures.

Under technical assistance from Pechiney Ugine Kuhlmann of France, TALCO was completing the expansion of its alumina plant from 76,000 to 140,000 tons per year by 1976 at an estimated cost of $53 million. Smelter capacity was likewise being expanded from 38,000 to 70,000 tons per year, at a cost of about $22 million. The target year of completion for this phase of the project was 1979.

Copper.—Taiwan Metal Mining Corp. (TMMC), a Government-owned company, controls most of the copper industry in Taiwan. Output of mine copper remained at the 2,500-ton-per-year level and was chiefly from the Chinkwashih auriferous deposit in northern Taiwan. A small amount was reportedly produced from the Tungshan cuperiferous pyrite deposit at Ilan-hsien. Imports of copper raw materials (mainly concentrate and cement copper) in 1975 totaled 10,000 tons, of which 8,000 tons were received from the Philippines and the remainder from Japan. Total production of refined metal by TMMC's 10,000-ton-per-year smelter at Keelung was 8,539 tons in 1975, down 1,320 tons from 1974. Plans were being considered to expand smelter capacity eventually to 30,000 tons per year. Feasibility studies to erect a 50,000-ton-per-year copper smelter at Taichung to use Indonesian ore were being considered. In addition to copper raw materials, Taiwan imported 16,734 tons of refined copper and around 10,000 tons of copper products to supplement domestic output as feed materials for its rolling and fabrication facilities.

Iron and Steel.—Iron ore production has been insignificant in Taiwan, averaging about 25,000 tons per year. The limited output came mainly from magnetite occurrences distributed along the northern coast between Tanshui and Wanli. Imports of iron ore and concentrates totaled 143,342 tons in 1975 and were chiefly from India (123,175 tons), Malaysia (10,291 tons), and four other countries (9,876 tons). Imports of pig iron were only 6,213 tons, wholly from Japan. Receipts of iron and steel scrap, chiefly from the United States, were 407,913 tons. In addition, 1,264,000 tons of ships and vessels were imported for dismantling and production of scrap metal.

Production of pig iron was 66,840 tons, down 44,303 tons from 1974 output. Production of cast iron pipe and iron wire during the year was 31,543 tons and 30,944 tons, respectively. Production of ferrosilicon was 23,178 tons, 15% less than in 1974. Manufacture of steel products follows, in tons: Ingots, 519,991; castings, 27,600; rod and bar, 665,141; sections, 291,277; tubes and pipes, 108,265; and ball, 1,474.

China Iron and Steel Corp., Ltd. (China Steel) continued construction of its integrated steelworks at Kaohsiung. Technical assistance was being provided by USS Engineers and Consultants, Inc., a subsidiary of United States Steel Corp. Upon completion of the first phase of the project in 1978, initial capacity will be 1.35 million tons of steel per year. The second phase of construction would roughly double the capacity by the end of 1982. The ultimate planned capacity was 6 million tons per year; however, no date has been set for attaining this output. This facility is the most expensive of Taiwan's 10 major development projects in progress; estimated cost for construction was $931 million and cost may exceed

$1 billion by completion. Cost of the second-phase expansion was roughly estimated at $700 million, depending on the product mix desired. The new facilities would include additional coke ovens, a blast furnace, and rolling mill.

The initial capitalization of China Steel was $240 million, and the additional financing was to be provided from domestic and foreign loans. The original plan called for 55% private ownership with the remainder resting with the Government. China Steel failed to attract the private equity investment required, and the Taiwan Government has assumed full responsibility for the financing. Japan, the United Kingdom, France, West Germany, and the United States have provided loans for purchasing equipment. In addition, foreign banks have reportedly provided about two-thirds of the financing for the steel mill.

While China Steel would be a state enterprise, it would be operated as a private undertaking with purchases, employment, and related procedures not subject to Government review. However, the annual budget for the company would require approval by the Legislative and Executive Yuan. The first budget submission for Government review was scheduled for 1976.

Other Metals.—In 1975, Taiwan produced 22,110 troy ounces of gold and 5,990 troy ounces of silver. Both gold and silver were recovered as byproducts from copper refinishing at Chinkwashih. Additional gold was derived from imported copper materials.

Taiwan does not produce any primary zinc, lead, tin, or nickel but consumes sizable tonnages of these metals. In 1975, 12,307 tons of unwrought zinc valued at NT$396 million were imported from Australia (4,872 tons), Japan (5,310 tons), and other countries (1,125 tons). In addition, 1,425 tons of scrap zinc was imported, mainly from the United States. Imports of unwrought lead totaled 5,171 tons valued at NT$88 million, most of which were from Australia (2,960 tons) and Japan (1,755 tons). Scrap lead imports were 4,474 tons valued at NT$218, with Malaysia providing 82% of the total shipments. Nickel imports totaled only 232 tons (compared with 1,601 tons in 1974) valued at NT$36 million, with Norway and Japan providing about one-third each of the country's receipts. During 1975, Taiwan produced 26,325 tons of galvanized sheet, 37,624 tons of galvanized wire, and 11,055 tons of tin plate.

NONMETALS

Cement.—Total manufacture of cement totaled 6.7 million tons, up 625,000 tons from the country's output in 1974. Exports continued to decline, going from 346,000 tons in 1974 to 134,253 tons in 1975. Principal destinations for export shipments of cement were Singapore, Saudi Arabia, and Hong Kong, in that order. While prospects for long-term exports were diminishing, domestic demand continued to rise due to consumption resulting from the construction on Taiwan's 10 major development projects. The total industry capacity was around 9.6 million tons per year and would reach 11 million tons by 1976.

There were 13 operating cement plants in Taiwan—six in the south, five in the north, and two in the east. Most of the cement plants have their own limestone quarries, and only the small plants purchased limestone raw material from quarries operated by others. While Taiwan has abundant limestone, the western reserves have been extensively quarried. The eastern reserves are huge, and mining of these resources has been limited owing to poor transport accessibility. The industry needs around 100,000 tons of gypsum for cement production. Domestic production of gypsum in 1975 was only 3,054 tons. The bulk of the gypsum supply was from imports, which totaled 111,403 tons, principally from Japan, the Republic of Korea, Thailand, and Mexico, in that order.

Taiwan Cement Corp. (TCC) was the largest producer on the island with four plants and a combined annual capacity of 3.8 million tons. Asia Cement Corp. ranks second with a total annual capacity of 2.5 million tons. Ten other companies, each with a plant, accounted for the remaining 3.3 million tons of the country's cement capacity.

Fertilizer Materials.—In 1975, Taiwan produced 482,916 tons of ammonium sulfate, 177,111 tons of urea, 135,330 tons of anyhydrous ammonium, 207,200 tons of calcium superphosphate, and 255,111 tons of compound fertilizers. Taiwan has no potash resources and little apatite. During 1975, Taiwan imported 210,600 tons of phosphate rock (251,340 tons in 1974), mainly from Jordan and the United States. Imports of potassic, mineral, and chemical fertilizers totaled 198,894 tons and were principally from the United States, Canada, Israel, and West Germany, in that order.

Taiwan Fertilizer Co. (TFC) continued the construction of a facility at Miaoli which would produce 186,000 tons per year of urea and 300,000 tons per year of liquid ammonia from petroleum refinery offgas. The Miaoli fertilizer plants were expected to be completed in 1977. TFC was also constructing a 10,000-ton-per-year melamine plant at Hsinchu, also scheduled for completion in 1977. By yearend 1975, the China Phosphates Industries Corp., a Government enterprise, was nearing the completion of its fertilizer facility at Kaohsiung which would produce 100 tons per day of phosphoric acid, 400 tons per day of sulfuric acid, 90 tons per day of calcium phosphate, 70 tons per day of sodium phosphate, and 400 tons per day of byproduct gypsum.

Salt.—The total production of salt was by Taiwan Salt Works, a Government monopoly. Salt output declined from 362,809 tons in 1974 to 283,000 tons in 1975. Salt consumption declined owing to decreased demand by the soda-chlorine industry. Imports of salt totaled 375,475 tons (509,329 tons in 1974) of which the principal suppliers were Australia, 313,929 tons, and India, 59,845 tons. During the year, production of caustic soda was 79,891 tons; "liquid soda," 190,892 tons; and soda ash, 67,274 tons.

Stone.—*Limestone.*—Important limestone deposits of commercial value occur throughout the island, and the large quarries are usually operated by cement companies. Limestone production in 1975 was 9,478,884 tons, most of which was used in the manufacture of cement. The sugar refining industry was the second major consumer of limestone in Taiwan. Limestone was also domestically used as a source of lime and in the production of carbide cyanamide fertilizer.

Marble.—Taiwan's marble reserves are extensive and located on the east coast near Hualien. Output of marble reached 531,746 cubic meters, compared with 312,593 cubic meters in 1974. Exports of marble were valued at NT$11.3 million; in 1975, 90% of the marble exported was shipped to Japan.

Other Nonmetals.—Taiwan's production of elemental sulfur was 5,476 tons compared with 96,308 tons of imports in 1975. The quantity of sulfur recovered from petroleum refining was not reported but is probably large. Pyrite production, mainly from the Chinkwashih copper mine, was 14,176 tons, or close to one half the output in 1972. Talc product declined to 12,050 tons, about one-half of the 1972 level of output. Domestic production of asbestos was only 1,737 tons, and Taiwan requirements were met by imports (13,363 tons), primarily from the Republic of South Africa. Close to 136,000 tons of dolomite was produced in 1975. Clays were both exported and imported. Taiwan relied totally on imports for abrasives, fluorspar, graphite, and mica.

Taiwan Alkali Corp. completed the first phase of the construction of a 30,000-ton-per-year titania plant at Kaohsiung. The second (and final) phase of construction was scheduled for completion in 1976. This plant uses a process developed by the Benilite Corp. of America whereby ilmenite ore is leached and beneficiated with hydrochloric acid which yields a suitable feedstock for chlorination to produce titanium dioxide pigment. Commercial production of titania was expected to begin in late 1976.

MINERAL FUELS

Coal.—Most of the coal deposits are found in northern Taiwan. The coalbeds may reach 1 meter in thickness, but the average thickness of the workable beds ranges from 35 to 60 centimeters. The coal is mostly of the subbituminous to high-volatile bituminous type, and only about 20% has coking property. Since 1969, coal production in Taiwan has gradually decreased. Production in 1975 was 3.1 million tons, an increase of 7% over that of 1974. However, the outlook for increasing coal production was dim, and coal production could be expected to stabilize at 3 million to 3.5 million tons per year. To guard against a possible fuel shortage, 541,830 tons of coal was imported in 1974. In 1975, receipts of coal were only 77,315 tons, of which nearly 90% was from Australia. The wholesale price for domestic coal averaged $32.61 per ton during 1975, which remained low compared with prices of some foreign coals. Most of the country's requirements for coking coal were met by imports. In 1975, 19,720 tons was imported, all from Japan.

Natural Gas.—Natural gas was the most important mineral fuel produced in Taiwan. Production was largely from the Chinshui and the Tiehchenshan Fields in northern Taiwan and fields in the north-central region. Output of natural gas in 1975 was 55,603 million cubic feet compared with 56,034 million cubic feet in 1974. During 1975, the Continental Oil Co. (CONOCO), under a drilling contract with the Government-owned Chinese Petroleum Corp. (CPC) made a gas strike off the coast of southern Taiwan. CONOCO's F3 well hit gas at 4,000 meters and was capped off. Gas was found at CONOCO's F1 well a year earlier. This well was about 60 miles southwest of Taiwan in 400 feet of water. Preliminary studies indicated that the well had a capability of 25 million cubic feet per day of gas and 250 barrels per day of condensate.

Petroleum.—Output of indigenous crude oil was 1.352 million barrels, a slight increase over crude production in 1974. Domestic production equaled only about 2% of crude oil imports in 1975. During the year, Taiwan imported 7.532 million tons of crude oil, of which 4.019 million tons was from Kuwait and 2.629 million tons from Saudi Arabia. Imports of crude oil in 1975 were valued at about NT$23.7 billion, and refined oil imports at NT$5.4 billion.

Taiwan's economy is greatly affected by oil. The country derived 70% of its energy in 1975 from petroleum. Two of its most important industries—textiles and plastics—depend on oil refining for most of the feedstock materials. CPC's total refinery capacity, embodied mainly at Kaohsiung, was 334,500 barrels per day at yearend 1975, compared with 230,000 barrels per day at yearend 1974. Domestic crude oil reserves were estimated at about 24.9 million barrels. The country also had about 5,000 barrels per day of condensate production and about 15,000 million barrels of condensate reserves.

The production of oil has increased in recent years, resulting from increased production of condensate associated with natural gas output. Offshore exploration for petroleum resources on the Continental Shelf has been actively conducted either by the Government or in collaboration with international enterprises. Foreign companies participating with CPC in offshore exploration include CONOCO, American Oil Co. (AMOCO), Oceanic Exploration, Clinton International, Ltd., Texfel Pacific Corp., Superior Oil Co., and Cemoro Petroleum.

Only a handful of wildcat wells had been drilled offshore, and all except two were dry. The first strike was CONOCO's F1 well, which was for natural gas with a minor associated capability of condensate. The second strike was by CPC, where oil was found 10 miles offshore Lukang in the Taiwan Straits in a 12,000-foot well in 50 feet of water.

The Mineral Industry of Thailand

By Gordon L. Kinney [1]

The Thai economy experienced major setbacks in 1975 as the rate of economic growth slowed, export prices of Thailand's main commodities fell, and the investment climate, affected by Thai Government policy decisions and political developments in neighboring countries, reached a low.[2]

The mining industry recorded its worst performance in more than 10 years, reflecting in part the general economic downturn and a decline in capital investment.[3] However, a main factor was the Government's cancellation of the leases held by Thailand Exploration and Mining Co., Ltd. (TEMCO), in March 1975. TEMCO was the country's largest single tin producer, operating three dredges off the coast of Phangnga Province. Originally a subsidiary of Union Carbide Corp., it was jointly owned after 1970 by Union Carbide and Billiton Co. of Royal Dutch Petroleum; shortly, it is expected to be totally transferred to Billiton, who will retain ownership of the dredges.

The reason cited for withdrawal of the TEMCO leases was that the leases had been obtained by methods that violated the country's Minerals Act. However, students, activists, and some provincial authorities had protested against a foreign company profiting from the nation's richest mineral deposits, and public pressure may have been a factor. The situation made potential mining investors hesitant. Continued lack of a predictable Government policy toward the mining industry hampered plans for capital expansion and new ventures.

Although the TEMCO lease withdrawal was the most significant event of the year to directly affect the industry, of possibly greater long-term importance was the confirmation of commercial amounts of natural gas in offshore waters. As of yearend, Union Oil Co. and the Thai Government were still negotiating a long-term pricing policy for the gas. Construction of production and transport facilities was expected to begin soon after a contract is ratified.

Continued delineation of the potash deposits reported last year showed very large tonnages. Further detailed drilling of the deposits is dependent on availability of Government funding.

Farming, which employs about 70% of the labor force, accounted for about 30% of the gross domestic product (GDP). Only modest increases in output in the important agricultural sector were recorded. The gross national product (GNP) for 1975 was reported to be $14.8 billion,[4] a growth of over 6% for the year. The mining industry contributed 1.2% of the GNP compared with 1.4% in 1974. Total value of mining output was $170 million in 1975, down 27% from that of 1974. Total value of mineral exports of $158 million in 1975 was, correspondingly, down about 26%.

Mining and quarrying employed only about 50,000 workers, or 0.33% of the total work force of 14 million. The export of minerals contributed nearly 7% of the total value of all Thai exports.

The inflow of direct foreign investment into all sectors of the economy picked up after a severe plunge in April and May 1975, following the change of Government in Phnom Penh and Saigon. In the first 8 months of 1975, foreign investment reached a total of $112.9 million compared with

[4] Where necessary, values have been converted from Thai baht (B) to U.S. dollars at the rate of B20.379=US$1.00.

$114.2 million during the same period in 1974. Although little of this 1975 investment went into mining, outflow in the form of loan repayments, dividends, and profits increased from $27.7 million through August 1974 to $59.6 million in the same period in 1975.

PRODUCTION

Production of each of Thailand's four most valuable minerals, tin, tungsten, fluorite, and antimony (in that order), dropped substantially. Tin output declined about 19% in 1975. Tungsten production was off nearly 20%, owing mainly to unrest in some of the mining areas and partly to depletion of some of the more easily mined surface deposits. Lower demand and prices for fluorite caused an overall drop of 33% in mine production from last year's record level.[5]

TRADE

Total trade in 1975 amounted to $5.7 billion, with $2.4 billion in exports and $3.3 billion in imports, resulting in a trade deficit of about $900 million. Japan remained the main market for Thai exports, taking 26% of the total; Hong Kong and the United States followed with 13% and 10%, respectively.

Agricultural exports generally account for more than 60% of foreign-exchange earnings. (Thailand was the world's leading exporter of rice and third-largest exporter of rubber.) Mineral exports represented only 6.8% of Thailand's total exports in 1975. Tin exports in that year were valued at $112 million, or about 70% of total mineral exports.

Major imports were machinery valued at $1.2 billion, mineral fuels and lubricants worth $710 million, and iron and steel worth about $250 million, which accounted for 36%, 22%, and 8%, respectively, of the total imports for 1975. Imports of nonferrous metals and fertilizers were also sizable. Thus, the aggregate of all mineral imports was equivalent to 6% to 7% of the GNP for 1975.

COMMODITY REVIEW

METALS

Antimony.—Mine output of antimony ore from stibnite and stibiconite occurrences in 1975 was over 7,000 tons, grading about 42% contained metal. The bulk of the production was from provinces in the north and central regions. There are about 30 important antimony occurrences in Thailand with several mines operating at each of the richer occurrences. Production from mines in Phrae and Lampang Provinces accounted for nearly one-half of the country's total output. Two mines in the central region, one each in Kanchanaburi and Ratchaburi Provinces, had an annual output of about 1,100 tons of ore. The remainder of the production was from mines in Nakhon Si Thammaret and Surat Thani Provinces in the south.[6]

Production of metal during the year was about 300 tons, primarily from the plant of Siam American Mining Enterprise Co., Ltd., at Ban Nasan in Surat Thani Province. This plant, which uses a distillation process, had an annual capacity of 500 tons of metal.

Only a small portion of the antimony production was consumed locally for battery plate manufacture, printing lead, and matchstick production. In 1975, nearly 5,000 tons of ore valued at $3.2 million and about 300 tons of metal valued at $0.6 million were exported, making antimony the fifth most valuable mineral export. Overall mine output from Thailand ranked seventh in the world.

Iron and Steel.—Thailand produced slightly more than 32,000 tons of iron ore in 1975. A cutback in production by Siam Iron Co., Ltd., was nearly offset by the start of output by South Siam Metal Enterprise Co., Ltd., which began operations in October. Most of this domestically produced ore was smelted in Siam Iron and Steel Co.'s small charcoal-fired blast furnace plant at Ta Luang in Saraburi Province.

Production of pig iron continued to be small, but production of crude steel, bars, and billets increased about 47% to more than 500,000 tons in 1975. Plans for a major increase in steel bar production were firmed up by yearend. Five new electric arc furnaces reportedly under construction will increase the country's capacity from 445,000 tons per year in 1975 to 635,000 tons per year when completed in late 1976 or early 1977. Three will be installed by Bankok Iron and Steel Co., one at Bankok Steel Co. and one at Thai India Steel. The size of charge varies between 13 and 20 tons.[7]

Lead.—Lead ore production remained virtually unchanged at 3,600 tons. Value of the ore placed lead 10th among domestically produced minerals. Lead content of the ore averaged 43%. World market prices remained depressed since consuming countries had large stockpiles.

Manganese.—Output of battery-grade manganese in 1975 was nearly 3,600 tons, a decline of about 60%, whereas output of metallurgical-grade manganese increased 2% to over 20,000 tons. During the year, new deposits were discovered in Chiangmai and Loei Provinces.

Tin.—Thailand's most valuable mineral product, tin, contributed about two-thirds of the total value of mineral production in recent years (excluding cement). In 1975, the reported production of 73% concentrates dropped 20% to 22,397 tons, all of which was smelted at the Thaisarco smelter. However, Thailand's share of world production was still nearly 10%. The decline in tin production was partially due to the Thai Government's decision to revoke TEMCO's mining concessions. TEMCO produced 9% of Thailand's 1974 tin output and was expected to produce about 15% in 1975. Late in the year, the Government failed to renew five of seven mining leases of Southern Kinta Consolidated, Ltd., further cutting production.

Following the closure of TEMCO operations in the shallow waters off Phuket, some areas were taken over by a large number of unlicensed operators, who subsequently started to extract large quantities of tin by primitive diving methods. Reports indicated that much of this unlicensed tin was smuggled from Thailand into Burma and then marketed in Malaysia. Malaysia imported nearly 5,000 tons of tin-in-concentrate from Burma in 1975 compared with about 500 tons in 1974, even though Burma's production for 1975 remained at the 1974 level of 600 tons.[8]

[7] Iron and Steel International. V. 49, No. 1, February 1976, p. 9.

[8] Work cited in footnote 3.

The Thai Government set aside certain offshore areas for some small-scale operators who were to be licensed to sell the tin concentrates within the country. The Government also established the State-owned Offshore Mining Organization (OMO) to administer and operate the former TEMCO leases. As an initial step, the Government decided to subcontract the OMO's offshore dredging to three companies—Billiton Thailand, Aokam Tin, and Thai Sanguan Co.—until the OMO could operate dredges on its own.

Exports of tin metal in 1975 were more than 16,000 tons valued at about $106 million, a decrease of 23% from 1974 exports of 20,768 tons. The major export markets for tin were the United States, Japan, the Netherlands, the U.S.S.R., and Singapore.

The worldwide recession had a marked effect on tin prices. Decreased demand caused tin prices to dip sharply, and the International Tin Council (ITC) had to resort to buffer stock purchases to support the market price during most of the year. The average Penang price for tin was 301 cents per pound in 1975 compared with 355 cents per pound in 1974, but prices were up again in early 1976.

Farber Merlin Ltd. developed an underground mine at Sichon and production was to begin in early 1976. Sierra Mining Co. continued to evaluate a proposed onshore dredging operation, also at Sichon. Chasintr Mining Co. opened the country's first open pit tin mine in Ban Juai Wan Khao, near Kanchanaburi and the Burma border. The mine was developed for $5 million and used unsophisticated but effective 2-cubic-meter excavators and a long conveyor-belt system. Tin concentrate production was eventually expected to reach 150 tons per month.

Labor problems were developing at yearend at two of Thailand's major offshore tin-dredging companies, Aokam Tin and Tongkah Harbour. A strike appeared imminent and, if extended, it could lower production significantly in 1976.

Tungsten.—Production of tungsten, Thailand's number two mineral, fell during 1975 to 3,441 tons of 60% WO_3 concentrates. This was nearly a 20% reduction from the 1974 tonnage and the third straight year of significant decline. Thailand ranked seventh in world production of tungsten, off from fourth place in 1973. The decline was attributed in part to political instability in the important Khao Soon mining area, and in part to the gradual depletion of the shallow, more easily mined ore reserves.[9] A decline in the output from Doi Mok in Chiangrai Province was also due to depletion of the deposit. Production from deeper ores in these major mines will involve difficult mining problems and higher costs.

Zinc.—Trial shipments of zinc concentrate continued to be made from the Mae Sot mine to the New Jersey Zinc Co. plant in Palmerton, Pa. Imports of zinc ore and concentrate at the Palmerton plant were reported at 28,000 tons of contained metal, about one-half of which was from inventories held at the Mae Sot mine. Mine output for the year declined.

Construction of a 60,000 ton-per-year electrolytic zinc refinery at Tak was awaiting Thai Government approval. The plant will be a joint venture between Thailand and the United States and the first such plant in Southeast Asia.

Other Metals.—As byproducts of tin mining, 103 tons of tantalite, 7 tons of columbite, and 367 tons of monazite were produced. Additionally, 1,760 tons of a tantalum-columbium (Ta-Cb) rich slag was recovered as the Thaisarco tin smelter. Prices obtained were not available for the individual concentrates, but in light of the high unit price for Ta-Cb oxide, the byproducts represent a substantial value-added in tin production.

NONMETALS

Barite.—Barite was the only important Thailand mineral to show increasing strength in 1975, ranking fifth in value of minerals produced. Production increased 28% in 1975 to over 258,000 tons, to meet the expanding demand in oil well drilling in Southeast Asia. Exports of 90,410 tons of ore were largely to beneficiation plants in Indonesia and Singapore. Exports of mud-grade barite, milled in Thailand, increased to 20,621 tons. Deposits are widespread, with output coming from about three major producers and many small independent ones. Recently, Dresser Industries opened a new large mine at Phetburi.

Cement.—Cement production remained at about 4 million tons in 1975. The International Finance Corp. (IFC) was lend-

[9] Pages 410–413 of work cited in footnote 3.

ing $10 million to help finance a $62 million expansion program for four companies in the Siam Cement Group. The portion of the plan for Siam Cement Co., Ltd., calls for adding 800,000 tons per year to cement capacity, constructing two cement distribution centers in Bangkok, and building facilities for loading clinker on ocean-going vessels. The increase in cement output was aimed at helping to meet growing domestic demand and take advantage of the export market. The new handling facilities would speed shipments and reduce transportation costs.[10]

Fertilizer Materials.—The potash deposits at Udon Thani were still being investigated by the Thai Department of Mineral Resources (DMR) with a view toward development. Because the deposits are located near the Laos border south of Vientiane, private prospecting in the area was prohibited. DMR applied for a budget of $1.25 million to finance a 2- to 3-year drilling program. Private interests estimated that at least $3.5 million would be needed to test the area thoroughly. The deposits are apparently large enough that with proper development Thailand could become an exporter of potash fertilizers to the Asian market.

Fluorspar.—The fluorspar market suffered a sharp decline during 1975 because of the severe drop in import demand by several countries, especially Japan, the major importer. Japan's cutback in Thai imports was due to a 20% reduction in steel output, adaptation of new steel-smelting techniques using less fluorspar, a more favorable long-term market supply from Kenya, and large politically motivated purchases from the People's Republic of China, which have left a surplus of fluorspar in stock.[11]

Production of metallurgical-grade fluorspar was about 175,000 tons, off 48% from the 1974 level. Low-grade fluorspar production was 111,000 tons, roughly a 26% increase over the 1974 level. However, an export market for the beneficiated acid-grade fluorspar was found for only one-quarter of the output. During the year, 32 mines closed, leaving 34 mines working at yearend. Prices of metallurgical-grade fluorspar sold to Japan began the year at about $44–$45 per ton but dropped later to $42 per ton as producers sold surplus stock to cover expenses. Value of fluorspar exports declined from $15 million in 1974 to $10 million in 1975.

DMR estimated recoverable reserves at 11,500,000 tons, based on prominent outcroppings of fluorspar that could be easily worked by open pit methods. No systematic exploration for fluorspar has been done, either on extensions of known lodes or for new deposits. Consequently, the possibility for major additional ore reserves was considered very high.[12] The long-term outlook for Thai exports appears promising despite the decrease in exports to Japan. As economic development of the region progresses, demand for fluorspar should increase significantly. Indonesia, Australia, and India are the likely new markets.

Gypsum.—Both domestic and export demand for gypsum declined for the first time in several years. Production fell to about 255,000 tons, a drop of 18%. Exports showed an even steeper slide from 117,672 tons to 89,000 tons. Malyaysia, Indonesia, and Taiwan were the major purchasers. The main cause of the decline was attributed to high freight and shipping costs, which have rendered Thai gypsum uncompetitive with other producers in the area.

MINERAL FUELS

Coal.—Lignite was the only domestically produced mineral fuel of significance, and output was just under 500,000 tons. DMR reported finding new deposits of lignite in Krabi Province in the south; the deposits were being evaluated. The Electricity Generating Authority of Thailand switched from heavy oil to lignite at some of its generating plants in an effort to save on expensive imported oil.

Petroleum and Natural Gas.—Petroleum imports continued to be a major expense in the Thai foreign-exchange picture. Total cost of mineral fuels imports in 1975 was $710 million, by far the largest single import category. Total domestic production of crude oil was reported as less than 300 barrels per day. Crude oil imports were refined at the country's three main refineries—Thai Oil Refinery Co., Esso Petroleum Co., Ltd., and Summit Industrial Corp.—which had a total processing capacity of nearly 170,000

[11] Business Review (Thailand). Association Report. V. 4, No. 2, March 1976, p. 83.

[12] Scholla & Associates (Bangkok). Fluorspar Deposits of Thailand. November 1975, 23 pp.

barrels per day. The Government was expected to take over Summit shortly and Thai Oil by 1981.

Exploration for petroleum and natural gas continued in the offshore areas under Thai control. Union Oil Co. announced separate natural gas discoveries in block 12 of 60 and 26 million cubic feet per day and condensate yields of about 2,000 and 1,000 barrels per day. Testing of the wells discovered earlier in blocks 12 and 13 indicated an average yield of 30 barrels of condensate per million cubic feet of gas.[13] Both the company and Thai officials felt that reserves were sufficient for commercial exploitation to begin at a projected rate of 150 million cubic feet per day. The main factor preventing signing of a long-term contract between Union Oil Co. and the Government was the price being asked, $1.60 per 1,000 cubic feet over a 20-year contract. Thai officials wanted the price adjusted downward every 5 years as the investment costs were repaid. Plans were being made for laying a pipeline from the field, which is located about 95 miles east of Surat Thani, northward to the capital. Cost of a 150-million-cubic-foot-per-day pipeline was estimated at $180 million and only slightly more than a 300-million-cubic-foot-per-day line. Financing of the pipeline was also being negotiated. Gas could be flowing within 3 years of contract signing. Initial customers for the gas would be the thermal powerplants in the Bangkok area, which would be converted to gas as soon as it became available. Market demand for the gas should expand quickly if the price of the delivered gas is held below the equivalent imported petroleum price.

Drilling was started in late 1975 by Union Oil Co. and Esso Exploration Inc., in their respective concessions in the Adaman Sea off the west coast. Esso was using the just-completed *Discoverer 534* self-contained drilling ship owned by the Houston-based Offshore Co. This was reported to be the most sophisticated drilling vessel in the world, and was being leased by Esso for $100,000 per day. Its first well was spudded in 2,300 feet of water, but proved dry, was sealed, and abandoned after reaching over 11,000 feet. Drilling was to continue throughout 1976 by both Esso and Union Oil Co. One of the planned holes was to be in 2,632 feet of water, a record depth for commercial exploration.[14]

Thailand had not been able to take advantage of 312,000 tons of Chinese crude oil arranged for at a friendship price. The high-pour-point oil posed major problems in handling and refining at the Bangchak refinery. Modification of the handling and refining equipment was reportedly underway at yearend.

The Mineral Industry of Tunisia

By E. Shekarchi [1]

The mining and chemical sectors of the Tunisian economy—the best performers of 1974—were depressed by a strong world market reaction to high phosphate prices. Although mining continued apace, a large portion of phosphate rock production was stockpiled rather than offered at lower prices to stimulate sales. Phosphate processors halted operations for several months due to the low world price for triple-superphosphate and phosphoric acid; overall production in the chemical industry declined 15%. The energy sector was mixed; petroleum revenues decreased because of a fall in crude prices for Tunisia. Increased production of lower grade crude from the Ashtart offshore field compensated for the continuing decline at El Borma oilfield. Announced offshore natural gas reserves of over 100 billion cubic meters promised future developments in the chemical industry.

The preliminary gross national product (GNP) for 1975 based on current prices, was estimated at \$3.5 billion,[2] a 9% increase compared with the 1974 GNP. Per capita GNP increased 10% in 1975 compared with that of 1974.

Details of the fifth plan (1977–81) were still being developed although some priority sectors and projects were announced by the latter part of 1975. Investment for the fifth plan was targeted at \$1.8 billion to \$2.1 billion per year. Projects and plans affecting the mineral industry were as follows:

Natural Gas.—The Government appeared committed to developing the offshore natural gasfield at a cost of about \$1.2 billion in order to attract gas-based industries. The Government was to seek foreign participation in the development, which will require major foreign engineering, construction services, and equipment.

Oil Refinery.—To reduce Tunisian imports of refined petroleum products, the Government plan called for immediate major expansion of the Bizerte refinery.

Phosphates.—A major expansion program in phosphate mining and processing was foreseen including a proposed nitrogenous-phosphatic fertilizer plant. Specifications for the plant were not given.

Cement.—To supplement the construction of three cement plants underway in 1975 which would increase cement production by over 2 million tons, the fifth plan proposed construction of two additional plants. Tunisia imported over half of its cement needs in 1975, but with the realization of the fifth plan, it could become a net exporter of this commodity.

Transportation.—The Tunisian fifth plan foresaw a railway modernization, including a new track, introduction of a standard gage line, rolling stock, signal systems, a new terminal for Tunis, and a linkup with the Trans-Maghreb railroads.

Energy.—A major investment program was to be undertaken by the State Power Company designed to double power output by 1981. Tenders were issued for a 300-megawatt steam-generating plant and two gas turbine plants totaling 90 megawatts. Further generating and distribution infrastructure was to be added to the 1975 facilities.

From numerous bids submitted to the Tunisian Government for chemical processing plants, only Oronzio De Noro of Milan and Spie-Batignolles of France were awarded a contract for the design of a 750-ton-per-day sulfuric acid plant for Société Industrielle d'Acide Phosphorique et d'Engrais at Sfax. Construction began in mid-1975 and completion was expected

[1] Supervisory physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from Tunisian dinars (TD) to U.S. dollars at the rate of TD1=US\$2.30.

in 1976. The financing arrangements of this project were not disclosed by yearend 1975.

The establishment of the El Borma natural gas pipeline and an agreement for the construction of the major Algerian-Tunisian-Italian natural gas pipeline to export natural gas to Europe remained in the planning stage at yearend 1975. No firm decision was made, because financial backing for the entire project was unresolved.

The Tunisian national oil company, Établissement Tunisienne pour l'Activité Pétroliers (ETAP), which was created by law in 1972, and actually established in mid-1974, became more actively involved in all phases of the country's petroleum activity in 1975 ETAP functioned as a diversified petroleum company, which participated in all joint ventures with foreign companies and planned eventually to conduct its own exploration and development program. While ETAP did not negotiate new concessions in 1975, the organization became directly involved in issuing drilling permits and other licenses and was free to inspect any petroleum activity in Tunisia as a consultant to the Tunisian Government.

PRODUCTION AND TRADE

The available data on mineral production and trade are given in the following tables:

Table 1.—Tunisia: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity [1]	1973	1974	1975 [p]
METALS

COMMODITY REVIEW

METALS

Iron and Steel.—Iron ore production decreased by 25% in 1975 compared with the 1974 output. Most iron ore was produced from the Djebel Djerissa mine with a lesser amount from the Tamera mine. The State-owned El Fouladh iron and steel mill produced a total of 129,000 tons of ingot, slightly more than in 1974. The proposed direct reduction iron plant at Qabis was tabled temporarily mainly because of the scarcity of natural gas for the plant and the estimated high construction cost of $55 million.

Lead.—Lead ore as well as lead metal production decreased substantially in 1975 from that of 1974. All of the lead ore was produced by the Government-owned mining company Société Tunisienne d'Expansion Minière (SOTEMI) and all lead concentrates were smelted by Société Peñarroya Megrine (SPM) smelter. The SPM smelter was dependent for feed upon imported lead concentrates from Morocco, Algeria, Italy, and other countries. Refined lead was exported to Greece, 7,700 tons; Italy, 6,000 tons; and Algeria, 4,000 tons. Lead ore production (43% to 55% Pb) in 1975 amounted to 17,827 tons compared with 20,761 tons in 1974. Refined lead production in 1975 amounted to 23,396 tons compared with 26,820 tons in 1974.

Zinc.—The Fradj Hassan mine remained in the development stage with no production reported by yearend 1975. Domestic production of zinc concentrate from mines located in western Tunisia was about the same in 1975 as in 1974. SOTEMI was the sole zinc producer in the country. Zinc ore (45% to 55% Zn) in 1975 amounted to 12,917 tons compared with 12,411 tons in 1974. No output of refined zinc was reported in 1975, but in 1974 output was reported as 534 tons.

Other Metals.—Production of silver, a byproduct of lead smelting, was reduced substantially in 1975 compared with 1974 output.

NONMETALS

Cement.—Production of cement in the Bizerte and Tunis plants reached a new height in 1975. Domestic demand for cement, particularly in the construction industry remained strong. In the fifth plan, the Government planning organization projected that by 1980 cement production from Tunisia would reach 2 million tons.

The construction of two new cement plants, Qabis with a 700,000-ton-per-year capacity and Thala with a 1-million-ton-per-year capacity, was on schedule. The Thala cement plant near the Algerian border was to be jointly operated by Algeria and Tunisia. Although the cement production of 620,000 tons was the highest in Tunisian history, an equal amount had to be imported during 1975 to meet demand.

Fertilizer Materials.—*Phosphates.*—Production of rock phosphate decreased 9% in 1975 compared with that of 1974. The fifth plan, announced by the Government in the latter part of 1975, envisaged doubling phosphate rock production to about 7 million tons annually within 6 years. Cie. des Phosphates de Gafsa (CPG), owned by the Tunisian Government, obtained clearance to invest $322 million on an expansion plan. The main goal of this expansion plan was to increase exports to 4.5 million tons by 1981 from 2.2 million tons in 1975. The Government also expected domestic demand for phosphate rock to be doubled from 1.2 million annually to 2.5 million tons by 1981. Under the new program CPG planned to invest $156 million in developing new phosphate deposits in Sehile and Kef Echfaier, south of the Metlaoui deposits. Also, $101 million was earmarked to finance the mechanization of production facilities at the Redeyef, Metlaoui, and M'Dhilla mines. About $66 million was to be spent in modernizing rail communication between the mines and Sfax, the phosphate export port on the Mediterranean. The gradual increase of phosphate production was predicted to be 3.5 million tons in 1975, to 4.1 million tons in 1976, to 6.2 million tons in 1980, and to 7.1 million tons in 1981.

About 90% of phosphate production in 1975 came from the seven mines of the Cie. des Phosphates et du Chemin de fer de Gafsa located in a line northwest from the town of Gafsa to the Algerian border. The remaining 10% was produced by Société Tunisienne d'Exploitations Phosphatières which operated the Kalao Djerda mines about 200 kilometers southwest of the capital.

The expansion program of the new Sehibe mine, in the Gafsa phosphate basin, financed by the World Bank, continued on schedule in 1975. Production at an initial rate of 1.2 million tons annually was to begin in 1976. When in full production in 1980, this mine alone was to contribute substantially to phosphate production for export. Apparently the World Bank loan of $2.3 million was at an interest rate of 7.25% per year for 15 years, including a 3-year grace period.

The Government, in order to strengthen its control over the chemical and the phosphate processing sector of the economy, was negotiating to purchase a nitrogen-phosphorus-potassium (NPK) triple superphosphate plant belonging to the Swedish company Supra Aktiebolag, International Finance Corporation, and a U.S. firm, Freeport International, a subsidiary of Freeport Minerals Company. Terms of the purchase were not available by yearend 1975. However, it appeared that the Government of Tunisia would assume a dominant role in all important sectors of the national economy and in the marketing of basic commodities.

Geologically the Gafsa basin extends from the town of Gafsa toward the Algerian border. The phosphate beds belonging to the Thanetian time range in thickness from 15 to 25 meters. Within the phosphatic suite much variation in the number, grade of ore, and thickness of individual ore-bearing beds was noted from one part of the basin to another. However, a total of eight beds was distinguished as constituting a potentially minable horizon. The phosphorite occurred generally as rather soft, friable, greenish or brown rocks, almost invariably separated by varying thicknesses of marl or limestone. These marls, when they formed hanging walls of a phosphate bed, were a continuing source of trouble to miners, because they had a marked tendency to expand and collapse into the working area as soon as they were exposed to the air. To overcome this problem, Tunisian operators imported a great deal of timber for roof supports from Poland and France each year, which constituted a sizable expense.

In the Gafsa basin, four beneficiation plants were set up, each one to treat specifically one of the various types of ore mined. However, as the mine reserves were depleted, the beneficiation procedure, geared to handle one specific type of ore, was found unsuitable for some of the rock mined; consequently, the company was forced to change from dry beneficiation to wet techniques. In some instances the ore had to be transferred to the wet beneficiation center at Meltaoui, 37 kilometers away.

Fluorspar.—Production of chemical-grade fluorspar at the mines in the Zaghousan region of central Tunisia in 1975 was 20% above that of 1974. Construction of the new aluminum fluoride plant at Gabes to utilize domestic fluorspar continued on schedule during 1975. The plant, slated to begin operation in the latter part of 1976, with a 23,000-ton-per-year capacity was being constructed under the direction of the National Chemical Fluorine Company at an estimated cost of $14 million. It was to be financed by the Tunisian Economic Development Bank and by loans from French banks and the International Finance Corporation, a member of the World Bank.

Fluorspar feed stock for the new plant was to come from SOTEMI, sulfuric acid from Maghribe Chemical Industries, and aluminum was to be imported from abroad. It was estimated that the new plant would earn close to $15 million in foreign exchange as early as 1977 and would provide 240 new jobs in the southern region of the country.

Other Nonmetals.—Barite production compared with that of 1974 decreased 14% in 1975, while the production of clay, hydraulic lime, shale, and sand and gravel increased significantly, reflecting a substantial demand for construction material. Most of the barite production was consumed locally for oil drilling mud. Production of marine salt in 1975 increased considerably compared with that of 1974. A greater portion of the salt production was consumed in the tanning industry.

MINERAL FUELS

Natural Gas.—According to reports published by the Ministry of National Economy, 1 billion cubic meters of natural gas were produced in 1975. Of this amount 212 million cubic meters were used for power generation and industrial purposes, and 800 million cubic meters were flared. Most of the production was from the El Borma Field, while a small amount, 2.3 million cubic meters, was produced in the

Cap Bon Field. No figures were available on production of natural gas from other oilfields by yearend 1975. According to the feasibility study on the Tunisian natural gasfields completed in 1975, Tunisia had a gas reserve of 50 billion cubic meters in the Continental Shelf area alone. The Government of Tunisia intended to put these reserves onstream with a collection system capable of producing about 3.5 billion cubic meters of natural gas annually. This energy source was to be used for the petrochemical industry and for fixed installations already established in Tunisia such as cement plants, steel facilities, and power generating stations which relied on fuel oil or coke in 1975. All the gasfields in the Continental Shelf were in a permit area held by the French company Société Nationale des Pétroles d'Aquitaine/Entreprise de Recherches et d'Activitiés Pétrolières (Aquitaine/ERAP). Additional gas reserves in the Gulf of Qabis, when discovered, were to be tied to the gathering system. The Government expected to undertake engineering studies and actual construction in 1976.

Petroleum.—Crude petroleum production increased about 11% in 1975 compared with that of 1974. Ashtart, an offshore oilfield was a leading producer with 2.3 million tons, followed by the El Borma Field with 1.8 million tons. Two smaller producers Douleb and Sidi El Itayem, contributed 174,000 tons and 210,000 tons, respectively, to the 1975 production.

At yearend 1975, there were approximately 14 valid exploration permits and 1 new production-sharing permit for a total of 150,000 square kilometers as compared with 21 permits for 187,000 square kilometers at the beginning of the year. Of these permits, six covered both onshore and offshore areas, three were for onshore areas, five were on the Continental Shelf, and one was in deep water (beyond a 200-meter depth). Exploration activity in 1975 was about one-half of that during 1974, with the major reduction taking place onshore. Eight wildcat wells were drilled, half of which were offshore, resulting in gas discovery in the Miskar Field east of Ashtart and at Hastrubal on an adjoining permit; both properties were held by Aquitaine/ERAP. The same company also made an oil discovery very close to the controversial Libyan-Tunisian shelf boundary. At the promising Isis oilfield, discovered in early 1975, very little offshore drilling was reported due to a dispute between the Tunisian and Libyan Governments. Although the Mediterranean median line between the two countries was under study, no solution had been agreed upon by yearend 1975.

Total consumption of refinery products in 1975 increased 13% over that of 1974, because of a 48% increase in consumption of distillate fuel oil, a 6% increase in motor gasoline, and a 5% increase in jet fuel and kerosine. The only decrease in consumption was of 7.5% in residual fuel oil.

The Mineral Industry of Turkey

By E. Shekarchi [1]

The mineral and metallurgical industry of Turkey in 1975 was not as successful as in the previous year. Slight decreases in production of iron ore, primary copper, and lead-zinc ores were noted, while a significant decline in the production of pyrite, mercury, magnesite, antimony, bauxite, and boron minerals were registered. The only production increases were in chromite and manganese. Based on the Turkish State Institute of Statistics' figures, the growth rate of real gross national product (GNP) in 1975 reached 7.9%. This compared favorably with real growth of 6.9% in 1972, 6.6% in 1973, and 7.1% in 1974. Per capita income at 1975 prices increased to $900.[2] Workers remittances from abroad were down by 9% for 1975 to $1.3 billion.

In mid-April, the Turkish Parliament passed legislation enabling the Government to set up a State Industry and Labor Investment Bank. The Government was directed to inaugurate the bank and its branch offices in 2 years. The Treasury Department was to own 85% of the total capital stock, and to the extent feasible, this was to be sold to workers abroad as well as domestically. The remaining 15% equity was to be raised by State-owned enterprises and the Ministry of Industry and Technology. Turkish workers abroad who bought shares in the bank were to be guaranteed a 12% return on investment. The bank envisaged, by this method, to induce Turkish workers abroad, particularly in West Germany, to remit funds in West German banks estimated at $3 billion.

Turkey's associate membership in the Economic Communities (EC) and the goal of full membership by 1995 worked for an advantage when, finally, the right of a large number of Turkish workers to remain in Europe and thereby keep incoming remittances of foreign exchange high was approved by the EC Council of Ministers.

Turkish Government policy and existing legislation welcomed foreign investment provided that it responded to clearly delineated national criteria. Foreign investment was to contribute positively to economic development, contribute to exports, and introduce new technology; it was not to displace Turkish enterprises or entail a monopoly. Nevertheless, foreign direct investment in Turkey, which appeared to have gathered momentum in the 1950's and early 1960's, has for a variety of reasons stagnated in recent years.

The State-owned Turkish Fertilizer Corporation (Azot Sanayi T.A.S.) announced in December that it had awarded a contract to Kellogg International for engineering and consulting services on its proposed $100 million ammonia plant at Gemlik. Financing details remained to be worked out, but it was reported that Libya has agreed to provide 50% of the financing for the new plant.

In April 1975, Gubre T.A.S. (Fertilizer Plant Corporation of Turkey) inaugurated at Iskenderun a major fertilizer complex with a capacity of 230,000 tons per year of sulfuric acid and 150,000 tons per year of phosphoric acid. The same corporation had previously established at Yarimca, Izmit, a similar complex which was designed to produce 150,000 tons per year of phosphoric acid and 100,000 tons per year of triple superphosphate. Total cost of the two projects was estimated at about

[1] Supervisory physical scientist, International Data and Analysis.

[2] Where necessary, values have been converted from Turkish lira (Lt) to U.S. dollars at the rate of Lt14=US$1.00.

$36 million and was to save Turkey $90 million per year through import substitution.

The International Finance Corp. (IFC) agreed to finance Boru Sanayii A.S. (BORUSAN) in building a new steel pipe plant at Gemlik. The IFC purchased 10% of the equity in BORUSAN's new investment which was eventually to cost approximately $4 million. The IFC also confirmed in mid-1975 that it would join Koc Holdings and other private investors in forming a company which was to set up a gray iron castings plant with a capacity of 22,000 tons per year. The project aimed to supply a substantial portion of the casting requirements of the tractor and automotive manufacturing industries of Turkey. IFC was to provide equity capital of $1.4 million and a loan of $7.5 million for this project.

The full text of the crude oil pipeline agreement between Turkey and Iraq was published in the Turkish Official Gazette of June 17, 1975. Remuneration for the transport across the Turkish territory of crude oil originating in Iraq and for the loading of such crude oils on tankers at the terminal was fixed at $0.35 per barrel. The Iraqis agreed to sell the Turkish Government crude oil from the Iraqi pipeline in the amount of 10 million tons per year between 1977–79, 12 million tons per year from 1980–82, and 14 million tons per year in 1982 and thereafter. Construction of the pipeline and other facilities was expected to be completed within a period of 14 months. Mannesmann-Thyssen of West Germany was handling the entire project, covering a distance of 981 kilometers. Some 640 kilometers of the pipeline was in Turkish territory. Turkey and Iraq also agreed to set up a joint transport company to handle miscellaneous imports and exports. The proposed company planned to handle most of Iraq's imports from Europe via Turkey.

In June, the Turkish Government and the Soviet Union reached an agreement to increase the capacity of the Iskenderun steel plant from 1 million to 4 million tons per year, to expand the Seydisehir aluminum installations, and to set up two lignite-fired thermal powerplants with a capacity of 400 megawatts each in Cannakale and Bolue Provinces. New areas for the expansion of economic technical cooperation between the two countries were under consideration, and a 10- to 12-year loan of approximately $600 million for the machinery, material, and equipment was to be provided by the Soviet Union. Turkey was to reimburse this loan by exports to the U.S.S.R. A joint committee was to be established to improve the management of economic and technical cooperation between these two countries.

The United Nations Development Program (UNDP) agreed to assist in the exploitation and development of uranium deposits in the southwestern part of Turkey. The project was to be carried out by the State-owned Maden Tetkik ve Arama Enstitüsü (MTA), the Mineral Research and Exploration Institute of Turkey, assisted by the Turkish Atomic Energy Commission, the Turkish Coal Enterprise, and Etibank, under the coordination of the Ministry of Energy and Natural Resources.

Mining activities in Turkey were governed by Mining Law 6309, enacted in 1954, Petroleum Law 6324 of 1954, and the amended Petroleum Reform Law 1702, of 1973. The bill to nationalize the extraction of boron, lignite, and other unspecified strategic minerals, which was drafted and revised by previous governments, had not yet been approved by parliament.

Exploration programs for base metal anamolies were continued and mineral water resources were catalogued by MTA. In 1975, on the basis of MTA's surveys, detailed geological and hydrogeochemical studies of the geothermal fields, geophysical resistance studies and gradient drilling, a pilot turbo generator of 0.5-megawatt capacity was installed in the Denizli-Sarakoy area.

PRODUCTION

Table 1 gives the production of primary minerals and processed metals and nonmetals.

TRADE

Ending a long-standing controversy between British Petroleum Ltd. and Mobil Oil Turk A.S. on the import price of crude oil, the Turkish Government announced in April that it had reached a provisional equitable solution with the companies. The agreement reportedly gave British Petroleum and Mobil Oil Turk the rights to import 36° API crude oil at $10.50 per barrel on terms of a 3-month credit. The agreement also gave the companies the right once again to distribute their products in Turkey, and exploration rights were given to British Petroleum.

Turkey in 1975 reported a severe trade deficit of $3.3 billion. Imports, led by machinery ($1.3 billion), crude petroleum ($811 million), and iron and steel ($679 million), reached $4.7 billion, an increase of 25%, over the 1974 import bill. Exports during the same period fell 8.6%, to $1.4 billion.

COMMODITY REVIEW

METALS

Aluminum.—Turkish bauxite deposits, located mainly in the Taurus mountains, were estimated to contain 400 million tons of 46% Al_2O_3 reserves. Only the Konya-Seydisehir deposit was in active production during 1975 while the Gaziantep-Islahiye, Hatay-Iskenderun, and Isparta deposits remained dormant. Bauxite production for 1975 was 14% below that of 1974 while aluminum production was the highest recorded for Turkey.

Seydisehir Integrated Aluminum plant (SIA) operated below capacity during the year due to the energy shortage. The cost of the Soviet financed plant, operated by Etibank, had tripled since the 1960 estimates. Also the plant suffered from slow deliveries of equipment, construction difficulties, and sharply increased prices on caustic soda and petroleum coke.

Antimony.—The antimony deposits of Turkey with estimated total reserves of 900,000 tons are found in four districts. Only the Tokat-Turhal District deposits were mined in 1975. The reported proven reserves were 124,000 tons with an antimony content ranging between 11% and 13%. Proven antimony reserves of the other three districts were as follows: Katahya-Simva 300,000 tons of 4% to 5% Sb; Balikesir 305,000 tons of 5% to 6% Sb, and Nidge-Grumusler 100,000 tons of 5% Sb content. Production of antimony in Turkey decreased 39% in 1975 compared with 1974 output.

Chromite.—Chromite ore production reached a new historical high in 1975 due to high prices and market demand. A total of about 941,000 tons of run of mine ore was produced during the year, of which 648,000 tons were from private mines and the remaining from State-owned Etibank mines. Etibank's Antalya ferrochrome plant produced at full capacity, 10,000 tons for the year. Some was used domestically and the remainder was exported to Western European steel mills. Establishment of a ferrochrome plant near Mardin in Elâzig Province with the technical and financial assistance of Metals and Chemicals Co. of Japan proceeded on schedule in 1975. Etibank, the sole owner of the Elâzig ferrochrome plant, expected high-carbon ferrochrome production to begin in 1977. At full-capacity production, the Elâzig plant would produce 50,000 tons of ferrochrome per year.

Copper.—The worldwide slump in copper prices affected both the private and public sectors copper production which showed a 9% decrease in 1975 output. Karadeniz Bakir Isletmeleri A.S. (KBI), (the Black Sea Copper Company), at Samsun, owned 49% by Etibank and the remainder by private Turkish banks, did not achieve its full capacity. When fully operational the Samsun flash copper smelter was to produce 41,000 tons of blister copper, 365,000 tons of sulfuric acid, 11,000 troy ounces of gold, and 210,000 troy ounces of silver per year. The complex was equipped with a 8,000-ton-per-day capacity slag cleaning plant.

Proven ore reserves in some of the copper bearing deposits were as follows: Ergani, copper-pyrite ore, 12 million tons; Cakmakkaya, copper-pyrite ore, 98 million tons; Damar, copper-pyrite ore, 92 million tons; Lahanos, copper-pyrite-zinc ore, 12 million tons; Cayeli, copper-pyrite-zinc ore, 25 million tons; Kure, copper ore, about 2 million; and Madenkoy, copper ore, 15 million tons.

Iron Ore.—Iron ore production in 1975 was 2.2 million tons, a decrease of 1.2% compared with that of 1974. Approximately 1.3 million tons of the total output was from the State-owned Divrigi mine in Central Turkey. Due to inflation, the cost of the iron ore concentrator and pelletization plant was increased from an estimated \$26 million in 1970 to \$138 million in 1975 as the feasibility study had indicated. The 2-million-ton-per-year roasting plant and 1.6-million-ton pelletizing plant were expected to be completed by 1976. Energy requirements at the mine and pelletizing plant were to be met by a new 180-megawatt thermal powerplant to be erected at Kangal. The thermal plant was to utilize lignite from a newly discovered 150-million-ton deposit in Sivas Province.

Feasibility studies continued on the Hassan Celebi iron ore deposits, which contained an estimated 306 million tons of iron ore with grades ranging from 28% to 48% iron.

Iron and Steel.—Crude steel production, including castings and pig iron, increased 13% in 1975 compared with that of 1974. A third Turkish iron and steel plant at Iskenderun, financed by the U.S.S.R., was officially inaugurated in 1975 in the presence of Soviet officials. The plant was expected to produce 2 million tons of steel per year when in full production. However, the management announced that new agreements with the Soviet Union had been reached to increase production capacity 50%. In 1975, the plant employed 14,000 workers and produced 200,000 tons of pig iron.

Colakoglu Metalurgi Co. installed a concast three-strand continuous billet caster in August. The machine was able to cast billets of 75 to 130 square millimeters. A similar concast machine was due to go into production in 1976 at Electrofer Celik Sanayii. Meanwhile, a Demag single-strand billet caster, delivered to Elektro Metal Sanayii in 1971, was due to go in full operation by 1976. This machine, with a capacity of 30,000 tons per year, could produce billets 80, 100 and 120 square millimeters in a variety of grades including spring, stainless, and tool steels. A concast slab caster was also in the process of being installed at the Eregli steel mill with an expected date of production in 1976.

A fourth integrated steelworks was planned for construction at Elâzig. The project was supported by Makina Va Kimya Endüstrisi Kurumu the State-owned machinery and chemical concern which already operated a steel plant at Kirikkale. No information was available on the financing or shareholders by the end of 1975.

Lead and Zinc.—Cinku-Kurusum Metal Sannayii of Turkey (CINKUR) continued mining in the Zamanti Valley and created stockpiles for further processing. The zinc smelter, owned 47% by Etibank and the remainder by private investors, was not completed at yearend 1975. However, trial runs were made and mid-1976 was given as the full production date. The CINKUR smelter was to process 238,000 tons of mined lead-zinc ore per year and was to produce 40,000 tons of zinc and zinc products. Production of lead and zinc in 1975 was 17% less than 1974 output.

Manganese.—Because of higher demand for manganese in international markets during 1975, Turkish manganese producers, in both the private and public sectors, produced about 34,000 tons of manganese ore, a 10-fold increase compared with 1974 output. Most of the manganese produced was metallurgical grade ore, which was consumed locally or exported to Western Europe.

Mercury.—Etibank's Sizma and Holikoy mercury mines in southwestern Turkey produced about 93,000 tons of ore, 39% below that of 1974. However, intense mapping and geochemical prospecting continued at Etibank's newly acquired 1,000-hectar Bolali concession in Usak Province. By yearend no progress reports were available.

Mercury consumption in the industrialized nations was sharply down in 1975 following reports of mercury pollution. Turkish representatives participated in a conference held in Geneva, Switzerland, to solve the problem of severe price drops of mercury on the international market by prorating production and exchanging data.

Tungsten.—Total reserves of Turkish tungsten deposits were reported to be about 15 million tons; Bursa-Uludag estimated at 14.5 million tons with 0.3% WO_3 and Elâzig-Keban District 0.5 million tons with 0.5% WO_3. Etibank, the sole owner of the Bursa-Uludag deposit, continued mine development and construction of a concentrator in the foot hills of Uludag during the year. Delays, caused by a fire and slow equipment delivery, postponed the production date from 1976 to early 1977. The concentrator was designed to treat sheelite, the typical ore of the Uludag deposit, at a rate of 560,000 tons per year. Reportedly, the estimated cost of the entire project earmarked at $26 million in 1974 was to increase because of worldwide inflation.

Uranium.—MTA's uranium and thorium exploration program continued during the year. The construction of a small pilot plant to process and enrich uranium ore found in western Turkey continued. Etibank, the owner of the plant, expected partial production in 1976. Other details on the operation were not available.

NONMETALS

Asbestos.—Production of asbestos, mostly chrysotile, remained about 16,000 tons in

1975. Turkish exports of asbestos in recent years have been nil because most of the asbestos production was consumed locally. In 1975, Amyan Sanayii A.S., which owned the concession rights at Mihaliceik, East Eskisehir, announced a tentative plan to build a plant with a 10,000-ton-per-year capacity by 1977, and to further expand the plant eventually to a 30,000-ton-per-year capacity. The plant was to process ore for both the local and export markets.

Barite.—Turkish barite deposits, with estimated total reserves of about 10 million tons, were located at Kahraman, Maras, Aksehir, Sarkikaraagac, Alanya, and Tavsanli. However, Barit Maden Turk A.S. (BMT) was the sole producer of barite in 1975. A new decision by the Government of Turkey required all barite producers to export their product in packaged ground form after yearend 1976. During 1975, until the grinding facilities were installed at the mine, BMT could export only 75% of its product in lump form.

Production of barite decreased 78% in 1975, partially because of governmental restriction and partially because of lower world demand and acute competition.

Boron.—Published figures indicated that total reserves of boron minerals in Turkey were about 490 million tons, which constituted more than 50% of world reserves. However, Turkey produced less than 20% of world boron supplies in 1975. Etibank, the State-owned banking and mining organization, mined and processed most of Turkey's boron mineral and derivatives, while private companies controlled the small remainder. Construction of Etibank's processing plant, which was to produce 180,000 tons of pentahydrate borax, 60,000 tons of anhydrous borax, and 17,000 tons of dehydrate borax per year, continued during the year. Furthermore, Etibank announced the construction of a second boric acid plant with a 100,000-ton-per-year capacity, a second sodium perborate plant with a 20,000-ton-per-year capacity, an alpha-hemihydrate plant with a 25,000-ton-per-year capacity, and a hydrogen peroxide plant with a 20,000-ton-per-year capacity to be completed by 1978. The estimated cost of these new installations was not available by yearend 1975.

Cement.—Cement production in Turkey showed a substantial increase in 1975, reaching a new high of 10.8 million tons compared with 8.9 million tons in 1974. The production increase was in line with predictions made in the 5-year plan. The European Investment Bank (EIB) provided a loan of $7.7 million for the construction of a cement mill at Yozgat, Central Anatolia. The capacity of the Yozgat cement plant was to be 500,000 tons per year of portland cement beginning in 1977. The project was to cost $25 million and was established by Yozgat Isci ve Sanayii A.S., a joint stock company especially formed in 1973 to provide a means by which Turkish workers employed abroad could channel their savings into production investments. In 1975 there were about 7,000 shareholders and these were expected to increase to 10,000.

Fertilizer Materials.—Etibank proposed a major capital investment project for the Karatas phosphate deposit in 1975. The project would require a total investment of $6.5 million of which about $1 million would be for equipment to be purchased abroad, and the remainder for development, mining, and extraction at the mine site. A major extension of Azot Sanayii's fertilizer complex at Samsun was commissioned, which made this installation the largest phosphate fertilizer complex in the country. Supplied and constructed by Davy Powergas of West Germany, production capacity of the complex was 1,450 tons of fertilizer per day. The plant employed Olin/Chemiebau technology and was to use Moroccan and Tunisian phosphate rock. By yearend 1975, total Turkish phosphate fertilizer production reached 200,000 tons, and during 1975, 110,000 tons was imported.

Magnesite.—The major magnesite deposits with a reported 17 million tons total reserves were located in Eskisehir, Konya, Denezli, Sivas, Erzincan, Kütahya, Mugla, and Bursa. Magnesite Anonim Sirketi Magnent Ltd., the most important producer, exported 45,000 tons of dead burnt magnesite in 1975. Total magnesite production by various companies was about 459,000 tons which was 12% less than the 1974 output. It was announced that Turkey's annual refractory brick requirements were 53,000 tons in 1973 and were to increase to 142,000 tons by 1985. The refractory brick plant at Konya, operated by the Government, was expanded to a 33,000-ton capacity.

Perlite.—Perlite production was estimated at 11,000 tons, a decrease of about 41% in 1975 compared with that of 1974. Turkey, a newcomer to the international perlite market, was not able to increase its exports, due to stiff competition in prices as well as in transportation. However, perlite producers were optimistic about the future export trade in perlite and their penetration into the market.

Pyrite.—Cupreous pyrite production decreased 69% compared with that of 1974. The decrease was attributed to sluggish copper markets in the Western World and decreased activities in copper production in Turkey. West Germany remained, as in the previous year, the main importer of Turkish pyrite, in exchange for processing it on a barter-like basis.

Salt.—Because of increased domestic consumption and exports of salt, principally to Cyprus, salt production reached a new high of nearly 740,000 tons in 1975. Most of the salt came from the rock salt mines in Anatolya, where some good-quality deposits had been reported. One of the major areas for rock salt consumption was in the tanning industry, where Turkey led among most of the Middle Eastern countries.

MINERAL FUELS

The new Iraq-Turkey petroleum pipeline, which was to give Iraq a new market and security in transit, was almost finished in 1975. The 640-kilometer, 40-inch pipeline from the Kirkuk Field complex in Iraq to the Turkish Iskenderun Bay on the Mediterranean was to be completed by yearend 1976. The pipeline, which was built by Mannesmann-Export Co. of West Germany, was to have an initial capacity of 500,000 barrels per day with an expected peak capacity of up to 700,000 barrels per day. Turkey was to buy 200,000 barrels daily of Iraqi crude from 1977 through 1979, with an option to expand the Turkish offtake to 280,000 barrels per day when the pipeline capacity expands. Iraqi petroleum authorities agreed to pay Turkey a transit fee of 35¢ per barrel for a 20-year period, starting with the transmission of crude.

The Iraq-Turkey pipeline was to extend 341 kilometers from the Kirkuk Field to the Turkish border, and 640 kilometers through Turkey from east to west, crossing the Tigris and Euphrates Rivers to the Mediterranean coast. Turkey was to pay $300 million of the expected $435 million total cost of the project. Feasibility studies on a 2-billion-cubic-feet-per day natural gas pipeline to transport Iraqi natural gas to Istanbul, Turkey, and possibly on to either Europe or the Soviet Union continued and no decision was made by yearend.

According to Türkiye Elekterik Energisi Tüketim Tahminleri, the first nuclear powerplant to produce electricity in Turkey was expected to start operating by 1985. Construction of the plant at Eregli by the Sea of Marmara began in 1975 but the heavy construction was hampered by foundation problems.

Coal.—The Afsin Elbistan lignite project, including an opencast lignite mine and a thermal powerplant, experienced financial difficulties during the year. Reportedly, details of the terms of financing had to be worked out between the World Bank and Türkiye Elektrik Karumu Genel Müdürlugu (TEK), (Turkish Electric Power Directorate General). The cost of the entire project was estimated at $500 million. Mining responsibilities were to be with the Türkiye Komur Isletmeleri (TKI), (Turkish Coal Works). The Elbistan lignite deposit was estimated to contain about 3 billion tons of lignite. TKI planned to mine 20 million tons of lignite annually of which 17.5 million tons were to be used in the power generation plant and 2.5 million tons for other domestic fuel requirements. Initial production of lignite was scheduled for 1978. The powerplant was designed to have four 300-million-watt units with other basic accessories.

Bituminous coal production by both private and the public sectors decreased 2% in 1975 compared with 1974 output, while lignite production in both sectors increased 6% in 1975. Although coke production registered a slight increase, Turkey was obliged to import coke for its growing steel industry from abroad and apparently was to do so in the coming years. Türkiye Demir ve Celik Isletmeleri, the Turkish iron and steel industry, proposed that the Iskenderun steel mill would have to import 1.2 million tons of metallurgical-grade coking coal for its operation in 1977.

Consumption information on bituminous

and lignite coal and coke was not available; however, it is thought that sale figures gave a good indication of domestic consumption. In the following tabulation, data on production and sales for 1974 and 1975 are given in thousand tons:

	Production		Sales	
	1974	1975	1974	1975
Bituminous coal	8,511	8,109	4,708	4,594
Lignite [1]	7,666	8,433	7,600	8,200
Coke	1,214	1,242	640	438

[1] Data do not agree with that shown on table 1 because of difference in source: Turkiye Komur Isletmeleri Kurumu.

Petroleum.—Türkiye Petrolleri A.O. (TPAO), a State-owned Turkish petroleum company, was evaluating the results of seismic and magnetic surveys carried out early in 1975. Reportedly, on the basis of this evaluation TPAO was to spot some wells in the Turgut and Bolgi areas in 1976. TPAO also made a seismic, gravity, and magnetic survey over 5,318 square kilometers in the Mediterranean offshore area during the year. A similar survey with an international group was planned for 6,000 square kilometers of the eastern Mediterranean during the 1976 exploration season.

A group of five companies headed by Marathon spudded a well in the Sea of Marmara. However, after drilling to a depth of about 7,500 feet, the well was abandoned and by yearend 1975 Marathon had surrendered to the Turkish authorities its entire block of eight exploration licenses in the area.

TPAO's research vessel *Sisimik* carried on preliminary exploration work in the Mediterranean during the year. However, actual offshore drilling was postponed because of still unsolved problems between Greece and Turkey. By yearend both countries were hopeful that, by putting the whole problem before the International Court at The Hague, some workable solution acceptable to both parties might be worked out.

During 1975, Turkey obtained 73% of its petroleum imports from Iraq, 15% from Libya, and the remainder from Saudi Arabia, Egypt, and other countries.

Badger Turkey Ltd. was awarded the contract for the refinery expansion of Istanbul Petroleum Refining Co. (IPRAS), a wholly-owned subsidiary of TPAO. The $70-million project was to increase capacity of the refinery at Yarimca, near Izmit to 13 million tons per year. Atmospheric crude distillation, naphtha reforming, kerosine, diesel, desulfurization, and other units were to be added to the refinery by yearend 1976.

Turkish imports and exports of crude petroleum and refinery products, in thousand tons, for the year 1975 are given in the following tabulation:

	Imports	Exports
Crude petroleum	9,600	--
Naphthalene	--	88
Supergasoline	--	143
Regular gasoline	--	117
Jet fuel	--	95
Diesel oil	103	11
Fuel oil No. 6	292	--
Liquefied petroleum gas	149	--
Lubricants	77	--
Paraffin and others	6	--

The Mineral Industry of the U.S.S.R.[1]

By V. V. Strishkov [2]

The U.S.S.R.'s completely nationalized economy maintained its position as the world's second largest producer of industrial products in 1975. In the Soviet Union, 1975 marked the end of the ninth 5-year plan for 1971–75. The following production increases, compared with 1974, have been reported, in million tons: Raw coal and lignite, 16.9; oil (including condensate), 32.1; iron ore, 8.0; pig iron, 3.1; crude steel, 5.0; finished rolled ferrous metals, 4.3; steel pipe, 1.0; mineral fertilizers, 2.6 (100% content); and cement, 6.8. Electric power output increased 62,200 million kilowatt-hours. Output of many nonferrous, rare, and precious metals, oil refinery and petroleum products, and nonmetallic minerals was higher than in 1974. In 1975, the annual plan for production of some mineral commodities was met, but for iron ore, pig iron, raw steel, rolled ferrous metals, aluminum, gold, copper, nickel, and other metals, production failed to meet even the reduced growth rate set for 1975.

The U.S.S.R. is the world's leading producer of petroleum, raw steel, iron ore, manganese ore, chromium, potassium salts, phosphates, and cement. It holds second place in the production of gold, platinum-group metals, aluminum, natural gas, and fluorite, and it is one of the leaders in the output of copper, nickel, lead, zinc, tungsten, molybdenum, mercury, and native sulfur.

Despite impressive gains in mineral production, as reported in the Soviet press, the efficiency of planning and production has left much to be desired, judging from consistent reports of the failure of output of mineral commodities to reach planned goals and to supply industrial needs. New goals were planned for the 1971–75 period, with efforts directed chiefly to fulfilling quantitative targets in the mineral commodities; a considerable part of industrial output did not meet Soviet standards of quality.

The U.S.S.R. Ministry of Ferrous Metallurgy was unable to fulfill the 1975 plan for production of many types of products, but the gross index in tonnage and value in rubles was fulfilled. Consuming plants, construction projects, transportation, industry, and agriculture did not receive many of the particular products ordered. Insufficient production of high-quality special steel required for such items as aircraft, nuclear reactors, and tubing and the shortage of many shapes of ferrous rolled products compelled the machine building industry to resort to the use of expedients. This was reflected in the quality of machines and led to excessive use of metal, a significant part of which was transformed into shavings.[3] The U.S.S.R. imported ordinary steel sections, steel pipe, and special steel from Japan and various Western countries.

With a total population of 255.5 million in January 1976, the Soviet economy (excluding agriculture) employed 102.2 million workers and employees. From 1955 to 1974 the number of women workers and employees more than doubled, and in 1974 it comprised 51.2 million. The number of women working in industry increased at a faster rate than the number of men. This resulted in the growth of the share of women working in industry from 45% in

[1] This publication is based on a review of the sources published by the U.S.S.R.

Pravda, Moscow. Sept. 24, 1975, p. 1.

1960 to 49% in 1974.[4] The average length of service of the Soviet woman as a worker, employee, or collective farmer increased from 28.7 years in the sixties to 35.5 years in the seventies.[5]

The Soviet ferrous and nonferrous industries employed over 3 million workers;[6] the ferrous industry alone accounted for about 2 million "production" workers and some 75,000 university graduate engineers and 125,000 graduate technicians. There were about 2.2 million employees in the coal industry, including 61,500 graduate engineers and 141,000 technicians. The oil, gas, and petrochemical industries employed 2.6 million, including over 250,000 in the development of oilfields and gasfields.[7] Crude oil extraction occupied about 740,000 persons.[8] As a whole, according to Soviet sources, 69% of the graduate Soviet engineers performed various kinds of work not requiring specialized university training. For example, in the Ukrainian coal industry, about 1,000 graduate engineers and more than 16,000 graduate technicians were employed as workers in 1975. The work week in the U.S.S.R. was 41 hours for standard workers and 36 hours for underground miners.

Based upon published reports, it may be concluded that the expansion in the Soviet mineral industry continued to be achieved mainly through increased labor and capital rather than advancing technology. Evident shortages of mineral commodities were offset by efforts directed chiefly toward fulfilling quantitative goals, while less attention was paid to quality. The productivity of labor and equipment continued to be below planned levels. More than one-half of the machinery employed in the mineral industry was idle, owing largely to the quality of machines and the unsatisfactory supply of spare parts and materials at the mines and plants.[9] Much of the equipment used in the Soviet mineral industry is standardized and of a type now obsolete in West Europe and the United States. The manufacture of mining equipment has increased substantially, but the technical standards and quality of the equipment have fallen short of planned goals.

The Soviets are faced with enormous difficulties in trying to build a rational automated management system. One fundamental problem has been the absence of commensurate incentives. Prices are fixed and essentially the same throughout the country. Wages similarly are rigid and do not always reflect the worker's value on the job. In Western terms, prices reflect production costs or capital costs to a significant degree. Under these conditions, the difficulties of applying automated management systems are compounded.

At many mines and plants, up to one-half of the production workers were employed in manual labor, including surface loading and unloading. At polymetal mines in Kazakhstan, the proportion of mechanized labor did not exceed 34%, with the majority of auxiliary operations performed manually. In underground coal mining, over 50% of the workers were employed on nonmechanized tasks. Some 50% to 65% of the workers were engaged in ancillary jobs in all branches of the Soviet mineral industry in 1975.[10]

The turnover of personnel in individual mineral industry operations ranged from 25% to 80% per year. This was caused mainly by the delays in building houses and in providing public and medical services, by low material incentives, and by heavy manual work and unsafe working conditions.[11] At certain mineral industry operations, especially in the eastern regions of the country,[12] there were insufficient workers. To ease the shortage of labor, many employees were permitted to hold more than one job, and able-bodied pen-

sioners were encouraged to supplement their incomes by returning to active employment.

The output quota-bonus principle, once condemned as an exploitation of the worker, has become an important feature of the mining industry. Soviet labor legislation requires that workers achieve a minimum output within a given period. This minimum is the work norm and is established for virtually every phase of employment. In connection with a significant increase in output quotas at enterprises, there was a substantial increase in the share of workers who did not meet the new quotas established during the last 2 years. For some mineral industry enterprises it amounted to 15% and more in 1975.[13]

Although the trade unions in Western countries are principally wage-bargaining organizations, their Soviet counterparts function largely as an avenue for increasing labor productivity and fulfilling planned quotas. The unions operate the insurance system and also work with management on safety. Practically every worker, including the entire management team, belongs to the union.

While the U.S.S.R. does not publish comprehensive data on injuries in the mineral industry, available Soviet information and Western mining engineering experience indicate that fatality rates are significant. In 1974 fatal injuries occurred at 48% of the Soviet coal mines and at 3% of the metal mines.[14] For many years, the largest number of accidents occurred at production and development faces as a result of roof collapse. Accidents caused by roof falls were the result of inadequate support, mainly due to prop shortages. Accidents at metallurgical plants have been caused mainly by the low level of equipment repair and by violation of technological processes.[15]

The administration of Soviet coal mines, with the approval of trade unions, has often used overtime work to fulfill the planned quota of coal production, has sometimes required workers to work two shifts in succession, and has even required underground miners to work an 8-hour shift instead of a 6-hour shift, in direct violation of the labor law.[16]

The concentration of airborne dust at workplaces in underground mines of the Soviet Union is high and often exceeds the industrial health standard.[17] Sanitary facilities such as toilets, locker rooms, showers, and drinking water are few and considerably below the Soviet official standard. There were especially unsatisfactory conditions at the Kuznetsk metallurgical complex, at the Zhdanov coke plant, at the Belov zinc plant, and at the enterprises of the Northeastern gold administration.[18]

Soviet statistical agencies do not publish data on the actual earnings of workers in the mineral industry. The average monthly earnings of Soviet workers and employees in 1975 was 146 rubles,[19] compared with 141 rubles in 1974, an increase of 3.5%. In 1975 the raising of the monthly minimum wage from 60 rubles to 70 rubles continued in the North and Soviet Far East and in some European regions of the U.S.S.R.

Soviet total goods transported in 1975 and planned for 1980, by mode of transport, follow:

[19] Official exchange rate is 1 ruble=US$1.32 (January 1, 1976). Approximate buying power of 1 ruble relative to prices in the United States for hard goods and food according to some estimates ranges from about 20 to 50 cents. According to Soviet sources the actual value of the U.S. dollar is 3 times higher than the official exchange rate.

	1975 (actual)		1980 (planned)	
	Goods transported (million tons per kilometer)	Percent of total	Goods transported (million tons per kilometer)	Percent of total

Source: Ekonomicheskaya gazeta (Economic Gazette), Moscow. No. 4, January 1976, p. 1.

About two-thirds of the total tonnage of mineral industry products moved in the U.S.S.R. in 1975 was shipped by rail. The average distance of railroad deliveries in kilometers in 1975 was:[20] Coal and lignite, 698; crude oil and petroleum products, 1,242; iron and manganese ores, 715; nonferrous ores, 895; ferrous metals, 1,413; and mineral fertilizers, 1,059.

In many sectors of the economy, more fuels and metals were consumed per unit of production than is required with modern technology. Soviet machines, as a rule, are lower in quality and productivity but higher in weight. For example, oxygen converters with a capacity of 100 tons, manufactured by the Zhdanov Heavy Machine Building Plant, are 200 tons heavier than similar converters produced by Western firms.[21]

Although the available losses of mineral commodities are not known completely and have not been adequately quantified, estimates have been reported widely in the Soviet press. A careful study of Soviet publications shows, for example, that only about 45% of the total raw steel production is efficiently used in the Soviet economy; 55% is remelted or lost as a result of low technology in the iron and steel industry.

The U.S.S.R. Ministry of Power Machine Building was organized in 1975. The ministry will have responsibility for construction of machinery and equipment for nuclear and thermal powerplants. The ministry will also be concerned with the transfer of technology for power stations.

Government Policies and Programs.—Soviet mineral policy continues to be based on the principle of maximum self-sufficiency. With State-owned and State-operated enterprises, low-wage labor, and low consumption, the U.S.S.R. has become the most self-sufficient of the world's leading industrial nations. In the Soviet economy, the selling price of a given commodity may be set at any reasonable level to yield the desired overall results; thus some mineral ventures in the Soviet Union might well be uneconomic by Western standards. Mineral development, as the basis of industrial growth, holds a key place in the Soviet economic policy. Very large sums are spent on mineral exploration and production, and the funds are distributed over a dozen specialized ministries.

The balancing of the Soviet economy is not possible in a pattern associated with a Western-style economy and can only be achieved by Government intervention or control through subsidies and similar measures. The U.S.S.R.'s 5-year plan and the year-to-year plans set a definite program for all mineral and energy resources. In addition to the national priorities and goals set for each industry, the plan is also law and carries mandatory obligations.

Considerable attention was being devoted to economic integration and industrial cooperation of the COMECON countries,[22] which makes East Europe, Mongolia, and Cuba more dependent upon the Soviet mineral industry. A program for economic integration over the next 15 to 20 years was adopted by the 25th Session of COMECON, which was held in Bucharest in July 1971. The eight COMECON nations regard the coordination of 5-year plans as one of the basic methods of planned cooperative development. Since 1949, the aims of COMECON have been

[20] Zheleznodorozhnyy transport (Railroad Transportation), Moscow. No. 3, March 1976, p. 35.

[21] Ekonomika Sovetskoy Ukrainy (Economics of the Soviet Ukraine), Kiev. No. 9, September 1975, pp. 11–16.

[22] COMECON—Council for Mutual Economic Assistance (CMEA) comprising the following countries: Bulgaria, Cuba, Czechoslovakia, East Germany, Hungary, Mongolia, Poland, Romania, and the U.S.S.R.

to increase the economic growth of member countries.

The 29th Session of COMECON held in Budapest in June 1975 concentrated primarily on closer integration of economic plans for the 1976–80 period and the specialization of industrial production. The Plan for Multilateral Integration Measures for the COMECON countries incorporates, among other Soviet projects, the joint construction and financing of the Kiyembay asbestos complex, the Orenburg gas condensate field, the gas pipeline from Orenburg to the Soviet Western border, the 750-kilovolt transmission line from Vinnitsa to the Hungarian border, and new facilities for iron ore mining and petroleum refining elsewhere in the Soviet Union. Reportedly, the total investment in joint projects involves about 9 billion transferrable rubles by participating COMECON countries with repayment in raw materials produced (asbestos, iron ore, natural gas, petroleum, and electric power).

The Kiyembay complex is to produce 500,000 tons of asbestos annually. The completion of enterprises for production of ferroalloys and processing of raw materials containing iron should make it possible for the U.S.S.R. to increase the deliveries of iron and iron ore 25% in 1980 over the 1975 level. When the Orenburg natural gas pipeline is put into operation, deliveries of Soviet natural gas to COMECON countries are to amount to 15,500 million cubic meters annually.

Actual and estimated consumption of fuel and power in COMECON European countries to the year 2000 is given in table 1.

According to COMECON agreements on economic integration, intra-COMECON trade is expected by 1980 to increase about 75% over that of 1975. The structure of Soviet exports to COMECON countries is "not entirely satisfactory." Although the Soviet Union is the greatest industrial power in the "socialist camp," its imports of machinery and equipment from COMECON countries are twice its exports to them.[23]

Under the long-range plan, there is to be progressively more integration of COMECON country plans, with an expected reduction of national independence. The management of economic assistance among COMECON nations is facilitated through the International Bank for Economic Co-operation and the International Investments Bank, a Soviet institution, which financed 39 projects. Of the funds allocated so far, 40% have been used in the metallurgical industry, 37% in engineering, and 11% in the chemical industry.

Yugoslavia is not a member of COMECON, although a 1964 agreement laid the foundation for Yugoslav participation. (It has observer status in half of COMECON's 24 commissions.) A protocol for the continuation of Soviet-Yugoslav economic and technical cooperation in 1976–80 was signed in July 1975. Both North Vietnam and North Korea also have observer status in the COMECON commissions.

At its 27th session, the COMECON Assembly ratified the agreement concluded in May 1973 for cooperation with Finland. In 1975, the initial cooperation agreements were concluded between COMECON and the developing countries Iraq and Mexico.[24] According to Soviet sources, Argentina and Colombia also intend to

[1] 1 ton of standard coal equivalent (SCE) =7,000,000 kilocalories.

collaborate with COMECON. COMECON is negotiating a proposal for the establishment of formal relations with the European Economic Community (EEC) as well as between the EEC and individual COMECON countries.

On July 9, 1975, the Supreme Soviet approved a new resource conservation law "Fundamental Principles of the Legislation of the U.S.S.R. and the Union Republics on Mineral Wealth." The legislation, which came into force on January 1, 1976, reflects the basic principles of the exclusive ownership of mineral resources by the State and specifies the task of enterprises, organizations, institutions, and citizens in this field. Those placed in charge of mineral resources are required to ensure a rational utilization of mineral resources with minimum losses and to prospect for minerals. Much attention is given in the legislation to the comprehensive use of mineral resources and to reclaiming land where mining has taken place. The basic principles of the legislation proceed from the need to enhance the role of planning and controlling State bodies in ensuring a rational use of mineral resources.[25]

Because of limited availabilities of good-quality mining machinery, the U.S.S.R., in an attempt to speed up development of mineral resources, is showing increasing interest in "joint" development ventures and in the exchange of scientific and technical services with foreign countries and Western firms. While the law prohibits any direct foreign capital investment in the U.S.S.R., the Soviet Union is anxious to attract West European, U.S., and Japanese firms to participate in "joint" production and marketing. Foreign investors are invited to develop deposits and to construct plants in the U.S.S.R., and repayment is promised in the form of commodities produced by these operations. The joint ventures should give the Soviets help with one of their biggest problems: The efficient introduction and application of new technology.

West German firms are designing the 2,500-million-Deutsche mark (DM) ($1,080 million) Staryy Oskol steel works in Belgorod Oblast'. Reportedly, Salzgitter AG is responsible for the 4-million-ton ore-pelletizing plant. Fried. Krupp GmbH is working on the electric steel mill, and Korf Stahl AG is designing a direct-reduction unit for 2.5 million tons of sponge iron. Recently, an agreement was signed between Japan's Sakhalin Petroleum Development Cooperation Co. (SPDC) and the Soviet Union under which SPDC will provide financing of $152.5 million for the joint development of oil and natural gas resources on the Continental Shelf off Sakhalin Island.

According to an October 1973 agreement, Finnish companies are building the joint Kostamus iron ore complex in Soviet Karelia about 30 kilometers from the Finnish border. This project is to be built in three stages and is to have an annual capacity of about 8.3 million tons of pellets (24 million tons of crude ore). Preliminary estimates show that the total project will cost about $600 million. Also, the Allis Chalmers Co. has received a $35 million contract for a two-line iron ore pelletizing plant to be built near Kremenchug in the Ukraine.

The U.S.S.R. and Japan have reached an agreement on joint development of a coal deposit in Yakut A.S.S.R. In repayment for machinery and equipment, Japan will receive South Yakutsk coal for 20 years. By 1986, annual exports will exceed 5 million tons. The Soviet firm Machinoimport signed an agreement with Japan Sumitomo Shoji Kaisha, Ltd., for ten 26-cubic-yard superfront Marion power shovels for the Yakutsk coal project. The excavators will be manufactured in Japan. The Austrian Oil Administration, German Ruhrgas, and Gaz de France recently concluded a basic contract concerning the construction of a natural gas pipeline through Austria which is to supply France and Upper Austria with natural gas from the Soviet Union and Iran.

The Soviet Union has been negotiating with West European, U.S., and Japanese companies to develop the Udokan copper deposit in East Siberia. Discussion on participation of U.S. and Japanese firms in a $400 million preliminary exploration of natural gas in Yakut A.S.S.R. continued in 1975.

The top three Western suppliers of machinery and equipment to the U.S.S.R. are West Germany, Japan, and France, but some of this trade involves U.S. companies with branches in West Germany,

[25] Pravda, Moscow. July 10, 1975, p. 1.

France, Japan, and other countries. Reportedly, Pullman Inc. and its subsidiary M.W. Kellog are building 13 ammonia plants through licensees in Japan and France. Computer companies are selling through subsidiaries in France and West Germany. A General Motors licensee in Japan has sold logging equipment, and General Electric has provided pumps and compressors through wholly owned plants in France.

In 1975, the Soviet Union ordered 50 pumps, valued (together with spare parts) at about DM10 million ($4.3 million) from KHD Industrieanlagen AG Humbold Wedag. Seventy such pumps are already used in the mines of Yakut A.S.S.R. Norway's Akker group is negotiating with the Soviet firm Sudoimport for the sale of two semisubmersible (Akker H–3 600-foot capability) drilling platforms for offshore drilling in the Caspian Sea.

The Soviet Union continued to sponsor an active exchange program. According to J. M. Gvishiani, deputy chairman of the U.S.S.R. State Committee for Science and Technology, the Soviet Union has signed 170 scientific and technological agreements with industrial corporations in the West. Some 38 of the agreements were made with U.S. companies.

A Long-Term Program for the Development of Economic and Industrial Cooperation between the U.S.S.R. and the United Kingdom was signed in February 1975. The Soviet Union is interested in coal, iron and steel, and equipment for roadbuilding and for the oil refining and petrochemical industries. The program also included the possible development of the Udokan copper deposit. A 10-year Soviet agreement on economic, industrial, and technological cooperation was signed with the Netherlands in July and with Denmark in August 1975.

An agreement on scientific and technological cooperation was signed in October 1975 by the U.S.S.R. State Committee for Science and Technology with the Sandvik Co. of Sweden. The cooperation will include the production of machine tools and the manufacture of special steels. Reportedly, Phillips Petroleum (United States) has signed technical cooperation agreements with Soviet officials for exploration and production of petroleum.

Exhibitions in the U.S.S.R. play a key role in Soviet planning and purchasing of machinery and equipment. Western companies have the opportunity to meet Soviet planners, engineers and administrators to provide information about their equipment. For example, Metallurgimport has ordered a ripping machine for coal mine roadways valued at over $200,000 from Gullick Dobson International Ltd., United Kingdom. This machine was exhibited in Donetsk in August to September 1975. Prior to this order, Gullick Dobson had already sold nearly 150 low-incline-seam roof supports, which are operating in the Donets coal basin. The first Aluminum Exhibition was held in Moscow in July 1975. The Soviets showed great interest in Western machinery and production technology.

The Soviet Union encourages State-managed mineral resource development in the developing countries. The U.S.S.R. sends technicians and makes loans to countries willing to promote State development and distribution of fuels and minerals. Soviet technical assistance and economic aid programs include 420 projects [23] in about 70 countries at a cost of about 5 billion rubles. The Comecon International Investment Bank has established a special fund of 1 billion rubles to grant credits for economic and technical assistance to the developing countries. The fund began functioning in January 1974. This work is conducted through bilateral agreements as well as appropriate agencies of the United Nations. In many instances, the assistance to developing countries is linked with mineral supply to the U.S.S.R.

Iran and the U.S.S.R. have signed a cooperation agreement valued at about $3 billion. The Soviet-built steel plant at Isfahan, which currently produces around 600,000 tons per year of crude steel, is to be gradually expanded to approximately 8 million tons per year at a cost of $1,800 million. In May 1975, a Turkish delegation signed an agreement providing for Soviet technical aid in expanding the capacity of the Iskenderun iron and steel works from 1 million tons to 2 million tons annually. Soviet assistance to Portugal included developing the aluminum and ce-

[23] Ekonomicheskaya gazeta (Economic Gazette), Moscow. No. 8, February 1976, p. 1.

ment industries through exploitation of nepheline deposits, the renovation of a coal mine, and possible assistance in construction of the nation's first nuclear powerplant. About 100 Soviet specialists were engaged in exploration in Sri Lanka for petroleum and natural gas in 1975. Sri Lanka shipped 1,200 tons of ilmenite concentrate to the U.S.S.R. for test purposes.

A 10-year agreement on economic and technical cooperation was signed by the U.S.S.R. and Cyprus in October 1975. Copper concentrates will be shipped by Cyprus to the U.S.S.R. A Soviet-Argentine cooperation agreement includes the construction of metallurgical and chemical plants and shipbuilding and port equipment. Mexico and the Soviet Union concluded an intergovernmental agreement on scientific and technical cooperation in 1975.

The 1976 plan, which was approved by the Supreme Soviet on December 3, 1975, calls for an overall increase in industrial output of 4.3%, including a 4.9% increase in consumer goods output. According to the chairman of the State Planning Committee, the low industrial growth rate of 4.3% set for 1976 is due to a shortage of agricultural raw materials from the 1975 harvest.

Capital investment in 1976 was to total 116,800 million rubles, a 4% increase over that of 1975. Major investment areas will be the fuel-energy sector (7% over the 1975 level), ferrous and nonferrous metallurgy (a 10% increase), the chemical industry (a 25% increase), and the machine building industry (a 12% increase). It was planned to increase the average monthly earnings of Soviet workers and employees in 1976 to 150 rubles, or 2.7% over those of 1975. The monthly minimum working wage was to increase to 70 rubles in a number of areas.

Special attention in the 1976 plan (as in the 1975 plan) is to be focused on the fuel and power sectors. The generation of electric power is to be increased by 75 billion kilowatt-hours to 1,095 billion kilowatt-hours. Crude oil extraction (including condensate) is planned at 420 million tons, 29 million tons over that of 1975. The total increase in petroleum production in 1976 is to come from West Siberia, where extraction of 180 million tons of crude oil was planned. Natural gas output is to amount to 313 billion cubic meters, an increase of 24 billion cubic meters over that of 1975. The main sources of increase in gas production in 1976 are to be West Siberia and Orenburg Oblast'.

Raw coal and lignite output is to be 715 million tons, 14 million tons over the 1975 level; the main annual increase in production of coal is to be of surface-mined lower rank coals from Siberia and Kazakhstan.

Raw steel output is to be increased by 6 million tons to 147 million tons. Finished rolled metal production is to be increased by 4.4 million tons. Captal investment in ferrous metallurgy is to be increased 10% over that of 1975. The 1976 nonferrous metallurgy plan calls for increased production of aluminum, copper, lead, and nickel. The output of platinum-group metals, gold, titanium, magnesium, and rare and other nonferrous metals are also to be increased. The planned increase of nonferrous metals in Kazakhstan follows: Alumina, 1.7%; refined copper, 6%; titanium, 5%; and rolled nonferrous metals, 4.3%. The output of aluminum at the Regar plant in Tadzhik S.S.R. is to be increased 56%, and that of copper in Georgian S.S.R., 130% over the 1975 output levels. The 1976 plan envisages the production of 94.5 million tons (Soviet standard) of mineral fertilizers, an increase of 4.5 million tons.

Annual production capacities in 1976 were to be increased as follows, in million tons: Raw coal and lignite, over 10; primary refining of crude oil, about 6; iron ore, 1; pig iron, 0.9; and mineral fertilizers, 0.24. New facilities for production of pig iron are to be put into operation at the Kommunarsk works and of steel pipe at the Seversk plant. Facilities for primary refining of crude oil were to be commissioned at the Pavlodar (Kazakhstan) and Novo-Bakinsk (Azerbaydzhan) refineries. The increase in iron ore capacity is to be obtained by constructing new facilities at the Krivoy Rog Basin, Kachkanar, and the Dneprovsk mining and processing complexes.

The declining reserves of raw material and fuels in the European part of the U.S.S.R. have forced Soviet planners to give increased attention to the north and east of the country. Developing these re-

Table 2.—U.S.S.R.: Industrial production in 1975 and planned 1976

(Million metric tons unless otherwise specified)

Commodity	1975 Originally planned	1975 Newly planned	1975 Actual	1976 Planned

NA Not available.

serves will be difficult owing to extreme climatic conditions and will also necessitate large capital investment in railroad and pipeline for long-distance transportation.

The Soviets plan to boost foreign trade 13.6% in 1976. Trade with Western countries, which will be primarily based on barter transactions, is to continue mainly with West Germany, Italy, Finland, France, the United States, and Japan.

The tenth 5-year plan (1976–80) foresees an increase in gross industrial production of 36%, down both from the 47% scheduled for the 5-year period ending 1975 and from the 43% actually achieved. The plan calls for lower growth rates in every key economic sector, except foreign trade which is planned to increase 33.5% during the next economic period (about the same goal as for the past 5-year period). Actually, the U.S.S.R. increased its trade during the last 5 years more than 50%, and the major increase was with Western countries.

Efficient use of capital investment and improved labor productivity both have high priorities under the tenth 5-year plan. The basic tasks of the new 5-year plan are the more intensive use of equipment, raw material, and supplies; improvement of product quality, reliability, and service life; increased productivity of machines; and increased profitability. The plan foresees reduction in consumption of rolled ferrous metals of 14% to 16% by machine-building and metal-processing industries and 5% to 7% in construction, as well as not less than a 5% to 6% decrease in cement consumption.

Accelerated development is planned for energy and mineral fuel commodities. During 1971–75 the share of petroleum and natural gas in total Soviet fuel and energy production amounted to 75% or more; in the future, however, the share is to decline. The share of coal will increase, especially during the next 5 years, because nuclear power will still not be supplying a major share of energy.

The country's potential wealth in water resources has been estimated at approximately 1,100 billion kilowatt-hours (of which about 160 billion kilowatt-hours has been developed); water resources are to continue to be among the less important energy sources (less than 20%) in the fuel-energy balance.

The following data show the principal goals for individual mineral commodities in the new 5-year plan:

1. The generation of 1,380 billion kilowatt-hours of electricity in 1980 is planned and the commissioning of an additional 71 million kilowatts of capacity (including 13 million to 15 million kilowatts at nuclear plants) is planned during the 1976–80 period. Construction of nuclear plants continues to be in the European part of the U.S.S.R. It is planned to construct large hydropower plants on the Yenisey and Angara Rivers in Siberia and to build a number of hydropower plants in European U.S.S.R., in particular in the northern Caucasus and Transcaucasus.

The plan provides for greater use of coal and lignite in thermal powerplants to make oil and natural gas available for export. The major plants scheduled for construction are near the Ekibastuz (Kazakhstan) and Kansk-Achinsk (Siberia) coal basins.

2. In 1971–75, crude oil and condensate output increased 39% (compared with

a 42% projected increase) to 491 million tons. The new plan estimates a 30% increase to 640 million tons by 1980. Pipeline networks are to be expanded—mainly to bring oil from Siberia to the European part of the U.S.S.R. It is planned to raise the 1975 volume of primary oil processing 25% to 30% by 1980.

3. Natural gas production is to be increased 50% to 435 billion cubic meters in 1980. This figure is more realistic than the one for the 1971–75 plan, which called for 62% growth and reached only 42%. A 36,500-kilometer addition to trunk and branch gas pipelines is also planned. There is to be a special effort to increase construction of underground gas storage units near large cities.

4. Raw coal (bituminous, anthracite, and lignite) production in 1980 is to be increased 14.8% over the 1975 level. This would bring production from 701 million tons in 1975 to 805 million tons in 1980.

The main base for coking and high-energy coals in the European part of the country continues to be the Donetsk Basin. Coal production there should rise to 226 million to 229 million tons in 1985. The Kuznetsk Basin in Siberia and the Karaganda Basin in Kazakhstan will be further developed, and production there in 1980 should reach 288 million tons. The Ekibastuz coalfield in Kazakhstan will become a major energy base; construction is being completed there of the country's largest open pit, Bogatyr'. Total production of the Ekibastuz coalfield in 1980 is to rise to 72 million tons. Accelerated development of the Nerungra coalfield in the southern region of Yakutia and the Kansk-Achinsk Basin in Siberia are both major elements in the new 5-year plan. During this period, production of coal by hydraulic methods is to be doubled.

5. Raw steel production is to reach 168.5 million tons in 1980, with finished rolled steel products at 117.5 million tons. In the iron and steel industry, special attention is to be devoted to improving quality and expanding the range of products. Technical changes will include the increasing use of surface mining of iron ores, erection of a large (5,000-cubic-meter) blast furnace, and increasing the use of oxygen and natural gas in pig iron production. The plan calls for improvement in iron ore preparation and more extensive use of pelletization and continuous casting. Also, additional and large (up to 400-ton capacity) oxygen converters are to be installed, and output of oxygen-converter steel is to be increased. It is planned to commission the direct iron ore reduction plant, which is to be constructed by West German companies in Kursk Oblast'.

6. In nonferrous metals, the plan calls for a significant increase in production by completing projects now underway, increasing capacities at existing facilities, and developing new installations. Production of aluminum, copper, and nickel is to be raised 20% to 30%; titanium production is to increase 40%. There will be increases in the production of lead, magnesium, tin, tungsten, molybdenum, and precious metals.

Priority is to be given to raising the output of natural diamond and nonferrous alloy metals, particularly lead, zinc, copper, tungsten, molybdenum, and gold. A main task is to increase metal recovery, especally from complex raw materials. The amount of open pit mining is to be increased. There will be a major expansion of the Norilsk copper-nickel and platinum-group metals complex. New investment in the nonferrous industry is estimated at 9 billion rubles, 50% more than was planned in 1971–75.

Kazakhstan will continue to be one of the largest producers of nonferrous metals. Capital investment in the nonferrous mining industry there is set at 1,900 million rubles, almost 50% more than in 1971–75. Three-quarters of the funds will be used for the development of mines and the construction of beneficiation plants for the production of copper, lead, zinc, and aluminum. It is planned to complete construction of the Orlovsk, Karagalinsk, mining and concentration plants and the No. 65 mine of the Dzhezkazgan complex by 1980. Development of the Annensk, Tishinsk, and Zharemsk mines will continue after 1980. In 1976–80, construction of the first stages of the Akzhalsk, Chatyrkulsk, and Boshchekulsk mining and concentration units and the Krasnooktyabrsk and Belinsk bauxite mines in Kazakhstan is to begin. In 1980, output of refined copper in Kazakhstan is to be increased 25%, lead 13%, zinc 9%, alumina 10%, and titanium 28% over the 1975 levels.[27]

7. Output of mineral fertilizers is programed to grow to 143 million tons per year (Soviet standard) by 1980 (including 5 million tons per year of chemical feed additives), an increase of 53 million tons over 1975 production. The growth is to be achieved by commissioning over 150 new production installations.

8. Geological prospecting activities are given special attention in the new 5-year plan, largely for exploration for oil, natural gas, and condensate fields in the Central Ob Valley and in Tyumen Oblast', in East Siberia, Yakut A.S.S.R., and Komi A.S.S.R., in Archangel Oblast', and in Central Asia and Kazakh S.S.R. in the region of the Caspian depression. Special efforts will also be put into offshore exploration for oil and natural gas.

Prospecting for deposits of coking and energy coals and lignites (particularly in the European part of the U.S.S.R.), for easily concentrated ores for ferrous and nonferrous industries, for precious metals and diamonds, and for raw material for the nuclear energy industry and for the production of mineral fertilizers will continue in 1976–80.

9. In order to carry out this plan, large resources will be required. Capital investment in the U.S.S.R. for the next 5 years has been set at a level of 621,400 million rubles, compared with 480,000 million to 490,000 million rubles under the 1971–75 plan, 352,000 million for 1966–70 plan, and 210,000 million rubles for the 1961–65 plan. One of the most important developments under the new plan is the geographical shift in new energy projects. In the development in the regions east of the coming 5 years, there is to be accelerated Urals, particularly in Siberia and Yakut A.S.S.R., where new fuel and power centers are to be developed.

The level of Soviet industrial production in 1975 and as planned for 1980 is given in table 3.[28]

Table 3.—U.S.S.R. Industrial production in 1975 and planned 1980

(Million metric tons unless otherwise specified)

Commodity	Production		Increase	
	1975 reported	1980 planned	Quantity	Percent
Coal, raw (bituminous, anthracite, and lignite)	701	805	104	14.8
Petroleum, crude, including condensate	491	640	149	30.4
Natural gas ..... billion cubic meters	289	435	146	50.5
Steel, raw	141	168.5	27.5	19.5

Cement	122	143–146	21–24	17–20
Power, electric ..... billion kilowatt-hours	1,038	1,380	342	33.0

PRODUCTION

A Soviet decree dated April 28, 1956, classifies as State secrets all data on production capacity and production plans of nonferrous, precious, and rare metals enterprises as well as data on fulfillment of these plans. Since Soviet mineral statistics were not published in most cases, many of the data in the production table were estimated, and represent at best an order of magnitude. The Soviet Union reported an increase in industrial activity of 7.5% in 1975. This achievement exceeded the revised goal of 6.7% but remained below the 8.8% set in 1971 at the beginning of the 5-year plan. The increase in Soviet mineral production in 1975 was largely due to additional inputs of capacity and labor rather than to productivity gains.

Reportedly, 70 elements were produced in the U.S.S.R. in 1975. The Asian part of the U.S.S.R. (east of the Urals) provided about 45% of the total Soviet coal and lignite output, more than 30% of the natural gas, about 25% of crude oil, and around 30% of the electric power.

---

[27] Kazakhstanskaya pravda, Alma-Ata. Feb. 7, 1976, p. 2.
[28] Pravda, Moscow. Mar. 2, 1976, p. 4.

The Russian Socialist Federated Soviet Republic (R.S.F.S.R.) continued to rank first among the 15 Soviet Republics in mineral production. It produced over 80% of the gold and silver, practically all of the platinum-group metals, more than 80% of the petroleum, about two-thirds of electric power, over 50% of pig iron, steel, and rolled ferrous products, and roughly 50% of the coal and natural gas. The Ukraine continued to rank first in the output of coking coal, manganese, and iron ores, and second in natural gas. During 1971–75, Ukrainian production of secondary aluminum increased 86.3%; secondary lead, 35.7%; alumina, 15.2%; and rolled nonferrous metals, 26.7%.

The Asian Republic of Kazakhstan, one of the most important base metal producing areas in the U.S.S.R., occupied third place in Soviet mineral production and was the nation's leading producer of chromite, copper, lead, zinc, and rare metals. The Urals produced over 26% of total Soviet pig iron, more than 30% of steel, and about 29% of ferrous rolled metal. The Ural-Volga region produced nearly one-half of the nation's total crude oil output. Most of the U.S.S.R.'s increased petroleum production was, however, derived from the West Siberian Fields.

The irregular geographical distribution of iron ores and ineffective planning of the development of the deposits led to long and expensive railroad shipments. For example, the ore from the Kola Peninsula, the Kursk region, and Krivoy Rog Basin is delivered to metallurgical plants in the Urals, a distance of 1,950 to 2,500 kilometers; the annual cost of railroad transportation amounted to hundreds of millions of rubles.[29] The Magnitogorsk, Novokuznetsk, and Nizhniy Tagil plants, where half of the Soviet pig iron is produced, have been relying on distant sources of ore for 50% of their requirements.[30] For 45 years, iron ore from the Magnitogorsk deposit in the Urals has been used by the Magnitogorsk complex and also has been shipped to Siberian metallurgical plants, a distance of about 2,000 kilometers. This deposit has been practically depleted, and now iron ore from the Magnitogorsk metallurgical complex, the largest in the U.S.S.R., is being transported more than 2,000 kilometers.

The Soviet nonferrous industry continued to be plagued by low worker productivity, although the total production of all nonferrous metals gained slightly in 1975. According to reports, there was an insufficiency of proved reserves of copper ores in the Urals, nickel on the Kola Peninsula, mercury in the Ukraine, and lead in Central Asia.[31] Because of the acute shortage of bauxite, the development of the aluminum industry was being delayed. To cover this shortage, nephelines and alunites were used. The following decrease of the index of metal content of mined ores is the main reason for low growth of nonferrous metals output:

Ore	Index of metal content in mined ores, 1970=100		
	1970	1974	1975 (planned)
Copper [1]	100	112.5	114.6
Lead	100	86.2	90.8
Zinc	100	87.6	89.6
Gold	100	94.8	82.7
Silver	100	81.9	77.0

[1] Increased production of high-copper content ores at the Rider mines in Kazakhstan.

Source: Narodnoye khozyaystvo Kazakhstana (National Economy of Kazakhstan), Alma-Ata. No. 7, July 1975, p. 9.

Beneficiation and metallurgical facilities of the nonferrous industry continued to experience poor metal recoveries; the industry recovered only about 60% of the total metal content of the ores. Some 80% to 90% of rare metals was lost during the beneficiation processes.[32] Between 15 and 20 tons of bismuth is lost at the Alaverdy complex in Armenia annually.[33] During the smelting of copper-zinc concentrates in the Urals, about 70,000 tons of zinc is lost annually.[34]

[34] Tsvetnye metally (Nonferrous Metals), Moscow. No. 8, August 1975, p. 11.

There are also important slag losses. Because of the lack of facilities, 2 million tons of pyrite slags, containing 18,000 tons of copper, 30,000 tons of zinc, 800 to 900 tons of cobalt, 50 tons of silver, and other useful minerals, are not processed annually.[35] The dumped slags of the Alaverdy plant in Armenia contain up to 1% copper.[36] All platinum-group metals, 50% of the silver, 30% of the sulfur, and 10% of the zinc, lead, and copper were produced in the U.S.S.R. as byproducts.[37]

The general level of technology in the Soviet mineral industry has lagged consistently behind that of the more advanced Western countries. Transfer of Western technology to the Soviet Union continued to be the most important factor in Soviet mineral industry development. A low degree of mechanization is characteristic in such areas as mine development, roof support, and hauling of coal and ores. The labor-intensive functions of mining and metallurgy occupy large numbers of workers who could be replaced by machinery. For example, in coal mining, manual labor is used almost exclusively in longwall work (49,000 workers), for roof support in development workings (24,000 workers), for loading of coal and rock in development of workings (20,000 workers), and for maintenance of workings (76,000 workers).[38] Many operations in loading and maintenance shops of nonferrous enterprises were performed manually.[39]

The Soviets are increasingly conscious of the age and obsolescence of their machine tools and of much of their mining and metallurgical machinery and equipment. The Soviet machine industry continues to turn out inefficient models because the emphasis is on production and no time is allowed for retooling. The Soviets prefer not to use new and untried equipment with its inherent risk of failure and are inclined to use old and established equipment.

Soviet reports have documented as obsolete equipment 43 blast furnaces, 80 open-hearth furnaces, 97 rolling mills, about one-half of the power units, and a large percentage of the metal products equipment. Ten-year-old units are being used to smelt 31% of the pig iron, 29% of the open-hearth steel, and 31% of the finished ferrous rolled metal.[40] Out of 200 coking batteries in the U.S.S.R., more than 100 have been operating for more than 20 years, some of them for 40 years. Many have become obsolete or are being used beyond their economic life.[41]

The use of obsolete drilling rigs and an inferior quality of drilling bits and drilling steel in underground metal mining increased the required number of manual workers.[42] The petroleum and gas industries have their own special problems. The drilling of exploratory and developmental wells in these industries failed to meet planned targets.[43] Automation of Soviet rolling mills lags behind that of the Western countries.[44]

Soviet investigations show that coal production equipment is utilized at an average rate of 40% to 45%; the plan calls for 65% utilization, or a downtime of 35%. As a result, the coal industry is losing production valued at more than 180 million rubles per year.[45] In the cement industry, for each rotary furnace, there is an average of 50 periods of idle time each year, resulting in industrywide losses of 18,000 to 20,000 hours per year.[46]

Extensive prospecting and exploration for practically all commodities is carried out on a large scale. There were over 500,000 employees in the geological and prospecting organizations of the U.S.S.R. in 1975, including a staff of about 65,000 graduate specialists with a university education and over 53,000 graduate technicians. Some 4 billion rubles was allocated for geological exploration in 1975.

Appropriations for prospecting for petroleum and natural gas increased from

689 million rubles in 1969 to 2,000 million rubles in 1975.[47] Over 2,500 geological and geophysical teams were permanently employed in the prospecting and exploration of petroleum and gas fields. Only 5% to 10.5% of the completed wells were in the Volga area and in Belorussian S.S.R.[48]

Although exploration for reserves of minerals and fuels, particularly petroleum and gas, has grown considerably, most of the reserves are located in relatively undeveloped areas. Even though many of the known ore bodies include deposits of manganese, chromite, diamond, asbestos, and lead metal content similar to ores mined in the rest of the world, some of the proved deposits are poor and the ore difficult to concentrate.

Until very recently, most of the nickel ores mined in the U.S.S.R. were low in mineral content. The situation is similar with regard to mercury, tin, and aluminum raw materials. Approximately 20% of the iron ore reserves require complicated methods of concentration. Recently, there has been some decline in the average metal content of lead, zinc, copper, molybdenum, tungsten, and other ores.

In many instances, exploratory surveys and geophysical work have not substantially improved the U.S.S.R.'s reserves position. This is particularly true of nonferrous metals, rare metals, and gold. The production facilities at 34 enterprises of the nonferrous minerals processing industry, which were built recently, continued to experience ore shortages and losses due to miscalculations in estimating ore reserves.[49]

As a result of the Soviet machine-building industry's deliveries of lower quality equipment, especially for drilling, drilling efforts were impeded, and drilling costs rose along with rising petroleum production costs.[50]

The U.S.S.R. continued to experience difficulties in completing mineral industry projects on schedule because of shortages of material, equipment, and labor, and organizational problems. Construction of new projects remained inadmissibly slow, expensive, and frequently widely dispersed with the work taking two to three times as long as specified by the U.S.S.R. State Construction Committee. This contributed to a disparity between mine, concentrator, and metallurgical plant capacity. The practice of putting mines and plants into operation with many expedients has resulted in great inefficiencies and prolonged delays before design capacity is achieved. For example, on January 1, 1975, planned capacity goals had not been reached at 12 lead-zinc, 4 copper, 7 aluminum, and 6 nonferrous rolled metals enterprises. At the Achinsk alumina plant design capacity achieved only 53.6%.[51] The Rovny nitrogen and Uvarovo chemical plants utilized only 40% to 60% of their capacities.[52] Construction plans of many installations were met according to ruble expenditures, but facilities were not put into operation.[53]

New enterprises that became operational in the iron and steel industry included the No. 4 blast furnace at the Karaganda complex, the No. 2 oxygen-converter shop with an annual capacity of 4 million tons at the Novolipetsk plant, the "2000" mill at the Cherepovets plant, and new facilities at the Lebedinsk, Novokrivorozhsk, Kachkanar, Sokolovsk-Sarbaysk, and Dneprovsk iron ore mining and processing combines.

In the field of nonferrous industry, the following facilities were put into operation in 1975: The first potline at the Regar aluminum plant in Tadzhik S.S.R., the second stage of the Madneulsk mining and processing combine in Georgian S.S.R., and the first stage of the No. 65 mine and the second stage of the No. 10 section of the dressing plant at the Dzhezkazgan complex in Kazakhstan. New facilities also were put onstream at the Kargalinsk, Irtysh, and Achisay polymetallic, Zyryanovsk lead, and Ust'-Kamenogrosk titanium-magnesium complexes in Kazakh S.S.R.

Large new capacities for the production of mineral fertilizers were started up

at the Rovny and Novomoskovsk chemical works and Ionava nitrogen fertilizer plants. New installations at the Dzhambul double-superphosphate plant and at the Karatau phosphorite complex were also commissioned in 1975.

In the coal and lignite industry, three underground mines were reported to have come onstream in 1975: Voroshilovskaya No. 1, in Komi A.S.S.R.; Pervomayskaya, in Kemerovo Oblast'; and Zapadno-Donbasskaya No. 25/26, in Dneprovsk Oblast'.

Construction of the Baykal Amur Railway (BAM) continued in 1975. There were about 60,000 people working on this railway. Once BAM is completed about 1982, the emphasis is to be transferred to the railway linking BAM with Yakutsk. Yakut A.S.S.R. is planned to become a major mineral producer during the 1980's.

Capital investment in the Soviet economy amounted to 114 billion rubles in 1975, 9% over that of 1974. In 1975, planned investment in the construction of new facilities and enlargement and renovation of existing facilities of the ferrous industry was 3 billion rubles, or 11.8% more than in 1974. About 2,500 million rubles was alloted for development of the Soviet coal and lignite industry. Capital investment in crude oil extraction was planned at 4 billion rubles, including about 1 billion rubles in West Siberia. The 1975 plan envisaged development of new installations for extracting 87 million tons of crude oil and drilling 8,520,000 meters (7,500,000 in 1974) of developmental wells.

Additional production capacities, including new or expanded plant and renovation of existing facilities, in million tons or as otherwise specified, follow:

Commodity	1972	1973	1974	1975

TRADE

Soviet foreign trade is a State monopoly, run by more than 60 commodity-oriented trading organizations under the supervision of the Ministry of Foreign Trade. Political objectives exert a strong, and often determining, influence on foreign trade. The Soviet Union traded with 112 countries, and in 89 cases the trade was based on interstate agreements. Soviet foreign trade continued to be oriented toward imports of needed production machinery and equipment, including complete industrial plants. Exports of minerals produced foreign exchange to help pay for imports, even though most of the minerals exported were in demand in internal markets. The sale of minerals, as of other Soviet products, is carried out largely under bilateral trade agreements negotiated on a state-to-state basis.

International trade ranks high in the mineral industry's priorities. Since the value and volume of trade is directed by the Ministry of Foreign Trade, planned exports and imports reflect national goals and priorities. There is, therefore, an implied commitment to exports to achieve a desired trade balance. The high priorities placed upon achieving such goals may result in commodity sales below world price levels.

The Soviet foreign trade turnover (exports plus imports) in 1975 reached 50.7 billion rubles, an increase of 11.1 billion rubles, or 28%, over that of 1974. Exports rose by 3.2 billion rubles to reach 24 billion rubles, while imports increased by 7.9 billion rubles to reach 26.7 billion rubles. Soviet trade with centrally planned economy countries amounted to 28 billion rubles (over 56% of total trade), of which 26.3 billion rubles (or about 52%) was with COMECON nations; 15.8 billion rubles (over 31%) of trade was with developed Western countries, and 6.3 billion rubles (about 13%) was with developing countries.

The volume of total official trade with leading Western developed countries in 1972, 1973, 1974, and 1975 follows, in million rubles:

Country	1972	1973	1974	1975
West Germany	827	1,210	2,209	2,800
Japan	816	994	1,683	1,900
Finland	602	777	1,540	1,700
Italy	468	614	1,137	1,400
France	544	722	941	1,200
United Kingdom	558	715	890	960
United States	538	1,161	742	1,600

Soviet figures for foreign trade in 1975 provide evidence of the declining importance of the centrally planned economy countries in the Soviet Union's external trade. Whereas trade with centrally planned economy countries represented 65.4% of the total in 1971, it was only 58.5% in 1973 and 56% in 1975. Trade with COMECON countries declined from 59.6% of the total in 1972 to about 52% in 1975.

The Soviet official trade turnover with COMECON nations in 1972, 1973, 1974 and 1975 follows, in million rubles:

Country	1972	1973	1974	1975
East Germany	3,705	3,965	4,315	5,623
Poland	2,803	3,000	3,584	4,853
Czechoslovakia	2,626	2,760	3,029	3,911
Bulgaria	2,345	2,555	2,904	3,991
Hungary	1,882	2,064	2,282	3,274
Romania	1,053	1,130	1,191	1,526
Cuba	822	1,110	1,642	2,589
Mongolia	287	338	404	480

Trade with the developing countries grew through the expansion of economic and technical assistance; the U.S.S.R. has concluded such trade agreements with more than 70 developing countries, Egypt being the largest trading partner, followed by India, Iran, Iraq, Brazil, and Argentina.

Official trade turnover with some leading nations of this group in 1973, 1974 and 1975 follows, in million rubles:

Country	1973	1974	1975
Egypt	541	728	710
India	589	615	685
Iran	275	496	510
Iraq	332	453	596
Brazil	126	202	396
Argentina	77	137	304

The Soviet Union, with a net debt of $10.7 billion, accounted for over 36% of overall COMECON net indebtness to the West. The breakdown of Soviet indebtedness at yearend 1975, in million dollars, follows:

Country	Value
France	3,300
West Germany	3,000
Italy	1,150
Japan	850
United Kingdom	700
United States	468
Austria	300
Sweden	125
Other	200
Total	10,093
Supplier credits	1,800
Private Western bank credits	5,992
Gross indebtedness	17,885
Undrawn official credits	5,010
Deposits with Western banks	2,208
Total	7,218
Net indebtedness	10,667

Source: Mariam Karr Eastwest Markets, Sept. 20, 1976.

Quantitatively, there was no significant change in patterns of Soviet mineral trade in 1975 from those of 1974. Fuels, metals, and mineral raw materials continued to play the largest role in Soviet exports and represented about 40% of total official exports during 1975. Along with gold, platinum-group metals, chrome ore, manganese ore, aluminum, zinc, lead, asbestos, apatite concentrate, potassium, cement, pig iron, ferroalloys, steel, coal, petroleum, and coke, the country now exports diamond, titanium, nickel, copper, rare metals, and natural gas.

The Soviet Union provides nearly 100% of the COMECON nations' imports of crude oil, natural gas, pig iron, and power; 66% of their petroleum products, rolled ferrous metals, and phosphorous fertilizers; 60% of coal and manganese ore; and up to 90% of iron ore. The export of Soviet petroleum to COMECON members increased from 138 million tons during 1966–70 to some 243 million tons between 1971 and 1975. In 1975, Soviet-Yugoslav trade reached a value of 1,558 million rubles. It is anticipated that trade turnover in 1976 may exceed a value of 2 billion rubles. The U.S.S.R. will supply Yugoslavia with petroleum, coal, metals and other raw materials in exchange for Yugoslav bauxite, nonferrous metals, and other goods. Soviet trade with Cuba increased from 1,045 million rubles in 1974 to 2,589 million rubles in 1975. Soviet exports to Cuba included ferrous and nonferrous metals, petroleum (over 7.6 million tons in 1974), anthracite, coke, sulfur, mineral fertilizers, etc. In addition to other goods, Cuba delivered nickel concentrates to the Soviet Union.

Soviet trade in selected mineral commodities in 1974 and 1975 by country group is presented in tables 5 and 6.

Mineral commodity imports in 1975 included ferrous and nonferrous semimanufactures, steel pipe, bauxite and alumina, tin, tungsten concentrate, talc, and mica. There was a considerable increase in imports of machinery and other industrial equipment, which came mainly from Western countries. The Soviet Union has also increased imports of large-diameter steel pipe, rolled steel, and nonmetallic minerals. Soviet import policy on petroleum consists of buying mainly from the Middle East and North Africa. Natural gas is imported from Iran and Afghanistan.

Trade tables 7 and 8 are derived from the official statistics of the Ministry of Foreign Trade for 1973 and 1974. Official detailed figures for 1975 are not yet available, but much the same general pattern can be expected.

Table 5.—U.S.S.R.: Exports of selected mineral commodities, by country group

(Thousand metric tons)

Year and commodity	COMECON countries	Other centrally planned economy countries	Total centrally planned economy countries	Developed market economy countries	Developing market economy countries	Total market economy countries	Total exports

Liquefied petroleum gas [1] -- do----	1,266	1,273	
Paraffin ---- do----	462	609	
Asphalt and bitumen ---- do----	118	146	
Petroleum coke ---- do----	843	754	
Unspecified ---- do----	827	411	
Total ---- do----	245,034	264,639	
Crude chemicals from coal, gas and oil distillation ---- thousand tons--	454	482	West Germany 78; France 75; East Germany 62; Italy 61.

r Revised. NA Not available.

[1] Data possibly incomplete; total not officially reported. Total given represents sum of quantities reported under individual countries.

[2] Detail on principal destinations includes shipments of vanadium slag and manganese metal if any to the listed countries, but total shipments of these commodities are reported separately under vanadium and manganese in this table.

[3] Details on destinations of crude oil and various refinery products are not officially reported individually. Total exports of all crude oil and refinery products are reported on a gravimetric basis by destination, but cannot be converted to a volumetric basis owing to the varying specific gravities of the different products that constitute any country total. Percentage figures provided here are each country's share of total crude oil and refinery products on a gravimetric basis.

r Revised. NA Not available.

[1] Data possibly incomplete; total not officially reported. Total given represents sum of quantities reported under individual countries.

[2] Details on origins of various refinery products are not officially reported individually. Total imports of all refinery products are reported on a weight basis by origin, but cannot be converted to a volumetric basis owing to the varying specific gravities of the different products that constitute any country total. Percentage figures provided here are each country's share of total refinery products on a gravimetric basis.

COMMODITY REVIEW

METALS

In 1975, metal output fell short of demand in the U.S.S.R. according to reports. Beneficiation and metallurgical facilities continued to experience low metal recovery principally from mixed ores of Kazakhstan and the Urals. Metallurgical plants frequently reported shortages in raw materials because of long lead times in scheduled new facilities for mining and processing. Despite these weaknesses, practically all metal commodity production expanded in 1975.

Aluminum.—The Soviet Union, second only to the United States in aluminum production, operated 14 primary reduction plants with a total probable annual capacity of 1.93 million tons by January 1976. Production in 1975 has been estimated at 1.68 million tons, including 150,000 tons of secondary aluminum. The estimated 7% increase in metal output was due mainly to new production from the Bratsk plant in East Siberia and the Regar plant in Tadzhikistan.

Under the 1971–75 plan, 1975 output was scheduled to be 50% to 60% over the 1970 level, or 2.1 million to 2.2 million tons. Production fell short of the planned increase because there were shortfalls at the Siberian plants, and output at the Regar plant started only in 1975. Under the 1976–80 plan, output in 1980 is scheduled to be 20% to 30% above the 1975 level.

In the Soviet Union, aluminum is produced more for export than domestic consumption. The U.S.S.R. exported more than 500,000 tons in each of the last 4 years (1972–75). Soviet aluminum exports are scheduled to increase from 368,000 tons in 1970 to about 700,000 tons in 1980. The U.S.S.R. exports primary and secondary aluminum to West European countries and Japan and plans to export large quantities of primary and secondary aluminum to the United States in the future.

Reportedly, the Soviet Union and Péchiney Ugine Kuhlmann were accelerating detailed negotiations for the 500,000-ton-per-year Sayanogorsk aluminum primary reduction plant in Krasnoyarsk Kray and the 1-million-ton-per-year Nikolayev alumina plant on the Black Sea. Financing, now estimated at $2,600 million, is to be provided by Péchiney and repaid with primary aluminum. Negotiations with Kaiser Aluminum & Chemical Corporation of the United States on the same project continued throughout 1975 with no firm agreement. Construction of the Sayanogorsk primary aluminum plant with the assistance of French experts began in 1975. The first potline is to be completed during 1976–80. Power is to be supplied from the Sayano-Shushensk hydroelectric plant, which is under construction.

Construction continued at the Bratsk, Krasnoyarsk, Irkutsk, and Regar primary aluminum plants. Three potlines were completed at the Bratsk plant in 1975, and design production capacity was attained without the final potline, which was still under construction in 1975. Production of aluminum at the Bratsk plant increased 91.5% during 1971–74 and 410% in the 1968–74 period.

The first potline at the Regar aluminum plant in the Gissar Valley in Tadzhikistan was commissioned in April and achieved design capacity in December. Construction started in 1964, and completion for the first potline was set for 1968. The second potline was under construction in 1975. Full operation was planned for 1977 but has been rescheduled for 1980. Regar operates on imported alumina. The output of aluminum at Regar is planned to increase 56% in 1976.

In comparison with the Bogoslovsk primary reduction plant, the production cost of metal was higher at Bratsk by 130%; Volkhov, 90%; Irkutsk, 30%; and Nadvoitsk and Volgogard, 20%.[54] The Krasnoyarsk plant reportedly produced low-quality metal, and many pots were idle in 1975.[55] Because of poor maintenance, many pots were also idle at the Irkutsk plant, especially at potline No. 7.[56] Production of primary aluminum at the Bogoslovsk plant in 1975 increased 10% over that of 1970.

A 10-day international exhibition on the production and use of aluminum was opened in Moscow on July 15 in conjunc-

---

[56] Ekonomicheskaya gazeta (Economic Gazette), Moscow. No. 44, October 1975, p. 6.

tion with a scientific and technological symposium. A total of 120 firms and industrial organizations from Australia, Belgium, the United Kingdom, Hungary, East Germany, Italy, the Netherlands, the United States, France, West Germany, Switzerland, and Japan participated in the exhibition.

Although the Soviet Union is a large producer of low-grade bauxite, supplies are insufficient, and the U.S.S.R. is developing alumina production from nepheline and alunite. The Achinsk alumina plant in Krasnoyarsk Kray and the Pikalevo plant in Leningrad Oblast' produce alumina from nepheline. The development of technology for producing alumina from the Kiya-Shaltyrsk (Belogorsk) nepheline open pit on the border of Krasnoyarsk Kray and Kemerovo Oblast' has been given priority. The Achinsk alumina-from-nepheline plant, which began operation in December 1971, showed very poor performance in 1975,[57] as did the Kirovobad alumina-from-alunite plant in Azerbaydzhan, which has been operated as a pilot plant for over 10 years with frequent changes of technology.

In 1975, attention was being paid to improving the raw material base and to erecting alumina facilities to overcome the gap between alumina and aluminum capacity. A serious deficit in alumina production seems probable in the future. The Soviet Union is also seeking to meet this deficit by integrating the aluminum industries of East Europe and by assisting projects in market economy countries—notably Greece, Guinea, and India. Meanwhile, the U.S.S.R. continued to import substantial quantities of high-grade bauxite and alumina from Hungary, Yugoslavia, Greece, Guinea, and elsewhere. Reportedly, the U.S.S.R. will build a 500,000-ton-per-year alumina plant in India. The $400 million project is to be financed by a loan from the Soviet Union and is to be repaid in alumina.

Bauxite remains the main raw material; nepheline and alunite are used in only small amounts for the production of alumina. Reserves of bauxite in the U.S.S.R. that are suitable for the production of alumina by the Bayer method are estimated at approximately 250 million tons, including some 65 million tons of proved, recoverable reserves. The principal reserves are situated on the eastern slope of the Urals, in the Turgay area of Kazakhstan, and in the Tikhvin region of Leningrad Oblast'. The northern Urals continue to be the main bauxite and alumina producing region. It is planned to increase production of alumina at the Bogoslovsk aluminum plant in the Urals in 1980 by 52.5% over that of 1975, using reserves of the Krasnaya Shapochka deposit.

The second largest bauxite (and alumina) producing region is Kazakhstan with the Pavlodar No. 1 alumina plant among the nation's largest in 1975. The No. 2 alumina plant was reportedly under construction. Since 1967, the Pavlodar plant has been processing bauxite containing 44.3% to 44.7% aluminum oxide instead of the planned 45.6%. Conversely, the iron oxide content was 16% to 17% compared with the expected 13.2% as called for in the plan. During 1971–75, production of alumina at the Pavlodar plant increased 25%. It is planned to increase alumina production in Kazakhstan 10% in 1980 over that of 1975. Production of alumina in this Republic in 1976 is to be increased 1.7% over that of 1975. Completion of development of the Krasnooktyabr'sk and Belinsk open pits in north Kazakhstan has been rescheduled for 1980. During 1971–75, production of alumina from imported bauxite in the Ukraine increased 15.2% and Ukrainian production of secondary aluminum increased 86.3%.[58]

Antimony.—Deposits of antimony occur at Kadamzhay in Kirgiziya, Dzhidzhikrut in Tadzhikistan, Turgary in Kazakhstan, and Sarylakh and Tazhdolinsk in Siberia. Kadamzhay remains the principal antimony center of the U.S.S.R. The second stage of this complex was under construction in 1975 and was scheduled for completion in 1976. Construction of the second stage of the Aznob mining and concentrating combine (Dzhidzhikrutskiy complex) in Tadzhikistan continued slowly in 1975. In 1973, the Ministry of Nonferrous Metallurgy planned for 9 million rubles to be allocated to the construction of this project in 1974 and 10 million rubles in 1975. Actually, 4.7 million rubles was allocated in 1974 and

[57] Page 6 of work cited in footnote 54.
[58] Ekonomika Sovetskoy Ukrainy (Economics of the Soviet Ukraine), Kiev. No. 11, November 1975, p. 12.

5.6 million rubles in 1975.[59] The Savoyardy antimony deposit in Kirgizia and the Skal'noye deposit in Tadzhikistan were under preliminary exploration in 1975.

Arsenic.—Arsenic reserves were estimated at about 12 million tons with an average As_2O_3 content of 0.2% to 2.5%. All output in 1975 was obtained as a byproduct from the smelting or roasting of metallic ores.

Beryllium.—The Soviet Union is one of the world's largest producers and consumers of beryl and beryllium alloys and metal. The production of these commodities is being increased rapidly. During 1971–75, estimated output increased about 23%. The increase indicated a probable production level of 1,600 tons of beryl (10% to 12% BeO) in 1975.

Bismuth.—As in previous years, bismuth was produced in 1975 almost entirely from complex ores, such as tungsten-molybdenum-bismuth ores of the North Caucasus, and scheelite and cassiterite ores of Kazakhstan and Siberia. Recovery of metal in concentrate was less than 50% of the metal contained in ores, and recovery in metallurgical process was about 88%. In 1975, bismuth was not recovered from Armenian and other complex ores.

Cadmium.—Cadmium was produced at various Soviet lead and zinc smelters as a byproduct. Kazakhstan recently became an important producer of cadmium. The Leninogorsk polymetallic complex in Kazakhstan, which produced the first Soviet cadmium in 1935 and the first electrolytic cadmium later, continued to be one of the largest producers. During 1971–75, the recovery of cadmium at this complex increased 4.5%. Average overall Soviet cadmium recovery was about 60%.

Chromium.—With an estimated output of 2.08 million tons, the U.S.S.R. was the leading world chrome ore producer and exporter in 1975. Chrome ore output in 1975 had been expected to be about 18% higher than in 1970. The planned goals were reportedly exceeded by 1%. Exports totaled 1.17 million tons in 1975, with about 80% going to Western countries. Except for the chemical-grade product going to Italy, virtually all the Soviet chromite shipped to Western countries is for metallurgical production. Output of chromite is expected to be 2.3 million tons in 1980. Approximately 60% of the total production is to be exported.

Chromite ores are located in Kazakhstan and in the Ural Mountains. Gross reserves (measured, indicated, and inferred) were estimated at over 100 million tons containing 15% to 63% Cr_2O_3, of which 20 million to 24 million tons are measured. About 94% of the total reserves are situated in Kazakhstan with the balance in the Ural Mountains. There are over 20 deposits in Aktyubinsk Oblast' in western Kazakhstan of which Molodezhnoye, Millionnyy, and Almaz-Zhemchugina are the largest with total gross reserves of some 60 million tons. The Donskoye mining administration at Khrom-Tau in Aktyubinsk Oblast' of Kazakhstan, which produces over 90% of the Soviet output, is the only supplier of high-quality ore. Deposits of chromium oxide content (20% to 40%) as well as a low Cr_2O_3–FeO ratio are mostly used in the chemical and refractory industries.

Most ores can be shipped without beneficiation, other than hand picking. The first Soviet chromite concentrator with an annual capacity of 1 million tons (300,000 tons of concentrate) was under construction at Donskoye. The first section went into operation in 1974, and completion is scheduled for 1980. The new mill will process lower grade ores that hitherto have been stockpiled. Development of the first underground mine, the 40 Let Kazakhskoy SSR-Molodezhnoye, with an annual capacity of 2 million tons of crude ore, continued at Donskoye and is scheduled for completion in 1980.

Reportedly, Soviet chrome ore was selling for $135 to $149.50 per ton, f.o.b. Black Sea ports, for the 48% Cr_2O_3 ore with a 4:1 iron ratio.

Cobalt.—In 1975, cobalt was produced at Norilsk in West Siberia; at Monchegorsk and Pechenga on the Kola Peninsula; and in the Urals at the Yuzhuralnikel, Ufaley, and Rezhsk nickel plants. Cobalt production increased 16% between 1970 and 1975. Only some 25% of the cobalt in slag was recovered. Average total recovery was about 55%. The planned production cost of cobalt in concentrate at the Pechenganikel complex was 6,780 rubles per ton in 1975.

Copper.—In 1975, the Soviet Union produced an estimated 925,000 tons of blister copper, including 160,000 tons of

[59] Page 5 of work cited in footnote 56.

secondary copper. An estimated 2.8% increase in metal output was due to increased production of blister copper from the new facilities which were commissioned in 1974. Ten percent of total production of primary copper was recovered as byproduct.[60] The 1971–75 plan scheduled Soviet copper output to rise 35% to 40% to a probable planned level of 960,000 to 995,000 tons of primary and secondary copper by 1975, but actual output was 5% to 10% lower. Under the new 5-year plan, output in 1980 is scheduled to be 20% to 30% over the 1975 level. If the 20% growth is achieved, the U.S.S.R. will produce 1.1 million tons of primary and secondary copper by 1980. This might allow more "surplus" for exports, which increased from 123,100 tons in 1970 to 205,600 tons in 1975. Exports in 1980 are estimated to reach 350,000 tons.

Kazakhstan continued to be the main center of copper production, and the Balkhash complex was the largest producer in the country. During 1971–74, 415 million rubles was spent on development of the Kazakhstan copper industry, and production of refined metal increased 50%. The 1976–80 plan calls for a 25% increase in refined copper production in Kazakhstan. It is planned to increase refined metal production 6% in 1976 compared with the 1975 level. In April 1975, the first stage of mine No. 65 at the Dzhezkazgan complex was commissioned, but equipment problems resulted in lower production than originally planned. Development of the second stage of this mine has proceeded slowly.[61] Development of the small Sayak-III open pit at the Balkhash complex was completed in 1975. Shortage of copper ore was experienced at the Balkhash and Dzhezkazgan complexes.[62]

Development of the Akchu-Spassk and Dzheladinsk mines continued, and that of a new mine began in 1975 at the Irtysh polymetallic complex in East Kazakhstan Oblast'. It is planned to complete construction of the Kargalinsk and Orlovsk mining and concentrating complexes by 1980. Development of mine No. 65 at the Dzhezkazgan complex and enlargement of the Tishinsk and Annensk mines are also to be completed by 1980. It is planned to begin construction of the Boshchekulsk and Chatyrkulsk mining and concentrating complexes in Kazakhstan in 1976. Completion of the first stage is planned for 1980. Exploration of the Saryoba, Intauz, Kirshakpay, and Karashoshak deposits in the Dzhezkazgan region continued in 1975.

The Urals was the second largest copper-producing region, but the Krasnouralsk, Kirovograd, and Karabash copper smelters in the Northern Urals experienced a major shortage of concentrates. The existing pyrite deposits no longer met the needs of the smelters, and one-third of total smelter consumption of concentrate was being shipped from Central Asia, the Altay Region, the Caucasus, and other regions.[63] Transport costs exceeded 10 million rubles per year. The imbalance between smelting and mining in the Urals resulted from a prolonged lag in exploration[64] and development of mines.[65] For example, development of the Volkov mine, which began in 1965, is scheduled for completion in 1980.[66]

During 1971–74 output of blister at the Kirovograd plant in the Urals increased 29.6%. During the same period, ore production at the Gaysk copper mining and concentration complex at Orenburg Oblast' increased 23.4%. The fourth stage of an underground mine at this complex is to be commissioned in 1976. A mine is to be developed at the 50-letiye Oktyabrya copper deposit in Orenburg Oblast'. At the Bashkir copper-sulfur complex, additional ore-processing facilities were completed in 1975.

The second stage of the Madneuli mining and concentrating complex in Georgia was commissioned in November 1975, and the complex is to be completed in the 1976–80 period. In 1976, copper ore extraction at this complex is to be increased 130% over that of 1975. Development of the Sary-cheku copper mine at the Almalyk complex in Uzbekistan was completed in 1975. The copper content in slag

Work cited in footnote 64.

of the flash-smelting unit at this complex was 1%, compared with a designed 0.5%; smelting rates of 10 tons of concentrate per square meter per day have been achieved, compared with a planned 12 tons.[67]

Recovery of copper in concentrate at the Sorskiy copper-molybdenum complex increased from 38.7% in 1972 to 45.93% in 1974. The production cost of copper in concentrate at the Pechenganikel complex on the Kola Peninsula was 455 rubles per ton in 1975.

Three Finnish firms were building copper and nickel smelters at the Norilsk complex. Reportedly the cost of the plants, with an annual capacity of 550,000 tons of nickel concentrate and 650,000 tons of copper concentrate, is to be $300 million. The Outokumpu flash-smelting technology will be used. At the Severonikel complex at Monchegorsk on the Kola Peninsula, a copper electrolysis plant was under construction in 1975, and its completion has been rescheduled for 1976. Development of the Erdent copper-molybenum complex in Mongolia continued in 1975. More than 3,000 Soviet technicians and workers were employed at this project in 1975.

Development of the Udokan copper deposit in East Siberia during 1976–90 is expected to require a capital investment of about 2 billion rubles. During a Moscow exhibition-seminar on copper ore processing in 1975, Soviet officials asked the United States and other Western countries to submit a proposal to build a pilot plant at the Udokan copper deposit to process 100 tons per day of ore. Reportedly, Rio Tinto-Zinc Corp., Ltd., (RTZ) has submitted a detailed proposal for this pilot plant.

The discussion on participation of Western companies in the development of the Udokan deposit continued in 1975. RTZ is interested in playing a major role in the development of this proposed 400,000-ton-per-year copper project.

Reportedly, agreements have been exchanged between the U.S.S.R. and India on the development of copper deposits at Malanjkhand and Madhya Pradesh. The Soviet Union has offered to supply earth-moving equipment to India.

Gold.—In 1975, the U.S.S.R. produced an estimated 7.5 million troy ounces of gold and was the world's second largest producer. The growth in Soviet gold production reportedly resulted mainly from expansion of placer mining in the northeast of the Asian part of the country. Over two-thirds of the total output came from the Soviet Far East and East Siberia; most of the balance came from gold and polymetallic ores in the Urals, Kazakhstan, Armenia, and Uzbekistan.

Prompted by the higher international prices, the Soviet Union planned to increase production and is importing large-scale equipment from West Europe, the United States, and Japan. Gold production is estimated at 8.6 million troy ounces for 1980.

There are no accurate figures, but according to some estimates, the U.S.S.R. sold less than 4.5 million troy ounces of gold in 1975 compared with 7.3 million troy ounces in 1974. At the beginning of 1975, the Soviet Union was a heavy seller of gold in its effort to raise foreign exchange to pay for grain purchased, but as prices of gold declined at yearend, the Soviet Union became a fairly heavy seller of platinum-group metals.

The inspectorate of the assay office of the Administration of Precious Metals of the U.S.S.R. Ministry of Finance exercises control over all industrial facilities in the Soviet Union which use precious metals in their production. In the U.S.S.R. the following gold purity standards were established for items of general use: 958, 750, 583, 500, and 375. This means that every 1,000 parts of alloy must contain the indicated number of parts of gold.

Potential reserves of gold in lode and placer deposits were estimated at about 200 million troy ounces in 1970. Measured reserves were reportedly sufficient for a 16- to 17-year operation at the current production rate. Extensive prospecting for gold continued in many regions of the Asian part of the country, but the amount of gold discovered was less than the quantity produced in 1975.[68] Several new small deposits were found in the Soviet Far East and Yakutia in 1975. Two new small deposits were prospected at the Baleyzoloto complex in Chita Oblast'. At the Maykan gold mining complex in Pavlodar Oblast' in Kazakhstan, several new

---

[67] Tsvetnye metally (Nonferrous Metals), Moscow. No. 10, October 1975, p. 6.
[68] Page 17 of work cited in footnote 26.

small deposits were discovered in 1975. The Kedrovsk gold deposit in the north of Buryat A.S.S.R., near the route of the BAM railway, was approved for development.

Magadan Oblast' was the main production center with 32 placer mines, 23 dredges, and over 500 sandwashing rigs. The Severovestokzoloto (Northeastern gold) Association of Magadan Oblast' fulfilled only 87% of its 1975 gold production quota. Overall profitability and return on capital had fallen, and labor productivity increased only 7.8% in 1971–74. The Association's mining enterprises had extensive unplanned idling of washing installations, bulldozers, and dredges in 1975. The poor operations of some placers during the washing season were attributed to the inadequate training of bulldozer operators. Owing to their lack of experience with large imported earthmoving equipment, there was excessive downtime according to reports. Nearly 70% of all machinery made for the mining industry in Magadan Oblast' is produced to the Severovestokzoloto Association design bureau's specifications.

In 1971–75, industrial output in Magadan Oblast' increased 12.8%. Capital investment in the development of the Oblast's economy amounted to 2,360 million rubles. More than 520 million rubles was allocated for prospecting and exploration of gold, tin, silver, tungsten, and coal deposits. The 5-year plan for increasing reserves of placer and lode gold was not fulfilled. The Anyuysk Expedition was the only one among all expeditions to fulfill its 1971–75 planned quota. Allocations for geological prospecting are to increase almost 50% in the tenth (1976–80) 5-year plan period. It is planned to increase peat stripping 21%, underground sand excavation 3.9%, and volume of sandwashing 10.5% in Magadan Oblast' in 1976 compared with the 1975 level.

In Yakutia, the second largest gold-producing region, the Lenzoloto Trust was the leading gold-dredging enterprise in the Soviet Union. The deepest shaft (890 meters) in the Soviet gold mining industry was under development at the Bestube mine in Tselinograd Oblast' in Kazakhstan. At the lead-zinc concentration plants in Kazakhstan, the losses of gold amounted to 25%.[69]

Iron Ore.—In 1975, 71 underground mines and 63 open pits, with a total capacity of over 265 million tons, produced 233 million tons of usable ore (direct-shipping ores plus concentrates), an increase of 8 million tons over 1974 production. About 82% of production was from open pit operations. The intensive growth of open pit mines follows the commissioning of five large taconite complexes in Krivoy Rog, the Ukraine. By 1980, the output of crude ore is planned to reach 550 million to 575 million tons. It is estimated that production of usable ore will reach 241 million tons in 1976 and 275 million tons in 1980.

Exports of iron ore increased from 36.1 million tons in 1970 to 43.6 million tons in 1975. The principal increase was in exports to Bulgaria, Hungary, East Germany, Romania, Poland, and Czechoslovakia, which total about 90% of exports.

Finnish companies were building the Kostamus iron ore complex in Soviet Karelia about 30 kilometers from the Finnish border. This project is to be built in three stages and is to have an annual capacity of about 8.3 million tons of pellets (24 million tons of crude ore). Preliminary estimates show that the entire project will cost about $600 million. The construction is to take from 8 to 10 years. In 1975, there were about 320 Finnish workers working on the Kostamus project on Soviet territory.

Reportedly, the Soviet Union and Czechoslovakia have signed a long-term contract on cooperation in the development of the Soviet iron ore industry. Czechoslovakia will supply the U.S.S.R. with machinery and equipment. The Soviet Union will repay in iron concentrates and ferromanganese. During 1976–80, Bulgaria is to take part in the construction of a number of iron ore mining and concentrating enterprises in the U.S.S.R.; in return, it is to be supplied with iron concentrates. There were over 2,000 Bulgarians working at the construction of the Lebedi ore-concentrating complex at Gubkin in Belgorod Oblast'.

Capital investment in Soviet iron ore mining for 1971–75 was set at 4,300 million rubles, 66% more than was invested during the preceding 5-year period. Annual production capacity of crude ore

[69] Tsvetnye metally (Nonferrous Metals). Moscow. No. 4, April 1975, pp. 77–79.

increased by 27.5 million tons in 1975, compared with a planned increase of 45.0 million tons. The following facilities were commissioned in 1975: The first and second stages of the Lebedi pelletizing plant in Belgorod Oblast', with a total annual capacity of 4.3 million tons; additional facilities for processing 3.5 million tons of crude ore and producing 0.6 million tons of concentrate at the Kachkanar complex in Kazakhstan; a new section of the concentrator at the Novokrivorozhskiy complex in the Ukraine, with an annual capacity of 1.4 million tons of concentrate; an open pit with an annual capacity of 6 million tons of crude ore at the same complex; a production facility of 0.5 million tons at the Dneprovsk complex in the Ukraine; the first section of the 2.5-million-ton-per-year crude ore underground mine at the Sokolovsk-Sarbaysk complex in Kazakhstan; and the first stage of the Irbin mine in West Siberia. The Lebedi pelletizing plant is the fifth pelletizing plant in the U.S.S.R.

Completion of the first stage of the Krasnokamskiy mine in Krasnoyarsk Kray with an annual capacity of 0.6 million tons was rescheduled for 1976. Construction of the Stoylensk complex in the Kursk Magnetic Anomaly area and the Kagarsk complex in Kustanay Oblast' in Kazakhstan began in 1975. The total capacity of the Kagarsk complex is to be 21 million tons of crude ore. The first stage is to be completed by 1980. Plans for the enlargement of the Olenogrosk complex on the Kola Peninsula were approved in 1975.

Ninety-two concentrators, 20 with sintering and 5 with pelletizing facilities, produced 151 million tons of sinter and 27.2 million tons of pellets in 1975. The average iron content was 59.3% in usable ore (including concentrate) and 32.3% in the ore shipped for upgrading.

Iron ore production in the U.S.S.R. is shown in the following tabulation:

	1950	1960	1970	1974	1975
Crude ore .... million tons..	48.2	141.9	355.1	455.2	472.0
Usable ore .... do....	36.6	105.8	195.5	224.9	233.0
Iron content in usable ore .... percent..	55.7	54.4	58.7	59.3	59.3
Surface mining .... do....	44.4	57.1	78.4	81.5	82.0
Underground mining .... do....	55.6	42.9	21.6	18.5	18.0

A contract for the second iron ore pelletizing plant in the Ukraine has been received from the U.S.S.R. by Allis Chalmers Co. This plant is to be similar to the first one under construction at the Dneprovsk complex near Kremenchug in the Ukraine. The cost of the 6-million-ton-per-year pellet plant is $52 million. Completion is scheduled for 1978.

Output of Soviet sinter and pellets follows:

	1965	1967	1968	1970	1973	1975
Sinter .... million tons..	111.3	123.1	128.2	137.8	148.8	151.9
Iron content .... percent..	52.0	53.1	53.4	53.5	53.5	53.9
Pellets .... million tons..	.3	2.9	7.2	10.6	21.5	27.2
Iron content .... percent..	59.8	62.5	61.3	60.6	61.8	61.8

The iron content of pellets at four Soviet plants follows:

	Percent
Sokolovsk-Sarbay, Kazakhstan	64.8
Kackanar, Kazakhstan	58.5
Tsentral'nyy, Krivoy Rog	58.7
Severnyy, Krivoy Rog	60.4

Source: Metallurgiya i gornorudnaya promyshlennost' (Metallurgy and Metal Mining Industry), Dnepropetrovsk. No. 4, April 1975, p. 8.

The Ukraine produced over 55% of Soviet iron ore, and the Krivoy Rog Basin produced 89% of the Ukraine's total in 1975. The Urals was the second largest producer, followed by Kazakhstan, the Kursk region, Siberia, and the Kola Peninsula. According to Soviet calculations, because of the shortage of iron ore (50% of consumption) in the Urals, the shipment of iron ore to the Urals will increase from

17 million tons in 1975 to between 18 million and 20 million tons by 1980. The annual cost of shipment will amount to 120 million rubles.[70] Iron ore was being shipped from Krivoy Rog, the Kola Peninsula, and the Kursk region to the metallurgical plants in the Urals. Shipment took 6 to 8 days by railway.[71] Excavators at the Soviet iron ore open pits were idle 40% to 75% of the time.[72]

In 1975, there were three mining enterprises in Belgorod Oblast': The Kursk Magnetic Anomaly Ore Combine (KMAruda), the Lebedin mining and concentrating complex, and the Stoylensk complex (under construction). These enterprises produced about 22 million tons of usable ore in 1975. The Yakovlevo mine in this Oblast' was under development in 1975. The Kursk Magnetic Anomaly area (Belgorod Oblast' and Kursk Oblast') produced an estimated 35 million tons of usable iron ore in 1975.

Iron and Steel.—The Soviet iron and steel industry held first place in the world in total quantity of iron ore mined and coke, refractories, crude steel, ferroalloys, and steel pipe production in 1975. However, the Soviet steel industry results relate to quantity based on total overall tonnage. The plan for production of metal is annually increased by a specific quantity, expressed in tons, regardless of the assortment and length and weight of the products. Tonnage is also used in evaluating the work of rolling shops and workers. Each year the plan for rolling steel is overfilled, and at the same time millions of tons of rolled products are not delivered to consumers. It must be assumed that the first concern of the management of Soviet enterprises is the achievement of production goals. A great portion of rolled products consists of sizes and shapes that are not in large demand. Such practices increase actual metal consumption and are wasteful. Thus, the shortage of particular steel products causes the U.S.S.R. to import large quantities of plate and sheet steel and steel pipe from Western countries.[73]

The advance of the iron and steel industry of the U.S.S.R. in terms of quantities produced was not matched by an advance in technology. The lag in the technical level of production facilities is characterized by obsolescence of equipment and low efficiency. The mechanization of production processes could be greatly improved. One area of potential improvement cited by press reports was the use of low-grade sinter in Soviet metallurgy. Another area was the siting of steel plants at great distances from the source of raw materials, thereby incurring additional transportation costs. In 1975, the Magnitogorsk complex in the Urals smelted more than 15 million tons of crude steel. The complex accounts for more than 11% of the output produced by the country's ferrous industry. The blast furnaces and open hearth furnaces were experiencing an acute shortage of oxygen. Only 7 out of 10 blast furnaces were operating with oxygen. The problem of providing the complex with iron ore has not been solved.[74]

The general level of iron and steel technology in the U.S.S.R. has lagged behind that of the more advanced Western countries. New technology, introduced and proved in the Western countries, has been accepted and applied in the U.S.S.R.[75]

Despite the expansion of iron and steel production in the U.S.S.R. in recent years, the supply of metal has not kept pace with demand. The Soviet Union was consuming much less steel per capita than West Europe in 1975, because growth was measured in tons of metal produced, not in tons of metal usefully consumed. Thus, the large gap in the average ferrous metal consumption is expected to persist.

A careful and exhaustive study of Soviet publications shows that only about 45% of total crude steel production is efficiently used in the Soviet economy; 55% is remelted or lost.

In 1975, 36 enterprises, operating 137 blast furnaces, produced 103 million tons of pig iron, a 3% increase over 1974 out-

put. Their estimated output for 1976 and 1980 is 107 million tons and 120 million tons, respectively. Average blast furnace capacity (useful volume) was reported at about 1,200 cubic meters. About half of all blast furnaces used oxygen for enrichment; some 85% of the pig iron was being produced by partial use of natural gas injection and oxygen enrichment at 110 blast furnaces. The construction of a 3,000-cubic-meter blast furnace at the Kommunar plant in Voroshilovgrad Oblast' in the Ukraine began in March 1975. Completion is scheduled for 1976. Six old blast furnaces are to be replaced by new 5,000-cubic-meter blast furnaces at the Magnitogorsk complex. Because of basic raw material deficiencies, the productivity of the Soviet blast furnaces was low.[76]

Crude steel production from 76 metallurgical works increased 4% to 141 million tons in 1975. Plans call for the production of 147 million tons of crude steel in 1976, and 168.5 million tons in 1980. Electric steel production was characterized by lower capacity furnaces and power transformers. The largest size of the electric furnaces was 100 tons, and that of transformers was 25,000 kilovolt-amperes. Distribution of steel production by process, in percent, follows:

Process	1960	1965	1970	1972	1973	1974	1975
Open hearth	84.4	88.0	72.6	68.7	67.8	66.6	64.8
Oxygen converter	3.8	5.0	15.3	20.5	21.4	22.7	24.6
Electric steel	8.9	4.9	10.7	9.8	9.9	9.9	9.9
Bessemer	2.9	2.1	1.4	1.0	.9	.8	.7

In 1975, the Soviet Union produced 98.6 million tons of finished rolled steel products, an increase of 5% over 1974 output. It is planned to produce 103 million tons in 1976 and 117.5 million tons in 1980.

In 1975, production of rolled steel in the U.S.S.R. was regulated by 480 State standards. Requirements of 32 standards were not being met because of the lack of the necessary equipment and finishing and heat-treatment facilities. Therefore, the Ukrainian ferrous industry in 6 months of 1975 was 2.5 million rubles short in the delivery of high-quality products to the Soviet economy.[77] To stimulate the production of small, labor-intensive, and economically effective types of products and shape sizes, starting on January 1, 1976, increased product prices will be introduced.

It had been expected that during the 1971–75 5-year period, the ferrous industry would have been able to produce 315 types of hot-rolled and about 200 types of cold-rolled shapes and also about 300 new grades of steel.[78] Actually, during 1971–75 the Soviet ferrous industry started up production of 128 hot-rolled assortments and 97 cold-rolled shapes.[79]

Production facilities—either new, expanded, or renovated—commissioned during the year (in million tons) follow: Pig iron, 1.8; crude steel, 4; and finished rolled ferrous metals, 3.3. The following main facilities were put into operation: The new blast furnace No. 4 at the Karaganda complex in Kazakhstan, the renovated unit No. 4 at the Lenin plant in Krivoy Rog and No. 4 at the Azovstal' plant in the Ukraine; oxygen converter shop No. 2, with an annual capacity of 4 million tons, at the Novolipetsk plant; the "2,000" wide-strip mill, with an annual capacity of 3 million tons, at the Cherpovets plant; the second stage of the transformer steel shop at the Verkh-Isetsk metallurgical plant; and a new shop at the Sinarsk steel pipe mill in the Urals. There were 14,000 workers on the construction of the No. 4 blast furnace at the Karaganda plant.[80] The total volume of capital investments in the ferrous industry in the ninth 5-year period (1971–75) was almost 40% higher than that during the 1966–70 period. In 1976 it is planned to invest 10% more than in 1975.

Technical plans for the first stage of the Oskol iron and steel works have been drawn up. The complex is to be built near the Oskol electrometallurgical works, which was already under construction by

[76] Pravda, Moscow. Oct. 16, 1975, p. 2.

[80] Kazakhstanskaya pravda, Alma-Ata. Nov. 6, 1975, p. 2.

West German firms. The first stage of the Oskol plant is to include two 5,000-cubic-meter blast furnaces, an oxygen converter shop, and a conveyor line for production of finished slabs, which will be shipped to the COMECON countries.

In terms of tonnage the Soviet Union was the largest world producer of steel pipe, with a total of 16 million tons in 1975, a 7% increase over 1974 production. The quality of the pipe produced in the U.S.S.R. is poor and does not correspond to the State standards. Moreover, fabrication was inadequate for internal demand, and some 10% of requirements had to be imported from West Europe and Japan. About 60% of the total Czechoslovak pipe production goes to the U.S.S.R. During 1971–75, the annual production capacity of the Chelyabinsk pipe works was increased by 0.5 million tons. The pipe made at the plant was intended for gas transmission lines. Production of welded steel pipe began at the repair and engineering works of the Zima electrochemical complex in Irkutsk Oblast' in East Siberia in October 1975. It was planned to put 0.425 million tons of new capacity into operation in 1975.

The U.S.S.R. was signing contracts for new Western technology and machinery to increase its steel output and upgrade steel products, especially the modernization of mills for the production of tinplate, steel sheet, and electric steel. In 1974, for example, the Soviet Union purchased 249.7 million rubles worth of metallurgical equipment, compared with 133.1 million rubles in 1973. About one-half of these purchases involved rolling mills. Along with COMECON countries (Hungary, East Germany, Poland, and Czechoslovakia), rolling equipment was imported from the United Kingdom, West Germany, and France. Purchases from East Germany tripled in 1 year. Two West German companies, Korf Stahl of Dusseldorf and Salzgitter Industriebau, are to supply an integrated iron and steel complex (5 million tons of sponge iron and 3 million tons of rolled steel per year) at Staryy Oskol in Belgorod Oblast'. The Oskol iron and steel complex is to have electric furnaces with total annual production capacity of about 3.5 million tons of steel. More than 4,000 workers were employed on the construction of the Staryy Oskol electrometallurgical plant in 1975. The first stage of this project is to be completed by 1980. The U.S.S.R. is to import two Sendzimir cold-rolling mills, to be installed in the Chelyabinsk and Sverdlovsk plants.

Iron and steel plant construction accounted for 22% of Soviet foreign economic and technical assistance to centrally planned economy and developing countries. The U.S.S.R. has signed agreements for 88 steel plants, of which 46 are already in operation.

Lead and Zinc.—With estimated output of primary lead at 480,000 tons and zinc at 690,000 tons, the U.S.S.R. was probably the world's second largest producer in 1975. Estimated production of primary metals in 1980 is placed at 530,000 tons of lead and 740,000 tons of zinc. Exports of lead increased from 92,400 tons in 1970 to 95,500 tons in 1974 and to 98,900 tons in 1975, and zinc exports rose from 95,100 tons in 1970 to 100,600 tons in 1975. Neither lead nor zinc output quotas were reached in 1975 or in previous years, owing to ore shortages, slow construction of new facilities, and low metal recoveries.[81] Many mines of the Soviet lead and zinc industry did not attain their production capacities.[82] Over 10% of total lead and zinc production was recovered as byproduct in 1975. During 1971–75, production of secondary lead in the Ukranian S.S.R. increased 35.7%.[83]

At the Chimkent lead plant in Kazakhstan, a slag-processing unit has been installed to process 40 years of accumulated slag and to recover zinc, lead, and other metals. One blast furnace at this plant was modernized in 1975, and lead output there is to be increased 5% as a result. The sinking of a main shaft and a ventilation shaft, both 800 meters deep, at the Nikolayevka polymetallic deposit of the Far Eastern mining and metallurgical complex in Primorskiy Kray was completed in October 1975. The Ozernyy lead-zinc mining and concentrating complex in Buryat A.S.S.R. was under construction in 1975. The first stage of the complex is to be put into operation in 1982. Construction of the Zharemsk lead-zinc-barite

[81] Tsvetnye metally (Nonferrous Metals), Moscow. No. 9, September 1974, p. 10.
[82] Narodnoye khozyaystvo Kazakhstana (National Economy of Kazakhstan), Alma-Ata. No. 8, August 1975, p. 4.
[83] Work cited in footnote 58.

mining and concentrating complex in Kazakhstan began in 1975.

Exploration of the Suvenir and Zhelandy polymetallic deposits in Kazakhstan has been completed, and development is to begin in 1976. The Sardana polymetallic deposit in Yakut A.S.S.R. and the Uchkulach deposit in Uzbekistan were under exploration in 1975.

Kazakhstan continued to be the leading lead and zinc producer, and output there is to be increased 13% and 9%, respectively, during 1976–80. At many concentrating plants, the recovery of metals was low. For example, at the Dzhezkazgan concentrator, where copper-lead-zinc ore is treated, recovery of metals in 1974 in percent was as follows:

	Planned		Actual	
	Copper	Lead	Copper	Lead
Copper concentrate:				
Content	30.61	3.89	21.02	4.33
Recovery	90.0	13.80	86.45	24.23
Lead concentrate:				
Content	4.0	50.0	8.28	44.41
Recovery	3.6	74.0	5.7	63.78

Source: Tsvetnye metally (Nonferrous Metals), Moscow. No. 11, November 1975, p. 73.

Employees have worked 12- to 14-hour shifts on weekends on the construction of the metallurgical shop at the Achisay complex in Kazakhstan. [84]

In the Urals, the second largest zinc-producing region, the problem of zinc and gold recovery from the copper-pyrite ores was still unsolved. Recovery of zinc in concentrate at concentration plants in this region amounted to only 50% to 60%. Slow development of the mines at the Adrasman Lead and Zinc Combine resulted in shortages at the concentration plant. The Vostochnyy Kanimansur mine, under development for 5 years, reported in 1975 that only 20% of programed costs were spent.[85] The same was true for the Far East mining and metallurgical complex in Primorskiy Kray [86] and the Almalyk complex in Uzbekistan.[87] The shortage of qualified workers and worn out equipment resulted in poor performance of the Elektrotsink zinc plant in the North Caucasus.[88]

Magnesium.—Five magnesium plants with an estimated combined annual capacity of 70,000 tons produced some 63,000 tons in 1975, 5% more than in 1974. Exports of metal decreased from 27,900 tons in 1974 to 11,400 tons in 1975. Production and consumption of rolled metal in the Soviet Union was small.[89] Since 1973 the Solikamsk magnesium plant has been part of the Berezniki titanium-magnesium complex.

Manganese.—The Soviet manganese industry remains the largest in the world; estimated output of marketable ores was 8.8 million tons in 1975, or 3% over that of 1974. Over 70% of the total production came from the Nikopol Basin in the Ukraine; next largest was the Chiatura Basin in Georgia. Small amounts of manganese were produced at the Dzezdinsk and Atasuysk mines in Kazakhstan. Exports of manganese ore increased from 1.2 million tons in 1970 to 1.41 million tons in 1975. Estimated production of marketable ore in 1980 is placed at 10 million tons.

In the Nikopol Basin in Dneprovsk Oblast' in the Ukraine, 80% of production is surface-mined and the remainder is deep-mined. The second stage of the Marganets mining and concentrating complex at the Nikopol Basin (annual capacity, 600,000 tons of crude ore) was under development in 1975 and was scheduled for completion in 1976. The underground mine No. 9–10 (annual capacity, 1 million tons of crude ore) was also under development at this complex. Three new mines, each with an annual capacity of 200,000 tons of crude ore (including the second stage of Ikhtvisi-Novyy and Ikhtvisi-West), were put into operation in the Chiatura manganese basin in 1975. Development of four new mines began in 1975. They are to be put into operation during the tenth 5-year plan period (1976–80).

A manganese deposit was found in western Georgia. The reserves are enough for five separate mines. Reportedly, Union Carbide and the U.S.S.R. are discussing

Union Carbide's cooperation in the design and construction of a ferromanganese plant in Nikopol in the Ukraine.

Mercury.—Output of mercury was estimated at 55,000 76-pound flasks, and the U.S.S.R. was apparently self-sufficient in mercury in 1975. Exports of mercury to Western countries started in 1975. The Khadarkan complex in Kirgizia, the largest Soviet mercury operation, had four mines and a recovery plant in operation in 1975. At the Khadarkan complex, mercury is mined by both underground and open pit methods. After attaining full capacity at the Ulug-Too mine at this complex, output of mercury is to be increased 10%. It is planned to renovate the metallurgical facilities of the Khadarkan complex and to develop a new mine in the 1976–80 period. This complex fulfilled the 1971–75 5-year production quota.

The Nikitovskiy combine in the Ukraine, where 95% of ore is mined by underground methods, was the second largest producer of mercury. Construction continued on the Dzhidzhikrutskiy mercury-antimony complex in Tadzhikistan, rescheduled for completion in 1976–80. In 1975, mercury output in Magadan Oblast' was about 30% higher than in 1970.

Molybdenum.—Output of molybdenum concentrate (metal content) was estimated at 9,060 tons, 3% above that of 1974. Reserves of molybdenum in ore (molybdenite, copper-molybdenum, and tungsten-molybdenum ores) in the U.S.S.R. may approach 200,000 tons. About 50% of production is based on copper-molybdenum ores from Armenia, Kazakhstan, Sorskoye, and others in Siberia; over 30% is from the tungsten-molybdenum ores of Tyrny-Auz (Kabardin A.S.S.R. in the North Caucasus) and Dzhida (Buryat A.S.S.R.); the remainder comes from molybdenite ore mined in Uzbekistan and at Umaltinsk and Chikaysk in Siberia.

Armenia was the largest producer of molybdenum concentrate from copper-molybdenum ores, but the concentrate was shipped out of the Republic for further treatment. The Kadzharan copper-molybdenum complex in this Republic supplied over 20% of Soviet molybdenum in 1975. The Sorskiy molybdenum combine in Krasnoyarsk Kray was the largest molybdenum producer in the country in 1975. The complex reportedly had produced low-quality products, but the recovery of molybdenum in concentrate increased at the Sorskiy complex from 85.61% in 1972 to 88.76% in 1974. The Balkhash metallurgical complex in Kazakhstan and the Almalyk complex in Uzbekistan increased the output of molybdenum concentrate during the year. The Tyrny-Auz tungsten-molybdenum complex, where 350 workers were employed, was being enlarged in 1975.

Nickel.—With an estimated 152,000 tons of smelter production, 4.8% more than in 1974, Soviet nickel output was second only to that of Canada. Sulfide ores are mined at Norilsk in West Siberia and in the Pechenga-Monchegorsk area on the Kola Peninsula. Oxide ores are produced in the Aktyubinsk area of the southern Urals, the Ufaley area of the central Urals, and the Ukraine. The centers of production in order of importance continue to be Norilsk, the Urals, and the Kola Peninsula. Of the seven smelters in operation, Norilsk is the most important; the Ufaley, Rezh, and Khalilovo smelters in the Urals follow. Then come the Monchegorsk and Pechenga smelters, followed by the Pobuzhsk ferronickel plant in the Ukraine. Production is estimated at a probable 160,000 tons in 1976 and 190,000 tons in 1980.

The experience of the Norilsk complex and other northern enterprises has demonstrated the advantages and the high degree of effectiveness of imported equipment designed for use in severe winter climates. However, the Norilsk complex does not have much of this equipment. Thus, of the presently operated excavators having a bucket size of 4.6 to 8 cubic meters, only 14% are specially designed for use in severe winter climates. Of the considerable number of excavators with a bucket size of up to 4 cubic meters, only a small percentage are specially designed for severe conditions. However, other hoisting and transporting equipment operated in the open air under conditions of the long Arctic winter is manufactured with proper consideration for the region's severe climate.[90]

One open pit (Medvezhiy Ruchey) and one underground mine (Zapolyarnyy) were in operation at the Norilsk-1 sulfide

[90] Page 46 of work cited in footnote 72.

deposit, where the ore averages 0.75% copper, 0.5% nickel, and up to 11 grams per ton platinum-group metals—mainly palladium and platinum. Two underground mines (Mayak and Komsomol'skiy) operate at the Talnakh deposit, where ores average about 3% copper, 1.5% nickel, and up to 11 grams per ton platinum-group metals. Two stages of the Oktyabr'skiy underground mine were in operation at the Oktyabr' deposit. The third stage of this mine was put into operation in December 1975. Full planned capacity is to be reached in four stages by 1980. The Oktyabr'sk mine is the largest underground mine in the Soviet nonferrous industry; ores average 3.65% nickel, 4.7% copper, and 0.13% cobalt and are associated with platinum-group metals. Prospecting is being carried out north of Norilsk.

Development of the Taymyr underground mine (Glubokiy), which began in 1972, continued in 1975. The ore will be mined at a depth of 1,500 meters from 6 vertical shafts. The project is planned for completion in 9 years. The ore output at Norilsk, Talnakh, and Oktyabr'sk deposits in 1975 was planned to be 60% greater than in 1970. Construction of the 1-billion-ruble Nadezhda copper-nickel plant at Norilsk, a major project of the tenth 5-year plan (1976–80), continued with the participation of Finnish companies; the first stage, scheduled for completion in 1974, has been rescheduled for 1977. Autoclaves are to be used there for the first time in the Soviet Union's nonferrous metallurgical industry. An additional agreement between the Soviet trade agency Tekhmashimport and a group of Finnish companies has been signed in Moscow on supplies of Finnish machinery and equipment for the Norilsk complex. The value of this further agreement is about 300 million markkas bringing the total value of Finnish deliveries to over 1,500 million markkas.

The Monchegorsk ore averages about 0.7% nickel, 0.4% copper, and some cobalt and precious metals. Ore at the Lovnozersk deposit averages 0.9% nickel, 0.5% copper, 0.04% cobalt, and some precious metals. The ores at the Severonikel complex are mined by both opencast and underground methods, and the Zdhanovskiy mining and ore-dressing complex is the largest of the operations in this area. Three underground mines (Kaula, Kotselvaara, and Kammikivi) and two open pits (Kaula and Kammikivi) were in operation at the Pechenganikel complex. The Northern mine of the Pechenganikel complex was put into operation in December 1975. The ore of this deposit is rich in nickel. The planned production cost of nickel in concentrate at Pechenganikel was 1,953 rubles per ton in 1975.

The port of Murmansk continued handling Norilsk ore for the Severonikel complex. During the 7 to 8 months of the navigation season, some 200,000 tons were shipped; this figure is to be increased in the future. Development of the Shcherbakov oxide-ore open pit at the Kimpersay region in the Aktyubinsk area of the south Urals in Kazakhstan began in 1975.

A cooperation agreement between Cuba, the U.S.S.R., and other COMECON countries provided for the construction of a nickel plant at Punta Gorda in Cuba with an annual capacity of about 30,000 tons of nickel and cobalt. The plant is to go into operation after 1980. The participating countries are delivering basic materials, equipment, and machinery to Cuba, and are also offering services and technical assistance. One-half of the output of the new project will go to the COMECON countries participating in the joint venture for a 10-year period following commissioning. The project will cost approximately $300 million. Also under the agreement, the Nicaro and Moa nickel plants are to be modernized by the Soviet Union.

Platinum-group Metals.—The U.S.S.R. remains the largest producer and exporter of platinum-group metals, supplying 20% of international exports of platinum and more than 50% of world consumption of palladium and rhodium. The Soviet Union is steadily expanding its output of platinum-group metals, with 1975 output estimated at 2.65 million troy ounces, more than 20% higher than in 1970. Production comes principally from Norilsk mines, with additional output from the Severonikel and Pechenganikel complexes on the Kola Peninsula. All the platinum-group metals are produced as byproducts of copper-nickel ores. Primary production of platinum-group metals is forecast to increase at an annual rate of 4% to 5% and may reach 2.75 million troy ounces by 1976 and 3.2 million troy ounces by 1980.

The U.S.S.R.'s substantial exports of gold and platinum-group metals in 1975 were assumed to be the result of the urgent need for foreign exchange to meet the cost of its large grain purchases from the United States and other Western countries. Reportedly, the Soviet Union was a heavier seller of platinum-group metals in 1975, thus reducing the need to sell gold. The United States and Japan were the major importers of Soviet platinum-group metals. The volume of further Soviet platinum-group metal sales depends largely on gold and platinum-group metal prices and on long-term credits made available by Western countries.

In the U.S.S.R. the following purity standards are established for items of general use, in parts per thousand: Platinum 950 and palladium 850 and 500.

Silver.—Output of silver in 1975 was estimated at 43 million troy ounces, 2.4% above that of 1974. Over 50% was produced as a byproduct of lead, zinc, and copper ores. Fourteen gold treatment plants also produced silver in 1975. Production continued to be centered in the Urals, Kazakhstan, the Soviet Far East, East Siberia, and Armenia. In 1975, production of silver increased at the Sikhali complex (one of the largest silver producers) in Maritime Kray, but output of metal at this complex was below the planned quota.[91] The recovery of silver at beneficiation plants in the Urals ranged from 15% to 50% from complex ores containing 6 to 15 grams of silver per ton. During the 1972–74 period recovery of silver at the Gay complex in the Urals increased 5.6%.

Soviet purity standards for silver are established as follows, in parts per thousand: 960, 916, 875, 800, and 750. Under the guidance of the Administration of Precious Metals of the U.S.S.R. Ministry of Finance, the inspectorate of the assay office is charged with the continuing responsibility of searching for ways to economize on precious metals by reducing waste and increasing substitution.

Tin.—Production of smelter tin, amounting to an estimated 30,000 tons (1.7% over that of 1974), was inadequate to meet domestic demand, and over 15% of requirements were imported in 1975. Deposits of commercial significance are found in Maritime Kray, Magadan Oblast', Khabarovsk Kray, and Yakut A.S.S.R. Maritime Kray is the largest producer and the Khrustal'nyy complex, which operates both lode and placer deposits, is the largest enterprise there. The following important lode deposits were mined in Siberia and the Soviet Far East in 1975: Valkumey, Lazo, Verkhniy Bastoy, Chapayev, Ege-Khaya, Okhotnichye and Iultin.

Three known tin refineries were operating in the U.S.S.R. in 1975: Novosibirsk, Ryazan', and Podol'sk (near Moscow). The Novosibirsk central smelter's 5-year plan (1971–75) envisaged a large increase in tin output. Concentrates from Siberia and the Soviet Far East were shipped to this plant. It was planned to increase output of metal at the Sherlova Gora, Ege-Khaya, Leningrad, Sinancha, and other smelters. Because of the slow development of the Ternistyy and Arsenyev mines, production of tin at the Krustal'nyy complex increased only 8% in 1971–75, compared with 26% envisaged in the plan.[92] Production of secondary tin began at the Ukrtsink zinc plant in the Ukraine.

According to Soviet sources, the first experimental installation in the U.S.S.R. for recovering tin offshore has been built and is operating at Vankin Bay in the Laptev Sea in Yakut A.S.S.R. A survey of the Festival'nyy tin deposit in Khabarovsk Kray was completed in 1975. The deposit, which also contains copper and tungsten, was given to the Solnechnyy mining and concentration complex for commercial operation.

Under a contract signed in La Paz, the Mining Corp. of Bolivia supplied the U.S.S.R. with 900 tons of tin concentrates. Shipments, in exchange for Soviet machinery and equipment, were made over the 1975 yearend period. Reportedly, the contract is to be expanded by 1,500 tons of tin concentrates.

In 1975, the Nakhodka tin can plant in Maritime Kray received from Fried. Krupp GmbH equipment for a new automatic production line to make oval tinplate cans. The line will turn out 100 cans per minute.

Titanium.—Titanium production in 1975 was estimated at 30,000 tons, about

[91] Work cited in footnote 86.
[92] Work cited in footnote 86.

8% over that of 1974. Large amounts of titanium sponge are now sold to the West. The industry continued to be based mainly on Ukrainian and Siberian ilmenite and rutile. During 1971–75, a 40% planned expansion was almost met. The new 5-year plan for the titanium-magnesium industry will be devoted to renovation of equipment at existing plants. Production of titanium is programed to be raised 40% in 1976–80. Exports of titanium sponge are to be increased significantly. Estimated output for 1976 and 1980 is 32,500 tons and 42,500 tons, respectively.

At the Verkhne-Dneprovsk mining and concentrating complex in the Ukraine, in addition to ilmenite and rutile concentrates, zirconium, disthene, and staurolite concentrates were recovered. But recovery of titanium and other components was not satisfactory.[93] Reports had indicated that a titaniferous slag containing 83% titanium dioxide was being made at the Zaporozhe titanium-magnesium plant in the Ukraine. During 1971–75, production of titanium and magnesium at the Ust'-Kamenogrosk plant in Kazakhstan increased over 32%. It is planned to increase production of titanium in Kazakhstan 5% in 1976 and 28% in 1980, compared with that of 1970.

In 1975, consumption of titanium in the Soviet economy was increasing rapidly and was exceeding production. The consumption of titanium during the past 10 years has increased more than 20 times in nonferrous metallurgy, in the chemical industry, and in chemical and petrochemical plant manufacture. The amount of titanium waste that has accumulated at metal-processing centers is significant, and Soviet plans are to create a secondary titanium industry in the near future.

The Soviet Union sponsored an active program of exhibitions and symposia on titanium as a means to attract new technology, equipment, and cooperative agreements. At the first International Symposium on Titanium, held in Moscow in November 1975, Soviet specialists initiated an exchange of technical-scientific information on production and use of titanium and its alloys.

Tungsten.—Production of tungsten in concentrate was estimated at 7,800 tons, 2.6% more than that of 1974, with the North Caucasus, Transbaykal, Soviet Far East, Central Asia and Kazakhstan remaining the principal producing centers. Production of tungsten has been insufficient to satisfy growing domestic needs, and about one-third of concentrate requirements has been imported from the People's Republic of China and other countries. Production is estimated at a probable 8,000 tons in 1976 and 8,700 tons in 1980. Consumption of tungsten by the Soviet steel industry is much higher than that of the ceramic hard alloys industry.

The main producer of tungsten concentrate is the Tyrny-Auz tungsten-molybdenum complex in the North Caucasus, where both underground and open pit methods are used; over 350 persons were employed at the concentrator in 1975. The concentrating plant at the Iultin complex in Magadan Oblast' began processing tungsten ore mined at the Tenke deposit in October 1975. The Inkur open pit and the first section of the Dzhida tungsten-molybdenum complex in Buryat A.S.S.R., which were put into operation in 1973, increased output in 1975. The Ukak (Tadzhik S.S.R.), Boguty, and Karooba tungsten deposits were under exploration in 1975.

Vanadium.—The Soviet Union, with large vanadium resources, is becoming an important producer and exporter. The principal sources of vanadium continue to be slag from smelting titaniferous magnetite from the Kachkanar mine in the Urals and iron ore from Lisakovsk (0.06% vanadium) in Kazakhstan. The Nizhniy Tagil metallurgical complex is the only modern enterprise in the U.S.S.R. that produces raw material for the production of vanadium and its alloys. The output of vanadium slag was low.[94] It is planned to develop the Kachkanr 2 and by 1980 to increase production of vanadium. It is also expected to put a vanadium recovery unit at the Serov plant in the Urals. The Ust'-Kamenogrosk titanium-magnesium complex in Kazakhstan has commissioned a unit for vanadium recovery from wastes. The Dneprovsk aluminum plant recovers

[93] Ekonomika Sovetskoy Ukrainy (Economics of the Soviet Ukraine), Kiev. No. 5, May 1975, p. 44.
Pages 5 and 6 of work cited in footnote 34.
[94] Second work cited in footnote 70.

vanadium pentoxide as a byproduct during the production of alumina from bauxite.

Minor Metals.—The Soviet Union possesses commercial deposits of all those rare metals that have assumed importance in modern rocketry, aircraft, and nuclear energy. The main deposits are in Kazakhstan, the Kola Peninsula, Armenia, the Urals, the Ukraine, Norilsk, Transbaykal, and the Soviet Far East.

Byproduct gallium is recovered from nepheline raw materials used to produce aluminum at the Volkhov and Pavlodar aluminum plants and at the Tikhvin alumina plant. The first industrial recovery of rhenium in the U.S.S.R. was at the Balkhash copper complex in June 1966 where rhenium salts are recovered from sulfuric acid plant washings. Rhenium is also recovered at the Kadzharan copper-molybdenum complex in Armenia, at the experimental installation of the Dzhezkazgan complex in Kazakhstan, and at other nonferrous plants. In 1975, recovery of rhenium began at the Chimkent lead plant in Kazakhstan.

Selenium and tellurium extraction has been organized at the electrolytic copper plant of the Norilsk complex in West Siberia. Selenium is also recovered at the nonferrous enterprises of Kazakhstan, the Urals, and the Kola Peninsula. Commercial production of indium began at the Almalyk complex in Uzbekistan in 1975. The Ust'-Kamenogrosk titanium-magnesium complex in Kazakhstan began recovery of scandium in 1975.

The bulk of tantalum and columbium reserves in the U.S.S.R. is in pyrochlore (Kola Peninsula, Urals), obruchevite (Kola Peninsula, Ukraine), and hetchettolite (Kola Peninsula, Khiba, and others). Reportedly, a rare metals deposit was discovered at Urminsk in the central part of Buryat A.S.S.R. in 1975.

NONMETALS

The Soviet Union produces a wide variety of nonmetallic minerals. However, the resource position varies from adequacy for many nometallic minerals to apparent shortages of others such as barite, fluorspar, mica, and talc.

Asbestos.—In 1975, total production of the six grades of asbestos produced by the Soviet Union was estimated at 1.9 million tons, 835,000 tons more than in 1970 but 300,000 tons less than that planned for the year.[95] Exports rose from 385,300 tons in 1970 to 528,000 tons in 1974 and to 613,000 tons in 1975, with about 60% going to Western markets. The price of asbestos rose from 118 rubles per ton in 1973 to 126 rubles per ton in 1974 and to an estimated 130 rubles per ton in 1975. Concurrent with the asbestos export expansion in recent years, the domestic deficit reached 200,000 tons in 1971; it was expected to be 100,000 tons in 1975.[96] The 1971–75 5-year plan foresaw an increase in new capacity by completion of the second mill at the Dzhetygara complex (400,000-ton capacity) in Kazakhstan and at the Tuvaasbest complex (205,000-ton capacity) in Tuva A.S.S.R. by 1975. Estimated outputs for 1976 and 1980 are 2 million tons and 2.6 million tons, respectively.

Development in the asbestos industry has been concentrated in the Urals, Kazakhstan, and Tuva A.S.S.R. Total output of six grades of chrysotile asbestos at the Uralasbest complex was estimated at 1,250,000 tons. The No. 6 mill at this complex, with an annual capacity of 12 million tons of low-grade crude ore (1.7%) and 320,000 tons of asbestos concentrate, began operation in August 1969. During the 1971–75 period, reconstruction of the No. 6 mill had been completed and its design capacity increased by 230,000 tons. Estimated output at the No. 6 mill increased from 155,000 tons in 1970 to 550,000 tons in 1975. Estimated production of all other mills at the Uralasbest complex increased from 650,000 tons in 1970 to 700,000 tons in 1975.

In Kazakhstan, a large complex has been organized for developing the Dzhetygara deposit in Kustanay Oblast', which is the second largest in the Soviet Union. This complex, which was a 7-year (1959–65) priority construction project, started operation in 1965. The first mill of this complex, with an annual capacity of 200,000 tons, was commissioned in October 1965. In April 1965, construction started on the No. 2 mill with an annual

[95] Stroitel'nye materialy (Construction Materials), Moscow. No. 1, January 1975, p. 3.
[96] Narodnoye khozyaystvo Kazakhstana (National Economy of Kazakhstan), Alma-Ata. No. 12, December 1971, p. 89.

capacity of 400,000 tons, and it was to be commissioned by 1970. During 1971–75 the Dzhetygara No. 1 mill was renovated and production increased from 259,000 tons in 1970 to an estimated 360,000 tons in 1975. The first and second stages of the Dzhetygara No. 2 mill were commissioned in February 1975, and this mill produced an estimated 255,000 tons in 1975. Total output of the Dzhetygara complex increased from 259,000 tons in 1970 to an estimated 615,000 tons in 1975. Over 6,000 workers were employed at the Dzhetygara complex in 1975.[97]

The first mill of the Tuvaasbest complex at Aktovrak in Tuva A.S.S.R., with an annual estimated capacity of 30,000 tons, construction of which started in 1959, was put into operation in 1966. Construction of the second mill, with capacity of 200,000 tons per year, began in 1967 and was scheduled to be completed in 1970; completion of this mill was rescheduled at first for 1975 and later for 1976. Estimated production of asbestos at Tuvaasbest increased from 30,000 tons in 1970 to 35,000 tons in 1975. Asbestos from this deposit is of the highest quality and has the greatest fiber length of any known Soviet reserves.

Development of the Kiembay deposit in Orenburg Oblast' (southern Urals) was started in 1968 and continued in 1975; more than 2,600 workers were employed on the site. Under an agreement signed in June 1973, seven COMECON member countries are participating in this project. Machinery and materials are supplied by the individual countries and are worth the following amounts in transferable rubles: Poland, 30 million; Bulgaria and East Germany, 24 million each; Romania, 18 million; Czechoslovakia, 8.4 million; and Hungary, 1.8 million. The design capacity is 500,000 tons per year of grades III to VI from 24 million tons of ore with an average grade of 4.4%. The complex is to be built in two equal stages. The first is to be completed in 1979, and its output will be shared among the COMECON members in proportion to their construction contribution. The design of the Molodezhyy asbestos complex in Buryat A.S.S.R. was completed in 1974, and construction will be started when the western section of the BAM railway is built.

Barite.—Estimated domestic production of barite in 1975 totaled 350,000 tons, or 6% over that of 1974. About 40% of the country's barite consumption in 1975 was imported, mainly from North Korea, Bulgaria, Yugoslavia, and Romania. The main centers of barite output continued to be Georgia, West Siberia, and Kazakhstan. Small deposits have been developed in the Urals, Azerbaydzhan, Armenia, and other regions. Over 30% of Soviet barite reserves are located in Georgia, which produced over two-thirds of the 1975 output. Construction of a 45,000-ton-per-year complex at Khaishi in Svanetia, Georgia, and development of the underground mine at the Zharemsk polymetallic complex in Kazakhstan continued in 1975. The increased output in 1975 was attributed largely to the completion of new facilities in Georgia and Kazakhstan.

Diamond.—Soviet diamond mining continued to expand in 1975, with output mainly centered in Yakut A.S.S.R. Production was estimated, very roughly, at 7.75 million carats of industrial diamond and 1.95 million carats of gem stones. Next to fossil fuel and precious metal exports, diamond accounts for the largest share of the Soviet Union's overall foreign currency balance. Production of diamond is estimated at a probable 9.8 million carats in 1976 and 10.6 million carats in 1980.

Production in Yakut A.S.S.R. started at a small plant in 1957. In January 1975, the industry consisted of the large Mirnyy open pit with five concentrators, the Aykhal open pit and concentrator, the Udachnaya placer mine and concentrator (near the Arctic Circle), and the Irelyakh placer mine with two dredges. Small quantities of gem and industrial stones were produced from the Vishera River Region in Perm Oblast', the western Urals, where four dredges and two separation plants were operated at two placer deposits in 1975.

Gem stones were being cut at Leningrad, Sverdlovsk, and Smolensk. Sales of cut stones were rising steadily, and substantial increases are expected in 1976–80. The U.S.S.R. arranged to market part of its diamond output in Antwerp through a newly formed Soviet-Belgian company.

[97] Kazakhstanskaya pravda, Alma-Ata. Aug. 8, 1975, p. 2.

The U.S.S.R. State Committee for Science and Technology signed an agreement with a Belgian company on scientific and technical cooperation in the production and use of diamond tools.

A substantial but unknown quantity of synthetic diamond was also produced in 1975 at plants in Kiev, Yerevan, Moscow, Tashkent, and Poltava.

Fertilizer Materials.—Production totaled 22.0 million tons in nutrient content, or 90 million tons in bulk fertilizer content,[98] an increase of 15% over that of 1974. Mineral fertilizer production was expedited during the ninth 5-year plan (1971–75). The average nutrient content increased from 29% in 1970 to 37% in 1975. Estimated production for 1976 and 1980 is 94.5 million tons (Soviet standard) and 140 million tons, respectively. Nitrogen fertilizers constitute around 37%; potassium fertilizers, 35%; phosphate fertilizers, 21%; and phosphatic flour, 7%.

The increase in production was obtained mainly through the commissioning of new capacities. In 1975, capacity was expanded by 11.7 million tons of fertilizers per year, including facilities at the Rovny, Novomoskovsk, Suma, Ionav, and Balakovsk chemical plants. The planned quota for construction of new facilities (13.7 million tons) was met by 85% in 1975.

The Soviet mineral fertilizers industry met its production goal for 1975, but 10 of the 23 plants operated by the Ministry of Chemical Industry U.S.S.R. did not meet the 1975 production quota.[99] A number of mineral fertilizers plants failed to attain their production capacity in 1975. A published review of the basic reasons for the prolonged period necessary for attaining planned capacities listed the following: Inadequacy in planning; turning over facilities for operation while substantial construction and installation work remains incomplete; equipment defects; inadequacies in raw materials supply; and failure to secure qualified personnel.[1] Because of the unsatisfactory conditions of the equipment at the Uvarovo double superphosphate and ammophos shops, the degree of capacity utilization at this plant was only 34.1% in 1974.

There was an increase in exports of mineral fertilizers. Despite substantial production, the large exports and a high national demand caused a shortfall in supplies of fertilizers. A high percentage of superphosphate and potassium fertilizers was not granulated. Difficulties were reported in the commissioning of some new projects and in attaining planned capacity of facilities.

Two plants, each with a capacity of 450,000 tons per year of ammonia, were commissioned at Novomoskovsk in Tula Oblast' in 1975. The plants are part of a Soviet and Toyo Engineering Co., Ltd., contract.

Under contracts signed in Moscow in July 1975, Mitsui & Co., Ltd., and Toyo Engineering will supply the U.S.S.R. in 1976–77 with equipment for four 1,360-ton-per-day ammonia plants with a total annual output of 1.8 million tons. For this purpose the Export-Import Bank of Japan has granted U.S.S.R. Foreign Trade Bank a credit of $245 million. The plants will be located at Cherkassy, at Dneprodzerzhinsk, at Drogobuzh near Smolensk, and in Leningrad Oblast'. Mitsui has already supplied the U.S.S.R. with five ammona plants, each with a capacity of 1,360 tons per day and using the Kellog process. They are located at Novomoskovsk, Nevinomysk, Novogorod, and Severodonetsk (two plants).

Four 1,360-ton-per-year ammonia plants, with a total annual capacity of 1.8 million tons, are being built by the United States Chemical Construction Co. (Chemico) under a $200 million contract, using Chemico technology, in the Togliatti-Kuybyshev area. Completion is scheduled for 1978. A contract for another four ammonia plants with similar capacities was awarded to Creusot-Loire. These plants are based on Kellog technology, and two plants will be built at Kemerovo and two at Gorlovka. The cost, about $200 million, will be met by supplies to France of up to 300,000 tons of the plants' output annually, beginning in 1978.

It is estimated that total Soviet ammonia capacity in January 1975 was over 12 million tons with 60% to 70% capacity

[98]The average content (nitrogen, phosphorus, and potash) is expressed in Soviet standard units. Nitrogen is expressed as ammonium sulfate, 20.5% N, phosphate is expressed as 18.7% P_2O_5, potash is expressed as 41.6% K_2O, and ground rock phosphate (phosphatic flour) is expressed as 19% P_2O_5.

[99] Sotsialisticheskaya industriya (Socialist Industry), Moscow. Jan. 15, 1976, p. 3.

[1] Khimicheskaya promyshlennost' (Chemical Industry), Moscow. No. 10; October 1975, pp. 71–74.

used. By 1980, ammonia capacity is to be increased to 20 million tons per year. There were quite a few mineral fertilizer enterprises in the U.S.S.R. that were operating stably and fulfilled the planned quota in quantity and quality of products.

An agreement between the Soviet Union and four COMECON nations has been signed for the construction of the Kingisepp mineral fertilizer plant in Leningrad Oblast'. Bulgaria, Czechoslovakia, Hungary, and East Germany will supply the equipment and materials for this plant in exchange for Soviet deliveries of ammonium phosphate over 10 years, beginning in 1976. The ore contains only 6% to 7% P_2O_5, but is easily beneficiated.

Phosphate.—Estimated output of phosphate rock totaled 61 million tons in 1975, including 35.6 million tons of apatite ore (17.7% P_2O_5) and 25.4 million tons of sedimentary rock (13% P_2O_5). The main centers continued to be the Apatit complex on the Kola Peninsula and phosphorite deposits at Karatau in Kazakhstan, Kingisepp in Leningrad Oblast', Egoryevsk and Lopatino in Moscow Oblast', and Upper Kama in the Urals.

The apatite-nepheline deposits of Khibiny on the Kola Peninsula provided about 75% of all raw materials for the production of phosphate fertilizers. Mined ore averaging 16% to 21% is upgraded to 39.4% P_2O_5 with 92% recovery. The Apatit complex produced an estimated 15.3 million tons of concentrate (35.6 million tons of ore) in 1975 from four mines and two concentrators. Production of concentrate at this complex is to be raised to 18 million tons per year by 1980. The Apatit complex employed 20,000 workers in 1975. In December 1975, commercial operations began at level 252 of the Kirov underground mine. This is the first mine in the country where ore is crushed underground and transported by conveyor. Its production capacity is 1.2 million tons per year of ore. A new technological section was put into operation at the concentrating plant in July 1975. The Apatit complex fulfilled its 1971–75 quota; it produced more than 63 million tons of apatite concentrate during the period.

A new apatite deposit at Mount Koashva was assigned to the Apatit complex in 1973. This deposit has reserves of 500 million tons of apatite ore and will play an important role in the future development of the Apatit complex. The first stage of the mine is to be put into operation in 1978 and will be linked to Kirovsk by railroad. Construction of the experimental mill at the Zabaykal'sk complex in Buryat A.S.S.R. continued in 1975. Between 1976 and 1980 this mill is to begin experimental production of an apatite concentrate from the Oshurkovo deposit, where reserves are large but have only a 4% P_2O_5 content. In the future the commercial Zabaykal'sk apatite complex, with an annual capacity of 1.3 million to 1.5 million tons of concentrate, is to be built. At the Kovdor iron ore complex on the Kola Peninsula, an apatite concentrate plant with a first stage capacity of 880,000 tons was commissioned in 1975. It processes tailings from the iron complex.

A group of Soviet specialists visited the United States to examine equipment which is to be supplied to the Apatit complex. The Tsentral'nyy open pit at this complex was being provided with 400-ton U.S. bulldozers and 120-ton dump trucks, which were due to arrive at Kirovsk at the end of 1975. Excavators of up to 8 cubic meters and dump trucks of up to 40 tons capacity were in use at the Apatit complex in 1975.

The 40 commercial deposits in the Karatau area of Kazakhstan contain 1,700 million tons of phosphorite and constitute 25% of Soviet phosphate reserves. The five largest deposits, the Dzhantas, Aksay, Chulaktau, Koksu, and Kokdzhone, contain about 1 billion tons. Seven open pits at the Aksay and Dzhantas deposits and the Molodezhnyy underground mine at the Chulaktau deposit produced a total of over 10 million tons in 1975. About 70% of total production in Karatau came from the Dzhantas deposit. The ore, containing up to 25% P_2O_5 and a high content of MgO and CO_2 was upgraded to 28.5% P_2O_5, but recovery was low. It is planned to produce about 11 million tons of phosphorite in the Karatau area in 1976. New mining facilities, with an annual capacity of 1.8 million tons of ore, were under development in Karatau in 1975 and are scheduled for completion in 1976. The second stage of the Chimkent plant was also under construction. The Karatau deposits have now proven to be of lower quality than first thought, and the

Dzhambul, Kokand, Chimkent, Samarkand, Almalyk, and Kuybyshev plants were having to downgrade their standard requirements for phosphate rock to process into fertilizers. Detailed exploration of the Chiliysk phosphate deposit in Aktuybinsk Oblast' of Kazakhstan was completed in 1975. The second stage for the production of monoammonium phosphate at the Kingisepp phosphorite complex in Leningrad Oblast' was under construction in 1975 and rescheduled for completion in 1976.

The Soviet Union has agreed to develop phosphate deposits in Morocco in exchange for Moroccan phosphate.

Potassium.—The U.S.S.R. is one of the largest potash producing and consuming countries in the world. Estimated 1975 output was 18.7 million tons (41.6% K_2O), about 12% higher than in 1974. Under the 1971–75 plan, output of potash was to increase from 9.8 million tons (41.6% K_2O) in 1970 to 19.8 million tons in 1975. Estimated levels of potash output for 1976 and 1980 are 20 million tons and 25 million tons, respectively.

Gross potash reserves are reported at 22,900 million tons of 16% to 40% K_2O content (3,800 million tons of K_2O). About two-thirds of the reserves are located at the Upper Kama Basin in the north Urals. Reserves are principally carnallite and sylvite with a 13% to 20% K_2O equivalent. The second largest reserve region (4,600 million tons) is Starobinsk (Soligorsk) in Belorussia which contains sylvite (16% to 20% K_2O). The third important basin, L'vov Oblast' (2,900 million tons) is in the West Ukraine. The most important potash mineral is hartsaltz (16% K_2O), with some deposits of carnallite, polyhalite, and langbeinite. The reserves of potassium ores in the Karlyuksk deposit in Turkmen S.S.R. were reported in 1975 at 2 billion tons, and those of the Tuva-Gatansk deposit were reported at 400 million tons. The Petryakovsk deposit in Belorussia was under exploration in 1975.

There are four potash-producing centers: Solikamsk and Berezniki on the western side of the central Urals, Soligorsk in Belorussia, and Stebnikov and Kalush in the West Ukraine. The following 10 complexes were in operation in 1975: Berezniki Nos. 1, 2 and 3, Solikamsk Nos. 1 and 2, Soligorsk Nos. 1, 2 and 3, and the first stages of the Novostebnikov and Kalush complexes. The second stage, with an annual capacity of 2.5 million tons of ore, was commissioned at the Solikamsk mine, which is the fifth mine of the Uralkaliy concern. The first stage of the Soligorsk No. 4 complex in Belorussia was under construction. In 1975, construction was begun at the Berezniki No. 4 and Novo-Solikamsk complexes, each having a capacity of 7 million tons per year of potassium chloride. Planning a mine which is to provide 50,000 tons of potassium salts per year from the Khodzhaikan deposit in Uzbekistan began in 1975.

Belorussia produced over 40% of the total Soviet output of potassium fertilizers in 1975. It is planned to produce 31.7 million tons of ore in 1980. In 1975, there were three potassium complexes in operation in Belorussia, and a fourth was being built. New facilities for mining 100,000 tons per year were developed at the No. 2 mine in 1975.

Fluorspar.—Despite the Soviet Union's efforts to achieve self-sufficiency, it remained a net importer of fluorspar with imports from Mongolia, China, Japan, and Thailand. Imports increased from 144,700 tons in 1970 to 487,400 tons in 1974 and to 493,900 tons in 1975. With an estimated production of 475,000 tons, 5.5% more than in 1974, Soviet consumption of fluorspar in 1975 was 975,000 tons; the iron and steel industry consumed more than three-quarters of the total. Estimated levels of fluorspar output for 1976 and 1980 are 490,000 tons and 540,000 tons, respectively.

Maritime Kray (Yaroslavsk deposit), Transbaykal (Kalaguysk, Abagatuysk, and Dar'insk), and Kazakhstan (Taskaynar) were the main production areas in 1975. The second stage (two new large mills) of a new production facility at the Yaroslavsk mining and concentrating complex in Maritime Kray, with the same capacity of 345,000 tons per year of ore as the first stage, was completed in October 1975. The complex works one of the richest and largest deposits in the U.S.S.R. by opencast methods. Prospecting of the Naran fluorspar deposit in Buryat A.S.S.R. was completed in 1975; it is planned to develop this deposit as a unit of the Kharankoy fluorspar mine, which is now in operation.

The Vostochnyy Taskaynar deposit in southern Kazakhstan was under detailed exploration in 1975.

Mica.—Output, estimated at 42,000 tons, 2.5% over that of 1974, was inadequate to meet demand, and strategic-grade mica continued to be imported from India for special industrial requirements. Imports of high-grade mica rose from 483 tons in 1970 to 498 tons in 1975.

Irkutsk Oblast' continued to be the main supplier of muscovite mica; 75% of all muscovite deposits in the country are in Mamsko-Chuysk County of Irkutsk Oblast'. Over 1,500 beds have been discovered in this area, and nine underground mines were in operation in 1975. There are three groups of Mamslyuda mica, depending on the size of crystal. The first group includes crystals having a surface of 100 square centimeters or more. The second and third include, respectively, areas between 50 and 100 and between 4 and 50 square centimeters. Only 10% of the ore is in group 1, while groups 2 and 3 constitute, respectively, 14% and 76%. All small mica goes to waste. The Irkutsk mica factory is the largest in the U.S.S.R. Mica is also mined in Murmansk Oblast' on the Kola Peninsula, Karelia and Yakutia. The Malinovaya Varakka and Plotina small mines were in operation near Chupa in Karel A.S.S.R. in 1975.

Salt.—The Soviet Union is one of the world's leading countries for salt reserves, production and exports. It was planned to increase production of salt from 12.4 million tons in 1970 to 14 million tons in 1975 and to 20 million tons in 1980. However, estimated production levels for 1975 and 1980 are only 13.8 million tons and 18 million tons, respectively. Exports increased from 293,600 tons in 1970 to 320,700 tons in 1975. Salt development is concentrated in the Donets Basin, the Urals, East Siberia, Armenia, and the West Ukraine.

The Donets Basin continued to account for over 40% of the total output in 1975. Development of a new mine, with an annual capacity of 2 million tons, at Artemovsk in this region continued in 1975. The construction of the Verkhnekams salt complex in Perm Oblast' and renovation of the Iletsk mine continued in 1975. Construction of the Mosyr salt complex in Belorussia, based on rock deposits which lie at a depth of 700 meters, continued in 1975. Surveying of the Belbazh salt deposit in Gor'kiy Oblast' has been completed. Exploration of a rock salt deposit near the town of Novaya Zima in Irkutsk Oblast' and the Gusev deposit in Kaliningradskaya Oblast' was continued in 1975.

Sulfur.—Estimated domestic production of contained sulfur totaled 8.2 million tons, of which 3.7 million tons was recovered from pyrite, 2.5 million tons from native sulfur, and 2.0 million tons from other sources. Sulfur exports, mainly to COMECON countries, decreased from 463,800 tons in 1970 to 441,000 tons in 1975. Consumption of sulfur from all sources totaled 8.2 million tons. Imports of sulfur increased from 216,700 tons in 1970 to 471,800 tons in 1974 and to 690,000 tons in 1975.

In 1975, the principal producing centers for native sulfur continued to be Rozdol and Yavorov (West Ukraine); Gaurdak, Shorsu, and Changyrtash (Central Asia); and Alekseyev and Vodnin of the Kuybyshev sulfur complex (Volga group). The Rozdol chemical complex was the country's major producer of native sulfur and, with the Gaurdak complex, provided the bulk of the country's sulfur requirements. The Kuybyshev sulfur complex accounted for less than 10% of the Soviet output of native sulfur in 1975.

The Gaurdak complex has been in operation for more than 40 years, but it has been modernized over the past 10 years and production has expanded from 40,000 tons to 360,000 tons, as may be seen from the following figures:

Gaurdak complex	1934	1940	1950	1960	1970	1974	1975 planned
Output of sulfur _____thousand tons__	2	4.2	7.7	18.9	189.6	309.6	360
Production of ore _____________do____	NA	NA	NA	138.9	535.1	1,342.8	1,222.1
Value of sulfur ____thousand rubles__	NA	NA	NA	NA	12,121	20,371	23,880

Sulfur production by the Frasch process at the Gaurdak complex has increased rapidly since the second commercial installation went into service at the end of the first quarter of 1975. Construction of a new (No. 3) installation using the Frasch process, to produce 100,000 tons per year of sulfur, is to be started under the tenth 5-year plan, and by 1980 production is planned at 300,000 tons. In January, the first stage of an open pit was commissioned at the Yavorov mining and chemical complex in L'vov Oblast'. The ore is to be sent to the Rozdol mining and chemical complex for sulfur recovery.

Sulfuric acid production began at the Gorlovka chemical complex in the Ukraine, at the Sumgait superphosphate plant in Azerbaydzhan, and at the second section for production of sulfuric acid at the Dzhezkazgan copper complex in Kazakhstan. A plant to recover sulfur from sour gas has been built at Orenburg. J.E. Pritchard and Co. and a French affiliate, Cie. Centrale d'Études Industrielles, provided equipment and management services for the $76 million plant, which produced 270,000 tons of sulfur in 1974 and 360,000 tons in 1975. A new Polish-Soviet transaction has been concluded in Moscow, providing for the delivery by Poland in 1978 of three new sulfuric acid plants with a capacity of 1,515 tons per day each. In previous years, the Soviet Union has purchased 25 sulfuric acid plants from Poland.

MINERAL FUELS

Production of primary energy derived from fossil fuels, fuelwood, and hydroelectric and nuclear generation increased from 699.1 million tons in standard fuel (coal) equivalent in 1960 to 1,237.5 million tons in 1970 and to an estimated 1,610.2 million tons in 1975. The output of primary energy (from all sources) in 1976 is placed at 1,725 million tons of standard fuel, and by 1980 is to rise to over 2,000 million tons. Compared with 1975 output, the 1980 production of oil is to increase 30%, natural gas 51%, coal 15%, hydroelectric power 47.9%, and nuclear power 233%.

The share of petroleum and natural gas in total Soviet primary energy production increased from 38.0% in 1960 to 65.0% in 1975, while that of coal (anthracite, bituminous, and lignite) declined from 53.4% to 30.6%. In 1980, the share of petroleum and natural gas in total energy production is to be about 69%, plus 27% in the form of coal and 4% for all other sources.

Total consumption of all types of primary energy in the Soviet Union increased from 646 million tons of standard fuel equivalent in 1960 to 1,085 million tons in 1970 and to an estimated 1,405 million tons in 1975. The share of petroleum and natural gas in total Soviet primary energy consumption increased from 34.6% in 1960 to 61.5% in 1975, while that of coal declined from 56.5% to 33.7%. Total consumption of all types of primary energy in the U.S.S.R. is expected to be equivalent to 1,480 million tons of standard fuel in 1976 and about 1,785 million tons in 1980. It is expected that the U.S.S.R. will make great efforts to substitute coal and natural gas for petroleum in order to make the latter available for export. The Soviet Union is expected to consume considerably less petroleum per capita in 1980 than West European countries.

In 1975, the U.S.S.R. produced 491 million tons of crude oil and gas condensate, 701 million tons of run-of-mine coal and lignite (402 million tons of comparable clean coal), and 289,000 million cubic meters of natural gas. Soviet long-range forecasting places the demand for raw coal and lignite at 805 million tons in 1980 and at 1,000 million tons by 2000.

Soviet fuel exports to COMECON countries increased from 320 million tons (standard fuel equivalent) during 1966–70 to 562 million tons in 1971–75. Planned exports to COMECON countries included 364 million tons of crude oil, 90 billion cubic meters of natural gas, and 67 billion kilowatt-hours of electric power in 1976–80.

According to published long-term agreements between the Soviet Union and other COMECON countries, agreements between COMECON nations, West European countries, and Japan, and trade objectives announced in the various COMECON countries' 5-year plans for 1976–80, it has been estimated that fuel exports from the U.S.S.R. to market economy countries would be increased from 94 million tons of standard fuel in 1975 to 125 million tons in 1980. Some 59 million tons of crude oil and petroleum products, 12 million tons of coal and coke, and about 22 billion cubic meters of gas are to be exported to market economy countries in 1980.

Despite expansion of Soviet primary energy production and exports during recent years, the fuel and energy supply in the U.S.S.R. has not kept up with the demand of the Soviet economy, which has experienced chronic energy shortages, particularly in the European part of the U.S.S.R. The Soviet economy sustains immense losses each year as a result of high-cost output and underutilization of energy.

The Soviet Union's reported energy consumption per capita approaches that of West Europe, although there is still a significant difference in the standard of living. One reason for the apparent difference is that the Soviet growth is measured in terms of energy "produced," not in terms of energy usefully consumed. In addition, fuel shortages encourage the production of substandard fuels, which are often marketed as standard-quality fuels.

Total primary energy balances of the U.S.S.R. for 1960, 1965, 1970, and 1975 and estimates for 1980 are shown in table 9.

Coal.—In 1975, the Soviet Union produced 701 million tons of run-of-mine coal—bituminous coal (459 million tons), anthracite (76 million tons), and lignite (166 million tons), or an estimated equivalent of 402 million tons of clean coal, according to Western practice and experience, placing it second among the world's coal producers. The 2.4% increase from the 1974 level was achieved mainly in coking coal, of which 180 million tons was produced (3% more than in 1974). The Soviet coal industry employed 2.2 million

Table 9.—U.S.S.R.: Total primary energy balance for 1960, 1965, 1970, 1975, and estimated 1980

(Million tons of standard fuel (coal) equivalent [1])

	Total primary energy	Coal (lignite, anthracite and bituminous) and coke	Crude oil and petroleum products	Natural and associated gas	Peat	Oil shale	Fuel-wood	Hydro-electric power	Nuclear power
1960:

[e] Estimate.
[1] 1 ton of standard coal equivalent (SCE) = 7,000,000 kilocalories.
[2] Less than ½ unit.

men and women, including about 1.2 million "production" workers, some 0.6 million "nonproduction" workers, 213,000 graduate engineers and technicians, and 28,000 managers and general managers.[2] The coal industry employed 770,000 women, including 109,000 at underground mines.[3] There were 638,000 workers in the Donets coal basin alone in 1975.[4]

The share of surface-mined coal in the total output was 32.2%, compared with 30% in 1974 and 24.3% in 1968. The Asian part of the U.S.S.R. (east of the Urals) contributed 56% of the total production in 1975, compared with 49.5% in 1965.

Although the U.S.S.R. does not publish statistical data on injuries in the coal industry, available Soviet information discloses that "The number of accidents in the coal industry remains high . . . It is because untrained people are being sent to the longwalls." [5]

There were about 800 underground mines with an average annual capacity of some 585,000 tons and 70 open pits with an average annual output of some 3.2 million tons of run-of-mine coal and lignite. Raw coal production by principal basin in 1975 was as follows, in million tons:

Basin	Total output	Coking coal
Donets	221.5	88.5
Kuznetsk	134.0	56.2
Karaganda	46.3	18.1
Moscow	34.1	--
Pechora	24.2	14.4
Others	240.9	2.8
Total	701.0	180.0

The Donets, Kuznetsk, Karaganda, and Pechora coal basins together produced 80% of the total coal output in terms of calorific value and about 97% of the coking coal in the Soviet Union.

The average working thickness of the coal seams, according to 1975 data, was 1.32 meters. The maximum depth of underground coal production reached 1,150 meters in 1975, while the average depth was about 380 meters.

The relative share of coal production coming from gently dipping seams was about 70%; that from inclined seams, 14%; and that from steep seams, 16%. The hand loading of coal at gently inclined seams was over 20% in 1975.

Distribution of coal production by mining method, in percent, follows:

Longwall	85
Slicing	8
Shield	3.2
Room and pillar	1.7
Others	2.1

In 1975, the average longwall length was 135 meters, and the average rate of advance was 39.1 meters per month. The average capacity of each underground mining section (longwall) was 454 tons of raw coal per day (four 6-hour shifts) in 1975. Some salient characteristics of coal and other data of main basins are given in table 10. Soviet coal and coke statistics are presented in table 11.

Natural Gas.—In a single decade the U.S.S.R.'s natural gas industry has raised the output at more than 650 gas, gas condensate, and gas-oilfields from 128 billion cubic meters in 1965 to 289 billion cubic meters in 1975; however, this output was below the original 5-year plan target of 300 billion to 320 billion cubic meters. Of this quantity, over 99% consisted of natural gas and oil associated gases and about 1% was gas from gasification of coal and oil shale. About three-fifths was produced in the European part of the country (eastern regions of the Ukraine, the North Caucasus region, the Lower Volga region, Komi A.S.S.R., and the Orenburg region). There were about 5,000 producing wells in 1975, but 15% to 20% of them were idle. In 1975, gas accounted for over 21% of Soviet primary energy production. Although the production of natural gas increased substantially during the past decade, the industry has not been able to meet a single original annual production goal set for it since 1956.

During the past decade, the recovery of associated gases more than trebled, reaching 55 billion cubic meters in 1975. In 1975, the utilization of associated gas was about 75%. In the Tatar and Bashkir A.S.S.R.'s, Kuybyshev and Perm Oblast's, Krasnodar and Stavropol Krays, and the Azov oil association, the utilization of associated gas reached over 80%. The utiliza-

Table 10.—U.S.S.R.: Major coal basins

Basin	Type of coal mined	Number of workable seams	Seam thickness (meters)			Depth of mining (meters)			Remarks
			Minimum	Maximum	Average	Minimum	Maximum	Average	
Donets	Bituminous and anthracite.	40	0.5	1.6	0.95	100	1,150	470	Large reserves represented mainly by thin seams. Two-thirds of reserves are high-grade coals of which one-half are coking coals. More than 70% of coal production comes from flat seams (0–25 degrees pitch).
Kuznetsk	Bituminous and lignite.	68	.8	20.0	2.23	50	400	250	Over 90% of coal is produced from seams over 1.2 meters thick and nearly 22% from seams over 6.5 meters thick. Coking coal comprises over 20% of reserves. Recently extensive use of opencast mining has taken place in the basin.
Karaganda	Bituminous	45	.7	7.5	1.79	100	400	330	About 97% of the coal seams are flat. More than 50% of reserves are coking coals.
Pechora	do	39	.5	4.5	1.90	150	500	430	The basin has large reserves of coking coals. Over 65% of coal is produced from flat seams.
Moscow	Lignite	2	.9	3.5	2.27	50	100	61	Brown coal with an ash content of about 45%. Coal seams are flat. Main consumers of the coal produced in this basin are powerplant and domestic heating in the central regions of the U.S.S.R.

Table 11.—U.S.S.R.: Coal and coke statistics

(Million metric tons)

	Actual				Forecast
	1960	1965	1970	1975	1980
Coal:					
Domestic output:					
Run-of-mine coal [1]	509.6	577.7	624.1	701.0	805.0
Clean coal [2]	306.0	331.0	357.0	402.0	460.0
Imports: From countries with centrally planned economies [3]	4.7	6.7	7.1	9.8	12.0

[2] Clean coal, estimated in accordance with Western practice and experience.
[3] None from market economy countries.

Source: Production data for 1960, 1965, and 1970 taken from the National Economy of the U.S.S.R., Moscow, 1960, 1965, and 1970; trade data from Foreign Trade of the U.S.S.R., Moscow, 1960, 1965, 1970, and 1975. Production data for 1975 reported in Pravda, Moscow, Feb. 1, 1976, p. 1.

tion of gas condensate resources was unsatisfactory at existing low-temperature separation facilities in the field; about 60% of the condensate produced with the gas was recovered, and the remaining portion was placed into gas pipelines where much of it was lost.

At yearend 1974, the Soviet gas supply system consisted of several hundred fields, 92,100 kilometers of pipelines, more than 80 compressor stations, 16 underground gas storage facilities, and about 300 commercial installations for the collection and processing of gas. The Soviet gas industry was reorganized into 46 production and commercial associations in 1975, through combining 200 independent enterprises and organizations.

The 1975 planned targets in the main gas-producing regions, in billion cubic meters, were as follows:

Ukraine (natural gas)	57.5
Turkmenia	47.5
Uzbekistan	36.2
Tyumen' Oblast'	34.5
Orenburg region	17.4
Komi A.S.S.R	17.2
Stavropol'	10.5
Ukraine (associated gas)	9.7
Kaspian (offshore associated gas)	7.9
Kuban'	5.5
Mangyshlak (associated gas)	4.5
Tatar A.S.S.R. (associated gas)	4.4
Other	32.2
Total	285.0

Thirty-four gasfields were in operation in the Ukraine, including Shebelinka and Efremovka. Some 60 new gas wells were put into operation in the Ukraine in 1975.

The Bukharo-Khivinskiy region (eastern Turkmenistan and western Uzbekistan) continued to occupy first place in the production of gas in the U.S.S.R. Production of gas in this region reached an estimated 83 billion cubic meters in 1975, an increase of 75% compared with that of 1971. The gross gas reserves as of January 1, 1975, were estimated at 2,761 billion cubic meters (including 1,856 billion cubic meters in eastern Turkmenistan). At the beginning of 1975, 21 gasfields were in operation (including 6 in eastern Turkmenistan) and 15 gasfields were under development (including 4 in eastern Turkmenistan).

Development of the North Achak, Naip, East Shaltyk, and West Shaltyk gasfields in eastern Turkmenistan resulted in the production of 47 billion cubic meters of natural gas in Turkmen S.S.R. in 1975, four times the amount produced in 1970. The Shaltyk gasfield was supplying 48 million to 50 million cubic meters of gas per day in 1975, compared with 40 million to 42 million cubic meters per day in 1974. It is planned to produce 57 billion cubic meters of natural gas in this Republic in 1976. Thirteen fields and new areas are to be covered by prospecting and exploratory drilling. Total exploratory drilling is to be 80,000 meters. Developmental drilling of 120,000 meters is to be done at eight fields in 1976. Uzbekistan produced an estimated 36 billion cubic meters of gas in 1975. The gasfield at Gazli, the largest in this Republic, produced from more than 200 developmental wells, over three-quarters of the Uzbekistan total.

West Siberian gas production increased from 9 billion cubic meters in 1970 to an estimated 38 billion cubic meters in 1975. The region is slated to produce 115 billion to 145 billion cubic meters in 1980, or 29% to 33% of the Soviet total. Almost two-thirds of total Soviet gross natural gas reserves are located in Tyumen' Oblast'. Four fields were in operation in this region—Punga, Igrim, Pakhomovsk, and Medvezhye. The latter is the largest of the four. The Medvezhye Field, development of which began in 1972, produced about 1.5 billion cubic meters in 1972, over 8 billion cubic meters in 1973, and 33 billion cubic meters in 1975, or about 88% of all West Siberian production. This field is expected to produce about 40 billion cubic meters in 1976 and almost 65 billion cubic meters in 1980.

Drilling of the first developmental well at the Urengoy gasfield in Tyumen' Oblast', the Soviet's biggest gasfield, was completed in June 1975. It is expected that gas production at the Urengoy Field will begin in 1978. In 1975, pipelines were being laid and installations for gas processing were being built. According to Soviet sources, capital investment per cubic meter of gas production in West Siberia is 50% to 80% higher than in the European part of the U.S.S.R.

The Orenburg gas condensate field was one of the largest projects of the ninth (1971–75) 5-year plan. It included three interlinked industrial projects: The extractive sector, the gas refinery plant, and the main pipelines. It was planned to extract 4.5 billion cubic meters of gas in 1972, 18.5 billion cubic meters in 1974, and 25 billion cubic meters in 1975. The actual production was 3.1 billion cubic meters of gas in 1972, 11.3 billion cubic meters in 1974, and 17.4 (plan) billion cubic meters in 1975. The first stage of the 15-billion-cubic-meter-annual-capacity Orenburg gas-processing plant, which processes gas condensate from this field, was put into operation in 1974. A second stage of the Orenburg gas complex, also with a 15-billion-cubic-meter annual capacity, was scheduled for service in 1976.

Drilling of developmental wells of the third stage of the Orenburg complex began in 1975. This stage will consist of 100 operational wells. Under a contract signed in September 1975, Creusot-Loire is to supply the U.S.S.R. with equipment for the extraction and field processing of 15 billion cubic meters of gas per year. The equipment will be used in the third stage of the Orenburg gas complex. Reportedly, the French Technip firm and Soviet Techmashimport have signed a 1-billion-franc contract for a natural gas desulfurizing plant, which will form the third stage of the Orenburg gas complex. The plant is to have a processing capacity of 17 billion cubic meters of gas per year, the same as that of the first two, which were also constructed by Technip. The third stage of the Orenburg gas complex is to go into operation in 1978.

Production of gas at the Vukytl condensate gasfield in Komi A.S.S.R. increased from 0.9 billion cubic meters in 1964 to an estimated 17 billion cubic meters in 1975.

Soviet natural gas statistics are presented in table 12.

Petroleum.—The U.S.S.R. continued to be the leading petroleum-producing country in the world in 1975. Crude oil and gas condensate output in 1975 increased 31.8 million tons, or 7%, to a total 491 million tons. The Soviet Union continued to expand exports of crude oil and petroleum products even though supplies for internal consumption have been critically short. Exports rose to 95.8 million tons in 1970, to 116.2 million tons in 1974, and to 130.4 million tons in 1975. About 60% of the total exports was sent to other centrally planned economy countries. The oil exports provide the U.S.S.R. with much of its convertible currency earnings, which were increasingly needed to pay for expanding imports of Western machinery and equipment. Soviet imports of crude oil and petroleum products increased from 4.6 million tons in 1970 to 14.7 million tons in 1973 and dropped sharply to 5.4 million tons in 1974 and 7.5 million tons in 1975.

In 1975, over 500 (including 36 large) oil and gas condensate fields were in operation with a total of 64,843 producing and about 10,000 injection wells. Out of the 64,843 producing wells, 60,172, or 92%, were active. The average crude output per well was 20.4 tons per day in 1975.[6] During 1971–75 about 9,500 producing wells were put into operation.

All three primary methods of crude oil production (flowing, 8,903 wells; pumping, 53,140 wells; and gas lifting, 2,800 wells) were used, and secondary recovery methods (repressuring and waterflooding) were employed at many other fields in the Soviet Union. Production of crude by the flowing method decreased from 53.4% of the total in 1971 to 45.1% in 1974. It is expected that by 1980 only 37% of the Soviet total will be produced by the flowing method. Waterflooding increased from 560 million cubic meters in 1970 to 887 million cubic meters in 1974, and second-

Source: Production data for 1970 and 1974 taken from the National Economy of the U.S.S.R., Moscow, 1970 and 1974; production data for 1975 reported in Pravda, Moscow, Feb. 1, 1976, p. 1; trade data from Foreign Trade of the U.S.S.R., Moscow, 1970, 1974, and 1975; 1980 forecast based on 5-year plan and delivery contracts.

ary recovery increased from 52 million tons to 280 million tons for the same period.[7]

During 1971–75, fuel and power production were increased annually by 65 million to 70 million tons of standard fuel equivalent, over half of which was provided by petroleum; 25,500 developmental and exploratory wells were drilled; and over 18,000 kilometers of trunk pipelines were placed in operation. During the same period, capital investment in crude oil production reached over 18 billion rubles, of which about 4 billion rubles was invested in 1975. The return on capital in 1975 was reduced 15% from that of 1970, corresponding to an estimated loss of more than 1 billion rubles in 1975; at the same time the average well production had grown from 18.5 tons to 20.6 tons per day, which should have raised the return on capital 7.4%.[8]

Crude oil extraction occupied 740,000 persons, including some 650,000 workers, 35,000 university graduate engineers, and 55,000 graduate technicians.[9] The total number of workers engaged in drilling reached about one-fifth of all workers in the crude oil production industry. The industry had 33 research and design establishments with a total staff of 25,000 persons. Expenditures for scientific research exceeded 90 million rubles per year.

The expansion of Soviet petroleum production was achieved through the use of a large number of rigs and the liberal use of manpower and materials. The production of petroleum equipment has grown substantially, but the technical standards and the quality of machinery and equipment produced are poor. Productivity and reliability of the equipment used in crude oil extraction are low. Drilling pipe used in 1975 (Government standard GOST 631–63) had low strength and inadequate sealing. In Western countries such products have long since been taken out of production; in the U.S.S.R., however, low productivity and obsolete equipment are still being included in plans.[10]

Reportedly, the value of Soviet imports of Western equipment for oil and gas exploration and production increased from $43 million in 1974 to $176 million in 1975. The value of U.S. exports to the U.S.S.R. jumped from $0.5 million in 1974 to $47 million in 1975. As a result, the United States became the leading supplier of petroleum-related equipment and facilities to the U.S.S.R., followed by West Germany, Romania, France, and the United Kingdom.

It was planned to put the following facilities into operation during 1975: Crude oil collection, 87.2 million tons; crude oil preparation, 69 million tons; petroleum pipeline, 2,750 kilometers; and developmental drilling (4,300 wells), 8.5 million meters. An investment of 2.7 billion rubles was planned for production facilities and oilfield exploration.

Development of the first underground oil-producing mine, with an annual capacity of up to 300,000 tons, is to begin in Azerbaydzhan in 1976; completion is scheduled for 1980. The crude is to be mined at a depth of 400 meters from two vertical shafts.

The annual Soviet crude and gas condensate production increase amounted to 28.6 million tons in 1973, 29.9 million tons in 1974, and 32.1 million tons in 1975. Production of crude oil (including gas condensate) is slated to rise to 520.6 million tons in 1976 and to 640 million tons in 1980.

Reportedly, the Soviet Oil Industry Minister has proposed to U.S. companies technical cooperation in the field of exploration and oil extraction using new methods and techniques. He also stressed that oil companies from any country could take part and that the U.S.S.R. is ready to pay for this cooperation.

Oilfields and Crude Oil Production.—During 1971–75 70% of the total petroleum was produced in the European part of the U.S.S.R. The Ural-Volga area continued to be the Soviet Union's major producing area, supplying nearly half of the nation's crude output in 1975. Most of the U.S.S.R.'s increased production is, however, derived from the West Siberian fields, where 148 million tons was pro-

duced in 1975. The Ural-Volga area will continue to lead until the developing oilfields of Siberia, Mangyshlak, and Turkmenistan come into their own. West Siberia was the second largest producer, followed by the North Caucasus and Kazakhstan.

Among the oil-producing regions, Tyumen' Oblast' held the leading place, followed by Tatar A.S.S.R., Bashkir A.S.S.R., Kuybyshev Oblast', Perm Oblast', and the Mangyshlak Peninsula in Kazakhstan. Of the country's 26 oil-producing regions, 24 regions met the 1975 production quotas. The Komi and Azerbaydzhan oil-producing associations did not meet the 1975 production targets.

There were 139 oilfields in Tyumen' Oblast' on December 31, 1975; 54 of them were discovered during 1971–75, including 10 oilfields in 1975. But only 15 oilfields were in operation in 1975, including the Kholmogorskoye Field which was put into operation in August 1975. The Samotlor oilfield in Tyumen' Oblast', the largest oilfield in the U.S.S.R., accounted for more than 50% of the oil extracted in West Siberia. More than 1,200 developmental wells were in operation at this field in 1975. Discovered in 1965, the Samotlor Field began commercial production in 1969 and produced 218 million tons during 1971–75. Production was 224,000 tons per day in 1975.

Since the development of the Pravdinsk Field in Tyumen' Oblast' began, 25 million tons of crude had been produced. The output at this field was 18,500 tons per day in 1975. The Southern Surgut oilfield, which was discovered in 1973, is among the largest fields in Tyumen' Oblast'; 23 developmental wells were put into operation in 1974–75. During the same period over 300 wells were drilled and more than 30 million tons of crude was extracted from the Sovietsko-Sosninsk Field in Tomsk Oblast'. It is planned to produce 180 million tons of crude oil in West Siberia in 1976 and 300 million to 310 million tons in 1980.

In the Ural-Volga area, the so-called Second Baku, output was concentrated in three regions: Tataria, Bashkiria, and Kuybyshev Oblast'. Tatar A.S.S.R. produced 1,472 million tons of crude oil in 1943–75 and for 17 years this region has been the main Soviet petroleum producer. Some 103.7 million tons of crude was produced in 1975. The Romashkino oilfield is the largest in this Republic. During 1971–75, about 5,000 developmental wells were drilled in Tatar A.S.S.R. In 1976, this region is to produce 101 million tons of crude. Bashkir A.S.S.R. produced around 40 million tons of crude in 1975. Udmurt A.S.S.R. had the second (after West Siberia) fastest growth rate for crude production in the country. Output of crude increased from 475,000 tons in 1970 to 3.7 million tons (from 458 wells) in 1975. Up to 1975, 24 oilfields were surveyed in Udmurt A.S.S.R., of which 5 were in operation in 1975. Perm Oblast', in the Ural-Volga area, produced 22.1 million tons of crude, and Orenburg Oblast' extracted 22.2 million tons in 1975.

Kazakhstan produced over 24 million tons of crude in 1975. Of this, 20.1 million tons came from the Mangyshlak Peninsula, where over 600 developmental wells were put into production during 1971–75. Oil output in Belorussia rose from 4.2 million tons in 1970 to over 8 million tons in 1975. There were over 300 developmental wells in this Republic in 1975; they produced over 23,000 tons of crude per day. Komi A.S.S.R.'s crude output increased from 5.6 million tons in 1970 to 7.1 million tons in 1975. For several years crude production on Sakhalin Island was held at about 2.4 million tons per year.

In Azerbaydzhan, for the past several years the extraction of crude oil has been declining. The reduction in output is taking place at the onshore and offshore fields.

Shifts in Soviet actual and planned production of crude oil are shown in table 13.

Refining and Petroleum Products Supply.—The petroleum refining and petrochemical industry developed widely as a large independent industry in the 10 years following its establishment in 1965. According to the volume of products sold by this industry, it occupied second place (after the ferrous metallurgy industry) among the heavy industries of the U.S.S.R.[11] There are three steps in the new management structure of the Soviet petroleum refining and petrochemical industry.

One scientific automation and 14 production associations were established in 1975.

Information pertinent to refining and utilizing petroleum products is a State secret, and material on the subject is not available. However, a great deal of indirect information is available. For many years Soviet practices in dehydration, desalting, and crude stabilization have lagged behind the technical level of other countries.

Most of the pipelines in West Siberia operate according to an oilfield-pipeline-refinery pattern. Under such conditions water and other impurities in the crude have amounted to several million tons. Moreover, even a short-term shutdown of a pipeline causes wells in the fields to be cut off and affects the performance of refineries.[12] Water content in crude received by the Soviet refineries ranged from 0.5% to 2% (average 0.76%), with 1,000 to 5,000 milligrams of chloride salts per liter (average 739 milligrams), while the norm permits only 0.2% water and 40 milligrams of salt per liter.[13] As a result of inadequate pretreatment of crude, according to Soviet sources, refinery consumption and losses amount to 13.4%.[14] The total loss incurred by refining insufficiently desalinated crude oil is more than 200 million rubles per year.[15] Losses in storage and transportation of crude oil to refineries are estimated at 1.6%.

While the Soviets do not publish output figures for petroleum products, reasonable estimates can be derived by assuming a yield of 85% of the reported crude petroleum input. Thus, Soviet output of refined products from crude oil (including condensate) in 1975 has been estimated at 344 million tons. Based upon production and trade figures, Soviet consumption of refined products in 1975 has been estimated at about 308 million tons.

The 1971–75 plan envisaged a 40% increase in product output by 1975 as compared with 1970 output. This goal was not met. Estimated refinery capacity at yearend totaled 380 million tons per year,

Sotsialisticheskaya industriya (Socialist Industry), Moscow. June 3, 1970, p. 1.

an increase of 85 million tons over the 1970 level.

With the assistance of Western firms, additional facilities for primary processing of oil and catalytic reforming at the Kherson, Kirishi, Novo-Ishimbay, Perm, Kremenchug, Angarsk, Omsk, Fergana, Polotsk, Ryazan', Khabarovsk, Ukhta, Saratov, Novokuybyshev, Mozyr, Novo-Gor'kiy, Novo-Ufa, and Groznyy imeni Sheripova refineries and at the Nizhnekamsk petrochemical complex were put into operation during 1971–75. In 1975, the following new oil refineries were under construction: Achinsk, Tobolsk, Tomsk, Lisichansk, Pavlodar, Mazeikiai, and Chardzhou. Plans have been drawn up for the construction of a large refinery near Nakhodka in the Soviet Far East. Most of the refinery's output will be exported.

Reportedly, the Soviet Ministry for Oil Refining and the Petrochemical Industry has asked the Pullman Kellog Corp. of the United States to submit proposals for construction of eight major petroleum refineries and four auxiliary installations. The total cost for all 12 units is estimated at over $3 billion. At the same time, the U.S.S.R. is to supply equipment for an oil refinery under construction with Soviet technical assistance at Mysore, India.

The 1980 petroleum product supply picture is reasonably clear. The output of petroleum products from crude oil would be 443 million tons, based upon 85% of the estimated crude petroleum input. A reasonably accurate consumption estimate of 399 million tons is based on the 5-year plan figures of industrial and other uses until 1980. Meanwhile, Soviet imports of petroleum products are expected to reach about 1 million tons. Thus, the supply balance shows that approximately 45 million tons of petroleum products could be available for export in 1980.

Actual and estimated exports of crude oil and products from the U.S.S.R. to European COMECON countries are shown in table 14. Soviet petroleum statistics are shown in table 15.

Table 14.—U.S.S.R.: Exports of crude oil and products to COMECON nations in East Europe

Sources: Production data 1960, 1965, 1970, and 1975 taken from the National Economy of the U.S.S.R., Moscow, 1960, 1965, and 1970; and Pravda, Moscow, Feb. 1, 1976, p. 1. Trade data from Foreign Trade of the U.S.S.R., Moscow, 1960, 1965, 1970, and 1975.

Other Fuels and Energy.—Among the other fuels and energy of lesser significance in the energy economy in 1975 were hydroelectric power, nuclear energy, oil shale, peat, and fuelwood. Peat (fuel), oil shale, and fuelwood together accounted for 7.7% of the total Soviet fuel production in 1960, but by 1975 their aggregate share had fallen to an estimated 3%. There was, in fact, an absolute increase in the production of these commodities, a trend which is expected to continue into the future.

Hydroelectric Power.—The economic technical potential of hydroelectric power in the U.S.S.R. was placed at 1,095 billion kilowatt-hours per year. In the overall energy economy of the Soviet Union, however, water power is of relatively small significance. Hydroelectric power supplied 138 billion kilowatt-hours or 13% of all electric power generated in 1975.

At the beginning of 1976, the total installed capacity of Soviet electric powerplants reached 218 million kilowatts, of which 40.8 million kilowatts represented hydroelectric capacity and about 5.1 million kilowatts nuclear capacity. Most of the future development of electric power capacity will be centered on new thermal electric powerplants, most of which will be fueled by lignite. There are plans to commission 12.19 million kilowatts of new electric-power generating facilities in 1976, including 8.48 million kilowatts thermal, 1.01 million kilowatts nuclear, and 2.7 million kilowatts hydraulic capactiy. Under the 1976–80 plan, 71 million kilowatts of new electric power generating facilities are to be commissioned and are scheduled to produce 1,380 billion kilowatt-hours of electric power annually by 1980. The output of hydroelectric power may reach 197 billion kilowatt-hours by 1980. In 1980, the capacity of hydroelectric powerplants may reach approximately 54 million kilowatts. Capital investment in construction of new powerplants for the next 5 years has been set at 26 billion rubles, compared with 22 billion rubles under the 1971–75 plan.

Nuclear Power.—The Soviet Union operated eight atomic powerplants with a total capacity of 4,052 megawatts, or about 2% of the capacity of all electric powerplants in the country on January 1, 1975. Novo-Voronezh had four reactors, total capacity 1,455 megawatts; Beloyarsk, two reactors, 300 megawatts; Melekess, one reactor, 50 megawatts; the Kola Peninsula two reactors, 880 megawatts; Shevchenko, one reactor, 350 megawatts; Bilibino, one reactor, 12 megawatts; Leningrad, one reactor, 1,000 megawatts; and Obninsk, one reactor, 5 megawatts. In 1975, the following nuclear powerplants were put into operation: The second stage (one reactor) at Bilibino with a capacity of 12 megawatts commissioned in January, and the third stage (one reactor) at this powerplant, with the same capacity, completed December 31; and the second stage (one reactor) at Leningrad, with a capacity of 1,000 megawatts, put into operation in November. Therefore, the total installed capacity of all eight Soviet nuclear powerplants on January 1, 1976, was 5,076 megawatts, or 2.3% of the capacity of all electric powerplants in the U.S.S.R.

In 1975, Soviet nuclear powerplants generated about 20 billion kilowatt-hours (25% more than in 1974; 80% of the 1975 planned quota), or 1.9% of all power supplied in 1975. Several nuclear powerplants were under construction in 1975, and some of these were scheduled for completion in 1980. It is planned to install 13,750 megawatts of new nuclear capacity by 1980 and to generate 80 billion kilowatt-hours of nuclear electricity in 1980. The estimated level of Soviet nuclear generating capacity for 1980 is about 17,500 megawatts. The U.S.S.R. will probably increase the production of nuclear power from an estimated 20 billion kilowatt-hours in 1975 to 65 billion kilowatt-hours in 1980. Nuclear power output is to represent about 4.7% of national electric power production and 0.4% of total Soviet primary energy output by 1980.

According to Soviet sources, construction and initial fueling of nuclear power stations is more expensive than that of conventional thermal powerplants of similar capacity. However, operating costs at nuclear power stations are being constantly reduced, particularly at the large-capacity stations. Thus, the generation cost of 1 kilowatt-hour at the Novo-Voronezh nuclear powerplant was reduced from 0.95 ruble in 1971 to 0.65 ruble in 1975.

Soviet nuclear energy statistics are presented in the following tabulation:

Nuclear plant and unit	Startup date	Capacity (megawatts)	
		Actual Jan. 1, 1976	Estimated Dec. 31, 1980

[1] The first dual-purpose nuclear powerplant using a sodium-cooled fast reactor with a designed capacity of 150,000 kilowatts and desalination capacity of 120,000 cubic meters per day of fresh water.

The U.S.S.R. is embarked on a major 5-year nuclear power expansion program. The reactors are to be installed in 10 new nuclear powerplants to be built under the 1976–80 plan. Each plant will have a projected capacity of 1 million kilowatts. The standard nuclear reactor now being produced at the Izhorsk plant in Leningrad is a 440-megawatt pressurized water reactor. Using this model, the U.S.S.R. can turn to the West for the supply of equipment and technology for its nuclear industry. The Soviets are interested in key components and equipment to be manufactured in West Europe, Japan, and the United States.

The Soviet Union has meanwhile embarked on a program to develop its own heavy-machine-building facilities. The key to this program is the establishment of a very large reactor production plant near Volgodonsk on the River Don. The new complex, to be known as Atommash ("atomic machines"), will specialize in serial production of 1,000-megawatt reactors and other equipment for nuclear powerplants. The first stage of the plant is to be onstream in 1978, and completion of the plant is scheduled for 1980.

The U.S.S.R. provided technical assistance in the construction of nuclear powerplants in COMECON countries. A nuclear powerplant with a capacity of 70 megawatts was put into operation at Rheinsberg, East Germany, in May 1966. Reportedly, a nuclear powerplant near Greifswald on the Baltic coast, with a capacity of 440 megawatts, was put into operation in December 1973; the second stage of this plant (with the same capacity) was completed in December 1974.

In December 1972, the first Czechoslovak nuclear powerplant, with a capacity of 140 megawatts, was put into operation at Yaslovske Bohunice in Western Slovakia. The second stage of this plant was under construction in 1975. The technical project of a second nuclear powerplant in this country, with a capacity of 440 megawatts, was completed by Soviet engineers in 1974. The first stage (440 megawatts) of the Kozloduy nuclear powerplant in Bulgaria was completed in 1975, and the second one, with the same capacity, is to be put into operation in 1976. Construction of similar nuclear powerplants, with a capacity of 440 megawatts each, began in Hungary (Paks nuclear powerplant) and Romania in 1974 and is scheduled for completion by 1985.

The first nuclear powerplant in Poland, with a capacity of 440 megawatts, is to be built on Lake Zarnowieckie, Gdansk Province, during the 1990's. Cuba's first atomic power station is to be built in Las Villas Province with Soviet assistance.

The first stage of the Loviisa nuclear powerplant in Finland, with a capacity of 440 megawatts, was under construction with Soviet assistance in 1975. Under a Finnish-Soviet agreement, the main machinery, reactor units, and turbines, as well as the nuclear fuel, will be delivered by the Soviet foreign trade organization Atomenergoexport. The Finns are responsible for the actual construction work and for delivering various components and electrical equipment. Reportedly, 750 Soviet engineers, technicians, and mechanics who are helping with nuclear powerplant construction have been living at the construction site.

According to a long-term agreement, Spain will import an estimated $400 million worth of Soviet uranium concentrate to fuel nuclear powerplants in Spain. Reportedly, Rheinische-Westfälisches Elektrizitätswerk AG has a contract with the Soviet Union, worth DM1 billion and valid until 1990, that will ensure a sufficient supply of uranium for the nuclear powerplants. The contract for the enrichment of uranium for Austria's second nuclear power project for the 12-year period was signed by the U.S.S.R. on May 23. This nuclear powerplant is scheduled for operation in 1980 or 1981.

Oil Shale.—Minable oil shale reserves, confined to deposits in Estonia, Leningrad Oblast', and the Volga region, amounted to over 5 billion tons of standard fuel equivalent (16.7 billion tons). The largest oil shale reserves are in Estonia. The production of oil shale increased from 33.3 million tons in 1974 to an estimated 34 million tons in 1975. The output of oil shale may possibly reach 35 million tons in 1976 and 38 million tons in 1980. Over two-thirds of the extracted shale in the U.S.S.R. is burned at the Pribaltiyskaya and Estonskaya thermal electric powerplants. The remainder is processed into furnace oil, gasoline, fuel gas, phenols, and aromatic hydrocarbons. Oil shale is also used in commercial everyday needs. The world's biggest powerplant in Tallin, fueled by oil shale, has reached a capacity of 1,600,000 kilowatts.

The main center of production, as in prior years, was Estonian S.S.R., where output totaled over 27 million tons in 1975 and is expected to be about 30 million tons in 1980. There were eight underground mines and four open pits in operation in Estonia in 1975. Some Estonian oil shale went for chemistry needs, while 23 million tons was used directly for the production of electricity and heat.

In 1975, three underground oil shale mines in Leningrad Oblast' produced some 5 million tons, and over 1 million tons of oil shale came from the Volga region.

Most of Estonia's oil shale comes from thin seams at a depth of 20 to 30 meters. An increasing proportion is obtained from open pits. The future development of the Republic's oil shale industry is impeded by the following factors: Limited reserves of untapped shale deposits, shortage of manpower, limited capacity of existing petrochemical enterprises and environmental protection. According to Soviet sources, both dust and pollution of air, rivers, and ground water at many places in the Estonian oil shale basin exceed permissible standards. It has been decided to begin the development of the middle-Dnepr oil shale deposit, which has been estimated to contain over 3 billion tons of oil shale.

Reportedly Thailand has accepted an offer from the Soviet Union of technical assistance for oil shale development.

Peat.—The Soviet Union produced an estimated 192 million tons of peat in 1975. Of this quantity, 60 million tons consists of fuel peat and 132 million tons of agricultural peat. The latter includes production of 45 million to 50 million tons from collective farms, some of wihch may be used for local fuel. The R.S.F.S.R. occupied first place in the production of peat in the U.S.S.R. and produced some 112 million tons, including an estimated 35 million tons of fuel peat. Belorussian S.S.R., with an estimated output of 42 million tons was the second largest peat-producing region.

Soviet gross reserves of peat were increased between 1955 and 1975 from about 20 billion tons to 39 billion tons of standard fuel equivalent. However, about 11% of today's minable reserves are located in the European part of the U.S.S.R., Belorussia, the Baltic States, and the Ukraine, which together produced over 80% of the national output in 1975. Analysis of past trends and Soviet potential facilities indicate that extraction of peat may reach 200 million tons (including 65 million tons of fuel peat) in 1980.

Reserves and estimated production of peat by the Soviet Union, in 1975 follow:

Republic	Reserves (billion metric tons)	Production (million metric tons)
R.S.F.S.R.:		
North-West	19.8	19.1
Center	5.3	44.8
Volga-Vyatka	2.0	20.6
Volga	.3	10.1
Urals	9.1	9.7
West Siberia	103.9	3.6
East Siberia	4.0	1.1
Soviet Far East	5.2	2.0
Other	.3	1.0
Total	149.9	112.0
Ukrainian S.S.R	2.3	27.6
Belorussian S.S.R	5.4	41.9

Lithuanian S.S.R	.8	3.4
Latvian S.S.R	1.7	5.3
Estonian S.S.R	2.3	2.6
Grand total U.S.S.R	162.5	193.0

Sources: Planovoye khozyaystvo (Planned Economy), Moscow. No. 3, March 1975, p. 124. Torfyanaya promyshlennost' (Peat Industry), Moscow. No. 6, June 1975, pp. 20–23.

There were 70 electric powerplants fueled by peat, with a total capacity of about 4,000 megawatts, in operation in the U.S.S.R. in 1975. A number of new powerplants, with a capacity of 600 megawatts each, were being constructed in different regions of the U.S.S.R. in 1975. Fuel peat is also used in domestic heating.

The Mineral Industry of the United Kingdom

By William F. Keyes [1]

The United Kingdom experienced its deepest recession of the post-World War II period in 1975. The gross domestic product fell 1.6% in real terms, and industrial production declined 4.8%, falling back to 1970 levels; unemployment reached the high level of 1.2 million in December (5% by official reckoning). Retail price inflation in 1975 was 24.2%. Government expenditure was the main buoyant element in the economy, but by yearend there were a few encouraging signs of recovery, particularly in chemicals and light industry.

The minerals and metallurgical sector participated in the general recession. The steel industry operated far below capacity and nonferrous metals smelter production, particularly of aluminum, copper, lead, and zinc, declined. Limited potash ore production began after a considerable delay. The chief hopeful prospect was for imminent growth in petroleum production, which began in 1975, and for increases in natural gas supplies, which already provided virtually all the United Kingdom's requirements. It was forecast that the United Kingdom would be self-sufficient in energy by the 1980's and might have an exportable surplus of hydrocarbons as well.

The mining industry of the United Kingdom was small by world standards, and production consisted primarily of coal, iron ore, certain other industrial minerals and metals, and construction aggregate materials. Recognizing that future mineral production would have to be carefully planned, the Government established the Stevens Committee in September 1972 to examine planning control and to recommend improvements; the report [2] was completed in 1975.

Some of the chief recommendations of the report may be summarized as follows: No separate planning control system for minerals is needed. The existing planning law (the Town and Country Planning Act 1971), which invests local governments (the county councils) with authority for land planning, should be amended to provide the councils with qualified minerals planning staff, probably to be shared among several counties. The Departments of Industry and of the Environment should coordinate the county planning to insure respectively that the national interests are considered and that definitive environmental policies are followed. Consultative committees, on which both the county councils and the mine operators are represented, should be established to consider proposed development in any "mineral consultation areas." Exploration activities should become "permitted development," requiring only notification of the local authorities. Another major recommendation was that progress in land restoration after mining be monitored for 10 years but that no financial guarantees be required unless, after that period, a review found it necessary.

PRODUCTION

The production index for mining and quarrying rose in 1975, but was still well below the 1970 base year. Other manufacturing indexes all showed declines, as given below:

	1974 r	1975
Mining and quarrying	79.0	86.0
Manufacturing:		
Ferrous metals	87.7	74.2
Nonferrous metals	104.2	92.2
Brick, pottery, glass, etc	117.5	108.5
Chemicals	127.7	115.6
Coal and petroleum products	106.0	92.0
All industry	106.1	100.9

e Estimate. p Preliminary. r Revised. NA Not available.
1 Includes antimony content of antimonial lead and antimony compounds.
2 Less than ½ unit.
3 Includes wheels, centers, tires, axles, and semimanufactures for sale.
4 Lead refined from imported bullion.
5 Lead refined from scrap materials and domestic ores.
6 Year ending May 31 of that stated.
7 Excludes plaster.
8 Consists of bricks, retorts, molds, and other refractory products made from clays, silica, siliceous material, magnesite, alumina and chrome materials.
9 Gas made at gasworks plus purchased coke oven refinery gas.

TRADE

The United Kingdom was almost entirely dependent upon imported petroleum in 1975, but this dependence was expected to diminish and eventually disappear over the next decade as North Sea production increased. The bulk of crude came from the Middle East. In addition, the United Kingdom traditionally had a moderate net import deficit of refined products, which was filled by refineries on the continent.

Ores and metals were imported largely from present or former Commonwealth countries: Lead and zinc from Australia and Canada, copper from Zambia, iron ore from Canada, and manganese and chromite from the Republic of South Africa. Other supplies came from major producing areas, such as copper from Chile and iron ore from Sweden.

The United Kingdom's trade with the United States was important to both nations and included smaller amounts of the major metals and relatively large amounts of the minor metals.

COMMODITY REVIEW

METALS

Aluminum.—Reduced aluminum demand during the year caused all the United Kingdom plants to operate below capacity.

British Insulated Callenders Cables, Ltd. sold its 19% interest in Anglesey Aluminium Ltd. late in 1975 to one of the remaining shareholders, Kaiser Aluminum & Chemical Corp., whose share thus increased from 34% to 66⅔%; the share of Rio Tinto Zinc Corp., Ltd. was cut from 47% to 33⅓%. Financial arrangements connected with the sale took account of a large operating deficit in 1975; Anglesey had been hampered by labor and technical problems, and Kaiser intended to bring new technical and managerial talent to bear.

There are no economic deposits of bauxite in the United Kingdom. Three recently constructed large aluminum smelters and two older, smaller plants formed the United Kingdom's aluminum industry. The large plants were the Lynemouth, Northumberland plant (capacity 120,000 tons per year) of Alcan (U.K.) Ltd.; the Holyhead, Anglesey Island, Wales plant (100,000 tons per year) of Anglesey Aluminium; and the Invergordon, Scotland plant (100,000 tons per year) of the British Aluminium Co., Ltd. British Aluminium also operated the two smaller plants at Kinlochleven, Scotland (10,000 tons per year) and Lochaber (Fort William), Scotland (30,000 tons per year).

Copper.—The only mine production of copper in 1975 was copper-zinc-silver concentrates produced by the Wheal Jane tin mine in Cornwall; these were shipped to Boliden A.B. in Sweden. There was some minor activity in exploration of other copper properties, but no results were announced.

No primary copper smelters operated in the United Kingdom during 1975. There was, however, a significant capacity for refining scrap and imported blister, amounting to about 279,000 tons per year. Some 80% or 90% of this capacity is at the two plants of British Copper Refiners Ltd. at Widnes and Prescott, both outside Liverpool, and at the plant of IMI Refiners Ltd. at Walsall, near Birmingham.

Iron and Steel.—The nationalized British Steel Corp. (BSC) made a profit before taxes of £89 million in the year to March 1975, but experienced an estimated loss of £250 million[3] in the succeeding 12 months, attributed to strikes, economic recession, rising costs, and price cuts. The industry operated at 60% of capacity in the latter half of the 1975 financial year. Basic to the industry's problems was low productivity, which did not exceed 150 tons of steel per year per employee and which was rooted in poor labor-management relations and obsolete plants.

Domestic production of iron ore in the United Kingdom has declined steadily from a post-World War II high of 17.4 million tons in 1960 to less than 5 million tons in 1975. The small Llanharry underground mine, which was the last iron mine in Wales, closed in July for economic reasons.

About a dozen mines continued to operate in England. Five were in the Scunthorpe, Lincolnshire area (Frodingham Field), including one underground mine (Scanton); these were operated by BSC's General Steels Division. The rest included opencast mines operated by BSC's Tubes Division in the general area of Corby and Kettering, east of Birmingham (Northampton Sand Field), and the Beckermet underground mine in Cumberland. All together, these mines provided less than a quarter of the ore (gross weight) used in the United Kingdom's blast furnaces. Virtually all domestic ore, which was a low-iron, high-lime type, was used, blended with foreign ores, at two steel plants near Scunthorpe.

BSC, which produced 90% of the United Kingdom's steel, continued with its investment strategy based on increasing BSC steel capacity to 36 million or perhaps 38 million tons per year by the early 1980's, at a cost estimated at £4.5 billion at 1975 prices. The major project underway in 1975 was the Redcar development near Lackenby, South Teeside, which included the first 10,000-ton-per-day blast furnace in the United Kingdom, coke ovens, and sintering and pelletizing facilities, and which was to cost £452 million with ancillary facilities. BSC's investment

[3] The value of the pound sterling (£) declined from about US$2.35 on Jan. 1, 1975, to US$2.02 on Dec. 31, 1975.

strategy was concentrated on the five "heritage" steelmaking sites taken over from private industry at the time of nationalization almost a decade before. These were the integrated plants at Port Talbot and Llanwern, Wales; the Appleby Frodingham plant (Anchor project) at Scunthorpe, Lincolnshire; the Lackenby and nearby plants at South Teeside, Yorkshire; and the Ravenscraig plant at Motherwell southeast of Glasgow, Scotland. All these plants are well sited to utilize economically the overseas ore on which the industry will increasingly depend.

A sixth major steelmaking area was foreseen when a contract to build a Midrex direct-reduction unit at Hunterston, Scotland, on the coast southwest of Glasgow, was awarded in 1975 to Korf Engineering GmbH of Dusseldorf. The two modules to be constructed were to have a total capacity of 800,000 tons per year of reduced iron, chiefly for the Ravenscraig plant. This was to be the first direct-reduction plant in the United Kingdom. A decision was also made to erect a 250,000-ton-per-year electric arc plant and associated primary mill near Hunterston. Plans were also under study for the development of an integrated steel mill in the area using imported ore, and probably imported coal, to produce 5 million to 6 million tons of steel per year by 1985 using blast furnaces and basic oxygen furnaces. Hunterston was also the site of the ongoing construction of a deepwater port capable of handling 350,000-ton ore carriers.

Port Talbot, a recently constructed port, capable of unloading 100,000-ton ore carriers, was to be deepened to handle 150,000-ton vessels and eventually those of 250,000 tons. Ore for Llanwern is unloaded here, replacing Newport, and railed from Port Talbot to Llanwern. Dredging was planned at Immingham, the port for Scunthorpe; at Redcar port capacity was increased to permit unloading of 150,000-ton ships.

Lead and Zinc.—A small production of lead and zinc was obtained as a byproduct of mining for other minerals. In the Peak District National Park, southeast of Manchester, Laporte Industries Ltd. produced lead-zinc concentrates in connection with its fluorspar operations. The Wheal Jane tin mine in Cornwall also produced copper-zinc-silver concentrates from its ore. Some production has also been reported from County Flint in Wales and from County Durham.

Two primary smelters or refineries operated during the year. At Avonmouth, a suburb of Bristol, Commonwealth Smelting Ltd., a subsidiary of AM & S Europe Ltd. and thus of Rio Tinto Zinc Corp. Ltd., smelted lead-zinc ores using the Imperial smelting process. At Northfleet, near Gravesend, east of London, the Britannia Lead Co. Ltd., a subsidiary of MIM Holdings Ltd., refined lead from the Mt. Isa mine in Australia.

Nickel.—Production of refined nickel increased during 1975, counter to the trend in production of most other metals.

Nickel was refined at the carbonyl refinery of International Nickel Ltd. at Clydach, near Swansea, Wales, from nickel matte produced at Sudbury, Canada. Capacity of the plant was a nominal 40,000 tons of nickel pellets per year.

Johnson Matthey & Co. also treated copper-nickel matte from Rustenburg Platinum Mines, Republic of South Africa, in order to separate platinum-group metals. Johnson Matthey operated blast furnaces and reverberatory furnaces at Brimsdown, near Enfield, Middlesex, and a wet-process plant at Royston, Hertford, to purify the platinum-group metals.

Tin.—Lower prices for tin caused difficulties for United Kingdom mines in 1975; one mine was reported operating at a loss, but prospects for 1976 were favorable.

Two net tin mining operations were in the planning and development stages. The Mt. Wellington mine, southwest of Truro and next to the Wheal Jane mine, was being developed at a cost of £5.3 million by Cornwall Tin and Mining Corp., Ltd., controlled by Prado Exploration Ltd. of Toronto, Canada, and Excomm of Bermuda. The second prospective operation was the dredging for tin off the north coast of Cornwall, near St. Agnes, planned by Marine Mining (Cornwall) Ltd., a subsidiary of Marine Mining Corp. of New Jersey. Approval of plans by the Ministry of Fisheries was awaited; this was required because of possible damage to the local fishing industry.

The tin mining industry was limited in 1975 to three major operations in Cornwall, each producing in the range of 800 to 1,500 tons of tin in concentrates per year; the total amounted to less than a quarter of United Kingdom domestic consumption. Geevor Tin Mines Ltd. operated the Geevor mine near the north coast, northwest of Penzance, and was preparing to sink a subincline shaft to follow the Geevor lodes seaward and to reach the lower levels of the adjacent Levant mine, which was not in operation. St. Piran Ltd. operated the South Crofty and Pendarves mines between Camborne and Pedrate; and Wheal Jane Ltd., owned by Consolidated Gold Fields, operated the Wheal Jane mine southwest of Truro.

With the closure of the Williams, Harvey & Co. Ltd. tin smelter in 1973, the only remaining tin smelter in the United Kingdom was the Capper Pass & Son Ltd. plant at North Ferriby, Yorkshire, west of Hull, a subsidiary of Rio Tinto Zinc. The smelter treated a variety of complex ores, but tin was the major product.

NONMETALS

Fertilizer Materials.—*Nitrogen.*—Imperial Chemical Industries Ltd. (ICI) was making satisfactory progress on construction of a new ammonia plant at Billingham, Cleveland, to produce 360,000 tons per year; completion was expected by the end of 1976.

Fixed-nitrogen plants operating in the United Kingdom in 1975 were as follows:

Company and location	Ammonia capacity (thousand tons per year)
ICI:	
Billingham, North Teeside	258
Do	258
Do	258
Immingham, South Humberside	172
Heysham, Lancastershire	127
Do	80
Redwick, Severnside	163
Nitrogas fertilizers: Flexborough (Scunthorpe), Lincolnshire	34
Shellstar Ltd. (UKF): Ince Marshes, near Liverpool	300
Total	1,650

Planning and paperwork for a scheduled new ammonia plant at Peterhead, northeast Scotland, to cost £50 million, also went ahead during the year. The plant would produce 300,000 to 350,000 tons per year and was to be built and operated by Scanitro, a company controlled by two Scandinavian fertilizer producers, Norsk Hydro and Supra A.B.

Shellstar Ltd., a subsidiary of Unie Van Kunstmestfabriken (UKF) of the Netherlands, also applied for planning permission to build a 330,000-ton-per-year plant near its existing facilities at Ince Marshes.

Potash.—The Boulby mine and plant of Cleveland Potash Co., near Loftus on the north coast of Yorkshire, started regular production and was attempting to reach a production rate of 1 million tons per year of 60% K_2O product. Delays were still being encountered because of the aftereffects of severe water inflows during shaft sinking and the difficulty of developing sufficient working faces.

Applications to extend planning permission for two additional potash mines by Whitby Potash Ltd. (Shell International) and Yorkshire Potash Ltd. (Rio Tinto Zinc) were turned down at yearend for environmental reasons. All three mining areas (including Boulby) are located within the North Yorkshire Moors National Park. It was suggested that a combined operation might be approved, and the companies were expected to appeal the decision.

MINERAL FUELS

The United Kingdom derived about half of its energy from net imported fuels, almost all of which was crude petroleum and refinery products. Coal continued its decline, both in actual consumption and in its participation in overall energy supplies, which was about 30% during the year. Natural gas from the United Kingdom's sector of the North Sea made a useful contribution, reaching about 14% of total energy consumed in 1975.

The prospect of self-sufficiency in energy within a decade was held out by the first production of petroleum from the North Sea.

Table 4 shows energy balances for 1973 and 1974 for the United Kingdom. It includes the relatively high percentage (4% to 5%) of energy from the United Kingdom's established and growing nuclear energy industry.

Table 4.—United Kingdom: Supply and apparent consumption of energy-producing materials in 1973 and 1974
(Million tons of standard coal equivalent) [1]

	Total energy	Coal and coke	Petroleum and refinery products	Natural gas	Hydro-electric and nuclear power
1973:					
Production	174.5	131.5	0.6	38.4	4.0
Imports	196.8	1.9	193.9	1.0	(4)
Exports	38.3	[2]11.7	[2]26.6	--	(4)
Apparent consumption	333.0	121.7	[3]167.9	39.4	4.0
1974:					
Production	161.7	109.9	.7	46.4	4.7
Imports	190.2	3.7	185.7	.8	(4)
Exports	31.1	[2]12.7	[2]18.4	--	(4)
Apparent consumption	320.8	100.9	[3]168.0	47.2	4.7

[1] 1 ton standard coal equivalent (SCE) = 7,000,000 kilocalories.
[2] Includes bunkers.
[3] Includes refinery fuel and losses.
[4] Less than ½ unit.

Coal.—Activity in the United Kingdom's coal industry centered on the development of the important new Selby coalfied between the cities of Selby and York in Yorkshire. By mid-1975 a total of 35 drill holes had been completed, spaced 3 to 4 kilometers apart. They first (by 1967) revealed that the Barnsley seam, traditionally the best of all the Yorkshire coal seams, did not end south of Selby but that the boundary actually turned north some miles west of Selby and afterwards turned eastward near York, thus encompassing the area between Selby and York. It was furthermore discovered that the Selby seam, which split into several seams south of Selby, recombined into one thick, high-quality seam at workable depths in this area. An average ash content of 5% and a sulfur content of 1.3% were indicated, with the seam varying from 3 meters thick at a depth of 300 meters in the western extremity to 2 meters thick in the east, near the River Derwent, at a depth of 1,100 meters. Indicated recoverable reserves in the Barnsley seam alone were of the order of 250 million tons, allowing for pillars for surface support, out of a total of some 600 million tons. Selby was expected to produce 10 million tons per year by 1985–86, and the estimated development cost was £300 million. Development was to start in October 1976 if problems of surface subsidence, including possible relocation of the London-Edinburgh rail line, were solved.

Selby was the major project to be undertaken under the 10-year, £600 million Plan for Coal announced in 1973, which was based on an intensive exploration program initiated the year before. This plan was formulated by the National Coal Board (NCB), the Government agency that operates the nationalized coal mines and related facilities, to arrest and eventually reverse the decline in the rate of the United Kingdom's coal production, which totaled almost 100 million tons per year in the period from 1955 to 1975. This was to be done: (1) By investment in collieries with good reserves; (2) by providing access to new reserves in certain existing collieries; and (3) by constructing new collieries in areas where exploration was successful. Without new investment, production potential, which was about 125 million tons in 1975 but which had fluctuated because of labor troubles, was expected to decline by about 40 million tons between 1975 and 1985. The Plan for Coal had the aim of bringing in new production sufficient to maintain the total at or near 120 million tons per year. Of the new 40 million tons, 20 million would come from existing mines, 10 million from Selby, and 10 million from smaller new mines in the Vale of Belvoir, in the Vale of Greet, and at North Newark (all in Nottinghamshire, northeast of Nottingham) and at Park in Staffordshire. Production was also planned at two still smaller mines at Betws Drift near Ammanford, South Wales, and at Royston, Yorkshire. Another potential area for development was also under consideration, west of

Barnsley, Yorkshire. In 1974–75 an increase in the NCB goal to 142 million tons by 1985, at a cost of £1,400 million, was recommended, and an ultimate production of 200 million tons was envisioned by the year 2000 after North Sea oil and gas production reached its peak. This massive development would entail some 80 separate major projects.

The coalfields of the United Kingdom, which supported 241 operating collieries at the end of the 1975–76 financial year, were concentrated in four main areas: Southern Scotland, roughly around Edinburgh and Glasgow; Durham in the northeast; the Midlands, from Birmingham to York, which produced about 68% of total output in 1975–76; and South Wales. The two belts of major exploration activity were located in the Midlands; the first extended north-south from Selby to the Vale of Belvoir in Nottinghamshire, and the second extended northwest to southeast through the cities of Birmingham and Coventry.

The total amount of coal existing beneath the land area of the United Kingdom, within technical limits on depth and seam thickness, was reported to be about 100,000 million tons in known coalfields, with the probability of a further 60,000 million tons in coalfields not proved but believed to exist by geological inference. The total technically recoverable reserve was probably of the order of 45,000 million tons. This contrasts with the 3,800 million tons of operating reserves accessible to existing collieries and capable of being won with existing technology at current costs and prices, and with a further 1,200 million tons available to new collieries, including Selby, still at the planning stage.[4]

Natural Gas.—Preliminary agreement was reached between Norway and the United Kingdom on rules for management of the Frigg Field, which straddles the mutual sector boundary in the North Sea. Division of the gas was to be dealt with on the basis of a forthcoming recommendation from a United States firm of consultants.

One new gasfield came into production in 1975; this was the Rough Field in the southern basin.

Natural gas provided 97% of total United Kingdom gas supplies in 1975. All of this came from the gasfields of the southern basin of the North Sea, between 53° and 54° north latitude.

Gas reserves in discoveries made up to December 31, 1975, in the United Kingdom sector of the North Sea were estimated to lie within the range of 800 billion to 1,400 billion cubic meters (29 trillion cubic feet). Proven reserves were 815 billion cubic meters, and the total, including both proven and possible reserves, consisted of 711 billion cubic meters in the southern basin and 719 billion cubic meters in the northern basin, where the gas is associated with oil. Drilling from fixed platforms in the gasfields of the southern basin continued to decrease as development work approached completion.[5] United Kingdom reserves were second in Europe only to the Netherlands' onshore gasfields.

The search for hydrocarbons in the North Sea began after the discovery of the onshore Groningen Field in the Netherlands in 1959. A broad belt of gasfields was subsequently located off the east coast of the United Kingdom. The major producing fields in 1975 were West Sole, Leman Bank, Hewett, Indefatigable, and Viking; in addition, the Rough Field went on production during the year. All gas was sold by the producers to the British Gas Corp. which had a policy of gas conservation, giving priority to premium markets.

Petroleum.—The first oil from the United Kingdom sector of the North Sea, from the small Argyll Field, was landed by tanker at the Thames estuary in June, following 6 years of exploration and development. In November the first oil from a major field, the BP Forties Field, was brought ashore by pipeline at Cruden Bay, north of Aberdeen. Total production from these two fields was over a million tons in 1975. Production from the Ekofisk Field in the Norwegian sector also began to be landed by pipeline to the Teeside area in October.

The 1976 "Brown Book"[6] estimated the United Kingdom's proven recoverable oil

[6] Work cited in footnote 5.

reserves in 1975 at 1,350 million tons; probable reserves were set at 960 million tons, and possible reserves at 880 million tons. All of these figures related to known fields. Ultimate potentially recoverable reserves from all designated areas of the United Kingdom Continental Shelf, including both licensed and as-yet-unlicensed areas, could be as high as 4,500 million tons.

Exploration and drilling activity reached a new peak in 1975; a record 115 exploration and appraisal wells were drilled, and 24 significant new oil (and 4 gas and condensate) discoveries were made, almost doubling the number of oil discoveries on the United Kingdom Shelf. The first seven developmental wells were drilled on North Sea oilfields during the year, and a further eight platforms were installed, bringing the total number in place (including one gas platform in the Frigg Field) to 11.

Onshore exploratory wells were drilled in Dorset and in the East Midlands. Some oil was produced in the Wytch Farm in Dorset and in the Beckingham, Axholme, Gainsborough, Coringham, and Torksey Fields; Beckingham was the major producer.

Negotiations continued on the division of the Continental Shelf with neighboring countries. Talks were in progress with the Irish Government and were shortly to begin with the Norwegian Government to settle the boundary north of the 62d parallel. The question of the United Kingdom-French boundary was before an international tribunal.

Seven fields under development in the United Kingdom sector in 1975 were scheduled to come into production by yearend 1976, and seven additional fields were targeted for 1977 production; all but Claymore were fairly close to the center of the North Sea. These are listed in table 5.

Table 5.—North Sea oilfields in the United Kingdom sector

Field	Approximate latitude °N	Approximate API gravity (degrees)	Startup date	Licensees (percent)
Argyll	56.2	30	1975	Hamilton Oil and Gas Ltd. (36), Rio Tinto Zinc (25), Texaco (24).
Auk	56.4	39	1976	Shell (50), Esso (50).
Montrose	57.4	39	1976	Amoco (30.77), British Gas Corp. (30.77), Amerach (23.08), Texas Eastern UK Ltd. (15.38).
Forties	57.8	37	1976	BP (100).

Ninian	61	35	1977	Chevron (24), Burmah (30), ICI (26).
Heather	61	35	1977	Unocal (31.25), Skelly Oil Exploration (UK) Limited (31.25), Tenneco (31.25).
Cormorant	61	36	1977	Shell (50), Esso (50).
U.K. Statfjord	61	38	1977	Conoco (33 1/3), Gulf (33 1/3), BNOC (33 1/3).

In addition to the two pipelines completed during the year, from Ekofisk to Teeside and from Forties to Cruden Bay, lines were under construction in 1975 from Piper and Claymore to Flotta, Orkney Islands, and from Ninian and the Brent System to Sullom Voe, Shetland Islands. During the 1975 pipelaying season, 392 miles of pipeline was laid in the United Kingdom sector of the North Sea.

The total throughput capacity of petroleum refineries in the United Kingdom was approximately 2.95 million barrels in 1975. Table 6 provides details of this capacity by individual refinery.

Table 6.—United Kingdom petroleum refineries, 1975

Company	Location	Approximate throughput capacity (barrels per calendar day)
Amoco U.K. Ltd	Milford Haven, Wales	80,000

The Mineral Industry of Venezuela

By Roland W. Merwin [1]

Venezuela's gross domestic product (GDP) at constant 1968 prices was $14,786 million[2] in 1975, compared with a revised $14,021 million in 1974, an increase of 5.5%. The increase in the GDP reflected the strength of the Venezuelan economy in the face of a substantial reduction in the quantity of petroleum produced.

As in prior years, the petroleum industry continued to dominate the Venezuelan economy, although it employed less than 1% of the Venezuelan work force. In 1975, petroleum accounted for 26% of the GDP, and revenue from oil operations accounted for 77% of government income. Additionally, petroleum and petroleum products accounted for 96% of the total value of exports.

In 1975, Venezuela retained fifth place among the world's crude-oil-producing nations, after the U.S.S.R., the United States, Saudi Arabia, and Iran. In addition, Venezuela remained the world's third leading petroleum-exporting country following Saudi Arabia and Iran. Venezuela, together with satellite refineries in the Netherlands Antilles, also maintained its position as the leading supplier of U.S. imports of petroleum and petroleum products.

At yearend 1975, Venezuela formally completed the nationalization of its petroleum industry, ending 62 years of private foreign control of the Nation's principal resource. The process of nationalization has dominated the petroleum sector during the past 2 years.

Nationalization proved to be an intricate process because of the complex industry infrastructure. The Government was aware of the need to retain access to foreign technology and to the markets that the private companies controlled, and sought arrangements that would satisfy these needs. Therefore, the nationalization law not only stipulated the payment of compensation for nationalized assets, but offered the former operating concessionaires an opportunity to engage in technical service and offtake contracts designed to maintain their participation in the industry.

Nationalization was initiated in March 1974 when Carlos Andres Perez, the then newly elected President of Venezuela, proposed that oil concessions revert to the Nation earlier than their expiration dates beginning in 1983. The draft of the nationalization bill was presented to the National Congress on March 11, 1975. After extensive debate, it was approved by Congress and signed into law on August 29, 1975. The law stipulated that nationalization would become effective on January 1, 1976, allowing, in effect, 4 months to organize the nationalized industry and reach agreements with foreign oil companies for their continuing participation in the industry during the postnationalization period. The day following the signing of the oil nationalization law, August 30, 1975, Petróleos de Venezuela (PETROVEN) was created by a presidential decree to administer the nationalized oil industry as of January 1, 1976.

These actions were followed by a series of legal steps involving offers of compensation to the 22 concessionaires and the additional 17 companies holding participating or joint operating agreements, the acceptance or refusal of the offers by the companies, and the formal signing of the

---

[2] Where necessary, values have been converted from bolivars (Bs) to U.S. dollars at the rate of Bs4.20=US$1.00.

compensation agreements. Only one company holding a minority interest in a concession as a participant elected not to accept the offers. The process of nationalization was completed on December 31, 1975, when the 22 private oil concessions were terminated.

The nationalization law stipulated that payment of compensation for a nationalized asset would be on the basis of net book value, with no payment to be made for concession rights or projected future value of concessions, less tax and other obligations to the Government. The final compensation totaled $1.01 billion for the concessionaires and $22.7 million for participating companies. Additionally, payment for warehouse inventories totaling an estimated $117 million would be made during the first quarter of 1976. Company oil inventories totaling over 70 million barrels were also to be acquired in the same manner with PETROVEN to pay cost plus a 20-cent-per-barrel profit for the inventories.

The major portion of the compensation, over $900 million, was to be paid with Government of Venezuela bonds. The bonds are to pay 6% interest, be free of taxes, and be amortized over a 5-year period with an initial 1-year grace period. The redemption schedule calls for the first 20% of the bonds to be payable on January 15, 1977, and the remaining 80% in 16 equal quarterly payments beginning March 29, 1977. Normally, the bonds may only be negotiated outside of Venezuela. Within the country, the bonds may be utilized under conditions determined by PETROVEN for acquisition of crude oil and derivatives, and to meet the obligations of the Guaranty Fund.

The nationalization law required concessionaires to deposit 10% of the value of gross accumulated investment into a Guaranty Fund to cover any obligations not otherwise deducted from the compensation amount. In lieu of cash, the companies could utilize compensation bonds to fulfill the obligation. The total to be deposited with the Central Bank of Venezuela was estimated at $404 million. Together with prior cash deposits made under the terms of the 1971 Reversion Law, the Guaranty Fund would total an estimated $964 million.

The fund was to be maintained until verification was completed that the assests had been received in good condition. The nationalization law permitted a period of 3 years for the verification, but the Venezuelan Government planned to complete the process within 1 year. It was understood that 80% of the funds would be released to the companies when verification was completed. The remaining 20% would be retained for 3 years, and could also be drawn on to renovate equipment at dormant oil installations.

In addition to nationalization of the petroleum industry, Government policies were strongly directed toward strengthening the position of the Government-owned development agency, Corporación Venezolana de Guayana (CVG), which had a mandate to develop all heavy metallurgical industries in Venezuela.

The operations of CVG were located in the vicinity of Ciudad Guayana near the mouth of the Orinoco River. CVG acted as a holding company and operated through a complex system of operating companies with various degrees of ownership that include State, private, and even foreign interests on a minority basis.

In addition to major operating companies concerned with iron ore mining, iron ore beneficiation, and steelmaking, CVG controlled a number of other subsidiaries engaged in hydroelectric power generation and aluminum and cement production. In effect, CVG was responsible for all developments in the region including not only mineral related projects, but such programs as city planning for Ciudad Guayana and regional reforestation and agriculture projects.

The Ministry of Mines and Hydrocarbons continued with a wide range of mineral-related programs covering all aspects of Venezuela's mineral development with the exception of those projects that have been specifically assigned to PETROVEN and CVG. The most significant of the ministry's programs was planning for the development of the Orinoco heavy-oil belt. With an estimated resource of 700 billion barrels of heavy crude oil, these fields not only contain one of the world's largest hydrocarbon resources but are basic to Venezuela's long-range future as a major petroleum producer.

PRODUCTION

As in prior years, Venezuela's mineral production, in terms of both quantity and value, was predominantly based on the export-oriented crude petroleum and iron ore sectors of the industry.

Production of crude petroleum declined sharply from that of 1974 because of poor market conditions for the types of crude petroleum produced by Venezuela. Natural gas production also declined substantially because production, as a coproduct, was directly related to petroleum production. Iron ore production declined slightly from that of 1974 because of a decrease in world demand for steel.

Production of other minerals, mainly for domestic consumption, did not change significantly from that of 1974.

[3] Liquid equivalent.

TRADE

Exports of mineral commodities continued to dominate Venezuela's overall foreign trade. In 1975, exports of crude petroleum and petroleum products were valued at $10,635 million and exports of iron ore were valued at $268 million. Together, they accounted for 98% of the total value of all exports.

The United States was the principal destination of direct petroleum shipments, followed by the Netherlands Antilles. However, almost all of the petroleum shipments to the Netherlands Antilles consisted of crude and unfinished oil destined for processing at two large refineries owned by the parent companies of Creole Petroleum Corp. and Cia. Shell de Venezuela Ltd., Venezuela's first- and second-ranking crude oil producers. These refineries export their output and are, in a sense, an integral part of Venezuela's petroleum industry.

Exports of Venezuelan petroleum from Venezuela and the Netherlands Antilles by principal areas of destination during 1973–75 are shown in the following tabulation.

Destination	Exports (thousand 42-gallon barrels)

COMMODITY REVIEW

METALS

Aluminum.—The Government of Venezuela, working through CVG, was actively engaged in the development of a major aluminum industry that would be based upon the cheap hydroelectric power available in the Orinoco region. In anticipation of future electric power requirements for the proposed aluminum smelters, CVG was expanding the hydroelectric power generating facilities of its wholly-owned subsidiary Electricacion del Caroni C.A. (EDELCA).

The sole producer of aluminum metal in 1975 was Aluminio del Caroni, S.A. (ALCASA). ALCASA, jointly owned by CVG and Reynolds Metals Co., (50% each), was managed by Reynolds. Using imported alumina, ALCASA's capacity of 50,000 tons per year of aluminum metal was fully utilized within the plant for the manufacture of a wide range of finished aluminum products. During 1975, expansions were underway to increase both the aluminum smelter and rolling mill capacity to 120,000 tons per year by 1977. It was planned that the entire output would be marketed within Venezuela and other Latin American areas.

During 1975, organizational plans were completed, and initial construction started on Venezuela's second major aluminum facility, Industria Venezolana de Aluminio, C.A. (VENALUM). Owned 80% by CVG and 20% by Japanese interests, the VENALUM smelter will have a capacity of 280,000 tons per year, using imported alumina. It was planned that the major part of the output, in the form of aluminum ingot, would be exported to the European and Japanese markets so as not to conflict with the present market arrangements of ALCASA.

Because Venezuela's aluminum industries are entirely dependent upon imported alumina, considerable thought was being devoted to establishing an alumina industry. One possibility was alumina production facilities using imported bauxite. The other possibility was the utilization of low-grade bauxite deposits in Venezuela. In this connection, the Ministry of Mines and Hydrocarbons was actively engaged in exploration programs and metallurgy research in an effort to develop a viable bauxite industry in Venezuela.

Iron Ore.—The formal reorganization of Venezuela's iron ore industry was completed late in 1975, following the nationalization of the foreign sector of the industry at yearend 1974.

Under the terms of the nationalization agreement, the United States Steel Corp. and Bethlehem Steel Corp. were compensated for their assets on the basis of net book value. The compensation totaled $110 million, payable in the form of Government bonds. These two companies accounted for approximately 99% of Venezuela's iron ore production at the time of nationalization, with most of the output being exported to the United States.

Additionally, under the terms of the nationalization agreement, the former concessionaires were guaranteed continued access to the iron ore output over a period of years. United States Steel could take an annual output of 11 million tons of iron ore or equivalent product for 7 years. This could be reduced 50% by 1981 at the option of the company or the Government of Venezuela. Bethlehem Steel contracted for 3.3 million tons annually for 1975 through 1977 and could, upon a 1-year notice, continue to purchase an equal amount in 1978 and 1979. Under both contracts, prices were tied to Mesabi non-Bessemer Great Lakes prices with upper adjustments possible if European prices were higher. The purpose of these contracts was to provide stability to Venezuela's iron ore industry.

Throughout 1975, the former concessionaires continued to operate their individual properties in much the same manner as prevailed when they were private companies, subject only to general Government overview.

On December 10, 1975, the nationalization process was completed by the formation of CVG Ferrominera Orinoco C.A., a wholly-owned subsidiary of CVG. This corporation assumed exclusive responsibility for the development of Venezuela's iron ore industries including mining, beneficiation, exports, and domestic sales. One of Ferrominera's objectives was to carry out nationalization in such a way that neither the national interest, the production activities, nor the need of traditional clients suffer.

Government planning was such that iron ore production levels were expected to remain relatively stable. Contractual commitments would be met, but output would be gradually diverted from export markets to meet growing domestic needs. By 1990, if plans materialize, completion of a third steel plant should effectively convert Venezuela from an exporter of crude iron ore to a vertically integrated producer of beneficiated ores, steel, and steel products.

Production and exports declined in 1975, owing largely to the weakened world demand for steel. Production decreased 6% below that of 1974. Exports, which accounted for approximately 87% of the production, were 18% below those of 1974. Despite the sharp drop in exports, export revenue for 1975 fell less than 2% due to higher prices for iron ore in foreign markets.

Venezuela's iron ore reserves, grading 55% Fe or better, have been estimated at 1.66 billion tons, equivalent to a life of approximately 65 years based on projected production rates. Most of the reserves are located in the region southwest of Ciudad Guayana, adjacent to the present operations of Ferrominera.

Iron and Steel.—Venezuela had plans to expand iron and steel production to 15 million tons per year. The long-range objective was to fully utilize all of Venezuela's present and projected iron ore output. Most of the steelmaking capacity would be owned and operated by Government entities.

In 1975, about 85% of Venezuela's steel output was produced by CVG Siderúrgica del Orinoco S.A. (SIDOR), a wholly-owned subsidiary of CVG. The steel mill, which is located in the vicinity of Ciudad Guayana near the mouth of the Orinoco River, had a capacity of 1.2 million tons per year. In 1975, plans had been completed and construction was proceeding on expanding mill production to about 5 million tons per year.

SIDOR's operations and expansion plans were mainly based upon direct reduction/electric furnace processes, due in large part to the ready availability of high-grade iron ore, natural gas, and cheap electric power. In view of uncertainties as to the best reduction process to be used, several advanced direct reduction processes were being tested on a plant-size scale, some by SIDOR and others by companies associated with CVG.

With SIDOR's expansion program now well underway, the Venezuelan Government turned its attention toward construction of a second national steel plant to be located in western Venezuela in the State of Zulia, in the Marciabo region. As proposed, the complex would have the capacity of 5 million tons of steel per year. The Government placed authority for coordination of this new steel mill project in the hands of the State Regional Development Agency, Corporación de Desarrollo de la Region Zuliana (CORPOZULIA). In contrast to SIDOR's steel complex, CORPOZULIA planned to use blast furnaces and oxygen converters. Blast furnace feed would consist of beneficiated iron ore from Ferrominera's operations in the Orinoco region, and coke would be largely produced from local coal deposits. It has been announced that these coal deposits have satisfactory coking properties for metallurgical use when mixed with 10% to 30% of imported metallurgical coal.

The Government was planning, in a very general way, for the construction of another steel mill, likewise with a capacity of 5 million tons per year. However, at yearend 1975, no plans had been announced for either the location of the mill or the process to be used.

Other Metals.—During 1975, the Ministry of Mines and Hydrocarbons continued exploration programs designed to further development of several known metallic mineral deposits in Venezuela. Among these were a copper-lead-zinc deposit near Bailadores in the State of Merida; gold deposits in the State of Bolivar; lateritic nickel deposits in the States of Araqua and Miranda; and titanium deposits in the State of Yaracuy. However, at yearend 1975, this work was still continuing without conclusive results having been obtained.

NONMETALS

Fertilizer Materials.—Operating under the general leadership of the Government-owned Instituto Venezolano de Petroquimica (IVP), which operates with varying degrees of private and foreign capital participation, the Venezuela fertilizer industry made substantial gains in production during 1975. The fertilizer industry is mainly based upon the production of anhydrous ammonia using natural gas and the utilization of sulfur produced as a byproduct at refineries. The production of anhydrous ammonia in 1975 was twice that of 1974. The phosphate sector uses both domestic and imported phosphate rock. Although quantities of phosphate rock are limited, there are ample supplies of other raw materials for further expansion of the fertilizer industry. The Ministry of Mines and Hydrocarbons was continuing its program to develop phosphate rock reserves in the State of Falcon.

Other Nonmetals.—Activities included the unorganized production of diamond by small miners from alluvium deposits in the State of Bolivar, the production of cement by the country's large and stable cement industry, and the production of lime, sand, gravel, gypsum, clays, and stone for construction purposes. There were no major developments in the nonmetallic industries during 1975 because production of nonmetallic minerals had not been receiving priority consideration by the Government.

MINERAL FUELS

Coal.—During 1975, CORPOZULIA continued geologic studies and test corings to delineate the Guasare coal deposits in the State of Zulia. At yearend 1975, it was announced that proven reserves amounted to 780 million tons, 190 million tons of which could be mined by open pit methods. Concurrently, mining plans were being developed and metallurgical work was underway to develop treatment processes that would make the coal useful as a metallurgical coal suitable for coke to be utilized in the proposed steel mill in the vicinity.

Petroleum and Natural Gas.—Foreign oil companies continued to dominate Venezuela's petroleum and natural gas industry until, as a result of nationalization, they were taken over by PETROVEN at yearend 1975. At the same time PETROVEN acquired the assets and control of the State-owned Corp. Venezolana del Petroleo (CVP).

As created, PETROVEN became one of the major oil companies of the world. It inherited 7.5 million acres of oil concessions, 12 oil refineries with a combined capacity of 1.55 million barrels per day, 14 oil tankers, 131 gas injection plants, over 6,000 miles of oil, gas, and multiple purpose pipelines, a potential production capacity of about 3 million barrels per day, and a work force of 24,000 employees. PETROVEN's net worth was estimated to be approximately $2.1 billion.

It was intended that PETROVEN be given complete autonomy by the Venezuelan Government. It would announce its own exploration plans and formulate and execute its own programs.

PETROVEN was organized as a holding company with ownership and general control over 14 subsidiary operating companies as shown in table 4. These operating companies were formed around the present activities of the former oil companies and CVP so as to maintain continuity of existing operations.

The operating companies were expected to operate in much the same fashion as when they were private concerns. The company staffs were to remain intact with the exception of the Board of Directors, all of whom would be Venezuelans. Individual operating companies were expected to take the initiative in developing annual operational plans for production and proposing new investments. They would pay oil income taxes and royalties at the same rates as did the former private companies, plus 10% of the net revenue to the holding company. It was hoped that these revenue-producing functions would strengthen the operating companies in their efforts to maintain operational efficiency.

Concurrently with the nationalization negotiations, PETROVEN was offering technical service and offtake contracts to major former concessionaires in order to maintain their participation in the nationalized industry.

Under the terms of the proposed service contracts, the former concessionaires would provide a wide range of management and technical services both within and outside of Venezuela, including retention of foreign technical personnel, which would continue to be carried on the payrolls of the foreign companies. The contracts would be individually negotiated; payments would be based upon the range and quantity of services provided. They would provide overhead and profit margins so as to make the contracts financially attractive to the foreign companies.

Offtake contracts would be individually negotiated on a confidential basis between PETROVEN and foreign concessionaires. They would provide for the purchase during a fixed period (initially 3 months) of an agreed-upon quantity of crude petroleum and refined products at a negotiated price. These contracts were designed to provide a substantial continuity in the marketing of Venezuela's petroleum products in export markets.

The timing of nationalization was not the most opportune in terms of Venezuela's interests. Oil production peaked in 1970, and higher prices in subsequent years permitted the Venezuelan Government to begin a long-desired conservation program. However, production cutbacks were soon overshadowed by depressed world markets in 1975. These conditions combined to reduce export sales temporarily below the level set by the Government to support the national budget.

In 1975, crude oil production declined for the second consecutive year to the lowest level since 1955. The output was 21% below that of the previous year and was only 63% of the peak production in 1970. Production dropped steadily during 1975 from an average of 2.7 million barrels per day in January to 1.8 million barrels per day in December.

The principal crude oil producers during 1975 were Creole Petroleum Corp. (Exxon Corp), Cia. Shell de Venezuela, (Royal Dutch/Shell Group), Mene Grande Oil Co. (Gulf Oil Corp.), and Venezuelan Sun Oil Co. (Sun Oil Co.). Together they accounted for 86% of the total output.

The decline in production rates between 1974 and 1975, and during 1975 were due mainly to poor market conditions for the types of crude and refined petroleum produced by Venezuela, and the desire on the part of the Government to conserve the Nation's petroleum reserves. Additionally, the declines in production rates were partially influenced by the impending nationalization of the industry.

Because of an increasing lack of customer acceptance for heavy crude oils and residual fuel oils, there was a shift toward the production of lighter crude oils in 1975 relative to heavy crude oil production. The distribution of crude oil production by gravity, in million 42-gallon barrels is shown in the following tabulation:

Type of crude oil	1974		1975		Decrease	
	Quantity	Percent	Quantity	Percent	Quantity	Percent
Light (more than 25° API)	573	53	492	58	81	14
Medium (14° to 25° API)	338	31	241	28	97	29
Heavy (less than 14° API)	175	16	123	14	52	30
Total	1,086	100	856	100	230	21

Proven reserves of crude petroleum remained essentially unchanged, amounting to 18.5 billion barrels at yearend 1975 as compared with 18.6 billion barrels at yearend 1974. The projected life of the reserves was approximately 22 years at 1975 production rates compared with approximately 17 years at the higher production rates prevailing in 1974.

Natural gas production was 18% below that of 1974, reflecting the decrease in crude oil production. Essentially all of the natural gas produced was in the form of associated gas produced jointly with crude oil.

The conservation of natural gas has been a longstanding Government policy. The stated objectives are: To maximize the use of natural gas for beneficial purposes such as reinjection, and/or use in selected industrial processes; and to minimize the loss of gas by flaring. Reinjection of natural gas is considered beneficial because the gas would enable a higher percentage recovery of the petroleum resources and would itself constitute a natural resource upon depletion of the oil reserves. The distribution of natural gas production by use, as a percent of total production, is shown in the following tabulation:

	1973	1974	1975
Reinjected	44	50	55
Sold and used	26	29	34
Flared	30	21	11
Total	100	100	100

Proven reserves of natural gas increased 2% from 41.3 trillion cubic feet at yearend 1974 to 42.3 trillion cubic feet at yearend 1975. Of the total reserves at yearend 1975, 97% were in the form of associated natural gas in oilfields.

Venezuela's refining capacity has remained stable for several years at 1,554,000 barrels per day. Throughput has not approached this level during the past several years, mainly due to lack of sufficient market demand for the range of products produced by Venezuela's refineries. Refinery throughput declined in 1975 to 860,000 barrels per day compared with 1,196,000 barrels per day in 1974, a decrease of 28%. This represented a refinery capacity utilization of 77% in 1974 compared with only 56% in 1975.

As presently designed, Venezuela's refineries were heavily slanted toward the production of residual fuel oils. In 1975, this product accounted for 56% of the refinery outputs. This is a product for which there was a declining demand in domestic and world markets. The problem had not been resolved at yearend 1975; however, during the year, there was considerable discussion in Government circles as to the advisability of revamping refinery processes in order to obtain better yields of lighter products, both from the standpoint of international markets and of Venezuela's domestic needs. However, it was recognized that revisions of refineries to obtain increased yields of lighter products would require major investments.

In anticipation of the exhaustion of Venezuela's conventional crude petroleum reserves during the next few decades, the Ministry of Mines and Hydrocarbons has given priority attention to the development of the Orinoco heavy oil belt. The belt is located along the northern bank of the Oronoco River, extending about 375 miles in length and with a width of approximately 30 or 40 miles. Within the belt is located a series of nearly continuous oil deposits containing an estimated resource of approximately 700 billion barrels. The deposits are geologically similar to conventional oilfield deposits except for the characteristics of the contained crude petroleum. The crude oil ranges from 8° to 18° API. The sulfur content of the oil ranges from 2% to 5% by weight, and the sum of the nickel plus vanadium content ranges from 200 to 500 parts per million.

Throughout 1975, the Ministry continued its long-range program of geological investigations designed to delineate and characterize the deposits. Additionally, it initiated the drilling of a number of production wells for the purpose of testing production rates and problems.

Concurrently with the geological investigations and initial production tests, the Ministry was investigating overall processes that could be employed to obtain relatively complete extraction of the petroleum and resolve refining and marketing problems. One scheme being considered would involve a massive steam drive for the extraction of heavy crudes. This could be followed by a preliminary refining stage that would produce a semirefined oil suitable for further refining at downstream refineries. The preliminary refining stage would produce a coke containing the sulfur and the heavy metals. The coke could be further treated to recover the sulfur and heavy metals, with a production of synthetic gas that could be used to provide fuel for the steaming operation.

In view of the advanced technology and the large capital investment that would be required to develop the Orinoco heavy oil belt, Venezuela was actively seeking technical and/or financial assistance, preferably on a government to government basis or by international organizations. Conceivably, foreign oil companies might be asked to participate in the development of the belt since one section of the nationalization law provided for this contingency, subject to the approval of the National Congress.

The Mineral Industry of Yugoslavia

By Roman V. Sondermayer [1]

During 1975, Yugoslavia remained one of Europe's leading producers of nonferrous metals. The most prominent minerals with mine production expressed in approximate percentages of the world totals were as follows: Mercury, 6%; lead, 3.8%; zinc, 1.8%; bauxite, 3%; and copper, 1.6%. Production of other minerals and fuels was only of domestic significance. During 1975, gross social product (GSP) [2] increased by about 4.5% when compared with 1974. The minerals industry of Yugoslavia shared about 12% in GSP of the country and employed about 296,800 persons or 6.4% of the employed labor force.

Increasing crude oil prices made the use of domestic coal more attractive, and plans for expansion of production were announced. However, most of the domestic coals were brown coal and lignite, and imports of high-rank coals and coke were necessary. Although crude oil output reached 3.7 million tons, an alltime high, imports were necessary to meet two-thirds of the country's requirement. Iron and steel output continued below demand. Consequently, imports of large quantities of iron and steel semimanufactures were essential.

There were a number of significant developments during 1975. A 280,000-ton-per-year alumina plant was completed at Mostar, Bosna i Hercegovina (BiH). Construction continued on an alumina plant at Vlasenica and an aluminum plant near Mostar, both in BiH. Development continued on the Bučim copper deposit and on the nickel deposit near Rzanovo, both in Makedoniji (Macedonia). Production started at a 550,000-ton-per-year cement plant near Kosjerić, Srbija (Serbia), and at a 330,000-ton-per-year cement plant at Plevlja, Crna Gora (Montenegro). At Lukavac, BiH, a new coking battery went onstream with an annual capacity of 700,000 tons of coke. Construction started on a crude oil pipeline from the Adriatic to inland refineries in Yugoslavia, Hungary, and Czechoslovakia. Construction also continued on Yugoslavia's first nuclear powerplant, at Krško, Slovenija (Slovenia).

The mineral industry of Yugoslavia is state-owned. Investments of foreign capital in Yugoslavia's mineral industry are, nonetheless, possible provided that Yugoslav partners retain controlling interest.

PRODUCTION

No significant changes in the mineral production of Yugoslavia took place during 1975. Mineral producers directed their efforts toward modernization of existing facilities and construction of new installations, to process minerals to a higher degree and reduce the country's dependence on imported energy. Although investments in building new facilities are expanding and renovating existing processing facilities were predominant, a shift continued in channeling available capital toward mine expansion. Shortages of ores and concentrates forced this trend. Mechanization and automation in both mining and processing continued during 1975.

Modern and efficient methods prevailed in petroleum exploration, production, and refining. All three primary methods of oil

[1] Physical scientist, International Data and Analysis.

[2] Gross social product (GSP) is an economic indicator published by Yugoslav authorities instead of gross national product (GNP). GSP and GNP are not comparable. GSP does not show value of services in its totals.

production—flowing, pumping, and gas lift—were used; dual completion was used at some wells, and secondary recovery at some older fields. Chemical and hydraulic methods for stimulating gas and oil production were everyday practices.

[1] In addition to the commodities listed, germanium, bentonite, kaolin, common clay, and diatomite are also produced, and tellurium may be recovered as a copper refining byproduct but available information is inadequate to make reliable estimates of production levels.

[2] Figure reported as gross weight is apparently derived from converting various grades of fertilizer with different P_2O_5 or N contents to a standard equivalent figure. Nitrogen fertilizers were converted to a gross weight figure containing 20% nitrogen and phosphate fertilizers to a gross weight figure containing 16.5% P_2O_5.

[3] Includes vacuum salt.

TRADE

During 1974, the latest year for which data are available, Yugoslavia's mineral trade was diversified, but European countries were again the major purchasers. Nonferrous metals were the most significant export items. Principal import items were bituminous coal, crude oil, and iron and steel semimanufactured products. The largest sources of mineral imports remained the U.S.S.R. and other COMECON countries.[3]

[3] COMECON (CMEA—Council for Mutual Economic Assistance) comprising the following countries: Bulgaria, Cuba, Czechoslovakia, East Germany, Hungary, Mongolia, Poland, Romania, and the U.S.S.R.

Commodity	1973	1974	Principal destinations, 1974
NONMETALS—Continued			
Sodium and potassium compounds, n.e.s	15,434	22,305	Italy 12,686; Brazil 6,206.
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked	54,364	58,319	Italy 35,069; West Germany 6,517; Czechoslovakia 5,281; East Germany 3,744.
Worked	6,809	11,151	East Germany 6,337; Austria 3,201; Czechoslovakia 1,354.
Dolomite, chiefly refractory grade	--	60	All to Greece.
Gravel and crushed rock	4,344	194	All to U.S.S.R.
Limestone (except dimension)	348	307	Hungary 175; Poland 103; U.S.S.R. 28.
Quartz and quartzite	15,582	23,276	East Germany 20,325; Austria 2,951.
Sand excluding metal bearing	238	3,404	Greece 2,975; Libya 277.
Sulfur:			
Elemental, other than colloidal	4,745	6,018	Romania 5,138; Bulgaria 792.
Sulfur dioxide	63	--	
Sulfuric acid	1,517	25,599	Romania 17,707; Italy 4,828; Albania 1,565.
Talc, steatite, soapstone, pyrophyllite	617	--	
Other:			
Crude:			
Calcite	60	100	All to Austria.
Unspecified	10	71	All to Greece.
Slag, dross and similar waste, not metal bearing	2,807	5,943	Italy 3,118; Austria 2,123; Albania 702.
MINERAL FUELS AND RELATED MATERIALS			
Carbon black	181	2,391	Czechoslovakia 1,411; Poland 935.
Coal and briquets:			
Anthracite and bituminous coal	1,156	--	
Lignite and lignite briquets	517,914	444,663	Austria 393,465; Italy 38,941.
Hydrogen, helium and rare gases kilograms	452	219	All to Libya.
Peat including peat briquets and litter	--	418	Libya 392.
Petroleum:			
Crude and partly refined:			
Crude thousand 42-gallon barrels	528	341	Greece 267; Cyprus 74.
Partly refined do	144	--	
Refinery products:			
Gasoline do	265	79	United Kingdom 33; Austria 12; West Germany 10.
Kerosine and jet fuel do	142	293	United Kingdom 98; France 30; U.S.S.R. 22.
Distillate fuel oil do	204	69	United Kingdom 28; Austria 10; East Germany 9.
Residual fuel oil do	406	107	People's Republic of China 15; Panama 14; Greece 12.
Lubricants do	7	55	United Kingdom 27; Austria 10.
Other:			
Liquefied petroleum gas do	178	12	All to Italy.
White spirit do	14	509	All to Austria.
Mineral jelly and wax do	41	33	Italy 16; East Germany 12.
Petroleum coke do	43	47	East Germany 45.
Unspecified do	403	1,249	Italy 283; Austria 216.
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals	3,776	13,943	Italy 10,804; Romania 5,790.

METALS			
Aluminum:			
Bauxite and concentrate thousand tons	170	219	Australia 187.
Oxide and hydroxide	42,220	66,876	Guinea 63,242.
Metal including alloys:			
Unwrought	56,664	48,931	U.S.S.R. 32,989; Austria 6,468.
Semimanufactures	20,036	23,092	West Germany 8,375; U.S.S.R. 5,174; Austria 2,730; Italy 2,636.
Antimony:			
Ore and concentrate	1,677	2,862	Turkey 2,475; Thailand 387.
Metal including alloys, all forms	71	40	West Germany 20; France 19.
Arsenic:			
Trioxide, pentoxide and acids	68	54	United States 40.
Metal including alloys, all forms	4	17	West Germany 11.
Beryllium including alloys, all forms kilograms	75	201	West Germany 193.
Bismuth including alloys, all forms	8	24	Japan 10; Switzerland 5.
Cadmium including alloys, all forms	21	6	Bulgaria 3; Switzerland 2.
Chromium:			
Chromite	161,399	176,463	Albania 131,093; U.S.S.R. 40,257.
Oxide and hydroxide	417	120	Hungary 74; West Germany 44.
Metal including alloys, all forms	35	17	United Kingdom 9; West Germany 7.
Cobalt:			
Oxide and hydroxide	19	34	West Germany 19; Belgium 14.
Metal including alloys, all forms	46	42	Belgium 21; Zambia 12; West Germany 4.
Columbium and tantalum, tantalum, including alloys, all forms kilograms	215	423	United States 215; Austria 160.
Copper:			
Ore and concentrate	34,957	78,456	Chile 78,280.
Copper sulfate	20	755	All from U.S.S.R.
Metal including alloys:			
Scrap	(1)	57	All from United States.
Unwrought	59,357	29,366	United Kingdom 20,732; Chile 4,967.
Semimanufactures	13,328	6,338	West Germany 2,164; Belgium 842.
Germanium including alloys, all forms kilograms	52	54	Poland 50.
Iron and steel:			
Ore and concentrate	389,870	430,528	Brazil 300,504; U.S.S.R. 130,021.
Metal:			
Scrap	298,636	427,780	U.S.S.R. 288,434; Poland 49,065; Bulgaria 38,835; Hungary 35,404.
Pig iron including cast iron	34,507	62,325	U.S.S.R. 30,006; Czechoslovakia 20,597; Canada 8,775.
Sponge iron, powder, shot	2,094	2,239	Sweden 1,767; France 379.
Ferroalloys:			
Manganese	3,619	2,761	West Germany 1,453; Austria 671; Italy 240.
Other	3,674	4,778	West Germany 1,963; Austria 779.
Steel, primary forms:			
Blooms, billets, slabs, sheet bars	168,810	258,503	Czechoslovakia 61,133; U.S.S.R. 52,768; East Germany 21,585; Hungary 20,789.
Coils for recoiling	208,579	247,546	U.S.S.R. 86,124; Czechoslovakia 71,830; Bulgaria 27,935; Japan 23,230.
Semimanufactures:			
Bars, rods, angles, shapes, sections	239,889	289,576	Czechoslovakia 88,463; Greece 59,945; U.S.S.R. 29,170; West Germany 27,199.
Universals, plates, sheets	594,135	686,586	West Germany 128,116; Czechoslovakia 104,811; Japan 108,353; Italy 76,667.
Hoop and strip	106,918	78,704	West Germany 39,283; Austria 10,334; Italy 7,357.
Rails and accessories	3,374	5,485	West Germany 2,673; Austria 1,699; U.S.S.R. 959.
Wire	39,761	45,188	Romania 16,380; West Germany 15,733; Austria 5,969.
Tubes, pipes, fittings	65,971	71,697	East Germany 24,386; West Germany 17,620; Italy 15,755.
Castings and forgings, rough	678	1,073	West Germany 553; Italy 92.

[1] Less than ½ unit.

COMMODITY REVIEW

METALS

The trend to greater processing of minerals and metals continued. The tabulation below shows the approximate share of the industry in GSP and in total employment of the country.

	Iron and steel	Nonferrous metals
Employment, number of persons	69,200	64,600
Percent of employed labor force	1.5	1.4
Percent of country's GSP	3.2	4.8
Percent of minerals industry	27.1	34.9

Aluminum.—The largest bauxite-producing areas were along the Adriatic coastline in Hrvatska (Croatia) (Obrovac), and inland at Montenegro (Nikšić) and BiH (Mostar and Vlasenica). During 1975, two aluminum plants and three aluminum electrolytic plants were in operation. The Sibenik plant, a 75,000-ton-per-year aluminum electrolytic plant located near Sibenik, Croatia, was the largest producer of aluminum in the country. Shortages of electric power limited production of aluminum to about 70% of capacity. Focal points of activities in the aluminum industry were the Bačevići-Mostar alumina and aluminum plant, the Vlasenica and Obrovac alumina plants, and the Titograd aluminum plant.

A 280,000-ton-per-year alumina plant went onstream at yearend at Bačevići near Mostar, BiH. The new plant was operated by Energoinvset of Sarajevo, BiH, and employed 700 persons. Total investment in the facility was equivalent to $30 million[4] and was financed by foreign and domestic credits. Alumina plants in production in 1975 are shown in the below tabulation.

[4] Where necessary values have been converted from Yugoslav dinars (din) to U.S. dollars at a rate of din 18=US$1.00.

Plant	Location	Approximate annual capacity (metric tons)
Kidricevo	Kidricevo-Slovenia	120,000
Titograd	Titograd-Montenegro	200,000
Bacevici	Mostar, BiH	280,000

Development continued at the Vlasenica project, a 600,000-ton-per-year alumina plant, at Karakaj, near Zvornik, BiH, partly financed with a $130 million loan from the U.S.S.R. Technicians from the U.S.S.R. designed the plant and Soviet factories started deliveries of equipment. Completion of the project was planned for 1976. For a 10-year period after completion, most of the alumina from the plant will be shipped to the U.S.S.R. in repayment of the loan.

At Obrovac, Croatia, construction continued on a 300,000-ton-per-year alumina plant, financed in part by East Germany and Hungary, and expected to start production in 1977.

Copper.—Rudarsko Topionicarski Bazen, Bor (RTB), Serbia, with its mine, flotation plant, and smelter at Bor; mine and flotation plant at Majdanpek; and new mine under development at Krivelj, remained the principal undertaking related to copper. However, development continued at the Bučim copper deposit, near Radovište, in Macedonia, expected to become the second-largest copper-producing facility in Yugoslavia.

During October, the eleventh section of the flotation plant in Majdanpek started production with a capacity of 1,400,000 tons of ore per year, increasing total annual flotation capacity to 12 million tons of ore. At the copper smelter in Bor, use of oxygen was introduced in furnaces for smelting copper. Management of Bor claims a 20% output increase without any actual smelter expansion.

Iron and Steel.—Renovation and expansion continued in the iron and steel industry. Domestic output of iron and steel products supplied only 64% of the country's demand, and imports of iron and steel semimanufactures were by value one of the largest import items. Shortages of electric power slowed production at ferroalloy and steel plants. During 1975, iron ore was produced at four mines and was upgraded at four concentrators, one pelletizing plant, and seven agglomeration (sintering) facilities. Iron ore mines at Vareš and Ljubija in Bosnia, operated by Rudarsko Metalurški-Kominat, Zenica, Bosnia (RMK-Zenica), remained the largest producers of iron ore in the country, accounting for 78% of the total iron ore output of Yugoslavia. Domestic iron ore production supplied 90% of the country's demand. Management of the Vareš mine announced plans for expansion of its mining and concentrating facilities to 3 million and 2.4 million tons, respectively, by the early 1980's. In Macedonia new iron ore deposits were discovered at the villages of Pozarna and Mitrova Krsta, near Gostivar. Reserves and date for startup of production at these deposits had not been made public by yearend.

Pig iron was produced in seven facilities, eight plants produced steel, and seven rolling mills were operational during 1975. RMK-Zenica remained the major producer of steel in the country with a 34% share in the total.

At RMK-Zenica expansion of steel producing and auxiliary facilities continued. When expansion is completed in 1977, RMK-Zenica should have the capacity to produce 2.6 million tons of steel per year. During 1975, a new 840,000-ton-per-year steel converter plant went onstream at Metalurški Kombinat Smederevo (Smederevo) in Smederevo, Serbia. In addition, construction of an 840,000-ton-per-year rolling mill continued at Smederevo and its completion is expected in 1977.

Lead and Zinc.—Programs continued on expanding mines and flotation plants. The aim was to increase output of ores and concentrates to meet future domestic smelter demand and export requirements. During 1975, 18 mines produced lead and zinc ores; 14 flotation plants produced lead and zinc concentrates; 2 lead smelters, and 1 lead refinery were in operation. One Imperial Smelting Process plant produced lead and zinc, and two major zinc electrolytic plants processed zinc concentrates. "Trepča," Rudarsko-Metalursko-Hemijski-Kombinat Olova i Cinka, Kosovska Mitrovica, Serbia, (Trepča), with its mine at Stari Trg, lead smelter and refinery at Zvečan, and zinc electrolytic plant at Kosovska Mitrovica, all in Serbia, remained the major producer of lead and zinc in the country. Principal activities related to the lead and zinc industry were exploration, expansion of the Blagodat and Kišnica mines, Serbia, and construction of the flotation plant at Lece, Serbia.

Exploration for lead and zinc deposits was underway throughout areas near existing mines. Discoveries were announced near Vareš, Bosnia, and on Besna Kobila Mountain in Serbia. Reserves of newly discovered deposits were not made public.

However, reserves near the villages of Draškovac and Veočani, Bosnia, were reported as "large." Based on those reserves, a new mine was planned in the area. Reportedly, start of production was scheduled for the latter part of 1977.

At the Lece mine, Serbia, construction continued on a new 250,000-ton-per-year mill, a new shaft, and a new aerial tramway.

At the Trepča smelter, Zvečan, work continued on improving efficiency and safety conditions at the sulfuric acid plant.[5]

The Kišnica and Blagodat mines were slated for expansion by about 4,000 tons of metal per year each.

Nickel.—During the summer of 1975, development of mines and construction of a ferronickel plant started at Rzanovo near Kavadarci, Macedonia. Yugoslavia's Feni-Rudnici i Industrija za Nikel, Celik i Antimon, Kavadarci (Feni), will be the operator. Production of 16,000 tons of contained nickel was slated for startup in late 1978. Proven reserves of 34 million tons of ore with an average nickel content of 0.9% are adequate to sustain production for more than 15 years. Arthur G. McKee & Co. is the major foreign contractor. Total investments will be $208.7 million. Bankers Trust Co., along with Moscow Narodny Bank and Chase Manhattan, put together the financing of the Feni project.[6]

Other Metals.—Yugoslavia also produced bismuth, cadmium, chromite, germanium, gold, manganese, mercury, selenium, and silver in 1975. Except for mercury produced at Idria, Slovenia, output of the other metals was modest by world standards. Bismuth was a byproduct of the lead and zinc operation at Trepča, Serbia; and cadmium was a byproduct at Trepča and at the Zorka plant at Sabac, Serbia. The Bor complex in Serbia yielded gold, germanium, and selenium as byproducts of copper. In addition, preparations were underway for production of platinum and platinum-group metals from sludges left after electrolytic copper recovery at Bor. Manganese was produced in Bosnia. Trepča was the main source of silver as a byproduct of lead and zinc processing.

NONMETALS

Cement and other construction materials remained the principal nonmetals produced in the country during 1975. Other nonmetals produced were magnesite, asbestos, pyrites, salt, and quartz sand. The estimated share of the nonmetals industry in the GSP of Yugoslavia was 1.3%; it was 11.6% of the total value of production of the minerals industry during 1975. The nonmetallic industry employed about 73,500 persons during 1975. Production of nonmetals remained the least developed segment of the mineral industry of Yugoslavia, and its significance was limited to the domestic economy. Mechanization and worker productivity was low. Lack of funds hampered successful development of the industry.

Asbestos.—Renovation continued at the Stragari asbestos mine, at Stragari, Serbia, operated by Stragari Asbest. New technology should enable the Stragari mine to produce 5,000 tons of asbestos per year by 1976.

Cement.—Cement output ranked first on the list of nonmetals produced in the country. Croatia and Serbia were the principal producing states, sharing in the country's total output by approximately 39% and 27%, respectively. Future plans call for a cement output of 17 million tons by 1985, compared with a domestic demand of 14 million tons. Consequently, some 3 million tons will be available for export. During 1975, controversy continued regarding the wisdom of such an extensive expansion of the cement industry.

Production started at a 550,000-ton-per-year plant at Kosjerić, Serbia, and at a 330,000-ton-per-year plant at Plevlja, Montenegro. Construction of a 1-million-ton-per-year plant near Anhovo in Slovenia continued during 1975. Reportedly, production will start during 1976.

Construction started on a 600,000-ton-per-year cement plant near Našice, Croatia, and on a 720,000-ton-per-year cement plant near Kakanj, Bosnia, both scheduled for production in 1978. Planning continued for a 600,000-ton-per-year cement plant at Ostruznica near Belgrade. Expansion and renovation continued at four plants: Beočin near Novi Sad, Serbia; Popovac, near Niš, Serbia; Podsused, near Zagreb, Croatia; and Dalmacija near Solin, also in Croatia.

Clays.—*Kaolin.*—Expansion of the kaolin mine near Karačevo, near Kosovska Kamenica, began. According to plans,

---

[5] Nijaz Selimovic. Olovo (Lead). Politika, Jan. 16, 1976, p. 13.

[6] Engineering and Mining Journal. V. 176, No. 9, September 1976, pp. 112–113.

output should reach 70,000 tons of kaolin per year in 1978. Reserves of about 3.5 million tons of kaolin were reported at yearend 1975.

Gypsum.—Construction started on a 55,000-ton-per-year gypsum plant located in Donji Vakuf, Bosnia. The new facility is an addition to the existing gypsum plant. "Komar," the operating enterprise, will become the largest producer of gypsum in Yugoslavia when the project is completed. Total costs were reported at 26.4 million dinars or $1.4 million.

Lime.—During 1975, focal points of the lime industry were at Jelen Do, and Kučevo in Serbia; Drniš and Slavonski Brod in Croatia.

Construction started on a 70,000-ton-per-year hydrated lime plant located at Jelen Do, near Cačak, Serbia. The total costs were reported at 40 million dinars or approximately $2.2 million.

Two new lime furnaces and an installation for lime hydration were completed near Kučevo, Serbia. New additions increased annual plant capacity to 240,000 tons of lime. Reportedly, the Kučevo plant was the largest lime producer in the country during 1975. Construction continued on a new 100,000-ton-per-year lime plant located near Drniš, Croatia, and production was scheduled for 1977. Plans were made to build a 120,000-ton-per-year lime plant near Slavonski Brod, Croatia. Production was scheduled for 1978. However, at yearend 1975, funds for this project were not secured.

Magnesite.—The first Yugoslav plant for production of sinter magnesia from sea water was planned in Bar, Montenegro. Magnochrome, the largest processor of magnesite in the country, will cover construction costs of about $0.57 million. The initial annual capacity will be 100,000 tons of sinter magnesia. Employment will be 300 persons.

Sand.—During 1975, major quartz sand producers in Yugoslavia were the Rgotina mines, near Zajecar in Serbia, Valjevo nonmetallic mines, near Valjevo, Serbia, and Istria Sand mines near Pula in Croatia.

At the Rgotina mine, a new installation for processing quartz sand started production. Annual capacity of the new facility was reported at 100,000 tons of processed sand. Equipment was purchased in the United Kingdom and the plant is highly automated.

Plans for increased output were approved for the Istria Sand mine, near Pula, Croatia. Production of 60,000 per year tons of sand was scheduled to start in 1978. When all new facilities become operational, imports of foundry sands are expected to be eliminated from Yugoslavia's foreign trade.

Stone.—Construction started on a plant for processing ornamental stone near Knjazevac, Serbia. Plant capacity was planned at 22,000 square meters of ornamental stone (gabbro) and 20,000 meters of curb stone (granite). Total costs were estimated at 40 million dinars ($2 million). Employment will be 140 persons.

Construction was completed on a new limestone quarry and plant located at Banjani near Skopje, Macedonia. Annual capacity of the new installation is 3 million tons of limestone, if operated on three shifts. Costs were reported $4.8 million. Equipment was purchased in Italy and West Germany. The limestone mine and classifier are operated by the Skopje iron and steel works which is the major consumer of limestone produced at Banjani.

MINERAL FUELS

During 1975, Yugoslavia was dependent on imports of high-rank coals, coke, and crude oil. Petroleum was the main energy producing material; however, domestic low-rank coals remained the principal source of energy produced in Yugoslavia. Table 4 shows supply and apparent consumption of energy for 1973 and 1974.

The approximate shares of the fuels producing and processing industry in the country's employment and GSP are shown in the following tabulation:

	Coal and coke	Petroleum, natural gas, and refining
Employment, number of persons	68,100	21,400
Percent of employed labor force	1.5	.5
Percent of country's GSP	1.5	1.8
Percent of minerals industry	10.8	15.6

Table 4.—Yugoslavia: Supply and apparent consumption of energy-producing materials for 1973 and 1974
(In million tons of standard coal equivalent) [1]

	Total energy	Coal and coke	Petroleum and refinery products	Natural gas	Fuelwood	Hydro-electric power
1973:						
Production	25.8	16.5	4.9	1.8	0.5	2.1
Imports	16.5	1.9	14.6	(2)	(2)	(2)
Exports	.6	.2	.4	(2)	(2)	(2)
Apparent consumption	41.7	18.2	19.1	1.8	.5	2.1
1974:						
Production	27.3	17.1	5.1	2.0	.5	2.6
Imports	18.6	2.5	16.1	(2)	(2)	(2)
Exports	.8	.4	.4	(2)	(2)	(2)
Apparent consumption	45.1	19.2	20.8	2.0	.5	2.6

[1] 1 ton of standard coal equivalent (SEC) =7,000,000 kilocalories.
[2] Less than ½ unit.

Coal.—Brown coal and lignite comprised the bulk (98%) of Yugoslavia's coal output. About 93 mines were in operation. However, about 60% of output comes from six large producers, of which four are opencast mines. Approximately 2.5 million tons of bituminous coal, coke, and related products had to be imported during 1975 to meet additional demand.

Preparations were underway to initiate coal production in Macedonia. Equipment from the U.S.S.R. and East Germany was on location and removal of overburden started.

In Bosnia and Hercegovina, the largest coal-producing State, expansion of the Raspotočje mine near Zenica was completed when a new 1-million-ton-per-year shaft was put into operation in 1975. In addition, a new opencast coal mine, Gračanica near Bugojno in Bosnia and Hercegovina, started regular production after a trial period that began in 1974. Also, the Kreka Banoviči mines near Tuzla started to switch from underground mining to opencast production.

In Montenegro, development of the Petujak mine near Ivangrad, to produce about 300,000 tons of coal per year, was underway during 1975. Plans were also made to open another mining field at the village of Polica, also near Ivangrad. Design capacity of the Polica operation was 550,000 tons of coal per year. Proven reserves of about 150 million tons of coal, with calorific value of 3,000 to 4,500 kilogram calories per ton, are reported in the Ivangrad coal basin. Expected costs of $19.5 million apparently would be financed by loans from the U.S.S.R., West European banks, and domestic funds.

In the Kolubara Basin in Serbia, removal of overburden started at the new Tamnava opencast mine, which should produce between 18 million to 20 million tons of lignite per year when completed in 1980. For the Tamnava project six large rotary excavators, valued at 85 million German marks, were ordered from Ornstein Koppel of West Germany. In addition, three large self-propelled excavators, valued at $3 million, were ordered from the U.S.S.R., also for use in the Tamnava mine. In the Kostolac Basin, development continued on two new opencast mines, Drmno and Cirikovac. Four excavators, valued at $18 million, to be delivered between 1978 and 1980, were ordered from East Germany.

The energy crisis made marginal lignite mines in Croatia attractive, and plans for reopening the closed lignite mines and increasing production in operating mines were underway during 1975. A draft plan for 1980 calls for an annual output of 2 million tons in Croatia (output in 1974, latest year for which data were available, was 500,000 tons).

Coke.—During 1975, a fourth coking battery (700,000 tons per year) started production at Lukavac, and construction of another 700,000-ton-per-year coke battery was planned. The installation is operated by the Chemical-Coking Combine Boris Kidric at Lukavac in Bosnia. The Yugoslav authorities expect to end imports of coke during 1976. When the fifth battery is completed in 1978, the combine will have an annual capacity for production of 2 million tons of coke.

Construction continued on an 820,000-ton-per-year coking plant near Bakar, Croatia. The plant, when completed in 1977, will be operated by the Sisak Iron and Steel Plant in Sisak, Croatia.

Natural Gas.—Increased output of byproduct natural gas and high prices of imported crude oil made domestic natural gas more attractive. During 1975, principal activities were construction of a large gas pipeline system, construction of a new natural gas processing plant, and planning for an installation for production of ethylene.

Preparations for construction of gas transmission lines were underway in Serbia and Croatia. In Serbia, financial arrangements between domestic and foreign banks were concluded for the domestic share of total costs for the 1,268-kilometer trunkline between Senta and Nis. Initial capacity of the pipeline was planned at 2.7 billion cubic meters yearly. In Croatia, a 50-kilometer segment, from Miholjac to Osijek, of the Budrovac-Osijek gas transmission line was under construction. The gasline will bring natural gas from Bokšić Lug gasfield to Osijek.

Construction of an 800-million-cubic meter-per-year natural gas processing plant started near the existing gas processing facility at Ivanić Kloštar, Croatia. The installation will produce about 80 million cubic meters per year of ethane. Ethane will be piped to Zagreb for use in a new 90,000-ton-per-year plant for production of ethylene. INA-Naftaplin was scheduled to manage the operation. INA-Naftaplin awarded the contract for design, engineering, purchasing, and site service for the ethane plant to J. F. Pritchard & Co., Kansas City, and Pritchard-Rhodes Ltd., London, subsidiaries of International Systems & Controls Corp. The contract value is about $26 million.[7] Financing for the gas processing plant was secured at yearend. A total of $72 million will be covered by loans from domestic banks and Lloyd Bank Ltd.

During 1975, INA and The Dow Chemical Co. were negotiating terms for a joint venture in Yugoslavia. Reportedly, a large petrochemical plant on Krk Island was considered. The Dow Chemical Co. would share 49% of total investment, and INA, the rest. If the agreement is concluded, the operation of the venture will be governed by the law permitting investments of foreign capital in the industry of Yugoslavia.

Oil Shale.—During 1975, Yugoslav authorities started reexamining technical and economic aspects of crude oil production from oil shales in Serbia near the town of Aleksinac. Reportedly, reserves total to 1,300 million tons of oil shale with an average oil content of 9% to 12%. Yugoslav oil reserves in oil shale are thus three times higher than oil reserves in oilfields. Financing and technology appeared to be the major problems in organizing the venture.

Petroleum.—Domestic production of crude oil reached an alltime high of 3.7 million tons in 1975. This increased output resulted from the startup of two new oilfields in Croatia and one in Serbia and in higher output from existing fields. The principal producing areas were in the Pannonian sedimentary basin, in the northern part of Yugoslavia, from east of Zagreb to the Romanian border and north from the Sava River to the Hungarian border. However, imports of about 68% of refinery throughput were required. Iran, Iraq, and the U.S.S.R. were the principal suppliers.

Industrija Nafta (INA), headquartered in Zagreb, Croatia, and Naftagas in Novi Sad, Vojvodina, Serbia, remained the only producers and most important refiners of crude oil in the country. INA was by far the larger, accounting for about 70% of the country's total crude oil output. Six refineries, three operated by INA, two by Naftagas, and one by Energoinvest had an installed annual capacity of 13.2 million tons.

Exploration, Development, and Production.—Exploration for hydrocarbons was conducted onshore in the Pannonian Basin and offshore along the Adriatic shoreline. INA in Croatia and Naftagas in Serbia carried out exploratory and development drilling for crude oil and natural gas. Both enterprises drilled a total of approximately 250,000 meters with 19 rigs in the Pannonian Basin. In Croatia, signs of possible crude oil production were reported on exploratory wells at Gakovo, Mihovljani, Kotoriba, and Peteranec. In Serbia, reports indicated discoveries of crude oil on exploratory wells at Karadjordjevo, Velike Livade, and natural gas near Begejac and Srpska Crnja. In addition to exploration in the Pannonian

[7] Wall Street Journal. No. 103, Dec. 22, 1975, p. 3.

Basin, INA and Jugopetrol-Adriatica (a joint venture between Buttes Gas & Oil Co. and Challanger Oil and Gas Co., a subsidiary of Global Marine Inc., and Jugopetrol-Kotor), carried out exploration offshore on the Yugoslav side of the Adriatic Sea. INA's activities were confined to the shoreline of Croatia (northern part of the Adriatic). During 1975, there was no offshore drilling in the northern part of the Yugoslav littoral. Data, obtained during previous offshore drilling, were studied. Locations were selected for drilling with INA's first offshore rig which should be delivered during 1976. The activities of Jugopetrol-Adriatica were conducted along the Coast of Montenegro (southern part of the Adriatic). Approximately 1,800 kilometers of seismic profile were recorded. Locations for the first offshore well were selected. The first well, Juzin Jadra, is located 17 miles offshore and is planned to be deeper than 10,000 feet. At yearend all preparations were completed and drilling was scheduled for early 1976. This well is the first well drilled in Yugoslavia under provisions of Yugoslav law permitting investment of foreign capital in the economy of the country.

All of the country's crude oil production comes from approximately 30 fields located in the Pannonian Basin. Beničanci, Croatia, operated by INA-Naftaplin, was the largest oil-producing field in Yugoslavia. Oilfields, Velebit and Kikinda, were the largest oil producers in Serbia. New oilfields Ladislavci-Kučanci and Obod in Croatia and Kikinda Zapad in Serbia statred production during 1975.

Refineries.—Six State-owned refineries processed a total of 10.9 million tons of crude oil during 1975 and operated at approximately 83% of its installed capacity. Imported crude accounted for about 66% of the total yearly throughput. Planning for construction of a new refinery near Skopje, Macedonia (2.5 million tons per year), planning to double present capacity of refinery Bosanski Brod, BiH (to 3 million tons per year), and reexamining economic aspects of a new refinery near Kopere in Slovenia were the focal points of the petroleum refining industry of the country. However, no actual action was taken on those projects at the yearend.

Transportation.—Rail, trucks, river barges, and tankers moved most of the crude oil and products. Only a small part was moved by pipelines. However, steps were taken to make pipelines the principal means for moving crude oil. Construction started on the first crude oil trunk pipeline connecting Omisalj on the island of Krk in the north Adriatic with inland refineries in Yugoslavia, Hungary, and Czechoslovakia. The pipeline will start at Omisalj, on the island of Krk in the north Adriatic, where a new port will be built and will lead to refineries at Rijeka, Sisak, Bosanski Brod, Novi Sad, and Pančevo, with a branch to the Hungarian border and to Lendava. The pipeline is planned to be about 1,200 kilometers long. Approximately 735 kilometers will be in Yugoslavia. It will have an annual capacity of 34 million tons, of which 10 million tons are reserved for INA refineries, 5 million tons for the Energoinvest refinery, 9 million tons for Naftagas refineries, and 10 million tons for refineries in Hungary and Czechoslovakia. At yearend, financing of construction was secured. Loans from Libya and Kuwait, $70 million and $125 million, respectively, brought the total of funds available for construction to $550 million, which is considered to be adequate for the project. The pipeline was scheduled for initial operation in 1976; however, completion of the whole project is not expected before 1980. In addition, planning for a crude oil pipeline from Thessaloniki in Greece to a newly planned refinery near Skopje in Macedonia was underway at yearend.

Uranium and Nuclear Energy.—Construction continued on the 615-megawatt nuclear powerplant near Krsko, Slovenia. Construction was 5 months behind schedule at yearend. To fuel the reactor, domestic uranium concentrates (yellowcake-U_3O_8) will be enriched in the United States. To provide necessary ores and concentrates, development continued on the domestic uranium deposit near Zirovski Vhr, Slovenia. Reserves at Zirovski Vrh were considered adequate to support production of 300 tons per year of concentrates for a period of 15 years.

The Mineral Industry of Zaire

By Miller W. Ellis [1]

Zaire continued to have the world's largest mine production of industrial diamond, cobalt, and germanium and ranked sixth in production of copper. Production of columbium-tantalum, tungsten, and tin from the Kivu region increased, and output of industrial diamond from the Kasai region declined slightly. Production of crude oil from offshore wells commenced at yearend. Congestion at the port of Lobito and disruption of transport on the Benguela Railway increased as the struggle for control of the emerging independent Angola intensified. Alternative routes for both exports and imports were overtaxed even before military action stopped rail traffic to the west of the mineral-rich Shaba region. The loss of revenue to the mining companies and to the Government of Zaire resulted in curtailment or postponement of plans for expansion of the mineral industry and has weakened the country's financial position. Austerity measures were proposed, and in some cases implemented, to alleviate shortages of foreign exchange and energy, and to reduce inflation. Lack of essential supplies adversely affected mineral production, and shortages of consumer goods continued through 1975.

Following the December 1974 agreement of the Conseil Intergouvernemental des Pays Producteurs et Exporteurs du Cuivre (CIPEC) to reduce copper production for world markets 10%, the Zairian Government instructed the copper-producing companies to continue operations but to stockpile metal and concentrate in compliance with the cutback.

In February, it was announced that future exploitation of copper and cobalt deposits would be reserved for three companies only: La Générale des Carrières et des Mines du Zaire (GÉCAMINES), Société de Dévelopment Industriel et Minière du Zaire (SODIMIZA), and Société Minière de Tenke-Fungurume (SMTF).

The CIPEC countries announced another cut of 5% in the production-export of copper effective April 15, but there was no indication that any deliberate cut was required in Zaire in view of the deteriorating facilities for export of Zairian metal and concentrates.

A number of directives to the entire country also applied to the mineral industry. These included a wage ceiling of $1,834 [2] per month, with cuts in pay to Zairians (except teachers) in the income group earning more than $302 per month; an increase in wages for the low-income group; and price controls for foodstuffs and other essential consumer goods.

PRODUCTION AND TRADE

Mine production of copper, manganese ore, and refined zinc in the Shaba region dropped only slightly below that of 1974. Because of intermittent recovery, byproduct germanium output decreased 80%, cobalt 22%, and cadmium 3%, but silver production increased 35% to the highest figure reported since 1961. Production of zinc for export as concentrate decreased 10%, and nearly 6% less coal was mined in the Shaba region, where it was largely consumed. In the Kasai region, industrial diamond pro-

[1] Physical scientist, Division of International Data and Analysis.

[2] Where necessary, values have been converted from Zairian currency zaires (Z) to U.S. dollars at the rate of Z1 = US$2.00.

duction decreased 4%, and recovery of gem-quality diamond reportedly dropped 36%. Gold production, largely from the Kivu region, decreased 20%, although production of other Kivu minerals increased as follows: Columbium-tantalum, 74%; tungsten, 27%; tin metal-in-concentrate, 13%; and monazite concentrate, 35%. Refined tin from the Shaba region increased 13%.

The State-owned company GÉCAMINES continued to account for most of Zaire's foreign exchange earnings, and despite the relatively low prices prevailing throughout 1975, copper was the chief source of income for both GÉCAMINES and Zaire. Copper sales prices averaged 51.8 cents per pound for 1975, a 37% decrease from the 82 cents per pound realized in 1974. Details of mineral production are shown in table 1, and export data are shown in table 2. The last reported official information on imports was for 1970 and appeared in the Zaire chapter of the 1972 Minerals Yearbook.

Table 1.—Zaire: Production of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1973	1974	1975 [p]
METALS			
Cadmium, smelter production	278	272	264
Cobalt:			
Mine output, metal content	15,052	17,532	13,638
Refinery production	15,052	17,565	12,355
Columbium-tantalum concentrate	56	46	80
Copper:			
Mine output, metal content	488,567	499,428	496,331
Blister and leach cathodes	460,479	454,000	462,600
Refined	[r] 223,557	254,572	225,900
Germanium, content of concentrates ----kilograms	3,296	61,653	11,865
Gold [1] ----troy ounces	133,650	128,989	103,217
Manganese ore and concentrate, gross weight	333,963	308,775	308,525

COMMODITY REVIEW

METALS

Copper, Cobalt, Zinc, and Associated Metals (Shaba Region).—The interruption of traffic over the Benguela Railway by military action in Angola delayed Zaire's plans for expansion of its mineral industry and, together with the low price of copper throughout 1975, seriously damaged the country's economic position. The Belgian firm Société Général des Minerais (SGM) continued to assist with copper marketing but was able to turn this function over to the Société Zairoise de Commercialisation des Minerais (SOZACOM) by yearend.

GÉCAMINES accounted for 93% of Zaire's production of copper, all of its production of cobalt, zinc, germanium, and cadmium, most of the silver, and 21% of the gold. Zinc was a coproduct at the underground Kipushi mine, with germanium, cadmium, and silver as byproducts. GÉCAMINES' two other underground and six open pit mines continued to produce copper and, as byproducts, cobalt, silver, and gold. Sulfuric acid was also produced and used in metallurgical processing.

As scheduled in the expansion program, GÉCAMINES commenced open pit mining of the deposits at Dikuluwe and Mashimba in the fall of 1975, but shortages of imported diesel fuel oil prevented full-time operation of heavy equipment at both mines. Construction of additional concentrating, smelting, and refining facilities as well as housing for employees in the Kolwezi area, was delayed by transport difficulties. Full utilization of these facilities depended on completion of the 1,000-kilovolt direct-current transmission line from Inga, which was also behind schedule.

The Japanese-operated company SODIMIZA produced 94,300 tons of concentrate containing 34.4% copper, or 32,439 tons of copper metal, from the Musoshi mine, and continued to develop the Kinsenda deposit and to explore known deposits in adjacent areas along the Zambian border to the east. The concentrator at Musoshi had the capacity for 140,000 tons of ore per month and was to treat ore from the Kinsenda mine, where problems with mining and water extraction had to be solved.

Zaire's third potential copper-cobalt-producing company, SMTF, was unable to maintain its schedule for construction of a new mining, roast-leach, and electrowinning complex east of Kolwezi because transport of essential supplies was interrupted. Restrictions on externalization of employees' earnings made it difficult to retain skilled staff. Zaire's deteriorating international credit position also contributed to the delay of the project, in which U.S. capital and contractors were involved. Contracts for construction of housing, awarded to French and Zambian firms, were nearing completion. Construction of the metallurgical complex by the U.S. firm Fluor-Utah, started in February 1975 but was delayed later in the year.

Columbium-Tantalum, Gold, Tin, and Tungsten.—Alluvial and eluvial cassiterite had been produced for more than 50 years from weathered soils overlying extensive pegmatite deposits south of Manono in the north-central part of the Shaba region. Hard unweathered ore was left in place or stockpiled for future treatment when the spodumene and other lithium minerals in the gangue could be recovered. The major tin-producing company in the Shaba region, Zairetain, investigated the feasibility of exploiting what it claimed as the world's largest spodumene deposit. Construction of a plant at a cost of $4 million for producing 5,000 tons of lithium carbonate per year was proposed. Meanwhile, Zairetain continued extraction of the heavier minerals, including 30 tons of columbite-tantalite and nearly 1,000 tons of cassiterite, and reported the production of 647 tons of tin metal worth more than $5 million from its smelter at Manono. The smelter used slightly more than one-fourth of the 45-megawatt capacity generated by Zairetain's hydroelectric plant on the Luvua River, 90 kilometers to the east.

Following the closure of the Benguela Railroad, some of the production was sent downriver to Matadi on the "National Route", which proved costly in terms of time and losses. Most of the production was shipped by truck to Muyumba on the Lualaba River, by barge to Kabalo 200 kilometers downstream, by rail to Kalemie on Lake Tanganyika, by lake steamer to Kigoma, and again by rail across Tanzania to the congested port of Dar es Salaam. Shipping time via this route averaged 3 months, only slightly longer than the Benguela–Lobito route in Angola.

In the Kivu region to the north, Compagnie Belge d'Enterprises Minières (COBELMINE) was the major operator following amalgamation of eight previously independent companies.

Arrangements were made for the incorporation of Syndicat Minière de l'Etain (SYMETAIN) and COBELMINE into a single organization. Production by the two companies for 1975 follows:

	COBEL-MINE	SYME-TAIN
Cassiterite --metric tons--	3,005	2,384
Tin content at 70% -do----	2,103	1,669
Wolframite ---------do----	405	10
Monazite -----------do----	298	--
Columbite-tantalite --do----	6	--
Gold ---------troy ounces--	18,500	--

Manganese.—Zaire's manganese ore production was from the Kisenge deposit near the Benguela Railway line, about 100 kilometers east of the Angolan frontier at Dilolo. Société Minière de Kisenge (SMK) mined and crushed oxide ore containing 48% to 51% metal and also mined carbonate ore with 35% manganese content. In 1975, SMK produced 171,147 tons of ore, including 6,415 tons of carbonate, and exported 127,866 tons for revenues of $11,794,826, which included some 1974 sales.

After closure of the Benguela Railway, the company continued to mine and stockpile ore because the unit price for manganese ore was too low for profitable export by any alternative route.

NONMETALS

Cement (Shaba Region).—Cimenteries du Shaba (CIMSHABA) marketed cement in the Shaba and neighboring Kasai regions and sold lime to GÉCAMINES from its plant in Lubumbashi. Production dropped to 76.5% of the 1974 level, largely owing to lack of firebricks from Europe, which failed to arrive during the year. CIMSHABA was taken over by the Zairian Government on March 15, 1975. It reported revenues of $3,700,260 with an after-tax loss of $1,099,118 for the production of 70,143 tons of cement, 6,646 tons of lime, and 3,667 tons of ballast.

Diamond, Industrial and Gem (Kasai Region).—With a decline of only 4.4% from the 1974 record, Zaire retained its leading position among world producers with 12,416,000 carats of industrial diamond from extensive deposits near Mbuji Maya. Production of gem-quality diamond dropped 36% to a new low of 394,000 carats. Most of the mines were operated by the Zairian company Société Minière de Bakwanga (MIBA), which also purchased diamond recovered by the few independent operators licensed to mine.

MIBA verified that exploration drilling had outlined a 4-million-ton deposit of nickel ore containing more than 1% nickel in the rugged country of Lushatsha, west of Mbuji Maya.

MINERAL FUELS

Coal (Shaba Region).—The Luena coalfields in northern Shaba produced 89,018 tons of coal in 1975, 6.4% less than in 1974. GÉCAMINES mined and consumed most of the high-ash coal. A small amount of coal was imported from Zambia.

Petroleum.—Zaire continued to import crude oil for the Moanda refinery north of the port of Banana. The Zairian-Italian Refining Company (SOZIR) produced 614,663 tons of petroleum products, a decrease of 11.9% compared with the 1974 output. Production of high-test and aviation gasoline increased 10%. The greatest decline, 33.7% in fuel oil, was particularly unfortunate for the mining industry. Substantial amounts of fuel oil were also imported, but from July through November, transport difficulties caused intermittent operation of diesel-powered equipment at several mines in the Shaba region.

SOZIR announced plans to increase the capacity of the Moanda refinery from 750,000 to 1.3 million tons per year. Three tugboats and nine 1,650-ton tanker barges shuttled crude oil from oceangoing tankers moored near the port of Banana to the unloading docks, where it was pumped through a pipeline to the crude oil storage tanks at the Moanda refinery.

Zaire became Africa's 10th oil-producing country in late 1975 when Gulf Oil Corp. and partners commenced production from two oilfields discovered off Zaire's 40-kilometer coastline in 1971 and 1973. The GCO Field (six wells in 20 meters of water 16 kilometers offshore); and the Mibale Field (three wells in 6 meters of water less than 5 kilometers from shore) tapped reserves estimated at 200 million barrels of oil and 50 billion cubic feet of natural gas. The gravity of the crude oil was between 31.7° and 33.2°, and the sulfur content was slightly more than 0.11%. The high wax base caused pour points of 65°F for GCO crude oil and 80° to 95°F for Mibale crude oil, which made it an unsatisfactory raw material for the Moanda refinery.

Crude oil from both fields was pumped through a submarine pipeline to a storage vessel moored north of the GCO Field. Another submarine pipeline conveyed it to a mooring buoy and loading point for tankers.

The Mineral Industry of Zambia

By Miller W. Ellis [1]

Zambia maintained its position as the world's fifth largest producer of copper in 1975. Despite a prolonged depression of prices on the international market, copper continued to provide most of Zambia's foreign exchange. The Government of Zambia, as majority shareholder, concluded agreements to terminate management and sales contracts with the chief minority shareholders of Nchanga Consolidated Copper Mines, Ltd. (NCCM), and Roan Consolidated Mines Ltd. (RCM). As compensation for early termination of these contracts, Anglo-American Corp. and American Metal Climax Inc. have accepted $51.5 million and $34.3 million,[2] respectively, paid in quarterly installments during a 3-year period. A separate company, the Metal Marketing Corporation of Zambia, Ltd. (Memaco), was made responsible for negotiating all sales of Zambia's metal products.

As a member of the Conseil Intergouvernemental de Pays Exporteurs de Cuivre, Zambia agreed in March to curtail copper production by 15%.

Civil unrest in Angola disrupted and finally halted traffic on the Benguela railway which had carried about half of Zambia's trade via the Atlantic port of Lobito. Alternative truck routes through Malawi and Mozambique were able to handle only about 20% of Zambia's traffic. The remainder moved slowly through the congested Indian Ocean port of Dar es Salaam, after Tanzania imposed weight restrictions on trucks carrying cargo in transit through Tanzania to or from the Kenyan port of Mombasa.

The Tanzania Zambia Railway TAZARA track was linked with the Zambia line in September and, although the new line was not fully commissioned, it carried an increasing amount of Zambia's trade during the last quarter of the year.

In September, the two major copper producers, RCM and NCCM, declared *force majeure* of 20% and 30%, respectively, on their copper deliveries. The following month this was increased to 30% and 40%, respectively. Both companies postponed projects for expanding the mining industry, and some smaller producers ceased operations because of increased delays in receipt of equipment and the escalation of production costs.

PRODUCTION AND TRADE

Transport of Zambia's products to, and its essential requirements from, the world's markets was a vital factor in Zambia's trade. In 1975 the cost of such transport increased drastically as did the time lag between the order and receipt of equipment and supplies, and between the shipment of products and delivery to the overseas market. Foreign exchange payment had to be made when orders were placed and exchange credit was not available until delivery was accomplished so that Zambia's overseas suppliers and customers benefited while goods were in transit.

Prior to the closure of the Rhodesian border in 1973, 55% of Zambia's exports

[1] Physical scientist, International Data and Analysis.
[2] Where necessary, values have been converted from the Zambian currency Kwacha (K) to U.S. dollars at the rate of K1.00=US$1.56.

and 66% of its imports had been shipped via Rhodesia and handled through Mozambique ports. With the closure of the border, rail shipments through Zaire and Angola via the Benguela railway were increased to 55% of exports and 45% of imports, and most of the remainder was trucked to the Indian Ocean ports of Dar es Salaam in Tanzania and Mombasa in Kenya. Some use was made of the completed portion of the Chinese-built TAZARA, which had progressed from Dar es Salaam into northeastern Zambia by the end of the rainy season in April 1974. Truck haulage to both ports continued but haulage to Mombasa was curtailed when Tanzania imposed weight restrictions on trucks carrying cargo to or from the Kenyan port of Mombasa. Construction of increased cargo handling facilities at Dar es Salaam was not sufficiently advanced to prevent congestion and accumulation of cargo at the harbor.

Civil disturbances in Angola began to disrupt traffic on the Benguela railway, and congestion at the Atlantic port of Lobito increased as did the number of ships awaiting berthing space at both Lobito and Dar es Salaam.

When Benguela traffic was stopped by hostilities in August, more than 100,000 tons of Zambia-bound cargo was stranded at Lobito. Much of it spoiled or was lost and the remainder was reconsigned, at considerable extra cost, to Indian Ocean Ports. A substantial amount of copper for export was impounded or lost, and nearly 800 railway cars were reportedly stranded in Angola.

Construction of a new road was accelerated for a more direct link with the Mozambique railway system and port of Beira, and truck haulage was increased across Malawi and Mozambique to the port of Nacala but deteriorating road conditions and port facilities were inadequate to handle more than about 20% of Zambia's traffic.

Track laying on the TAZARA route was also accelerated and the line was linked to Zambia's railway at Kipiri Mposhi in September 1975 when trial shipments started on a limited basis moving wheat from and Zambian copper to Dar es Salaam. Upgrading of the track and construction of loading facilities continued into the rainy season (November through March), but provision of adequate rolling stock and commissioning of full-scale operations were not anticipated before mid-1976. Increased dockage and cargo-handling facilities at Dar es Salaam were relieving port congestion by yearend.

The normal escalation of transport cost was further increased by demurrage and transshipment charges, and by increased production costs due to delayed arrival of vital equipment. The results were reduced profits and even net losses on the part of the mining companies and a loss of tax revenue by the Government of Zambia. Depressed copper prices and increased costs contributed to the negative balance in 1975. The value of Zambia's 1971–75 trade, in millions of dollars, is shown in the following tabulation:

	1971	1972	1973	1974	1975
Total exports (A)	679	845	1,160	1,401	[e] 816
Copper exports (B)	654	814	1,092	1,309	[e] 735
Total imports (C)	559	628	544	794	[e] 936
Balance (A–C)	120	217	616	607	[e] –120

[e] Estimate.

The balances do not indicate an accumulation of foreign exchange credits which were also required for loan repayments, dividends to overseas shareholders, and other disbursements. A satisfactory balance was held at yearend 1973 but this was largely exhausted in 1974, and by yearend 1975 a current account deficit of more than $650 million was only partially offset by new loans to the mining companies and by government borrowing from overseas sources.

Zambia's mineral production is shown in table 1. Table 2 shows exports and destinations of mineral commodities, and table 3 lists the amounts and sources of mineral imports.

COMMODITY REVIEW

METALS

Copper and Byproduct Cobalt.—Mine production of copper decreased 3% from 697,956 tons in 1974 to 676,921 tons in 1975, but because of price declines the value of copper exported declined 44% from $1,308 to $729 million for the same periods.

During their fiscal year which ended June 30, 1975, RCM produced 288,564 tons of copper and reported sales of 289,747 tons, increasing by 3% and 4%, respectively, the figures reported for 1974. The average sale price was $1,423 per ton, a decrease of 63% from the average of $2,253 realized in fiscal 1974. The Mufulira underground operation continued as RCM's largest producer, contributing 44% of RCM's production. Development work continued at the Baluba ore body which produced about one-sixth of the 6.4 million tons of ore treated at the Luanshya concentrator. The remainder came from the lower levels and western extension of the Roan Antelope ore body where bad ground was responsible for dilution resulting in a concentrator head grade of 1.47% copper. Sulfuric acid production diminished to 12,718 tons because of reduced demands from the mining industry. A plant to pulverize coal from the Maamba Colliery was under construction at Luanshya.

Ore production at the Chambishi open pit was halted for more than 4 months to accelerate overburden stripping during the dry season, and trackless methods were used for underground mining down dip from the pit bottom. Equipping of the 1,000-meter shaft on the footwall of the pit continued. The Chambishi roast-leach plant produced 523 tons of cobalt contained in hydroxide recovered from cobaltiferous concentrate from Baluba and Chibuluma. Plans for producing cobalt metal instead of hydroxide were implemented. Shaft sinking was continued at the Chibuluma West ore body and production came from both the main and western ore bodies. Plans for shaft sinking at the Kalulushi East deposit were postponed. RCM continued construction of a plant at Ndola for the recovery of copper, selenium, and precious metals from refinery tankhouse slimes which were previously treated abroad. Completion was scheduled for April 1976.

The following tabulation shows ore produced and ore reserves at RCM mining properties:

Mine	Ore produced		Ore reserves	
	Thousand tons	Percent copper	Thousand tons	Percent copper
Mufulira	6,930	2.21	143,932	3.15
Luanshya	6,420	1.47	136,501	2.56
Chambishi pit	1,120	2.19	42,309	2.91
Chambishi U/G	511	2.43		
Chibuluma	646	3.25	8,414	4.58
Kalengwa	208	5.90	978	6.95
Kalulushi East	--	--	5,900	4.09
Total	15,835	2.01	338,034	2.96

Total copper production from mines operated by NCCM during its 1975 fiscal year included 381,714 tons of refined copper and 26,952 tons of blister copper. The Nchanga operation included open pit and underground mines and, as NCCM's largest producer, reported 274,000 tons of copper. The Chingola low-grade tailings leach plant experienced low copper recovery rates after more than a year of operation, and expansion was deferred. The open pit mine and oxide treatment plant at the Mindola section of the Nkana ore body ceased operations at yearend. Expansion of the Mindola underground mine continued and Mindola ore was treated at the Rokana concentrator-smelter-refinery complex. At Konkola, production dropped 5% to 52,609 tons of copper. Drainage remained a major problem and water was pumped at an average rate of 91 million gallons per day (345,110 cubic meters per day). The Nampundwe pyrite mine west of Lusaka produced about 58,000 tons of concentrate containing 2.48% copper and 41% sulfur. The concentrate was stockpiled at the mine pending depletion of a stockpile at the Nkana complex which contributed to the production of sulfuric acid and copper. The Nkana cobalt plant recovered 1,578 tons of cobalt metal and shipped byproduct gypsum to Chilanga Cement Limited at a rate of more than 2,000 tons per month.

Ore production and ore reserves for mines operated by NCCM are tabulated below:

Mine	Ore produced		Ore reserves	
	Thousand tons	Percent copper	Thousand tons	Percent copper
Nchanga	9,786	3.40	252,280	3.42
Rokana	5,471	1.66	119,943	2.44
Konkola	1,773	2.96	125,093	3.55
Bwana Mkubwa	1,095	2.75	3,187	3.53
Total	18,125	2.79	500,503	3.22

Kansanshi mine, 160 kilometers west of the copperbelt, was the site of ancient workings before its "discovery" in 1899, and was operated intermittently until 1957. Construction of an oxide treatment plant and housing for staff to start an open pit operation was halted in 1975.

Excessive water hampered operations of the Romanian-managed Mokambo mine near the Zaire border north of Mufulira. The Mkushi mine, 130 kilometers southeast of the copperbelt, and the Chifumpa mine 240 kilometers to the southwest, ceased operations.

Table 4 shows exports of copper by country for 1974 and 1975.

Lead, Zinc, and Byproduct Silver.—The Broken Hill Division of NCCM produced 380,000 tons of galena-sphalerite ore from the Broken Hill mine at Kabwe, 110 kilometers north of Lusaka. Recovery of metals from the recently-installed Waelz kilns was lower than anticipated, but 18,900 tons of lead, 20,680 tons of high-purity zinc, 26,243 tons of plus 98.5% zinc, 13,345 tons of sulfuric acid, 7,150 kilograms of cadmium, and 276,560 troy ounces of silver were produced.

NONMETALS

The Chilanga Cement Co. operated quarries and cement kilns 30 kilometers south of Lusaka, and the Ndola Lime Co. Ltd. produced lime and crushed stone for flux and aggregate from quarries east of Ndola.

Amethyst was produced by Northern Minerals Ltd. from several open pit mines in the Zambezi scarp area, 135 kilometers northeast of Livingstone. Amethyst production declined 14% from 37,425 kilograms in 1974 to 32,000 kilograms in 1975. The mineral was recovered from vein swarms cutting schistose rock. The weathered rock was ripped, loaded, and hauled to a central washing plant where it was washed free from clay in trommels, handpicked, and stockpiled or hauled 400 kilometers to Lusaka. It was there wet-cobbed, graded, and sacked for export or sold to a local manufacturer for cutting and polishing. Foreign exchange earnings exceeded $1 million per year and most of the production was shipped to Hong Kong and West Germany.

Feldspar and fluorspar were produced by the Government-operated Mines Development Corp. (Mindeco) from a deposit 20 kilometers northwest of the Kariba Dam. The rock was sorted and hauled to the glass factory near Kipiri Mposhi where quartzite was quarried for the silica.

In March 1975, the Kalulushi brick factory commenced operations 8 kilometers northwest of Kalulushi township, where staff housing was nearing completion. The 130 million-units-per-year plant cost about $23 million and was part of Zambia Clay Industries Ltd.'s plan to provide construction material near expanding industrial centers throughout the country. In April, the 70 million-units-per-year Nega Nega brick factory was started some 60 kilometers southwest of Lusaka. Completion of two additional plants was scheduled for 1978.

MINERAL FUELS

The Indeni Petroleum Refining Co. Ltd. imported 8,858,000 barrels of crude oil via the Tanzam pipeline to the refinery at Ndola, from which most of Zambia's petroleum requirements were supplied. Ammonium nitrate-fuel oil explosives were manufactured at Kafironda near the Kafue River southwest of Mufulira. Heavy fuel oil supplemented coal in metallurgical operations at copperbelt smelters. In 1975, a pipeline was planned to carry diesel fuel to Lubumbashi for Zaire's mining industry. Lack of finance caused postponement of the project.

Maamba Collieries Ltd. produced 898,154 tons of coal from an open pit mine at the foot of the Zambezi scarp, 240 kilometers southwest of Lusaka. The coal was washed in a heavy-media separation plant at the mine, and transported to storage and loading facilities at Batoka. Railway cars transported it to consumers at Chilanga, Lusaka, the copperbelt, and to storage silos along the line of rail.

The Mineral Industry of Other Areas of Africa

By Staff, Bureau of Mines

CONTENTS

BOTSWANA [1]

The mineral industry of Botswana contributed approximately \$72 million[2] to the nation's gross domestic product (GDP) in 1975, compared with \$73 million (at current prices) in 1974. Mine production included nickel-copper matte, valued at \$30.3 million; coal, valued at \$876,000; diamond, valued at \$40.4 million; and semiprecious stones, valued at \$29,000.[3] The rand was devalued 18% in September 1975, making the financing of imports increasingly difficult. Botswana experienced an annual inflation rate of about 15%, owing to heavy dependence on external sources of fuel and other goods. Imported petroleum products were valued at approximately \$3.8 million in 1975.

Botswana became a beneficiary of the U.S. Generalized System of Preferences (GSP) trade act, to be implemented January 1, 1976. With the addition of products from the GSP list, a total of 97.5% of Botswana's exports to the United States was to be duty-free. The main Botswana exports to benefit from GSP will be materials containing over 10% copper, lead, or zinc. On February 28, 1975, Botswana also became a member of the Lomé Convention,

[2] Where necessary, values have been converted from South African rand (R) to U.S. dollars at the rate of R1=US\$1.3663.

[3] Central Statistics Office, Ministry of Finance and Development Planning, Gaborone, Botswana. Statistical Bulletin, v. 1, No. 1, June 1976, p. 7, table 8.

establishing financial and industrial cooperation with the European Economic Community (EEC).

A $16 million loan from the Canadian International Development Authority (CIDA) was granted to finance an aeromagnetic survey of the Kgalagadi District. The survey was expected to reveal the disposition of major sedimentary basins and subsurface rocks and aid in economic evaluation of the area. The African Development Bank (ADB) allotted about $6 million for construction of the 48-kilometer Lobaste to Kanye road, and the International Bank for Reconstruction and Development (IBRD) granted $5.8 million for a tarred road between Molepolole and Gaborone as well as other smaller projects related to infrastructure development. A U.S. organization was to establish a vocational training center Opportunities Industrialization Centre International (OICI), in Gaborone for teaching industrial skills relevant to development needs.

With the increase in gold prices on world markets, there was renewed interest in the gold deposits occurring in the Archean greenstone belts of the Rhodesian Craton in northeastern Botswana. The only production has been from the Tati schist belt where peak gold production reached 600,000 grams in 1938. Output ceased in 1964. Silver was a minor byproduct. There were over 60 abandoned mines southeast of Francistown; some constituted promising prospects. The Bonanza mine was estimated to have indicated reserves of 70,000 tons grading 41.5 grams of gold per ton. The Rainbow and New Zealand mines were estimated to contain 20,000 tons with 10 grams of gold per ton. The Map-Nora mines had reserves indicated at 150,000 tons with 17 grams of gold per ton. Most were quartz veins or reefs except the Golden Eagle mine, where disseminated ore in a structurally disturbed area contained estimated reserves of 10,000 tons grading 10 grams of gold per ton.[4]

The Otse manganese deposit, associated with conglomerates and chert breccias at the base of the Transvaal sequence, was under reinvestigation, but reserves were not yet delineated. Known occurrences also include Kgwakgwe, which was formerly a producing mine situated south of Kanye within rocks of the Transvaal Supergroup. The mineralization was confined to a shale horizon with an upper zone about 2 meters thick composed of metallurgical-grade ore and a lower layer composed of massive accumulation of manganese nodules with a grade in excess of 70% MnO_2. High-grade material has been almost worked out, but over 200,000 tons of metallurgical-grade ore was estimated to remain. The Lobatse and Ramotswa manganese deposits occurred in the Pretoria group, forming a continuation of the small deposits from the South African side of the Botswana border. The size of reserves was unknown but was thought to be small. At Chadibe and Tswapong, the Waterberg succession overlying the Limpopo belt rocks contained a persistent manganiferous sandstone horizon, rarely more than 2 meters thick, but with a total strike length of 45 kilometers. No systematic exploration had been undertaken, but grades ranged from 30% to 60% MnO_2.

By yearend 1975, the Selebi-Pikwe copper-nickel mine operated by Bamangwato Concessions Ltd. (BCL) had started to make progress on the technical and production problems that had beset them in 1974. Production had risen from 1,027 tons of copper-nickel matte in January to 2,403 tons in December 1975. A total of 16,513 tons of copper-nickel matte (39% nickel and 39.3% copper) was produced in 1975, valued at $30.3 million, compared with 6,663 tons in 1974. The year was not without problems, however, as the smelter was closed for 5 weeks in March for overhaul while production continued at a lower rate from two electric furnaces using materials mainly accumulated last year when operations were interrupted. A strike by the 2,700 mine workers also halted production temporarily in August. The strike was a demand for a uniform wage increase rather than the system of merit increases agreed upon between unions, management, and government in 1974. Even so, the mine reportedly came near to breaking even on an operating basis. When allowing for interest on loans totaling $262 million, however, a loss of $47.3 million was recorded. Progress continued to be made in discussions regarding financial restructuring with the principal lenders, including the World Bank, German banks, the South African Indus-

[4] Baldock, J. W., J. V. Hepworth, and B. S. Marengwa. Gold, Base Metals, and Diamonds in Botswana, Econ. Geol., v. 71, No. 1, January–February 1976, pp. 139–156.

trial Development Corp., American Metal Climax, Inc. (Amax), and Anglo-American Corp. A major refinancing program was considered vital for the mine's future. New management was also called in at yearend, and continuing research by BCL was being directed to solution of problems in the concentrator circuit and the final treatment of the concentrates prior to smelting.

Pikwe had 22.1 million tons proved reserves (including open pit reserves to 140 meters depth, 4.0 million tons with 0.84% nickel and 0.83% copper) with an average grade 1.45% nickel and 1.14% copper and 9 million tons probable reserves containing an average 1.13% nickel and 1.09% copper. Selebi had 10 million tons proved reserves containing 0.70% nickel and 1.56% copper with 2.6 million tons probable reserves of 0.88% nickel and 1.28% copper. Selebi North had 1.9 million tons probable reserves with 0.86% nickel and 0.97 copper.[5] The two major ore bodies are genetically related to the main host amphibolite in a succession of strongly refolded paragneisses, anorthositic gneisses, and amphibolites in the Limpopo mobile belt. Other similar mineral occurrences were known at Dikoloti and Lentswe, but their economic potential had not yet been determined.

Nickel-copper mineralization in the Tati schist belt comprised two medium-sized ore bodies near Francistown and a small satellite occurrence. One of these, the Phoenix deposit, is composed of massive veinlike bodies impersistently developed within shear zones. Disseminated sulfides also occur in the associated amphibolites and some of the migmatites, but are of little economic importance. Two sets of larger, steeply plunging ore shoots occur at the center of the Phoenix deposit, containing nickeliferous pyrrhotite, pentlandite, chalcopyrite, and minor pyrite. The nickel-to-copper ratio is higher in the Phoenix deposit than in other deposits in Botswana. Reserves were estimated to be 4.5 million tons grading 2.1% nickel and 0.8% copper. Located near the Phoenix is the Selkirk deposit, which consists of a massive sulfide core concentrated in the nose and along the axis of a syncline and surrounded by disseminated ore in the layered metaoctolite host. The massive ore pinches out at depth, but the disseminated ore persists down dip and was presumed to be subeconomic. Reserves of 3 million tons with about 0.9% nickel and 0.8% copper were estimated. Tekwane is a small nickel-copper deposit near and similar to Selkirk. Indicated reserves were 600,000 tons averaging 1.2% nickel and 0.6% copper.

The Morupule colliery, established mainly to serve the Selebi-Pikwe power stations and smelter, was starting to supply the Gaborone power station and the Botswana Meat Commission in Lobatse as steps to convert to coal were being taken. The importance of this shift to self-sufficiency was heightened by increasing prices for imported coal (from Rhodesia) and by escalating energy costs caused by the increase in price of imported diesel fuel. Conversion to Botswana coal was well advanced at the Gaborone power station. Coal production for 1975 was 71,248 tons, steadily increasing throughout the year from 1,000 tons produced in February to 11,900 tons produced in December. The production was valued at $875,798.[6]

Plans for further development of Botswana's diamond resources were agreed upon in 1975 between the Government and De Beers Consolidated Mines, the two shareholders in De Beers Botswana Mining Co. (Pty.) Ltd. (Debswana). Under terms of that agreement the Government acquired equal representation on Debswana's board and increased the Government's share from 15% to 50%. A new royalty and profits tax system was also agreed upon in which the taxation level may vary depending on the profitability. The 10% profits tax was scrapped, but the normal income tax and withholding taxes still applied. As a partner in the industry, the Government received between 65% and 70% of the profits through royalties, taxes, and dividends. Debswana was planning to double the production at the Orapa mine to 4.5 million carats per year in 1979. The Letlhakane mine (Dk ½ pipes) was also to start production by early 1977 at a rate of 300,000 carats per year, rising to 400,000 carats per year by 1980. Gravels surrounding the pipes at Letlhakane were to be mined in the first development stage at a capital cost of about $16.4 million. The concentrated and screened gravels were to be sent to

[5] Baldock, J. W., J. V. Hepworth, and B. S. Marengwa. Gold, Base Metals and Diamonds in Botswana. Econ. Geol., v. 71, No. 1, January–February 1976, pp. 139–156.

[6] Ministry of Finance and Development Planning, Gaborone, Botswana. Statistical Bulletin. V. 1, No. 1, June 1976, p. 8.

Orapa for final recovery. The second development stage would involve establishing a crushing plant for the kimberlite and would cost another $13.7 million, raising the production to 400,000 carats per year.

Production at the Orapa mine fell by 300,000 carats to 2.4 million carats for 1975. Although revenues were higher per carat than expected, higher operating costs resulted in an overall drop in profits. The main focus of De Beer's prospecting in 1975 was a kimberlite labeled 2125 B/K9 where stripping of overburden continued. Heavy rains hindered progress. Core drilling, sample pitting, and ground geophysical traversing continued around several other kimberlites to the west of Orapa. An airborne magnetic survey was carried out to the west of Mopipi at yearend. The discovery of a new kimberlite field was reported in the Jwaneng area, located 90 kilometers northwest of Kanye.

Diamonds were sorted and valued in London before 1974. Since then, preliminary sorting has been carried out in Gaborone by the Botswana Diamond Valuing Co., a joint venture between the Botswana Development Corp. (55%) and Debswana (45%). The valuation of Debswana's production must be confirmed by a government valuation and the production is then bought by the Diamond Corp., which is a part of the Central Selling Organization (CSO) for sale to the world's cutters and dealers.

Gulf Resources and Chemical Corp. was actively considering investment in the Sua Pan soda ash project as new markets were being identified for Botswana soda ash. The Overseas Private Investment Corp. (OPIC) of the United States was to assist with the program. By November 1975, Gulf had decided to make application for a prospecting license for exclusive rights to develop the project and hoped to negotiate a mining concession before commencing investment in a pilot plant. The pilot plant construction was expected to cost about $3 million and take 2 years to complete. Gulf was hoping to attract a consortium of investors including South African, U.S., and Australian interests. The project was to have at least a 500,000-ton-per-year capacity.

[e] Estimated. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the countries listed individually in this table, Equatorial Guinea, the French Territory of the Afars and Issas, The Gambia, Guinea-Bissau, and Upper Volta, all covered textually in this chapter, presumably produce modest quantities of crude construction materials such as clays, stone, sand, gravel, and may produce minor amounts of other mineral commodities (most notably gypsum, lime, and salt), but output is not reported quantitatively and available information is inadequate to permit formulation of reliable estimates of output levels.

[2] In addition to the commodities listed, modest quantities of unlisted varieties of crude construction materials (including clays, stone, sand, and gravel) presumably were produced, but output is not reported quantitatively, and available information is inadequate to permit formulation of reliable estimates of output levels.

[3] Limited quantities of tungsten minerals, columbite-tantalite, or other pegmatite minerals may also be produced, but output is not recorded.

[4] Includes production of the Province of Eritrea.

[5] In addition, Ethiopia excluding Eritrea produces clay for the manufacture of bricks. Clay output for this purpose is unreported, but brick production was as follows (number of bricks): 1973—1,846,652; 1974—575,326; 1975—2,101,123.

[6] Production of the Province of Eritrea only; additional quantities may be produced in other areas of Ethiopia.

[7] Reported as marble, without the modifying term cipoline.

[8] Less than 1/2 unit.

[9] In addition to the commodities listed, corundum and kyanite may also be produced, but output is not recorded.

[10] Products marketed under the trade names "baylifos" and "phosphal".

[11] All figures reported are sales; actual production not reported.

BURUNDI [7]

The general economy of Burundi, particularly the mineral industry, registered one of its lowest recorded levels of activity in 1975, owing to the world economic recession, trade deficit, and poor agricultural yield. Mineral production was limited to a small tonnage of bastnäsite and cassiterite concentrates. Statistical data on mineral production were not available. Sobumines, in which the Government held a 49% interest, produced 82 tons of bastnäsite at Karonge mine and an undisclosed amount of cassiterite concentrates in Muyinga Province. The United Nations Development Program (UNDP) survey team continued exploration work on the nickel deposits at Musongate and Nyabikere. The team also evaluated other nickel occurrences along a 30-kilometer mineralized zone between the town of Rutana and Mahana, in the southeastern section of Burundi. A proposed feasibility study on the exploitation of nickel deposits which was to be undertaken by the UNDP did not materialize by yearend 1975; however, a loan from the World Bank to the Burundi Government was earmarked to finance the feasibility study and to improve the Government planning process. Owing to difficulties in UNDP funding, it was anticipated that the Government would seek other financing from abroad to complete the economic feasibility study. Apparently the preliminary drilling had delineated a large tonnage of 1.5% nickel content ore, which could become a major exchange earner if exploited.

A loan of about 4.5 million obtained from the ADB was to be used for building a paved road from Bujumbbura south along Lake Tanganyika, with an extension to Nyanza Lake and to the southwestern frontier of the country. Another roadbuilding program, suggested by a group of West German engineers, was to run from Citega, south to the Mosso Valley region. This project was to be financed by the Government of Burundi. Louis Bergar Co., a U.S. firm that was doing feasibility studies on some specific highways in Burundi under a World Bank funded contract, was designated to prepare a national survey of the Burundi road transport system.

Preliminary work was planned for the future exploitation of Burundi's extensive peat reserves in the vicinity of Musongati. Small quantities of sand, gravel, and crushed stone were produced primarily for local consumption.

Finally, a UNDP survey team based in Bukodba, Tanzania, completed its study for regional development of the Kagera River Basin, which involves Burundi, Rwanda, Uganda, and Tanzania. The Burundi Government was particularly interested in this project because of the possibility of erecting a hydroelectric powerplant at the Kagera River. Such a plant would facilitate development of known nickel deposits in the country.

CAMEROON [8]

The mineral industry has traditionally been a minor factor in the economy of the Federal Republic of Cameroon, which in fiscal year 1975 balanced its budget at approximately $380 million.[9] Aluminum and cement were the foremost mineral industries and accounted for about 5% of total exports. Small amounts of limestone, gold, marble, and cassiterite were also produced. The Government continued to actively support prospecting for mineral resources, with the primary focus on offshore exploration for crude oil.

Infrastructure development was also emphasized as the Government sought funds for the provision of adequate electric power and transportation facilities. About 80% of Cameroon's energy supply was in the form of hydropower obtained from the Edea dam complex in the western part of the country. In mid-1975, the commissioning of the Bamendjin dam on the Noun River increased the capacity of the Edea plant from 200 to 240 megawatts. The Lagdo dam, which was to be constructed on the Bénoué River near Garoua with financial and tech-

[7] Prepared by E. Shekarchi, supervisory physical scientist, International Data and Analysis.

[9] Where necessary, values have been converted from Communaute Financiere African francs (CFA) to U.S. dollars at the rate of CFAF224 = US$1.00.

nical assistance from the People's Republic of China, was to provide an additional 70 megawatts of hydropower. In 1975, Cameroon also received $230 million in aid, primarily from the Saudi Arabian Development Fund, the Kuwait Development Bank, and other Arab donors, for the Song Loulou dam project on the Sanaga River, which would have a capacity of 288 megawatts.

Cameroon's primary export center, the port of Douala, was to undergo an expansion program including extensive dredging of the port, the expansion and addition of docks, and the construction of new repair facilities. The total cost was estimated at $110 million, to be provided by an international consoritum of donors, with the major share coming from the Canadian Agency for International Development, the IBRD and the ADB. The Transcameroon Railway, which established a continuous link of about 1,250 kilometers between Douala and Ngaoundere, was completed during the year. Studies were in progress for the construction of an additional railroad linkage from Belaba to the Central African Republic and for the rehabilitation of the original rail section between Douala and Yaounde.

The production of aluminum by the Compagnie Camerounaise de l'Aluminium Péchiney-Ugine (ALUCAM) increased 11% from 46,842 tons in 1974 to 51,913 tons in 1975. The ALUCAM smelter located at Edea processed approximately 250,000 tons of alumina imported from Guinea. Output has remained below the rated capacity of 60,000 tons per year owing to problems in the supply of electricity from the Edea complex. Domestic consumption of aluminum ingot was 45% of production, with the remainder of the output exported, primarily to France.

The Société d'Études des Bauxites du Cameroun (SEBACAM) completed its feasibility study on development of bauxite deposits in the Minim Martap District southwest of Ngaoundere. Reserves were estimated at 2 billion tons averaging 43% aluminum oxide and 3.4% silica. Shareholders in SEBACAM, created in 1969 for the exploitation of the reserves, included the Cameroon Government (40%), the Bureau de Recherches Géologiques et Minières (BRGM) (25%), Péchiney Ugine Kuhlmann (PUK) (25%), Kaiser Aluminum and Chemical Corp. (5%), and Vereinigte Aluminium Werke AG (VAW) (5%). During the year, SEBACAM actively sought financial partners for the development of the bauxite deposits, which would necessitate the completion of numerous infrastructure projects. Although the deposits were situated approximately 800 kilometers via the Transcameroon Railway from the port of Douala, the railroad was not considered suitable for the transport of bauxite. Other problems included insuring an adequate supply of electric power and developing deepwater port facilities for large-scale exports.

The two cement plants operated by Cimenteries du Cameroon (CIMENCAM) had a combined output of 238,071 tons in 1975, an increase of 18% over the 1974 level of 201,399 tons. CIMENCAM completed expansion programs at both plants during the year and announced plans to further increase production capacity. Annual capacity at the Bonabéri clinker-grinding plant near Douala, which served southern Cameroon, was increased from 150,000 tons to 300,000 tons. The Fijuil cement plant near Garoua, which served northern Cameroon and Chad, underwent an expansion from 26,000 to 50,000 tons per year. Raw material for the Fijuil plant was obtained from nearby limestone deposits, where production decreased from about 49,193 tons in 1974 to 46,951 tons in 1975. Limestone reserves at Fijuil were estimated at 600,000 tons. The Bonabéri plant was supplied primarily by imports, and prospecting for limestone was ongoing in the Nkonpina area north of Douala and Ngol area south of Nkongsamba. Extensive deposits of pozzolan in the southwest coastal area were also being mined for use in the manufacture of hydraulic cement at Bonabéri.

Cameroon also had limited production of gold, marble, and cassiterite. Gold produced from local alluvial workings was reported at 96 troy ounces in 1975. Marble production was reported at 1,047 tons, a slight decrease from the 1974 level. Marble reserves at the Bidzar deposits in the northern part of the country were estimated at 2.5 million tons. Cassiterite production from the deposits at Mayo Darlé near the Nigerian border was 35 tons of concentrates averaging 54% tin.

In 1975, the Cameroon Government signed an agreement with an Italian firm, Sacomi Impianti S.A., for the construction of a ceramics factory. The estimated cost of the project, which was to be under the supervision of the Céramique Industrielle du Cameroun (CERICAM), was $8 million. Output capacity was set at 750 square meters of tiles and 300 square meters of mosaics per day. Raw materials were to be obtained from deposits of clay and kaolin at Bamenda and Bamboutos in the northwest.

Offshore petroleum exploration remained the focal point of the Government's efforts to develop the country's mineral resources. Preliminary results were promising and efforts continued during 1975 to delineate the quantity of reserves. Oil was discovered by Essence et Lubrificant de France de Recherches et d'Exploitation des Pétroles au Cameroun (Elf-SEREPCA) in the area of Rio del Rey, but disagreement with Nigeria concerning the extension of territorial waters hindered further evaluation of the deposits. Drilling by Elf-SEREPCA in its second concession area in the Douala Basin near the seaport of Victoria indicated additional crude deposits. Oceanic Exploration Co. of West Africa intensified its drilling activity in its 7,500-square-kilometer tract off the mouth of the Sanaga River, while the Norwegian Oil Co. (NORMINOIL) indicated that it would begin seismic surveys in its Sanaga North concession area. Other exploration companies that held offshore prospecting permits but that reported no drilling activity in 1975 were Shell Camerounaise de Recherches et d'Exploitation (Shell-CAMEREX), Mobil Oil Co., and Gulf Oil Co. of Cameroon.

The construction of a petroleum refinery at Victoria, which was the subject of a protocol agreement in 1973 between the Cameroon Government and the Compagnie Française des Pétroles (CFP), was deferred until more definite results were obtained from ongoing exploration. Pending the development of domestic crude reserves, Cameroon would continue to import refined petroleum products. Domestic consumption was estimated at 2.3 million barrels of petroleum products per year, over half of which was supplied by Gabon.

Exploration for several other minerals was also scheduled in Cameroon in 1975. Utah Development Co. signed a 2-year contract providing for further evaluation of radioactive mineralization cited in the northern Poli District. BRGM planned a more comprehensive study of copper mineralization in the area between Bibemi and Maroua in the northernmost part of the country. In addition, the UNDP in conjunction with the Canadian Agency for International Development outlined the next steps in their ongoing mineral exploration program in Cameroon. The first phase, which cost approximately $450,000, included aeromagnetic and photogeologic studies completed in 1975. In the second phase, certain promising areas were to undergo more intensive study. These included copper, manganese, and magnetite deposits in the Nza region, hematite deposits in the northwestern Ndop area and at Kribi, manganese in the south, diamond at Batouri and Bétaré-Oya, sand deposits on Manoka Island, and corundum and sapphire in the Mamfe area.

CAPE VERDE ISLANDS [10]

The Republic of Cape Verde, an archipelago of 10 volcanic islands located about 500 kilometers from the African coast west of Dakar, gained independence from Portugal in July 1975. No mineral industry activity was reported, although unexploited deposits of phosphates and gypsum were known. Neveril Enterprises began construction on a 6-million-ton-per-year oil refinery and chemical plant in 1975 on San Vicente Island. No oil exploration activity was reported during the year.

In 1975, Portugal provided over $18 million in aid, much of it paid to farmers for work on antidrought measures. The Cape Verde Islands Government planned the development of small industries to aid economic stability.

[10] Prepared by David E. Morse, physical scientist, International Data and Analysis.

CENTRAL AFRICAN REPUBLIC [11]

Diamond and gold were the principal mineral products of Central African Republic, and exports of these commodities continued to be a major and growing source of the country's foreign exchange. Diamond production decreased 1% in 1975 compared with 1974 output, although the total value of both gem and industrial diamonds increased. As a byproduct of diamond mining, an estimated 530 troy ounces of gold was produced in 1975.

A document was published by the Ministry of Plans, International Cooperation and Statistics, which outlined development priorities of the Central African Republic. The document was prepared for presentation to the members of the European Development Fund (EDF), who visited the Central African Republic in March 1975. According to this document, the primary objectives of the Central African Republic Government were the following: To improve internal and external transport systems with emphasis on the nation's access to the sea, rivers, air, and neighboring railroads; to develop the nation's agricultural and mineral resources; and to assure its citizens a higher standard of living. In the implementation of various proposals, the Central African Republic Government would rely heavily on EDF, and, as in the past, expect EDF not only to finance but also take on technical responsibilities.

COMMODITY REVIEW

Diamond.—At yearend 1975, the future of Société Centrafricaine d'Exploitation Diamantifere (SCED) remained undecided. SCED was formed in 1972 for the expansion of diamond mining in the country with ownership divided between the Central African Republic Government (20%), Diamond Distributors, Inc. (20%), and Cominco Ltd. (60%). Cominco was to invest $8 million in the exploration for and development of diamond mines at N'Zaku and Becherati. Because no true kimberlite had been discovered in the Central African Republic and diamond production was primarily from the alluvial deposits and river basins, large-scale mining operations were uneconomical. Many thousands of small mine operators sold diamonds to collectors who were in a position to export them. The quality of the diamonds in the Central African Republic was very high; 60% to 70% were gem stones and the remainder were industrial.

Petroleum.—Shell and the Continental Oil Co. (CONOCO) of the United States conducted a series of seismological oil tests in northeastern Central African Republic in 1975. Preliminary results were encouraging; however, no test wells were drilled by yearend 1975.

Uranium.—In June 1975, the Central African Republic Government and the French Atomic Energy Commission joined Swiss Aluminium Ltd. (Alusuisse) in forming a local company, Société d'Uranium Centrafricaine, in order to exploit the uranium deposits at Bakouma. The Bakouma deposits were estimated to contain 20,000 tons of uranium reserves. Owing to the high phosphorus content, Alusuisse started a feasibility study on methods for separation and beneficiation of the ore. Also, Alusuisse concluded that for the first stage of the mining operation, owing to transportation difficulties, most of the machinery and personnel would have to be airlifted. This would increase mining costs and lengthen the time before commercial production could begin.

Other.—A magnetic anomaly, the first of its kind to be discovered from a satellite, was found by the U.S. Geological Survey to exist in the Central African Republic. At yearend 1975, the nature of the anomaly, with its associated minerals, was to be studied by UNDP scientists and the members of the Office de la Recherche Scientifique et Technique Outermer of France.

CHAD [12]

The mineral industry of Chad is very small and the only mineral exported was natron (hydrous sodium carbonate, equivalent to trona). It was mined in blocks weighing up to 35 kilograms from saliferous basins northwest of Bol, near Lake

[11] Prepared by E. Shekarchi.
[12] Prepared by David E. Morse.

Chad. Its uses included animal and human consumption, preservation of meat and hide, and soap manufacture. Based on a reported nearly 2,500 tons for the first half of the year, the 1975 annual production was estimated at 5,000 tons. This 6 month's production was greater than the total produced in 1974, indicating depletion of stockpiles. Clays (used at the N'Djamena brickyard), salt, sand, and gravel for local consumption were the only other minerals mined in 1975.

The Continental Oil Co. of Chad (CONOCO—Tchad), had been exploring for oil in Chad since 1969. CONOCO—Tchad's preliminary discoveries of a small show in the Kanem prefecture northeast of Lake Chad had been sufficiently encouraging so that the head of state, General Malloum, forecast the construction of a small petroleum refinery. This would have some effect on Chad's trade deficit since all the petroleum products used in the country have been imported. CONOCO—Tchad continued petroleum exploration near Doba in the south and in the Kanem area.

Chad's transportation system was inadequate for the needs of economic development. The road system had about 290 kilometers of paved roads that were in constant need of repair from the ravages of heavy seasonal rains and overuse by heavy trucks. Chad had no rail transport, and surface contact with the outside world was generally through Cameroon and Nigeria. Imports generally moved by air to N'Djamena, which has a good airport.

In April 1975, the military assumed control of the Government. There was no indication that there would be changes in the Government's position towards mining and petroleum ventures.

Production data for Chad is shown in table 1.

CONGO [13]

The mineral sector continued to be a major contributor to the economy of the Congo in 1975, when petroleum surpassed lumber as the country's foremost export commodity. A decline in petroleum production and the accompanying reduction in oil receipts, however, necessitated a revision in the country's budget from $313 million[14] to $260 million. At yearend, the French Government authorized payment to the Congolese Government by Essence et Lubrificants de France–Entreprise de Recherches et d'Activités Pétrolières (Elf-ERAP), the major oil producer in the Congo, for a shortfall of about 800,000 tons of projected crude oil production. The Congo still suffered a severe balance of payments deficit, which caused a reduction in the investment projects to be included in the country's 3-year development plan (1975–77). In 1975, the Congo also produced cement, potash, gold, and copper, lead, and zinc concentrates for export, and natural gas for local consumption.

Petroleum production in the Congo declined in 1975 owing to falling output in the two older fields, Pointe Indienne and Emeraude, and delays in bringing the new Loango Field onstream. Oil was produced by Elf-CONGO, a subsidiary of France's State-owned Elf-ERAP, and by Azienda Generale Italiani Petroli S.p.A. (AGIP), a subsidiary of Italy's Ente Nazionale Idrocarburi (ENI), which held 35% interests in each other's concessions. The Congolese Government, which held a 20% interest in the operations of both companies through the national company Hydro-Congo, commenced negotiations to increase its participation during the year.

Crude output at Pointe Indienne, the small onshore field discovered in 1957, had been declining since 1965, with production in 1975 totaling only 220 barrels per day. The Emeraude Field, situated 19 kilometers off the southern coast, evidenced a 31% decline as crude production fell from 49,000 barrels per day in 1974 to 34,000 barrels per day in 1975. Various production difficulties due to low reservoir pressures and the complex geology of the Congo's offshore oil basin limited the feasibility of reaching the early production target of 100,000 barrels per day. Although the field was estimated to have 7,000 million barrels of viscous 22° API gravity crude, it was projected that only 7% would be recovered owing to inherent technical problems.

The Loango Field, located about 48 kilometers offshore northwest of Emeraude, was due to begin production in late 1976.

[13] Prepared by Candice Stevens.
[14] Where necessary, values have been converted at the rate of CFAF224=US$1.00.

Because of the prohibitive costs of driving piles into the seabed at Loango, special drilling and production platforms to be anchored by their own deadweight were commissioned from Tecnomare of Italy. Although reserves at Loango were estimated at less than those at Emeraude, it was hoped that recovery would be facilitated by the early use of water injection and other factors. Targeted output was between 40,000 and 50,000 barrels per day. A 97-kilometer, 18-inch-diameter petroleum pipeline was to link the Loango Field with the Djeno terminal on the coast, which also handled Emeraude crude shipped by subsea pipeline.

The Congo's first petroleum refinery under construction at Pointe Noire was scheduled for startup in 1976. Construction work was by the Belgian consortium Sybetra. The refinery, which was to have a capacity of 1 million tons per year, would produce primarily fuel oil from the Congo's high viscosity crude. Because the Congo's consumption of petroleum products was less than 50,000 tons per year, the major share of production was to be exported. At yearend, the Congo was reported to be entering negotiations with Spain and Iran regarding the construction of a second refinery.

The production of natural gas at the Pointe Indienne Field began in 1965. Marketed production, approximately 590 million cubic feet, was sold to the Compagnie des Potasses du Congo (CPC) for use in the Hollé potash plant. Reserves of natural gas at the Pointe Indienne Field were estimated at 14 billion cubic feet.

Both Elf-CONGO and AGIP continued exploration in their concession areas in 1975. Elf-CONGO conducted seismic surveys in its offshore Pointe Noire Grands Fonds and Haute Mer permit areas and its onshore Loeme permit area. AGIP also did seismic work in its offshore Mandingo concession area. Four unsuccessful wildcats were drilled by AGIP and ELF. In 1975, a seismic survey option was also granted to a consortium consisting of Getty Oil Co., AGIP, Phillips Petroleum Co., and Hispanoil on the deepwater block adjacent to the Elf-CONGO Haute Mer concession area.

Potash, mined at the Hollé mine located 45 kilometers northeast of Pointe Noire, was the Congo's other important mineral product. Although it was scheduled to produce 800,000 tons of potassium chloride per year, the mine never yielded more than 475,000 tons (in 1974), and production fell to approximately 460,000 tons in 1975 (280,000 tons K_2O). Various French interests, including BRGM, Entreprise Minière et Chimique, and Elf-ERAP, owned over 75% of the CPC but were negotiating a withdrawal of shares at yearend 1975. Output was marketed by Société Commerciale des Potasses et de l'Azote, the sales branch of Entreprise Minière et Chimique, in 14 countries including the Republic of South Africa and Brazil. With financial backing from the French Aid and Cooperation Fund, studies continued regarding the exploitation of large deposits of carnallite ore upon the depletion of the sylvinite reserves at the Hollé mine.

Other mining activity was small-scale, with local gold panning at an annual rate of 500 troy ounces. In 1974, the Société Nationale des Mines de Sounda-Kakamoéka (SONAMIS) was established as a joint venture between the U.S.S.R. and the Congo to exploit gold deposits in the Kouilou area north of Pointe Noire. Small amounts of copper, lead, and zinc concentrates continued to be produced by Société Minière de M'Passa. Base metal production was to be greatly augmented by the mining of copper, lead, and zinc ores by Société Nationale des Mines de M'Fouati (SONAMIF) in the Yanga-Koubenza and Djenguilé regions.

Mineral exploration was active in 1975 and several new mineral occurrences were reported during the year. A Bulgarian geological mission reportedly discovered a copper, zinc, and lead deposit at Minouli, 241 kilometers west of Brazzaville. Bulgaria and the Congo were also planning the formation of a joint company for the exploitation of phosphate reserves at Tchicoula near the Cabinda border. Iron ore reserves discovered in the southwest Mount Lekoumou area were to undergo further study by Romanian geologists.

Production of cement at the Loutété plant was approximately 50,000 tons in 1975. Output was exported primarily to countries in central Africa. As part of the current 3-year plan, the capacity of the plant was to be increased from 100,000 to 300,000 tons per year.

The 3-year plan also included major infrastructure projects to alleviate serious electric power and transportation inadequacies. Electric power generation, which totaled 100 million kilowatt-hours in 1975, was to undergo a 50% increase over a 3-year period. An agreement was signed for the construction of a dam at M'Pama on the Koukouya plateau in the eastern plateau region by the Swiss firm Universal Engineering Co. The construction of a second dam at Bouenza in the south was to be financed by China. A large diesel unit was planned for Pointe Noire. The Congo Ocean Railroad (CFCO), whose 5-million-ton-per-year capacity was overtaxed by large shipments from Gabon, Cameroon, Chad, and the Central African Republic, was being modernized and realigned. In 1975, the first 87-kilometer section from Boulingui to Loubomo (formerly Dolisie) was completed. The project, which was to be finished in 1977, was financed by the IBRD, the EDF, the French Aid and Cooperation Fund, the ADB, and the Arab Bank for Economic Development in Africa.

DAHOMEY [15]

In 1975, the production of mineral commodities in Dahomey was limited to small quantities of salt, gravel, and cement. The mineral industry played a minor role in the nation's economy, and several development projects were held in abeyance during internal political and economic reorganization. At yearend, however, the Bureau Centrale des Projects was formed to secure financing for and supervise the execution of a number of proposed projects, which included the construction of a petroleum refinery and a cement plant and the exploitation of offshore oil deposits.

In addition, Dahomey scheduled several infrastructure projects, the most important of which was the development of the port city of Cotonou. Plans called for the repair of the bridge linking the cities of Cotonou and Porto Novo and the doubling of the port's cargo handling capacity. Dahomey received loans of $4.4 million [16] from the ADB and $10.9 million from the U.S. Agency for International Development (AID) to finance the project.

During the year, the Government continued its negotiations regarding terms of indemnification with the seven companies affected by the nationalization of petroleum product distribution in 1974. The firms involved were Texaco Inc., Mobil Oil Corp., Royal Dutch/Shell Group, British Petroleum Co. Ltd., AGIP, TOTAL Compagnie Française de Distribution, and the Dépôt d'Entreposage des Produits Petroliers, a holding company formed by these six interests for petroleum storage. At yearend, the only settlement reached was with Royal Dutch/Shell, which also renegotiated its offshore concession agreement signed in 1971. Two new amendments to the agreement extended the company's exploration rights and granted additional offshore acreage that had previously been held by Union Oil Co. (United States). Royal Dutch/Shell announced plans to commence development drilling in the small oilfield discovered in 1971 by Union Oil Co., the exploration rights of which were terminated in 1974 by the Dahomey Government.

In 1975, Dahomey imported approximately 2 million barrels of petroleum products from Algeria, Niger, the Ivory Coast, and Venezuela. In midyear, the Société Nationale de Commercialization des Produits Petróliers (SONACOP) lowered prices of petroleum products by an average 10% as a social welfare redistribution measure. The construction of a petroleum refinery remained in the planning stages, as efforts to secure financing were continued by Société Nationale de Raffinage (SONARAF), a joint venture between the Dahomey Government and the United Kingdom firms Litwin Ltd. and Inha International Ltd.

In June 1975, the Dahomey Government acquired a 50% interest in Société des Ciments du Dahomey, which operated the cement plant at Cotonou. Annual capacity of the plant, which manufactured cement from imported clinker, was reported at 200,000 tons, although production has remained at approximately 90,000 tons per year. The Société des Ciments d'Onigbolo, a collaboration of the Dahomey and Nigerian Governments, was formed in July 1975.

[15] Prepared by Candice Stevens.
[16] Where necessary, values have been converted from CFAF to U.S. dollars at the rate of US$1.00=CFAF224.

Discussions continued regarding the construction of a second cement factory to exploit the limestone deposits at Onigbolo and Masse, situated in the southeast Pobe area. Reserves at the two deposits were reported at 36 million tons.

Salt production decreased from 2,500 tons in 1974 to 150 tons in 1975. The decline in output was caused by the inundation of production facilities which manufactured salt from seawater at Cotonou.

The output of gravel from deposits in the southwestern Mono District remained at about 15,000 tons.

A ceramics factory operated by the Société Nationale de Céramique (SONAC) opened at Cotonou during the year. Construction of the plant, which was estimated to cost $2.1 million, was financed primarily by Société de Céramique Industrielle, owned 80% by the Government and 20% by the German firm AGROB AG. The plant was to produce 630 tons of ceramic and earthenware tiles, sanitary fixtures, and dishes per year.

The UNDP continued its mineral exploration program in Dahomey, which included airborne geophysical surveys, an underground water survey, the training of nationals through prospecting in selected areas, the establishment of a geochemical lab, and the drafting of a mining code for the Government's Geological and Mining Service. In the past 4 years, the UNDP survey has located phosphate, gypsum, gold, lignite, and diamond mineralization in various parts of the country, although none has been considered of commercial significance. The discovery of marble deposits estimated at 5 million tons in the Dadjo region prompted consideration of the construction of a marble works in the area. The most interesting deposits cited were the oolitic iron ore occurrences in the northern Kandi District. The deposit at Loumbou-Loumbou was estimated to contain 250 million tons of hematite ore averaging 50% iron, and the nearby Madékali deposit was estimated to contain 40 million tons of ore averaging 58% iron. Cost factors and lack of infrastructure prohibited the development of the deposit.

EQUATORIAL GUINEA [17]

The Republic of Equatorial Guinea included the Isla de Macias Nguema Biyogo (changed from Fernando Po in July 1973), the mainland province of Rio Muni including several near-coast islands to the southwest, and the small island of Annobón in the Atlantic Ocean some 650 kilometers southwest of the capital city, Malabo (changed from Santa Isabel in 1973). Stone, gravel, and sand were probably produced for local consumption in 1975, but the country's economy continued to depend on agriculture. No changes in the oil concessions were recorded and no exploratory drilling or surveys have been reported.

ETHIOPIA [18]

The value of mineral output, excluding refinery petroleum products, increased 16% in 1975 over that of 1974 to approximately $14.9 million.[19] This contributed less than 1% to the estimated 1975 gross national product (GNP) of $2.9 billion. Minerals produced included cement ($6 million), gold ($3.5 million), limestone ($282,000), platinum ($25,630), marine salt ($4.3 million), marble ($610,000), and small amounts of kaolin, brick clay, lignite, sand, silica sand, stone, and talc.

The Ethiopian economy maintained a real economic growth of approximately 2%, in spite of the political, social, and economic changes that had started in 1974. In addition to nationalization of most major industries and all financial institutions, the Ethiopian Provisional Military Government (EPMG) also nationalized land and instituted new labor laws. Even so, the private sector continued to play an important role in the economy. Petroleum exploration companies were not nationalized, and foreign investment for that industry was

[17] Prepared by Miller W. Ellis, physical scientist, International Data and Analysis.
[18] Prepared by Janice L. W. Jolly.
[19] Where necessary, values have been converted from Ethiopian birr (B) to U.S. dollars at the rate of B2.0855=US$1.00.

being encouraged. The Government acquired a 51% share in the four petroleum distributing companies.

The new Government policy for the mining industry, effective on February 7, 1975, was contained in Proclamation No. 39 of 1975, which may be summarized as follows:

1. Prospecting, exploration for, and exploitation of the following minerals have been reserved exclusively for the Government: Gold, platinum, silver, and other precious minerals; uranium, radium, and other radioactive minerals; large-scale salt mining operations; and geothermal power.
2. Exploration and exploitation of the following may be jointly undertaken with foreign capital: Petroleum, natural gas, carbon, and other hydrocarbons; iron, copper, nickel, and other metallic minerals; potash, phosphate, sulfur, and other nonmetallic minerals.
3. Exploration and exploitation of the following may be in the private sector: Marble, limestone and other quarry materials; small-scale salt operations; industrial clays and minerals used for bricks, chinaware, etc.; mineral waters and thermal waters.

The current mining laws were to remain in effect including Mining Proclamation No. 282 of 1971 and Mining Regulations (Legal Notice No. 396 of 1971). Under these laws, prospecting was legal under either a nonexclusive prospecting permit or an exploration license with exclusive rights within a defined area, initially for 2 years but renewable to 8 years. Mineral production was authorized under a mining lease granted for terms of 5 to 30 years. An annual quarry license was required for stone, sand, gravel, and clay. Extensive exploration program conditions, such as for petroleum, were negotiated under special agreement with the Government.

A transaction tax of 5%, a sales (turnover) tax of 2%, and a profits tax of 20% on taxable income was required for ordinary businesses. The Mining Proclamation provided for an additional tax on petroleum and natural gas so that the total of royalty, business income tax, and other eligible taxes, together with the additional tax would be 51% of the taxable income as defined for income tax calculations. For minerals other than petroleum and natural gas, there was provision for application for a flat rate of income tax of 51% or alternatively, for a profit sharing arrangement in lieu of all royalty and taxes. In addition there were moderate fees and annual rents.

Ethiopia increased the spending budget for economic development from $440 million in 1974–75 to $637.7 million in 1975–76. The proportion of the national budget allotted for development increased from 26% of the 1974 budget to 32.5% in 1975 with amounts spent on infrastructure nearly doubled.[20] Loans in 1975 came from the Federal Republic of Germany $41.5 million for water and electrical supply), the United States ($32 million for highway construction), International Development Association (IDA) ($48 million for highways and communications), and the Arab Loan Fund for Africa ($14.2 million for financing oil imports).

The total value of Ethiopean exports in 1975 was $238.7 million, a decrease of 11% compared with that of 1974. At the same time, the cost of imports increased 14% over 1974 to $309.2 million (c.i.f.). Oil imports accounted for 9% of the total import value for both 1974 and 1975. Refined petroleum products accounted for less than 3% of the total export value for 1975. About 400,000 barrels of refined oil products were exported to Afars and Issas, South Yemen, and Singapore.

The Ethiopian Petroleum Co.'s refinery at Assab processed about 3.7 million barrels of crude oil in 1975, 400,000 barrels less than in 1974. Crude petroleum imports were also down slightly in 1975 but were costing more—about $8.50 per barrel in 1974, compared with about $11.70 per barrel in 1975. Crude oil was imported from Iran and Saudi Arabia. Total petroleum imports for 1975, including refinery products, were valued at an estimated $52.9 million, compared with $47.9 million for 1974. The decline in refinery production was in part caused by insurgency action late in 1975 that shutdown the refinery for several weeks. Destruction of bridges and other interruptions to the petroleum truck convoys making deliveries to Addis Ababa also caused temporary fuel shortages throughout 1975. Gasoline rationing was instituted in June, but no vital industries were severely affected.

[20] The Financial Times (London). Budget Stresses Socialism. No. 26,754, Aug. 28, 1975, p. 5.

Gold production increased slightly over that of 1974 and came from the large alluvial deposits near Adula in southern Ethiopia. Gold was being recovered mostly by traditional handworking methods. Exploration continued on a large placer deposit that may prove to be suitable for large-scale mechanical recovery in western Wollega Province. Preliminary assessment was expected to be completed during 1976. Copper exploration by the Geological Survey continued in Tigre Province where a number of mineralized zones were known. Test drilling was to begin on a deposit in Precambrian metavolcanics. The copper-bearing zone was estimated to be 100 meters wide and to extend over several kilometers along the strike.

Large deposits of potash were known in the Danakil Depression in northwestern Ethiopia and were described in a recent report[21] as still being of economic interest. Mining of these deposits by the Ralph M. Parson Co. of the United States ended in March 1967 when the workings were flooded by an influx of freshwater and Parsons abandoned the project. The main constituent of the evaporite deposits was halite with lesser amounts of anhydrite and potassium salts. Holes drilled during exploration and mining, although exceeding 1,000 meters, did not reach the base of the evaporites. Two areas, the Crescent and Musley ore bodies, were explored in detail. A joint United Nations—Ethiopian Government geothermal survey in 1972 also indicated that the Dallol area had potential for generation of electricity by geothermal means.

Large deposits of diatomite were located near Awash and along the Lakes District and quality testing was in progress. Industrial minerals for local glass and cement companies were also under investigation. Exploration for soda ash, fluorite, borates, and phosphates also continued.

Decisions were made for the Whitestone International-Louisiana Land and Exploration Co. joint venture in oil exploration to continue in 1975, and agreements for a new work program were affirmed with the Government in August. The Whitestone group conducted 1 month of field geology and 8 months of photogeology during 1975. Royal Dutch/Shell did a brief seismic survey on its Red Sea concession. The Tenneco/Texaco/Chevron group withdrew from its concession in October as a result of disagreement over drilling schedules with the Government, unfavorable geologic indications, and uncertain investment future. The Ethiopian Government obtained a U.S. Federal court ruling in Texas against the Baruch Foster Co. for $782,368. The dispute stemmed from Ethiopia's decision in April 1970 to end a petroleum development agreement with the company. The company did not meet the deadline set for drilling a test well.

THE FRENCH TERRITORY OF THE AFARS AND ISSAS[22]

Activity in the mineral sector of the French Territory of the Afars and Issas was limited to foreign trade in 1975. Petroleum products, cement, metals, and semimanufactured metal products were the primary mineral imports and contributed to the total import value of approximately $117 million.[23] The total value of exports in 1975 was estimated at $20 million, as the territory continued to evidence a severe balance of trade deficit.

The territorial budget was scheduled for a 13% increase, from $28.4 million in 1975 to $32.6 million in 1976, with supplemental subsidies to be provided by France. The Territory of the Afars and Issas took significant steps towards independence in 1975.

The mainstay of the territory's economy continued to be transit activities related to the port of Djibouti and the Chemin de Fer Franco-Ethiopian (CFE) railroad. Events in Ethiopia that limited access to the ports of Massawa and Assab greatly enhanced Djibouti's function as an entrepôt port. Of the more than 600,000 tons of cargo transiting the port in 1975, 75% consisted of Ethiopian imports and exports. Activity at Dijibouti was further increased by the reopening of the Suez Canal in June 1975 and plans were made for a general modernization and expansion of port facilities. Another major project was the con-

[22] Prepared by Candice Stevens.

[23] Where necessary, values have been converted from Djibouti francs (DF) to U.S. dollars at the rate of DF175=US$1.00.

struction of a road linking Djibouti and the Ethiopian capital of Addis Ababa, which would provide additional transport capacity to supplement the overtaxed CFE railroad. The 247-kilometer road would facilitate the transport of approximately 240,000 tons of goods annually, and was to be completed in 1976 at a total cost of $15 million.

With French technical and financial assistance, the Geological and Mining Exploration Office continued its survey of the territory's geothermal resources in the area of Lake Asal. Although a borehole completed in 1975 at a depth of 1,554 meters did not not find steam, an earlier borehole revealed usable steam at 1,137 meters. A feasibility study on the construction of a geothermal powerplant based on these resources was planned. The total cost of the survey was estimated at $2.2 million.

THE GAMBIA [24]

Gambia, a country with 520,000 people and a GDP of approximately $80 million,[25] had negligible mineral production in 1975. Small amounts of unrecorded sand, stone, and gravel for local use undoubtedly were produced. The only significant known mineral deposits in Gambia were kaolin, located in the Upper River District, and black ilmenite sands, found near Brufut and Sanyang in the Western District.

UNDP studies initially revealed 5 million tons of ilmenite sands in 1972. Development of this resource was seriously considered, and a letter of intent concerning beneficiation and smelting of ilmenite was signed by Gambia and Iceland in late 1973. The realization of this venture was dependent on the results of feasibility studies conducted by the UNDP during 1974. In 1975, the Gambian Ministry of Economic Planning and Industrial Development engaged Matthew Hall Ortech of the United Kingdom to conduct an economic feasibility study for the exploitation of the black sands. These ilmenite sand deposits remained undeveloped in 1975.

In 1975, Shell conducted about 3 months of seismic surveys onshore and subsequently relinquished its onshore petroleum exploration concession. Shell and Aracca Petroleum Corp. of New York retained offshore petroleum exploration rights in Gambian waters. The Government of Gambia continued to seek aid from Middle East petroleum producing countries to help finance and supply crude oil to a planned petroleum refinery. In 1975 Gambia did not have a petroleum refinery and was totally dependent on imports for petroleum products.

Gambia's road system consisted of about 300 kilometers of asphalt-surfaced roads and nearly 600 kilometers of all-weather gravel roadways. The surfacing of an additional 250 kilometers of roadway and improvement to 330 kilometers of major and secondary roads were underway in 1975.

GUINEA [26]

Bauxite and alumina were the principal mineral products of Guinea, and exports of these commodities continued to be the country's major source of foreign exchange.

Guinea produced an estimated 9 million tons of bauxite in 1975 and became the world's third largest bauxite producing country. Guinea Bauxite Co. (CBG), operator of the Boké project, produced over 5 million tons, and Friguia and Kindia Bauxite Office (OBK) each produced nearly 2 million tons.

CBG, owned by Halco (51%) and the Government of Guinea (49%), shipped high-grade bauxite from its plant and port at Kamsar primarily to members of Halco, a consortium of aluminum producers consisting of Aluminum Co. of America (Alcoa) (27%), Alcan Aluminium Ltd. (27%), Martin Marietta Aluminum, Inc. (20%), PUK (10%), VAW (10%), and Alumetal S.p.A. (6%).

Friguia, owned by Frialco Co. (51%) and the Government of Guinea (49%), mined bauxite for its alumina plant in

[24] Prepared by David E. Morse.

[26] Prepared by Horace F. Kurtz, industry economist, Division of Nonferrous Metals.

Guinea. Frialco was another consortium consisting of Noranda Mines, Ltd., (38.5%), PUK (36.5%), British Aluminium Co., Ltd. (10%), Alusuisse (10%), and VAW (5%). OBK mined bauxite at Débélé in the Kindia region entirely for export to the U.S.S.R.

The Government and Alusuisse joint venture, Société Minière et de Participations Guinée-Alusuisse (SOMIGA), continued to plan for the mining of bauxite deposits at Tougué, estimated to contain 2 billion tons. Reported plans included construction of facilities to produce 8 million tons per year of bauxite and 1.2 million tons per year of alumina. The alumina plant would be constructed with Yugoslav assistance.

The Governments of Guinea, Egypt, Kuwait, Libya, Saudi Arabia, and the United Arab Emirates signed an agreement to form an aluminum company that would exploit bauxite deposits in the Ayékoyé area north of the CBG Boké concession. Reserves were estimated at 500 million tons with an alumina content of 51.6% to 59.6%. Reported plans for the new venture included a 9-million-ton-per-year bauxite mining operation and a 2-million-ton-per-year alumina refinery.

In January 1975, the Government adopted new tax legislation covering mineral ores exported from Guinea. The taxes on bauxite and alumina were indexed to the market price of aluminum ingot. The tax per ton of bauxite ranged from 0.5% of the price per ton of aluminum for the lowest grade ores to 0.75% for bauxite containing over 55% Al_2O_3. The rate per ton of alumina was 1.0% of the price per ton of aluminum. Iron ore, reportedly, would be taxed at the rate of 1.0% of the price per ton of metal.

Extensive iron ore deposits occur at Mount Simandou in southeastern Guinea and in the Nimba Mountains adjacent to the Liberian deposits mined by Liberian-American-Swedish Mining Co. (LAMCO). A multinational company, Mifergui-Nimba, has been formed to develop the Nimba deposits. The Government of Guinea holds 50% of the shares of Mifergui-Nimba, and the remainder is divided among a group of government and private interests from Africa, Europe, and Japan. The Nimba deposits were believed to contain over 500 million tons of ore, in which the iron averages 65% and occurs largely as hematite. Geological studies and drilling programs were used to prospect the Nimba deposits during 1969–72, and in 1975 a preliminary feasibility study was conducted by the Swedish company, Luossavaara-Kiirunavaara AB. Plans for the project anticipate initial production by yearend 1979 and eventual output at the rate of 15 million to 25 million tons per year. The Nimba deposits and plans for their development were described.[27]

GUINEA-BISSAU [28]

Guinea–Bissau, a small west African nation of about 800,000 people, had no important mineral production in 1975. Small amounts of sand, stone, gravel, and marine salt were produced for local consumption. Resources of bauxite, gold, iron, phosphate rock, and zircon have been reported but remained undeveloped in 1975. Esso Exploration Guinea Inc., the sole rightholder, relinquished its shelf and deepwater oil exploration permits.

IVORY COAST [29]

Since independence in 1960, the Ivory Coast's economy, based mostly on diamond, cocoa, coffee, and timber, has grown at a rapid pace. After an extraordinary year of real growth in 1974, the impact of a worldwide recession, inflation, and the upsurge in oil prices hit the Ivory Coast's economy in 1975. However, by yearend 1975, coffee and cocoa prices strengthened and the GDP reached $3.7 billion, an increase of 20% when compared with that of 1974. Per capita GDP reached $546 in 1975, which was a new high in the country's economic history.

[27] World Mining. Guinea-Nimba—Plans To Develop Huge, High-Grade Fe Deposit. V. 28, No. 9, August 1975, pp. 56–59.
[28] Prepared by David E. Morse.
[29] Prepared by E. Shekarchi.

A new 5-year development plant (1976–80) was under consideration at yearend 1975. The plan envisaged a diversified economy, provided for the production of more hydroelectric energy, and stressed agro-industrial development and improved mining of the substantial Mount Klahoyo iron ore deposits.

Increased petroleum prices continued to put pressure on the economy during 1975, since almost 75% of the Ivory Coast's energy needs were met by petroleum-generated power. Petroleum imports accounted for approximately 13% of total imports. The cost of imported crude oil, however, was partially offset by reexports of refined products to Upper Volta, Mali, and other African countries. Following its successful 1974 strategy, the Government again raised gasoline and other fuel prices to discourage consumption; import levels remained at almost the same volume as in the preceding year. Esso Exploration Co. drilled eight holes during 1975, which, except for one that showed some positive indications, were all reported dry. The consortium of Phillips/Hispanoil/Getty and AGIP concluded their seismic studies and evaluated most of the data in 1975; drilling was scheduled to begin by mid-1976.

To sustain its development program, the Government of the Ivory Coast estimated that its production of electricity must be tripled by 1980. Therefore, during 1975 the Government's efforts were directed toward the maximum development of hydroelectric power. Thus, the 500-megawatt-capacity Kossan Dam was scheduled to go into production by 1979; a second dam with 210-megawatt capacity, was under construction on the Bandama River at Taabo. Also, studies were underway to build two dams on the Sassandra River.

Iron ore deposits were found in the mountainous area near Bangolo, 600 kilometers northwest of Abidjan. The deposits, with an average grade of 33% iron, were estimated to contain 310 million tons around Mount Klahoyu and about 232 million tons at Mount Tia. A consortium consisting of British Steel Corp. (20%), Mitsubishi Shoji Kaisha (20%), Union Siderurgique du Nord et de l'Est de la France (USINOR) (10%), Hoogevens (10%), Pickards Mather (15%), and Société Pour le Development Minier de la Cote d'Ivoire (SODEMI) (5%), was organized in 1974 and was conducting feasibility studies in 1975. By yearend, no decision was made on whether the concentrates should be shipped by railroad to Port San Pedro as pelletized ore or as a slurry by pipeline. Ivory Coast Government representatives were inclined more toward a railroad system at a cost of $300 million, rather than a slurry pipeline at a cost of $80 million, since the railroad would tend to open this section of the country for further mineral prospecting and agricultural development. The planned capacity of the mine by yearend 1975 was given as 12 million tons per year; feasibility studies were to be completed by mid-1976.

Gold deposits at Ity, 60 kilometers west of Man, remained undeveloped in 1975 owing to lack of transportation and water. Recoverable reserves were reported as 583,000 troy ounces of gold.

Société Ivoirienne d'Engrais (SIVENG) produced most of the Ivory Coast's fertilizer requirements during the year. The company was awarded tax exemption on imported raw material to keep abreast of/or compete with imported fertilizer material. The plant also produced 80 tons of sulfuric acid per day.

Société Ivoirienne de Raffinage (SIR) processed about 1.5 million tons of crude petroleum in 1975; most of the refinery product aside from domestic consumption was exported to neighboring countries on the west coast of Africa.

LESOTHO [30]

The production of diamond, Lesotho's only reported mineral commodity, declined nearly 78% from about 11,300 carats in 1974 to slightly more than 2,500 carats in 1975, the lowest figure reported since 1963. The percentage of gem diamonds increased slightly to nearly 18% of the total production. Local diggers were responsible for this production, virtually all of which was exported. The reported value of approximately $275,000 [31] was less than one-half of 1% of Lesotho's foreign exchange credits of about $68 million reportedly derived from the earnings of Lesotho migrant workers in the Republic of South Africa. Rising costs of imports including petroleum products contributed to an increase in Lesotho's trade deficit.

On March 4, 1975, an agreement was signed between the Government of Lesotho and De Beers Consolidated Mines Ltd. that provided for the establishment of the Letseng-la-Terai open pit diamond mine at an elevation of about 3,050 meters in the Maluti Mountains of northeastern Lesotho. The De Beers Lesotho Mining Co., Ltd. was incorporated in Lesotho to construct and operate this $35-million project in which the Lesotho Government held a free 25% interest and the right, after De Beers' recovery of capital investment, to participate in the profits on a sliding scale ranging from 62½% to 72%. The airstrip and the road to the mine were improved to provide access except during severe weather conditions, and all-weather roads were under construction around the minesite, where high winds were frequent and subzero temperatures were recorded during the winter season. Power supply was increased to 125 kilovolt-amperes, and a permanent water supply was being installed. De Beers had completed a crushing plant and was constructing the diamond recovery plant, staff quarters, and other facilities.

From the outcrop of the Letseng-la-Terai kimberlite pipe, more than 55,000 tons of overburden and 2,500 tons of kimberlite were stripped and stockpiled. An access tunnel and a service raise were being excavated to facilitate underground sampling of a satellite pipe. The Letseng-la-Terai kimberlite was considered to be of lower grade (fewer carats of diamonds per 100 tons of rock) than that at most of the diamond pipes mined in southern Africa, but there were indications that the Letseng-la-Terai production would include an above-average proportion of larger diamonds and therefore, would have a higher value per carat. It was estimated that the mine and treatment plant would be operating at the rated capacity of 4,000 tons per day by late 1976.

A UNDP team, and the staffs of the Lesotho National Development Corp. (LNDC) and the Department of Mines and Geology, continued to assess and promote utilization of the country's mineral (and

[30] Prepared by Miller W. Ellis.
[31] Lesotho was a member of the Southern Africa Monetary Union. Where necessary, values have been converted from South African rands (R) to U.S. dollars at a rate of R1=US$1.3663.

other) potential. As part of the UNDP assessment, Canada provided $972,000 for the purchase of equipment and services, and the Northway Survey Corp. was completing field surveys of about 40% (12,000 square kilometers) of the area of the country. When the results of the surveys have been compiled, they are scheduled to be interpreted by another Canadian firm.

Westrans Petroleum, Inc., stopped its first test well at a depth of about 1,650 meters and reportedly surrendered its license for oil exploration in Lesotho.

Crushed stone for concrete aggregate, clay for bricks and pottery, and semiprecious stones were also produced in Lesotho, but the quantity was small and production statistics were not available.

MALAGASY REPUBLIC [32]

The National Office for Strategic Industries was established by decree in January 1975 to supervise all exploration or exploitation of mineral resources of military or strategic nature, particularly uranium and radioactive minerals, petroleum, and bituminous materials.[33] The Government stated in 1975 that it would require 51% or greater ownership in any new mining ventures. The Malagasy Republic, Botswana, Ethiopia, Kenya, Somalia, Tanzania, and Uganda agreed to the adoption of statutes establishing the East African Mineral Resources Development Center at Dodma, Tanzania. The center would be established if agreement was ratified by three of the signatory governments. The center was designed to provide the participating governments with the spectrum of services necessary to establish a basis for development of mineral resources.[34]

The $100 million Rogez hydroelectric project on the Vohitra River in east-central Malagasy Republic remained in the planning stage. Electricity to be produced from this project would provide power for a planned ferrochrome processing plant and to exploit the lateritic Ambotavy nickel deposits. The planned hydroelectic complex on the Namaroua River in the southeast was nearing the construction stage. Power to be provided by this complex is to go to proposed aluminum smelters.

Didier Ratsiraka, who became President of the Malagasy Republic in June 1975, chartered a program to provide for state takeover of all basic means of production (energy, mines, basic industries, etc.), nationalization of foreign trade, and the institution of necessary controls over the other sectors of the economy to ensure that they were not exploitive.[35] New private investment remained low, owing mainly to uncertainties concerned with the State's eventual participation in the economy. Incentives promulgated in the Investment Code of 1973 had been inadequate to stimulate much interest.

In January 1975, West Germany and the Malagasy Republic signed a $3.7 million loan agreement that enabled the island's Government to purchase roadbuilding and agricultural equipment. In April 1975, the EEC authorized the granting of about $6.8 million to finance work on the Malagasy Republic's central south axis road. Chinese technicians were reported to have been in the Republic during the first months of 1975 studying the road system and teaching roadbuilding techniques to the local people. The Tamatave–Tananarive rail link carried most of the mineral exports to Tamatave, the largest port in volume handled in 1975. Large ships had to be loaded by lighters as Tamatave was not a deepwater facility.

PRODUCTION

The mineral industry contributed less than 1% to the GDP in 1975. The primary minerals produced were chromite, graphite, and mica. Chromite production increased moderately to 194,000 tons, graphite production increased slightly to 17,800 tons and mica production dropped to 544 tons. Oil prospecting continued at a reduced level, and there had been no discoveries of exploitable reserves on or off shore through 1975. Dependence on imports of foreign crude oil contributed to the overall 1975 trade deficit.

TRADE

The value of mineral commodities exported, nearly $18.4 million, reflected worldwide price increases. Exports of chromite concentrate exceeded 180,000 tons, an increase of 80% over those of 1974, and were valued at $13.4 million, an increase of 250%. Graphite exports in 1975 decreased 14% to 14,600 tons but increased in value 17% to $4.4 million. Phlogopite mica exports fell 90% to 137 tons and were valued at $0.033 million. The value of gem, semiprecious, and ornamental stones exported in 1975 decreased nearly 50% owing to new government export policies. Crude petroleum imports increased 14% to 5.6 million barrels but only 8% in value during 1975.

The Government continued its tight control on imports, imposed extensive export licensing requirements, and raised export taxes on many commodities to minimize the overall trade deficit, which was $36.5 million for 1975. The Government also nationalized the nation's largest trading company and took majority control of the Malagasy Republic's main shipping lines in 1975.

Detailed statistics on mineral commodity trade are given in tables 4 and 5.

COMMODITY REVIEW

Metals.—*Bauxite.*—Development of the 165-million-ton Manantenia bauxite deposit was being evaluated. Japan loaned $14 million for construction of a hydroelectric complex on the Namoroua River that would supply electric power to proposed aluminum smelters.

Chromite.—Madagascar Chrome Resources Development Co., a joint venture company, began exploration for chromite. The new company was a partnership between seven Japanese ferroalloy producers and C. Itoh & Co. (Japan), BRGM, and Compagnie de Financiese Eurofricaine, a subsidiary of Anglo American Corp. (Republic of South Africa).[36] Geologic survey and diamond drilling, to delineate dimensions of more than 350 known outcrops of chromite ore, were expected to take several years to complete. The 8,000 square-kilometer area of interest is in the Andilamena and Tsaratanana Districts, north and west of Lake Alaotra.[37]

Late in 1975, the Government nationalized the country's only chromite mining firm, formerly controlled by PUK. PUK reportedly received a contract to manage the mining operations in the negotiated settlement. Chromite production was expected to remain near 200,000 tons per year for the next several years, nearly 100% of capacity of the mines in 1975. Exports to Japan from Madagascar Chrome Resources and Development Co.'s venture was expected to begin in 1979. A 40,000-ton fer-

[36] Engineering and Mining Journal. E/MJ Exploration Roundup. V. 176, No. 3, March 1975, p. 17.

[37] Mining Journal (London). Malagasy: New Company for Chrome Prospect. V. 284, No. 7274, Jan. 17, 1975, p. 45.

rochrome plant was planned to begin operation in 1979–80 and would use power generated from the planned Rogez power project.

Iron.—Iron ore deposits discovered at Ambatavy, Bekiskopa, Fastensara, and Ambohipaky were being evaluated. The 200-million- to 300-million-ton deposit near Soalala on the northwest coast was being studied for possible development.

Nickel.—The lateritic nickel deposit at Ambatavy was being evaluated and could be exploited with power generated from the proposed Rogez power project on the Vohitra River.

Nonmetals.—*Cement.*—The cement plant located at Amoania continued to operate close to full capacity. The construction of a second plant near Tananarive was under consideration because the capital district was the major area of usage.

Graphite.—Graphite production remained close to the levels of 1973 and 1974. Production was limited by the producer's reluctance to make significant improvements due to uncertainties in Government policies although demand for quality flake remained high in the world market.

Phlogopite Mica.—Production decreased to 550 tons and exports fell to 137 tons. Logistical difficulties and erratic market conditions due to synthetic competition contributed to decreased production and exports.

Mineral Fuels.—*Coal.*—UDC maintained a coal prospecting permit in the Tulear region in the southwest. Little activity had resulted owing to infrastructure requirements for development.

Petroleum.—Chevron Oil Co., a subsidiary of the Standard Oil Co. of California, continued exploration for oil; the presence of oil and/or gas had been indicated in several areas but no exploitable reserves had been found. The petroleum refinery at Tamatave, with a capacity of 31,000 barrels per day, continued operation.

Other Minerals.—Interest in mining the ilmenite and zircon beach sands along the east coast near Tamatave was expressed by Italy's Montedison Co.

United States Steel Corp. and BRGM were interested in developing beach sand deposits in the Fort-Dauphine area along the southeast coast.

MALAWI [38]

The mineral industry of Malawi contributed very little to the nation's 1975 GDP of $741.7 million[39] (at current prices), but imported mineral products, such as fertilizers and petroleum, were significant in their effects on inflation. Mineral production consisted mainly of cement (up 26% to 102,330 tons), dolomite (91 tons), agates (down 85% to 3.2 tons) and limestone (158,000 tons).

The Malawi economy continued to grow steadily in 1975; the GDP increased 6% in real terms despite the worst deterioration in its balance of trade and terms of trade since independence. Total 1975 exports increased 18% in value, but imports increased 38% over those of 1974 to an estimated $246.5 million.[40] The Republic of South Africa, the source of 22% of imports, and the United Kingdom, with 30%, continued to be Malawi's chief suppliers in 1975. Imports from Southern Rhodesia (8.6%), Japan (7%), West Germany (4.5%), Zambia (3.5%), and the United States (3%) also remained important. Trade with the EEC was expected to expand when the Lome agreement became operational in 1976. Trade with the United States was also expected to expand with the addition of export products allowed under the GSP, making a total of 89% of Malawi exports to the United States duty-free. Products from the United States also received most-favored-nation treatment under Malawi's tariff revision effective July 1, 1975, which eliminated the Commonwealth preference structure.

The changing political situation in southern Africa was expected to place additional strain on the economy of Malawi through the closure of the Mozambique-Southern Rhodesia border and suspension of direct transportation links between Malawi and Southern Rhodesia in 1976. Trade with both Rhodesia and the Republic of South Africa would be affected. By late 1975, the increased Zambian traffic

[40] U.S. Embassy, Lilongwe, Malawi. State Department Airgram A–21, June 17, 1976, 7 pp.

through Malawi caused by the closure of the Angolan route resulted in a backlog of goods at the Port of Beira in Mozambique, including 28,000 tons of fertilizer for Malawi. Some problems were caused by the lack of adequate Zambian vehicles to forward goods from Malawi at the Salima railroad terminus. The heavier loads were being picked up by trucks at Blantyre for transport to Zambia. Improvements to the Blantyre-to-Salima railroad were to be finished in 1976, allowing heavier loads to be moved beyond Blantyre. Only 10 to 12 locomotives on the Malawi Railroad were operative at a time owing to mechanical problems. The Beira to Katete road through Moatize (Mozambique) to Malawi and Zambia, which would alleviate pressures on the railroad, was not expected to be surfaced until mid-1976. Under an arrangement with the Zambian Government, Malawi Railways was moving the maximum feasible 24,000 tons of Zambian imports each month, including 12,000 tons from the Port of Nacala, 7,000 tons from the Republic of South Africa via Rhodesia, and 5,000 tons from Beira. Approximately 6,000 tons per month of Zambian copper via road and rail through Malawi went to the Port of Nacala, with the objective of reaching 10,000 tons of copper per month.

In the third quarter of 1975, 854 persons were employed by the mining and quarrying industry, earning an average of $35 per month.[41] The Mwanakatwe Salaries Commission announced salary increases for the mining industry on July 1, 1975, with the lowest paid receiving the highest increases. By yearend 1975, Malawi had moved closer to lifting the 17-month ban on recruiting labor for South African gold mines when discussions to lift the ban were initiated.

Construction started in May 1975 on the second stage of the Tedzani Falls hydroelectric project on the Shire River where two 10-megawatt power units were to be added. The project report was completed on the Nkula Falls State II hydroelectric project. The Nkula Falls State II project was to be financed through the United Kingdom's technical aid by the Ministry of Overseas Development.

The major mineral produced in Malawi for 1975 was limestone or marble for manufacture of cement, quarried by the Portland Cement Co. of Malawi at its Changalumi quarry west of Zomba. A $1.2 million prestressed concrete railroad ties plant was officially opened in Salima. The plant was designed and constructed with South African aid. Production started in June 1975 employing 190 people. The railroad ties were to be used in the new Salima to Lilongwe rail line. The Malawi Geological Survey sampled and drilled marble deposits near Golomoti south of Salima indicating substantial reserves.

A UNDP team, assisted by the Malawi Geological Survey, completed their ground survey following up the airborne geophysical surveys of the Nsanje, Dzlanyama, Rumphi, and Karonga areas. Several new mineral occurrences were found, but none was of major economic significance.

The South Africa Chamber of Mines was aiding the Malawi Government in the development of mineral resources. Attention was being particularly given to coal, pyrite/pyrrhotite, and apatite. Coal seams in the Karroo sediments of the Ngana Basin were drilled confirming previous estimates of 14 million tons of workable coal. The phosphate deposits near Tundulu were being considered for development. A Chamber of Mines fertilizer production expert began work on a model for the manufacture of sulfuric acid, ammonium sulfate and phosphatic fertilizers. Ten acres with apparent potential for commercial concentration of apatite for fertilizer were sampled. The Geological Survey team drilled the Chisepo pyrite deposit located 50 kilometers northwest of Lilongwe.

Lonrho (Malawi) Ltd. continued to investigate the strontianite monazite deposit at Kangankunde Hill, located 15 kilometers south of Balaka. Gypsum Industries Ltd. continued its sampling of the Kapirikamodzi vermiculite deposit, located 35 kilometers west of Blantyre. Eland Exploration (Pty.) Ltd. continued geochemical, geophysical, and drilling surveys for base metals in southern and central Malawi. An aluminum smelting plant utilizing Cabora Bassa electricity and the Malawi bauxite ores from the Lichenya Plateau at Mount Mlanje was still under consideration.

Malawi imported 7% more gasoline by volume in 1975 than in 1974, and the total value of petroleum products imported in

---

1975 rose 5%. The suppliers of petroleum products continued to be the Republic of South Africa, Iran, and Mozambique. The Oil Co. (Malawi) Ltd. and Shell (Malawi) Ltd. signed an agreement during 1975 to merge their business and trading activities. The the name of the new company was to be Shell BP and Oilcom Ltd., controlled by directors representing both local and overseas shareholders.

MALI [42]

The mineral industry of Mali in 1975 consisted primarily of salt mined at Taoudeni, small amounts of gold extracted from the Kalana mine, and cement processed by the plant at Diamou. No official production figures were available. Deposits of bauxite, lithium, uranium, iron ore, copper, phosphate, diamond, and manganese exist, but were still in the exploration stage. Some gold was exported. Total exports were valued at $53.9 million[43] while total imports were valued at $188.3 million for 1975.

On January 8, 1975, Mali was one of 12 Francophone Africa countries that signed an agreement aimed at strengthening the African Regional Labor Administration Center, based in Cameroon. The center

[42] Prepared by Janice L. W. Jolly.
[43] Where necessary, values have been converted from Malian francs (MF) to U.S. dollars at the rate of MF42C=US$1.00.

was to be reorganized into an international body to foster professional education. In April 1975, the border dispute between Mali and Upper Volta erupted at the West African Economic Community (CEAO) meeting held in Niamey, Niger, and threatened continued cooperation between member nations. Despite this, the first summit conference of the CEAO was deemed a success on the economic level.

The U.S.S.R. was expected to provide aid aimed at doubling the capacity of the Diamou cement works and for the exploitation of the Kalana gold deposit, located in western Mali. Full-scale mining of the Kalana deposit was to have started in 1975. A formal agreement was signed in May 1975 between the Mali Government and the Japanese Power Reactor and Nuclear Fuel Development Corp. for uranium prospecting over 100,000 square kilometers in the Adrar de Iforas area. Plans included a 3-year exploration program beginning with a 3-month aerial survey.

The French BRGM prospected for copper and other minerals under an exclusive license in the Bougouni-Sikasso area of western Mali. Two recent BRGM publications pertaining to areas of known mineralization were of interest. In the first,[44] the geology of the Upper Precambrian rocks at the southern border of the Mandiques Plateau in western Mali was described. The report is basically a sedimentological discussion, but some ferrugenous sediments, which may contain ore at places, are also described. Iron ore has been described in the Bafoulobe area and the Mandinque plateau with resources estimated at 1 billion tons, half of which was estimated to contain 50% to 60% iron. The second report was a chapter in the BRGM Memoire, Géologie du Diamant,[45] which describes in some detail eight kimberlites occurring near Kenieba. Diamond has been discovered in several of them, and some diamonds have been recovered from river gravels, including a 98-carat white stone at Sansanto. Although limited prospecting has been done in the area, no large-scale production was ever instituted.

Prospecting for petroleum continued in 1975 with Esso Exploration owning a 50% interest in the Texaco permit. Texaco was operator and conducted an 11-party month seismic and gravity survey, as well as 7 party months of ground magnetics. The Sun-Global Menaka permit was extended, and they carried out 4 party months of seismic and gravity survey.

MAURITANIA [46]

In 1975, the dominant mineral industry in Mauritania was the production of iron ore, which was nationalized at yearend 1974. During the year, the Mauritanian Government completed the takeover of its mineral sector when the Akjoujt copper mines were nationalized. The balance of mineral production consisted of gypsum and small amounts of salt and byproduct gold, which were under the direction of the Société Nationale Industrielle et Minière (SNIM), the State's industrial holding company in charge of mining operations. A unit of SNIM, the Division de la Recherche Geoligique (DRG), was responsible for the supervision of all mineral and petroleum exploration in the country, and proposed a number of prospecting activities in selected areas. SNIM was also involved in mineral-related industrialization projects, which included the construction of a petroleum refinery, a copper foundry, an integrated steel mill, and an explosives factory.

In 1975, the Government further increased its participation in the economic sector by establishing provisional state control over the largest commercial bank, the Banque Internationale pour le Mauritanie, and nationalizing the production of electric power. The State-owned Société Nationale d'Eau et d'Électricité (SONELEC) replaced the Société Mauritanienne d'Eau et d'Électricité (MAURELEC), and assumed responsibility for the production and distribution of water and electricity, and the construction and operation of reservoirs, purification facilities, and power stations.

In June 1975, Mauritania was one of the first three countries, together with Vene-

[44] Carrere, J. M. Le Pre'cambrian Superieur de la Bordure Sud des Monts Mandinques (Mali Occidental) (The Upper Precambrian of the southern border of the Mandiques mountains (western Mali). Bull. BRGM, v. 2, Sec. 2, No. 5, 1975, pp. 461–772.

[46] Prepared by Candice Stevens.

zuela and Algeria, to sign the charter of the Association of Iron Ore Exporting Countries (AIEC). The goals of the AIEC included ensuring the orderly and healthy growth of iron ore export trade; securing fair and remunerative returns from its exploration, processing, and marketing; and promoting close cooperation among member countries for economic and social development. After year-long negotiations, the Mauritanian Government also reached agreement with the former owners of its iron ore mines, the shareholders in the Société Anonyme des Mines de Fer de Mauritanie (MIFERMA). The terms of compensation provided that the Government pay shareholders $40 million by March 31, 1976, and five payments thereafter of $10 million each over a 5-year period. Prior to nationalization, MIFERMA had been owned principally by various French industrial and banking interests, 18% by Finsider (Italy), 5% by August Thyssen Hütte AG (West Germany), and 3% by the International Minerals & Chemical Corp. (United States).

Iron ore production at the Zouerate mines, situated in northeastern Mauritania near the Spanish Sahara border, was under the direction of the newly-formed Complexe Minier du Nord (COMINOR), a division of SNIM. Combined output of the three mines—Tazadit, Rouessa, and F'Derick —was 8.7 million tons of 64.5% iron ore, a 26% decrease from the 1974 level of 11.7 million tons. However, due to higher prices and the better grade of the ore, income from iron ore exports increased from $130 million[47] to $138 million, accounting for approximately 84% of Mauritania's export revenue in 1975. SNIM negotiated new supply contracts with European and Japanese customers to replace the previous arrangements under MIFERMA; a new agreement with five major Japanese steelmakers provided for the export to Japan of 1 million tons of iron ore per year up to 1980. In 1975, the primary purchases continued to be France (24%), the United Kingdom (19%), Italy (17%), and Japan (10%).

Aside from the three producing ore bodies, whose combined reserves were estimated at 2 billion tons, there were extensive lower-grade ore reserves in outlying bodies known as the Guelb deposits. Situated within a radius of 50 kilometers of Zouerate, total reserves of the Guelbs were estimated at 2 billion tons of magnetite ore averaging 38% iron. In 1975, SNIM announced plans to commence development of the Guelb deposits; production was to begin in 1980 at an annual rate of 6 million tons which would complement and eventually replace output from F'Derick and Tazadit mines. The study of methods of concentrating ore from the Guelbs, as well as the lower-grade ore (28% to 35%) interspersed with the high grade deposits, continued at the pilot plant at Zouerate.

In February 1975, the Mauritanian Government was prompted by depressed world copper prices and the continuation of technical difficulties in ore concentration to nationalize the copper mines at Akjoujt. SNIM acquired the foreign shareholdings in the Société Minière de Mauritanie (SOMINA), which were held by Charter Consolidated Co. (44%), International Finance Corp. (15%), and a French consortium headed by Peñarroya (29%). The arrangement provided for the stockholders to pay approximately $50 million of the guaranteed debts of the deficit-ridden company, while the Government agreed to take over up to $20 million of SOMINA's nonguaranteed debts, in particular the money owed to suppliers. During the year, Mauritania applied for membership in the CIPEC, which sought to moderate the worldwide fluctuation of copper prices.

Due to the closure of the mines from May to October after the departure of foreign technicians, copper production declined more than 19%, from 20,079 tons of concentrate in 1974 to 16,203 tons in 1975. The Akjoujt mines were situated approximately 200 kilometers northeast of the capital, Nouakchott. The ore body was comprised of overlying copper oxide grading into copper sulfide at a depth of about 30 meters. Copper oxide reserves were estimated at 2.3 million tons averaging 2.7% copper and 2.3 grams of gold per ton; copper sulfide reserves were estimated at 13.7 million tons averaging 2.3% copper and 1.3 grams of gold per ton. Charter Consolidated Co. developed the TORCO process (treatment of refractory copper ore) for exploitation of the Mauritanian copper

[47] Where necessary, values have been converted from Mauritanian ouguiya (UM) to U.S. dollars at the rate of UM45=US$1.00.

oxide ore which could not be profitably floated or leached. The second stage of mine development would be exploitation of the sulfide ore which, though less difficult to treat, would necessitate new installations. SNIM was considering the construction of a conventional copper sulfide flotation plant at Akjoujt, but no decision had been made at yearend.

In 1975, bids were solicited for construction of a copper smelter at Nouakchott, scheduled to go onstream by 1978. Financing was to be provided by Société Arabe d'Industries Metallurgiques (SAMIA), a joint venture between SNIM and a consortium of Kuwaiti interests. The smelter was to have an annual processing capacity of 140,000 tons of copper concentrate, and was to recover 30,000 tons of metal, 1,820 kilograms of gold, 2,500 kilograms of silver, and 100,000 tons of sulfuric acid per year.

The production of gypsum, completely under the control of SNIM, increased 52% from 8,312 tons in 1974 to 12,669 tons in 1975. Most of the year's output was exported to Senegal for use in the West African Cement Co. plant at Rufisque, and earned Mauritania about $150,000 in foreign exchange income. Mining at the gypsum quarry at Sebkha de N'Drahamcha, located 65 kilometers north of Nouakchott, began in October 1973. The evaporite gypsum deposits were comprised of 92% hydrous calcium sulfate, 2% clay, and a negligible quantity of sodium chloride. Reserves were estimated at 11 million tons.

Exploration for petroleum resources in Mauritania was limited in 1975. Texaco Mauritania Inc. and AGIP Recherches et Exploitation (Mauritania) relinquished their concession areas in the latter part of the year due to unsuccessful onshore exploration activity. Also, Shell Mauritania Co. ceased drilling in its 31,800-square-kilometer offshore area in early 1975. The only drilling activity reported was that of Western Enterprises, Inc., which acquired rights to 93% of Planet Oil and Mineral Corporation's Cap Timeris concession area.

Texaco also sold its interests in marketing operations to SNIM, which established the L'Unité de Commercialisation de Produits Pétroliers (UCPP) for the sale and distribution of petroleum products in Mauritania. In 1975, Mauritania consumed approximately 1 million barrels of petroleum products, all of which were imported. Under the supervision of UCPP, construction began in September on a petroleum refinery at Nouadhibou. The Austrian firm, Vöest-Alpine, contracted to build the refinery at a cost of about $75 million. Scheduled for completion in July 1977, the refinery was to have an annual capacity of about 7 million barrels of crude oil, supplied primarily from Algeria. Annual production was to consist of approximately 2 million barrels of gasoline, 1.4 million barrels of diesel fuel, 2.5 million barrels of fuel oil, 580,000 barrels of jet fuel, and 180,000 barrels of liquefied petroleum gas. Approximately 1/3 of output was to be consumed domestically with the balance destined for European markets.

In addition to the petroleum refinery, September also marked the initiation of construction of an explosives factory at Nouadhibou. SNIM was the director of the project, which was to be built by the Société Française des Explosifs at an estimated cost of $2 million. Daily capacity was to be 28 tons of explosives, all of which would be utilized in the mining operations at Zouerate and Akjoujt.

Construction of a 1 million-ton-per-year steel mill at Nouadhibou remained in the planning stages at yearend 1975. The results of a feasibility study conducted by H. K. Ferguson Co. (United States) were under consideration by SAMIA, which was to assume financing and management responsibilities for the project. Questions regarding infrastructure requirements for the steel mill, particularly sources of coking coal and electric power, had yet to be resolved.

Exploration for additional mineral resources, particularly uranium and phosphate, was active in 1975. In addition, the Mauritanian Government announced a number of mineral research projects to be executed during the period 1975–80. The proposed projects for the exploration and development of Mauritania's mineral resources were based on a comprehensive geological survey by BRGM.[48] Promising uranium mineralization was cited in various areas, and in July, the Mauritanian Government renegotiated its exploration agreement with the Compagnie Française des Pétroles (CFP). Prospecting was being

---

[48] Bureau de Recherches Geologiques et Minières (Paris). Plan Mineral de la Republique Islamique de Mauritania. June 1975.

carried out in the northern Tasiast and Dorsale Reguibat areas by CFP on behalf of a French-Japanese consortium comprised of CFP, Péchiney Ugine Kuhlmann, the Commissariat à L'Energie Atomique, TOTAL Compagnie Minière et Nucleaire, and Tokyo Uranium Development Co., Ltd. The new agreement provided for the Mauritanian Government to acquire a 51% share of any joint venture formed to exploit uranium findings.

An agreement for phosphate exploration was renewed with a consortium consisting of SNIM, BRGM, the Sociètè Sénégalaise des Phosphate des Thies, and the Romanian firm, GEOMINES. The area under study was a triangular region bordered by the towns of Aleg, Bohe, and Kaedi in the Senegal River Basin. The Government plan also scheduled phosphate exploration for the Tankarkart area southwest of Akjoujt and a region along the eastern border of the Taoudenni Basin. At yearend, Mauritania and Morocco were negotiating the formation of a joint company to undertake the exploration and development of mineral resources in the Western Sahara. A tripartite agreement concluded in November 1975 was to place the phosphate-rich territory of Western Sahara, previously controlled by Spain, under joint Moroccan/Mauritanian administration.

Several other areas identified by BRGM as having mineral potential were to be fully evaluated under the direction of the DRG of SNIM. Prospecting for iron ore was to continue in the Akjoujt region, where the Gleibat El Khader was estimated to have reserves of 18 million tons averaging 51% iron. The copper reserves of Akjoujt were to be reevaluated, and a feasibility study of the potentially significant copper deposits in the northern Sebkhas Ghallaman region and southern areas of Selibaby and Affolé was to be conducted. Portions of the northern Dorsale Reguibat region were to be examined for gold (Conchita-Florence), tin (Catherine), and manganese. Black sands along the Atlantic coast, which were estimated to contain 250,000 tons of ilmenite, were to be examined for rutile, zircon, and monazite content. A feasibility study of developing construction materials, particularly ornamental stone, vermiculite, and sillimanite in the Tasiast region, was to be completed. A total of 27 projects were outlined, with an initial estimated cost of $4 million.

Plans were also underway for the construction of a 1,100-kilometer road from the port of Nouakchott to the eastern city of Nema, which would open up the eastern part of the country. The Brazilian firm, Mendes Junior, contracted to construct the first segment of the road between Nouakchott and Kiffai. The project was to be financed by Saudi Arabia, Kuwait, and the United Arab Emirates. At the same time, the Government had under study a plan for the construction of a deepwater port at Nouakchott. An agreement concluded in 1971 provided for the feasibility study and financing to be supplied by China; in a later agreement, the Chinese credited Mauritania approximately $53 million in an interest-free loan over a 37-year period for the construction of the port. The port's capacity was to be increased from 200,000 to 500,000 tons per year and would accommodate vessels of 10,000 deadweight tons.

MAURITIUS [49]

The mineral industry of Mauritius contributed less than 1% of the estimated 1975 GDP of $500 million[50] at current prices. The 1975 mineral production consisted of 6,000 tons of salt valued at $299,000 and 7,300 tons of lime valued at $4,100. Both commodities increased in amount produced and in value over that of 1974; salt production rose 20%, and lime, 82%. In spite of the devastating cyclone Gervaise in 1975, Mauritius came through the year with a thriving economy. The rate of inflation had fallen to 14%, compared with 29% a few years earlier. There had been significant achievement in the nation's growth during the 4-year plan period which ended in mid-1975. The GDP increased from $151 million in 1970 to $470 million in 1974. The manufacturing sector had increased by 138% since 1970. Continued progress was anticipated as the 1975–80 5-year development plan was launched. The GDP was expected to grow 6.9% per year. Capital investment over the plan period was planned at about 28% of the GDP with estimated external assistance resources for the programing period totaling approximately $256 million. The main objectives of the 5-year plan were to create employment and to develop self-sufficiency in food, exportation of petroleum products through petrochemical development, and a 250% increase in hydroelectric capacity. The private sector was to provide about 25% of the necessary development funds.

One of the Government's tools for development was the Development Bank of Mauritius, of which the Government Financial Secretary was ex-officio chairman. The UNDP and the World Bank were to assist in establishing the bank's operations and to train Mauritian personnel. Foreign aid for development was to come from France ($25 million for hydroelectric projects), India ($12 million in commercial credits for industrial equipment), the United Kingdom ($10 million for port development), the ADB ($10 million for the Guibes reservoir and hydroelectric plant), and the Arab League. The Arab League was to subsidize the purchase of petroleum products. Aid in the form of subsidies from the Arab League was to be calculated on the annual oil import figures. The loan was to be refundable over a long period and carry 1% interest. In 1975, Mauritius received petroleum import aid amounting to $2.3 million from the Arab League as compensation for the increase in petroleum prices. The UNDP was doing geological studies in support of the Quātre Soeurs hydroelectric power project. The EDF was to aid in establishing technical schools. CIDA was to finance the cost of the first three phases of the water supply development in Rodriques (about $1.4 million).

In July 1975, a port authority was created with the principal objective of modernizing the harbor. The first deepwater harbor was to be built and completed within 2 years. The new piers were to be built with a World Bank long-term loan of $10.5 million. A United Kingdom firm was to dredge the Roche Bois harbor, with financing from the United Kingdom. The Roche Bois harbor was to have a deepwater pier completed around the end of 1978.

A Ministry of Power, Fuel, and Energy was set up in January 1974. Mauritius has no known mineral resources of great significance, although oil prospecting was taking place near the islands of the St. Brandon Group; drilling had commenced by the Texaco Group and was expected to continue during the 1975–80 plan period. Development of water resources was of fundamental importance to the Mauritian economy. The Quatre Soeurs hydroelectric scheme, aimed at development of the Grand River South-East, started in April 1975. This activity was being carried out in conjunction with the Central Electricity Board and Central Water Authority.

NIGER [51]

The mineral industry of Niger accounted for 39% of all export revenue earned during 1975. Government revenues from mining operations in 1975 were about $6 million.[52] A new profit sharing arrangement negotiated with the French Government in 1975 was expected to boost revenues to over $18 million in the future.

The Government encouraged foreign investment in the industrial sector through its liberal investment code, as revised in 1974. The code encouraged investments in energy production; mineral exploration, production and processing; and fertilizer production. Numerous obstacles, such as underdeveloped infrastructure, extremely high energy costs, and lack of trained manpower, had to be resolved.

In 1975, Niger ranked fifth among the world's producers of uranium, having produced 1,535 tons of uranium concentrate—16% higher than 1974 production. Niger also ranked fifth in the world in known uranium reserves with over 40 million tons estimated. Mining operations at the Arlit mine were carried out by the Société des Mines de l'Air (SOMAIR), an international consortium founded in 1968, composed of the Government of Niger, the French Commissariat à L'Énergie Atomique (CEA), Compagnie Française des Minerais d'Uranium (France), Péchiney-Mokta Mining Co. (France), Urangesellschaft AG (West Germany), and Agip Nucleare S.p.A. (Italy). The Arlit mine employed 90 engineers and about 600 workers during 1975. A second company, a French, Japanese, and Spanish consortium Compagnie Minière d'Akouta (COMINAK), continued development and infrastructure at the Akouta mine toward an output of 2,000 tons of uranium concentrate by 1979, Japan was to receive 4% of the production from this mine. A third uranium consortium, in which COMINAK was a participant, anticipated production of uranium concentrate at its Imouraren mine, south of Arlit, beginning in 1980.

To facilitate the transportation of uranium concentrate to railroads in neighboring countries and to open the northeast of Niger for further mineral prospecting, the Government asked the consortium members to contribute up to $70 million in 1976 and 1977 for the construction of road between Tahoua and the uranium mines around Arlit. The details of this project were not known by the yearend.

In addition to uranium, there was a small production of cassiterite concentrates by Société Minière de Niger, a mixed private and public enterprise. Tin production in 1975 totaled 137 tons, of which 127 tons were exported to the European market. Most of the tin production was from Taroudji and El Meki mines in the southern Air Mountains.

By yearend 1975, a mixed private and public company, Société Niger Charbon (SONICHAR), was established to exploit the coal deposits at anou-Ararene. Reserves of these deposits were estimated at 4.5 million tons. However, the economics of exploiting the deposits and the opening date were not available by yearend.

Petroleum exploration by several foreign firms including four U.S. companies, after

[51] Prepared by E. Shekarchi.
[52] Where necessary, values have been converted at a rate of CFAF224.5=US$1.00.

an investment of approximately $50 million, practically ceased by yearend 1975. Although some indication of petroleum was reported by companies active in 1974 and 1975, fields had yet to be proven exploitable. The companies had halted their drilling activities during the year. apparently to evaluate seismic data, as well as logs from drilled holes. Reportedly some new phosphate deposits were found in the Parc W game reserve by a French exploration group in 1975. Preliminary resources were estimated at 100 million tons with no specific grade. An agreement was signed between the Niger Government and a group of French companies for further study of the phosphate deposit and possibly for an exploration scheme. The details of agreement and sharing of the investment venture were not available.

Cement production decreased 14% in 1975 compared with the 1974 output. Although the rated capacity of the cement factory was 40,000 tons, it was never reached in 1975 owing to shortage of energy. Except for energy, the raw materials for cement manufacturing were supplied indigenously.

RWANDA [53]

Rwanda's mineral production increased in both quantity and value and provided 15% of the country's export sales in 1975. Cassiterite (tin ore) continued to be the principal mineral product and was the second largest source of foreign exchange earnings. Several factors combined to increase drastically the cost of transporting supplies to and exports from the small, landlocked nation of Rwanda. Civil unrest in Angola disrupted and, in August, halted traffic via the Benguela Railway to the Atlantic port of Lobito. Zaire's transport requirements exceeded the capacity of road, rail, and river carriers on two alternative routes to its port of Matadi, and Rwanda's consignments moved slowly when spare capacity was available.

Transport through Uganda to Kenya's Indian Ocean port of Mombasa was unreliable and the Ugandan frontier was at times unpredictably closed. China provided funds for tarmac surfacing of the road from Rwanda's capital, Kigali, to the Tanzanian border, but the connecting road to a railhead in Tanzania was incomplete at the yearend and this route to the east coast port of Dar es Salaam was seldom used.

Transport delays increased the delivered cost of petroleum products, and shortages of gasoline and diesel fuel caused intermittent stoppages of both mining machinery and transport vehicles. The resultant escalation of production costs largely offset the advantages of higher prices of export commodities in the world markets. Dispatch of most of Rwanda's mineral products by air freight obviated transport delays and provided rapid returns of foreign exchange credits.

Most of Rwanda's mineral industry was controlled by the Société Minière du Rwanda (Somirwa), 49% owned by the Government of Rwanda. The Compagnie Géologique et Minière des Ingenieurs et Industríals Belges (GEOMINES) held the remaining 51% and was responsible for operations at the mines.

Cassiterite continued as the chief mineral product and had an export value of approximately $5 million.[54] Société Général des Mines (SGM) purchased the entire production of more than 2,000 tons, and smelted approximately 1,400 tons at its plant in Hoboken, Belgium. The remainder, which contained excessive arsenic, was resold to consumers in other countries.

Tungsten ore (wolframite-ferberite) was Rwanda's fifth-ranking export commodity. Ore production increased 22% from nearly 530 tons in 1974 to nearly 650 tons in 1975. In December 1975, Somirwa absorbed the larger of two tungsten mining operations and became responsible for 90% of Rwanda's tungsten production. The remaining 10% was produced by Mines de Bugarama but marketed through Somirwa. Production of columbite-tantalite by Somirwa increased about 22% to more than 45 tons in 1975.

A methane gas recovery pilot plant on Lake Kivu provided a domestic source of energy and supplied a local brewery with part of its fuel requirements.

SAÕ TOMÉ AND PRINCIPE [55]

These Portuguese islands became the independent Democratic Republic of Saõ Tomé and Principe in July 1975. With a total area of less than 1,000 square kilometers and less than 80,000 inhabitants, it was the smallest of African nations. The two islands are about 150 kilometers apart and are aligned approximately 250 and 400 kilometers southwest of the Equatorial Guinean Province of Fernando Po. Of volcanic origin and with 1 to 7 meters of annual rainfall, the islands had no mineral exports. The mineral industry was probably limited to the production of stone and other material for local construction. The chief exports were cocoa, coffee, and palm products via ships on the Portugal-Angola run, but this transport service ceased with independence. The departure of most of the Portuguese technicians and supervisors also affected the country's economy. Foreign aid, the acquisition of coastal freighters (promised by Portugal), the development of a fishing industry, and other measures were under consideration for establishing economic stability for the new nation.

SENEGAL [56]

The production and export of phosphates was the dominant mineral industry activity in Senegal during 1975. Calcium phosphate production increased 9% over that of 1974 to nearly 1.6 million tons although exports fell 17% to 1.3 million tons. Aluminum phosphate production decreased to 201,000 tons and exports to 150,000 tons, declining 50% and 29% respectively, below 1974 levels. Poor farming conditions in Europe and lower world phosphate prices were the cause of the decrease in foreign sales of phosphate rock and its products. The 1975 production of attapulgite (fuller's earth) increased 70% to 16,700 tons; cement, 8% to 359,000 tons; and solar evaporated sea salt, 10% to 165,000 tons. Building stone, crushed basalt, sand, and gravel were produced for local consumption.

The value of phosphate rock and its products exported in 1975 was approximately $93.7 million, or 27.5% of the value of Senegal's total exports. Phosphate mining contributed significantly to the GDP of

[55] Prepared by Miller W. Ellis.
[56] Prepared by David E. Morse.

Senegal, which was $1.27 billion in 1975. Phosphate mining employed nearly 1,500 persons out of over 160,000 nonagricultural workers. The Government of Senegal established a 6-square-kilometer free trade zone near Dakar to stimulate foreign investment in manufacturing facilities.

Two companies mined phosphate rock in Senegal during 1975. Compagnie Sénégalaise des Phosphates de Taiba mined calcium phosphate and the Société Sénégalaise des Phosphates de Thiès produced a natural aluminum phosphate. The high quality of Senegalese phosphate allowed the companies to follow the world trend of raising export prices substantially beginning in 1972. By yearend 1974 they had been able to pay off much of their long-term debt. In January 1975, the Government of Senegal negotiated an agreement with each company to buy 50% of both operations. Payment for the Government's share was to be made out of future earnings. Shareholders in Société Sénégalaise des Phosphates de Thiès were the Government of Senegal (50%), and Société Rhône Progil of France (50%). Shareholders in Compagnie Sénégalaise des Phosphates de Taiba were the Government of Senegal (50%), Bureau des Etudes & Recherches Minières of France (13.5%), International Minerals and Chemicals of the United States (12.3%), Compagnie Financière pour l'Outer-Mer (COMIFER) of France (7.4%), Caisse Centrale de Cooperation Economique of France (5.4%), and other (11.4%).[57]

The Taiba company mined calcium phosphate from two deposits located near Tivaouane and had a capacity of 1.65 million tons per year with a planned capacity of 1.8 million tons per year by 1980. Proven reserves at yearend 1975 were 30 million tons with an additional 90 million tons proven reserve at the contiguous Tobène deposit. Value of export sales from the Taiba mine was over $90 million in 1975, a 22% drop from that of 1974, although net profits increased 25% over those of the preceding year. The product exported was powdered 82% calcium phosphate and was shipped to 15 countries, with about 24% going to France, 18% to the United Kingdom, 14% to Greece, 9% to the Netherlands, 17% to other European countries, and the rest to the Americas and India.

The Société Sénégalaise des Phosphate de Thiès mined natural calcium aluminum phosphate from the Pallo mine north of Thiès and had an annual capacity of over 400,000 tons in 1975. The ore was crushed, screened, and either calcined at Lam-Lam near the mine or at Nante in France to increase the P_2O_5 content to 34%. This product when sold for fertilizer purposes was called Phosphal. Some of the calcined product was used to manufacture an animal feed supplement called Polyfos. Value of 1975 exports from the Pallo mine dropped to $3.59 million from $4.87 million in 1974.

A new 50/50 intergovernment company, Société Irane Sénégalaise des Petrols et des Mines (IRANESCO), was formed between Iran and Senegal in 1975. IRANESCO was to develop the Tobène phosphate deposit, build a new petroleum refinery at Kayar, expand the port facilities at Dakar, and construct a new phosphate fertilizer plant near the mine site. The new mining complex was to produce about 2 million tons per year from the Tobène deposit of which 1 million to 1.5 million tons per year would be purchased by Iran. The proposed 2.5- to 3-million-ton-per-year petroleum refinery at Kayar north of Dakar would be supplied with crude oil by the National Iranian Oil Co. The $100 million expansion of the port at Dakar began in 1975. IRANESCO had the Krupp Engineering group perform a preliminary study of the new mine in relation to the complementary projects. It was planned to have all phases of the project in full operation by mid-1980.

Prospecting for phosphates in the Lac de Guires area of northwestern Senegal and between Bakal and Matam along the Senegal River in the east was begun by BRGM of France in association with United States Steel Corp., Société Sénégalaise des Phosphates de Thiès, and the Government of Senegal. The Government was to own 51% of any mining venture resulting from this work. The areas under consideration were in isolated sections of the country and would require several years for development.

In July 1975, a joint company, Iron Ore Mines of Eastern Senegal (Miferso), was formed. The partners in the company were Krupp of West Germany, Screm of France, Kanematus-Gasho of Japan, and the Senegal

[57] U.S. Embassy, Dakar, Senegal. State Department Airgram A-49, Mar. 30, 1976, enclosure 4 and 5.

Government. Proven iron ore reserves at Miferso's concession included 40 million tons of iron ore with an average grade of 63% and 45 million tons of iron ore averaging 53% iron. Owing to the remoteness of the deposits, commercial development was expected to be several years away. Krupp and BRGM made a feasability study of the 1.2 billion to 1.6 billion tons Falémé iron ore deposits in Senegal Oriental.

The capacity of Senegal's only cement plant, owned and operated by Société Ouest-Africaine des Ciments at Rufisque, was 400,000 tons in 1975. Most of the 1975 production was consumed locally with 23% exported.

Société Prochimat exported about 13,800 tons of attapulgite in 1975, an increase of 36% over that of 1974. Attapulgite was used as a drilling mud in petroleum exploration.

Exports of solar evaporated sea salt produced in western Sine-Saloum were over 110,000 tons in 1975. About 30% of the production, or 50,000 tons, was consumed locally.

The oil refinery at M'Boa near Dakar processed 5 million barrels of crude oil in 1975, a 6% increase over that of 1974. The oil refinery was able to supply local demand in 1975. Countries supplying a significant share of the crude oil imported by Senegal in 1975 were Nigeria, Iraq, United Arab Emirates, and Gabon. All of the production from the proposed oil refinery at Kayur would initially be exported, and as the country's demand for refined oil products increased, some would be used for local consumption.

Petroleum exploratory activity by Shell in 1975 included 1 party—month for seismic marine surveys and less than 1 party—month for land surveys. In September 1975, Shell also terminated drilling on the first well drilled in Senegal since 1972. The dry hole, drilled to 9,300 feet on a marine concession area off the southwest coast of Senegal, was the only exploratory well drilled in 1975. The Shell, Senrex, Pecten Senegal, and Demenix group returned 15,400 square miles of its 28,400-square-mile concession to the Senegal Government during 1975.

SOMALIA [58]

The mineral industry of Somalia was largely confined to the production of meerschaum, marine salt, local building materials, and small amounts of tin. No production or detailed trade figures were available. All fuel needs were imported and were valued at $14 million[59] for 1974; data for 1975 petroleum imports were not available. Total imports in 1975 were valued at $144 million and total exports at $72 million, leaving a negative trade balance of $72 million. Foreign aid and grants, mostly from East European and Arab donors, however, more than compensated for the trade gap. These foreign inputs were for the most part motivated by the drought.[60] Prices remained relatively stable, increasing about 8% in 1975.

As partial fulfillment of the bilateral agreement for economic and technical assistance signed in June 1975 by the U.S.S.R., 72 Soviet specialists were working on the 5,000-kilowatt hydroelectric project on the Juba River. Soviet assistance, in general, was to be aimed toward enabling Somalia to fulfill its second 5-year development plan (1974–78). The Italian firm Citaco S.p.A. completed a preliminary study of the Scebeli River dam project in 1975. The United Arab Emirates were to lend $40 million for constructing a dam at Bardera. The 158-kilometer Harguisa-Berbera road was officially opened in June 1975. This highway construction, which began in

[59] Where necessary, values have been converted from Somalian shillings (Ss) to U.S. dollars at the rate of Ss6.2950=US$1.00.
[60] American Embassy, Mogadiscio, Somalia. Department of State Foreign Economic Trends and Their Implications for the United States. No. 76-132, November 1976, 9 pp.

1972, was financed by a $9.2 million loan from the IDA and a $1 million loan from the ADB. Ground was broken on October 16, 1975, at Suria Malableh for construction of a cement plant utilizing nearby gypsum deposits. The $12 million project was financed jointly by the North Korean and Somalian Governments. The gypsum deposits were estimated at 7 million tons.

The UNDP was to begin strengthening the Somali Geological Service in mid-1976. Mapping, groundwater survey, and mineral exploration were to be consolidated, and improvements were to be made in chemical, mineralogical, and cartographic facilities. The UNDP was also to further pursue the investigation of the Mudugh carnotite deposits, which were found by a UNDP project that ended in 1974. The Somali Government was also actively seeking potential foreign investors for extraction of this uranium in cooperation with the Government. Both western and eastern block investors were being considered. Ilmenite sands described by the UNDP at Chismaio were estimated at 10 million tons with an average content of 1.0% TiO_2.

A Bulgarian geological team was doing systematic exploration including mapping, drilling, and sampling in the Majayahn-Dalan area of Bosaso Province in northeast Somalia. Tin was reportedly being produced from placer deposits at Dalan and the pegmatite and quartz veins at Majayahn. At Majayahn, an ore dressing plant produced about 80 tons of cassiterite concentrate averaging 55% tin. About 100 tons of concentrate was shipped to Bulgaria for testing and processing. Development of tin mining was made possible by a $1.5 million Bulgarian loan made in 1972.

Small low-grade iron ore deposits were also located (120 million tons grading 35% iron) at Bur Gulan, and 50 million tons, at Dinsor. Nickel, chrome, lead, zinc, and piezoelectric quartz in northern Somalia have also been described. Reportedly, sepiolite and bentonite deposits occur near El Bur in central Somalia.

An Italian company was to begin construction in 1976 on a petroleum refinery with a 10,000-barrel-per-day capacity. The refinery was to be Iraqi financed and to take 2 years to complete. At the beginning of 1975, companies holding oil exploration permits included Elf-Exxon, Elf-Exxon-Aquitaine, CONOCO-Shell-AGIP, and Deutsch Texaco in the northern coastal areas of Somalia; and Burmah Oil, Texaco, and Elf-TOTAL in the southern part of the country. CONOCO was operating two airplanes and three helicopters in its concession, employing nearly 300 people. Under its agreements with the Government, CONOCO reportedly[61] was to give Somalia a 15% royalty on production, plus a 45% tax on profits. By yearend, however, CONOCO had announced intentions to withdraw, leaving only one U.S. firm, Exxon, retaining an interest in petroleum prospecting in Somalia. The Burmah Group had also withdrawn.

SPANISH SAHARA[62]

The principal mineral production in Spanish Sahara during 1975 was phosphate rock. Fosfatos de Bu-Craa, S.A. (Fosbucraa), a wholly-owned subsidiary of the Spanish Government's Instituto Nacional de Industria, operated the province's only major mine at Bu-Craa in northern Spanish Sahara, about 100 kilometers southeast of El Aaiun. In 1975, this mine produced 2.76 million tons of phosphate rock for export with a value of approximately $170 million. The ore was crushed at the mine and transported by conveyor to El Aaiun where it was washed with seawater to wet and separate the sands and slimes from the phosphate bearing nodules. The nodules were then washed with freshwater and dried to yield a product grading 34% to 37% P_2O_5. Phosphate exports from El Aaiun were loaded from a 3,200-meter-long pier with berths for three 100,000-ton ore carriers.

The production capacity of the mine was 5.6 million tons annually in 1975; however, output was limited by the freshwater supply at the beneficiation facility at El Aaiun. Proven reserves of phosphate rock at Bu-Craa were 1.7 billion tons with an additional 10 billion tons of probable ore. Nearly all of the 1975 production was exported to Spain, West Germany, and Japan.

[62] Prepared by David E. Morse.

In October 1975, Spanish Sahara's northern neighbor, Morocco, staged an unarmed "march of conquest" into the province, which resulted in Spain relinquishing control of the territory; subsequently, Morocco's Office Cherifen des Phosphates (OCP) acquired a 65% interest in the Bu-Craa mine with 35% retained by Fosbucraa. The mine continued to operate with a Spanish staff until it was closed down in mid-December; however, OCP planned to reopen the mine using Moroccan personnel in early 1976. The conveyor system was also shut down owing to damage caused by sabotage to five sections. Repairs to the conveyor were scheduled to be completed by the spring of 1976. The loading facility's capacity at El Aaiun was reduced when part of the pier was damaged by a freighter ramming it on December 15, 1975.

No oil exploration activity was carried out in 1975.

SUDAN [63]

The mineral industry of Sudan was a minor contributor to the nation's economy in 1975, although plans were made for the exploitation of Sudan's promising mineral potential. The mineral sector, which was limited to the exploitation of chromite, small-scale gold and mica mining, a salt industry, the quarrying of gypsum and limestone for use in cement manufacture, and the refining of petroleum products, accounted for approximately 2% of the 1975 GDP of $2.8 billion.[64] Sudan continued to evidence a severe balance of payments deficit, approximately $400 million in 1975, due to increased outlays for food and petroleum imports, which increased from $106 million in 1974 to $265 million in 1975, and large imports of capital goods in support of an ambitious development program. Spending on development projects more than quadrupled since 1973, and the Government was embarking on a $6.5 billion, 6-year development plan to be financed largely by Arab donors who pledged $5.7 billion over the next 10 years. The Geologic and Mineral Resources Department formulated a long-range development plan that included a major increase in cement industry capacity, a new petroleum refinery, further development of chromite, gold, and gypsum mining, and the exploitation of iron ore, asbestos, and copper deposits.

A major focus of investment was the effort to rectify the infrastructural problems of inadequate transport, communications, and electricity, which constituted key obstacles to Sudan's development. As the largest nation in Africa, Sudan's 2.5-million-square-kilometer area was serviced by 5,000 kilometers of railway, which transported the bulk of both passengers and commodities. Financed by a $24 million loan from the IDA, the Sudan Railway was to be modernized and capacity increased from 2.2 million to 3.6 million tons in 1976, and eventually to 4 million tons. During the year, a contract was signed with a French consortium, Francorail-Materiel de Traction Électrique (Francorail-MTE) for construction work including the addition of new tracks, improvement of existing rail links, modernization of the signaling system, and upgrading of rolling stock.

The Sudanese Corp. of Public Works continued its wide-scale road construction program, financed by the United Kingdom, China, and Arab sources in conjunction with the ADB. The existing system comprised 19,000 kilometers of roads, which were to be supplemented by 1,600 kilometers of new highway. The 996-kilometer road linking Port Sudan with Khartoum was to be completed in 1978. Construction began during the year on a 187-kilometer road connecting Debeibat, Dilling, and Kadugli in Southern Kordofan Province. At yearend, an important agreement was signed between Sudan and Kenya to construct a road between Juba and Kitale in Kenya, which would give southern Sudan direct access to the port of Mombasa. In providing an alternative transport route to the longer and less reliable route through Khartoum and Port Sudan, the new road was to be an important development asset to Sudan's southern region.

At Port Sudan, studies were being conducted for the modernization and expansion of port facilities with technical

[64] Where necessary, values have been converted from Sudanese pounds (£S) to U.S. dollars at the rate of £S1=US$2.87.

assistance from the United Kingdom. In addition, West Germany was aiding in drafting plans for the construction of a new port at Suakin, 50 kilometers south of Port Sudan. The port, which was to have an initial capacity half of that of Port Sudan, was to be completed in 1980 at a cost of $37 million.

A $40 million program was to provide Sudan with additional electrical facilities over a 5-year period. The bulk of electric power generation and consumption was concentrated in the central part of the country, where the Public Electricity and Water Corp. operated its Blue Nile grid based on five generating stations. Total power-generating capacity in 1975 was 208 megawatts, of which 108 megawatts was hydropower. The generating capacity of the Blue Nile grid was to be increased by 55 megawatts, and diesel units were to be installed at Port Sudan, Juba, Atbara, El Obeid, Bari, and Geda.

Cement production in 1975 fell to approximately 140,000 tons owing to technical difficulties that left Sudan's two cement plants operating at half capacity. At the same time, Sudan's development program increased cement requirements and necessitated the importation of 77,000 tons of cement in 1975, primarily from Japan, West Germany, Kenya, Italy, and the United Kingdom. However, a scheduled improvement and expansion of facilities was to convert Sudan from an importer to an exporter of cement with the eventual annual production goal set at 1.5 million tons. The Maspion Cement Corp., situated at Atbara in Nile Province, failed to reach its production target of 225,000 tons owing to electric power shortages. This was to be remedied by the installation of a new diesel generator, and a contract was also signed with the Danish firm F. L. Smidth for the design, supply, and erection of a new production line. The Nile Cement Co. at Rabak in White Nile Province was to reach a production capacity of 120,000 tons by 1977. Contracts were signed with West German firms for the expansion. A third cement plant was under construction by the Arab Cement Co. Ltd. at Derudeb in Red Sea Province. The plant, a joint venture of the Sudanese Government, the Kuwait Foreign Trading and Investment Co., and Lazard Brothers of London, was scheduled for startup in 1980 with an annual capacity of 500,000 tons. Of three other proposed cement projects, the most promising was a combined American-Sudanese undertaking to build a 400,000-ton plant at a site north of Port Sudan. A feasibility study was conducted by Klockner Industrie Anlagen for a 100,000-ton plant at Kapoeta in Equatoria Province to provide cement for the southern region. Another proposal was the construction of a cement plant at Damazin in Blue Nile Province with a 100,000-ton capacity.

Sudan continued negotiations for 50% ownership in the Port Sudan Shell and British Petroleum (Sudan), Ltd., refinery in Port Sudan. In 1975, the Public Petroleum Corp., responsible for the supervision of the Government's interest in oil production, refining, and internal distribution, imported approximately 8 million barrels of crude oil from Iran, Iraq, and Kuwait for processing at the 22,000-barrel-per-day refinery. Construction continued at the 200,000-barrel-per-day refinery being built at Port Sudan by the Sudanese Government and the Saudi Arabian firm Triad Naft. An 815-kilometer pipeline linking Port Sudan with Khartoum was to be completed in mid-1976. Work was being done by the West German firm Sodrobrau and the United Kingdom firm Macklebane. The pipeline, which was to have a daily capacity of 12,000 barrels, was financed by the Kuwait Investment Co.

The discovery of natural gas in the Red Sea was a promising sign as prospecting for oil and gas continued during 1975. Five companies held exploration licenses covering 58,500 square kilometers offshore and 500,000 square kilometers onshore. In October 1975, the Sudanese Government signed exploitation agreements with the operating companies whereby the firms would recover their costs over a 5-year period through partial ownership of any commercial discovery, after which the Government would assume full ownership. Chevron Overseas Petroleum, Inc., a subsidiary of Standard Oil of California, and Texaco Sudan, Inc. were the operators for various partnerships. In a 2,500-square-kilometer offshore concession shared with American Pacific International, Inc., Chevron-Texaco drilled the 1A Bashayer well, which tested at a rate of 9.5 million cubic feet per day of gas. In one of 39 tracts covering 29,000 square kilometers, Chevron-Texaco was to undertake drilling the 1 Suakin wildcat about 40 kilometers off the Sudanese coast. Two other offshore license holders conducted preliminary seismic work during the year. Chevron-Texaco was the operator for Ball and Collins (Oil and Gas) Ltd., which held 17 onshore and offshore exploration permits. The Sudanese Resources Development Corp., a subsidiary of Oceanic Exploration Co., held 18 offshore licenses covering 14,500 square kilometers. Chevron also held exploration permits for an extensive area in the south and southeast interior that was being surveyed by Hunting Geology and Geophysics of the United Kingdom.

Approximately 20,000 tons of chromite was mined in the Ingessana Hills in southeast Blue Nile Province. Both the Government-owned Ingessana Hills Mines Corp. and the privately-owned Blue Nile Chromium Ltd. shipped their production through the Damazin railhead to Port Sudan for export. Production of chromite began in 1963 from open pits, which continued to operate in addition to one underground mine. In 1975, the Sudanese Government announced plans to double production capacity from 25,000 to 50,000 tons per year over the next 2 years. Since early 1974, Sudan's chromite resources have been the subject of a surveying and mapping program by a geologic team from China, which indicated the existence of 133 new chromite occurrences. Total reserves in the Ingessana Hills and also at Qala en Nahl in Red Sea Province and Sol Hamed in the north were estimated at 2 million to 4 million tons averaging 50% Cr_2O_3. During the year, the Sudanese Government began negotiations with Japanese firms for the development of chromite mining in the eastern part of the country and the construction of a ferrochrome plant.

Gold mined at the Gebeit mine in the Red Sea Hills and from smaller alluvial deposits totaled about 300 troy ounces in 1975. During the year, an agreement was signed with the United Kingdom firm Robertson International Co. for the study of gold deposits in the Serakoit region of the Red Sea Hills. The survey, which was to be completed in 1976, was to include an evaluation of the ore, a determination of means for gold extraction, and specifications and designs for required machinery.

Approximately 15,000 tons of gypsum was mined for local use in cement manufacture and other construction purposes. Gypsum deposits in three districts along the Red Sea coast north of Port Sudan were estimated to contain 92 million tons. The Red Sea Gypsum Mining Co. was reported to be conducting a feasibility study for the expansion of gypsum mining in the area. Other minerals produced in 1975 were 66,000 tons of salt from the saltworks near Port Sudan, and 250 tons of mica from a model project in the Shereik area of Northern Province.

Sudan once again invited bids for the construction of its long-planned chemical fertilizer complex at Port Sudan. Cremer and Warner (United Kingdom) were the original consultants on the project, which was to include a 450-ton-per-day ammonia plant and 650-ton-per-day urea plant. Plans called for the fertilizer complex to be completed in 1978 at an estimated cost of $30 million.

The assessment of Sudan's mineral resources continued during 1975 with assistance from West Germany, France, China, and the U.S.S.R., and a number of new exploration agreements were concluded. The United Nations Revolving Fund for Natural Resources Exploration was to finance a project for the exploration of copper, gold, and other minerals in the Sabidana Hills of Red Sea Province. A total area of 750 square kilometers was to be surveyed over a period of 1 to 2 years at a cost of $400,000 to $500,000. Sudan also concluded an agreement with West Germany to explore for copper, tin, mica, and other minerals in the Baiyuda Desert in Northern and Nile Provinces. The U.S.S.R. continued its study of a 75,000-square-kilometer area in Red Sea Province that focused on the identification and evaluation of iron ore deposits. Estimated reserves in three Red Sea districts were 13.5 million tons of ore with an average iron content of 40% to 50%.

An agreement was signed between the Sudanese Government, Johns-Manville Co. Ltd. (Canada), and Gulf International Corp. for a feasibility study of asbestos deposits in the Jibal and Qala en Nahl areas. Initial exploration by the Geologic and Mineral Resources Department outlined reserves of 20 million tons of asbestos ore in the Jibal District, and total deposits in the area were believed to contain 60 million tons.

AGIP was granted a license in November 1975 for uranium exploration in the Nuba Mountains of Southern Darfur Province. Gulf International Corp. and Westinghouse also signed a contract for preliminary uranium exploration in North Darfur and Red Sea Provinces. Exploration was to begin in mid-1976 for a period of 6 months, following which their findings were to be submitted to the Sudanese Government.

A Sudanese agreement with the West German firm Preussag AG for the exploration of minerals on the Red Sea bed was abrogated during the year. The newly formed Joint Sudanese-Saudi Arabian Commission for the Exploitation of Red Sea Resources was to enter into negotiations with various firms for geologic studies of the seabed. Previous exploration in 1968 indicated the existence of gold, silver, copper, zinc, and manganese mineralization in deposits at a depth of 7,000 feet midway between the Arabian peninsula and Sudan.

SWAZILAND [65]

The mineral industry continued to be an important factor in Swaziland's general economic growth, and contributed to a 6% increase in the country's GDP, from $184 million[66] in 1974 to $195 million in 1975. Asbestos and iron ore dominated mine production, comprising 95% of the total value of mineral sales. Minerals produced were asbestos ($12.3 million), iron ore ($10.8 million), coal ($965,000), granite ($220,000), kaolin ($32,000), barite ($7,000), and tin ($3,000). Asbestos and iron ore, the two main export minerals, accounted for approximately 13% of total export receipts, which reached $183 million in 1975. Swaziland's greatly increased export earnings resulted in an overall balance of payments surplus of $51 million in 1975.

Swaziland's monetary, exchange rate, and economic policies remained closely intertwined with those of the Republic of South Africa. This was reinforced by Swaziland's membership, with Lesotho and South Africa, in the Tripartite Rand Monetary Area, and in the four-nation South African Customs and Currency Union, which included Botswana, Lesotho, and the Republic of South Africa. In 1975, approximately 90% of Swaziland's imports came from the Republic of South Africa. Imports of refined petroleum products, predominantly from the Republic of South Africa, were valued at approximately $14.5 million, or about 13% of total import value.

Discussions continued between the Swaziland Government and the IBRD regarding construction of a large thermal power station based on domestic coal resources. In 1975, generating capacity of the Swaziland Electricity Board (SEB) was limited to small hydro and diesel units producing about 20 megawatts, with additional power purchased from the Electricity Supply Commission of South Africa (ESCOM). The proposed project was initially to consist of two 100-megawatt generators powered by coal from a new mine with a 384,000-ton-per-year capacity to be developed near Mpaka. Plans called for the entire electric power output to be purchased by ESCOM and integrated into the South African grid system, with Swaziland buying back requisite power at cost. The Government of the Republic of South Africa was to partially finance the project through a long-term loan of $40 million.

The production of iron ore at the Ngwenya mine, situated 25 kilometers northwest of Mbabane, remained at the 1974 level of 2.2 million tons. The Swaziland Government held a 20% interest in the mine, which was operated by the Swaziland Iron Ore Development Co. (SIODC), a subsidiary of the Anglo American Corp. The entire production was railed 298 kilometers to the port of Maputo (formerly Lourenço Marques) in Mozambique for export. Except for small shipments to the Netherlands, iron ore was exported exclusively to Japan under a long-term contract. Swaziland's rail freight costs, which increased substantially due in part to irregularities in shipments through Mozambique, were a critical factor in renegotiating a supply agreement with Japanese steel mills. Upon the completion of a 10-year high-grade iron ore contract in mid-1975, a 3-year contract for 2 million tons per year of medium-grade ore (minimum 60% Fe) was concluded. SIODC was expected to discontinue operations at the Ngwenya mine during 1978 after stockpile depletion.

The evaluation of Swaziland's low-grade iron ore continued during 1975. Low-grade ores are found chiefly in the northwest highlands between Ngwenya and Hoho and in the south between Gege and Maloma. Total reserves were estimated at 576.4 million tons with an average 34.2% iron. However, preliminary laboratory investigation of samples obtained by drilling several formations indicated that iron content, average grain size, and beneficiation and transport factors mitigated against exploiting the deposits in the near future.

The export value of asbestos surpassed that of iron ore for the first time in 1975. Asbestos production at the Havelock mine, located at Bulembu in the northwest, increased from 32,421 tons in 1974 to 37,600 tons in 1975 despite increasing difficulties in ore extraction at lower mine levels. The major part of output of asbestos fiber was exported from Maputo to the United Kingdom, Ireland, Belgium, Denmark, and Malaysia. The Havelock mine, which

[65] Prepared by Candice Stevens.
[66] Where necessary, values have been converted from Swaziland Emalangeni (E) to U.S. dollars at the rate of E1=US$1.3663.

opened in 1939, was owned 40% by the Swaziland Government and 60% by Turner and Newall, Ltd. (United Kingdom). Discussions were held during the year between Havelock Asbestos Mines (Swaziland), Ltd., which operated the mine, and Lonrho Ltd., concerning the best approach to optimizing reserves in the lower part of the ore body. Lonrho Ltd. held a prospecting concession adjacent to the Havelock mine but reported no new results at yearend.

Although it was indicated that remaining reserves of iron ore and asbestos were limited, Swaziland's minable coal reserves were estimated at 200 million tons. In 1975, production of bituminous coal by Swaziland Collieries Ltd. at Mpaka increased slightly to 126,900 tons. Coal production was used by Swaziland Railways and local industrial and agricultural interests and was exported to Kenya and Mozambique. During the year, Swaziland Collieries proposed the development of a new coal mine to produce low-ash, metallurgical coal for export. The project, which would involve the sale of 371,000 tons of coal per year for approximately 15 years, was to be further evaluated.

New prospecting licenses were issued for the study of Swaziland's coalfields, which extended 150 kilometers in a north-south direction between Bordergate and Pongola. Shell Coal (Swaziland) Ltd. was awarded an 800-square-kilometer tract for exploration for coal, radioactive minerals, and oil shale. To the south of this area, Sir Alfred McAlpine and Son Ltd. was awarded a 260-square-kilometer tract for coal prospecting. A third tract was held by Johannesburg Consolidated Investments (JCI), who was conducting a feasibility study of mining the large anthracite reserves at Maloma. In addition, as part of the preliminary work for the proposed thermal power station, the Swaziland Government assumed the financing of the evaluation of coal reserves in the area around the Mpaka mine.

A fertilizer plant, operated by Swaziland Chemical Industries (Pty.) Ltd., commenced operation at Matsapa at yearend 1975. Initial production of the plant, which manufactured chemical fertilizer from ammonia and phosphoric acid imported from Iran, was to be 1,000 tons per month increasing to 4,000 tons. Output was to be marketed in Swaziland and the Republic of South Africa. Swaziland Chemical Industries was also planning to construct a $3 million phosphoric acid plant at its Matsapa complex, which was to be completed by 1977.

A potential addition to Swaziland's mineral sector was the Piggs Peak gold mine, the reopening of which was under consideration by the Government. The Piggs Peak mine, situated in the northwest corner of the country, was first mined in the early 1880's but has been dormant since 1951. Geological examinations during the year indicated the extension of one of the main veinlets below the old workings, and prompted the dewatering of the lower mine levels and the refurbishing of the main shaft. Although applications from interested companies were invited for working the deposit, the Government planned to complete the assessment of remaining grade and tonnage prior to issuing development permits. Three other gold occurrences were also investigated in 1975, and the initiation of a small gold leaching operation just south of Forbes Reef was planned.

Approximately 780 kilograms of tin concentrates were produced at the Pentoyz mine, owned by R. D. and B. Tin Mine (Pty.) Ltd. As a result of the discovery of workable eluvial tin deposits in 1974, a small-scale tin sluicing operation was set up during 1975. Further evaluation of the deposits, situated north of Kubuta about 6 kilometers west of the Pentoyz mining lease, indicated about 100 tons of cassiterite.

Kaolin production increased slightly from 2,236 tons in 1974 to 2,660 tons in 1975. The mine at Mahlangatsha northeast of Sicunusa was bought in 1974 by the Swaziland Government from Kaolin (Swaziland) Pty. Ltd. Tests were in progress to ascertain the commercial value of lower-grade kaolin reserves in the concession area.

Barite production at the Londosi mine operated by Swaziland Barytes Ltd. declined from 296 tons in 1974 to 200 tons in 1975. Continued drilling at the mine, situated northwest of Mbabane, proved 90,000 tons of salable barite and indicated another 200,000 tons of reserves. A dry beneficiation plant was commissioned and the installation of a flotation plant was proposed.

Approximately 40,700 cubic meters of granite was produced at the Van der Meer quarry and sold for use in the domestic construction industry.

De Beers Consolidated Mines continued prospecting operations for diamond on their Ehlane, Dokolwaya, and Spekboom tracts, which cover an area of over 260 square kilometers. At Ehlane, operations consisted of soil sampling, drilling, trenching, and pitting, while on the other two licenses, operations were confined to soil sampling. De Beers renewed its prospecting rights in 1975 and agreed to spend approximately $5 million on diamond exploration.

Other exploration was conducted by Eland Exploration, which held three prospecting licenses covering an area of 115 square kilometers. In the Elangeni tract, operations were directed toward outlining copper-nickel-cobalt mineralization by means of geochemical prospecting and geological mapping. In the Forbes Reef and Ngwenya areas, the objective of exploration was copper and nickel with associated gold. Activity in 1975 consisted of mapping, trenching, and geochemical soil sampling.

The Swaziland Geological Survey and Mines Department, responsible for the regulation and development of mineral resources, undertook several other investigations during the year. Calcite veins at Nsalitshe were found to contain approximately 5,000 tons of coarse-grained calcite. The preliminary assay showed the material to consist of 97.4% calcite, 1.3% combined iron, magnesium, and aluminum oxides, and 0.9% silica. An occurrence of talc north of Sicunusa was examined and proved to be schist with primary constituents of talc, tremolite, chlorite, and anthophyllite. In addition, testing was conducted on samples of beryl obtained from eluvial workings north of Kubuta. The Department planned to investigate the economic feasibility of developing these mineral deposits as small-scale operations.

TOGO [67]

Since the nationalization of the country's only large industry, the Compagnie Togolaise des Mines du Bénin (CTMB) in early 1974, and the concomitant rise in phosphate sale prices from $16 to $75 per ton,[68] Togo's economic picture changed radically but unevenly. The dramatic rise in foreign exchange holdings resulted in a spending boom and a consequent overstimulated economy characterized by high inflation. In 1975 the economic scene shifted as demand for phosphate rock was down 55%, from 2.6 million tons in 1974 to 1.2 million tons in 1975, owing to overstocking during the previous year. The last quarter of 1975 registered, according to Office Togolaise des Phosphate, phosphate prices at about $50 per ton. The drop in sales coupled with a high rate of government spending throughout 1975 resulted in a significant 80% reduction in foreign exchange holdings and a difficult balance of payments situation.

The construction of the country's only phosphoric acid fertilizer plant at an estimated cost of $200 million, and other facilities that would produce, among other products, 1,000 tons of phosphoric acid, remained at the study stage. Some French firms showed interest in financing and building the plant. The initial capacity of the plant calls for the annual utilization of 1 million tons of phosphate rock as a feedstock.

A joint venture between the Government of Togo, the Ivory Coast, and Ghana to construct a cement plant, Ciments de l'Afrique de l'Ouest (CIAMO), at a cost of approximately $280 million came closer to reality by yearend 1975. The World Bank agreed to participate in financing of the cement project by providing $50 million. The cement plant, with an annual 1.2-million-ton capacity, was to be financed primarily from European sources, and most of the plant's production was to be shared among the three governments.

Construction of a 30,000-barrel-per-day petroleum refinery, located at Tahligbo, financed and built by British firm, was to go onstream by mid-1977. Seventy-five percent of the refinery output was slated for export, mostly to the European market. The balance would be used to fuel the phosphate industry and about 20,000 registered vehicles in the country.

The second 5-year development plan (1971–75) period closed at yearend with generally unfavorable results. Reportedly, only 50% of its declared objectives were

[67] Prepared by E. Shekarchi.
[68] Where necessary, values have been converted at a rate of CFAF255=US$1.00.

accomplished, since the rural sector never recovered from their chronic problems. Although the third (1976–80) plan's objectives were announced more than a year ago, the plan document was not yet released at yearend 1975. The spending ceiling of this plan was given at over $1 billion, and the focus of the plan was on industrialization, expanded communications, and transportation facilities.

After almost 7 years of exploration, the West German firm Uranerzberghau delineated a section of northeastern Togo as the most promising uranium mineralization area of the country. The uranium finds covered an area from Bafilo to Nimatongon and a second area extending from Sokode to Kaude and perhaps to the Bénin border. The company was looking into narrowing the mineralized area to an exploitable target area in the future. Neither type of mineralization nor the grade of ore was given by yearend.

UPPER VOLTA [69]

The mineral industry of Upper Volta was an insignificant factor in the country's economy in 1975, with no mineral products exported during the year and very little produced for local consumption. However, progress was made on the nation's major mineral project, the exploitation of extensive manganese deposits at Tambao. It was hoped that the creation of the necessary infrastructure for this primary venture would stimulate further development of mineral resources in Upper Volta. The Office Général des Projets de Tambao was created in 1974 not only to oversee the manganese project, a related rail link, and energy and water supplies, but also to develop a cement operation at Tin-Hrassan. Other prospective ventures in the mineral sector were the construction of a second cement plant, the exploitation of phosphate deposits, and the reopening of a gold mine that ceased production in 1966.

A new government policy adopted during the year stipulated that the Government of Upper Volta must have a 51% share in all enterprises and joint ventures in the agricultural, industrial, and mining sectors. In general, the economy again evidenced a substantial balance of trade deficit in 1975, but this was more than offset by extensive foreign assistance in the form of loans and grants. Foreign aid, which totaled more than $60 million,[70] was obtained primarily from France, West Germany, Canada, the Netherlands, the United States, China, the EDF, and the IBRD. Approximately $2 million was received from the ADB to alleviate the effects of oil price increases, which considerably widened the balance of trade gap. In 1975, Upper Volta imported approximately 585,000 barrels of refined petroleum products from Venezuela, Curaçao, and the Ivory Coast.

Plans were finalized during the year for exploitation of the manganese deposits at Tambao, situated 300 kilometers northeast

[69] Prepared by Candice Stevens.
[70] Where necessary, values have been converted at the rate of CFAF224=US$1.00.

of the capital Ouagadougou. The Tambao deposit, discovered 17 years ago, was estimated to contain reserves of 13.5 million tons of manganese oxide ore with an average of 54% manganese content and an additional 13 million tons of manganese carbonate ore averaging 48% manganese. The annual extraction rate was projected at 625,000 tons of manganese ore through a surface mining operation. Completion of the project was expected to be in 1980, with development costs set at $30 million.

In 1975, the Société Minière de Tambao was established to finance the development of the Tambao deposits. The major shareholder was the Upper Volta Government, which held 51% equity. Other participants were the Tambao Manganese Reserves Development Co., a consortium of 11 Japanese firms (30%); Union Carbide Corp. of the United States (7%); Exploration and Bergbau (9%); and the Société du Managanese (3%). The foreign partners in the venture were pledged to buy the entire production of the mine in proportion to their shareholdings. This formula provided for the output to be allocated 383,000 tons to Japan, 115,000 tons to West Germany, 89,000 tons to the United States, and 38,000 tons to France per year.

The Tambao mine development costs took second place to the financing of a railroad link with the Regie des Chemis de Fer Abidjan-Niger railroad system terminating at Ouagadougou. The cost of the 340-kilometer railroad, which would provide a continuous linkage from Tambao to the port city of Abidjan in the Ivory Coast, was set at approximately $114 million. This included the cost of construction, the purchase of locomotives, the development of supporting facilities, and a 10%-per-year reevaluation rate until 1979. An international group of donors pledged varying amounts for the financing of the project, and the Upper Volta Government was to assume the balance of the costs. This consortium included France ($23 million), the EDF ($18 million), Japan ($15 million), West Germany ($15 million), Kuwait ($14 million), the ADB ($13 million), and the Arab Bank for Economic Development in Africa ($10 million). In August 1975, the Upper Volta Government issued a tender for bids for the construction of the railroad, which was scheduled to begin in early 1976.

The Tambao railroad was also to serve a cement factory to be built at Tin Hrassan, situated 29 kilometers northwest of Tambao. The plant was to utilize limestone from a nearby quarry, where reserves were reported at 56 million tons of rock averaging 46% CaO and 3% MgO. In addition, the Société Voltaïque pour l'Avancement de l'Industrie, du Commerce et de l'Agriculture was to undertake as its first major project the construction of a cement plant processing imported clinker. Startup was to be in 1976 at an initial capacity of 30,000 tons of cement per year.

The new railroad was further expected to boost the joint development projects of the three-nation Liptako-Gourma Development Authority. This office was created in 1972 to promote the advancement of an underdeveloped area covering east-central Niger, western Mali, and northeastern Upper Volta. In 1975, the Authority received a loan of $500,000 from the ADB for the construction of a road connecting Dori in Upper Volta to the Niger capital of Niamey. The Authority also sought financing for the extension of the projected Tambao railway to Ansonga in Mali, with a branch to Niamey.

Several mineral research programs were conducted in previous years in Upper Volta, most notably by BRGM and the UNDP. Although significant mineral deposits were located and evaluated, exploitation of mineral resources has been inhibited by Upper Volta's lack of infrastructure and deteriorating economic situation. Among the most noteworthy deposits were copper reserves at Dienemara estimated at 40 million tons of ore containing 0.8% copper and 2 grams of gold per ton; a second manganese deposit at Kiéré estimated at 500,000 tons; titaniferous and vandiferous magnetite at Tin Edia with estimated reserves of 50 million tons of ore containing 40% to 45% Fe, 9% to 14% Ti, and 1% V_2O_5; and bauxite deposits in the Kaya-Kongoussi area believed to contain from 3 million to 5 million tons. Other mineralization of potential commercial value included marble deposits at Tiara, diamonds in the Camoe Basin, lead deposits at Gan, and antimony in the Mafoulu region.

Another possible development was the reopening of the Poura gold mine, situated 175 kilometers southwest of Ouagadougou. The mine was closed in 1966 after it was estimated that approximately 75% of the deposit was exhausted. However, Société de Recherches Minières (SOREMI) announced in 1975 that the mine could be operated for 4 additional years at a rate of 80,000 tons per year of ore. The rehabilitation of the Poura mine facilities was under consideration at yearend.

Mineral exploration was active in Upper Volta during 1975, and a number of new agreements were concluded during the year. An agreement was signed for the evaluation of phosphate mineralization in the southeastern Diapaga area with the French Aid and Cooperation Fund. The first phase of the study was estimated to cost $200,000. The reserves at Arly were previously reported to contain between 3 million and 4 million tons of ore grading between 27% and 31% P_2O_5. A second program for a general mineral survey of the southwestern part of the country was organized by the UNDP. The survey was to begin in 1976 for a period of 1 year, with costs set at $830,000. In addition, Upper Volta received aid from Canada in the amount of $20 million over a 5-year period, which was to finance, among other things, a geophysical survey of selected areas.

The Mineral Industry of the Islands of the Caribbean

By Nicholas G. Theofilos [1]

CONTENTS

BAHAMAS

Although the Bahamas are endowed with interesting geologic conditions, with a potential for petroleum, no exploration activity was undertaken during 1975. The only exploration interest in the island and its offshore potential was in connection with the proposed leasing of the Blake Plateau offshore towards the U.S. coast.

The Bahamas Oil Refining Co. (BORCO), whose refinery in Freeport has a capacity of 500,000 barrels of oil per day, was one of the largest employers in the Bahamas, as well as the largest single industrial enterprise. The refinery's crude petroleum was imported from Iran, Saudi Arabia, and Nigeria.

The Bahamian Government had been redrafting its petroleum law for 2 years, but at yearend 1975 it had not been completed.

The production of mineral commodities in the Bahamas is shown in table 1.

e Estimate. p Preliminary. r Revised. NA Not available.

[1] In addition to the countries listed individually in this table, Bermuda, Grenada, and St. Lucia presumably produced crude construction material (clays, sand, gravel, and stone), but output is not reported and available information is inadequate to make reliable estimates of output levels.

[2] In addition to the commodities listed, mineral commodity output may also include crude construction materials (clays, sand, gravel, and lime) other than those listed, but data on such production are not collected and available information is inadequate to make reliable estimates of output levels.

[3] In addition, gypsum, iron ore, manganese ore, pyrite, and salt, all produced in significant quantities prior to the termination of publication of official statistics, presumably were produced during the period covered by the table, but information is inadequate to formulate reliable estimates of output.

[4] Period covered is for year ending June 30 of that stated.

[5] Includes nickel content of nickel oxide and nickel fonte in addition to metallic nickel and ferronickel.

[6] Export figure, all production presumed to be exported.

[7] Presumably, salt is also produced but output is not reported and information is inadequate to make reliable estimates of output levels.

[8] Consumption figure.

[9] Figure reported in thousand cubic meters.

[10] Figure included in gasoline.

[11] Less than ½ unit.

[12] Figure reported in thousand metric tons.

BARBADOS

The gross domestic product (GDP) of Barbados (at market prices) rose from $592 million in 1974 to $700 million in 1975. The outputs of petroleum products, natural gas, chemicals, and electricity increased over those of 1974. Production of quarry products and other construction materials decreased substantially from 1974 output, owing to reduced activity in the construction sector.

General Crude Oil Co., the only producer in Barbados, more than doubled crude petroleum production in 1975 from that of 1974. Average output from the Woodbourne Field was about 338 barrels per day, compared with about 160 barrels per day in 1974. Five development wells were drilled during the year; all were producers. A local refinery owned by a Mobil Oil Corp. affiliate, with a capacity of 3,000 barrels per day, processed both domestic and imported crude oil.

The linkup between the national distribution grid and the natural gas supplies at Woodbourne was completed in October 1975, and Natural Gas Corp. took delivery of 244 million cubic feet of natural gas. It was estimated that natural gas found in association with crude oil at the Woodbourne and Lowthers Fields would satisfy local demands over the next 5 years.

Production of mineral commodities in Barbados is shown in table 1.

BERMUDA

The principal mining activity in Bermuda was the production of small quantities of sand, dimension limestone, and crushed limestone. Construction activity, which had been in a steady decline for the past few years, appeared to have bottomed out. Production of crushed limestone was about 67,000 tons in 1975. The majority of this output was used as an aggregate in asphalt mixes, and the remainder in concrete construction.

CUBA

Estimates of Cuban mineral production for 1975 are shown in table 1. In 1974 (latest data available), industrial output, measured in terms of constant 1965 prices, was almost one-third higher than in 1970. Nickel production was one of the most important items of the industrial sector. Production increased significantly with the opening of a new plant in the 1960's and then stabilized at around 35,000 to 37,000 tons per year. In 1975 nickel production accounted for about 14% of the value of Cuban exports.

Construction of two new 30,000-ton-per-year nickel plants was planned after Cuba was assured technical and financial assistance from the U.S.S.R. and other centrally planned economy countries. At the Nicaro and Moa Bay nickel plants, where most of Cuba's nickel was produced, modern equipment was installed to replace older machinery which was becoming obsolete. The Nicaro mine produced almost one-half of the country's nickel in the form of nickel oxide and sinter, with a metal content of about 90%. The remaining production came from the Moa Bay plant in the form of a concentrate containing slightly more than 60% nickel.

Alcan Canada Products, a subsidiary of Alcan Aluminium Ltd., contracted with Cuban aluminum producers to assist in the expansion of an aluminum plant near Havana.

Production of construction materials tripled over the last 5 years, and the present capacity of the cement industry was estimated at 2.4 million tons per year. Another cement plant with a capacity of 1.5 million tons per year was scheduled to go onstream in 1975.

DOMINICAN REPUBLIC

The real rate of growth of the gross national product (GNP) of the Dominican Republic was about 5.5% in 1975, significantly below the 8.9% rate which was registered in 1974. This was mainly attributed to drought and electric power shortages combined with the inflated price of petroleum and other imports. The mining industry, however, has been playing an increasingly important role in the economy of the country for the last few years, with the value of mineral production increasing 26.5% in 1975.

During the year, two mining ventures of world status were in operation. The first, a nickel project, was the fourth largest producer in the market economy countries. It was operated by Falconbridge Dominicana C. por A. (Falcondo), a subsidiary of Falconbridge Nickel Mines of Canada. Falcondo's ferronickel was purchased and marketed by Falconbridge International Ltd., which exported ferronickel ingots to Europe, the United States, and Japan. About 2.1 million tons of ore was mined in 1975; ore reserves at yearend 1975 were about 57.8 million tons grading 1.58% nickel.

The second mining venture of world status was the Pueblo Viejo open pit gold-silver mine, which became one of the largest gold mines in the Western Hemisphere. The mine, located in Sanchez Ramirez Province in the north-central region of the country, was operated by Rosario Dominicana, S.A., a joint venture of private U.S. investors and the Dominican Republic. Total investment in the complex was $45 million, with a 40% interest held by Rosario Resources Corp., 40% by Simplot Industries, and 20% by the Dominican Republic Central Bank.

Startup problems were resolved during the year, and design capacity of 7,260 tons per day was reached in October 1975 along with anticipated metal recoveries. In 1975, the mill treated 1,542,566 tons of ore grading 0.130 troy ounce of gold and

0.148 troy ounce of silver per ton and produced 307,142 troy ounces of doré bullion containing 195,488 troy ounces of gold and 109,463 troy ounces of silver. Reserves of oxide ore at yearend 1975 were 26.5 million tons averaging 0.139 troy ounce of gold and 0.749 troy ounce of silver per ton. The underlying sulfide reserves were estimated at 21.1 million tons grading 0.115 troy ounce of gold and 0.839 troy ounce of silver per ton, 1.40% zinc, and 0.14% copper. Since conventional methods of processing these sulfide reserves were not economic, an active sulfide ore research program was started during the year to supplement previous work.

Work was in progress to restore and improve the area of the Pueblo Viejo mine. Tailings from the cyanide milling operation were being retained behind the new 1-kilometer-long tailings dam, which cost nearly $5 million for the first phase which raised the dam to a height of 140 meters. Total cost was expected to be nearly $10 million when the dam is completed to a height of 166 meters.

In accordance with the provisions of the Mining Law, Rosario Dominicana applied to convert its Los Cacaos exploration concession, adjacent to the Pueblo Viejo mine, on which Rosario discovered a lower grade gold-silver ore body, to a mining concession. This application was held up owing to a difference of opinion between the Government and the company regarding the manner in which the concession was to be exploited. The authorities proposed that a new 8,000-ton-per-day mill should be installed, but the company maintained that the deposit should be developed by an enlargement of the Pueblo Viejo mill by a 4,000-ton-per-day expansion program.

During 1975, the Aluminum Company of America (Alcoa) shipped 753,601 tons of bauxite to its processing facilities at Point Comfort, Texas, from its Cabo Rojo mine in the Dominican Republic. The comparable tonnage for 1974 was 1,209,548 tons. Some 54 out of the 300 employees that were employed at the beginning of 1975 were not with the company at yearend, owing to attrition and layoffs. In November 1975, Alcoa signed a new contract with the Dominican Republic increasing the return to the Dominican Government for each ton of bauxite exported by about 50%. The contract was to expire in December 1976.

As of yearend 1975, there was no production of crude petroleum in the Dominican Republic. Four companies were negotiating with the Government for exploration concessions. The only refinery in the country was equally owned by Shell Oil Co. and the Government. The refinery had a capacity of 30,000 barrels per day. Almost all of the crude petroleum input was imported from Venezuela.

All local cement production was by a state-owned company. During 1975, about 500,000 tons of cement was produced. Approximately 150,000 tons was imported to fulfill the country's consumption demand. Two new cement plants were scheduled for completion in 1976, which would make the Dominican Republic a net exporter of cement.

HAITI

The only significant mining in Haiti in 1975 was for bauxite and was conducted by Reynolds Haitian Mines S.A., a subsidiary of Reynolds Metals Co. Following the partial recovery in bauxite prices in 1973, Reynolds increased its exports substantially. This was followed by higher taxation on the bauxite industry. Negotiations led to agreement between Reynolds and the Government on the 1975 tax rates. The company was to pay 8% of the price of aluminum ingots realized in the United States, plus a levy of 50 cents per ton. The 8% tax was to be reduced by any income or other taxes which may be payable. A severance levy of $2 million in 1975 also was to be paid by Reynolds.

Kennecott Copper Corp. and Peñarroya, a subsidiary of a French concern, were granted mineral prospecting rights by

Haiti. Each of the firms was awarded 100 square kilometers in northern Haiti where large copper deposits were reportedly found earlier in the year.

On March 25, 1975, the President of Haiti signed a decree establishing an independent agency to coordinate mineral activities. Specifically, the new agency was to be responsible for the exploration, conservation, development, and utilization of the country's resources.

JAMAICA

The worldwide inflation, accompanied by a recession in the manufacturing industries of the Western World, had an adverse effect on the Jamaican bauxite and alumina industries. The United States and Canada, Jamaica's major outlets for its bauxite and alumina, reduced their demand significantly. Nevertheless, Jamaica remained the second largest bauxite-producing country in the world, after Australia. The loss of Government revenue from the declining bauxite and alumina exports was largely compensated for by the higher production taxes levied in 1974 and 1975.

Reynolds Jamaica Mines, Ltd., a subsidiary of Reynolds Metals, and the Government entered into a preliminary agreement concerning future operations by Reynolds in Jamaica. The agreement contemplated the sale by Reynolds to the Government of a 51% share in the mining assets, and all of Reynolds' land holdings in Jamaica, at book value, to be paid in 10 equal annual installments, with interest. A partnership between the Government and Reynolds was to continue the mining operations. The partnership was to be managed by Reynolds Jamaica Mines under an initial 7-year management contract, subject to policy direction by an executive committee composed of an equal number of representatives from the Jamaican Government and Reynolds. The agreement was reported to include reductions in Jamaican income taxes paid by Reynolds. This agreement was contingent on a commitment by Reynolds to construct a new alumina plant in Jamaica. This plant was to be part of the 600,000-ton-per-year alumina plant planned by the Governments of Jamaica and Mexico for the projected aluminum smelter in Mexico.

In August 1975, Revere Jamaica Alumina, Ltd. (RJA), a subsidiary of Revere Copper & Brass Inc., temporarily suspended its mining and alumina operations. Under Jamaican mining law, suspension of mining beycnd 6 months required the consent of the Minister of Mining. RJA had sought such consent but as of year-end had received no response. During the year, the Minister of Public Utilities and Transport announced the establishment of a national merchant shipping fleet to be known as Jamaica Merchant Marine, Ltd. The establishment of the fleet was based on an agreement with the national shipping line of Mexico. The national shipping line was to help strengthen and protect Jamaica's trade and reduce the loss in foreign exchange paid to transport the substantial volume of bauxite and alumina exports to extraregional destinations such as the U.S. gulf coast and eastern Atlantic ports. Long-range plans for the fleet included the transport of alumina from Jamaica to the Mexican smelter when it is established.

The Government announced plans for a new petroleum refinery to be built on the southwest coast (St. Elizabeth) between 1976 and 1978. The refinery was to have a capacity of 80,000 barrels per day and was to cost about $100 million. Mexico was expected to provide financial and technological aid. The Government was also negotiating terms for the purchase of Esso's 32,500-barrel-per-day refinery at Kingston. The Government expected that the state-owned complex would form the basis for new industrial developments in chemicals, fertilizers, and caustic soda.

MARTINIQUE

The economy of Martinique experienced strong inflationary pressures in 1975, and relatively little progress was made in the small industrial sector. Export-import trade increased, and the GNP increased at current prices from $654 million in 1974 to $769 million in 1975.

The major minerals produced in Martinique were construction aggregates, clays, marine salt, fertilizers, cement, and petroleum refinery products. Martinique's only refinery, S.A. Raffinerie Antilles, at Fort de France, had a capacity of 11,000 barrels per day. Principal refinery products were gasoline and residual and distillate fuel oil. Almost 40% of the refined petroleum products were exported.

The economy of Guadeloupe also experienced strong inflationary pressures in 1975. Mineral production was limited to construction aggregates and cement.

NETHERLANDS ANTILLES

Petroleum refining continued to be the most important industry in the Netherlands Antilles during 1975. Shell Curaçao, N.V., accounted for 40% of the GNP of Curaçao, one of the six islands in the Netherlands Antilles. Its refinery, covering more than 1,000 acres, employed about 3,000 workers. About 50% of the crude came from Venezuela, and the remainder came from the Mideast and Nigeria.

At the Aruba refinery of Lago Oil and Transport Co., a subsidiary of Standard Oil Co. (New Jersey), energy conservation became the highest priority in the last few years when the price of imported crude oil increased. Thus, strict control of process furnaces and boilers slashed fuel cost by $2.5 million in 1975.

Because of the shortages of cement, which the construction industry faced, along with the increase in the price of cement, a group of Netherlands Antilles investors formed Aruba Cement Co. and initiated plans for the construction of a cement plant in Aruba. Projected production was to be about 100,000 tons of cement per year, using local materials as much as possible. Construction of the facility was scheduled to begin in 1976.

The production of mineral commodities in the Netherlands Antilles is shown in table 1.

TRINIDAD AND TOBAGO

Trinidad and Tobago produced an average of 215,000 barrels of crude oil per day in 1975. Thus, oil was a significant factor in the country's large balance-of-payments surplus, and a major contributor to the country's strong economy. The Trinidad and Tobago Government inaugurated an 8-year development program, the object of which was to foster new basic industries and to fully utilize the higher oil revenues. The Government's policy of acquiring participation in the foreign-owned oil operations in Trinidad continued during 1975. The negotiations were rescheduled to begin in January 1976.

Most of Trinidad's production came from offshore fields. Recent increases in offshore production more than offset the long-term decline in onshore production. Of the total crude oil produced in Trinidad and Tobago in 1975, approximately 81% came from offshore. A large part of this crude was exported, but some was refined at the island's two major refineries. The refineries, with a combined capacity of 465,000 barrels per day, also imported a substantial quantity of crude oil from other countries for processing and subsequent reexporting as refined products, mostly to the United States. The major suppliers of the crude were Saudi Arabia and Indonesia.

Amoco Trinidad Oil Co. Ltd., a subsidiary of Standard Oil Co. of Indiana, produced and exported about 135,000 barrels per day of high-quality, low-sulfur crude. The crude was piped through a 16-inch underwater line to the Galeota Point base, where it was stored in 500,000-barrel tanks prior to shipment to Amoco's refinery in the United States.

Trinidad and Tobago Oil Co., Ltd. (TRINTOC), formed in 1974 to operate the Shell properties purchased by the Government, refined all of its crude production. The refinery's main products were bunker C fuel oil, motor gasoline, diesel fuel, and aviation fuel.

The Texaco refinery closed down for 52 days during March and April 1975 owing to a strike by the Oilfield Workers Trade Union (OWTU) during negotiations for renewal of OWTU's 3-year contract which had expired in February. Many manufacturing concerns were forced to reduce production and to lay off workers owing to the lack of fuel. As a result, on April 9 the Government took control of existing stocks of petroleum products and ordered military and police personnel to make deliveries of these products to the general public.

In mid-August the Government formally constituted the National Gas Co. of Trinidad and Tobago as a wholly-owned Government operation. The company was to own the natural gas pipeline network, which was being expanded. Upon completion, the pipeline network was to receive gas from 20 miles offshore and distribute it to industrial users.

Amoco's discovery of a substantial natural gasfield about 45 miles offshore Trinidad increased Trinidad's proven natural gas reserves to around 6 trillion cubic feet.

Deminex, a West German oil company, began exploratory drilling operations from a semisubmersible platform about 20 miles off the northern coast of Trinidad. Seismic surveys made the company optimistic that hydrocarbons were present. The company expected natural gas rather than oil in commercially exploitable quantities.

Texaco also conducted exploratory drilling in a concession known as the "L-shaped block" southeast of Trinidad. This area was adjacent to Amoco's offshore crude oil production area and presently untapped natural gasfield.

Plans for a trination (Guyana, Jamaica, and Trinidad and Tobago) joint-venture aluminum smelter, to be built in Trinidad, utilizing local natural gas to produce power to smelt alumina from Guyana and Jamaica, received a sharp setback towards yearend 1975. At that time Jamaica and Guyana, which were to supply the smelter with alumina, announced that they would be unable to proceed with the project because of the need to divert alumina to Venezuela and Mexico, where large-scale aluminum production was projected. The Trinidad smelter was to have been designed to produce 200,000 tons of aluminum per year.

It was proposed that the Iron and Steel Co. of Trinidad and Tobago be formed as a joint venture among the Trinidad and Tobago Government with a 67% interest, ESTEL NV Hoesch-Hoogovens of West Germany 16.5%, Kawasaki Steel of Japan 11.5%, and Mitsui & Co., Ltd., of Japan 5%. A basic agreement was signed by the participants to construct a steel mill at Point Lisas, the site previously chosen for an aluminum smelter. Plans called for a natural-gas-fired direct-reduction plant with a designed capacity of 1.2 million tons of steel per year. Production was to start by yearend 1978.

Plans for a $250 million petrochemical complex to utilize local crude oil and refinery products were announced in 1975. Technical assistance was to be sought from Austria and Romania.

The production of mineral commodities in Trinidad and Tobago is shown in table 1.

The Mineral Industry of Central American Countries

By Nicholas G. Theofilos [1]

CONTENTS

BELIZE

The mineral industry of Belize in 1975 was limited to the production of limestone, marl, sand, and gravel, all of which were primarily used on public work projects. Exploration for petroleum continued during the year. It included seismic surveys and exploratory drilling. Belize Chevron drilled one wildcat hole in northern offshore Belize. Ajax Chemical Limited, and Ariel International Ltd., the subsidiaries of a major international corporation, who have had an exploration permit since 1967, undertook seismic work in southern offshore Belize. Anschutz Overseas, Inc., drilled exploratory wells in the northern and southern parts of the country. All resulted in dry holes.

e Estimate. p Preliminary. r Revised. NA Not available.

[1] Production reported in cubic meters was as follows: 1974—210,000 and 1975—215,000.

[2] Excludes an amount reported in volumetric units of 8,000 cubic meters.

[3] Previously reported figures of refinery output for 1973 were actually 1974 data.

COSTA RICA

During 1975 economic activity in Costa Rica was maintained at a high level, led by the construction industry, with cement production increasing 11% for the second consecutive year.

The Government of Costa Rica was interested in a number of petroleum related projects. The Costa Rica Development Corp. (CODESA), in conjunction with Elf-Petroleos, a French concern, began drilling an offshore oil well just north of Port Limon. Also, the Government authorized the construction of a 93-mile, 48-inch cross-Isthmus pipeline to carry Alaskan and other crude oil from the Pacific to the Atlantic for ultimate shipment to the U.S. east coast. The pipeline was to have a capacity of 1.6 million barrels per day and was to be constructed by a consortium of Italian companies.

During 1975, Venezuela announced conceptual plans for a big refinery to be built in Costa Rica.[2] The crude oil will be supplied by Venezuela on a preferential basis.

About the middle of the year, the World Bank approved a $41 million loan for a fifth hydroelectric project in Costa Rica. This project will help Costa Rica reduce its dependence on imported petroleum while enabling the country to better meet its demands for electricity.

The search for alternative sources of power was given considerable thought in 1975. The Instituto Costarricense de Electricidad prepared a preliminary study of the country's geothermal potential. The volcanic range in Guanacaste Province was found to be the most promising site.

Kaiser Engineers of California made a feasibility study for a 500,000-ton-per-year cement plant. The plant could be in operation in 1978 if there were no delays in construction.

Towards yearend 1975, the Aluminum Company of America (Alcoa), confirmed that it was still seriously considering erecting a primary aluminum smelter in Costa Rica. Alcoa wished to provide alumina for the smelter from its Philippine or Jamaican facilities. However, the Government's plan was for the establishment of an aluminum plant based on local bauxite deposits, which to date had been largely unexploited.

Bulora Corp. Ltd.'s operations at the El Libano gold mine continued to improve after several startup problems. Underground workings were expanded and the reserves were added to with a fair increase in grade. The milling plant had been running steadily at 100-tons-per-day capacity with only minor shutdowns.

Hearne De Costa Rica, a subsidiary of United Hearne Resources, controlled three former gold producers. At the most promising operation, in Santa Clara, the exploration phase of the work had advanced to the stage where it was necessary to start bulk sampling. Studies showed reserves of about 750,000 tons of ore grading 0.10 troy ounce of gold per ton.

Table 2.—Costa Rica: Imports of mineral commodities—Continued

(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal sources, 1974
NONMETALS—Continued			
Stone, sand and gravel:			
Dimension stone:			
Crude and partly worked	121	273	Nicaragua 110; Guatemala 88; Italy 74.
Worked	95	47	Italy 16; Guatemala 15; Nicaragua 15.
Industrial stone	55	52	Nicaragua 48; France 4.
Sand, gravel, crushed rock, n.e.s	292	148	United States 143.
Other	2	(2)	Mainly from United States and Belgium-Luxembourg.
Sulfur:			
Elemental, all forms	(2)	49	NA.
Sulfur dioxide	(2)	1	United States 1.
Sulfuric acid	369	451	El Salvador 389.
Talc, soapstone, pyrophyllite	617	681	Italy 397; United States 146; Republic of Korea 96.
MINERAL FUELS AND RELATED MATERIALS			
Carbon black	1,395	1,748	Colombia 802; Mexico 613; Venezuela 236.
Coal and coke including briquets	496	383	West Germany 156.
Petroleum:			
Crude and partly refined thousand 42-gallon barrels	3,440	2,948	All from Venezuela.
Refinery products:			
Gasoline do	423	435	Venezuela 208; Netherlands Antilles 72; Trinidad and Tobago 54.
Kerosine do	110	57	Panama 43; Netherlands Antilles 14.
Distillate fuel oil do	695	673	Venezuela 494; Netherlands Antilles 158.
Lubricants (including grease) do	109	95	United States 33; Trinidad and Tobago 20; Netherlands Antilles 19.
Other:			
Liquefied petroleum gas do	118	225	Panama 71; Nicaragua 22.
Naphtha do	(2)	(2)	All from United States.
Paraffin do	20	66	West Germany 32; United States 14.
Petrolatum do	3	8	United States 8.
Unspecified do	157	353	United States 349.
Total do	1,635	1,912	
Mineral tar and other coal-, petroleum- or gas-derived crude chemicals	1,959	1,480	United States 912; Netherlands Antilles 520.

r Revised. NA Not available.
1 Metal oxides and hydroxides excluded as they were reported inseparably from metal salts and other compounds.
2 Less than ½ unit.

EL SALVADOR

The real growth in the gross domestic product (GDP) of El Salvador in 1975 was about 3.5%, somewhat above of the Central American average. A major contributor to this growth was the continued high level of public investment, such as the hydroelectric project at Cerrón Grande, and extensive road construction. The Government also continued its efforts in the geothermal energy area. The Comisión Ejecutiva Hidroelectrica del Rio Lempe (CEL) signed a contract with a French firm for a study of the geothermal potential in two zones near the existing facility at Ahuachapán. Meanwhile, the Comisión Nacional de Petróleo continued its invitations for oil exploration.

Canadian Javelin Ltd. expanded its exploration and diamond drilling and planned to explore known mineralized veins around the existing Los Encuentos and San Cristóbal silver and gold mines.

Bruneau Mining Corp., a subsidiary of Rosario Resources Corp., initiated a 5,000-foot diamond drilling program at the El Dorado gold property. The objective of the drilling was to extend the known ore occurrences and to indicate sufficient ore to justify dewatering the mine. The mine was operated from 1948 to 1953 by Rosario during which time 297,843 tons of ore averaging 0.28 troy ounce gold and 1.58 troy ounces silver were produced. The remaining reserves were reported to be 48,320 tons of ore grading 0.31 troy ounce gold and 1.78 troy ounces silver per ton.

A coal-based direct reduction sponge iron plant was proposed in order to relieve the expanding steel industry from its dependence on the volatile and uncertain international scrap market. The proposed plant was near Acajutla where Acero, S.A., the largest steel company, was in process of building a 100,000-ton-per-year electric furnace continuous-billet casting plant.

GUATEMALA

In December 1975 Guatemala's Congress passed a petroleum law clarifying some of the provisions in the 1974 petroleum code. Among the revisions added was the requirement for a $1 million signature bonus for each new concession. The law called for a 51%–49% production revenue split in favor of the Government, with the Government's share including credit for the operator's tax liability. Contracts were to be for a maximum of 20 years (versus 30 years previously). Finally, concession blocks were limited to 400,000 hectares (988,400 acres) with 5-year exploration terms.

The proving of considerable reserves of crude oil in southeast Mexico, and recent apparent discoveries in the Alta Verapaz District of Guatemala near the Mexican border, increased Guatemala's hopes of attaining self-sufficiency in crude petroleum and perhaps of becoming an exporter by the end of the decade.[3] As of yearend 1975, the country fully depended on imports to meet its petroleum requirements.

Shenandoah Oil Corp., which had previously drilled in northeast Guatemala, drilled Rubelsanto No. 3 and No. 4 wells in this area. Tests of the Rubelsanto No. 4 well showed oil from a dolomite limestone interval. The interval tested was at depths from 7,011 feet to 7,049 feet. The well flowed at a rate of 9,348 barrels per day through 3-½-inch tubing with two ¾-inch chokes.

The Guatemala-California oil refinery, a subsidiary of Chevron Oil Co., closed down around the middle of the year. The output of the refinery was to be replaced by the importation of finished petroleum products. The only refinery in operation in Guatemala at yearend 1975 was owned by Texaco, Inc.; its capacity was about 14,000 barrels per day.

Construction of facilities for the nickel project of Exploraciones y Explotaciones Mineras Izabal, S.A. (Exmibal), a consortium of International Nickel Co. Inc., and The Hanna Mining Co., reached the halfway point in 1975. It was scheduled to start producing in 1977, at an annual rate of 28 million pounds of nickel contained in nickel matte.

Basic Resources International, S.A., a Luxembourg firm, was seeking a partner for joint venture development of a nickel concession, adjacent to the Exmibal concession. Three lateritic ore deposits were reported to contain over 63 million tons of ore grading 1.7% nickel. Through subsidiaries, Basic Resources also holds several other mineral concessions in Guatemala. Their Oxec copper mine northeast of Guatemala City was operating at the rate of 400 tons per day, while producing 40 tons per day of copper concentrate.

The Instituto Nacional de Electrificacion, (INDE) began a project to develop geothermal resources in the southeastern part of the country. Drilling of exploratory wells was scheduled for early 1976.

Industria Centroamericana de Vidrio, S.A. (CAVISA), Guatemala's only glass manufacturing company, was expanding glass production and installed a new plant to produce silica and feldspar.

[3] The Petroleum Economist. Self-Sufficiency for Guatemala. July 1975, pp. 263–264.

HONDURAS

The mineral industry of Honduras continued to experience increases in the production of cement, silver, gold, lead, and zinc. On December 8, 1975, the Government issued by decree a new law which was expected to have an adverse effect on the profits of mineral companies in Honduras. This law replaced the 2.5% export tax with a graduated royalty. The royalty ranges from 5% for the first $50,000 to 20% for $5,000,000 and above. The Government had not decided whether to apply the royalty on the net smelter return, or on the net value f.o.b. of the material. The production tax for gold and silver was also raised from 4% to 5%. The 2% production tax on lead, zinc, and cadmium was not changed.

Rosario's El Mochito mine recorded the best year in overall metal production in its history. The mine produced 346,352 tons of ore, and the mill processed 345,737 tons containing 7.82% lead and 8.69% zinc and 10.98 troy ounces of silver and 0.007 troy ounce of gold per ton. Reserves at yearend 1975 were reported to be 6,323,249 tons of ore with an average grade of 5.20 troy ounces of silver and 0.003 troy ounce of gold per ton; 4.78% lead, 8.07% zinc, and 0.27% copper. Production at El Mochito in 1975 is shown in the following tabulation:[4]

[4] Rosario Resources Corp. Annual Report 1975, p. 5.

	Silver (troy ounces)	Gold (troy ounces)	Lead (metric tons)	Zinc (metric tons)	Cadmium (pounds)
Lead concentrates	2,510,924	1,354	22,453	3,490	--
Zinc concentrates	848,294	690	2,041	24,321	508,000
Doré bullion	182,004	227	--	--	--
Total	3,541,222	2,271	24,494	27,811	508,000

NICARAGUA

Despite a recession in several key sectors, including mining, the Nicaraguan economy as a whole had a 1.5% real growth in 1975. A major depressant was the collapse of the construction boom, which followed the destruction of Managua in the 1972 earthquake. Annual production of portland cement decreased from the 1974 record of 235,732 tons to 193,488 tons.

The large increase in the price of petroleum imports had a strong impact on the negative trade balance. All of Nicaragua's crude and partly refined petroleum came from Venezuela. Esso Standard Oil, S.A., a subsidiary of Exxon Corp., operated the only refinery in Nicaragua at 22,000 barrels per day. During 1975 the offshore potential of Nicaragua drew considerable attention from several interested oil companies, with about 30 concessions being granted.

Plans for a larger increase in public investment were underway, due to the infrastructure needs required for economic development. Since almost two-thirds of the country's electric power was being generated from petroleum-fed powerplants (the remainder was hydroelectric) the cost of electricity in Nicaragua was the highest in Central America. The Government and the National Power and Light Co. gave the development of alternative sources of power the highest priority.

One such project, a hydroelectric dam on the Rio Grande de Matagalpa, was being designed and the construction of it was planned to begin within 2 years. Another such project, the Momotombo geothermal project, involved the drilling of wells to produce enough steam to generate 10 megawatts of electric power, and plans were proposed to drill additional wells to reach 50 megawatts within tne next 2 years.

Rosario's Rosita mine was converted from copper production to gold production in March 1975 after the world price of copper dropped to about 50 cents per pound. During most of the remainder of the year gold-silver ores mined from surface workings at the Riscos de Oro, Blag, and California ore deposits were milled at the Rosita flotation mill while a cyanide plant with a 500-ton-per-day capacity was erected as an addition to the Rosita mill. Rosario started shaft sinking at the Blag and Riscos de Oro gold-silver veins in order to develop the underground reserves which were disclosed the previous year.

Rosario also continued work at the Siuna mine to dewater the open pit and underground workings. This former gold producer was shut down in 1968 following the loss of the hydroelectric plant in a flood. Restoration and repair of the mill buildings was started. Exploration drilling and other surface work indicated additional areas of interest.

At Noranda's Empresa Minera de El Setentrion gold mine, 129,000 tons of ore averaging 0.5-troy ounce gold per ton were treated to produce 59,400 troy ounces of gold. At yearend proven ore reserves were 209,000 tons of similar grade.

Neptune Mining Co.'s mill treated 181,-138 tons of sulfide ore grading 0.10 troy ounce of gold and 0.60 troy ounce of silver per ton, 1.0% lead and 7.2% zinc, and 31,764 tons of gold ore grading 0.15 troy ounce of gold per ton. The sulfide mines' reserves at yearend 1975 were estimated at 1,169,118 tons of ore grading 1.23% lead, 9.78% zinc, 0.44% copper and 0.108 troy ounce gold and 0.84 troy ounce of silver per ton. Gold ore reserves were estimated at about 61,000 tons grading 0.411 troy ounce of gold per ton.

Cerro Minas de Cerro Dorado started work on the former Santa Rosa gold-silver mine. A diamond drill and equipment for a 15-ton-per-day pilot plant were moved to the property.

PANAMA

At yearend 1975 Panama's major mineral industries were still limited to the production of building materials, salt, and petroleum refining. But the development of Cerro Colorado, a porphyry copper ore body located in the Province of Chirique, had been drawing considerable interest since its discovery in the 1960's. During 1975 the Government of Panama and Pavonia Exploration, S.A., the Panama subsidiary of Canadian Javelin Ltd. failed to agree on a contract to develop the mine. The Government spokesman cited two points of disagreement on the talks. First, Javelin's participation in the profits of the operation and second the duration of the operation. Since no agreement was reached, Javelin's participation in the venture was terminated. Javelin was compensated with $5 million in cash plus $18.6 million worth of 8% tax-free 20-year direct obligation bonds of Panama.

At yearend 1975 tentative agreements were reached with Texasgulf, Inc., for the development of Cerro Colorado. Under terms of the agreements, Texasgulf, as manager, was to initially conduct a feasibility study of the project for a fee. Texasgulf was to have a 20% equity participation in the project, and would have a management contract to construct the project and manage it for 15 years after startup. The Panamanian Government was to retain 80% ownership with an option to buy Texasgulf's share after 20 years. The deposit reportedly contained over 1 billion tons of ore grading 0.6% copper with some molybdenum and precious metals. The first phase of the project was planned to include a mine, concentrator, smelter, and refinery to produce 150,000 tons of copper metal per year. In a later phase, a phosphate fertilizer complex was contemplated, using sulfuric acid from the copper smelter. Texasgulf was to have a 49% interest in this phase.

In the Petaquilla area of Colón Province, Cobre Panamá, S.A., which was formed by Japanese interests headed by Mitsui Mining

& Smelting Co., Ltd., completed several diamond drill holes at a porphyry copper deposit.

Tuquesa Mining, S.A., a U.S. based company, was granted a 15-year concession to exploit the placer gold deposits in Darien Province covering an area of 3,750 acres. The company had been conducting exploration for the past 5 years. Pending completion of the Panamanian Highway, the site was only accessible by plane.

A local subsidiary of Texaco, Inc., and Panama signed a contract for offshore petroleum exploration in the Caribbean. Four exploratory wells were to be drilled over a period of 3 to 7 years.

The Mineral Industry of Other Areas of the Far East and South Asia

By Staff, Bureau of Mines

CONTENTS

AFGHANISTAN[1]

The mineral industry of Afghanistan has traditionally accounted for less than 6% of the gross national product (GNP), which in 1975[2] was about $1.6 billion.[3] Of the mineral deposits known to exist in Afghanistan, only natural gas, coal, salt, and lapis lazuli were mined in significant quantities in 1975. Potentially important deposits of iron ore, copper, beryl, and chromite remained largely unexploited. Other minerals of value to the domestic economy included marble, talc, and barite; all were produced in small quantities in 1975. The balance of activity in Afghanistan's mineral sector consisted of the production of cement and fertilizers.

The most significant development in 1975 was Iran's offer to finance construction of a railway system linking landlocked Afghanistan with Iran's transportation network and its Persian Gulf ports. The project, which was estimated to cost $1 billion, was scheduled for completion in 1983. In its initial stage, the railway was to run from the Iranian border point of Islam Qala to Herat in western Afghanistan, south to Kandahar, and then north to the capital Kabul. In its second stage, several branch lines were envisaged with top priority given to one opening up the Hajigak iron ore deposits 140 kilometers northwest of Kabul. Other extensions were to provide links with the railway systems of the Soviet Union and Pakistan. The proposed railway system would provide Afghanistan with an alternative trade route to the traditional transit arrangements with Pakistan.

The Afghan Government, in 1975, invited international bids for the exploration and exploitation of mineral resources in various parts of the country, with particular emphasis given to oil and natural gas. To govern these activities, a law was passed creating the Afghanistan National Oil Company (ANOC). Among ANOC's responsibilities were the development and implementation of a National Petroleum Law, all negotiations with foreign firms for exploration rights and permits, over-

[1] Prepared by Candice Stevens, economist, International Data and Analysis.
[2] All data are for Afghani calendar year beginning March 21 of year indicated and ending March 20 of following year.
[3] Where necessary, values have been converted from Afghanis (Af) to U.S. dollars at the rate of Af45=US$1.00.

sight of the firms' activities, and determination of the best uses of indigenous oil and gas reserves. The company's charter included the provision that any joint ventures between ANOC and domestic or foreign investors be at least 51% ANOC-owned. This corresponded to a revision made in 1974 to the Foreign and Domestic Private Investment Law requiring that all new ventures be 51% Afghan-owned and that all existing ventures conform to this stipulation after a negotiated interval. At yearend 1975, few ventures had been approved under the revised act.

In April, the Afghan Government granted what was believed to be the first exploration license to a western company. France's Compagnie Française des Pétroles (CFP) was awarded a 20,000-square-kilometer exploration area in the Katawaz Basin in the southeast, which constituted a geological extension of CFP's exploration tract in northern Pakistan. As part of the agreement, CFP contracted to train Afghan personnel in oil and gas technology in France, to make maximum use of the local Afghan labor force, and to carry out the future production and transfer of gas and/or oil commodities within the framework of joint companies.

Natural gas maintained its position as Afghanistan's most important mineral commodity in 1975, with production totaling almost 3 billion cubic meters. Under an agreement signed in February 1975, a total of 2.8 billion cubic meters was exported to the Soviet Union; the remainder was used in domestic power production and to fuel the Mazar-i-Sharif fertilizer plant. Export earnings from natural gas increased greatly in 1975, from $26.29 million in 1974 to $46.80 million, due to a doubling of the Soviet price paid for the commodity. The combined reserves of Afghanistan's five principal gas deposits, all situated in the northern part of the country just south of the Soviet border, were estimated at 100 billion cubic meters. In 1975, production was concentrated in the Khwaja-Gogirdak Field, while drilling continued at the Yatim Tag, Khwaja-Borhan, Juma, and Jarqduq Fields.

Afghanistan's natural gas production facilities were financed by the Soviet Union, which also assisted in the construction of a pipeline extension completed in 1975. The new surface pipeline, which had an annual capacity of more than 4 billion cubic meters of gas, spanned the Amu Darya River to link the Khwaja Gogirdak wells with the Turkmenistan area of the Soviet Union. The Soviet Union further contributed to the construction of two gas treatment plants, one at Khwaja Gogirdak, which was completed in 1975, and one at Jarqduq Field in Jowzjan Province, to be opened in 1976.

Afghanistan had no crude oil output in 1975 and a flow of only about 150 barrels per day of condensate from the Sar-i-pul Field in southern Jowzjan Province. The Soviet Union provided Afghanistan with nearly all its petroleum product requirements, which were estimated at about 2 million barrels. The search for indigenous petroleum resources continued in 1975, and exploratory drilling indicated a second oil-bearing area in the Aq Darya District of Jowzjan Province. Reserves of 2.5 million tons of recoverable oil had previously been discovered at Angut, approximately 7 kilometers from Aq Darya. Details pertaining to the oil refinery planned for Jowzjan Province were also announced in 1975. Afghanistan's first oil refinery was to be located 65 kilometers from the Angut and Aq Darya Fields and to be built with Soviet technical assistance. The refinery was scheduled to process approximately 1,400,000 barrels of crude oil and produce about 728,000 barrels of fuel oil, 371,000 barrels of diesel oil, 133,000 barrels of tar, 91,000 barrels of gasoline, and 42,000 barrels of kerosine per year.

Eleven coal deposits with total reserves of 300 million to 500 million tons have been identified in Afghanistan, but only four of these were believed to be of potential importance in meeting future energy demands. The Karkar, Ishpushta, and Darra-i-Suf mines, located in northeast Afghanistan, accounted for the total 1975 output of about 160,000 tons. The Sabzak deposit, near Herat, which was estimated to contain reserves of 9 million tons of coal, had yet to be exploited owing to its more isolated location.

Afghanistan's salt production began in 1954 and rose steadily to a level of 60,000 tons in 1975, an increase of 20% over the 1974 level. Approximately two-thirds of this output was rock salt from the opencast mines near Tallequan in Takhar Province, while the balance was brine salt from salt lakes near Herat, Andkhoi, and Kandahar.

The surveying of Afghanistan's several gem stone deposits progressed in 1975, but lapis lazuli continued to be the only one of significance with reserves estimated at 1,300 tons. Afghanistan has consistently been the world's leading producer of lapis lazuli. In 1975, production at the State-controlled mines in the northeast Province of Badakhshan was approximately 8 tons of jewelry-grade lapis lazuli, most of which was exported. Other gem minerals that were explored on a preliminary basis during 1975 were ruby deposits in the Jegdalek area east of Kabul, emerald deposits in the Nooristan and Panjshir Districts, kunzite in the Kulam Valley of Nooristan and in Nangarhar Province, and aragonite-onyx deposits southwest of Lashkargah.

Small amounts of marble, talc, and barite were extracted in 1975. Marble was mined commercially at three locations in Afghanistan: Near Kandahar, outside Kabul, and in Nangarhar Province. Annual output in 1975 and previous years averaged about 10,000 tons, most of which was used by the domestic construction industry. The production of both barite and talc was reported for the first time in 1974. The output of talc from deposits in Shinwar and Nagarhar increased from 3,000 tons in 1974 to 6,300 tons in 1975. Two deposits of barite were identified, one in the Farinjal area of Ghorband and the other in the Sanglon area of Herat, but the 1975 production of 5,200 tons was derived primarily from the Sanglon mine.

Afghanistan's only other commercially significant mineral commodities in 1975 were cement and fertilizers. The total output of Afghanistan's two cement plants, the Ghouri plant near Pul-i-Khumri and the Jabal-i-Seraj plant north of Kabul, remained at the 1974 level of approximately 140,000 tons. Aside from domestic use in Government and private construction projects, about 40% of cement production was exported to the Soviet Union and Iran. At yearend 1975, the Government was considering projects for the expansion of the Ghouri facility and for the construction of a third cement plant, with the expectation of making cement a principal export item.

Approximately 45,000 tons of urea fertilizer and diammonium phosphate from Afghanistan's single fertilizer plant at Mazar-i-Sharif was distributed to farmers throughout the country during 1975. The Mazar-i-Sharif facility, which opened in July 1974 at an annual capacity of 105,000 tons, was under the operation of the State-owned Afghan Chemical Fertilizer Co. In an agreement concluded in December, an expected 15,000 tons of fertilizer was to be exported to the Soviet Union during 1976. Also under negotiation was a joint Soviet-Afghan project for the construction of a second artificial fertilizer plant in the northern part of the country.

The most significant potential addition to Afghanistan's mineral industry comprised the Hajigak iron ore deposits, situated in the Hindu Kush Mountains northwest of Kabul. Reserves were estimated at 2 billion tons with an average iron content of more than 60%. The lack of infrastructure has thus far made the cost of developing these reserves prohibitive.

The appraisal of reserves at the copper deposits at Ainak in Lowgar Province was also favorable, and exploitation of the deposits together with the construction of a copper smelter was planned for 1977. Reserves were estimated at between 1.5 million and 2 million tons grading 1.3% copper. Surveying also took place at the Darbard and Jowhar copper deposits, both in the general vicinity of Ainak. Total copper reserves in the Kabul region were estimated at 3.5 million tons.

[1] In addition to the countries listed individually in this table, Nepal, covered textually in this chapter, presumably produces a variety of crude construction materials such as clays, stone, sand, gravel, and may produce cement, but production statistics are not available, and general information is inadequate to make reliable estimates of output levels.

[2] In addition to the commodities listed, a variety of crude construction materials such as clays, stone, sand, and gravel presumably were produced but production statistics are not available and general information is inadequate to make reliable estimates of output levels.

[3] Data for years beginning March 21 of that stated.

[4] Data for years beginning April 21 of that stated.

[5] For the year ended June 30 of that stated.

[6] Gross production not reported. Marketed output is reported in lieu of gross production estimate because the quantity flared, vented, and/or reinjected is believed to be small.

[7] For cement production only.

[8] Value only reported at $23,821,974 in 1974 and $19,964,571 in 1975.

[9] In addition to the commodities listed chromite, iron ore, and lead-zinc ores were mined in the past, and the country produced pig iron, crude steel, and smelter zinc from its industrial facilities but the status of these industries under prevailing conditions is not sufficiently clear to permit preparation of reliable estimates of output. Similarly no data on crude construction materials is available and no reliable basis for estimation is available.

[10] From official import statistics of the U.S.S.R.

[11] The South Vietnam Directorate of Natural Resources estimates a kaolin production level of 420,000 cubic meters annually for the years 1972–73, but the figure is inordinately high for true marketable china clay grade kaolin. No such estimate was made for 1974 or 1975.

[12] Additional varieties of stone are produced, but production statistics are not available, and general information is inadequate to make reliable estimates of output levels.

Table 2.—Afghanistan: Estimated imports of petroleum refinery products [1]

(Thousand 42-gallon barrels)

Commodity	1972	1973	1974
Gasoline, all grades	1,210	1,270	1,201
Jet fuel and kerosine	344	420	485
Distillate fuel oil	967	991	875
Residual fuel oil	200	225	268
Lubricants	38	48	40
Other	124	115	121
Total	2,883	3,069	2,990

[1] Data revised to agree with that appearing in the International Petroleum Annual for years 1972–74.

BANGLADESH [4]

During 1975, Bangladesh experienced serious political problems which involved several changes in leadership. By yearend, stability was restored and the new Government was able to address the challenge of feeding its more than 80 million citizens. The annual population growth of over 3% hampered economic gains made in recent years, and the balance of payments deficit climbed to around $1 billion in 1975. The population density rose to 2,300 per arable square mile, with nearly 90% of the people dependent on agriculture for livelihood. Bangladesh was one of the least industrialized of the world's more populous countries. The manufacturing industry contributed only about 10% of the GNP, and most of this was from processing a limited number of agricultural products.

The mineral industry contributed very little to the overall economy, although hydraulic cement, kaolin (china clay), salt, crude steel, and natural gas all recorded healthy gains in output.

Natural gas was the only mineral product of consequence. While the seven known gasfields were not fully developed, the reported reserve of 300 billion cubic meters was sufficient to support substantially increased production for many years. Gross production for 1975 was reported to be 934 million cubic meters, or an average of 90 million cubic feet per day. The major consumption was as a feedstock and fuel for nitrogenous fertilizer production, and as a fuel in the generation of electric power. The Government was looking into the use of natural gas for firing bricks. Construction bricks were in short supply, and currently the industry uses imported coal for firing its kilns.

Expansion of the gas pipelines network progressed satisfactorily with nearly 200 kilometers of new pipeline being laid. Reconstruction of a permanent 35-centimeter-diameter pipeline across the Meghna Bridge was completed. Previously, gas supplies to Dacca were delivered through small temporary lines because the main line was damaged during the "War of Liberation." In addition, a connection was made from the Chhatak gasfield to the Chhatak Bazar pulp and paper mill. Plans were being made to expand the pipeline network in the greater Dacca area and to provide a connection for a proposed nitrogen fertilizer plant at Ashuganj. An 80 kilometer pipeline was planned to service the major port of Chittagong.

The only petroleum refinery in the country, located at Chittagong, runs entirely on imported crude oil. Because of higher cost for crude and a complete refinery overhaul in October and November, the refinery input was cut back to about 800,000 tons per year. Imports of refined petroleum products were estimated at 400,000 tons in 1975, compared with 600,000 tons in 1974. The refinery planned to install a 12,000-ton-per year liquefied petroleum gas (LPG) unit to utilize refinery gases that were presently flared. A small amount of naphtha production from the refinery operations was exported for the first time in 1975.

Six foreign oil companies were authorized to conduct oil exploratory work in Bangladesh waters. The State-owned company, Petrobangla, conducted extensive gravity and seismic surveys and some onshore drilling. The first offshore hole was drilled by Bengal Oil Development Corporation, a subsidiary of Japan Petroleum Development Corporation. The site was 40 kilometers offshore, west of the Burma-Bangladesh border. The 4,500-meter well, the deepest drilled to date in the country, was a dry hole. An Atlantic Richfield Co. subsidiary, Arco Bangladesh Inc., also drilled a dry hole offshore late in the year. The company subsequently reduced its resident staff. Other companies were expected to begin offshore drilling early in 1976.

Bangladesh produced no coal, and all coal requirements were met by imports. India was by far the biggest single supplier, having furnished about 700,000 tons during 1975. Large coal deposits exist in the Bogra District at a depth of 1,000 meters or more. Foreign experts were asked to prepare a feasibility study on developing deep-seam coal resources, because domestic capital and technical expertise were not readily available.

Bangladesh produced a little over 700,000 tons of fertilizer, well below the rated capacity of the two operating plants. Construction was due to begin in 1976 on a

[4] Prepared by Gordon L. Kinney, physical scientist, International Data and Analysis.

1,300-ton-per-day urea fertilizer plant at Ashuganj; planned completion date was 1981. Several foreign countries and international agencies were to fund the $200 million project.

The Bangladesh Atomic Energy Commission (BAEC) decided to make a preliminary radiometric survey to identify uranium-thorium occurrences in the Sylhet, Mymensingh, Comilla, Chittagong, and Faridpur Districts, to be followed by geochemical surveys and drillhole-radioactive logging in the promising areas.

BAEC was reportedly sponsoring a detailed study of beach sand deposits near Cox's Bazar. The area was believed to contain more than 2 million tons of heavy mineral sands.

BRUNEI [5]

Brunei's economy continued to be dominated by the production and export of oil and associated natural gas. The country's gross domestic product (GDP) was estimated to be over $1,375 million.[6] Total exports were about $1,150 million, nearly all of which was from the sale of crude oil, natural gas, and petroleum products. Rubber and timber were also exported but contributed little to the overall economy. Imports totaled $262 million and consisted mainly of manufactured goods, machinery, transport equipment, and food.

During the year, the Government increased its equity in Brunei Shell Petroleum Co., Ltd., the country's only oil and gas producer. The exact terms of the new agreement were not released, but it was believed the Government's share was increased from 25% to over 50%. This would considerably increase the Government's share of revenue from oil and gas production.

The Brunei Government planned to diversify the economy and lower the country's nearly total dependence on oil revenues. The start of construction of a $100 million pulp and paper mill at Kuala Belait was delayed by a conflicting proposal to establish a palm oil industry in the same area. The country is virtually without organized commercial agriculture, but proposals were made for developing tapioca and coconut plantations. The Government approved in principle plans for a 1,000-ton-per-day ammonia and urea plant at Muara. The $200 million plant would be based on the use of excess natural gas from oilfield production. Competition from increased European production, however, has put the project in jeopardy.

Revenue from oil sales funded the establishment of the Royal Brunei Airlines, wholly-owned by the Government. The airline consisted of two Boeing 737's which began scheduled flights in May. Establishment of a brickworks was considered during the year. The pressing need for establishing construction industry projects was evident since shortages of cement, bricks, and building materials have delayed completion of Government housing units.

Crude oil production fell 6.3% to 65.9 million barrels in 1975. The reported value of the crude oil was $787.6 million, down about 4% from the 1974 value. The drop in production was due mainly to a well blowout in late 1974 at a Champion Shoals offshore platform. Production from that unit had not been resumed by yearend 1975. Four oilfields produced most of the country's oil. The average production per day for the first 6 months of 1975 was reported as follows: Southwest Ampa Field, 94,000 barrels; Seria Field, 34,000 barrels; Champion Shoals Field, 24,000 barrels; and Fairley Field, 23,000 barrels.

Crude oil reserves for the country were reportedly 1.9 billion barrels at yearend.

Drilling activity, mostly by Brunei Shell Petroleum Co., Ltd., increased by nine wells over that of 1974. Thirty-eight development wells and 12 exploration wells were completed. Four to six offshore rigs worked during the year, but no new oil or gas discoveries were made. Most of the development drilling was done in the Champion Shoals and Southwest Ampa oilfields. Some onshore seismic survey work was begun near yearend.

Gross production of natural gas in 1975 was 7.6 billion cubic meters, or about 735 million cubic feet per day. Most of the gas was produced in conjunction with the

[5] Prepared by Gordon L. Kinney.
[6] Where necessary, values have been converted from Brunei dollars (B$) to U.S. dollars at the rate of B$2.48=US$1.00.

oil production. A considerable amount was consumed or wasted during the production cycle. Sales of liquefied natural gas (LNG) totaled 3,514,000 tons, valued at about $321.8 million. The natural gas was liquefied at the Shell-Mitsubishi LNG plant near Seria. Specially designed tankers were loaded with LNG from an offshore mooring facility in deep water. The entire output of LNG was sold to Japan. Natural gas reserves in Brunei were estimated at 187 billion cubic meters at yearend 1975.

CAMBODIA (FORMERLY KHMER REPUBLIC) [7]

The year opened in Cambodia with intense fighting around the capital of Phnom Penh, but by the end of April the military action was over and a new Government, the Royal Government of National Union of Cambodia, was firmly in place. The new Government inherited a chaotic economy and no food stockpiles to feed the urban population. With imports of food cut off, the Government ordered the immediate evacuation of the more than 2 million people in Phnom Penh to the countryside. Several other major towns across the country were also reportedly evacuated.

Even before the war, minerals and manufacturing had only a minor role in Cambodia's agrarian economy. However, with stable conditions, a variety of minerals might be developed for local and foreign markets. The only significant minerals that have been produced were phosphate rock, cement, gem stones, gold, salt, and nonmetallic construction materials. Continued production of phosphate rock will probably receive priority attention. No mineral production figures were available for phosphate rock, gem stones, or construction materials for the year.

Bauxite occurs in commercial quantities, and there was a plan, based on a United Nations study, to develop an aluminum industry in the Mekong Basin. As yet, the plan has not gone beyond the blueprint stage. In addition, deposits of iron, manganese, gold, copper, and coking-grade coal reportedly have been identified.

Crude oil was not produced domestically. The old 12,000-barrel-per-day French refinery at Kompong Som was damaged during the war, and the Government had not reopened the plant by yearend. Repair and reactivation of the plant after years of neglect would require a considerable outlay of money and technical expertise.

Offshore oil exploration came to a halt during the hostilities, but two holes had been drilled by a subsidiary of France's Essence et Lubrifiant de France—Entreprise de Reserches et d'Activités Pétrolières (Elf-ERAP). The results of the drilling were never announced, but it was reported that the French company was hopeful that the new Government would allow exploration to continue.

HONG KONG [8]

The economy of Hong Kong in 1975 continued to be influenced by soft international market conditions which affected industrial production and exports. The GDP in current prices was $7.2 billion in 1975, compared with $6.8 billion in 1974. In terms of constant 1966 prices, the GDP in 1975 was $3.9 billion, an increase of 2.8% from that in 1974.

Despite efforts to diversify, Hong Kong remained highly specialized in industries and markets. The majority of Hong Kong's manufacturing industries produced light consumer goods. The production of textiles and clothing, electronic components, plastic products, and toys accounted for about 70% of the total industrial workforce and more than 70% of the total domestic exports. The value of textiles and clothing exported amounted to $2.5 billion in 1975.

Hong Kong's foreign trade in 1975 was as follows in billion dollars: Imports, $6.97 billion; domestic exports, $4.68 billion; and reexports, $1.76 billion. Japan, the People's Republic of China, and the United States, in that order, were the major sources of Hong Kong's imports, accounting for $3.64 billion, or 52% of the total. The major export destinations in 1975 were the

[7] Prepared by Gordon L. Kinney.

[8] Prepared by E. Chin, physical scientist, International Data and Analysis.

United States, followed by the Federal Republic of Germany, the United Kingdom, and Australia.

The only mineral industries of any consequence were cement and iron ore. Cement clinker was imported and ground into finished cement by the Green Island Cement Co. at its Hung Hom, Kowloon, plant. In 1975, about 575,000 tons of cement were produced, most of which was locally consumed.

The Ma On Shan mine produced 167,200 tons of iron ore concentrate in 1975, an increase of 7,500 tons over the 1974 output. Because there were no smelting facilities, the ore was exported to Japan. Mo On Shan had been producing iron ore concentrate at an annual rate of 150,000 to 200,000 tons for more than a decade. However, the ore reserves were reportedly being depleted, and the mine was approaching the closure stage.

In addition, about 1,500 tons of kaolin clays, 2,000 tons of feldspar, and 800 tons of quartz were produced in 1975. Output of these minerals was shipped primarily to Taiwan, Thailand, and Indonesia.

Table 3.—Hong Kong: Exports and reexports of mineral commodities
(Metric tons unless otherwise specified)

Commodity	1973 [1]	1974	Principal destinations, 1974
METALS			
Aluminum:			
Bauxite and concentrate	1,756	6,287	Taiwan 6,037.
Oxide and hydroxide	r 187	302	Indonesia 190; Nigeria 100.
Metal including alloys, all forms	r 12,295	18,991	Japan 4,886; Taiwan 2,489; United States 1,992.
Arsenic, trioxide, pentoxide, acids	r 30	17	Taiwan 5; North Vietnam 5; Thailand 3.
Chromium oxide and hydroxide	17	19	Indonesia 10; Taiwan 5.
Cobalt oxide and hydroxide	2	4	People's Republic of China 3.
Copper:			
Oxide and hydroxide	5	2	Malaysia 1.
Metal including alloys, all forms	r 7,723	8,628	Japan 2,650; United States 2,178.
Gold metal, unworked or partly worked thousand troy ounces	448	308	United Kingdom 193; Switzerland 78.
Iron and steel:			
Ore and concentrate thousand tons	159	179	All to Japan.
Scrap do	r 213	246	Japan 97; People's Republic of China 80; Taiwan 48.
Pig iron, steel ingot and similar material do	4	2	Mainly to Malaysia.
Semimanufactures do	r 79	71	Indonesia 33; Malaysia 9.
Lead:			
Oxide	r 17	11	Mainly to Indonesia.
Metal including alloys, all forms	4,193	4,141	Taiwan 1,525.
Magnesium metal including alloys, all forms	113	144	Mainly to United States.
Manganese:			
Oxide	70	30	Mainly to Taiwan.
Nickel:			
Oxide and hydroxide	7	3	Mainly to Thailand.
Metal including alloys, all forms	r 51	218	United States 105; United Kingdom 52; Taiwan 21.
Silver metal including alloys thousand troy ounces	665	2,011	United Kingdom 1,315; Switzerland 277; France 237.
Tin metal including alloys, all forms	r 320	432	Taiwan 168; Singapore 154.
Titanium, oxide	722	609	Taiwan 342; Philippines 58.
Tungsten metal including alloys, all forms	15	7	Mainly to Philippines.
Zinc:			
Oxide	192	81	Japan 37; Indonesia 21; Ghana 10.
Metal including alloys, all forms	1,392	3,077	United States 718; Netherlands 386.
Other:			
Oxides, hydroxides, peroxides of metals, n.e.s	43	92	Mainly to United States.
Metals including alloys, all forms:			
Metalloids	(1)	5	Mainly to Indonesia.

Lime	53,817	34,299	People's Republic of China 26,472; North Vietnam 5,525.
Magnesite	503	533	All from People's Republic of China.
Mica, all forms	185	95	India 47; United States 26; Japan 12.
Pigments, mineral including processed iron oxides	651	657	People's Republic of China 235; West Germany 194; India 115.
Precious and semiprecious stones including synthetic other than diamond value, thousands	$81,340	$58,581	Japan $12,467; Australia $6,584.
Salt	33,394	46,377	People's Republic of China 31,592; Thailand 8,214.
Sodium and potassium compounds, n.e.s	r 20,238	23,726	Singapore 11,778; Taiwan 6,114.
Stone, sand and gravel:			
Dimension stone	11,689	19,702	Italy 7,917; People's Republic of China 4,528.
Dolomite	51	--	
Gravel and crushed rock	r 19,875	83,280	Macao 73,901; People's Republic of China 9,026.
Limestone except dimension	7,762	7,312	All from People's Republic of China.
Quartz and quartzite	1,031	2,474	Mainly from People's Republic of China.
Sand, excluding metal bearing	6,546	2,212	Do.
Sulfur:			
Elemental, all forms	1,585	2,419	Singapore 1,556; France 305; Poland 278.
Sulfuric acid	487	330	United Kingdom 217; Taiwan 52; People's Republic of China 52.

See footnote at end of table.

Table 4.—Hong Kong: Imports of mineral commodities—Continued
(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal sources, 1974
NONMETALS—Continued			
Talc and related material	2,824	2,765	Mainly from People's Republic of China.
Other nonmetals, n.e.s.:			
Crude	5,236	4,560	Do.
Mineral waste	740	882	People's Republic of China 562; Thailand 246.
Oxides, hydroxides and peroxides of strontium, barium and magnesium	26	28	Taiwan 15; Japan 9.
Fluorine, bromine, iodine	1	1	Mainly from United Kingdom.
Building materials of asphalt, asbestos, and fibre materials and unfired nonmetals	11,784	12,023	United Kingdom 4,298; People's Republic of China 2,240; Singapore 1,620.
MINERAL FUELS AND RELATED MATERIALS			
Asphalt and bitumen, natural	56	320	Singapore 203; United States 93.
Carbon black and gas carbon	705	580	Japan 270; United States 115; Taiwan 96.
Coal, coke, and peat including briquets	26,813	16,146	People's Republic of China 5,745; North Vietnam 5,227; Japan 4,327.
Petroleum and refinery products:			
Gasoline, including natural thousand 42-gallon barrels	1,182	1,130	Singapore 695; Republic of Korea 211; Iran 197.
Kerosine, aviation, industrial and white spirits do	5,792	5,912	Singapore 4,193.
Diesel and distillate fuel oil do	6,638	7,340	Singapore 3,748; People's Republic of China 1,418; Republic of Korea 843.
Residual fuel oil do	20,241	20,452	Singapore 12,309; Saudi Arabia 5,171.
Lubricants do	r 353	501	Singapore 138; Japan 89; United States 88.
Mineral jelly and wax do	98	101	People's Republic of China 45; Singapore 35.
Other:			
Bitumen and other mixtures do	r 144	151	Singapore 123; Republic of Korea 20.
Liquefied petroleum gas do	r 854	890	Singapore 563; Republic of Korea 110; Thailand 109.
Pitch do	48	51	Japan 28; United Kingdom 23.
Unspecified do	r 167	20	All from Singapore.
Mineral tar and other coal-, petroleum, or gas-derived crude chemicals	r 246	118	United Kingdom 63; Japan 55.

r Revised.

LAOS [9]

Laos emerged after two decades of civil strife encumbered with economic problems, a poor transportation system, a high birthrate, and a population that was 80% dependent on agriculture for a livelihood. On December 2, 1975, the country was officially declared the People's Democratic Republic of Laos. The economy, shaken further by the 1974 cutoff of funds by the U.S. Agency for International Development, began 1975 with uncontrolled inflation that reached a rate of 40% per year by midyear. The strength of the new political regime, however, enabled the Government to initiate severe economic controls. New policies, enacted during the year, began to take effect, and the economy seemed to be stabilizing at yearend.

Both the People's Republic of China and North Vietnam were aiding in the construction of roads needed to upgrade the transportation network in this landlocked, mountainous country. An added benefit of the roadbuilding program will be easier access to areas of potential mineral development.

Projects to increase electric power generation and transmission were also under consideration. A major powerplant expansion program was scheduled for the Nam Ngum dam, and construction was to begin in early 1976. Capacity was to be raised from 30 megawatts to 110 megawatts. The plant exports most of its power to Thai-

[9] Prepared by Gordon L. Kinney.

land, thereby earning much-needed foreign exchange. The Thai Government was expected to buy most of the added power output when the plant expansion was completed. A 115-kilovolt powerline was to be installed from Nam Ngum to Phonthong, and a feeder connection would further provide transmission facilities to the southern part of Vientiane Province.

The only significant mineral production in Laos was tin. Production was mainly from mines managed by the Société d'Études et d'Exploitations Minières de l'Indochine at Phontiou, about 80 kilometers north of Thakhek. The concentration plant has a rated capacity of 1,800 tons per year of 60% tin concentrate. Total domestic production, however, was about 520 tons of tin-in-concentrate, 15% less than 1974 output. About 100 tons of this amount was possibly contributed by a small mine reported to be in the Boneng District. The estimated tin reserves in Laos were 65,000 tons (metal content) with ore grading 0.5% to 1.0% tin. However, the country's mineral resources have not been thoroughly explored, and the tin reserves could be much larger. Japanese entrepreneurs were reportedly interested in developing iron ore deposits on the Plain of Jars in Xiangkhouang Province. Lead and zinc occurrences with silver values have been discovered in several areas.

Rich potash deposits were confirmed north and east of Vientiane city. Test drillings made about 16 kilometers north of the city reportedly located a 30-meter-thick layer of interbedded sylvite and halite containing around 30% K_2O. The deposit extended over a considerable area, and reserves were thought to be around 1 million tons of ore. The same geologic formation extends across the border into Thailand where similar ore bodies have been reported. The development and exploitation of this deposit would require a large capital investment, but would also provide a major source of potash for the Asian market.

A salt mine in Kong hamlet, Vientiane Province, was expected to begin operation at yearend. It was expected to supply about 5,000 tons per year of refined salt for domestic consumption.

Coal was mined near Muang Vangviang, and a small amount was reportedly exported for the first time. Coal deposits were also known to exist in Saravane Province. Laos produced no crude oil or natural gas in 1975, and its modest needs for fuels were met by importing about 120,000 tons of petroleum products from Thailand.

MONGOLIA [10]

Total Mongolian Government expenditures in 1975 were estimated at $810 million, distributed as follows: National economy, 37%; social and cultural projects, 45%; and defense, 14%. In the 5-year economic plan (1976–80), over $1,500 million was scheduled for investment in developing industry. Most of the funding would be for developing fuel and power, extracting construction materials, and the food processing industry.

Industrial production averaged around 7% for 1970–74. In 1975, the level of industrial production was to be about 6% over the 1974 output, principally due to coal production, which is by far the largest mineral industry in Mongolia. The major coal mining areas are centered at Nalayha, Sharyn Gol, and Chuluun. Production of coal in 1975 was estimated at 2.5 million tons from 14 opencast mines. About 150 coal deposits have been discovered in Mongolia. Under the provisions of the next economic plan, new mines were scheduled for development to add 5 million tons of coal production capacity per year to the existing capacity. Additionally, a coal-fired power station was planned for construction based on projected coal output. The Nulalayha-Kapitalnaya, Sharyn Gol, and Aduun Chuluun coal mines were specifically designated for expansion.

Fluorspar production, around 302,000 tons in 1975, was from a fairly large mine at Berhin. Between 100 and 200 tons of tungsten concentrate was produced at the Burentsogt mine. Estimated output of other mineral products were as follows, in tons: Gypsum, 25,000; lime, 40,000; salt, 11,000; and cement, 175,000.

Plans were formed to reorganize the Ministry of Fuel, Power Industry, and Geology to coordinate the development of Mongolia's mineral resources. A ministry

[10] Prepared by E. Chin.

for geology and mining and a ministry for fuels and power were proposed to implement the country's industrial development. In June 1975, the Council for Mutual Economic Assistance (CMEA) approved a comprehensive plan to develop science and technology, and to organize the development of mineral resources in Mongolia, particularly nonferrous metals, coking coal, and phosphorite. Reportedly, an international team of CMEA technicians was scheduled to conduct geological surveys in northeastern Mongolia on a proposed budget of $4 million.

The U.S.S.R., which has provided most of Mongolia's aid, was planning to concentrate on the development of fluorspar, tin, and wolfram deposits. Moreover, Soviet technicians were expected to evaluate copper and molybdenum occurrences in the South Gobi Province and gold in northern Mongolia.

The Erdenet copper and molybdenum complex in Bulgan Province, under construction with Soviet aid, is Mongolia's largest industrial project. When completed, Erdenet will be a major producer of copper and molybdenum by world standards with a total output of 16 million tons of ore annually. Reportedly, work had been completed on the building-materials depot, motor road, and power lines at the site. Additionally, a railway was constructed between the complex and Darhan in Bulgan to provide access for the Erdenet copper and molybdenum project. Stripping had begun at the deposit site; 12 million cubic meters of overburden were to be removed annually to provide access to the ore. The complex was scheduled to be commissioned in 1980.

The bulk of Mongolia's trade is with the U.S.S.R. Imports of mineral commodities included coal, coke, and petroleum products. The U.S.S.R. also supplied crude oil for the small refinery at Dzuun Bayan. Other imports included semimanufactured products of iron and cement. Tungsten concentrates and metallurgical-grade fluorspar were the only significant domestically mined materials to be exported.

NEPAL [11]

Minerals play a very minor role in the Nepalese economy. During fiscal year 1974–75,[12] mineral production was valued at about $1.2 million, compared with Nepal's GDP of $1,425 million. The rate of growth of the GNP was only 2.3%, barely ahead of the over 2% rise in population.

Plans to set up a joint venture company to undertake exploitation of a lead-zinc deposit at Lari, high in the Ganesh Himal, were reported. The company as proposed would be owned 50% by the Government and citizens of Nepal and 50% by foreign companies. The foreign companies have done preliminary reconnaissance work and would provide technical expertise for the project. The deposit is located 35 miles northwest of Kathmandu at an elevation of 14,500 feet (4,420 meters) above sea level. The proposed ore concentration plant would be located at Somdang at an elevation of 10,000 feet (3,048 meters).

The deposit was not adequately explored because the extremely rough terrain allowed only a very limited amount of diamond drilling. The geologic findings, however, indicated a 12% to 13% lead-zinc content in an estimated 300,000 tons of ore. Commercial success of the operation would depend on the amount of ore confirmed by subsequent detailed drilling. Because of the physical location of the deposit, a great deal more reserve would have to be confirmed before mining of the deposit would be justified. If plans do materialize, however, this would be the first metallic ore processing plant in the country. Proceeds from the export of the concentrate would provide a significant amount of foreign exchange to the Nepalese economy.

Nepal's first cement plant began operation during 1975 and produced over 10,000 tons by end of the fiscal year. The cement was valued at more than $600,000, and while this was not a large figure by international standards, it was more than double the value of Nepal's next largest mineral commodity. Output from the new plant, capacity of which is rated at 50,000 tons per year, should meet about 25% of the domestic demand and save a considerable amount of foreign exchange spent on im-

[11] Prepared by Gordon L. Kinney.
[12] Fiscal year runs from July 17 to July 16.

ported cement. The Government of Nepal was striving for self-sufficiency in cement and has announced plans for a second plant, to be located at Hetauda, south of Kathmandu. The 260,000-ton-per-year plant was to reportedly cost at least $21 million.

Consumption of cement in Nepal during 1975 was estimated at 170,000 tons. Demand has been rising at about 10% per year.

Nepal produces virtually no mineral fuels and is dependent on imports for all of its petroleum needs. Petroleum imports at the rate of about 70,000 tons per year were supplied by the Soviet Union and Middle East countries through a swap agreement in which India took control of the incoming oil at various ports of entry and supplied an equal amount to Nepal from the refinery most convenient to the Nepal border.

SINGAPORE [13]

Singapore's GNP reached $5.6 billion[14] in 1975, a gain of 23% in current prices. Manufacturing, which encompasses mineral-related fields like petroleum refining, metal fabrication, cement, and chemicals, remained the leading component of the GNP. However, manufacturing output, measured in terms of value added, decreased to $1.4 billion, compared with $1.5 billion in 1974. Approximately 17% of the value added in 1975 was attributed to petroleum refining. The major contribution to the slowdown in growth of the manufacturing sector was the downturn in the oil refining industry due to decreased demand and loss of the Vietnamese market. Oil rig construction and industries related to shipbuilding and repair fared reasonably well on account of past orders. The shipbuilding and repair industry increased its turnover by 13% to $251 million. Singapore is the world's fourth largest port, and its oil rig construction was ranked as the third largest in the world.

Entrepôt trade continued to represent the lifeblood of Singapore's economy. For the first time, the United States was Singapore's largest trading partner in 1975. Imports from the United States consisted primarily of lift cranes, compressors, power generators, marine diesel engines, and iron pipe and fittings. Exports to the United States declined by about 16%, however, owing primarily to the reduced level of demand for consumer goods. Other major trading partners in 1975 were Malaysia, Japan, and the member countries of the European Economic Community.

Despite a record trade deficit of $2.7 billion during 1975, Singapore added $320 million to its foreign exchange reserves, which totaled over $3.2 billion at yearend. The surplus resulted from invisible earnings from tourism and from the financial sector, long-term capital inflows, and a large positive errors-and-omission item (reflecting a favorable balance of trade with Indonesia). While Indonesia ranks high as a trade partner, Singapore-Indonesian trade data are not available.

PRODUCTION

Singapore's production of refined petroleum products was valued at $1.8 billion in 1975, compared with $2.4 billion in 1974.[15] Production of residual fuel oil was first in quantity of output, followed by distillate fuel oil, jet fuel, gasoline, kerosine, and lubricants, in that order. Sulfur, recovered as a byproduct of oil refining, was around 6,000 tons in 1975. The sluggishness in petroleum refining was attributed to a slackening in demand in the major consuming markets and to the loss of the Vietnamese market early in 1975. Hence, local refineries, which have a potential throughput of close to 1 million barrels per day, at times operated at less than 50% of capacity.

Production of steel ingot remained around 240,000 tons as in 1974. Construction was brisk owing to expanded expenditures by the public sector on housing projects and infrastructure, including utilities and port development. Activity in this sector sustained cement production, which was more than 1 million tons for the 5th year in a row. Output of stone (broken

[13] Prepared by E. Chin.

[14] Where necessary, 1975 values have been converted from Singapore dollars (S$) to U.S. dollars at the rate of S$2.39=US$1.00. In 1974, the average exchange rate was S$2.31=US$1.00.

[15] Monthly Digest of Statistics (Singapore). V. 15, No. 9, September 1976.

granite) exceeded 2.3 million cubic meters in 1975, compared with the 1.8-million-cubic-meter level of 1973–74. The country's mineral production statistics are shown in table 1.

TRADE

Total trade in 1975 was $13.3 billion, down 7% from that of 1974. Imports totaled $8.0 billion, while exports were $5.3 million. For the first time, the United States was Singapore's largest trading partner, notwithstanding an overall decline of 3% from the trade level in 1974. Singapore's external trade by major destination in 1975 was as follows: United States, 15.0%; Malaysia, 13.8%; Japan, 13.6%; United Kingdom, 4.7%; Hong Kong, 4.3%; Australia, 4.1%; West Germany, 3.5%; and other, 41%. (Data relating to Singapore-Indonesian trade are not available.)

The major mineral-related imports by value and by commodity group were as follows, in million dollars: Crude petroleum, 1,499; petroleum products, 472; crude rubber, 311; and wrought steel shapes, 217. Over 75% of Singapore's imports of crude petroleum was high-sulfur crude oil, mainly from Kuwait, Saudi Arabia, and Iran. Most of the locally produced refined oil products and the imported refined materials were exported, primarily to other Asian countries, or sold for bunkering. Singapore's most noted export was refined petroleum products, valued at $1.4 billion in 1975.

Table 5.—Singapore: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1973	1974	Principal destinations, 1974
METALS			
Aluminum:			
Bauxite and concentrate	320	1,030	Taiwan 900; United States 130.
Oxide and hydroxide	1,781	962	Mainly to Malaysia.
Metal including alloys, all forms	r 1,465	3,190	Malaysia 1,483; People's Republic of China 748.
Chromium oxide and hydroxide	17	28	Mainly to Malaysia.
Cobalt oxide and hydroxide	1	(1)	All to Malaysia.
Copper metal including alloys, all forms	1,758	1,408	Malaysia 1,298; Hong Kong 102.
Iron and steel:			
Ore and concentrate	10,630	--	
Roasted pyrite	--	1	All to Malaysia.
Metal:			
Scrap	1,070	1,945	Taiwan 732; Republic of Korea 576; Netherlands 429.
Pig iron, ferroalloys, and similar materials	3,158	7,685	Malaysia 3,824; Pakistan 2,000.
Steel, primary forms	7,122	15,676	Malaysia 9,074; Bangladesh 6,328.
Semimanufactures:			
Bars, rods, angles, shapes, sections	r 43,133	65,099	Malaysia 48,700.
Universals, plates, sheets	68,539	82,904	Malaysia 62,116; United States 11,702.
Hoop and strip	1,905	1,949	Mainly to Malaysia.
Rails and accessories	8,802	6,126	Do.
Wire	4,558	3,378	Malaysia 2,161; Zambia 500.
Tubes, pipes, fittings	22,463	44,599	Brunei 17,958; Malaysia 7,858.
Castings and forgings, rough	326	680	Malaysia 208; Japan 194.
Total	r 149,726	204,735	
Lead:			
Ore and concentrate	--	2	All to India.
Oxides	21	19	Mainly to Malaysia.
Metal including alloys, all forms	r 730	1,073	Malaysia 552; Netherlands 100.
Manganese:			
Ore and concentrate	2,320	2,404	Malaysia 1,179; Kenya 399.
Oxides	150	44	All to Malaysia.
Mercury ______76-pound flasks	592	17	Mainly to Malaysia.
Nickel metal including alloys, all forms	34	44	Do.
Platinum-group metals and silver:			
Waste and sweepings ____kilograms	r 17,214	25,690	Mainly to United Kingdom.
Metals including alloys:			
Platinum group ____troy ounces	450	108,026	Do.
Silver ____thousand troy ounces	766	308	United Kingdom 200; Taiwan 100.
Tin:			
Ore and concentrate	2,841	1,629	Brazil 669; Spain 517; Mexico 351.
Metal including alloys, all forms	r 697	661	Taiwan 192; Malaysia 136; Hong Kong 105.

Bitumen and bituminous mixtures, n.e.s ... do	1,283	1,140	Australia 442; South Vietnam 245.
Other ... do	r 4,221	13,277	Japan 8,893; Thailand 1,457; South Vietnam 1,398.
Total ... do	r 120,851	115,756	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals ... thousand tons [4]	r 725	1,481	Japan 832; New Zealand 256.

r Revised.

[1] Less than 1/2 unit.

[2] Total excludes bricks of baked clay valued at $23,389 in 1973 and $32,218 in 1974.

[3] In addition to the products listed, liquefied petroleum gas valued at $4,350,062 in 1973 and $15,022,948 in 1974 was exported.

[4] Excluded from this total are benzol and creosote oil.

Total do	r 48,491	30,746	
Mineral tar and other coal-, petroleum-, or gas-derived crude chemicals[6]	r 69,482	327,615	Mainly from Malaysia.

r Revised.
[1] Erroneously reported as manganese metal in 1974 edition.
[2] Revised to none.
[3] Less than ½ unit.
[4] Total excludes bricks of baked clay valued at $644,946 in 1973 and $943,914 in 1974.
[5] In addition to the products listed, liquefied petroleum gas valued at $126,996 in 1973 and $255,194 in 1974 was imported.
[6] Creosote oil is excluded from this total.

COMMODITY REVIEW

Metals.—*Iron and Steel.*—The National Iron & Steel Mills, Ltd. (NISM), and Malaysia Iron & Steel Mills, Ltd. were the only two steel producers of any consequence in Singapore. NISM, the larger of the two companies, has the capacity to produce more than 200,000 tons of steel products annually at its plant in Jurong. However, total industry output of steel products was only about 240,000 tons, with an estimated value of $59 million.

Nonmetals.—*Cement.*—Three companies, Asian Cement (Malaysia), Ltd., Singapore Cement Manufacturing Co., Ltd., and Parr Malaysia Cement Works, Ltd., comprise the cement industry of Singapore. All the producers were actually grinding operations and relied on imports of clinker. Total output of cement was around 1.1 million tons valued at $72 million. The value added on Singapore's output of finished cement was $20 million in 1975, compared with $14 million in 1974.

Mineral Fuels.—*Petroleum.*—At yearend 1975, Singapore's total crude refinery capacity per day totaled 922,650 barrels, distributed as follows in barrels per day: BP Refinery Singapore Pte., Ltd., 25,650; Esso Singapore Pte., Ltd. (Esso), 192,000; Mobil Oil Singapore Pte., Ltd., 175,000; Shell Eastern Petroleum, Ltd. (Shell), 460,000; and Singapore Petroleum Co., Pte., Ltd., 70,000. Expansion of the Shell refinery at Prilau Bukom to 530,000 barrels per day was expected to be completed in early 1976, making this operation the second largest in the world. Esso was completing the expansion of its plant at Palau Ayer Chawan to 231,000 barrels per day. In addition, total downstream refining capacity at this plant was as follows, in barrels per day: Catalytic reforming, 20,000; catalytic hydrotreating, 206,000; catalytic hydrodesulfurization, 96,000; vacuum distillation, 80,000; lube manufacture, 5,000; and asphalt, 5,200.

Two Japanese companies, Maruzen Oil Company, Limited, and Daikyo Oil Co., Ltd., were considering a joint venture to build a 120,000-barrel-per-day refinery on Padang Island. Construction of the $833 million petrochemical project of Japan's Sumitomo Chemical Co., Ltd. was delayed for 1 or 2 years. Rather than financial difficulties, the major potential obstacle for the petrochemical project was severe competition from the introduction of excess supplies in the Asian market by other petrochemical producers.

SRI LANKA [16]

Mineral production again showed a mixture of ups and downs for the various commodities. Gems constituted the major foreign exchange earner in the mineral sector, with output value increasing more than 60%, to $22.6 million in 1975. Exports were up nearly 40% to $21.8 million. Demand for Sri Lankan gems continued high from Switzerland and Hong Kong, the two largest buyers in recent years. Sapphires and rubies went mainly to Western countries, while alexandrites, cat's eye, and star stones went mainly to Japan.

A lapidary center was setup in 1975 by the Government-owned State Gem Corporation (SGC) with the intention of improving the standards of workmanship of the local gem cutters. However, the expected profits from the SGC purchases and sales did not materialize, and it was reported that the company's stock of gems had a market value far below the actual cost to the company. A Government commission was appointed to look into the situation.

Production increases were also recorded for feldspar, graphite, zircon, and clays (for the brick and tile industry). Rutile, massive quartz, and salt production remained stable. Cement and ilmenite recorded drops of 23% and 21% from the 1974 production of 474,000 tons and 81,000 tons, respectively. China clay, dolomite, limestone, and mica also showed production decreases for 1975.

The severe inflation suffered by Sri Lanka in 1974 continued unabated in 1975. Industrial development was slowed, and real income was adversely affected. The cost of living index hit a new high in July 1975. The balance of payments deficit stood at nearly $100 million for the first 6 months of 1975. The deficit for the whole year may reach $200 million, brought about mainly by commodity price increases, especially in imported food and raw materials. High world prices for traditional exports failed to offset the increased costs of imports, because domestic production of tea and rubber had declined significantly.

Production at three major graphite mines, Bogala, Kahatagaha, and Kolongaha, continued satisfactorily. It was reported that development work began on the new Rangala graphite mine in Yatiyantota District. Work continued on a graphite flotation plant, expected to be completed by mid-1976. Graphite sales to the United States in 1975 totaled about 1,400 tons, valued at nearly $500,000.

It was reported that the People's Republic of China had offered to help design and construct a large flat-glass factory using local raw materials. The plant would be the first in Sri Lanka and would cost over $8 million.

Apparently, the Chinese had also offered to help build a phosphate fertilizer plant. This plant would process the apatite discovered near Eppawala in Anuradhapura District by the Sri Lanka Geological Department in 1974. Kellogg Overseas, a subsidiary of Pullman Kellogg Co., has contracted to build the 300,000-ton-per-year Sapugaskanda urea fertilizer plant, and construction could begin in early 1976. This will be the first urea fertilizer plant in the country, and should help eliminate fertilizer imports and increase agricultural production in the process. Planned completion of the project is 1979. Expansion of the Sapugaskanda oil refinery from 38,000 barrels per day to over 50,000 barrels per day, which began in 1975, was scheduled for completion in 1977. The urea fertilizer plant located nearby is to use naphtha feedstock from this refinery.

Sri Lanka continued to be totally dependent on foreign sources for its crude oil supplies. Imports in 1975 were nearly 1.5 million tons valued at over $100 million. To facilitate unloading of crude imports, the port of Colombo has reportedly begun construction of a new anchorage to accommodate 60,000-ton tankers. Present facilities are limited to 36,000-ton ships.

Development of offshore petroleum potential is moving ahead rapidly. Twelve offshore exploration blocks have been outlined

[16] Prepared by Gordon L. Kinney.

by the Government. The first 10 blocks nearly surround the island and extend out to the 100-fathom line. Blocks 11 and 12 are deep-water sections farther offshore. One unnumbered area in the northwest near Mannar Island has been reserved for the State-owned Ceylon Petroleum Corporation. The first offshore exploratory well is to be drilled in the unnumbered area in 1976. Production-sharing contracts will be offered for the other 12 blocks. Main terms offered for the contracts are that all expenses are born by the prospector with costs being repaid from the first 30% of commercial production. Thereafter, the remaining production will be split 80–20 in favor of Sri Lanka.

NORTH VIETNAM [17]

Warfare ceased in April 1975, and rehabilitation of bomb-damaged industrial facilities was nearly completed by yearend. Gross output value for central industries during the year was 34% higher than in 1974. Reconstruction and expansion of the electric power system were stressed because the Government realized that major improvements in the power system were necessary in order to restore the economy to a satisfactory level. Particular emphasis was to be paid to the power distribution system. Two major powerplants, Uong Bi and Ninh Binh, were returned to partial operation. Reconstruction of powerplants in Cao Ngan and Viet Tri was progressing satisfactorily, and plans were being laid for new thermal stations in Pha Lai and Dap Cau. It was reported that two-thirds of the electric power requirement in the country was generated by thermal powerplants fueled by locally produced coal. Electric power output was up nearly 30% over that of 1974.

Data on the country's mineral industry are difficult to obtain and seldom given in specific quantities. The few figures that are available are often couched in terms of percent increase over an indefinite base period. According to various sources, at least some production was reported in 1975 for coal, iron ore, chromite, apatite, tin, zinc, cement, gypsum, salt, antimony, and several nonmetallic construction materials.

COMMODITY REVIEW

Metals.—The Vietnamese were apparently constructing a small antimony-processing plant which would utilize locally mined ore. They were planning to begin production in the second quarter of 1976. The plant was to be the first of its kind in the country.

The Co Dinh chromite mine in Thanh Hao Province was operating during 1975. No reliable details were available on production rate or grade of ore.

It was reported that the Thai Nguyen Iron and Steel Works was operating all of its furnaces satisfactorily and that the capacity of the rebuilt plant was now 200,000 tons of ingot per year. It is questionable, however, whether the plant attained its rated capacity. No production figures are available for the iron ore mine at Trai Cau, the supplier for the Thai Nguyen plant. The rolling mill at Gia Sang was recommissioned in September 1975. The plant produces plates and rods, which were not produced domestically during the hostilities.

Tin continues to be mined at Cao Bang. Mine production was believed to be little changed at about 250 tons.

Zinc ore production continued at Cho Dien for smelting at Quang Yen.

Nonmetals.—Cement production was believed to have increased a small amount to

[17] Prepared by Gordon L. Kinney.

over 650,000 tons, but apparently this was not enough to meet the Government-planned production increase for 1975. The Haiphong cement plant continued as the Nation's largest producer but probably did not reach its prewar output level. Cement was therefore the only product in the mineral sector whose output had not surpassed prewar levels. Plans call for an over 20% increase in cement output in 1976 and the start of construction of a new cement plant at Binh Son and Phu Xuan.

Brick production was estimated at over 1,700 million with a rather ambitious increase of over 32% planned for 1976.

Fertilizer production has received a high priority since the end of the war, and projects are planned, underway, or recently completed that will greatly increase both the capacity and the variety of fertilizers produced. All planned production norms were reportedly met by the apatite mines and fertilizer plants in 1975. The Ha Bac fertilizer plant began Vietnam's first production of nitrogen fertilizer in December 1975. Its phosphate fertilizer capacity was being expanded at yearend, as was the phosphate plant at Van Dien. The Lao Cai apatite mine, which supports the superphosphate plant at Lam Thao, was also under expansion. The Vietnamese have been negotiating with a Japanese firm for the construction of a fertilizer plant worth about $50 million. The plant would have an annual capacity of 290,000 tons of sulfuric acid, 189,000 tons of phosphoric acid, and 90,000 tons of diammonium phosphate. Contract signing was awaiting the approval of financing by the Japan Export-Import Bank.

Mineral Fuels.—Coal production claims for the year were uniformly optimistic, with no hint of production problems. The target output was 5.3 million tons in 1975. Actual production was believed to be at least 4.0 million tons. Washed coal production exceeded the 1974 output by 30% to 40%. The Coc Sau unit of the anthracite complex at Hon Gai produced over 1 million tons. Several other units reported major production increases resulting from mine expansions and improvements. Further increases were believed hampered by inadequate coal washing capacity and bottlenecks in the transportation of coal to the consumer. Up to 650,000 tons of Hon Gai anthracite were exported to Japan during the year. A Japanese company was expected to help finance a coal-calcining plant to produce semifinished carbon anodes from high-grade anthracite.

Hanoi announced in August the formation of an Oil and Natural Gas Commission under the Council of Ministers. Rumors that Soviet geologists have found onshore oil in North Vietnam remain unconfirmed. At yearend, plans were being made to resume offshore geological exploration, possibly with Japanese or other foreign technical assistance.

SOUTH VIETNAM [18]

April 1975 saw the end of the prolonged war which left over 57% of the population homeless and over 16% killed or wounded. The new Government, headed by Nguyen Huu Tho, subsequently took over control of all major industrial and commercial undertakings.

Geological conditions in South Vietnam are favorable for mineral discoveries; however, no significant mineral surveys using geochemical or airborne geophysics had ever been conducted. No metallic ores of any consequence have ever been mined, but prospects for bauxite, iron, and nickel are promising. As a result of the protracted hostilities, mineral production was at a virtual standstill through most of the year.

The old Bien Hoa rolling mill was reopened with North Vietnamese technical assistance. The production level was 86 tons per day of structural and reinforcing steel. The capacity of the plant, which uses scrap steel as raw material, was rated at 20,000 tons of reinforcing bars per year.

Some salt and gypsum were produced, and cement production dropped to an estimated 50,000 tons.

Only toward yearend, when some semblance of order had been restored, did production of fertilizers from small plants resume after repairs. No reliable production figures are available, but fertilizer plants were reportedly operating in Dong

[18] By Gordon L. Kinney.

Nai, Thuan Hai, and Can Tho, and the first lime fertilizer plant in An Giang Province was under construction in Long Xuyen.

Coal deposits were limited to one small field near Nong Son in central South Vietnam. Coal production reportedly resumed late in the year, but no output figures are available.

No oil or natural gas has ever been produced in South Vietnam. Developments in offshore oil exploration, however, were of major significance. After the two discoveries by the Shell-Cities Service consortium in 1974, exploration by the Mobil Group continued, with a strike in February 1975 about 190 kilometers southeast of Saigon. The well tested at 2,400 barrels per day of 35° API gravity crude oil. The fall of the Government 2 months later forced the halt of all operations. The wells were plugged, and the oil companies returned to their bases in Singapore. It was reported that the companies had invested nearly $100 million in the concession rights, surveys, and drilling.

A few months after the Provisional Revolutionary Government consolidated control in Saigon, it announced a willingness to talk with the international oil companies. As of yearend only the Shell-Cities Service Group was reported to have had meetings with Vietnamese officials. What terms or conditions the Vietnamese were asking for are not known. It can be expected, however, that very tight controls will be placed on whatever companies are allowed to return to Vietnamese waters.

The Mineral Industry of Other Countries of the Near East

By Candice Stevens [1]

CONTENTS

In 1975, the petroleum industry was the focal point of mineral activity in the nations along the eastern edge of the Mediterranean Sea and the eastern and southern edges of the Arabian peninsula, which are the subject of this chapter. Oil revenue constituted the major source of Government income in the United Arab Emirates, Qatar, Oman, Bahrain, and Syria. Of the non-oil-producing countries, Jordan, Lebanon, and the People's Democratic Republic of Yemen were important centers for the refining of imported crude. In addition, Jordan, Lebanon, and Syria received supplemental income from pipeline transit fees.

A general trend began in 1974 and continued in 1975 towards increased government participation in indigenous oil operations. In 1974, two United Arab Emirates Governments—those of Abu Dhabi and Dubai—Oman, Qatar, and Bahrain each acquired a 60% share in the operations of foreign oil companies within their borders. In 1975, Dubai negotiated 100% control of its domestic oil industry, and Abu Dhabi, Qatar, and Bahrain announced their intentions of a similar takeover. As in Dubai, future arrangements were expected to keep the foreign companies involved in oil operations, providing technical assistance, markets, and transportation.

The area was the scene of major oil exploration activity during the year. The search for additional petroleum reserves continued both onshore and offshore in the countries of Bahrain, Oman, and Qatar, and in the Emirates of Abu Dhabi, Dubai, and Sharjah. Taking a new policy direction, Syria opened up both onshore and offshore tracts for foreign oil exploration. Concession areas were also granted in the non-oil-producing countries of Jordan, the People's Democratic Republic of Yemen, and the Yemen Arab Republic, and in the Emirates of Ajman, Fujairah, Ras al-Khaimah, and Umm al-Qaiwain. In Lebanon, continuing civil disorders interrupted the review of bids and granting of oil exploration rights.

The substantial oil price increases since 1973 considerably enhanced the liquidity position of the region's oil-producing countries, which invested a large part of their petrodollars in domestic industrialization projects. The less advantaged countries re-

[1] Economist, International Data and Analysis.

ceived indirect benefits from augmented petroleum revenue, in the form of foreign aid and loans extended through national and multinational channels. Abu Dhabi, in particular, earmarked a large share of its oil income for foreign assistance; the countries that received loans and grants from the Abu Dhabi Fund for Arab Economic Development included Bahrain, Jordan, Syria, the People's Democratic Republic of Yemen, and the Yemen Arab Republic and most of the other members of the United Arab Emirates. For the most part, any constraints encountered in the region's development efforts were nonfinancial ones posed by manpower shortages, infrastructure bottlenecks, and administrative shortcomings.

Priority was given to projects based on the utilization of the area's vast oil and natural gas resources. Refinery construction or expansion was underway in Jordan, Qatar, Syria, and Abu Dhabi. Previously flared natural gas was to be extracted for the production of natural gas liquids (NGL) in Oman, Qatar, Abu Dhabi, and Dubai, and converted into liquefied natural gas (LNG) in Qatar and Abu Dhabi. Also planned were fertilizer plants based on natural gas feedstocks in Oman and Qatar and a large petrochemical complex in Qatar.

Oil wealth was also being put to use in long-range attempts at economic diversification. Bahrain centered its efforts on the development of its aluminum industry, using abundant natural gas supplies, while both Syria and Dubai embarked on the construction of aluminum-processing complexes. Syria also contracted for the expansion of its steel mill capacity, and the construction of a direct reduction steel mill was in progress in Qatar. In Oman, the development of copper-processing facilities based on domestic copper reserves was under study. Cement production was already established in the region, with Jordan, Lebanon, Syria, Qatar, and the Yemen Arab Republic having cement plants in operation; Oman, Dubai, and Sharjah also planned to commence cement production for domestic use. Perhaps the most massive projects undertaken were the construction of major dry docks both in Bahrain, for the Organization of Arab Petroleum Exporting Countries (OAPEC), and in Dubai, which was to be the world's largest at its completion in 1978.

Table 1 lists production of selected mineral commodities in the countries covered by this chapter.

e Estimate. p Preliminary. r Revised. NA Not available.

[1] In addition to the commodities listed, crude construction materials such as common clays, stone, sand, and gravel presumably are produced, but output is not recorded quantitatively and general information is inadequate as a basis for formulation of estimates of output levels.

[2] Excluding gas used for gas lift.

[3] Includes gas reinjected to reservoirs, if any.

[4] In addition to the emirates listed (Abu Dhabi, Ajman, Dubai, and Sharjah), there are three others: Fujairah, Ras al-Khaimah, and Umm al-Qaiwain; these record no mineral production but presumably produce small quantities of crude construction materials.

[5] No marketed production reported; there probably is some small field use.

BAHRAIN

Bahrain's oil revenue increased from $85 million[2] in 1974 to approximately $280 million in 1975, due to both a rise in price and a greater government share in oil income. The petroleum industry continued to be the main pillar of the Bahraini economy, accounting for nearly 83% of government revenue despite declining rates of production at both the Abu Safah and Awali Fields. The Abu Safah Field in the Persian Gulf, in which Bahrain shares a 50% interest with Saudi Arabia, yielded only about 22 million barrels in 1975, compared with 44 million barrels in 1974. The Awali Field, situated at the center of the main Bahrain island, evidenced a similar downward trend as output fell from 25 million barrels in 1974 to 21 million barrels in 1975. Although exploration continued onshore and also offshore by the Superior Oil Co., which was granted a 35-year concession for exploration of 4,235 square kilometers of offshore waters, no new oil discoveries were made. However, Bahrain maintained its position as an important refining center in processing a substantial portion of Saudi Arabian crude, approximately 55 million barrels in 1975, in addition to all domestic production. Total throughput at the refinery at Awali, which had a total capacity of 250,000 barrels per day, averaged 215,500 barrels per day in 1975.

The conservation, production, refining, and marketing of Bahrain's petroleum has been controlled since 1930 by Bahrain Petroleum Co., Ltd. (BAPCO), a subsidiary of California Texas Petroleum Co. (CALTEX). BAPCO and the Bahrain Government reached an agreement in 1974 in which the Government acquired a 60% participation in BAPCO's crude oil production; in 1975 the Government announced its intention to extend this to 100% ownership. BAPCO will, however, continue to operate the refinery at Awali.

The production of natural gas in Bahrain was also to continue under the supervision of BAPCO, whose gas systems in the Khuff and Arab zones were expanded in 1975 to meet increased demand for the Government's industrial development projects and the BAPCO refinery. Natural gas production increased approximately 1.5% from 274 million cubic feet per day in 1974 to an average of 278 million cubic feet per day in 1975. Bahrain's gas reserves, which were estimated at 8 trillion to 11 trillion cubic feet, were projected as lasting another 50 to 75 years at current levels of consumption. In addition to fueling the country's single aluminum smelter, the natural gas was used for pressure maintenance in the Awali Field and for the commercial production of electricity.

Faced with the prospect of ultimate oil depletion, Bahrain has in recent years attempted to diversify its economic base, principally through the development of an aluminum industry using the abundant natural gas supplies. The production of aluminum at the smelter operated by Aluminium Bahrain, Ltd. (ALBA) continued as a successful venture in 1975 and prompted the Bahrain Government to increase its equity by buying out three of the remaining six shareholders. ALBA, originally a consortium of seven shareholders (the Bahrain Government, Kaiser Aluminum & Chemical Corp., Amalgamated Metal Corp., General Cable Corp., AB Elektrokopper, Western Metals Corp., and Breton Investments), was owned 77.9% by the Bahrain Government, 17% by Kaiser Aluminum, and 5.1% by Breton Investments at yearend 1975. The smelter, which opened in May 1971 near Askar on the island's east coast, produced 116,300 tons of aluminum in 1975, only 1,700 tons less than in 1974. This decrease was caused by a rectifier fire in November which necessitated the temporary closure of the plant. All ingot production was allotted to shareholders in proportion to their equity holding, and although the Amalgamated Metal Corp. no longer held equity, it was expected to continue marketing a large part of ALBA's production on behalf of the Bahrain Government.

Plans were made in 1975 for further additions to the aluminum operation, which received its alumina feedstock from Western Aluminium of Australia, a subsidiary of Aluminum Co. of America (Alcoa). A public company was formed to setup an aluminum extrusion plant which would permit local industries to obtain aluminum

---

[2] Where necessary, values have been converted from Bahraini dinars (BD) to U.S. dollars at the rate of BD1=US$2.53.

in a workable form and provide a foundation for ancillary industries using aluminum products. In addition, Vereinigte Aluminium-Werke (VAW) of West Germany was contracted to study the feasibility of building a $100 million aluminum rolling mill in Bahrain, using rolling slab from the primary smelter.

Bahrain also planned to compensate for decreasing oil reserves by capitalizing on its favorable location at the crossroads of the bulk of international petroleum shipping. Site work began in early 1975 on a major drydock to be located on Muharraq Island, 6 kilometers off the northern coast of the main Bahrain island. The OAPEC-sponsored drydock, known as the Arab Shipbuilding and Repair Yard (ASRY), was estimated to cost $200 million and was expected to be fully operational by 1977–78. The Lisnave Group, a Portuguese shipbuilding company, was the original consultant for the project, while the final construction contract was acquired in late 1975 by the South Korean firm Hyundai. ASRY was to carry out hull repairs in its initial stages, and later extend its operations to superstructure work and overhauls of engines and turbines. The single drydock, which was projected at a length of 375 meters and a width of 75 meters, was to be capable of accommodating vessels up to about 500,000 deadweight tons. Apart from servicing tankers in transit, it was predicted that the dock would become pivotal to the Arab Maritime Petroleum Transport Co. (AMPTC), operated by OAPEC.

Further infrastructure development supported the Government's diversification program. Construction continued in 1975 on the new power and desalination plant at the north end of Sitra Island, which was initially to generate 60,000 kilowatts and produce 2½ million gallons of desalinated water per day. In addition, improvements were scheduled for Bahrain's port and transit facilities in support of anticipated increases in aluminum and petrochemical exports as well as of entrepôt trade. In 1975, as in previous years, about one-third of the goods traversing Bahrain's single port, Mina Sulman, were reexported, principally to other Persian Gulf States. The Mina Sulman port, which consisted of six berths, was designated for an extension of six additional berths and supporting facilities. Bahrain's position as a cargo transit port was also to be enhanced by the construction of a causeway linking it to the eastern province of Saudi Arabia, which was to cover the cost of approximately $250 million.

JORDAN

Phosphate rock, produced primarily for export, continued to dominate Jordan's mineral industry in 1975. This was true despite a decline in phosphate exports from 1.5 million tons in 1974 to 1.1 million tons in 1975, due to weakened international demand. However, because of high prices at the beginning of 1975, phosphate export earnings remained at the record level of $61 million[3] and accounted for about 37% of the value of total exports. Increased phosphate revenues were a contributing factor in Jordan's general upswing, which began in 1972 and continued in 1975 when the gross national product (GNP) again attained the 1974 level of about $1 billion. The mining sector contributed about 15% of this total; key industries in addition to phosphate production were cement manufacturing and petroleum refining based on imported crude. Included in the 15% were the earnings of the gypsum, clay, lime, and salt, industries production levels of which remained virtually the same as in 1974. Production of Jordan mineral commodities in 1975 is reported in table 1. Potential additions to Jordan's mineral sector, subject to further exploration and development, were reserves of potash, copper, manganese, uranium, and vanadium.

One objective of Jordan's focus on expansion of export-oriented industries based on indigenous mineral resources has been the need to reduce its chronic balance of trade deficit. In 1975, Jordan's exports increased very slightly while its volume of imports continued upward rapidly, producing a record trade deficit of $606 million. However, as in past years, budget support from other Arab countries and the United States and development loans and grants helped to cover the shortfall of domestically generated revenues. Foreign assistance, which in 1975 ran at the high figure of $870 million, plus large remittances from Jordanians working abroad, helped achieve a balance of payments surplus of about $150 million for the year.

The reopening of the Suez Canal in July greatly strengthened Jordan's position in relation to its important East European mineral markets and necessitated the upgrading of port and transportation facilities. The anticipated growth in mineral exports was expected to be through the single Red Sea port of Aqaba, where handling capacity was slated for an increase from 600,000 tons to 1.5 million tons per year. In addition to this expansion scheme, phosphate storage capacity was to be increased from 180,000 tons to 410,000 tons, and average phosphate loading time to be improved from 2,000 tons per hour to 4,700 tons per hour. The new rail line between the El Hasa phosphate mines and Aqaba, completed in October 1975, greatly facilitated phosphate transport to the port in addition to providing a continuous rail link from Aqaba to the Syrian border. Concurrently with the port expansion, improvements in road access to Aqaba were to be implemented, most notably a new road linking Aqaba directly with the Dead Sea.

The importance of phosphate production to the Jordanian economy was illustrated in the 5-year plan to be launched in 1976, which anticipated that phosphate exports would contribute almost 60% of total commodity exports by 1980. While the 3-year plan of 1972–75 proved a little over optimistic in its aims, substantial progress was made in mineral production, which achieved an average annual growth rate of 23%. As in the 3-year plan, a major objective in the next 5 years will be further expansion of the phosphate operations at the El Hasa and Ruseifa mines, both of which are operated by the Government-owned Jordon Phosphate Mines Co. Specifically, the plan involved increasing productive capacity at El Hasa, located nearly 200 road kilometers north of Aqaba, from 1.2 million to 2.4 million tons per year from the existing opencast mine, and developing a 1.8-million-ton-per-year underground operation at that same location. A smaller expansion project to increase phosphate production capacity to 1 million tons per year was scheduled at Ruseifa, located about 15 kilometers by road northeast of Amman or about 160 kilometers farther from the port of Aqaba than El Hasa. Plans were also made to further explore and develop the major phosphate deposits situated near the Amman-Aqaba rail link, where reserves were estimated at over 300 million tons. Total phosphate re-

[3] Where necessary, values have been converted the rate of JD1=US$3.18.
from Jordanian dinars (JD) to U.S. dollars at

serves in the country were estimated at 3 billion tons, with about 15 million tons extracted at yearend 1975.

The largest project designated by the 5-year plan was the construction of a $180 million fertilizer export plant near Aqaba, which was expected to produce approximately 600,000 tons per year of monoammonium phosphate and diammonium phosphate for distribution in Asia, Africa, and the Middle East. The scheme was undertaken jointly by the Jordan Fertilizer Industry Co., the Government, the International Finance Corp., and the U.S.-based contractor, Agrico Chemical Co. It was hoped that by 1980 the plant's export earnings would be nearly $100 million.

Cement manufacturing declined slightly, from 596,000 tons in 1974 to 572,200 tons in 1975. Nevertheless, the West German firm Polysius was contracted to build a new cement plant in south Jordan, expected to operate at a capacity of 2,000 tons per day.

Oil exploration in 1975 in the northern and western parts of the country under the aegis of the U.S. Filon Corp. produced some promising results, and the drilling of the first exploration well based on these studies was scheduled for the fall of 1976. Contracts were awarded to expand the Zerqa refinery, situated a few kilometers northeast of the capital, Amman, which would increase its capacity from 16,000 to 60,000 barrels per day. In 1975, the Zerqa refinery continued to receive crude oil deliveries over the Trans-Arabian Pipeline (TAPline), even though Jordan's payment to TAPline ceased in protest of the company's request for a sixfold increase in the price of crude. At the same time, TAPline terminated its payment of transit fees to Jordan for the passage of crude oil over the pipeline through Jordan to Lebanon. The price dispute had not been resolved by yearend 1975.

While phosphate remained the key mineral product in 1975, several other minerals loomed as potential significant contributors to Jordan's economy. Work was begun on a project to recover more than a million tons of potash per year from deposits off the southeastern shore of the Dead Sea. The potash project, supervised by the Jacobs Engineering Group, Inc., of California, was to include a full-scale solar evaporation plant and facilities for refining the extracted brine. An investment was also made in a further study of the copper deposits in the southern Wadi Araba region and the viability of establishing a copper processing plant on that site. Reserves were estimated at 65 million tons grading 1.6% copper, which would permit extraction of 10,000 to 15,000 tons of ore per day.

In addition to copper, the Wadi Araba region was identified as rich in manganese ore, with proved reserves at 1.5 million tons. Further evaluation of the economic importance of the manganese deposits was anticipated, as the Nation's total reserves were believed to be about 5 million tons. In November, preliminary uranium finds were made in the Dead Sea area of Ghor Al Safi, where reserves were reported at between 200,000 and 300,000 tons of ore. This discovery was being investigated for commercial possibilities, as were reports of the existence of 1 million tons of vanadium in the same region.

LEBANON

Lebanon's mineral activities have been primarily limited to cement manufacturing based on domestic raw materials, and petroleum refining based on crude oil imported from Iraq and Saudi Arabia. In 1975, internal disorders virtually halted the production of gypsum, limestone, and clay for use in Lebanon's three cement plants and brought cement production to a standstill. Total throughput at the country's two oil refineries was approximately 15 million barrels in 1975, a decrease of 12% from the 1974 level. This decline in input, coupled with a reduction in prices, resulted in a 15% decrease in the total value of Lebanon's refined petroleum products, from $65.5 million[4] in 1974 to $55.7 million in 1975.

Despite continued exploration activities in 1975, indigenous petroleum resources had not been found. In an attempt to expand oil exploration in its offshore acreage, the Lebanese Government in midyear invited international bids for exploration rights to the entire Continental Shelf under production-sharing service contracts. Permits which covered approximately 90% of Lebanese onshore territory had previously been granted to three companies—Compagnie Libanaise des Pétroles, Shaheen Oil Co., and Shaheen and Abdini Oil Co. A law passed in July 1975 gave the Government authority to cancel existing offshore and onshore exploration permits upon failure of the companies to fulfill financial obligations or scheduled technical programs. However, the civil disorder in Lebanon interrupted the review of the earlier agreements and caused the deadline for the submission of new bids to be postponed indefinitely.

The contracts under which Lebanon received Iraqi and Saudi Arabian crude oil as feedstock for its two refineries were both under renegotiation at yearend 1975. In accordance with an agreement concluded in early 1973, the nationalized Tripoli refinery in northern Lebanon was supplied by pipelines operated by the Iraq National Oil Co. (INOC) with a maximum annual allocation of 11.5 million barrels of Kirkuk crude oil for a 3-year period. Since the quantity was not entirely used by the Tripoli refinery during 1975, the Iraqi Government agreed to supply the unused balance during the early part of 1976 at the reduced contract price of $3.05 per barrel. All further crude oil supplies from Iraq were to be transferred under the financial provisions of a new Iraqi-Lebanese transit agreement. The revised terms, however, were being negotiated under circumstances that had significantly changed since the conclusion of the original contract in 1973. In 1975, Iraq constructed a strategic pipeline linking its northern oilfields to export terminals on the Persian Gulf. Crude oil exported from Iraq's southern ports was less costly than that exported from Mediterranean ports, due in part to prevailing low tanker rates and continued disagreement with Syria regarding transit fees. Consequently, the transfer of Iraqi crude oil by overland pipeline for export from Tripoli, which in 1975 earned Lebanon gross revenues of $14 million, was expected to decline. At yearend 1975, Iraq and Lebanon had not set terms for the delivery of Kirkuk crude oil to the Tripoli refinery, nor for the export of Iraqi oil from that Mediterranean port.

For similar reasons, in early 1975, Saudi Arabia ceased pumping crude through TAPline for export from Lebanon's other major terminal, Sidon. A considerable price advantage was realized by shipping Saudi Arabian oil to Europe from the port of Ras Tanura on the Persian Gulf via the Cape of Good Hope. The cessation of TAPline's export operations in Lebanon, however, interrupted the crude oil supply to Lebanon's second refinery at Zahrani, just south of Sidon. Although owned by the Mediterranean Refining Company (MEDRECO), which in turn was owned by CALTEX and the Mobil Oil Co., the 17,500-barrel-per-day-capacity refinery was taken under Government sequestration in August 1973. As an outgrowth of a lengthy dispute regarding exrefinery pricing, the Lebanese Government confiscated the MEDRECO refinery's daily crude oil requirements from TAPline without payment for the period of August 1973 to February 1975. After that time, the MEDRECO refinery resorted to processing crude oil from the 2 million barrels held in storage at

---

[4] Where necessary, values have been converted from Lebanese pounds (L£) to U.S. dollars at the rate L£1=US$0.3922.

Sidon, which stocks were replenished later in the year by limited deliveries from TAPline. The additional crude oil was supplied under a provisional pricing agreement concluded by Lebanon, Saudi Arabia, and TAPline, which fixed the rate per barrel at the lesser of either the tax-paid cost or the realized market price. In accordance with this formula, the Lebanese Government paid approximately one-third of its $1 million debt to TAPline for the crude sequestered since 1973. At yearend, no agreement had been reached on a formula for the payment of the cost of future deliveries to the MEDRECO refinery.

Arrangement were not concluded regarding the construction of Lebanon's long-planned third refinery, which was to be a joint venture in conjunction with Saudi Arabia's General Petroleum and Mineral Organization (PETROMIN). Negotiations between the Governments of Lebanon and Saudi Arabia regarding the new refinery were postponed pending the resolution of the TAPline dispute and the resumption of internal order in Lebanon.

OMAN

Increased oil production and a greater Government share in petroleum earnings accounted in large part for Oman's sustained economic growth in 1975. Aside from petroleum and some natural gas, which was flared, no mineral commodities were produced. The petroleum industry contributed approximately 75% of Oman's GNP of $1.6 billion,[5] an increase of 14% over the 1974 GNP of $1.4 billion. Since 1974, the Oman Government has controlled 60% of the country's only oil-producing company, Petroleum Development (Oman), Ltd. (PDO). PDO bought back most of the Government's participation oil for resale to other shareholders in the company, whose equity was held 34% by Royal Dutch/Shell, 4% of Compagnie Française des Pétroles, and 2% by Portuguese Participations and Explorations Corporation (PARTEX).

Production of crude oil in Oman totaled 124,600,000 barrels (341,370 barrels per day), in 1975, compared with 106,046,000 barrels (290,500 barrels per day) in 1974. Approximately 82% of the 1975 output was derived from the four older fields, Fahud, Natih, Yibal, and al-Huwaisah, all situated in an area 280 kilometers southwest of the capital, Muscat. Four new fields, brought onstream between February and August 1975 about 128 kilometers southeast of the older fields, accounted for the balance of production. The Ghaba North, Qarn Alam, Saih Nihayda, and Saih Rawl Fields averaged 61,040 barrels per day for the year and attained a level of 100,000 barrels per day by yearend. These fields were expected to compensate in future years for declining production at Oman's older fields, where secondary recovery waterflood programs were in operation.

Continued exploration during 1975 yielded no new oil discoveries. However, development of the Lehkwair Field, located to the west of Saih Rawl, was to begin in early 1976. Future exploration and development activities were scheduled for the southern province of Dhofar, where the Amal Field was estimated to hold significant reserves of high-viscosity crude. The Oman Government awarded two new oil exploration concessions in 1975. France's Essence et Lubrifiant de France—Enterprise de Recherches et d'Activité Pétrolières (Elf–ERAP) and Japan's Sumitomo Petroleum Development were granted a 7,000-square-kilometer tract in the Abu al-Tubul area near the Saudi Arabian border. The Sunaina tract in northern Oman was awarded to the Texas-based company, Quintana Overseas. Offshore, exploration drilling was continued by West Germany's Wintershall consortium in a 480-kilometer stretch off Oman's northern coastline. Another consortium, consisting of Sun Oil Co., Home Oil Co., Canadian Industrial Gas and Oil, and Deutsche Shachtbau, maintained prospecting activities in a 13,000-square-kilometer tract south of Masirah Island. A third offshore concession is held by Elf-ERAP in a 5,000-square-kilometer area in the Straits of Hormuz along the shore of Musandam Peninsula.

Except for additions to stocks, all crude oil produced in Oman in 1975 was exported. Crude was transported from the four older fields by a 320-kilometer pipe-

[5] Where necessary, values have been converted from Omani rials (RO) to U.S. dollars at the rate of RO0.346=US$1.00.

line to a tanker-loading terminal at the Mina al Fahal port on the Gulf of Oman. During 1975, a 144-kilometer pipeline was completed, linking the four new oilfields to the original pipeline. Petroleum accounted for 95% of Oman's exports in 1975, earning revenues of $1,200 million. The principal destinations of Oman's crude exports were Japan and Western Europe. Western Europe was also the leading source of Oman's imports, and the United Kingdom continued to be the country's leading trading partner. Petroleum products, supplied primarily by Iran and the United Kingdom, accounted for about 5% of total imports and cost an estimated $31.8 million.

During 1975, the Oman Government considered various proposals for using the associated natural gas from oil production activities; reserves were estimated at 2.1 trillion cubic feet. Although the flow of gas was not deemed adequate to support an export industry and the limited production of past years was mostly flared, gas production was considered sufficient for the support of local industries. Gazocean of France entered into a joint venture with the Oman Government for the construction of a $400 million ammonia-urea complex, scheduled to produce 2,000 tons of fertilizer per day. Negotiations continued between the Oman Government and interested firms concerning the construction of facilities for the production of liquefied petroleum gas and pipelines for the transport of gas from the oilfields to the industrial areas along the coast.

Oman's first major industrial project outside the oil and gas industry was to be the construction of a new cement works near Muscat. Although the contract was awarded in 1973 to Associated Portland Cement Manufacturers, Ltd. (APCM) (United Kingdom) and Cementia Holding A.G. (Switzerland), the cement plant was still in the planning stages at yearend. Projected annual capacity of the plant was 300,000 tons, which would make Oman the largest producer in the Gulf area and give the country a surplus of cement over domestic requirements. The Oman Portland Cement Company Ltd., owned 49% by APCM and Cementia and 51% by the Oman Government, was formed to manage the cement plant.

Exploration activities by the U.S.-based firm Marshall-Oman, Inc., and the Canadian firm Prospection, Ltd., under a mining concession granted in 1973, uncovered significant copper deposits in the northern Oman Mountains. Estimated reserves were 11 million tons grading 2.25% copper. At yearend 1975, the Oman Government was actively considering the development of three mines west of Sohar and the construction of associated processing facilities, including possibly a copper smelter.

PEOPLE'S DEMOCRATIC REPUBLIC OF YEMEN

In 1975, the mineral industry of the People's Democratic Republic of Yemen was limited to the production of salt and the refining of imported crude petroleum. However, the Government embarked on a program during the year, to diversify the mineral sector by issuing tenders for the exploration and development of oil and other mineral resources.

In advertising for foreign oil companies to submit bids for oil exploration in the country, the Petroleum and Minerals Board offered a production-sharing arrangement on the basis of the first 40% of output for the foreign enterprise and the division of the remaining 60% in the proportion of 12% for the company and 48% for the Government. The most promising open zone for oil exploration was a 37,000-square-kilometer area in the eastern Thamud region. At yearend, the Soviet firm Technoexport was awarded a contract for oil exploration and development in 10,000 square kilometers of the Thamud area. A Canadian firm, Siebens Oil and Gas Ltd., contracted for oil exploration rights in the southern part of Socotra Island and its offshore for a 6-year period. In addition, the South Yemeni Algerian Petroleum Company (SYAPCO), owned 49% by the Algerian firm SONATRACH and 51% by the Yemen National Oil Co., was to continue its prospecting activities in the Hadramaut area in the central part of the country.

Another tender was issued for mineral exploration in selected areas, including Maahir-Ghabar, 50 kilometers southwest of

Mukalla, and Wadi Ghabar. Previous geological studies indicated the existence of copper, silver, gold, titanium, and zircon deposits in these zones. In July, the United Arab Emirates concluded a financing agreement with the People's Democratic Republic of Yemen Government for a large-scale mineral exploration program. The extensive surveying and prospecting project was to be conducted under the aegis of the Petroleum and Minerals Board over a 2-year period. At yearend, discussions were being held between the Petroleum and Minerals Board and a number of foreign firms regarding execution of the project.

The nation's sole refinery was located in Aden and operated by British Petroleum Refinery Ltd., (Aden). The refinery, capacity of which was reported at 160,000 barrels per day, processed crude imported from other countries, principally Iran, Kuwait, and Egypt. Domestic petroleum consumption in 1975 was estimated at 1,600 barrels per days; the balance of refinery output was exported. Salt production, which was centered at Khawr Maksoir under the direction of the State-owned General Salt Organization, was chiefly for local consumption.

The reopening of the Suez Canal in June 1975 was expected to greatly increase shipping activity at the port of Aden and to make it once again a major contributor to government revenues. After the closure of the canal in 1967, the number of ships entering the port, the primary function of which was bunkering oil tankers, fell from a yearly average of 6,000 to 3,000. In anticipation of increased shipping traffic at Aden, the Government initiated a renovation and improvement program, including redredging the harbor to a depth of 41 feet, adding underwater anchorages, and modernizing the port's loading equipment. Two international consulting agencies were also contracted with to prepare long-range development plans for expanding the port. Cost of the complete renovation program was estimated at $17.4 million, to be financed in part by a $13.5 million loan from the Arab Fund for Economic and Social Development.

QATAR

Qatar's substantial oil revenues in 1975 provided for continued economic growth and financed the Government's numerous industrial projects. Qatar's planned industrialization program included the construction of an oil refinery, natural gas processing facilities, a direct-reduction steel mill, and a petrochemical complex, as well as the expansion of the country's existing refinery and cement and fertilizer plants. Qatar's petroleum income soared to $1,700 million[6] in 1974, compared with $400 million in 1973, and reached $1,850 million in 1975 despite decreased oil production. The oil sector accounted for more than 52% of the GNP of $3,517 million in 1975, and provided well over 90% of government revenues.

During 1975, the Qatar Government was in the process of negotiating a 100% takeover of the two oil companies operating in Qatar, the Qatar Petroleum Co., Ltd. (QPC) and Shell Oil Co. of Qatar (Shell). The Qatar General Petroleum Organization (QGPO) was formed in 1974 to administer the Government's 60% share in both these ventures as well as its equity in all other petroleum related industries. The Royal Dutch/Shell Group and the Italian firm Ente Nazionale Idrocarburi held the remaining 40% equity in the Shell concession. QPC's remaining shares were held by British Petroleum (BP) (9.5%), Royal Dutch/Shell (9.5%), Compagnie Française des Pétroles (9.5%), Near East Development (9.5%), and Portuguese Participations and Explorations Corporation (2%). The conditions of the Government's 100% acquisition, which was expected to provide for management contracts for the concessionary companies, were to be finalized by mid-1976.

In an attempt to conserve oil resources, Qatar began in 1975 to moderate the pace of petroleum development and production. Crude output in 1975 totaled 159,482,000 barrels, a decrease of 16% from the 1974 level of 189,348,000 barrels. Production from Qatar's three offshore oilfields operated by Shell was at the rate of 260,000 barrels per day and accounted for over one-half of Qatar's overall production. The two major offshore fields, Bul Hanine and Maydan-Mahzan, produced about equally over 75% of the total offshore output. They were linked by pipeline to storage and loading facilities on Halul Island, which also served Shell's first-discovered (1960) smaller field, Idd el Shargi. QPC operated the onshore Dukhan Field, which averaged 176,936 barrels per day in 1975. Crude oil reserves in Qatar were estimated at 6 billion barrels.

An imminent addition to Qatar's producing fields was El Bunduq, an offshore discovery which straddled the Qatar/Abu Dhabi median line 23 kilometers northwest of Das Island. Startup was scheduled for early 1976 at an initial rate of 30,000 barrels per day. Crude output was to be transported via a 27-kilometer pipeline to the Abu Dhabi Marine Areas (ADMA) export terminal on Das Island, with the major part of production destined for Japan. Owned jointly by BP, Compagnie Française des Pétroles, and United Petroleum Developments of Japan, El Bunduq was under ADMA management. State revenue from the field was to be shared equally by Qatar and Abu Dhabi.

Qatar's petroleum exports in 1975 totaled 156,605,664 barrels, or about 98% of total crude production. Petroleum export earnings were approximately $1,700 million and accounted for over 97% of all export revenues. The remainder of crude production was used to fuel electric power and water desalination facilities and as feed for Qatar's oil refinery at Umm Said. In 1975, plans were made for the expansion of the 7,500-barrel-per-day refinery to a capacity of 30,000 barrels per day in light of growing domestic requirements. At the same time, the Qatar Government contracted Universal Oil Products Management Services to carry out a market survey and feasibility study for a second oil refinery with a capacity in the 80,000- to 90,000-barrel-per-day range.

Qatar's natural gas reserves, mostly associated with oil, were estimated at 7.5 trillion cubic feet. However, a new nonassociated gasfield discovered in 1974 off the northeast tip of the Qatar peninsula was expected to make a substantial addition to Qatar's reserves. Production in 1975 and prior years averaged about 200 billion

---

[6] Where necessary, values have been converted from Qatar riyals (QR) to U.S. dollars at the rate of QR3.95=US$1.00.

feet of gas, most of which was flared. Beginning in 1974, gas from Dukhan Field was transported by a 97-kilometer pipeline to QPC's new NGL facility at Umm Said. Production of gas liquids in 1975 totaled 2,149,697 barrels, including 1,002,566 barrels of propane, 701,333 barrels of butane, and 445,798 barrels of natural gasoline. Qatar began exporting natural gas liquids in January 1975, with exports for the year totaling 1,867,397 barrels.

The Qatar Gas Co. (QGC), a joint venture between the Qatar Government (70%) and Shell International Gas, Ltd. (30%), was formed in 1974 to supervise the utilization of offshore associated and nonassociated gas. The new company's first project was to be the construction of a second NGL plant at Umm Said to process gas produced in association with Shell's offshore oilfields. The plant, estimated cost of which was $350 million, was to begin production in 1978 at a rate of 7,700 barrels of propane, 6,300 barrels of butane, and 6,300 barrels of natural gasoline per day. An offshore gas pipeline network was planned in conjunction with the project.

A more ambitious venture under consideration by QGC was the construction of an LNG facility based on the recently discovered major dry gasfield in the Shell offshore concession area. At yearend 1975, Shell was conducting feasibility studies of the proposed LNG plant, which was to be built in the north of the Qatar peninsula at an estimated cost of $1.5 billion.

Associated gas piped from Dukhan Field was also used as feedstock for the Qatar Fertilizer Co. (QAFCO) plant at Umm Said. Controlling equity in the plant, which was brought onstream in 1973, was held by the Qatar Government, with 20% held by Norsk-Hydro (Norway) and 7% by Power-Gas Corp., Ltd. (United Kingdom). In 1975, the Qatar Government awarded a $21 million contract for expansion of the fertilizer facility to John Howard & Co., Ltd., of the United Kingdom and its Qatari partnership, Alattiyah Contracting and Trading Co. The expansion project, which was scheduled for completion in late 1978, was designed to double the plant's capacity to 1,800 tons per day of ammonia and 2,000 tons per day of urea. In 1975, Qatar exported 31,731 tons of ammonia and 148,098 tons of urea to earn about $40 million in foreign exchange.

Another expansion program was designated for Qatar's only cement plant, at Umm Bab on the west coast of the peninsula. Under the direction of the Qatar National Cement Co., the plant's annual capacity was doubled in 1974 to 220,000 tons. The second-stage expansion was to add an extra 100,000 tons per year by mid-1976, and a further 900 tons per day (328,000 tons per year) by yearend 1978. The total estimated cost of the expansion project was $200 million.

Construction began in 1975 on a 400,000-ton-per-year direct-reduction steel mill in the Umm Said industrial area. The plant, scheduled for completion in 1977, was to produce construction steel for both domestic consumption and export. The estimated cost of $200 million was to be allocated among the shareholders of Qatar Steel Co., Ltd. (QASCO), owned 70% by the Qatar Government, 20% by Kobe Steel Ltd., Japan, and 10% by Tokyo Boeki Ltd. of Japan.

The largest of Qatar's industrial projects was the $500 million petrochemical complex under construction at Umm Said. The complex was to consist of an ethylene production plant and a low-density polyethylene unit with annual capacities of 300,000 tons per year and 145,000 tons per year, respectively. The Qatar Petrochemical Co. (QAPCO), owned 80% by the Qatar Government, 15% by Charbonnages de France-Chimie (CDF-Chimie), and 5% by France's Gazocean, was established in 1974 to build, operate, and market the output of the plant. In 1975, QAPCO entered into a second joint venture with CDF-Chimie for the establishment of a $300 million petrochemical plant near Dunkirk in northern France. Owned 40% by QAPCO and 60% by CDF-Chimie, the plant was to produce 450,000 tons of ethylene per year. Both plants were to go onstream in early 1979.

SYRIA

Increased petroleum production and higher prices for petroleum exports in 1975 contributed to continued economic expansion in Syria and accounted in large part for the real increase in the gross domestic product (GDP) from $1.9 billion[7] to $2.5 billion since the 1973 Arab-Israeli conflict. The emphasis in 1975 was again placed on the petroleum sector, when, as part of a newly adopted policy, Syria invited Western firms to participate in its plans for increasing oil exploration, development, and production. Having opened 11 onshore tracts and 1 offshore tract for petroleum exploration, the Syrian Government signed three foreign contracts. One was with a U.S. consortium consisting of TRIPCO Petroleum Co., American Express, Reserve Oil & Gas Co., and City Investing Co. The production-sharing agreement granted the U.S. group prospecting rights in a 4,500-square-kilometer offshore area for 6 years. The other contracts were acquired by the Romanian firm Rompetrol, for an exploration tract in northeastern Syria, and the Hungarian firm Chemokomplex, for a tract in the central part of the country. Syria invited foreign bids for the investigation and development of mineral potential in other areas, principally phosphate rock, natural gas, sulfur, iron ore, and rock salt. Syria's mineral production in 1975 is reported in table 1.

In 1975, petroleum production in Syria reached 65.9 million barrels, a substantial increase over the modest initial production rate of 10 million barrels in 1968. The Karatchuk, Rumailan, and Suwaidiyah Fields, all in Syria's extreme northeast corner, were the source of the bulk of the crude production. A small portion was derived from the Djubissa Field, also in northeast Syria, which was opened in May 1975 at an initial rate of 5,000 barrels per day. The reserves of the new field were

[7] Where necessary, values have been converted from Syrian pounds (£S) to U.S. dollars at the rate of £S3.65 = US$1.00.

estimated at 130 million barrels of oil, which, in contrast to the heavier, high-sulfur crudes of the three older fields, was found to be both lighter (40° API gravity) and lower in sulfur content (0.62%). The added production from the Djubissa Field, which was to be greatly expanded in its second stage of development, was expected to increase Syria's crude output to the minimum rate required for membership in the Organization of Petroleum Exporting Countries (OPEC). In 1975, earnings from petroleum exports, which accounted for the major part of Syria's oil production, were approximately $451 million. A 60-kilometer spur line, with a throughput capacity of 21 million barrels per year, connected the new Djubissa Field with the main pipeline running from the northeastern fields to the Mediterranean port of Tartus.

The remainder of Syria's crude production was transferred to the refinery at Homs, located just north of the Lebanon border, and was combined with lighter Kirkuk crude from Iraq in a mixture of 20% Syrian and 80% Iraqi crude. The Homs facility was virtually destroyed during the Arab-Israeli conflict in 1973 but was rebuilt to attain a capacity of approximately 2.5 million tons per year. Refinery output increased 29% in 1975 to total 2,284,000 tons, which included 827,000 tons of fuel oil, 629,000 tons of gas oil, 374,000 tons of kerosine, and 343,000 tons of gasoline. Secondary refinery products and refinery losses made up the balance of output. This production covered three-fourths of Syria's domestic comsumption, which in 1975 was 3.1 million tons, including 1.8 million tons of residual fuel oil.

The Homs refinery was to be further expanded to a 5-million-ton yearly capacity by the addition of two distillation units under contracts to the Czechoslovak firm Technoexport and the Italian firm Ingeco S.p.A. of Milan. In July, the Banias Oil Refinery Co. was created with a capital of $420 million to undertake the management of a new state-owned refinery in the port city, which was slated for completion by yearend 1977. Constructed by Romania's Industrial Export Organization, the plant was to add an annual capacity of 6 million tons to Syria's refining operations, with the feed again a blend of heavier domestic oil and lighter Iraqi crude.

Revenue obtained from petroleum production and processing was supplemented by transit fees levied on Iraqi and Saudi Arabian crude transported via pipeline en route to Mediterranean ports. In 1975, Syria's transit revenues were reported at approximately $150 million, compared with $164 million in 1974. The relative decrease was due to the suspension of Lebanon operations in February 1975 by TAPline, which traversed a 127-kilometer stretch of southern Syria in carrying Saudi Arabian crude to the Sidon port in Lebanon. The bulk of Syria's transit income was earned on crude carried in the pipelines of the INOC to the ports of Banias in Syria and Tripoli in Lebanon. In 1975, the shipments of Iraqi crude averaged nearly 893,000 barrels per day. However, the agreement under which Iraq transported crude to the two Mediterranean outlets as well as to Syria's Homs refinery expired in December 1975 amidst a dispute regarding transit rates and the price of crude. The financial provisions, which had provided for Syria to purchase Iraqi crude oil at $3.05 per barrel in addition to collecting a 45-cent-per-barrel transit fee, were under negotiation at yearend.

The production of phosphate, Syria's other major mineral commodity, increased from 603,000 tons in 1974 to 857,000 tons in 1975 but fell short of the Government's goal of 1.3 million tons. Production was concentrated at Syria's three principal phosphate mines, all in the central part of the country, approximately 50 kilometers south of Palmyra and 160 kilometers southeast of Homs. Combined reserves at the Khunaifis mine, developed by the Romanian firm Industrial Export, and the al Sharqiyah mines A and B, developed respectively by Centrozap of Poland and Technoexport of Bulgaria, were estimated at 500 million tons. Most of the phosphate production in 1975 was trucked to the port of Tartus for export, earning approximately $8.6 million in foreign exchange; the remainder was feed for the Homs fertilizer plant. In support of phosphate exports, Syria has undertaken the construction of a 240-kilometer railway, to be completed by 1978 linking the phosphate deposits and the Mediterranean port.

Plans were announced in 1975 to supplement Syria's only existing nitrogen fertilizer plant at Homs, the output of which totaled 90,000 tons in 1975, with a second nitrogen facility to be built by the French company Creusot-Loire. Homs was also designated as the site for a large ammonia urea plant based on a 1,000-ton-per-day ammonia unit, which was to be financed by development loans from Saudi Arabia. In addition, a contract was granted in February 1975 to the Romanian firm Industrial Export for the erection of a 1,400-ton-per-day triple superphosphate plant, also in the Homs area. The contract, which was valued at $180 million, provided for a construction period of 35 months from the effective date of the agreement and for the Romanian contractor to assist in the operation of the plant during an initial 1-year period.

The diversification and expansion of Syria's mineral sector was provided for by investments made in 1975 in aluminum, steel, and cement operations. As part of the planned erection of an integrated continuous casting and aluminum rolling complex at Latakia, a contract was signed with Segim Company of France for the construction of a rolling mill scheduled for startup in mid-1976. Cement production was to be increased by the addition of two new production units, each with a capacity of 1,600 tons per day, at the Tartus cement plant, and by the construction of a new cement plant with a capacity of 3,000 tons per day in the northwestern city of Aleppo. The East German firm Investexport contracted for the expansion of the Tartus facility, while the Romanian firm Usine Export-Import concluded a $110 million agreement with the Syrian Government for the new plant. In addition, plans were made to expand, with Polish aid, the steel plant located in Hama by the installation of a 100,000-ton-per-year light-section rolling mill.

In November 1975, a new railway was inaugurated linking Qamishli in northeast Syria near the Iraqi border and the port city of Latakia. The port at Latakia was to undergo a substantial expansion program, including the construction of additional piers with a total length of 2,400 meters, the deepening of the harbor to accommodate ships of up to 50,000 tons, and an increase in storage capacity from 1.6 million to 3 million tons. Syria's other main export terminals, Tartus and Banias, were also slated for further extensions, and the improvements to all three port facilities were to be accomplished by yearend 1978.

UNITED ARAB EMIRATES

The oil sector was the most significant source of income in 1975 to the United Arab Emirates, formed in 1971 of seven former Trucial Coast sheikdoms. Petroleum revenue of the three oil-producing emirates —Abu Dhabi, Dubai, and Sharjah— amounted to about $4.8 billion.[8] Abu Dhabi, which held the presidency of the United Arab Emirates, was by far the largest oil producer and the only United Arab Emirates member of OPEC. The other four members of the federation—Ajman, Fujairah, Ras al-Khaimah, and Umm al-Qaiwain —each had awarded exploration licenses to foreign concessions. (See table 9).

Although united politically, the individual emirates exercised independent control over their budgets and oil receipts. The rapidly expanding incomes of Abu Dhabi, Dubai, and Sharjah prompted these emirates to embark on numerous development projects, centered primarily around the use of their massive oil and natural gas reserves. To stimulate investment in the nonoil-producing emirates, the United Arab Emirates Government established a development bank to provide loans and financing for both petroleum- and nonpetroleum-related projects. In 1975, the Government contracted Hunting Geology and Geophysics Ltd. (United Kingdom) to conduct a comprehensive survey of the mineral potential of the emirates of Dubai, Sharjah, Ajman, Fujairah, Ras al-Khaimah, and Umm al-Qaiwain. Aerial photography, airborne magnetometry, gamma-ray spectrometry, and satellite studies were to be used in the exploration for both metallic and industrial minerals and in the preparation of geologic maps. The study was to cover 11,500 square kilometers of United Arab Emirates territory and to be completed in 16 months.

[8] Where necessary, values have been converted from United Arab Emirates Dirhams (UAED) to U.S. dollars at the rate of UAED3.95= US$1.00.

Abu Dhabi.—Abu Dhabi was the United Arab Emirate's largest petroleum producer in 1975 with a flow of approximately 1.4 million barrels per day from both onshore and offshore fields. Although the Government announced its intention of acquiring 100% ownership in ongoing oil operations, this action was postponed indefinitely at yearend. The Government-owned Abu Dhabi National Oil Co. (ADNOC) retained its 60% participation in the major oil operations, as well as its 100% control of natural gas reserves. However, owing to ADNOC's increasing marketing experience and ability, Abu Dhabi did conclude new marketing arrangements with its operating oil companies for 1976. In 1975, the production split was 40% equity, 40% buyback, and 20% state crude; in 1976, equity would remain at 40%, but buyback was to be cut to 30%, with ADNOC taking the remaining 30% of crude production.

Onshore, the Abu Dhabi Petroleum Co. Ltd. (ADPC) continued development drilling and the construction of extensive water injection projects in its three main oilfields, which had a combined output of about 891,000 barrels per day in 1975. A water injection scheme, operating at the rate of 500,000 barrels of water per day, was commissioned in Bu Hasa; a similar but larger scheme in Asab was partly installed, with final completion due in early 1976. The Asab, Bu Hasa, and Bab Fields were linked by pipeline to the Jebel Dhanna terminal on the coast. In addition, the new Sahil Field was brought onstream in mid-1975 at an initial rate of 5,000 barrels per day, and development drilling was in progress to raise output capacity to 20,000 barrels per day in 1976. ADPC's total production in 1975 was about 327 million barrels, or 64% of Abu Dhabi's annual output.

Offshore, Abu Dhabi Marine Areas Ltd. (ADMA) was the operator for Abu Dhabi's two major fields, Umm Shaif and Zakum, which averaged 421,500 barrels per day in 1975. These two fields, linked by pipeline to the Das Island terminal, were to undergo a $750 million waterflood and oil production expansion program to ultimately boost production to 1.2 million barrels per day. The offshore area administered by ADMA was the scene of exceptionally high activity during 1975, and the year closed with nine rigs drilling in the 31,080-square-kilometer concession area. Two further oil discoveries were made during the year, at Ghasha 2 and Sateh 1. ADMA's annual output fell about 9% from 169 million barrels in 1974 to 154 million barrels in 1975 owing to cutbacks early in the year.

Abu Dhabi's remaining three active oilfields were all offshore under the ownership of foreign concessionaires. The latest field to come into production (in August 1974) was Abu Al Bu Koosh, which had an output of about 66,000 barrels per day. Operated by a consortium including Sunningdale Oils Ltd., and Amerada Hess Corp., the field was 65 kilometers north of Das Island and constituted as extension of Sassan Field in Iranian waters. The smaller Mubarraz Field, operated by the Japanese consortium Abu Dhabi Oil Co. (ADOC), produced about 20,000 barrels per day. The BP, Compagnie Française des Pétroles, and between Abu Dhabi and Qatar, was scheduled for startup in early 1976 at 30,000 barrels per day capacity. ADMA was the operator for El Bunduq, owned jointly by BP, Compagníe Française des Pétroles, and United Petroleum Development of Japan. Crude was to be piped to Das Island by subsea pipeline, where it was to be processed and stored pending export, primarily to Japanese markets.

Development drilling was continued in the Arzanah Field by Amerada Hess, which projected startup for the field in late 1976. No activity was reported in the only other Abu Dhabi offshore concession, held by Sunningdale Oils. Onshore, the Phillips Petroleum Co. relinquished its 12,943-square-kilometer exploration tract which it had acquired in January 1967.

Progress was made during 1975 on Abu Dhabi's varied projects for the utilization of its petroleum and natural gas resources. The construction of the 15,000-barrel-per-day refinery at Umm al-Nar Island, initiated in 1974, neared completion. The refinery, which was to process crude piped from Abu Dhabi's onshore oilfields, was designed, engineered, and constructed by the Kellog Co. (United States) at a cost of $35 million. It consisted of four major processing units—crude distillation, hydrotreating, catalytic reforming, and gas recovery—for the conversion of crude into 5,280 barrels per day of light distillate, 4,410 barrels per day of diesel oil, and 5,310 barrels per day of reduced crude.

On Das Island, 170 kilometers offshore, the natural gas facility under construction by the Abu Dhabi Gas Liquefaction Co. Ltd. (ADGLIC) was scheduled for startup in the fall of 1976. The plant was built by the Bechtel Corp. (United States) and Chiyoda Chemical Engineering and Construction Co. Ltd. (Japan) under the direction of ADGLIC, in which the State held 51% equity. Designed to utilize 550 million cubic feet per day of associated gas from the offshore Umm Shaif, Zakum, and El Bunduq Fields, the Das Island project's annual production would consist of 2.2 million tons of LNG, 800,000 tons of liquefied petroleum gas (LPG), 220,000 tons of light distillate, and 230,000 tons of pelletized sulfur. Under a 1972 agreement, Tokyo Electric Power Co. Ltd. (TEPCO) of Japan contracted for the plant's annual output of LNG and LPG over a 20-year period at a price slightly under $1 per million Btu. In the course of renegotiation of the TEPCO supply contract in 1975, Abu Dhabi requested an increase in LNG prices which would link rates to current oil prices; the price dispute was not settled by yearend.

Also in 1975, the Abu Dhabi Government decided to implement a scheme to gather and process associated gas from the onshore Bab, Bu Hasa, and Asab oilfields operated by ADPC. Although the project was originally to be a joint venture with ADPC's foreign shareholders, which included BP, Compagnie Française des Pétroles, Shell, Exxon, and Mobil, negotiations reached a deadlock in September owing to the companies' refusal to assume their proportion of the expenses. The construction of the complex at Jebel Dhanna, which was to process 1.3 billion cubic feet of gas per day, was entrusted to the State-owned ADNOC. Output was to consist of approximately 185,000 barrels per day of NGL, in the proportion of 114,000 barrels per day of propane and butane and 71,000 barrels per day of natural gasoline.

Abu Dhabi entered the tanker business in 1975 with the establishment of the Abu Dhabi National Tanker Co. (ADNTC) for the maritime transport of hydrocarbon products. ADNTC, placed under the control of ADNOC, was to be responsible for the purchase, charter, and management of hydrocarbon tankers, as well as for the construction of terminals, storage tanks, and other facilities. In April, the company acquired its first tanker, the 269,000-ton *al-Dhafra,* as the initial step in building a national tanker fleet.

Ajman.—Oil exploration in Ajman proved unsuccessful in 1975, and in the latter part of the year, United Refining Co. (United States) relinquished its onshore and offshore concession areas. The only remaining prospecting rights in the emirate were held by Occidental Petroleum Co., which held claims to adjacent offshore areas in Ajman and Umm al-Qaiwain waters.

Dubai.—In July 1975, Dubai became the first Arab State in the Persian Gulf to negotiate a 100% takeover of its oil and gas industry. Dubai credited the foreign companies operating its two offshore oil- and gasfields, Fateh and Southwest Fateh, with $110 million in compensation for past investment. Equity shares in the Dubai Petroleum Company (DPC) were held 30% by Continental Oil Co., 50% jointly by French CFP and Spanish Hispanoil, 10% by Deutsche Texaco, and 5% each by Sun Oil Co. and German Wintershall. Under the new agreement, the companies were to maintain their responsibility for exploration, production, equipment, and marketing, as well as to provide all financing.

During 1975, DPC continued its waterflood and gas reinjection scheme designed to raise production of the Fateh and Southwest Fateh Fields from 250,000 barrels per day to 400,000 barrels per day in 1976. However, a severe gas blowout and fire occurred in Fateh in July and interrupted the secondary recovery program. Production was restored to 149,000 barrels per day at Fateh and 102,000 barrels per day at Southwest Fateh, but the plan to average over 300,000 barrels per day in late 1975 had to be abandoned. Overall, production increased about 5% over the 1974 output and contributed nearly $700 million to Dubai's revenues.

DPC also had promising prospects in the 1 Rashid wildcat drilled in 1973 about 24 kilometers south of Fateh, which tested oil and gas in significant quantities. Drilling was also in progress by Texas Pacific Dubai Inc., a subsidiary of Distillers Corp.-Seagrams, Ltd. (Canada), in its 2,020-square-kilometer offshore concession area acquired in 1974. The group, whose shareholders included Texas Pacific Dubai (50%), Union Texas Dubai Inc. (25%), Louisiana Land & Water Co. (12.5%), Quintana Dubai Inc. (7.5%), and Natomas of Dubai Inc. (5%), signed a second agreement in 1975 for exploration rights to a 4,177-square-kilometer onshore area.

The Dubai Government announced plans to construct a complete industrial zone city at Jebel Ali, situated about 17 kilometers from the city of Dubai. Among the projects envisaged for the industrial area were an aluminum smelter, a natural gas liquefaction facility, a steel plant, a 200,000-barrel-per-day refinery, and a deepwater port. In April 1975, the Dubai Government contracted British smelter Construction Ltd. (BSCL) for a 1-year feasibility study and subsequent construction of the aluminum smelter at Jebel Ali. Equity in the Dubai Aluminium Co. (DUBAL), formed in 1975, was held 80% by the Dubai Government and 20% by BSCL. Production at the smelter, whose cost was estimated at $300 million, was to begin in 1979 at a capacity of 135,000 tons per year. At yearend, however, details regarding raw material supply, fuel supply, and financing for the project had not been announced.

At the same time, Sunningdale Oils of Canada was contracted by the Dubai Government to extract natural gas liquids from all gas produced in the emirate, which was about 102 million cubic feet per day in 1975. Construction was to begin in May 1976 on a $120 million gas processing plant at Jebel Ali. Sunningdale would also market the output of the plant, which was expected to produce 4 million barrels per year of NGL.

Construction of the Dubai national cement plant by Costain Civil Engineering began in May 1975 and was due for completion in mid-1978. The $50 million plant, located 10 kilometers south of the city of Dubai, was to have a capacity of 500,000 tons per year.

Fujairah.—No mineral production was reported in the emirate of Fujairah in 1975. Petroleum exploration continued offshore by Reserve Oil and Gas Co. (United States), which held a 1,500-square-kilometer concession in the Gulf of Oman off Fujairah's east coast. Seismic surveys were conducted during 1974 and 1975, and exploratory drilling was scheduled for late 1976.

Ras al-Khaimah.—Ras al-Khaimah, the northernmost emirate, had no proven oil reserves despite continued exploration activity in 1975. During the year, participation in the 2,330-square-kilometer offshore concession area held equally by Vitol Exploration B.V. (Netherlands) and Weeks Natural Resources Ltd. (United Kingdom) was broadened to include a multinational group. The new equity allocation was 25% each to Vitol and Weeks, 20% to the Italian firm Société Italiana Resine (SIR), 10% to the West German Deutsche Schactbau, 6% to United Refining (United States), 6% each to the Canadian firms Canadian Superior and Asamera, and 2% to Kewanee (United States). At yearend, the group was drilling a 1,600-foot exploratory well situated about 39 kilometers east of Sharjah's Mubarek Field off Abu Musa Island. Onshore, Norsk-Hydro A/S held a 1,700-square-kilometer concession, although no activity was reported.

In February 1975, Ras al-Khaimah awarded a joint venture group, consisting of Contracting and Trading Co. of Lebanon and Archirodon Construction Co. of Greece, a $40 million contract for the construction of a deepwater port at Kohr Kuwait. Consultants to the project were Halcrow Middle East Ltd., an affiliate of the British consulting firm Sir William Halcrow and Partners, Ltd. The contract provided for two berths, both 200 meters long and 12.5 meters deep, to accommodate 20,000-ton cargo vessels, and also for rights to the eventual expansion of the port facilities.

Sharjah.—Although Sharjah's oil production was still minimal compared with that of Abu Dhabi and Dubai, the emirate's crude output expanded rapidly and increased 38% over the 1974 level to reach 38,000 barrels per day in 1975. Production was limited to Sharjah's offshore Mubarek Field, situated in a 2,000-square-kilometer concession area around Abu Musa Island, in territory claimed by Sharjah, Iran, and Umm al-Qaiwain. Pending resolution of the dispute, state revenue from the field was to be allocated among the three parties. The Mubarek concession was operated by the Crescent Petroleum Co., owned 25.7% by Buttes Gas and Oil Co., 25% by Ashland Oil, Co., 25% by Skelly Oil Co., 12.5% by Kerr-McGee, 10% by Cities Service, and 1.8% by Juniper Petroleum.

During 1975, Crescent Petroleum Co. commenced drilling a third development well in the Mubarek Field. No other offshore activity was reported, although Reserve Oil and Gas Co. held exploration rights to a 1,500-square-kilometer area in the Gulf of Oman through a joint arrangement with the emirates of Sharjah and Fujairah. Onshore, the only concession area was held by a consortium consisting of U.S.-owned Crystal Oil Company (65%), Norway's Norsk-Hydro (30%), and France's Sogedip (5%). Crystal completed its seismic work in 1975, and planned to begin drilling its first development well in early 1976.

With its increased oil revenues, Sharjah planned and executed a number of development projects, including a 220,000-ton-per-year cement plant in the capital city. Valued at about $25 million, construction of the plant was by Six Construct of Belgium and under the supervision of Pacific Consultants of Japan. On the Sharjah waterfront, the first two phases of a new deepwater harbor designed and supervised by Sir William Halcrow and Partners, Ltd., was under construction by ARCHOSI, a consortium consisting of Archirodon S.A. of Greece, Hochtief AG of West Germany, and Six Construct of Belgium. The project, valued at $48 million, was initially to provide for seven deep water berths and over 4 kilometers of breakwaters. A third phase would allow the harbor to be expanded to 11 berths plus facilities for 1 tanker.

Umm al-Qaiwain.—Petroleum exploration was the only mineral activity in the emirate of Umm al-Qaiwain during 1975. The Umm al-Qaiwain Oil Group, with Zapata Exploration Co., (United States) acting as operator, began drilling at year-end in its 1,200-square-kilometer offshore concession area. Participation in the United States–Canadian consortium was altered during the year, with shares held 7.5% by Zapata, 25% by Canadian Superior, 20% by United Refining Co., 20% by Asamera Oil Corp., 10% by Kewanee Oil Co., 10% by Gulf Oil, and 7.5% by Andarko Production Co.

YEMEN ARAB REPUBLIC

The mineral industry of the Yemen Arab Republic played a minor role in the economy of the country, with mineral activities in 1975 limited to the manufacture of cement, the mining of small quantities of salt, and ongoing oil exploration. The Yemen Arab Republic's economy continued to evidence a substantial trade deficit, which in 1975 reached $200 million,[9] although this was offset by remittances from Yemenis working abroad and growing foreign economic assistance. During the year, the Yemen Arab Republic received increased loans and grants from the Arab countries, channeled both bilaterally, such

[9] Where necessary, values have been converted from Yemen rials (YR) to U.S. dollars at the rate of YR4.5=US$1.00.

as budget subsidization from Saudi Arabia estimated at $500 million, and multilaterally, in the form of numerous project loans from the Arab Fund for Economic and Social Development. Although preliminary mineral surveys of selected areas of the Yemen Arab Republic were being conducted by the United Kingdom and the U.S. Geological Survey, in 1975 Abu Dhabi offered to underwrite the cost of a comprehensive surveying and prospecting program of the country's mineral potential.

Owing to a large-scale expansion program at the port of Salif, funded by the Kuwait Fund for Arab Economic Development, the export of salt by the Yemen Arab Republic was suspended for the most part in 1973. Prior to that time, yearly exports of rock salt mined at open pit operations at Salif averaged 70,000 tons. The modern salt-handling facilities under construction at Salif were expected to increase the port's export potential to between 500,000 and 1 million tons per year, although foreign markets for these quantities were yet to be procured. The resumption of large-scale salt production was scheduled for late 1976.

The capacity of the Soviet-built cement plant at Bajil, northwest of Hodeida port, was 50,000 tons per year, though the plant was reported as operating at less than capacity since its construction in 1972. Most of the Yemen Arab Republic's cement needs continued to be supplied by imports. Plans were being discussed to expand the Bajil facility and build a second cement plant in the Hodeida area, but no arrangements had been finalized at yearend.

No oil was produced in the Yemen Arab Republic, although concessions were awarded in 1974 for exploration rights in the Red Sea and on the coastal Tihama plain. Royal Dutch/Shell announced that it would start exploration drilling in early 1976 in its 10,000-square-kilometer offshore concession in the Red Sea. However, a joint Japanese-United States venture, consisting of Sante Fe Minerals, Inc., and Toyo Menkakaisha Ltd., announced in the late 1975 its intention to abandon further attempts to locate petroleum and/or natural gas deposits in its Red Sea and Tihama concession areas. The company cited prohibitive cost factors and the lack of commercial quantities of crude in the offshore as prompting the decision to shut down its Yemen Arab Republic's operations.

During 1975, as in previous years, all domestic petroleum product requirements were met through imports under an agreement with the Shell Oil Co. The products were refined at the BP refinery at Aden in the People's Democratic Republic of Yemen and were shipped to the ports of Hodeida and Mokha on a biweekly basis. At yearend, however, the Yemen National Petroleum Co., which controlled product distribution, was negotiating a new agreement with the Kuwait National Oil Co. in regard to providing the Yemen Arab Republic's refined petroleum needs. In 1975, petroleum product imports were estimated as follows, in thousand barrels:

Motor gasoline	674
Kerosine	368
Jet fuel	67
Diesel oil	939
Residual fuel oil	211

The Mineral Industry of Other Areas of South America

By Nicholas G. Theofilos [1]

CONTENTS

ECUADOR

Ecuador's gross domestic product (GDP) in 1975 rose 23% at current prices (6% in real terms) despite a decline in the output of the country's key product, crude oil. The downturn in oil-export earnings was due to Ecuadorean oil being overpriced and thus noncompetitive in world markets during the early part of 1975. Also, production was cut back because of breaks in the trans-Andes pipeline and the attaining of full capacity storage at the Balao terminal near Esmeraldas.

The bulk of the crude oil production came from operations of the consortium composed of Corporación Estatal Petrólera Ecuatoriana (CEPE), Texaco, Inc., and Gulf Oil Co., in Oriente Province east of the Andes. After a 15% production decline in this region during 1974, a further 9% decline took place in 1975. Additionally, production from the fields in the Santa Elena Peninsula declined from 2,568 barrels per day in 1974 to 2,278 barrels per day during 1975.

No new major mining operations were brought onstream during 1975. However, following the signing of a concession agreement with the Government, development work started at the La Plata mine to exploit the estimated 180,000-ton reserve of copper, zinc, silver, and gold ore, with a proposed investment of $2.5 million. The project was expected to come onstream by yearend 1976.

Mineral exploration and assessment were carried out by the Dirección General de Geologia Minas (DGGM) in cooperation with foreign technical-assistance missions. A Belgian mission was expected to arrive to assess a porphyry copper deposit discovered by an earlier United Nations mineral survey. A five-man United Kingdom mission was allocated an 8,000-square-kilometer area in the western chain of the Andes for systematic geochemical exploration. Work on about 1,250 square kilometers had been completed and drilling was started on a copper prospect at San Miguel. Exploration for limestone and phosphate rock was also carried out.

In July 1975, Ecuador became the first nation in the Organization of Petroleum Exporting Countries (OPEC) to cut oil prices; it reduced its price 43 cents to $10.12 per barrel. At that time, shipments had dropped to 125,000 barrels per day against an authorized ceiling of 210,000 barrels per day. The price cut was achieved

[1] Foreign minerals specialist, International Data and Analysis.

by lowering the income tax rate to 53.06% from the previous rate of 58.83%, and raising allowable production costs for tax purposes from 45 cents to 51.2 cents per barrel. In addition, the Government raised its authorized production ceiling for the Texaco-Gulf consortium from 210,000 barrels per day to 225,000 barrels per day.

Three exploratory wells were completed during 1975 in the Oriente region, compared with six in 1974. Of the three wells, two were successful field extensions and one was a dry hole. One party-month of geologic work and about 3 party-months of seismic work were completed during 1975. Seismic work was also conducted offshore by both Northwest Pipeline Corp. and CEPE. Northwest signed a contract to drill in an area of 200,000 hectares; drilling was scheduled to begin in mid-1976. Included in the contract signed by Northwest was the requirement that it form a separate company with CEPE for the construction and operatiton of a petrochemical plant and an ammonia-urea plant.

[1] In addition to the commodities listed, a variety of crude construction materials (common clays, sand, gravel, and stone) undoubtedly is also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.
[2] Gem and industrial diamond production are estimated based upon a reported total production.
[3] In addition to this total, the Central Bank of Uruguay reported 63,161 cubic meters of granite as exports.
[4] Recovered from refinery gases.

FRENCH GUIANA

The mineral industry of French Guiana played no significant role in the Nation's economy. Minor quantities of clay, gold, sand, gravel, and crushed stone were produced in 1975.

The only exploration activity during 1975 was for petroleum. An offshore wildcat well was drilled by Entreprise de Recherches et d'Activité's Pétrolières (ERAP), but it was abandoned when basement rock was reached.

GUYANA

Complete nationalization of Guyana's bauxite industry occurred on January 1, 1975, when Reynolds Guyana Mines Ltd. was taken over and operated as Berbice Mines (Bermine). The Government of Guyana originally had agreed to compensate Reynolds for the approximate book value of the company's assets, which amounted to $14.5 million. However, this compensation was reduced to $10 million because of a settlement of claims between the Government and Reynolds regarding income-tax and bauxite-production levies.

The decrease in demand for raw materials by the U.S. aluminum industry caused a decline in actual output of bauxite and alumina during 1975. These lower production rates still remained profitable owing to the higher prices producers were able to obtain, mainly on calcined bauxite. Sales of calcined bauxite were not greatly affected by the widespread drop in demand for ordinary bauxite.

Guyana Bauxite Co. (GUYBAU), the larger of the two national companies, was expected to add 150,000 tons per year to its bauxite-calcining capacity with the construction of a new calcining kiln, which was to be completed by the middle of 1976. As protection against future fluctuations in foreign exchange rates, GUYBAU announced an innovative plan to set payment prices for its worldwide sales of calcined bauxite by using a composite currency unit based on the U.S. dollar, the pound sterling, the West German deutsche mark, and the Swiss franc.[2]

PARAGUAY

In 1975, Paraguay's gross national product (GNP) in real terms increased about 5%, in spite of declining industrial production and continuing poor market conditions for some of its most important exports. The mineral industry played a minor role in the economy of Paraguay. The only mineral commodities of any importance produced were 28,000 tons of lime and 265,000 tons of limestone. Iron ore as well as manganese and copper deposits are believed to exist, but difficulties of transportation contribute to making their development uneconomic.

Cement continued to be the most important mineral product produced. New installations to existing cement plants contributed to an increase of about 34%, bringing cement production to 138,000 tons. A Brazilian company, Camargo Correa Industrial, was evaluating a proposal to build a 1,000-ton-per-day cement plant to supply cement for three planned giant hydroelectric dams—Itaipú, Corpus, and Yacyretá-Apipé.

The interest in petroleum in recent years had not resulted in any discoveries, but exploration activities continued. Texaco Inc., Exxon Corp., Pennzoil Co., and Aminoil, Inc., were prospecting in the Balo Santo area. A 10,000-barrel-per-day refinery at Asuncion was operated by the State-owned Refineria Paraguaya, S.A., which held a refining monopoly.

SURINAM

Surinam achieved its independence on November 25, 1975. The country was expected to undergo a transition from a free-enterprise economy, dependent on large foreign mining companies, to a mixed economy of joint ventures between the Government and private investors, especially in the mining sector.

The bauxite industry has traditionally set the pace of Surinam's economy. Shipments of bauxite decreased drastically in 1975 owing to the worldwide recession, thus eroding the country's balance of trade. Production of bauxite decreased from 6.7 million tons in 1974 to 4.9 million tons in 1975. Two producing companies, Suriname Aluminum Co. (SURALCO), a wholly owned subsidiary of Aluminum Co. of America (Alcoa), and Billiton Maatschappij Suriname, N.V., owned by Royal/Dutch Shell, accounted for about one-third of the GDP. These two firms also accounted for 20% of the gross private investment and for about 90% of commodity exports (by value).

The bauxite deposits in Surinam have never been fully assessed, but known reserves have been estimated sufficient to last 25 years at the current rate of extraction. Total deposits have been calculated to be between 800 million and more than 1,000 million tons.

The Government of Surinam reportedly does not intend to nationalize the present bauxite industry. In joint ventures, the companies are to bring capital and technology to the ventures, and the Government is to contribute the use of public lands, concessionary rights, tax write-offs, and other investment inducements. Eventually, the Government would seek to buy into the bauxite companies with money provided by Netherlands development aid.

An offshore oil exploration program began in 1975, with ELF-Petroleum Surinam drilling a wildcat well that was subsequently abandoned. Esso Standard Oil Co. was to start seismic and geophysical work early in 1976.

URUGUAY

Despite the adverse world economic conditions, Uruguay's GDP, in real terms, grew almost 4% to $1.8 billion. In 1975, the Government attempted to solve the chronic economic problems by liberalizing foreign trade in the form of realistic foreign exchange rates and a foreign investment law guaranteeing profit repatriation.

The only significant mining activity in Uruguay was in marble quarrying, for which Uruguay is noted, and various construction materials. However, there was considerable interest in the country's iron ore deposits. At Zapucay, in the north, the deposits were believed to contain about 400 million tons of ore with an iron content of over 40%. Also, in the southeastern Departments of Florida and Treinta y Tres, deposits were estimated to contain 100 million tons of ore of 40% iron content.

Lack of coal and oil resources necessitate the development of the country's hydroelectric potential. A joint Argentina-Uruguay venture to build a $400 million hydroelectric plant at Salto Grande was proposed, with partial operation to start in 1979.

Cement plants of the Administración Nacional de Combustibles, Alcohol y Portland (ANCAP) operated at 97% capacity to produce 637,000 tons of cement, which was a record high in production. To meet further demands for cement, especially for the Salto Grande Dam project, ANCAP signed a contract with a South African firm, GATX-FULLER a subsidiary of General American Transportation Corp. of the United States, for $11 million in technology and equipment to expand the Paysandu plant on the Argentine border.

In August 1975, ANCAP announced plans to award to a Uruguayan firm, through competitive bidding, a 5-year contract to take over ANCAP's distribution of gasoline, kerosine, gas-oil, and lubricants. The sale of ANCAP's retail gasoline operations should lead to greater operational efficiency and lower distribution costs.

Uruguay's only refinery, operated by ANCAP, had a capacity of 49,000 barrels per day; all of its crude was imported. Chevron Oil Co. won a contract to explore for oil on the Continental Shelf off the Uruguayan coast, with work scheduled to begin in January 1976. A seismic survey over a 300-kilometer strip in the Santa Lucia basin was to be started by the Argentine State oil company, Yacimientos Petrolíferos Fiscales.

The Mineral Industry of Other South Pacific Islands

By Charlie Wyche[1]

CONTENTS

BRITISH SOLOMON ISLANDS

During 1975, the British Solomon Islands Protectorate (BSIP) reported no new activities in the mineral industry. In 1974, Mitsui Mining & Smelting Co., Ltd., established a joint venture with BSIP to mine about 1.2 million tons of bauxite per year. Bauxite production appeared imminent, but there were no definite indications when it would start.

Gold production, mostly from Guadalcanal, declined slightly compared with that of 1974. Production for the last 5 years follows, in troy ounces:

Year	Quantity
1971	444
1972	200
1973	520
1974	873
1975	803

[1] This area undoubtedly produces crude construction materials (common clays, sand, gravel, and/or stone) in addition to the listed commodities, but output is unrecorded and information is inadequate to make reliable estimates of output levels.

[2] Nickel-cobalt content of metallurgical plant products, plus nickel-cobalt in exported ores.

CHRISTMAS ISLAND

In 1975, phosphate rock and dust was the only mineral commodity produced on Christmas Island. Christmas Island, which is located in the Indian Ocean 1,046 kilometers south of Singapore and about 2,413 kilometers west of Darwin, Australia, has produced phosphate since 1900.

Production of phosphate rock increased about 11% in 1975 owing to strong demand in New Zealand and Malaysia. Phosphate dust, obtained in screening the rock, was exported principally to Malaysia, where it was used on plantations for direct application as a fertilizer.

The base volcanic rock of the island has been covered by coral limestone, which forms an irregular pattern of pinnacles. This in turn was covered by phosphates in beds averaging 6 meters in depth. There are three basic grades of phosphate. The highest grade is mainly apatite, about 36.5% phosphorus oxide. The next highest grade, containing about 33% phosphorus oxide, is basically a mixture of apatite, crandallite, and millisite. Crandallite and millisite predominate in the lowest grade ore, giving an average composition of 25% phosphorus oxide.

FIJI ISLANDS

The value of Fiji's mineral output declined, compared with that of 1974. Gold remained the principal mineral commodity, supplying 66% or $6.3 million [2] of the total mineral value estimated at $9.5 million. River sand and gravel contributed $2.1 million, quarried stone supplied an additional $0.6 million, and the remaining minerals accounted for $0.5 million.

Output of gold by the only producer, Emperor Gold Mining Co. Ltd., declined, as did the price of gold. At mid-year, the gold price was below Fijian production costs, and the company was forced to reduce its workforce of 2,000 employees about 15%. Total mineral output by Emperor Gold Mining was 68,744 troy ounces of gold, 26,462 troy ounces of byproduct silver, and several thousand pounds of byproduct tellurium.

In nonmetallic minerals, production of coral sand for cement, and river sand declined, while output of quarried stone increased.

In late 1975, the diamond drilling program for copper by Amax Exploration (Australia) Inc. and Anglo American Corp. of South Africa Ltd., ended on Viti Levu island. Four large drills were at work at the peak of the program. Drilling was difficult because of the highly weathered overburden and very friable and badly fractured rock. Nevertheless, wire line drilling using triple core barrels resulted in good core recovery. Footage drilled totaled about 25,900 meters. Drilling and assay results were being evaluated to determine if additional exploration was warranted.

[2] Values have been converted from Fiji dollars (FD) to U.S. dollars at the rate of FD1=US$1.25.

NAURU AND OCEAN ISLAND

The Republic of Nauru and Ocean Island lie just south of the equator, halfway between Honolulu, Hawaii and Melbourne, Australia. Nauru is the smallest independent republic in the world; its total area is 22 square kilometers. Phosphate rock was the only mineral produced on both islands, and the total production was exported.

During 1975, total combined output of the Republic decreased 4% below that of 1974, because of decreased demand in Australia and New Zealand, which had imported over 95% of the phosphate produced. Nauru rock was high grade, averaging 83% phosphate.

Installation of a calcining plant by Nauru Phosphate Corp. was completed in early 1975. However, calcined rock production, originally scheduled to start in June, was delayed. Samples were exported to Japan in late 1975 for testing by local manufacturers. If satisfactory, it was expected that commercial exports would commence in early 1976. Surface rock not previously exported was to be treated in the new plant. The product was lower in both carbon and cadmium than the untreated rock. Capacity of the two calciners in the plant was approximately 400,000 tons per year.

NEW CALEDONIA

The French island territory of New Caledonia is situated in the South Pacific. Its area covers approximately 20,720 square kilometers. Melanesians and Europeans, in about equal numbers, account for 80% of a population totaling 130,000. The political and administrative organization of New Caledonia was located at Noumea and was headed by a High Commissioner, a Territorial Assembly, and a Council of Government. In Paris, the Territory was represented in the French Parliament by one deputy and one senator.

A significant development in 1975 was the resolution of the long-standing tax problem between Société Nationale des Pétroles d'Aquitaine (SNPA), a French oil company, and the Government of New Caledonia. Taxes in the past were based on an 11% value—added tax on all nickel exports. The new tax would be a 50% tax on profits from the export of ferronickel and matte. The French Government would make up any differences in revenues to the Government of New Caledonia that occur during a 5-year transition period.

PRODUCTION

The economy of the island was almost exclusively concerned with producing nickel, and New Caledonia was the second largest producer among the market economy countries during 1975. The principal New Caledonian nickel producer was Société Anonyme le Nickel S.A. (SLN). During the year ownership of SLN was acquired equally by Imétal and SNPA. A record 71,000 tons of nickel was produced as a result of improvements in pyrometallurgical techniques. The furnaces were originally designed to produce only 60,000 tons of nickel. The company's research facilities at Trappes perfected an electrowinning process for treating New Caledonian matte that could result in a high-purity nickel product suitable for use in the most demanding alloys.

TRADE

Mineral exports, consisting mostly of nickel ore, ferronickel, and nickel-cobalt matte, were valued at about \$371 million[3] in 1975, compared with \$259 million in 1974. Exports of nickel ore, principally to Japan, decreased from 3.3 million tons in 1974 to 2.5 million tons in 1975. The average grade of nickel ore exported increased slightly to 2.65% nickel, from 2.46% nickel in 1974. Exports of ferronickel and matte during 1975 totaled 62,076 tons nickel content, 42,659 tons in ferronickel, and 19,417 tons in matte. Most of the ferronickel (70%) and matte (50%) exported went to France. The United States received 22% of the ferronickel, Japan, 6%, and Australia, 2%. Japan and the United States received 30% and 20%, respectively, of the matte.

COMMODITY REVIEW

Metals.—*Chromite.*—Société de la Tiebaghi produced 2,050 tons of chromite ore. The ore contained 47% Cr_2O_3 and 2.5% moisture. Japan received 1,000 tons of this ore as a 48.8% Cr_2O_3 concentrate.

Nickel.—Nickel ore production dropped in 1975 to 6,693,000 tons, compared with 6,961,000 tons in 1974. Again, SLN was New Caledonia's main ore producer and the only producer of refined nickel. In 1975, SLN's Doniambo refinery produced 71,068 tons of nickel (18,266 tons in matte and 52,802 tons in ferronickel), compared with 67,370 tons in 1974 (18,837 tons in matte and 48,533 tons in ferronickel). The production capacity of the Doniambo works, provided entirely by electric furnaces, was more than 70,000 tons of nickel per year. An extensive expansion program in both mineral and metallurgical processing was completed. As a result, metallurgical production was conducted in three electric melting furnaces, each of 33,000 kilowatt power rating. The main product of the Doniambo works was ferronickel. The other largest product was nickel matte, which was exported to Japan where it was converted into nickel oxide. Matte was also exported to France, where it was refined to nickel metal.

New Caledonia contains large reserves of the mineral garnierite, which contains 2% to 3% nickel and is well suited for pyrometallurgical processing. Company officials estimate the reserves of garnierite ore on the island to be 300 million tons. Laterites, which are also present on the island, contain 1.2% to 1.6% nickel but require a complex technology that consumes more energy. Reserves of laterite in New Caledonia were estimated at several billion tons.

Agreement on the development of lateritic nickel deposits on the island was reached between Patino N.V. of the Netherlands and the French Government. Under the agreement, Patino is to sell a 90% interest in its French subsidiary, Compagnie Française d'Entreprises Minières Metallurgiques et d'Invistessements (COFREMMI), to Bureau de Recherches Géologiques et Minières, (BRGM), a French Government agency. The price is $9 million in cash, in addition to royalty and profit participation valued at about $8 million. According to Patino officials, COFREMMI would then develop its Tiebaghi and Poum deposits in the northern part of the island, as well as the Ile Art deposit, which is to be transferred to COFREMMI by BRGM. Feasibility studies and metallurgical testing have begun. When the mining and milling complex in New Caledonia is completed, output is expected to be 33,000 to 44,000 tons of ferronickel per year. The agreement concluded 2 years of negotiations over the fate of the nickel deposits.

NEW HEBRIDES

In 1975, mineral activity in the New Hebrides was confined to the production of manganese ore. Production by Compagnie Française des Phosphates de L'Oceanie at the Forari manganese mine on Efate (Vate) Island declined slightly below that of 1974. The ore was exported mainly to Japan as a 42% manganese concentrate. The 10-year production and export data follow, in tons of contained manganese:

Year	Production	Exports
1966	29,553	25,236
1967	27,658	27,948
1968	21,306	17,432

PAPUA NEW GUINEA

The mineral industry in the newly independent nation of Papua New Guinea faced problems in both marketing and production during 1975. A decline in domestic mine production, dominated by copper, was evident in early 1975, as the world-wide recession was felt. The sharp fall in world copper prices forced earnings of Bougainville Copper Pty. Ltd., the nation's principal mine, down from $114.5 million[4] in 1974 to $46.1 million in 1975. This drop in earnings followed a $100 million drop in gross sales revenue, from $294 million in 1974 to $194 million during 1975. This resulted in an overall value of mineral output of $230 million, a decrease of nearly 22% below the $294 million reported for 1974.

Political independence came to Papua New Guinea on September 16, 1975, and the country's currency, the kina, was introduced in April 1975. Although the budget was expected to depend heavily on Australian aid, new taxes were generated within the country, principally from revised mining taxation laws. The Government moved to create a firm financial foundation which will obviate the need for another Bougainville contract negotiation in which taxes are increased.

PRODUCTION

Kennecott Pacific Pty. Ltd., and the Government were involved in negotiations with regard to taxes and royalties on development of the copper deposit of OK Tedi Development Co. for about 3 years. The two were unable to reach a satisfactory agreement, and Kennecott withdrew from the project.

The new tax law provided for only one charge on sales (a 1.25% royalty on proceeds of sales), and net transportation and smelting charges. This royalty is to be paid to the central Government, which in turn makes a portion of the proceeds available to the respective landowners. This payment meets all obligations to reward local groups for the use of their land. Companies were required to work within the Income Tax Act, which provides for a tax on company income (presently 33.33%) and on dividends paid overseas (a dividend withholding tax of 15%). There was no withholding tax on interest, and amortization of nondepreciable assets extends over the life of the mine.

A number of other issues were involved in Papua New Guinea's mineral development. These included investment guarantees by the Government and also the right of the operator to develop a project once it had been proven to be commercially viable. It is expected that these issues will be resolved during 1976. In the meantime, a number of firms continued to invest sizable sums of money in various mineral prospects. Kennecott, before its withdrawal, spent approximately 6 years and $18 million developing the OK Tedi copper prospect. Oil companies have spent almost $100 million over the years in search for oil or natural gas in commercial quantities. This work was continuing in the Gulf of Papua and onshore along the coast.

COMMODITY REVIEW

Metals.—*Copper.*—As in preceding years, total Papua New Guinea copper output was from the Panguna mine on Bougainville Island. This mine accounted for virtually all mine output, and contributed nearly 11% of the total ($425 million) export earnings in 1975. The operating company is Bougainville Copper Pty. Ltd., in which Conzinc Riotinto of Australia holds 53.6% of the shares, the Government 20%, and public shareholders 26.4%. The public shareholders include 9,000 Papua New Guineans. Production in 1975 totaled 172,477 tons of contained copper, compared with 182,868 tons in 1974. Output in the first half of the year was restricted for a short period because of a civil disturbance on the island. This caused copper production to fall to 79,171 tons in the 6 months ending June 30, some 10,000 tons below the corresponding period of 1974. Concentrate production for the year fell from 640,818 tons to 595,946 tons. The average grade for gold and copper, however, rose slightly giving a better yield from ore. The concentrate grade was 29.23% copper, 35.8 grams of gold per ton, and 70.94 grams of silver per ton.

The Panguna copper deposit is a porphyry type situated in the Kawerong Valley on the western slope of the Crown Prince Range in south-central Bougainville. Copper-gold mineralization with small quantities of silver and molybdenum is associated with a group of acid-to-intermediate intrusives. In the mineralized area the principal member is the Panguna andesite, consisting of massive flow rocks; they have been exposed and drilled to a

[4] Unless otherwise indicated, values have been converted from Papua New Guinea kinas (K$) to U.S. dollars at the rate of K$1=US$1.32.

thickness of some 900 meters. A recently completed evaluation program indicated reserves of approximately 870 million tons averaging 0.47% copper and 0.62 gram of gold per ton.

The Government-owned OK Tedi Development Co. was trying to establish total copper reserves of a deposit in the Star Mountains in northwest Papua New Guinea. Initial drilling results from a new test program were released in September 1975. Three vertical holes were drilled along the southern perimeter of the main porphyry deposit and three in a magnetite skarn deposit. The assays for the main deposit were: Hole one, 0.72% copper from 183 to 200 meters and 0.78% copper from 226 to 261 meters; and hole two, 0.99% copper from 125 to 331 meters; the third bore showed low-grade ore, and no figures were given. In the northwestern skarn deposit, drilling intersected 5.6 grams of gold per ton of ore from 30 to 40 meters, 1.14% copper from the surface to 105 meters, and 1.95% copper near the surface of the third drill hole. A government statement said preliminary metallurgical tests indicated 88% of the copper in the porphyry body can be recovered, and in the skarn ore 82% can be recovered.

Several companies led by Broken Hill Proprietary Ltd. (BHP) were negotiating with Papua New Guinea to develop the OK Tedi deposit. Companies expected to be involved are Mount Isa Mines Ltd., Placer Development Ltd., and Sumitomo Metals Mining Co. Ltd. Mount Isa and Placer were already involved in mining exploration in Papua New Guinea. Sumitomo participation was likely because Japan will probably be the biggest consumer of Papua New Guinea production. If the project proves economically attractive, production at an annual rate of 100,000 tons per year of copper concentrates was scheduled for 1983.

Three other copper prospects appeared promising. The most advanced was at Frieda River, where Mount Isa and Sumitomo spent about $10 million on development work. Reserves were estimated at approximately 500 million tons of low-grade porphyry ore. Another $10 million has been expended at the Yandera copper prospect, which is near the Frieda River Prospect. Drilling at Yandera has outlined indicated reserves of 124 million tons of ore, plus inferred reserves of an additional 214 million tons reported by Triako Mines, one of the three joint venturers. Mineralization was contained within three zones, with average grades assaying 0.42% copper, and 2.16 grams of silver ore per ton. Triako also announced that additional mineralization occurred in two of the three zones, but further work was required for tonnage assessment. Results of initial metallurgical testing were described as encouraging but uneconomic at present copper prices.

Other metals exploration was being financed by a variety of Japanese, Australian, and South African groups. Known mineralization included nickel, bauxite, gold, and titanium. A possible gold mine on Misima Island in Milne Bay was being tested. Work was in the initial stages, but geologists were optimistic that if the price of gold remained high the mine would be a profitable venture.

Mineral Fuels.—*Petroleum.*—There have been no commercial discoveries of oil and gas in Papua New Guinea. However, the U.S., Japanese, United Kingdom, and Australian companies were searching for oil and gas. In the Gulf District a partnership of BHP and Mobil Oil Corp. found a natural gas deposit containing estimated reserves of 1,000 billion cubic feet. It is considered that three times this reserve would be needed for a commercial field. A Japanese consortium, registered in Papua New Guinea as the PNG Petroleum Pty. Ltd., planned to drill nine wells. Half of the company is owned by Japan Petroleum Development Corp., and the other half is owned by Nippon Mining Co. Ltd. and several other Japanese firms.

Gas has also been found offshore in the Gulf of Papua by Phillips Petroleum Corp. Esso Australia Ltd. committed $17 million for which it will be entitled to 50% of any new discoveries by Phillips Petroleum Corp.
