Europe.—The British-French blockade caused a scarcity of bismuth in Germany, and early in 1940 the medical profession was asked to reduce prescriptions containing bismuth to a minimum. Germany has exported considerable quantities of bismuth compounds and salts; for the first 7 months of 1939 these exports totaled 126,103 pounds compared with 153,662 and 162,481 pounds for all of 1938 and 1937, respectively. The importation of salts into the United States from Germany dropped from 2,000 pounds in 1938 to 28 in 1939. The United Kingdom and France probably continued to be the world's largest importers of bismuth in 1939. Data are not available on British imports in 1939, but in 1937 they aggregated 703,847 pounds, of which 624,557 pounds were reported as from the United States and 75,506 from Canada. Shipments recorded as from the United States doubtless included bismuth metal of foreign origin (shipments en route, or from bonded warehouse, which originated in Peru and Mexico) as well as of domestic origin. The basis for British bismuth quotations was changed from sterling to the dollar in September owing to fluctuations in the monetary exchange. The metal is on the "no export except under license" list. French imports in the first 8 months of 1939 totaled 264,555 pounds (352,740 in all of 1938). In 1939 the Central Scientific Experimental Institute of Rare and Small Metals at Novosibirsk, U. S. S. R., began production of bismuth metal. This experimental plant will continue to recover metal from Zabaikal tungsten-molybdenum concentrates and from Adrasmansky copper-bismuth concentrates. The electrolytic zinc plant at Ordzhonikidze also is producing bismuth, and recovery of bismuth is contemplated from the lead-zinc ores mined at Tetiukhe. Data are not available on the resumption of bismuth-ore production in Spain, once the principal European producer.

Africa, Asia, and Australia.—The Union of South Africa, Uganda, and other countries in Africa probably produced small quantities of bismuth ore in 1939.

Native bismuth produced in the Tavoy district, Burma, totaled 224 pounds in 1935, 112 in 1936, 246 in 1937, and none in 1938. Bismuth ore originating in China and exported from Hong Kong totaled only 9,733 pounds in 1939 (51,454 in 1938) and went to Australia and the United Kingdom.

Queensland, Australia, produced concentrates containing 1,120 pounds of bismuth metal and 5,600 pounds of bismuth-tungsten ore in 1939. Operations were resumed at the wolframite-molybdenite-bismuth mines, Bamford Hill.

MAGNESIUM

By Herbert A. Franke and M. E. Trought

SUMMARY OUTLINE

Production (sales) of primary magnesium in the United States in 1939 was more than double the previous peak established in 1938, owing to large increases in domestic and foreign demand for the metal. The aircraft industry was chiefly responsible for the sharp advance in domestic demand. It not only produced more planes in 1939 but also substituted magnesium products for other materials in many parts of airplanes. The automobile, portable and high-speed equipment, textile, and other industries also extended their use of magnesium. Total consumption of structural and nonstructural products of primary magnesium and magnesium-rich alloys, used in these industries, advanced 77 percent; the use of structural products alone gained 84 percent and the manufacture of castings 73 percent. Nonstructural fabrications consumed by the munitions, chemical, and electrical industries increased 26 percent in 1939 over those in 1938. Doubtless the quantity of magnesium employed as a component in aluminum and other alloys and as a scavenger and deoxidizer in the metallurgical industry also rose appreciably. Although official data are not available, it is believed that a substantial part of the sales of domestic magnesium were exports, chiefly to the United Kingdom. Demand for metal from domestic and foreign consumers was so great in 1939 that exports had to be restricted. The lack of data on exports and stocks makes it impossible to evaluate the actual increase in domestic consumption of magnesium in 1939 compared with previous years.

The Dow Chemical Co., sole domestic producer of magnesium, enlarged its production facilities at Midland, Mich., in 1939 and began construction of a new plant at Freeport, Tex., in March 1940. The new magnesium plant will more than double the company capacity and will give the United States facilities to produce about 25,000,000 pounds of metal annually.

The quoted nominal price of magnesium at New York was reduced from 30 cents per pound (prevailing since 1931) to 28 cents in March 1939 and 27 cents in August 1939.

As a result of the rapid increase in demand for military aircraft abroad, consumption of magnesium probably established new peaks in 1939 in other countries. World output of magnesium may have increased about 35 percent over that indicated for 1938. Germany continued to be the chief producer and consumer, using magnesium alloys extensively in airplanes and automobiles and in place of heavier imported materials in other industries. The United Kingdom probably exceeded the United States in production and consumption of the metal, and France and Japan advanced rapidly.

Some authorities believe that consumption of magnesium will continue to expand because of the abundance of magnesium raw materials, the metal's lightness and strength, the improvements being made in corrosive resistance and fabrication technique, and the recent reductions in prices. America has not progressed as far as Europe in the use of magnesium alloys as construction materials, owing largely to the availability of aluminum and other alloys, the lower resistance to corrosion of magnesium, and the greater difficulties in fabrication.

Salient statistics of the magnesium industry in the United States, 1937–39

	1937	1938	1939
Primary magnesium sold or used....short tons..	2,270	2,410	5,325
Quoted price per pound [1]....cents..	30.0	30.0	27.0
Imports....pounds..	1,321	60	76
World production (estimated)....short tons..	21,900	26,400	36,200

[1] Lowest nominal price (New York) for primary metal ingot 99.8 percent pure, carload lots.

PRODUCTION

Production (sales) of primary magnesium in the United States in 1939 was the largest in history and totaled more than the combined output in 1937 and 1938; however, the 10,650,121 pounds sold or used in 1939 included some metal withdrawn from stocks.

Magnesium sold or used by producers and imported into the United States, 1935–39

Year	Sold or used by producers		Imports for consumption [1]	
	Pounds	Value	Pounds	Value
1935	4,241,218	(2)	884	$1,292
1936	3,903,312	(2)	1,126	1,479
1937	4,539,980	(2)	1,321	1,727
1938	4,819,617	(2)	60	188
1939	10,650,121	(2)	76	49

[1] Includes alloys and scrap (magnesium content).
[2] Bureau of Mines not at liberty to publish figures.

The Dow Chemical Co. enlarged its production facilities at Midland, Mich., in 1939 and to meet the tremendous demand for metal began construction of a $5,000,000 plant at Freeport, Tex., in March 1940 for completion late in the summer of 1940. The Texas plant will more than double the present annual capacity of 12,000,000 pounds. Magnesium chloride for the electrolytic process to be used at the Freeport plant will be obtained from sea water instead of underground brines, as at Midland. No data are available on the method to be used for extracting the $MgCl_2$ from the sea water, but apparently the reduction process will be similar to the one now employed at Midland, which was described by Gann in 1930 and 1932.[1] Minor changes

[1] Gann, John A., The Magnesium Industry: Ind. Eng. Chem., vol. 22, 1930, p. 694; Magnesium: Min. and Met., vol. 13, 1932, pp. 179-183.

since Gann described the process include the use of near-anhydrous $MgCl_2$ in the feed to 60,000-ampere cells.

Figure 1 shows trends in magnesium production and prices since 1915.

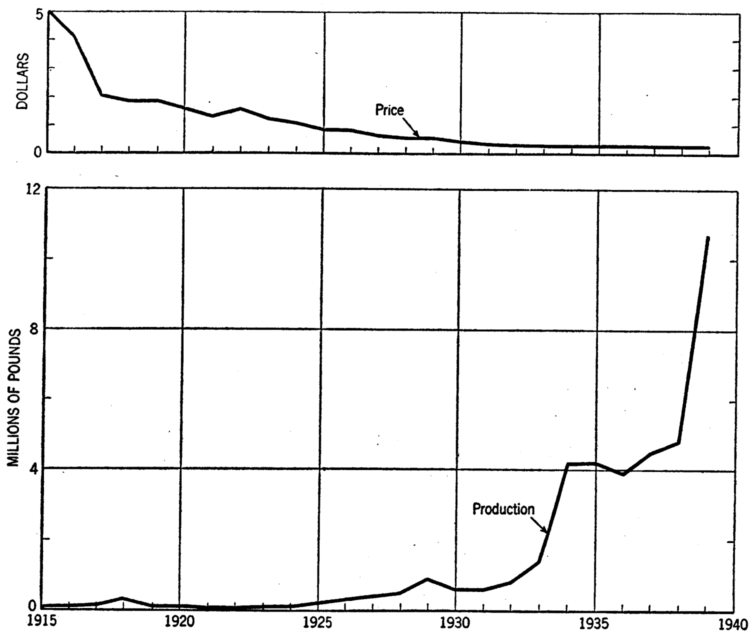

FIGURE 1.—Trends in quoted price and production of magnesium in the United States, 1915–39.

CONSUMPTION

As stated the large increase in demand for magnesium in the United States in 1939 is attributed chiefly to consumption by the aircraft industry. There was also a broader adoption of magnesium products in 1939 by certain nonaircraft industries, such as textiles, sewing machines, automobiles, conveying equipment, typewriters and other business machines, and heavy machinery.

The huge advance in use of magnesium alloy in the aircraft industry indicates not only augmented aircraft production but also the use of magnesium for more parts than formerly. Both military and civil authorities have accepted magnesium alloys to a greater extent since the corrosion resistance of the alloys has been improved. Because of the lightness and strength of these alloys, their use in aircraft results in increased pay loads and improved performance.[2] As aircraft-production capacity is expected to exceed 2,000 planes monthly in 1940, consumption of magnesium should be larger than ever.

[2] Winston, A. W., Magnesium Alloys and Their Use in Aircraft: Metal Progress, vol. 36, No. 3, September 1939, pp. 237–242.
Grant, L. B., Magnesium Alloys for Aircraft Parts (paper presented before Nat. Aircraft Production Meeting of Society of Automotive Engineers, Los Angeles, October 7, 1939): Iron Age, vol. 144, No. 18, November 2, 1939, pp. 36–39.

Quantitative data are not available on the increase in total consumption of domestic magnesium owing to the lack of information on exports and stocks. Complete data, however, are available on the manufacture of structural and nonstructural products of magnesium or high-magnesium alloys, sales of which gained 77 percent in 1939. Sales of structural products advanced 84 percent and nonstructural products 26 percent.

Magnesium products (other than ingot and stick magnesium) manufactured in the United States and sold or used by the companies manufacturing the products, 1937–39

[This table includes only the products made from magnesium or alloys containing high percentages of magnesium. It does not include the large quantity of metal used as a deoxidizer and in alloys with low magnesium content]

Product	1937		1938		1939	
	Pounds	Value	Pounds	Value	Pounds	Value
Structural products:						
Castings:						
Sand and permanent mold	1,180,190	$1,375,884	1,067,310	$1,392,882	1,321,080	$2,030,175

Grand total	1,519,058	1,669,595	1,462,593	1,788,415	2,588,504	2,975,585

[1] Some products formerly classified as "Wire and ribbon" are included under "Structural shapes, rods, and tubing."
[2] Minor quantities of shavings included under "Powder"; separate figures not available.

Castings comprised 78 percent of the structural products sold or used in 1939; of these, 72 percent were sand and permanent-mold castings (chiefly the former) and 28 percent die castings. The value of magnesium sand and permanent-mold castings in 1939 averaged $1.54 per pound; die castings, $0.73 per pound; and all castings, $1.31 per pound (the same as in 1938). Approximately 60 percent of all castings were used in airplane and aircraft-engine construction, and the remainder by the automobile, portable-equipment-and-tool, electric-motor (chiefly in squirrel-cage rotors), and foundry-equipment industries. Magnesium-alloy die castings were adopted for three starter and generator parts of a popular low-priced automobile and for many additional applications in the textile, business machine, and optical equipment fields. The engine hood, radiator shell and grille unit, control quadrant, and most of the instrument panel of a new lightweight tractor also are made of magnesium alloy. The European automotive industry has made wide use of magnesium alloys for a number of years, particularly for castings for bus and truck crankcases and transmission housings.[3]

[3] Alwicker, H., Use of Magnesium Alloys in the European Automotive Industry: Soc. Automotive Eng. Jour., vol. 45, No. 3, September 1939, pp. 9–13, 17–19.

In 1939 sales of sheet rose 45 percent; structural shapes, rods, and tubing, 285 percent; and forgings, 188 percent. The aircraft industry, which for the last few years has used increasing quantities of sand castings, also began using rolled sheet, extruded shapes, tubing, forgings, and die castings in 1939. In the United States magnesium-alloy sheet was produced for the first time for such interior parts of airplanes as walls, floors, seat and berth parts, partitions, doors, and other secondary structures. The Railway Express Co., Inc., adopted a portable roller-type gravity conveyor made almost entirely of magnesium alloy for loading and unloading. In Europe considerable quantities of magnesium alloy were used to construct tubes for thermit type incendiary bombs.[4] Magnesium wire was employed by the domestic electrical-equipment industry; magnesium ribbon for chemical uses; and magnesium shavings, powder, and sawdust for pyrotechnic, chemical, and welding applications. Shavings and coarse powder also were used for the synthesis of certain organic chemicals by the Grignard reaction, as in the production of phenyl ethyl alcohol and butyl alcohol.

Pure magnesium ingot and some magnesium alloy were used as scavengers and deoxidizers in the metallurgical industry, particularly for the degasification and cleansing of nickel, nickel-silver, monel metal, copper, brass, bronze, and aluminum. Magnesium also was employed to debismuthize lead by the Betterton refining process. Aluminum alloys carrying as much as 10 percent magnesium are more resistant to alkaline corrosion than other aluminum alloys and, when heat-treated, develop the highest tensile strength of any aluminum casting alloy.

All the magnesium fabricators in the United States in 1938 (listed in Minerals Yearbook, 1939, pp. 708–709) were active in 1939 except the Madison-Kipp Corporation. The Hoover Co., however, discontinued production and use of magnesium die castings during the year. The Ford Motor Co., 3674 Schaefer Road, Dearborn, Mich., resumed manufacture of magnesium sand castings in 1939, and the Magna Manufacturing Co., Inc., Haskell, N. J., began producing magnesium powder early in 1940. The Dow Chemical Co. began operating a new foundry at Bay City, Mich., and during the summer of 1940 will complete construction of a new sheet-rolling mill at Midland, Mich. The American Magnesium Corporation began operation of a magnesium foundry at 5151 Magnolia Avenue, Los Angeles, Calif., and Magnesium Fabricators, Inc.,[5] a division of the Bohn Aluminum & Brass Corporation, extended its plant at Adrian, Mich. Magnesium Products, Inc., 1119 Santa Fe Avenue, Los Angeles, Calif., and the Hills-McCanna Co., 2353 Nelson Avenue, Chicago, Ill., made magnesium products for the first time in 1939. Doubtless, other fabricating concerns mentioned in Minerals Yearbook, 1939, also enlarged manufacturing facilities in 1939.

Only a little magnesium scrap is on the market, and it is remelted by the Dow Chemical Co. and a new firm, Aluminum & Magnesium, Inc., Sandusky, Ohio, which produces secondary magnesium ingots. Most foundries remelt their own scrap, adding it to primary-alloy charges.

PRICES

The nominal New York price for 99.8-percent ingot magnesium, carload lots, was reduced from 30 cents per pound (prevailing since 1931) to 28 cents in March 1939 and 27 cents in August 1939. Ingot quotations for less than carload lots, 100 pounds or more, fell to 29 cents per pound. The price for extruded sticks, carload lots, was reduced to 34 cents per pound; for less than carload lots, 100 pounds or more, to 36 cents per pound. Alloy ingot normally is quoted at 3 cents per pound more than pure magnesium ingot. London quotations for magnesium ingot and stick advanced from 1s. 5d. to 1s. 6d. late in 1939. At the close of the year powder ranged from 3s. 9d. to 8s. 6d. per pound, according to grade and specification.

FOREIGN TRADE

Although official export data on magnesium are not separately recorded, it is reported that a substantial quantity of metal was exported in 1939, chiefly to the United Kingdom. Owing to the enlarged domestic demand and limited production facilities the domestic producer was unable to meet the greater demand from abroad in 1939. Imports in 1939 comprised only 66 pounds of magnesium metal and scrap valued at $24 and 10 pounds of magnesium alloys valued at $25, all from Germany. In 1938 imports totaled 60 pounds of sheets, tubing, ribbons, etc., valued at $188.

TECHNOLOGIC DEVELOPMENTS

The Dow Chemical Co. now can produce magnesium with improved resistance to corrosion by reducing such harmful impurities as iron by a special settling process. Surface-treatment methods for the decoration and protection of magnesium alloys from corrosion were developed further in 1939.[6] Exposure tests on magnesium alloys coated with chemicals and paint showed higher stability and very satisfactory performance. Magnesium-manganese alloys and magnesium-aluminum alloys with additions of zinc or tin offered more resistance to corrosion, and surface treatments using either the phosphoric-acid or chrome-pickle process seem satisfactory.[7] New primers also were developed for painting magnesium-alloy surfaces not chemically treated.

The art of die-casting magnesium alloys has advanced rapidly, and sound, dense metal now can be obtained at costs comparable to those of other die-cast alloys. The principle improvements in die casting have been the construction of strong, rigid, high-pressure machines that fill the die rapidly through well-placed gates and the introduction of cast-steel melting pots designed to maintain sulfur dioxide in contact with the molten metal and thus to inhibit active oxidation. An experimental die-casting alloy with superior tensile and yield strength after heat treatment was developed in 1939.

Alloys with improved mechanical properties and chemical stability that were introduced in 1939 included a sand-casting alloy, Dow-

[6] Grant, Leo, Surface Treatment of Magnesium Alloys: Metal Ind. (New York), vol. 37, Nos. 11 and 12, November and December 1939, pp. 544–545 and 605–606.

metal C (AM 260), characterized by better pressure tightness and more uniform properties; a sheet alloy, Dowmetal J-1 (AM C57s), characterized by high strength and resistance to corrosion; and a relatively low cost extrusion alloy, Dowmetal FS (AM 52s), which has greater stability than those used before.[8] An experimental wrought alloy containing 5.5 percent silver, Dowmetal Z, exhibits high hardness and high yield and ultimate strengths when heat-treated and aged. Extrusion and forging alloys put on the market have better resistance to corrosion than heretofore and are specified both by the Navy Bureau of Aeronautics and the Army Air Corps. Better corrosion resistance is obtained from new magnesium alloys by adjustment of the alloy composition and careful control of iron, copper, and nickel impurities.

Manufacturers also learned more about the art of forming and drawing magnesium-alloy sheet, particularly as to correct temperature control, rate of deformation, and type of equipment required.[9] Electric-spot- and gas-welding methods progressed and proved important in aircraft assemblies.

The Metallurgical Division of the Bureau of Mines obtained an appropriation in 1939 to continue its magnesium research at Pullman, Wash., and during the year discovered that better results are obtainable in the concentration of low-grade magnesite ores by flotation when cationic and anionic collectors are used alternately in successive steps. Other developments included a floating cathode cell which produces a superior quality of metal in electrolyzing crude $MgCl_2$. Hydrocarbon oil is used instead of hydrogen to chill and condense the magnesium vapor produced in the electrothermal reduction of magnesium oxide by carbon, and the magnesium and oil are separated by distillation.[10]

In Italy, Montecatini plans to produce magnesium from sea water by first freeing the water of carbonates by the addition of calcium oxide, then adding milk of lime to precipitate magnesium hydroxide, which is washed with carbonate-free sea water and treated with carbon dioxide. Next the crystalline magnesium carbonate recovered by filtration is treated with sodium chloride and water to give sodium-hydrogen carbonate and $MgCl_2$. The latter is dried, dehydrated, and electrolyzed in the molten form.[11]

WORLD PRODUCTION

Official data on world production of magnesium continues to be unavailable, but recently more trustworthy estimates of output have appeared in the literature than heretofore. Magnesium has strategic importance because of its use in military aircraft, flares, and bombs, therefore information on the industry is shrouded in secrecy in most countries. The figures in the following table are based entirely upon estimates except those for the United States, which represent actual sales. These data show that total world output of magnesium increased 21 percent from 1937 to 1938 and about 35 percent from 1938 to 1939. The United States produced 15 percent of the total in 1939.

Estimated world production of magnesium, 1937–39, by countries, in metric tons

Country	1937 [1]	1938 [1]	1939
France	1,500	1,800	2,500
Germany	12,080	14,100	16,500
Italy	66	102	300
Japan	1,200	1,500	(2)
Switzerland	230	300	700
U. S. S. R.	700	1,000	(2)
United Kingdom	2,000	3,000	5,000
United States (sales)	2,059	2,186	4,831
	19,800	24,000	32,800

[1] Partly based upon data supplied by Consul Sydney B. Redecker, Frankfort on the Main, Germany, and published in Bureau of Mines Mineral Trade Notes, vol. 9, No. 3, September 20, 1939, p. 9; and Lumsden, J., Magnesium, Magnesite, and Dolomite: Imperial Inst. (London), 1939, p. 23.
[2] Estimate included in the total.

Australia.—An electrolytic magnesium plant has been proposed at Hobart, Tasmania, to utilize dolomite occurring near Smithton.

Canada.—Adequate magnesium-bearing raw materials (including brucite, impure magnesite, dolomite, serpentine, and sea water) and cheap hydroelectric power are available in Canada, and, according to reports, Canada soon will begin to produce magnesium. The Consolidated Mining & Smelting Co. of Canada, Ltd., is experimenting with various magnesium-reduction processes. Interests in eastern Canada also are contemplating production of the metal. The National Research Council, Ottawa, is experimenting on electrolytic and electrothermic production methods.[12]

France.—Reports indicate that the four French magnesium producers increased output 40 percent in 1939. The output of the two principal works, at Saint-Auban and Jarrie, is sold by the Sté. Général du Magnesium. The two smaller producers are the Sté. Bozel-Malétra, at Villard, and the Sté. Astral, at Moissac. During the first 7 months of 1939, imports of magnesium totaled 213 metric tons compared with 121 tons during the same period of 1938.

Germany.—The German and Austrian production of magnesium probably reached full capacity in 1939 despite the shortage of power in some sections of the country. Adequate raw materials were available for the plant at Bitterfeld, which utilizes magnesium chloride solution from potash waste liquors in conjunction with domestic dolomite and Austrian magnesite, and for the plant at Heringen, which uses specially selected carnallite. Both plants employ an electrolytic process, whereas the Radenthein (Austria) plant uses magnesite and a new thermal reduction process. Germany has adequate magnesium-fabrication facilities; one of the larger producers and fabricators of magnesium alloys is the Rachwitz plant near Leipzig, belonging to Bernhard Berghaus & Co., a subsidiary of I. G. Farbenindustrie. War demands for magnesium are said to exceed output, and in the fall of 1939 use of the metal was restricted to purposes authorized by control authorities.

Italy.—New magnesium plants under construction in Italy in 1939 included one at Bolzano belonging to the Società Anonima Italiana per il Magnesio e le Leghe di Magnesio, of Milan; another at Cogne, Aosta Valley, owned by the Società Nazionale Cogne; and a third at Apuania, near Rome, to be operated by Montecatini. The first two

[12] Pidgeon, L. M., Production of Magnesium: Canadian Chem. and Process Ind., vol. 23, No. 8, August 1939, pp. 395–400.

plants, each having an annual capacity of 2,400 tons, will utilize dolomite from new deposits discovered in the Dolomite Mountains, while the third plant (1,200 tons annual capacity) plans to use sea water. The dolomite is expected to yield from 8 to 10 percent magnesium. At Bolzano the magnesium oxide will be reduced with ferrosilicon. The plant and dolomite deposits near Palmos Suergiu, Cagliari, Sardinia, belonging to the Società Anonima Magnesio Italiano Sulcis, sole Italian magnesium producer for several years, was purchased by the Società Nazionale Cogne and German interests and apparently was abandoned. The three new plants plan to attain capacity production (6,000 tons) by 1941.

Japan.—Magnesium and aluminum plants will be constructed in Korea and Manchuria to utilize the low-cost power of the Suiho hydroelectric works on the Yalu River, which is to be completed in 1940. Magnesium plants are proposed by the Korean Riken Metals Co. at Heijo (1,000 to 2,000 tons annual capacity), the Dai Nippon Salt Industrial Co. in the Antung-Shingishu district, the Japan Soda Co., Ltd., and the Kokusan Light Metal Industrial Co. Large reserves of magnesite are available in Manchuria and Korea. Three concerns, Minami-Nippon Kagaku, Minami-Nippon Engyo, and Asaki Denka, proposed to establish magnesium plants on the Island of Formosa, but reports indicate that only the last-mentioned concern received official authorization. No data are available on the production of magnesium in 1939 by the established Japanese producers, Nichiman Magnesium Co., Ltd., Japan Magnesium Metal Co., Ltd., Asahi Electro-Chemical Industry Co., Ltd., and Japan Soda Co., Ltd., but it is believed that output increased substantially. Licenses to construct new or to extend old magnesium plants were recently granted to the Kwanto Electro-Chemical Co. at Shibukawa, the Biken Kinzoku Co. at Ube, the Nippon Magnesium Co. at Toyama, the Toyama Keikinzoku Co. at Hakata, and the Okuro Kogyo Co. at Shimada.

United Kingdom.—The number of companies active in the production of magnesium is believed to have increased from two [13] in 1938 to five by the end of 1939. The latter include Magnesium Elektron, Ltd., at Clifton Junction; Magnesium Metal & Alloys, Ltd., at Rainham, Essex; Magnesium Metal Corporation, Ltd., at Port Tennant, Swansea, England; Lancashire Metal Subliming Corporation, at St. Helens, Lancashire; and the Cardiff Corporation, Cardiff, South Wales. In addition, a pilot plant is operated at Avonmouth, England, by the Imperial Magnesium Corporation, Ltd. British dolomite is used as raw material by the first producer, and the others probably use either domestic dolomite or imported magnesite. The direct Government control of supplies and prices of primary aluminum and some other materials has not yet been applied to magnesium.

During the first 8 months of 1939 the United Kingdom imported 1,521 metric tons of magnesium compared with 1,491 tons for the same period in 1938. Most of the tonnage imported in 1939 probably came from the United States, whereas Germany supplied 1,361 tons and the United States only 208 tons in 1938. Metal imports totaled 1,637 tons in 1938, 2,265 in 1937, 2,488 in 1936, 1,449 in 1935, and 995 in 1934.

ANTIMONY AND CADMIUM

By E. W. Pehrson and John B. Umhau[1]

SUMMARY OUTLINE

ANTIMONY

The antimony industry experienced an unusual year in 1939. The war in Europe and increasing industrial activity in the United States stimulated demand, particularly during the last third of the year when the world supply of ore appeared to be shrinking. For the fourth consecutive year the output of China, formerly the chief world producer, declined substantially. Japanese occupation of eastern China virtually has stopped exportation of antimony over the normal trade routes, but shipments on a reduced scale were maintained via French Indochina. For a portion of the year Oriental shipments were fairly well maintained by deliveries from Hong Kong; but toward the close of 1939 stocks were depleted, and shipments from this port were curtailed sharply. Production in Mexico likewise decreased in 1939, but during the latter part of the year the heavy export taxes that had been imposed in 1938 were removed with respect to the low-grade antimony ores, and exports rose appreciably. World production in 1939 is estimated to have been only a little lower than in 1938, as decreases in China and Mexico were largely offset by increases, chiefly in Bolivia and Yugoslavia.

The divergent trends in production and consumption brought about higher prices, although the increase may be considered moderate in view of the unusual conditions prevailing. For example, the New York price for American brands averaged only 12.36 cents a pound in 1939 compared with 12.35 cents in 1938. From a low of 11.25 cents in February the quotation gradually rose to 14.00 cents the latter part of September and remained at this level the rest of the year. Quoted prices for Chinese brands were nominal throughout 1939, averaging 14.44 cents at New York. After the outbreak of war in Europe the demand for domestically smelted metal became so heavy

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

that the chief domestic producer stipulated in its selling contracts that its metal was not to be used for war or speculation. This action was in line with the request of the Army and Navy Munitions Board that excessive exports of strategic raw materials be avoided to conserve domestic supplies.

Domestic mine output in 1939 was disappointing. Production of antimony from antimony or gold-antimony ores declined 40 percent. The antimony contained in antimonial lead derived from domestic ores (all kinds) was 50 percent less than in 1938, but comprised only 8 percent of the apparent consumption of antimony. The decline in domestic output was offset by larger imports of ore and regulus. As actual consumption of antimony probably increased appreciably because of greater production of storage batteries, bearing metals, oxides, and other compounds, it is believed that producer and consumer stocks were reduced to a considerable extent in 1939.

The Laredo and Los Angeles smelters reported substantial increases in production. Oxide-production facilities at the Laredo plant were enlarged during 1939, making more furnace capacity available for the production of metal. A third producer of antimony metal will begin operations in 1940; the Bunker Hill Mining, Smelting & Concentrating Co. has announced the construction of a new plant at Kellogg, Idaho, to recover electrolytic antimony and other metals from the tetrahedrite contained in the dry-belt silver ores of the Coeur d'Alene region. Formerly these ores were treated in lead furnaces, where the bismuth content was a troublesome impurity.

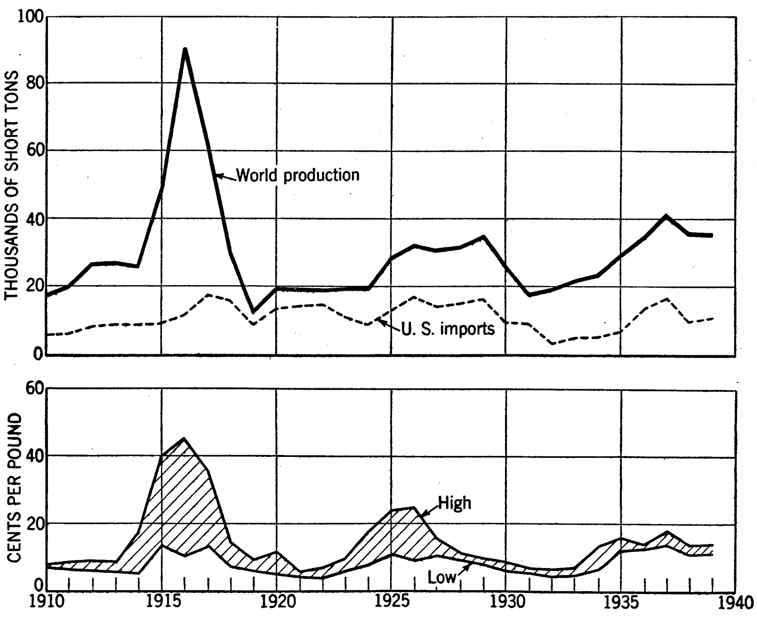

FIGURE 1.—Trends in world production, United States imports, and New York price of antimony, 1910–39.

Figure 1 shows trends in world production, United States imports, and prices from 1910 to 1939.

Late in 1939 the State Department announced that the tariff on antimony oxide would be considered in negotiations for a new reciprocal trade treaty with Belgium. Domestic producers formally protested any reduction in the existing import duty. No official action had been taken by the end of the year.

Salient statistics for antimony in the United States, 1935–39

	1935	1936	1937	1938	1939
Production of antimony ore and concentrates......short tons..	3,616	3,867	4,250	2,730	3,174

National defense.—The national defense aspects of antimony, which is classified as a strategic raw material by the Army and Navy Munitions Board, and domestic antimony resources were discussed in detail in Minerals Yearbook, 1939.

The Strategic Materials Act, Public No. 117, 76th Congress (referred to as the Thomas bill, S. 572, 76th Cong., in Minerals Yearbook, 1939) was signed by the President on June 7, 1939. The bill authorizes the expenditure of $100,000,000 over a period of 4 years for the purchase of stock piles of strategic raw materials and $500,000 annually for the investigation of domestic resources of strategic minerals by the United States Department of the Interior. Owing to the limited fund available for stock-piling, purchases have been confined to materials having a higher order of priority than antimony. The Bureau of Mines and the Geological Survey conducted extensive drilling, trenching, and stripping in the Yellow Pine district of central Idaho, but the results of the investigation have not been published as yet. The Bureau of Mines has developed an electrolytic method for improving the recovery of antimony from antimony-gold ores such as are found in that area.

DOMESTIC PRODUCTION

MINE OUTPUT

Antimony produced in the United States is derived from both antimony ores and lead ores. Data on the quantity derived from lead ores are not available, because the Bureau of Mines cannot obtain full information on the output of various commodities made from byproduct antimonial drosses obtained in lead refining. These drosses are used in the manufacture of antimonial lead, other alloys, and chemical compounds, such as oxides and sulfides. In 1939 antimonial lead containing 929 tons of antimony of domestic origin was produced at primary lead refineries, but this antimony was obtained from antimony ores as well as from lead ores in unknown proportions. Likewise, information on the amount of domestic antimony recovered in other alloys and compounds is not available.

The quantity of antimony contained in domestic antimony ores and concentrates produced in 1939 totaled only 393 tons—40 percent less than in 1939. Despite the decline in output, there was considerable interest in antimony deposits during the year. Eighteen producers shipped ore containing 1 ton or more of antimony—1 in Idaho, 1 in Alaska, 7 in Nevada, and 9 in California. As in previous years the Yellow Pine district, Idaho, and the Kantishna district, Alaska, were the outstanding producing areas. Production in both areas declined in 1939.

Alaska.—A small concentrating mill capable of treating 25 to 35 tons of ore a day was installed in 1939 at the Stampede mine of Morris P. Kirk & Son, Inc., in the Kantishna district. The ore contains approximately 22 percent antimony in sulfide form. It is planned to operate the mill during the summer months only and to haul concentrates as well as direct-shipping crude ore to the railroad at Lignite during the winter for reshipment to the company smelter in Los Angeles. Transportation difficulties from mine to railroad were eased in 1939, when trail was broken for 50 miles to permit the use of tractors.

California.—Some activity at antimony deposits was reported in 1939. According to press dispatches, it is planned to reopen the Buzzard mine in the Rattlesnake district near Auburn, Calif. Besides antimony, the mine is said to contain values in gold, copper, silver, lead, and zinc. Some prospecting was done at an antimony property near Frazier Mountain and at another 10 miles west of Randsburg, Calif., which was worked during the World War. The ore body, which outcrops for 1,500 feet, is being developed for production.

A custom antimony concentrator with a daily capacity of 150 tons, known as the Amalia mill and believed to be the only custom mill for antimony ores in the United States, has been completed by the S. T. M. Mines in Pine Tree Canyon near the Los Angeles Aqueduct Station about 17 miles north of Mojave, Calif. The company owns or controls antimony deposits in Kern and Inyo Counties, which it states are large enough to insure continuous operation of the mill for an extended period; however, custom ores are to be given preference.

Idaho.—The Bradley Mining Co. in 1939 produced concentrates containing 209 tons of antimony compared with 379 tons in 1938. More ore was produced in 1939 than in 1938, but the antimony content was lower. The concentrates are largely ferruginous and contain gold and silver as well as antimony. The product is shipped to the lead smelter at Midvale, Utah. The capacity of the mill was enlarged during the year. Formerly the Meadow Creek mine was the chief source of ore, but owing to exhaustion at depth operations were shifted in the latter part of 1938 to surface deposits at the Yellow Pine mine. The activities of the Bradley Mining Co. were described in the May 1940 issue of Mining World.

The Antimony Gold Ores Co. was actively prospecting deposits in the Yellow Pine area during 1939. Early in 1940 it was reported that the company had optioned 63 claims to the New York & Honduras Rosario Mining Co. at a purchase price of $1,500,000, payable over 12 years.

The antimony deposits of Valley County were investigated by the Federal Bureau of Mines and the Geological Survey as part of the program authorized by the Strategic Materials Act. Pamphlet 44, entitled "Geology and Ore Deposits near Edwardsburg and Thunder Mountain, Idaho," by P. J. Shenon and C. P. Ross, was released by the Idaho Bureau of Mines in cooperation with the Geological Survey.

The Bureau of Mines has developed a pyrometallurgical and electrolytic method for treating gold-silver-antimony ores of the type found in Valley County.[2]

Nevada.—Small shipments were reported from Lander, Nye, Pershing, and White Pine Counties in 1939. Some prospecting also was reported under way in Humboldt County.

Washington.—A 20-ton mill was installed at the Cleveland mine in Stevens County 18 miles west of Springdale, Wash. The mine produces ore containing antimony, lead, and zinc.

SMELTER OUTPUT

From 1935 to 1937, inclusive, the only active primary antimony smelter in the United States was that of the Texas Mining & Smelting Co. at Laredo, Tex. In 1938 the Menardi Metals Co. reported the production of antimony at its plant in Los Angeles, Calif. Both plants reported substantial increases in output during 1939.

The Texas Mining & Smelting Co. completed an addition to its oxide plant at Laredo in 1939. In an endeavor to keep domestic consumers supplied during the latter part of the year when the demand for antimony was exceptionally large, the company stipulated in its contracts that none of the metal manufactured at its smelter should be used for war or speculative purposes.

The Los Angeles plant reported production of antimony metal from foreign and domestic ores in 1938 for the first time. The antimony is derived largely from livingstonite concentrates produced in Mexico. The principal product of the plant to date has been mercury.

Data on production of antimonial lead at primary lead refineries are shown in the accompanying table. The figures cover only part of the antimonial lead output, as large quantities are produced at plants that operate exclusively on scrap, and some hard lead is made by mixing antimony and soft lead.

Antimonial lead produced at primary lead refineries, 1935–39, in short tons

Year	Production	Antimony content				
		From domestic ores	From foreign ores [1]	From scrap	Total	
					Quantity	Percent
1935	16,384	1,110	26	593	1,729	10.6
1936	23,230	1,434	37	691	2,162	9.3
1937	27,524	1,636	90	853	2,579	9.4
1938	24,123	1,871	209	729	2,809	11.6
1939	21,995	929	179	923	2,031	9.2

[1] Includes lead ores, antimony ores, and metallic antimony.

[2] Koster, J., and Royer, M. B., Progress Reports—Metallurgical Division. 37. Electrolytic Recovery of Antimony from Antimonial Gold Ores: Bureau of Mines Rept. of Investigations 3491, 1940, 19 pp.

According to press reports, high-grade electrolytic antimony soon will be produced by the Bunker Hill Mining, Smelting & Concentrating Co. at Kellogg, Idaho. A new plant is being constructed to treat the concentrates produced in the dry-ore silver belt of the Coeur d'Alene region by the Lee-Muir process, which employs a combination of hydro-, pyro-, and electro-metallurgy. The concentrates consist largely of tetrahedrite, the bismuth content of which is an undesirable impurity in lead smelting. The new process separates the silver, copper, bismuth, and antimony of the tetrahedrite.

Secondary production.—Data on the recovery of secondary antimony in 1939 were not available when this report was written. The Bureau of Mines canvasses of the secondary-metal industries are being revised to develop more detailed information on the origin and flow of scrap, and the revision has delayed completion of the figures for 1939. Additional information on developments in 1939 is given in the Secondary Metals—Nonferrous chapter of this volume.

DOMESTIC CONSUMPTION

Precise data on the consumption of primary antimony in the United States are not available owing to lack of information on dealer and consumer stocks and on the quantity of domestic antimony recovered in alloys other than antimonial lead and in compounds; however, an approximate idea of the trend of consumption can be obtained from the following table, which shows the annual supply available for consumption.

Primary antimony available for consumption in the United States, 1935–39, in short tons [1]

	1935	1936	1937	1938	1939
Domestic antimony recovered in antimonial lead	1,110	1,434	1,636	1,871	929
Imports for consumption (antimony content):					
Antimony ore	4,587	10,545	13,818	8,322	9,448
Needle or liquated [2]	946	830	540	63	160
Compounds [3]	502	975	909	336	138
Type metal, etc	209	309	410	355	121
Regulus	1,248	1,171	1,043	821	1,045
Total available	8,602	15,264	18,356	11,768	11,841
Exports under draw-back	251	224	224	211	232
Available for consumption	8,351	15,040	18,132	11,557	11,609

[1] Excludes domestic antimony recovered as miscellaneous alloys, oxides, and other compounds.
[2] Content estimated at 70 percent. [3] Content estimated at 80 percent.

Apparent consumption of primary antimony in 1939 increased only slightly over 1938, a moderate rise in imports having been offset largely by a decline in domestic output. Actual consumption, on the other hand, is believed to have gained substantially. One of the principal uses of antimony is in the manufacture of storage batteries. According to the American Bureau of Metal Statistics, 106,500 tons of antimonial lead were used for this purpose in 1939 compared with 92,000 tons in 1938. The antimony content of this material ranges from 4 to 12 percent, and although a large part of the total is supplied by battery scrap a substantial quantity of new antimony is required annually to "sweeten" the alloy.

Another important use of antimony is in the manufacture of babbitt metals employed in bearings. According to the Bureau of the Census, shipments of white-base antifriction bearing metals, produced for sale and for plant consumption by 39 manufacturers representing approximately 84 percent of the total industry, increased from 8,259 tons in 1938 to 11,785 in 1939.

The use of antimony in the manufacture of chemicals rose 75 percent in 1939 compared with 1938. In 1939, 7,668 tons of oxides and other compounds with an estimated antimony content of 6,188 tons were produced, whereas in 1938 only 4,393 tons (3,539 content) were made. Figures for the 3 preceding years are as follows: 1937, 6,992 tons (5,667 content); 1936, 4,852 tons (3,940 content); and 1935, 3,969 tons (3,227 content). Foreign ores are used largely in the manufacture of chemicals. The principal compound is the oxide, which is employed extensively as a pigment in sanitary enamelware and nitrocellulose enamels. The following companies reported production of antimony oxide and other salts in 1939:

American Smelting & Refining Co., 120 Broadway, New York, N. Y.
Antimony Corporation, New Brunswick, N. J.
Harshaw Chemical Co., Elyria, N. Y.
John D. Lewis, Inc., Mansfield, Mass.
McGean Chemical Co., Cleveland, Ohio.
Texas Mining & Smelting Co., Laredo, Tex.

FOREIGN TRADE

The following tables show imports and exports of antimony and antimony products.

Antimony imported for consumption in the United States, 1935–39

Year	Antimony ore			Needle or liquated antimony		Antimony metal		Antimony oxides and other compounds	
	Short tons	Antimony content		Short tons	Value	Short tons	Value	Short tons	Value
		Short tons	Value						
1935	14,205	4,587	$544,608	1,352	$165,446	1,248	$250,771	628	$94,783
1936	30,486	10,545	1,200,132	1,185	139,784	1,171	243,474	1,219	217,505
1937	42,453	13,818	1,775,011	772	101,963	1,043	228,485	1,136	249,152
1938	19,811	8,322	1,095,497	90	12,016	821	155,420	420	94,400
1939	21,000	9,448	1,132,359	228	30,102	1,045	196,812	173	29,786

Antimony imported for consumption in the United States, 1938–39, by countries

Country	Antimony ore			Antimony metal	
	Gross weight (short tons)	Antimony content		Short tons	Value
		Short tons	Value		
1938					
Argentina	1,101	715	$69,931		
Belgium				25	$5,009
Bolivia	1,880	1,133	159,407		
Chile	1,201	776	127,156

United Kingdom				11	3,799
Yugoslavia				1	345
	19,811	8,322	1,095,497	821	155,420
1939					
Argentina	332	218	21,700		
Belgium				191	35,954
Bolivia	3,926	2,454	371,099		
China				661	117,072
France				56	10,566
Mexico	16,036	6,346	676,471	125	29,915
Peru	706	430	63,089		
United Kingdom				12	3,305
	21,000	9,448	1,132,359	1,045	196,812

[1] Less than 1 ton.

Estimated antimony content in type metal, antimonial lead, and other alloys imported for consumption in the United States, 1935–39, in short tons [1]

Year	Type metal and antimonial lead	Other alloys [2]	Total	Year	Type metal and antimonial lead	Other alloys [2]	Total
1935	89	120	209	1938	[3] 59	296	355
1936	[3] 56	253	309	1939	59	62	121
1937	[3] 17	393	410				

[1] For details of gross weight and values see imports shown in Lead chapter of this volume.
[2] Chiefly in special antimony-lead alloys containing high percentage of antimony.
[3] Type metal only.

Foreign antimony (regulus or metal) exported from the United States, 1935–39

Year	Short tons	Value	Year	Short tons	Value
1935	318	$62,167	1938	711	$96,836
1936	392	56,308	1939	58	16,736
1937	437	86,991			

As in other recent years imports of antimony ore in 1939 came principally from Mexico and Bolivia. Shipments from both countries were larger than in 1938. Imports credited to Argentina and Chile probably originate in Bolivia.

In addition to the foreign exports reported above, 232 tons of antimony were exported in 1939 in manufactures (chiefly storage batteries) under the draw-back provisions of the tariff law; 211 tons were so exported in 1938. Stocks of needle or liquated antimony and rejects on hand in bonded warehouses totaled 685 tons at the end of 1939 compared with 345 tons on December 31, 1938.

PRICES

The antimony market always has been subject to rapid and wide fluctuations in price; however, in recent years variations have been less violent, and quotations have been maintained at higher levels.

The price of antimony, which dropped very low after the World War of 1914–18 (less than 5 cents per pound in 1921), continued at that level until 1924, when an upward trend was noted. For 5 years quotations were well-maintained, but with the advent of the depression they again slumped. In 1934 there was a noticeable increase, and for the past 5 years yearly quotations have continued above 12 cents per pound at New York. The average spot quotation for domestic metal in New York in 1939 was 12.36 cents compared with 12.35 cents in 1938. The year 1939 opened with the price at 11.75 cents, New York, and remained at a fraction over 11 cents (low for the year, 11.25 cents) until May 25, when it advanced to 12 cents as industrial activity moved upward; then the price increased gradually to 14 cents on September 25, where it remained until the close of the year.

Throughout the year Chinese antimony was scarce, owing to Japanese blockade of the normal trade routes from producing cities. Prices were nominal throughout the year and higher than those for domestic metal. On January 3 the quotation for Chinese metal, duty paid, was 14.00 cents at New York. This price was maintained until October 27, when it advanced to 16.50 cents and remained at this figure for the rest of the year. The average price for the year for Chinese metal was 14.44 cents compared with 14.59 cents in 1938.

On the London Metal Exchange quotations for English brands (99 percent minimum) remained stable at £70–71 per long ton from July 1, 1938, through August 1939. At the beginning of September there was a slight increase to £71–73; in October it rose decidedly to £80–82; and on November 1, it reached £87½, which figure was maintained for the rest of the year. Foreign regulus (spot deliveries from warehouse, duty paid) was quoted at £52–53 on January 1. For the first 8 months of the year the price fluctuated between £49 and £54; it increased to £58 on September 1, and in October to £78–80, and from November 1 to the close of the year it was £87½.

Average monthly quoted prices of antimony, prompt delivery at New York, 1935–39, in cents per pound [1]

Month	Chinese brands (duty paid)					American brands			
	1935	1936	1937	1938	1939	1936	1937	1938	1939

[1] Metal Statistics, 1940, pp. 521, 529.
[2] No average owing to lack of offerings during greater part of month.

Quotations for antimony ore on January 5, 1939, were reported as follows by Engineering and Mining Journal Metal and Mineral Markets: "Per (short-ton) unit of antimony contained, 50 to 55 percent, $1.20 @ $1.25; 58 to 60 percent, $1.30 @ $1.40; 60 to 65 percent, $1.40 @ $1.60. London, 60 to 65 percent, 6s. 6d. @ 6s. 9d. per long-ton unit." There was no variation in the domestic market price and very little in the London quotation until the latter part of April, when the domestic price for 50- to 55-percent ore was $1.25 @ $1.35; 58- to 60-percent ore, $1.40 @ $1.50; and 60- to 65-percent ore, $1.50 @ $1.60. In London the quotation for 60- to 65-percent ore was 6s. 6d. @ 7s. per long-ton unit. For the rest of the year there was a slight gradual increase in the domestic market price; the highest quotation was for the weeks of December 7 and 14, when domestic antimony ore was offered for $1.55 @ $1.60 for 50- to 55-percent ore; $1.60 @ $1.65 for 58- to 60-percent ore, and $1.80 @ $1.90 for 60- to 65-percent ore. The London market price for these respective weeks was 9s. 6d. @ 10s. 6d. for 60- to 65-percent material. The year closed with the domestic price of the lower-grade ore $1.50 @ $1.60 and of the other grades $1.60 @ $1.70 and $1.80 @ $1.90. The London price closed at 10s. 6d. for 60- to 65-percent ore.

WORLD PRODUCTION

Data on world production in 1939 are incomplete, but statistics from countries that contributed 89 percent of the total in 1938 indicate a 1-percent decline to an estimated 32,000 metric tons. China, formerly by far the outstanding source of antimony, dropped to third place in 1939, its output (exports) having been exceeded by that of Bolivia and of Mexico. Bolivia increased its output (exports) 7 percent in 1939 compared with 1938, whereas Chinese exports declined 17 percent and Mexico's output fell 2 percent. Yugoslavia, the fourth largest producer, made a notable gain in production, as did Canada where the recovery of byproduct antimony recently was inaugurated at the lead smelter at Trail, British Columbia. In 1939 Bolivia produced 29 percent, Mexico 23 percent, China 20 percent, and Yugoslavia 10 percent of the world supply of antimony; the United States produced only 1 percent.

World production of antimony, 1935–39, by countries, in metric tons [1]

REVIEW BY COUNTRIES

Bolivia.—The antimony situation in Bolivia is described in a report by C. W. Wright, foreign mineral specialist, Bureau of Mines, entitled "Bolivia's Mineral Resources, Production, and Trade," La Paz, Bolivia, September 15, 1939. The section on antimony is quoted in full:

General statement.—Mining of antimony in Bolivia started in 1903, and from 1915 to 1917 Bolivia was second only to China in world's output. From 1926 to 1929 this industry was again active, and since 1934 production has increased steadily each year from 2,000 tons to 16,576 tons of concentrates or 9,427 tons of metal in 1938.

Antimony production in Bolivia is not restricted to any single area but is found in many of the provinces. The Districts of Tupiza, Department of Potosi, and of Challapata, in the Department of Oruro, are the most important.

Excepting the few antimony-producing mines belonging to the larger mining companies, most of the mines are small and subject to intermittent operations dependent upon the market price for antimony and the local cost of mining. The average grade of the concentrate produced is from 60 to 65 percent. Lead, arsenic, and copper are sometimes present in the product and tend to reduce its selling value. Gold is also present, amounting in some instances to 20 grams or more, and this naturally adds to the selling value.

An attempt was made during the World War to smelt the antimony ore at Uyuni, in Bolivia, but the plant was soon abandoned. Plans are being studied whereby this may now be done by the use of domestic crude oil. At present all of the product is exported, 75 percent of it going to Belgium in 1938 and most of this was re-exported to Germany. The average tenor of the product is 60 percent antimony, 1 percent lead, 0.2 percent copper, and 0.2 percent arsenic.

Were the market for antimony to improve as it did during the World War, it is probable that Bolivia could again increase the output of antimony ore to a few times present production.

General occurrence of antimony ore.—Though the antimony deposits occur in the tin belt, the ore occurrence is not directly associated with that of the tin deposits.

Quartz veins traversing narrow belts of fractured black slates, often tens of miles in length, carry the antimony ore. These veins are usually narrow and irregular, and often ore masses occur where the veins intersect one another. At some of the mines veins 3 feet or more in width occur, and in these the antimony ore is found in large masses and disseminated in the quartz. A brief description is given in the following text of the principal mine in each of the nine zones.

The antimony deposits are more frequent in the southern part of the mineral belt away from the granite intrusive masses, which are exposed on the surface to the north. This granite intrusive, even though it does not outcrop on the surface, underlies this southern portion of the mineral zone, and it is believed that both the granite and the mineral deposits have been derived from the same underlying igneous magma.

In general, the development of these deposits is limited to the preparation of sufficient ore for only a few months' output. If capital were available to open up new ore bodies along the antimony-bearing zones, under proper technical guidance, it is probable that the present known ore reserves could be increased many times.

Descriptions of principal mines.—Nearly 60 percent of the antimony output, as well as the richest product, comes from the mines in the Department of Potosi. These occur in the vicinity of Tupiza, and the antimony veins here are usually wider and more persistent than in the other districts. This district is on the east slope of the Andes at a relatively low altitude. Next in importance are the mines near Challapata in the Department of Oruro.

In discussing the principal mines, first those in the Department of La Paz are described, followed by those in the antimony mineral belts to the south.

Espiritu Santo mine.—(Bustos, owner, Rafael Taborga lessor.) This mine is in the Caracata District, Province of Loayza, 40 miles from La Paz.

At this mine irregular quartz veins containing antimony occur in a zone of black shale 160 feet wide which crosses the Caracata River diagonally, in a northwesterly direction and with an easterly dip of 60°. The ore bodies are developed by several adits, and the ore is mined by hand drilling without any special system and only the richer ore is stoped. From the mine the ore is trammed to the sorting floor at the mouth of the lowest adit, where it is concentrated by the usual hand methods. Present production of concentrates is 50 tons a month. As much of the ore is disseminated in the quartz and is discarded, it would be possible with a small mechanical concentrating plant to double the present output. The locality, however, is unfavorable, as the water supply is small and malaria dominant. The mineral zone extends for some miles beyond this mine, and in it the reserves of possible ore are believed to be large.

Malliri mine.—(Empresa "Junkers," Jose Domingues, owner.) This mine is in the Province of Abaroa, northeast of Challapata, 15 miles from the railway station.

Here stibnite is found in quartz veins forming masses from 2 to 8 feet wide, and from 30 to 80 feet in length and depth. The general strike of these veins and the black slate country rock in which they occur is north-south and the dip 75° to the east. The ore is mined by open-cuts and adits up to 600 feet in length. The monthly output is 75 tons of 60-percent antimony product, which is made by 15 hand sorters, a hand crusher, a hand jig, and two buddles. Fifty men and women are employed, and the output per man-shift is about 60 kilos of product. It is claimed that, with higher metal prices, the output could be largely increased.

Challviri mine.—(M. Hochschild, owner.) The Challviri mine is located 25 miles north of Uncia on the southeast side of the Morocala plateau at an elevation of 11,200 feet.

The ore deposits are quartz veins with stibnite occurring in masses and disseminated in the quartz. Chalcopyrite is also present in small amounts. The country rock is the friable black slate. Monthly output is 50 tons, all of which is hand mined and treated. Ore reserves are small.

La India mine.—(Fadic, owner.) This mine is in the Province of Bustillos, 30 miles south of Uncia. This mine lies in a mineral zone 984 feet wide traceable for 20 miles in a southeast direction from La India to Terremoto.

Small irregular deposits of stibnite in quartz are found at a number of places along this zone of black slates. The India mine is at 13,200 feet elevation. Formerly this mine produced 100 tons a month, but present output is limited to 25 tons. Ferberite is also found in this mine in separate veins, and of this ore an output of from 1 to 2 tons a month is made, averaging 70 percent WO_3. Although ore reserves are small, it is believed that this zone is a potential source of antimony ore.

Irpa Irpa mine.—(Manuel Solares, owner.) The mine is located in the Province of Chayante 40 miles southeast of Uncia.

This mine also lies in a zone of black slates extending from Amayapampa to beyond Morochata on the Colorado River, a distance of about 40 miles. Within this zone several other mines have been worked in the past, namely at Amayapampa, Capacirca, Cebadillas, and Chuquiuta. In general, these deposits are irregular quartz veins or lenses containing stibnite, and the product contains gold in payable quantities. At the Irpa Irpa mine the monthly production is 30 tons of concentrates and 34 workmen are employed. All work is done by hand. The ore reserves within this zone are very limited, but with exploration work it is believed that new important deposits will be found.

Churata mine.—(Stevenson, owner.) This mine is located in the Province of Porco near Canton Yura.

This is only one of a number of mines which occur in the slate zone extending from Aguas Castillas to Tupiza, a distance of 85 miles. There are about 100 small mines along this zone which were largely responsible for the high output of antimony ore during the World War. Besides the Churata mine in the northern part of the zone, mining is in progress at the Putina, Dolores, and Uyuni Chico mines, owned by Rocsabado, and the Oropeza mine near Tocla, owned by Guerra and Paredes. In the southern part of the zone on Rio Blanco are the Huarojla and Thapi mines, owned by Hugo Gericke. The Churata mine, which is representative of the others, happens to be the largest producer at present. The ore deposit consists of a series of quartz stibnite veins with occasional ore concentrations in masses as at the other mines already described. This mine alone produced 407 tons in 1937. The total annual output of the zone is about 1,500 tons of concentrates.

Churquini mine.—(Prisk & Wright, owners.) The Churquini mine is in the Province of Sur Chichas 20 miles north of Escoriani.

Here a large number of small quartz veins with nests of antimony occur in a much disturbed zone of friable slates. In places a network of these veins is formed, and it is in these that the concentrations of antimony usually occur. This mine has been one of the largest producers in recent years, and in 1937 the output was 660 tons containing 68 percent antimony. The ore reserves at this mine are limited and the mineral zone is relatively small.

Cobija mine.—(Rocabado, owner.) This mine is situated 25 miles west of the railway station of Oro Ingenio. This mine is the most important of several that have been developed along a fractured zone in a black slate belt extending for 20 miles in a northwesterly direction. The ore body at Cobija is a rich antimony quartz vein 3 feet in width which is being mined from a shaft 500 feet in depth. Other mines along this zone are Candelaria, owned by Pedro San Juan, and La Tesorera, owned by Hugo Gericke. No estimate can be made of the possible ore reserves along this zone, but it is believed that it is one of the richest antimony zones in Bolivia. At the Cobija mine there is a small mechanical concentrating mill with a Krupp ball mill, two jigs, and one table, also a sorting floor with hand jigs and buddles. The production in 1937 was 328 tons.

Santiago mine.—(Cia. Minera y Agricola Oploca de Bolivia, owners.) The Santiago mine is situated 3 miles west of Oploca.

In this area a mineralized zone of black slates has been traced for 3 miles, beginning with the San Pedro mine, of Hugo Gericke, on the south which has been intensely worked in the past and ending at the Santiago mine to the north. The zone at Santiago is 300 feet wide. Within it is a wide barren quartz vein and on each side of it a number of irregular and nested quartz veins with stibnite. At this mine the known ore reserves are estimated at 9,000 tons of antimony metal, but because of the lead content of from 2 to 4 percent in the concentrate the mine is not now being worked. The mine is well-developed by several adits.

Methods of mining and concentrating the ores.—With few exceptions all of the antimony mines in Bolivia are worked by the most primitive methods, and much of the ore is wasted in the attempt to produce a high-grade concentrate. Only the richer portions of the ore bodies can be mined by this system. As is usual at most mines in mountainous districts, the ore bodies are first explored by surface cuts and trenches along the veins and then by adits to explore the deposits in depth. These adit levels are usually from 50 to 100 feet apart vertically and up to 600 feet or more in length. They are connected by raises, and from these stopes are started and the ore between the levels is stoped and sorted underground, the richer ore being dumped down the raises and trammed to the surface by car or wheelbarrow, while the waste rock and low-grade ore is usually left in the stopes as filling. Most of the mines are limited to hand mining operations.

The sorting floor is usually near the mouth of the lowest adit. Here women sort out the rich ore, using hammers to break off bits of waste rock from the larger pieces. The remaining poor ore is crushed and concentrated by hand methods.

The total cost of mining, concentrating, and transport of the antimony concentrates to the railway station, according to schedules filled in by the operators, varies from 600 to 1,000 Bolivianos, or $20 to $30 a ton, and of this total only about 40 percent is for labor, the rest being for supplies, transport, and overhead, including local taxes.

Marketing of antimony concentrates.—Until recently the producers of antimony concentrates sold their product to one of the several ore-purchasing firms, who in turn advanced funds to the mine operators for supplies and wages. Today, however, the Banco Minero is the sole local purchaser in Bolivia. The concentrates are usually purchased at a fixed price based upon the London market quotations, and for delivery at the railway station nearest the mine.

The large companies, however, make contracts directly with the smelting companies for specified amounts within a definite period.

Prices are based on a 60-percent product, and a premium of B. 20 is paid per unit above this and a deduction of B. 30 is made per unit below 60 percent.

Generally there is no fixed penalty for copper in antimony ores, but concentrates containing a considerable amount of copper (over 0.5 percent) can only be sold with difficulty or may be unsalable.

Arsenic and lead contents combined are usually free of penalty up to 0.5 percent in the "pure" ores and up to 1 percent in the "impure" ores. In the United States for excess content of lead, a deduction of 1 unit of antimony is made for each unit of lead in excess of 1 percent and 2 units for each unit of arsenic in excess of 0.2 percent arsenic. The "impure" ores are sold for the most part to Japanese ore buyers, who also pay for the gold content.

Ores containing over 10 percent lead may be sold without lead penalty, and only in case of a 15-percent or greater lead content is it possible to obtain payment for lead.

Exports of antimony concentrates since 1937 and their value per ton were:

1937—11,971 valued at $1,264,330 or $105.59 per ton
1938—16,576 valued at $1,167,474 or $73.08 per ton
1939—7,400 valued at $584,137 or $78.94 per ton
(6 months)

These figures are from the official export statistics, the average grade of the ore shipped being 60.5 percent antimony.

Possibility of increasing antimony output.—The output of antimony jumped from 6,093 tons of concentrates in 1929 to 15,976 tons in 1938. Just how much the output can be further increased will depend, first of all, on the market price of the metal and to what extent the Government will encourage production by a reduction of present high taxes and by financial and technical assistance through the Banco Minero, which bank is now the sole local purchaser of ores in Bolivia. Any increase in the output of antimony in Bolivia will thus depend largely upon the attitude the Government takes toward the industry and the extent of its financial and technical aid to the industry. It is the announced intention of the Government to give financial and technical aid to the small mine operators through the Banco Minero and the Department of Mines and Petroleum. In some instances this aid may consist in helping the operator to install a small mechanical plant for the treatment of low-grade ores, and in other cases in the construction of a road to facilitate transport.

The Department of Mines and Petroleum estimates the total reserves of probable antimony ore at 50,000 tons metal content, while the possible reserves are much greater—sufficient for some decades at the present rate of production. There is thus plenty of ore available from which, with favorable market conditions and Government assistance, Bolivia could more than double her present output.

Bolivia as a source of antimony supply for the United States.—Present-day world conditions justify an opinion that there may soon be a real opportunity for Bolivia to enter the United States market.

In 1937 the United States consumed 18,132 tons of antimony metal, over 80 percent of which was imported. Of this tonnage Bolivia supplied 1,678 tons of concentrates containing 1,047 tons of metal in 1937, and 1,880 tons of concentrates with 1,133 tons of metal in 1938.

Purchases of Bolivian antimony ore by American consumers would have to be made through the Banco Minero or from the large producing companies. If long-term contracts could be concluded for specific tonnages at a fixed price over a period of years, this would be a big help to stimulate a greater output of antimony in Bolivia. Because of the impurities in the antimony concentrates, exports to the United States have been relatively small, even though the grade of the product is high.

Canada.—Antimony production consisted of antimony metal produced at the new plant of the Consolidated Mining & Smelting Co., Ltd., at Trail, British Columbia, and antimony in ores exported from a property near Fort St. James, British Columbia. The output totaled 606 short tons. Imports of metallic antimony declined from 428 tons in 1938 to 119 in 1939. At the Trail plant it was reported that production was being obtained from accumulated antimony-arsenic flue dusts. An excellent product was being made, but all of the difficulties that developed in the process have not yet been overcome.

China.—Japanese occupation of eastern China caused a further decline in exports during 1939. Apparently the Chinese have maintained control of the producing areas, but Japan controls the normal trade routes. Early in 1940 it was reported that reopening of the Yangtze River by the Japanese had not resulted in any increase in shipments. Most of the material exported in 1939 went via French Indochina. According to official reports, Chinese exports of crude antimony increased from 544 metric tons in 1938 to 1,053 in 1939. In 1938, 531 tons were shipped to Hong Kong, whereas in 1939 only 2 tons were consigned there. In the latter year 1,051 tons were sent to "other countries," presumably largely to French Indochina. Exports of regulus declined from 7,183 tons to 5,707. No oxide (etc.) was shipped in 1939 compared with 257 tons in 1938. In 1939, 5,228 tons of regulus were sent to French Indochina and 474 to Hong Kong, whereas in 1938, 6,617 went to Hong Kong and only 378 to French Indochina.

Exports from Hong Kong increased from 2,994 to 5,721 tons, but toward the end of the year it was reported that stocks were nearly exhausted and exports almost nil. Ore shipments from this port declined from 545 tons to 1 ton.

Germany.—German imports of antimony increased from 2,105 metric tons in 1936 to 3,642 in 1938. Receipts during the first 6 months of 1939 were 1,597 tons. Of the 1938 total China supplied 71 percent, Czechoslovakia 13 percent, Yugoslavia 8 percent, and other countries 8 percent. Germany has intensified mining operations in conquered territory in an endeavor to meet its mineral deficiencies. In Slovakia antimony ores have been produced near Medzibrod, near Poproc, and near Spisska Bana. Exploration is under way at various other localities. An antimony smelter at Vajskova has produced about 1,300 tons of metal annually in recent years.

Mexico.—Antimony is derived from three types of ore in Mexico. The most important source is straight antimony ore, which is mined in several localities, chiefly in San Luis Potosi, Oaxaca, Nuevo Leon, and Sonora. Considerable antimony is recovered in elemental form and in alloys at the lead refineries near Monterrey as a byproduct of lead ores. The third source is the mercury-antimony ores of the Huitzuco district, Guerrero. The greater part of the straight antimony ore is shipped to the smelter at Laredo, Tex., and imports of these ores into the United States increased during 1939. Mixed concentrates from the Huitzuco district are treated at a Los Angeles plant where both mercury and antimony are recovered. Production of antimony from this source was higher in 1939 than in 1938.

The 12-percent export tax imposed in 1938 on virtually all products shipped from Mexico proved unduly burdensome on producers of low-grade antimony concentrates. To alleviate the situation the Government in August 1939 removed the tax on all ores containing less than 25 percent antimony.

Yugoslavia.—The increase in output reported for Yugoslavia in 1939 resulted from the first full-year operation of the new 1,800-ton per year smelter of Podrinje Consolidated Mines, Ltd., near Krupanj and completion of another smelter near Loznica, owned by Montania A. G.

CADMIUM

The cadmium industry experienced a more satisfactory year in 1939 than in 1938. Domestic production of cadmium as metal and in compounds increased 15 percent over 1938 and nearly equaled the record output of 1937. Apparent consumption was 37 percent higher in 1939 than in 1938, and in consequence the United States returned to its former position as a net importer. Imports of metal increased fourteenfold, whereas exports fell from 458,283 pounds in 1938 to none in 1939. Sales of metallic cadmium more than doubled and exceeded production by 19 percent. Producers' stocks of metal declined from an estimated 1,750,000 pounds at the end of 1938 to approximately 950,000 pounds on December 31, 1939.

Most of the increase in demand in 1939 came from the plating and pigment industries. The high prices for cadmium in 1937 and 1938 stimulated the use of substitutes for cadmium plating, but with the return of more normal prices in 1939 some manufacturers employed cadmium again. The use of cadmium in bearing metals, which exhibited such a meteoric rise a few years ago, apparently did not increase in 1939 in proportion to the advance in automobile production. Production of the red and yellow cadmium lithopones, as well as straight cadmium sulfide, was substantially higher in 1939 than in 1938.

Data on the cadmium industry in 1939 are not available for many countries. Canada and South-West Africa established new output records. These countries and the United States, which supplied 58 percent of the 1938 output, produced 21 percent more cadmium in 1939 than in 1938. Production in Australia declined. Germany is reported to have restricted the use of cadmium in pigments, whereas British Empire resources were said to be adequate for all essential needs.

The downward trend in prices evident in 1938 continued during the first half of 1939. The New York quotation for commercial sticks, wholesale lots, dropped from 60 to 50 cents a pound between January 2 and the latter part of March. Early in August, as buying improved in anticipation of the European crisis, the price began moving to higher levels, and at the close of the year stood at 75 cents. The average quotation for the year was only 64.1 cents compared with 98.0 cents in 1938, but the price made a substantial net gain during the year. In March the premium for platers' sticks was reduced from 25 to 5 cents a pound.

Cadmium produced, sold by producers, imported, and consumed in the United States, 1935–39, in pounds

Year	Produced			Metallic cadmium sold by producers	Metallic cadmium imported	Apparent consumption
	Metallic cadmium	Cadmium compounds (estimated Cd content)	Total cadmium			
1935	3,477,091	507,400	3,984,000	4,023,900	185,387	4,169,000
1936	3,633,495	626,800	4,260,000	3,626,669	576,139	4,836,000
1937	3,995,739	828,000	4,824,000	3,801,321	828,535	5,652,500
1938	3,753,323	431,000	4,184,000	[1] 2,191,035	22,582	3,748,000
1939	4,141,242	679,000	4,820,000	4,933,778	309,874	5,130,000

[1] Of this quantity 458,283 pounds were exported.

DOMESTIC PRODUCTION

The figures on cadmium production in the foregoing table include metal derived from domestic and foreign raw material refined in the United States. Data are not available on the quantity produced from each source, but foreign metal apparently represents a substantial part of the total. In the first 11 months of 1939 Mexico reported shipments of crude material to the United States containing 816 tons of cadmium compared with 838 tons in all of 1938.

Cadmium is derived chiefly as a byproduct from zinc ores, and its production depends to some extent on the rate of zinc output. In recent years, however, stocks of cadmium-bearing flue dusts and similar products accumulated over several years have made possible an increase in cadmium production that is relatively more rapid. By 1937 much of this material had been used, and since then production has been limited to some extent to that derived from current zinc operations. The recovery of metallic cadmium was discontinued at the Herculaneum (Mo.) plant of the St. Joseph Lead Co., and the Baltimore plant of the Chemical & Pigment Co., Inc. No new producers were reported in 1939.

The following companies produced cadmium or cadmium compounds in 1939:

	Location of plant
American Smelting & Refining Co	Denver, Colo.
American Steel & Wire Co	Donora, Pa.
American Zinc Co. of Illinois	Fairmont City, Ill.
Anaconda Copper Mining Co	Great Falls, Mont.
Ceramic Color & Chemical Manufacturing Co	New Brighton, Pa.
Chemical & Pigment Co., Inc	Baltimore, Md.
E. I. du Pont de Nemours & Co	Cleveland, Ohio.
Eagle-Picher Mining & Smelting Co	Henryetta, Okla.
Harshaw Chemical Co	Elyria, Ohio.
New Jersey Zinc Co	Palmerton, Pa.
St. Joseph Lead Co	Josephtown, Pa.
Sherwin-Williams Co	Chicago, Ill.
Sullivan Mining Co	Kellogg, Idaho.
United Color & Pigment Co	Newark, N. J.
U. S. Smelting, Refining & Mining Co	Midvale, Utah.

A small but increasing quantity of secondary cadmium is recovered from scrap resulting largely from the manufacture of automobile bearings. It is not included in the statement of production, as it would represent duplication of metal previously reported.

Recent additions to the technical literature on production processes include a description of operations at the cadmium plant of the Sullivan Mining Co. at Kellogg, Idaho.[3] The separation of cadmium from zinc by the use of granular aluminum is described by Townsend and Cade.[4] Patent 2,178,763, issued November 7, 1939, covers various methods of purifying cadmium by the addition of caustic soda while the metal is in the molten state.

DOMESTIC CONSUMPTION

The statistical trends in consumption during 1939 have been discussed in the summary at the beginning of the cadmium section of this chapter.

Sanderson [5] has described the uses of cadmium as follows:

> Cadmium is a metal which, in various forms, is becoming of increasing economic importance. It has been used, when tin was scarce, as its substitute in solders, but this is not now a particularly valuable application. Its main value is as an alloy of copper for the production of telegraphic, telephonic, and power transmission wires, because of the properties it gives to wire so produced. It has durability, good tensile strength, hardness, a high annealing temperature, and electrical conductivity, all of which are desirable properties in these uses. It thus possesses the virtues of both hard-drawn copper and the bronzes. Copper-cadmium trolley wire for tramcar systems has, in fact, proved extremely successful, having three times the life of hard-drawn copper wire.
>
> Copper-cadmium rolled plates have been used with some success for locomotive firebox plates, and castings made from a similar alloy have been used in electrical apparatus. Alloys into whose composition the metal enters have been used for watch and clock hairsprings, because they have certain of the characteristics of steel, but add to these a resistance to corrosion and a nonmagnetic property. A small proportion of the cadmium produced is used with cerium earth metals for producing spark-emitting alloys for use in cigarette lighters.
>
> Alloys of cadmium with gold have been used in making jewelry. Silver-cadmium alloys are used for producing domestic silver. The most encouraging employment of the metal today, however, is as a constituent of bearing metals, on account of the low coefficient of friction obtained. Alloys of lead and cadmium appear to be the best for this purpose, though magnesium has also been introduced with good results. Cadmium in combination with bismuth and lead bismuth and tin, or lead and tin, has produced a range of fusible alloys for the production of fire-extinguishing devices, safety devices, electric fuse wires, and for certain copies for the reproduction of type matter in newspaper work. Cadmium is also a good deoxidizer for alloys of aluminum, silver, and nickel.
>
> Cadmium is also used for electroplating and rustproofing, having certain advantages, such as thinness of coating, freedom from peeling, etc. Another valuable use is for accumulator cells, often in combination with nickel. Cadmium amalgams have been used in dentistry, but only where better and more expensive alloys could not be used. Cadmium oxide has been used as an electric-furnace high-temperature resistance material. A cadmium vapor arc lamp has been designed. Nor can one omit the very great use of the metal in paints, colors, and glazes; in photography for preparing the sensitive plates; and in medicine as "salts."

The toxic effect of cadmium in foods contaminated by contact with cadmium-plated containers is being investigated by the United States Department of Agriculture (Food Research Division Contribu-

[5] Sanderson, L., Cadmium: Canadian Min. Jour., vol. 60, No. 8, pp. 481–483.

tion No. 455). Anemia and marked enlargement of the heart were observed in rats fed on a diet containing 0.0031 to 0.025 percent cadmium. The Food and Drug Administration filed a libel action in the Federal Court of New York for the seizure of 40,000 lipsticks imported from France on the grounds that the cadmium and selenium they contained rendered them dangerous and in violation of section 601 (*a*) of the new food, drug, and cosmetic act.[6]

FOREIGN TRADE

Official statistics record separately only the imports of metallic cadmium. There is a limited import and export trade in cadmium compounds, and some metal is known to have been exported in former years, but the quantities involved are believed to be relatively unimportant except in 1938 when exports totaling 458,283 pounds were reported to the Bureau of Mines. No exports of metal were reported in 1939. Exports of cadmium with benefit of draw-back, mostly in bearings, totaled 52,149 pounds in 1939 and 36,081 in 1938. Imports of metallic cadmium in 1939 were much larger than in 1938 but were considerably below those of 1936 and 1937. Of the 309,874 pounds shipped in 1939 Belgium supplied 197,454 pounds, Netherlands 38,038, Italy 35,304, Canada 30,068, Norway 6,720, Poland and Danzig 2,240, and Germany 50. Belgium contributed 20,067 pounds of the 22,582 imported in 1938. The average value of the cadmium imported in 1939, as reported by the Customs Bureau, was $0.42 a pound compared with $1.35 in 1938, $1.30 in 1937, and $0.71 in 1936. The United States also imports crude materials containing cadmium for refining. Shipments of material of this type from Mexico to the United States for 11 months of 1939 contained 816 tons of cadmium compared with 838 tons for all of 1938.

PRICES

According to Engineering and Mining Journal Metal and Mineral Markets, the average price of cadmium in 1939 was 64.1 cents a pound compared with 98.0 cents in 1938, $1.223 in 1937, 97.8 cents in 1936, and 55 cents in 1933 and 1934. These prices represented the average of the producers' and platers' quotations. As stated in Minerals Yearbook, 1939, this authority established in 1939 another average monthly price based solely upon quotations by producers for ordinary commercial shapes, quantity business. For 1939 this average was 59.2 cents a pound. Incomplete data obtained by the Bureau of Mines from producers indicate that the average value realized on sales of metallic cadmium in 1939 was 54 cents a pound compared with 75 cents in 1938, $1.14 in 1937, 80 cents in 1936, and 50 cents in 1935.

At the beginning of 1939 patented shapes for platers were quoted at 85 cents a pound, New York, and quantity business, commercial sticks, at 60 cents a pound, but before the end of the month (January 23) these prices were reduced 5 cents owing to the weakness of the foreign market. On March 28 there was a second reduction of 5 cents in the price of commercial sticks, whereas the price on cadmium in patented shapes, for platers, was reduced 25 cents; thus the quotations became 50 and 55 cents, respectively. Prices remained at these

[6] Oil, Paint and Drug Reporter, Cadmium and Selenium Held Dangerous in Cosmetics: Vol. 135, No. 26, June 26, 1939, p. 3.

levels until August 9, when the quotation for each item was advanced 5 cents. On September 5, commercial sticks were quoted at 65 cents a pound and patented shapes at 70 cents a pound; again on October 3, there was a further increase of 10 cents to 75 cents for commercial sticks and 80 cents for patented shapes. These prices remained unchanged for the rest of the year.

Effective January 1, 1939, the duty on cadmium was reduced from 15 cents to 7.5 a pound under the Canadian Trade Agreement.

The London quotation on January 5 was 2s. 1d. a pound. Between this time and August the trend in prices was downward, but after the outbreak of war in Europe quotations rose from less than 2s. late in August to 5s. 6d. at the close of 1939.

WORLD PRODUCTION

Data on world production of cadmium in 1939 are very incomplete, but production in the United States, Canada, and South-West Africa (which furnished 58 percent of the estimated output of 4,000,000 kilograms in 1938) increased 21 percent. The United States produced 47 percent of the 1938 total and increased its output 15 percent in 1939. Notable gains also were made by Canada and South-West Africa, but Australia produced 12 percent less cadmium in 1939 than in 1938. Press reports indicate that Italy's output should have been about 100,000 kilograms in 1939. Production in Norway and Belgium probably decreased slightly, whereas that in the United Kingdom gained slightly.

World production of cadmium, 1935–39, by countries, in kilograms

[5] Estimated cadmium content.

REVIEW BY COUNTRIES

Australia.—The Electrolytic Zinc Co. of Australia, Ltd., produced 172 long tons of cadmium in the year ended June 30, 1939, of which 12 tons came from precipitates produced at the lead smelter at Port Pirie and 160 tons from zinc-plant residues from Risdon.

Canada.—Owing to exhaustion of accumulated stocks of cadmium precipitates, cadmium production at Flin Flon declined farther to 70 short tons compared with 94 tons in 1938 and 154 in 1937. This decline apparently was more than offset by an increase in output at Trail as a result of the larger production of zinc.

Germany.—Cadmium is used chiefly in the manufacture of metal bearings, and consumption for this purpose is understood to have increased in recent years. Owing to the relative scarcity of the metal, its use in pigments was restricted in 1939. Cadmium is being substituted for nickel in some plating applications.

South-West Africa.—The Otavi Mines Co. is the sole producer of cadmium dust in the territory. The dust is recovered as a smelter byproduct from the copper-lead-zinc ores of the Tsumeb mine. No output of this product was made in 1937, but in 1938 production amounted to 387 metric tons as against 351 in the first 9 months of 1939. Exports, marked for Antwerp, rose sharply from 436 metric tons in 1937 to 672 in 1938 and for the first 9 months of 1939 totaled 214 metric tons. The estimated value of these exports was £50,784 in 1937, £51,072 in 1938, and £16,078 in 1939.

PLATINUM AND ALLIED METALS

By H. W. Davis

SUMMARY OUTLINE

Although the United States is by far the largest consumer of platinum metals in the world, before 1935 it had contributed only a negligible quantity to the world output. For example, during the 10 years 1925–34 production averaged only about 8,300 ounces annually—1,000 ounces of placer platinum, 600 ounces of palladium-bearing copper ore, and 6,700 ounces as byproducts of gold and other metals. Since 1935, however, chiefly because of large-scale mining in Alaska, production of platinum metals in the United States advanced progressively from 11,552 ounces in 1935 to 48,269 ounces in 1938—40,932 ounces of placer platinum, 7,247 ounces recovered from gold and copper refining, and 90 ounces obtained from platinum-bearing ore. Thus, the United States attained the rank of fourth largest producer of platinum metals in 1938. Although production dropped to 43,760 ounces in 1939, the country retained its rank.

[1] Subject to revision.
[2] In 1938 includes 6,376 ounces of new platinum from domestic sources, comprising 2,590 ounces derived from crude placer platinum, 25 ounces recovered from ore, and 3,761 ounces obtained from domestic gold and copper ores as a byproduct of refining; in 1939 includes 8,205 ounces of new platinum from domestic sources, comprising 2,919 ounces derived from crude placer platinum, 16 ounces recovered from ore, and 5,270 ounces obtained from domestic gold and copper ores as a byproduct of refining.

In addition to now being the fourth largest source of supply of platinum metals the United States is an important refining center and occupies a prominent position in the international platinum trade. In 1939, for example, 41,441 ounces of new platinum metals and 63,443 ounces of secondary platinum metals were recovered by domestic refiners, 306,627 ounces of unmanufactured platinum metals were imported for consumption, and 46,329 ounces of platinum and

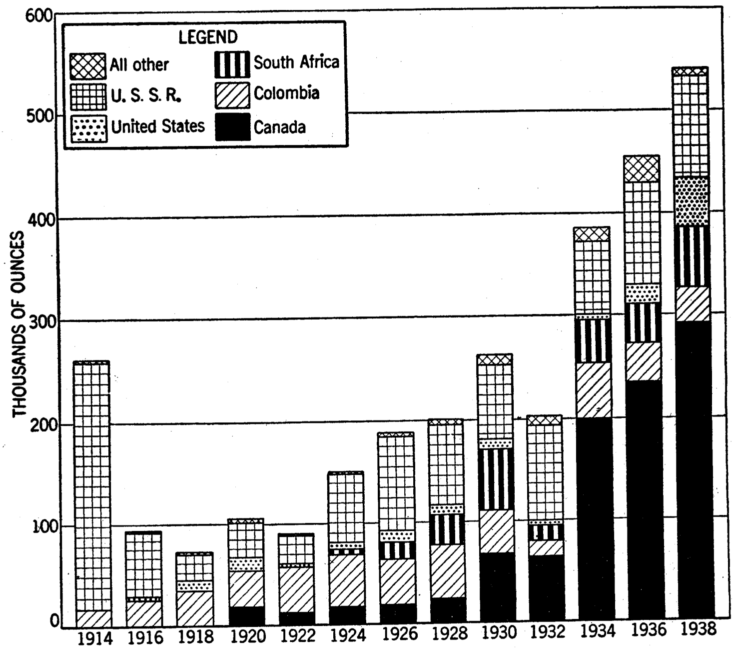

FIGURE 1.—Trend in world production of platinum metals, 1914–38.

allied metals (ingots, sheets, wire, alloys, and scrap) and a considerable quantity of placer platinum were exported.

Despite the much larger output of domestic placer platinum, most of the new platinum metals recovered by refiners in the United States in 1939, as in previous years, were derived from crude platinum from foreign sources, notably Colombia, as most of the Alaska platinum was refined abroad. The major part of the refined new platinum metals now consumed in the United States emanates from the United Kingdom; the metals are recovered there chiefly as byproducts in refining nickel-copper matte from the Sudbury district of Ontario and, to a smaller extent, from matte from the Rustenburg district of the Union of South Africa and from placer platinum originating in the Goodnews Bay district (Alaska).

Figure 1 shows graphically the trend in world production of platinum metals from 1914 to 1938. The prominent position of Canada since 1930 and especially since 1934 is strikingly revealed, as well as the rise in production in the United States since 1936. The figures plotted for the U. S. S. R. for 1918, 1920, 1922, 1936, and 1938 are rough estimates of crude-platinum metals, whereas those for 1930, 1932, and 1934 are exports of refined platinum.

CRUDE PLATINUM

Production.—Mine returns for 1939 indicate a production of 33,900 troy ounces of crude platinum in Alaska, 1,140 ounces in California, and 20 ounces in Oregon—a total of 35,060 ounces. Comparable figures for 1938 are 39,889 ounces in Alaska, 1,000 ounces in California, and 43 ounces in Oregon—a total of 40,932 ounces. Most of the production in Alaska came from placers in the Goodnews Bay district south of the mouth of the Kuskokwim River. Smaller quantities were recovered in placer-gold mining in the Koyuk district, Seward Peninsula. Some platinum metals, especially palladium, also were obtained by reworking the tailings from earlier lode mining in the Ketchikan district, Kasaan Peninsula. In California most of the output of platinum was a byproduct of dredges working the gold placers in Merced, Placer, Sacramento, Shasta, Stanislaus, Tehama, Trinity, and Yuba Counties. The principal production in Oregon came from the ocean beach near Cape Blanco in Curry County.

Many gold and copper ores in the United States contain small quantities of platinum metals. In 1939, 8,634 ounces of platinum metals were recovered as a byproduct of refining gold and copper ores compared with 7,247 ounces in 1938.

The platinum deposits of the Goodnews Bay district, Alaska, have been described recently by Mertie,[1] and operations of the Goodnews Bay Mining Co. have been discussed by Spencer.[2] The report by Mertie includes 27 commercial analyses of platinum metals of the Goodnews Bay district, arranged by creeks in numerical order downstream. The average commercial analysis of platinum metals of the streams is as follows:

Average commercial analysis of platinum metals of the Goodnews Bay district, Alaska, in percent

	Platinum Creek	Squirrel Creek	Salmon River	Clara Creek
Platinum	60.09	68.48	73.40	73.29
Iridium	22.04	13.12	8.93	5.90
Osmium	3.91	3.27	2.05	.69
Ruthenium	.36	.26	.15	.13
Rhodium	1.83	1.40	1.88	.42
Palladium	.21	.26	.30	.56
Gold	.28	.41	2.22	1.01
Impurities	11.26	12.80	11.07	18.00

Purchases.—Platinum refiners in the United States reported purchases of domestic crude platinum from the following sources in 1939: Alaska, 3,222 ounces; California, 1,225 ounces; and Oregon, 32 ounces—a total of 4,479 ounces (4,993 ounces in 1938). Domestic refiners also reported purchases of 35,135 ounces (28,324 ounces in 1938) of foreign crude platinum in 1939—53 ounces from Canada, 31,748 ounces from Colombia, 1,624 ounces from Ethiopia, and 1,710 ounces from the Union of South Africa.

Prices.—Buyers reported purchases at $19.39 to $40.80 an ounce for domestic and $22.06 to $38 an ounce for foreign crude platinum in 1939.

REFINED PLATINUM METALS

New metals recovered.—Reports from refiners of crude platinum, gold bullion, and copper indicate that 41,441 ounces of platinum metals were recovered in the United States from these sources in 1939, an increase of 14 percent over 1938. It is estimated that 12,299 ounces of the total output in 1939 were derived from domestic sources.

New platinum metals recovered by refiners in the United States in 1939, by sources, in troy ounces

	Platinum	Palladium	Iridium	Osmiridium	Others	Total
Domestic from—						
Crude platinum	2,919	12	295	344	29	3,599
Ore	16				50	66
Gold and copper refining	5,270	3,330	34			8,634
	8,205	3,342	329	344	79	12,299
Foreign from crude platinum	27,828	149	722	383	60	29,142
Total recovery: 1939	36,033	3,491	1,051	727	139	41,441
1938	30,444	3,653	1,247	384	485	36,213

New platinum metals recovered by refiners in the United States, 1935–39, in troy ounces

Year	Platinum	Palladium	Iridium	Osmiridium	Others	Total
1935	37,284	1,432	2,438	449	457	42,060
1936	39,728	4,682	1,678	541	317	46,946
1937	36,174	5,945	1,998	640	501	45,258
1938	30,444	3,653	1,247	384	485	36,213
1939	36,033	3,491	1,051	727	139	41,441

Secondary metals recovered.—In 1939, 63,443 ounces of secondary platinum metals were recovered from the treatment of scrap metal, sweeps, and other waste products of manufacture that contain platinum, a decrease of 1.3 percent from 1938.

Secondary platinum metals recovered in the United States, 1935–39, in troy ounces

Year	Platinum	Palladium	Iridium	Others	Total
1935	47,107	7,852	2,191	1,975	59,125
1936	55,959	6,786	2,204	1,217	66,166
1937	55,926	12,680	2,320	1,280	72,206
1938	44,654	13,489	2,150	3,998	64,291
1939	45,432	13,039	3,150	1,822	63,443

Prices.—Refiners reported the following prices for platinum, palladium, and iridium: Platinum, high \$45, low \$26, and average \$36 an ounce for 1939 compared with \$43, \$24, and \$33.83 an ounce, respectively, for 1938; palladium, high \$25, low \$19, and average \$23.25 an ounce for 1939 compared with \$28, \$17, and \$23.21 an ounce, respectively, for 1938; iridium, high \$200, low \$50, and average \$112.67 an ounce for 1939 compared with \$90, \$50, and \$69.29 an ounce, respectively, for 1938.

Consumption and uses.—Platinum and its allied metals (palladium, iridium, rhodium, ruthenium, and osmium) are characterized by high melting point, white color, and resistance to oxidation at high temperatures and to attack by destructive chemical compounds. As pure metals, combined, clad, or alloyed with other metals, the platinum metals are used in jewelry and dentistry, in the chemical and electrical industries, and for numerous miscellaneous purposes.

A material gain in world output of platinum metals, owing chiefly to improvements in metallurgical processes used in refining copper-nickel ores, has made available large quantities of platinum, palladium, iridium, rhodium, ruthenium, and osmium. For example, in 1938 world production of platinum metals was about 540,000 ounces, of which about 57 percent was recovered as byproducts in the refining of nickel, copper, and gold ores, whereas in 1929 world production was about 231,000 ounces, of which about 17 percent was so obtained. With increased supplies, relative stability in the price of platinum and palladium has been reached at levels that permit their use for plant equipment and other industrial purposes. Despite the rapid advance in output of the platinum metals during the past decade, research has found new uses for them, and developmental activities are opening up larger and more diversified markets in which these uses are becoming accepted.

The most widely used metal of the group is platinum, which constituted 100,266 ounces (63.3 percent) of the total platinum metals sold by domestic refiners in 1939. The largest single consumer of platinum is the jewelry industry, where, alloyed with iridium, it is used as a setting for diamonds and other precious stones in rings and various forms of jewelry. About 47 percent (47,385 ounces) of the total sales of platinum by domestic refiners went to the jewelry trade in 1939.

Second in magnitude as a consumer of platinum in 1939 was the chemical industry, which took 20 percent (20,306 ounces) of the total domestic sales. It is used as a catalyst to produce sulfuric acid and for ammonia oxidation to produce nitric acid and nitric oxide, lining processing and reaction vessels, hydrogenation of organic compounds, rayon spinnerets, nozzles for the production of glass fiber, glass insulators for the bases of electric-light bulbs, tubing, valves, siphons, and safety disks for handling corrosive liquids and gases, anodes for the production of "per" salts, gas-analysis cells, crucibles, and laboratory equipment.

The dental industry ranked third as a consumer of platinum in 1939, taking 14 percent (13,755 ounces). Platinum, either pure or alloyed, is used in tooth pins, bridges, and bracings for artificial teeth, as matrices on porcelain inlays, and in orthodontic appliances.

The electrical industry, the fourth largest consumer of platinum in 1939, took 12 percent (11,952 ounces). It is used for thermocouples, temperature measuring and recording instruments, precision resistance thermometers, high-temperature furnace windings, spark-plug electrodes, magneto contacts, electrical contacts, relays, thermostats, automobile voltage regulators and direction indicators, and switches for potentiometric recorders.

Platinum leaf was made available during 1939 for outdoor signs and for interior decoration and book stamping. Palladium leaf was first introduced for somewhat similar purposes in 1933.

Next to platinum, palladium is the most extensively used metal of the platinum group; it is about half as common as platinum but less costly. It comprised 51,406 ounces (32.5 percent) of the total platinum metals sold by domestic refiners in 1939. Palladium, pure or alloyed, is adapted to many of the uses of platinum and during the past 2 decades has been employed in increasing quantities by the dental, electrical, and jewelry industries. The conservation of gold by many countries has stimulated the demand for the platinum metals, particularly palladium, and the use of palladium as a substitute for gold alloys for dental restoration, pen points, and articles of jewelry has made substantial progress. The largest consumers of palladium in 1939 were the dental and electrical industries, which purchased 22,989 and 21,510 ounces, respectively, from domestic refiners. The jewelry industry is the next largest consumer of palladium, and small quantities are used in the manufacture of chemical ware.

Iridium ranks third in consumption among the platinum-group metals. Of the total sales of platinum metals in 1939, 4,322 ounces (2.7 percent) were iridium. This metal is used chiefly as a hardening addition to platinum, rendering it suitable for laboratory vessels, surgical tools, hypodermic needles, thermoelements, and jewelry. Its compounds are used as fixing agents, porcelain pigment, and (in the form of black) as a catalyst.

The consumption of the other platinum metals—rhodium, osmium, and ruthenium—is small and comprised only 1.5 percent of the total for the group in 1939. Rhodium is alloyed with platinum for high-melting-point thermocouple wire, furnace windings, and laboratory ware for certain special uses. Rhodium plating is employed as a finish for glassware and silverware and in surfacing reflectors for searchlights and projectors. During 1939 platinum-rhodium spinnerets replaced the older platinum-gold spinnerets, because of their superior resistance to the various corrosive agents used in the production of rayon. Osmium, in association with other metals, provides pen points that will resist wear and corrosion by ink. These alloys also replace jewels as bearings in fine instruments. The oxide is used as a biological stain for fats and for fingerprint work. Ruthenium also is used as a hardener for platinum metals, and one of its salts serves as a biological stain.

The following table shows sales of platinum metals to domestic consumers by refiners in the United States in 1939. The figures include sales of platinum metals recovered from crude platinum, gold bullion, copper and nickel bullion and matte, electrolytic muds, and scrap materials and sweeps; in addition they include sales of imported platinum metals that are handled by domestic refiners. Sales by refiners totaled 158,357 ounces in 1939 compared with 127,306 in 1938.

Platinum metals sold by refiners in the United States in 1939, by domestic consuming industries, in troy ounces

Industry	Platinum	Palladium	Iridium	Others	Total	Percent of total
Chemical	20,306	468	187	626	21,587	14
Electrical	11,952	21,510	917	429	34,808	22
Dental	13,755	22,989	120	19	36,883	23
Jewelry	47,385	5,899	3,014	432	56,730	36

1938	71, 058	30, 071	8, 041	8, 741	117, 911
1939	71, 393	29, 273	7, 796	9. 088	117, 550

FOREIGN TRADE [3]

Imports of platinum metals into the United States during 1939 amounted to 306,627 ounces, establishing an all-time high. The principal sources of imported platinum metals in 1939 were the United Kingdom (250,699 ounces), Colombia (26,747 ounces), and the U. S. S. R. (19,846 ounces). Imports of palladium (chiefly from the United Kingdom) were noteworthy in 1939, increasing to 96,829 ounces from 26,858 ounces in 1938 and 45,427 in 1937, the previous record year.

Platinum metals imported for consumption in the United States, 1935–39

Year	Troy ounces	Value	Year	Troy ounces	Value

WORLD PRODUCTION

The following table shows world production of platinum metals by countries from 1935 to 1939, insofar as statistics are available. Returns for 1939 are incomplete, but except for the U. S. S. R. those for 1938 are nearly complete. If the production of the U. S. S. R. is estimated roughly at 100,000 ounces in 1938, world production of about 540,000 ounces is indicated, of which Canada furnished 54 percent, U. S. S. R. 19 percent, Union of South Africa 11 percent, United States 9 percent, and Colombia 6 percent—a total of 99 percent. The 1938 production comprised about 57 percent of platinum metals recovered as byproducts of nickel, copper, and gold ores, 33 percent of crude platinum metals from placers, and 10 percent recovered from sulfide and oxidized ores.

World production of platinum and allied metals, 1935–39, in troy ounces

[1] Data not available.
[2] Year ended June 30 of year stated.
[3] Recovered from nickel-copper mattes.
[4] Produced from platinum ores.
[5] Produced from treatment of gold ores on the Rand.
[6] Estimated production.
[7] Subject to revision.
[8] New platinum metals recovered in gold and copper refining of domestic materials.
[9] Exclusive of Ethiopia and Japan.

Canada.—Recoveries of platinum metals from the nickel-copper ores of the Sudbury district, Ontario, were 148,877 ounces of platinum and 135,402 ounces of other platinum-group metals in 1939 compared with 161,310 ounces of platinum and 130,893 ounces of other platinum-group metals in 1938.[4] Residues from the Port Colborne and Copper Cliff refineries are shipped to the International Nickel Co. precious-

[4] Dominion Bureau of Statistics, Preliminary Report on the Mineral Production of Canada During the Calendar Year 1939: Ottawa, 1940.

metals refinery at Acton, England, for the recovery of platinum, palladium, iridium, rhodium, and ruthenium. The platinum and palladium contained in the ore of the Falconbridge Nickel Mines, Ltd., are recovered at the precious-metals separating plant at Kristiansand, Norway. It is announced that this plant is now ready for separation of iridium, rhodium, and ruthenium. The Sudbury copper-nickel ore does not contain enough osmium to make recovery of this metal commercially important. Placers in British Columbia yielded 25 ounces of stream platinum in 1939 compared with 16 ounces in 1938.

Sales of platinum metals by the International Nickel Co. of Canada, Ltd., were 240,778 ounces in 1939 compared with 193,195 ounces in 1938. The metals were sold principally in the United States and the United Kingdom.

Colombia.—Colombia exported 39,070 ounces of crude platinum in 1939 (34,549 ounces in 1938). Of the 1939 exports, apparently about 64 percent went to the United States and 36 percent to Germany; a small amount went to Japan.

The South American Gold & Platinum Co. produced 27,975 ounces of crude platinum and 59,416 ounces of crude gold in 1939 compared with 20,714 ounces of crude platinum and 63,622 ounces of crude gold in 1938.

Union of South Africa.—According to the Department of Mines and Industries, the estimated content of platinum metals produced in the Union of South Africa was 65,853 ounces in 1939 compared with 58,734 ounces in 1938.

The enlarged Rustenburg plant of Potgietersrust Platinum, Ltd., for handling sulfidic ores, which was brought into operation in July 1938, was operated at capacity in 1939. The output, in the form of crude platinoids and matte, was shipped to England for treatment.[5]

Sales of platinum metals from South Africa were 47,914 ounces valued at £302,370 (£6.31 an ounce) in 1939 compared with 38,862 ounces valued at £223,776 (£5.76 an ounce) in 1938. The average composition of the product sold in 1938 was platinum 78.20 percent, palladium 16.33 percent, iridium 0.13 percent, osmium and osmiridium 0.08 percent, ruthenium 1.20 percent, and gold 4.06 percent.

Sales of osmiridium were 6,094 ounces valued at £36,665 (£6.02 an ounce) in 1939 compared with 5,884 ounces valued at £36,523 (£6.21 an ounce) in 1938. The average composition of the product sold in 1938 was osmium 28.90 percent, iridium 26.56 percent, ruthenium 13.81 percent, platinum 10.78 percent, gold 2.37 percent, rhodium 0.52 percent, and undetermined 17.06 percent.

MINOR METALS

By Paul M. Tyler

SUMMARY OUTLINE

In Minerals Yearbook, 1937, brief references were made to the commercial status and utilization of all metallic elements, but space limitations have restricted subsequent annual reviews of the minor metals to the presentation of such information as seemed timely and important enough to include in the record for a given year. Therefore, the following review makes no reference to certain elements that are more important commercially and even scientifically than those discussed at some length.

A glance backward shows that most of the metals falling within the purview of this chapter had little or no commercial significance until a relatively few years ago. As recently as 1919 a compendium on Our Mineral Supplies [1] grouped the minor elements in a single chapter, and the only commodities discussed therein were antimony, arsenic, bismuth, molybdenum, nickel, tin, tungsten, and vanadium. Attesting the wider variety of materials demanded by modern industry, all of these items are now considered important enough to be discussed elsewhere in this volume; and most of those now included in the coverage of the present chapter as "minor metals"—even those that now have well-established commercial uses—were deemed quite unimportant laboratory curiosities only 20 years ago.

At the threshold of a new decade, one wonders how many more obscure metals may emerge from the laboratory and be put to work. Even more beguiling speculations are the possible harnessing of atomic energy and the refabrication of elements. The accomplishments of nuclear physicists have been amazing, particularly in view of the few short years in which they have been aided in their researches by massive, modern atom-smashing devices. Natural transmutation of radioactive elements was discovered in 1898, when Mme. Curie identified the element that she named polonium. Artificial transmutation has been accomplished on an accelerated scale in various laboratories for more than a decade, but not until January 1939 did we know that it could do more than modify existing atoms to make them slightly heavier or slightly lighter. As noted in the chapter of this series for 1938, news of the actual splitting of an atom surprised

[1] Hess, Frank L., Our Mineral Supplies—the Rarer Metals: Geol. Survey Bull. 666–U, 1919, 13 pp.

the world of physics and, more important, opened new vistas of research. It is premature to assume that these disclosures will enable man to utilize atomic energy. The implications of such a revolutionary development, however, are indicated by Princeton's Prof. Malcolm C. Henderson, who calculated that if one could split economically the atoms of 8 pounds of uranium, enough energy would be released to drive the largest ocean liner across the Atlantic, in substitution for 6,300 tons of oil.[2] Discouraging is the statement that 16 times as much energy is needed to split a uranium atom as can be obtained from it; there is the further possibility that the only one of the various uranium isotopes that can be split is present to the extent of only about 1 percent; its atomic weight is 235. On the other hand, it is possible that one or more new neutrons actually are released by the initial splitting and that these in turn may make the disintegration continue, once it is initiated.

More immediate practical results are being obtained by less violent transmutations. Common table salt may be made artificially radioactive, so that for a time it will emit rays similar to those from natural radium. Neutron yields equivalent to what would be obtained by using 50,000 grams of radium are obtained by allowing the accelerated positive ion (proton) beam from the Cyclotron to bombard beryllium, which is thereby transmuted to boron and an ejected neutron. Another important use of the products of nuclear transformation, as recently described by Prof. John R. Dunning, of Columbia University,[3] arises from the artificially radioactive isotopes produced. Isotopes of iodine are being investigated for the treatment of malignant diseases. Single atoms—such as those of phosphorus, sulfur, and carbon—may be made radioactive and then used for biological tracer work. Sensitive detecting apparatus makes it possible to follow them wherever they go in the body. Radioactive copper has been used in research on the diffusion of metals. The dream of the alchemists to transmute common elements into precious metals no longer seems impossible. Already precious metals have been converted into more common ones, accomplishing the transmutation in reverse; for example, silver has been changed into cadmium.

The rarer metals used in only small amounts commercially and needed chiefly for scientific or academic purposes hitherto have been produced principally in Germany and so were virtually eliminated by wartime blockade after September 1939. In contrast with the conditions that followed similar elimination of German laboratory products and supplies in 1914, the substances most needed are now being produced in American laboratories, and necessary readjustments in price have been surprisingly few. Hafnium, however, has proved an exception and even small orders for experimental purposes are almost impossible to fill. Enough cyrtolite raw material is available, but extraction of the metal has proved overdifficult. On the other hand, a prominent dealer reports that a new process has been worked out in the United States for obtaining rhenium, another German specialty, but that it could not be commercialized owing to lack of domestic raw materials.

Imports of specified rare metals and alloys during the last 3 years are summarized in the accompanying table.

BERYLLIUM

The beryllium industry was featured on the front pages of newspapers throughout the country as the result of the open hearings by the Temporary National Economic Committee which began on February 28, 1939. The reports of these hearings, minutes of which were subsequently printed,[4] tended to show an international interest entirely out of proportion to the small size of this infant industry.

Definite progress was made commercially in 1939, however, and the gradual expansion in sales (interrupted in 1938) was resumed. For several years the metal or its compounds has been produced in the United States by two companies, both of which are prepared to supply master alloys for fabrication by other companies. Early in 1939 the Beryllium Corporation of Pennsylvania undertook to integrate its operations and subsequently has produced not only master alloys but castings, low-spark tools, fabricated products, and mis-

[4] Temporary National Economic Committee, 76th Cong., 1st sess., Hearings; Investigation of Concentration of Economic Power: Part 5, 1939, pp. 2011-2163, 2276-2304.

cellaneous items. The fabricated products include beryllium-copper rod available in diameters up to 3 inches, strip up to 8 inches wide, and wire drawn to a minimum of 10/1000 inch. Arrangements have been made with another metal-fabricating company to produce drawn tubing in desired sizes. An interesting new development is the use of beryllium copper in cast-setting diamond core bits and reaming shells. J. K. Smit & Sons, Inc., has in recent years developed a mechanical setting method that permits a very large number of small diamonds to be set in drill bits at perfectly spaced intervals. This is one phase of the general trend away from former methods of using a few large, high-priced carbonados for core drilling and toward the employment of a large number of smaller stones, including bort or ordinary diamonds of nongem quality. A typical bit may contain 178 stones having an aggregate weight of 7 carats or, roughly, 25 stones to a carat. Instead of setting stones by hand, methods for casting metal around the stones have been developed. Alloys with high melting points must be avoided, as excessive heat may harm the diamonds. The new bit composition, "Vankolite," is a beryllium-copper alloy and is claimed to have, among other advantages, increased tensile strength and improved holding qualities.

The main advantages of beryllium copper are the combination of extraordinary high-fatigue properties with good electrical conductivity. In contrast with certain competitive materials, it has the further advantage that it can be worked soft and hardened later instead of its hardness being rolled into it at the mill. Several new applications in electrical devices and office machines are reported.

Hitherto reductions in the price of the beryllium content of master alloys have not been made available to consumers. Some years ago, when beryllium content of the alloy was quoted at $30 a pound, a 96-cent base price on strip was established, but later when the price was cut to $15 the base price of the fabricated product was held at $1.15. The 96-cent price has been reestablished on the basis of copper at 10 cents (98 cents at 12-cent copper) for strip 2 to 8 inches wide and No. 16 gage or heavier; this applies to the standard alloy containing 2 to 2¼ percent Be. Alloys containing smaller percentages are offered, including a No. 70 at 65 cents base. Base prices on wire and tubing are higher, and new lists of extras have been established to cover smaller sizes and orders under 1,000 pounds.

In addition to alloys, the Brush Beryllium Co., 3714 Chester Avenue, Cleveland, Ohio, produces the pure metal and various beryllium compounds, such as the oxide, sulfate, nitrate, and fluoride. Notable commercial progress has been made with its high-fired flux-free oxide for use in ceramic materials, where good electrical resistance and thermal conductivity may be required. This company first put pure beryllium metal on the market in 1939, after several years, experimentation. A certain amount of somewhat impure metal was made several years ago in Germany and sold in this country for experimental purposes. With domestic metal available at a substantial reduction below the $100 heretofore asked for imported beryllium, commercial applications may be developed.

Beryl, the only ore of beryllium, nominally is quoted unchanged at $30 to $35 a short ton at the mine or around $45 to $55 at consuming plants. However, imported ore can be bought for around $3.25 or $3.50 per short ton unit f. o. b. United States Atlantic ports. The blockade of Germany has diverted South American supplies to the United States, and one distress lot was offered at $30 a ton delivered in New York. A little beryl is used in ceramics, and small quantities are consumed in England, Italy, Japan, and France, but with Germany cut off the two American beryllium companies are the only consumers of any substantial tonnage and their consumption is far from large. Imports of beryl into the United States rose to 459 short tons valued at $14,574 in 1939 compared with 146 tons valued at $5,990 in 1938, 182 tons ($8,031) in 1937, and 162 tons ($6,681) in 1936. No data are available as to shipments of domestic beryl, but probably they have not exceeded about 100 or at most 150 short tons a year, and the consumption in the United States has been supplied principally by imports.

BORON

Boron alloys are supplied by domestic manufacturers, small quantities being used in the nonferrous-metals industries and in steel making. In cast iron,[5] boron opposes graphitization on solidification and exerts an energetic whitening effect, producing a hard, strong iron but reducing malleability. The Metallurgical Division of the Bureau of Mines recently investigated the electrometallurgical production of calcium boride, metallic boron, and boron alloys from colemanite.

COLUMBIUM AND TANTALUM

The world's meager needs of columbite continue to be supplied mainly from Nigeria and of tantalite from the Pilbarra district of Australia. However, Geomines, the important tin producer at Manono, Katanga (Belgian Congo), reported an output of 105 metric tons of tantalum-columbium ore during the fiscal year ended June 30, 1939. Shipments of columbite in Nigeria dropped to 530 long tons in 1938 compared with 707 tons in 1937; exports declined to 324 tons. According to official statistics, the output of tantalite in Uganda was less in 1938 than during the preceding year, owing to a drop in price and the rather low tantalum content of the ores from that colony; the hope was expressed, however, that 60 percent Ta_2O_5 concentrates might be produced from alluvial workings in the Buhwezu district. Two occurrences of columbite are reported in Chosen;[6] and the European press reported active development during 1939 of loparite deposits in the Kola Peninsula, from which columbium and tantalum as well as thorium and various rare-earth metals may be separated. Tantalite deposits and operations in Northern Territory of Australia were described recently.[7]

Tantalum is used in pure wrought form for a variety of purposes, and the hard carbide is used in cutting tools. The bulk of the domestic production of tantalite hitherto has come from the Black Hills of South Dakota. The Fansteel Mining Corporation, a wholly owned subsidiary of the Fansteel Metallurgical Corporation which is the leading manufacturer of tantalum metal and compounds, has a

property at Tinton, S. Dak. The deposit and the mill on this property have been described by Guiteras.[8]

Shipments of tantalum-bearing ores in the United States, 1935–39

Year	Pounds	Value	Year	Pounds	Value
1935	7,681	$4,521	1938	36,189	$35,127
1936	----------	----------	1939	340	200
1937	16,307	13,317			

Ferrocolumbium, 50 to 55 percent Cb, has been quoted recently at $2.25 to $2.35 a pound. Ore prices are subject to negotiation between buyer and seller. For tantalite, nominal quotations by Engineering and Mining Journal at the end of 1939 were $1.50 to $2.50 a pound of contained Ta_2O_5 in 60-percent concentrate.

GALLIUM, GERMANIUM, AND INDIUM

As noted in previous volumes of Minerals Yearbook, gallium, germanium, and indium could be produced in substantial quantities as byproducts of the zinc industry and from other sources, provided commercial outlets were available. In 1939, J. W. Whittemore and P. S. Dean, professors in the ceramic department of Virginia Polytechnical Institute, were credited with the discovery of a mineral containing 0.2 percent gallium, which is probably the richest "ore" of this metal known so far.

No use at all has been found for germanium. Gallium has been made in Germany by the Vereinigten chemischen Fabriken in Leopoldshall from metallurgical residues of the Mansfeld copper-slate ores, but the total output has been reported as being only 50 kilograms a year and used mainly for experimental purposes. Prices have been quoted usually at more than $2 or $3 a gram, although manufacturers of medium-high-temperature thermometers, which seem to be almost the only quasicommercial outlet, may have made purchases at $1.50 a gram. According to a usually well-informed dealer, however, the metal could be had in quantities at 60 to 80 cents a gram. The German press reported that the price was 10 RM. a gram (about $4) in 1939 compared with 200 RM. some years ago, also that gallium was used in the manufacture of optical reflectors and dental alloys.

Uses for indium have been investigated in many laboratories, and a long list of possible applications may be compiled. But aside from its use in silverware by one or more companies, in quite small quantities in dental and certain other alloys, and for contact points for certain electrical apparatus, no commercial consumption has developed. There are still promising possibilities for indium in superquality automobile bearings but not at more than about half the present "bottom" price of say $20 an ounce for fairly large quantities. Similar bearings are used in at least one airplane engine. Small quantities of indium for laboratory requirements are quoted in dollars per gram. The Belgochimie in Belgium and the Furukawa Mining Co. in Japan were understood to have undertaken the production of indium in 1939. Domestic supplies could be developed by the

Grasselli Chemical Co., the Anaconda Copper Co., the American Smelting & Refining Co., and other smelting concerns or producers of lithopone.

RADIUM

Imports of radium salts into the United States, after jumping to an all-time record of 38.75 grams valued at $787,025 in 1938, more than doubled in 1939, reaching 78.631 grams valued at $1,953,820. Undoubtedly much of the increased imports went into stock; nevertheless, in 1939, the National Bureau of Standards under the supervision of Dr. L. F. Curtiss tested 2,448 radium preparations containing 21.95 grams compared with 1,280 preparations containing 10.5 grams in 1938 and 1,703 preparations containing 9 grams in 1937. As noted in Minerals Yearbook, 1939, a marketing agreement was concluded early in the year between the two leading producers, and during 1939 virtually all the imports (except 2.797 grams valued at $70,753) came from Belgium. The New York office of the Eldorado Gold Mines, Ltd. (Canada), was discontinued and the syndicate's sales to the United States subsequently have been handled by the Radium Chemical Co., Inc., 570 Lexington Avenue, New York, N. Y.

The price of radium, after reaching $135 a milligram during the World War, was cut to $70 in 1923 and to $50 in 1930. The quotation since August 1936 has been nominally $40, but competition resulted in sales at $20 or even less in 1937, after which the price became firmer and at the end of 1939 was around $27.50 a milligram for orders of 1 to 5 grams. For hospital use, radium salts can be leased at 40 cents a milligram a month. Radon or emanation implants are sold on a sliding scale ranging from $2.50 for those having a radium content of 1 millicurie (at hour used) to $7.50 for those containing 3.0 millicuries.

The Eldorado mine in the Great Bear Lake district of Canada, which currently produces nearly 40 percent of the world's radium, yielded 1,100 tons of concentrate during the year ended August 31, 1939. Ore reserves are increasing; and as the capacity of the refinery at Port Hope, Ontario, was doubled in 1939 the radium output is understood to be in the neighborhood of 8 grams monthly. After completing a 100-ton mill building, Canada Radium Mines, which owns property in the Wilberforce area in Ontario, began construction of a chemical plant and was reported to be planning to start actual production in 1940 from ore reserves estimated to be adequate for 2 years milling.[9]

The St. Joachimsthal mines, formerly part of Czechoslovakia, were incorporated in the German Reich in October 1938. These deposits are estimated to contain more than 300 grams of radium still unmined and at the time of their incorporation into Germany were producing about 180 to 190 metric tons of pitchblende ore yielding about 5 grams of radium a year. Operations were under control of the Czech Government; and the output, ranging from 2 to 10 grams annually in recent years, has been purchased principally in England. In March 1939 the Auergesellschaft A. G., Berlin, Germany's leading manufacturer of radioactive metals (one of its products being mesothorium from gas-mantle residues) obtained a concession from the German Government to operate the Joachimsthal mines under lease

[9] Jeffries, Zay, Work cited in footnote 2, pp. 11-12.

and extract the radium at its works in Berlin. Henceforth the entire product doubtless will be used in Germany, and under the stimulus of Germany's Four-Year Plan it was thought that production would be increased to cover not only Germany's own needs (3 grams in 1935) but possibly exports, even though production costs exceed the world price. Before the radium mines were acquired, the only German source of radium, apart from imports, was an annual accumulation of about 20 metric tons of radioactive silt at Bad Kreuznach, yielding about 1.75 milligrams of radium per ton in addition to certain quantities of thorium and actinium.[10]

Uranium and radium are byproducts of the vanadium-mining operations of the Union Carbide & Carbon Corporation. Nearly 8 grams of radium came from this source in 1938 and 3¼ grams in 1937.[11]

World production of radium since the earliest experiments by Mme. Curie in 1898 probably has aggregated almost 1,000 grams. A statement posted at the New York World's Fair credited 800 grams to the following sources: United States, 338; Belgium, 160; Czechoslovakia, 55; France, 51; England, 42; Sweden, 8; Denmark, 4; Argentina, 2; unaccounted for, 140. It will be noted that these figures do not include Canada, which has produced at least 180 grams; according to the meager data available in the files of the Bureau of Mines the output of the United States probably has not exceeded 300 grams so far, whereas the Belgian output from ores mined in the Belgian Congo since 1922 undoubtedly has exceeded that amount. The production of radium in France and England and probably in Sweden and Denmark as well has been derived in large part from ore mined elsewhere. As no substantial production has been reported in these countries except in the Cornwall district of the United Kingdom, additional sources of of radium-bearing ores include, in the order named, Portugal, Madagascar, the U. S. S. R., Australia, and South Africa, although the total production from these minor sources probably has not been 5 percent of the world total.

The dangers accompanying actual manipulation of bare radium salts are well known to most of those who have worked in this field. Lead usually has been the principal means of protecting the medical operator or investigator from actual exposure to the damage-dealing radiations, but in certain procedures lead may restrict the work. To avoid danger to the operator a new technique of protection has been described by De Ment [12] which depends on electromagnetic diversion of the rays from their normal paths, positive particles being absorbed upon a negatively charged magnetic pole and negative particles by a positive pole. The operator then can station himself in the field of minimal radiation.

The National Bureau of Standards has undertaken to prepare a series of radium standards covering the weakly radioactive range equivalent to between 10^{-4} and 10^{-11} grams of radium. These standards are needed by investigators of the radioactive content of geological specimens, particularly those used for determining the age of the earth. They are also needed in standardizing equipment for measuring artificial radioactivity.

[12] De Ment, Jack, Electrical Protective Devices in Radium Work: Am. Jour. Roentgenology and Radium Therapy, vol 42, No. 6, December 1939, pp. 930–933.

Uranium.—Increased output of radium has raised again the question of disposing of the jointly recoverable uranium. At present the chief use of uranium is in the form of oxides which produce golden glazes on pottery and yellow- and orange-colored glasses. In small amounts uranium oxide produces luster or irridescence. At the close of 1939 sodium uranate, Na_2UO_4, was quoted unchanged at $1.75 and $1.80 a pound; uranium oxide, 96 percent U_2O_6, in 100-pound lots at $2.65 a pound for the black and $1.75 for the yellow or orange product.

Ionium.[13]—The Canadian National Research Council has investigated extraction of radioactive substances other than radium from Great Bear Lake pitchblende, which contains the amazing number of 53 different elements. Ionium, the product intermediate between uranium and radium, has a much slower break-down (100,000 years) than radium (2,500 years). Under equilibrium conditions an ore carrying about 120 milligrams of radium a ton should contain about 4,800 milligrams of ionium. As ionium gives off only alpha rays, it would not be useful like radium for therapeutic purposes, but it should be serviceable for such uses as the preparation of luminous paints. Although it is less potent, weight for weight, the total ionium content of the ore would equal in value the total radium content, insofar as production of luminous paints is concerned.

Polonium.[14]—Polonium has an average life of about 6 months, so the equilibrium amount present in the ore is very small, although very potent. Like ionium, it is lost in the present Port Hope refinery process; but radium D, which accompanies and is inseparable from the lead isolated in the process, continually generates polonium during its entire 24-year life, so that by the time a given quantity of polonium disappears a corresponding amount may be generated from a stock of radium lead. Polonium emits only alpha rays, but unlike ionium it is afterward "dead," a distinct advantage for some purposes. The chief established use of polonium is in meteorological stations for measuring the electrical potential of the air, and the meager supply needed for the purpose is obtained from old radon seeds.

RARE EARTHS

To encourage research in the field of rare earths and illumination the Auer Research Foundation, named for the Austrian chemist who invented the Welsbach mantle, posted in 1939 a 10,000-RM. ($4,000) prize for the best process submitted for better utilization of gases and more effective lighting with mantles containing thorium and cerium oxides. Although the use of Welsbach mantles has declined in Europe, as in America, they are still used extensively in Germany for portable lanterns and street lighting. Another Auer prize of similar amount was put up for the development of new commercial uses of lanthanum compounds. So far no practical use has been found for lanthanum, although its suggested use in compounds for loading silk and rayon is being reconsidered now that the patent has expired. Lanthanum oxide is the major rare-earth constituent of the residues from the extraction of thorium and cerium oxides from monazite, and the quantities of such residues have increased owing to the greater pro-

[13] Whitby, G. S., Some New Metals: Canadian Min. and Met. Bull. 333, January 1940, pp. 56–64.
[14] Whitby, G. S., work cited in footnote 13, pp. 56–64.

duction of thorium, especially for use as a catalyst in the Fischer-Tropsch benzine synthesis.[15]

Cerium, praseodymium, and neodymium compounds, which also occur in Welsbach mantle residues, have been used extensively in the glass and ceramic industries for coloring and glazing. A recent patent (United States 2,150,694) covers nonsilicate glasses formed by the fusion of rare earth and other metallic oxides without silica. In the search for more rapid and efficient photographic lenses, Dr. George W. Morey of the Carnegie Institution, to whom this patent is issued, has created an entirely new series of optical glasses with indexes of refraction roughly midway between that of the best ordinary flint glass and that of the diamond. As these new glasses combine low dispersion with high index of refraction they can be used for camera lenses of greater light-gathering power and afford better corrections for chromatic aberration. One glass, with 60 percent lanthana and 40 percent boron oxide, has a refractive index of 1.72 and dispersion index of 54. Another, with 33 percent lanthana, 41 percent thoria, and 26 percent boron oxide, has a refractive index of 1.76 and dispersion index of 52.

A pure oxide of cerium, called [illegible]aline, recently has been developed for the production of gray nickel or cobalt ground enamels for sheet metal and is claimed to have remarkable opacity and to be unaffected by furnace atmospheres.[16] Misch metal, though hitherto used almost exclusively in making sparking alloys and lighter flints, often has been proposed for use in the iron and steel industry. In cast iron, cerium opposes graphitization, and misch-metal additions in small amounts afford interesting possibilities for making malleablized iron. According to a French authority,[17] cerium and allied metals have even more affinity than manganese for sulfur; moreover, they form harmless rounded particles.

One of the important uses of rare-earth compounds at present is in the textile industry, wherein they are used in printing and dyeing and also, to an increasing extent, for mothproofing and rotproofing fabrics.

RHENIUM

A little rhenium finds its way into radio and power tubes, but the consumption is very small and hitherto Germany has been the only commercial source. According to Wm. G. Rinehart, who collected the samples, Dr. Clarence F. Hiskey, University of Wisconsin, found rhenium in 30 out of about 150 manganese-bearing samples from the Batesville-Cushman district, Arkansas, but the content is only about 1 part in 10 million.

SELENIUM AND TELLURIUM

Selenium finds its chief use in glassmaking; a few ounces added to clear glass batches neutralize the greenish cast imparted by traces of iron in the sand. Ruby signal lenses carry 0.25 percent Se. Minor uses are for photoelectric cells, to improve machinability of stainless steel, in rubber goods, and in red-paint pigments containing

cadmium and barite. It also has been employed in antiknock compounds for gasoline, in insecticides and bactericides, in certain organic syntheses, and to protect magnesium metal from corrosion—but never in any substantial amounts.

Tellurium is used to toughen rubber and to harden lead.

Prices of selenium (black, powdered, 99.5 percent) and of tellurium remained at $1.75 a pound. To offset declining exchange the London prices at the end of the year had risen to 8s. 6d. and 7s. to 7s. 6d. respectively.

Production, sales, and imports of selenium and production and sales of tellurium in the United States, 1935–39

Year	Selenium				Tellurium	
	Production (pounds)	Sales [1] (pounds)	Imports		Production (pounds)	Sales [1] (pounds)
			Pounds	Value		
1935	244, 710	232, 831	179, 331	$322, 332	37, 096	22, 610
1936	352, 480	226, 402	122, 806	215, 835	57, 956	25, 453
1937	435, 821	282, 598	92, 523	161, 382	51, 409	23, 365
1938	225, 674	166. 494	101, 034	163, 598	11, 076	26, 944

[1] Bureau of Mines not at liberty to publish value.

THORIUM

Welsbach's invention of an incandescent gas mantle composed of 99 percent thorium oxide created after 1890 a world-wide demand for thorium, which was furnished by working monazite sands produced successively in North Carolina, Brazil, Ceylon, and Travancore. The wider use of electric lighting, following introduction of ductile tungsten filaments in 1910, virtually eliminated gas mantles, except for liquid-fuel equipment in remote regions. In 1890 thorium oxide cost $125 a pound; by 1910 it had dropped to $2.50 a pound. It can be made from thorium nitrate, which recently averaged a little over $2 a pound. Monazite, the ore of thorium, has recently been quoted at $60 a ton for 8-percent grade.

Thorium metal is soft and malleable and probably could be produced at prices not greatly exceeding that of platinum. It has been used to eliminate brittleness in the manufacture of ductile filaments. Other alloys might be developed; those with aluminum, chromium, cobalt, copper, molybdenum, tungsten, and vanadium already have been briefly investigated.[18] An alloy claimed to be suitable for neon-sign electrodes contains copper plus 0.005 to 10 percent thorium and a third element (United States Patent 2,136,918, November 15, 1938, F. R. Hensel and Earl I. Hensel, assigned to P. R. Mallory & Co., Indianapolis, Ind.). Some thoria is used in high-quality refractories, and diminishing quantities are employed in gas mantles. Monazite is the chief source. Mesothorium is also obtained from monazite residues. No data are available as to domestic production, but in 1939 the National Bureau of Standards tested only three specimens containing 49 milligrams of mesothorium compared with 18 specimens and 373 milligrams during the preceding year.

[18] Fink, Colin, Thorium and Chemical Research: Ind. Eng. Chem., News ed., vol. 17, No. 24, December 20, 1939, p. 775.

TITANIUM

The Bureau of Mines is not at liberty to publish figures for domestic production of ilmenite and rutile. As in former years, Virginia was the leading producing State for both these minerals, but in 1939 Arkansas furnished a substantial quantity of rutile-brookite concentrate and could have produced more had the concentrating plant been able to operate steadily during the prolonged drought. According to the California State mineralogist, Harry R. Smith shipped ilmenite sand, containing over 30 percent TiO_2 and valued at $10 a ton, for use as roofing granules. The duPont interests continued to develop titanium deposits in the San Gabriel Mountains, Los Angeles County, Calif.

The bulk of the ilmenite used in the United States is imported from British India and is consumed in the manufacture of titanium pigments. Domestic production of rutile exceeds imports, but both domestic and imported rutile is sold abroad. The principal uses of rutile are in welding-rod coatings and ceramics.

Imports of ilmenite rose in 1939 to still another all-time record. Early in the year the second unit of the National Lead Co. titanium pigment plant at Sayreville, N. J., was opened, and a third unit is expected to begin producing in 1940, tripling the capacity of the original unit completed in 1935. The first commercial production of titanium white was probably in 1919, and in 1922 Travancore made its first shipment of ilmenite. As recently as 1926 the British Indian output of ilmenite was only about 5,000 tons, and the 50,000-ton mark was not approached until 1932. The mining of ilmenite and associated minerals in India has been described by the vice president of the Foote Mineral Co.[19] who presents the following composite analysis of recent shipments: TiO_2, 60.35; Fe, 22.69; SiO_2, 0.41; S, 0.01; and P, 0.03 percent.

Imports of rutile were almost twice as large in 1939 as in the preceding year but failed to equal the high record of 665 tons valued at $67,643 in 1937. Australia is the leading foreign source, with Brazil second. However, rutile has also been separated from mineral concentrates imported from British India. Actually the import figures reveal little, because, on the one hand, some of the rutile so reported has to be reconcentrated after arrival in the United States and, on the other hand, rutile is recovered from ores imported under other statistical classifications, chiefly as "Zirconium ore." Other countries that have produced rutile are Norway, Cameroons, and South Africa. Brazilian rutile has been exported to other countries besides the United States, notably Germany and the United Kingdom. Australian operations, which lie along the coast of New South Wales, some 300 miles from Sydney, have been described by Poole.[20]

Kennametal, a tungsten-titanium carbide, is a new, high-priced, ultrahard carbide used in cutting tools, valve seats, and other wearing surfaces.

Engineering and Mining Journal quotations in 1939 were the same as in 1938: Ilmenite, 45 to 55 percent TiO_2, f. o. b. Atlantic seaboard,

[20] Poole, W. R., Zircon and Rutile from Beach Black Sand Deposits: Chem. Eng. and Min. Rev., vol. 31, Nos. 365–366, February–March 1939.

$10 to $12 per gross ton according to grade and impurities; rutile, guaranteed minimum 94 percent concentrate, 10 cents per pound (nominal); 88 to 90 percent, $55 per ton, c. i. f. New York; ferrocarbon-titanium, $142.50 per short ton f. o. b. producer's plant. The price of titanium dioxide after dropping to 14 cents at the beginning of the year was reduced further to 13 cents a pound. Barium- or magnesium-base titanium pigment was quoted at 5¼ cents and calcium-base pigment at 5 cents early in 1940.

ZIRCONIUM

Domestic consumption of zirconium compounds is growing but falls far short of the quantity indicated by the importation of zirconium ores as officially reported. It is common knowledge that the bulk of the imports so classified comprises rutile-bearing concentrates from Australia, which are not all zircon. Moreover, not all the zircon content of the concentrates after separation of rutile is utilized currently but goes into stock pile.

An important outlet for zirconium compounds is as opacifier in all kinds of vitreous enamels, replacing tin oxide. The potential size of this market is indicated roughly by the world output of tin oxide, which the International Tin Research and Development Council estimates as averaging 3,500 to 4,000 short tons a year for 1929–37. According to Chambers: [21]

> A composite analysis of many shipments from F. X. Pereira and Company to Philadelphia is given below: ZrO_2 66.80 percent, SiO_2 31.50 percent, TiO_2 0.84 percent, Fe 0.08 percent, P_2O_5 0.07 percent.
>
> One of the first commercial uses for zircon was in refractory crucibles and for this purpose it has some excellent properties. It has the lowest linear thermal expansion among the usual ceramic raw materials, having even less expansion than sillimanite and fused aluminum oxide. It has a melting point of about 4622° F. and a softening point of approximately 3272° F. For these reasons zircon refractories show excellent resistance to spalling and fusion except in the presence of iron oxide and certain basic fluxes.
>
> Zircon is of even greater interest in the field of specialized porcelains. Vitreous porcelain bodies containing 30 to 70 percent zircon have a long firing range, exceptional mechanical strength, good heat shock resistance and remarkable dielectric strength at high temperatures. All of these properties are particularly necessary in electrical appliances as well as in sand molds for stainless steel and alloy castings.
>
> Considerable quantities of zircon sand are also employed in refractory insulating cements for electrical appliances as well as in sand molds for stainless steel and alloy castings.
>
> Zircon is now used in certain types of heat-resisting glass and it is possible that the glass industry will eventually be the largest market for this versatile mineral. The most desirable feature of zirconia glasses is their greater impact strength and thermal endurance. In other words, the addition of zircon to the batch produces tougher glass which is less likely to break in use. It also increases the chemical durability of glass, particularly its resistance to caustic soda. Until recently these advantages were outweighed by the cost, but the present low-market price of zircon now puts it approximately on a parity with alumina.
>
> Zircon is also the usual raw material for manufacturing zirconium oxide and zirconium salts. The most important of these are the zirconium opacifiers which to a large extent have supplanted tin oxide in vitreous enamels and ceramic glazes. Other zirconium compounds such as the pure oxide, tetrachloride and tetraiodide are used in producing zirconium metal. The metal is used in photo-flash bulbs, radio transmitting tubes, ammunition primers, spot welding electrodes, and a number of other unusual applications.

[21] Chambers, G. H., Work cited in footnote 19, pp. 8–10.

Engineering and Mining Journal quotations during 1939 were still nominal: Zircon ore, 55 percent ZrO_2, f. o. b. Atlantic seaboard, carloads, \$55 a short ton; crude granular zircon, \$70 f. o. b. Suspension Bridge, N. Y., milled, \$90. Zirconium metal, commercially pure, powdered, \$7 a pound. Zirconium alloys, 12 to 15 percent Zr, 39 to 43 percent Si, \$97.50 to \$102.50 a gross ton; 35 to 40 percent Zr, 42 to 52 percent Si, 14 and 16 cents a pound.

PART III. NONMETALS

BITUMINOUS COAL[1]

By M. E. McMillan, R. L. Anderson, and W. H. Young

SUMMARY OUTLINE

Bituminous-coal production in 1939 was considerably greater than in 1938. During the first quarter production was high to fill orders purchased for storage by consumers in anticipation of possible suspension of mining when the wage contract expired on March 31. Output declined sharply in April and May when work ceased pending the signing of a new wage contract. The outbreak of war in Europe in September stimulated general business, particularly the heavy industries, and the production of coal increased substantially.

During the year the Bituminous Coal Division, United States Department of the Interior (formerly the National Bituminous Coal Commission), proceeded with the task of building a minimum price structure that would comply in detail with requirements of the law.

[1] The collection of production statistics of the bituminous-coal industry previously conducted by the Bureau of Mines was transferred to the National Bituminous Coal Commission July 1, 1937. The cooperation of the Coal Commission (now the Bituminous Coal Division, U. S. Department of the Interior) in contributing this chapter to Minerals Yearbook to maintain the continuity of the bituminous-coal series is gratefully acknowledged.
Data for 1939 are preliminary; detailed statistics with final revisions will be released later. Data for 1938 are final.

Production.—The output of soft coal in 1939 was 393,065,000 tons, a 13-percent increase over 1938. The coal industry made substantial gains in common with general business activity during the latter half of the year, and the total output for the year was 27 percent above the record low of 1932, although 27 percent below the 534,989,000 tons of 1929. (See figs. 1, 2, and 4.)

Imports and exports.—Exports of bituminous coal rose from 10,490,-269 tons in 1938 to 11,590,478 in 1939, a 10-percent increase. At the same time imports, which are relatively insignificant, rose 47 percent from 241,305 tons in 1938 to 355,115 in 1939. As in the past, virtually all these imports and more than 90 percent of the exports represented trade with Canada. (See fig. 10.)

Changes in stocks.—The reserve supply of coal in the hands of industrial consumers and retail coal yards rose from a total of 40,720,000 tons at the beginning of the year to 44,571,000 at the close. Between the same periods, stocks on the upper Lake docks declined 295,000

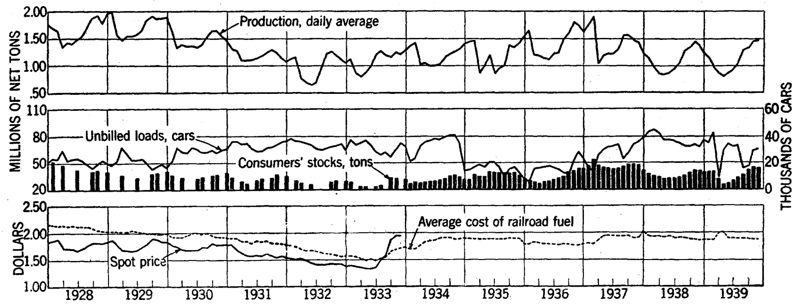

FIGURE 1.—Trends of production, stocks, and prices of bituminous coal, 1928–39.

tons, and unbilled coal in cars at the mines or classification yards fell 74,000 tons. (See fig. 1 and table 18.)

Consumption.—After allowances have been made for foreign trade and changes in consumers' stocks the consumption of bituminous coal in 1939 totaled 377,978,637 tons, an increase of 33,328,837 from 1938. Each of the more important classes of consumers shared the increase, which ranged from 69 percent for beehive coke ovens to 7 percent for railroads. (See fig. 3 and table 4.)

Distribution.—Shipments of bituminous coal during 1939 rose substantially above the 1938 level in each of the primary channels of distribution. Changes in the monthly volume of the more important movements are shown in figure 4.

Freight rates.—The average railroad freight charge per net ton of revenue bituminous coal amounted to $2.23 in 1939 compared with $2.27 in 1938.

Trend of prices.—Spot market quotations indicate that producers averaged less per ton for their coal in 1939 than in 1938. (See tables 1 and 15.)

Mechanization.—Data available early in 1940 [2] indicate continuation of the sharp advance in mechanical loading of bituminous coal.

Sales of mechanical loading equipment for use in bituminous-coal mines, in terms of total capacity, increased 21.4 percent in 1939 over

[2] Coal Age, February 1940, p. 63, and Mining Congress Journal, February 1940, p. 23.

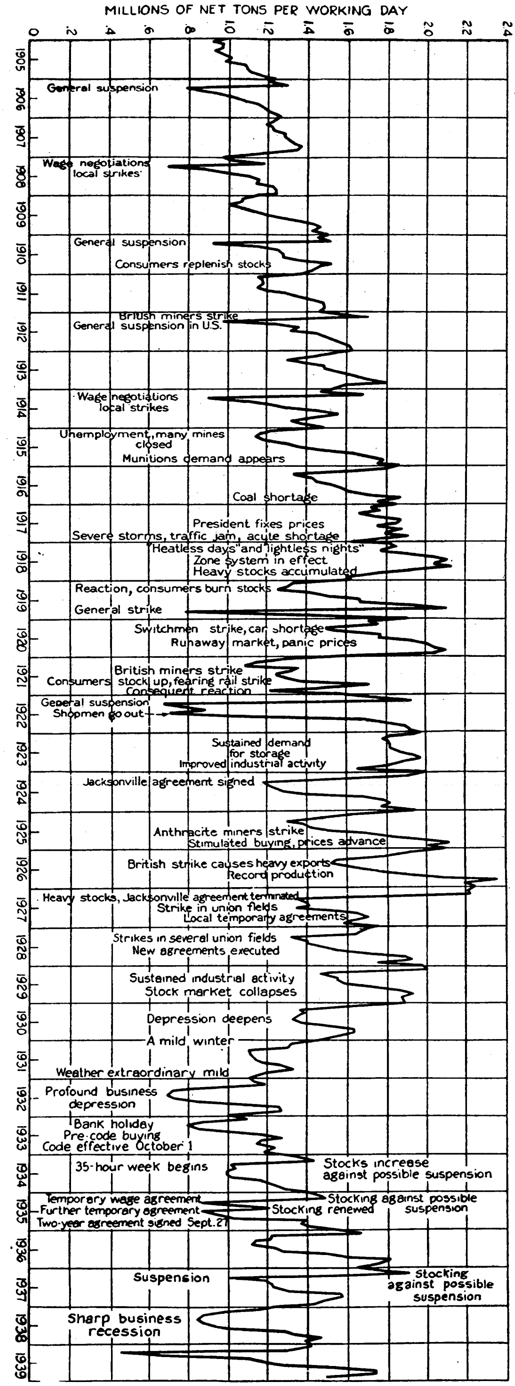

FIGURE 2.—Average production of bituminous coal per working day in each month, 1905–39.

1938. Reports from 31 manufacturers show sales of 292 mobile loaders for the current year as against 241 in 1938 and 344 in the peak year 1936. Conveyor sales totaled 1,095 in 1939 compared with 749 in 1938 and 682 in 1936.

Stripping operations.—The volume of bituminous coal produced by stripping decreased from 31,750,853 tons in 1937 to 30,406,855 in 1938.

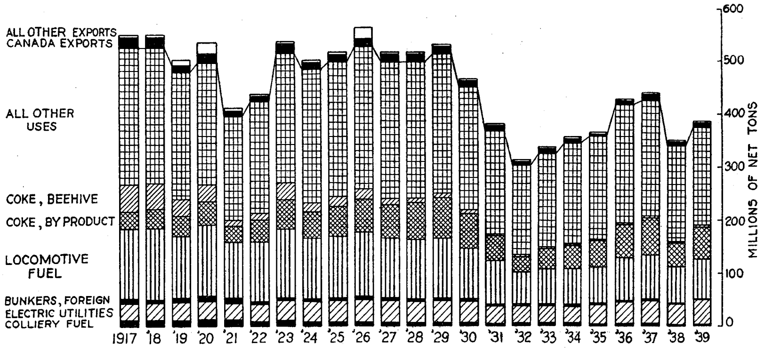

FIGURE 3.—Tonnage of bituminous coal absorbed by the principal branches of consumption, 1917–39.

However, the percentage of total production represented by strip coal rose from 7.1 percent in 1937 to 8.7 percent in 1938.

Trend of employment.—Estimates of the number of men employed at bituminous-coal mines in 1939 indicate a slight drop from the 1938 figure (441,333). Indexes compiled by the Bureau of Labor Statistics

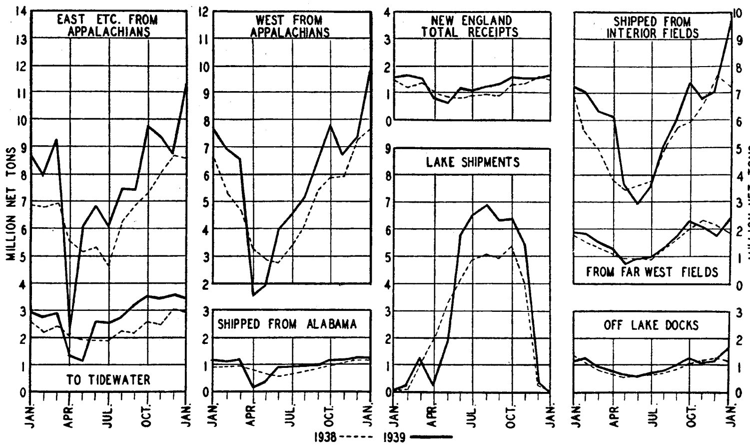

FIGURE 4.—Monthly movement of bituminous coal in the major channels of distribution, 1938–39.

upon the basis of a sample that includes more than half the workers in the industry show a 1-percent drop in employment for 1939 if normal operations during the April-May suspension are assumed. Reports from the mining departments of nine States with more than 60 percent of the bituminous-coal employees in the United States indicate an average decline of 0.4 percent for the same period. These data suggest an estimate of 437,000 employees for 1939. In comparison with 1929, when the average number of men at bituminous-coal mines totaled 502,993, the 1939 figure represents a decrease of 66,000.

Statistics of employment for bituminous-coal workers cannot be interpreted properly without considering the intermittent operations that characterize most coal mines. In 1938, for instance, the bituminous mines were operated an average of 162 days out of the 261 possible under the 5-day week of the union wage agreement. Consequently, a substantial proportion of the manpower on the rolls of the industry was idle throughout the year, the number depending on the market and the season.

Trend of capacity.—The potential full-time output of active mines in the bituminous-coal industry decreased 7 percent between 1937 and 1938. The coal industry reached its peak capacity in 1923 when, upon the basis of 308 operating days, the potential output was 970,000,000 tons. Subsequent liquidations forced the closing or abandonment of thousands of mines and reduced the indicated capacity to 622,000,000 tons in 1934. The potential output upon a 308-day basis was 663,000,000 tons in 1938. Under the 5-day week full-time operations are limited to approximately 261 days. The potential capacity of operating mines upon a 261-day basis was 562,000,000 tons in 1938 compared with the total actual production of 348,544,764 tons.

Trend of fuel efficiency.—Since the World War period, improvements in the technology of fuel application have contributed to a continuing decline in the demand for coal for industrial uses. Although the effect of such improvements is cumulative from year to year, the rate of decline is smaller in recent years as the remaining margin of possible increase in fuel efficiency becomes progressively less.

The class I steam railroads reduced the average coal consumption by coal-fired locomotives from 117 pounds per 1,000 gross ton-miles of freight service in 1938 to 115 pounds in 1939. For all railroad freight service, including oil-burning and electric locomotives, the average energy consumption, converted to coal equivalent, was reduced from 115 pounds per 1,000 gross ton-miles in 1938 to 112 pounds in 1939. During the same period, public utility power plants lowered the average fuel consumption from 1.41 to 1.39 pounds per kilowatt-hour. In the iron and steel industry, the average consumption of coke in iron blast furnaces was reduced from 1.801 in 1938 to 1.778 pounds in 1939 per net ton of pig iron produced, representing a drop from 2,583.9 to 2,547.3 pounds of coking coal per net ton (2,894 and 2,853 pounds per gross ton) of pig iron for 1938 and 1939, respectively.

Improvements in combustion practice among domestic consumers and small industrial and commercial establishments also are helping to decrease the aggregate volume of fuel consumption. Furthermore, increasing economy in combustion methods is being supplemented by improvements in space-heating methods and by progress in building construction and insulation.

Competing sources of energy.—While improvements in fuel technology have acted to lessen the demand for coal in the industries affected, these same improvements have constituted a defense of coal against the spread of other sources of energy into the previous markets for coal. In the electric utility field, for example, consumption of coal has increased coincident with the development of hydroelectric projects. During the past five years, production of public utility electrical energy by steam power plants increased from 54,649,829,000 kilowatt-hours in 1935 to 85,006,941,000 in 1939, an increase of 45 percent. Statistics of current and projected expenditures for new steam plant construction indicate a continuation of this trend in the near future. Edison Electric Institute reports expenditures in 1939 of $70,560,000 for steam plants, and budget estimates for 1940 indicate a probable expenditure of $183,700,000, which will add approximately 1,650,000 kilowatt-hours to the total steam-generating capacity in 1940.

Despite the improvements in fuel economy in the utilities industry, the total coal consumption for power generation has continued to increase since 1933 except in 1938, when there was a 10-percent decrease compared with the previous year, attributable to the general slump in industrial activity and total power consumption. The upward trend was resumed in 1939 with a total coal consumption of 46,223,000 tons, an all-time high record for this industry. In addition, the utilities steam power plants used 17,423,000 barrels of fuel oil (approximately equivalent to 4,356,000 tons of coal) and 191,131,-000,000 cubic feet of natural gas (equivalent to 8,310,000 tons of coal). During the past 20 years the growth of the utilities industry has approximately offset the effect of improved fuel technology in relation to aggregate coal consumption, and the annual tonnage used has moved up and down from the low of 30,000,000 to the high of 46,000,000 as general industrial activity varied. Use of fuel oil also has followed an irregularly horizontal course during this period, but the consumption of gas in utility electric power plants has increased from 22 billion feet in 1920 to 191 billion in 1939.

In the field of domestic heating comparable figures are available for mechanical firing equipment only. In this category, the use of oil and gas appears to be growing more rapidly than coal, basing estimates upon sales of new equipment. Sales of oil burners for domestic use rose from 106,933 units in 1938 to 165,711 in 1939, a 55-percent increase, whereas sales of domestic stokers (under 61 pounds per hour capacity) using bituminous coal, rose from 71,978 units in 1938 to 78,332 in 1939, a 9-percent increase. However, this does not entirely represent the relative positions of the two competing fuels in new plants because the oil-burner sales cover virtually all installations in which oil is used, while the sales of coal cover only mechanical stokers and do not consider new installations of hand-fired equipment. During the same period sales of natural gas for domestic use increased from 352,949,000,000 to 367,733,000,000 feet, a 4-percent gain (not including natural gas in mixtures sold by manufactured-gas companies).

The use of coal for locomotive fuel by railways decreased 17 percent in 1938 compared to 1937 and came back 7 percent in 1939, while the use of fuel oil followed an almost identical course, decreasing 13 percent in 1938 and increasing 3 percent in 1939. The consumption of railroad fuel varies with the fluctuations in volume of traffic.

The use of Diesel fuel increased rapidly, rising from 25,470,248 gallons in 1937 to 34,842,982 in 1938 and 48,754,423 in 1939. In the aggregate, however, Diesel fuel constitutes as yet only about a quarter of 1 percent of the total railroad fuel.

Statistics for 1939 show that the use of coal and oil by railroads, electric utility power plants, and steamships exceeded that in 1938 by 10 percent, while the oil consumption increased 7 percent. In the same period, consumption of natural gas by all industrial, commercial, and domestic consumers increased 7 percent.

Statistical tables—1939.—Tables 1 to 5 give a statistical record of the bituminous-coal industry in 1939, as indicated by available preliminary data. They also show comparative statistics for the indicated earlier years, including final figures for 1938. (See fig. 5.)

TABLE 1.—*Salient statistics of the bituminous-coal industry, 1938–39*

[All tonnage figures represent net tons]

	1938	1939 (preliminary)	Change in 1939
Production	348, 544, 764	393, 065, 000	+12. 8%
Exports to Canada and Mexico [1]	9, 560, 717	9, 975, 919	+4. 3%
Exports overseas and all other [1]	929, 552	1, 614, 559	+73. 7%
Imports [1]	241, 305	355, 115	+47. 2%
Consumption in the United States (calculated) [2]	344, 649, 800	377, 978, 637	+9. 7%
Stocks at end of year:			
Industrial consumers and retail yards	40, 720, 000	44, 571, 000	+9. 5%
Stocks on upper Lake docks	7, 885, 516	7, 590, 254	−3. 7%
Unbilled loads, at mines or in classification yards [3]	1, 607, 200	1, 533, 100	−4. 6%
Price indicators (average per net ton):			
Average cost of railroad fuel purchased, f. o. b. mines [4]	$1. 92	$1. 91	−1¢
Average cost of coking coal at merchant byproduct ovens [5]	$4. 61	$4. 57	−4¢
Average cost of bunker coal to vessels in foreign trade [6]	$4. 85	$4. 83	−2¢
Average value of exports to all countries (at port) [7]	$3. 63	$3. 69	+6¢
Average retail price—38 cities [8]	$8. 61	$8. 52	−9¢
Average railroad freight charge per net ton [9]	$2. 27	$2. 23	−4¢
Underground loading machinery sold to bituminous mines: [10]			
Mobile loading machines (number)	241	292	+21. 2%
Scrapers (number)	6	18	+200. 0%
Conveyors, including those with duckbills (units)	749	1, 095	+46. 2%
Pit-car loaders (units)	139	2	−98. 6%
Average number of men employed at mines operating [11]	441, 333	437, 000	−1. 0%
Fuel-efficiency indicators:			
Pounds coal per kw.-hr. at electric power plants [12]	1. 41	1. 39	−1. 4%
Pounds per 1,000 gross ton-miles—railroads [13]	115	112	−2. 6%

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.
[2] Production plus imports minus exports plus or minus net changes in consumers' stocks.
[3] Association of American Railroads.
[4] Interstate Commerce Commission. Excludes freight charges.
[5] As reported by coke operators to the Bureau of Mines.
[6] Computed from records of the Bureau of Foreign and Domestic Commerce.
[7] Computed from records of the Bureau of Foreign and Domestic Commerce. The figure represents the average value at the point of export of shipments to all foreign countries including Canada.
[8] Bureau of Labor Statistics.
[9] Average receipts per net ton of revenue bituminous coal originated, as reported by the Interstate Commerce Commission.
[10] Fraser, Thomas, Tryon, F. G., Gallagher, J. J., and van Siclen, M., Mechanization Sales: Coal Age, February 1940, pp. 63–65, and Mining Congress Journal, February 1940, pp. 23–27.
[11] The figure for 1938 is based upon reports of mine operators producing over 1,000 tons. The figure for 1939 is estimated from the employment index of the Bureau of Labor Statistics, which covers about half of the men employed in the industry, and from current monthly reports of 9 State mine departments which represent approximately 60 percent of all the bituminous-coal-mine workers in the United States.

Quantity cleaned by wet or pneumatic processes [8] .... do....	22,069,691	20,140,385	32,271,950	27,357,599	35,853,714	53,332,040	(4)	(4)

[1] The earliest year in which figures were collected in strictly comparable form was 1933, when commercial sales by truck and wagon were 15,462,739 tons.
[2] The total production differs from the sum of the items shown by the amount of the changes in inventory and of tonnage not accounted for in the distribution analysis.
[3] The increase in number of mines shown for 1934–37 over preceding years is due partly to more complete coverage of small trucking mines (producing over 1,000 tons a year). See Minerals Yearbook, 1936, pp. 561–564.
[4] Data not available.
[5] The figures represent the full-time week as reported by the operator, not the hours actually worked by the men.
[6] Affected by changes in length of working day.
[7] Figures for 1914, the year of earliest record.
[8] Exclusive of central washeries operated by consumers.

TABLE 3.—*Preliminary statistics of coal production in 1939, by States, with final figures for earlier years*

State	Production, in thousands of net tons								Change in 1939 (percent)	Percent of total bituminous							
	1913	1923	1929	1932	1936	1937	1938	1939 (preliminary)		1913	1923	1929	1932	1936	1937	1938	1939 (preliminary)

[1] Less than 0.01. [2] Included in "Other States." [3] Lignite figures from Bureau of Mines.
[4] Includes Arizona, California, Georgia, Nebraska, Nevada, and Oregon. The States reporting are not identical from year to year.

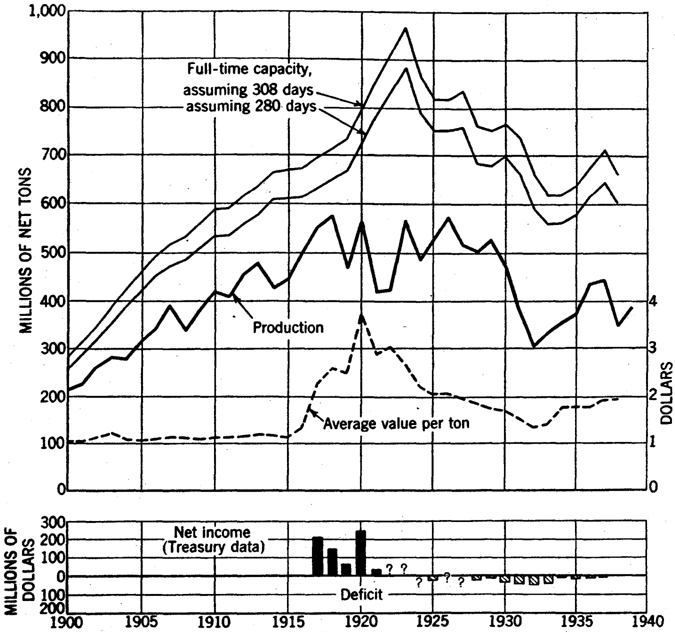

FIGURE 5.—Trends of bituminous-coal production, realization, mine capacity, and net income or deficit in the United States, 1900–39.

TABLE 4.—*Changes in the United States consumption of bituminous coal by such classes of consumers as report currently, and by all other consumers, 1929 and 1934–39, in thousands of net tons* [1]

[Information on several other classes of consumers is available for certain years. The items shown in this table are selected because they are available in strictly comparable form for each year]

Year	Consumed in the United States								Exported [3]		Total of consumption and exports [8]
	Colliery fuel	Electric power utilities [2]	Bunkers, foreign trade [3]	Locomotive fuel, class I roads [4]	Coke [5]: Beehive ovens	Coke [5]: By-product ovens	All other uses [6]	Total consumption [7]	To Canada and Mexico	To other countries (seaborne)	
1929	4,663	44,937	4,287	113,894	10,028	76,759	264,987	519,555	14,727	2,702	536,984
1934	3,175	33,555	1,321	70,496	1,635	44,343	192,518	347,043	10,213	656	357,912
1935	3,103	34,807	1,576	71,335	1,469	49,046	198,956	360,292	9,044	698	370,034
1936	3,227	42,025	1,622	81,130	2,698	63,244	228,850	422,796	9,912	743	433,451
1937	3,052	44,766	1,832	82,667	4,927	69,575	221,678	428,497	12,052	1,093	441,642
1938	2,493	40,212	1,352	68,794	1,360	45,266	185,173	344,650	9,561	929	355,140
1939 [9]	2,810	46,223	1,477	73,833	2,298	61,216	190,122	377,979	9,976	1,614	389,569

[1] Comparable data for other earlier years in Minerals Yearbook, 1937, p. 799.
[2] Geological Survey and Federal Power Commission. Represents all coal consumed by public utility power plants in power generation, including a small amount of anthracite.
[3] Bureau of Foreign and Domestic Commerce.
[4] Interstate Commerce Commission. Represents bituminous coal consumed as locomotive fuel by class I steam railways, excluding switching and terminal companies.
[5] Bureau of Mines.
[6] Obtained by subtracting the known items from the calculated total consumption. Includes general manufacturing, domestic, and many miscellaneous uses.
[7] Production plus imports minus exports, plus or minus changes in consumers' stocks.
[8] Includes imports. [9] Subject to revision.

TABLE 5.—*Trends in distribution of bituminous coal, 1923, 1929, 1934, 1936–39*

SOURCES OF DATA AND ACKNOWLEDGMENTS

Bituminous-coal production statistics for 1939 are preliminary estimates based upon (1) weekly or monthly reports of railroad carloadings of coal and beehive coke by all the important carriers, (2) shipments by river as reported by the United States Army Engineers, (3) direct reports from a number of mining companies, and (4) monthly production statements compiled by various local operators' associations, including the following: Central Pennsylvania Coal Producers Association, Georges Creek and Upper Potomac Coal Association, Hazard Coal Operators Association, Kanawha Coal Operators Association, Eastern Ohio Operators Association, North Dakota Board of Railroad Commissioners, Utah Coal Operators Association, Virginia Operators Association, Winding Gulf Operators Association, and Operators Association of the Williamson Field. Especial acknowledgment for detailed monthly production reports is made to: Thomas Allen, Colorado inspector of coal mines; James McSherry, director, Illinois Department of Mines and Minerals; Jonas Waffle, managing director, Coal Trade Association of Indiana; J. I. Thomas, secretary, Pennsylvania Department of Mines; N. P. Rhinehart, chief, West Virginia Department of Mines; J. E. Bergin, chief inspector, Washington Department of Mines.

In the estimates for 1939 allowance has been made for commercial truck shipments, local sales and colliery fuel, and small trucking or wagon mines producing over 1,000 tons a year. Production of mines on the border between two States has been credited to the State from which the coal is extracted rather than that in which the tipple is situated. If the coal is mined from lands in both States the tonnage has been apportioned accordingly.

Valuable assistance was rendered in the preparation of this chapter by the following members of the research section of the Bituminous Coal Division: L. H. Barber, E. M. Hall, M. S. Kengla, and J. G. Kirby.

The data in this report on the output of bituminous coal in 1938 are based upon detailed annual reports of production and mine operation courteously furnished by the producers. As in previous years, all but a small percentage of the output was covered by the reports submitted. For the remaining output not directly reported, consisting chiefly of small mines, it has been possible to obtain data of reasonable accuracy from the records of the State mine departments, which have statutory authority to require such reports, or in a few instances, from railroad carloadings.

Acknowledgment is made to the many individuals and agencies both public and private that have cooperated generously in making the survey possible.

RELATIVE RATE OF GROWTH OF COAL, OIL, AND WATER POWER, 1889–1939

According to preliminary data, the total supply of available energy in the form of coal, oil and natural gas, and water power in 1939 was 24,415 trillion B. t. u., an increase of 7.2 percent over the preceding year. (See fig. 6.)

The figures are expressed in British thermal units, because some common denominator is necessary for such unlike quantities as tons of coal, barrels of oil, and cubic feet of gas. Table 6 summarizes the equivalent of each of the fuels in British thermal units. Water power is represented by the equivalent fuel required to perform the same work. The table covers the years since 1933, but corresponding data are given in graphic form for the entire period back to 1890. Details for 1889 to 1932 are given in Minerals Yearbook, 1937, page 807.

In converting water power into its fuel equivalent, two alternative assumptions have been made. The first, as in previous issues of these tables, assumes a *constant* fuel equivalent of 4.02 pounds of coal for each kilowatt-hour of water power produced throughout the

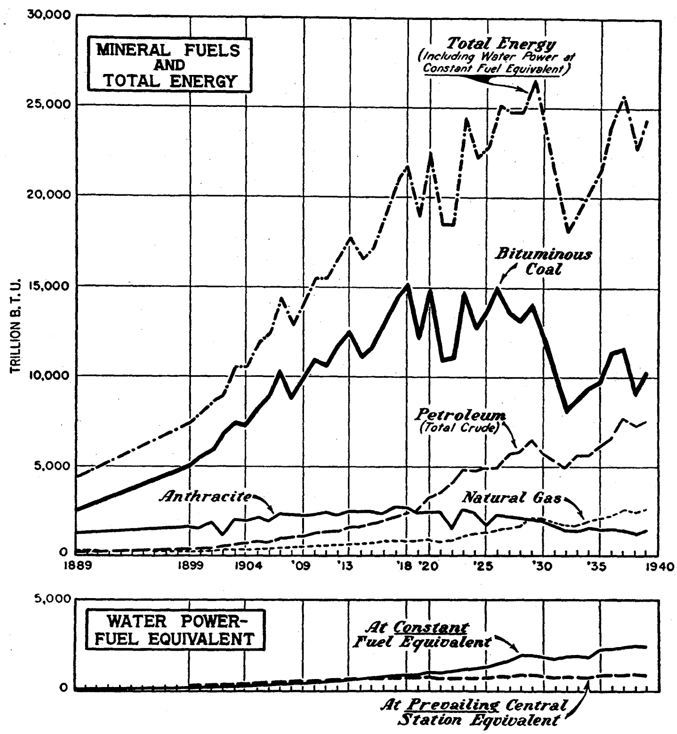

FIGURE 6.—Annual supply of energy from mineral fuels and water power in the United States, 1889–1939.

entire period from 1889 to 1939. This factor was selected because it represents, in round numbers, the average efficiency of all central stations generating steam-electric power in 1913, the midpoint of the period under review. The usefulness of the *constant* factor lies in showing the rate at which water power is being developed. It permits direct comparison between the relative increase in kilowatt-hours of water power and the corresponding increase (or decrease) in tons of coal, barrels of oil, or cubic feet of gas produced. On the other hand, the constant factor makes no allowance for the fact that coal and other fuels produced today are used more efficiently than formerly.

To throw light on the influence of improving fuel efficiency, a second computation of the energy equivalent of water power has therefore been made. This assumes a *prevailing* fuel equivalent, diminishing year by year, which represents the average performance of all fuel-burning central electric stations for the year in question. This average has declined from about 7.05 pounds of coal per kilowatt-hour in 1899 to 1.39 pounds in 1939. (The *prevailing* factor is thus much above the *constant* factor in 1899 and much below it in 1939.) The *prevailing* fuel equivalent indicates more nearly the amount of fuel that would have been needed in any one year to generate the same power in a steam-electric station. It should be noted, however, that the ultimate uses to which the water power generated is put often displace fuel burned much less efficiently than in central stations and that in any instance no other important branch of fuel consumption has made advances in fuel efficiency approaching that of the central stations.

As these tables attempt to determine the total energy from all fuels and from water power, the ideal factor for converting water power into fuel equivalent would be the average efficiency of all forms of fuel consumption in each year. No basis for determining such an all-embracing average exists at present, but enough is known to make certain that it would show much less reduction from 1899 to 1939 than did the central stations. For the present, a just comparison of the changing contributions of water power and of fuel to the national energy supply would lie somewhere between the results shown by the *constant* equivalent and the *prevailing central-station* equivalent in these tables.

As in earlier issues of these tables, the figures for oil and natural gas represent the entire production of crude petroleum and of gas. Most of this production does not come into direct competition with coal. Much of the supply of both oil and gas is used in regions of the country, such as California and portions of the Southwest, where coal is available only at unusually high cost because of heavy transport charges. Nearly half of the natural gas is used in the field for drilling or operating oil and gas wells and pipe lines, or for the manufacture of carbon black. More than half the oil is used in the form of gasoline, kerosene, and lubricants, for which purposes coal cannot well compete, except at very much higher levels of oil prices. Even these refined products, however, involve a certain measure of indirect competition with coal, for the energy market of the country is becoming more fluid and competitive, and a demand that cannot be met by one source of supply tends to fall back on the others.

The subject of interfuel competition is exceedingly complex, and an elaborate analysis and the accumulation of data not now available would be required to determine even approximately how much of any one fuel actually has been displaced either by other fuels or by water power. The present tables do not permit determination of such displacement; their purpose is rather to measure the long-time trends in the total demand for energy.

The figures for anthracite represent the output from established operations only and do not include bootleg or stolen coal, the amount of which is not accurately known. The bootleg tonnage has been estimated by the Commonwealth of Pennsylvania Anthracite Coal Industry Commission at the rate of 2,400,000 tons a year during 1936 and 1937, which is equivalent to 5 percent of the output of the legitimate operations. (Trade estimates place the figure as high as 3,000,000 to 3,500,000 tons.) The Pennsylvania Department of Mines estimates the bootleg tonnage at 2,500,000 tons in 1938 and 3,500,000 in 1939. If the additional item of 2,500,000 tons were included, the total energy from anthracite in 1938 would be 1,323 trillion B. t. u. and the total energy from all sources 22,833 trillion B. t. u. If the additional item of 3,500,000 tons were included, the total energy from anthracite in 1939 would be 1,492 trillion B. t. u. and the total energy from all sources 24,510 trillion B. t. u.

Table 7 compares the relative increase in the several sources of energy by means of index numbers in which production for 1918 is represented by 100. Production of anthracite in 1939 was 48 percent below 1918 (44 percent if bootleg coal is included) and of bituminous coal 33 percent below 1918. Production of domestic petroleum increased 255 percent and natural gas 238 percent over 1918.

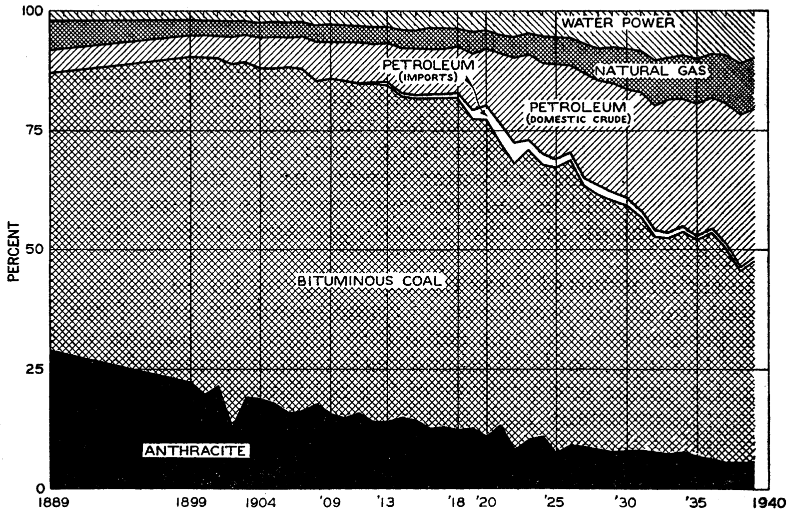

FIGURE 7.—Percent of total B. t. u. equivalent contributed by the several sources of energy, counting water power at constant fuel equivalent, 1889–1939. If water power is counted at the prevailing fuel equivalent of central stations in each year, its proportion is 3.2 percent in 1899 and 3.7 percent in 1939, and the proportions of the other sources of energy are affected accordingly.

There was a 189-percent increase in the amount of water power developed (represented by the constant fuel equivalent).

Table 8 gives the percentage composition of the total energy supply, on the alternative assumptions of water power at constant and at prevailing central-station equivalents in fuel. On the assumption of constant equivalent, the proportion contributed by water power has increased from 1.8 percent in 1899 to 9.9 in 1939. On the assumption of prevailing central-station equivalent, it has remained substantially unchanged at 3 to 4 percent. As already noted, the truth lies somewhere between the two assumptions. Upon either basis, water power furnishes a relatively small fraction of the total energy budget of the Nation, although, of course, a much larger fraction of the electric power produced by public utilities.

Coal remained the largest source of energy in 1939, contributing 47.5 percent with water power counted at constant fuel equivalent and 50.7 percent with water power at prevailing central-station equivalent.

TABLE 6.—*Annual supply of energy from mineral fuels and water power in the United States, 1933–39,*[1] *in trillions of B. t. u.*[2]

Year	Pennsylvania anthracite	Bituminous coal	Total coal	Petroleum (total crude, including that refined)		Natural gas (total production)	Total petroleum and natural gas	Total mineral fuels	Water power (fuel equivalent)		Grand total energy	
				Domestic production	Imports				At constant fuel equivalent [3]	At prevailing central station equivalent [4]	Water power at constant fuel equivalent	Water power at prevailing central station equivalent
1933	1,348	8,741	10,089	5,434	191	1,672	7,297	17,386	1,931	711	19,317	18,097
1934	1,555	9,415	10,970	5,448	213	1,904	7,565	18,535	1,896	698	20,431	19,233
1935	1,419	9,756	11,175	5,980	193	2,060	8,233	19,408	2,207	806	21,615	20,214
1936	[5] 1,485	11,504	12,989	6,598	194	2,330	9,122	22,111	2,256	812	24,367	22,923
1937	[5] 1,410	11,673	13,083	7,675	165	2,588	10,428	23,511	2,446	871	25,957	24,382
1938	[5] 1,255	9,132	10,387	7,286	158	2,468	9,912	20,299	2,466	866	22,765	21,165
1939 [6]	[5] 1,397	10,192	11,589	7,586	199	2,618	10,403	21,992	2,423	838	24,415	22,830

[1] Comparable data for earlier years in Minerals Yearbook, 1937, p. 807.

[2] The unit heat values employed are: Anthracite, 13,600 B. t. u. per pound; bituminous coal, 13,100 B. t. u. per pound; petroleum, 6,000,000 B. t. u. per barrel; natural gas, 1,075 B. t. u. per cubic foot. Water power includes installations owned by manufacturing plants and mines, as well as Government and privately owned public utilities. The fuel equivalent of water power is calculated from the kilowatt-hours of power produced wherever available, as is true of all public utility plants since 1919. Otherwise the fuel equivalent is calculated from the reported horsepower of installed water wheels assuming a capacity factor of 20 percent for manufactures and mines and of 40 percent for public utilities.

[3] Assuming 4.02 pounds per kilowatt-hour, which is the average of central electric station practice in 1913, the midpoint of the period for which data are available.

[4] Assuming the average central-station practice for each of the years for which data are available, which declined from about 7.05 pounds per kilowatt-hour in 1899 to 1.39 pounds in 1939.

[5] Does not include an unknown amount of bootleg or stolen coal. If this were included, the energy for anthracite would be approximately 1,550 trillion B. t. u. in 1936, 1,476 in 1937, 1323 in 1938, and 1,492 in 1939, and the total energy would be increased accordingly.

[6] Subject to revision.

TABLE 7.—*Index numbers for relative rate of growth of coal, oil, and water power in the United States* [1]

[The figures are expressed as a percentage of the 1918 rate]

Year	Pennsylvania anthracite	Bituminous coal	Total coal	Petroleum (total crude)		Natural gas (total production)	Total petroleum and natural gas	Total mineral fuels	Water power (at constant fuel equivalent)	Grand total	
				Domestic production	Imports					With water power at constant fuel equivalent	With water power at prevailing central station equivalent
1933	50	57	56	252	90	205	229	82	231	87	83
1934	58	62	61	255	94	246	241	88	227	94	89

[2] If bootleg coal were included the proportion from anthracite would be 5.7 percent in 1937, 5.8 in 1938, and 6.1 in 1939 at *constant* and 6.0 in 1937, 6.2 in 1938, and 6.5 in 1939 at *prevailing* water power equivalents.
[3] Subject to revision.

FINAL BITUMINOUS STATISTICS FOR 1938

Tables 9 to 34 give the final detailed statistics of bituminous mine operations in 1938. The subjects covered include production, number and size of mines, employment, fuel economy, stocks, foreign trade, and world production.

In accordance with the practice followed by the Bureau of Mines in previous years the statistics in this report relate to mines having an output of 1,000 tons a year or more and do not attempt to include many small mines producing less than 1,000 tons per year that sell their output by wagon or truck. Unless otherwise indicated, the net or short ton of 2,000 pounds has been used as a standard unit of measurement.

These statistics include for convenience and historical comparison the small output of anthracite and semianthracite produced outside Pennsylvania and the production of lignite. Details regarding these coals are given in tables 26 to 34, inclusive. In the standard statistics of the American coal trade they have ordinarily been combined with bituminous coal.

PRODUCTION

SUMMARY BY STATES

TABLE 9.—*Production, men employed, days operated, man-days of labor, and output per man per day at coal mines in the United States in 1938, by States*

[Exclusive of product of wagon mines producing less than 1,000 tons]

State	Net tons					Number of employees				Average number of days mines operated	Man-days of labor	Average tons per man per day
	Loaded at mines for shipment by rail or water	Shipped by truck or wagon	Coal used by employees or taken by locomotives at tipple or other uses at mines	Used for power and heat or made into coke at mines [1]	Total quantity	Underground	Surface: In strip pits	Surface: All others	Total

[1] Included under "Other States."

PRODUCTION BY WEEKS AND MONTHS

The following tables summarize the statistics of weekly and monthly production of bituminous coal first published in the Bituminous Coal Division Weekly Coal Reports. The figures are estimates based on daily and weekly statements of cars of coal and beehive coke loaded by the principal railroads and of shipments over the more important originating rivers. The estimates are revised afterward to agree with the results of the annual statistical reports from the coal producers; therefore, the figures given here differ slightly from those issued originally in the weekly reports.

For the method used in counting holidays, see chapter on Coal in Mineral Resources of the United States, 1930, page 631.

TABLE 11.—*Estimated weekly production of bituminous coal in 1938*

Week ended	Production (net tons)	Number of working days	Average production per working day (net tons)	Week ended	Production (net tons)	Number of working days	Average production per working day (net tons)

					348,545,000	306.0	1,139,000

[1] Figures represent output and number of working days in that part of the week included in the calendar year shown. Total production for the week of January 1, 1938, was 6,225,000 net tons.

[2] Average daily production for the entire week and not for the working days in the calendar year shown.

TABLE 12.—*Monthly production of coal in 1938, by States, in thousands of net tons*

[The totals for the year are based upon final complete returns to the Bituminous Coal Division from all operators known to have produced more than 1,000 tons a year. The apportionment of the known yearly total among the 12 months is based upon the best information available, in some States upon direct tonnage reports by operators to the State mine department, in most cases upon current records of railroad carloadings and waterway shipments.]

TREND OF AVERAGE VALUE PER TON, F. O. B. MINES, 1929 TO 1938

Before the Bituminous Coal Act of 1937 was passed the most valuable single index of the trend of prices at the mines was the "average value per ton, f. o. b. mines," as given in the familiar annual coal reports of the Bureau of Mines, United States Department of the Interior. This series was referred to in the Bureau of Mines reports as representing "bituminous coal," and it covered all coal other than Pennsylvania anthracite produced in the United States. It represented the bituminous-coal industry as the term ordinarily was used in the trade and included the lignite of the Dakotas, Texas, and Montana, as well as any small tonnages of hard coal produced outside of Pennsylvania.

With the passage of the Coal Act the Bureau of Mines relinquished the collection of statistics relating to bitumonous coal, effective June 30, 1937, though continuing to compile data regarding lignite. Effective on the same date, the Coal Commission became responsible for the compilation of data on bituminous coal, though not attempting to collect data regarding lignite, which was specifically exempted by the act. The records of the Commission (now Bituminous Coal Division, United States Department of the Interior), relate to all coal other than Pennsylvania anthracite and lignite, no exemptions other than lignite having been approved under the act.

To permit comparison of the old and new series, therefore, it is necessary to separate the lignites from the bituminous coals, though for convenience of the student the combined average for the two is continued in a form as nearly comparable as possible to the old series.

A more important change in the two series relates to the treatment of selling expenses. The old Bureau of Mines series of "value at the mines" excluded the selling cost. The reporting operator was asked to state the "Amount received at the mines f. o. b. cars less the selling expense." No details were asked regarding the items included in the value, and no systematic effort was made to follow up the exclusion of selling expenses. It was realized at the time that some producers might find it impractical to exclude selling costs and that some part of the selling expenses of the industry might be included in the results. Nevertheless, the reports were checked for consistency from year to year, the questions were retained in the same form without change, and the results are believed to have been comparable from one year to the next. The new series of the Coal Commission represents the total or gross realization on all coal produced and specifically includes the selling cost.

It is also possible that the two sets of data are not precisely comparable with respect to coal produced but not sold on the commercial market. In the Bureau of Mines series the reporting operator was instructed that the "value of coal not sold but used by producer, also mine fuel and coal made into coke should be estimated at average prices that might have been received." The instructions of the Coal Commission regarding such items were in effect similar, though given in greater detail.

A comparison of the two series is possible for 1936. In that year the average value per ton on the old (Bureau of Mines) basis amounted to $1.761 per ton for bituminous coal excluding lignite. The average gross realization, as collected by the Coal Commission, was $1.831 per ton. The difference amounts to $0.07 per ton, an amount somewhat less than the average selling expenditure computed per ton of all coal produced, as reported to the Coal Commission. The comparison confirms previous indications that the great majority of operators reporting in earlier years had followed instructions and omitted selling expenses in computing the average value but that some of them had included the selling expense. The change in method of reporting should be kept in mind in comparing the two sets of data. As the reports to the Commission were submitted on a detailed accounting return and made under oath they are to be accepted. The returns of earlier years, on a voluntary basis and not in all instances uniform as to treatment of selling costs, seem to have been thoroughly comparable from one year to the next and afford the best available index to the rise and fall of the mine prices received by the operator down to 1936.

TABLE 14.—*Trend of average value of bituminous coal and lignite per ton, f. o. b. mines, 1929–38*

Year	Bituminous[1] coal (subject to regulation under 1937 Act)	Lignite[2]	Total
Average value per ton less selling expense (Bureau of Mines series):			
1929	$1.782	$1.548	$1.781
1930	1.702	1.556	1.701
1931	1.542	1.410	1.541
1932	1.313	1.313	1.313
1933	1.337	1.188	1.336
1934	1.751	1.387	1.749
1935	1.772	1.120	1.767
1936	1.761	1.061	1.756
Average gross realization including selling expense (Coal Commission series):			
1936	1.831	[3] 1.061	1.826
1937	1.946	[3] 1.080	1.939
1938	1.955	[3] 1.071	1.947

[1] Includes all coal produced other than Pennsylvania anthracite and the lignite included in the second column.
[2] North Dakota, South Dakota, and the lignite counties of Montana and Texas.
[3] Figures of the Bureau of Mines, excluding selling expense as before. Data on sales realization were not collected from lignite mines by the Coal Commission.

SPOT PRICES

Spot prices afford a basis for measuring the relative strength of the forces of demand and supply in the competitive market for bituminous coal. The market quotations published in the leading trade magazines usually are based upon posted prices of larger producers, and oftentimes represent "asked" rather than "actual" prices.

Spot prices are not to be confused with sales realization, as the latter includes a large volume of coal either sold at relatively stable prices under long-term contracts or consumed by producers and their affiliates at purely nominal prices.

The following table of average spot prices is offered as an indication of trends in 1937, 1938, and 1939.

TABLE 15.—*Trend of spot prices of bituminous coal per net ton, f. o. b. mines, as indicated by trade journal quotations, 1937–39* [1]

[Based upon 130 series of comparable quotations currently published in the Black Diamond, Saward's Journal, and Chicago Journal of Commerce. These have been grouped into prepared sizes, run-of-mine, and screenings or slack, and simple averages obtained. The 3 groups have then been combined into a weighted average, counting prepared sizes at 43 percent, run-of-mine at 27 percent, and screenings or slack at 30 percent. The resulting average for all coal is not intended to show the actual realization obtained, but gives a ready comparison of the trend of prices in the 3 years.]

Month	Prepared sizes			Run-of-mine			Screenings or slack			All coal			Change in 1939 (percent)

Average:													
12 months	2.40	2.37	2.32	2.10	2.10	2.09	1.67	1.49	1.51	2.10	2.04	2.02	−1.0

[1] Except as noted, these averages are based upon the following number of quotations: Prepared sizes: Chicago market, 25 quotations; Cleveland market, 29 quotations; Norfolk market, 18 quotations; Pittsburgh market, 3 quotations; total, 75 quotations. Run-of-mine: Chicago market, 7 quotations; Cleveland market, 2 quotations; Norfolk market, 7 quotations; Pittsburgh market, 0; total, 16 quotations. Screenings or slack: Chicago market, 19 quotations; Cleveland market, 11 quotations; Norfolk market, 7 quotations; Pittsburgh market, 2 quotations; total, 39 quotations. Total of all quotations used, 130.

[2] Quotations for Cleveland and Pittsburgh in January and February and for Pittsburgh in June and December have been excluded from the computed averages due to lack of comparable data.

[3] Insufficient quotations during the greater part of April and May 1939, owing to suspension of mining operations pending the completion of a new wage agreement.

LABOR STATISTICS

MEN EMPLOYED

An average of 441,333 men was employed at bituminous-coal mines in 1938, a 10-percent decrease from the total of 491,864 for 1937. (See fig. 8.) Statistics of men employed in 1938 represent annual averages of the number of workers on the rolls on the days when the mines were in operation. Except for the slight discrepancy in comparability with 1937, the figures of employment for 1938 are comparable with similar date for earlier years. (See Minerals Yearbook, 1939, pp. 776 and 787–788.)

The method used here in calculating employment gives an accurate measure of the working force in the coal industry, but it does not consider the time lost by men on the rolls through intermittent opera-

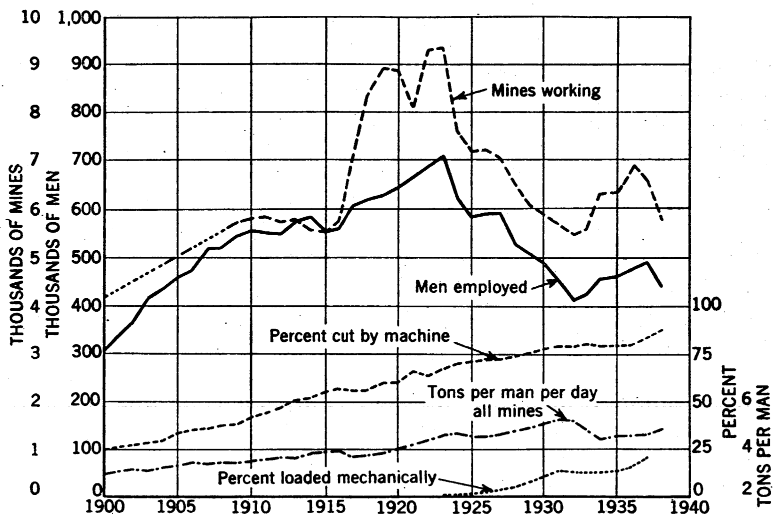

FIGURE 8.—Trends of employment, mechanization, and output per man at bituminous-coal mines, 1900–1938.

tions. To measure the influence of intermittency upon employment the factor of mine activity as indicated by the average number of days of plant operation was recorded separately. The average number of men employed when the mines were in operation was then used, in conjunction with the average number of days of operation, as a measure of the total volume of employment in the industry.

In recent years a special problem has arisen in recording employment through the adoption of local "share-the-work" agreements, by which the employees of a mine are divided into two crews or groups who work on alternate days. Such agreements for "staggering" or alternating the work are not to be confused with the practice of operating both a day and a night shift but relate rather to division of the available work between two groups of workers on the same shift, usually the day shift.

Specific inquiries regarding such agreements by the Illinois Department of Mines and Minerals in 1938 indicated that 45 mines in that State were operating with alternate crews under share-the-work agreements. If the number of men on the pay rolls had been used as a measure of employment instead of the average number of men working, the employment figures for Illinois would have been increased approximately 8 percent. A small number of employees was involved in similar reports from Indiana.

The figures on "number of men employed" as given in this report are therefore somewhat less than the total number of men on the rolls in the States where there were mines that followed the practice of spreading employment by means of share-the-work agreements. No formal agreements for dividing work have been reported to the authors from mines outside of Illinois and Indiana in 1938; however, local share-the-work agreements may have existed in other fields, which were not reported, and occasionally at still other mines a certain amount of work sharing may have been practiced without written agreement between operators and their employees.

DAYS OPERATED

The average number of days of operation at bituminous-coal mines in 1938 was 162. This represents a decline from the average of 193 days for 1937. All statistics on days of mine operation included in this report are weighted averages, in which the operating time of each mine has been weighted by the number of its employees. Several coal-mining States publish series on the number of days worked that are simple averages of the figures for each reporting mine regardless of size. As these unweighted averages are likely to be unduly depressed by small mines, which generally operate fewer days than the larger ones, they tend to understate the working time of the typical mine employee.

MAN-DAYS OF LABOR

Only a small proportion of the bituminous-coal-mine operations, however, keep an accurate record of man-days or man-hours worked. Consequently, man-days have been computed by multiplying the number of workers employed by the number of operating days. Although these computations were made for each individual mine the combined total is necessarily only an approximation.

Until the American coal industry arranges to keep an accurate record of man-days or man-hours of employment all computations of accident rates, daily earnings, and output per man will remain subject to qualification. Meanwhile, the method of multiplying men by days must be accepted as the best available procedure.

Data for 1938 indicate that bituminous-coal-mine employees performed 71,325,374 man-days of labor during the year. Table 9 gives a summary record of men employed, days operated, and output per man per day at bituminous-coal mines by States in 1938. Details by counties for 1938 are shown in table 25.

LENGTH OF WORKING DAY

Data for computing the number of hours in the average working day of bituminous-coal miners have not yet been completed for 1938. As there was no change in the provision of the union wage agreement regarding hours of work it can be assumed that the 7.02-hour-per-day average for 1935 and 1936 also would apply to 1937 and 1938. For further discussion of length of working day and detailed statistics of earlier years see Minerals Yearbook, 1937, pages 821–823.

FUEL EFFICIENCY

TABLE 17.—*Indicators of the effect of fuel economy on consumption of coal per unit of performance since the World War*

	Pounds	Reduction from base period (percent)
Steam railroads:		
Pounds per 1,000 gross ton-miles freight service:		
Average, 1919–20	170	
Average, 1938	115	32.4
Average, 1939	112	34.1
Pounds per passenger-train car-mile:		
Average, 1919–20	18.5	
Average, 1938	14.9	19.5
Average, 1939	14.8	20.0
Electric public utility power plants:		
Pounds per kilowatt-hour, 1919	3.2	
Pounds per kilowatt-hour, 1938	1.4	56.2
Pounds per kilowatt-hour, 1939	1.4	56.2
Iron and steel—pounds coking coal per gross ton of pig: [1]		
1918	3,577	
1938	2,894	19.1
1939	2,853	20.2
Coke manufacture: Savings of heat values through recovery of gas, tar, light oils, and breeze by extension of byproduct in place of beehive coking, 1913–1939, expressed as percent of coal used for all coke in 1939 [2]		20.6

[1] Includes only savings through higher yields of merchantable coke per ton of coal charged and lower consumption of coke per ton of iron. Excludes economies through recovery of byproducts, which are treated in next item.

[2] These byproducts are used in part for boiler fuel, in part for metallurgical purposes, in part for domestic heating and cooking, and to a small extent for automotive fuel.

STOCKS HELD BY CONSUMERS

TABLE 18.—*Stocks of bituminous coal in hands of commercial consumers and of anthracite and bituminous coal in retail dealers' yards, 1938–39*

Date	Total stock of bituminous coal estimated (net tons)	Days' supply at current rate of consumption on date of stock taking									
		Byproduct coke plants	Steel plants	Other industrials	Coal-gas plants	Electric utilities	Retail yards, bituminous	Railroads	Cement mills	Total bituminous	Retail yards, anthracite

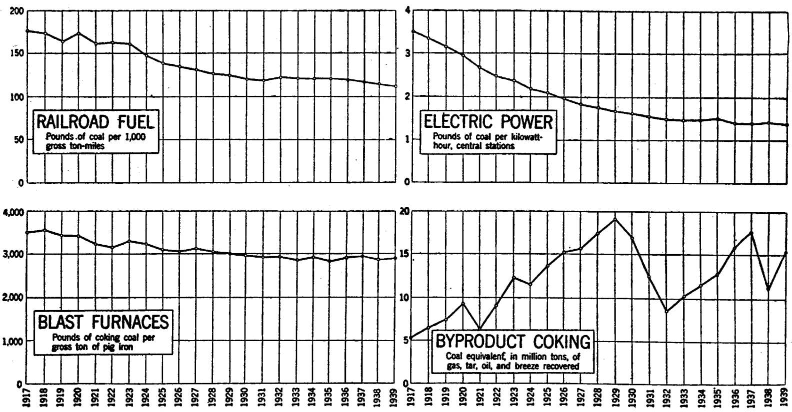

FIGURE 9.—Trends in fuel efficiency in the United States, 1917–39.

COAL LOADED FOR SHIPMENT BY INDIVIDUAL RAILROADS AND WATERWAYS

Table 19 shows the quantity of bituminous coal originated on each railroad and waterway in 1938, as reported by mine operators in answer to the following inquiry:

a. List railroads or waterways on which product was first loaded for shipment:

(Name of road or waterway)	(Net tons loaded on each)
--	----------------
--	----------------
--	----------------

b. On coal hauled by truck, if any, to railroad siding or to river for shipment, report below:

Name of railroad -------------------- Shipping point ---------------- Distance hauled ------ miles.

Name of river ------------------------ Loading point ---------------- Distance hauled ------ miles.

As these statistics include nonrevenue railroad fuel they may differ from those compiled by the railroad companies, which often show only revenue freight and include coal received from connecting lines or coal shipped off the Lakes docks, as well as that originating at mines on the lines reporting.

In general, the figures are given under the name reported by the operator, and the Bituminous Coal Division does not attempt to combine them under the name of the larger system, believing that such combination can best be made by those using the figures, as they are probably familiar with coal-traffic problems. If such combination is made, the total usually will be found to check reasonably well with the statistics issued by railroads that keep records of total coal originated.

Where the road serving the district is a subsidiary of a larger road some operators may report their coal as loaded on the subsidiary and others as loaded on the parent system (a few subsidiaries have been consolidated under the name of the parent road).

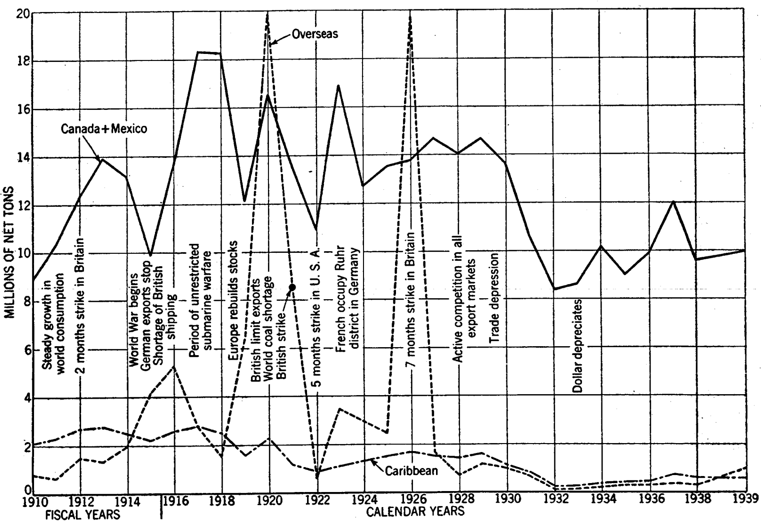

FIGURE 10.—Exports of bituminous coal to Canada and Mexico, the Caribbean, and "overseas" destinations, 1910–39.

Shipments to Alaska, Canton and Enderbury, Hawaii, Midway Islands, Puerto Rico, and the Virgin Islands.—In addition to export trade proper the United States supplies a small tonnage of anthracite and bituminous coal to Alaska, Canton and Enderbury, Hawaii, the Midway Islands, Puerto Rico, and the Virgin Islands. Shipments of bituminous coal to each of these possessions in 1939 were as follows: Alaska, 17,587 net tons; Canton and Enderbury, 3 net tons; Hawaii, 1,540 net tons; Midway Islands, 81 net tons; Puerto Rico, 14,709 net tons; and Virgin Islands, 69,751 net tons. Comparative shipments for 1938 were: Alaska, 23,465; Canton and Enderbury, none; Hawaii, 773; Midway Islands, none; Puerto Rico, 19,967; and Virgin Islands, 93,065.

WORLD PRODUCTION

Lignite (total of items shown above)	204,000	225,000	254,000	264,000	(2)
Bituminous and anthracite (by subtraction)	1,119,000	1,228,000	1,296,000	1,202,000	(2)

[1] Coal is also mined in Argentina, Iran, and Italian East Africa. Production figures for these countries are not available, but estimates are included in the totals. All figures for 1939 are to be considered as preliminary and subject to revision.
[2] Data not yet available.
[3] Exclusive of mines in the Saar.
[4] Mines under French control until Mar. 1, 1935
[5] Estimate included in total.
[6] Production less than 1,000 tons.
[7] Production of most important coal mines.

DETAILED STATISTICS, BY STATES AND COUNTIES

Detailed production and employment statistics are given in table 25 for each coal-producing county in the United States from which three or more operators submitted reports in 1938. Statistics for counties with less than three reporting producers have been combined with data for other counties in the same State to avoid disclosing individual returns, unless permission to publish has been granted by the operators.

In this series the reported production is classified according to the principal methods of distribution or use. Beginning with 1932 the series was expanded to include data on the growing volume of coal moving from mine to consumer by truck. For 1933–36 this tonnage was shown as "commercial sales by truck or wagon." In 1937 this tonnage was shown as "truck deliveries, including local sales." (See Minerals Yearbook, 1939, p. 813.) In 1938 the truck tonnage was shown as "shipped by truck or wagon." The truck figures for 1933 to 1936, inclusive, and 1938 are reasonably comparable.

The data in this report, like those published for many years by the Bureau of Mines, relate only to mines with an annual output of 1,000 tons or more. Although all mines, regardless of size, are subject to regulation under the provisions of the National Bituminous Coal Act of 1937, it seemed advisable to maintain the continuity of the old series by excluding the very small mines that sell by truck or wagon. This fact should be borne in mind when the statistics in this report are compared with similar data compiled by State mine departments. Differences arise largely from variations in coverage of the State reports, some of which include data for all mines regardless of size and others only data for mines employing more than a specified minimum number, which ranges from 2 to 10 men.

Because of a change in the method of reporting, the statistics of average production per man per day for 1932 to 1936 and 1938 are not precisely comparable with those for earlier years. Before 1932 they were based upon the calculated number of man-shifts, obtained by multiplying the average number of men employed at each mine by the number of days worked at the mine. Since 1932 operators have been asked to make a special report of the number of man-shifts actually worked if possible. The number of operators able to furnish this information has been small, although it is increasing from year to year. These reports were utilized to improve the accuracy of the record. Otherwise, the man-shifts were calculated by multiplying the number employed underground and on the surface by the number of days worked by the mine and tipple, respectively.

TABLE 25.—*Production, men employed, days operated, and output per man per day at bituminous-coal mines in specified States and counties in 1938*

[Note that figures relate only to active mines of commercial size, excluding truck and wagon mines producing less than 1,000 tons. Waste and refuse are not included in tonnage]

ALABAMA

County	Net tons					Number of employees				Average number of days mines operated	Man-days of labor	Average tons per man per day

[1] No coal was made into beehive coke at mines in 1938.
[2] Includes 84,172 tons made into beehive coke at mines in Las Animas County, Colo., in 1938.
[3] Other counties include Adams, Bond, Crawford, Greene, Hancock, Jasper, Livingston, Logan, Macon, Marion, Marshall, Morgan, Putnam, Warren, White, Will, and Woodford.
[4] Much of the output of the State is obtained from strip pits or by the use of loading machines, in which types of operations the production per man per day is large.
[5] Production of Home Riverside and Alston mines is credited to Missouri rather than to Kansas.
[6] The output is obtained chiefly from strip pits in which the production per man per day is large.
[7] Data on lignite compiled by L. Mann, Bureau of Mines: see Lignite tables, 1938.
[8] Includes coal made into beehive coke at mines in the following counties in Pennsylvania in 1938: Cambria, 38,777; Fayette, 333,216; Indiana, 121,489; and Westmoreland, 271,771—a grand total of 765,253 tons.
[9] Includes 10,000 tons made into beehive coke at mines in Grundy County, Tenn., in 1938.
[10] Includes 15,667 tons made into beehive coke at mines in Carbon County, Utah, in 1938.
[11] Figures compiled by L. Mann, Bureau of Mines; see Anthracite and Semianthracite Outside of Pennsylvania tables, 1938.
[12] Includes 234,765 tons made into beehive coke at mines in Wise County, Va., in 1938.
[13] Includes 250,019 tons made into beehive coke at mines in Fayette and Preston Counties, W. Va., in 1938.

STATISTICS OF LIGNITE AND OF ANTHRACITE AND SEMI-ANTHRACITE OUTSIDE OF PENNSYLVANIA [4]

PRODUCTION OF LIGNITE

In addition to the study of Pennsylvania anthracite, the Bureau of Mines canvasses the operators of lignite properties included in the areas mapped as "lignite" in Geological Survey Professional Paper 100–A, The Coal Fields of the United States. Subbituminous coal, sometimes known as "black lignite," is not included.

Fewer lignite mines were active in 1938 than in 1937, and output, number of employees, and days of operation decreased. The length of the working day in most mines was 8 hours, but many smaller operations failed to reply to the request for this information. Mechanical loading underground was not practiced to any extent, as only one or two operators in North Dakota recorded the use of mobile loaders in the year. No labor disturbances were reported.

Detailed data of production in 1938 are presented in the following tables. An historical table of world output of lignite is also given.

TABLE 26.—*Summary of production, value, men employed, days operated, man-days of labor, and output per man per day at lignite mines in the United States in 1938, by States* [1]

State	Net tons					Value	
	Loaded at mines for shipment	Commercial sales by truck or wagon	Other sales to local trade, used by employees, or taken by locomotives at tipple	Used at mines for power and heat	Total quantity	Total (thousands of dollars)	Average per ton
Montana	3,939	46,943	2,595	68	53,545	88	$1.64
North Dakota	1,465,374	416,904	160,075	7,746	2,050,099	2,380	1.16
South Dakota	27,148	20,570	340		48,058	65	1.35
Texas	813,096	21,302	6,245	5,576	846,219	679	.80
Total: 1938	2,309,557	505,719	169,255	13,390	2,997,921	3,212	1.07
1937	2,437,702	569,266	195,600	15,851	3,218,419	3,477	1.08

State	Number of employees				Average number of days mines operated	Man-days of labor [2]	Average tons per man per day [2]
	Underground	Surface: In strip pits	Surface: All others	Total			
Montana	67	7	19	93	162	15,081	3.55
North Dakota	667	344	359	1,370	174	237,751	8.62
South Dakota	18	23	9	50	170	8,507	5.65
Texas	446	22	38	506	219	110,768	7.64
Total: 1938	1,198	396	425	2,019	184	372,107	8.06
1937	1,239	462	429	2,130	189	403,510	7.98

[1] Includes 212 active mines of commercial size; excludes wagon mines producing less than 1,000 tons.
[2] Based upon the "reported" number of man-shifts where the operator keeps a record thereof; otherwise upon the "calculated" number of man-shifts obtained by multiplying the average number of men employed underground and on the surface at each mine by the number of days worked by the mine and tipple, respectively. Using the "calculated" man-shifts throughout as developed before the year 1932. the average output per man per day was 8.51 in 1937 and 8.59 in 1938.

[4] Compiled by L. Mann, Coal Economics Division. Bureau of Mines.

[1] Based upon the "reported" number of man-shifts where the operator keeps a record thereof; otherwise upon the "calculated" number of man-shifts obtained by multiplying the average number of men underground and on the surface at each mine by the number of days worked by the mine and tipple, respectively. Using the "calculated" man-shifts throughout as developed before 1932, the average output per man per day in 1938 was 3.55 in Montana, 9.57 in North Dakota, 5.17 in South Dakota, and 7.67 in Texas.

[2] Output obtained chiefly from strip pits in which the production per man per day is large.

NUMBER AND SIZE OF LIGNITE MINES

There were 212 active lignite mines in 1938, as reported to the Bureau of Mines (exclusive of many small mines in Montana and North Dakota producing less than 1,000 tons annually). Of these, 24 were in Montana, 165 in North Dakota, 15 in South Dakota, and 8 in Texas. In the field as a whole the classification by size of output is as follows:

TABLE 28.—*Number and production of lignite mines in 1938, classified by size of output*

Net tons	Mines		Production		
	Number	Percent of total	Total (net tons)	Average per mine (net tons)	Percent of total
Over 200,000	4	1.9	1,511,698	377,925	50.4
100,000 to 200,000	3	1.4	511,222	170,407	17.1
50,000 to 100,000	3	1.4	210,723	70,241	7.0
10,000 to 50,000	19	9.0	391,957	20,629	13.1
Under 10,000	183	86.3	372,321	2,035	12.4
	212	100.0	2,997,921	14,141	100.0

LENGTH OF WORKING DAY IN LIGNITE MINES

The following table summarizes the replies of mine operators to the question, "Number of hours operated per shift."

Reports from mines in the lignite field in 1938, including those reporting a day of irregular length, indicate that 77 percent of the men employed were in 8-hour mines and that the weighted average working shift was 8 hours.

The established working day does not necessarily measure the length of time actually worked or the time underground, because a miner may work overtime, the mine may shut down before the full day is over, the miner may go home before work at the mine stops, and he may spend considerable time in going to and from his place of work underground. As interpreted in the wage agreements, the day means the hours of labor at the usual working place, exclusive of any time for lunch and exclusive of the time spent in going from the entrance of the mine to and from his working place (see Coal chapter in Mineral Resources, Bureau of Mines, 1930, p. 656).

TABLE 29.—*Number of lignite mines in the United States having established working shift of certain length and number of men employed therein, in 1938, by States*

State	7 hours		8 hours		9 hours		Not reporting and all others [1]		Total	
	Mines	Men	Mines	Men	Mines	Men	Mines	Men	Mines	Men
Montana			12	59	1	3	11	31	24	93
North Dakota	10	104	121	983	3	88	31	195	165	1,370
South Dakota			5	11	1	3	9	36	15	50
Texas			8	506					8	506
	10	104	146	1,559	5	94	51	262	212	2,019

[1] Includes mines in which the day was more than 9 or less than 7 hours, was irregular, or was changed during the year; also mines where the operator has included time when the men were entering or leaving the mine, where the operator has reported the time of men in occupations in which the workday is longer than for other employees (as in stripping overburden), or where the work is staggered and two crews of men overlap.

LIGNITE LOADED FOR SHIPMENT BY INDIVIDUAL RAILROADS

TABLE 30.—*Lignite loaded for shipment by individual railroads in 1938, as reported by operators, in net tons*

Railroad	State	Quantity
Chicago, Milwaukee, St. Paul & Pacific	North Dakota; South Dakota	46,994
Great Northern	Montana; North Dakota	342,332
International-Great Northern	Texas	
Missouri-Kansas-Texas	do	
Rockdale, Sandow & Southern	do	813,096
St. Louis Southwestern of Texas	do	
Texas Short Line	do	
Minneapolis, St. Paul & Sault Ste. Marie	North Dakota	524,438
Northern Pacific	do	582,697
		2,309,557

METHODS OF RECOVERY

TABLE 31.—*Lignite mined by different methods in 1938, by States*

State	From underground workings (net tons)					From strip pits		Grand total production
	Mined by hand	Shot off the solid	Cut by machines	Not specified	Total underground	Net tons	Percent of grand total	
Montana	[1] 78,281	[1] 756,588		5,954	[1] 840,823	[1] 58,941	[1] 6.6	53,545
North Dakota	53,708	175,461	[2] 535,696	22,426	787,291	1,262,808	61.6	2,050,099
South Dakota	1,420			2,589	4,009	44,049	91.7	48,058
Texas	(1)	(1)			(1)	(1)	(1)	846,219
	133,409	932,049	[2] 535,696	30,969	1,632,123	1,365,798	45.6	2,997,921

[1] Texas included with Montana. [2] 22 machines were used—15 "permissible" and 7 of other types.

STRIPPING OPERATIONS

TABLE 32.—*Statistical summary of stripping operations that produced lignite in 1938, by States*

State	Strip pits [1]	Shovels, dragline excavators, and coal-loading machines [2]	Production (net tons)	Value		Number of employees			Average number of days mines operated	Man-days of labor [3]	Average tons per man per day [3]
				Total (thousands of dollars)	Average per ton	In strip pits	All others	Total			
Montana and Texas	4	2	58,941	35	$0.59	29	1	30	115	3,454	17.06
North Dakota	58	31	1,262,808	1,452	1.15	344	142	486	180	87,288	14.47
South Dakota	5	2	44,049	59	1.34	23	7	30	224	6,718	6.56
	67	35	1,365,798	1,546	1.13	396	150	546	178	97,460	14.01

[1] Includes some pits in which the stripping is done by hand.
[2] In some operations the same equipment was used for stripping or excavating and for loading the coal; this duplication has been eliminated. In others the coal was excavated by machine and loaded by hand.
[3] Based upon the "reported" number of man-shifts where the operator keeps an accurate record thereof, otherwise upon the "calculated" number of man-shifts obtained by multiplying the number of men employed at the tipple, in loading coal, etc., and in stripping overburden by the number of days worked in each department, insofar as separately reported by the operator.

WORLD PRODUCTION OF LIGNITE

TABLE 33.—*World production of lignite (including brown coal), 1934–39, in metric tons*

PENNSYLVANIA ANTHRACITE

By M. van Siclen, L. Mann, and J. R. Bradley

SUMMARY OUTLINE

The anthracite industry is of great economic importance in the 500 square miles comprising the Pennsylvania anthracite region. Regardless of the fact that production in the anthracite industry has suffered drastic reductions in recent years, in 1938—when production was the lowest since about the turn of the century—freight-commodity statistics of the Interstate Commerce Commission showed that anthracite ranked second in tonnage originated by class I railways and fourth in revenue produced. In 1939 the value of anthracite production at the mines was $187,175,000, and the gross revenue accruing to the railroads was $102,180,268.

Prices at the mines in 1939 were lower than in 1938; wholesale prices continued to decline, and retail prices in the leading markets remained at about 1938 levels. The index of employment also decreased, although average weekly earnings advanced. Freight rates on intrastate shipments were increased. The Anthracite Institute and Anthracite Industries, Inc., continued their cooperative and trade-promotion activities, and State legislation intended to promote stabilization of the industry was defeated by a narrow margin.

Increasing competition of other fuels, unfavorable weather in several recent years, the production of illicit or "bootleg" anthracite, and competition within the industry have combined to undermine the price structure. Early in 1940 virtually the entire industry agreed to a voluntary scheme of allocation of production that apparently has brought some relief. The fairly low temperatures in the early months of 1940, together with improved business conditions and higher coastwise freight rates on bituminous coal from Hampton Roads to New York and New England, promise further increase in consumption of anthracite in 1940.

More favorable weather conditions, an increase in exports, and improved business conditions resulted in an increase in the output of anthracite in 1939. Production was 51,487,000 tons, a gain of 12 percent over 1938. Commercial shipments (excluding illicit or "bootleg" coal) were 41,063,869 tons in 1938 and 45,992,282 in 1939.

Shipments of anthracite from breakers and washeries in the first quarter of 1939 were less than in the corresponding period of 1938. In the second quarter, however, shipments advanced 13 percent over the second quarter of 1938; in the third quarter they were 32 percent

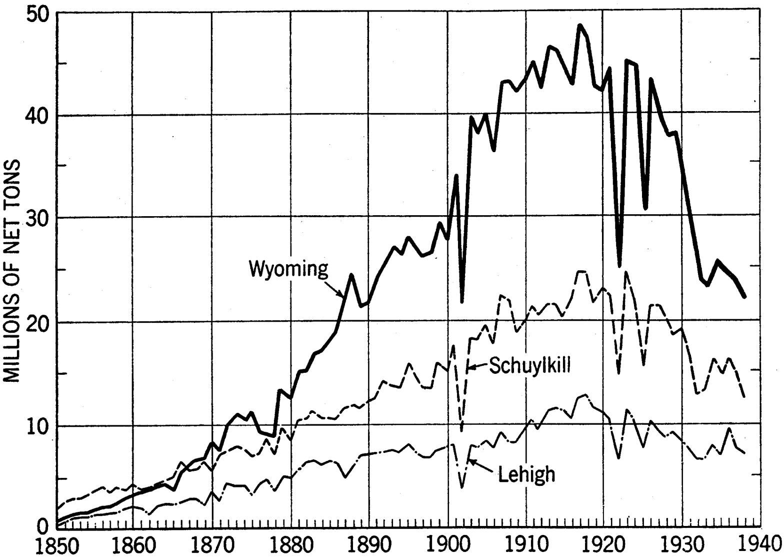

FIGURE 1.—Anthracite shipped from the Lehigh, Schuylkill, and Wyoming regions, 1850–1938.

higher; and in the last quarter shipments were 5 percent above 1938.

Receipts of anthracite at the upper Lake docks increased 8 percent in 1939 over 1938, and stocks declined 2 percent during the year.

Completion of the Huber central breaker of the Glen Alden Coal Co. denotes optimism for the future of the industry. The Huber breaker is one of the first to use Menzies cone separators to treat sized feed. The plant is expected to prepare 7,000 tons of anthracite daily.

The production of anthracite increased steadily from the early years of the nineteenth century to 1924, the last normal year under old competitive conditions. The peak was reached in 1917 at 99,611,811 tons. Since 1924 competitive fuels have increased in importance. Figure 1 shows shipments of Pennsylvania anthracite by regions since 1850.

The second annual anthracite conference of Lehigh University was held at Bethlehem, Pa., April 28–29, 1939, and the third annual conference was held May 9–10, 1940. The papers presented covered a wide field and contained much new and valuable information for both the producer and consumer of anthracite. Research, new uses of anthracite, modern mechanical burning equipment, and problems of the industry arising from the general trend toward smaller sizes were discussed. Papers also were presented on combustion, economics, marketing, mining, and preparation of anthracite. The conferences were attended by persons interested in all phases of the anthracite industry. The following papers presented at the conferences are of economic interest:

CONFERENCE OF 1939

Paper 10. Use of Anthracite Ash in Building Materials and in Agriculture, by Dr. Raymond C. Johnson, Anthracite Industries fellowship, Mellon Institute of Industrial Research, Pittsburgh, Pa.

Paper 13. Some Economic Aspects of Anthracite, by Dr. Neil Carothers, dean of the College of Business Administration, Lehigh University.

CONFERENCE OF 1940

Paper 2. The Present Status of Anthrafilt Illustrated by Case Histories, by Homer G. Turner, filtration consultant, Anthracite Institute.

Paper 4. Mineral Wool from Anthracite Colliery Refuse and Anthracite Ashes, by H. J. Rose and R. C. Johnson, Anthracite Industries fellowship, Mellon Institute of Industrial Research, Pittsburgh, Pa.

Paper 8. Effect Upon the Economy of the Anthracite Industry of Grinding Large Sizes to Pea and Smaller, by Cadwallader Evans, Jr., vice president and general manager, and Harold G. Boyd, engineering statistician, Hudson Coal Co.

TABLE 1.—*Statistical trends of the Pennsylvania anthracite industry, 1935–39*

	1935	1936	1937	1938	1939
Production:					
Loaded at mines for shipment:					
Breakers net tons	44,369,285	46,256,132	44,016,915	39,010,935	[1] 43,660,662
Washeries do	1,794,402	2,066,973	1,837,879	1,679,509	1,766,384
Dredges do	374,142	324,895	348,350	373,425	565,236
Sold to local trade and used by employees net tons	2,874,970	3,226,887	2,981,391	2,722,206	3,081,073
Used at collieries for power and heat net tons	2,745,984	2,704,648	2,671,898	2,312,952	2,414,022
Total production do	52,158,783	54,579,535	51,856,433	46,099,027	51,487,377
Value at breaker, washery, or dredge	$210,131,000	$227,004,000	$197,599,000	$180,600,000	$187,175,000
Average sales realization per net ton on breaker shipments:					
Lump and broken	$5.16	$5.05	$5.08	$5.24	$4.63
Egg	$5.44	$5.60	$5.06	$5.18	$4.73
Stove	$5.87	$6.09	$5.21	$5.33	$4.84
Chestnut	$5.64	$5.91	$5.23	$5.36	$4.87
Pea	$4.16	$4.30	$4.01	$3.88	$3.65
Total domestic	$5.45	$5.67	$5.01	$5.10	$4.64
Buckwheat No. 1	$2.88	$2.91	$2.95	$3.03	$2.90
Buckwheat No. 2 (Rice)	$1.74	$2.01	$2.26	$2.35	$2.20
Buckwheat No. 3 (Barley)	$1.08	$1.23	$1.45	$1.61	$1.62
Boiler	----------	----------	$.78	----------	----------
Other, including Buckwheat No. 4	$.57	$.68	$.79	$.87	$.91
Total steam	$2.03	$2.10	$2.21	$2.33	$2.25
Total, all sizes	$4.29	$4.42	$4.03	$4.16	$3.85
Percentage by sizes in total breaker shipments:					
Lump and broken percent	0.3	0.3	0.4	0.3	0.6
Egg do	7.0	6.5	5.7	5.4	5.2
Stove do	21.8	21.3	22.1	23.7	24.1
Chestnut do	26.1	26.4	26.2	26.0	25.8
Pea do	10.7	10.4	10.8	10.6	11.0
Total domestic do	65.9	64.9	65.2	66.0	66.7
Buckwheat No. 1 do	15.1	15.1	14.7	14.8	14.3
Buckwheat No. 2 (Rice) do	9.3	8.4	7.9	7.7	7.8
Buckwheat No. 3 (Barley) do	7.8	8.8	8.9	8.6	8.5
Boiler do	----------	----------	(2)	----------	----------
Other, including Buckwheat No. 4 percent	1.9	2.8	3.3	2.9	2.7
Total steam do	34.1	35.1	34.8	34.0	33.3
Producers' stocks on Dec. 31 [3] net tons	1,911,000	2,259,000	2,154,000	1,458,000	994,000
Exports do	1,609,000	1,678,000	1,914,000	1,909,000	2,590,000
Imports do	571,000	615,000	396,000	363,000	298,000
Consumption (calculated) do	51,100,000	53,200,000	50,400,000	45,200,000	49,700,000
Capacity in operation (calculated) do	84,000,000	87,000,000	83,000,000	82,000,000	(4)
Average number of days worked	189	192	189	171	(4)
Man-days lost on account of strikes and lock-outs	763,307	407,372	580,462	579,457	(4)
Number of men on strike during year	26,127	27,574	34,346	27,435	(4)
Average number of men employed	103,269	102,081	99,085	96,417	[5] 93,000
Output per man per day net tons	2.68	2.79	2.77	2.79	(4)
Output per man per year do	505	535	523	478	(4)
Quantity cut by machines do	1,848,095	2,162,744	1,984,512	1,588,407	1,881,884
Quantity mined by stripping do	5,187,072	6,203,267	5,696,018	5,095,341	5,486,479
Quantity loaded by machines underground net tons	9,279,057	10,827,946	10,683,837	10,151,669	11,773,833
Distribution:					
Total receipts in New England [6] net tons	5,402,000	5,287,000	4,761,000	4,468,000	4,907,000
Exports to Canada do	1,592,000	1,664,000	1,893,000	1,896,000	2,577,000
Loaded into vessels at Lake Erie [7] net tons	559,000	689,000	674,000	450,000	531,000
Receipts at Duluth-Superior [8] do	182,000	309,000	296,000	155,000	202,000

[1] Includes a small quantity of washery coal. [2] Less than 0.1 percent.
[3] Anthracite Institute. Figures represent prepared coal on the ground at the breaker.
[4] Data not yet available.
[5] Estimated from the report of the Pennsylvania Department of Mines; Bureau of Mines data not yet available.

Anthracite Institute.—The usual functions of the Anthracite Institute were carried on during the year, and especial attention was given to proposed Pennsylvania legislation to regulate the industry and to the Canadian market.

Anthracite Industries, Inc.—Laboratory tests of new anthracite-burning equipment were continued by Anthracite Industries, Inc.; approval was given to equipment meeting its requirements; and efforts were redoubled to promote the use of such equipment. Schools in anthracite merchandising were conducted, as well as a series of stoker schools, and a summer selling plan was presented to anthracite dealers. Exhibits of equipment were maintained at Boston, Philadelphia, and New York. Manufacturers cooperated with Anthracite Industries, Inc., in its exhibit at the New York World's Fair where stokers, furnaces, boilers, cooking stoves, thermostats, and other equipment were on display. It is reported that 1,152,330 persons visited the exhibit in 1939, thousands of whom saw anthracite as a thoroughly modern fuel for the first time.

There is little doubt that increased efficiency and the rapid strides made in the modernization of anthracite-burning equipment such as stokers, hand-fired boilers, and water heaters have created a favorable impression on the consuming public.

Nonfuel uses of anthracite and anthracite refuse.—The nonfuel use of anthracite, especially anthrafilt used in the purification of water, continued to expand. During the year attention was also given to the use of anthracite ashes as a soil conditioner and, after processing, as an insulating material.

Technologic developments.—There were no important technologic developments during 1939. The Pennsylvania General Assembly appropriated funds, which were matched by the anthracite industry, for a program of research, and the Secretary of Mines appointed a committee to consider a program to be conducted by the School of Mineral Industries of the Pennsylvania State College. Two specific problems will be studied: The gasification of anthracite and the production of carbon products from anthracite. Certain technologic developments, present or prospective, were discussed at the Third Annual Conference of Lehigh University in May 1940.

Weather.—According to the Monthly Weather Review, the year 1939 was slightly cooler than 1938 but was still warmer than normal in most regions. Departures from normal temperatures in some of the chief anthracite-consuming States were: New England States—January −0.8, February +2.7, March −4.5, April −3.4, October normal, November −3.1 and December +0.5; New York—January +0.2, February +4.1, March −2.2, April −2.5, November −3.0, and December +1.4; Pennsylvania—January +1.8, February +5.3, March +0.9, April −1.9, October +1.0, November −1.6, and December +2.6; New York City (one of the leading anthracite markets)—January +1.4, February +6.1, March +1.1, April −1.6. October +0.1, November −1.0; and December +1.2.

Distribution.—According to the Pennsylvania Department of Mines, rail, tide, and truck shipments of Pennsylvania anthracite to destinations in the United States totaled 44,869,453 tons in 1939 compared with 35,292,731 tons in 1938. In 1939 truck shipments were 4,824,537 tons, or 11 percent of total shipments, as against 9 percent in 1938. Virtually all truck shipments go to the Middle Atlantic States. Rail and tide shipments in 1939 totaled 40,044,916 tons, 63 percent domestic sizes and 37 percent steam sizes. Of the total steam sizes shipped by rail and tide, 95 percent went to the Middle Atlantic States.

Details covering distribution of shipments of Pennsylvania anthracite by rail and tide (truck shipments excluded) for 1937–39 are shown in table 3.

TABLE 3.—*Shipments of Pennsylvania anthracite, 1937–39, by States of destination, in net tons* [1]

Grand total	41,406,889	33,604,936	42,490,442

[1] Department of Mines, Harrisburg, Pa.

Freight rates.—Increases in freight rates ranging from 3 to 12 cents a gross ton were granted the railroads by the Interstate Commerce Commission on intrastate movement of coal. The so-called motor-compelled railway freight rates initiated in 1935 were extended to June 20, 1940. The trucking of anthracite to market, which became important about 1930, has expanded until it is now estimated at 4,000,000 tons annually, not including several million tons trucked from illicit or "bootleg" operations.

Competitive fuels in the United States and in the principal markets.—Sales of liquefied petroleum gases for domestic purposes throughout the United States totaled 2,084,047 barrels in 1939 compared with 1,376,952 in 1938. Sales for domestic use in 1939 represented 39 percent of total deliveries for all purposes compared with 35 percent in 1938. At the end of 1939, according to the American Gas Association, liquefied petroleum gas was being delivered through mains to consumers in 178 communities in 30 States by 82 companies supplying 49,800 customers.

According to the American Gas Association, sales of natural gas in the United States in 1938 and 1939, respectively, were as follows:

Sales for domestic use, including house heating, 349,285,000,000 and 367,731,500,000 cubic feet, an increase of 5 percent; commercial sales, 99,845,000,000 and 107,769,900,000 cubic feet, an increase of 8 percent; and industrial sales, 565,674,000,000 and 626,096,400,000 cubic feet, an increase of 11 percent.

Shipments of oil burners (for all uses other than ranges, stoves, water heaters, and space heaters) within the United States gained 56 percent over 1938 and to Canada 84 percent. Factory sales of anthracite stokers for domestic purposes were 7 percent less than in 1938.

Sales of heating and range oils in the United States increased about 13 percent in 1939 over 1938. An unusual feature of the sales of heating and range oils in 1938, as revealed in a study by the Petroleum Economics Division of the Bureau, is the fact that in New England 46 percent of the total sales represented range oil.

Principal markets.—In 1939 shipments of Pennsylvania anthracite to the principal markets (New England, New York, New Jersey, Pennsylvania, Delaware, Maryland, and the District of Columbia) were only 5 percent less than in 1936, whereas in 1938 they were 26 percent lower. New England, New Jersey, and Delaware received larger tonnages than in 1936, but receipts in the other States declined. Although these principal markets continue to take by far the greater part of the anthracite produced, their percentage of the total production declined steadily until 1939, when it was slightly greater than in 1936. In 1936, 1937, 1938, and 1939, the respective percentages were 84.2, 80.2, 73.9, and 84.5. Imports of anthracite, virtually all into New England, have declined each year since 1936.

Of the total fuels represented in this study (which do not include bituminous coal, petroleum coke, or wood because of lack of statistics showing the necessary break-down), Pennsylvania anthracite comprised 64 percent in 1936, 60 percent in 1937, and 55 percent in 1938. In the same years coke for domestic use was 7, 6, and 6 percent, and heating and range oil 28, 33, and 38 percent, respectively. Imports of anthracite, briquets, and coke were only about 1 percent in each year. Imported fuel oils are included in the totals.

Of the principal anthracite markets, only New York and Pennsylvania consume much natural gas. In 1939 natural-gas sales in these States for domestic use and home heating (by utility companies making 93 percent of the sales in New York and 56 percent in Pennsylvania) totaled 42,161,945,000 cubic feet, the equivalent of about 1,730,000 tons of coal.

Shipments of briquets to these markets (including imports which declined to 1 ton in 1939) have decreased steadily since 1936, but in 1939 shipments of briquets of domestic origin were slightly higher than in 1938.

Deliveries of coke of domestic and foreign origin for domestic use also declined in 1937 and 1938 but improved in 1939.

Details showing the apparent consumption of anthracite and selected competitive fuels in the principal anthracite markets, 1936–39, are shown in table 4.

TABLE 4.—*Apparent consumption of anthracite and selected competitive fuels in the principal anthracite markets, 1936–39*

1 Pennsylvania Department of Mines, illicit coal not included.
2 An important but undetermined part of anthracite shown as shipped to New Jersey is reshipped to New York City.
3 Bureau of Foreign and Domestic Commerce.
4 Less than 0.05 percent.
5 Estimated on the basis of distribution in 1936.
6 Converted to coal equivalent on the basis of 4 barrels of fuel oil equaling 1 ton of coal.
7 Date not yet available.
8 Does not include bituminous coal.

Receipts of Pennsylvania anthracite in the New England States declined nearly 61 percent from 1917 to 1939; receipts by rail decreased 44 percent and by tide 80 percent. The drop in total receipts between 1917 and 1927 was 23 percent and between 1927 and 1937, 52 percent. Table 5 gives details of receipts of anthracite in New England.

1939	[4]	[4]	[4]	[4]	[4]	865	4, 042	298	4, 609

[1] Commonwealth of Massachusetts, Division on the Necessaries of Life.
[2] Bureau of Foreign and Domestic Commerce.
[3] Total receipts by rail and by tide less imports. [4] Data not available.

According to a survey of the Commonwealth of Massachusetts, Division on the Necessaries of Life, the consumption of domestic sizes of anthracite in Massachusetts in the coal year 1938–39 (2,320,000 tons) decreased about 7 percent compared with 1937–38 and that of Buckwheat (176,000 tons) declined about 8 percent. Consumption of bituminous coal, coke, and briquets also declined, but that of fuel oil increased slightly.

Stocks.—Stocks of anthracite in the hands of railroads, electric-power utilities, and other industrial consumers at the end of 1939 were 10 percent (148,000 tons) less than at the end of December 1938. Producers' stocks declined 32 percent (464,000 tons) during the year.

Consumption.—Calculated consumption of anthracite—production, plus imports, minus exports, and plus or minus changes in producers' stocks at the beginning and end of the year—was 49,700,000 tons in 1939, a 10-percent increase over 1938. Illicit coal has not been considered in either year.

Consumption of anthracite by railroads in 1939 was 20 percent above 1938; consumption by electric power utilities rose 14 percent and other industrial consumption 1 percent over 1938.

Labor.—A new 2-year labor contract (expiring April 30, 1941) was concluded between the anthracite-mine operators and the United Mine Workers of America. The contract provides for recognition of the United Mine Workers of America as the exclusive bargaining agency and continues the 35-hour workweek, the prevailing rates of pay, and the general provisions of the previous agreement.

Favorable relations between the anthracite-producing companies and labor have resulted in closer cooperation on matters vitally affecting the industry.

TABLE 6.—*Total supplies of fuels commonly used for domestic purposes in the United States, 1924 and 1936–39*

[Wherever available the figures represent the quantity actually consumed for domestic heating or for heating offices, apartments, hotels, schools, hospitals, etc. Where such figures are not available but where the fuel is known to be used chiefly for domestic purposes, the total production (or imports) is shown to indicate the trend of growth]

[1] A considerable part of the Buckwheat No. 1 is used for domestic purposes.
[2] Production plus imports less exports. [3] Revised figures. [4] Partly estimated.
[5] Subject to revision. [6] Data not available. [7] An estimated two-thirds is used for domestic purposes.
[8] Exact data not available; estimated between 55,000,000 and 77,000,000 tons a year, including lignite and anthracite and semianthracite outside of Pennsylvania, which are shown separately.
[9] Range oil is a light distillate used for house heating, hot-water heating, and cooking.
[10] Estimated. [11] Includes all grades of fuel oil used for heating buildings.
[12] Includes gas used for heating offices, hotels, apartments, schools, hospitals, and stores and other large buildings, as well as houses.
[13] American Gas Association. Data revised as of March 1940.

Pennsylvania anthracite industry.—Trade practice and historical usage recognize two major divisions in the coal industry of the United States—bituminous coal and Pennsylvania anthracite. Anthracite and semianthracite also are mined in parts of Virginia, Arkansas, Colorado, and New Mexico. Locally these coals represent distinct and important industries, but the tonnages involved are small and for statistical convenience usually are grouped with the totals of the bituminous-coal industry. Tables in the chapter on Bituminous Coal in this volume record the 1938 production of anthracite and semianthracte outside of Pennsylvania; data for 1939 are not yet available.

The Pennsylvania anthracite industry, as here defined, includes all nonbituminous fields of that State. Trade usage commonly includes with Pennsylvania anthracite the output of the Bernice Basin in Sullivan County, although the coal of this basin is classified officially as semianthracite.

SOURCES AND ACKNOWLEDGMENTS

Annual statistics of the Pennsylvania anthracite-mining industry are prepared from a canvass by mail of all known anthracite operations, including over 400 active producers. About 95 percent of the tonnage is reported directly by producers, and the remaining 5 percent is estimated on collateral evidence. The data on individual operations furnished by the producers are voluntary and confidential, as is customary in the statistical services of the Bureau of Mines.

The standard form of report, as developed by the Bureau and its predecessor in mineral statistics, the Geological Survey, provides for data on production, shipments, mine realization of products, mine stocks, plant and equipment, and employment.

In assembling available detailed information free use has been made of the pertinent figures prepared by the Anthracite Institute, the American Association of Railroads, and the Pennsylvania Department of Mines, to all of whom thanks are extended for their cordial and continued cooperation. Thanks are due especially to the producers for reporting so promptly and, in general, so fully upon their operations in 1939, when the year as a whole was so critical for the industry.

PRODUCTION

By weeks and months.—The following tables summarize the statistics of weekly and monthly production of anthracite. Statistics of current output are estimated from tonnage reports from trade sources and from records of car loadings. The weekly and monthly figures in tables 7 and 8 have been adjusted to the annual total ascertained by direct canvass of the operators.

TABLE 7.—*Estimated weekly production of Pennsylvania anthracite in 1939, in net tons*

[1] Production is estimated from weekly car loadings as reported by the Association of American Railroads and includes mine fuel, coal sold locally, and dredge coal. Does not include an unknown amount of "bootleg" production. In computing the average rates per working day, New Year's, Eight-hour Day (Apr. 1), Memorial Day, Independence Day, Labor Day, Mitchell Day (Oct. 29), Thanksgiving Day, Christmas, and, since the war, Armistice Day, have been counted as holidays. Beginning with 1927, Washington's Birthday is counted as a half holiday. No allowance, however, has been made for church holy days, which are observed by many of the miners. Monthly statistics from 1905 to 1925 will be found in Coal in 1925, pp. 427–428, and from 1926 to 1930 in Coal in 1930, p. 741.

Illicit coal.—A survey by the Pennsylvania Department of Mines shows that, in the latter part of 1939, 2,500 illicit or "bootleg" holes were in operation in the Pennsylvania anthracite region and that 9,000 men were employed. November production is shown as 340,000 tons. There were 337 breakers in the region, and 1,353 truckers hauled coal to the breakers. The estimated illicit production of coal in the region in 1939 was between 3,500,000 and 4,000,000 tons, or about 8 percent of the total Pennsylvania anthracite output. Competition resulting from the production of illicit coal is out of all proportion to the tonnage produced. Low market prices are possible because the capital invested is small and nothing is paid for the coal. Wages are well below the regular scale. Safety measures are inadequate, and 58 lives were reported lost during the year.

Regions, fields, and counties.—The main anthracite region covers an elongated area of about 480 square miles in eastern Pennsylvania, with its longer axis running northeast and southwest. It embraces three subregions as follows, from the northeast to the southwest: The Wyoming region, which covers a single geologic anthracite basin and is about 54 miles long by 6 miles wide at its widest point; the Lehigh region, which comprises the anthracite lands tributary to the Lehigh River that forms its eastern boundary and contains the Eastern Middle field and the section of the Southern field lying east of Tamaqua; and the Schuylkill region, which consists of the Western Middle field and the section of the Southern field lying west of Tamaqua.

The area may also be divided into four fields, using the grouping of the anthracite geologic basins as a framework, as follows: The Northern field, which is the same as the Wyoming region; the Eastern Middle or Lehigh field, which consists of a group of at least 10 small basins; the Western Middle field, a single basin about 36 miles long by 4½ miles at its widest point; and the Southern field, also a single basin, about 54 miles long by 6 miles at its widest point, which breaks into a long "fishtail" toward its western ends.

Both classifications (by regions and by fields) are used in the Bureau tables.

In order of magnitude of present production, the Northern field comes first, followed by the Western Middle, the Southern, and the Eastern Middle.

In order of length of life, based upon estimated minable reserves, the Southern field comes first, followed by the Western Middle, the Northern, and the Eastern Middle fields.

[1] Value given is value at which coal left possession of producing company, f. o. b. mines, and does not include margins of separately incorporated sales companies.
[2] Small quantity of washery coal included with breaker.
[3] For purposes of historical comparison and statistical convenience the mines of Sullivan County are grouped with the Pennsylvania anthracite region, although the product is classified as semianthracite according to the American Society for Testing Materials Tentative Standard.

TABLE 10.—*Pennsylvania anthracite produced, by fields, 1935–39, in net tons*

[The figures of breaker product include a certain quantity of culm-bank coal, which amounted to 585,564 tons in 1938. Data for 1913–25 will be found in Coal in 1925, p. 517, and for 1926–30 in Coal in 1930, p. 747]

[1] Value given for shipments is value at which coal left possession of producing company, f. o. b. mines and does not include margins of separately incorporated sales companies.
[2] Counties producing dredge coal only.

Fresh-mined and culm-bank coal, breaker, and washery product.—Anthracite is now produced from three sources—from mines, from old culm banks, and from the rivers that drain the anthracite region. As the three sources contribute to the country's supply, it is important to consider all of them to ascertain the total production. No difficulty is experienced in assembling the figures of production by dredges, as these are separate, distinct operations. A statistical detail requiring especial attention is the occasional practice of putting culm-bank coal through a breaker, either directly from the bank or after preliminary treatment in a washery. Table 14 shows the aggregate annual tonnages of culm-bank coal so treated.

[1] Figures of shipments from breakers include 585,564 tons of culm-bank coal handled in the breakers.
[2] The quantity of lump included is insignificant.
[3] Includes Birdseye.
[4] Includes all steam sizes.

Table 16 reveals an interregional variation in the breaker production of domestic sizes as related to that of steam sizes and to total production. In 1939 the Wyoming region produced 71 percent domestic sizes and 29 percent steam sizes from a given tonnage of breaker feed; the Lehigh region, 64 percent domestic and 36 percent steam sizes; and the Schuylkill region, 59 percent domestic and 41 percent steam sizes. These percentages are relatively constant from year to year. The variations among the regions are due to differences in the physical situation and condition of the anthracite beds.

TABLE 16.—*Sizes of Pennsylvania anthracite shipped from breakers, 1937–39, by regions, in percent of total*

[4] Less than 0.1 percent.

AVERAGE SALES REALIZATION

The valuation figures in this study represent value at the breaker or washery reported by the operating companies. The company is requested to "estimate value of the product not sold" and to "exclude selling expenses" in making its report.

From this it will be seen that when a producing company sells its output to a separately organized sales company (the practice of many, including certain larger producers) the value reported will exclude the margin of the sales company and may therefore be somewhat less than the circular price at which the coal is placed on the general market. This fact should be borne in mind in considering the variations in value between different regions shown in the tables for the same sizes of coal.

The average sales realization per net ton on breaker shipments only fell to $3.85 in 1939 from $4.16 in 1938, or 7 percent. By far the greater decrease was in the domestic sizes—9 percent. The drop in steam sizes was only 3 percent.

If local sales, colliery fuel, and washery and dredge coal are included, the average value per net ton on the total 1939 production was $3.64 compared with $3.92 in 1938. (See table 18.)

TABLE 17.—*Average sales realization per net ton on Pennsylvania anthracite shipments from breakers, 1937–39, by regions and sizes*

[Value does not include margins of separately incorporated sales companies]

[1] Value given for shipments is value at which coal left possession of producing company, f. o. b. mines, and does not include margins of separately incorporated sales companies.

NUMBER OF OPERATIONS

The total number of active plants reporting increased from 390 in 1937 to 442 in 1938. (See table 19.) Figures for 1939 are not yet available, but indications are that the upward trend continued.

TABLE 19.—*Number of active operations in the Pennsylvania anthracite industry in 1938* [1]

Region and type of product	Total active plants reporting [2]	Breakers [3]	Other preparation plant [4]	Washeries [5]	Culm banks operated in conjunction with breakers	Dredges	Reporting strip-pit tonnage

Sullivan County: Breakers	5	4					
Grand total	442	140	39	12	15	34	113

[1] Figures for 1939 not yet available.
[2] The number of active plants contains numerous duplications, that is, successions known and unknown, and leases and subleases. Each report received which was tabulated for production or for employment has been counted separately.
[3] Equipped to prepare standard sizes of fresh-mined coal.
[4] For preliminary crushing, screening, or cleaning. Usually old breakers are used for this purpose. The number reported for dredges represents reports showing men employed at tipple.
[5] Preparation plant for the sizing and cleaning of culm-bank coal.

LABOR STATISTICS

According to the Pennsylvania Department of Mines about 93,000 men were employed in the anthracite region in 1939. The number employed in 1938, as based upon direct reports to the Bureau of Mines from operators and including the employees of dredges and strip contractors, was 96,417.

Man-days lost on account of strikes were 0.2 percent less in 1938 than in 1937, and suspension of work owing to strikes and the number of men involved also declined. Comparable statistics covering 1939 are not yet available, but there were no widespread labor disputes during the year.

According to the Bureau of Labor Statistics, average weekly earnings ranged from a low of $17.16 in December to a high of $35.84 in May and averaged $25.52 during 1939, or 9 percent above the 1938 average. The index of employment (1929 average equals 100) fluctuated between 44.7 in July and 53 in April and averaged 3.3 percent below 1938. The index of pay rolls reached a low of 25.2 in July and a high of 57 in May and averaged 3.4 percent above 1938.

EQUIPMENT AND METHODS OF MINING

Mechanical loading.—The percentage of total deep-mined production of anthracite loaded mechanically continued to increase. In 1939 the 11,773,833 tons so loaded were 27.7 percent of the total underground output compared with 26.6 percent (10,151,669 tons) in 1938 and 25.1 percent (10,683,837 tons) in 1937. The total tonnage loaded mechanically underground increased 16 percent from 1938 to 1939; hand-loading advanced 10 percent.

There were 8 scrapers and 216 conveyors (including hand-loaded conveyors and conveyors equipped with duckbills or other self-loading heads) sold in the anthracite region in 1939; some were installed late in the year. No sales of mobile loading machines were reported. Returns direct from operators indicated that 535 scrapers and 1,997 conveyors were in use during the year.

TABLE 23.—*Relative growth of mechanical loading, hand loading, and stripping in Pennsylvania anthracite mines, 1935–39*

[Mechanical loading includes coal handled on pit-car loaders and hand-loaded face conveyors]

Year	Net tons			Index numbers, 1927=100		
	Mechanical loading underground	Stripping	Hand loading	Mechanical loading underground	Stripping	Hand loading
1935	9,279,000	5,187,000	34,400,000	417	241	48
1936	10,828,000	6,203,000	33,899,000	487	288	47
1937	10,684,000	5,696,000	31,883,000	481	265	45
1938	10,152,000	5,095,000	27,990,000	457	237	39
1939	11,774,000	5,486,000	30,798,000	530	255	43

TABLE 24.—*Pennsylvania anthracite loaded mechanically underground, 1935–39*

Strip-pit mining.—The percentage of fresh-mined anthracite produced from strip pits remained virtually constant—11.4 percent in 1939 and 11.8 percent in 1938. The tonnage mined by this method in 1939 rose in all regions. Table 27 gives the figures for several years.

TABLE 27.—*Relative growth of Pennsylvania anthracite mined from strip pits, 1915, 1920, 1925, 1930, and 1937–39, in net tons*

Year	Number of power shovels in use [1]	Quantity mined by stripping		Percent of fresh-mined total that was stripped	Number of men employed	Average number of days worked
		Total	Average per shovel

Total, 1939 [3]	[4] 346	5,486,479	15,857	11.4	(2)	(2)

[1] Certain of the equipment reported by stripping contractors may have been counted twice when moved from one small job to another during the year. The amount of such double counting is unknown but presumably is not great.
[2] Data not available.
[3] There was no strip-pit mining in Sullivan County during 1939.
[4] Includes 109 gasoline, 15 steam, 47 electric, 166 Diesel, and 9 other types of shovels.

Dredge operations.—Both the tonnage and average value of anthracite produced by dredges increased in 1939 compared with 1938.

TABLE 28.—*Pennsylvania anthracite produced by dredges, 1938–39, by rivers*

FOREIGN TRADE [4]

Exports of anthracite in 1939 increased 36 percent over 1938 and comprised 5 percent of the domestic production. Imports declined 18 percent and were equivalent to 0.6 percent of United States output; the U. S. S. R. supplied 71 percent, Great Britain 23 percent, French Indochina 4 percent, and Canada (reexports) 2 percent.

The Canadian market.—The United States strengthened its position in the important Canadian anthracite market further in 1939, notwithstanding obstacles such as an import duty, the depreciated Canadian dollar in terms of United States currency, and Canadian subventions to aid its own coal industry. In 1939 the United States supplied 66 percent of Canada's total imports of anthracite compared with 53 percent in 1938. On the other hand, of the bituminous coal available in 1939 (production, plus imports, minus exports), the United States supplied 47 percent as against 49 percent in 1938. This decline indicates Canada's efforts to make greater use of its bituminous-coal resources. The tonnage of all coal available in 1939 (29,028,000 tons) was 6 percent more than in 1938. Details of the coal and coke industry and foreign trade of Canada are given in table 34.

TABLE 34.—*Coal and coke industry and foreign trade of Canada, 1938–39* [1]

[Thousands of net tons]

	Coal										Coke from coal

[1] Quarterly Report on Coal and Coke Statistics for Canada, October–December 1938 and 1939. Canadian coal charged to ovens in 1938, 1,064,302 tons; 1939, 1,104,371 tons. Imported coal charged to ovens in 1938, 2,215,469 tons; 1939, 2,207,707 tons.

Imports of anthracite into Canada in 1939 were 3,977,805 tons, a gain of 7 percent over 1938. Of the total imports into Canada in 1938 and 1939, respectively, 60 and 64 percent were received from January to August, inclusive, before the outbreak of war in Europe. Of the total tonnage supplied by the United States in 1938 and 1939, respectively, 68 and 61 percent were received from January to August.

Canadian official statistics for 1939 show that of the total imports of anthracite into Canada 24 percent (941,017) tons were steam sizes—44 percent from Great Britain, 40 percent from the United States, 13 percent from Germany, and 3 percent from French Indochina.

The upward trend in the use of hydroelectricity, natural gas, and doubtless fuel oil continued. Although coal production in 1939 was 1,224,746 tons greater than in 1938, hydroelectric power, in terms of coal, increased 1,623,000 tons. Excluding 1937, coal production was greater in 1939 than in any year since 1929.

The tonnage of Canadian coal moved under assisted (railroad) rates continued to increase.

The additional subvention (not to exceed 50 cents a ton) granted November 8, 1938, by the Canadian Government to aid shipments of Nova Scotia bituminous coal to central Canada was withdrawn effective December 8, 1939.

In 1939 the Canadian Government appointed a coal administrator, and effective December 1, the coal industry and trade were required to operate under license.

The outlook for anthracite in Canada in 1940 is obscured by the international situation and developments that may result therefrom.

Among the possible developments is further depreciation of the Canadian dollar, which would facilitate the purchase of British anthracite. On the other hand, the increased cost of coal production in Britain and high ocean-freight and insurance rates should much more than offset the lower value of the Canadian dollar; however, as Britain will require Canadian timber and grain it seems probable that Canada will continue to receive British anthracite in order to conserve foreign exchange.

The trade agreement between the United States and U. S. S. R. was renewed in August for another year, during which period U. S. S. R. agreed not to ship more than 400,000 tons of anthracite to the United States.

World anthracite production.—Because of the international situation, anthracite production data for 1939 were not released in a number of countries. Available data for 1934–39 are presented in table 35.

TABLE 35.—*World production of anthracite, 1934–39, in metric tons*

[1] Data not available.
[2] Estimate included in total.
[3] The anthracite production of Japan is said to average about 225,000 tons a year. Production figures are not available.

COKE AND BYPRODUCTS

By M. van Siclen, M. M. Otero, and M. F. Cooke

SUMMARY OUTLINE

The coke industry in 1939 on the whole recovered strongly from the recession noted in 1938, but output still fell short of that in 1937 and 1936.

The total production of beehive and byproduct coke increased about 36 percent—from 32,495,815 net tons in 1938 to 44,326,641 tons in 1939. The output from beehive ovens in 1939 increased 72 percent over 1938, rising to 1,444,328 tons from the near-all-time low of 837,412 tons in the preceding year. Byproduct coke, representing 97 percent of the total, increased 35 percent in 1939 and totaled 42,882,313 tons compared with 31,658,403 in 1938. Whereas in 1938 the production of byproduct coke at furnace plants declined 43 percent when total byproduct output dropped 36 percent, in 1939 the production from furnace coke plants increased 54 percent, with an attendant gain of 35 percent in all byproduct coke.

Accompanying the upturn in the industry during 1939, producers' stocks of byproduct coke dropped 29 percent—from 3,631,623 net tons on January 1, 1939, to 2,569,690 tons at the beginning of 1940. At beehive plants the decrease in stocks was from 44,931 to 32,409 tons.

The calculated consumption of all coke in 1939 was 44,953,082 net tons, a 45-percent increase over 1938.

Export trade increased 21 percent in 1939; shipments totaled 589,925 net tons compared with 486,571 tons in 1938. Canada again was by far the leading customer, taking nearly one-half million tons. Coke imports into the United States comprised 24 percent of coke exports in tonnage and 36 percent in value.

Fluctuations in price quotations for byproduct foundry coke at various markets included increases of 11 to 12 cents and decreases

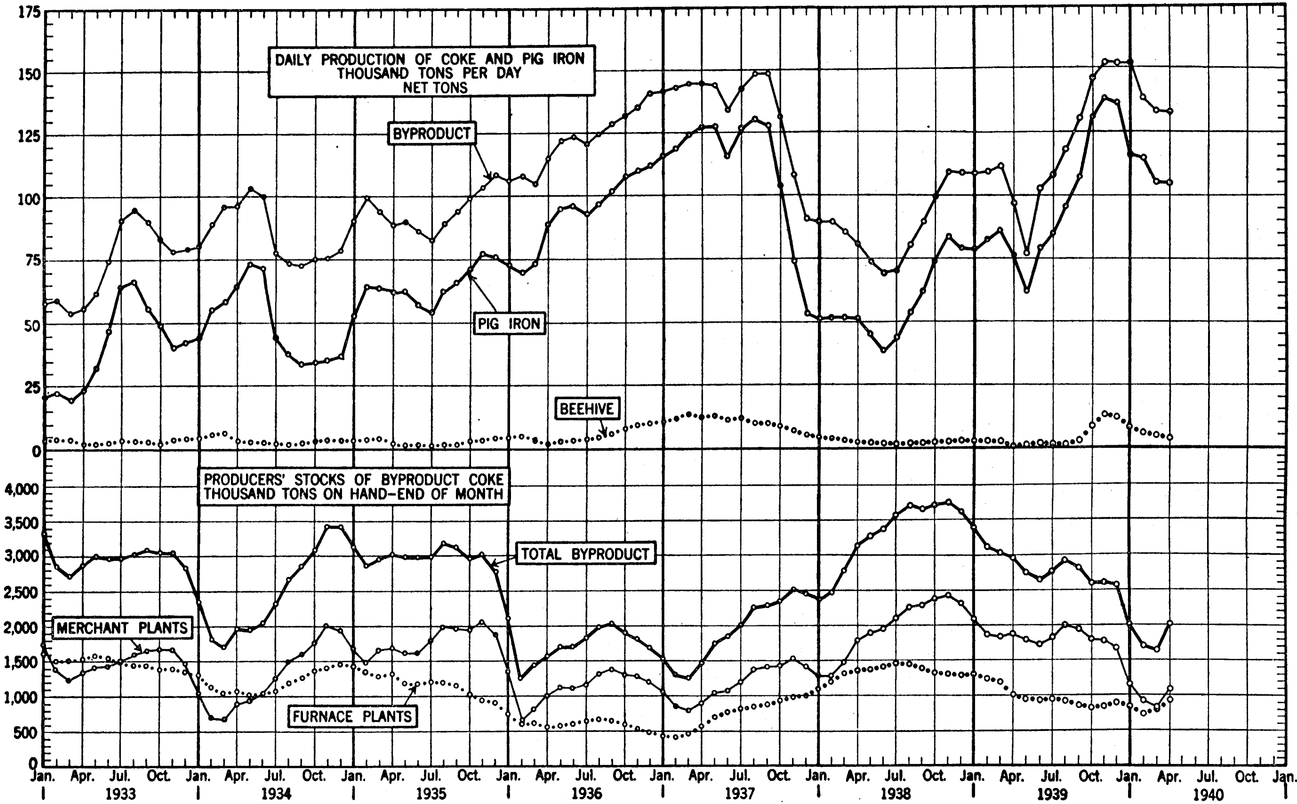

FIGURE 1.—Average daily production of beehive and byproduct coke and pig iron; and producers' stocks of byproduct coke, 1933–40, by months.

ranging from 13 to 35 cents. Connellsville prices rose 16 cents for foundry coke and 23 for furnace coke.

The byproduct-coke industry followed the 1937–39 curve for coke. Except for the tar derivative ("creosote oil, distillate as such," output of which rose to 18,479,962 gallons in 1939—20 percent above the 1937 figure) the yield of all coke byproducts dropped rather sharply in 1938 but recovered a good proportion of the production losses in 1939.

Of special interest is toluol, an important ingredient of TNT, which is obtained as a light-oil derivative from coke-oven operations and tar refineries. The output in 1939 as a byproduct from coke operations was 19,767,200 gallons compared with 13,021,080 in 1938 and 20,896,724 in 1937. These figures do not include toluol obtained from tar refineries. Sales of toluol in 1939 were 20,484,568 gallons valued at $3,974,367, an average of $0.194 per gallon. The trade-journal quotation of $0.27 per gallon advanced 3 cents at the beginning of 1940.

TABLE 1.—*Salient statistics of the coke industry in the United States, 1938–39*

	Byproduct	Beehive	Total
1938			
Coke produced:			
At merchant plants:

Byproduct under construction, end of year	629	305	259	146	0
Cost of coal charged, byproduct ovens, average per ton	$4.76	$3.69	$3.74	$3.92	$3.75
Prices of coke:					
Average spot price of Connellsville furnace coke, f. o. b. ovens	$5.33	$3.68	$4.29	$3.86	$4.09
Average realization on byproduct coke sold:					
Furnace coke (merchant sales)	$6.74	$5.09	$4.34	$4.41	$4.38
Foundry coke	$10.54	$7.44	$8.47	$8.39	$8.15
Other industrial (including water gas)	$9.06	$5.51	$6.08	$5.68	$5.64
Domestic	$9.05	$6.07	$6.53	$6.17	$5.90
Yield of byproducts per ton of coal charged:					
Tar ... gallons	8.1	8.86	8.67	9.27	9.06
Ammonium sulfate or equivalent ... pounds	21.2	22.14	21.84	23.36	22.33
Light oil ... gallons	2.7	2.91	2.86	2.99	2.99
Surplus gas sold or used ... M cubic feet	5.9	6.85	6.66	7.14	7.08
Average gross receipts of byproducts per ton of coke produced:					
Tar sold and used	$0.51	$0.541	$0.588	$0.654	$0.622
Ammonia and its compounds	$0.84	$0.287	$0.326	$0.380	$0.341
Light oil and its derivatives (including naphthalene)	$0.51	$0.438	[3] $0.443	$0.423	$0.414
Surplus gas sold or used	$1.37	$1.589	$1.483	$1.907	$1.676
Total byproducts, including breeze	$3.48	$3.057	[3] $3.068	$3.647	$3.315

[1] Furnace and foundry coke only.
[2] Before 1934 the figures represent general imports; beginning with 1934 they represent imports for consumption only.
[3] Revised figures.

SCOPE OF REPORT

This report contains final figures covering production of both beehive and byproduct coke, and the major byproducts of the latter, for 1938 and 1939. Inclusion of the 1939 statistics in final form marks resumption of an earlier custom, made possible through a slight increase in funds allotted to Coal Economics Division. To complete the record by including 1938 final figures, which were lacking in the previous chapter in this series, it has been necessary throughout the report to complete the permanent record by publishing tables covering both years. Preliminary statistics of coke production and the byproducts obtained in 1939 were published as a 2-page supplement on February 26, 1940, to Monthly Coke Report 143. Salient statistics, giving final data on the coke industry and the byproducts obtained, were published as a 2-page supplement to Monthly Coke Report 146 on May 24, 1940.

Coke is produced by four different industries in the United States. In addition to that made in the familiar beehive and byproduct ovens, it is obtained in refining petroleum and tar, and in manufacturing coal gas. Moreover, within the last few years production of a smokeless fuel by low-temperature carbonization of coal has been established commercially in the United States. The commodity produced by each of these processes, however, differs greatly from other cokes in character, and the problems affecting the several industries are quite distinctive.

About 1,666,400 tons of petroleum coke were produced in 1939 compared with about 1,602,200 tons in 1938. A small tonnage of coke from coal tar is also produced commercially. Only coke from byproduct and beehive ovens is adapted to blast-furnace and foundry uses, which consume the larger part of all the coke produced. Practically, therefore, the coke trade is concerned only with byproduct and beehive coke, and the statistics of this report are confined to these two types.

For reasons explained in a later section, the statistics on byproduct coke in this chapter cover operations of all byproduct coke ovens, including those installed and operated by public utilities engaged primarily in manufacturing gas for city supply.

The standard unit of measurement in the coke industry is the short or net ton of 2,000 pounds, and unless otherwise specified that unit is employed throughout this report.

COKE AND COKE BREEZE

MONTHLY AND WEEKLY PRODUCTION

TABLE 3.—*Byproduct, beehive, and total coke produced in the United States, 1936–39, by months, and average per day, in net tons*

PRODUCTION BY FURNACE AND NONFURNACE PLANTS

The terms "furnace" and "merchant" operators originated in the Connellsville beehive-coke trade. As the name implies, the beehive-furnace interests are those affiliated with the producers of iron and steel whose output does not ordinarily enter the open market. There are, however, a number of byproduct plants financially affiliated with iron furnaces, in which most of the product is nevertheless foundry and domestic coke that must be sold on the competitive market. Inasmuch as the beehive-coke trade has dwindled during the past decade to an insignificant position in the coke industry (supplying only 3.3 percent of the total production in 1939) the statistics presented in the two following tables cover byproduct coke only.

A "furnace" plant is defined herein as one that has for its main business the production of furnace coke and that has an assured outlet for such coke either through financial affiliation with or direct ownership by an ironworks or through long-time contracts. Under this definition the class designated as "other" plants includes a few plants affiliated with local iron furnaces but producing much more coke than the furnaces can absorb and therefore depending chiefly on the foundry and domestic trade or on merchant sales of furnace coke. It also includes merchant producers of furnace coke who have to sell their output on the competitive market; the plants affiliated with alkali works; and, in addition, a number of plants that, although not public utilities, were constructed primarily to supply city gas and that must sell their coke where they can for domestic and industrial as well as metallurgical use.

In 1939, 45 furnace plants produced 31,811,807 tons of byproduct coke and 39 "other" plants produced 11,070,506 tons. The relative proportion furnished by furnace plants has remained fairly constant, except in the years of iron and steel depression. Thus, in 1913 and again in 1918, furnace plants produced approximately 73 percent of the total byproduct coke output. In 1932, a year of great recession in the steel industry, the proportion fell to 54 percent; it rose to 73 percent in 1937, fell again to 65 percent in 1938, and increased to 74 percent in 1939.

TABLE 7.—*Number and production of byproduct coke plants connected with iron furnaces and of other byproduct plants in the United States, 1913, 1918, and 1937–39*

Year	Number of active plants		Coke produced (net tons)		Percent of production	
	Furnace plants	Other plants	Furnace plants	Other plants	Furnace plants	Other plants
1913	20	16	9, 277, 832	3, 436, 868	73. 0	27. 0

PRODUCTION BY STATES AND DISTRICTS

Except in Minnesota and New Jersey, the losses sustained in 1938 production were recovered to a considerable extent in 1939; in Maryland and Michigan the 1939 output even slightly exceeded that of 1937. The total output of byproduct coke (exclusive of screenings and breeze) in 1939 was 36 percent greater than in 1938 and 13 percent less than in 1937.

As in previous years, Pennsylvania was the leading producing State, contributing 26 percent of the byproduct-coke output, 78 percent of beehive, and 27 percent of the United States total. Next in importance is Ohio, followed by Indiana, New York, and Alabama, in the order named.

TABLE 9.—*Coke produced, value, number of ovens, coal charged, and average yield in the United States in 1938, by States*

[Exclusive of screenings or breeze]

	15	1,862	8,631,389	71.09	6,135,949	28,502,924	4.65

[1] Includes plants at Hamilton, Ironton, Lorain, Painesville, Portsmouth, Toledo, and Warren.

NUMBER AND TYPE OF OVENS

In the byproduct branch of the coke industry 286 new byproduct ovens were completed and put into operation during 1939; of these, 20 were in Illinois, 140 in Indiana, and 126 in Michigan. At the close of the year no ovens were reported under construction, and none had been abandoned; the number in existence at the 88 plants totaled about 13,010.

Beehive coke ovens have been dismantled steadily during the past 3 decades and in 1937 were exceeded in number by byproduct ovens for the first time. In 1910 there were 100,362 beehive ovens; in 1920, 75,298; and in 1930, 23,907. In 1939, only 10,934 remained. Byproduct ovens rose during the same period from 4,078 in 1910 to 10,881 in 1920, to 12,831 in 1930, and 13,010 in 1939, the net change during the past 9 years being slight. There is of course no basis of comparison between a byproduct and a beehive oven with respect to operating capacity, but the figures show the changing trend of coking practices.

The 76 beehive coke plants in existence at the close of 1939 comprised 10,934 ovens. Fifty-eight plants with a total of 8,857 ovens were active. The survey, inaugurated in 1938, covering the average number of ovens active during each month, was continued, and showed a high of 6,408 in November and a low of 990 in April. The average for the year was 2,711 ovens compared with 1,846 in 1938.

[1] Includes the Koppers-Becker type.
[2] Includes 26 Curran-Knowles, 27 Parker-Russell, 60 Improved Equipment Co., and 8 Piette ovens in 1938 and 46 Curran-Knowles, 27 Parker-Russell, 60 Improved Equipment Co., and 8 Piette ovens in 1939.

CAPACITY OF BYPRODUCT OVENS

The reported maximum capacity of the byproduct ovens in existence is seldom attained, for various practical reasons that may be due to operating, economic, or labor conditions. It has been stated that the efficient life of a coke oven is limited to 20 years, as radiation losses after that period are high; other claims have been made that ovens built 25 years ago still can operate efficiently. Had it not been for the depression years much replacement building probably would have been done. The closing of ovens over an extended period added to their life and made replacement unnecessary in many instances.

The maximum daily capacity of the 88 byproduct coke plants in existence December 31, 1939, was 172,479 tons compared with 167,868 tons for the 87 plants at the end of 1938. The daily capacity at the 42 merchant plants was 42,581 tons, an average of 1,014 tons per plant, while at the 46 furnace plants the capacity was 129,898 tons (2,824 tons per plant); the furnace plants as a rule carry larger batteries of ovens.

Production of byproduct coke in 1939 was 69 percent of the calculated capacity of all byproduct ovens compared with 51 percent in 1938 and 91 percent in the peak year 1929. Furnace plants operated at 68 percent of capacity, while merchant plants operated at 72 percent.

TABLE 16.—*Estimated annual potential production of coke and coal required for charge of byproduct coke ovens in the United States, 1938–39, when operated at different percentages of maximum capacity, in millions of net tons*

QUANTITY AND COST OF COAL CHARGED

Although the quantity of coal used in the manufacture of coke has fluctuated widely during the past decade, the proportion of the total output of bituminous coal carbonized each year has remained remarkably constant, ranging from 10.3 to 16.8 percent during the past 10 years. In 1939, coke ovens consumed 63,513,684 tons—about 16 percent of the total output of bituminous coal. Of this quantity, 61,215,899 tons were used in byproduct ovens.

The cost of coal constitutes the chief item of expense in the manufacture of coke. In 1939 the cost of raw coal f. o. b. ovens ranged from $1.81 in Virginia, where all the coke is made in beehive ovens at the mines, to $5.49 in Minnesota, where the cost includes heavy freight charges from distant mines.

The average cost of coal in byproduct ovens in 1939 was $3.75 a ton, and the cost of the coal equivalent of 1 ton of merchantable coke was $5.36. The corresponding figures for beehive coke were $1.99 and $3.16, respectively.

PREPARATION AND SOURCE OF COAL

The coal used for coking in Colorado and Tennessee, as well as in certain parts of Alabama, Illinois, New York, Ohio, Pennsylvania, and West Virginia, is washed before it is charged in the ovens. The washing sometimes is done by the operator at the mines and sometimes by the coke producer at the plant. For the country as a whole in 1939, 26 percent of the coal used in byproduct ovens and 21 percent of that in beehive ovens was washed before charging. In 1938, 30 percent of the coal for byproduct ovens and 31 percent of that for beehive ovens was washed.

Pennsylvania and West Virginia are the leading sources of coal used in byproduct coke manufacture. In 1938 each of these States supplied approximately 38 percent; in 1939 Pennsylvania led with 42 percent followed by West Virginia with 36 percent. Next in order of importance are Kentucky and Alabama with 10 and 9 percent, respectively, and Virginia with 2 percent. Colorado and Utah together furnished nearly a million tons of coal for that purpose in 1939, and smaller tonnages were obtained from Illinois, Ohio, and Tennessee.

TABLE 22.—*Coal used in manufacture of byproduct coke in the United States, 1938–39, by fields of origin, in net tons*

[Based upon detailed reports from each coke plant. The difference between these totals and those shown in tables 1, 9, 19, etc., is due to change in stock, loss of weight in handling, and the fact that these sometimes represent purchases during the year rather than actual consumption]

State and district where coal was produced	Total used	States where coal was consumed—in order of importance
1938

Pittsburgh	6,375,832	Pennsylvania, New York, Ohio, Michigan, Illinois, Minnesota, and Wisconsin.
Somerset	266,965	Pennsylvania and West Virginia.
Westmoreland	468,591	Maryland, New York, and Pennsylvania.
Tennessee	79,695	Tennessee.
Utah: Carbon County	228,175	Utah.
Virginia: Southwestern [1] [2]	315,682	New Jersey, New York, Pennsylvania, and Massachusetts.
West Virginia: [2]		
Coal and Coke [3]	149,628	Pennsylvania, Minnesota, and New York.
Kanawha and Logan (including Coal River).	6,857,522	Massachusetts, Ohio, Illinois, New York, Indiana, New Jersey, Michigan, West Virginia, Pennsylvania, Wisconsin, Kentucky, Connecticut, Minnesota, Rhode Island, and Missouri.
New River, high-volatile	923,805	New York, New Jersey, Connecticut, Massachusetts, and Pennsylvania.
New River, low-volatile (including Winding Gulf).	1,539,972	New York, Massachusetts, New Jersey, Illinois, Rhode Island, West Virginia, Minnesota, Kentucky, and Missouri.
Northern	2,035,601	Maryland, Pennsylvania, Ohio, West Vriginia, and New York.
Pocahontas [2]	5,871,901	Indiana, Ohio, New York, Michigan, Illinois, Wisconsin, Maryland, Pennsylvania, Minnesota, Kentucky, Connecticut, Alabama, Missouri, Massachusetts, Tennessee, and West Virginia.
Webster-Gauley	209,537	Pennsylvania and Massachusetts.
Miscellaneous	10,316	Indiana.
	45,843,671	
1939		
Alabama	5,283,591	Alabama.
Colorado:		
Canon, Crested Butte, and Walsen	97,022	Colorado.
Trinidad	507,273	Do.
Illinois: Southern	124,491	Illinois and Missouri.
Kentucky, Eastern:		
Elkhorn (including Hazard)	1,516,089	Indiana, New York, New Jersey, Ohio, Michigan, Minnesota, Illinois, Wisconsin, and Kentucky.
Harlan	3,310,488	Indiana, Illinois, Ohio, Minnesota, Michigan, New York, and Wisconsin.
Kenova-Thacker [4]	1,406,177	Michigan, Ohio, Wisconsin, West Virginia, New York, and Missouri.
Miscellaneous	10,679	Missouri, Ohio, and Indiana.
Ohio	1,296	Ohio.

See footnotes at end of table.

TABLE 22.—*Coal used in manufacture of byproduct coke in the United States, 1938–39, by fields of origin, in net tons*—Continued

State and district where coal was produced	Total used	States where coal was consumed—in order of importance
1939—Continued		
Pennsylvania:		
Central Pennsylvania:		
Medium-volatile	523, 153	New York and Pennsylvania.
Low-volatile	1, 123, 597	Pennsylvania and New York.
Connellsville	13, 084, 727	Pennsylvania, Ohio, West Virginia, New York, Illinois, and Minnesota.
Freeport	1, 354, 891	West Virginia, Ohio, Michigan, New York, and Pennsylvania.
Pittsburgh	8, 675, 795	Pennsylvania, New York, Ohio, Michigan, Illinois, and Wisconsin.
Somerset	471, 923	Pennsylvania and West Virginia.
Westmoreland	485, 505	Maryland, New York, Minnesota, Ohio, and Wisconsin.
Miscellaneous	37, 000	Pennsylvania.
Tennessee	90, 902	Tennessee.
Utah: Carbon County	324, 100	Utah.
Virginia: Southwestern [1]	758, 998	Michigan, New Jersey, Ohio, Illinois, Minnesota, New York, and Pennsylvania.
West Virginia: [2 4]		
Coal and Coke [3]	199, 327	Pennsylvania, Minnesota, and New York.
Kanawha and Logan	7, 228, 279	Massachusetts, Ohio, Illinois, Indiana, New York, Kentucky, West Virginia, Michigan, New Jersey, Wisconsin, Pennsylvania, Connecticut, Rhode Island, Minnesota, and Missouri.
New River, high-volatile	1, 266, 674	New York, New Jersey, Connecticut, Massachusetts, Michigan, and Pennsylvania.
New River, low-volatile (including Winding Gulf).	2, 006, 606	New York, Massachusetts, New Jersey, Illinois, Maryland, Michigan, Missouri, Rhode Island, Pennsylvania, Kentucky, West Virginia, Minnesota, and Ohio.
Northern	3, 103, 359	Maryland, Pennsylvania, Ohio, Michigan, West Virginia, New York, and Massachusetts
Pocahontas [2]	8, 936, 553	Indiana, Ohio, New York, Michigan, Illinois, Maryland, Pennsylvania, Wisconsin, Minnesota, Kentucky, Connecticut, Massachusetts, Alabama, Tennessee, and West Virginia.
Webster-Gauley	133, 557	Pennsylvania.
	62, 062, 052	

[1] Coal from the extension of Thacker field in Virginia is included under Kenova-Thacker (Kentucky).
[2] Coal from the extension of the Pocahontas field in Virginia is included under Pocahontas (West Virginia).
[3] Includes coal from all Bituminous Coal Division field 24a-b-c except Webster-Gauley.
[4] Coal from the extension of Thacker field in West Virginia is included under Kenova-Thacker (Kentucky).

Table 23.—*Coal used in the manufacture of byproduct coke in the United States, 1938–39, by States where produced and consumed, and by merchant and furnace plants, in net tons*

State where coal was used	Coal produced in—										
	Alabama	Colorado	Illinois	Kentucky	Ohio	Pennsylvania	Tennessee	Utah	Virginia	West Virginia	Total
1938

[1] Included under "Undistributed." [2] Yield computed by dividing production of breeze at the few plants reporting by the quantity of coal charged at these plants.
[3] As reported; quantity produced but not used was undoubtedly greater. See Mineral Resources of the United States, 1922, part 2, pp. 726–727.

CONSUMPTION OF COKE

Allowing for imports and exports and for changes in producers' stocks the indicated consumption of coke in 1939 was 44,953,082 tons. Of this amount 31,422,272 tons (about 70 percent of the total) were, according to figures compiled by the American Iron and Steel Institute, consumed by blast furnaces in the manufacture of pig iron and ferro-alloys. The remainder—13,530,810 tons (30 percent)—was used in foundries, in smelting nonferrous metals, manufacturing water gas, miscellaneous other industrial uses, and domestic heating.

The noteworthy improvement in efficiency of fuel utilization in blast-furnace operations during recent years is shown clearly by the fact that the quantity of coking coal required to make 1 ton of pig iron dropped from an average of 3,247.5 pounds in 1913 to 2,547.3 in 1939.

TABLE 26.—*Coke consumed in manufacture of pig iron and for other purposes in the United States, 1913, 1918, and 1937–39, in net tons*

Year	Total production of coke	Imports	Exports	Net changes in stocks	Indicated United States consumption [1]	Consumed by iron furnaces [2]		Remainder consumed in other ways

[1] Production plus imports minus exports, plus or minus the decrease or increase, respectively, of the net changes in stocks.
[2] From Report of American Iron and Steel Institute. Figures include coke consumed in the manufacture of ferro-alloys.
[3] Data not available.

TABLE 27.—*Pounds of coke and coking coal consumed per net ton of pig iron made in the United States, 1913, 1918, and 1937–39*

Year	Pounds of coke per net ton of pig iron and ferro-alloys [1]	Percent yield of coke from coal	Calculated pounds coking coal per net ton of pig iron and ferro-alloys	Year	Pounds of coke per net ton of pig iron and ferro-alloys [1]	Percent yield of coke from coal	Calculated pounds coking coal per net ton of pig iron and ferro-alloys
1913	2, 172. 6	66. 9	3, 247. 5	1938	1, 801. 0	69. 7	2, 583. 9
1918	2, 120. 7	66. 4	3, 193. 8	1939	1, 778. 0	69. 8	2, 547. 3
1937	1, 830. 6	70. 3	2, 604. 0				

[1] From report of American Iron and Steel Institute; the consumption per ton of pig iron only, excluding the furnaces making ferro-alloys, was 2,172.6 in 1913, 2,120.7 in 1918, 1,806.7 in 1937, 1,774.6 in 1938, and 1,760.0 in 1939.

FURNACE, FOUNDRY, DOMESTIC, AND OTHER COKE

The terms "furnace coke" and "foundry coke," as used in the trade, refer to the size and grade of the coke as well as to the use for which it may be intended. Byproduct furnace coke ordinarily is run-of-oven coke from which the breeze and all small coke less than, say, three-fourths-inch diameter have been removed. Byproduct foundry coke ordinarily is a blocky coke of maximum size much greater than that of furnace coke, from which all sizes under 2½ to 3 inches are screened out. Coke of smaller size than furnace or foundry (exclusive, however, of breeze) often is called domestic coke. It may result from the screening of foundry or furnace coke, or, where the principal demand is for domestic coke, may be obtained by crushing the larger fragments. Other special sizes and grades may be prepared for special purposes. Thus, not all furnace coke finds its way to blast furnaces or all foundry coke to iron foundries proper, for either grade may be purchased by other classes of consumers.

Coke enters the domestic fuel market mainly under two conditions: (1) In or near areas of surplus metallurgical coke production and (2) in localities where the manufacture and distribution of large quantities of city gas result in the yield of correspondingly large quantities of coke. As this fuel is, on the average, not transported as far as coal, its consumption for domestic purposes tends to be localized in regions near the centers of production. In recent years the majority of the coke operators have reported that their plants are equipped to screen and size coke for domestic use.

TABLE 28.—*Byproduct coke produced and sold or used by producers in the United States, 1938–39, by States*

[Exclusive of screenings or breeze]

[1] Includes coke used for other purposes than in blast furnaces as follows: 1,124 net tons, valued at $4,626.
[2] Includes coke sold as follows: 196,956 net tons valued at $855,858 to financially affiliated corporations for blast furnace use; 16,260 tons, $79,349 for other purposes; and 441,685 tons, $1,909.857 as merchant sales.
[3] Iucluded under "Undistributed."
[4] Includes coke sold for manufacture of water gas as follows: 85,191 net tons valued at $315,429.

STOCKS OF COKE AND COKING COAL

The plotted monthly curve of producers' stocks of byproduct coke takes a typical shape as related to the corresponding monthly curves of byproduct-coke and pig-iron production for the 2 years 1938 and 1939. That is to say, as pig-iron and coke production increases stocks of coke decrease, and vice versa. (See fig. 1). On January 1, 1939, producers' stocks of byproduct coke had risen by 1,112,303 net tons (44 percent) over the January 1, 1938, figure to a total of 3,631,623 tons but by January 1, 1940, had fallen again by 1,061,933 tons to 2,569,690 tons, or nearly to the January 1, 1938, figure. Of the totals on January 1, 1939 and 1940, 72 percent (2,611,645 tons) and 75 percent (1,922,369 tons) were for domestic and general industrial use, respectively. Beehive plants as a rule carry but low stocks on hand, partly because of sporadic activity of the ovens during the year. At the close of 1939, 32,409 tons of coke were in inventory.

Stocks of bituminous coal closely follow fluctuations in the trend of monthly coke production. In 1939 the highest reserves of coking coal were built up in November; and at the end of May stocks were at the lowest level of the year. The low month in coke production was May 1939, and highest production was reached in December.

VALUE AND PRICE

Reference has been made in previous chapters to the varying accounting practices of coke operators financially affiliated with iron and steel plants, by which the coke sometimes is charged to the furnace department at cost and sometimes at a price that includes a percentage of profit or at the prevailing market price.

According to trade-journal quotations published currently during 1939, prices on byproduct foundry coke advanced in four markets, decreased in six other markets, and remained stationary in New England. The increases ranged from 11 to 12 cents per ton, and decreases ranged from 13 cents at Birmingham and Indianapolis to 35 cents at Detroit. Connellsville prices, which have until recent years been regarded as basic reference prices for the entire industry, rose 16 cents for foundry coke and 23 cents for furnace coke.

Price cutting, long-time contracts, and other factors, however, materially affect the prices at which coke operators actually dispose of coke on the open market. According to sales data furnished by operators, average receipts for byproduct coke declined in 1939 from those of 1938 by as much as 27 cents for domestic coke; sales realizations for beehive coke varied from 1938, as follows: An increase of 22 cents for furnace, and a decrease of 15 cents for foundry and 11 cents for other industrial.

EXPORTS AND IMPORTS [1]

Exports of coke from the United States totaled 589,925 net tons valued at $3,878,235 in 1939, an increase of 103,354 tons from the 1938 total of 486,571 tons. As usual, the principal export movement was to Canada, which received 495,389 tons (84 percent of the total), the bulk going through the gateways of Buffalo and Michigan. Outside of Canada the export market for American coke is small, although France took 45,901 tons in 1939, a vast increase over the 6,013 tons bought the year before. Between 5,000 and 10,000 tons were exported in 1939 to Cuba, to British West Indies, to Brazil, and to Japan.

[1] Includes values under $5,000.

[1] Figures on exports and imports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Coke imports supply an insignificant part of the requirements of the country and are a factor in the home market in restricted localities only. In 1939, 141,911 tons were received in the United States, nearly all supplied by four countries—Canada, Belgium, the United Kingdom, and Germany—in order of importance.

WORLD PRODUCTION

With 14 of the 27 countries listed in the following world table involved in the European war, production figures for 1939 are few, and any world total would be meaningless. Of the 6 countries whose 1939 output is reported, only the Union of South Africa shows a consistently rising quantity during the past four years. Production in the U. S. S. R. dropped from 20,700,000 metric tons in 1938 to 16,670,000 metric tons in 1939, or a decrease of 19 percent.

TABLE 42.—*Coke produced in principal countries of the world, 1929 and 1936–39, in metric tons* [1]

[Compiled by M. T. Latus]

Country [2]	1929	1936	1937	1938	1939
Australia:					
New South Wales	471,813	907,537	955,030	1,153,670	(3)
Queensland	4,144	23,701	30,949	31,481	31,057
Belgium	6,192,960	5,252,360	6,083,910	4,894,980	5,176,650
Bulgaria		1,683	4,550	3,923	(3)
Canada	1,986,532	1,830,101	1,984,581	1,808,588	1,825,178
China (exports)	13,467	11,422	9,062	11,630	(3)

Union of South Africa	99,297	75,459	109,133	163,315	184,480
U. S. S. R.	4,700,000	19,883,000	20,000,000	20,700,000	16,670,000
United States	54,325,427	41,979,921	47,513,978	29,479,553	40,212,242
	142,941,000	[7] 137,000,000	[7] 153,000,000	[7] 135,000,000	(3)

[1] Gas-house coke is not included.
[2] In addition to countries listed above, coke is produced in Chosen and Japan, but data of production are not available.
[3] Data not available.
[4] Excluding Sudetenland since October.
[5] In Great Britain the production of gas-house coke (including breeze), not included above, is especially important and was as follows: 1936, 12,935,933 tons; 1937, 13,151,057 tons; 1938, 13,049,139 tons.
[6] Figures for 1929 represent "hard" and "soft" coke made at collieries only (73,616 tons of "hard" coke and 769,888 tons of "soft" coke). Data for other years shown represent total "hard" coke manufactured. In addition, the following quantities of "soft" coke were made at collieries: 1936, 932,534 tons; 1937, 850,581 tons; 1938, 921,479 tons.
[7] Exclusive of Mexico and Spain.

COKE-OVEN BYPRODUCTS

The statistics in the following tables are confined to the major products obtained in high-temperature byproduct ovens, which fall into five general groups, some of which are subdivided further. They are (1) gas, by far the most valuable byproduct, followed by (2) light oil and derivatives, (3) tar, (4) ammonia, and (5) miscellaneous products. In recent years an increasing number of operators have installed equipment at their plants for making tar derivatives on the premises. The sales value of such derivatives during 1938 and 1939 totaled $2,438,075 and $3,270,208, respectively, including phenol and sodium phenolate (except for phenol and tar acids produced at Clairton, Pa.), and the tar that went into the distilling of these products totaled 111,782,843 gallons, reported from 9 plants in 1939. Total sales values of all byproducts in 1938 and 1939 were $103,671,849 and $124,814,434. If to these amounts are added values for the tar used by the producer ($5,780,776 in 1938 and $10,081,205 in 1939) and the values of the breeze production ($5,995,267 in 1938; $7,271,050 in 1939), the ratio of the value of byproducts to the value of coke produced was 71 percent in 1938 and 69 percent in 1939.

Of particular interest at present is toluol, a light-oil derivative from coke-oven operations and tar refineries. The output in 1939 as a byproduct from coke operations was 19,767,200 gallons compared with 13,021,080 in 1938 and 20,896,724 in 1937. These figures do not include toluol obtained from tar refineries. Sales of toluol in 1939 totaled 20,484,568 gallons valued at $3,974,367—an average of $0.194 a gallon. At the beginning of 1940 the trade-journal quotation of $0.27 a gallon advanced 3 cents.

Statistics covering the production and sales of coke-oven byproducts during 1938 and 1939 are shown in the following tables:

TABLE 43.—*Byproducts obtained from coke-oven operations in the United States, 1938–39* [1]

[Exclusive of screenings or breeze]

Product	Production	Sales

[1] Includes products of tar distillation conducted by coke-oven operators under same corporate name, except, however, phenol and other tar acids produced at Clairton, Pa.
[2] Includes gas wasted and gas used for heating retorts.
[3] Refined on premises to make the derived products shown: 1938, 117,248,545 gallons; 1939, 163,947,167 gallons.
[4] Total gallons of derived products.
[5] Ammonia thiocyanate, asphalt paint, cyanogen sludge, calcium ferrocyanide, light carbolic oils, pyridine oil, sodium carbolate, sodium prussiate, spent soda solution, sulfur, and vented vapors.
[6] Exclusive of value of breeze, which was $5,995,267 in 1938 and $7,271,050 in 1939.

TABLE 44.—*Coal equivalent of byproducts of byproduct coking in the United States, 1913, 1914, 1918, and 1938–39*

1939	46,551,432	727,947	1.6	1.7

BYPRODUCT COKE OVENS OWNED BY CITY-GAS COMPANIES (PUBLIC UTILITY PLANTS)

Adaptation of byproduct coke ovens to the needs of city-gas manufacture has led a number of gas companies to install batteries of byproduct ovens to supplement or even to replace their coal or water-gas plants. From the point of view of ownership and accounting, these installations are part of the gas utility system, and the Bureau of the Census therefore groups them with the manufactured-gas industry under the title "The Gas and Coke Industries."

From other points of view, however, these installations belong to the byproduct coke industry. The coke produced is superior to gas-house coke. In practical operation of a byproduct coke plant the fact that the gas may be distributed through city mains has less consequence than the fact that the coke must be marketed for foundry, furnace, or household use. Considered with reference to oven design and the technique of manufacture, and still more with reference to the supply and demand for coke, these ovens should be included with other byproduct coke plants; they are so included in the statistics published by the Bureau of Mines.

These differences in classification are followed by the Bureau of the Census and the Bureau of Mines after consultation with leaders of the gas and coke industries, and the two offices have collaborated in the collection and analysis of the statistics.

The following table presents salient features of the byproduct coke industry separated with respect to plants owned by city-gas companies and those not so owned.

That the public utility plants have been increasing in number and volume of output is evidenced by the fact that the number rose from 9 in 1918 to 21 in 1929. In the latter year the coke produced from the 21 active plants amounted to 3,232,307 tons, or 6 percent of the total output of byproduct coke. In 1939, with only 17 plants active, the coke output was 3,159,129 tons, or 7 percent of national byproduct production.

TABLE 51.—*Production of coke, breeze, gas, and byproducts at byproduct coke plants owned by city gas companies (public utilities) and included by Bureau of the Census in manufactured-gas industry, and at all other byproduct coke plants, 1938–39*

[1] Includes all byproduct ovens built by city gas companies, some of which are operated in conjunction with coal, oil, and water gas plants. Does not include independent byproduct plants, which may sell gas to public utility companies for distribution.

FUEL BRIQUETS AND PACKAGED FUEL [1]

By G. S. Goodman

SUMMARY OUTLINE

The domestic production of fuel briquets in the past 33 years has risen from 66,524 net tons in 1907 (the first year of record) to 1,107,720 [2] net tons in 1939; the potential annual capacity of the 31 fuel-briquet and 103 packaged-fuel plants active in 1939 is three times this amount.

Compared with the production of Germany and France—the most important fuel-briquetting countries of the world, producing 56 million and 8 million net tons, respectively, in 1938—the United States production seems small. Conditions that favor the successful operation of briquetting plants in Germany are the abundant supplies of brown coal, which can be briquetted without a binder to make a product that finds a ready domestic market.

The gradual development of the briquetting industry in the United States is significant because it reveals definite progress in utilization for domestic heating of the enormous stocks of slack and culm produced in mining operations and also that accumulated at the large Lake dock distribution centers. These coal fines were formerly wasted or sold at less than actual cost. The current trend of thought toward conservation of our National resources has directed attention [3] to the vast deposits [4] of low-rank bituminous and subbituminous coals and lignite in the United States, and to the rapidly diminishing known reserves of petroleum—which in the past 20 years has become such an important source of fuel and of energy.[5] Because of its convenience, fuel oil has replaced coal in the heating of many homes, but raw coal and coal processed into briquets remain cheaper and therefore are likely to continue as the chief fuels.

[1] Directories of fuel-briquetting and packaged-fuel plants operating in 1939 and names of manufacturers of equipment will be furnished on request by the Coal Economics Division, Bureau of Mines, Washington, D. C.

Data on the principal expenses in the manufacture of fuel briquets may be obtained from the Bureau of the Census, which collects and publishes such data in alternate years.

Briquets made from charcoal, wood wastes, and fruit pits are not included in the Bureau of Mines review.

[2] Includes 215,507 net tons of packaged fuel (treated separately in this report).

Briquets are made in this country mostly from high-quality, low-volatile bituminous screenings or slack; of the lower-grade fuels, lignite has been used successfully, particularly by one briquetting company in North Dakota since 1929.

The production of packaged fuel in the past 5 years has risen from 25,244 tons in 1935 (first canvass made by the Bureau of Mines) to 215,507 tons in 1939, an eightfold increase in tonnage over 1935 and 34 percent over 1938. In 1937 it became a million-dollar industry, and in 1939 it rose to nearly 2 million.

Technologic developments.—Fieldner [6] states that public policy in the conservation of fuels should center on stimulation of research and wide dissemination of technological improvements. He [7] summarizes recent experimental work on fuel briquetting as follows:

> Experimental work in the United States showed that a binder of sodium silicate for anthracite culm, if modified by the addition of silicic acid gel, gave much greater resistance to disintegration by water.[8] Some Alabama lignites were successfully briquetted experimentally without a binder by preheating to 900° F., adding 8 percent water, and pressing at 13,500 pounds per square inch for 30 seconds.[9] Not all Alabama lignites could be so treated with like results, but with modification of the preheating and pressing treatments they gave satisfactory results. In Germany one of the large briquet plants, at the Hohenzollern mine at Beuthen, Upper Silesia, by using the Fohr-Kleinschmidt process, has reduced the amount of pitch required, eliminated cancer among the workmen, and made stronger briquets. Soft molten pitch instead of the powdered hard pitch previously used is atomized and sprayed under a pressure of 20 atmospheres on the coal, which has been preheated to 50° to 60° C.[10] At another plant an automatic apparatus for continuously recording the moisture content of coal for briquetting was installed; this is measured by means of variations in the capacity of an electrical condenser.[11] The principal factors affecting the mechanical strength and stability of brown-coal briquets and modern methods of manufacture are receiving special attention in Germany in view of the use of such carbonized briquets for the production of synthesis gas used in the manufacture of liquid fuels by the Fischer-Tropsch method.[12] Differences in the capillary networks of different coals have been found to influence the strengths of the briquets.[13] The nature of the capillary network is determined by vapor-pressure measurements. Trials of compounds of calcium, magnesium, barium, etc., mixed with coal in briquets for the purpose of fixing sulfur and preventing its emission during combustion showed that barium oxide was the best fixing agent.[14] The Canadian Department of Mines has published a comprehensive review of fuel briquetting which includes history, processes, binders, and the results of experimental work.[15]

The General Assembly of Illinois appropriated $85,000 in 1937 to demonstrate the feasibility of the Piersol [16] process of making smokeless

briquets on a commercial scale from Illinois coals. A further appropriation of $95,000 was allotted for an applied research laboratory. The laboratory is expected to be completed by September 1940, and demonstrations of briquetting by the Piersol process are scheduled immediately thereafter. Comments on these proposed experiments have appeared in the various trade journals.[17]

A new type of briquet for heating orchards has been patented under the name of "Briquette Frost Fighter;" [18] this is unique in that the "briquette" is manufactured complete with container and kindling charge, making it immediately available in emergencies. Another advantage claimed is elimination of refilling—as the entire container, except the metal cover, is consumed, thus eliminating the necessity of refilling and considerably reducing labor costs. It is understood that plans are already under way for the construction of a plant for making these briquets on the Pacific coast.

Smoke tests [19] of packaged fuel made from high-volatile bituminous screenings from various sources are said to indicate a considerable reduction in smoke. Some of these experiments have been made with the thought of furnishing an answer to the smoke problem of St. Louis and other cities.

FUEL BRIQUETS

The salient statistics of the fuel-briquetting industry from 1935 to 1939 are summarized in the following table. Similar data for earlier years are to be found in annual issues of Mineral Resources and Minerals Yearbook, which include chapters on briquetting, beginning with 1907.

Salient statistics of the fuel-briquet industry in the United States, 1935–39

[Data regarding packaged fuel are given separately at end of this chapter]

Year	Production: Eastern States	Production: Central States	Production: Pacific Coast States	Production: Total	Imports	Exports[1]	Consumption[2]	Value of production (thousands of dollars)	Plants in operation	Average output per plant (thousands of net tons)	Average value per net ton, f. o. b. plant: Eastern States	Central States	Pacific Coast States

[1] Exports not reported separately by Bureau of Foreign and Domestic Commerce prior to 1937.
[2] Production plus imports minus exports.

Production.—The production of fuel briquets in 1939 showed a total increase in tonnage of 2 percent for the entire country, principally in the Central States, where the production was 5 percent greater than in 1938 although there were fewer plants operating in 1939 in this region. This increase is notable when it is realized that 1939 temperatures averaged above normal yearly everywhere in the

United States. Of the 16 States producing fuel briquets in 1939, all but 4 showed increases in production despite the fact that 4 less plants were operating than in the preceding year.

Reports received by the Bureau also indicate that several plants expect to start operations in 1940 or 1941.

A few fuel-briquet operators, making pillow and cube briquets, are selling part or all of their product in bags or cartons as an experiment; some 6,000 tons was so marketed in 1939. One operator re-

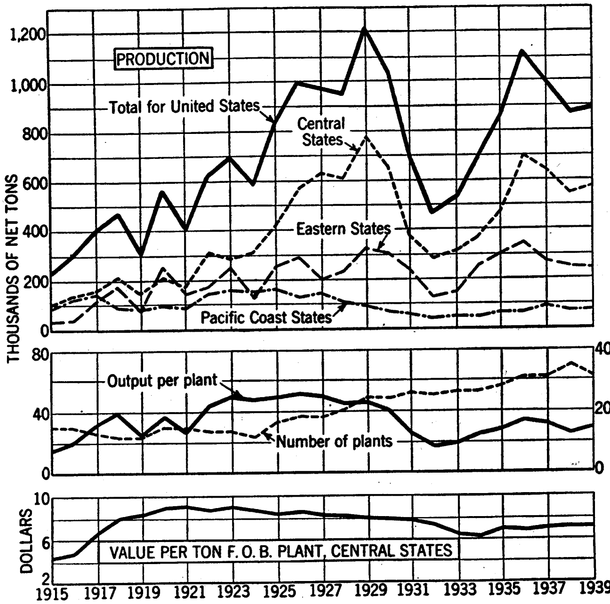

FIGURE 1.—Production of fuel briquets, number of plants in operation, and average value per ton, f. o. b. plant (Central States), 1915–39.

ported that his experiment in bagging briquets had not proved successful, owing to deterioration of the bags by mildew.

Fuel briquets produced in the United States, 1938–39

	1938			1939				
	Plants	Net tons	Value	Plants	Net tons	Value	Percent of change in— Tonnage	Percent of change in— Value
Eastern States	4	251,443	$1,090,055	4	243,429	$1,028,852	−3.2	−5.6
Central States	25	545,848	3,917,936	21	574,108	4,103,496	+5.2	+4.7
Pacific Coast States	6	73,969	693,899	6	74,676	669,318	+1.0	−3.5
	[1] 35	871,260	5,701,890	[1] 31	892,213	5,801,666	+2.4	+1.7

[1] 1938: 10 plants in Wisconsin; 3 each in Minnesota, North Dakota, and Washington; 2 each in California, Michigan, Nebraska, and West Virginia; and 1 each in Arkansas, Illinois, Massachusetts, Missouri, Ohio, Oregon, Pennsylvania, and Wyoming; 1939: 10 plants in Wisconsin; 3 in Washington; 2 each in California, Minnesota, Nebraska, and West Virginia; and 1 each in Arkansas, Illinois, Massachusetts, Michigan, Missouri, North Dakota, Ohio, Oregon, Pennsylvania, and Wyoming.

Wisconsin again produced about half of the annual output; the 10 plants in this State, 1 in Pennsylvania, and 2 in West Virginia produced 76 percent of the total tonnage of the country.

Fuel briquets produced in Wisconsin, 1934–39

Year	Plants	Net tons	Value	Year	Plants	Net tons	Value
1934	5	329,942	$2,174,168	1937	10	507,462	$3,639,183
1935	6	410,715	2,986,847	1938	10	422,281	3,085,873
1936	9	588,163	4,178,981	1939	10	430,554	3,158,859

In Washington 3 plants produced a total of 20,067 tons valued at $153,202. Output for each of the other 14 States producing briquets in 1939 cannot be published, as to do so would reveal operations of individual companies. However, in relative order of importance the States producing more than 20,000 tons in 1939 are Wisconsin, West Virginia, Pennsylvania, Oregon, Missouri, North Dakota, Minnesota, and Washington.

Monthly production of fuel briquets in the United States, 1937–39, in net tons

Month	1937	1938	1939	Month	1937	1938	1939
January	140,969	141,397	113,698	August	43,389	51,098	57,267
February	92,816	79,414	99,195	September	87,153	78,128	78,012
March	47,872	36,556	58,840	October	128,266	87,446	113,315
April	36,541	28,806	34,001	November	113,809	99,651	89,465
May	71,077	49,599	51,384	December	135,894	120,351	83,579
June	57,936	61,531	71,273				
July	40,208	37,283	42,184		995,930	871,260	892,213

January and October were the months of highest production in 1939, but the output did not fluctuate as markedly from month to month as in former years. Production in October normally is high in anticipation of winter demand; the marked decreases in November and December are directly traceable to the abnormally warm winter weather, particularly in the north-central sections, where departures from normal were as high as 13.7°. Of the 31 active plants, 18 operated every month in the year, 10 between 8 and 11 months, and 3 less than 5 months.

Value.—The sales realizations on briquets in the scattered producing centers in a given year vary considerably. An average value per ton for the entire industry therefore is of doubtful significance because of the different conditions under which briquets are manufactured in various parts of the country. The most important factors that influence the value per ton at any plant are probably cost of raw materials and prices of competing fuels. Hence, the general trend of fuel-briquet prices [20] from year to year is indicated best in this review by the average values in the Eastern, Central, and Pacific Coast States, as shown in the last three columns of the foregoing table of salient statistics.

These figures are not the prices paid by the consumers. Some plants are distant from the markets they serve, and to the value at

[20] Retail fuel-briquet prices for certain cities are issued by the Retail Price Division, Bureau of Labor Statistics, Department of Labor, Washington, D. C., in their releases entitled "Retail Fuel Prices by Cities."

the plant must be added transportation charges and the margin of the wholesaler or retailer, sometimes both.

The total value of fuel briquets manufactured in 1939 was $5,801,666 f. o. b. plant, an increase of $99,776 or 2 percent compared with 1938.

In the eastern part of the country the average value of $4.23 per ton is relatively low because the entire output comes from plants in the low-volatile bituminous fields of West Virginia and in the anthracite region of Pennsylvania, where the freight charges are not an important item in the cost of the raw fuel. In the Central States most of the raw fuel comes from the Lake docks, and the average value of $7.15 per ton reflects the freight charges. In the Pacific Coast States, where carbon residue from the manufacture of oil gas forms the greater part of the raw fuel used, the average value dropped from $9.38 in 1938 to $8.96 in 1939.

Number of plants.—Thirty-one plants reported commercial production in 1939; of these, one (in Michigan) reported for the first time. A plant in Minnesota, idle for several years, resumed operations in December. Three plants—one in Texas (in experimental operation in 1939), one in Minnesota, and one in North Dakota—expect to start commercial operations in the near future.

Fifteen plants were idle in 1939; 9 of these were also idle in 1938. Five went out of business in 1939, although one was active part of the year.

Size of plants.—The following table classifies the plants according to actual production as well as actual capacity; however, a better indication of the size of the plants is gained from their capacity, even though the latter is affected by seasonal variations in production.

The total annual capacity of the 31 active plants operating in 1939, as reported by the operators, is 3,161,000 net tons, well over three times the 1939 production of 892,213 tons.

Although fewer plants operated in 1939, the output of the individual plants generally increased. Eighteen plants, which operated every month in the year, produced 765,330 tons or 86 percent of the total production.

Classification of briquetting plants in the United States, 1938–39, by size of output and annual capacity

Output (net tons)	Plants		Annual capacity (net tons)	Plants	
	1938	1939		1938	1939
Less than 2,000	11	6	Less than 5,000	3	2
2,000 and less than 5,000	4	2	5,000 and less than 10,000	5	3
5,000 and less than 10,000	5	6	10,000 and less than 25,000	8	6
10,000 and less than 25,000	5	8	25,000 and less than 100,000	12	13
25,000 and less than 100,000	8	6	100,000 and less than 200,000	2	2
100,000 and over	2	3	200,000 and less than 400,000	3	3
			400,000 and over	2	2
	35	31		35	31

Raw fuels.—The briquetting process is now applied to a wide variety of raw fuels ranging from North Dakota lignite (after carbonization at low temperature) to Pennsylvania anthracite, petroleum coke, and the carbon residues of oil gas and natural gas.

In the Eastern States low-volatile bituminous slack and Pennsylvania anthracite fines are the raw fuels used in briquet manufacture. Plants in the Central States use virtually all the fuels, their selection depending on their availability to the point of manufacture.

In the Pacific Coast States petroleum coke and the carbon residues from the manufacture of oil gas and from the pyrolysis of natural gas are the raw fuels now used. In previous years considerable bituminous coal was used in this region, particularly by the Pacific Coast Coal Co. of Seattle, Wash., which had been engaged in briquet manufacture from 1914 till May 1939, when it closed its plant permanently. The operations of this plant at one time reached an annual tonnage of over 100,000 tons.

The decrease in briquetting operations in the Pacific Northwest during the past 20 years may be attributed to changing conditions in the fuel market owing to the consumer trend toward cheaper grades of coal, to the introduction of coal stokers and oil burners, and to competition with new types of briquets made from oil and gas residues.

Ten operators reported washing a total of 359,605 net tons of Pennsylvania anthracite and bituminous coal before making it into briquets.

One large plant in Wisconsin reported making two kinds of briquets—one of Pennsylvania anthracite exclusively and the other a mixture of low-volatile bituminous and Pennsylvania anthracite. Another operator in Nebraska also makes two kinds—one of petroleum coke and the other of semianthracite.

Classification of fuel-briquetting plants in the United States in 1939, by kinds of raw fuel used

Kind of raw fuel used:	Plants
Anthracite or semianthracite fines exclusively	5
Mixture of anthracite and bituminous	5
Bituminous:	
Low-volatile	12
High-volatile	2
Semicoke (lignite char)	1
Mixture of petroleum coke with semianthracite	1
Residual carbon from pyrolysis of natural gas	1
Residual carbon from manufacture of oil gas	2
Petroleum coke	4
	[1] 31

[1] Two plants made two kinds of briquets; hence the sum of these items exceeds the total number of plants.

Raw fuels used in making fuel briquets in the United States, 1938–39

	Net tons		Percent of total	
	1938	1939	1938	1939
Anthracite and semianthracite culm and fine sizes	200,347	196,758	23.9	23.5
Bituminous and subbituminous slack	505,917	503,431	60.5	60.2
Residual carbons from oil-gas manufacture and natural-gas pyrolysis; petroleum coke; and semicoke (lignite char)	130,143	136,213	15.6	16.3
	836,407	836,402	100.0	100.0

The success of a briquetting plant depends largely on its location with relation to the source of the raw-fuel supply and to the consuming market for the finished product, freight rates, cost of raw fuel, and prices of competing fuels to the consumer. In 1939 the plants drawing upon the nearby Lake docks for their raw fuel produced about 450,000 tons or about half of the total output; those near coal mines, about 280,000 tons; and those near petroleum refineries and gas plants, about 100,000 tons.

Binders and recarbonization.—Asphaltic pitch continues to be the preferred binder in the briquetting of coal and petroleum coke. Two plants briquetting the carbon residue from the manufacture of oil gas and one plant using low-volatile bituminous coal used no binder. The percentage of binder by weight ranged from less than 5 to more than 9 percent; the majority of plants used 5 to 7 percent.

Partial recarbonization to drive off smoke caused by the binder was reported by one operator using Pennsylvania anthracite as raw fuel.

Classification of briquetting plants in the United States in 1939, by type and percent of binder used

Type of binder	Plants	Ratio of binder to raw fuel (by weight)	Plants
Asphaltic pitch	22	Less than 5 percent	4
Mixed pitches	2	5 and less than 7 percent	17
Petroleum asphalt	2	7 and less than 9 percent	4
Asphalt and starch	1	9 percent and over	3
Starch	1	No binder	[1] 3
No binder	[1] 3

[1] Two plants use residual carbon from manufacture of oil gas, and one uses bituminous coal as raw fuel.

Weight and shape.—In 1939 all but 2.2 percent of the total production was made in pillow-shape and cylindrically briquets weighing less than 5 ounces.

Pillow-shape briquets seem to be the most popular in the United States; 24 of the 31 active plants made briquets of this type. Of the other plants, three made large cubes, two cylindrical briquets, one 3 types—pillow, cube, and cylindrical; and one both pillow and cube.

Prevailing weight of briquets produced in the United States in 1939

Weight (ounces)	Plants	Production: Net tons	Production: Percent of total	Weight (ounces)	Plants	Production: Net tons	Production: Percent of total
Less than 2	4	55,254	6.2	5 and under 6	1	19,568	2.2
2 and under 3	12	496,773	55.7	6 and under 10	1		
3 and under 4	5	220,225	24.7	10 and under 16	--------		
4 and under 5	6	100,393	11.2	16 and under 25	4		
					[1] 31	892,213	100.0

[1] 4 plants made briquets of more than 1 size; hence the sum of the items exceeds the number of active plants.

Distribution.—In 1939 fuel briquets were shipped into 38 States, Alaska, the District of Columbia, and Canada. Wisconsin was the largest consumer of fuel briquets in 1939; other States consuming more than 50,000 tons in 1939 were, in order of importance: Minnesota, North Dakota, South Dakota, and Michigan.

Fuel briquets of domestic manufacture consumed in the United States and exported to Canada, 1938–39, in net tons

[1] As reported by the operators to the Bureau of Mines; official figures on imports and exports are given in following tables.

Imports and exports.—Imports of fuel briquets have ceased since the beginning of the war in September 1939. One shipment of 1,344 net tons, valued at $5,572, from Belgium to Massachusetts, was received in February. Exports dropped in 1939 to 12,756 net tons valued at $97,725—all but 201 tons destined for Canada.

[1] Less than 1 ton.

World production.—Owing to the war, official data for 1938 and 1939 are less complete than usual; such revisions as are possible will be made in forthcoming issues of this series.

The world production of fuel briquets in 1938 reached a high of about 65 million metric tons, of which about 51 million were produced by Germany, about 7.5 million by France, 1.7 million by Belgium, 1.3 million by The Netherlands, and about 1 million by the United States.

United States production, as compared with world production of fuel briquets, has risen from less than 0.50 percent in 1913 to nearly 1.5 percent in 1938.

World production of fuel briquets, 1935–39, by countries, in metric tons

[7] Totals incomplete, representing sum of figures given in table only.

PACKAGED FUEL [21]

Packaged fuel consists of 3- to 4-inch cubes (usually six to a package), wrapped tightly in heavy paper and sealed with gummed tape. It is made from various types of high-quality coal or coke screenings, usually mixed with a neutral binder. The majority of packaged-fuel manufacturers use shipped-in coal from the mines or Lake docks; some, however, use the accumulated screenings in coal dealers' yards and others both shipped-in and "yard" screenings.

This fuel has achieved popularity because of its cleanliness and convenience in handling and its appeal to the purchaser, who finds it

[21] For results of research and technologic developments in the fuel-briquetting and packaged-fuel industries see Technologic Developments, in first section of this report.

especially adapted to the home equipped with stoves or central heating. The success of the industry is due in no small degree to the close cooperation between the machine manufacturers and the operators.

At the request of the American Institute of Mining and Metallurgical Engineers, Ray F. Mitten,[22] of the C. M. Eberling Co., Cleveland, Ohio, reviewed briefly the packaged-fuel industry before members of the Coal Division of the Institute at its February (1940) meeting in New York City.

This industry, which began in 1932, has been canvassed by the Bureau of Mines each year since 1935. The results of these canvasses are included in the chapters on Fuel Briquets and Packaged Fuel in the Minerals Yearbooks since 1936.

The first canvass, covering 1935, revealed 25 packaged-fuel plants, which produced 25,244 net tons. The canvass for 1939 showed 103 plants in operation, with a production of 215,507 net tons valued at $1,866,751. This represents an eightfold increase in tonnage over 1935 and a 34-percent increase over 1938. The production in 1939 probably would have been even greater if it had not been for the abnormally mild winter of that year. These plants were reported to be equipped to produce an annual output of 700,000 tons.

The National Association of Packaged Fuel Manufacturers, whose membership is open to owners of all kinds of packaged-fuel equipment,[23] held several meetings in June and August 1939 in Chicago, Ill. The association plans to compile and disseminate information on technical methods and costs of manufacture of packaged fuel, general publicity, group and national advertising to broaden the field and further stimulate sales. In July 1939 the association issued a new organ called "Sales-Merchandizing Bulletin" and is pursuing an energetic program for the handling of trade problems. Late in 1939 it introduced a thermostat control, the "Packaged Fuel Comfort Regulator," for users of packaged fuel; this is being distributed by several members of the association.

Processes.—The Eberling process,[24] introduced about 5 years ago for the briquetting and wrapping of slack or screenings with a starch binder and further described in previous reports of this series, was used by 85 operations in 1939. This type of briquet is adapted primarily for local consumption. The processes used by the other operations are described briefly in the following paragraphs.

The Johnson Coal Cubing Co.,[25] of Detroit, Mich., uses a process and equipment of its own design, producing cubes bearing the trade-mark "Koal Pak," eight to a package, wrapped in heavy paper; in 1939 it also produced pillow-shape fuel briquets in bulk known as "Black Knight Fire Quets."

In the Glenn Smith process,[26] used in the manufacture of both bulk briquets and packaged fuel, the heated mixture of raw fuel and liquid binder is poured into molds under very high pressure. The resulting cubes are cooled on a conveyor that feeds them to the wrapping machine; this automatically wraps and labels the packages (eight

cubes to each package). Packaged-fuel operators using this process in 1939 sold part of their product unwrapped. A similar installation, completely automatic throughout, was completed in 1939 for the Cleveland Cliffs Iron Co. at Green Bay, Wis.; [27] commercial operations are scheduled for January 1940. This process also is used by four fuel-briquet companies in the Central States.

The Leemon process [28] was introduced commercially in 1939 by 13 packaged-fuel operators in Michigan, Wisconsin, and Ohio. Equipped with a mixture of slack and volatile binder, the machine produces under tremendous pressure 3- to 4-inch cubes, which are wrapped six to a package, averaging 190 to 200 packages to the net ton.

Production and value.—The 103 plants, most of them in the Central States, produced 215,507 net tons of packaged fuel in 1939. Michigan again led in tonnage, the number of plants in operation increasing from 21 in 1938 to 41 in 1939. Ohio, Wisconsin, and Minnesota followed in order.

Packaged fuel produced in the United States, 1938–39, by States

[The plants and production in this table are not included in the preceding fuel-briquet tables]

State	1938			1939		
	Plants	Net tons	Value	Plants	Net tons	Value

[27] Retail Coalman, vol. 76, No. 1, January 1940, pp. 14–15; Black Diamond, vol. 104, No. 3, February 10, 1940, pp. 14–15.
[28] Black Diamond, vol. 102, No. 12, June 17, 1939, p. 15.

Number of plants.—There were 103 active packaged-fuel operations in 1939, of which 29 reported for the first time; 13 of the new operations started in the fall of the year. All but one of the new plants are in the Central States. Several of the smaller operators reported using their plants only to utilize accumulated yard screenings and to take up labor slack.

Eleven plants were idle in 1939 (eight of these were also idle in 1938). Nine companies—all in the Central States—went out of business in 1939; of these, seven sold their equipment to new entrants in this field and one is experimenting in research work on binders.

Five additional plants were under construction in 1939 and expect to start commercial operations in 1940.

Size of plants.—Eighty-five plants produced less than 3,000 tons each during the year. A number of plants, however, produced a considerably larger tonnage, the Johnson Coal Cubing Co., of Detroit, Mich., leading with the highest recorded production since 1937.

Reports submitted on individual capacities indicate that the 103 active plants were equipped to produce about 700,000 tons if operated at full capacity throughout the year.

Classification of packaged-fuel plants in the United States, 1938–39, by size of output and annual capacity

Output (net tons)	Plants		Annual capacity (net tons)	Plants	
	1938	1939		1938	1939
Less than 500	17	[1] 28	2,000 and less than 5,000	38	58
500 and less than 1,000	14	18	5,000 and less than 10,000	26	31
1,000 and less than 3,000	30	39	10,000 and less than 15,000	6	5
3,000 and less than 5,000	10	10	15,000 and less than 25,000	2	5
5,000 and less than 10,000	3	6	25,000 and less than 40,000	3	3
10,000 and less than 25,000	1	1	40,000 and less than 60,000		
25,000 and over	1	1	60,000 and over	1	1
	76	103		76	103

[1] Thirteen of these are new plants, which started operations in the fall of 1939.

Raw fuels.—Low-volatile bituminous slack (194,023 net tons) was the principal raw fuel used by 93 operators; 18,018 tons of petroleum coke, high-volatile bituminous, Oklahoma semianthracite, and Pennsylvania anthracite were used by the other operators, several reporting the use of mixtures of these various fuels.

The use of shipped-in slack from the mines and Lake docks by the majority of the operators appears to be definitely established, its exclusive use being reported by 60 operators; however, 26 plants used both shipped-in slack and yard screenings; and 17 plants utilized only yard screenings.

Binders.—Cornstarches, averaging about 15 pounds per ton of packaged fuel produced, are the principal binders. Eight plants reported the use of cement, asphalt, or glue; one, starch and cement; and one, starch and asphalt.

Several operators indicated an interest in obtaining more effective and cheaper binders.

PEAT

By Joseph A. Corgan and A. L. Richardson

SUMMARY OUTLINE

The total production of peat in the United States in 1939, as reported by producers to the Bureau of Mines, was 55,483 short tons valued at $362,066—a substantial increase over 1938, when 45,933 tons valued at $286,127 were produced. Imports of peat moss in 1939 amounted to 78,611 short tons valued at $1,204,883, an increase over 1938 of approximately 13 percent in quantity and 11 percent in value. No exports were reported. Thus, the total quantity available for domestic consumption in 1939 (domestic production plus imports) was 134,094 tons, a gain of 18,652 tons compared with 1938. In this country peat is used primarily for soil improvement. As in past years, producers reporting in 1939 showed no record of the use of peat as fuel.

Every effort has been made to cover all commercial operations. A list showing the names and addresses of operators who reported production in 1939 to the Bureau of Mines has been prepared and will be furnished upon request to those who may be interested.

Reserves.—The known peat reserves in the United States are extensive. The total, calculated as air-dried peat, has been estimated to be 13,827,000,000 short tons,[1] centered chiefly in the Great Lakes region, in New England, and in the Atlantic and Pacific Coast States. Three of the Great Lakes States—Minnesota, Wisconsin, and Michigan—together contain 75 percent of the reserves, while 14 percent of the country's total is in Florida. In the Pacific Coast region, California contains most of the known deposits.

About half of the States in the Union contain some peat reserves. All are not workable and vary in composition and characteristics. Taken together, however, they constitute an important asset to the natural resources of the country.

Production.—Commercial production of peat in 1939 was reported by 39 producers, in 15 States. As the following table indicates, the total output was 55,483 short tons valued at $362,066—an increase over 1938 of 21 percent in quantity and 27 percent in value. The average per-ton value, at the plant, in 1939 was $6.53, while in 1938 it was $6.23. The trend of peat production and value from 1908 to 1939 is shown graphically in figure 1.

[1] Soper, E. K., and Osbon, C. C., The Occurrence and Uses of Peat in the United States: Geol. Survey Bull. 728, 1922, p. 92.

Peat produced in the United States, 1935–39

Year	Short tons	Value	Year	Short tons	Value
1935	37,060	$199,377	1938	45,933	$286,127
1936	46,126	266,883	1939	55,483	362,066
1937	51,223	305,156			

The producing States, in order of output, were: New York, New Jersey, Michigan, California, Connecticut, Florida, Iowa, Ohio, Maine, Colorado, Minnesota, Washington, Pennsylvania, Massachusetts, and New Hampshire.

Peat humus comprised 51 percent of the total production; reed or sedge peat, 38 percent; and peat moss and other, 11 percent. Peat humus was produced in 10 States, reed or sedge peat in 7 States, and peat moss in 6 States.

One plant reported production of kiln-dried peat, 1 of air-dried peat, 8 of cultivated peat, 28 of shredded peat, and 17 of raw peat.

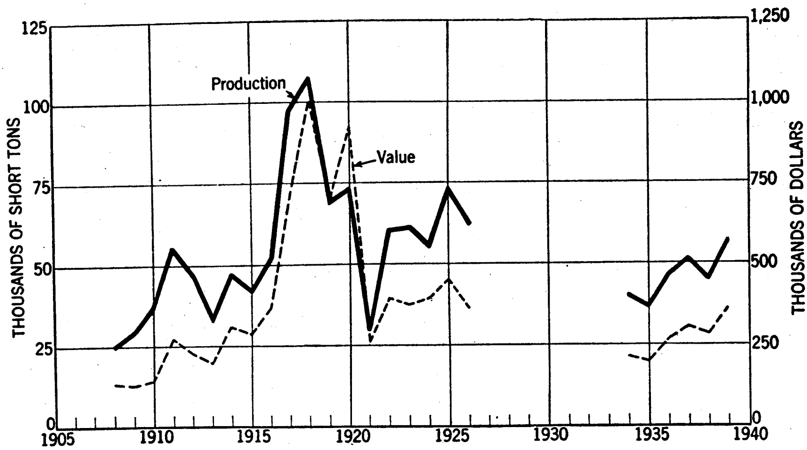

FIGURE 1.—Quantity and value of peat production, 1908–39. No data are available for the period 1927–33.

Uses.—The principal use of peat in the United States is for improving soil. Of the sales in 1939, 90 percent (41,964 tons) was used for this purpose. Two percent of the sales went for mixed fertilizers and 8 percent for other uses, such as improving lawns and golf courses, and in nurseries and greenhouses. Peat also is used as litter for barns; as packing material for plants, eggs, shrubs, vegetables, fruits, and fragile articles; and as an insulating material. No sales of peat for fuel were reported. In European countries, especially in Eire, peat is used extensively for fuel and power purposes, owing to lack of a plentiful supply of other fuels. In this country, with its ample supplies of higher-grade fuels available at reasonable cost, peat has been unable to compete successfully in the fuel market.

United States Government specifications.—There is a great difference in the kinds of peat, both in character and value, for specific uses. In purchasing its peat requirements, the Federal Government has certain specifications that must be met. These are shown below: [2]

Peat.—Reed muck or sedge muck (peat humus); dark brown to black; granulated; uniform in composition and size; slightly acid to slightly alkaline in reaction (pH 5.0 to 7.5); free of lumps; low in ash content (8 to 15 percent); low in content of woody material, and mineral matter such as sulfur and iron; water-absorbing capacity ranging from 100 to 350 percent; water content not to exceed 60 percent by weight on oven-dried basis; moisture content in excess of 60 percent may be accepted, but settlement will be made on basis of weights corrected to 60 percent moisture content.

Reed peat or sedge peat; brown; raw, shredded or granulated; low ash content (5 to 10 percent); low in mineral material such as iron and sulfur; low in content of woody material; water-absorbing capacity ranging from 350 to 800 percent; water content not to exceed 50 percent by weight on oven-dried basis; if satisfactory in other respects, moisture content in excess of 50 percent may be accepted, but settlement will be made on basis of weights corrected to 50 percent moisture content: Acid grade; reaction may vary from 4.5 to 5.5 pH; slightly acid to slightly alkaline grade, reaction may vary from 5.5 to 7.5 pH.

Imports.[3]—The quantity of peat moss imported in 1939 was 78,611 tons, an increase over 1938 but 10 percent less than the record year 1937, when 86,871 tons was imported. Germany, as for many years in the past, was the chief source of imports, supplying 28,127 tons (36 percent of the total). It should be noted, however, that in 1936 and 1937 Germany contributed 60 and 61 percent, respectively, of our total peat imports. The Netherlands was next in order of importance, with 17,824 tons, a gain of 166 percent over 1938. Sweden and Canada were third and fourth.

Peat moss was imported into Continental United States through 27 customs districts, indicating the wide distribution of its use in this country. The New York district received 25 percent of the total imports.

For the first time in several recent years, the average per-ton value of imported peat moss has declined from the preceding year. It was $15.33 in 1939 compared with $15.72 in 1938, evidently owing to the decrease in imports of German peat, whose reported value is comparatively high, and the increase in supplies from the Netherlands, which are lower in value. The average value varies considerably with the country of origin.

Peat moss imported for consumption in the United States, 1935–39

Year	Short tons	Value	Year	Short tons	Value
1935	54,547	$677,513	1938	69,509	$1,092,942
1936	75,066	955,807	1939	78,611	1,204,883
1937	86,871	1,219,127			

[2] Procurement Division, General Schedule of Supplies, Agricultural Implements and Materials (Class 70), for the period Nov. 1, 1939, to Oct. 31, 1940, prepared under direction of the Secretary of the Treasury, Washington, D. C., p. 5.

[3] Figures on imports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Peat moss imported for consumption in the United States, 1938–39, by countries

Country	1938		1939

	69, 509	1, 092, 942	78, 611	1, 204, 883

[1] For statistical purposes, trade with Danzig and that part of Poland occupied by Germany has been included with Germany and trade with that part of Poland occupied by U. S. S. R. has been included with U. S. S. R., after Nov. 16, 1939.

World production.—The following table would seem to indicate that the world production of peat is increasing. Several countries show a material increase since 1936. Complete data regarding world production of peat are difficult to obtain. Some countries evidently do not have information on quantities produced. The data in this table are the latest available and may be of interest to those concerned with world production of peat.

World production of peat, 1936–38, by countries

[1] In addition to the countries listed Argentina, Austria, Germany, Hungary, Norway, and Poland produce peat, but data of production are not available.
[2] About 60 percent of the farmsteads in the country depend entirely on peat fuel, the annual consumption of which is estimated at 6 to 8 million tons. About 50,000 tons of peat-moss litter and peat mull are manufactured annually in Eire, and some 10,000 tons of air-dried turf are used annually for power purposes. (The Mineral Position of the British Empire, London, 1937, p. 30.)
[3] Data not available. [4] Estimated.

CRUDE PETROLEUM AND PETROLEUM PRODUCTS[1]

By A. G. White, G. R. Hopkins, and H. A. Breakey

SUMMARY OUTLINE

World production of crude petroleum increased to 2,077 million barrels in 1939, a gain of 89 million barrels compared to 1938 and 38 million above the previous peak, attained in 1937.

The domestic petroleum industry improved in all its principal branches during 1939. Production of crude petroleum increased by 50 million barrels, but the relative position of the United States remained virtually unchanged at 61 percent of the world total. However, owing to a decrease of some 37 million barrels in domestic crude stocks, the available supply of domestic crude oil was relatively greater than the production figures would indicate.

The principal changes in world production in 1939 outside of the United States were an increase of 18 million barrels in Venezuela, a 4-million-barrel gain in Netherland India, and an increase of 8 million barrels in Soviet Russia. Production in Rumania continued to decline and was 15 million barrels less in 1939 than in 1935. Production in Mexico increased by over 4 million barrels, although it was still substantially below the 1937 level. The completion of new pipe lines in Colombia and eastern Venezuela promises to increase the production of these countries substantially in 1940.

The tremendous expansion in world oil production since 1914–18 has materially altered the character and sources of world supply. Russia and Rumania are still the chief producers in Europe, but other available sources have expanded. In 1914 war requirements had to be met mainly from the United States and Mexico, with the newly developed Persian fields furnishing minor amounts. Today Venezuela, Colombia, Trinidad, Iran (Persia), Iraq, Bahrein Island, and Saudi Arabia offer greatly augmented supplies.

[1] Data for 1939 are preliminary; detailed statistics with final revisions will be released later.

The opening of the European war in September 1939 had less effect on the oil industry of the United States than was anticipated. Industrial operations in the last quarter were stimulated by a rush of domestic orders to anticipate any war inflation in costs and prices, and this situation was evidenced by a very active fuel-oil market. The comparatively small decrease in total exports in 1939 was due primarily to reductions in crude exports earlier in the year. Possibly the most significant factor was that large foreign war demands did not materialize as many had anticipated and that refinery operations proved to be too optimistic and resulted in a large excess production of gasoline in the last quarter, although additions to fuel-oil stocks proved inadequate.

Operations during the first quarter of 1940 have, however, clarified the complexity of the changes in world oil consumption and in the sources of world oil supply in relation to our foreign trade in oil. World consumption of oil products has expanded so universally that much of the increase in war demands apparently may be met by restrictions of civilian consumption. Furthermore, important markets were cut off by blockade, and consumption in many neutral countries was reduced by scarcity of tankers and by a severalfold rise in tanker rates that increased the delivered cost of oil 2 to 3 cents per gallon. Legislative restrictions affecting credit and movement of American registry ships into the war zones have tended to divert the demand for oil to Caribbean sources, where new production in both Venezuela and Colombia has become available. As a result of these varied influences, our total oil exports were over 9 million barrels (23 percent) less in the first quarter of 1940 than in the same period of 1939.

The trend of domestic demand in the first quarter of 1940 also is significant in interpreting oil-industry operations during 1939. The lack of balance in the last quarter between refinery production and yields of gasoline and distillate fuel oils on the one hand and demand on the other resulted in an increase of over 11 million barrels for the year in gasoline inventories. This situation was accentuated further by unusually cold weather in the first quarter of 1940. All sources of heating-oil supply were strained to the utmost, including larger runs to stills, and on March 31, 1940, total inventories of finished and unfinished gasoline reached the all-time peak of 103.7 million barrels—16.6 million barrels above the level of the previous year. The proper seasonal balance between production of gasoline and heating oil and stocks has become one of the most acute problems of the industry and probably was the most important disturbing factor in 1939, a record year in the total demand for oil products.

The total demand for all oils in 1939—1,418 million barrels—set a new record some 87 million barrels above that in 1938 and 75 million above the previous high in 1937. Total exports—189 million barrels—were 5 million barrels less than in 1938 but still 16 million above 1937. The major factor in 1939 was the 8-percent increase in the domestic demand for all oils, which rose to 1,229 million barrels—92 million barrels greater than in 1938 and 59 million above the previous peak in 1937.

Total demand for all oils 1930–39

[Millions of barrels]

Year	Domestic demand	Exports	Total demand	Year	Domestic demand	Exports	Total demand
1930	926.4	156.5	1,082.9	1935	983.7	129.0	1,112.7
1931	903.2	124.4	1,027.6	1936	1,092.7	132.0	1,224.7
1932	835.5	103.3	938.8	1937	1,169.7	172.8	1,342.5
1933	868.5	106.7	975.2	1938	1,137.1	193.7	1,330.8
1934	920.2	114.5	1,034.7	1939 [1]	1,228.8	189.0	1,417.8

[1] Subject to revision.

Total stocks of all oils were reduced by over 42 million barrels—from 567 million at the close of 1938 to 525 million at the end of 1939. The major factor in this decline was the reduction of about 34 million barrels in refinable domestic crude stocks, caused primarily by a 2-week curtailment in State production allowables for the first half of August in the more important States east of California that had proration laws.

The total stocks of all oils probably were close to an economic minimum at the end of the year, although stocks of specific products were out of balance in some districts. A large excess of fuel-oil stocks, accumulated in 1938, remained unliquidated in California, while such stocks were relatively low east of California. Stocks of finished and unfinished gasoline generally were considered excessive and increased by over 11 million barrels during the year. Of this increase, 3 million were accumulated in California and over 8 million in districts east of California.

[1] Subject to revision. [2] 42 gallons. [3] As reported to the Bureau of Mines.
[4] Bureau of Foreign and Domestic Commerce; exports include shipments to Alaska, Hawaii, and Puerto Rico.
[5] California heavy crude and fuel oil included under refined products.
[6] For comparison with succeeding year. [7] Figures not available. [8] Estimated.
[9] American Petroleum Institute. [10] Dealer's net; comparable tank-wagon prices no longer available.

The domestic production of crude petroleum in 1939—1,264 million barrels—was supplemented by the importation of 33 million barrels of foreign crude and a reduction of 38 million barrels in the stocks of all crude oils. The resultant figure shows a total demand for all crude oils of 1,335 million barrels, comprising 72 million for export and 1,263 million for domestic requirements. As 5 million barrels less crude were exported in 1939 than in 1938, the increase in domestic demand was about 70 million barrels. The total demand for California crude oil being 228 million barrels—12 million less than in 1938—the increase in the demand for crude produced east of California and imported was 77 million barrels. The outstanding domestic factor, as regards sources of supply, was an increase of 66 million barrels in the demand for Illinois crude, or from a total demand of 23 million in 1938 to 89 million in 1939.

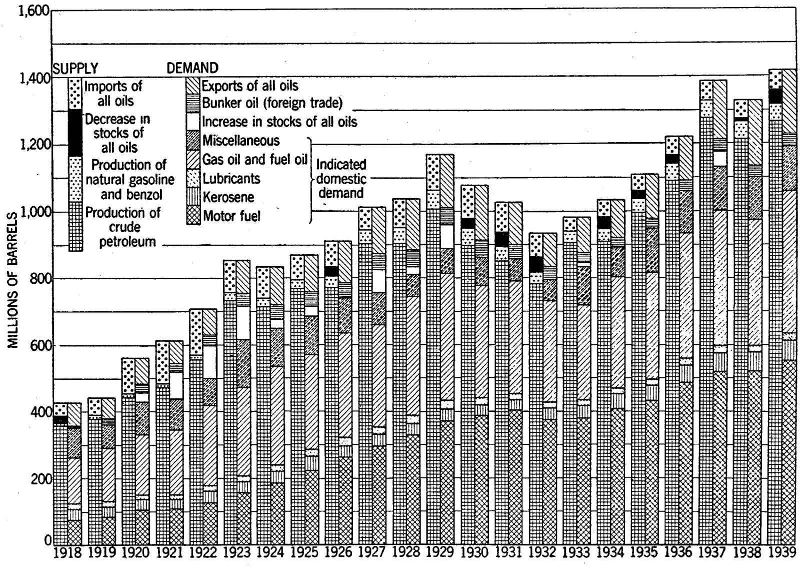

FIGURE 1.—Supply and demand of all oils, 1918–39

The total demand for motor fuel reached a new peak of 597 million barrels in 1939, an increase of 24 million barrels (4 percent). As exports declined by 5.5 million barrels, the increase in domestic demand was 29.5 million barrels (5 percent).

The total demand for distillate-fuel oils in 1939 increased to a new record of 171 million barrels. Exports increased over 2 million barrels and domestic demand by 22 million barrels. The domestic demand figure includes about 6 million barrels of transfers from crude oil and the net change in terminal stocks east of California, for which no corresponding data were available in 1938. With data for both years on the old basis, an increase of about 11 percent in domestic demand is indicated.

The total demand for residual fuel oils, including transfers from crude, increased from about 310 million barrels in 1938 to over 338 million in 1939. As exports decreased slightly, all of the gain was in domestic demand and amounted to about 29 million barrels (9 percent).

The total demand for kerosene rose from approximately 64 million barrels in 1938 to 69 million in 1939, a gain of almost 8 percent. The relative increase in exports was somewhat greater than in domestic demand. The growing demand for kerosene can be attributed largely to its uses for range oil and tractor fuel.

The total demand for lubricants increased by 16 percent, indicating a recovery from the decline in 1938 and an actual increase in demand over 1937. The export market was very strong, with an increase of about 28 percent over the previous year.

The variation in the relative rate of increase in demand for the several major products created a problem in the adjustment of refinery operations, with the net result of high gasoline inventories and low fuel-oil stocks at the end of the year.

The long-term trends in supply and demand are shown in figure 1.

RESERVES

The proved oil reserves of the United States as of January 1, 1940, were estimated at 18,483 million barrels in a report prepared by the Committee on Petroleum Reserves of the American Petroleum Institute. This estimate may be subject to later revision. It presents only the quantity of crude oil that may be extracted by present known methods from fields completely developed or drilled or explored thoroughly enough to permit reasonably accurate calculations. The following table shows the previous estimates of reserves by this committee, the data for January 1, 1935, 1937, 1938, and 1939, being final and those for 1940 preliminary.

Estimates of proved oil reserves in the United States on January 1, 1935 and 1937–40, by States [1]

[1] From reports of Committee on Petroleum Reserves, American Petroleum Institute.
[2] Final revised estimates of the amount of crude oil which may be extracted by present methods from fields completely developed or sufficiently explored to permit reasonably accurate calculations.
[3] Subject to revision.

Other estimates of reserves published by trade journals or made by individuals have been considerably above or below these estimates. The main factor of importance, however, is that the rapidly growing demand for oil products tends to offset the increase in reserves, in terms of years' supply. The known reserves of oil are smaller than for any of our other major sources of fuel and power, and future domestic supply depends more on the extent of new exploration and the rate of discovery.

LEGISLATION AND PRORATION

Several developments of national importance in the legislative field occurred during 1939. Michigan passed a proration law and joined the compact, which had included Texas, Oklahoma, Illinois (not properly registered), Kansas, New Mexico, and Colorado. Mississippi has had oil-conservation laws for a number of years, but on September 25, 1939, it issued its first proration order, which covered the Tinsley field.

State allowables and Bureau of Mines estimates of market demand,[1] compared with actual production [2] in the United States, in 1939

[1] Beginning November 1936, the State figures have been estimates of demand rather than required production as formerly; hence in comparing the demand data with actual production due regard should be given to changes in stocks by States of origin. (Changes in stocks and demand are given elsewhere in this chapter.)

[2] Comparisons of actual production with State allowables are complicated further by variations in the method of applying pipe-line deductions for B. S. and water. Thus it is believed that the allowables in Texas and California are on a 100-percent basis, in Oklahoma and Kansas on a 97-percent basis, in New Mexico on a 98-percent basis, and in Louisiana on a 99-percent basis. The bases used in reporting production to the Bureau of Mines are not definitely known, but indications are that the average for the United States is about 99 percent.

[3] Railroad Commission of Texas.

[4] Central Committee of California Oil Producers.

[5] Corporation Commission of Oklahoma. State allowable figures as shown do not include production permitted in accordance with "underage" and other special provisions of State orders.

[6] Department of Conservation, Louisiana. State allowable figures shown do not include production permitted under special orders of said Department.

[7] State Corporation Commission of Kansas.

[8] Oil Conservation Commission of New Mexico. State allowable figures as shown do not include production permitted in accordance with "underage" and other special provisions of State orders.

[9] Oil and Gas Commission.

Hearings on the oil industry before the Temporary National Economic Committee and before the Cole Committee of Congress, pursuant to H. Res. 290 and H. R. 7372, were held in 1939. A reciprocal trade agreement with Venezuela became operative late in the year. Under this treaty an import quota (5 percent of crude runs of preceding year) was assigned at half of the regular excise taxes.

The Bureau of Mines forecasts of demand by States were issued monthly throughout the year. As indicated in the table, actual production averaged about the same as the estimates of demand. The Bureau estimate of domestic demand for motor fuel in 1939 was about 0.25 percent too low, but because of the collapse of exports to Europe the estimate of total demand was about 0.5 percent too high.

EMPLOYMENT AND LABOR PRODUCTIVITY

Lower prices, less drilling, and a smaller output were the primary factors leading to a decrease in the average number of oil-field workers from 121,371 in 1937 to 117,570 in 1938. These figures include part-time workers, who averaged 12,321 and 10,120, respectively, in the 2 years.

Most of the States had fewer workers in 1938 than in 1937, Illinois and Louisiana being the chief exceptions.

The total man-hours worked was 237,857,000 compared with 239,834,000 in 1937. Estimating part-time hours as 800 for 1938, the average number of hours per week for full-time workers increased from 40.5 in 1937 to 40.8 in 1938. The labor-productivity average was influenced by the decreased production and fell from 5.33 barrels per man-hour in 1937 to 5.11 barrels in 1938.

Employment at wells, crude petroleum produced, and average output per man in the United States, 1937–38, by States [1]

CRUDE PETROLEUM

SUPPLY AND DEMAND

The increased domestic demand for refined products in 1939 not only absorbed the 50-million-barrel gain in production but caused a larger withdrawal from crude-oil stocks. The total demand for 1939 was 1,335,138,000 barrels or 5 percent above 1938. Virtually all of the gain went into the consumption of domestic crude at refineries as exports, transfers, other fuel, and losses showed minor decreases. Imports of foreign crude made a material relative gain, but the proportion to the total demand was less than 3 percent.

[1] Subject to revision. [2] As reported to the Bureau of Mines.
[3] Exclusive of changes in stocks of heavy crude in California, 1935–37. [4] California only, 1935–38.
[5] Includes 2,298,000 barrels used for industrial purposes east of California, 616,000 barrels transferred to gas oil, etc., in California, and 5,918,000 barrels transferred to residual fuel oil in California.
[6] East of California.

PRODUCTION

As indicated in figure 2, the general trend of crude-oil production in 1939 was upward; the daily average in January was 3,306,000 barrels and in December 3,704,000 barrels. The upward trend was

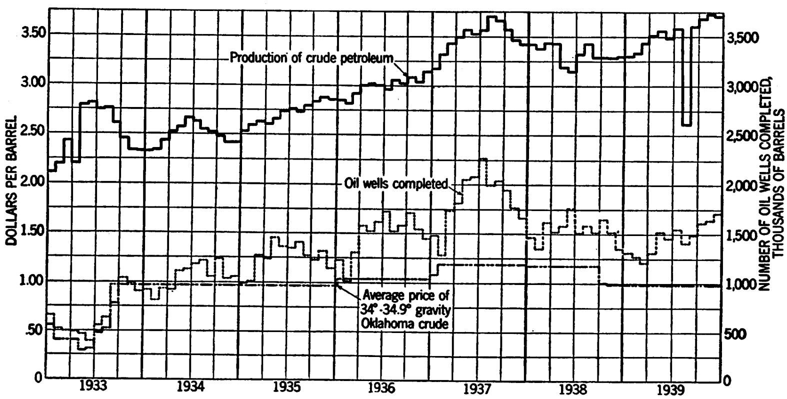

FIGURE 2.—Daily average production of crude petroleum, total number of oil wells completed, and average price per barrel of a selected grade of Oklahoma crude petroleum, 1933–39, by months.

not uninterrupted, as there was a marked slump in June (when the number of shut-down days in Texas was increased to 8) and in August, when most of the important producing States instituted a 15-day shut-down. The leading factor in the general upward trend of output in 1939 was the gain of more than 200,000 barrels in the daily average for Illinois.

About half the producing districts increased in output in 1939 over 1938. The most notable gain was that for the Illinois-Southwest Indiana district. The Gulf Coast region continued to reach new high levels. The most important decline in 1939 was in California.

Production of crude petroleum in the United States in 1939, by districts, States, and months

[2] Subject to revision.
[3] Oklahoma included with Kansas in 1905 and 1906.
[4] Includes Tennessee, 1883–1907.
[5] Figures represent 1925–39 production only; earlier years included under "Other States."
[6] Figures represent 1924–39 production only; earlier years included under "Other States."
[7] Early production in New York included with Pennsylvania.
[8] Includes Alaska, 1912–33; Arkansas, 1920; Michigan, 1900–1919; Mississippi, 1933–35, 1939; Missouri, 1889–1911, 1913–16, 1919–23, 1932–39; New Mexico, 1913, 1919–23; Tennessee, 1916–39; Utah, 1907–11, 1920, 1924–39.

The percentage of total crude petroleum produced by each of the three leading States—Texas, California, and Oklahoma—dropped in 1939, and the three States combined contributed 68.7 percent of the total, which was 5.5 percent below the combined percentage for 1938; it is noteworthy that Illinois' share rose in the same proportion, or from 2.0 percent in 1938 to 7.5 percent in 1939. Michigan and Arkansas were the only other States that made an appreciable gain in percentage.

The relative rank of the producing States is shown graphically in figure 3.

Percentage of total crude petroleum produced in the United States, 1931–39, by principal States

State	1931	1932	1933	1934	1935	1936	1937	1938	1939[1]

[1] Subject to revision.

The East Texas field easily retained first place both in production in 1939 and in total output since discovery. The Oklahoma City field, which ranked second in 1938, fell to third in 1939, being displaced by the Salem (Ill.) field.

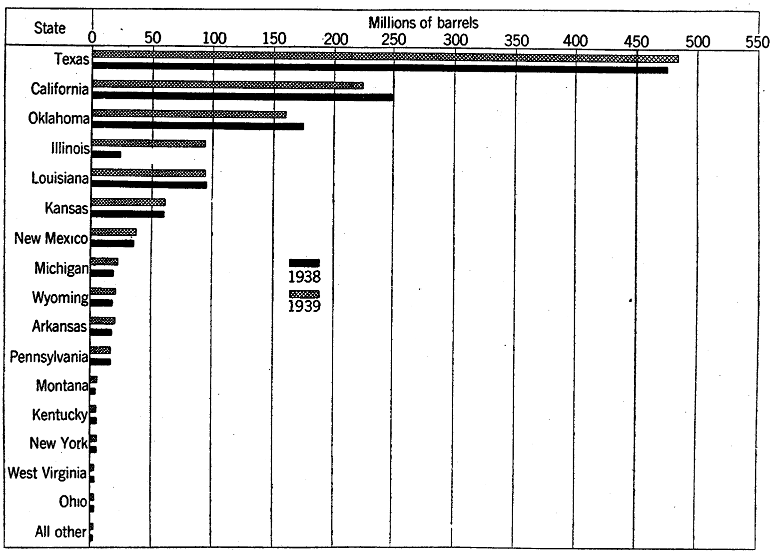

FIGURE 3.—Production of crude petroleum, 1938–39, by States.

Production of crude petroleum in leading fields in the United States, 1938–39,[1] *with total production since discovery*

[1] Oil and Gas Journal, except as noted. [2] Bureau of Mines. [3] Subject to revision. [4] Revised figures.

The production of Pennsylvania Grade oil dropped again in 1939, but the decrease was much less than in the previous year. Of the four States yielding this type of crude oil, only New York increased its output in 1939. The average price of Pennsylvania Grade oil increased about 15 cents per barrel in 1939, but the higher postings came just too late to prevent output from declining to 27,175,000 barrels in 1939 from 27,316,000 in 1938.

Pennsylvania Grade crude oil produced, 1930–39, by States

[Thousands of barrels]

State	1930	1931	1932	1933	1934	1935	1936	1937	1938	1939[1]

[1] Subject to revision.

Arkansas.—The Magnolia field of Columbia County, discovered in 1938, proved to be of major importance and yielded about 3,600,000 barrels in 1939 compared with 68,000 barrels in 1938. This gain was the principal factor in the rise in State production from 18,180,000 barrels in 1938 to 21,143,000 in 1939. The number of oil wells completed decreased from 204 in 1938 to 183 in 1939; furthermore, the average initial production of the oil wells declined materially.

Attempts to find new Smackover lime fields similar to Magnolia were continued, and two commercial discoveries were made—Dorcheat, the deepest (nearly 9,000 feet) producing field in the State, and Big Creek, a distillate field. Lewisville, the only other discovery worth noting, was a small Glen Rose field.

The Arkansas Oil and Gas Commission was established early in 1939, replacing the Arkansas Conservation Board. The commission has concentrated on proration plans in several of the newest fields, with acreage and bottom-hole pressure the dominant factors in the allocation formulas.

Production of crude petroleum in Arkansas, 1934–38, by districts [1]

[Thousands of barrels]

Year	Buckner	Champagnolle	El Dorado	Irma	Magnolia	Rodessa	Schuler	Smackover	Urbana	Village	Other	Total

[1] Figures by districts for 1939 not yet available.

California.—In 1939 production decreased in California for the first time since 1933. Although exports were materially lower, the domestic demand for all oils rose roughly 11 percent, hence a 30-million-barrel increase in stocks of all oils for 1938 was transformed into a withdrawal of several million barrels in 1939. The daily average production of crude oil in 1939 was 615,000 barrels compared with the proration "objective" of 600,000 barrels. However, as the trend in stocks indicated, efforts at curtailment were much more successful in 1939 than in 1938. The voters defeated a bill that would have established compulsory regulation.

Drilling declined nearly 15 percent from 1938, and 852 oil wells were completed compared with 993 in 1938. The successful completions in 1939 had the high average initial production of 909 barrels compared with an average of 927 barrels in 1938.

Production in all three producing districts—Valley, Coastal, and Basin—was lower in 1939 than in 1938. In the San Joaquin Valley the Canal and Coalinga fields were about the only ones where output increased in 1939. The important Kettleman Hills field slipped in production from 25,609,000 barrels in 1938 to 19,568,000 in 1939, but again ranked second to the Wilmington field in production. In the Coastal district, Ventura Avenue had an important extension, and the output was slightly above that in 1938. In the Los Angeles Basin the only important increase was in the Montebello field, where drilling was active on the edge of the structure.

New reserves discovered declined materially from 1938, but exploration was far from barren of results, as four new fields were discovered—South Mountain View (Arvin), Palima, and Strand, in Kern County; and Northeast Coalinga, in Fresno County.

Colorado.—Production in Colorado fell from 1,412,000 barrels in 1938 to 1,391,000 in 1939—a small decline compared to that in 1938. Drilling continued at a low ebb, and only seven oil wells were completed, the same number as in 1938. No new fields were discovered, but deeper sand production (in the Dakota) was found in the Fort Collins field.

Production of crude petroleum in Colorado, 1934–38, by districts [1]

Illinois.—Production in Illinois continued to rise sensationally during 1939; in 1938 it trebled, but in 1939 it nearly quadrupled. The output was 94,302,000 barrels compared with 24,075,000 in 1938. Daily average production established new records in every month except October and November.

The Salem pool (Marion County) became second only to the East Texas field as a producer in 1939. Its output was about 50 million barrels in 1939, or more than half the State total. The Louden field (Fayette County) was second with about 18,000,000 barrels.

In every month of 1939, 200 to 300 oil wells were completed in Illinois, the total for the year being 2,943 compared with 1,806 in 1938. The average initial production per well per day rose from 271 barrels in 1938 to 285 in 1939.

About two dozen new fields were discovered in Illinois during 1939. These were quite well scattered over the south half of the State, several extending the oil-producing basin much farther than had been thought possible from the standpoint of geology. One of these was the Junction pool in Gallatin County. Some of the new discoveries were in the extreme eastern edge of the State in "old" territory—for example, Griffin and Keensburg in Wabash County. In addition to new fields, important discoveries of new zones and extensions were being made continually. Most important of these was the finding of "deep" production in the Devonian formation in the Salem field late in November. Devonian production was largely responsible for the gains in output in the first quarter of 1940, although the formation "does not hold up well."

[1] Subject to revision.

Indiana.—The successful developments in Illinois and Michigan have caused a great revival of interest in the oil and gas possibilities of Indiana. In 1939, 176 oil wells were brought in compared with 46 in 1938. The production rose from 995,000 barrels in 1938 to 1,443,000 in 1939, the highest total since 1911. The Griffin field (Gibson and Posey Counties) discovered late in 1938, was the most active region in 1939. The New Harmony field (Posey County) was the most promising new discovery.

Kansas.—In 1939 the demand for Kansas crude oil continued to be influenced adversely by the expansion in Illinois, although not to the extent generally predicted. In any event drilling fell again, and 977 oil wells were brought in compared with 1,108 in 1938. Production in 1939 was 60,723,000 barrels, slightly higher than in 1938 but about 10 million barrels below the record of 1937.

In 1939, as usual, numerous discoveries were made in Kansas; the number of new fields ranges from 20 to 40, depending on whether some of the new areas are connected to older fields later. The Hittle, Bemis, Silica, and Trapp pools were among the most active in drilling in 1939. Silica and Trapp are reported to rank second and third, respectively, to Eldorado in point of proved acreage.

Three new counties—Norton, Phillips, and Sherman—were added to the producing column in 1939; Northeast Kansas shared in the Forest City basin drilling activity, but Nebraska achieved the most tangible result—a small oil well near Falls City.

[1] Oil and Gas Journal.

Kentucky.—Lower prices and Illinois competition had adverse effects on developments in western Kentucky, where most of the output is produced, and the total production fell from 5,821,000 barrels in 1938 to 5,581,000 in 1939. Only 275 oil wells were completed in 1939 compared with 484 in 1938. The eastern part of the State witnessed a revival of interest; production increased owing to repressuring, and many thousands of acres were leased, chiefly on prospects for deeper production.

Louisiana.—Production in Louisiana declined in 1939, largely because the decrease for the Rodessa field was not matched by gains in the coastal district. The output for the year was 93,869,000 barrels compared with 95,208,000 in 1938.

The output in the northern fields in 1939 was 25,403,000 barrels, about 3 million barrels less than in 1938. All of the decrease was at Rodessa, which was quiet after active years in 1937 and 1938. The Cotton Valley and Cross Lake fields were the only ones to show substantial gains over production in 1938. Cross Lake, the only important discovery during 1938, yielded 1,875,000 barels in 1939, but the output was dropping rapidly as the year closed. Drilling fell sharply in 1939 and total initial production even more. No new fields were found in the northern district in 1939, and virtually all deep test wells, particularly the deepest (11,419 feet)—that at Pine Island (Caddo)—were disappointing.

The coastal district continued to set new production records; in 1939 the output was 68,466,000 barrels compared with 66,630,000 in 1938.

A dozen or more new fields were discovered in the Louisiana Gulf coast in 1939, in addition to numerous extensions. The Eola field, Avoyelles Parish, was the most interesting of the new discoveries. The Ville Platte and University fields were extended and made rapid gains in output. The Jennings field retained its top rank, although its production slumped rapidly in the latter half of the year.

[3] Leeville includes New Iberia.

Michigan.—Production in Michigan reached a new peak of 22,799,000 barrels in 1939 compared with the previous record of 18,745,000 barrels in 1938. Prices improved materially, with the result that drilling increased; 813 oil wells were completed in 1939 compared with 566 in 1938. The most active fields were Walker, Kent County, and Bloomingdale, Van Buren County. The Freeman-Redding (Temple) field in Clare County assumed the rank of the leading field, displacing Buckeye.

In spite of active wildcatting, few discoveries were made; the two most promising were the Bangor field in Van Buren County and the Wyoming Park field in Kent County. New reserves discovered increased over 1938 but did not equal production, hence net reserves declined.

A new conservation law was passed, and the first order thereunder became effective June 1. Under this law new wells are prorated, but as the wells generally decline rapidly actual curtailment is limited to the newest fields.

Production of crude petroleum in Michigan, 1934–38, by districts [1]

[Thousands of barrels]

[1] Figures by districts for 1939 not yet available. Data from Department of Conservation, Michigan.

Mississippi.—Mississippi, which produced a few thousand barrels of low-grade oil from the edge of the Jackson gas field some years ago, really entered the ranks of the oil-producing States in 1939 with discovery of the Tinsley field, Yazoo County. By the close of the year nine oil wells had been brought in, and interest in the area was at a high pitch. The output for 1939 was 107,000 barrels.

Missouri.—Interest in Missouri, particularly in the northwest corner, was stimulated by the discovery of oil near Falls City, Nebr., but the production, all from the stripper area south of Kansas City, remained several thousand barrels monthly.

Montana.—Although the producing branch of the industry in Montana appeared to have had a very successful year in 1939, with the output increasing about a million barrels, no new discoveries of importance were made, and reserves declined. The output was 5,961,000 barrels (second only to 1926) compared with 4,946,000 in 1938. There were 114 oil wells completed, compared with 69 in 1938. Most of the 1939 completions were in or near the Cut Bank field, which was extended several times.

Production of crude petroleum in Montana, 1934–38, by districts [1]

[1] Figures by districts for 1939 not yet available. [2] Included under "Other districts."

Nebraska.—Leasing activity in the Forest City Basin in the extreme southeast corner of Nebraska yielded a discovery well near Falls City, rated at 130 barrels daily. The well decreased rapidly in output but produced about 2,000 barrels before the close of the year.

New Mexico.—Although production in New Mexico increased from 35,759,000 barrels in 1938 to 37,323,000 in 1939, it failed to attain the peak of 38,854,000 barrels achieved in 1937. The Eunice and Monument fields (Lea County) continued to be the leading producing areas. A gain for the Vacuum field was an important factor in the rise in total output in 1939 over 1938. Several new fields were discovered; of these the Loco Hills field, Eddy County, was the most promising. The light-oil area in the northwest corner of the State was quiet, with little activity outside the Rattlesnake field.

Production of crude petroleum in New Mexico, 1934–38, by districts [1]

[Thousands of barrels]

Year	Artesia	Hobbs	Hogback	Lea [2]	Rattlesnake [3]	Total

[3] Includes Aztec and Table Mesa in 1934–35; Aztec, Bloomfield, Red Mountain, and Table Mesa in 1936; Aztec, Bloomfield, Hospah, and Table Mesa in 1937; Aztec, Bloomfield, and Table Mesa in 1938.

New York.—Drilling increased in New York following the price advances of 1939, and the output rose to 5,098,000 barrels from 5,045,000 in 1938. The price of Bradford crude rose in six steps from $1.68 per barrel on January 1 to $2.50 on December 1; this substantial gain, occasioned largely by the increased demand for lubricants, gave the producers great encouragement for successful operations in 1940.

Ohio.—Nothing occurred in Ohio in 1939 to arrest the receding production, which fell from 3,298,000 barrels in 1938 to 3,156,000 in 1939. The number of oil wells completed increased from 189 in 1938 to 216 in 1939, but the total initial production dropped. During 1939 a bill was passed legalizing water-flooding in Ohio. The first horizontal well was drilled in Ohio in 1939.

Oklahoma.—Further losses of markets to Illinois and falling potentials featured the general picture in Oklahoma in 1939. The output was 160,072,000 barrels compared with 174,994,000 in 1938.

In an effort to maintain reserves, drilling was speeded in 1939, and 1,045 oil wells were brought in compared with 986 in 1938; however, the total initial production was less than in 1938, and the percentage of dry holes increased. Active areas in drilling were Creek County and the Cement and Sac and Fox fields.

The performance in the Seminole district was about the only encouraging feature of production in Oklahoma. The output in that district in 1939 was 30,700,000 barrels compared with 28,073,000 in 1938 and 30,704,000 in 1937. Most of the credit for the showing belongs to the St. Louis-Pearson field. Production of Oklahoma City, the leading field of the State, declined from 40,905,000 barrels in 1938 to 37,554,000 in 1939. Production at Fitts showed another drastic decline—from 16,655,000 barrels in 1938 to 9,120,000 in 1939.

Big wells continued to be completed in the Ramsey field, which produced about 1,500,000 barrels in 1939 compared with about 500,000 in 1938.

About a score of new pools were opened in Oklahoma in 1939, but most of them were on "pimples" passed over in previous years. The Hobart field (Kiowa County) probably was the most important discovery. A well was drilled to 14,582 feet in Washita County but was a failure after experiencing mechanical difficulties. Interest in the extreme southern and northwestern parts of the State was quite active as the year closed.

[1] Oil and Gas Journal.

Pennsylvania.—Higher posted prices revived production in Pennsylvania during the last quarter of 1939, but the total output for the year failed by a small margin to equal that of 1938—17,426,000 and 17,337,000 barrels in 1938 and 1939, respectively. Fewer oil wells were completed in 1939, but the total initial production increased, probably owing to the addition of a number of exceptional wells in the Music Mountain pool of the Bradford field.

Tennessee.—No important discoveries were made in Tennessee in 1939, and production continued to be around 3,000 barrels monthly.

Texas.—The Saturday and Sunday shut-downs instituted by the Texas Railroad Commission in 1938 were continued into 1939. In addition, most of the fields were shut in during the latter half of August. In spite of this curtailment, production in every important area of the State except East Texas increased during 1939, and the total for the State rose from 475,850,000 barrels in 1938 to 484,527,000 in 1939.

No new discoveries were made in the Texas Panhandle in 1939, and fewer wells were drilled; but the potential of the wells increased, and the output rose from 23,556,000 barrels in 1938 to 24,165,000 in 1939.

The North Texas district experienced another satisfactory year in 1939. Production increased to about 40,000,000 barrels from about 37,000,000 in 1938 and reserves were augmented by the discovery of a score or more new pools. Fewer wells were drilled in 1939, mostly because the drilling program in the K-M-A field reached its peak in 1938. The Hull-Silk field, a 1938 discovery, lived up to expectations and became an important producer in 1939. Clay, Cooke, and Montague Counties led in new discoveries in 1939.

In the North-Central Texas district, sometimes called West-Central Texas but included in North Texas by the Bureau of Mines, wildcatting was active, and a dozen or more new productive spots were found. Most of the drilling was on the Palo Pinto lime trend in Jones and Shackelford Counties. The Griffin and Guitar pools (Jones County) were active; in the latter a deeper lime zone—the Hope—was discovered.

Production in the West Texas district recovered from its slump in 1938 and established a new record of 79,793,000 barrels in 1939. The gain of 1939 over 1938 was related closely to the State's allowable program, as drilling declined again. Ector County continued to lead in drilling, but Yoakum County showed the largest gain over 1938.

The number of new discoveries was again small in West Texas, and only two deserved special mention—the Apco pool (the first Ordovician discovery of Pecos County) and Cedar Lake, Gaines County. A deeper lime zone was found in the North Cowden pool, which opened a large area for similar exploration.

Production in the East Texas field proper decreased from 152,116,000 barrels in 1938 to 145,469,000 in 1939; it would have been about the same, except for the 2-week shut-down in August. Drilling continued to decrease rapidly in the East Texas field, and only 365 oil wells were brought into production during 1939 compared with 1,599 in 1938. Abandonments began to exceed new completions in 1939, but the number of producing wells increased from 25,700 on January 1 to 26,000 on December 31. The average bottom-hole pressure dropped from 1,110 pounds the first of the year to about 1,060 at the close.

Production in the other fields of the East Texas district fell from nearly 33,000,000 barrels in 1938 to about 31,000,000 in 1939. In 1939 the Talco and Rodessa (Texas portion) fields produced nearly 10 million barrels each, followed by Van with 5 to 6 million barrels New discoveries in 1939 were few and of little apparent consequence.

The Central Texas district, including chiefly the fault-line pools, passed another year of declining production and there were no important discoveries. The output was about 11,700,000 barrels—approximately 1 million barrels less than in 1938.

Production in the South Texas (Laredo) district showed another slight decrease; the total for 1939 was about 29,400,000 barrels compared with 29,597,000 in 1938.

Routine drilling declined in 1939, but interest in the area continued high and several dozen new discoveries were made. The chief activity was along the Frio-Vicksburg trend in Jim Wells, Brooks, Hidalgo, and Starr Counties and along the Cockfield trend in Duval County. Prominent new fields were Reynolds, Ben Bolt, Chiltipin, Muralla, Sejita, and Southland. The new Adami field of Webb County was active in drilling. Two deep Wilcox tests were drilled during the year, and whereas both had mechanical troubles and were plugged back, they showed considerable promise.

Although in 1939 the Texas coastal district had a comparatively poor year from the standpoint of new fields and reserves, production rose to a new high point of 122,443,000 barrels from 115,587,000 in 1938. Nearly as many oil wells were completed in 1939 as in 1938—1,663 against 1,728—but the average daily initial production of the 1939 completions was only 256 barrels compared with 518 in 1938.

About 15 new fields were discovered in the Texas Gulf Coast field during 1939, several of which were distillate producers. The most promising of the new fields were Anchor (Angleton), Brazoria County, and Caplen, Galveston County. Important new sand discoveries were made in the Ace and Thompsons fields; and the West Ranch field in Jackson County, discovered in 1938, was greatly extended.

Conroe easily retained its rank as the leading field of the district, though its output fell from 11,606,000 barrels in 1938 to about 9,200,000 in 1939.

[5] Includes other fields in Falls, Freestone, Limestone, and Navarro Counties.
[6] Includes the districts in and between Wilbarger, Wichita, Clay, Montague, and Cooke Counties on the north and Runnels, Coleman, Brown, and Comanche Counties on the south.
[7] Carson, Gray, Hutchinson, Moore, Potter, and Wheeler Counties.
[8] Includes fields in Duval, Hidalgo, Jim Hogg, Jim Wells, Starr, Webb, and Zapata Counties.
[9] Includes Westbrook and other fields in Glasscock, Howard, and Mitchell Counties.

Utah.—No wells were drilled in Utah in 1939, and the production of oil continued negligible.

West Virginia.—Despite a slight decline in number of oil wells completed in 1939, the total initial production increased; however, this was not enough to compensate for the natural decrease in the output of the many old wells, and it dropped from 3,684,000 barrels in 1938 to 3,580,000 in 1939.

Wyoming.—Deeper drilling and extensions in the Lance Creek field increased the output from 4,846,000 barrels in 1938 to about 6,700,000 in 1939. This was about the proportion by which the State production increased—from 19,022,000 barrels in 1938 to 21,417,000 in 1939. The reliable Salt Creek field was displaced by Lance Creek as the leading producer for the first time in about a score of years, but its production of 5,331,000 barrels was creditable considering its age.

Drilling in 1939 proceeded at about the same pace as in 1938, 99 and 95 oil wells having been completed in the respective years. Exploratory drilling was not especially successful; no new fields were found, and deeper sands at Lance Creek and Wertz were the only important discoveries.

WELLS

In consequence of the price recession of October 1938 drilling entered 1939 at a much lower level than prevailed the first of 1938. The drilling rate accelerated gradually in 1939, so that by the end of

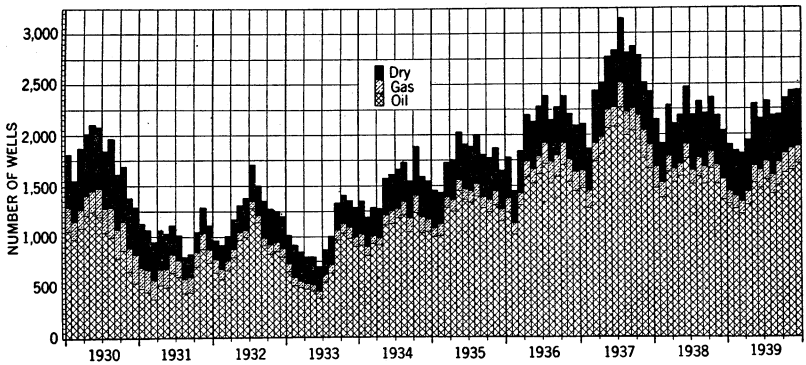

FIGURE 4.—Wells drilled, 1930–39, by months.

the year it was running ahead of 1938. However, the number of oil wells completed decreased 5 percent—from 18,433 in 1938 to 17,485 in 1939. The percentage of failures (dry holes) again increased materially—from 22.8 percent in 1938 to 24.6 in 1939 (see fig. 4); this trend is largely a result of the decline in drilling in the East Texas field, where less than 2 percent of the holes drilled since discovery to the end of 1939 (26,355) have been failures.

There were 369,640 producing wells in the United States on December 31, 1938; this was 6,610 more than were producing at the beginning of the year. Allowing for somewhat more than the usual percentage of abandonments on account of the lower prices, there probably were somewhat less than 375,000 producing oil wells at the end of 1939. However, the average daily production per well, which declined materially in 1938, rose to 9.3 barrels from 9.1 in 1938.

[1] Oil and Gas Journal. Water-intake wells not included. [2] Revised figures.
[3] Total by months does not agree with total by States published elsewhere in the Yearbook, as latter has been revised on basis of annual data from State officials.

Because of rapid decline in drilling in the East Texas field, the Bradford-Allegany district became the leader in completions in 1939. Completions in Wichita County, one of the leaders in 1938, dropped nearly 50 percent in 1939. Increases in field activity in the Central States (Illinois, Michigan, and Indiana) were leading developments during 1939.

STOCKS

Crude-oil stocks increased moderately in the first 4 or 5 months of 1939, followed by material reductions in June and July; however, these were small compared with that in August in consequence of the 2-week shut-down. Thus stocks of refinable grades decreased about 32,000,000 barrels or from 270,570,000 barrels on July 31 to 238,479,000 on August 31. The net change over the remaining 4 months was unimportant. Virtually all the 35-million barrel reduction in refinable grades in 1939 was in pipe-line and tank-farm stocks, as producers' stocks gained slightly and refinery stocks showed a relatively minor decline. Stocks of heavy crude in California, kept separate from statistics of refinable grades to maintain comparisons, were reduced by about 3 million barrels in 1939, or from 16,467,000 barrels on January 1 to 13,330,000 on December 31.

Stocks of crude petroleum, natural gasoline, and refined products in the United States at end of year, 1935–39

[1] Subject to revision. [2] Revised figures. [3] For comparison with succeeding year.
[4] California heavy crude included under refined products as residual fuel oil from 1923 to end of 1937.
[5] Includes also equivalents for wax, coke, and asphalt in barrels.

An important factor in the rise of Pennsylvania Grade prices was a drop of just over a million barrels (about 20 percent) in stocks of that crude. The data on stocks of crude oil by States of origin for 1939 show that most of the figures trended downward; in fact, a gain of about 5,500,000 barrels of Illinois crude was the chief exception. The most important decreases were about 20 million barrels in stocks of Texas crude and nearly 10 million of Oklahoma crude.

New lows in days' supply for recent years were set continuously in 1939 as demand increased and stocks were reduced. The low point of 64 days' supply for all crudes, including California heavy, was reached on September 30.

Stocks of refinable crude petroleum [1] *in the United States in 1939, by States of location and origin and by months* [2]

[1] Excludes stocks of California heavy crude; for 1939 figures see p. 947. [2] Subject to revision.
[3] Revisions of preliminary figures for 1938 (Minerals Yearbook, 1939, p. 957) are as follows (thousands of barrels): Pipe-line stocks, Jan. 31, N. Louisiana and Arkansas, 6041, and producers' stocks, Jan. 1, 11,240, Jan. 31, 12,124; Feb. 28, 12,453; Mar. 31, 13,220; Apr. 30, 11,777; May 31, 11,822; June 30, 11,957; July 31, 11,853; Aug. 31, 11,690; Sept. 30, 11,434; Oct. 31, 11,873; Nov. 30, 12,045; Dec. 31, 11,476.

CONSUMPTION AND DISTRIBUTION

Runs to stills.—Crude run to stills in 1939 totaled 1,238 million barrels, an increase of 73 million over 1938 and 54 million above the previous record figure of 1937. Foreign crude runs were 7 million barrels greater in 1939 than in 1938 but represented less than 3 percent of the total.

The outstanding change in refinery operations by districts was the further increase in runs in the Texas Gulf Coast and Illinois-Indiana districts. Crude runs in the Texas Gulf Coast district have risen from 282 million barrels in 1937 to 308 million in 1938 and 334 million in 1939. These increases represent a continuation of long-term trends that favor refining in the Gulf ports as convenient points for distribution of finished products via water to East Coast markets and for export. Crude runs in the Illinois-Indiana district were 164 million barrels in 1937, declined to 163 million in 1938, and rose to almost 192 million in 1939. The growth of refining in this district illustrates the advantage of the pipe-line movement of crude over rail movements of finished products to the important markets of the North Central States and has been stimulated further by the rapidly expanding production of crude in Illinois.

Crude runs of 192 million barrels in the East Coast district during 1939 were substantially above 1938 but not as large as in 1937. In the California district runs of 199 million barrels represented an additional small decline. Compared to 1938 there were minor changes in the amount of crude run in the Oklahoma-Kansas-Missouri district and in the Texas Inland district, but in both instances runs remained substantially below the 1937 level.

The increase in crude runs to stills in 1939 can be ascribed to improvement in domestic demand, as exports of refined products were substantially the same as in 1938. A small decrease of about 4 million barrels in total stocks of refined oils indicated that refinery operations as a whole closely approximated market demand for the year. Excess inventories for particular products represented the failure to liquidate previous accumulations or lack of balance in refinery yields.

[1] Subject to revision.

Distribution.—Receipts of domestic and foreign crude petroleum at refineries in the United States totaled 1,167 million barrels in 1938 and 1,237 million in 1939. In 1939, receipts of foreign crude were 33 million barrels (less than 3 percent of the total); interstate receipts of domestic crude were 450 million barrels (36 percent of the total); and intrastate receipts were 754 million barrels (61 percent of the total). The interstate movement of crude declined further in relative importance in 1939, and the intrastate movement increased. The relative importance of the increase in intrastate deliveries in Illinois, Texas, Louisiana, and Michigan was offset to a considerable extent by a slight actual decrease in California and by the total increase in runs in districts receiving their supply mainly by interstate movement.

Refinery receipts of crude in 1939, by methods of transportation, indicated that 73 percent of the total was delivered by pipe lines, 24 percent by boat, and 3 percent by tank car and truck. These data show only fractional variations from the 1938 figures. The most important boat movement of crude is from Gulf ports to the East coast. These shipments increased from 151 million barrels in 1938 to 158 million in 1939.

[1] Subject to revision.

The total demand for domestic crude in 1939 was 1,301 million barrels, an increase of 58 million over 1938. The amount of domestic crude run to stills rose to over 1,204 million barrels in 1939, an increase of 65 million.

The total market demand for crude by States of origin is computed from production and changes in stocks of State origin. This demand includes deliveries to domestic refineries, crude transferred to fuel oils, losses, and exports.

The most important changes in total market demand by States of origin in 1939 compared to 1938 were an increase of 66 million barrels in the demand for Illinois crude, a recession of 26 million barrels in the demand for Oklahoma crude, an increase of 15 million in the demand for Texas crude, and a drop of 12 million barrels in the demand for California crude. The increase in the demand for Louisiana crude was 3 million barrels, for Michigan crude 4 million, for Kansas crude 1 million, and for Wyoming crude 1 million. The demand for New Mexico crude was about the same.

Data on receipts of crude petroleum at refineries represent the principal bases for determining the trends of distribution of the market demand by States of origin. In 1939 Texas, Oklahoma, California, Louisiana, Illinois, Kansas, and New Mexico supplied about 91 percent of the total refinery receipts of domestic crude, or approximately the same percentage as in 1938. As the relative standing of these seven States as a whole remained the same, the principal factor of interest was the competitive change in individual position.

The total demand for California crude fell from 240 million barrels in 1938 to 228 million in 1939. California crude is primarily refined in California or exported, as shipments to Eastern States totaled only about 1 million barrels in both 1938 and 1939. The 12-million-barrel decrease in the demand for California crude in 1939 represented a reduction of 6 million barrels in exports, of 2 million in the amount run to stills, and of 4 million in crude transfers to fuel and losses.

The total demand for Texas crude was about 505 million barrels in 1939, almost 15 million barrels more than in 1938 but only 3 million greater than in 1937. All of the increase in demand in 1939 can be attributed to deliveries to intrastate refineries, as exports were less and deliveries to refineries in other States declined by 4 million barrels. Deliveries to the East Coast district totaled 116 million barrels—a gain of 4 million—while shipments to Louisiana fell to 18 million—a loss of 6 million barrels.

The total demand for Louisiana crude was 97 million barrels in 1939, a gain of less than 3 million over 1938. Intrastate deliveries increased by 6 million barrels, but there was a decrease in shipments of crude to other States, mainly the Texas Gulf district. Total deliveries to the East Coast district remained the same at about 17 million barrels.

The total demand for New Mexico crude was about 39 million barrels, essentially the same as in 1938. The major part of the production was marketed in other States, as intrastate deliveries were less than 2 million barrels. Shipments to the East Coast district totaled 12 million barrels in 1939, an increase of about 2 million that was offset by a reduction in shipments to the Illinois-Indiana district.

The total demand for Illinois crude increased from 23 million barrels in 1938 to 89 million in 1939, a rise of 66 million barrels. Intrastate deliveries to refineries increased by 29 million barrels—from 8 million in 1938 to 37 million in 1939. Deliveries to refineries in other States rose from 12 million in 1938 to 41 million in 1939, a gain of 29 million. Interstate deliveries represented an increase of 8 million barrels to refineries in Indiana, of 12 million to Ohio, of 3 million to western New York, of 2 million to Kentucky, and of 2 million to Michigan. Pipe-line shipments to East Coast refineries totaled over 1 million barrels and will increase materially in 1940. Exports to Canada gained about 8 million barrels, replacing Oklahoma crude in the movement across the northern border. A considerable part of the increased demand for Illinois crude was due to the cheaper transportation costs from fields close to refinery centers and to a greater relative increase in total refinery operations in the Illinois-Indiana district.

The total demand for Oklahoma crude dropped from 195 million barrels in 1938 to 169 million in 1939, a decline of 26 million. The major part of this decrease was in interstate and export movements, as intrastate deliveries declined by only 1 million barrels. The major changes in deliveries to refineries in other States were a decline of 12 million barrels in Illinois, of 6 million in Ohio, of 2 million in Indiana, and of 2 million in Michigan. On the other hand, deliveries to the Gulf Coast district increased 3 million barrels and to the East Coast district 2 million.

The total demand for Kansas crude was 61 million barrels in 1939, an increase of about 1 million. Intrastate deliveries were about the same, at 34 million barrels. The interstate market is restricted primarily to Indiana, Illinois, Oklahoma, and Missouri. Combined deliveries to Indiana and Illinois amounted to 22 million barrels in 1939, a decline of 1 million, while total shipments to Oklahoma and Missouri increased by almost 2 million barrels.

The demand for Wyoming crude increased by about 1 million barrels (largely in pipe-line shipments to Missouri and Indiana) to a total of 24 million. Deliveries to refineries in Wyoming and other Mountain States remained about the same. The total demand for Michigan crude rose from less than 19 million barrels in 1938 to about 23 million in 1939, most of this increase being in deliveries to refineries within the State. The demand for Arkansas crude increased by over 2 million barrels in 1939 to a total of 21 million. About half of this crude was delivered to refineries in the State.

PRICES AND VALUE

The average value of crude petroleum at wells receded in 1939, although most postings remained unchanged throughout the year. The average in 1938 was $1.13, whereas that in 1939 is estimated at $1.00. The final figure for 1939 may be several cents lower, as under-

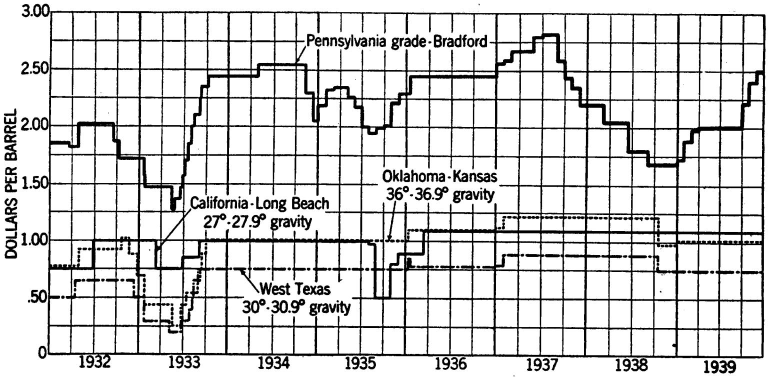

FIGURE 5.—Posted prices of selected grades of crude petroleum, 1932–39, by months.

selling was reported rife in Illinois and a few other States. This underselling weakened some quotations, which were restored after the August shut-down. The only active price was that for Pennsylvania Grade, which advanced from $1.68 on January 1 to $2.50 on December 31, in six steps; it rose 25 cents more on January 1, 1940.

Details of price changes for selected grades of crude petroleum are presented in the tables that follow and in figure 5.

Average monthly prices per barrel for selected grades of crude petroleum at wells in 1939

[1] Figures for 1939 not yet available. [2] Missouri, Tennessee, and Utah.

ROYALTIES ON INDIAN AND FEDERAL LANDS

Minerals Yearbook, 1938 (p. 853), presented data up to 1937 on royalty receipts, bonuses, etc., concerning Indian and Federal lands. Minerals Yearbook, 1939 (p. 966), gave similar data for 1938. Corresponding information for 1939 is as follows: Acreage of leases on Indian lands for the fiscal year 1939, 59,360; bonuses from sale of these leases, $170,215; royalty from production of oil and gas, $3,938,056; and advance royalty and annual rentals, $535,245. For the calendar year 1939, the production of crude petroleum on Government lands was 42,331,057 barrels, of which 5,093,276 barrels (valued at $5,168,248) was royalty.

REFINED PRODUCTS

Crude oil run to stills increased from 1,165 million barrels in 1938 to 1,238 million in 1939, but production of natural gasoline fell from 51,347,000 barrels to 49,896,000. In response to increased activity in the steel industry, benzol production recovered from 1,764,000 barrels in 1938 to 2,440,000 in 1939.

The new record of 552,557,000 barrels for domestic motor-fuel demand is 5.7 percent higher than the 1938 demand. Gas-oil and distillate fuel-oil consumption at 131,935,000 barrels (old basis) was 12 percent above the 1938 demand, while that for residual fuel oil at 321,228,000 barrels (old basis) was 10 percent higher. The demand was also higher for kerosene, lubricants, wax, coke, asphalt, road oil, and still gas.

Comparative analyses of statistics for the major refined products, 1935–39

[Thousands of barrels, except as otherwise indicated]

	1935	1936	1937	1938	1939 [1]
Motor fuel:

[1] Subject to revision.
[2] Net transfers from crude oil to fuel oil; California only, 1935–38; in 1939 all transfers east of California included in gas oil, etc.
[3] Figures not available.
[4] Includes terminal stocks; compares with succeeding years.
[5] On new basis; see p. 1011.
[6] California heavy crude included.
[7] For comparison with succeeding year; California heavy crude included in crude-oil stocks.
[8] For comparison with succeeding years.

The total refinery output of gasoline in 1939—of about 596 million barrels—included about 261 million barrels of straight-run gasoline, 295 million of cracked gasoline, and 40 million of natural gasoline.

The yield of gasoline again increased comprising 44.9 percent of the crude oil run to stills in 1939 compared with 44.3 percent in 1938. The yield of gas oil and distillate fuel oil remained virtually the same as in 1938 at 13.1 percent, while the yield of residual fuel oil declined further from 25.3 percent in 1938 to 24.8 in 1939. (See fig. 6.)

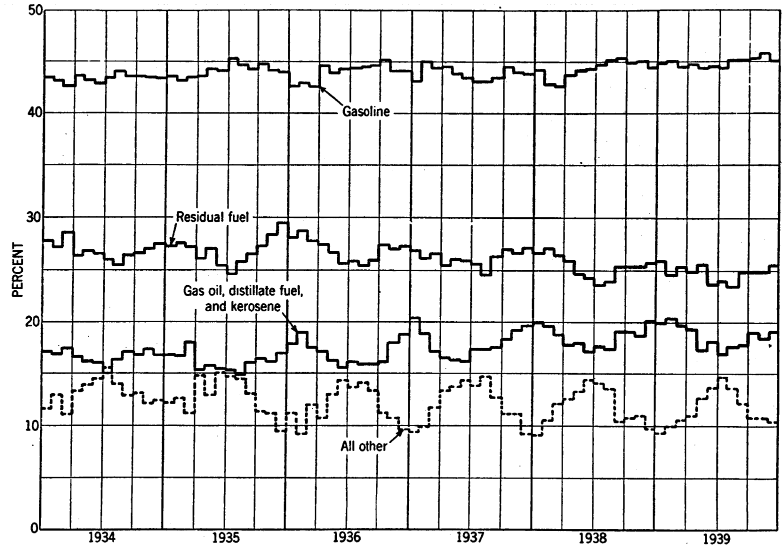

FIGURE 6.—Yields of principal petroleum products from crude oil run to stills, 1934–39, by months.

[1] Detail by districts and months in section on "Consumption and distribution of crude petroleum."
[2] Includes 1,349,000 barrels run through pipe lines in California in 1938 and 1,147,000 barrels in 1939.
[3] Included above in crude petroleum input.
[4] Negative quantity; represents net excess rerun over production. [5] Negative quantity (overage). [6] Subject to revision.
[7] Data on "other" oils charged to cracking stills not available after July 1939.

Heating-oil requirements jumped the demand for distillate fuel oil 11 percent above that for 1938, and high-capacity industry and transportation operations raised the demand for residual fuel 9 percent compared with an increase of only 4 percent in total motor-fuel demand. The lack of adjustment between yields and the relative demand for products, particularly in the last quarter of 1939, resulted in an abnormal increase in gasoline stocks, which stood at 82,865,000 barrels (including unfinished) at the end of 1939 compared

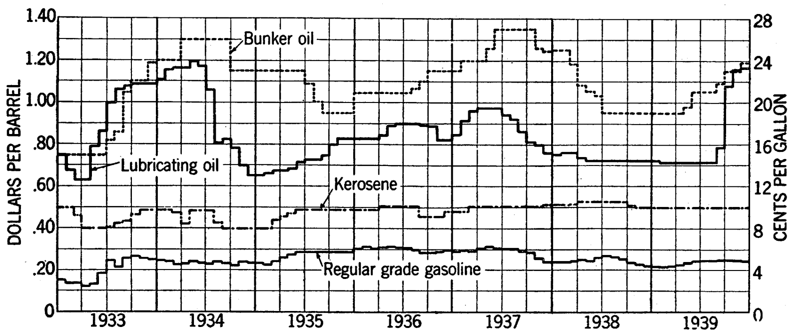

FIGURE 7.—Prices of refined petroleum products, 1933–39, by months.

with 71,680,000 barrels at the end of 1938. This is equivalent to a 60-day supply on December 31, 1939, and a 54-day supply on December 31, 1938.

As indicated in figure 7, prices moved from weakness to strength during the year; in spite of the large inventories, those for gasoline were higher at the close of the year than at the end of 1938, although the average for the year was lower. Lubricating-oil prices were high, many having gained over 100 percent during the year, while Pennsylvania-wax prices almost tripled. Although the average 1939 price for fuel oils in general was lower than the 1938 average, most grades were selling higher at the end of the year than at the beginning.

Stocks of refined products in the United States, 1938–39, by months

[4] Less than 0.1 percent.

Refinery capacity including that of refineries under construction, was 4,650,805 barrels a day on January 1, 1939 (16,634 barrels more than on January 1, 1938), even though the number of refineries had dropped from 561 to 545.

The number of shut-down plants decreased from 120 to 103, but their capacity increased from 380,955 to 574,770 barrels a day, leaving the capacity of 3,933,785 barrels for the operating plants 36,411 barrels less than in 1938. The new Illinois plants, some of which were moved from Texas, and the new "pot-still" plants in Montana were largely responsible for this. The number of operating refineries in the Rocky Mountain district increased from 73 to 85, the greatest of any district, yet their daily capacity was 1,000 barrels less than in 1938, while the growth from 49 to 56 operating refineries in the Indiana-Illinois district raised the capacity only 11,000 barrels. In contrast with this, the Texas Gulf Coast district, with two additional plants operating, had an increased capacity of 64,000 barrels.

The operating ratio, or the proportion of crude runs to capacity, was 82 percent compared with 78 in 1938 and 83 percent in 1937.

Although more than half the capacity being built at the beginning of the year was for replacement, much of the construction during the year represented additions of newer-type refining equipment, such as catalytic polymerization units, catalytic cracking plants, and alkylation plants. However many refiners, particularly in the Midwest, have been postponing such additions because rapid developments in these processes made some plants obsolete soon after they were put in operation.

The principal advances in refinery technology during 1939 were expansion in catalytic cracking and in catalytic polymerization and progress in catalytic cracking and alkylation.

A number of catalytic cracking plants were put in operation during 1939, and some of the operators are claiming to produce a better grade of motor fuel than they formerly marketed. Likewise, a number of new catalytic polymerization units were installed during 1939.

Summary of refinery capacity in the United States, January 1, 1935–39 [1]

Year	Number				Capacity (barrels per day)			
	Operating	Shut down	Building	Total	Operating	Shut down	Building	Total
1935	435	196	7	638	3,614,749	443,751	13,900	4,072,400
1936	422	210	15	647	3,749,835	367,212	46,899	4,163,946
1937	423	149	11	583	3,966,616	328,265	81,200	4,376,081

[2] New basis; for complete information see Bureau of Mines Information Circular 7034.

Alkylation is a development akin to polymerization. Whereas polymerization unites 2 molecules of the paraffin series to produce 1 unsaturated molecule, which must be hydrogenated to obtain isooctane, alkylation unites 1 molecule of the paraffin series with 1 molecule of the olefin series to produce 1 saturated molecule of isooctane. Both processes are being used almost entirely for the production of high-octane aviation fuel.

The sulfuric-acid alkylation process, in which isooctane is produced by using sulfuric acid as a catalyst at low temperature and pressure, was the principal development in alkylation in 1939.[2] In addition to this a process was announced for producing neohexane by thermal alkylation,[3] although this process was not in commercial operation during the year.

Although isooctane has a knock rating of 100 octane compared with a 95-octane rating for neohexane, the boiling range is so high—225°–263° F.—that it is necessary to blend it with other motor fuels, usually isopentane and a high-octane straight-run gasoline. This blend, when treated with 3 cc. of etraethyl lead per gallon, will produce a 100-octane aviation fuel. Although thermally cracked gasoline produces a high-octane motor fuel its knock rating is improved but little by the addition of lead, and for that reason selected straight-run gasoline is used in the blend.

The boiling range of neohexane is only 120°–122° F.; it can be blended with isooctane and isopentane, and with the addition of tetraethyl lead it produces an aviation fuel with an octane rating considerably above 100.

High-octane fuel is important in military aircraft because of the greater power it gives and the smaller engine needed per unit of power as the compression ratio increases. One hundred-octane fuel, which is now required for all new Army and Navy airplanes, gives an increase of 20 to 30 percent in power over that of 87-octane fuel and adds the advantages of quicker take-off, more rapid climbing, greater cruising radius, and increased speed.

Petrol. Inst. 20th ann. meeting, Chicago, Ill., November 13–17, 1939; pub. in Oil and Gas Jour., vol. 38, No. 27, 1939, p. 104.

[3] Oberfell, G. G., and Frey, F. E., Thermal Alkylation and Neohexane: Am. Petrol. Inst. 20th ann. meeting, Chicago, Ill., November 13–17, 1939; pub. in Oil and Gas Jour., vol. 38, No. 28, 1939, p. 50, and No. 29, p. 70.

The principal source of charging stock for both polymerization and alkylation is gas from the cracking stills, although some is obtained from natural gas; thus, the gasoline made by these processes creates a net addition to the output of gasoline without any additional consumption of crude oil. Furthermore, the gasoline so produced is superior as fuel to that obtained by other methods.

Other progress in refinery technology includes improved methods for desulfurization and cyclization.

The presence of sulfur in gasoline not only gives it a lower knock rating but also makes it less susceptible to tetraethyl lead. A number of recent developments have contributed to the facility and reduced the expense of extracting sulfur from gasoline.

Cyclization, or aromatization of straight-run gasolines, converts straight-chain paraffins into benzol, toluol, and xylols. These products have an octane rating of over 100 and can raise the quality of motor fuel, although they cannot at present be used as aviation fuel.[4]

MOTOR FUEL

Demand.—The domestic demand for motor fuel in 1939 was 552,557,000 barrels, a 5.7-percent increase over the 1938 record of

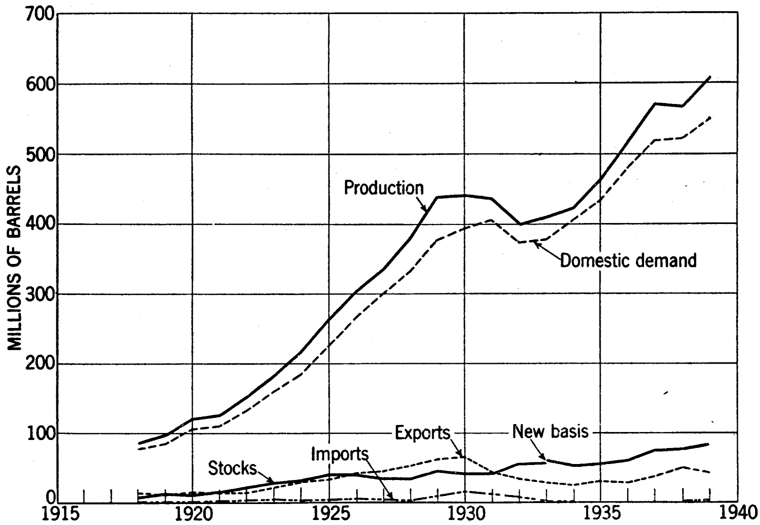

FIGURE 8.—Trends in production, domestic demand, exports, imports, and stocks of motor fuel, 1918–39.

523,003,000 barrels. Exports, however, declined from 50,109,000 barrels in 1938 to 44,559,000 in 1939, making the total demand 597,116,000 barrels, a 4-percent increase over the 1938 demand. (See fig. 8.)

Grand total	481,606	519,352	523,003	552,557

[1] Subject to revision. [2] 89 percent of total motor-fuel demand.

The 11-percent recession in exports for the year 1939 may be ascribed chiefly to the European war; during the last quarter alone exports were 33 percent less than in the corresponding quarter in 1938 compared with a 3-percent loss for the first 9 months of the year. This decrease was unexpected, as many persons had predicted that the immense demand for aviation gasoline and gasoline for powering the mechanized units of the armies would create a large draft on American sources. However, gasoline-rationing policies for neutral countries as well as belligerents, the small amount of actual fighting, the large supplies of gasoline and oil that the warring countries had been accumulating during recent years, and the tremendous risk of ocean transportation cut deeply into United States exports of petroleum and its products during the last quarter of 1939. More detailed information on exports and imports is given in another section of this chapter.

There were 3,140,000 new motor-vehicle registrations in 1939, according to R. L. Polk & Co., compared with 2,256,000 in 1938 and 4,100,000 in 1937. Preliminary estimates of cars in use on July 1, as shown in the accompanying table, indicate an increase of approximately 420,900 vehicles and a total of 28,607,400. Gasoline consumption per motor vehicle in use responded to improved business conditions by rising from 18.57 barrels in 1938 to 19.32 in 1939.

The effect of weather on motor-fuel demand was discussed in another publication of the Bureau,[5] which also included the gasoline-temperature index; this index is calculated by weighting the departures of temperature from normal for the various sections of the country (as reported in the Monthly Weather Review) by the quantity of gasoline consumed in the individual sections. The gasoline-temperature indexes for 1939 and the estimated influence of weather upon motor-fuel demand are given below.

Gasoline-temperature index and estimated influence of weather on motor-fuel demand in 1939, by months

Month	Gasoline-temperature index [1]	Influence on motor-fuel demand (thousands of barrels)	Month	Gasoline-temperature index [1]	Influence on motor-fuel demand (thousands of barrels)
January	4.1	996	September	3.2	646
February	1.9	46	October	1.8	−3
March	1.5	−169	November	.0	−482
April	−.7	−414	December	3.4	732
May	2.5	384			
June	1.8	−4	Average index	1.9	
July	1.0	−355	Total influence		1,542
August	2.1	165			

[1] In degrees departure from 46-year normal.

Although temperatures have averaged 1 degree above normal for the past 12 years, it can be seen from the table that the weather in 1939 was even milder. It is estimated that motor-fuel demand was 1,542,000 barrels greater because of the favorable weather.

Production.—Motor-fuel production in 1939 of 607,941,000 barrels was 38,779,000 barrels more than that in 1938—569,162,000 barrels. The 1939 production comprised 260,463,000 barrels of straight-run gasoline, 295,142,000 barrels of cracked gasoline, 2,440,000 barrels of benzol, and 49,896,000 barrels of natural gasoline, the latter being made up of about 40 million barrels of blended natural and about 10 million barrels of unblended natural. The ratio of straight-run gasoline to total motor-fuel production continued its downward trend, falling from 43.1 percent in 1938 to 42.8 in 1939, while that of cracked gasoline followed its rising trend, increasing from 47.5 percent in 1938 to 48.6 in 1939. The ratio of natural gasoline declined from 9.0 percent in 1938 to 8.2 in 1939.

[1] Subject to revision. [2] Includes aviation gasoline (thousands of barrels): October 859, November 811, December 909.

Yields.—Gasoline produced from crude oil run to stills increased for the second consecutive year to establish a new record of 44.9 percent in 1939 compared with 44.3 percent in 1938. This increase probably is attributable in part to various new technologic improvements, including polymerization, alkylation, and catalytic cracking, discussed elsewhere in this chapter.

Most of these new processes utilize still gases as raw material; consequently the yield of still gas decreased from 5.7 percent in 1938 to 5.4 percent in 1939, whereas the yield of gasoline increased 0.6 percent. The remainder of the rise in gasoline yield (0.3 percent) probably was taken out of residual fuel-oil yield, which declined 0.5 percent.

Nearly all of the higher yield of gasoline was incident to the production of cracked gasoline, which increased from 23.2 percent in 1938 to 23.9 in 1939, while the yield of straight-run gasoline was virtually unchanged.

The yield of gasoline in 1939 did not experience the usual slump during the early part of the year, probably because the mild winter (see gasoline-temperature index) did not require the diversion of cracking stock to heating oil. Otherwise it conformed to the usual seasonal pattern, except that the summer sag was only slight, while the November yield (45.8 percent) established a new record.

One of the paradoxes of the industry is that in the autumn, when it is logical to expect a decline in the yield of gasoline because motor-fuel demand is decreasing rapidly and heating-oil demand is increasing, gasoline yield actually has reached its peak. During the warmer months of the year unfinished heavy oil is stored, and as cool weather approaches it is rerun, most of it probably being cracked to increase the winter supply of heating oil. The gasoline and heating oil resulting from such reruns constitute net additions to the products from the crude oil run to stills, but they are in no sense products of that particular oil. However, yields are computed on the basis of the ratio of the total products produced to quantity of crude oil run. Hence, when the actual yields of gasoline probably are declining in the fall, they appear to be increasing.

Net unfinished oil rerun during the last 4 months of 1939 amounted to 7,124,000 barrels—1.7 percent of crude-oil runs—compared with 229,000 barrels for the 4 preceding months.

Rerunning of imported unfinished oil also will cause yields to appear higher than they actually are. Imports of unfinished oils in 1939 totaled 9,193,000 barrels, 5,798,000 barrels of which were designated for domestic use.

Among the districts Inland Texas continued its upward trend, the output mounting to 56.5 percent in 1939 compared with 54.0 percent in 1938 and 51.2 percent in 1937. The yield of 45.1 percent for the Texas Gulf Coast district also was materially higher than its 1938 production of 43.4 percent.

Prices.—The average Group 3 refinery price per gallon of regular-grade gasoline for 1939 was 4.76 cents compared with 4.90 cents for 1938. After a gradual decline since 1936 it reached its lowest point early in February 1939—3.88 cents. From that point it improved until it met the usual seasonal weakness in the winter but kept considerably stronger than during the winter of 1938, in spite of the larger accumulation of stocks.

The 50-city average service-station price of regular-grade gasoline (ex-tax), as compiled by the American Petroleum Institute, dropped further in 1939 to an average of 13.30 cents from the 14.07-cent average for 1938. The general trend during the year, however, was upward. The lowest price was 13.04 cents on March 1, from which it rose to a high of 13.65 cents on October 1 and then relapsed to 13.51 cents on December 1. The prices for these 2 months were almost the same as during the same months in 1938, but the January 1, 1940, price of 13.53 cents was ⅓ cent higher than that at the beginning of 1939.

It is extremely difficult to determine service-station prices in States that have the dealer-marketing plan. As the dealer sells at whatever price will give him enough profit, posted prices often vary considerably throughout a city. Frequently discounts are given from the posted prices either generally or to selected customers.

The greatest change in price was at Cheyenne, Wyo., where the increase from January 1, 1939, to January 1, 1940, was 3.0 cents (12.0 to 15.0 cents ex-tax). The price change in Omaha, Nebr., ranked next, but in the opposite direction, falling from 13.0 to 10.5 cents from the beginning to the end of the year. The price in Salt Lake City, Utah, which dropped from 18.5 cents on January 1, 1938, to 15.0 on January 1, 1939, dropped another 3.5 cents to 11.5 cents by June 20, 1939. It recovered, however, to 14.5 cents on September 18 and was only 0.5 cent lower at the end of the year than at the beginning.

The highest prices prevailed in the Rocky Mountain area as usual, where the average increased from 15.85 cents per gallon (revised) at the beginning of the year to 16.66 cents at the end of the year. Boise, Idaho, after a short period of lower price, again recovered the distinction, along with Twin Falls, Idaho, of having the highest price—25.1 cents, including 6 cents for State and Federal taxes and 1 mill as a toll-bridge tax. Helena, Mont., with a price of 24.5 cents including 6 cents in taxes, was next highest at the end of the year. Bristol, Tenn., with a price of 23.75 cents including 8 cents in taxes, and Montgomery, Ala. with a price of 23.5 cents including 9 cents in Federal, State, county, and city taxes, were next highest.

Providence, R. I., supplanted Wichita, Kans., in attaining the distinction of having the lowest price at the end of the year; it was 14.0 cents a gallon compared with 14.6 cents at Wichita. Detroit, Mich., however, had a price of 13.9 cents for a few days in November. Motorists in the New England and North Atlantic States continued to enjoy the lowest prices for gasoline, although the average rose from 11.7 cents (revised) per gallon at the beginning of the year to 12.2 cents at the end of the year.

There were no price changes in the principal cities on the Pacific coast throughout the year, and the only price changes in important places in the California marketing area were in Spokane, Wash., where the price fell from 18.0 cents at the beginning of the year to 16.5 cents at the end of the year, and in Phoenix, Ariz., where the price dropped from 16.5 to 15.0 cents.

The 12-month average of the 50-city average dealer's net price of 9.58 cents was 0.46 cent lower than that for 1938. The average on January 1, 1940 (9.78 cents), was 0.22 cent higher than the January 1, 1939, average.

A State gasoline-tax increase from 4 to 5 cents for North Dakota in July was the first change in tax rates for 2 years, the average rate for the country having remained at 4.44 cents for 25 months. Excepting a 1-mill toll-bridge tax in Idaho there were no other changes in State taxes on gasoline, but an event heralded by the oil industry was the repeal in New Orleans, effective October 1, of the 2-cent city tax. Although a 5-cent State tax, a 2-cent Parish tax, and the 1-cent Federal tax remain, the distinction of having the highest gasoline tax in the country has passed from New Orleans to Mobile and Montgomery, Ala., and to Pensacola, Fla., each of which pays a total tax of 9 cents a gallon on its gasoline. Only Alabama, Missouri, New Mexico, and Wyoming have no restrictions on the levying of gasoline taxes by cities. A small number of selected cities in Florida and Nevada also are permitted to levy a gasoline tax.

[1] National Petroleum News. [2] American Petroleum Institute. [3] Revised figures.

During 1939 one State (Missouri) and the District of Columbia had a tax rate of 2 cents, 10 States a tax rate of 3 cents, 17 States a tax rate of 4 cents, 10 States a tax rate of 5 cents, 1 State a tax rate of 5.1 cents, 5 States a tax rate of 6 cents, 1 State a tax rate of 6½ cents, and 3 States a tax rate of 7 cents.

In addition to the State taxes a Federal tax of 1 cent per gallon and numerous municipal and county taxes prevailed throughout the year.

Although there was no increase in octane number in the general price quotations for gasoline in 1939, the quality of gasoline, particularly during the last few months of the year, was generally improved, especially along the Atlantic coast.[6]

A dissatisfaction with octane rating as a means of describing the quality of gasoline, which has been developing for a number of years, reached the point during 1939 where many refiners have stopped mentioning octane in connection with their gasoline and instead emphasize quality to meet the needs of the individual driver. As the quality of the various gasolines depends on so many factors—such as the type of crude oils from which they were refined, the proportions of straight-run and cracked gasolines, the quantity of tetraethyl lead, and practical operating conditions under which the gasoline will be used—it is difficult to describe the relative quality of any gasoline by one number, as well as to devise a method for determining that number. Some gasolines have an advantage when the octane number is determined in one way, while others obtain a higher rating by a different method. There has been considerable confusion as to just what an octane number means, because, when making claims for their gasoline, refiners sometimes use that method by which their product receives the best rating, whether or not it is standard.

The method now known as the C. F. R. (Cooperative Fuel Research Committee) research method was the one first generally accepted for rating octane number. After practical tests had disclosed weaknesses in this method a new one—the C. F. R. motor method—was published as tentative in 1933, revised in 1934, 1936, 1937, 1938, and adopted as standard in 1939; it has been officially designated as D357–39, but is generally known as the A. S. T. M. method. At the same time the research method, which has been used as a check method for research purposes, was revised for adaption to the equipment used for the motor (D357–39) method. The motor method is at present most widespread throughout the world.[7]

The L–3 method is a compromise method used by the Ethyl Gasoline Corporation in dealing with its licensees. Although it is not standard and is official only between the corporation and its licensees, published price quotations at present usually are based upon ratings by this method.

Other methods of octane rating, generally used in connection with aviation fuel, include the United States Army Air Corps, the British Air Ministry, and the low-temperature methods, while a number of others for rating aviation fuel do not use octane number at all.

The near future probably will see some agreement upon octane rating, with consequent elimination of much of the confusion now existing, as well as even better grades of motor fuel than are being sold.

Aviation gasoline.—Late in 1939 the Bureau of Mines began to collect statistics on production and stocks of aviation gasoline. Data on exports of this grade of gasoline had been published by the Bureau of Foreign and Domestic Commerce since the first of 1939.

---

[6] Miller, Walter, Petroleum Refining: Min. and Met., vol. 21, No. 397, January 1940, p. 51; also Lane, E. C., Cooperative Fuel Research Motor Gasoline-Survey, Summer 1939: Bureau of Mines Rept. of Investigation 3492, 1939, p. 2.

[7] Phillippovich, Alexander, Engine Fuel Testing and Proposals for Its Further Development: Nat. Petrol. News, vol. 31, No. 50, December 13, 1939, p. R–526.

The first report, a press release of December 21, 1939, gave total aviation-gasoline production in October 1939 as 859,000 barrels, of which 265,000 barrels was in California. The average octane was 84 (A. S. T. M.) and the average vapor pressure 6.6 pounds. The returns indicated that there were about 25 producing companies, with a monthly capacity for producing about 1,500,000 barrels of aviation gasoline. The next report (total given in Bureau of Mines Monthly Petroleum Statement for November 1939) showed that the indicated domestic demand for this grade of gasoline was 411,000 barrels compared with exports of 274,000 barrels. In December exports increased to 372,000 barrels, but domestic demand declined to 292,000.

Stocks.—The seasonal pattern for gasoline stocks in 1939 was just the opposite of that for 1938. During the early months of the year stocks were lower than in 1938, and during the middle of the year were comparable with them. During October, however, they began to rise rapidly, and by December 31 finished gasoline on hand had reached 77,301,000 barrels or 11,352,000 barrels more than on December 31, 1938. Unfinished stocks, however, declined from 5,731,000 barrels to 5,564,000 making a total of 82,865,000 barrels for finished and unfinished gasoline on December 31, 1939.

Finished stocks were higher in all districts at the end of 1939 than at the end of 1938. Those in the Texas Gulf Coast district increased the most, with a 41-percent gain from 9,626,000 to 13,609,000 barrels. While the generally higher stocks in excess of what might be required because of the greater gasoline demand are attributable largely to expanded runs to stills to meet heating-oil requirements, part of the stocks in Texas Gulf Coast district probably resulted from the lack of tankers to move both the gasoline and fuel oil to the East coast, where finished stocks were only 8 percent more at the end of 1939 than at the end of 1938.

Finished stocks in California increased from 13,192,000 barrels to 16,121,000 (22 percent). As California had stocks of all products adequate, under ordinary refinery operations, to meet the most optimistic demands, such inflation can be ascribed to maladjustment in refinery operation, considering that the increment in total motor-fuel demand for that area was only 4 percent.

[1] Subject to revision. [2] Includes aviation gasoline (thousands of barrels): October 31, 2,400; November 30, 2,526; December 31, 2,771.
[3] Revised figures (thousands of barrels)—stocks of unfinished gasoline, Louisiana Gulf January 31, 555; February 28, 414; March 31, 498; April 30, 516.

The smallest additions to inventories were in the Rocky Mountain and Inland Louisiana-Arkansas districts, where they amounted to 6 and 7 percent, respectively.

The table of days' supply of gasoline shows that stocks increased relatively as well as actually. At the end of the year they amounted to 56.2 days of finished gasoline compared with 49.4 days at the end of 1938.

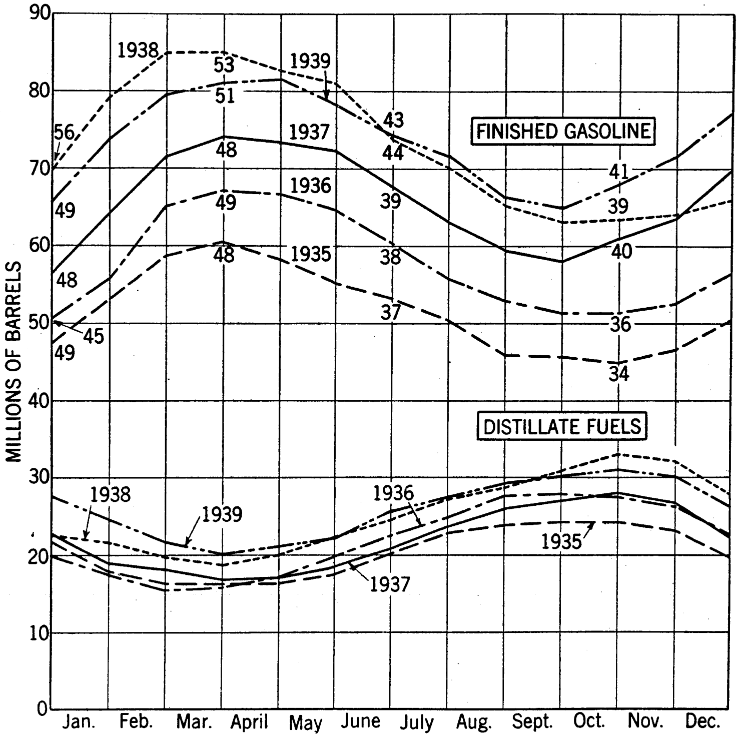

FIGURE 9.—Stocks of finished gasoline and distillate fuels, 1935–39, by months.

[1] Stocks divided by the daily average total demand (domestic demand plus exports) for succeeding month.
[2] Revised figures. [3] Subject to revision.

Seasonal variations in gasoline stocks in recent years appear in figure 9, which gives the quantity of finished gasoline stocks in millions of barrels for the last day of each month for December 1934 to December 1939, together with equivalent days' supply at certain periods.

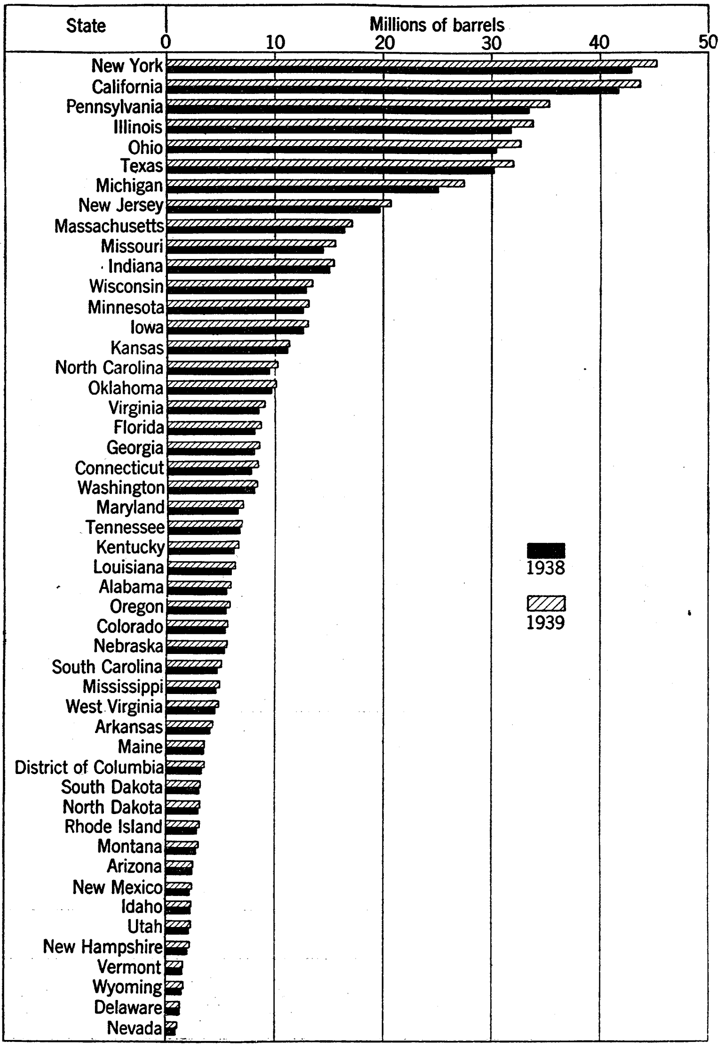

FIGURE 10—Gasoline consumption, 1938–39, by States.

The figures for days' supply on the chart represent the quantity of finished gasoline on hand at the end of a month divided by the total demand for the succeeding month.

Figure 9 also includes stocks of distillate fuels for the same period to stress the contrast in seasonal variations in stocks of the two products. It will be seen that at the end of 1939 there were 1½ million barrels less distillate fuel oil than at the end of 1938 to meet a 2,287,000-barrel (14-percent) increase in total demand for the succeeding month.

Production and consumption by States.—Texas ranked highest in gasoline production, furnishing 33 percent of the gasoline output. Other important States were: California, 13 percent; Pennsylvania, 8 percent; and Oklahoma and Illinois, 6 percent each.

The principal gasoline-consuming States maintained the same relative position in 1939 as for the past several years. (See fig. 10.) The 45,255,000 barrels (8.4 percent) consumed in New York, however, were only slightly more than the 43,760,000 barrels (8.1 percent) consumed in California. Pennsylvania followed with 6.5 percent and Illinois, Ohio, and Texas came next with 6 percent each.

Production and consumption of gasoline in the United States, 1937–39, by States

Distribution.—Motor fuel in the United States moves by pipe line, tanker, barge, tank car, and truck.

Pipe lines take the gasoline from refining centers and marine terminals to shipping points and consuming areas. The longest originates in Texas and transports Mid-Continent gasoline as far north and east as Minneapolis and Detroit. Others carry gasoline from Inland Texas and Louisiana to the Gulf coast, while a number of lines operate from the vicinity of New York City and Philadelphia as far west as Cleveland and as far north as Buffalo and Rochester, N. Y. One line runs from Providence, R. I., to Worcester, Mass., and thence to Hartford, Conn.

The quantity of motor fuel transported by pipe lines rose from 85,297,000 barrels in 1938 to 94,708,000 in 1939, an increase of 11 percent compared with the 6-percent increase in domestic demand.

Shipments of motor fuel by pipe lines in the United States in 1939, by months

[1] Overage.

The tanker movement is almost entirely from the Gulf coast to the Atlantic coast, with a small amount moving from California. Boat shipments from the Gulf coast to the East coast, which include virtually all gasoline transportation between these points, rose from 105,036,000 barrels in 1938 to 114,633,000 in 1939. Tanker shipments from California to the East coast partly recovered from their slump to 2,965,000 barrels in 1938 by rising to 3,665,000 in 1939.

Tanker rates from the Gulf to North Atlantic ports, which were as low as 14.5 cents per barrel several times during the year, began rising rapidly during the fall and stood at 60 cents per barrel at the end of the year.

Except for a movement along the coast of the Gulf of Mexico, shipments by barge are principally up the Mississippi River and its tributaries, where domestic transportation of gasoline (without adjustment for duplications) rose from 46,060,000 barrels in 1937 to 51,808,000 in 1938.[8]

Tank cars are necessary for inland movement where pipe lines are not available, while tank trucks, although used to some extent in long hauls, function principally in short-haul distribution.

[8] Chief of Engineers, U. S. Army, Annual Report: Pt. 2, table 38, 1938, p. 43, 1939, p. 45.

KEROSENE AND RANGE OIL[9]

Refinery statistics for kerosene in 1939 compared with 1938 reveal gains in the indicated domestic demand as well as in exports; these increased markets were supplied by a greater production, supplemented by a nominal draft on stocks. The higher production of 68,521,000 barrels of kerosene in 1939 compared with 64,580,000 barrels in 1938 was due to the larger runs to stills, as the kerosene yield remained at 5.5 percent or the same level as in 1938. The domestic demand for kerosene increased 7 percent—from 56,360,000 barrels in 1938 to 60,501,000—the largest increment in the domestic market in several years. The improved demand for kerosene in 1939 was confined largely to the first half of the year; it slackened noticeably in the third and fourth quarters, as indicated by actual losses in July, October, and December 1939 compared with the corresponding months of 1938.

Comparative analyses of statistics for kerosene the in United States, 1938–39, by months and districts

[1] Subject to revision. [2] Figures not available.

Year-end stocks of kerosene for 1939—7,576,000 barrels—are below the 1938 final inventory—7,799,000 barrels. The decline in stored kerosene during 1939 contrasts with pronounced gains in stocks of 716,000 barrels in 1938 and 1,450,000 barrels in 1937. Kerosene held in storage at the end of 1939 represented 46 days' supply compared with 51 days' supply at the end of 1938 and 47 days' supply at the end of 1937. Kerosene stocks held in the Texas Gulf Coast refinery district declined by 805,000 barrels to a year-end total of 1,917,000 barrels during 1939, while noticeable increases of 387,000 and 246,000 barrels are indicated in the Indiana-Illinois and Louisiana Gulf districts, respectively. The Indiana-Illinois district moved from fifth

[9] By A. T. Coumbe, Petroleum Economics Division, Bureau of Mines.

to third place in importance as a kerosene storage area in 1939, supplanting California, which dropped to fourth place.

Exports of kerosene increased from 7,504,000 barrels in 1938 to 8,243,000 in 1939, a gain of 10 percent; this expansion is in contrast to a decline of 16 percent in the 1938 overseas demand compared with the 1937 total. Netherlands, Sweden, Brazil, the Philippine Islands, and China, including Hong Kong and Kwantung, all important markets for American kerosene, required increased quantities in 1939 compared with 1938, while kerosene exports to the Netherland West Indies and the United Kingdom in 1939 were below the 1938 totals.

[1] Revised figures.

The annual survey of the Bureau covering distribution of kerosene by principal uses showed total sales of 55,570,000 barrels in 1938 compared with 54,548,000 in 1937. Kerosene deliveries in 1938 were reported as follows: Range oil 30,805,000 barrels, comparable with 29,512,000 in 1937; tractor fuel 3,955,000 barrels in 1938, a slight decline from the 1937 total of 4,251,000 barrels; and all other uses, 20,810,000 barrels in 1938 and 20,785,000 in 1937. The growing market for range oil absorbs an ever-increasing proportion of kerosene deliveries each year and made up 55.4 percent of the total in 1938 compared with 54.1 percent in 1937 and 53.1 percent in 1936. Furthermore, the available kerosene does not entirely satisfy the market for range fuel, and the distributors make up the difference with No. 1 fuel oil; 2,902,000 barrels of the latter product were delivered as range oil in 1938 and 2,747,000 barrels in 1937. The total demand for range oil, including both kerosene and No. 1 fuel oil, was reported as 33,707,000 barrels in 1938 compared with 32,259,000 barrels in 1937.

The upward trend of recent years in refinery kerosene prices, as measured by the quotations for 41°–43° gravity water-white grade in Oklahoma, was reversed in 1939, and the average for the year declined to 3.97 cents per gallon compared with 4.19 cents in 1938. The average monthly price of 4.09 cents per gallon for December 1938 dropped to 4.06 cents in January 1939 and remained at that quotation until May, when the average decreased further to 4.05 cents per gallon. Summer prices for Oklahoma kerosene trended downward until they reached an average of 3.88 cents per gallon in September and remained at that point until the middle of December 1939, when a slight increase brought the average to 3.91 cents per gallon for the final month of the year.

The tank-wagon price of kerosene, as represented by the quotations at Chicago, dropped from an average of 10.31 cents per gallon in 1938 to 10 cents per gallon in 1939. A price of 10 cents a gallon, effective October 8, 1938, remained unchanged at that level throughout all of 1939.

Sales of range oil in the United States, 1936–38, by States [1]

FUEL OILS [10]

The domestic market for fuel oils recovered from its 1938 losses and reached a new all-time high in 1939. Exports of fuel oils in 1939 continued the upward trend of recent years and established a record for the second consecutive year, while imports declined noticeably in 1939 compared with 1938. Fuel-oil stocks at the end of 1939 were considerably below comparable quantities held on December 31, 1938.

Salient statistics of fuel oils in the United States, 1938–39

[1] Subject to revision. [2] Figures not available.
[3] Includes production by cracking: 1938, 252,252,000; 1939, 260,441,000.
[4] California only. [5] Includes 616,000 barrels in California.
[6] All in California—no transfers to residual fuel oil east of California.
[7] Interstate Commerce Commission; total includes Diesel fuel.
[8] Federal Power Commission. [9] 337,756,000 on old basis, comparable with 1938.
[10] 131,935,000 on old basis, comparable with 1938.
[11] 321,228,000 on old basis, comparable with 1938.

There are two sets of refinery statistics for fuel oils in 1939, one on the old basis comparable with 1938, and one on a new basis, which considers transfers of light grades of crude petroleum to the gas-oil and distillate fuel-oil account in refinery districts east of California and changes in bulk-terminal stocks, also in refinery districts east of California. Bulk-terminal stocks of fuel oil in California have been included in refinery stocks since 1924. The crude petroleum transferred to distillate fuel oil has previously been part of the fuel-and-loss item of the crude-oil account. The transfer of 5,875,000 barrels of crude oil to the distillate fuel-oil total on the new basis reduces "fuel and losses" under crude oil by that quantity and increases the indicated domestic demand for distillate fuel oils by the same amount. Furthermore, the changes in bulk-terminal stocks of distillate fuel oils in refinery districts east of California in 1939 adds an additional 1,007,000 barrels (the net reduction in these stocks in 1939) to the indicated domestic demand for distillate fuel oils. Bulk-terminal stocks of residual fuel oil held east of California increased by 291,000 barrels in

[10] By A. T. Coumbe, Petroleum Economics Division, Bureau of Mines.

1939, therefore the indicated domestic demand for residual fuel oil is reduced by the same quantity on the new basis. The following table, in thousands of barrels, shows the transition from the old to the new basis in 1939 and the crude-oil and fuel-oil items involved in the change.

Domestic demand for fuel oil on old and new bases, 1938–39.

	1938	1939	
		Old basis	New basis
Gas oil and distillate fuel oil:			
Transfers in California	623	616	616
Transfers east of California [1]	(2)	(2)	5,875
Change in terminal stocks	(3)	(3)	−1,007
Domestic demand	117,449	131,935	138,817
Residual fuel oil:			
Transfers in California [1]	10,037	5,918	5,918
Change in terminal stocks	(2)	(3)	+291
Domestic demand	291,833	321,228	320,937
Crude oil:			
Losses and other crude used as fuel	[2] 16,751	18,691	12,816

[1] All transfers east of California classified as light fuel oil.
[2] Available only for lease and pipe-line fuel totaling 3,382,000 barrels in 1938 and 3,577,000 barrels in 1939. These amounts included as "Losses and crude used as fuel" in this table.
[3] Not available.

Generally improved economic conditions resulted in higher domestic requirements for fuel oils, and deliveries increased from 409,282,000 barrels in 1938 to 453,163,000 (459,754,000 on the new basis) in 1939, a gain of 11 percent. The domestic demand for distillate or light fuel oils, which changed little in 1938 over 1937, moved upward to a new high of 131,935,000 barrels (138,817,000 on the new basis) in 1939, an increase of 12 percent over the 1938 total of 117,449,000 barrels. A more active market for residual or heavy fuel oils, associated with higher industrial consumption, brought the domestic requirements to 321,228,000 barrels (320,937,000 on the new basis) in 1939, a 10-percent gain over the 291,833,000 barrels credited in 1938 and but little below the record demand of 325,514,000 barrels reported in 1937.

Sales of gas oil, and fuel oil [1] and of range oil 1934–38, by uses [2]

[1] Includes some crude oil burned as fuel. [2] Figures for 1939 not yet available. [3] Figures not available.
[4] Revised figures.

The market for distillate fuel oils was at the same level in the final quarter of 1938 as in the corresponding period of 1937; however, a review of light fuel-oil deliveries in 1939 by quarters shows a marked upward trend in demand. In the first two quarters of 1939, sales of distillate fuel oils were approximately 20 percent above the requirements in the first half of 1938. The market slumped sharply in the third quarter of 1939, yet the total for the period is 4 percent above that for the same months of 1938. There was some improvement as the heating season opened, and the final quarter of 1939 closed with a 7-percent gain compared with the year-end period of 1938. An expanding market for residual fuel oils, noticeable in the final quarter of 1938, gained momentum in the early months of the new year and reached gains as high as 13 percent in the second and third quarters of 1939 over similar periods of 1938. The year closed with a 7-percent rise in the fourth quarter of 1939 over the same quarter of 1938.

Preliminary statistics released by several Government agencies indicate a higher demand for fuel oils in 1939 compared with 1938. Bunker loadings of 35,841,000 barrels for vessels in foreign trade are 3 percent above the 1938 total, according to the Bureau of Foreign and Domestic Commerce, Department of Commerce, while reports of the Interstate Commerce Commission indicate fuel-oil and Diesel-fuel purchases of 62,235,000 barrels by class I railroads, a gain of 8 percent over 1938 requirements (57,758,000 barrels). Public utility electric-power plants bought 17,331,000 barrels of fuel oil in 1939, a total nearly a third greater than the 1938 purchases of 13,077,000 barrels, as revealed by figures compiled by the Federal Power Commission. If these known items are deducted from the indicated domestic demand of 453,163,000 barrels (459,754,000 barrels on the new basis) there remain 337,756,000 barrels to supply the various other fuel-oil markets, such as manufactured-gas plants, bunkers for coastwise vessels, oil fuel for mines, smelters, and manufacuring establishments, space heating, Government requirements for the Army and Navy, and oil-company fuel, a total comparable to 303,598,000 barrels for the same group of consumers in 1938. Final distribution of fuel-oil deliveries for 1939 will not be available until the annual survey of fuel-oil sales by distributors is completed; it is believed, however, that all principal use items will show a gain for the year.

Figure 11 shows graphically the fluctuations in fuel-oil sales by principal uses during 1929–38. The sales cover all grades of light and heavy fuel oils, including kerosene delivered as range oil.

Exports of fuel oils, including shipments to noncontiguous Territories of the United States, were of record volume in 1939 for the second consecutive year, when the overseas trade totaled 49,511,000 barrels, a gain of 4 percent over the 1938 quantity (47,561,000 barrels). Expansion in the fuel-oil export trade was confined to the distillate grades, which increased 8 percent from 29,641,000 barrels in 1938 to 32,021,000 in 1939. Exports of 17,490,000 barrels of residual fuel oils in 1939 show little change from the 1938 quantity—17,920,000 barrels.

Larger exports of distillate fuel oils in 1939 compared with 1938 are associated with increased takings by the United Kingdom, Netherlands, Sweden, Canada, Panama Canal Zone, Japan, and the Philippines. The larger light-fuel-oil purchases by the above-named countries were partly offset by smaller consignments in 1939 to Belgium, Denmark, Germany, and the Netherland West Indies. Japan re-

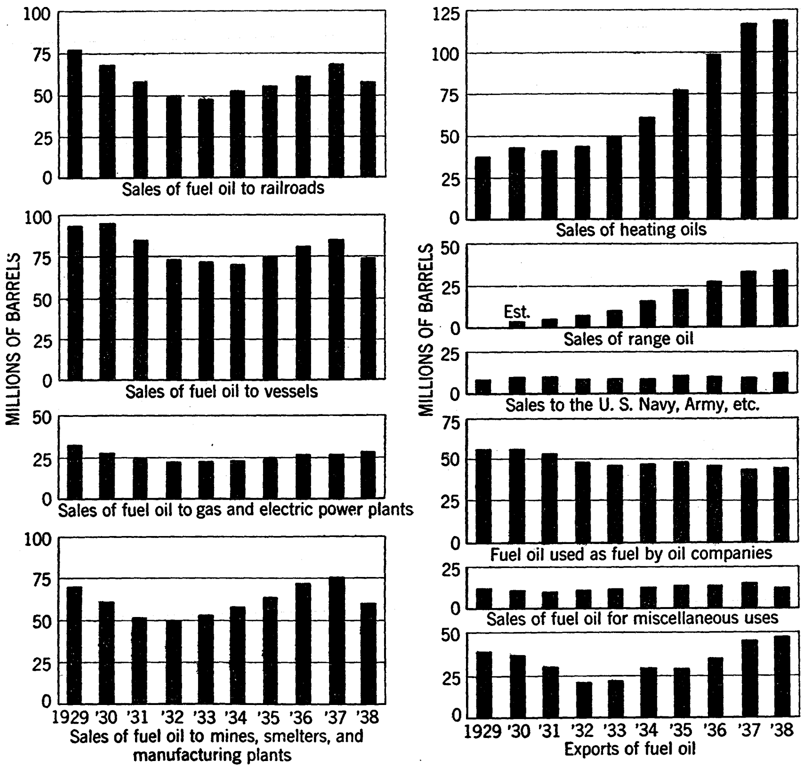

FIGURE 11.—Sales of fuel oils and range oil, 1929–38, by uses.

tained first place as the most important export customer for distillate fuel oils, receiving 6,020,000 barrels in 1939 compared with 5,297,000 in 1938.

Gains made in residual or heavy fuel oil exports in 1939 over 1938 to Italy, Spain, Japan, and the Philippines were wiped out by the smaller quantities required in 1939 by the United Kingdom, Netherlands, Canada, Cuba, Mexico, and Chile. Exports of residual fuel oil to Cuba had increased from 247,000 barrels in 1937 to 1,356,000 in 1938, and the larger share probably was intended for reexport; these declined to 322,000 barrels in 1939.

[1] Subject to revision. [2] Not available prior to 1939. [3] For comparison with 1938.
[4] New basis including transfers east of California and changes in bulk-terminal stocks east of California.
[5] Includes bulk-terminal stocks east of California—bulk-terminal stocks in California included in refinery stocks since 1924.
[6] Not available.

Larger production of both distillate and residual fuel oils can be credited almost entirely to the running of more crude oil to stills in 1939 compared with 1938. The refinery throughput of crude petroleum increased from 1,165,015,000 barrels in 1938 to 1,237,-840,000 in 1939, a gain of over 6 percent, in contrast to a decline of nearly 2 percent in 1938 from 1937. The distillate fuel-oil output of 161,-670,000 barrels in 1939 is 6 percent above the 1938 yield—151,774,000 barrels. Only a small portion (about 1.2 million barrels) of the 9.9-million-barrel increase in production in 1939 over 1938 can be attributed to a change in the percentage of yield, as this factor varied only slightly, or from 13.0 percent in 1938 to 13.1 percent in 1939. Refiners, with a more active market for residual fuel oils, increased the production from 294,890,000 barrels in 1938 to 306,896,000 in 1939, or 4 percent, in contrast to a contracted output of over 5 percent in 1938 compared with 1937. The pressure for light heating oils in recent years explains in part the declining yield for residual fuel oils, which dropped to 24.8 percent in 1939 compared with 25.3 percent in 1938.

The California production of 30,023,000 barrels of distillate fuel oil during 1939 was about 4 percent over the 1938 quantity, while east of California the yield of 131,647,000 barrels of light fuel oil in 1939 was 7 percent above the 1938 output. In districts that make important quantities of light fuel oils, refineries in the Texas Gulf increased their production from 47,529,000 barrels in 1938 to 54,362,000 in 1939, a gain of 14 percent, while plants in the Indiana-Illinois and East Coast districts reported greater yields of distillate fuel oils by 9 and 7 percent, respectively, in 1939 compared with 1938. The output of light fuel oil declined in the Oklahoma-Kansas, Texas Inland, and Arkansas-Louisiana Inland refinery districts in 1939 over 1938. The output of residual fuel oils in California continued the downward trend of recent years and dropped from 86,041,000 barrels in 1938 to 80,982,000 in 1939, a loss of 6 percent. All refinery areas east of California turned out more heavy fuel oil in 1939 than in 1938 except the Oklahoma-Kansas and Texas Inland districts, where the declines were nominal. The production of residual fuel oil in the Indiana-Illinois district, where there was a great expansion in crude petroleum production and in refinery runs in 1939, increased from 23,319,000 barrels in 1938 to 28,962,000 in 1939, a gain of 24 percent. The yield of 55,392,000 barrels of heavy fuel oil in the East Coast area during 1939 represents an increase of 9 percent over the 1938 total, while a gain of 6 percent in the Texas Gulf Coast district to a total output of 78,391,000 barrels in 1939 places the latter area very near California in importance as a source of residual fuel oil.

Comparative analyses of statistics for residual fuel oil in the United States, 1938–39, by months and districts

[1] Subject to revision. [2] For comparison with 1938.
[3] New basis including changes in bulk-terminal stocks east of California.
[4] Includes bulk-terminal stocks east of California, bulk-terminal stocks in California included in refinery stocks since 1924.
[5] Not available.

Transfers of non-gasoline-bearing crude oil to the residual fuel-oil account in California continued downward in 1939 for the second consecutive year, or from 10,037,000 barrels in 1938 to 5,918,000 in 1939. Virtually the same conditions, such as lack of active market demand, absence of price incentive, and ample heavy fuel-oil stocks, which governed these transfers in 1938, held in 1939. There was some improvement in the domestic demand for heavy fuel oil in the California marketing area, from 68 million barrels in 1938 to 76 million in 1939, but with ample refinery production and stocks of heavy fuel oil on hand, transfers of crude oil to the fuel-oil account were unnecessary during 1939 in the same volume as in recent years. Furthermore, there was also lack of inducement for transfers of crude from the price angle in 1939, although the quotation for heavy fuel oil moved upward from 80 cents to 87.5 cents per barrel in the 2 closing months of the year.

Although transfers of heavy crude oil to the residual fuel-oil account date back to 1932 in California, light crude used as fuel does not appear in refinery statistics of that area until 1938, when 623,000 barrels were transferred to the distillate fuel-oil supply, followed by a comparable total of 616,000 barrels in 1939. Distillate fuel-oil statistics for 1939 on a new basis include transfers of 5,875,000 barrels of crude oil used as fuel in refinery districts east of California, and the domestic demand of that area is increased correspondingly. The transfers of light crude oils east of California consist of the following items: 1,452,000 barrels used as fuel on leases, 2,125,000 barrels used by pipe lines, and 2,298,000 barrels consumed as industrial fuel.

There has been an excise tax of 21 cents a barrel on imported crude petroleum, topped crude petroleum, residual fuel oil, and gas oil since June 21, 1932. A new reciprocal trade agreement signed with Venezuela and effective December 16, 1939, lowers the tax on the above petroleum products imported from that country to 10½ cents a barrel; however, the quantity imported at the lower rate in any 1 year is limited to 5 percent of the crude oil run to stills in American refineries in the previous year. Runs to stills were 1,237,840,000 barrels in 1939; consequently 61,892,000 barrels of crude and fuel oil can be imported in 1940 at the reduced tariff, but quantities exceeding this amount are subject to the usual tax of 21 cents a barrel. Other nations as well as Venezuela are allowed the benefit of the lower excise tax on our imports of crude and fuel oil; and allotments based upon their respective shares of this trade during the first 10 months of 1939 are approximately as follows: Venezuela, 72 percent; Netherlands and colonies, 20 percent; Colombia, 4 percent; and all other foreign countries, 4 percent.

At this time it is impossible to foresee the effect of the lower tariff on fuel oil—10½ cents per barrel—on the quantity brought into this country for domestic use. Imports of duty-paid residual fuel oil rose sharply in December 1939 and in January and February 1940, but it is uncertain whether this expansion was due to the lower rate of duty or to the unusually heavy winter demand and greatly depleted stocks in eastern refinery areas. Dwindling American exports are now forcing a larger portion of the fuel-oil production on local markets.

No distillate fuel oils were received from foreign sources in 1938; however, small quantities totaling 171,000 barrels were imported in January and February 1939. Imports of residual fuel oil decreased from 21,065,000 barrels in 1938 to 15,932,000 in 1939. Heavy fuel oil brought into the country under bond for ships' bunkers or for refining into products for reexport decreased from 18,390,000 barrels in 1938 to 14,972,000 in 1939, or 19 percent, while duty-paid fuel oils intended for domestic consumption dropped from 2,675,000 barrels in 1938 to 960,000 in 1939, or nearly two-thirds in volume. Most of the imported heavy fuel oil in 1939, as well as in 1938, was shipped from refineries in the Netherland West Indies and was entered in the New York customs district.

Data covering fuel oils held at bulk terminals for refinery districts east of California are not available before 1939, but beginning January 1, 1939, this information was reported and calculations of the indicated domestic demand for fuel oils on a new basis consider changes in bulk-terminal stocks as well as in refinery stocks. A net decline of 1,007,000 barrels in bulk-terminal stocks held east of California, plus a transfer of 5,875,000 barrels from crude oil to the fuel-oil account previously mentioned, increases the indicated domestic demand for distillate fuel oils in 1939 from 131,935,000 barrels, as originally reported, to 138,817,000 barrels on the present basis. Residual fuel oils stored at bulk terminals increased by 291,000 barrels during 1939; consequently the domestic demand for heavy grades in 1939 is decreased correspondingly or from 321,228,000 barrels on the old basis to a revised total of 320,937,000 barrels.

Increased domestic requirements and exports were instrumental in reducing refinery fuel-oil stocks by nearly 11.5 million barrels in 1939, or from 125,619,000 barrels held at the end of 1938 to 114,148,000 on December 31, 1939. Distillate fuel-oil inventories declined 1.5 million barrels (5 percent) during 1939, or from 27,873,000 barrels at the close of 1938 to 26,374,000 reported 1 year later. Residual fuel-oil stocks were drawn upon at a relatively greater rate in 1939 and were reduced by 10 percent (nearly 10 million barrels), or from 97,746,000 barrels in 1938 to 87,774,000 in 1939.

Monthly totals show that light fuel-oil stocks for January 1939—24,650,000 barrels—were higher by over 3 million barrels than in the first month of 1938. May 1939 stocks dipped below quantities reported in the same month of 1938, but after the heating-oil season the usual summer build-up raised the June-through-August 1939 inventories again above those in the same months of 1938. In the fall of 1939 the demand for heating oils forced stocks of light fuel oils down below the comparative totals reported for the final 4 months of 1938. Stocks of residual fuel oils in the first quarter of 1939 exceeded quantities in storage in the same period of 1938; but beginning in April 1939 heavy fuel-oil inventories were consistently liquidated, and the year's change netted a reduction of 9,972,000 barrels in stocks.

The great reduction in stocks of fuel oil was limited to refinery districts east of California, where inventories declined by 7.8 million barrels (17 percent) in 1939 compared with the quantities held at the end of 1938. Heavy fuel oils stored in eastern areas were reduced by 6.1 million barrels (nearly 23 percent) in 1939, while light grades declined 1.7 million barrels (over 9 percent). All eastern refinery districts reported diminished residual fuel-oil stocks in 1939 except

Texas Inland, where the increase was relatively small. The most pronounced decline in residual stocks in 1939 was reported for the East Coast, where heavy grades contracted nearly one-half or from 7,413,000 barrels in 1938 to 3,930,000 in 1939. The Indiana-Illinois, Oklahoma-Kansas, and Rocky Mountain refinery districts netted minor gains in light fuel-oil stocks during 1939, but all other eastern areas showed losses. As with residual grades, declines in stocks of distillate fuel oils were most outstanding in the East Coast, where year-end supplies in 1939 were about 23 percent below the comparable 1938 total. The California marketing area reported a 2-percent gain in stocks of light fuel oil during 1939, while residual fuel-oil inventories were reduced by 5 percent or from 70,755,000 barrels in 1938 to 66,893,000 at the end of 1939.

Shipments of heavy fuel oil from California to the Atlantic coast, revived in October 1938 after a lapse of about 4 years, continued throughout 1939, although California prices plus tanker rates did not seem to favor this traffic. West coast residual fuel oils reaching eastern markets totaled 2,289,000 barrels received in 1939 compared with 338,000 barrels in 1938. The movement of California light fuel oils to the East coast is unimportant; however, it increased from 321,000 barrels in 1938 to 633,000 in 1939.

Active demand and dwindling stocks in eastern markets during 1939 noticeably stimulated the shipments of fuel oils from the Gulf area to Atlantic ports, and this expanded trade held in spite of greatly increased tanker rates during the closing months of the year. The Gulf-to-Atlantic movement of light fuel oils increased from 29,187,000 barrels in 1938 to 34,701,000 in 1939, a gain of 19 percent, while the traffic in residual fuel oils over the same route in 1939 (65,446,000 barrels) is 15 percent above the 1938 total (56,987,000 barrels).

In sympathy with rapidly rising quotations by tankers entering the European war zone, Gulf coast to North Atlantic tanker rates increased severalfold from August to the close of 1939. The tanker rate per barrel for light fuel oils rose from a normal slack-season quotation of 17 cents in August 1939 to 34 cents by the end of September and then moved rapidly upward to an average of 65.5 cents by the end of December, a rate more than double the 30.5 cents quoted for December 1938. Tanker rates for heavy fuel oils in the same movement went from 17 cents per barrel in August to an average of 53 cents in December 1939 compared with 25.5 cents in December 1938.

The average price for crude petroleum dropped from $1.15 per barrel in 1938 to $1.00 in 1939; this lower value for crude oil was indicated in the average quotation for representative grades of fuel oils, which although in better demand show lower average prices for 1939 than for 1938. Light distillate fuel oils at Oklahoma refineries, Bunker C fuel oil in California, and Diesel oil for ships' bunkers in all marketing areas were at lower annual averages in 1939 than in 1938. The initial price of $0.95 per barrel, for Bunker C at New York, influenced by smaller stocks and rising tanker rates, turned upward in May to an annual average of $1.04 or to the same level as for 1938. Quotations for Bunker C at Gulf ports in 1939 averaged $0.83 per barrel or 2 cents above the 1938 price.

[2] Figures not quoted.
[3] Quotations discontinued Nov. 13.

Scarcity of Bunker C fuel oil on the Gulf and Atlantic coasts forced up the New York and Boston prices 10 cents a barrel in early May. Suppliers were slow in adopting the higher quotation, and it was well into June before the new price of $1.05 for North Atlantic points and of $0.80 to $0.85 per barrel for the Gulf area was in full effect. Uncertain supplies, some improvement in crude prices, oil-field shut-downs, and the unsettled conditions in Europe moved fuel-oil prices upward at Gulf ports late in August 1939, and a top quotation of $0.90 per barrel for Bunker C was general by the middle of September. Prices for heavy oil at North Atlantic supply points responded, and a price of $1.15 per barrel gradually became established. The price of Bunker C in the Gulf district increased again, and by the second week in October 1939 was quoted at an average of $0.95 per barrel; it remained at this level to the end of the year. Gulf to North Atlantic tanker rates, which advanced from 17 cents per barrel in August to about 55 cents in December 1939, were responsible for an increase from $1.15 to

$1.50 per barrel in Bunker C prices at New York during the closing week of the year. Bunker C at California seaboard points remained at $0.80 per barrel until early November 1939, when increased demand forced the price to $0.85–$0.90 per barrel by the end of the year.

Average retail prices for heating oils, as represented by quotations for No. 2 grade on the Chicago and New York markets, show net fractional advances in 1939 over 1938, according to data compiled by the Bureau of Labor Statistics, United States Department of Labor. The price of No. 2 heating oil in Chicago, which was 7.15 cents per gallon in December 1938, averaged 7.44 cents in the spring and summer months of 1939 and advanced to 7.62 cents for the quarter closed September 15. A lower average price of 7.47 cents per gallon for December 1939 represents only a slight net change for the year. The average retail price of No. 2 heating oil in New York dropped from 6.22 cents per gallon in March to 5.87 cents in June 1939. Some tightness in the supply, higher tanker rates, and better demand pushed the average price to 6.38 cents in September and to 6.69 cents in December 1939 compared with 6.60 cents in December 1938.

LUBRICANTS

Domestic demand for lubricants increased 11 percent, or from 21,233,000 barrels in 1938 to a new record of 23,613,000 in 1939. Exports increased 27 percent—from 9,417,000 to 11,981,000 barrels. These increases, amounting to 16 percent for the total demand, resulted in material advances in the prices of all lubricants, as well as Pennsylvania Grade crude oils. The increase in domestic demand is attributable largely to the expanded industrial activity in 1939, which carried the consumption of lubricants for industrial purposes well above the 1937 record.

The distribution of domestic demand for lubricants, by uses, has been revised on the basis of new studies by the American Petroleum Institute of the ratio of oil to gasoline consumption by automobiles.[11]

Estimates based upon the American Petroleum Institute study indicate that the types of lubricants used in 1939 were divided as follows:

Automotive consumption of lubricants in 1939 [1]

[Thousands of barrels]

Use	Passenger cars	Trucks	Busses
Crank case oil	7,650	2,036	219
Transmission oils	550	197	39
Total lubricating oils	8,200	2,233	258
Chassis greases	477	98	11
Total lubricants	8,677	2,331	269

[1] Subject to revision.

Domestic demand for lubricating oils, 1930–39 [1]

[Thousands of barrels]

Year	Automotive				Industrial	Total demand
	Passenger cars	Trucks	Busses	Total		
1930	9,708	2,192	216	12,116	9,473	21,589
1931	9,599	2,144	225	11,968	8,100	20,068
1932	8,340	1,839	220	10,399	6,215	16,614
1933	7,852	1,805	212	9,869	7,283	17,152
1934	7,995	1,922	227	10,144	8,280	18,424
1935	7,950	1,993	241	10,184	9,477	19,661
1936	8,297	2,165	254	10,716	11,607	22,323
1937	8,453	2,285	267	11,005	12,318	23,323
1938	8,152	2,168	259	10,579	10,654	21,233
1939	8,200	2,233	258	10,691	12,922	23,613

[1] 1930–38 revised; 1938 and 1939 subject to revision.

The production of lubricating oils rose from 30,826,000 barrels in 1938 to 35,036,000 in 1939, somewhat less than the 1937 figure of 35,321,000 barrels. The East Coast district produced 25.8, the Texas Gulf Coast district 24.1, and the Appalachian district 17.5 percent. The Louisiana Gulf Coast district is noteworthy because its 4.3 percent of total production is the highest reached so far in an upward trend that started from a 1.3-percent share in 1932.

Stocks of lubricating oils responded to the heavy demand by dropping from 7,695,000 barrels on December 31, 1938, to 7,142,000 on December 31, 1939. The decrease in stocks was striking in the Inland Texas and the Appalachian districts, where it was 67 and 36 percent, respectively, bringing lubricating-oil inventories to the lowest levels in a decade, while Texas Gulf Coast stocks fell 15 percent. Lubricating-oil stocks increased in the Oklahoma-Kansas, Louisiana Gulf Coast, Inland Louisiana-Arkansas, and California districts.

[2] Figures not available.

The skyrocketing of lubricating-oil prices was one of the sensational developments during 1939. Quotations for many Pennsylvania Grade oils advanced more than 100 percent in distinct contrast with their lethargy during 1938. The advance in prices of Mid-Continent grades, although not as large as in Pennsylvania, was material. The two grades quoted in the accompanying table rose 37 and 60 percent. The Gulf Coast oils benefited least, the range of their price advances being only between 17 and 24 percent. Nearly all these increases were attained during the latter part of the year, as prices remained dormant or even decreased until August.

Increased prices for lubricants were shown in prices for Pennsylvania Grade crude oil; Bradford crude, for example, rose more than a dollar—from $1.68 to $2.75 per barrel.

Average monthly refinery prices of five selected grades of lubricating oils, 1938–39, in cents per gallon [1]

OTHER PRODUCTS

WAX

Domestic demand for wax rose 46,928,000 pounds, or from 278,532,000 pounds in 1938 to 325,460,000 in 1939—the greatest demand since 1933. Exports also increased 31,217,000 pounds to 232,664,000, while production increased only 29,120,000 pounds to 464,520,000; in consequence, stocks dropped from 129,340,000 pounds to 75,648,000, the lowest (except for 1933) in more than a decade.

Paraffin wax is one of the most widely used petroleum products; it is employed in numerous ways by cosmeticians and confectioners and has many functions in munitions plants. The largest quantities, however, are consumed in the manufacture of waxed paper, paper cartons, and candles. The practice of marketing milk and other products in waxed-paper cartons, which has seen rapid development recently, is one of the factors in the increased demand for wax.

Prices responded to the expanding demand and depleted stocks of wax; for Pennsylvania Grade crude scale wax these almost tripled during the year. Early in January the quotations for this wax were 2.32 cents per pound and in December had risen to 6.75 cents. The gain in price for fully refined wax on the Chicago market was not so great, being only 1.90 cents for most grades, although the 122°–124° rose from 4.00 to 6.10 cents.

COKE

Domestic demand for petroleum coke totaled 1,422,100 short tons in 1939 compared with 1,117,700 in 1938. Exports established a record of 285,800 tons, which was 130,200 tons (84 percent) above the 1938 figure—155,600 tons. Somewhat more than half of the coke exports go to Canada, and Japan, France, and Norway come next in order of importance. By far the greatest proportion of the domestic coke demand is consumed as fuel, and the next largest proportion (probably 10 to 15 percent) is employed in the manufacture of carbon electrodes, brushes, and such products. The latter uses probably are more important for exported coke, except that going to Canada, where it is used mostly as fuel.

The most significant changes in production of coke occurred in the California and Louisiana Gulf Coast districts. The output in California, which was only 400 tons in 1937 and 17,000 in 1938, leaped to second place with 187,400 tons in 1939. Production in the Louisiana Gulf Coast district, after mounting from 16, 600 tons in 1937 to 60,600 in 1938, virtually disappeared in 1939, when it dropped to 400 tons. The Indiana-Illinois district still ranked first, contributing 55 percent of the national total, while the California, Oklahoma-Kansas, and Texas Gulf Coast districts came next, in close order.

Comparative analyses of statistics for petroleum coke in the United States, 1938–39, by months and districts

ASPHALT AND ROAD OIL

Domestic demand for asphalt was 4,887,000 tons in 1939, 495,300 tons greater than in 1938. Production (4,954,400 tons) was 613,000 tons more than in 1938, while stocks (550,000 tons) were 59,600 tons higher. Imports of 44,200 tons represented an 11,000-ton gain, while exports of 42,600 tons involved a 7,300-ton loss.

The 1939 domestic demand for road oil remained virtually the same as the 1938 demand at 7,846,000 barrels. The production of 7,868,000 barrels, however, was 325,000 barrels above that in 1938 and is shown in an increase in stocks from 680,000 to 702,000 barrels.

Detailed statistics on asphalt and road oil appear in the chapter on Asphalt and Related Bitumens.

STILL GAS

The production of still gas in 1939 was 254,520 million cubic feet, or 66,979,000 barrels. The increase of 4,138 million cubic feet over production in 1938 (250,382 million cubic feet) is the smallest since 1931 and probably can be attributed to the use of refinery gases as raw materials in the polymerization and alkylation processes.

Refineries used 233,791 million cubic feet of still gas for fuel in 1938, constituting 49.5 percent of the British thermal units supplied by all refinery fuels.

The Texas Gulf Coast district still leads in the production of still gas; the Indiana-Illinois and East Coast districts follow in order.

Production of still gas in the United States, 1937–39, by districts

[1] Subject to revision.

MISCELLANEOUS PRODUCTS

The domestic demand for miscellaneous products recovered from its slump to 1,776,000 barrels in 1938 and increased to 2,223,000 barrels in 1939, approximately what it was in 1937. Exports rose from 112,000 barrels in 1938 to 123,000 in 1939, and production recovered to 2,359,000 barrels from the 1938 figure of 1,921,000.

The principal products in 1938 were liquefied petroleum gas (591,000 barrels), petrolatum (311,000 barrels), medicinal oil (172,000 barrels), and absorption oil (169,000 barrels). There are many other products that are much more important economically than quantitatively.

Production of miscellaneous oils in the United States, 1937–38, by districts and classes [1]

[1] Figures for 1939 not yet available.

WORLD PRODUCTION [12]

The world production of crude petroleum resumed its upward trend, increasing 4 percent in 1939 over 1938. There was no change in the rank of the 10 leading countries. As the United States likewise increased its production 4 percent from 1938 to 1939, its share in the total output remained fixed at 61 percent in both 1938 and 1939.

North and South America together continued to supply more than three-fourths of the world total. Peru and Bolivia were the only exceptions to the general increase in petroleum production in the Western Hemisphere. In Venezuela larger yield in the Maracaibo fields, in Quiriquire, and in the newer fields of Temblador, Oficina, and Jusepin raised the national total 9 percent from 1938 to 1939. Greater output in Mexico, chiefly from Poza Rica, was due primarily to a 30-percent increase in the export market, principally for crude petroleum to be refined in the United States for export, in Italy, and in Germany. In Colombia the opening of the new pipe line from the Barco concession to Covenas in October 1939 permitted a small increase in the total crude production from 1938 to 1939. In Argentina both Government enterprise and private companies enlarged their output at Comodoro Rivadavia, at Plaza Huincul, and in Mendoza. In Canada continued increase in production in Alberta along the eastern front of the Rocky Mountains raised the petroleum production of the Dominion from 1938 to 1939.

Two countries in eastern Europe supplied 98 percent of the petroleum production of the Continent in 1938 and 96 percent in 1939. The U. S. S. R. increased its output 4 percent from 1938 to 1939 but fell 14 percent short of its quota for 1939 under the Third Five-year Plan. In Rumania production decreased 5 percent from 1938 to

[12] By A. H. Redfield, Petroleum Economics Division, Bureau of Mines.

1939 owing to the lower yield in the Dambovitza district and the reluctance of most major producers to engage in new drilling under the existing petroleum laws, the currency restrictions, and the prevailing political situation. Of the minor European producers, Germany was able to increase its petroleum production not only in its original area but also in the former Austria and to add to its 1939 output about 227,000 barrels from former Polish territory. The Hungarian petroleum production more than trebled, and Italian engineers succeeded in increasing the yield of the Albanian fields but not of Italy. The nations of northern and western Europe and of the Mediterranean area continued to depend on imports of crude and refined oils from the United States, from Latin America, from Rumania, from the Near East, and from the Netherland East Indies to meet their requirements.

Crude petroleum produced in principal countries of the world, 1935–39, in thousands of barrels

[1] Approximate production. Derived in part from World Petroleum, vol. 11, No. 2, February 1940, pp. 42–43.
[2] Includes fields in Russian Asia other than Sakhalin. [3] Approximate production.
[4] Exclusive of U. S. S. R. fields in Asia, other than Sakhalin, which are included with U. S. S. R. in Europe.

In Asia the petroleum production of Iran, controlled by a single enterprise, remained virtually static, while that of Iraq, equally closely controlled, declined 6 percent from 1938 to 1939 owing to disruption of tanker schedules by the outbreak of the war during the last 4 months of 1939. Increased output in Sumatra, in eastern Borneo, and in Ceram raised the production of the Netherland East Indies 5 percent, in spite of declines in Java and in the Tarakan heavy-oil field. The production of Burma and of British India, destined chiefly for consumption in peninsular India, was less in 1939 than in 1938. The opening of a pipe line and of a terminal at Ras Tanura on May 1, 1939, permitted the production of Saudi Arabia to rise sharply, while production on nearby Bahrein Island was reduced in 1939. Japanese wells in Japan proper and in Taiwan increased their output in 1939 over 1938 but made no significant contribution to the requirements of a predominantly importing country. The small indicated increase in the production of northern Sakhalin was due to the activity of the local Soviet "Trust" rather than to that of the Japanese concessionnaire.

Discovery of a new field at Ras Gharib nearly trebled the small production of Egypt but left the country still dependent on imports to meet its mineral-oil requirements.

FOREIGN TRADE [13]

Imports.—An 8-percent increase in the domestic demand for mineral oils in continental United States in 1939 over 1938 was duplicated by a corresponding 8-percent increase in imports of mineral oils, crude and refined, as well as in greater production of crude petroleum in the United States and larger withdrawals from stocks from 1938 to 1939. Imports constituted, however, only 4 percent of the total new supply of mineral oils in continental United States in 1939, as in 1938. Although the excise taxes on imported oils were halved by the Venezuelan Trade Agreement of November 6, 1939, and the reduction was generalized to other nations through the most-favored-nation clause, this reduction had no appreciable effect on mineral-oil imports during 1939, as it did not become effective until December 16, 1939.

The increase was due principally to imports of crude petroleum, which were 25 percent larger in 1939 than in 1938. Eighty-four percent of these imports in 1939 were for direct consumption on payment of excise tax; of these, Venezuela supplied 90 percent. More crude was also imported, chiefly from Mexico, for refining in bond and export of the finished products.

More unfinished oils were imported in 1939 than in 1938, both for direct consumption in continental United States and in bond for refining and export of the finished products. The Netherlands West Indies supplied most of these products in 1939.

On the other hand, imports of residual fuel oil were 24 percent less in 1939 than in 1938. There was a marked decrease in receipts of fuel oil in bond in continental United States for the supplies of vessels. Imports of fuel oil into continental United States for direct consumption declined to insignificance in 1939. The Netherland West Indies furnished 97½ percent of the bonded fuel oil and 94 percent of the fuel oil for direct consumption in continental United States in 1939.

Exports.—Continental United States continued to be a net exporter of mineral oils. Exports and shipments of mineral oils to noncontiguous Territories in 1939 were more than three times as large as imports. They constituted 13 percent of the total demand for mineral oils in 1939 compared with 15 percent in 1938. Although imports obtained from neighboring countries of North and South America consisted almost entirely of crude and semirefined oils for processing and bunker oil for supplies of vessels, exports included both crude petroleum to be refined in other countries and refined oils shipped for consumption to all parts of the world.

The outbreak of the war in Europe on September 1, 1939, had little appreciable effect on the petroleum export trade of continental United States, as a whole, although individual products were variously affected. The expected increase in demand, based upon analogy to the World War of 1914–18, failed to materialize; the defensive type of warfare waged by both sides after the brief Polish campaign did not call for the large quantities of gasoline and fuel oil required in a comparable period of the last war, and the drastic restrictions imposed on civilian consumption of mineral oils not only in belligerent but also in nonbelligerent countries kept down the total demand and conserved supplies for military and naval purposes. In fact, exports and territorial shipments of mineral oils from continental United States were 2 percent lower in 1939 than in 1938. The decrease occurred principally during the first 8 months of 1939, before the outbreak of the war. During the last 4 months of 1939 outward shipments changed little from their level during the corresponding months of 1938 and 1937.

Exports of crude petroleum were 7 percent lower in 1939 than in 1938. The decrease occurred during the first 8 months of 1939; during the last 4 months of the year the exports of crude were 4 percent larger than in the corresponding period of 1938. In contrast to the general trend, exports to Canada were 5 percent larger during the first 8 months of 1939 and 30 percent larger during the last 4 months of 1939 than in the corresponding periods of 1938. But France, which had maintained its 1938 level of imports of American crude during the first 8 months of 1938, reduced its receipts 31 percent during the last 4 months in comparison with the corresponding period of 1938. Japan, lacking dollar exchange for purchases of American crude, curtailed its purchases 45 percent during the first 8 months of 1939 in comparison with the first 8 months of 1938 but increased its purchases 59 percent during the last 4 months of 1939. Italy took less American crude throughout the year, replacing it in part with petroleum from Mexico, Venezuela, and Albania. Germany, because of exchange difficulties, bought less crude petroleum from the United States and substituted, at least in part, crude obtained from Mexico on a barter basis and from the Netherland West Indies through clearing agreements.

Mineral oils, crude and refined, shipped from continental United States and including shipments to noncontiguous Territories, 1938–39, by months [1]

[1] Compiled from records of the Bureau of Foreign and Domestic Commerce; figures may differ slightly from those used throughout other sections of this report.
[2] Includes benzol and natural gasoline.

Europe remained the premier foreign market for American refined oils, taking 47 percent of the major liquid products exported from the United States in 1938 and 48 percent in 1939. Asiatic countries increased their share in the total trade from 16 percent in 1938 to 19 percent in 1939. On the other hand, the share of North American countries in the entire trade decreased from 20 percent in 1938 to 18 in 1939 and of South American countries from 5.3 percent in 1938 to 4.6 in 1939.

Decreased purchases by countries of northern and western Europe, notably the United Kingdom, France, Germany, and Belgium, were chiefly responsible for the 11-percent decline in exports and Territorial shipments of motor fuel from continental United States from 1938 to 1939. Less motor fuel was sold to Canada, Brazil, Japan, the U. S. S. R., the Union of South Africa, Australia, and New Zealand in 1939 than in 1938. The total included 4,111,000 barrels of natural gasoline and 4,234,000 barrels of aviation gasoline. The Netherland West Indies received 36 percent of the natural gasoline and 21 percent of the aviation gasoline for blending with gasoline produced in the refineries of Curaçao and Aruba and exported principally to Europe. Canada, the United Kingdom, France, Japan, and Italy took an additional 58 percent of the natural gasoline; and France, Japan, the United Kingdom, Italy, and Canada bought 50 percent of the aviation gasoline shipped from continental United States in 1939.

Gulf coast refineries of Texas and Louisiana furnished 61 percent and California refineries 25 percent of the motor fuel shipped from continental United States in 1939.

Major petroleum products shipped from continental United States, by countries of destination, and shipments to and exports from noncontiguous Territories, 1938–39 [1]

[1] Bureau of Foreign and Domestic Commerce. [2] Includes natural gasoline, naphtha, and benzol.
[3] Subject to revision. [4] By Bureau of Foreign and Domestic Commerce through March 20, 1940.
[5] Negative quantity.

More kerosene was exported to eastern Asia and to the smaller countries of northern and western Europe and to Africa in 1939 than in 1938. These increases offset the declines in shipments to the Netherland West Indies and to the United Kingdom and raised the total outward shipments of kerosene 10 percent in 1939 over 1938.

The growing use of the Diesel motors for ships, motortrucks, industrial machinery, and even airplanes is evidenced by the continued increase in exports and Territorial shipments of gas oil and distillate fuel, which were 8 percent larger in 1939 than in 1938. More gas oil and distillate fuel oil were shipped to Japan, to the United Kingdom, to the Netherlands, to the Canal Zone, to Canada, and to the Philippine Islands; less to the Netherland West Indies for reshipment chiefly to Europe; and less to Germany and to Belgium, especially after the outbreak of the war in September.

Outward shipments of residual fuel oil were slightly lower in 1939 than in 1938 but 14 percent higher than in 1937. Marked increases in exports to Japan, to Italy, to Spain, and to the Philippine Islands were offset by decreases in shipments to Cuba, Chile, Canada, Spanish Africa, Sweden, and the Netherlands.

The outbreak of the war in Europe dislocated the export trade in residual fuel oil. During the first 8 months of 1939 they were 5 percent higher than in the corresponding months of 1938; but in the last 4 months of 1939 they were 15 percent lower than in the corresponding period of 1938. The increase in foreign and Territorial shipments of lubricating oils from continental United States was general but was greatest in shipments to Europe (except to France and Germany). The outbreak of the war stimulated exports of lubricating oils; during the first 8 months of 1939 they exceeded the exports of the corresponding period of 1938 by 15 percent, but in the last 4 months of 1939 they were 53 percent larger than in the last 4 months of 1938.

Motor fuel exported and shipped to noncontiguous Territories from continental United States in 1939, by refinery districts and months [1]

[1] Compiled from data of Bureau of Foreign and Domestic Commerce as of March 20, 1940; figures may differ slightly from those used throughout other sections of this report.

Considerably more wax was shipped from continental United States in 1939 than in 1938. The increase was greatest in exports to Europe, especially to the Mediterranean countries and to the smaller nations of northern Europe bordering the North Sea and the Baltic. Canada and in general Latin America bought more paraffin wax from United States refineries in 1939 than in 1938. Decreased shipments to Africa and to the Far East were not adequate to offset the greater demand from Europe. Increased exports of paraffin wax from Burma and from the Netherlands East Indies would appear to explain the decrease of United States exports of wax to Africa and the Far East.

INTERCOASTAL SHIPMENTS [14]

Receipts of mineral oils, crude and refined, on the East coast from Gulf coast ports were nearly 10 percent larger in 1939 than in 1938. Crude petroleum was the largest single item in this movement, constituting 39 percent of the total shipments in 1939. In keeping with a 7-percent increase in 1939 over 1938 in runs to stills in East coast refineries, receipts of Gulf coast and Mid-Continent crude were 5 percent larger in 1939 than in 1938. They constituted 82 percent of the total runs of crude petroleum in 1939 compared with 83 percent in 1938. Receipts of refined oils from Gulf coast ports were 13 percent larger in 1939 than in 1938, in response to the improved demand in the marketing area of the East coast refineries.

Receipts of California mineral oils at East coast ports were larger in 1939 than in 1938; but they contributed relatively little to the supply of mineral oils in the East coast territory. The increases were chiefly in fuel oil, gas oil, and crude petroleum.

NATURAL GAS [1]

By F. S. LOTT AND G. R. HOPKINS [2]

SUMMARY OUTLINE

Marketed production of natural gas in the United States resumed its customary upward trend in 1939, after a temporary set-back in 1938. The estimated total was 2,437,200 million cubic feet, exceeding volume in 1938 by 6 percent and representing a new peak for the industry.

All types of demand except field use responded vigorously to improved business conditions, particularly in the Eastern States. In the last 4 months of 1939 abrupt expansion of operations in the steel and related industries, induced by the war in Europe, was responsible for conspicuous gains in the industrial use of gas in Pennsylvania, Ohio, and West Virginia. Western New York industrial plants were forced to reduce their consumption of natural gas because of inadequate supply.

Consumers in the United States used an estimated 2,434,154 million cubic feet (marketed production less net exports of 846 million cubic feet) in 1939 compared to 2,294,097 million in 1938. The average value at points of consumption, which had declined in 1938 to 21.8 cents per thousand cubic feet, is estimated to have increased to 22.2 cents in 1939. Higher average values are indicated for each of the three major classes of consumption, with industrial showing the greatest increase—from 9.4 cents in 1938 to 9.9 cents in 1939. Miscellaneous demand, the industrial component of greatest average value and economic significance, expanded most (13 percent) in 1939 and was the chief cause of the large gain in value of industrial gas. Domestic and commercial average values are estimated to have increased 0.2 cent each to 74.4 and 49.4 cents, respectively.

On the basis of the average values mentioned, the total value at points of consumption of natural gas consumed in the United States was $539,431,000 in 1939, an 8-percent increase over the 1938 total of

[1] Data for 1939 are preliminary; detailed statistics with final revisions will be released later.
[2] Tables compiled by H. Backus, Petroleum Economics Division, Bureau of Mines.

$500,550,000. The 1939 total was the greatest ever attained by the natural-gas industry. The total industrial value was slightly below its 1937 peak, but domestic and commercial sales were substantially above any previous levels, both in value and volume.

Steady growth in domestic and commercial gas business has been accomplished by developing many market areas as the network of gas pipe lines extended into new territory. Construction was at very low ebb in 1938 but revived in 1939, when approximately 1,500 miles of line were laid. Large gas and utility holding companies built almost all of these lines; small organizations seldom are in a position to solve the many problems involved in carrying to successful completion a new gas pipe-line project of major proportions.

The most important movement of natural gas across the national boundaries is in export to Mexico; however, political considerations have caused it to dwindle rapidly since 1936. Little information is available regarding the extent of this movement in 1939, but it is estimated at approximately 3,100 million cubic feet, almost 80 percent less than the 1938 volume of 1,743 million. Exports to Canada were 77 million and imports 131 million cubic feet in 1939. The import movement ceased in June 1939.

As shown in figure 1, the average value of natural gas at the wells is estimated to have increased from 4.9 cents per thousand cubic feet in 1938 to 5.0 cents in 1939. The total indicated value of marketed production was $113,571,000 in 1938 and $121,750,000 in 1939. Although total value at the wells in 1939 was 25 percent larger than the depression low point in 1933 it was 23 percent smaller than the 1929 figure.

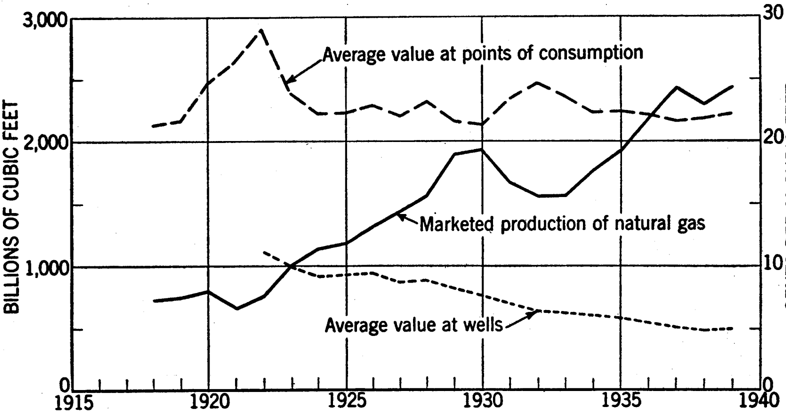

FIGURE 1.—Production and value of natural gas in the United States, 1918–39.

LEGISLATIVE AND LEGAL REVIEW

The Federal Power Commission has been active in a large number of proceedings initiated or pending in 1939 in connection with its administration of the 1938 Federal law to regulate interstate shipment of natural gas. Actions affecting gas rates have been brought by State regulatory bodies, municipalities, distributing companies, gas-producing companies, and the Power Commission on its own initiative. These actions deal with the sale or transmission of natural gas in at least 12 States, including most of the important producing areas.

On November 3, 1939, the Federal Power Commission adopted a ruling that prescribes a uniform system of accounts for natural-gas companies subject to the act; it became effective as of January 1, 1940. It requires the original cost of the plant to be stated within 2 years of the effective date, with the purpose of establishing this cost as a basis for calculating depletion, depreciation, and retirements.

Recent decisions of the Supreme Court of the United States indicate the probability of higher taxes on interstate gas operations. They have weakened the old, established doctrine which held that strictly interstate commerce was free from the burden of State taxes. Certain operations recognized as essential to and exclusively concerned with interstate transmission of natural gas are now taxable by States, provided duplication of taxes does not result.

Conservation laws applying to oil and gas production were enacted early in 1939 by the State legislatures of Arkansas and Michigan.

EMPLOYMENT AND PRODUCTIVITY

The average number of workers employed at gas wells declined 11 percent to 8,090 in 1938 from 9,073 in 1937. Curtailment of producing operations was widespread because of the generally reduced market demand for gas. Against the general trend, employment increased in New York, Illinois, New Mexico, and California, where new gas areas were expanding.

The total man-hours of labor required in gas-well production decreased less than the number employed (only 5 percent) in 1938 from 1937, especially in West Virginia, Pennsylvania, and Kansas, as many of the men laid off were part-time employees.

Average labor productivity increased 2 percent for the entire country chiefly because production of gas wells was better maintained in States with high productivity factors than in those where production per man-hour is small. As a group, the four States of highest productivity per man-hour—Louisiana, New Mexico, Texas, and Wyoming—increased their "dry"-gas production 44.4 billion cubic feet in 1938. Marked declines in output were common in the Eastern States, whose multitude of small wells require a large expense for labor per unit volume of gas produced.

In general, average annual employment at gas wells varies with the volume of gas produced but is characteristically more stable from year to year; hence the factor of labor productivity tends to increase with expanding production, and vice versa.

Employment at gas wells, natural gas produced from gas wells, and average output per man-hour in the United States, 1937–38, by States

State	Average number of workers		Total man-hours (thousands)		"Dry"-gas production (millions of cubic feet)		Labor productivity (thousands of cubic feet per man-hour)

GROSS PRODUCTION

Gross production of natural gas in the United States, as estimated in the accompanying table, increased slightly in 1938 over 1937, although the demand from established gas markets contracted 5 percent. The output of gas wells, which is habitually responsive to consumers' requirements, declined 3 percent (45.6 billion cubic feet). The volume of gas withdrawn from oil wells, however, was 4 percent larger (61.4 billion cubic feet) in 1938 than in 1937, causing an increase in the total production of gas. These changes suggest the contrasting economic and physical conditions that chart the separate courses of the two classes of gas-producing activity. The position of natural gas in oil production is incidental economically, under methods of operation still in common use, even where the gas output per barrel of oil produced is very high. However, much convincing evidence is now available of the great value of natural gas for increasing recovery of oil and reducing production expense and economic waste. This rapidly growing fund of knowledge may be expected to strengthen the sentiment among oil operators continually in favor of methods that retard the uneconomic dissipation of reservoir energies.

The practice of returning natural gas to oil sands for repressuring has expanded slowly. Fifteen States reported gas so used in 1938, an addition of 1 since 1937 and 4 since 1935. The volume of gas returned was the largest in 1938 of any year recorded, reflecting moderate growth in a number of States, notably in Texas. Reported repressuring in Oklahoma has declined over 50 percent since 1935, a trend in conformity with that of casing-head gas production in the State.

The storage of gas in depleted natural reservoirs has increased somewhat in recent years because this method of "delayed marketing" has been adopted in several eastern fields. Excess productive capacity was developed in several deep Oriskany-sand fields, and some of this gas was moved to storage points near important market areas to await periods of peak demand or eventual decline in productive capacity of the high-pressure fields.

Gross production and disposition of natural gas in the United States, 1937–38, by States, in millions of cubic feet

	1,566,975	1,481,225	3,048,200	2,295,562	101,551	14,981	636,106

[1] Marketed production plus quantities used in repressuring, stored in the ground, lost, and wasted (see footnote 2).
[2] Includes gas (mostly residue gas) blown to the air, shrinkage at natural-gasoline plants, and transportation losses but does not include direct waste on producing properties.
[3] Revised figures.
[4] Produced approximately as follows: 2,071 million cubic feet in Texas, 2,254 million in Oklahoma, 1,033 million in Kansas.
[5] Produced approximately as follows: 2,951 million cubic feet in West Virginia, 531 million in Kentucky, 1,528 million in Ohio.
[6] North Dakota (1938 only), South Dakota, Tennessee, Utah, and Washington. [7] Subject to revision.
[8] Produced approximately as follows: 2,770 million cubic feet in Texas, 1,780 million in Oklahoma, 893 million in Kansas.
[9] Produced approximately as follows: 1,981 million cubic feet in West Virginia, 530 million in Kentucky, 1,021 million in Ohio.
[10] Produced approximately as follows: 736 million cubic feet in West Virginia, 216 million in Kentucky, 59 million in New York, 1,349 million in Pennsylvania.

Losses and waste comprised 21 percent of estimated gross production in 1938, 17 percent in 1937, 15 percent in 1936, and 19 percent in 1935. The percentage increase in 1938 over 1937 is attributable in part to curtailment of gas-well production in 1938, but its principal cause is to be found in oil-production operations in several active areas where high gas-oil ratios are common. The most important of these were in New Mexico, Texas, California, Louisiana, and Arkansas.

MARKETED PRODUCTION

Marketed production of natural gas in the United States is estimated to have increased 6 percent in 1939 to 2,437 billion cubic feet, exceeding the 1937 peak. Expansion appears to have been general in almost all the leading producing States. Among States of secondary importance in gas output, sharp upward trends in natural-gas utilization have been evident for several years in Arkansas, Kansas, Kentucky, Michigan, Mississippi, Montana, New Mexico, New York, and Pennsylvania.

The dearth of available reserves may soon reverse the trend in Mississippi, New York, and Pennsylvania unless important new discoveries are promptly made. In the other States named and in all the States whose 1938 marketed production exceeded 100 billion cubic feet, known gas supplies appear adequate for a number of years.

Final 1938 data indicate that marketed production declined in most States. The only sharp increase occurred in New York through rapid withdrawal of gas from the recently developed Oriskany-sand fields.

The average price of gas at the wells declined to a new low of 4.9 cents per thousand cubic feet in 1938. Of 24 States reporting production in 1937 and 1938, however, 13 reported higher average values, 7 were lower, and 4 were unchanged. The average value at points of consumption of the gas produced dropped in 1938 to 21.8 cents, the lowest price in recent years.

Natural gas produced in the United States and delivered to consumers, 1934–38, by States, in millions of cubic feet

WELLS

During 1939, 2,145 gas wells were completed in the United States a 4-percent reduction from 1938, which in turn was 21 percent below 1937. Curtailment of drilling for gas was general in the Southwestern States, whose developed reserves greatly exceed current needs. Development increased, however, in all important Eastern States except West Virginia, where there was a material decline as drilling in the prolific Oriskany-sand fields passed its peak.

The number of producing gas wells in the country dropped from 55,050 on December 31, 1937, to 53,770 in 1938. The sum of this decline (1,280) and the 2,236 gas-well completions indicates that 3,516 gas wells were abandoned in 1938, a sharp increase over the total in any recent year. Abandonments exceeded completions in 13 States and were especially numerous in the old fields of Ohio, Pennsylvania, New York, Kansas, and West Virginia. The number of gas wells in

Michigan, Mississippi, Missouri, and Wyoming is comparatively small, but an unusually large percentage of them was abandoned in 1938.

Gas wells in the United States, 1937–39

[1] From Oil and Gas Journal and State sources.
[2] Tennessee included with Kentucky.
[3] New York included with Pennsylvania.
[4] Revised figures.

In 1931 total gas wells in the United States reached a peak of 55,756, which has not been equaled since, although gas production has risen to new highs about 25 percent above the earlier record of 1930. Modern practices of wider spacing of wells and deeper drilling have increased the average recoverable gas per well and reduced the cost per unit volume of producing natural gas, despite rising costs of labor and material.

REVIEW OF FIELD DEVELOPMENTS, BY STATES

Arkansas.—Production of natural gas in Arkansas in 1939 declined 9 percent to 18,770 million cubic feet, according to records of the Arkansas Department of Revenue furnished by Geo. C. Branner, State geologist. Production in the old gas fields in the northwestern part of the State increased 12 percent over 1938 to 4,061 million cubic feet in response to greater industrial demand. In the southern fields, however, where most gas is produced with oil, gas withdrawals were 14,710 million, about 14 percent less than in 1938. The greatest decline—2,100 million cubic feet—occurred in Miller County coincident with a marked recession in production of oil from the Rodessa field. Production and waste of casinghead gas were no doubt reduced by administration of a comprehensive proration and conservation law, which was enacted by the Arkansas Legislature on February 20, 1939.

Some of the casinghead gas produced in the Village, Atlanta, and Schuler fields was provided with pipe-line outlets in 1939 and utilized for drilling and refinery fuel. As most of the gas from southern Arkansas fields is rather high in sulfur, its distribution for general use has been restricted in favor of the abundant supplies of "sweet" gas from northern Louisiana. An estimated 40 million cubic feet daily of gas capacity in southern Arkansas fields is awaiting markets.

Six gas-well completions were reported in 1939. Three of these, with a total capacity of 7,460,000 cubic feet, were in secs. 33 and 34, T. 10 N., R. 26 W., Franklin County. Sebastian County had one completion in sec. 16, T. 8 N., R. 29 W., which produced 1.5 million cubic feet initially from a total depth of 2,709 feet; and a shallow well (1,275 feet) in sec. 6, T. 9 N., R. 32 W., Crawford County, had a capacity of 250 thousand cubic feet. In southern Ouachita County the No. 1 Cook Estate, sec. 27, T. 15 S., R. 18 W., found an estimated 20 million cubic feet of gas in the Nacatoch sand at 1,588 feet; it is several miles west of the abandoned McDonald (Mt. Holly) field.

The Big Creek and Dorcheat fields, Columbia County, were discovered in 1939. They appear to have the general characteristics of "gas-condensate" fields and are substantial additions to available gas reserves. Extensions to several oil fields in 1939 increased further the available gas supplies. Three structures, which were tested in 1939 in Nevada, Ouachita, and Faulkner Counties, gave some indications of gas reserves of commercial value.

California.—Natural-gas production in California during 1939 was about 370 billion cubic feet, a small reduction from that of 1938. Information has been received from E. F. McNaughton, California Railroad Commission, and F. F. Doyle, Pacific Gas & Electric Co. Of the total production, 198 billion cubic feet were taken from San Joaquin Valley fields, 48 billion from Coastal fields, and 124 billion from the Los Angeles Basin. Twenty-six billion cubic feet came from the "dry"-gas fields, and the remainder was casinghead gas. "Dry"-gas production is becoming a more important factor in California operations. Almost 99 percent of all gas sold in the State is now natural gas, very little manufactured gas being delivered.

In the first half of 1939, 17,285 million cubic feet of gas were blown to the air, representing 9 percent of the total production during that period. State agencies are attempting to reduce this waste through cooperative action. Serious waste still occurs, however, in some fields of the Los Angeles Basin, where town-lot development and highly divided ownership are common. Losses in the Montebello field were approximately half those for the entire State.

Preliminary data indicate that gasoline plants processed 370 billion cubic feet of gas in 1939, 7 percent less than in 1938.

Fifteen gas wells were completed in 1939. Their location by fields, with total initial capacity, was as follows: Trico, 11 wells with 219 million cubic feet; Rio Vista, 1 with 20.3 million; Woodland (Yolo County), 1 with 14.1 million; Marysville Buttes, 1 with 20.9 million; and Eureka, 1 with 75 thousand. Producing gas wells in California totaled 63 at the end of 1938 and 70 on December 31, 1939.

Pipe-line deliveries of gas were begun in 1939 from the Trico and Marysville Buttes gas fields. Drilling at Trico was stimulated by its new market outlet.

Additional supplies of casinghead gas were developed in the new Paloma and Arvin fields, Kern County, and by extensions in the Coalinga, Fruitvale, Strand, Canal, Coles Levee, and Wasco fields in the San Joaquin Valley. In the Los Angeles Basin extensions were made to the Montebello, Rosecrans, and Aliso Canyon fields.

Sales of gas for domestic, commercial, and miscellaneous industrial use increased moderately in 1939. Sales to power plants for electric generation increased sharply from 9 billion cubic feet in 1938 to 22.5 billion in 1939.

Colorado.—The total production of gas in Colorado in 1939 was 1,719 million cubic feet, an increase of 16 percent over 1938, according to H. J. Duncan, supervisor, Federal Geological Survey, Casper, Wyo. Output was moderately higher from all fields except Berthoud, which fell 10 percent. The production by fields was as follows: Berthoud, 50,396,000 cubic feet; Craig, 4,659,000; Garcia, 57,500,000; Hiawatha, 1,517,693,000; Thornburg, 89,142,000.

No new gas wells were completed in 1939, the only drilling being the deepening of one well at Hiawatha and recompletion for 2 million cubic feet at 2,420 feet (old total depth, 2,232 feet).

About 3 million cubic feet of gas were wasted through leakage in the Hiawatha and Powder Wash (shut-in) fields and 32,500,000 at Garmesa (shut-in) owing to leakage at an old well that is being plugged. About 32,600,000 cubic feet of gas, produced with oil with a gas-oil ratio of 252 cubic feet per barrel, were wasted in the Wilson Creek oil field.

Illinois.—Gas was marketed from two Illinois fields in 1939—Russellville in Lawrence County and Ayers in Bond County. The source of information is a report by A. H. Bell and G. V. Cohee, Illinois Geological Survey.

Russellville produced 964 million cubic feet from 920 productive acres. The old Ayers field produced 13,600,000, making its total production since 1922, 180,600,000 cubic feet.

Large gas reserves were found by the Storms Heirs No. 1, completed in July 1939 in sec. 14, T. 6 S., R. 9 E., White County, as a gas well in the Waltersburg sand of the Chester series at a depth of 2,215 feet, with an open flow of 12,300,000 cubic feet. By March 5, 1940, 5 gas and 30 oil wells had been drilled in the Storms field, with an initial capacity ranging from 4 to 30 million cubic feet of gas per day. It is reported that 100 million cubic feet per day of gas from the oil wells are being burned in flares, only a small amount being used for field purposes.

It is estimated that an output of 250 million cubic feet of 1,600 B. t. u. gas per day was being produced early in 1940 in the Salem oil field, Marion County, from five different producing horizons and that approximately half the ultimate gas production from this field already has been withdrawn from the ground. About 1 million cubic feet per day are being injected in 11 input wells for repressuring, a small amount is used in field operations, and the remainder is wasted by burning in flares.

In the Louden field, Fayette County, a daily yield of approximately 30 million cubic feet of gas is being produced along with oil. In the north end of the field where there is a "gas cap," gas is passed through absorbers that extract 1.3 to 1.5 gallons of natural gasoline per thousand cubic feet. About 1 million cubic feet of gas per day are used for repressuring, 3 million for lease operations, and 3.5 million as fuel; the remaining 22.5 million are burned in flares.

In other new oil fields in Illinois small amounts of natural gas are produced and used on leases or burned in flares.

In late 1938 and early 1939, five shallow gas wells were completed in Hillyard Township near Plainview, Macoupin County. Their average depth is 440 feet in basal Pennsylvanian sandstone, and initial production ranged from 125,000 to 750,000 cubic feet of 806 B. t. u.

gas per day; there is no market outlet as yet. Three abandoned gas fields, which produced 1.2 billion cubic feet in all, are situated in Macoupin County.

Indiana.—Production of natural gas in Indiana decreased from 1,244 million cubic feet in 1938 to 875 million in 1939, according to a report from G. F. Fix, State gas supervisor. Part of the decline was due to depletion in old fields and part to the fact that Oaktown, the largest gas-producing field in the State, was shut in during most of the year. It produced only 92 million cubic feet in 1939 compared to 299 million in 1938.

Gas-well completions in 1939 totaled 44; five were in unproved or wildcat territory and 39 in old areas. Completions in the active fields were: Rockport, 13; Old Trenton, 6; Greensburg, 5; Shelburn-Graysville (Sullivan County), 5; and Alford, 4. The total initial capacity was 112 million cubic feet, including 100 million from the 13 wells in the new Rockport field, Spencer County.

Production at Rockport (discovered in the summer of 1939) is from the Palestine sandstone of Upper Chester age at an average depth of 900 feet. Well capacity has ranged from 3 to 15 million cubic feet, with a rock pressure of 390 pounds.

A new gas area was discovered in sec. 19, T. 6 S., R. 12 W., Posey County, by a well that made 2.2 million cubic feet from a Pennsylvanian sand lens at 368 feet, with a rock pressure of 200 pounds. Another interesting development was the discovery of gas in a new horizon (Eden or Cynthiana) at a depth of 473 feet in Wayne County.

Several million cubic feet of gas per day are being produced from new oil wells, chiefly in the Griffin oil field developed in 1939; this gas is not marketed.

A pipe-line outlet was provided for the Rockport gas in December 1939, but no production was marketed until 1940. Gas production in Indiana is expected to increase in 1940 because of this and other new developments. The current active search for new oil reserves increases the prospect of developing new gas supplies in the near future.

Kansas.—Gas production in Kansas increased substantially in 1939 over 1938 in response to heavier market demand. The fields of largest production, as recorded by the Kansas Corporation Commission, were as follows: Hugoton, 28,964.5 million cubic feet; Otis, 8,062.9 million; Burrton, 6,387.1 million (chiefly casinghead gas); Medicine Lodge, 6,380.6 million; Lyons, 2,838.7 million; and Cunningham, 2,453.1 million. The total accumulated production of the great Hugoton field through 1939 was 188,964 million cubic feet; of Otis, 44,426 million; of Medicine Lodge, 36,437 million; of Cunningham, 8,525 million; and of Lyons, 5,051 million.

A total of 96 new gas wells (68 in western Kansas and 28 in the eastern fields) was reported in 1939, according to R. P. Keroher, geologist, Kansas Geological Survey. The total reported daily initial capacity of new wells was 1,168,500 thousand cubic feet, including 69,500 thousand (5 per cent) in eastern Kansas. Seventy-three percent of the total new production was in two large fields in western Kansas—the Hugoton (with 202 million cubic feet) and the Cunningham-Cairo-Lunt-Gilcrist area (with 643 million). Twenty-two percent (254 million cubic feet) was distributed among pools in Barton, Barber, Harvey, McPherson, and Sherman Counties in descending importance.

Probably the most important addition to gas reserves was developed in the Cunningham field of Kingman and Pratt Counties, where active drilling in 1939 proved an estimated 100 billion cubic feet of new gas reserves from the Viola limestone. Twenty-eight wells in this area had a daily open-flow capacity of over 600 million cubic feet.

A gas discovery in the Kansas City-Lansing limestone, which usually does not produce dry gas, was made by the No. 1 Oeser well in sec. 17, T. 16 S., R. 11 W., Barton County, called the Prusa field. It was completed March 14, 1939, with an initial capacity of 11.6 million cubic feet. Another discovery was made in T. 8 S., R. 29 W., near Goodland in Sherman County, in the far northwestern portion of Kansas. Two wells were drilled, with a total daily capacity of about 100,000 cubic feet of gas from a depth of 1,100 feet; they are currently supplying gas to the town of Goodland. Other additions to known gas reserves were reported in Barber, Franklin, Greenwood, Jefferson, Johnson, and Woodson Counties. A wildcat in sec. 4, T. 10 S., R. 20 E., Jefferson County, found 8.5 million cubic feet of gas in the Bartlesville sand at 1,443 feet. The discovery is of particular interest because it opened the first production of apparent commercial value in the Kansas portion of the Forest City Basin.

Six wells were drilled in the Medicine Lodge gas field, Barber County, with open flows ranging from 2 to 25 million cubic feet. In the Hugoton field five wells were drilled in Stevens County, four in Haskell County, and two in Grant County, with an initial production of 2.5 to 39.5 million cubic feet per well. A large gas well (24.5 million cubic feet) was completed in the Albert pool, Barton County, and one (60 million cubic feet) in the nearby Otis area. New gas capacity of minor importance, principally associated with oil, was developed in 1939 in the Beaver, Kruckenburg, Ritz-Canton, Wherry, Hall, Gurney, Coralena, and Burrton fields.

Approximately 275 gas wells were plugged during 1939 compared to 320 in 1938.

A new carbon-black plant was under construction at Ryus as the year ended. It will use about 3 million cubic feet of gas daily from the Hugoton field in manufacturing high-grade carbon blacks.

Gas pipe-line construction in 1939 is discussed in the pipe-line section.

Kentucky.—Gas developments in Kentucky in 1939 were routine, according to information from C. D. Hunter, I. B. Browning, R. N. Thomas, and G. M. Stranghan of Ashland and R. E. Stouder of Louisville.

In eastern Kentucky about 50 gas wells were drilled, the most active counties being Floyd, Knott, Martin, and Pike. With excess reserves already developed in this area there has been little incentive to drill for gas. Heavy demand during the past winter, however, is expected to cause more active development during 1940. Repressuring is now playing an important role in production of the eastern oil fields.

An extensive leasing campaign is in progress in the eastern counties, involving several hundred thousand acres on all known structures. The intention is to seek production from deeper horizons, particularly from the top of the "Corniferous" down to the St. Peter sandstone.

Gas activity in western Kentucky was unimportant and probably on a reduced scale in 1939. Geologic information was obtained from several wells drilled in the deeper parts of the Western Coal Basin, making available for the first time accurate data on the Pennsylvanian and Devonian formations.

Louisiana.—Gas and "gas-condensate" well completions in northern Louisiana declined further in 1939, the total being 86 against 137 in 1938, according to data supplied by Cyril K. Moresi, State geologist. Of the new wells, 66, with a total capacity of 454 million cubic feet per day, produced dry gas; the remaining 20 produced condensate with gas. Drilling in the Cotton Valley and Rodessa fields fell sharply in 1939, and activity in the Monroe area declined slightly from 53 new wells in 1938 to 49 in 1939. Completions were reported from 13 fields in 1939 and from 10 in 1938.

Reports for 1939 covering south Louisiana for the first time indicate that 53 gas and high gas-oil ratio wells were completed; of these, 5 were dry gas wells. Six completions were in the Ville Platte field, 5 in North Tepetate, and 4 at Lake Arthur; the remainder were scattered through 24 other fields.

Gross reported production of natural gas in 1939 was 402,751 million cubic feet, a 12-percent increase over 1938 and the highest on record. Production at gas wells rose to 284,895 million cubic feet in 1939 from 259,946 million in 1938, and casinghead-gas output increased to 117,857 million cubic feet from 100,849 million the year before.

The northern fields produced 313,333 million cubic feet, including 273,933 million from gas wells. The output of the Monroe field in 1939 was 189,557 million cubic feet, 10 percent higher than in 1938. Rodessa gas wells produced 33,149 million, an increase of 25 percent over 1938. Cotton Valley and Sligo, the next largest producers, supplied slightly less gas than in 1938, with 18,816 million and 13,718 million cubic feet, respectively. Most of the casinghead gas from northern fields in 1939 came from Rodessa, which produced 27,101 million cubic feet, followed by Cotton Valley with 4,562 million and Shreveport with 2,836 million. Markets for northern Louisiana gas doubtless will be expanded somewhat by a new line to Jackson, Miss., built in 1939.

Gas production in the southern part of the State totaled 89,418 million cubic feet, including only 10,962 million from gas wells. Small amounts of gas are obtained from gas wells in many fields, the most important of which are Bosco (3,915 million cubic feet) and North Tepetate (2,393 million). The most important sources of casinghead gas in 1939, with volumes in millions of cubic feet, were: Ville Platte, 10,045; Tepetate, 9,799; English Bayou, 6,978; Lafitte, 5,784; Bancroft, 4,504; Roanoke, 4,157; Iowa, 3,937; Lake Long, 3,399; Jennings, 2,880; Bosco, 2,816; and Lake Arthur, 2,608. The output at Ville Platte for 1939 increased from 1,193 million cubic feet in 1938. Other fields showing important growth in output were Bancroft, Lake Arthur (south Roanoke), Lake Long, and English Bayou. In all, 82 south Louisiana fields reported casinghead-gas production in 1939, 12 more than in 1938.

Field development in northern fields ordinarily was limited to routine drilling, and no new discoveries were reported. In the coastal area, however, active exploration led to the finding of several new fields and many new pay zones in older fields, with potentially important gas reserves. The Perkins field, Calcasieu Parish, was a new gas discovery, and deeper sands productive of gas or gas-condensate were opened at North Tepetate, Baton Rouge, Ville Platte, Leeville, Lake Mongoulois, and Bateman Lake.

Michigan.—Production of natural gas in Michigan in 1939 was 10,137 million cubic feet, a 10-percent increase over 1938, as reported by F. R. Frye, petroleum engineer, Michigan Department of Conservation. The total included 1,147 million cubic feet of casinghead gas; the remainder was from gas wells.

Gas-well completions in 1939 totaled 56—about double the 1938 total of 27. Nineteen gas wells were abandoned during the year.

The principal new gas field discovered in 1939 was in Lincoln township (T. 18 N., R. 5 W.), Clare County. A considerable supply of gas was developed from an upper sand (Berea) in the Clayton oil field, Arenac County, at a depth of about 1,200 feet. New pipe lines were built to market gas from both these fields.

During development of the Wise oil field commercial amounts of gas were found in the Michigan Stray sand, and approximately 1,400 acres were considered proved at the end of 1939. Gas was discovered in the Berea sand at 1,100 feet in the Walker oil field near Grand Rapids.

In December 1939 a well in Wright township (T. 8 N., R. 13 W.), Ottawa County, found 3.5 million cubic feet of gas from the Berea sand. Two older wells in this area had shown about one-half million cubic feet of capacity. A wildcat in Monroe County produced 108 thousand cubic feet of gas from the Trenton limestone.

Projects are reported for marketing residue gas from two new gasoline plants. From the Walker oil field, Kent County, gas will go through 22 miles of 8-inch pipe to connect with an existing trunk line. Another line is contemplated from a gasoline plant in the Redding oil field, Clare County, to a chemical plant at Midland.

The Six Lakes field produced 4,868 million cubic feet of gas in 1939—almost 50 percent of the State total. The Austin field, with 800 million cubic feet, was the next largest producer, followed by New Haven, Home, and Broomfield.

Mississippi.—Production from the Jackson gas field, which continued to be the only commercial source of gas in Mississippi, in 1939 reached an all-time peak of 15,233 million cubic feet—almost 7 percent above the 1938 record. Data have been supplied by H. M. Morse, supervisor, State oil and gas board.

However, the field is approaching exhaustion, as is indicated by the rapid encroachment of salt water in the producing formation. The strong water drive sustains gas pressures as the size of the productive area diminishes. At the end of 1939 only 30 productive gas wells remained, in contrast to 60 and 90, 1 and 2 years before. Twenty of the remaining wells are producing salt water. One gas well and three dry holes were drilled on the Jackson structure in 1939.

In December 1939 a well was started in the old Amory gas field in an attempt to bring that area back into production. Wildcatting over a wide area of Mississippi was stimulated by discovery of oil in Yazoo County in September 1939.

Anticipating reduced gas supply from the Jackson field, an 18-inch line was laid from northern Louisiana fields to connect with the trunk gas line south of the city of Jackson.

Missouri.—Fifteen gas wells with a total daily initial open flow of 6,383,150 cubic feet were completed in Missouri in 1939, according to records prepared by Frank C. Greene, geologist, Missouri Geological Survey. This is a sharp reduction from 1938, when intensive development of a gas field was in progress in Jackson County. Completions, by counties, were as follows: Jackson, 6; Platte, 3; Cass, 2; Clay, 2; Bates and Clinton, 1 each.

One new gas pool was opened in Platte County but remained undeveloped at the end of the year. Wildcatting increased markedly in the northern half of the State. Drilling operations were begun in Bollinger, Butler, and Wayne Counties in the southeastern portion of the State, but no completions were reported.

Montana.—The natural-gas industry in Montana recovered somewhat in 1939 from the curtailed operations of 1938 but remained less active than in 1937, according to information supplied by H. J. Duncan, supervisor, Geological Survey, United States Department of the Interior, Casper, Wyo. Gas-well completions increased to 26 from the 1938 total of 21. The combined daily open-flow capacity of the new wells was 201,485,000 cubic feet, 65 percent more than the capacity developed in 1938 and a larger total than that of any recent year. Two gas wells of unusual size were drilled in the Cut Bank field and shut in. Spruce Oil Co. No. 1, in sec. 24, T. 37 N., R. 5 W., about 3 miles south of the international boundary, had an initial gaged production of 43 million cubic feet from the Sunburst sand at 2,552 to 2,601 feet and a shut-in pressure of 725 pounds. Glacier Production Co. No. 2, in sec. 35, T. 36 N., R. 6 W., 13 miles north of the town of Cut Bank, had an estimated daily capacity of 80 million cubic feet from the Sunburst sand at 2,905 to 2,959 feet. No new gas fields were discovered in 1939.

All gas production, except part of that from the Cedar Creek field, is used within the State. Importations from the Rogers Imperial well in Canada were 131,244,000 cubic feet in 1939 to June 1, when the importation permit expired and was not renewed. The rock pressure of the well had dropped below the pressure maintained in the trunk line from the Whitlash field to Great Falls. The only other gas piped into Montana is from the Wyoming side of the Elk Basin field, which supplied 1,609,848,000 cubic feet to the Billings region.

Gas withdrawals increased nearly 2 billion cubic feet in northwestern Montana owing to increased demand from beet-sugar refineries and copper smelters and a reduction of rates at Great Falls. In southern Montana withdrawals decreased about 45 million cubic feet, showing the influence of milder weather and curtailed industrial operations, which were partly offset by increased demand from electric power plants.

Wastage of gas is estimated at 65 million cubic feet from gas fields and 15 million from oil fields, exclusive of about 300 million lost from Glacier No. 2 well mentioned above, which blew wild for 4 days before being brought under control.

Source and distribution of natural gas in Montana in 1939 [1]

Field	Total production (M cubic feet)	Utilization: Domestic and commercial (M cubic feet)	Industrial: M cubic feet	Industrial: Consumer	Location of principal markets
Bowdoin	673, 059	504, 794	168, 265	Steam boilers	Glasgow, Malta, Fort Peck etc.
Bowes	628, 404	314, 202	314, 202	Sugar refinery	Havre and Chinook.
Box Elder	311, 671	233, 753	77, 918	do	Do.
Cedar Creek	7, 107, 335	2, 617, 335	2, 322, 165 2, 167, 835	Cement and sugar factories. Electric power plants	Miles City, Sydney, Glendive, Montana; Rapid City, S. Dak.; Bismarck Bowman, Williston, N. Dak., etc.
Cut Bank	9, 025, 820	3, 610, 328	5, 415, 492	Smelter and steam boilers.	Anaconda, Butte, Helena etc.
Dry Creek	911, 844	911, 844			Big Timber, Bozeman, Livingstone, etc.
Hardin	71, 475	71, 475			Hardin.
Kevin-Sunburst	2, 976, 039	1, 487, 515	1, 488, 524	Smelters, steam boilers.	Great Falls, Shelby, etc.
Whitlash	639, 360	415, 584	223, 776	do	Great Falls, etc.
	22, 345, 007	10, 166, 830	12, 178, 177		

[1] Data supplied by H. J. Duncan, supervisor, Geological Survey, U. S. Department of the Interior.

New Mexico.—Only 10 gas wells were completed in southeastern New Mexico fields during 1939 compared to 19 in 1938, and the total open-flow capacity was 52,072 thousand cubic feet, a decline of 80 percent from 1938, according to E. A. Hanson, supervisor, Geological Survey, United States Department of the Interior, Roswell, N. Mex. As is usual in this area, most gas wells were incidental to the development of oil-bearing formations.

One discovery was made in April in Eddy County by Smith No. 1, which produced 750 thousand cubic feet of gas from the Permian at a total depth of 2,436 feet.

Dry-gas production increased 11 percent in 1939 to 27,106 million cubic feet—26,356 million from Lea County and the remainder from Eddy County. The quantity of gas processed at gasoline plants declined slightly to 88,671 million cubic feet from 91,800 million in 1938. The use of gas lift in oil production increased consumption 20 percent in 1939 over 1938 to 3 billion cubic feet, and field consumption for fuel and miscellaneous purposes was 10 percent greater in 1939 (2,750 million cubic feet).

Slight drilling activity continued in the fields that produce carbon dioxide gas in Harding, Torrance, and Mora Counties. Completion of six wells was reported.

In the northwestern gas fields output increased 13 percent in 1939 to 2,577 million cubic feet owing to increased withdrawals from the Kutz Canyon field, which totaled 1,869 million cubic feet. The other two active fields produced in 1939 as follows: Ute Dome, 676 million, and Blanco, 32 million cubic feet. Three gas wells were completed at Kutz Canyon in 1939.

State records indicate that the total production of gas in New Mexico was 142.5 billion cubic feet in 1939 compared with 167.6 billion in 1938—the peak year. The most important producing fields in 1939 were Eunice (46.3 billion), Monument (26.4 billion), and Cooper (19.7 billion).

New York.—The initial production of gas wells in New York during 1939 dropped sharply compared with the previous year, according to information compiled by C. A. Hartnagel, assistant State geologist. Intensive drilling was conducted in the southern New York Oriskany-sandstone area, where existing gas pools were being depleted rapidly. A total of 56 wells was drilled, including 18 producers with a total initial capacity of 104,793,000 cubic feet.

Eight producers and two dry holes were completed in the Woodhull field, Steuben County, making 46 gas wells and 4 dry holes for this area. Four producers with a combined daily open flow of 39,000,000 cubic feet were drilled in the Beach Hill and State Line pools, Allegany County.

A wildcat well in Andover, Allegany County, came in with an initial daily production of 12 million cubic feet and a rock pressure of 2,000 pounds. This well is now making salt water, and three of the four wells being drilled near by will be abandoned. Six other Oriskany tests in Allegany County were failures.

In Cameron, Steuben County, a wildcat located 13,900,000 cubic feet of gas in the Oriskany, but eight wells drilled in the immediate vicinity were failures. Other productive wells in Steuben County included one each in the towns of Jasper (4,200,000), Troupsburg (1,400,000), and Tuscarora (115,000).

The most easterly Oriskany production in New York was discovered in Danby, Tomkins County, by a well that made 5,000,000 cubic feet daily and was followed by four dry holes in the area. Dry holes also were drilled in Baldwin and Erin, Chemung County.

The discouraging results of exploration and the depletion of present active fields are rapidly causing a local scarcity of gas reserves that may threaten the life and usefulness of certain existing gas lines. The use of gas for industrial purposes has been curtailed.

Ohio.—Drilling in Ohio in 1939 increased about 12 percent over that in 1938 and resulted in the completion of 501 gas wells—68 more than in 1938—as reported by J. E. Schaefer, geologist, East Ohio Gas Co. The average initial volume was 596,000 cubic feet per well in 1939 compared with 459,000 in 1938. The higher average was due to numerous completions in the Clinton (170) and Newburg (33) sands, whose average capacity was 1,071 and 1,367 thousand cubic feet per well, respectively.

Gas wells completed in the most active counties were: Licking, 67; Athens, 57; Noble, 52; Washington, 41; Cuyahoga, 26; Guernsey, 25; Meigs, 25; Knox, 24; Stark, 24; and Monroe, 22. In 1939 the combined initial open flow of all gas wells was 298,564,000 cubic feet—50 percent larger than in 1938 and 34 percent above 1937. The Clinton sand continued to be the dominant source of new gas, contributing 182,199,000 cubic feet of the total open-flow capacity in 1939. The Newburg sand had 45,098,000 cubic feet, the Berea sand 42,027,000 feet from 179 new wells, and shallow sands 26,977,000 feet from 105 wells. Small amounts of new gas were found in the Devonian shale (seven wells), Oriskany sand (four wells), and Trenton limestone (three wells).

Gas production in Ohio has followed a declining trend for many years. It seems probable, however, that in 1939 there was a moderate increase over the 1938 marketed production (35,257 million cubic feet).

Although most of the Clinton-sand wells were drilled as extensions to productive areas, one important new pool was developed in 1939 in the contiguous corners of Mary Ann, Newton, Newark, and Madison Townships, Licking County. The discovery well was completed on December 1, 1938, in Newark Township, with an open flow of one-half million cubic feet. Interest was greatly stimulated by a well on the Van Wey farm in south Mary Ann Township, which began producing at 6,500,000 cubic feet daily in February 1939, with a rock pressure of 725 pounds. In 1939, 48 gas wells, 1 oil well, and 11 dry holes were drilled in this pool in the Clinton sand. During the drilling campaign, six Newburg-sand gas wells also were completed.

The only important development in the shallow-sand fields of eastern Ohio was the Yoker Valley gas field in Wayne and Beaver Townships, Noble County. The discovery well was drilled late in 1938, and during 1939, 34 gas wells and 4 dry holes were completed in the Berea sand at a depth of 1,500 to 1,700 feet. The initial open-flow capacity in this pool averaged less than 1 million cubic feet, but some wells were making as high as 3½ million. Rock pressure was about 600 pounds.

Ten dry holes were drilled in 1939 in searching for a producing zone from the "Green Sand" of western Ohio, which lies 500 to 700 feet below the Trenton. These holes ranged from 1,443 to 2,513 feet in depth.

Oklahoma.—The total output of natural gas in Oklahoma declined further in 1939 from the peak attained in 1937, according to Oklahoma Tax Commission records. The production of 275 billion cubic feet during 1939 was 16 percent less than that of 1938. The output of gas wells was unchanged at 75 billion cubic feet, but casinghead-gas production dropped to 200 billion cubic feet from 252 billion in 1938, owing chiefly to continued depletion and reduction of reservoir pressures in the Oklahoma City, Fitts, and Edmond pools, which have been major sources of casinghead gas in recent years. The domestic and commercial use of gas increased moderately over 1938 in 1939.

In 1939, 151 gas wells were completed—about the same as in 1938. Their total daily open-flow capacity was about 857 million cubic feet. In addition, the completion of 69 combination oil and gas wells was reported, with a total gas capacity of 252 million cubic feet. Fifteen gas and combination wells in the Cement field, Caddo County, comprised about 25 percent of the new-gas potential for the entire State. Other fields in which important additions to gas-producing capacity were made were: Chickasha, Meridian, Kellyville, Carter-Hamilton, Jesse, Fitts, South Stroud, Lafoon North, Weleetka, Onapa, Cushing, and Seminole County. About 150 gas- or water-injection wells were drilled in connection with projects for secondary recovery of oil.

From the standpoint of new gas reserves, perhaps the most important development of 1939 was the opening of gas production from deeper sands in the Chickasha field, Grady County. On April 4, 1939, the No. 1 Smith well, in sec. 26, T. 5 N., R 8 W., was completed with an output of 13.2 million cubic feet of gas daily from a depth of 5,330 to 5,350 feet. The No. 4 Carlson, an old gas well in sec. 22, T. 5 N., R. 8 W., was deepened from 2,398 to 3,968 feet and completed with an open flow of 72 million cubic feet and a rock pressure of 1,880 pounds.

In sec. 8, T. 5 N., R. 10 E., Hughes County, new gas reserves were discovered by the No. 1 Shemwell, which found about 30 million cubic feet of gas in the Calvin sand at 4,505 to 4,525 feet, with a rock pressure of 1,650 pounds. A rank wildcat well in Kingfisher County—No. 1

Geis in sec. 15, T. 18 N., R. 9 W.—gaged 2.5 million cubic feet of gas daily, with about 12 barrels of condensate, from a depth of 7,365 feet, plugged back from 8,507 feet (total depth).

Tests of gas wells in the Oklahoma City field indicate that in October 1939 there were 101, with a total daily capacity of 422 million cubic feet from 8 different horizons. The most important formations were: Oswego-Prue, with 66 wells having 265 million cubic feet of potential capacity; Hoover, with 10 wells having 73 million; Layton, with 10 wells and 34 million; and Oolitic, with 7 wells and 20 million cubic feet.

At the year end a new carbon-black plant was under construction in the Fitts field, Pontotoc County. Initially it will burn 3 million cubic feet of stripped casinghead gas a day and may later be enlarged to handle 7 million.

Gas pipe-line construction in 1939 was limited to a few very small projects, the largest being a 10-inch line from the Doyle area in eastern Stevens County, which runs southeastward 11 miles to connect with a 12-inch main line, which carries gas southward into Texas.

Pennsylvania.—The most important gas development in Pennsylvania during 1939 was in the Oriskany-sand fields of Potter County, where 27 producing wells with a total daily open-flow volume of 365,410,000 cubic feet were completed. The capacity of these wells ranged from 175,000 to 50,000,000 cubic feet and the rock pressure from 230 to 2,235 pounds. Information is taken from a report by J. G. Montgomery, Jr., vice president, United Natural Gas Co. Two of the wells opened a new field near Brookland, but their small productive capacity (500,000 and 175,000 cubic feet) does not give great promise to the area. All other wells were in proved fields. Twenty-two dry holes were drilled; 11 wells were being drilled at the end of the year.

Dry holes as follows were drilled in the Oriskany sand: In Armstrong County, 1; Beaver County, 2; Butler County, 1; Clarion County, 1; and McKean County, 3. No new fields of commercial importance were discovered during 1939. A test of the Medina sand in Mercer County was dry and was abandoned at 5,485 feet.

The first output from the Oriskany in Fayette County was found by a well which produced 1,500,000 cubic feet from that formation and 747,000 from the cherty zone of the overlying Onondaga lime. Another well located 926,000 cubic feet of gas in this cherty zone and a third well was a failure through these horizons. The depth of the wells ranged from 7,115 to 7,826 feet. Two additional wells were being drilled at the end of the year.

Gas was discovered in the Bradford sand in Cowanshannock Township, Armstrong County, at a depth of 3,637 feet. Sixteen producing wells and 2 dry holes were drilled in 1939. The average open flow was 1,650,000 cubic feet and the original rock pressure 1,140 pounds. The total area of the pool is reported to be small.

The use of rotary equipment for drilling deep holes in Pennsylvania apparently has been abandoned by operators after experimental drilling by this method in 1938 and early 1939. After the last rotary hole was completed in 1939 the material was shipped away.

Oriskany production totaled about 30 billion cubic feet in Potter and Tioga Counties, a 5-billion increase over 1938, owing chiefly to larger output of the Sharon and State Line fields. A marked decrease in the production from these areas was experienced during the latter part of the year. To offset this decline, shallow-sand production was increased.

South Dakota.—A small production of gas (estimated at 8 million cubic feet) by the cities of Pierre and Fort Pierre, S. Dak., continued in 1939. According to a statement by E. P. Rothrock, State geologist, there were no important new gas developments. The possibility of increased gas production was indicated by a well drilled on a good structure near Pierre, which struck a considerable quantity of dry gas.

A sample of gas from an old well at the Lacy Post Office was tested in the laboratory of the Bureau of Mines, Amarillo (Tex.) helium plant and found to contain 0.02 percent helium.

Texas.—The gross production of natural gas in Texas during 1939 continued the upward trend that has persisted without interruption since 1932. According to records of the Texas Railroad Commission, 1,298 billion cubic feet of gas were produced, an 18-percent increase over 1938. Of this total, 872 billion were from gas wells and 426 billion from oil wells. The gas output of both types of wells has increased consistently in recent years, as suggested by the fact that casinghead gas equaled 32 percent of the total gas produced in 1936 and 33 percent in 1939. Increases in production over 1938 were: Casinghead gas, 7 percent; sour (high-sulfur) gas, 8 percent; and sweet gas, 32 percent.

Utilization of gas increased in all major classifications, but by far the greatest growth was that incident to repressuring and gas-lift operations, which rose from 44.3 billion in 1938 to 155.3 in 1939, or 251 percent. This was due chiefly to the phenomenal growth in throughput at recycling plants, which process natural gas and vapors at very high pressures and return stripped gas to the natural reservoirs. Data concerning them first were made available for January 1939, when 10 plants extracted liquid condensate from a daily average of 116,444,000 cubic feet of gas. In December, 22 plants reported an average gas volume of 470,442,000 cubic feet processed daily. About 90 percent of the volume withdrawn from the ground usually is forced back into the producing sand to maintain pressure. Several additional plants are under construction, and others are planned. A large number of high-pressure condensate reservoirs have been discovered and await exploitation in the South Texas, Gulf Coast, and East Texas districts, and new discoveries are being made, hence the rapid expansion of recycling promises to continue for a considerable time.

A total of 462 billion cubic feet of gas was delivered to gas pipe lines in Texas during 1939—13 percent more than in 1938. Carbon-black plants burned 317 billion cubic feet (9 percent over 1938), and plant fuel and lease operations required 171 billion (a 1-percent increase). Extraction loss of 51 billion cubic feet at gasoline plants also represented a 1-percent increase, and waste of gas through blowing to the air rose to 142 billion cubic feet—a 4-percent increase. The reported waste, which includes only tail gas from gasoline plants, is greatest in the South Texas, West Texas, and Gulf Coast districts. The volume of gas processed at gasoline plants was 870 billion cubic feet in 1939 and 821 billion in 1938. The Panhandle district furnished 64 percent of the 1939 total—525 billion.

Gas wells completed in Texas numbered 314 in 1939 and 341 in 1938. The most active districts again were Southwest Texas (87) and the Panhandle (81), despite reduced operations. Completion of 62 gas wells on the Gulf Coast in 1939 was a sharp gain over the 36 completed in 1938. Activity in other areas was changed little from 1938, except in West Texas, where only 4 new wells were reported in contrast to 16 in 1938.

From the standpoint of discoveries of new gas reserves, South Texas overshadowed other districts, with 8 new fields in as many counties and 13 new productive horizons in old fields. Graham No. 1, in Survey 572, Duval County, opened the Chiltipin field in June 1939, producing 10 million cubic feet of gas from the Pettus formation at 4,795 feet. Pettus production was discovered in Karnes County in December by No. 1 Newberry, which made 3 million cubic feet from a depth of 2,949 feet. Gas discoveries were completed in the Catahoula formation in Calhoun, Goliad, and Victoria Counties, the largest (that in Goliad County) having an initial capacity of 15.5 million cubic feet. Other new fields in Bee, Live Oak, and San Patricio Counties produced from the Vicksburg, Hockleyensis, and Frio sands, respectively.

The West Texas district reported a small discovery of gas by the Hopper No. 1 well in Taylor County. In Limestone County, East Texas district, Barron No. 1 was drilled to the Pettit zone, and at 5,611 feet the well flowed 13.7 million cubic feet of gas daily. A new area was opened in Shackelford County and one new "pay" horizon in Stephens County, West Central Texas. A new source of gas was developed in Young County, North Texas, from the Strawn formation, and in the Panhandle a new gas area producing from the Permian lime was opened by Freeman No. 1 in Sherman County. The Gulf Coast district reported a discovery in Matagorda County which produced gas from the Miocene at 4,143 feet and a large well completed at 6,520 feet from a new sand—the Yegua—in the Fairbanks field, Harris County, which showed an initial daily flow of 55 million cubic feet.

Utah.—Following an 89-percent increase in 1938, Utah gas production in 1939 rose an additional 11 percent to 4,180,000,000 cubic feet, according to data supplied by H. J. Duncan, supervisor, Geological Survey, Casper, Wyo. The output of the Clay Basin field was 4,133,000,000 cubic feet and of the Ashley Valley field 47,000,000. The Farnham dome produced 51,172,000 cubic feet of carbon dioxide, which was used in the manufacture of dry ice.

It is estimated that of the 11,938 million cubic feet of gas produced in the Baxter Basin-Clay Basin-Hiawatha areas near the Colorado-Utah-Wyoming border, 11,498 million were delivered to Utah markets.

No gas-well completions were reported in 1939.

Virginia.—In June 1939 natural gas was first supplied to consumers in the city of Bristol, on the Virginia-Tennessee line. Output is from four gas wells in a small field about 10 miles northwest of Bristol in Scott County, Va., and is the only commercial production of natural gas in the State.

Washington.—The Rattlesnake Hills field, Benton County continued during 1939 to produce the only natural gas in commercial quantities in Washington. Its output dropped 45 percent from 1938 to 67 million cubic feet valued at $53,563. Of this quantity, 7 percent was used in the field and the remainder sold to consumers.

The Shallow gas field, Whatcom County, produced a little gas from the Chuckanut formation, which was consumed locally. No gas wells were completed during 1939, and prospecting generally was less active than in 1938.

Carbon dioxide production from wells near Klickitat, Klickitat County, continued to increase. In 1939, 22 million cubic feet of this gas was used to produce 2,149,195 pounds of dry ice valued at $60,786.

This information was supplied by Sheldon L. Glover, of the Department of Conservation and Development, State of Washington.

West Virginia.—Gas-well completions in West Virginia declined in 1939 to 366 from the 1938 total of 504 as a result of the slowing of Oriskany-sand development in Kanawha County and a general decline in activity in other fields. Information is taken from a report by David B. Reger, consulting geologist, Morgantown, W. Va.

A total of 68 Oriskany-sand gas wells was completed in 1939; of these 55, with an initial daily open flow of 349 million cubic feet, were in Kanawha County; and 13, with an open flow of 86 million cubic feet, were in Jackson County. The proved areas in Kanawha County are approaching full development. Most of the completions in Jackson County are in Ripley and Washington districts and are northwestern outposts of the Elk-Poca pool of Kanawha County. One of the new wells (Parsons No. 1) in Ripley district is 15 miles north of this pool and may therefore open a new field. It was completed in the Oriskany sand for 328,000 cubic feet, with a rock pressure of 1,870 pounds and a total depth of 5,139 feet. Another well far removed from older production—the Currey No. 1 at the northern edge of Ravenswood district—showed an initial daily flow of 2,534-000 cubic feet in the Oriskany with a rock pressure of 1,900 pounds and a total depth of 4,707 feet. Two other wells completed near Ravenswood City seem to indicate another productive area. These scattered wells are expected to stimulate an extensive drilling campaign in the central and southern parts of Jackson County.

In Kanawha County, Oriskany-sand drilling was largely routine in proved territory. A number of wells started for this objective were completed in upper sands, chiefly the Salt Sand, Big Lime (Mississippian), and Devonian Brown Shale. The Maxton No. 2 in Poca district had a Big Lime open flow of 17.3 million cubic feet. About 50 active rigs were reported in the two counties at the end of the year.

Reger estimates that about 200 billion cubic feet of gas have been withdrawn from the three Oriskany fields of the Charleston area and that an approximately equal volume of gas remains to be produced, indicating a total recovery of about 6 million cubic feet per acre. Rock pressures in the Campbell-Davis Creek and Cooper Creek pools have declined to around 275 pounds, suggesting that compression plants soon may be required to maintain production against prevailing line pressures of 200 to 250 pounds.

Drilling outside Jackson and Kanawha Counties failed to discover additional production from the Oriskany sand. Testing of strata below the Oriskany resulted in two productive gas wells in the Newburg sand (Silurian) in Butler district, Wayne County. A well in Peytona district, Boone County, on the western slope of the Warfield anticline was drilled to 6,004 feet and found gas in the Big Lime (249,000 cubic feet), Newburg (99,000 cubic feet), and Clinton (Silurian) sand (70,000 cubic feet). This is the first Clinton-sand production recorded in West Virginia and may stimulate deep drilling over a large area.

Three new areas producing from the Devonian Brown Shale were opened in Cabell County, two in Putnam, and one in Wayne. The Villa Nova gas pool in Clay and Braxton Counties was developed into an important reserve in 1939. The discovery well, drilled in late 1938, was first thought to be producing from the Webster Springs sand. Later information indicates the productive sand is Edray, just above the Big Lime of the Greenbriar series. About 1,500 acres have been proved by 17 wells, 1,500 to 1,800 feet deep and with an average open flow of 1.1 million cubic feet. Limits of the pool are not defined, and 16 wells were being drilled at the end of 1939.

Gas wells were drilled in 27 counties in 1939, the most active areas with number of wells completed being: Boone, 12; Braxton, 11; Cabell, 30; Calhoun, 27; Clay, 24; Gilmer, 32; Jackson, 13; Kanawha, 73; Lincoln, 17; Ritchie, 27; Roane, 20; Wayne, 21; and Wetzel, 15. The total open-flow capacity of new gas wells was 602.4 million cubic feet, a sharp reduction from the 1938 aggregate. Production for the year is estimated as 147 billion cubic feet. Available gas reserves in the State probably were increased during 1939.

Four treating plants were built to remove sulfur and moisture from the gas being produced in the northern part of the Elk-Poca pool. They are designed to handle 110 million cubic feet of gas per day.

The laying of two small pipe lines was reported in Kanawha County.

Wyoming.—According to a report by H. J. Duncan, supervisor, Geological Survey, Casper, Wyo., gross gas production in Wyoming in 1939 was 37,779 million cubic feet, almost the same as in 1938, including estimated field use of 918 million cubic feet and waste of 740 million, in addition to metered gas. A total of 19,532 million cubic feet of metered gas was delivered to gas companies for distribution, 11,647 million being used in recycling and repressuring and 4,942 million in other field operations.

In repressuring and recycling the following quantities of gas were used, by fields: Salt Creek, 6,510 million cubic feet; Lance Creek, 3,171 million; Rock Creek, 1,928 million (including 1,427 million purchased from Big Medicine Bow); and LaBarge, 38 million.

Gas production from the most important fields in 1939 was as follows, in millions of cubic feet: Salt Creek, 9,590; Baxter Basin, North and South, 5,798; Lance Creek, 4,556; Big Sand Draw, 3,410; Big Medicine Bow, 3,156; Muskrat, 2,210; Little Buffalo Basin, 1,797; and Elk Basin, 1,610. Changes up or down from 1938 were minor. The largest increase—936 million—occurred at Lance Creek.

Gas processed in Wyoming in 1939 for extraction of natural gasoline totaled 18,027 million cubic feet, which included virtually all gas produced from the Salt Creek, Lance Creek, and Big Sand Draw fields and that of the Rock Creek field (501 million).

About 600 million cubic feet of gas were wasted in 1939 in the Lance Creek field owing to inadequate gathering facilities. These were improved after September 1939 and reduced waste to 500,000 cubic feet per day. In gas fields waste was negligible, except for 100 million lost at three wellheads during drilling.

Only 7 gas wells were reported as completed in 1939 compared to 14 in 1938. Six wells completed with a total initial capacity of 26,200,000 cubic feet were in old fields, and one was a new discovery with a capacity of 2,500,000. It was drilled on the Horne structure in sec. 22, T. 22 N., R. 78 W., and shut in for lack of pipe-line connection. Gas supplies in old fields were augmented by new wells in Big Sand Draw, Garland, Billy Creek, and Baxter Basin and by deepening wells at Elk Basin and Little Buffalo Basin. In the Muskrat field a new well was reported in December to have gaged

75 million cubic feet. The reserves of the Billy Creek field appear to be nearly exhausted, and as there is no other developed gas production in the northeast quarter of the State supplies for Buffalo and Sheridan probably will be piped from Big Sand Draw and Muskrat by means of an extension from Casper.

The Allen Lake-Laramie pipe line was extended 5.2 miles, with a 6-inch line to the Oil Springs field in secs. 2 and 3, T. 23 N., R. 79 W. (a 1938 discovery), from which production was begun in November. The Mahoney dome-Rawlings gas line was connected to the Bunker Hill field in secs. 29 and 32, T. 27 N., R. 89 W., with 10 miles of 6-inch and 2 miles of 4-inch welded line.

CONSUMPTION

The decline in natural-gas consumption to 2,294 billion cubic feet in 1938 from 2,403 billion in 1937 was caused by less demand from all classes of consumers except those in oil fields. The "other industrial" load fell most sharply and comprised 79 percent of the total decline.

Domestic consumption was 1 percent less in 1938 than in 1937, despite an increase in the number of consumers to 8,634 thousand from 8,348. Consumption per domestic meter declined 4 percent to 42,600 cubic feet in 1938, reversing an upward trend of the preceding 3 years.

The average value at points of consumption of all gas sold in 1938 was 21.8 cents per thousand cubic feet, 0.2 cent below the 1937 average. The sharp reduction in industrial-gas value more than offset the increase in average value of domestic and commercial gas.

Natural gas consumed in the United States, 1934–38

Year	Domestic and commercial consumption							
	Consumers (thousands) [1]			Billions of cubic feet			Average number of M cubic feet used per domestic and commercial consumer	Average value at points of consumption per M cubic feet (cents)
	Domestic	Commercial	Total	Domestic	Commercial	Total

[1] Includes natural gas piped from Canada.

Treated for natural gasoline.—Gasoline plants processed an estimated 2,080 billion cubic feet of natural gas in 1939, 2 percent more than the 1938 total of 2,035,562 million. The recovery of gasoline, in gallons per thousand cubic feet of gas treated, is estimated to have declined about 4 percent in 1939 from the 1938 average of 1.06, chiefly because of reduced yields in Texas. The 1939 volume of gas treated equaled about 85 percent of total consumption of natural gas compared to 89 percent in 1938.

Although total 1938 throughput of gasoline plants was 3 percent less than in 1937, there were sharp increases in volume in Arkansas, New Mexico, and California. Important declines occurred in Louisiana, Oklahoma, and West Virginia.

Natural gas treated at natural-gasoline plants in the United States, 1934–38, by States, in millions of cubic feet

State	1934	1935	1936	1937	1938

Percent of total consumption	[1] 101	95	84	88	89

[1] Exceeds 100 percent, as part of the natural gas treated for natural gasoline is blown to the air and not ncluded in total consumption.

Domestic and commercial.—After the small decline in domestic consumption in 1938 the demand for natural gas for home use is estimated to have expanded over 5 percent in 1939 to 388 billion cubic feet. The average value at points of consumption was approximately 74.4 cents per thousand cubic feet, indicating that the total revenue from domestic customers was $288,672,000 in 1939 compared to $273,070,000 in 1938.

Commercial establishments consumed about 122 billion cubic feet of natural gas in 1939, a 7-percent increase over 1938. With the average value of commercial gas estimated at 49.4 cents per thousand cubic feet in 1939, the total sales value was $60,268,000.

In recent years commercial markets have been expanding more rapidly than domestic, doubtless as a result of intensive cultivation of this type of load by gas-utility organizations. Since 1933 domestic consumption has increased 37 percent, while commercial has grown 43 percent. Trends in rates for the two classes of consumption have been slightly more favorable to commercial customers.

Domestic and commercial consumption of natural gas in the United States in 1938, by States [1]

State	Domestic				Commercial				Total

[1] Includes natural gas used with manufactured gas. [2] Maryland includes District of Columbia and Virginia. [3] Utah includes North Dakota and Washington.

Field.—Oil-field operations are thought to have consumed slightly less gas in 1939 than in 1938, the estimated total being 650 billion cubic feet—a decline of 9.2 billion from 1938. There was a substantial decrease in drilling in California and Texas and a small increase in Oklahoma. These three States report such great amounts of field gas that their activities largely control the trend for the United States. The field uses and handling of natural gas have become increasingly complex, particularly in high-pressure areas. As a result, the statistical treatment of these functions has grown more difficult. Problems have been introduced by expansion of such activities as pressure maintenance, repressuring, gas lift, and recycling that tend to enlarge the field use of gas substantially above the amounts used in routine drilling and pumping.

Carbon black.—Carbon-black plants burned 348 billion cubic feet of natural gas in 1939, an increase of 7 percent over 1938 and a new all-time high for this type of gas use. The previous peak (in 1937) was 341,085 million cubic feet.

Consumption of gas for carbon-black manufacture increased in Texas and Oklahoma-Kansas, offsetting the continued decline in Louisiana. No carbon black was manufactured in Wyoming in 1939, as the single plant in that State was closed permanently on February 23, 1938. New plants were constructed or definitely planned in Texas (Gulf Coast district), Oklahoma, and Kansas.

Petroleum refineries.—The quantity of natural gas employed as fuel at petroleum refineries is estimated to have increased 8 percent in 1939 to 119 billion cubic feet. Of the 19 States reporting this type of consumption in 1938, four (Colorado, Indiana, Michigan, and Tennessee) have been added to the list since 1935. In the same interval increased refinery consumption of gas was indicated in eight States, notably in Texas, California, and Louisiana. Important declines occurred in New York, Oklahoma, West Virginia, and Wyoming. In 1938 Texas used 40 percent and California 30 percent of the United States total of natural gas consumed at refineries.

Electric public utility power plants.—Greater output of electrical energy and dry weather in some localities in 1939 caused a 12-percent increase in consumption of natural gas by public utility power plants. The 1939 total was 191,131 million cubic feet compared to 169,988 million in 1938.

The accompanying table indicates that in 1938 power plants in 29 States utilized natural gas for at least part of their fuel requirements. As might be expected, the largest consumption usually is in States having abundant supplies of cheap gas. Indiana is perhaps the outstanding exception. In 1938 power plants in that State consumed 10,153 million cubic feet of natural gas, despite the relatively high gas rates.

Portland-cement plants.—Portland-cement production increased 16 percent in 1939, and consumption of natural gas in cement manufacture increased to 40,233 million cubic feet from 37,336 million in 1938. Consumption of gas usually follows the trend in cement production rather closely. However, over a period of years the increasing thermal efficiencies of modern equipment have tended to reduce the amount of fuel consumed per barrel of product.

Industrial consumption of natural gas in the United States in 1938, by States and uses

Other industrial.—A higher rate of manufacturing operations caused increased demand for natural gas in industry in 1939. The outbreak of war in Europe on September 1 started a boom, particularly in steel and metal-working industries in eastern cities, that sharply expanded industrial gas markets in the region of the Ohio Valley. The total quantity of natural gas used by miscellaneous industries in 1939 is estimated to have been 575,790 million cubic feet, exceeding the comparable 1938 figure by 13 percent.

Among recent applications of natural gas to industrial processes may be mentioned the production of inert atmospheres from products of gas combustion. These inert gases are useful in the manufacture and storage of a number of materials, notably paints and varnish, to prevent or reduce oxidation. Gas has been widely adopted for melting type metal in the newspaper industry, replacing electricity as the source of heat. Gas-operated air-conditioning equipment, which is still in the development stage, appears to offer possibilities as a new type of natural-gas market.

The greatest potentialities for the future, however, are indicated by new chemical techniques and discoveries that will utilize natural gas as raw material. The manufacture of such bulk products as fabrics, a variety of plastics, and synthetic rubber is emerging on a commercial scale. Immediate construction of a plant in Louisiana with the capacity to produce 10,000 pounds per day of synthetic rubber has been announced.

A brief summary of the principal chemical methods employed in treating natural gas and the classes of products obtained has been published by the Bureau of Mines as Information Circular 7108, Utilization of Natural Gas for Chemical Products, by Harold M. Smith.

Mixed gas.—The amount of natural gas used as a blend with manufactured gas in 1938 was 55,825 million cubic feet, less than 1 percent below the 1937 total. Declines in most States indicated the reduced demand incident to unsatisfactory general business conditions. However, the sharp decline in Michigan (79 percent) was due chiefly to the transfer of all domestic and commercial meters (46,990 in 1937), which had been using mixed gas, to other types of gas service. Only a small industrial load remained. Mixed-gas sales in California, which were 338 million cubic feet in 1937, were eliminated in 1938 by a similar change.

In Ohio almost four times as much natural gas was sold with manufactured gas in 1938 as in 1937, apparently owing to the use of a larger proportion of natural gas in the mixed gas sold, with the effect of increasing the heating value per unit volume.

Average value at points of consumption of the natural gas used in mixed gas was 91.8 cents per thousand cubic feet in 1938 and 90.7 cents in 1937.

Consumption of natural gas used with manufactured gas in the United States in 1938, by States

State	Domestic		Commercial		Industrial (M cubic feet)	Total	
	Consumers	M cubic feet	Consumers	M cubic feet		M cubic feet	Value at points of consumption

NEW MARKETS

Natural gas was brought in 1939 to more than 80 towns and cities, with a total population of over 250,000, that formerly had not enjoyed this service. The largest number of new markets was connected in Minnesota and Iowa adjacent to the new trunk line built from Sioux City, Iowa, to Minneapolis in 1939. In southern Minnesota about 20 communities with a total population of about 60,000 and in Iowa about 10 communities with population of about 25,000 were added. Several Michigan towns were first supplied in 1939, the largest being Ann Arbor, whose approximate population is 30,000.

Other communities of substantial size that began consuming natural gas in 1939 may be summarized as follows: In Ohio, 8 towns (population, 28,000); in Arizona, 7 towns (population, 19,000); in California, 10 towns (population, 22,000); in Illinois, 5 towns (population, 10,000); in Louisiana, 3 towns (population, 11,000); and in Tennessee-Virginia, the city of Bristol (population, 21,000). Smaller additions to domestic and commercial markets were reported in Indiana, Kansas, Mississippi, New Mexico, Oklahoma, Texas, and Wyoming. The new markets mentioned do not include extensions to distribution systems in communities served with natural gas before 1939. Important new industrial markets were acquired in Arizona, New Mexico, Texas, and California.

INTERSTATE SHIPMENTS

In 1938, for the first time since 1931, the total movement of natural gas in interstate commerce declined appreciably, falling to 636,626 million cubic feet from 687,428 million in 1937, or 7 percent.

Declines in interstate movements from producing States were general, and the most severe affected Oklahoma, Pennsylvania, and Louisiana. The outstanding exception was New York, whose shipments more than doubled—from 9,954 million in 1937 to 22,384 million in

1938. Virtually all this gas went into Pennsylvania. Slightly increased movements were reported from Indiana, Mississippi, Missouri, and Utah. Illinois and North Dakota were added to the interstate list in 1938. Marketed production exceeded consumption in 1938 in Texas by 153 billion cubic feet, in Louisiana by 122 billion, and in West Virginia by 77 billion, indicating that these three leading States supplied the major portion of the total interstate movement.

The States with the largest interstate receipts continued in 1938 to be Ohio, with 72.9 billion cubic feet, and Illinois, with 65.4 billion. There has been particularly rapid growth in recent years in shipments from Kentucky to West Virginia, Texas to Louisiana, and Texas to Michigan.

PIPE-LINE DEVELOPMENTS

Construction of pipe lines for transmitting natural gas revived sharply in 1939 from the unusually low level of 1938. About three times as many projects were completed in 1939, and their aggregate mileage exceeded 1,500 in contrast to less than 400 miles laid in 1938.

Except for a few small lines, all the construction was in States west of the Mississippi River.

The largest new line was of 16-inch pipe running from Sioux City, Iowa, to Minneapolis, Minn., a distance of about 240 miles; it will augment the supply of gas for Minneapolis-St. Paul and bring natural-gas service to towns in northwestern Iowa and south-central Minnesota. Another large line was laid from the Monroe field, La., eastward to connect with existing trunk lines near Jackson, Miss. It consists of 125 miles of 18-inch pipe and 50 miles of various sizes from 4-inch to 20-inch. The approaching depletion of the Jackson (Miss.) gas field made necessary a new source of gas supply to serve growing markets in Mississippi and States to the east.

A new line consisting of 73 miles of 8⅝-inch and 117 miles of 6⅝-inch pipe was laid from a main-line connection near Gage, N. Mex., to supply fuel to smelters at Miami and Globe, Ariz. Two loops—62 miles of 16-inch and 56 miles of 12¾-inch—were installed on the main line east of Gage, N. Mex., to provide the additional capacity required by the growing demand for gas in Arizona and adjacent territory.

In California a number of short additions to the gas-utility systems were reported, with a total length of a little over 100 miles, mostly of 8- and 10-inch pipe. New outlets for gas were provided for the Rio Bravo, Kettleman Hills, Sutter Buttes, and Delano fields. One of the new 8-inch lines brought gas to a pottery at Lincoln, Calif., and a line along the crest of the San Bernardino Mountains supplied 11 communities with natural-gas service for the first time.

Nine new gas lines were laid in Texas, none of which, however, was of major proportions. Their total length was about 250 miles. New lines were built to transport gas from the Spanish Camp, Page, Buffalo, Joaquin, Katy, and Wasson fields. Additional supplies of gas were piped to Beaumont and Houston for industrial use, and new lines brought gas to McNeil and Carlsbad, Tex., and several other small towns.

A few short lines were built in Louisiana, and one 50-mile, 6-inch line was run from the Joaquin (Tex.) gas field to Natchitoches, La. New connections were made with the Sibley, Sligo, and Lake Bastineau fields.

About 40 miles of 20-inch line were laid in Clay and Washington Counties, Kans., as a loop to increase the capacity of a main line. In addition, an 8-inch line 35 miles long was built from the Cunningham field to Hutchinson, Kans., and a small 10-mile line from the Wackerle gas field to Oswego, Kans. There was very little gas-line construction in Oklahoma in 1939. The largest of three projects consisted of 11 miles of 10-inch and 8-inch pipe running from the Doyle area in northeastern Stevens County southeastward to connect with a 12-inch trunk line 20 miles north of Healdton.

In Mississippi 32 miles of 18-inch line were installed, extending an existing system from the town of Onward to the new Tinsley oil field near Yazoo City. The chief demand for this gas is from drilling and oil-production operations.

Michigan was the most active of the Eastern States in gas pipe-line construction, three lines having been built as follows: 22 miles of 6-inch from the trunk line at Milan to Ann Arbor; 45 miles of 6-inch from the Arenac field to Midland; and 30 miles of 4½-inch from the Austin field to Claire. Two 24-inch loops with a total length of 16.2

miles were added to the Texas-Detroit line at points in Indiana. A line was laid in Illinois from Streator to Pontiac, a distance of 23 miles; and about 15 miles of 6- and 8-inch line were run from Lawrence County fields, Ill., eastward to connect with a trunk line in Indiana. Point Marion, Pa., obtained a new gas supply through a new 4½-inch line laid from the Wasson No. 1 gas well in West Union Township, 19 miles away.

Eight miles of 12-inch line were laid to replace old 8-inch pipe in the line from the Elk Basin field to Billings, Mont.; and in Wyoming, 11 miles of 8-inch were laid in the James Lake area, Carbon County.

At the end of 1939 several large loops were being added to the Texas-Detroit line involving a reported 140 miles of 22- and 24-inch pipe. A 75-mile, 8⅝-inch line was under construction from the Cotton Valley (La.) field northward to Hope and Okay, Ark., and in New Mexico a 31-mile extension of a line from Albuquerque to Belen and other towns was progressing.

NATURAL GASOLINE

AND LIQUEFIED PETROLEUM GASES[1]

By G. R. Hopkins

SUMMARY OUTLINE

NATURAL GASOLINE

The natural-gasoline industry appeared headed for another drab year in 1939 until the oil fields were shut down for 2 weeks during August. This shut-down, which affected all the important producing States except California and Illinois, caused production in 1939 to fall below that in 1938 but also entailed a scarcity of supplies sufficient to raise the price 1 cent or more per gallon. The market situation continued strong for several months, or long enough to insure a small profit for most companies; but price declines in December placed the industry in States east of California in an uncomfortable position, which grew worse during the first 4 months of 1940. Prices in California, however, have shown remarkable steadiness.

The proportion of natural gasoline in refinery gasoline, which increased in both 1937 and 1938, declined from 7.2 percent in 1938 to 6.8 in 1939. Although the shut-down brought about a net decrease in stocks of natural gasoline for 1939 the apathy in refinery demand quickly reversed this trend during the first quarter of 1940.

Owing principally to the war abroad, exports of natural gasoline fell about a third, or to 172,662,000 gallons in 1939. Direct sales to jobbers and retailers also decreased materially during the year.

No spectacular advances were made in established production methods in 1939, but use of the recycling process continued to expand rapidly, and much progress was made in producing high-octane gasoline from the lighter hydrocarbons. Most of this research was at refineries, but the natural-gasoline industry played an important role.

[1] Data for 1939 are preliminary; detailed statistics with final revisions will be released later.

Salient statistics of the natural-gasoline industry in the United States, 1935–39, in thousands of gallons

PRICES AND MARKET CONDITIONS

Although natural-gasoline prices in 1939 were far below the 20-cent quotations of 20 years ago, there was some improvement over 1938. The price of a representative grade of natural gasoline (26–70 in Oklahoma) was just under 4 cents as the year opened and dropped to 2.50 cents in the slack months of April and May, but was 4.25 cents during most of September, October, and November, the months of heaviest consumption. The rapid decline of this quotation in December was disappointing, as it made prospects for 1940 discouraging.

Figure 1 shows that the average value of natural gasoline (estimated for 1939) remained below the refinery price of United States motor gasoline in Oklahoma, although the gap was not as wide as in 1938.

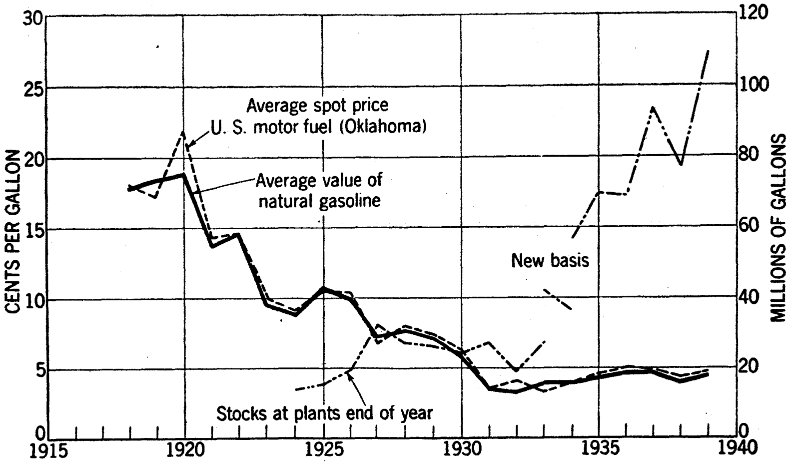

FIGURE 1.—Trends in average value of natural gasoline, spot price of gasoline, and stocks of natural gasoline, 1918–39.

Spot price of Oklahoma natural gasoline, grade 26–70, on specified dates in 1939, with monthly and yearly averages, in cents per gallon

EMPLOYMENT AND PRODUCTIVITY

The average number of workers at natural-gasoline plants dropped from 9,429 in 1937 to 9,205 in 1938. Most of the decrease was in part-time workers, who averaged 595 in 1938 compared with 734 in 1937.

Man-hours for 1938 totaled 18,818,000, assuming 1,000 hours per year for each part-time worker. The hours per week for full-time workers accordingly declined from 41.3 in 1937 to 38.1 in 1938. Average productivity increased again as less efficient plants were weeded out; in 1938 the average was 114.6 gallons per man-hour compared with 106.6 in 1937.

Employment at natural-gasoline plants, natural gasoline produced, and average output per man-hour in the United States, 1937–38, by States [1]

PRODUCTION

Trends in total output.—As most natural gasoline is made from casinghead gas there is close relationship between its output and that of crude oil; however, in 1939, the production of crude petroleum increased 4 percent whereas the output of natural gasoline probably

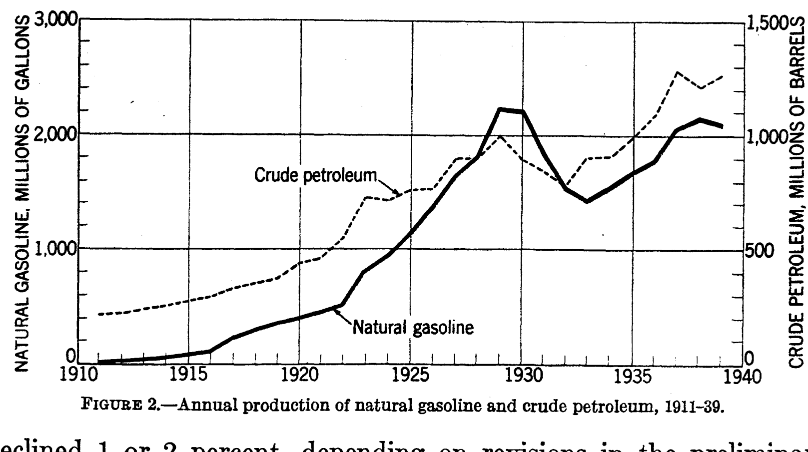

FIGURE 2.—Annual production of natural gasoline and crude petroleum, 1911–39.

declined 1 or 2 percent, depending on revisions in the preliminary figures. This discordant trend is due primarily to developments in Illinois, which were largely responsible for the gain in crude-oil production but which, as explained more fully elsewhere, were not conducive to a proportionate increase in the output of natural gasoline. (See fig. 2.)

[1] Subject to revision.

The monthly trend of production was fairly uniform over the first 7 months of 1939 but slumped drastically in August owing to the shutdown. An upward trend was discernible over the last 4 months.

California.—Production of natural gasoline in California decreased from 660,890,000 gallons in 1938 to 606,631,000 in 1939. This, the first decrease in output since 1933, reflects the downward trend in crude-oil production through proration rather than a declining gas supply.

The output of all the important fields or districts (except Ventura Avenue, in which new oil zones were opened), was less in 1939 than in the preceding year. Despite a 30-million gallon decrease in output, the Kettleman Hills field still ranks first among the producing fields; it produced slightly more than a fourth of the State total in 1939.

Louisiana.—With the decline of casinghead-gas production in the Rodessa field the output of natural gasoline continued to trend downward, although the decrease in 1939 was not as large as in 1938 because of the gain in production in the coastal district. The output in 1939 was 92,066,000 gallons compared with 95,634,000 in 1938 and with 106,415,000 in the peak year 1937.

Oklahoma.—The production of natural gasoline in Oklahoma during 1939 continued to fall more or less in consonance with the decline in crude-oil production. The output was 434,797,000 gallons compared with 468,499,000 gallons in 1938. As in the preceding year, production at Oklahoma City declined materially, Seminole held up remarkably well, and "Other districts" besides Osage County made the only gain.

Texas.—Production in Texas increased in 1939, the gain being relatively higher than in crude-oil production because of the increased use of recycling. The output reached a new record of 704,707,000 gallons compared with 685,920,000 in 1938. A year ago the statement was made that Texas probably would pass California as the leading producer of natural gasoline in 1939. Actually, final figures for 1938 show that Texas took first place in that year.

Natural gasoline produced in the United States, 1935–39, by States, in thousands of gallons

[1] Subject to revision. [2] Includes Utah.

The output of the Texas Panhandle, the leading producing district of the country, declined slightly in 1939, but that of the East Texas field gained, passing Kettleman Hills as the second ranking field. However, the largest gains in Texas were in the Gulf Coast—the result of rapidly expanding recycling operations—and in "Other districts."

Other States.—Arkansas did not continue the substantial gain in output attained during 1938; in fact, output declined slightly in 1939. There was a material increase in Illinois although the general character of the gas production in the new fields of that State is not particularly attractive to plant operators. Kansas and New Mexico reached new peaks in production in 1939. West Virginia and Wyoming made slight gains, the former because of the Oriskany gas development, the latter as a consequence of the gain in crude-oil production.

Natural gasoline produced and natural gas treated in the United States in 1938, by States [1]

State	Number of operators [2]	Number of plants operating	Natural gasoline produced: Thousands of gallons	Value at plants: Thousands of dollars	Value at plants: Average per gallon (cents)	Natural gas treated: Millions of cubic feet	Natural gas treated: Average yield per M cubic feet (gallons)

[1] Complete figures for 1939 not yet available.
[2] A producer operating in more than 1 State is counted only once.

CONSUMPTION AND MOVEMENTS

The indicated demand for natural gasoline in 1939 may reach 2,130,000,000 gallons, or about 1 percent below that in 1938. The refinery utilization probably will exceed 1,700,000,000 gallons. This represents about 80 percent of the total, or about the same proportion as in 1938. Exports and "direct" shipments declined in relative importance; this loss automatically raises the percentage for "Losses."

Distribution of natural gasoline in the United States, 1938–39, by months, in thousands of gallons

Refinery utilization.—The proportion of natural gasoline in refinery gasoline, an important index as to whether natural gasoline is maintaining its relative importance, dropped to 6.8 percent in 1939 from 7.2 percent in 1938, bringing the percentage to about the level that prevailed during 1935 and 1936.

Blending of natural gasoline increased in 1939 in the East Coast, Appalachian, Indiana-Illinois, Texas Gulf Coast, and California districts, but of these only the first and last gained in the percentage of total refinery-gasoline production.

Percent of natural gasoline in refinery gasoline in the United States, 1935–39, by districts

Year	East Coast	Appalachian	Indiana, Illinois, Kentucky	Oklahoma, Kansas, Missouri	Texas Inland	Texas Gulf Coast	Louisiana Gulf Coast	Arkansas and Louisiana Inland	Rocky Mountain	California	Total

"Direct" sales.—The sale of low-pressure natural gasoline directly to consumers, attractive in theory, has proved generally uneconomic in practice, probably because of the difficulty of meeting certain motor-fuel specifications. Anyway, sales to jobbers and retailers dropped from 137,970,000 gallons in 1938 to 121,128,000 in 1939; however, this decline may be halted in 1940, as more complete reports on recycle plants may reduce "Losses" and raise direct shipments.

Texas led in total direct sales, although shipments from Oklahoma to Illinois constituted the largest single interstate movement. Direct sales from Louisiana made the largest relative increase in 1939.

Water-borne shipments.—Exports of natural gasoline, as reported to the Bureau of Foreign and Domestic Commerce and as used in this publication, dropped from 256,914,000 gallons in 1938 to 172,662,000 in 1939. Bureau of Mines export figures, formerly used in this publication, were 202,230,000 and 167,806,000 gallons, respectively. The largest export movement continued to be that to the Netherland West Indies, with exports to United Kingdom, Canada, and France following in that order. Japan took about 7,600,000 gallons, or less than half as much as in 1938. Germany took none, but exports of about 4,250,000 gallons to Italy represented a substantial rise over 1938. Although the war-risk situation apparently should have favored movement from the West coast, that movement declined more than 40 percent in 1939 (from 54,000,000 gallons in 1938 to 30,000,000 in 1939), whereas movement from points east of California was only about 30 percent less than in 1938.

STOCKS

Unlike the situation in the gasoline industry, stocks of natural gasoline declined during 1939—from 202,860,000 gallons on January 1 to 185,682,000 on December 31. The monthly trend of stocks in 1939 followed the usual seasonal pattern, with sharp increases in the second quarter and material decreases in the last quarter. It is noteworthy that if there had been no shut-down of crude-oil production in August the usual increase in stocks probably would have occurred during that month, and stocks would have increased over the year.

The relationship of the trends of stocks and posted prices was quite close in 1939, particularly in August, when the shut-down caused a rise of 1 cent per gallon.

TECHNICAL DEVELOPMENTS

Recycling plants.—Facilities for the recovery of "condensate" from high-pressure reservoirs were expanded rapidly during 1939.

Better understanding of "retrograde condensation" and of the phase relations of the lighter hydrocarbons (under varying reservoir conditions) indicated the need for maintaining pressure during condensate-producing operations. It was found that there were material underground losses of the recoverable liquid fractions if reservoir pressures were allowed to fall below certain critical points. Hence recycling plants were developed to remove condensate by absorption and refrigeration at very high pressures (usually above 1,000 pounds) and to return the stripped gas to the reservoir to maintain its pressure.

In January 1939, 8 such plants were operating in Texas, recovering 2,235 barrels per day of condensate from an average of 116.4 million cubic feet of gas; in December 1939, 22 plants reported daily recovery of 6,612 barrels from a volume of 470.4 million cubic feet. About 90 percent of the volume of gas withdrawn from the producing sands was returned. The data above are based upon reports of the Railroad Commission of Texas.

As a large number of gas-condensate fields have been discovered and await exploitation, much additional expansion of recycling activities is in prospect.

There is great diversity in the manner of marketing condensate from the various plants. The principal factors that control the method of disposing of the product are situation of plants, specifications of the liquid produced, and facilities owned or available to plant owners. Some plants are equipped with stabilizing or fractionating units and produce a finished motor fuel that is sold wholesale or retail. Others sell raw condensate, which is mixed with crude oil or natural gasoline in pipelines or shipped by tank cars and trucks to refineries or natural-gasoline terminals.

Yields.—As predicted a year ago the average yield of natural gasoline increased in 1938, when it was 1.06 gallons per thousand cubic feet compared with 0.98 gallon in 1937. This increase was related to the gain in the relative importance of the East Texas field, a high-yield area. In 1939 the yield is expected to fall to about 1.00 gallon, as State figures for Texas indicate a sizable decrease, owing both to enlarged pipeline takings in the Panhandle and to the spread of recycling. Yields from recycling are relatively low, and probably the average is less than 0.75 gallon per thousand.

Production by processes.—In 1939 the number of compression plants again declined, and the number of absorption plants again increased, but the number of charcoal plants remained at 9. Production by the absorption process increased and by the other two processes decreased during 1939.

Trends in vapor pressures.—The weighted average vapor pressure of all shipments of natural gasoline, which had been dropping steadily, increased from 19.6 pounds in 1938 to 20.1 in 1939. This gain was all in refinery shipments, as the weighted average for "direct" shipments fell from 15.6 pounds in 1938 to 14.6 in 1939 and for exports from 17.2 pounds to 16.7.

Technical improvements.—The year 1939 probably witnessed as many activities in the chemistry of the lighter hydrocarbons as any previous 12 months. Although most of the work on alkalization, isomerization, and similar problems was done at refineries, the natural-gasoline industry is bound to play a large part in any program involving use of the fractions generally termed "liquefied petroleum gases" as the base for motor-fuel production.

Natural gasoline produced in the United States in 1938, by States and by methods of manufacture [1]

LIQUEFIED PETROLEUM GASES [2]

The trend in sales of liquefied petroleum gases, which had showed some slackening in 1938, again turned sharply upward in 1939 with domestic sales totaling 223,580,000 gallons. The improved demand for liquefied petroleum gases in 1939 is indicated by the 35-percent gain over the 1938 total of 165,201,000 gallons, which in turn was 17 percent above domestic requirements in 1937. The expansion in the market in 1939 measures up to gains of 33 and 39 percent, respectively, in 1937 and 1936. All important uses of these gases showed marked advances in 1939 over 1938, with the exception of chemical manufacturing. Sales of "bottled gas," which makes it possible to employ modern kitchen equipment in rural districts beyond the city gas mains, rose over 50 percent in 1939. Gas companies, which use liquefied petroleum gases for enriching manufactured gas or for direct distribution through their mains, increased their purchases of these gases 37 percent in 1939. Industrial demand, which declined in 1938 compared with 1937, made an outstanding gain of 59 percent in 1939, as manufacturing activities again advanced. The spread in their use as motor fuel, especially in western areas, is evidenced by a 37-percent increase in deliveries for this purpose in 1939. The quantity of liquefied petroleum gases required for chemical manufacturing was reported as 20 percent below the 1938 total.

Exports of liquefied petroleum gases, which have fallen steadily since 1936, again turned upward in 1939, and the total—1,570,000 gallons—is approximately double the quantity in 1938. Distributors supplied a domestic and export demand of 225,100,000 gallons in 1939, a 36-percent gain over the 1938 total of 166,026,000 gallons.

[1] Subject to revision.

Domestic deliveries of liquefied petroleum gases in 1938 comprised approximately equal portions of propane, butane, and propane-butane mixtures; however, in 1939 (probably owing to the large increase in the demand for "bottled gas," which is predominantly propane) the proportion of total sales accredited to propane increased from 33 to about 36 percent, and there was a corresponding drop in propane-butane mixtures from 34 percent of total sales in 1938 to 31 percent in 1939. The proportion of pentane in domestic deliveries is comparatively small; however, the percentage gained slightly in 1939 over 1938.

Except for the larger sales of the relatively unimportant pentane, sales of propane made the greatest proportionate gain in 1939, increasing 47 percent, or from 54,130,000 gallons in 1938 to 79,323,000 in 1939. Deliveries of butane, reported as 71,351,000 gallons in 1939, were 35 percent above the 1938 total, while the demand for propane-butane mixtures was 23 percent above, rising from 56,050,000 gallons in 1938 to 69,020,000 in 1939. Sales of pentane, a petroleum gas of chief importance to chemical manufactures, increased greatly in 1939 to 3,886,000 gallons, a 72-percent gain over the quantity in 1938.

The rapid growth in demand for "bottled gas" is revealed in the constantly increasing proportion of total liquefied-petroleum-gas sales required for this trade. In 1937 about 29 percent of the total deliveries of liquefied petroleum gases was reported for domestic consumption; this share increased to 35 percent in 1938 and to over 39 percent of all requirements in 1939. Gas companies absorbed about 7 percent of deliveries in 1938 and 1939 compared with 8 percent in 1937. The use of these gases as industrial fuel declined from 31 percent of the total demand in 1937 to 24 percent in 1938 but, with increased manufacturing activities, rose to 28 percent in 1939. About 20 percent of the sales were credited to chemical plants in 1937 and 1938; however, this share dropped to 12 percent in 1939. Sales items for recent years show a slowly increasing proportion consumed as fuel for internal-combustion engines, a use that has increased from 12 percent of total deliveries in 1937 to over 13 percent in both 1938 and 1939.

The demand for propane increased from 54,130,000 gallons in 1938 to 79,323,000 in 1939. As in former years, the larger share of propane deliveries was reported for domestic or household use; deliveries for industrial fuel use ranked second. The proportion credited to domestic sales was 66 percent in 1939 compared to 69 percent of the total in 1938 and 65 percent in 1937. It is believed that the percentage sold for domestic use during 1938 was larger because of the slackened industrial fuel demand in that year. This shift likewise is shown in the percentages of total propane sales reported for industrial consumption in the corresponding years, as follows: 31 percent in 1937, 26 percent in 1938, and an increase to 30 percent of all propane sales in 1939.

The marketed production of butane increased from 52,768,000 gallons in 1938 to 71,351,000 in 1939. The larger part of marketed production of butane is consumed as an industrial fuel; however, the percentage of total sales reported under that classification dropped from 62 percent in 1937 to 44 percent in 1938 and then reverted to 51 percent in 1939, as manufacturing activities expanded. Twenty-five percent of the total butane deliveries was accredited to domestic consumption in 1938 and 1939, or about double the 1937 share employed for the same purpose. This upward trend is due largely to mounting consumption of butane as a household fuel in south central areas, where natural gas is not readily available. The percentage of the butane total sold to gas-manufacturing companies has decreased gradually from over 16 percent in 1937 to 14 percent in 1939.

Sales of propane-butane mixtures reported totaled 69,020,000 gallons in 1939 compared with 56,050,000 in 1938. In 1937 and 1938 slightly more than half of all deliveries of propane-butane mixtures were made to manufacturers of chemicals, but in 1939 this proportion declined to about one-third of the total. Liquefied petroleum gases used as motor fuel are predominantly a mixture of propane and butane. Propane-butane mixtures consumed as internal-combustion-engine fuel constitute about one-third of all such sales; however, the proportion declined to 29 percent in 1938 and then returned to 34 percent of the total demand during 1939. The domestic or "bottled-gas" market is taking a rapidly expanding share of total deliveries of propane-butane mixtures. The percentage of all sales of propane-butane mixtures credited to domestic use has increased from about 8 percent in 1937 to over 23 percent in 1939.

The demand for pentane increased from 2,253,000 gallons in 1938 to 3,886,000 in 1939. Most of the marketed production of pentane is used as solvents and raw material in the manufacture of chemicals, and the quantity diverted to this trade rose from 63 percent of all sales of pentane in 1938 to 68 percent in 1939.

The American Gas Association is the source of the following statistics covering the distribution of liquefied petroleum gases by manufactured-gas companies:

At the end of 1939, liquefied petroleum gas was being delivered through mains to consumers in 178 communities in 30 States by 82 companies supplying 49,800 customers.

Butane-air gas with heating value ranging from 520 to 1,000 B.t.u. per cu. ft. was supplied to 125 communities in 30 States by 72 companies. A mixture of undiluted butane and propane gas with a heating value of 2,800 to 3,000 B.t.u per cu. ft. was supplied to 12 communities in California by 5 companies. Undiluted propane gas with a heating value of 2,550 B.t.u. per cu. ft. was supplied to 41 communities in Maryland, Minnesota, New Jersey, North Dakota, Virginia, and Wisconsin by 6 companies.

The rapidly expanding household demand for liquefied petroleum gases is again indicated in the mounting percentage of shipments in cylinders and drums compared to corresponding losses in the share of bulk distribution. Gases handled in cylinders comprised 23.6 percent of the marketed production in 1939 compared to 22.5 percent in 1938 and 21.2 percent in 1937. It is noted from a second angle that 96.5 percent of all shipments in cylinders during 1939 were reported for domestic use compared to 95.4 percent of the 1938 total so shipped.

CARBON BLACK

By G. R. Hopkins and H. Backus

SUMMARY OUTLINE

Under the stimulus of the war and the recovery in rubber production the carbon-black industry reached record levels in all phases of

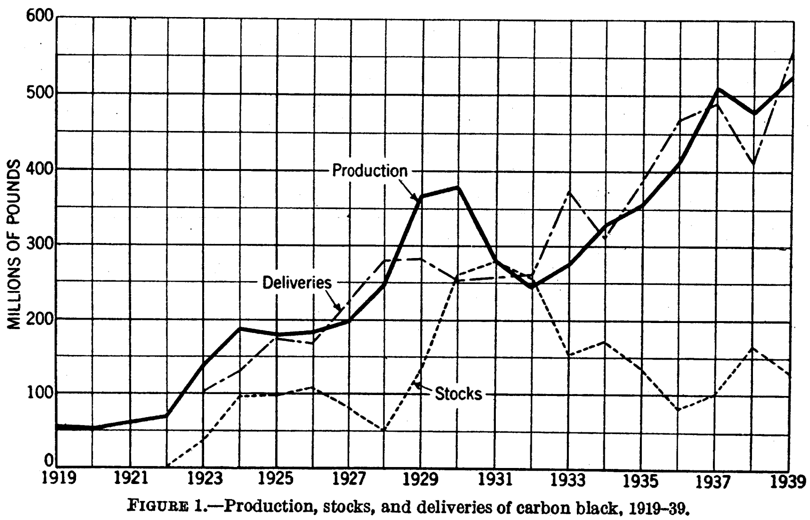

Figure 1.—Production, stocks, and deliveries of carbon black, 1919–39.

production and consumption in 1939. The output was 525,166,000 pounds, 10 percent more than in 1938, and sales totaled 560,533,000 pounds, 36 percent more than in 1938. The position of stocks improved considerably, but prices continued distressingly low. The domestic price rallied slightly, but the trend of export quotations continued downward. The average f. o. b. price rose from 2.41 cents per pound in 1938 to 2.45 cents in 1939—about enough to cover the increase in the average price of gas from 0.89 cent per thousand cubic feet in 1938 to 0.94 cent in 1939. Increases up to a quarter of a cent on domestic quotations on April 1, 1940, were heartening.

Figure 1 shows the sharp recovery in production and deliveries from the slump of 1938.

PRODUCTION

By States.—Production in Louisiana, which declined so materially in 1938 as to foreshadow disappearance of the industry in a few years, scored a notable come-back in 1939, rising to 51,734,000 pounds compared with 39,534,000 in 1938. Production in Kansas and Oklahoma continued at about 20 million pounds. Texas production rose to a new peak of 453,174,000 pounds—9 percent (36,070,000 pounds) above 1938. In 1939 the output in the Panhandle was 410,130,000 pounds, equivalent to 91 percent of the State total compared with 92 percent in 1938. Wyoming, which has been a producer since the first statistics were collected in 1919, ceased to produce in 1939.

By months.—According to estimates based upon monthly figures of the National Gas Products Association, the monthly output of carbon black averaged just above 40 million pounds until the last quarter, when under the stimulus of the war it increased to nearly 50 million pounds.

Carbon black produced from natural gas in the United States, 1935–39, by States

[1] Monthly figures obtained by allocating the Bureau's annual total proportionately to the association's monthly data.

Methods and yields.—Production by processes other than channel increased materially in 1939, nearly compensating for the loss in 1938. The output by "other" processes in 1939 amounted to 60,578,000 pounds, equivalent to 12 percent of the total, compared with 35,755,000 pounds comprising only 7 percent of the total in 1938.

The yield of carbon black rose from 1.47 pounds per thousand cubic feet in 1938 to a new peak of 1.51 pounds in 1939. This gain was due to the rise in relative importance of "other" processes, several of which give unusually high yields.

Despite the low price level, research in the fundamentals of carbon-black production and consumption continued, as it is quite generally recognized that the behavior of different blacks under varying conditions is a fertile field for experiment. One of the products of this research ("dustless" carbon black) increased steadily in popularity in 1939; it is doubtful if more than 10 percent of the present output is of the old nongranular type.

Number and capacity of plants.—New construction continued at a low ebb in 1939. About a half dozen plants were dismantled, and only two new ones were added to the operating list.

The total daily capacity of the operating plants, which remained virtually at a standstill in 1938, declined from about 1,736,000 pounds in 1938 to about 1,714,000 in 1939. The capacity in Texas increased about 30,000 pounds, but this was outweighed by a decline of about 70,000 pounds in Louisiana. The operating ratio, or the ratio of daily average production to average capacity, increased from 75 percent in 1938 to 84 percent in 1939.

Number and daily capacity of carbon-black plants operated in the United States, 1938–39, by counties or parishes

[1] 1938: Kansas and Wyoming included with Oklahoma; 1939: Kansas included with Oklahoma.
[2] 1 plant, in both Carson and Hutchinson Counties, counted in Hutchinson County.

Producers.—The latest complete list of carbon-black producers (as of December 31, 1937) was given on page 967 of Minerals Yearbook, 1938. Changes in the list for 1938 were given on page 1073 of Minerals Yearbook, 1939. The changes in 1939 are as follows: The Southern Carbon Co. discontinued operations, and its three Louisiana plants at Fowler, Perryville, and Swartz were dismantled; the J. M. Huber Corporation closed its plants in Louisiana and Wyoming permanently; the Columbian Carbon Co. closed its plant at Pampa but opened one at Corpus Christi; and the General Atlas Carbon Co. began operations at its plant near Guymon, Okla.

DEMAND

Total deliveries.—Sales of carbon black in 1939 totaled 560,533,000 pounds—36 percent more than in 1938. Domestic sales in 1939 were

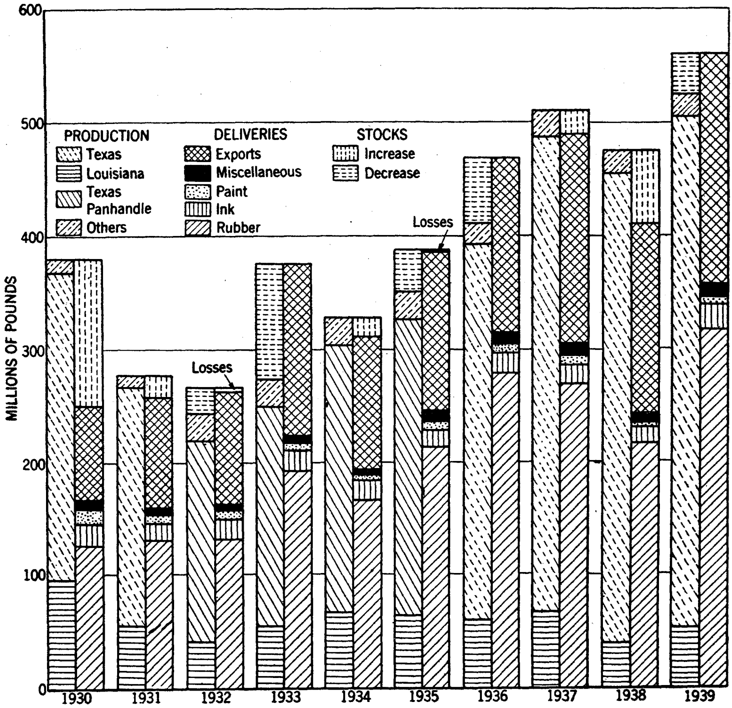

FIGURE 2.—Production and consumption of carbon black, 1930–39.

356,705,000 pounds and exports 203,828,000 pounds, both figures new records, with domestic deliveries showing the largest increase. (See fig. 2.)

Domestic consumption.—Domestic sales in 1939 (356,705,000 pounds) were 47 percent higher than in 1938 and 14 percent above the previous high of 1936. Reports from producers indicate that they were divided as follows: Rubber companies, 316,621,000 pounds (89 percent); ink companies, 21,929,000 pounds (6 percent); paint companies, 6,382,000 pounds (2 percent); and miscellaneous purposes, 11,773,000 pounds (3 percent). These data indicate that all four classes of consumption maintained their relative positions in 1939.

According to E. G. Holt, of the Bureau of Foreign and Domestic Commerce, who has again supplied data on rubber consumption, the total consumption of rubber in the United States reached the record-breaking total of 763,700 long tons, or 37 percent above the total of 558,800 tons consumed in 1938. Of the 1939 total, 592,000 tons was crude rubber, 170,000 tons reclaimed rubber, and 1,700 tons synthetic rubber. According to statistics of the Rubber Manufacturers Association 57,078,000 casings were produced in 1939 compared with the revised figure of 40,907,000 for 1938. Returns from the Federal excise tax on tires and tubes indicate that the total weight of casings sold in 1939 was 56 percent greater than in 1938. The production of camelpack for retreads has expanded rapidly in recent years and may have reached 50,000,000 pounds in 1939. This type of rubber utilizes more carbon black per pound of rubber than the average casing. As far as carbon-black consumption is concerned, these data indicate chiefly that an increase in the average size of casings outweighed a larger increase in the use of reclaimed (which uses relatively little carbon black) than in crude rubber.

The apparent world consumption of crude rubber was 1,090,000 long tons compared with the revised figure of 942,000 long tons in 1938. As the gain in consumption in the United States was somewhat larger than in the rest of the world, this country greatly strengthened its position as the leading rubber manufacturer.

The pick-up in business in 1939 was attended by a marked increase in advertising; consequently the apparent consumption of newsprint increased materially over 1938, though it fell far short of the 1937 total. According to data supplied by B. M. Frost, of the Bureau of Foreign and Domestic Commerce, the supply of newsprint available for domestic consumption in 1939 was 3,541,000 short tons compared with 3,089,100 in 1938. Sales of carbon black to ink companies increased 55 percent—from 14,131,000 pounds in 1938 to 21,929,000 in 1939. Possibly a higher percentage of carbon black is being used in inks, although probably further additions to manufacturers' stocks were made at the favorable prices.

Sales of carbon black to paint companies also rose materially—from 4,229,000 pounds in 1938 to 6,382,000 in 1939. According to E. C. Wood, of the Bureau of Foreign and Domestic Commerce, paint production in 1939 probably was about 15 percent higher than in 1938, with perhaps a much larger increase for black paints alone.

Sales of carbon black for miscellaneous purposes increased sharply; the 1939 total of 11,773,000 pounds was about 50 percent higher than in 1938 and slightly above the previous record (11,503,000 pounds) of 1937. No data are available as to which of the many miscellaneous uses expanded in 1939.

Exports and imports.[1]—Exports of carbon black passed the 200-million-pound mark for the first time in 1939, when the total was 203,828,000 pounds compared with 167,968,000 in 1938. Shipments to Germany declined in 1939, but this decrease was far outweighed by larger exports to British possessions.

The average export value continued to decline—4.36 cents per pound compared with 4.51 cents in 1938.

[1] Figures on exports and imports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce

Exports of carbon black to the United Kingdom increased about 50 percent in 1939 to a total of 66,215,000 pounds. Exports to France (still second in importance) gained moderately in 1939, reaching 29,391,000 pounds, while those to Germany declined although the total (19,661,000 pounds) was third most important. There were notable increases in shipments to Brazil and China in 1939.

No particular trend was apparent in exports of carbon black by months, even after the war started. The highest monthly total was in April, the month of lowest exports in 1938. About 70 percent of the exports was shipped from the Galveston customs district, a slightly lower ratio than in 1938.

Carbon black exported from the United States, 1937–39, by countries

Imports of "gas black and carbon black," as reported by the Bureau of Foreign and Domestic Commerce, totaled 6,901 pounds valued at $784 in 1939 compared with 390 pounds valued at $30 in 1938. Imports of acetylene black (all from Canada) nearly doubled in 1939, rising from 1,220,781 pounds valued at $127,889 in 1938 to 2,381,572 pounds valued at $248,332 in 1939.

STOCKS

The situation as to stocks of carbon black improved considerably during 1939; in place of a material increase, as in 1938, there was a moderate decline. Stocks on December 31, 1939 totaled 130,792,000 pounds, which was 35,367,000 pounds below stocks of January 1. In terms of quantity present stocks compare with those on hand during the early part of 1936 and in terms of days' supply, with those prevailing in the spring of 1937. Stocks in the form of finished rubber goods changed but slightly in 1939; stocks of casings held by manufacturers increased only from 8,451,000 on January 1, 1939, to 8,688,000 at the year end.

PRICES AND VALUES

In general, carbon-black prices in 1939 remained at the low levels reached in the early part of 1938. Although demand, both domestic and export, reached record levels, competitive conditions were such as to prevent any consistent advance.

The weighted average f. o. b. value at plants increased from 2.41 cents per pound in 1938 to 2.45 cents in 1939. This slight change is substantiated by the quotation for Zone A, the standard price in the industry, which has remained at 2.75 cents per pound since April 4, 1938.

In spite of the fact that exports expanded rapidly in the first 2 months of the war on a "seller's market," prices at the close of the year were slightly below those at the beginning. The average export value for 1939 was 4.36 cents per pound compared with 4.51 cents in 1938.

Quoted prices on various grades of carbon black, 1938–39, in cents per pound

HELIUM

By C. W. Seibel and H. S. Kennedy

SUMMARY OUTLINE

Operation of Amarillo plant.—During the fiscal year 1939 the Bureau of Mines helium plant near Amarillo, Tex., continued to operate on an intermittent schedule and produced 6,281,800 cubic feet of helium. The cumulative production is 90,541,000 cubic feet for the first 10 years of the plant's operation, from April 1929 to June 30, 1939. During the first half of the fiscal year ending June 30, 1940, an additional 3,906,000 cubic feet of helium was produced, making a total production of 94,447,000 cubic feet of helium to December 31, 1939.

Sales of residue natural gas from which the helium was extracted were 318,601,000 cubic feet valued at $16,727. The cumulative sales of such gas for the 10-year period of operation of the Amarillo helium plant total 4,684,149,000 cubic feet, for which $245,918 was received.

Cliffside gas field.—In the fiscal year 1939 a total of 383,062,000 cubic feet of helium-bearing natural gas was produced by the Bureau of Mines from the Government's Cliffside gas field to supply the Amarillo plant, giving a cumulative production from the field of 5,436,215,000 cubic feet.

During the year a deep test was made for oil in the Cliffside field, in which the Government owns all gas rights for 50,000 acres covering the entire geologic structure but does not own the oil rights. After drilling to a depth of more than 6,000 feet without finding oil, the company responsible for the work abandoned the test. Under the terms of a "working agreement" between the Government (as owner of the gas rights) and the owners of the oil rights, which was entered into when the Bureau of Mines purchased the gas rights in the land, the Bureau acquired the well with equipment and casing for a fraction of its cost. The casing was "gun-perforated" opposite the gas strata, and a gas well having an open-flow capacity of 12 million cubic feet per day was developed. This well, now known as Bureau of Mines Bush A-2, is about 3,500 feet deep and cased with heavy 10¾-inch casing. Its open-flow capacity and closed-in pressure (709 pounds per square inch) compare favorably with those of the best wells in the field, and it cost the Government considerably less than any other well in the field.

Purchase of additional properties.—An amendatory act authorizing the conservation, production, exploitation, and sale of helium gas, approved September 1, 1937 (50 Stat. 885), provided that

> the Secretary of the Interior is hereby directed, if possible under the terms hereof, to acquire by purchase all properties developed or constructed by private parties prior to the passage of this Act for helium production * * *.

Pursuant thereto, the helium properties of the Girdler Corporation of Louisville, Ky., were acquired November 3, 1938. These properties comprise helium-production plants at Dexter, Kans., and Thatcher, Colo., with related gas leases and wells to supply helium-bearing natural gas. Both plants had been in a stand-by condition for some time before the purchase and have been maintained in that condition by the Government because the Amarillo plant, completed in 1929, can now supply all Government and private demands for helium when operating at a fraction of its capacity. The purchase places all helium plants under the control of the Government.

Sales.—The act approved September 1, 1937, authorized the sale of helium to the public, and from the time it became effective until the close of the fiscal year ended June 30, 1938, 73,082 cubic feet of helium were sold and delivered to non-Government purchasers. The production for Government agencies in that period was 5,757,680 cubic feet.

During the fiscal year 1939, the first full year of operation under the act, the public took advantage of the opportunity and purchased 1,068,300 cubic feet of helium under 30 contracts with the Bureau. Of this quantity, 265,800 cubic feet were purchased for medical, 9,600 cubic feet for scientific, and 792,900 cubic feet for commercial purposes. In the same period various agencies of the Federal Government obtained 5,213,400 cubic feet of helium. All the helium was produced in the Amarillo plant.

Government uses.—The United States Army and Navy continue to be the largest users of helium. They employ it for inflating observation and meteorological balloons as well as dirigible lighter-than-air craft. The Navy also uses helium in diving operations. The use of large balloons that carry radio-sonde apparatus has increased the desirability, from the standpoint of safety, of using helium instead of explosive hydrogen in meteorological balloons, so the Weather Bureau is rapidly becoming a large user of helium. The National Bureau of Standards has procured helium from the Bureau of Mines for determination of specific heats and other scientific studies, and the Public Health Service uses helium in research on its medical applications.

In 1925 the Bureau of Mines, in cooperation with the Navy Department, experimented on the use of synthetic mixtures of oxygen and helium in deep-sea diving. The actual use of such mixtures in diving operations was given considerable publicity in connection with the raising of the submarine *Squalus*, and it has been stated that if helium had not been available the efforts to raise the submarine probably would have been ineffective.

Non-Government uses.—The present-day medical use of helium in the treatment of asthma and other respiratory diseases is an outgrowth of research on the use of helium in diving. Helium also is being employed in the administration of anesthetics. Other promising medical uses are being investigated by research workers.

Influenced by growing evidence of the efficacy of helium in medical applications, hospitals and physicians now use about 25 percent of all helium sold for non-Government purposes, and the demands are increasing. Helium also is being used to an increasing extent in technical research, as is indicated by sales of helium to educational and research institutions for scientific studies.

The largest non-Government user of helium in lighter-than-air craft has been the Goodyear Tire & Rubber Co., which maintains small passenger-carrying blimps, filled with helium produced in the Amarillo plant, at the New York and San Francisco Fairs, as well as several other points. These blimps give reserve pilots active training in airship operation.

Near the end of the fiscal year 1939 the Committee for Organization of the First Polish Flight into the Stratosphere purchased 220,000 cubic feet of helium for filling a stratosphere balloon, but the flight was prevented by the European War.

Laws or ordinances in some localities prohibit the use of hydrogen or any explosive gas in filling toy balloons. Helium is the only safe gas for such use, and some toy-balloon vendors have purchased helium in considerable quantities. Helium also is being used to some extent in "sky advertising"; by large balloons that hold approximately 1,000 cubic feet and carry advertising on their envelopes or on banners which they support.

Prices.—As the Government desires to encourage use of helium and to make it generally available for medical purposes, helium is sold at prices near the cost of production. The regulations governing sales of helium to private parties provide that, in accordance with a provision of the act requiring payment in advance, deposits made by purchasers of helium shall be based upon an estimated cost of production prepared by the Bureau of Mines and approved by the Secretary of the Interior. For the fiscal year 1939 the estimate was \$14.25 per thousand cubic feet. As helium is sold virtually at cost, the sales regulations require that, to protect the Government, purchasers of helium for medical and scientific use deposit 120 percent of the estimated cost of the helium, which now is \$17.10 per thousand cubic feet, and that purchasers of helium for commercial use deposit 134.4 percent of the estimated cost, now \$19.15 per thousand cubic feet.

At the end of each fiscal year the actual cost of producing helium is determined and approved as provided for in the regulations. In accordance with the act, the cost used as a basis for determining the price to be paid by non-Government users includes items for depreciation, depletion, and interest on certain investments, whereas the amounts paid by Government agencies are based upon operating costs only.

For the fiscal year 1939 the prices per thousand cubic feet charged non-Government purchasers of helium, as approved by the Secretary of the Interior, were \$12.80 for helium to be used for medical purposes, \$13.44 for helium for scientific use, and \$15.05 for helium for commercial use. After the total charges against the various purchasers of helium were determined, the surpluses to their credit were refunded.

The refunds for the fiscal year 1939 were \$4.30, \$3.66, and \$4.10 per thousand cubic feet, respectively, for helium sold for medical, scientific, and commercial uses. The price charged Government agencies was $11.47 per thousand cubic feet, irrespective of the use to which the helium was put.

The prices per thousand cubic feet charged non-Government users of helium for the fiscal years 1938 and 1939 are compared in the following table:

	1938	1939
Medical	$13. 471	$12. 80
Scientific	13. 471	13. 44
Commercial	15. 088	15. 05

The lower rate charged for helium for medical use is in accord with the Government's desire to make helium available to the public for medical use at the lowest practicable cost. There is no difference in the quality of the helium sold for the three classes of use, as it has a purity of about 98.2 percent, and the impurity is largely nitrogen.

Before the act approved September 1, 1937, was passed, helium obtained for private use from non-Government sources sometimes cost as much as $150 per thousand cubic feet, and even in quantities as large as a million cubic feet it sold for $75 per thousand cubic feet.

ASPHALT AND RELATED BITUMENS

By A. H. Redfield [1]

SUMMARY OUTLINE

To meet an 8-percent increase in total demand, domestic and foreign, for petroleum asphalt (including small quantities of imported lake asphalt and grahamite), petroleum refineries in the United States increased their output 10 percent from 1938 to 1939. In consequence, their inventories rose 12 percent from December 31, 1938, to December 31, 1939, in contrast to a 12-percent reduction during 1938. The entire increase in demand was on the domestic market, as exports of asphalt were slightly less in 1939 than in 1938. Imports both of petroleum asphalt and natural asphalt advanced from 1938 to 1939, but they constituted 1 percent of the total demand in 1939. Only 4 percent of the petroleum asphalt produced by refineries in the United States was sold to foreign countries in 1939.

NATIVE ASPHALT AND BITUMENS

Bituminous rock.—As a result of decreased demand east of the Mississippi River sales of bituminous rock by producers in the United States declined from 449,091 short tons (revised figure) in 1938 to 422,484 tons in 1939. The value of the rock asphalt sold decreased from $2,219,159 in 1938 (revised figure) to $2,007,810. Rock-asphalt operators in Kentucky and Alabama sold 215,142 tons valued at $1,379,138 in 1938 but only 175,602 tons valued at $1,214,476 in 1939. On the other hand, sales by operators in Texas, Oklahoma, and New Mexico advanced in quantity from 206,443 tons (revised figure) in 1938 to 221,497 tons in 1939 but declined in value from $727,032 in 1938 to $684,808 in 1939. Sales by producers in California and Kansas were lower in quantity and value in 1939 than in 1938, but sales in Missouri were slightly higher.

Gilsonite and wurtzilite.—Sales of gilsonite by producers in northeastern Utah increased from 28,574 short tons valued at $649,724 in 1938 to 37,289 tons valued at $1,053,192 in 1939. Demand for the better grades was good during the greater part of 1939; prices were firm; and the loss of sales to Germany during the last quarter of the year did not affect the general market for gilsonite.

Sales of wurtzilite totaled 76 tons valued at $5,920 in 1938 and 75 tons valued at $5,842 in 1939.

Sulfonated bitumen.—In 1939, as in 1938, a small quantity of natural sulfonated bitumen was produced in Box Elder County, Utah, near Ogden.

Exports.—Exports of natural asphalt, unmanufactured, changed little from 1938 to 1939. They amounted to 13,546 short tons valued at $543,509 in 1938 and 13,784 tons valued at $577,031 in 1939. Of the total exports Europe took 75 percent in 1938 and 74 percent in 1939; Canada 10 percent in 1938 and 8 percent in 1939; South America 2 percent in 1938 and 4 percent in 1939; and Asia, chiefly Japan, 10 percent in 1938 and 1939.

MANUFACTURED OR PETROLEUM ASPHALT

Production.—Petroleum refineries in the United States produced 10 percent more asphalt in 1939 than in 1938. The most marked gains were in the Indiana, Illinois, Kentucky, etc., district, in the East Coast district, and in the Texas Gulf Coast district. On the other hand, decreases were considerable in the Rocky Mountain, Arkansas, and Louisiana Inland, and Texas Inland districts. These decreases were not sufficient, however, to offset the increases east of the Mississippi River, in the Gulf Coast districts of Louisiana and Texas, and in California.

Stocks.—To meet an increase of 364,100 short tons in the indicated domestic demand for asphalt (offset to a slight extent by a decline of 2,800 tons in export demand), petroleum refineries in the United States enlarged their output of asphalt 447,500 tons in 1939, while imports of lake asphalt, grahamite, and petroleum asphalt rose 40,400 tons. Consequently, stocks of asphalt at refineries were 59,600 tons higher on December 31, 1939, than on December 31, 1938, compared to a drop of 67,000 tons during 1938. The principal advances in inventories were in the Illinois, Indiana, Kentucky, etc., district, in the Oklahoma, Kansas, and Missouri district, and in California. In contrast to the general increase, stocks were reduced considerably in the Texas Inland district and to some extent in the Rocky Mountain and East Coast districts during 1939.

Production, receipts, stocks, consumption, transfers and losses, and sales of asphalt (exclusive of road oil) at petroleum refineries in the United States in 1939, by districts, in short tons

District	Production	Receipts from other sources	Stocks		Consumption by companies, transfers, and losses	Sales	
			Dec. 31, 1938	Dec. 31, 1939		Domestic	Foreign
East Coast	1,841,900	56,900	134,100	129,000	26,100	1,840,300	37,500
Appalachian	142,200	--------	14,800	20,000	7,200	129,800	--------

1938	4,506,900	95,500	557,400	490,400	192,800	[1] 4,476,600	(1)

[1] Foreign included with domestic.

Sales.—Total sales of petroleum asphalt by refineries increased 8 percent in quantity but decreased 1 percent in value from 1938 to 1939. The average value at the refinery of asphalt sold in 1939 was $8.47 per short ton compared with $9.24 in 1938.

Of the total sales of petroleum asphalt in 1939, 26 percent was manufactured from foreign petroleum, imported chiefly from Venezuela and Mexico, compared with 32 percent in 1938. Although runs of foreign crude to stills rose from 26,187,000 barrels in 1938 to 33,490,000 in 1939, sales of asphalt made from foreign crude declined from 1,449,664 short tons in 1938 to 1,278,786 in 1939. Apparently more of the foreign crude was run to fuel oil in 1939 than in 1938. East Coast refineries sold 96 percent of the asphalt made from foreign crude in 1939 compared with 91 percent in 1938.

Sales of asphalt (exclusive of road oil) at petroleum refineries in the United States, 1938–39, by districts

District	1938		1939	
	Short tons	Value	Short tons	Value
East Coast	1,774,744	$18,840,860	1,877,834	$18,417,699
Appalachian	117,922	1,489,664	129,843	1,499,740
Indiana, Illinois, Kentucky, etc.	652,373	6,509,542	810,985	6,847,378
Oklahoma, Kansas, and Missouri	358,246	2,485,080	365,381	2,121,986
Texas:				
Gulf Coast	159,295	1,412,779	206,840	1,570,306
Inland	214,568	1,402,950	181,959	1,330,904
Total, Texas	373,863	2,815,729	388,799	2,901,210
Louisiana-Arkansas:				
Louisiana Gulf Coast	228,619	2,153,334	244,703	2,108,695
Arkansas and Louisiana Inland	226,677	1,553,073	232,818	1,459,166
Total, Louisiana-Arkansas	455,296	3,706,407	477,521	3,567,861
Rocky Mountain	166,140	1,486,292	106,960	810,493
California	578,043	4,047,506	668,508	4,725,709
Total	4,476,627	41,381,080	4,825,831	40,892,076

Average sales values of asphalt at the refineries decreased in nearly all districts from 1938 to 1939. The only exceptions were the Texas Inland, where the average sales value increased from $6.54 per short ton in 1938 to $7.31 in 1939, and the California, where the average sales value rose from $7.00 in 1938 to $7.07 in 1939. The general decline was ascribed to overproduction in California and the Texas Inland district of heavy crude that could be run cheaply to asphalt and sold at reduced prices. However, prices became firmer in the last quarter of 1939 as a result of continued improvement in demand.

Statistics of sales of asphalt by varieties in 1939 are not strictly comparable with the corresponding figures for 1938. The 1939 data refer only to sales to domestic consumers, while those for 1938 include export sales; however, as export sales amounted to only 4 percent of the total sales in both 1938 and 1939 the discrepancy is not great, and rough comparisons are possible. Statistics of sales to domestic consumers will give for 1939 and future years a more accurate picture of the type of demand in the major market for asphalt.

[1] DEFINITIONS

Paving asphalt.—Refined asphalt and asphaltic cement, fluxed and unfluxed, produced for direct use in the construction of sheet asphalt, asphaltic concrete, asphalt macadam, and asphalt block pavements, and also for use as joint filler, in brick, block, and monolithic pavements.

Roofing asphalt.—Asphalt and asphaltic cement used in saturating, coating, and cementing felt or other fabric and in the manufacture of asphalt shingles.

Waterproofing asphalt.—Asphalt and asphaltic cement used to waterproof and dampproof tunnels, foundations of buildings, retaining walls, bridges, culverts, etc., and for constructing built-up roofs.

Briquetting asphalt.—Asphalt and asphaltic cement used to bind coal dust or coke breeze into briquets.

Mastic and mastic cake.—Asphalt and asphaltic cement for laying foot pavements and floors, waterproofing bridges, lining reservoirs and tanks, capable of being poured and smoothed by hand troweling.

Pipe coatings.—Asphalt and asphaltic cement used to protect metal pipes from corrosion.

Molding compounds.—Asphalts used in the preparation of molded composition, such as battery boxes, electrical fittings, push buttons, knobs, handles, etc.

Miscellaneous uses.—Asphalt and asphaltic cement used as dips and in the manufacture of acid-resisting compounds, putty, saturated building paper, fiber board and floor coverings, and not included in the preceding definitions.

Flux.—Liquid asphaltic material used in softening native asphalt or solid petroleum asphalt for paving, roofing, waterproofing, and other purposes.

Cut-back asphalt.—Asphalt softened or liquefied by mixing with petroleum distillates.

Emulsified asphalt and fluxes.—Asphalts and fluxes emulsified with water for cold-patching, road laying, and other purposes.

Other liquid products.—Petroleum asphalt, exclusive of fuel oil used for heating purposes, not included in the preceding definitions.

244615—40——71

Highway construction absorbed three-fifths of all asphalt sold to domestic consumers in 1939 in the form of paving asphalt, paving flux, cut-back asphalts, and emulsions. In general, such statistics as are available indicate an increase in street and road construction in 1939 over 1938. According to the Engineering News-Record awards for street and road contracts exceeding $25,000 increased 1 percent in value (from $637,862,000 in 1938 to $643,771, 000 in 1939) and about 1 percent in volume, as construction costs changed little from 1938 to 1939. The total highway mileage constructed by State highway departments, according to the same journal, rose from 28,310 in 1938 to 30,428 in 1939. According to the American Association of State Highway Officials, the total mileage completed increased from 30,977 in 1938 to 31,628 in 1939. However, average employment for construction and maintenance of Federal and State highways, as reported to the Bureau of Public Roads, decreased from 273,055 in 1938 to 220,843 in 1939.

The increase in mileage of State highways built during 1939 reported by the Engineering News-Record was in bituminous types, untreated surfacing, and grading and draining operations. Asphaltic types (asphaltic concrete, asphaltic macadam, and low-cost bituminous mixtures) gained 7 percent from 1938 to 1939—they constituted 78 percent of the mileage of higher and intermediate types laid on State highways in 1938 and 85 percent in 1939.

No comprehensive statistics are available to show the proportions of the various types of surface laid on city and town streets. Apparently there was a small increase in the yardage of municipal street paving, especially in the larger cities, an important but little-recorded field of demand.

Awards of street and road contracts increased in the Middle Atlantic States, in the Ohio Valley and Great Lakes States, and in the States west of the Mississippi River and east of the Rocky Mountains, according to the Engineering News-Record. They decreased considerably in the Rocky Mountain and Pacific Coast States and New England and to a smaller extent in the Southeastern States.

Increased construction of lighter types of surface, both on State highways and secondary roads, as well as continued use of cut-back asphalts for soil stabilization and revetments, is indicated by a 4-percent gain in sales of cut-back asphalts from 1,392,997 tons in 1938 (includes export sales) to 1,454,846 in 1939 (domestic sales only). A considerable advance in sales by East Coast refineries and smaller increases in sales by refineries of the Appalachian, the Indiana, Illinois, Kentucky, etc., the Texas Gulf Coast and Texas Inland, and the Louisiana-Arkansas Inland districts offset declines in sales by the other districts west of the Mississippi River. The entire increase was in sales in medium-curing cut-backs—from 500,087 tons valued at $3,828,718 in 1938 to 602,917 valued at $4,444,303 in 1939, as sales of rapid-curing cut-backs declined from 892,910 tons valued at $9,129,262 in 1938 to 851,929 tons valued at $7,725,225 in 1939.

Petroleum refineries sold 56,953 tons (13,417,238 gallons) of asphalt emulsions valued at $678,779 in 1938 and 55,881 tons (13,164,691 gallons) valued at $635,881 in 1939. In addition, 43,928,186 gallons valued at $3,659,258 were sold in 1938 by major industrial companies that purchased asphalt from petroleum refineries and 49,826,902 gallons valued at $3,899,958 in 1939. Accordingly, total known sales of emulsified asphalts and fluxes advanced from 57,345,424 gallons valued at $4,338,037 in 1938 to 62,991,593 gallons valued at $4,535,839 in 1939.

Roofing manufacture furnished the second-largest demand for asphalt, absorbing 25 percent of the total sales in 1938 and 26 percent in 1939. Although shipments of prepared roofing and asphalt siding reported to the Bureau of the Census decreased slightly—from a total of 35,238,029 squares in 1938 to 34,823,305 in 1939—sales of roofing asphalt and roofing flux combined increased from 1,127,635 tons in 1938 to 1,229,046 in 1939. The 1939 figure, it may be noted, includes only domestic sales, whereas the figure for 1938 includes both domestic and export sales. The principal increases occurred in the East Coast district, the Indiana, Illinois, Kentucky, etc., district, and California.

DOMESTIC DEMAND

The indicated domestic demand for petroleum asphalt (including small quantities of imported lake asphalt and grahamite) was 8 percent greater in 1939 than in 1938, increasing from 367,071 short tons per month in 1938 to 397,413 in 1939.

In terms of the long-term trend the indicated demand was 30 percent above the expected demand for 1939, whereas it was 23 percent above the expected demand for 1938; that is, if the national demand had continued the average rate of growth it manifested from 1908 to 1936, it would have averaged 297,864 tons a month in 1938 and 306,533 in 1939. If these averages are used as a standard of comparison, the indicated demand of 367,071 tons a month in 1938 was 123 percent of the expected demand (297,864 tons), and the indicated demand of 397,413 tons a month in 1939 was 130 percent of the expected demand (306,533 tons).

The demand for asphalt is seasonal to a marked degree, reaching its maximum in August and its minimum in February. Normally, 65 percent of the indicated consumption of asphalt occurs in the 6 months from May 1 to October 31; from 1937 to 1939, 69 percent of the annual total apparently was consumed in these months. Consequently, to furnish an adequate standard of comparison the monthly trend values are multiplied by a "seasonal factor" for each month.

Relation of indicated asphalt demand in the United States to basic trend multiplied by seasonal factors, 1938–39, by months

Month	1938			1939		
	Trend multiplied by seasonal factors	Indicated monthly demand	Relation of indicated monthly demand to trend	Trend multiplied by seasonal factors	Indicated monthly demand	Relation of indicated monthly demand to trend
	Short tons	*Short tons*	*Percent*	*Short tons*	*Short tons*	*Percent*
January	174,310	229,001	131.4	179,401	198,502	110.6
February	159,983	153,342	95.9	164,655	146,917	89.2
March	205,139	254,351	124.0	211,130	230,991	109.4
April	281,243	297,329	105.7	289,457	317,551	109.7
May	345,999	398,654	115.2	356,104	483,030	135.6
June	385,228	475,112	123.3	396,478	499,270	125.9
July	396,368	478,289	120.7	407,943	546,799	134.0
August	411,856	581,820	141.2	423,885	629,709	148.6
September	395,950	541,739	136.8	407,154	594,823	146.1
October	387,730	489,368	126.2	399,053	528,534	132.4
November	248,091	310,373	125.1	255,336	351,431	137.6
December	182,471	195,468	107.1	187,800	241,403	128.5
	3,574,368	4,404,846	123.2	3,678,396	4,768,960	129.6

In the first quarter of 1939 the indicated demand averaged 104 percent of the long-time trend multiplied by seasonal factors compared with 118 percent in the first 3 months of 1938. In the second quarter of 1939 it rose to 125 percent of the expected demand for these months compared with 116 percent during the second quarter of 1938. From July to September 1939 the demand was highest, averaging 143 percent of the expected demand compared with 133 percent for the same months of 1938. In the last quarter of 1939 the indicated demand averaged 133 percent of the expected demand compared with 122 percent in the last 3 months of 1938.

DISTRIBUTION BY RAIL

The tonnage of asphalt (natural, byproduct, or petroleum) terminated by class I railroads in the United States rose from 4,295,232 short tons in 1938 to 4,826,245 in 1939, according to freight-commodity statistics compiled by the Interstate Commerce Commission. The increase was general, but more than nine-tenths of the gain occurred on railroads operating principally north of the Potomac and Ohio Rivers and east of Lake Michigan and the Illinois River.

Fifty-one percent of the asphalt (petroleum, lake, and natural-rock) terminated in the continental United States by land carriers and intraport vessels was delivered to consumers in the Northeastern district, lying north of the Potomac and Ohio Rivers and east of the Mississippi and Illinois Rivers. Railroads and minor carriers terminated 2,418,722 short tons of asphalt in this district in 1938 and 2,452,957 in 1939. In the Southeastern district, lying south of the Potomac and Ohio Rivers and east of the Mississippi and Pearl Rivers, land deliveries of asphalt rose from 663,802 tons in 1938 to 697,391 tons in 1939. In the Southwestern district, lying west of the Mississippi and Pearl Rivers and south of St. Louis, Kansas City, and Amarillo, asphalt deliveries by rail and truck increased from 372,610 tons in 1938 to 402,416 in 1939. In the North Central district, lying between the Great Lakes and the Rocky Mountain front, 677,478 tons were delivered in 1938 and 667,199 in 1939. In the Pacific-Rocky Mountain district, lying west of Great Falls, Cheyenne, Denver, Albuquerque, and El Paso, the tonnage of asphalt terminated dropped from 768,773 in 1938 to 596,053 in 1939.

Supply and distribution of asphalt (petroleum, lake, and natural rock), exclusive of road oil, in continental United States in 1939, by districts, in short tons

FOREIGN TRADE

Imports.—Imports of natural asphalt and bitumens into the United States rose in quantity from 23,645 short tons in 1938 to 26,586 tons in 1939, but declined in value from $378,209 in 1938 to $362,559 in 1939. Imports of lake asphalt from Trinidad increased from 19,396 tons valued at $205,038 in 1938 to 21,440 tons valued at $227,223 in 1939. Imports of grahamite from Cuba likewise increased—from 3,826 tons valued at $65,344 in 1938 to 4,676 tons valued at $83,734 in 1939.

Atlantic Coast ports (chiefly New York) received 23,188 tons of natural asphalt and bitumen and Gulf Coast ports (Mobile, New Orleans, and Galveston) 3,364 tons in 1939.

Imports of petroleum asphalt, including cut-backs, and road oil advanced from 9,786 short tons valued at $38,883 in 1938 to 47,261 tons valued at $189,052 in 1939. All the petroleum asphalt imported in 1939 came from the Netherland West Indies; 37,763 tons were received in the customs district of New York and 9,498 tons in the customs district of New Orleans.

Exports.—Exports of petroleum asphalt, manufactured and unmanufactured, were 1 percent less in 1939 than in 1938. The principal decreases were in shipments to Europe, especially the United

Kingdom, France, and Belgium. Less asphalt was exported to other North and South American countries (except Brazil) in 1939 than in 1938. On the other hand, more asphalt was exported to eastern Asia, especially Netherland India, British India, and French Indochina, to Africa (especially the Union of South Africa), and to Australia in 1939 than in 1938; however, these increases were insufficient to offset the decline in shipments to northwestern Europe.

Petroleum asphalt exported from the United States, 1937–39, by countries

ROAD OIL

Increased construction of oil-treated macadam, gravel, and sand-clay highways resulted in a gain of 5 percent in refinery sales of road oil—from 7,741,843 barrels in 1938 (revised figure) to 8,108,400 in 1939. As a result of lower prices, however, the value at the refineries of sales of road oil decreased 11 percent—from $9,464,114 (revised figure) in 1938 to $8,458,600 in 1939.

Increases occurred in the following districts: Indiana, Illinois, Kentucky, etc.; Oklahoma, Kansas, and Missouri; Texas; Louisiana-Arkansas; and California. Declines in the East Coast, Appalachian, and Rocky Mountain districts were inadequate to offset the general increase.

Of the road oil sold in 1939, only 293,100 barrels valued at $592,300 were made from foreign petroleum, imported chiefly from Venezuela and Mexico. Of the road oil made from foreign crude, 98 percent was sold by refineries of the East Coast district in 1939.

Road oil sold by petroleum refineries in the United States, 1938–39, by districts

District	1938		1939	
	Barrels	Value	Barrels	Value
East Coast	943,073	$1,544,169	881,900	$1,208,100

California	2,413,311	2,453,810	2,429,500	2,096,600
	[1] 7,741,843	[1] 9,464,114	8,108,400	8,458,600

[1] Revised figures.

Petroleum refineries in the United States reported the production of 7,868,000 barrels of road oil in 1939 compared with 7,788,000 barrels (revised figure) in 1938. The refinery output of road oil in 1939 was augmented by 1,222,700 barrels of other petroleum products, chiefly fuel oil, transferred to road-oil stocks compared with 722,100 barrels similarly transferred in 1938. Stocks of road oil and transferred oils rose 22,000 barrels in 1939 and 13,000 in 1938. Consumption of road oil at refineries in operations, transfers, losses, and adjustments were 960,300 barrels in 1939 compared with 755,257 in 1938.

Production, receipts, stocks, consumption, transfers and losses, and sales of road oil in the United States in 1939, in barrels

1938 [1]	7,788,000	722,100	667,000	680,000	755,257	[2] 7,741,843	[2]

[1] Revised figures. [2] Foreign included with domestic.

The average value of road oil sold in the United States f. o. b. refinery fell from $1.22 (revised figure) in 1938 to $1.04 in 1939. The principal decreases were in the East Coast district (from $1.64 in 1938 to $1.37 in 1939); the Indiana, Illinois, Kentucky, etc., district (from $1.36 to $1.02); the Louisiana-Arkansas district (from $1.35 to $0.95) the Oklahoma-Kansas-Missouri district (from $0.92 to $0.74); and California (from $1.02 to $0.86). Gains in Texas (from $1.50 to $1.56) and the Rocky Mountain district (from $1.26 to $1.34) were too slight to check the general decline.

CEMENT

By Oliver Bowles and E. V. Balser

SUMMARY OUTLINE

Production of portland cement in the United States increased from 105,357,000 barrels (376 pounds) in 1938 to 122,259,154 in 1939, a 16-percent gain, according to final annual reports submitted by cement companies to the Bureau of Mines. Shipments increased from 106,324,127 barrels valued at $153,977,226 to 122,651,459 barrels valued at $180,893,208, a gain of 15 percent in quantity and 17 percent in value. The preliminary figures on production for 1939, published by the Bureau of Mines in January 1940, were 0.4 percent less and shipments 0.3 percent less than the final figures. There was a consistent gain in shipments each month of 1939 compared with the corresponding month of 1938.

The Federal Reserve Board annual index for cement production in 1939 was 82 compared with 95 for the durable-goods industries and 72 for the construction industries. Corresponding figures for 1938 were cement 70, durable-goods industries 65, and construction industries 64.

In 1939 portland cement was manufactured at 150 plants, and shipments were made from 150 plants compared with 149 producing and 151 shipping in 1938.

The average factory value was $1.47 a barrel in 1939 compared with $1.45 in 1938.

Shipments included 3,670,506 barrels of high-early-strength portland cement valued at $6,910,099 (an average of $1.88 a barrel) in 1939 compared with 3,385,523 barrels valued at $6,247,699 (an average of $1.85 a barrel) in 1938.

The quantity of natural, masonry (natural), and puzzolan cements produced increased 34 percent and shipments 29 percent compared with 1938. The value of shipments of these varieties gained 23 percent.

The preceding data show briefly the condition of the cement industry in the United States as a whole. The accompanying chart, figure 1, shows the percentage gains or losses in shipments from mills into each State in 1939 compared with the shipments in 1938. Unusually large gains generally indicate that demands were heavy for extensive reclamation or other projects and drastic declines reflect the completion of such projects.

The following tables present the outstanding features of the cement industry during recent years.

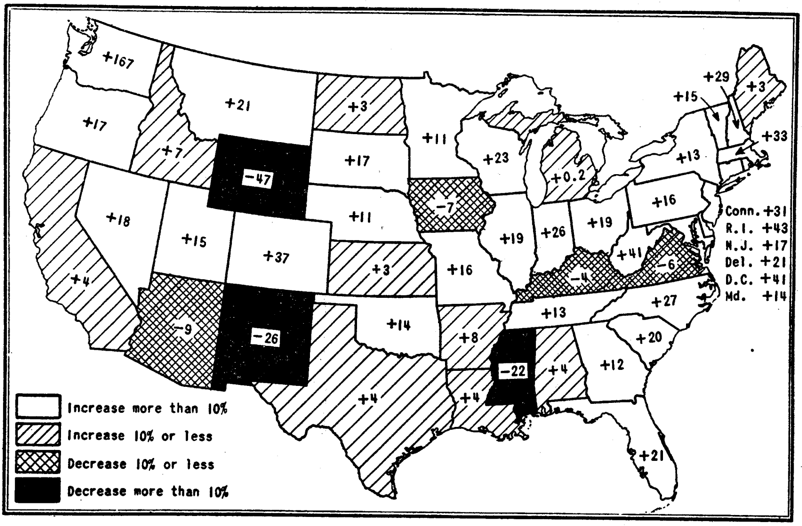

FIGURE 1.—Shipments of portland cement from mills into States in 1939 compared with 1938. The figures represent percent of change based upon preliminary figures for 1939.

Salient statistics of the cement industry in the United States, 1936–39

PORTLAND CEMENT

PRODUCTION, SHIPMENTS, AND STOCKS

Although all portland cements had fairly constant and uniform properties some years ago, during recent years the varied demands of construction have led to the development of a variety of portland cements, each adapted to a particular use. These include high-early-strength, masonry, low-heat, and oil-well cements. All varieties are included in the general portland cement tables that follow, and the special types are discussed in more detail, with statistics wherever available, in a later section of this report. The special portland cements are not to be confused with certain other types, such as natural and slag-lime cements, that are quite distinct from portland cement and are covered in a separate section of this chapter.

The following tables present the principal statistics for portland cement. In the first, which relates to production, shipments, and stocks by States and districts, the term "active plant" is applied to a mill or group of mills situated at one place and operated by one company. If a company has establishments at different places, its mill or group of mills at each place is counted as one plant. The districts are groups of States related geographically and commercially.

The tables giving data by months, compiled from monthly reports of the producers, include figures of clinker or unground cement produced and in reserve at the mills awaiting manufacture into finished cement. Although the figures may differ slightly from those based upon annual reports of the producers, they reflect accurately seasonal fluctuations in the industry.

Portland cement produced, shipped, and in stock in the United States, 1938–39, by States and districts

	Active plants		Production			Shipments							Stock at mills (Dec. 31)		
			Barrels		Increase or decrease in 1939 (percent)	1938		1939		Average factory value per barrel		Increase or decrease in quantity in 1939 (per cent)	Barrels		Increase or decrease in 1939 (percent)

[1] Revised figures.

DOMESTIC CONSUMPTION

Apparent consumption (shipments plus imports minus exports) for a series of years is indicated in the table of salient statistics. The only available gage of consumption by States is the record of shipments into States by manufacturers; it is therefore merely approximate. Cement shipped to destinations within a State in which it is manufactured is of course added to that shipped from other States. Shipments into a State during any 1 year may not equal the consumption during that year but over a series of years should afford a fair index of consumption. The following table shows shipments into States in 1938 and 1939 and per capita consumption in each State.

The official figures for exports of cement differ from those reported by manufacturers in the following table, because cement forwarded from mills and destined to foreign countries and to Alaska, Hawaii, and Puerto Rico is reported by shippers as exported, whether or not it leaves the country during the calendar year, whereas the export figures of the Bureau of Foreign and Domestic Commerce record the cement that actually leaves the country during the period specified. The exports recorded by the Bureau of Foreign and Domestic Commerce include all hydraulic cement exported, whereas the figures supplied by producers relate to portland cement only.

The per capita consumption indicated in the table falls short of the total apparent consumption by the quantity of imports, which slightly affects certain States near the Canadian border and the seaboard.

Shipments of domestic portland cement from mills into States and per capita, 1938–39, in barrels [1]

State	1938		1939

[1] Per capita figures based on latest available estimates of population made by the Bureau of the Census.
[2] Non-cement-producing State. [3] Includes shipments to Alaska and Hawaii.

The following table of monthly shipments from portland-cement mills into States in 1939 is based upon monthly reports of producers. Although the totals may vary slightly from figures shown in tables based upon annual reports they reflect seasonal fluctuations with fair accuracy.

Portland cement shipped from mills into States in 1939, by months, in barrels

USES

Portland cement is applied to a multitude of uses that may be grouped in a few general classes. The Bureau of Mines has no facilities for collecting statistics of consumption by uses; but engineers of the Portland Cement Association, who are in touch with construction throughout the country, have estimated the quantities of portland cement used in the principal groups of consuming industries.

Estimated distribution of portland cement in the United States in 1938, by uses [1]

Classification	Percent	Barrels
Paving: Roads, streets, and airports	24	25,210,000
Structural: Buildings (including multiple dwellings), bridges, and railroads	29	30,463,000
Conservation: Reclamation, water supply, and sewerage	17	17,857,000
Housing (1- and 2-family dwellings), and miscellaneous uses	20	21,009,000
Farm	10	10,504,000
	100	105,043,000

[1] Compiled by the Portland Cement Association, based upon limited available data. Not comparable with published distributions for previous years because of changes in classifications.

LOCAL SUPPLIES

The following table compares the shipments from mills within a State or group of States with the estimated consumption (State receipts of mill shipments) and indicates the surplus or deficiency in the supply of cement locally available. Consumption in the States that do not produce cement also is indicated in the table showing consumption per capita.

The surplus in the following table was distributed by years as follows: In 1938, to non-cement-producing States and Puerto Rico 12,359,897 barrels, foreign countries, Alaska, and Hawaii 868,944 barrels, and unspecified 18,539 barrels; in 1939, to non-cement-producing States 13,743,088 barrels, foreign countries, Alaska, and Hawaii 1,311,901 barrels, and unspecified 148,737 barrels.

Estimated surplus or deficiency in local supply of portland cement in cement-producing States, 1938–39, in barrels

TRANSPORTATION

As charges for transportation and delivery are large items in the cost of cement to consumers the accompanying table, showing the quantities of portland cement shipped in 1934, 1936, and 1939 from mills by truck, railroad, and boat in bulk and in containers, is of interest. Detailed data as to mode of shipping were not reported in 1934 for 2,982,924 barrels—a little less than 4 percent of the total shipments; in 1936, the detailed data were lacking for 16,870,730 barrels—nearly 15 percent of the total shipments; in 1939, the detailed data are lacking for 5,681,405 barrels—a little less than 5 percent of the total shipments for the year.

The only comparable figures for earlier years are those for 1928, when reports of producers to the Bureau of Mines showed that of the total shipments 2.4 percent were in bulk and 97.6 percent in containers.

Of the plants furnishing detailed information on the methods used in shipping their output for 1934, 131, representing 32 States, reported shipments in bulk; for 1936, 130 plants, representing 33 States, and for 1939, 137 plants, representing 33 States, reported bulk shipments.

Shipments of portland cement from mills in the United States in 1934, 1936, and 1939, in bulk and in containers, by types of carriers

[Unit of measure, barrels of 376 pounds]

Type of carrier	In bulk		In containers				Mode of shipping not stated	Total shipments	
			In bags		In other containers[1]	Total in containers

[1] Includes steel drums and iron and wooden barrels.
[2] Includes cement used at mills by producers as follows: 1934, 32,200 barrels; 1936, 103,893 barrels; 1939, 132,238 barrels.
[3] Includes cement for which mode of shipping is not stated as follows: 1934, 2,296,801 barrels; 1936, 8,081,196 barrels; 1939, 4,493,317 barrels.

PRICES

The average selling price of portland cement, f. o. b. factories (excluding the price of containers and cash discounts), as reported to the Bureau of Mines, is stated on a preceding page in the table of shipments by States and districts during 1938 and 1939. The average factory value of portland cement may be higher in certain States than it would be if ordinary structural cement were the only kind considered. For these States the average includes certain special cements that command higher prices, including the white portland cement made in California and Pennsylvania and the high-early-strength portland cement now manufactured in many States. The average selling price per barrel, f. o. b. factory, of white portland cement in 1939 was $3.72; in 1938, $3.66. The average factory selling price of high-early-strength portland cement was $1.88 a barrel in 1939 and $1.85 a barrel in 1938. The sales value of other hydraulic cements is given later in this chapter.

The following table shows the average factory value of portland cement from 1935 through 1939.

Average factory value per barrel in bulk of portland cement in the United States, 1935–39

1935	$1. 51	1938	$1. 45
1936	1. 51	1939	1. 47
1937	1. 48		

PLANT CAPACITY

At the end of 1939 the capacity for producing finished portland cement of the 150 plants active and shipping in 1939 and the 9 plants inactive in 1939 but producing or shipping from stock on hand within the 7 previous years is shown in the following table, with similar figures for 1938. Figures for plant capacity are based upon manufacturers' reports, supplemented by a few estimates.

Portland-cement-manufacturing capacity of the United States, 1938–39, by commercial districts

District	Estimated capacity (barrels)		Percent of capacity utilized	
	1938	1939	1938	1939
Eastern Pennsylvania, New Jersey, and Maryland	50, 712, 000	49, 545, 000	39. 2	47. 7
New York and Maine	17, 124, 000	17, 199, 000	36. 5	42. 5
Ohio, western Pennsylvania, and West Virginia	28, 447, 000	28, 627, 000	33. 0	39. 6
Michigan	16, 605, 000	16, 605, 000	43. 1	49. 5
Wisconsin, Illinois, Indiana, and Kentucky	29, 046, 000	29, 046, 000	34. 2	42. 3
Virginia, Tennessee, Alabama, Georgia, Florida, and Louisiana	25, 755, 000	25, 778, 000	46. 7	51. 8
Eastern Missouri, Iowa, Minnesota, and South Dakota	22, 917, 000	22, 915, 000	43. 6	45. 7
Western Missouri, Nebraska, Kansas, Oklahoma, and Arkansas	17, 159, 000	16, 159, 000	44. 3	49. 7
Texas	12, 042, 000	12, 058, 000	57. 7	60. 8
Colorado, Montana, Utah, Wyoming, and Idaho	6, 125, 000	5, 765, 000	43. 9	53. 1
California	22, 820, 000	25, 280, 000	46. 1	43. 5
Oregon and Washington	6, 945, 000	7, 095, 000	42. 9	82. 9
Puerto Rico		350, 000		92. 6
	255, 697, 000	256, 422, 000	41. 2	47. 7

The following estimates, based upon the monthly reports of producers, of the relationship between the production of finished portland cement and the manufacturing capacity of the industry for each month in 1938 and 1939 and for the 12 months ended with each month indicate the seasonal changes in capacity utilized.

Ratio (percent) of finished portland cement produced to manufacturing capacity of the United States, 1938-39

Month	Monthly		12 months ended—		Month	Monthly		12 months ended—	
	1938	1939	1938	1939		1938	1939	1938	1939
January	20.7	24.2	44.5	41.3	July	50.2	57.8	40.8	44.9
February	19.8	26.9	43.7	41.9	August	50.4	56.5	40.4	45.5
March	26.9	37.3	42.7	42.8	September	49.9	56.4	40.2	46.0
April	37.7	45.7	41.8	43.4	October	52.9	57.3	40.2	46.4
May	47.4	51.1	41.3	43.7	November	48.2	52.2	40.6	46.7
June	49.8	56.4	41.0	44.3	December	36.9	42.9	41.0	46.8

The following table gives statistics of capacity, 1937–39, by the two general methods—the "wet" and the "dry"—used in manufacturing portland cement at plants in the United States.

Portland-cement-manufacturing capacity of the United States, 1937-39, by processes

Process	Estimated capacity						Percent of capacity utilized			Percent of total finished cement produced		
	Thousands of barrels			Percent of total								
	1937	1938	1939	1937	1938	1939	1937	1938	1939	1937	1938	1939
Wet	122,638	119,776	121,337	48.1	46.8	47.3	49.2	46.1	51.8	51.9	52.4	51.4
Dry	132,585	135,921	135,085	51.9	53.2	52.7	42.1	36.9	43.9	48.1	47.6	48.6
	255,223	255,697	256,422	100.0	100.0	100.0	45.5	41.2	47.7	100.0	100.0	100.0

RAW MATERIALS

In 1938—the latest year for which data on raw materials were collected—the producers reported that approximately 32,244,000 short tons (revised figure) of raw materials (exclusive of fuels and explosives) entered into the manufacture of 105,357,000 barrels (19,807,116 short tons) of portland cement in the United States, an average of about 612 pounds to a barrel of finished cement (376 pounds).

The totals were as follows: 26,193,000 tons (revised figure) of limestone and cement rock, 3,054,000 tons of clay and shale (including kaolin for the manufacture of white cement), 428,000 tons of blast-furnace slag, 618,000 tons of marl, 93,000 tons of iron ore, 663,000 tons of gypsum, and 1,195,000 tons of other materials, such as oystershells, sandstone, sand, cinders, fluorspar, diatomite, diatomaceous shale, fuller's earth, bentonite, silica, quartz, ashes, pyrite ore, and pyrite cinder. In cements like the puzzolan portlands, which require highly siliceous materials in their manufacture, the use of a wider variety of materials, such as diatomite, diatomaceous earth and shale, pumicite, and tufa, is being reported.

Gypsum and anhydrite.—About 3 percent by weight of gypsum (or gypsum and anhydrite mixtures) is added to the cement clinker at the time of grinding to retard the time of setting. Data[1] on the uses of gypsum show that 774,982 short tons of gypsum and anhydrite were employed as cement retarder in 1939. This represented 17 percent of the total crude-gypsum supply (domestic and imported) of the country.

NEW DEVELOPMENTS

New plants.—The Permanente Corporation (address, San Jose) has virtually completed its new 7,000-barrel-a-day wet-process plant near Los Altos, Santa Clara County, Calif. Production was begun in December 1939. The limestone used had been rejected by previous cement-plant investigators because of its high chert content, but this impurity is greatly reduced in the new plant by means of froth flotation. The entire output of this modern plant will be used in constructing the Shasta Dam, for which the company has been awarded a contract for 5,800,000 barrels. Addition of a third kiln to increase capacity to 9,000 barrels a day is contemplated.

The new wet-process plant of the Puerto Rico Cement Corporation near San Juan, Puerto Rico, began production in January 1939 and operated continuously throughout the year.

A new small pilot plant was built by the Carneva Portland Cement Co. at Carrara, Nev., in 1939. It is designed for manufacture of white cement, using marble and white clay as raw materials. If the pilot plant operates successfully and markets are adequate erection of a large mill is planned.

Plant rehabilitation.—The Universal Atlas Cement Co. has entirely rebuilt its Leeds (Ala.) plant, making it a modern wet-process operation. Special mention may be made of its Woodford remote-control rock-haulage system, Dorr thickeners for dewatering slurry, and air-quenching of clinker to facilitate grinding. The Lehigh Portland Cement Co. has virtually completed rehabilitation of its Alsen (N. Y.) plant at a reported expense of about $3,000,000.

The Louisville Cement Co., Speed, Ind., the Kosmos Portland Cement Co., Kosmosdale, Ky., and the Medusa Portland Cement Co., Wampum, Pa., have put in operation new, highly efficient dust-collecting systems. The last company sells the recovered dust for liming land. The Medusa Portland Cement Co. has added recuperators to conserve heat at its Dixon (Ill.) plant and has equipped its Silica (Ohio) clinker grinding mills with "electric ears." The Keystone Portland Cement Co., Bath, Pa., has put in new clinker coolers, and the Dewey Portland Cement Co., Davenport, Iowa, has adopted truck haulage for its raw materials.

The Lone Star Cement Corporation now operates direct-firing kilns at its Limedale (Ind.) plant. Instead of maintaining an independent coal-grinding plant and holding pulverized coal in storage, as in ordinary practice, coal ranging in size from slack to ¾ inch is fed by automatic control, as required, to bowl mills that pulverize it and feed it directly to the kilns.

Unburned magnesite brick are being used more and more in cement-kiln linings, in some instances in a layer between the magnesite lining and the shell. Their use in the burning zone is new.

[1] Details in chapter on Gypsum in this volume.

Flotation.—Since 1934 the Valley Forge Cement Co., West Conshohocken, Pa., has used froth flotation to improve the composition of its raw materials. An important modification of the method developed during 1939 was the employment of cationic reagents to concentrate and remove excess mica from the raw materials. Froth-flotation equipment has been added to the plant of the National Portland Cement Co., Brodhead, Pa.

Mineralizers and grinding aids.—The National Bureau of Standards has devoted much study to the use of mineralizers to facilitate clinkering and accelerate the rate of silicate formation, thus conserving fuel. Calcium fluoride (fluorspar) and magnesium fluosilicate were found to be effective and advantageous.

During the grinding of cement clinker to the extreme fineness now demanded, the fine particles tend to flocculate or draw together into masses or lumps that cushion the blows of balls or other grinding mediums and thus retard the rate of disintegration. To overcome this difficulty a way must be devised to counteract the electrical charge that makes the particles attract each other. The Dewey & Almy Chemical Co., Cambridge, Mass., has developed a dispersing agent known in the trade as TDA, a mixture of triethanolamine salts and highly purified soluble calcium salts of modified lignin sulfonic acid. Addition of 1 part in 3,000 is said to increase mill capacity 20 to 40 percent. The material also increases the strength and workability of the concrete. The cost of the dispersing agent is about 1½ cents per barrel of finished portland cement and 3 cents per barrel of high-early-strength cement.

Specifications.—To crystallize the trend toward special cements Committee C–1 of the American Society for Testing Materials has grouped cements under five general types, as follows: (1) Ordinary portland cement requiring no special qualities; (2) cement for use in concrete subject to moderate sulfate action and moderate freezing and thawing; (3) high-early-strength; (4) low-heat; (5) sulfate-resistant. The new or improved specifications covering these five types will, if adopted, tend to increase production costs, for they will demand careful preparation of raw materials with rigid supervision of insoluble material, free lime, and alkali. The tendency toward increasing fineness of finished cement also adds to the cost.

Electric eyes and ears.—Delicate instruments that measure light and sound are winning an important place in the cement industry. Fineness is measured with a turbidimeter that utilizes a beam of light transmitted through a kerosene suspension of the cement particles. Several companies use "electric ears" to control the feed of ball mills. The mills are noisiest when running with a light load. The volume of sound carried through a microphone is converted into electrical energy in a control box, and the mechanism is so adjusted that when the noise is loud the mill feed is increased automatically, while deadening of sound in turn reduces the feed. The latest adaptation of such devices is the "electric eye," which controls the fuel supply upon the basis of the intensity of light in the burning zone of the kiln.

New cements.—A new product known as "Sealithor" supersulfate cement developed in Belgium consists of a mixture of granulated blast-furnace slag, a small quantity of slaked lime, and a larger quantity of calcium sulfate. It contains 26 percent soluble silica, 45 percent calcium oxide, and 7 percent sulfur trioxide. Tests made under supervision of the Belgian Government show that the new cement is unusually impervious, that it hardens in sea water and expands slightly on setting, is a little stronger than portland cement, and is resistant to chemical attack.

A new type of plastic masonry cement ("Mortar-mix") is now on the market; dried clay replaces lime in this mixture.

Achievements.—The Margaret Hayden Rorke award for the highest achievement among American Trade Association executives was won in 1939 by the Portland Cement Association for its design of a "farm-to-market" light-traffic soil-cement road surface costing only $5,000 a mile.

New publication.—In 1939 the Bureau of Mines issued Information Circular 7102, The Cement Industry of Latin America, covering raw-material supplies, cement-plant equipment, present and prospective plant capacity, market situation, production, consumption, and imports for each country in South and Central America, Mexico, and the West Indies.

FUELS AND POWER

Fuels.—According to monthly reports of producers, supplemented by a few estimates by the Bureau of Mines, the following quantities of fuel were consumed at portland-cement plants in the United States (including Puerto Rico) in 1939 for making 121,620,000 barrels of clinker (unground cement) and 122,259,154 barrels of finished cement: Coal, 5,227,756 short tons; oil, 2,378,762 barrels (42 gallons); and natural gas, 40,233,089,789 cubic feet. Corresponding figures for 1938 are: Clinker produced, 104,117,000 barrels; and finished cement produced, 105,357,000 barrels. Fuels consumed were: Coal, 4,482,758 short tons (revised figure); oil, 1,927,584 barrels; and natural gas, 37,496,315,988 cubic feet (revised figure).

Electric power.—The accompanying table gives the electric energy produced at portland-cement plants and that purchased from power companies during 1938 and 1939. The cement industry generated 50 percent of its electric-power requirements in 1939 compared with 51 percent in 1938 and 53 percent in 1937.

Electrical energy used at portland-cement-producing plants, 1938–39, by processes, in kilowatt-hours

Process	Electrical energy used: Generated at portland-cement plants		Electrical energy used: Purchased		Electrical energy used: Total		Finished cement produced	Average electrical energy used per barrel of cement produced

SPECIAL PORTLAND CEMENTS

Although regular or standard portland cements have been improved greatly during recent years and are well-adapted for all ordinary uses, new conditions have arisen in industry that demand cements having special qualities, such as high early strength, unusual plasticity, low or moderate heat of setting, or high resistance to chemical action. Special types of portland cement are discussed in the following paragraphs.

White portland cement.—White cement has been manufactured for many years in Pennsylvania and since 1932 in California. It is simply a standard portland cement, the raw materials of which are unusually pure, with an especially low iron content. To avoid contamination and discoloration from fuel these cements are calcined with gas. They are produced at so few plants that the Bureau is not at liberty to publish figures of production separately.

Alumina cement.—A product known as alumina or high-alumina cement was first manufactured in France under the name "ciment fondu." Modifications of alumina cement have been made in the United States for many years under patent. The raw materials are bauxite and limestone or lime, which are completely fused in a furnace. The melted product is cooled rapidly and ground to fine powder. Production figures cannot be published separately.

High-early-strength cement.—For street work where traffic is heavy, construction work where one step must follow another rapidly, and similar uses a cement that attains adequate strength in 24 hours or less is much in demand. This has led to the development of special high-early-strength cements that are now manufactured in many States.

Masonry cement.—Cements suitable for masonry must be plastic and of low shrinkage.

In addition to "masonry portland" and "masonry natural" (discussed on a following page) producers also report masonry cements, hydraulic but not portland, that evidently are specially prepared from portland-cement clinker and other ingredients. Production of such cements, made at 35 plants in 1939, totaled 1,865,192 barrels and shipments 1,838,820 barrels valued at $2,473,127—an average of $1.34 a barrel. Corresponding data for 1938, representing the output of 32 plants, are: Production 1,246,263 barrels and shipments 1,225,960 barrels valued at $1,589,908—an average of $1.30 a barrel. To avoid duplication the above figures are not included in the portland-cement totals, because portland-cement clinker evidently is the principal constituent used.

Low and moderate heat-of-hardening portland cement.—Because of the enormous masses of concrete used in large dams, such as those in the Tennessee Valley and the Far West, a demand has arisen for cements that develop little heat in the process of setting. They include Tennessee Valley Authority Type B and other cements that must conform with Federal specifications.

Portland-puzzolan cement.—Portland-puzzolan cements, including those reported as "high-silica," are especially adapted for resistance to chemical attack, such as the reaction with salts contained in sea water. They are made by adding them to portland cement, pumicite, slag, or other materials that react with the calcium content of the cement.

Oil-well cement.—In the oil-producing States, particularly California, Texas, and Wyoming, special types of portland cement have been developed that are suitable for grouting wells.

Miscellaneous.—Other special portland cements include those suitable for resisting high temperatures.

The following table presents statistical data for recent years insofar as they are available. All figures given in this table except those for masonry cement are included in the general tables appearing earlier in this chapter.

Special portland cements produced and shipped in the United States, 1937–39, by kinds

Kind and year	Active plants	Production (barrels)	Shipments		
			Barrels	Value	
				Total	Average
High-early-strength:					
1937	64	4,192,959	3,845,314	$7,134,468	$1.86
1938	72	3,340,582	3,385,523	6,247,699	1.85
1939	79	3,751,331	3,670,506	6,910,099	1.88
Masonry or mortar:					
1937	10	257,385	273,144	362,807	1.33
1938	5	84,875	88,905	124,239	1.40
1939	3	(1)	(1)	(1)	(1)
Low and moderate heat:					
1937	29	3,169,593	3,511,674	5,008,217	1.43

NATURAL, MASONRY (NATURAL), AND PUZZOLAN CEMENTS

The term "masonry cement" is used here to designate certain cements made by calcining argillaceous limestone at a comparatively low temperature and grinding the calcined material to a fine powder. This product is known as "natural" cement. Portland cements that are also used for masonry are discussed under the special portland cements on the previous page.

In addition to portland-puzzolan cements discussed on the previous page, another type known as slag-lime cement is now made at Birmingham and Graystone, Ala., by mixing granulated blast-furnace slag with hydrated lime and grinding them to a fine consistency. The mixture is not subsequently calcined.

Figures for production and shipments of special types of cement other than portland are presented in the following table.

Natural, masonry (natural), and puzzolan (slag-lime) cements produced, shipped, and in stock at mills in the United States, 1935–39

Year	Production		Shipments		Stock (Dec. 31)
	Active plants	Barrels (376 pounds)	Barrels (376 pounds)	Value	Barrels (376 pounds)
1935	13	1,006,064	1,011,411	$1,437,542	172,572
1936	13	1,819,488	1,760,993	2,362,396	230,788
1937	12	1,900,643	1,873,400	2,578,885	[1] 253,518
1938	[1] 12	[1] 1,820,795	[1] 1,867,949	[1] 2,725,776	[1] 373,816
1939	12	2,439,110	2,405,135	3,361,724	407,791

[1] Revised figures.

TRENDS IN EMPLOYMENT AND OUTPUT PER MAN [2]

In Minerals Yearbook, 1935 (pp. 891–905), trends in employment and output per man in the cement industry were traced from 1928 to 1933. It seems desirable at this time to add similar data for the succeeding 5 years and thus reveal significant trends over an 11-year period.

Total employment.—The Bureau of the Census biennially compiles data on employment at cement plants, but that organization obtains the figures for each year by averaging the monthly totals of employment, whereas Bureau of Mines data represent the total number employed, irrespective of how short a time some of them had worked. In other words, as pointed out in the earlier report, the Bureau of Mines figure is the total number of men actually employed in the cement industry, and the Bureau of the Census figure represents more closely the number of men to whom the industry might have provided full-time employment throughout the year.

It may be observed from the table that follows that the coverage of the study in the earlier years ranged from 87.3 to 89.1 percent, whereas for 1937 and 1938 it was 100 percent. The estimated total number of employees in 1928 was 35,100, and the number recorded in 1938 was 25,036.

Output per man.—Production in 1928 was 176,298,846 barrels, or 5,023 barrels per man; in 1938 it was 105,357,000, or 4,208 barrels per man. Production in this interval declined 40 percent, whereas employment dropped only 29 percent. Maintenance of a relatively larger number of employees for a given tonnage of production shows the results of the shorter week and the fewer hours per day of employment during 1938. In 1928 each employee averaged 324 days of work and was occupied 9.5 hours per day; in 1938 he worked only 256 days and averaged 7.5 hours per day. Although employees worked fewer days and shorter hours in 1938 than in 1928 the productivity per hour of labor increased considerably in 1938 compared with the earlier year. As may be noted in the accompanying table, production per man per hour in 1928 was 1.63 barrels; in 1938 it was 2.21 barrels. This 36-percent increase in output indicates improvements in equipment and increased efficiency of operation.

[2] Statistics on employment and output per man presented in this discussion were compiled by E. T. Shuey from records of the employment statistics section, Bureau of Mines.

Employment in the cement industry, finished cement produced at mills included in study, and average output per man in the United States, 1928–38

Year	Employment					Production			Percent of industry represented [1]
	Average number of men	Time employed				Finished portland cement (barrels)	Average per man (barrels)		
		Average number of days	Total man-shifts	Man-hours			Per shift	Per hour	
				Average per man per day	Total				
1928	31,295	324	10,137,187	9.5	96,541,428	157,121,800	15.50	1.63	89.1
1929	29,274	319	9,345,890	9.5	88,528,269	152,116,204	16.28	1.72	89.1
1930	27,775	308	8,562,897	9.2	78,771,352	140,771,728	16.44	1.79	87.3
1931	22,036	279	6,146,564	8.8	53,833,283	111,501,887	18.14	2.07	88.9
1932	17,440	231	4,020,861	8.4	33,799,409	67,449,096	16.77	2.00	87.9
1933	19,536	196	3,835,657	7.3	28,048,172	56,463,620	14.72	2.01	89.0

[1] Calculated for each year by dividing the quantity of finished cement produced at mills included in study by the total production.

Mill employees.—At the average cement plant, mill employees outnumber quarry and crusher employees more than 4 to 1. In 1928 mill employees averaged 9.5 hours a day for 332 days and produced 1.98 barrels of finished cement per man-hour; in 1938 they averaged 7.4 hours a day for only 264 days but produced 2.71 barrels of cement per man-hour. Thus productivity per man per hour increased 37 percent during this 11-year period.

Mill employees in the cement industry, finished cement produced at mills included in study, and average output per man in the United States, 1928–38

Year	Employment—cement mill only					Production			Percent of industry represented [1]
	Average number of men	Time employed				Finished portland cement (barrels)	Average per man (barrels)		
		Average number of days	Total man-shifts	Man-hours			Per shift	Per hour	
				Average per man per day	Total

[1] Calculated for each year by dividing the quantity of finished cement produced at mills included in study by the total production.

Quarry and crusher employees.—Data in the accompanying table on quarry and crusher employees are not as complete for recent years as formerly because the tonnage of material handled has not been recorded. The table shows, for 1938 compared with 1929, a moderate decline in the number of men employed and a striking reduction in both the average number of days worked and the hours of employment per day.

Quarry and crusher employees in the cement industry, material (quarry rock and overburden) handled at quarries included in study, and average output of material per man in the United States, 1929–38

Year	Employment—quarry and crusher only					Material handled—quarry rock and overburden				Percent of industry represented [1]
	Average number of men	Time employed				Short tons	Percent of overburden included	Average per man (short tons)		
		Average number of days	Total man-shifts	Man-hours				Per shift	Per hour	
				Average per man per day	Total					
1929	5,123	281	1,441,964	9.6	13,779,252	44,113,986	15.3	30.59	3.20	78.1

[1] Calculated for each year by dividing the quantity of finished cement produced at mills included in study by the total production.
[2] Figures not available.

Hours per day.—From 1928 to 1938 there was a striking decrease in the number of hours in the working day. In 1928 no cement plant maintained for any of its employees a working day of less than 8 hours; in 1938, 49.2 percent of them were in this classification. Those working 8 to 9 hours a day in 1928 comprised 42.2 percent and in 1938, 48.4 percent of the total. In 1928, 57.8 of the employees worked more than 9 hours a day, and in 1938 such workers comprised only 2.4 percent of the total.

Almost invariably the production per man-hour is higher where men work short shifts than where they work longer hours per day. For instance, in 1937 employees working less than 7 hours a day produced 2.3 barrels of cement an hour, while those employed between 11 and 12 hours a day produced only 1.1 barrels during each hour of labor. Factors other than length of the working day may, however, affect productivity per hour. In general, plants that maintain a short working day are more efficient than those that exact long hours, therefore the output per man-hour in the former group will be relatively high. Data at hand are inadequate to show a definite relationship

244615—40——73

between man-hour output and length of day; but, from the figures in the accompanying table, one would infer that a relatively high production per man-hour is to be expected when the working day is short.

Number of men employed in the cement industry in the United States and output per man-hour, 1933–38, classified according to hours of labor per day

District and State tables.—The following tables show a geographic break-down by districts and States of the statistical record of employment and productivity of labor in the cement industry. These data are primarily of interest in the study of regional relationships. The first table, covering employment in the cement industry as a whole, and the second, relating to mill employees, give data for 1934 to 1938, supplementing similar data for 1928 to 1933 on pages 897 to 902 of Minerals Yearbook, 1935. However, the third table, covering quarry and crusher employees, applies only to 1934, because data for quarry rock and overburden handled during the years since 1934 have not been recorded.

Employment in the cement industry, finished cement produced at mills included in study, and average output per man in the United States, 1934–38, by districts and by States

[1] Calculated for each year by dividing the quantity of finished cement produced at mills included in study by the total production.

[2] Arkansas, Colorado, Florida, Georgia, Idaho, Indiana, Kentucky, Louisiana, Maine, Maryland, Minnesota, Montana, Nebraska, New Jersey, Oklahoma, Oregon, South Dakota, Utah, Virginia, Washington, West Virginia, Wisconsin, and Wyoming.

Mill employees in the cement industry, finished cement produced at mills included in study, and average output per man in the United States, 1934–38, by districts and by States

	Employment—Cement mill only					Production			
	Average number of men	Time employed				Finished portland cement (barrels)	Average per man (barrels)		Per cent of industry represented
		Average number of days	Total man-shifts	Man-hours					
				Average per man per day	Total		Per shift	Per hour

FOREIGN TRADE [3]

Imports.—The figures in the following table cover imports of hydraulic cements of all kinds. The values assigned are supposed to represent values in the foreign countries from which the materials are exported, including the cost of containers or coverings.

Hydraulic cement imported for consumption in the United States, 1935–39

Year	Barrels	Value	Year	Barrels	Value
1935	619,404	$615,866	1938	1,727,411	$1,436,730
1936	1,658,902	1,421,620	1939	1,913,853	1,860,543
1937	1,803,932	1,392,633			

The following table of imports by countries of origin and import districts includes all hydraulic cements except "white nonstaining portland cement," which was reported "imported for consumption" as follows: 1939, 22,883 barrels valued at $75,983, of which 11,029 barrels valued at $42,864 came from Denmark, 2,323 barrels valued at $7,405 from Belgium, 4,279 barrels valued at $7,686 from France, and 1,278 barrels valued at $4,413 from the United Kingdom; 1938, 12,227 barrels valued at $38,557, of which 277 barrels valued at $1,038 came from Denmark, 5,439 barrels valued at $17,466 from Belgium, 3,262 barrels valued at $6,394 from France, and 1,555 barrels valued at $5,892 from the United Kingdom.

Roman, portland, and other hydraulic cements imported for consumption in the United States, 1938–39, by countries and customs districts [1]

Exports.—Although the United States is the major cement-producing country of the world its export trade is small. As indicated in the following table, exports in 1939 were larger than in any other recent year but still comprised less than 1 percent of total domestic shipments. The value of exports is the actual cost at United States ports as indicated by the shippers on the export declarations.

Hydraulic cement exported from the United States, 1935–39

Year	Barrels	Value	Percent of total shipments from mills
1935	416,099	$1,012,942	0.6
1936	334,673	886,560	.3
1937	378,554	1,044,161	.3
1938	558,226	1,294,883	.5
1939	1,146,339	2,352,693	.9

WORLD PRODUCTION

The following table of world production has been compiled by the Bureau of Mines from consular reports, official statistics, and trade literature. The figures are in metric tons (1 metric ton equals 2,204.622 pounds). The table shows the latest reported plant capacity and the production from 1935 to 1939, inclusive. Although figures for certain countries are still lacking the table presents a reasonably complete picture of the cement industry throughout the world. Figures on capacity are the best estimates that can be made from available data.

World production of cement, 1935–39, and latest reported plant capacity, by countries, in metric tons [1]

[1] Table includes all kinds of cement. Few data are available for Afghanistan, Burma, Eritrea, Ethiopia, Hong Kong, Luxemburg, and Taiwan, and they do not permit the establishment of production figures at this time, but estimates of production and capacity of these countries are included in the totals. The present plant capacity of China and war-affected Europe is in reality unknown owing to the destructive effects of military operations.

[2] Figures are approximate only and are subject to revision.

[3] Data not available, estimate included in total.

[4] Data not yet available.

[5] Shipments.

[6] Approximate production.

[7] 12 months ended June 30 of the year indicated.

[8] 12 months ended March 31 of the year indicated.

Canada.—According to the Dominion Bureau of Statistics sales of portland cement by Canadian producers increased 4 percent in quantity and 3 percent in value in 1939 compared with 1938. The same plants were in operation both years. The following table presents the principal statistics of the Canadian industry.

Salient statistics of the cement industry in Canada, 1938–39 [1]

	1938		1939	
	Barrels	Value	Barrels	Value
Output	5,558,047		5,721,447	
Sales:				
Quebec	2,730,320	$3,693,188	3,027,759	$4,035,294
Ontario	1,818,032	2,555,214	1,709,263	2,437,777
Manitoba	330,889	754,427	343,717	773,363
Alberta	304,373	611,790	377,846	744,357
British Columbia	335,488	626,731	272,679	520,420
Total sales	5,519,102	8,241,350	5,731,264	8,511,211
Stocks, Dec. 31	1,875,288		1,865,471

STONE

By Oliver Bowles and M. S. Jensen

SUMMARY OUTLINE

Sales of stone in 1939 attained an all-time record of more than 147,000,000 tons. Their value was the highest since 1930. Sales of crushed and dimension stone combined increased 18 percent in quantity and 14 percent in value over 1938. Sales of dimension stone (exclusive of slate) were 30 percent higher in quantity and 17 percent higher in value. For the crushed-stone industry the corresponding gains were 18 and 13 percent. The smaller proportional increase in value than in tonnage indicates a trend toward lower unit prices.

The present chapter follows the general plan of the chapter on Stone in Minerals Yearbook, 1939, data on dimension stone being separated from that on crushed stone, except in the introductory general tables.

The tables in this report give the quantities sold or used by producers and the values f. o. b. quarries and mills insofar as these figures are obtainable. Stone quarried and used by the producer is considered as sold and is included in the statistics of sales. The data, however, do not include stone made into abrasives (such as grindstones) or that used in making lime and cement. These materials are reported in terms of finished products in the Abrasive Materials, Lime, and Cement chapters of this volume. The following tables show total sales of stone by kinds, uses, and States.

Stone sold or used by producers in the United States, 1935–39, by kinds

[Quantities approximate]

Year	Granite		Basalt and related rocks (trap rock)		Marble		Limestone	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1935	6,013,990	$13,507,165	9,671,950	$9,315,040	132,450	$3,415,861	57,492,760	$50,668,765
1936	15,442,150	22,893,289	14,014,440	13,386,933	165,760	5,761,554	87,735,740	81,559,984
1937	9,265,830	20,192,882	13,581,460	12,508,276	207,760	5,456,191	94,577,270	90,901,877
1938	10,432,980	20,915,609	13,908,790	12,280,016	219,390	5,248,290	81,679,690	82,286,555
1939	12,041,360	22,495,983	16,091,250	14,164,016	228,080	6,688,662	100,846,090	94,817,481

Year	Sandstone		Other stone [1]		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1935	3,009,790	$4,568,093	6,838,110	$6,349,573	83,159,050	$87,824,497

DIMENSION STONE

The term "dimension stone" is applied to blocks or slabs of natural stone, of which most are cut to definite shapes and sizes. These products are quite distinct from crushed, broken, and pulverized stone, which comprise irregular fragments or grains sized chiefly by mechanical screening or air separation. Crushed and broken stone is covered in a later section of this chapter.

Dimension-stone producers fall in three main groups upon the basis of plant operation: (1) Those who quarry stone and sell it as rough blocks or slabs; (2) those who quarry stone and manufacture it into finished products; and (3) those who have no quarries but who buy their rough stock and manufacture it into finished products. The Bureau of Mines statistical canvass covers the first and second groups, but as the third group comprises manufacturers rather than quarrymen it is canvassed by the Bureau of the Census. Bureau of Mines statistics are compiled from reports of tonnages and values of original sales, hence they include some material sold as rough blocks and some sold as finished products.

Total sales of dimension stone in 1939 rose 30 percent in quantity and 19 percent in value over 1938. These figures include slate, but details of the slate industry are given in a separate chapter of this volume. All varieties of stone shared the advance except miscellaneous stone, which declined 26 percent in quantity although it gained 22 percent in value.

The following table of salient statistics includes final figures for both 1938 and 1939 and the percentage of change from 1938 for each type of stone by principal products.

Dimension stone sold or used by producers in the United States, 1938–39, by kinds and uses

Kind and use	1938	1939	
		Total	Percent of change
Granite:

[1] To avoid disclosing confidential information, paving blocks in 1939 are included under "Curbing."
[2] Includes paving blocks.
[3] Includes soapstone, mica schist, volcanic rocks, argillite, and other varieties that cannot be classified in the principal groups.
[4] Details of production, by uses, are given in the chapter on Slate in this volume.

BUILDING STONE

The largest use of dimension stone is for building. The following table gives the quantity and value of each kind of stone used for construction in 1938 and 1939.

Building stone sold or used by producers in the United States in 1939, by kinds

Kind	Rough			
	Construction		Architectural	
	Cubic feet	Value	Cubic feet	Value
Granite	2,241,800	$410,395	273,140	$253,537
Basalt	127,910	14,619		
Marble			313,270	664,998
Limestone	3,872,640	424,230	3,367,550	1,426,020
Sandstone	836,130	190,940	291,110	360,572
Miscellaneous	601,880	654,342		
	7,680,360	1,694,526	4,245,070	2,705,127

Kind	Finished				Total	
	Sawed [1]		Cut [1]			
	Cubic feet	Value	Cubic feet	Value	Cubic feet	Value
Granite	297,470	$932,540	294,520	$1,479,128	3,106,930	$3,075,600
Basalt					127,910	14,619
Marble	232,040	464,900	501,520	3,574,149	1,046,830	4,704,047
Limestone	1,430,700	925,250	2,059,130	3,627,180	10,730,020	6,402,680
Sandstone	121,000	153,332	118,850	452,153	1,367,090	1,156,997
Miscellaneous					601,880	654,342
	2,081,210	2,476,022	2,974,020	9,132,610	16,980,660	16,008,285

[1] For granite, sawed stone corresponds to dressed stone for construction work (walls, foundations, bridges) and cut stone to architectural stone for high-class buildings.

GRANITE

Sales of granite as dimension stone were 9 percent greater in quantity and 1 percent greater in value in 1939 than in 1938. The gains were chiefly in rough monumental and rubble. Both paving blocks and curbing showed large declines in 1939.

Granite (dimension stone) sold or used by producers in the United States in 1939, by States and uses

[1] Included under "Undistributed."

[2] 2,241,800 cubic feet (approximate).

The following tables show sales of monumental granite in the Quincy (Mass.) and Barre (Vt.) centers.

Monumental granite sold by the quarrymen at Quincy, Mass., 1935–39 [1]

Year	Active plants	Cubic feet	Value	Year	Active plants	Cubic feet	Value
1935	3	63,450	$95,529	1938	3	33,360	$73,832
1936	3	46,570	85,013	1939	3	25,620	61,955
1937	3	36,020	80,248				

Quincy granite is sold also for construction, curbing, rubble, riprap, and crushed stone.

Monumental granite sold by the quarrymen in the Barre district, Vermont, 1935–39 [1]

Year	Cubic feet	Value	Year	Cubic feet	Value
1935	676,820	$1,844,006	1938	605,660	$1,849,607
1936	771,230	2,109,526	1939	684,310	2,029,801
1937	847,740	2,390,377			

[1] Barre granite is sold also for construction, paving blocks, and crushed stone.

Estimated output of monumental granite in the Barre district, Vermont, 1937–39

	1937	1938	1939
Total quarry output, rough stock.....cubic feet..	765,390	589,440	614,256
Shipped out of Barre district in rough.....do....	153,078	117,888	122,852
Manufactured in Barre district.....do....	612,312	471,552	491,404
Light stock consumed in district.....do....	478,369	294,720	307,128
Dark stock consumed in district.....do....	287,021	176,832	184,276
Number of cutters in district	1,550	1,550	1,550
Average daily wage	$8.00	$8.00	$8.50
Average number of days worked	230	220	220
Total pay roll for year	$2,852,000	$2,813,250	$2,898,500
Estimated overhead	1,426,000	1,406,625	1,449,250
Estimated value of light stock	1,554,699	1,176,987	1,247,714
Estimated value of dark stock	1,234,191	934,347	990,494
Estimated polishing cost	484,263	372,938	388,639
Output from saws	161,421	124,312	129,546
Total value of granite	7,712,574	6,828,459	7,104,143

[1] Through the kindness of the Granite Manufacturers' Association, Barre, figures covering the entire granite industry of the Barre district are given in this table to supplement figures of sales reported by quarrymen.

BASALT AND RELATED ROCKS (TRAP ROCK)

Because of its dark color, basalt is not used extensively for building. However, its use as rubble increased substantially in 1939. Some of these dark rocks are used for memorials, but such stones are classed commercially as black granites, therefore they are included with the figures for monumental granite.

Basalt and related rocks (trap rock) (dimension stone) sold or used by producers in the United States in 1939, by States and uses

State	Active plants	Building stone: Rough construction, Short tons	Building stone: Rough construction, Value	Building stone: Rubble, Short tons	Building stone: Rubble, Value	Total: Short tons	Total: Value

[1] Included under "Undistributed." [2] 127,910 cubic feet, approximate.

MARBLE

Sales of marble in 1939 increased 39 percent in quantity and 27 percent in value over 1938. The greatest advances were in rough and finished exterior building marble. Much larger quantities of rough monumental stone were sold, but sales of finished memorial stone declined. The principal gains in value of sales were in Tennessee, Georgia, Missouri, Vermont, and Massachusetts.

Marble (dimension stone) sold by producers in the United States, 1938–39, by uses

Use	1938: Cubic feet	1938: Value	1939: Cubic feet	1939: Value
Building stone:				
Rough:				
Exterior	13,880	$24,424	179,520	$358,053

[1] Includes 10,540 cubic feet of serpentine marble (verde antique) valued at $119,797, which was sold as building and ornamental stone.
[2] Onyx rough blocks for the manufacture of mantels, lamp bases, desk sets, clock cases, and novelties.
[3] Included under "Undistributed."

LIMESTONE

Limestone is used more extensively than any other type of building stone in the United States, and Indiana supplied 77 percent of the total architectural limestone (rough and finished) sold in 1939. All branches of the limestone industry showed decisive gains in 1939 compared with 1938. Sales of rough architectural stone increased 37 percent and sales of cut stone 33 percent. The average price per cubic foot of cut and sawed stone was $1.30, which was 2 cents lower than in 1938. The total of all products sold in 1939 was 51 percent greater in quantity and 35 percent greater in value than in 1938.

SANDSTONE

Sales of sandstone increased 18 percent in quantity and 33 percent in value in 1939 over 1938. Rubble and stone for rough construction showed little change, but sales of rough architectural stone increased more than fourfold. Dressed stone (sawed and cut) declined 11 percent in quantity but increased 52 percent in value. Sandstone paving stones have receded to such insignificance that a column for them is no longer carried in the table. Sales of sandstone flagging increased considerably in quantity, but the unit value was much lower than in 1938.

Sales of bluestone shown in the second table have declined greatly, particularly in Pennsylvania.

Sandstone (dimension stone) sold or used by producers in the United States in 1939, by States and uses

[2] Building stone, approximately 601,880 cubic feet; flagging, approximately 27,750 cubic feet.

TRENDS IN THE USE OF BUILDING AND MEMORIAL STONE

Despite the moderate decline during 1939 in nonresidential building, where stone finds its chief market, all branches of the building-stone industry made encouraging gains, as indicated in figures 1 and 2. Sales of building marble made the most substantial gain, attaining the highest value since 1933. The value of sandstone sales in 1939 was higher than in any year since 1931, and sales of limestone reached the same value as in 1933. Granite recovered its loss of 1938, the value of sales in 1939 being about the same as in 1937. This substantial upward trend in the use of natural stone indicates wider recognition of its endurance, dignity, substantiality, fire resistance, and low

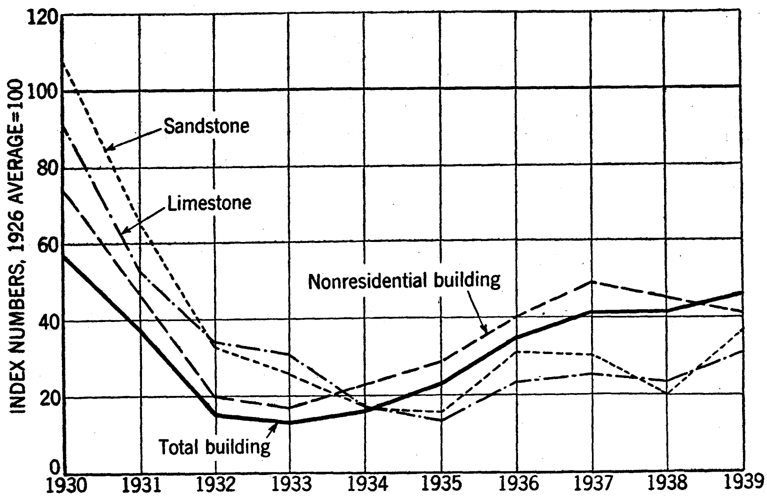

FIGURE 1.—Sales value of limestone and sandstone compared with total building and nonresidential building, 1930–39. To facilitate comparison, unlike units have been reduced to percentages of the 1926 value. Stone figures include rough and dressed stone; building contracts are from F. W. Dodge Corporation.

maintenance expense. Further gains are to be expected if nonresidential building experiences an upward trend.

Sales of memorial granite in 1939 were slightly higher both in quantity and value than in 1938. Sales of memorial marble increased in quantity but declined in value.

NEW DEVELOPMENTS

Prof. George W. Bain, of Amherst College, Amherst, Mass., has developed a new technique for determining the lasting qualities of marbles, for assisting fabricators in obtaining maximum translucence and weather resistance and for studying the effects of fabricating methods on marble endurance and appearance. These studies are based upon knowledge of crystallographic orientation of marble grains, size of intergranular spaces, index of irregularity, and other physical phenomena. They illustrate how a skilled geologist, chemist, and physicist may help in the solution of problems relating to utilization and fabrication, not only of marble but of many industrial minerals.

The Shawnee Stone Co., a producer of building limestone near Bloomington, Ind., is employing wire saws successfully in its quarries. Several other companies in the district are considering the use of this equipment.

The Georgia Marble Co. has changed from open-pit to underground operation at one of its quarries. The floor of the new drift will

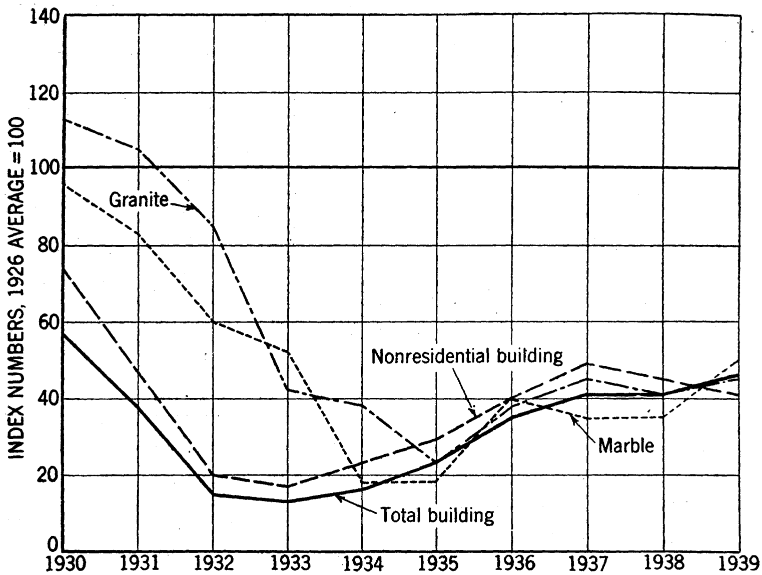

FIGURE 2.—Sales value of building marble and granite compared with total building and nonresidential building, 1930–39. To facilitate comparison, unlike units have been reduced to percentages of the 1926 value. Stone figures include rough and dressed stone; building contracts are from F. W. Dodge Corporation.

parallel the color banding, thus improving the pattern of the finished product and conserving stone. Markets for building marble in the South have improved, but demands for monuments have declined.

CRUSHED AND BROKEN STONE

More than 145,000,000 tons of crushed and broken stone were sold in 1939, exclusive of that used for making cement and lime. Sales increased 18 percent in quantity and 13 percent in value in 1939 compared with 1938. The largest proportional gains were in metallurgical and refractory stone.

The following table of salient statistics shows the quantity and value of crushed and broken stone sold during 1938 and 1939, by uses. Detailed data on asphaltic stone and slate granules and flour are given in the chapters of this volume on Asphalt and Slate.

Crushed and broken stone sold or used by producers in the United States, 1938–39, by principal uses

[1] Included under "Undistributed."
[2] To avoid disclosing confidential information certain totals are somewhat incomplete, the figures not included being combined under "Undistributed."

Commercial and noncommercial operations.—The following table shows production of crushed stone for concrete and road metal and railroad ballast during recent years by Government agencies of various kinds contrasted with that by commercial enterprises. Production by Government agencies increased 29 percent in 1939 compared with 1938, whereas commercial production decreased 1 percent.

Concrete and road metal and railroad ballast sold or used by commercial and noncommercial operators in the United States, 1935–39

[Figures for "noncommercial operations" represent tonnages reported by States, counties, municipalities, and other Government agencies. produced either by themselves or by contractors expressly for their consumption often with publicly owned equipment; they do not include purchases from commercial producers. Figures for "commercial operations" represent tonnages reported by all other producers]

Year	Commercial operations				Noncommercial operations				Total	
	Short tons	Average value per ton	Percent of change in quantity from preceding year	Percent of total quantity	Short tons	Average value per ton	Percent of change in quantity from preceding year	Percent of total quantity	Short tons	Percent of change in quantity from preceding year
1935	38,090,660	$0.90	−11.9	69.6	16,663,860	$0.87	−3.7	30.4	54,754,520	−9.6
1936	57,494,430	.93	+50.9	65.9	29,776,390	.95	+78.7	34.1	87,270,820	+59.4
1937	62,315,350	.88	+8.4	70.5	26,117,220	1.06	−12.3	29.5	88,432,570	+1.3
1938	60,254,170	.88	−3.3	63.6	34,508,880	1.04	+32.1	36.4	94,763,050	+7.2
1939	59,516,270	.86	−1.2	57.3	44,374,750	.97	+28.6	42.7	103,891,020	+9.6

Methods of transportation.—The following table shows the quantities of concrete and road metal conveyed by each of the principal methods of transportation during 1938 and 1939.

Concrete and road metal sold or used by commercial producers in the United States, 1938–39, by methods of transportation [1]

Method of transportation	1938		1939	
	Short tons	Percent of total	Short tons	Percent of total
Truck	32,779,040	60.4	33,495,870	63.8
Rail	12,032,490	22.2	11,712,330	22.3
Waterway	5,398,770	9.9	4,886,820	9.3
Unspecified	4,067,900	7.5	2,424,450	4.6
	54,278,200	100.0	52,519,470	100.0

[1] For practical purposes the entire output of noncommercial operations commonly is moved by truck. Including noncommercial production, crushed stone for concrete and road metal moved as follows: 1938: Truck 76 percent, rail 13 percent, waterway 6 percent, and unspecified 5 percent; 1939: Truck 80 percent, rail 12 percent, waterway 5 percent, and unspecified 3 percent.

GRANITE

Sales of crushed and broken granite rose 16 percent in quantity and 14 percent in value in 1939 compared with 1938. The principal gain was in stone used for concrete aggregate and highway construction. Sales of both riprap and railroad ballast declined, reversing the trend of 1938.

Noncommercial production, which is a substantial part of the total, is reported by city, county, and State governments, highway commissions, or other Government agencies. From the reports submitted it is impossible to determine the number of plants that supply materials. For instance, the report of a Federal agency such as the W. P. A. may include the output of one or two large plants or 25 to 50 small portable plants. Because the number of individual operations supplying noncommercial crushed stone cannot be determined with any degree of accuracy, the columns indicating the number of active plants, which have appeared in past years in the granite and other tables covering the crushed-stone industry, have been omitted in this report.

Granite (crushed and broken stone) sold or used by producers in the United States in 1939, by States and uses

BASALT AND RELATED ROCKS (TRAP ROCK)

Basalt, gabbro, diorite, and other dark igneous rocks, known commercially as trap rock, are used widely for highway construction and concrete aggregate. Sales of crushed and broken trap rock increased 15 percent in both tonnage and value in 1939 compared with 1938, with gains for all major uses. Sales of riprap in the major producing States fluctuate greatly, as they depend chiefly on special reclamation and other projects. Prices per ton at the quarry were virtually the same in 1939 as in 1938.

Basalt and related rocks (trap rock) (crushed and broken stone) sold or used by producers in the United States in 1939, by States and uses

MARBLE

Manufacturers of marble products find outlets for their waste material in virtually the same fields as those in which limestone is utilized. The great variation in unit value that appears in the accompanying table is due to the diversity in use. Waste blocks may be sold for riprap at only a few cents a ton or may be pulverized to an extremely fine powder and sold for special uses at several dollars a ton.

Marble (crushed and broken stone) sold by producers in the United States in 1939, by States [1]

State	Active plants	Short tons	Value	State	Active plants	Short tons	Value
Arkansas	1	600	$3,000	Texas	3	13,080	$100,744

Missouri	2	9,900	12,544				
Tennessee	5	13,910	42,782		27	104,340	383,583

[1] Includes stone used for artificial stone, crushed stone, flux, poultry grit, riprap, stucco, terrazzo, whiting substitute, and uses not specified.
[2] Alabama, California, New York, Virginia, and Washington.

LIMESTONE

Limestone comprised 69 percent of all crushed and broken stone sold in 1939 (excluding that used for making cement and lime). It is employed more extensively than other rocks because it can be quarried and crushed at moderate cost, is available to a multitude of markets, and is essential to many chemical and manufacturing industries. The following tables show production by States and uses in 1939 and sales for miscellaneous industrial uses in 1938 and 1939.

Limestone (crushed and broken stone) sold or used by producers in the United States in 1939, by States and uses

Use unspecified	27,480	60,615	52,990	80,403
	6,780,400	7,073,004	9,122,820	8,997,793

[1] Includes stone for filler for graphite, calcimine, linoleum, paint, pigments, pottery, putty, regrinding, rubber, sealing wax, soap, and tile.
[2] Includes stone for acetic acid, acid neutralization, bird gravel, chemicals (unspecified), concrete blocks and pipes, dye works, explosives, fill, fireplace stone, foundry facings, roofing gravel, spalls, and waste rock.

Sales of dolomite (calcium-magnesium carbonate) and its primary product of calcination, dolomitic lime, for certain special uses, are covered in the following table:

Dolomite and dolomitic lime sold or used by producers in the United States for specified purposes, 1938–39

	1938	1939
Dolomite for—		
Basic magnesium carbonate:		
Short tons	62,540	89,390
Value	$99,684	$147,129
Dead-burned dolomite or refractory stone:		
Short tons	263,930	824,930
Value	$274,624	$713,991
Dolomitic lime for—		
Refractory (dead-burned dolomite):		
Short tons	366,626	671,561
Value	$3,095,355	$5,447,554
Paper mills:		
Short tons	42,000	41,000
Value	$288,000	$267,000
Total (calculated as raw stone) short tons	1,144,000	2,339,000

Limestone is quarried not only for use raw but also for manufacture into cement and lime. The large and important industries manufacturing these products are covered in separate chapters of this volume. It is of interest, however, to show in one table the total tonnage of limestone used for all purposes.

Limestone sold or used for all purposes in the United States, 1937–39, in short tons

Use	1937	1938	1939
Limestone (as given in this report) (approximate)	94,577,000	[1] 81,680,000	100,846,000
Portland cement (including "cement rock") [2]			
Natural cement ("cement rock") [2]	29,547,000	[1] 26,193,000	30,463,000
Lime [3]	8,250,000	6,694,000	8,509,000
	132,374,000	[1] 114,567,000	139,818,000

[1] Revised figures. [2] Value reported as cement in chapter on Cement.
[3] Value reported as lime in chapter on Lime.

SANDSTONE

The sandstone industry, which made substantial gains in 1938, continued its upward trend in 1939. Production was 41 percent greater in quantity and 48 percent greater in value than in 1938. A gain of 70 percent in sales of refractory stone (ganister) indicates the increased activity of steel plants. Sales of riprap, which are subject to extreme fluctuations, declined greatly, but sales for all other major uses made large gains. The average sales value at the quarry for all crushed sandstone was 6 cents a ton higher in 1939 than in 1938.

Sandstone (crushed and broken stone) sold or used by producers in the United States in 1939, by States and uses

State	Refractory stone (ganister)		Riprap		Crushed stone				Other uses		Total	
					Concrete and road metal		Railroad ballast

MISCELLANEOUS STONE

Stone other than the five principal varieties already discussed includes light-color volcanic rocks, schists, boulders from river beds, serpentine, and flint. The following table shows sales of stone of these types by uses in 1939. Total sales declined 24 percent in quantity and 21 percent in value compared with 1938.

Miscellaneous varieties of stone (crushed and broken stone) sold or used by producers in the United States in 1939, by States and uses

MARKETS

As indicated in figure 3, sales of crushed stone used as concrete aggregate or in road construction made gains in 1939 commensurate with the marked increase in portland-cement shipments; however, as in 1938, the gain was of no advantage to the commercial producers whose sales declined more than 700,000 tons from 1938. The increase was due to an advance of nearly 10,000,000 tons in production by noncommercial agencies. In view of the moderate gain in total build-

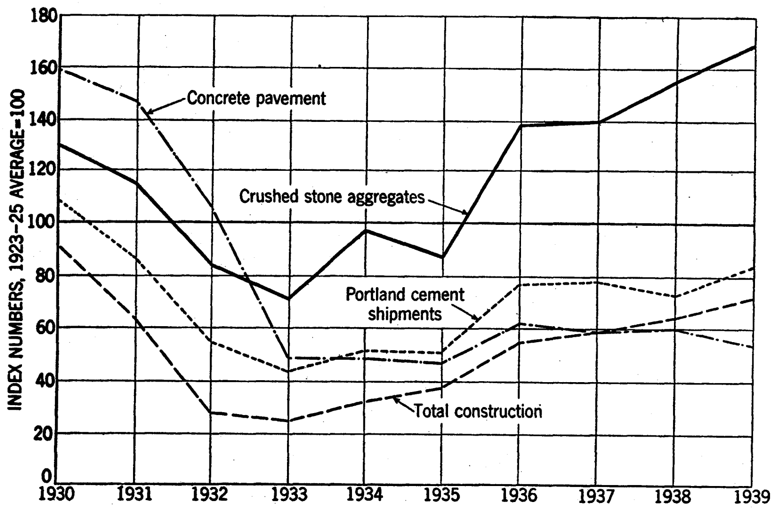

FIGURE 3.—Sales of crushed-stone aggregates (tons) compared with total construction, portland-cement shipments, and contracts for concrete pavements 1930–39. Data are plotted as index numbers with the 1923–25 average as 100. Figures on concrete pavements compiled by Portland Cement Association and on construction contracts by F. W. Dodge Corporation.

ing and the decline in concrete-pavement construction, the disproportionate gain in output of aggregates probably is due to their wide use in secondary roads.

Sales of limestone for use as a flux in blast furnaces producing pig iron rose decidedly in 1939 in consonance with increased furnace activity. Sales of dolomite and ganister for use as refractories in steel furnaces made a much greater proportional gain than sales of steel ingots. The abnormal demand probably was due to the relining of furnaces that were formerly inactive to meet the growing demands of the steel trade. Figure 4 shows the close relationship between sales of fluxing stone and refractories and the output of iron and steel mills.

NEW DEVELOPMENTS

An important contribution to the literature on crushed stone was published in 1939.[1] According to this report the annual production per man employed jumped from 1,200 tons in 1913 to 2,800 tons in 1936.

Further simplification of aggregate specifications (Simplified Practice Recommendation R163–36) involves consolidation of the two original groups of sizes into one, eliminating 12 sizes. Closer tolerances have been fixed for the lower limits of each size, and one size has been added to meet the need for fine seal surface treatment at

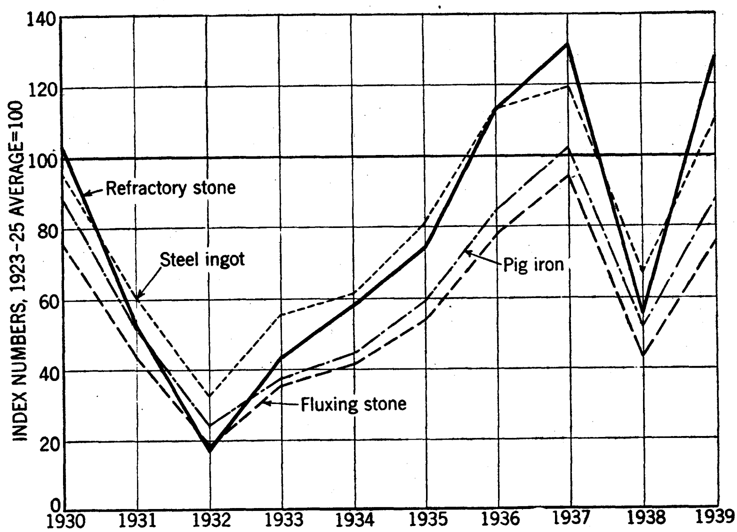

FIGURE 4.—Sales of fluxing stone and refractory stone (tons) compared with production of steel ingot and pig iron, 1930–39. All data are plotted as index numbers, with the 1923–25 average as 100. Statistics of steel-ingot and pig-iron production compiled by American Iron and Steel Institute.

airports. Producers of crushed stone, gravel, and slag have accorded this revision (R163–39) the required degree of acceptance. Another trend in specifications is to combine two diverse sizes of concrete aggregate to obtain maximum density of the mixture. Common requirements are ¼ to 1 inch and 1 inch to 2½ inches.

The extensive use of graded aggregates impregnated with bituminous material on secondary roads has led to accumulations of fines (minus ⅜-inch) at crushed-stone plants. Several hundred thousand tons of such aggregates were used in concrete construction in Pennsylvania in 1939. The use of low-price materials including field stone, discarded ganister, mine waste, "red dog" (burned shale), and slag on secondary roads in that State has been growing.

FOREIGN TRADE [2]

Imports.—Total imports of stone in 1939 dropped 3 percent in value from 1938. Imports of marble increased, those of granite declined, and imports of quartzite and travertine showed little change. The following tables show the quantities and values of stone imports in 1939, by kinds. Imports from Canada were higher in value, whereas those from South America were slightly lower than in 1938.

Stone [1] imported for consumption in the United States in 1939, by classes

Class	Quantity	Value
Marble, breccia, and onyx:		
In blocks, rough, etc. cubic feet	73,737	$236,746

SLATE

By Oliver Bowles and M. S. Jensen

SUMMARY OUTLINE

Sales of slate as dimension stone increased 25 percent in quantity and 30 percent in value in 1939 compared with 1938. The quantity sold was the highest since 1929 and the value the greatest since 1931. In general, unit prices were higher than in 1938.

The quantity of roofing slate sold was the highest since 1929 and the value the greatest since 1930. The average value per square in 1939 was $7.18 whereas in 1938 it was $6.98. Sales in the Pennsylvania district advanced 21 percent in quantity and 24 percent in value over 1938. In the New York-Vermont district sales increased 26 percent in quantity and 29 percent in value. Virginia sales made a substantial gain of 46 percent in quantity and 49 percent in value. Unusual residential building activity in and near Washington, D. C., has stimulated the Virginia industry. This is the seventh consecutive year that Virginia sales have increased.

An increase of 37 percent in the value of mill stock compared with a gain of only 13 percent in the quantity indicates marked improvement in the prices of most products. Whereas total building construction advanced from 64 percent of the 1923–25 average in 1938 to 72 percent in 1939, sales of structural and sanitary slate advanced 19 percent in quantity and 33 percent in value. Thus slate is regaining to some extent its former place in interior construction. Sales of electrical slate, which declined so drastically in 1938 that it seemed evident that synthetic products were being substituted for it to an increasing extent, recovered remarkably in 1939. Sales of blackboards, bulletin boards, and billiard-table tops made large gains, while those of vaults and covers declined moderately. Owing chiefly to disruption of foreign markets the quantity of school slates sold dropped to little more than half the 1938 figure. Sales of slate for flagging, cross walks, and stepping stones increased moderately, but average prices were considerably lower than in 1938.

Statistics on slate granules and flour are included in this chapter, although these products have little connection with the dimension-slate industry. Most of the slate used for their manufacture is unsuitable for other slate products. Sales of granules increased slightly, whereas sales of flour declined. The average sales value of granules, f. o. b. mill, was $8.70 per short ton in 1939 compared with $8.57 in 1938. Figures for sales of granules made of rock other than slate are given in the Stone chapter of this volume.

The following table gives the principal statistical data for the slate industry during 1938 and 1939 and is arranged to permit ready comparison for the 2 years.

SALES

Dimension slate.—The following table shows sales of dimension slate for several years, that is, slate sold in blocks or slabs cut to specified sizes and shapes. Such a classification excludes granules and flour.

Figure 1 compares sales of slate, except granules and flour, with the value of contracts awarded for residential building and total building from 1930 to 1939. Sales of slate followed closely the trends in building construction until 1938, when they declined drastically. Although the recovery in 1939 is encouraging the value of slate sales is only slightly higher than the point reached in 1937.

Slate (other than granules and flour) sold by producers in the United States, 1935–39

1939	399,320	149,410	2,868,961	21,710	1,168,671	8,480	63,493	179,600	4,101,125

[1] Includes flagstones, walkways, stepping stones, and miscellaneous slate.

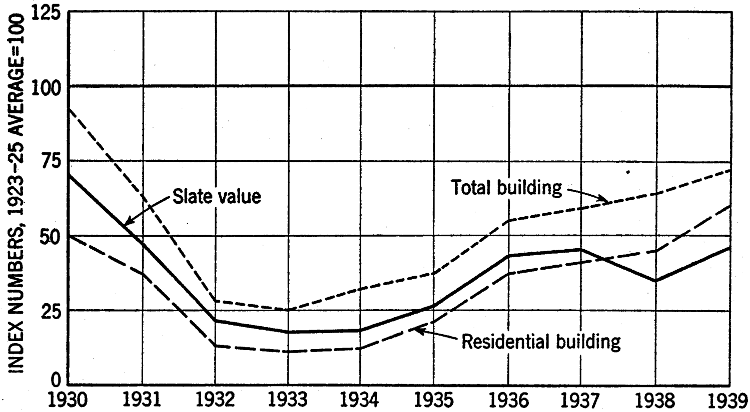

FIGURE 1.—Sales of slate compared with residential building and total building, 1930–39. Data on building from F. W. Dodge Corporation.

Trends in roofing slate.—Roofing slate is used chiefly in residential building for new construction and reroofing. No figures are available as to the proportion used for each, but new construction is the

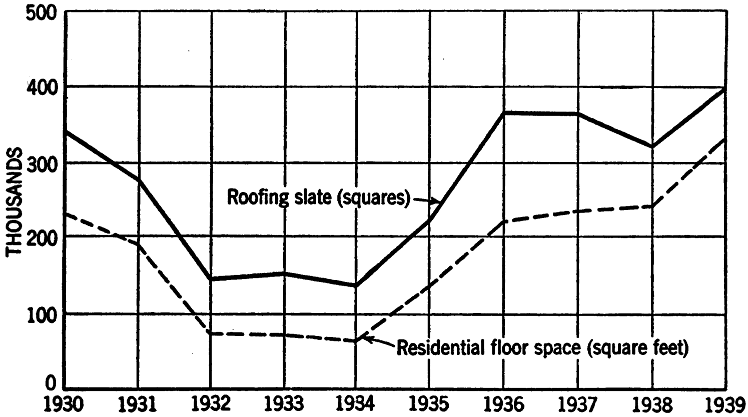

FIGURE 2.—Sales of roofing slate compared with new residential floor space, 1930–39. Statistics on floor space from F. W. Dodge Corporation.

principal market. Statistics are lacking on the roof area of new residential construction; but roof area bears a fairly definite relation to floor space, for which data are compiled. Floor space may therefore be regarded as a rough index of the area covered with roofing.

Figure 2 compares sales of roofing slate in squares with residential floor space of new construction from 1930 to 1939. The declining trend in sales of roofing slate during 1937 and 1938 was reversed in 1939. Residential building made rapid gains in 1939, and slate sales almost kept pace with it.

Granules and flour.—Sales of granules, which are used extensively for surfacing prepared roofing, increased slightly in 1939, and sales of slate flour, which is used as a filler, decreased slightly compared with 1938. There were small gains in the average selling price of both products. The following table shows sales of granules and flour by producers from 1935 to 1939.

Crushed slate (granules and flour) sold by producers in the United States, 1935–39

Year	Granules		Flour		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1935	166, 520	$1, 112, 081	59, 990	$196, 264	226, 510	$1, 308, 345
1936	202, 730	1, 372, 095	86, 920	274, 685	289, 650	1, 646, 780
1937	193, 950	1, 309, 549	83, 060	268, 465	277, 010	1, 578, 014
1938	258, 930	2, 220, 306	90, 070	269, 656	349, 000	2, 489, 962
1939	265, 830	2, 312, 177	85, 950	268, 912	351, 780	2, 581, 089

PRICES

The average price of roofing slate f. o. b. quarry or mill, as reported to the Bureau of Mines, advanced 20 cents a square in 1939 compared with 1938. In Pennsylvania and in the New York-Vermont area the price increased 18 cents a square and in Virginia 20 cents a square.

Mill-stock prices, which had maintained an average of 29 cents a square foot for several years, dropped to 24 cents in 1938 but rose again to 29 cents in 1939. Average values of blackboards and bulletin boards, billiard-table tops, and structural and sanitary slate

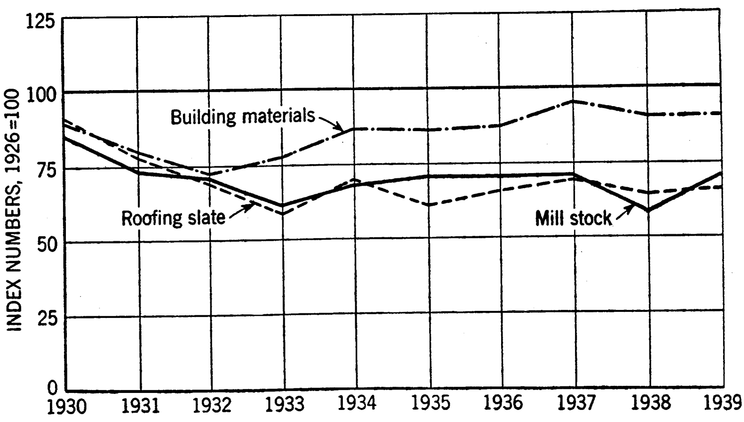

FIGURE 3.—Prices of slate compared with commodity prices of building materials in general, 1930–39. Commodity prices are from the Bureau of Labor Statistics.

each advanced 3 cents a square foot; those for electrical slate declined 1 cent; and those for vaults and covers and school slates remained virtually unchanged.

Trends in recent years.—Figure 3 shows the trend of slate prices over a 10-year period compared with prices of building materials in general. The price of slate increased more from 1938 to 1939 than that of building materials as a whole.

REVIEW BY STATES AND DISTRICTS

The following table gives sales of slate in 1939 by States and uses.

Slate sold by producers in the United States in 1939, by States and uses

State	Operators	Roofing		Mill stock		Other uses[1] (value)	Total value
		Squares (100 square feet)	Value	Square feet	Value		
Arkansas	1	------	------	------	------	(2)	(2)
California	2	------	------	------	------	(2)	(2)
Georgia	1	------	------	------	------	(2)	(2)
Maine	3	3,840	$32,768	(2)	(2)	(2)	$215,951
Maryland	1	------	------	------	------	(2)	(2)
New York	12	2,020	15,740	(3)	(3)	[3] $450,097	465,837
Pennsylvania	27	236,710	1,607,929	3,648,690	$888,571	560,353	3,056,853
Tennessee	1	------	------	(2)	(2)	(2)	(2)
Vermont	44	106,500	763,846	162,470	96,506	1,087,963	1,948,315
Virginia	5	50,250	448,678	------	------	(2)	(2)
Undistributed[4]	------	------	------	233,370	183,594	546,169	995,258
	97	399,320	2,868,961	[3] 4,044,530	[3] 1,168,671	[3] 2,644,582	6,682,214

[1] Flagging and similar products, granules, and flour.
[2] Included under "Undistributed."
[3] A small amount of mill stock in New York included under "Other uses."
[4] Includes output of States entered as "(2)" above.

Maine.—The principal product of the Maine quarries is electrical slate, for which it is unusually well-adapted. Sales of electrical slate suffered a serious decline in 1938 and although there was a decided recovery in 1939, the quantity of this product now used is still far below that employed a decade ago. The value of slate sales in Maine in 1939 was below the 1935 level.

New York-Vermont.—Sales of the attractively colored roofing slates of the New York-Vermont area that are popular with architects and builders increased 26 percent in quantity over 1938. The quantity of mill stock sold in Vermont advanced 20 percent and the value of other products, chiefly granules and flour, was 4 percent over 1938. The value of all slate products sold in Vermont in 1939 was 13 percent higher than in 1938 and in New York 5 percent higher.

Peach Bottom district.—Granules, slate flour, and roofing slate are manufactured in the Peach Bottom district on the Maryland-Pennsylvania border near Delta, Pa. Some development work has been done on a southern extension of the slate belt in Frederick County, Md.

Lehigh district.—The Lehigh district, comprising Lehigh and Northampton Counties, Pa., is the most productive slate area in the United States. All types of slate products are manufactured in this district. As separate figures cannot be shown for York County, it is included with Northampton County in the accompanying table.

The value of total sales of slate products in the area was 22 percent higher in 1939 than in 1938. Sales of roofing slate increased 21 percent in quantity and 24 percent in value, and sales of blackboards and bulletin boards increased 26 percent in quantity and 44 percent in value. Sales of electrical slate were virtually double those of 1938, and sales of structural and sanitary products (including vaults and covers) increased 10 percent in quantity and 19 percent in value. Sales of school slates showed a large decline, and sales of other products, chiefly granules and including billiard tables, increased 6 percent.

Slate sold by producers in Pennsylvania in 1939, by counties and uses

County	Operators	Roofing slate		Mill stock					
				Electrical		Structural and sanitary		Vaults and covers	
		Squares (100 square feet)	Value	Square feet	Value	Square feet	Value	Square feet	Value
Lehigh	10	14,730	$99,438	29,720	$14,261	9,750	$2,796	(1)	(1)
Northampton and York [2]	17	221,980	1,508,491	14,250	5,785	912,340	268,629	[1] 240,280	[1] $54,125
	27	236,710	1,607,929	43,970	20,046	922,090	271,425	240,280	54,125

County	Mill stock—Continued						Other uses (value)	Total value
	Blackboards and bulletin boards		Billiard-table tops		School slates			
	Square feet	Value	Square feet	Value	Square feet	Value		
Lehigh	437,250	$101,602			276,210	$5,769	(3)	[1 3] $223,866
Northampton and York [2]	1,628,580	399,207	100,310	$36,397			[3] $560,353	[1 3] 2,832,987
	2,065,830	500,809	100,310	36,397	276,210	5,769	560,353	3,056,853

[1] Small amount of slate for grave vaults and covers produced in Lehigh County included under Northampton and York Counties.
[2] York County produced roofing slate, granules, and flour only.
[3] Small amount of flagging produced in Lehigh County included under Northampton and York Counties.

Virginia.—Roofing slate is the principal product of the Buckingham County area. Small quantities of flagging are sold, but no mill-stock products are manufactured. Granules are made at Esmont, Albemarle County, and New Canton, Buckingham County.

Other districts.—Small quantities of granules alone, or granules and slate flour, are manufactured 16 miles southeast of Mena, Polk County, Ark.; at Placerville, Eldorado County, and near Jamestown, Tuolumne County, Calif.; and in Bartow County, Ga., near Fair Mount. Structural and sanitary products and flagging are made at Chilhowee, Blount County, Tenn.

NEW DEVELOPMENTS

Parsons Bros. Slate Co., Pen Argyl, Pa., has designed a new method of applying slate to roofs. It simplifies the process, reduces the weight, requires only half as much slate for a given area as the old method, and utilizes small sizes that accumulate around quarries and ordinarily are difficult to market. The small slates are placed edge to edge with no side lap but with a 3-inch head lap. Between the slates and the sheathing are strips of heavy asphalt-impregnated felt with an asphalt coating which also have a 3-inch head lap. Such low-cost roofs are said to be enduring.

Further tests by the Eastern Experiment Station of the Bureau of Mines indicate that waste slate is suitable for making lightweight aggregate. When calcined at a carefully controlled temperature, the slate will expand to more than five times its original volume and still have a fairly high compressive strength.

FOREIGN TRADE [1]

Imports.—The value of slate imported for consumption in the United States in 1939 dropped to less than one-sixth the 1938 figure. The drastic decline doubtless is due chiefly to war conditions. Imports are relatively unimportant even when trade is normal. The following table shows the value of imports in 1938 and 1939 by countries.

Slate imported for consumption in the United States, 1938–39, by countries

Country	1938	1939	Country	1938	1939
Canada	$543	$570	Italy	$994	$356
China	3	26	Japan	68	61
Czechoslovakia	1,037		United Kingdom	3,089	
France	895				
Hong Kong	59	4		6,688	1,017

Exports.—The following table lists exports of slate products from 1937 to 1939, as reported to the Bureau of Mines by shippers. Exports in 1939 fluctuated greatly from those in 1938, some items increasing and others declining, but there was a net gain of 13 percent in the value of foreign sales.

Slate exported from the United States, 1937–39, by uses [1]

Use	1937		1938		1939	
	Quantity	Value	Quantity	Value	Quantity	Value
Roofing squares	1,025	$9,382	660	$5,070	569	$5,244
School slates cases [2]	4,434	35,011	4,642	35,717	[3] 2,151	[3] 17,739

Billiard tables do	30,443	16,580	17,788	10,182	37,326	18,111
Structural [4] do	26,462	4,393	18,188	1,314	15,202	5,791
Slate granules and flour short tons	11,184	77,576	11,229	93,675	13,316	120,731
		152,151		157,597		177,790

[1] Figures collected by Bureau of Mines from shippers of products named.
[2] Cases weigh 130 to 165 pounds each; average is 135 pounds. They contain 8 to 18 dozen slates, depending on size. Sizes run from 5 by 7 to 9 by 13 inches (inside frame).
[3] Value includes slate used for pencils and educational toys; quantity not available.
[4] Includes slate for floors and walkways.

[1] Figures on imports and exports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

SAND AND GRAVEL

By H. Herbert Hughes and G. E. Tucker

SUMMARY OUTLINE

Despite an 11-percent drop in concrete-pavement contract awards in 1939, the quantity of sand and gravel sold or used by producers for all uses increased substantially over 1938. Virtually the entire advance was due to a 12-percent increase in output of commercial operations, as Government-and-contractor [1] production rose only 1 percent. The slight gain in tonnage at plants operated by or for States, counties, municipalities, and other Government agencies halted the recent sharp upward trend in output of this material. The continuous rise in total production and value from the low of 1933 has been interrupted only in 1938. (See fig. 1.)

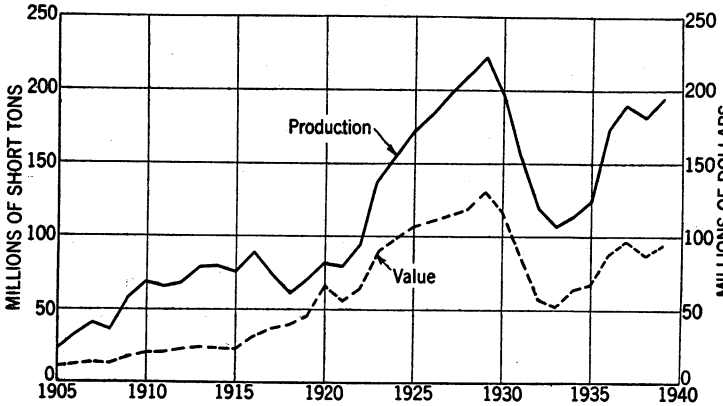

Figure 1.—Principal trends in the sand and gravel industry, 1905–39.

Except for concrete paving, the construction industry in 1939 showed moderate improvement over 1938. According to the F. W. Dodge Corporation, the total value of construction contracts awarded was 11 percent above 1938. Engineering News-Record data indicated a 7-percent gain in engineering construction. Of especial significance was the 23-percent increase in privately financed construction, whereas public contracts showed no gain. Residential construction was particularly active—35 percent above that in 1938.

Salient statistics of the sand and gravel industry in 1938 and 1939 are summarized in the following table.

[1] Formerly classified as "noncommercial"; details of change in designation given in section headed "Government-and-contractor operations."

Sand and gravel sold or used by producers in the United States, 1938–39, by commercial and Government-and-contractor operations and by uses

[1] Includes blast sand as follows: 1938, 205,753 tons valued at $509,178; 1939, 220,240 tons, $542,915.
[2] Includes ballast sand produced by railroads for their own use as follows: 1938, 128,079 tons valued at $25,806; 1939, 152,723 tons, $21,998.
[3] Includes some sand used by railroads for fills and similar purposes as follows: 1938, 113,606 tons valued at $17,466; 1939, 137,158 tons, $21,366.
[4] Includes ballast gravel produced by railroads for their own use as follows: 1938, 3,590,684 tons valued at $645,133; 1939, 4,617,468 tons, $752,670.
[5] Includes some gravel used by railroads for fills and similar purposes as follows: 1938, 922,742 tons valued at $75,893; 1939, 824,959 tons, $80,090.
[6] By States, counties, municipalities, and other Government agencies directly or under lease.

Sand and gravel sold or used by commercial producers in 1939 for all purposes except gravel for paving increased substantially over 1938. The largest advances were in railroad-ballast, filter, molding, and fire or furnace sand. Sales of railroad-ballast gravel also were appreciably higher.

In general the average value per ton of sand and gravel sold or used by commercial producers in 1939 was slightly below 1938, indicating somewhat lower prices.

PRODUCTION

Except for small supplies to meet seasonal peaks, stocks are of little consequence in the sand and gravel industry, and the quantity of materials sold or used by producers is virtually equivalent to production. Throughout this report sales and production are used interchangeably.

Because of the drop in production of paving gravel the increase in relative importance of gravel was interrupted in 1939. It comprised only 66 percent of the total tonnage compared with 69 percent in 1938 and 67 percent in 1937. Although a large part of the rise in gravel output in recent years represents Government-and-contractor production used in low-type roads there also is evidence that gravel is being used increasingly as coarse aggregate, particularly in bituminous-highway construction.

Complete production data for 1939 are included in this report. Statistics of sand and gravel sold or used by commercial and Government-and-contractor producers from 1935 to 1939 are summarized in the following table.

Sand and gravel sold or used by commercial and Government-and-contractor producers in the United States, 1935–39

Year	Sand		Gravel (including railroad ballast)		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1935	40,433,559	$25,867,222	83,490,364	$36,110,157	123,923,923	$61,977,379
1936	60,303,394	35,926,994	118,026,420	54,380,758	178,329,814	90,307,752
1937	63,385,071	40,412,497	126,275,352	57,060,500	189,660,423	97,472,997
1938	57,113,828	33,935,725	124,206,405	51,987,122	181,320,233	85,922,847
1939	67,078,060	39,562,338	127,740,473	55,661,709	194,818,533	95,224,047

New York, California, Illinois, Ohio, and Michigan were the leading States in output of sand and gravel by commercial producers in 1939. Pennsylvania, however, ranked second in value because of its large production of glass and other relatively high priced industrial sands.

Details of production in 1939 by States and uses are given in the following tables.

Sand and gravel sold or used by commercial and Government-and-contractor producers in the United States in 1939, by States and uses

[Commercial unless otherwise indicated]

State	Sand							
	Glass		Molding		Building

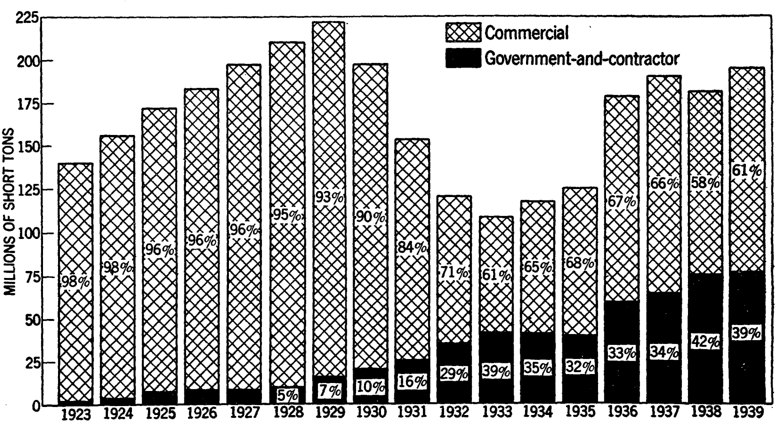

FIGURE 2.—Sand and gravel sold or used by commercial and Government-and-contractor producers, 1923–39.

Government-and-contractor production.—Production of sand and gravel by State highway departments and other similar Government agencies has been largely a development of the depression. (See fig. 2.) Before 1929 less than 5 percent of the total tonnage of sand and gravel reported to the Bureau of Mines was from such operations. By 1931, however, this material had increased to 16 percent of the total tonnage, and in the canvass for 1932 it received special attention. As a result there is some upward bias in the "noncommercial" figure for 1932. Since then, however, the coverage has been reasonably comparable from year to year. The growth of the material included in this category seems to parallel the development of portable plants for production of sand and gravel. It also has been allied closely with secondary-roads programs throughout the United States and various phases of work relief. Production of road materials from wayside sources has been one of the most common forms of relief activity.

This so-called "noncommercial" production comprised 42 percent of the total tonnage in 1938 and 39 percent in 1939. The somewhat astonishing quantity in 1938 brought to a head the growing realization that "noncommercial" is not the proper term to classify this material. In 1939, 52 percent of the material was reported to have been produced directly by construction and maintenance crews of State highway departments, county road supervisors, municipal street departments, and agencies of the Federal Government such as the Forest Service, National Park Service, Bureau of Public Roads, Bureau of Reclamation, and others. The remaining 48 percent, although reported to the Bureau of Mines by these same agencies, actually was produced by contractors for use on specific jobs being done for the State highway departments or other units of local or Federal Governments. It is evident that this contractor production should not be included in a category labeled "noncommercial," even though it represents sand and gravel business that is not a part of the established commercial industry.

In this report the term "noncommercial" has been eliminated, and material formerly included in this category is referred to as "Government-and-contractor." Considerable thought has been given to the possibility of a direct canvass of contractor-producers, but it is impossible with funds now available to make this enlargement in the scope of the canvass. It is believed, however, after careful scrutiny of the 1938 and 1939 figures, that the reports from the State highway departments are accurate and reasonably complete. The same may be said of the reports from various Federal agencies, although for 1939 it was necessary to include estimates for material produced on W. P. A. projects. The greatest weakness of the coverage is in the county figures, but for the most part it is believed that activities of counties not reporting are limited to production of low-grade pit-run material that possibly should not even be considered part of the sand and gravel industry. As a matter of fact, of the 76,425,413 tons of sand and gravel reported by Government-and-contractor operations in 1939 only 23 percent was washed or screened. The rest was unprepared material having an average reported value of only 26 cents per ton. On the other hand, only 12 percent of the 118,393,120 tons reported by commercial operations was unprepared. The complete record of Government-and-contractor production is summarized in the following table:

Sand and gravel sold or used by Government-and-contractor producers in the United States, 1924–39, by uses

Year	Sand				Gravel				Total Government-and-contractor sand and gravel

[1] Includes a small quantity of filter sand.

The quantity of material reported by State highway departments in 1939 was 47 percent of the total Government-and-contractor output, and 63 percent of it was produced by contractors. Counties reported 21 percent of the total, of which only 27 percent was produced by contractors. Municipalities reported only about 3 percent of the total, and the remaining 29 percent was supplied largely by various Federal agencies. For the most part this material was produced on work projects of all types, reclamation projects, and road construction in the national parks, national forests, and elsewhere in relatively remote localities. Further details are given in the following table:

Sand and gravel sold or used by Government-and-contractor producers in the United States, 1936–39, by types of producers

Type of producer	1936		1937		1938		1939	
	Short tons	Average value per ton	Short tons	Average value per ton	Short tons	Average value per ton	Short tons	Average value per ton
Construction and maintenance crews	31,206,204	$0.23	38,637,673	$0.21	44,745,693	$0.21	40,143,981	$0.25
Contractors	27,203,215	.40	25,680,272	.40	30,814,754	.37	36,281,432	.39

	58,409,419	.31	64,317,945	.29	75,560,447	.28	76,425,413	.31

The State break-down of sand and gravel production in 1938 shows that the largest centers of production were in the Northeastern and Great Lakes States and that California, Texas, and Washington also were large producers. (See fig. 3.) Government-and-contractor

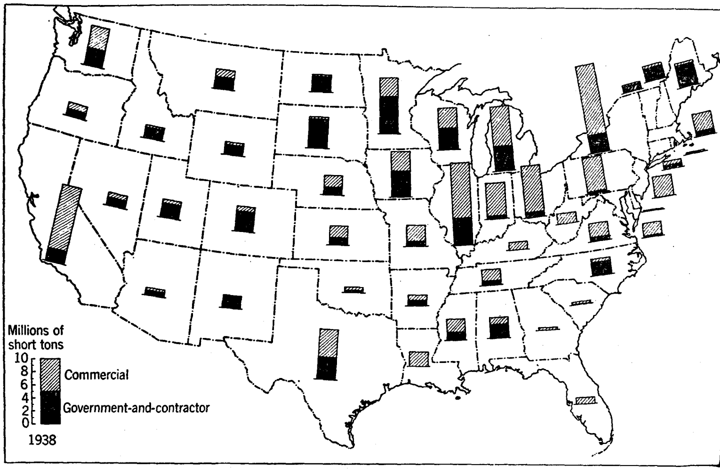

FIGURE 3.—Sand and gravel sold or used by commercial and Government-and-contractor producers in 1938, by States.

production is concentrated in northern New England, the Middle West, and the Rocky Mountain and Pacific Coast States, plus North Carolina and Alabama in the South. In only a few States—Michigan, Wisconsin, Minnesota, Iowa, Illinois, Texas, and Washington—is

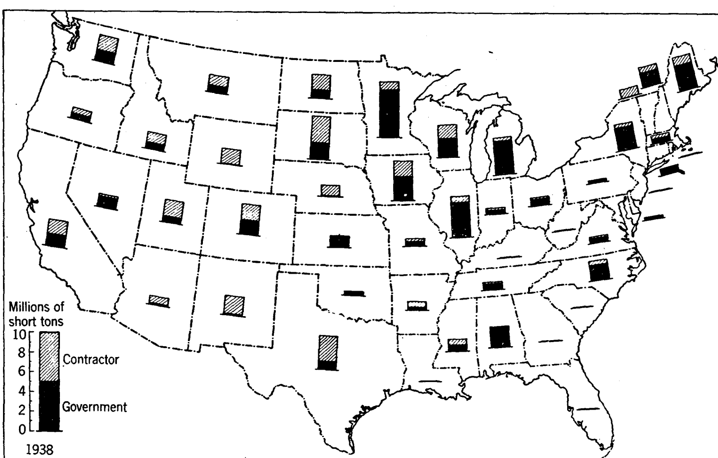

FIGURE 4.—Sand and gravel sold or used by Government and contractor producers in 1938, by States.

both commercial and Government-and-contractor production large. Commercial production predominates in the East and South and Government-and-contractor output in northern New England and the Rocky Mountain States.

Of even greater significance, perhaps, is the break-down between Government and contractor output. (See fig. 4.) Actual production by Government agencies on a large scale seems to be confined to relatively few States and is concentrated largely in the Middle West. This area, with Texas and the Rocky Mountain and Pacific Coast States, has witnessed the greatest development of contractor production. In general, data for 1939 show a similar relationship.

Method of transportation.—Shipments of sand and gravel originating on class I railroads in 1939 were 28,990,146 short tons, an increase of only 2 percent over the 28,383,925 tons shipped in 1938. This quantity was only 29 percent of the total commercial production reported in 1939, exclusive of glass and molding sand and nonrevenue railroad ballast, and indicates a continuing gain in sand and gravel moved by other means than rail, as rail shipments were equivalent to 31 percent of commercial production in 1938 and 36 percent in 1937.

Direct reports of methods of transporting sand and gravel were received from producers responsible for 90 percent of the total commercial output. These figures substantiate the drop in rail shipments and show a corresponding increase in shipments by truck. Details of shipments, by methods of transportation, follow.

Sand and gravel sold or used by commercial producers in the United States, 1938–39, by methods of transportation [1]

Method of transportation	1938		1939	
	Short tons	Percent of total reported	Short tons	Percent of total reported
Truck	39,142,876	43.0	48,040,422	45.2
Rail	37,675,155	41.3	42,118,042	39.6
Waterway	14,278,779	15.7	16,208,607	15.2
Total reported	91,096,810	100.0	106,367,071	100.0
Percent of total commercial production		86.1		89.8

[1] For practical purposes the entire output of Government-and-contractor operations commonly is moved by truck. Including Government-and-contractor production, sand and gravel moved as follows—1938: Truck 69 percent, rail 23 percent, and waterway 8 percent; 1939: Truck 68 percent, rail 23 percent, and waterway 9 percent.

Preparation.—The average value per ton of sand and gravel reported by commercial producers is characteristically much higher than that of Government-and-contractor output. This difference is a direct result of the cost of washing, screening, or other preparation, as 88 percent of the commercial production in 1939 was prepared material compared with only 23 percent of the Government-and-contractor output.

Sand and gravel (prepared or unprepared) sold or used by producers in the Unite States, 1938–39, by commercial and Government-and-contractor operations

	1938			1939		
	Quantity		Average value per ton	Quantity		Average value per ton
	Short tons	Percent		Short tons	Percent	
Commercial operations:						
Prepared	92,825,363	88	$0.66	103,771,791	88	$0.64

Grand total	181,320,233		.47	194,818,533		.49

EMPLOYMENT AND OUTPUT PER MAN

Employment in the commercial sand and gravel industry, as well as output per man per hour, fluctuated only moderately from 1933 to 1938, inclusive. Available data for operations reporting about four-fifths of the total production of sand and gravel indicate that employment in the industry averaged about 19,000 men from 1936 to 1938. Before 1936 the total was somewhat lower because of curtailed output.

Production per man per hour likewise has not varied widely from year to year, although there was a definite upward trend from 2.8 tons in 1933 to 3.3 in 1937. The slight recession to 3.2 tons in 1938 apparently was due directly to the drop in production.

The average working day remained fairly constant throughout the period, dropping from 8.7 in 1933 to 8.1 in 1934, then increasing after the demise of the N. R. A. to 8.6 in 1936 and 1937 and 8.5 in 1938. The number of actual working days has fluctuated widely, however, in direct ratio to volume of production. In 1933, the low point of sand and gravel output, the average employee worked only 155 days compared with 215 in 1937.

Employment in the commercial sand and gravel industry, sand and gravel produced at plants included in the study, and average output per man in the United States, 1933–38 [1]

Year	Employment					Production			Percent of commercial industry represented
	Average number of men	Time employed				Commercial sand and gravel, short tons	Average per man, short tons		
		Average number of days	Total man-shifts	Man-hours			Per shift	Per hour	
				Average per man per day	Total				
1933	12,536	155	1,947,225	8.7	16,937,862	47,215,123	24.2	2.8	71.4

1938	14,971	201	3,001,796	8.5	25,578,807	81,742,896	27.2	3.2	81.1

[1] Does not include plants operated by or directly for States, counties, municipalities, and other Government agencies.

In general the output of sand and gravel per man-hour of employment ranges from a relatively low figure in the Eastern and Southeastern States to much higher production in the Middle Western and Far Western States. The unusually high productivity in region 16 comprising Montana, Washington, Oregon, and Idaho apparently is due largely to the highly mechanized operations in connection with dam construction.

Complete details by regions from 1935 to 1938 are summarized in the following table. Comparable data for 1934 were published in Minerals Yearbook, 1936 (p. 844), and for 1933 in Minerals Yearbook, 1935 (p. 942).

Employment in the commercial sand and gravel industry, sand and gravel produced at plants included in the study, and average output per man in the United States, 1935–38, by regions [1]

Analysis by the Bureau of Labor Statistics[2] of the records of 24 sand and gravel plants indicated that the production and distribution of 100 tons of sand and gravel required 94.5 man-hours of labor, distributed as follows:

	Man-hours per 100 tons
Production labor:	
Dry-pit	25. 4
Wet-pit	26. 3
Marine:	
Processing on dredge	41. 2
Processing on land	57. 9
Weighted average of all types	31. 0
Fuel and power	1. 6
Haulage to construction site	61. 9
Total labor requirements	94. 5

[2] Ball, J. A., Labor Requirements in Production and Distribution of Sand and Gravel: Bureau of Labor Statistics Serial R. 944, 1939, 13 pp.

PRICES

The general trend of sand and gravel prices continued slightly downward in 1939. The average value per ton, f. o. b. plant, of all sand and gravel reported by commercial producers dropped only 1 cent per ton—from $0.61 in 1938 to $0.60 in 1939—but that of material sold for major uses fluctuated more widely. Building sand declined from $0.56 to $0.54 per ton in average value, paving sand from $0.56 to $0.52, and building gravel from $0.70 to $0.65, whereas paving gravel and railroad-ballast gravel each increased 1 cent. Slightly higher average values were reported for glass and engine sand in 1939, but the values of other industrial sands dropped, the decline of 23 percent for filter sand being the most pronounced. The increase in value per ton of material reported by Government-and-contractor producers is due directly to the higher percentage of prepared material included in this category (18 percent in 1938 and 23 percent in 1939) rather than to actual higher valuation.

Wholesale price indexes for sand and gravel, compiled by the Bureau of Labor Statistics from returns of representative plants throughout the United States, confirm the decreases indicated by reports of commercial producers to the Bureau of Mines. The price index of building sand (1926=100) declined from 102.1 in 1938 to 99.7 in 1939, and that of gravel from 93.2 to 91.4. These decreases are especially significant because the index for all building materials was virtually the same—90.3 in 1938 and 90.5 in 1939. The composite index for all commodities dropped from 78.6 to 77.1 despite the sharp upturn in prices in the last 4 months of 1939 following outbreak of war in Europe.

NEW DEVELOPMENTS

Although the only huge new sand and gravel plant built in 1939 was one to supply aggregates for construction of a large dam, it was reported that producers were spending more money on improvements than at any time in the past decade.[3] The research program of the National Sand and Gravel Association was continued actively, and contacts with the University of Maryland were strengthened through establishment of the Stanton Walker fellowship available to graduate students in engineering. Of particular significance was the exemption early in 1940 of the northern branch of the sand and gravel industry from the maximum-hours provisions of the Fair Labor Standards Act.[4] Various phases of labor relations assumed increasing importance in the affairs of the industry during 1939.

The trend in plant construction in 1939, as in recent years, was toward medium and small plants designed for efficiency and flexibility of operation and for serving relatively small market areas. The problem of meeting seemingly ever-changing specifications was possibly the outstanding technical topic of the annual convention of the association.[5] In view of this interest in preparation of aggregates to meet rigid and varying specifications a series of articles begun in 1939

by Shaw [6] on washing and classifying sand has proved to be most timely. A new plant in Illinois using a sand-dewatering wheel is designed for blending any gradation of sand and gravel desired, as well as for ample storage.[7] Two types of sand and two grades of gravel are produced simultaneously for direct loading into barges by a Diesel-electric dredge operating in Maryland.[8] Methods of refining and grading sands have been changed completely at a large plant in Ohio.[9] At another Ohio plant masons' sand and concrete sand are produced as independent operations through a single blade-type sand washer.[10] Two plants featuring unusual flexibility have been described by Trauffer.[11] Nordberg [12] described a rather unique plant designed to receive pit-run material using large earth movers powered by tractors and to take care of intraplant handling by the same power units fitted with "dozing" attachments. The ingenious use of a suspended flume to dispose of excess fines when the river is below normal is an interesting feature of a Kansas plant.[13]

Problems of labor relations, research, and Federal and State legislation occupied producers of industrial sands during the year.[14] A combination of desliming and tabling methods has reduced the iron content of glass sand at a Texas plant to 0.06 percent.[15]

The eleventh annual accident-prevention contest, conducted by the Bureau of Mines in cooperation with the National Sand and Gravel Association, revealed an accident-frequency rate in 1939 of 26.132 accidents per million man-hours of exposure for the 77 participating plants. This was an improvement of 2 percent compared with the 1938 rate of 26.715. The Van Sciver lake plant, Tullytown, Bucks County, Pa., operated by the Warner Co., worked 142,982 man-hours without a disabling injury and won the trophy for the group of plants operating 100,000 or more man-hours. The trophy for the group operating less than 100,000 man-hours was won by the Oxford dry-bank plant, Oxford, Oakland County, Mich., operated by Ray Industries, Inc., which had a record of 59,655 man-hours without a disabling injury.

FOREIGN TRADE [16]

Except for 23,690 tons of glass sand (30 percent less than in 1938 and virtually all from Belgium consigned to the Pacific coast glass industry) imports of sand and gravel in 1939 were largely movements

of construction materials from Canada. As they are important only locally, the 61-percent drop in total imports is of no especial significance to the sand and gravel industry.

Exports of sand and gravel also declined, but the quantity of material involved is so small that they too are of little consequence.

Sand and gravel imported for consumption in the United States, 1937–39, by classes

Class	1937		1938		1939	
	Short tons	Value	Short tons	Value	Short tons	Value
Glass sand [1]	51,090	$79,112	33,889	$68,315	23,690	$33,604
Other sand [2]	319,134	134,430	611,468	157,992	192,106	79,272

1937	67,141	80,197			

[1] Classification reads: "Gravel and building stone."

BLAST-FURNACE SLAG

The principal material competing with gravel is crushed stone, statistics for which appear in the Stone chapter of this and previous volumes of the Minerals Yearbook and Mineral Resources series. Blast-furnace slag is also important in the same markets in some areas.

The National Slag Association continued the canvass inaugurated in 1938 and reported that 36 companies operating 72 plants sold or used 7,920,281 short tons of air-cooled slag valued at $6,122,718 in 1939. This output represents an 8-percent increase in quantity but a 1-percent decrease in value from the 7,321,259 tons valued at $6,167,892 reported by 34 companies operating 70 plants in 1938. In addition, 1,188,094 tons of granulated and foamed slag valued at $122,017 were reported in 1939 and 656,807 tons valued at $78,723 in 1938. Details are given in the following tables.

Air-cooled blast-furnace slag sold or used by producers in the United States, 1938–39, by States [1]

State	1938			1939		
	Quantity		Value	Quantity		Value

GYPSUM

By Forrest T. Moyer

SUMMARY OUTLINE

Consumption of gypsum and gypsum products in 1939 recovered strongly from the mild set-back in 1938 and resumed the progressive rise that had persisted from 1934 through 1937. Largely because of the high level of residential building construction throughout the year, the value of all gypsum products sold or used in the United States rose to $45,928,239, representing by a wide margin the highest annual volume of business for the industry in the decade just ended. The total value in 1939 was 27 percent above 1938 and, after adjustment for comparability, surpassed the total value in 1930, the next largest of the past decade, by 19 percent. However, the improvement in 1939 does not apply to all parts of the gypsum industry but is derived entirely from an advanced rate of consumption of calcined products, particularly gypsum lath, in building. Sales of uncalcined products in 1939, although the highest in recent years and 15 percent above 1938 were far below sales in 1930. This decline reflects the reduced activity of the portland-cement industry, which was about one-fourth lower in 1939 than in 1930. In contrast to the lower proportion of sales of uncalcined products in 1939, the tonnage of calcined building products surpassed that of 1938 by 26 percent and, after adjustments for canvass changes, was 11 percent over 1930. The net gain in this group more than overcame the decreased consumption of industrial gypsum plasters, so that the tonnage of all calcined products in 1939 was 7 percent higher than the comparable figure for 1930.

The outstanding feature of the gypsum business in 1939 was the spectacular gain in sales of lath, which increased 41 percent over the previous record volume, set in 1938. The increment amounted to 327,944 M square feet, a gain that was larger than the sales of this product in any year from 1930 through 1935. On the comparable base used to compile the chart published as figure 1 in the Gypsum chapter of Minerals Yearbook, 1939 (p. 1184), the index of the record square footage for 1939 was 319 (1928=100). The remarkable increase in demand in recent years, which has made gypsum lath the dominant lathing material, is illustrated best by comparison with the index of sales for the low year, 1933, which was 32.

There was a strong revival in consumption of gypsum tile, block, and plank in 1939, when sales (square feet) increased 51 percent over 1938. This group of related products, used chiefly in nonresidential construction, constituted a more important proportion of the total sales of the industry during the 1920's than in recent years. Although sales in 1939 still were well below those 10 to 15 years ago, the substantial gain over 1938 is encouraging when compared with the 4-percent decline in floor area of nonresidential building reported by the F. W. Dodge Corporation.

Salient statistics of the gypsum industry in the United States, 1935–39

	1935	1936	1937	1938	1939

[1] Each mine, plant, or combination mine and plant is counted as 1 establishment; beginning in 1937 plants utilizing byproduct gypsum are included.
[2] To avoid revealing confidential data, byproduct gypsum is excluded. [3] Data not collected.
[4] Includes byproduct gypsum. [5] Gypsum products from domestic and imported crude.

Technologically, 1939 may become an important landmark of the industry in that it marks the first commercial utilization in this country of heated hammer mills in a gypsum-processing plant. During the year two units of this revolutionary type were installed in a California plant. These mills grind and calcine the crude gypsum in one operation, replacing the fine-grinding mills and calcining kettles in the usual flow sheet of a gypsum plant. The economies effected by their use are reported to be substantial.

The apparent supply of crude gypsum, which normally approximates closely actual annual consumption, was nearly one-third greater in 1939 than 1938. However, anomalous conditions caused by the outbreak of the war in Europe distorted the normal situation with respect to imported crude. Data compiled from records of the Bureau of Foreign and Domestic Commerce show that imports during the first three quarters of 1939 were closely in line with current activity but increased markedly in the fourth quarter, when they were more than double those of the similar period of 1938. The total for the year was two-thirds greater than in 1938. This disproportionate gain compares with a 20-percent rise in domestic mine production, which more nearly represents the increased consumption over 1938. A slightly greater than proportional gain in importations of crude had been expected because two newly constructed calcining plants using Canadian crude started operations early in 1939, but the exceptional gain noted indicates that operators of calcining plants on tidewater along the Atlantic coast apparently have built up large stocks of crude as a precaution against any immediate shortage of Canadian gypsum. A study of the somewhat similar situation during the World War shows that shipments of crude to this country, mostly from Canada, declined about one-third from 1914 to 1917, but in 1918, after the United States entered the war, total importations dropped to 50,653 short tons—86 percent below those of 1914. This rapid decline in 1918 was caused entirely by shipping difficulties, as most of the gypsum boats were commandeered by the Government to transport coal from Middle Atlantic ports to the New England States.

Although the effect of continuation of the present European war upon consumption of gypsum in this country cannot be foreseen, it is interesting to note that during the World War annual consumption, as measured by the apparent supply of crude, continued from 1914 through 1917 at approximately the same average level as from 1910 to 1913 but declined about one-fourth in 1918 after the United States began hostilities.

Thus far the current war has had no appreciable effect on building construction, and the trend early in 1940 has followed that of 1939.

DOMESTIC PRODUCTION

Domestic supplies of crude gypsum in 1939, which were the highest for any year since 1930, were obtained from 28 underground mines, 27 open quarries, and 5 combinations of mines and quarries in 16 States; New York, Michigan, Iowa, and Texas were the leading producers. The tonnage from New York (which with Iowa had the largest number of operations) was 22 percent of the total. In Michigan, mining activity increased more than in the other States, with the result that its production in 1939 comprised 20 percent of the total, contrasted with 18 percent in 1937 and 1938. The average estimated value of the domestic crude produced in 1939 was $1.37 per ton, a reduction of 22 cents per ton from the 1938 figure. This value, as returned by the producers, is essentially a bookkeeping figure because run-of-mine material is not bought and sold in open market. Data in the following table apply only to natural crude gypsum and do not include byproduct gypsum.

Crude gypsum mined in the United States, 1937–39, by States

State	1937			1938			1939		
	Active mines	Short tons	Value	Active mines	Short tons	Value	Active mines	Short tons	Value
California	5	186,158	$355,834	5	162,056	$334,208	5	188,364	$306,350

[1] 1937: 1 active mine each in Arizona, Idaho, South Dakota, and Wyoming; 2 each in Kansas, Montana, Ohio, and Virginia. 1938: 1 active mine each in Idaho, South Dakota, and Wyoming; 2 each in Kansas, Montana, Ohio, and Virginia. 1939: 1 active mine each in Arizona and South Dakota; 2 each in Kansas, Montana, Ohio, Virginia, and Wyoming.

PROCESSING PLANTS AND EQUIPMENT

Production of calcined gypsum in 1939 exceeded that in 1938 by 28 percent, a gain that compares favorably with a 20-percent increase over 1938 in the floor area of residential and nonresidential building reported by the F. W. Dodge Corporation. The 1939 tonnage was produced in 56 calcining plants operating in 25 States; 42 plants processed domestic crude, 13 imported crude, and 1 byproduct crude gypsum.

Although three newly constructed calcining plants, one each in California, Florida, and Georgia, began operations in 1939, the total number of active kettles was nine less than in 1938 because a number of kettles in old plants were withdrawn from service. Moreover, two less rotary kilns were active owing to abandonment of a plant in New York during the latter part of 1938. In the accompanying table the new type of grinding-calcining equipment—the heated-hammer mill—is classed arbitrarily with the rotary kilns because its operation is continuous.

Active calcining plants and equipment in the United States, 1937–39, by States

[1] Includes 2 grinding-calcining units. [2] Revised figures.
[3] 1937: 1 calcining plant each in Arizona, Connecticut, Florida, Illinois, Indiana, Massachusetts, Nevada, New Hampshire, Pennsylvania, South Dakota, Vermont, and Wyoming; 2 each in Colorado, Kansas, Montana, New Jersey, Ohio, Oklahoma, and Virginia. 1938: 1 calcining plant each in Arizona, Connecticut, Florida, Illinois, Indiana, Massachusetts, Nevada, New Hampshire, Oklahoma, Pennsylvania, South Dakota, Vermont, and Wyoming; 2 each in Colorado, Kansas, Montana, New Jersey, Ohio, and Virginia. 1939: 1 calcining plant each in Arizona, Connecticut, Georgia, Indiana, Massachusetts, Nevada, New Hampshire, Oklahoma, Pennsylvania, South Dakota, Vermont, and Wyoming; 2 each in Colorado, Florida, Kansas, Montana, New Jersey, Ohio, and Virginia.

According to returns from the producers, 33 gypsum-board and 20 automatic tile machines were active in the country in 1939. The productive capacity of individual board machines, which is determined by the capacity of the board drier, varies considerably. Capacity of machines of recent construction commonly ranges between 105,000 and 115,000 square feet of ⅜-inch lath and 90,000 to 100,000 square feet of ⅜-inch wallboard in 8 hours. Older machines operate at a slower rate, so that the average capacity of all active machines in the country is estimated by several technical experts at about 87,500 and 75,000 square feet, respectively, of ⅜-inch lath and wallboard in 8 hours.

The automatic machine for perforating gypsum lath that was introduced in 1938 evidently has been successful; in 1938 three board machines were equipped with it, and in 1939 five additional units were installed. The machine is placed near the discharge end of the board machine and replaces the old method of bundling the lath and drilling the holes with a battery of augers.

DISTRIBUTION OF SALES

Sales of uncalcined gypsum products in 1939 exceeded those in 1938 by a substantial margin but were only slightly higher than in 1937. Indicated consumption for portland-cement retarder was 15 percent above 1938, a gain that correlates closely with the increased activity in the portland-cement industry. Sales of agricultural gypsum in 1939 gained 10 percent over 1938 compared with a 5-percent increase reported for total cash farm income. Approximately 60 percent of the 1939 total was consumed in the peanut-growing region of southern Virginia. Tonnages of pulverized raw gypsum sold or used as a fertilizing agent formerly were much larger than at present but declined slowly as the use of superphosphate expanded. The latter commodity, made by treating phosphate rock with sulfuric acid to convert the contained phosphorus into a more available plant food, contains approximately 50 percent by weight of precipitated gypsum formed in the process. As a result, the contained gypsum greatly reduced the agricultural market for natural gypsum, which in recent years has been confined largely to sales for fertilizing certain legume crops and for correcting black alkali soils. During the past few years the use of highly concentrated phosphate fertilizers that contain little or no sulfur or sulfate plant foods has expanded somewhat because the Federal Government has offered this newly developed type of fertilizer to farmers in lieu of cash benefit payments. Should use of this material become more widespread, as appears likely, consumption of natural gypsum in agriculture probably would increase. In addition to supplying an essential plant food, gypsum has several beneficial effects upon soil, and recently investigators [1] have shown that gypsum increases the moisture content of clover and is effective during droughts.

Sales of all groups of calcined building products in the Bureau of Mines classification in 1939 showed gains of varying proportions over 1938 except "Prepared finishes," which declined appreciably in quantity. Consumption of base-coat plasters increased 22 percent in 1939, and that of gaging and molding plasters, used for finish-coat work, rose 24 percent over 1938. The slightly higher than proportional gain for finishing plasters is caused chiefly by the increased use of gypsum lath, which effects a saving in the required quantity of base-coat plasters by furnishing a smooth plastering surface and tending to eliminate droppings. It is claimed that 1 ton of base-coat plaster mixed with 2 tons of sand will plaster 225 square yards of gypsum lath but only 180 square yards of wood lath. In other words, 100 square yards of gypsum lath requires 889 pounds of gypsum plaster for a base coat of proper thickness, whereas a similar area of wood lath requires 1,111 pounds. The gypsum-lath requirements represent a reduction of 20 percent for any given area. In connection with consumption of base-coat plasters, it is interesting to note the development of a 2-inch-thick building partition constructed by applying sanded plaster

[1] Krugel, C., Dreyspring, C., and Heinrich, F., The Importance of Sulfate as Plant Food: Commercial Fertilizer, vol. 58, No. 5, May 1939, pp. 11-15.

to each side of gypsum or metal lath supported by steel channels. This type of solid partition is used extensively in the low-cost housing projects being built by the United States Housing Authority. This Federal agency recently estimated [2] that its entire construction program would require approximately 800,000 tons of gypsum plaster.

Gypsum products (made from domestic, imported, and byproduct crude gypsum) sold or used in the United States, 1938–39, by uses

Use	1938		1939

[1] Includes uncalcined gypsum sold for use as filler and rock dust, in paint manufacturing, and for minor purposes.
[2] Includes joint filler, patching and painter's plaster, and unclassified building plasters.
[3] 1938: 809,471 M square feet; 1939: 1,137,415 M square feet.
[4] 1938: 371,767 M square feet; 1939: 410,876 M square feet.
[5] 1938: 19,942 M square feet; 1939: 30,191 M square feet.
[6] Includes statuary, industrial casting and molding plasters, dead-burned filler, and miscellaneous sales.

Sales of gypsum lath (square feet) were 41 percent above the previous annual record set in 1938. Because of the large volume of sales, the value of the lath, which commands a relatively higher price than most other gypsum products owing to the greater degree of fabrication, was the most important single item in the classification shown in the preceding table and, together with the value of wallboard sales, comprised more than half the total of all gypsum products. Shipments of wallboard during 1939 were well above those in 1938 but were still far below annual sales in the late 1920's. Although this product is meeting stiffer competition each year from several other prefabricated materials, such as fiberboard and steel paneling, apparently it is holding its proportional share of the market.

[2] U. S. Housing Authority, Federal Works Agency, Public Housing Weekly News: Vol. 1, No. 31, March 12, 1940, p. 3.

Consumption of gypsum tile (square feet) in 1939 showed the remarkable increase of 51 percent over 1938. Contributing to this gain, the square footage of partition tile sold was nearly one-half higher than in 1938, and the volume of all other tile, including roof, shoe, and soffit tiles and gypsum plank, rose more than two-thirds over 1938.

Total shipments of industrial plasters in 1939 were well above the tonnages in 1938 but did not equal those in 1937 when industrial activity was at a higher level. In 1939 consumption increased in all classified groups except "other industrial uses," in which it remained at the same level as in 1938.

PRICES

Values of gypsum products requested by the Bureau of Mines in its annual survey of the industry are net sales values, including containers, at the producing plants. Although the average values per sales unit do not represent selling prices, they indicate price trends of the various products in the country as a whole. The slight increase in average values in 1939 over 1938 for most of the products shown in the following table suggests a slight stiffening of prices from the general downward trend of the last 4 or 5 years. Values of several important products were lower in 1939 than in 1929, when competition forced prices to the lowest point since before the World War. From values of the few products for which data are available it may be inferred that present prices generally are below those of 1925. A similar inference may be drawn from the wholesale prices of the Bureau of Labor Statistics for plaster and ⅜-inch plasterboard, f. o. b. cars at destination, which in 1939 were 91.5 and 82.4 percent, respectively, of the prices in 1926.

Average values, f. o. b. plant, of gypsum products sold or used in the United States, in selected years, 1925–39 [1]

[1] Includes products from domestic crude only in 1925; from domestic and imported crude in 1929, 1933, and 1935; and from domestic, imported, and byproduct crude, 1937–39.
[2] Data not available.

RECENT DEVELOPMENTS

Standard specifications [3] for gypsum plastering and requirements for lathing and furring were approved by the American Standards Association. The specifications cover all materials and operations necessary to complete a gypsum plaster job.

[3] American Standards Association, Standard Specifications for Gypsum Plastering: No. A42.1–1938, September 29, 1938, 11 pp.

New products of gypsum developed in 1939 or recent years include a vermiculite plaster designed particularly for use as a fire-protective covering for steel columns and beams. The most practical mix appears to be 3 parts of neat gypsum plaster to 1 part of fine expanded vermiculite by weight. In Georgia a lime manufacturer [4] utilizes calcined gypsum in making a prepared masonry mortar to control the setting time of the finished product. The gypsum is added just before grinding in a tube mill and comprises about 2 percent by weight of the mixture. A new supersulfate cement made from a mixture of blast-furnace slag, slaked lime, and as much as 15 percent gypsum or anhydrite has been developed in Belgium. It has several desirable properties that may expand its use and thus enlarge the market for gypsum. In 1939 a specially processed, high-strength gypsum plaster that can be used as an oil-well cement was made available commercially.

A grand-jury investigation of the gypsum industry was begun early in 1940 by the Antitrust Division of the Department of Justice as part of its Nation-wide investigation of the reportedly high cost of abor and materials for building.

FOREIGN TRADE [5]

Imports.—The import situation in 1939 was disturbed by the greatly increased quantities of crude gypsum imported during the fourth quarter of the year on account of the present European war. Virtually the entire gain was in crude from Canada and was distributed to the calcining plants along the Atlantic coast as far south as Florida. In contrast to the marked gain in the tonnage of crude, imports of gypsum products remained at essentially the same negligible level as in 1938.

The value of alabaster manufactures imported for consumption during each of the past 5 years is included in the following table for the first time. The major part, by far, of the annual imports reported in this classification is from Italy in which are situated the famed alabaster deposits near Volterra and Castellina. In addition to these imports of manufactured alabaster, a small tonnage of crude alabaster blocks is brought from Italy for working into lamp bases and other objects.

Gypsum and gypsum products imported for consumption in the United States, 1935–39

Year	Crude		Ground		Calcined		Keene's cement		Alabaster manufactures [1]	Other manufactures n. e. s.	Total value
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value			
1935	450,250	$463,050	1,241	$15,440	601	$11,364	64	$1,290	$207,491	$20,958	$719,593

	897,484	854,835	789,429	772,026	1,308,078	1,174,117

[1] Less than 1 ton.

Exports.—The total value of exports of crude gypsum and gypsum products in 1939 gained slightly over 1938 and continued the gradual rise that has persisted since 1933. Exports do not form an appreciable part of the domestic industry.

Gypsum and gypsum products exported from the United States, 1935–39

Year	Crude, crushed, or ground		Plasterboard and wallboard		Plaster, calcined, and manufactures		Other manufactures, n. e. s.	Total value

[2] Not separately classified before 1937; included with "Plaster, calcined, and manufactures."
[3] Data not available; value reported as follows: "Crude, crushed, calcined, or ground," $107,732; "Plasterboard, wallboard, plaster, and manufactures, n. e. s.," $148,171.

WORLD PRODUCTION

In the following table total world production of gypsum is not given because data of several countries that annually produce large quantities are not available for any of the years shown.

In 1939 Germany resumed production [6] of sulfuric acid from a mixture of gypsum or anhydrite, with coke and clay as a substitute for pyrite. This method, developed during the World War when supplies of Spanish pyrite were stopped in a similar manner by the British blockade, has been perfected and is being applied at the Wolfen works of the I. G. Farbenindustrie A. G. Annual capacity of this plant is reported to be 80,000 metric tons of sulfuric acid and 75,000 tons of cement, a byproduct of the process.

[6] Bureau of Mines, Mineral Trade Notes: February 1940, p. 15.

[1] In addition to the countries listed, gypsum is produced in Chosen, Cuba, French Morocco, Poland, Spain, Switzerland, U. S. S. R., and Yugoslavia, but production data are not available.
[2] Data not yet available. [3] Rail and river shipments. [4] Approximate production.
[5] Data for crude gypsum mined not available. Shipments of crude (lump, crushed, and ground) and calcined gypsum amounted to 1,277,480 tons.
[6] Exports of crude and calcined gypsum.
[7] Figures supplied by Deutscher Gips-Verein, E. V., Berlin, Germany. Figures are exclusive of rock gypsum from their own quarries used by cement, paint, and other factories.
[8] Estimate furnished by Bundesministerium für Handel und Verkehr.

LIME

By Forrest T. Moyer and A. T. Coons

SUMMARY OUTLINE

Recovering sharply from the relatively low rate of 1938, consumption of lime in 1939, as indicated by total sales of 4,254,348 short tons, was the highest of any year since 1929. The total quantity sold was 27 percent higher than in 1938 and was only 7 percent below the record volume for 1925 (4,580,823 tons). Sales of quicklime rose 35 percent above 1938, a larger proportional gain than the increase of 13 percent for hydrated lime which customarily is subject to lesser fluctuations in demand than quicklime.

Generally, demand for lime by most consuming industries was low during the first 6 to 8 months of 1939 but increased materially in the latter part of the year. The improvement was marked in all but a few States in which the apparent consumption was about the same or slightly lower than in 1938. Owing to the probable excess of production over demand in the beginning of the year, prices fluctuated downward and by midyear were well below the averages of 1938. However, with improved demand, they became stable and at the end of the year were slightly above the low point. The average value at producing plants of all lime sold or used in 1939 was $7.06 per ton, a decline of 15 cents from 1938 and of $2.24 from the value of $9.30 received in 1925. According to the operators, production costs in many States were higher than in 1938 owing to higher prices for some fuels and increased wages for labor. Southern operators found the increased labor costs particularly burdensome.

The quantity of lime used in agriculture declined slightly from 1938, despite the reduction in price and a reported increase of 5 percent in total cash farm income. Sales of hydrated lime for this purpose, approximately 60 percent of the total, fell below those of 1938, while the tonnage of agricultural quicklime consumed increased nearly one-fifth. Although hydrated lime is admittedly the best liming agent for soils, the cheaper materials, especially pulverized limestone, have become increasingly popular with farmers.

In contrast to the general conditions in other sections of the industry demand for building lime was good throughout 1939, and the average value at the plant increased 18 cents per ton. The total quantity of lime sold for construction was the highest of any year since 1930 and surpassed that of 1938 by 17 percent, a gain that correlates fairly well with the increased activity reported in the building industry. Hydrated lime comprised more than two-thirds of all building lime sold during 1939. A further loss of the mason's lime market to prepared masonry mortars was reported by some operators. The prepared mortars containing 10 to 50 percent of lime are made by only a few lime producers who have entered this business to protect their market. The greater part of the annual production of these mortars is said to be made by mixing companies, which purchase the required raw materials, and by cement companies.

Salient statistics of the lime industry in the United States, 1938–39

	1938			1939

Exports	13,222	121,662	9.20	21,477	236,497	11.01	+62.4	+19.7

[1] Dead-burned basic refractory material containing 6 percent or more lime and consisting chiefly of magnesia and lime.

Total sales of lime for chemical and industrial uses in 1939 surpassed those of 1938 by 26 percent and set an all-time record, exceeding the previous high of 1937 by 68,510 short tons. According to the Bureau of Mines classification, metallurgical-lime consumption, which depends largely on activity in the steel industry, was more than 50 percent greater than in 1938 and reached a new high—8 percent above the previous record of 1937. The sole disturbing factor in the strong lime market for this purpose after July was the marked reduction in price during the second quarter of the year. Sales to the paper industry, the second largest consumer of chemical-grade lime, were higher in 1939 than in any other year. Lime sold for purifying water (municipal and industrial) increased materially over sales in 1938 and, like the other two principal chemical uses, reached a new record. Sales in 1939 for nearly all other chemical and industrial uses of lime were higher than in 1938 and compared favorably with those for 1937.

The heavy demand for refractory lime (dead-burned dolomite) was due to the high level of operations in the steel industry and to the reconditioning of the refractory linings in idle furnaces necessitated by rapid expansion in utilization of open-hearth capacity from 54 to 95 percent between July and December. This demand, coupled with an average price decline of 33 cents per ton, pushed sales of refractory lime in 1939 to a new high, surpassing those of 1938 by 83 percent and 1937 (the former record), by 9 percent. In this chapter data on dead-burned dolomite do not represent the entire consumption in the United States, as some steel companies calcine their own refractory material from dolomite purchased raw or obtained from their quarries. Such tonnages of raw dolomite, which are included in the chapter on Stone in this volume, totaled 824,930 short tons, a threefold increase over 1938.

Exports of lime in 1939 were notably higher than in 1938 and exceeded those of any year since 1916. The total tonnage brought into the country declined from 1938 chiefly because imports of dead-burned basic refractory from Canada virtually ceased.

PRODUCTION

As quicklime is a semiperishable commodity and many plants have only small storage facilities, stocks of lime are said to be inconsequential. In this chapter the tonnages of lime sold or used by the producers are considered equivalent to production and are used interchangeably.

The lime industry in 1939, reviving strongly from the recession of 1938, resumed the uptrend in sales that had persisted from 1933 through 1937. The average value per ton was the lowest since 1933.

Lime sold or used by producers in the United States, 1935–39

Year	Plants in operation	Short tons [1]	Value [2]	
			Total [1]	Average
1935	301	2,987,133	$21,748,655	$7.28
1936	301	3,749,383	26,933,719	7.18
1937	314	4,124,165	30,091,168	7.30
1938	321	3,346,954	24,137,638	7.21
1939	311	4,254,348	30,049,394	7.06

[1] Includes lime used by producers (captive tonnage) as follows—1935: 143,716 tons, valued at $750,155; 1936: 224,693 tons, $1,179,820; 1937: 270,192 tons, $1,388,052; 1938: 168,245 tons, $985,003; 1939: 270,087 tons, $1,454,285.

[2] Value given represents value of bulk lime f. o. b. at point of shipment and does not include cost of barrel or package.

Production by States.—The total tonnage of lime marketed in 1939 was produced at 311 plants (10 less than in 1938) in 37 States and 2 Territories. Production increased in most States, and the output of the ranking States—Ohio, Pennsylvania, Missouri, and West Virginia—aggregated 60 percent of the total, Ohio alone contributing 26 percent. Production in Missouri, which had been severely curtailed during 1938 by labor difficulties, gained sharply in 1939.

Hydrated lime.—Despite the reduced number of active plants in 1939 (11 less than the record number in 1937), production of hydrated lime was higher than in any year since 1930. The average value per ton, following the general downward trend in lime prices during the year, was 11 cents below the 1938 figure. Production in the important producing States was substantially higher than in 1938 and more than offset the small declines reported in more than half of the 34 producing States. The combined output from the ranking States—Ohio, Pennsylvania, and Missouri—comprised 60 percent of the total for the country.

Hydrated lime sold or used by producers in the United States, 1935–39

Year	Plants in operation	Short tons	Value	
			Total	Average
1935	167	1,005,619	$7,939,513	$7.90

SHIPMENTS

Total shipments.—Sales, shipments, and supplies of lime available for consumption in continental United States by States and groups of States that comprise approximate freight zones are listed in the two following tables. Reshipments beyond the original destination from the producing plants are disregarded. These data do not include a small quantity of lime (about 1 percent of the total) produced in Hawaii and Puerto Rico, foreign shipments, and tonnage for which distribution is not recorded.

Lime supplies available in continental United States in 1939, by States, in short tons

[1] Includes 17,860 tons exported or unclassified as to destination. [2] Included under "Undistributed."
[3] Includes items entered as "(2)."

Apparent consumption of lime in the leading consuming States—Pennsylvania, Ohio, New York, Illinois, and Michigan—represented nearly half of the total for the country. Of these ranking States, only in Ohio was production greater than consumption. In Pennsylvania consumption usually is slightly greater than production during years of high-capacity operations in the steel industry and slightly lower than production during years of low-capacity operations. Shipments of lime from Ohio and Missouri in 1939 were considerably higher than from any other State.

Lime shipped (supply) in continental United States in 1939, by origin and destination of shipments, in short tons

SALES BY USES

The only major uses for which the average value of lime increased in 1939 over 1938 were in the building and sugar-refining industries. Prices for lime sold for metallurgical and water-purification purposes showed the largest declines—45 and 49 cents per ton, respectively. Consumption of hydrated lime, which is more stable than that of quicklime, represented a slightly smaller proportion of the total in 1939 than in 1938.

Lime sold or used by producers in the United States, 1938–39, by uses

Use	1938				1939			
	Quantity		Value		Quantity		Value	
	Per-cent of total	Short tons	Total	Average	Per-cent of total	Short tons	Total	Average
Agricultural	10.9	364,312	$2,376,108	$6.52	8.5	362,335	$2,214,759	$6.11

Hydrated lime (included in above totals)	35.0	1,169,804	9,111,575	7.79	31.0	1,318,053	10,124,241	7.68

[1] Details of distribution shown in a following table.
[2] Includes lime used by producers (captive tonnage) as follows—1938: 168,245 short tons, valued at $985,003; 1939: 270,087 tons, $1,454,285.

Agricultural lime and other liming materials.—Pulverized limestone, by reason of its low price and availability, is by far the most important liming agent. Its effectiveness, however, is not as rapid or subject to as close control as that of lime.

Agricultural lime and other liming materials sold or used by producers in the United States, 1938–39, by kinds

Kind	1938				1939			
	Short tons		Value		Short tons		Value	
	Gross	Effective lime content [1]	Total	Average	Gross	Effective lime content [1]	Total	Average
Lime from limestone:								
Quicklime	126,539	106,000	$666,550	$5.27	149,903	126,000	$753,325	$5.03
Hydrated	237,773	166,000	1,709,558	7.19	212,432	149,000	1,461,434	6.88
Lime from oyster shells [2]	14,789	12,000	93,338	6.31	(3)	(3)	(3)	(3)
Oysters shells (crushed) [2]	63,832	27,000	223,986	3.51	(3)	(3)	(3)	(3)
Limestone	4,367,410	1,878,000	5,637,485	1.29	5,459,260	2,347,000	6,592,827	1.21
Calcareous marl	23,572	10,100	40,270	1.71	22,114	10,000	38,492	1.74

[1] Estimated by method described in Mineral Resources of the United States, 1921, pt. II, p. 164.
[2] Bureau of Fisheries.
[3] Data not yet available.

Building lime.—Total sales of building lime in 1939 (1,000,498 short tons) reported by operators for the important uses of lime in construction include: Finishing lime, 393,668 short tons; mason's lime, 435,216 short tons; for manufacture of prepared masonry mortars, 72,032 short tons; and unspecified uses, 99,582 short tons.

Average values per ton for these classifications are \$9.37, \$8.10, \$6.73, and \$8.70, respectively. Finishing lime produced in Ohio comprised 87 percent of the total for this purpose. The combined production of mason's lime in the ranking States—Ohio, Massachusetts, and Pennsylvania—was 40 percent of the total.

Chemical and industrial lime.—The quantities and average values of metallurgical lime sold or used in 1939 are reported by the producers as follows: Fluxing lime in open-hearth steel furnaces, 558,678 short tons, \$5.54; fluxing lime in electric steel furnaces, 11,344 short tons, \$7.22; fluxing lime in smelting nonferrous metals, 12,029 short tons, \$6.13; wire drawing, 12,666 short tons, \$8.08; mold paints, foundry uses and unspecified, 1,475 short tons, \$6.29; ore concentration (including cyanidation), 152,661 short tons, \$6.33. In production of fluxing lime for steel furnaces Pennsylvania, West Virginia, Missouri, and Alabama led all other States, and Arizona and Utah outranked other States in production of lime for ore concentration.

The quantity and value of chemical-grade lime, designated as "Other uses" in a previous table, are reported by uses in 1939 as follows:

Chemical and industrial lime sold or used by producers in the United States for "Other uses" in 1939

Use	Short tons	Value
Alcohol	943	\$5,878
Alkalies (ammonium, potassium, and sodium compounds)	7,837	45,684
Asphalts and other bituminous materials	1,415	10,489
Bleach, liquid and powder (excludes bleach for paper manufacture)	10,573	57,002
Brick, sand-lime and slag	25,367	158,974
Brick, silica (refractory)	10,946	80,894
Calcium carbide and cyanamide	85,218	418,061
Calcium carbonate, precipitated	5,600	46,736
Coke and gas (gas purification and plant byproducts)	13,229	82,612
Food products:

SIZE OF PLANTS

Studies of groups of active commercial companies, arranged by volume of annual sales, indicate that those selling 25,000 to 49,999 short tons each year are growing in number and thus contribute an increasing proportion to total annual sales by the industry. Sales by the smaller groups, although fairly persistent, represent a lower percentage of total sales in 1939 than in 1929. The number of plants in these groups is declining. Sales in the groups over 50,000 tons are the most sensitive to prosperity and depression periods. According to Bowles and Coons,[1] the number of active lime companies, plants, and kilns declined appreciably from 1910 to 1938, individual kiln capacity increased, and production by the industry from 1917 to 1938 averaged about 51 percent of capacity.

Sales of lime (including dead-burned dolomite) by producers in the United States, 1929, 1934, and 1939, by size of companies

TRENDS IN PRINCIPAL USES

Largely because of the record consumption of metallurgical lime and dead-burned dolomite in 1939, sales of chemical-grade and refractory lime represented 68 percent of total sales by the industry as

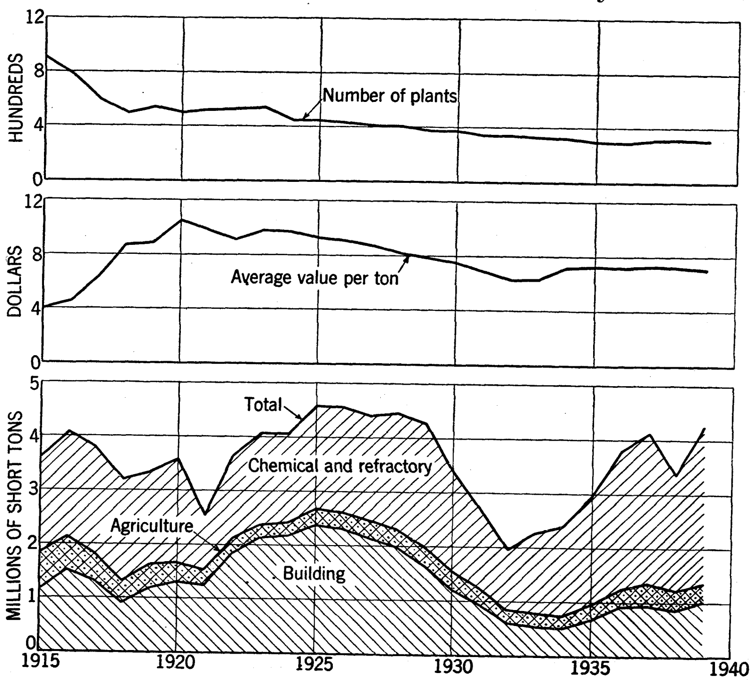

FIGURE 1.—Trends in the number of active plants, average value per ton, and principal uses of lime, 1915–39.

contrasted with 64 percent in 1938. Although sales of building lime increased considerably in 1939, they represented a slightly smaller proportion of the total than in 1938.

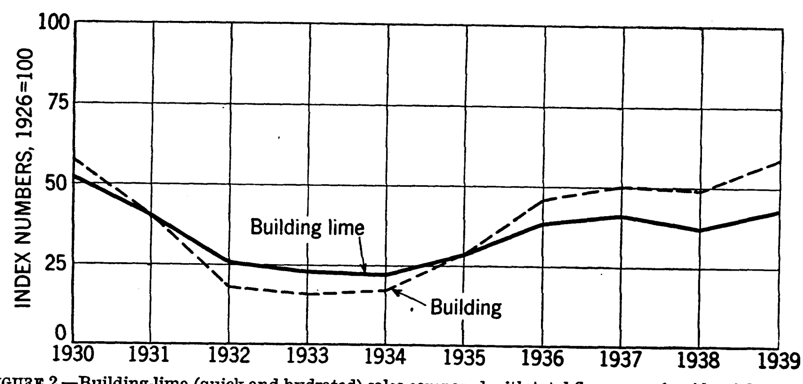

FIGURE 2.—Building-lime (quick and hydrated) sales compared with total floor area of residential and nonresidential building, 1930–39. Index numbers on building computed from F. W. Dodge Corporation data.

The disproportionate gain in consumption of refractory lime in 1939 compared to steel-ingot production probably resulted from extensive repairs required to condition furnaces that had been idle for some time and from substitution of this refractory for other higher-price materials. Dead-burned dolomite is readily available, as the producing plants are close to the important steel-producing centers of the country.

NEW DEVELOPMENTS

The methods of making and the properties of quicklime and hydrated lime for use in important consuming industries are discussed in a general symposium [2] on lime by the American Society For Testing Materials. Plasticity studies [3] show no correlation between Emley plasticity values and particle-size distribution down to 1 or 2 microns in masonry mortars made with hydrated lime and quicklime putties. Quicklime putties prepared with an excess of water were very much finer than commercial hydrated limes.

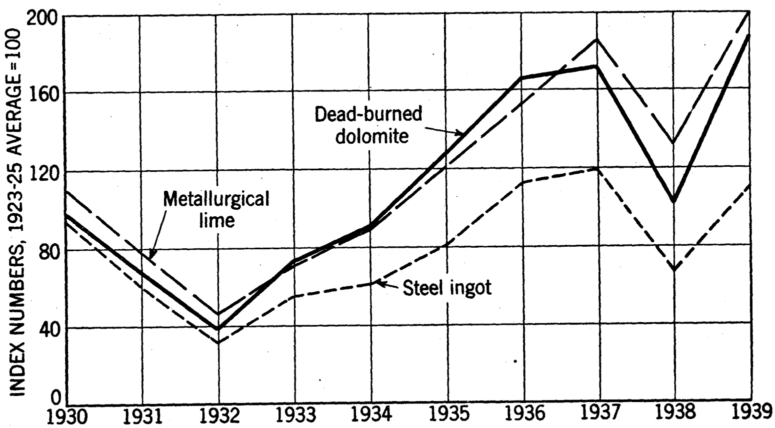

FIGURE 3.—Metallurgical lime and dead-burned dolomite sales compared with steel-ingot production, 1930–39. Index numbers on steel ingots computed by Federal Reserve Board from data of American Iron and Steel Institute.

Quantity requirements of lime in the paper and pulp industry are given by Rowley [4] as follows: 150 to 200 pounds per ton of pulp made by the sulfite process; 600 to 785 pounds per ton by the soda process; 500 to 550 pounds per ton by the sulfate process; 120 to 250 pounds per ton of rags in pulp; and about 500 pounds for pulping straw. However, new lime requirements are much lower in mills where the calcium carbonate sludge from the causticizing step is recovered and recalcined. For example, new lime requirements in a sulfate-process mill in southern United States are only 85 pounds per ton of pulp produced, although the process needs a total of 540 pounds.

The treatment of waste sulfite liquors from paper mills by the Howard process,[5] a three-stage precipitating treatment with lime, has resulted in a number of valuable byproducts such as vanillin and lignin plastics and should provide an expanding market for lime. Other newly developed uses for lime are in the manufacture of synthetic fibers of the nylon and polyvinyl acetal resin types and as a control of the starfish invasion, which seriously threatens continuance of the New England oyster beds.

The 41 lime plants that entered the fifth annual safety competition [6] conducted by the Bureau of Mines in cooperation with the National Lime Association, showed a marked decline in the severity rate of accidents and a slight improvement in frequency rate over the 1938 data.

FOREIGN TRADE [7]

Imports.—The marked decline in imports of dead-burned dolomite, composed largely of impure Canadian magnesite, from 13,928 short tons in 1936 to only 186 in 1939, is attributed to the reported manufacture of a similar refractory in the United States from dolomite with additions of brucite and serpentine. Imports of other types of lime in 1939 increased slightly over 1938.

Lime imported for consumption in the United States, 1935–39

Year	Hydrated lime [1]		Other lime [1]		Dead-burned dolomite [2]		Total

CLAYS

KAOLIN (CHINA CLAY AND PAPER CLAY), BALL CLAY, FIRE CLAY, BENTONITE, FULLER'S EARTH (BLEACHING CLAYS), AND MISCELLANEOUS CLAY

By PAUL M. TYLER AND A. LINN [1]

SUMMARY OUTLINE

Sales of domestic china clay and paper clay, ball clay, and bentonite attained new high records in 1939. Fire-clay sales, on the other hand, although more than 50 percent above those in 1938, fell below those of several earlier years, including 1937, and failed to pace recovery in iron and steel manufacture, the principal consuming industry. Discouraging, too, was a further decline in the consumption of natural bleaching clays or fuller's earth, which has persisted since 1930 owing to competitive bleaching materials and changes in oil-refining technique. The tonnage of miscellaneous clay sold was only a trifle higher in 1939 than in 1938, and the total value was much lower. Sales of all kinds of clay, as reported to the Bureau of Mines, totaled 3,927,764 tons valued at $17,046,773 in 1939 compared with 2,901,713 tons valued at $13,483,441 in 1938 and 4,463,551 tons valued at $18,004,158 in 1937.

Imports of clay were somewhat higher in 1939 than in 1938 but were less in quantity or value than in any other year since 1934. Total imports of clay of all kinds were 151,420 tons valued at $1,378,735 in 1939 compared with 113,059 tons and $1,127,462 in 1938 and 205,304 tons and $1,950,043 in 1937. During the 5-year period 1925–29 imports averaged 420,310 tons valued at $3,841,462 annually.

Exports of fire clay, fuller's earth, and other clays totaled 136,480 tons valued at $1,873,110 in 1939, 132,147 tons valued at $1,565,567 in 1938, and 168,810 tons valued at $1,948,425 in 1937. Comparable figures for 1925–29 were 109,344 tons and $1,217,769 annually.

There were outstanding gains in sales of domestic clay for paper, whiteware pottery, rubber, and high-grade tile, and minor gains in sales of clay for other uses. Compared with 1937, sales for refractory uses show the same unfavorable trend as sales of fire clay alone.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce. Domestic figures for fuller's earth compiled by R. W. Metcalf, of the Bureau of Mines.

These decreases were the principal cause of the decline in the total quantity and value of sales of all clays in 1939 compared with 1937 and a few earlier years, although substantial losses also occurred in apparent consumption of oil-well drilling mud and bleaching clays and minor losses in a few other outlets.

The consumption of paper-filler clay has increased greatly but not as spectacularly as that of domestic paper-coating clays. After exceeding 10,000 tons in only one previous year, 1922 (10,243 tons), sales of domestic paper-coating clays jumped to 33,034 tons in 1929, advanced fairly steadily to 91,146 tons in 1937, and after a slight drop in 1938 rose to 116,980 tons in 1939. The record sales of 94,057 tons of rubber clay in 1939 may be compared with less than 30,000 tons in any year before 1927. The consumption of clay in paint is less now than in the late 1920's, but consumption in the manufacture of oilcloth and linoleum has increased by a large percentage.

Salient statistics of the clay industry in the United States, 1930–34 (average) and 1936–39

	1930–34 (average)	1936	1937	1938	1939

Terminology on clays has been notoriously loose. To remedy this lack of uniformity a Committee on Geological Surveys, under the active leadership of H. Ries, has recommended a series of 58 definitions for adoption by the American Ceramic Society.[2] An Illinois State report shows that a clay from the Goose Lake area, Grundy County, Ill., formerly thought to be bentonite or beidellite, is composed of a distinctive clay mineral of the illite group which is unique in that it combines good oil-bleaching, high bonding, and excellent mud-forming properties. Like bentonite, it is used for rebonding foundry molding sand, for oil-well drilling muds, for setting casing in oil wells, and for special adhesives, and like fuller's earth it is used for refining mineral and edible oils.

CHINA CLAY OR KAOLIN

Sales of kaolin or china clay by domestic miners in 1939 totaled 780,804 short tons valued at $6,200,606, a gain of 31 percent over the quantity shipped in 1938 (595,054 tons, $4,740,880) and 7 percent above the previous all-time record of 732,282 tons valued at $5,349,636 in 1937. Imports recovered moderately to 114,696 short tons having a nominal value of $1,015,813 compared with 84,180 tons valued at $753,858 in 1938 and 146,523 tons valued at $1,211,266 in 1937.

As usual Georgia contributed nearly two-thirds of the national output, but South Carolina's share increased to more than 20 percent of the total in 1939 compared with 17 percent in 1938. The Georgia output exceeded the 1937 record, and that of South Carolina was greater than ever before. Pennsylvania, the third ranking State, also managed to break previous records, and California produced more than twice as much as in any previous year. Because of better demand for domestic pottery clays, sales of North Carolina clay likewise rose to an all-time high.

Largely as a result of work done by Frank L. Hess, of the Bureau of Mines, the major residual kaolin deposits of North Carolina are now believed to have been derived from large alaskite granite bodies rather than from pegmatite veins as previously thought. These deposits probably are far greater than was previously estimated, approximating 51 million tons in the Spruce Pine district of Avery, Mitchell, and Yancey Counties. The clay is notably low in iron and contains only a trace of titanium. High-grade kaolin for ceramic use is now being produced in the district by two modern plants [3] and several older plants, and the clay is used to an increasing extent also for various fillers and in special products. According to Hunter,[4] 50 geologically separate kaolin deposits are associated with the Spruce Pine alaskite. The outcrops range in size up to 100 acres or more. Residual quartz, muscovite mica, and some unkaolinized feldspar accompany the kaolin, but the mixture is easily mined by mechanical methods or hydraulicking. One deposit near the town of Spruce Pine was mined to a depth of 100 feet before the percentage of unaltered feldspar increased enough to discourage mining. The percentage of recoverable kaolin varies, and many deposits yield 10 percent or more. Mica is recovered as a joint product and is used chiefly for roofing but also as filler. The quartz is milky white and might be employed as high-grade glass sand.

By using a micronizer, it is claimed not only that clay can be ground finer than was previously possible, but also that undesirable accessory minerals can be eliminated.[5]

Clay drying and grinding may be conducted simultaneously. At some plants in the South rotary driers remove only part of the moisture, and the drying is completed in the milling equipment. This method is advantageous in preparing paper clays because, when drying is completed before grinding, the temperature may rise too

high or the clay may remain very hot for too long a period, thereby impairing the quality of the product.

Further progress has been made in the use of air separators to remove silica sand or other impurities from clay. Wet centrifugal fractionation methods also are employed to separate ultrafine particles from Georgia kaolins used as special paper coatings. The coarser fractions are sold to the ceramic industries.

Prices.—Prices were nominally unchanged in 1939, but during the first 8 months there was some softening with the result that virtually all producers reported a lower average realization per ton from their sales than in 1938. In anticipation of an increase of 50 cents a ton on January 1, 1940, the prices of most varieties of clay were firmer during the last quarter, but the average price of all domestic sales throughout 1939 dropped to $7.94 a ton compared with $7.97 in 1938 and $7.31 in 1937. Corresponding figures for South Carolina, where most of the output is paper-filler and rubber clays, were $8.18, $8.75, and $8.16, respectively. These figures do not cover as wide a variety of products, but they fail to measure the actual decline in unit values because the South Carolina clays are much better prepared now than they were even in 1937. In Georgia the average sales realization was $8.07 in 1939 compared with $8.03 in 1938, but this average is a composite of clays ranging from the cheapest refractory kaolins worth less than $2 a ton to the highest-grade paper-coating clays worth $30 or more a ton. Paper-filler clay, produced principally in Georgia and South Carolina, ranged in price from less than $6 to $8 a ton f. o. b. mines, whereas coating clays ranged as high as $20 and even $30 or more a ton. The average values as reported by producers were approximately $7 and $12 for filler and coating clays, respectively, in 1939 compared with $8 and $12 in 1938 and $7 and $11 in 1937; however, the comparability of these figures for different years also may be questioned because of the steady improvement in average quality. Sales of rubber clays during 1939 ranged from about $6 to $10 a ton f. o. b. Georgia or South Carolina shipping points and averaged $9.65 compared with $9.75 in 1938 and $8.80 in 1937. North Carolina potting clays were sold at $13 to $15 a ton, Florida clays were slightly cheaper, and Delaware clays somewhat more expensive, f. o. b. mines. Shipments of Georgia and South Carolina clays for ceramic use increased in 1939, but they brought only $5.50 to $8.50 a ton, about the same price range as paper-filler or rubber clays. These clays are not white burning, as they contain not only iron and a little titanium but also, as recently discovered, up to 0.08 percent vanadium oxide.

BALL CLAY

Production of domestic ball clay exceeded by a wide margin the 1937 all-time record, advancing to 128,601 short tons valued at $935,721 in 1939 compared with 94,968 tons worth $739,691 in 1938. Imports classified as "common blue and ball clay" totaled 28,540 short tons valued at $233,094 compared with 20,199 tons valued at $199,523 in 1938, and much larger amounts in earlier years. Virtually all of these imports were ball clay, and all but 1,208 tons (from Germany) were English clay. An increasing number of American potters are substituting Kentucky and Tennessee clays for imported ball clays that they formerly used. The domestic clays are of good quality, carefully prepared, uniform, and much cheaper than English clays.

Seventy-four percent of the shipments of domestic ball clay in 1939 was used in white pottery or cream-color ware, 12 percent in high-grade tile, and the remaining 14 percent in a variety of products, including architectural terra cotta, linoleum, refractory brick, enamels, and miscellaneous articles.

FIRE CLAY

The output of fire clay from American mines, which lagged slightly behind recovery in iron and steel manufacture, the main consuming industry, rose to 2,222,295 short tons valued at $5,801,993 in 1939 compared with 1,458,941 tons valued at $4,060,160 in 1938. As shown in figure 1, the sales of domestic clay for refractories, chiefly fire clay, after following closely the trends in the iron and steel industry for many years, began to run ahead about 1934 and rose much higher in 1937 but fell back in step in 1938 and 1939. Variable factors are the longer life of modern clay refractories, the substitution of nonclay refractories, and variations in the relative requirements of consumers other than steel makers.

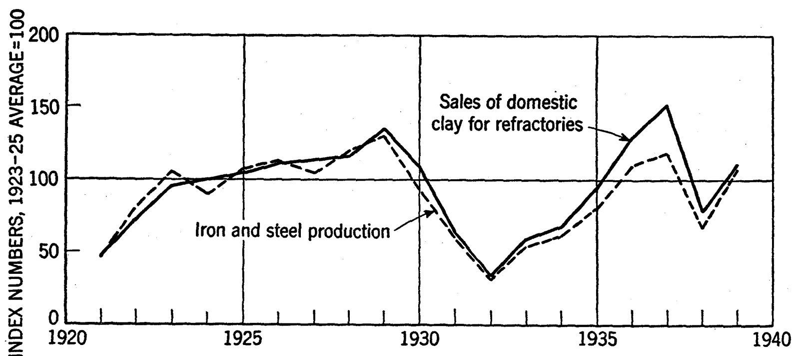

FIGURE 1.—Sales of domestic clay for refractories compared with iron and steel production (Federal Reserve Board Index), 1921-39.

Imports.—Imports of Gross-Almerode glass-pot clay in 1939 did not recover significantly from the sharp decline in 1938, aggregating only 332 short tons valued at $4,684 compared with 205 tons and $2,470 in 1938, 1,737 tons and $21,645 in 1937, and 2,145 tons and $26,852 in 1936. Imports of miscellaneous clays decreased further, totaling only 5,330 short tons valued at $69,056 in 1939 compared with 5,683 tons and $83,384 in 1938, 15,558 tons and $203,383 in 1937, and 18,034 tons and $281,592 in 1936. This group includes imports of specializedproducts such as pipe clays, pencil clays, emery-wheel clays, and enamel clay (other than kaolin and ball clay), but the largest item probably is fire clay, which includes (among other items) Klingenberg clay, a highly plastic clay produced since 1742 in Bavaria and shipped by barge down the Main River and thence on the Rhine to tidewater. In midyear of 1939 this clay cost $38.50 a metric ton for No. 1 grade delivered at United States Atlantic ports, exclusive of the 25-percent extra duty recently applied to all imports from Germany into the United States. This grade is considered essential by American graphite-crucible makers. A second grade, which cost $25 a ton on the same basis, has been used principally for graphite-clay ladle-stopper heads. During the World War, English (Dorset) bond clay and various domestic clays were substituted for Klingenberg clay, but virtually all crucible makers returned to the German clay as soon as it became available again, even though the price was raised much higher. The main advantage of this clay for making crucibles, especially brass crucibles, seems to be that it becomes dense at a comparatively low temperature, thus sealing the carbon grains and protecting them from oxidation. Consumption has dropped with the decline in production of graphite crucibles and apparently averages only about 1,000 tons a year.

BENTONITE

Further expansion in consumption of bentonite for miscellaneous uses and recovery in demand for foundry uses boosted sales to new records in 1939. As compiled from producers' reports to the Bureau of Mines, the output of American mines in 1939 rose to 219,720 short tons valued at $1,702,393 compared with 192,183 tons and $1,373,182 in 1938 and the previous record of 194,768 tons and $1,500,758 in 1937. Of the 1939 sales more than 43 percent was used for filtering and decolorizing oils, chiefly after activation with acid; another 16 percent was used by the petroleum and natural-gas industries in rotary-oil-well drilling muds; and almost 25 percent was employed in foundries and steel works, chiefly as a conditioning or revivifying agent for molding sands. Increasing quantities of bentonite are used for sealing dams and reservoirs, in soap making, and for various other purposes.

The largest increase in production was in the Black Hills area of Wyoming and South Dakota. The output in Mississippi also has increased, but outside of Mississippi, which furnishes most of the subbentonite used in the manufacture of acid-treated bleaching clays (activated earths), it would seem that type 2 bentonite has tended to give way to the swelling type of bentonite. On the other hand the American Colloid Co., which has been a leading producer in Wyoming, has begun to produce Mississippi bentonite. It is claimed that this bentonite may supplement the Wyoming type; and for certain foundry uses, particularly small iron castings and cores,[6] may be even better.

Recently a 40-inch layer of high-grade bentonite has been traced a considerable distance in Clarke County, Ala. The deposit is the first one of size and quality suitable for commercial exploitation that has been found in the State.[7] Quality Earths, Inc., operating a mill near Thomasville, formerly treated local fuller's earth but is now using this bentonite and producing therefrom a satisfactory bonding clay.

The following notes on the Wyoming industry are digested from a report by Heathman: [8]

> Bentonite seams occur in all the Upper Cretaceous rocks in Wyoming, but the best grade and the largest quantities are in the lower formations of the series. As a rule the seams thicken and thin from place to place so that one that may be prominent in one area may not be found in another; nevertheless, there is one thick seam at the top of the Mowry formation that is present throughout more than half of the area of the State. The Black Hills and Bighorn Basin areas are likely to continue to be the principal producing areas in Wyoming because of low mining costs and proximity to railroads. An example of a bentonite area presenting favorable conditions is found around Newcastle, Wyo., where the bentonite is of the best grade, the seam averages 30 inches in thickness, the dips are less than 5°, there are large tonnages of bentonite with less than 15 feet of overburden, and transportation costs are low because of good roads and short hauls to the mills on the railroad. In the Newcastle area the overburden (average not over 7 feet) is cleared away by bulldozers and the bentonite loaded into trucks by power shovels. In some cases the bentonite is hauled 25 miles to mills. In the Greybull area there is no overburden, and the material is shoveled into trucks or sacks by hand. This bentonite is hauled approximately 18 miles. As the crude clay freezes in winter, all mining is done in the summer, and large stock piles are accumulated so the mills can run all winter.

According to findings of the Wage and Hour Division, United States Department of Labor, most of the production of bentonite in the Wyoming-Dakota area is furnished by the American Colloid Co., the Wyodak Chemical Co., and the Silica Products Works of the National Lead Co. The first two companies engage in both excavating and milling, but the third buys crude bentonite and engages in milling only. An application for seasonal exemption from the maximum-hours provisions of the Fair Labor Standards Act of 1938 was denied.

The Wyoming type of bentonite is still used principally in manufacturing synthetic molding sand and rebonding old sand. A new development, however, is the use of southern (nonswelling) bentonites for rebonding molding sands, for which purpose, as previously stated, they may be even better than the Wyoming type. Another new use for bentonite is as a coagulant in the white water at paper mills. The bentonite clarifies the water so that it can be used again, and some of it adheres to the fiber and improves the paper. Bentonite is used

[8] Heathman, J. H., Bentonite in Wyoming: Wyoming Geol. Survey Bull. 28, June 1939, 20 pp.

for oil-well drilling mud; for bleaching petroleum products; in the manufacture of cement and ceramic products, soaps, refractory materials, paper, cosmetics, water softeners, sealing agents, paints, medicinal emulsions, and roofing; for deinking newsprint and clarifying dry-cleaner fluids; as the core of earth-fill dams; and as lining for irrigation ditches. Grit-free bentonite (all under 5 microns and 90 percent minus 0.2 micron) may be included in the new National Formulary owing to its important uses in pharmaceuticals. By using bentonite to seal the expansion joints serious leakage was averted in a 10,000,000-gallon municipal water reservoir at Corpus Christi, Tex.

Further work at the Massachusetts Institute of Technology on Alsifilm, the proposed substitute for mica, has given much fundamental information as to the general nature of colloids and the action of electrolytes and elevated temperatures on bentonite films.[9] A new and simple device for measuring the yield point of clay suspensions used for oil-well drilling muds and other purposes has been developed by A. George Stern, of the Eastern Experiment Station, Bureau of Mines, College Park, Md.[10] Among the more important functions of an oil-well drilling mud, many of which depend on the "gel" characteristics that can now be measured with the aid of this novel instrument, are: (1) To plaster the sides of the hole to prevent caving of the walls, (2) to prevent loss of fluid by seepage, (3) to carry out sand and cuttings, and (4) to form a gel that will prevent the cuttings from falling down and packing at the bottom of the hole even if circulation stops owing to a shut-down or other unavoidable cause.

Imports and exports.—Imports of bentonite, which have been insignificant since 1930, increased slightly to 62 short tons valued at $895 in 1939 compared with 8 tons valued at $228 in 1938. Exports, as reported by producers to the Bureau of Mines, exceeded 20,000 tons, excluding shipments by dealers and the large quantities of acid-treated bentonites shipped to oil refineries throughout the world.

Prices.—Prices have remained virtually unchanged for several years. Processed bentonite sells for $10.50 a short ton f. o. b. Wyoming mills. In dried, coarsely crushed form shipped in carloads in bulk, quotations run $7.50 a ton or less, whereas the clay prepared for oil-well drilling brings higher prices than bentonite milled and sold for other purposes. As reported to the Bureau of Mines, crude sales ranged from $4 to $8 a ton, and the average returns on all sales ranged from less than $7 in South Dakota to nearly $12 a ton in California.

The most widely used bentonite is 200-mesh powder, which currently is worth $10.25 per ton f. o. b. Black Hills shipping point in 100-pound bags, carload lots. However, Wyoming-type bentonite is prepared also in pellet form (30- to 40-mesh), and a dried and finely crushed product (mostly 4- to 20-mesh) is sold in carload lots at $7 a ton in bulk and $8.75 in bags. Bentonite producers, in common with shippers in other industries, had some difficulty in getting bags, as the cost of burlap and kraft paper increased 50 percent or more.

FULLER'S EARTH

After declining almost steadily for 9 years, the production of fuller's earth or natural bleaching clays in the United States dropped further in 1939 to 167,070 short tons valued at $1,691,855 compared with 170,852 tons worth $1,707,869 in 1938 and a peak of 335,644 tons worth $4,326,705 in 1930. Until 1930 the output had increased almost in direct proportion to the rapid expansion in petroleum refining, occasional minor set-backs never lasting more than a year; but in 1930, the trends began to diverge and in 1939, when sales of fuller's earth again dropped, the Federal Reserve Board index of petroleum refining rose to 214 compared with 200 in 1938 and only 161 in 1930. Expressed as percentages of the 1930 figures, the domestic output of fuller's earth apparently had fallen 50 percent whereas petroleum refining, once the leading barometer of demand for bleaching clay, had risen 33 percent.

In recent years imports of fuller's earth have amounted to only 1 or 2 percent of domestic production. In 1939 they totaled 1,818 short tons valued at $22,215, a small increase over the 1938 total of 1,506 tons valued at $18,951 but less than imports in any other year since statistics were first available in 1897.

Exports likewise increased. Shipments to foreign countries are not reported separately in the Department of Commerce statistics, but reports to the Bureau of Mines by producers show exports of 11,090 short tons valued at $90,117 in 1939 compared with 10,046 tons valued at $81,175 in 1938 and 8,104 tons valued at $70,985 in 1937.

The decline in the use of fuller's earth is due partly to new methods of oil refining and partly to the substitution of other bleaching and clarifying agents. Activated earths, made by acid treatment of suitable bentonites, have made deep inroads into the market for natural bleaching clays; although more expensive they are much more efficient. Bauxite came into use in 1937 and has the advantage that it can be reused indefinitely, whereas fuller's earth deteriorates after too many burnings. In 1939 another competitor appeared in the form of Magnesol, a patented product having the composition of a magnesium silicate. The original company making this synthetic product has been acquired by the Westvaco Chlorine Products Corporation (Chrysler Building, New York, N. Y.) and the process is patented (U. S. Patent 2,183,590, Ernest Wayne Rembert, December 19, 1939). Magnesol, in addition to being used in oil refining, is being marketed as a continuous clarification and purification agent for all solvents used by dry-cleaning establishments.

The average value per ton of the fuller's earth produced in the United States in 1939 ($10.13) was virtually the same as in 1938 ($10.00) and 1937 ($10.15). Prices vary according to particle size. Fine material, such as that used in contact-refining processes, is much cheaper than the carefully sized particles used in percolation processes. Recently, however, at least two companies have been converting part of their fines into a granular product that is claimed to be superior to the grains produced by ordinary crushing and screening.

Technologic developments in the fuller's earth industry have been summarized in a previous review as follows: [11]

According to Schroter,[12] bleaching clays may be divided into (1) naturally adsorptive, (2) activable, and (3) natural semiadsorptive clays. The first class comprises natural bleaching clays, which hitherto have been classed as "fuller's earth," a term rapidly losing favor because it is not precise. The second group consists mainly of bentonites whose latent adsorptive capacity is increased or improved by drastic chemical treatment (usually leaching with mineral acids). The third class comprises common bauxite. Natural and activable bleaching clays consist mainly of montmorillonite. This mineral may be replaced by saponite or beidellite, but the kaolinite group of minerals is usually absent.

Owing to the wider use of colored fuel the use of bleaching clays to produce water-white gasoline has declined, but the big outlet is still in the petroleum-refining industry for percolation or contact processes. Naturally adsorptive clays have been used widely in percolation treatment, and percolation pellets have been made recently from fine fuller's earth by a simple extrusion method that forces the moist clay through perforated dies in spaghettilike strands, which are cut into short lengths and dried. The other principal method of treating petroleum is contact filtration, wherein finely ground clay is agitated with the oil and later removed in a filter press. This method is used not only for lubricating oils but for all manner of edible and nonedible oils, fats, hydrogenated shortening compounds, some oleomargarine, and even inorganic substances. Both methods are being used outside of the oil or fats industry—especially for decolorizing and recovering chemical-plant solvents and dry cleansers' liquids.

Finely ground activated adsorbent clay recently has been used in a patented method of combined fractional distillation and contact filtration, the oil-and-clay slurry being subjected to normal fractionation and the various fractions that pass off through the tower being decolorized and purified on the way. Perhaps the latest and most spectacular application of adsorbent clays is in the catalytic refining of petroleum oils, whereby the heavier hydrocarbons are broken up so as to increase the gasoline yield. With the addition of activated adsorptive clays cracking takes place at slightly lower temperatures and at much lower pressure, and about 50 percent of the heavy residues that would remain in thermal cracking may be converted into gasoline of a natural octane rating equivalent to that of the best premium motor fuels.

[11] Tyler, Paul M., and Bowles, Oliver, Nonmetallic Mineral Industries in 1939: Bureau of Mines, Inf. Circ. 7106, 1940, pp. 10–11.

[12] Schroter, G. A., Bleaching Clays Find Increasing Use: Eng. and Min. Jour., vol. 140, No. 11, November 1939, pp. 35–38, 40.

Although most activable clays are bentonites, some definitely are not because they have not been formed by devitrification of ash or tuff. Most activable clays are of the nonswelling type and do not form stable clay-water gels; however, they are soapy and seldom contain under 25 percent free moisture. The structure of the best types reminds one of yeast cake, and the color is commonly white, yellow, or some light pastel tint.[13]

Another comprehensive review of bleaching-clay technology was published by Schroter.[14]

MISCELLANEOUS CLAY

Although more than half the output of "miscellaneous clays," as reported by the Bureau of Mines in some years, is used in the manufacture of heavy-clay products, the clay utilized for making common brick, sewer pipe, and other clay products ordinarily is not included in statistics either of the Bureau of Mines or the Bureau of the Census. However, the census of mines and quarries for 1939 is expanding its canvass to include this material. Such clay often comprises 90 percent of the clay dug, but only when it is sold to another company or shipped from place to place has it seemed feasible to report the tonnage. Rotary-drilling mud is another important item in this miscellaneous category, for several fine-grained clays are used alone or admixed with bentonite for this purpose. Additional tonnages of unclassified clays are employed in cement manufacture, in foundries and steel works, and for various minor uses. Most of these clays or shales are not worth more than $1 a ton, but the average value of the tonnage so classified in recent years has been much higher, occasionally exceeding $2 a ton. The items that increase the average value are specially prepared clays or shales used for mortar mix and drilling mud that may be worth $8 to $10 a ton. This classification also includes slip clay and a few other relatively high-priced specialities.

HEAVY-CLAY PRODUCTS

Monthly statistics of shipments and employment at brick, tile, and terra-cotta works in the United States indicate an improvement of 15 to 20 percent in production and sales of heavy-clay products in 1939 compared with 1938 but perhaps not enough to equal the 1937 figures.

The Bureau of the Census reports that in 1938 the value of all clay products made in the United States, exclusive of pottery and nonclay refractories, was $117,176,038 compared with $159,008,896 in 1937 and an all-time record of $317,930,245 in 1926. The value of common brick alone declined to $28,373,292 in 1938 from $34,009,775 in 1937, and the quantity decreased to 2,730 million from 3,253.

A brief survey of the structural-clay-products industry was published in 1939 by the Department of Commerce,[15] and a comprehensive review of the entire burned-clay-products field with special emphasis on marketing was issued by the Bureau of Business Research Staff, Ohio State University.[16]

Clay-products manufacturers recently have become increasingly interested in *pH* control as a means of improving the workability, strength, and other properties of their raw materials. This interest is due partly to sales pressure from concerns having for sale materials reputedly superior to the usual sodium compounds employed for *pH* control and partly to an increase in the use of sodium carbonate and sodium chloride for improving the properties of clays that usually require reasonably close *pH* control to give satisfactory results.

On the other hand, deairing appears to be on the wane. Some clay-products plants have discontinued deairing entirely, and others are operating with less vacuum than they originally used.

[16] Chute, A. H., Marketing Burned-clay Products: Ohio State Univ., June 1939, 374 pp.

Figure 2 shows graphically the value of pottery and other clay products produced in the United States, 1920–39, compared with contract awards for construction and indices of industrial production. Figure 3 shows the domestic output of specified heavy-clay products, 1920–38.

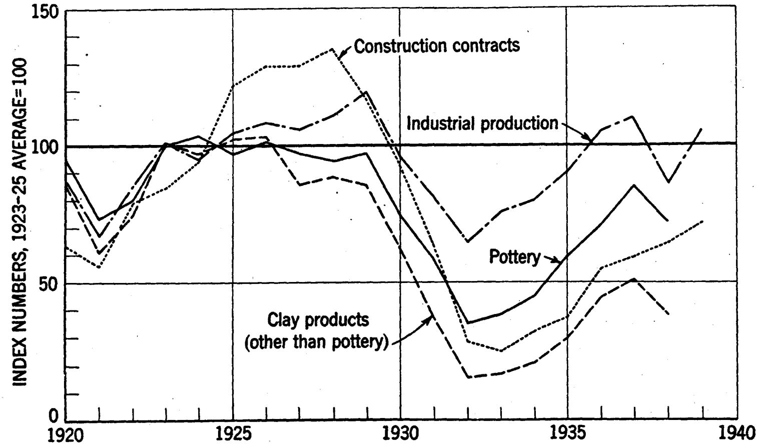

FIGURE 2.—Values of domestic production of pottery and clay products other than pottery compared with construction contract awards and indices of general industrial production, 1920–39. Indexes of industrial production and construction contracts are from the Federal Reserve Board; construction calculated from data of the F. W. Dodge Corporation.

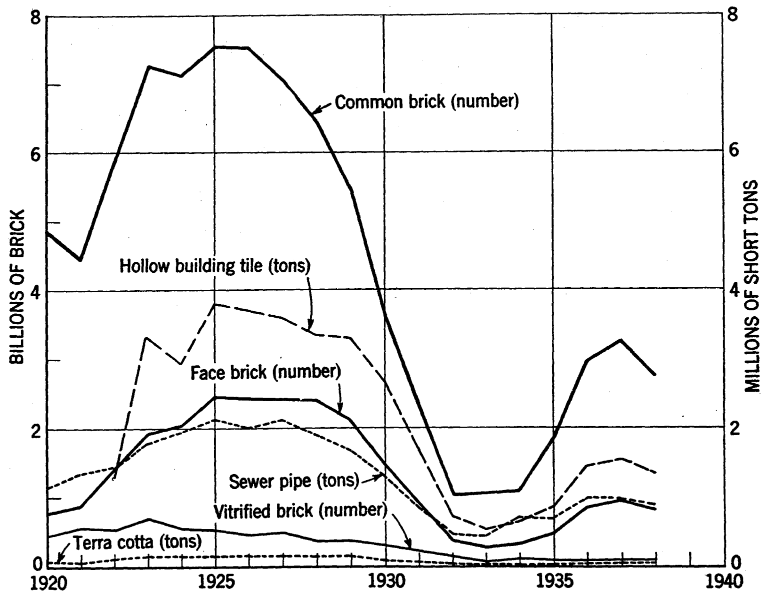

FIGURE 3.—Production of specified heavy-clay products in the United States, 1920–38. Data are from Bureau of the Census.

Light-weight aggregates, weighing only 6¾ pounds to a cubic foot, have been produced in the laboratory from clay, and the manufacture of processed clay products is becoming increasingly important commercially.

On November 15, 1939, application to the Wage and Hour Division of the United States Department of Labor for exemption from the maximum-hour provisions of the Fair Labor Standards Act was granted to brick manufacturers of Maine, New Hampshire, and Vermont because open-air drying yards and scove kilns could not be operated in freezing weather, but it was found that important plants in southern New England manufactured brick throughout the year.

POTTERY [17]

During the last decade the value of the pottery produced in the United States has fluctuated between 40 and 112 million dollars annually. In total value the most important classes are earthenware (so-called semivitreous china type), table and kitchen articles, vitreous china sanitary ware, electrical porcelain, and vitreous china tableware and kitchenware for hotel and restaurant use.

In the 10-year period 1929–38 imports, which are mainly household table and kitchen articles, were about 12 percent of domestic production of all products and about 20 percent of domestic production of tableware and kitchenware only. These percentages are based upon foreign valuations of imports; if based upon values of the imported goods in the United States, imports of table and kitchen articles would correspond to about 40 percent of the domestic output of similar classes.

During the same 10-year period exports, which comprise preponderantly electrical porcelain and sanitary articles, were about 3 percent of production.

Value of production, imports, and exports of pottery in the United States, 1929–39 [1]

Year	Production	Imports [2] (foreign value)	Exports
1929	$112,019,000	$18,538,000	$5,036,000
1931	66,582,000	7,853,000	2,150,000
1933	44,024,000	5,449,000	955,000
1937	97,365,000	9,911,000	2,704,000
1938	82,631,000	6,511,000	2,488,000
1939	(3)	6,736,000	2,668,000

[3] Data not yet available.

CONSUMPTION AND USES

The accompanying tables, which give sales of specified domestic clays by kinds and uses in 1939, continue a series begun in 1921. Figure 4 shows graphically data for total clay used by major uses or industrial groups. These figures, however, do not include imported clays, and, as domestic clays have displaced imported clays to an increasing extent, the data for certain items may exaggerate the apparent gain in consumption. This is especially true for china clay used in hotel china, sanitary ware, electrical porcelain, and other whiteware and in coating paper—the industries in which English

[17] Abstracted from pamphlet of U. S. Tariff Commission, Pottery and Reciprocal Trade Agreement April 1940, 15 pp.

clays have been chiefly used. Minor displacements have taken place in other items, such as clays used for refractories and plotted against iron and steel production in figure 1, but these are probably too small to affect general conclusions. Exports likewise are not large enough to affect most items. Exports of fire clay may represent as much as 10 percent of the clay for refractory uses in some years, but a correction of the figures to show domestic consumption alone would have no perceptible effect on apparent trends. Rubber clays also are exported, but domestic demand is so much larger that variations in

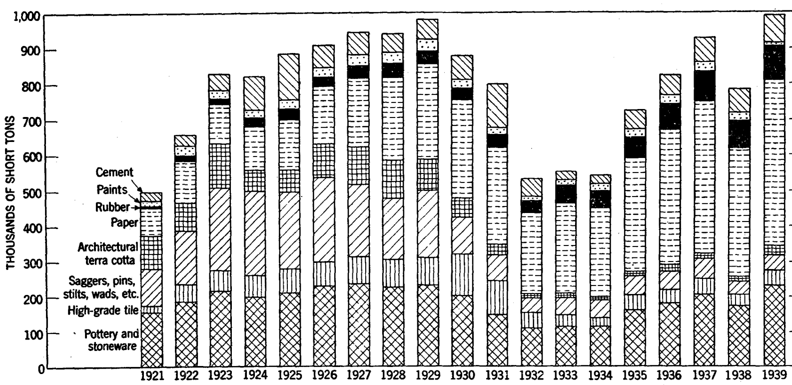

FIGURE 4.—Sales of domestic clay for specified uses, 1921–39.

the percentages of exports would have little effect upon the comparability of figures for different years.

Leading items in the list of miscellaneous uses during the past few years have been oil-well drilling muds, which reached a peak of 171,706 tons in 1937, and filtering clays (essentially type 2 bentonites for acid treatment) which reached a peak in 1939 after fluctuating between 82,000 and 91,000 tons annually during the preceding 5 years.

Sales of fuller's earth are shown in a separate table because the quantities used for uses other than refining oils and fats are relatively small.

ABRASIVE MATERIALS

By Robert W. Metcalf

SUMMARY OUTLINE

The marked recovery of the natural abrasives industry from 1938 levels ran far ahead of the 22-percent increase in general industrial activity and almost matched the 44-percent increase in the automobile industry. The total value of its products rose about 40 percent over 1938, although unit values for the most part declined. Virtually all classes of natural abrasive materials shared the improvement; the rate of increase in values of production in 1939 over 1938 ranged from 35 percent for ground sand and sandstone to nearly 200 percent for millstones. Sales of pumice and pumicite set an all-time record. The value of exports and imports increased 32 and 117 percent, respectively.

The output of crude artificial abrasives showed a small gain in 1939 only because of an increase in steel shot and grit. Shipments of crude silicon carbide and aluminum oxide were smaller in 1939 than in 1938 and much smaller than in 1937, but the tonnages of these items actually consumed in 1939 increased 55 and 56 percent, respectively, over 1938. Stocks of all three classes of crude artificial abrasives were reduced considerably in 1939.

Salient statistics of the abrasives industries in the United States, 1938–39

	1938	1939	Percent of change in 1939
Domestic production (sold or used by producers):			
Natural silica abrasives:			
Diatomite	[1] $1,459,118	(2)	----------
Tripoli	329,081	$466,380	+41.7
Quartz	88,197	153,038	+73.5
Ground sand and sandstone	1,425,445	1,930,301	+35.4
Special silica-stone products:			
Grindstones and pulpstones	240,006	426,375	+77.7
Oilstones and related products	130,277	115,805	−11.1
Millstones	3,743	11,084	+196.1
Flint lining and grinding pebbles	(2)	(2)	----------

Exports	1,075,070	1,415,589	+31.7

[3] Excludes value of diatomite and flint lining and grinding pebbles, which the Bureau of Mines is not at liberty to publish.
[4] Includes some material produced in Canada; Bureau of Mines not at liberty to publish United States data separately.

This chapter includes most of the materials used chiefly as abrasives, although certain oxides, clays, and other substances mentioned later under "Miscellaneous abrasive materials" are not included in the statistics given herein. Some commodities listed as abrasives for which data are presented also have important nonabrasive uses.

Hardness, particle shape, bulking power, and purity are important factors in selection of the proper abrasive for use in soaps and scouring powders. Abrasives used in the soap industry include pumice, pumicite, feldspar, diatomaceous earth, talc, silica, bentonite and other clays, chalk, powdered or dust marble, and sawdust. The properties and suitability of each of these are discussed briefly by Roley.[1] Other ingredients added to soap formulas to aid in keeping the abrasive elements from settling include glue, gelatin, albumen, various carbohydrates, glycerin, petrolatum, sodium alginate, sodium silicate, trisodium phosphate, bentonite, and colloidal kaolin.

Collingridge [2] has discussed the trend in composition of metal polishes; the kinds of abrasives used; and the introduction of and changes in type of other ingredients employed as detergents, emulsifying agents, and mechanical buffers to modify abrasive action, as suspending vehicles, and as coloring or perfuming agents.

Liquid polishes are more in favor now than the once-popular pastes and "putz creams" or pomades; and the older brass polishes, which contained relatively coarse abrasives, have been largely displaced by finer and more carefully graded polishes suitable for chromium, silver, stainless steel, aluminum, and glass. Historically, the trend has been from the earlier tripoli-pumice-oxalic polishes to the diatomite-soap types, thence to ferric oxide and "putz-oil" polishes, and finally to the paraffin-abrasive mixtures and naphtha-soap-abrasive suspensions of the present day.

According to Collingridge [3] the following abrasives have been used in metal polishes: Pumice, emery, diatomite, silica flour, amorphous silica, tripoli, precipitated and prepared chalks or whiting, putty

[1] Roley, Richard J., Abrasives—Their Use in Soaps and Scouring Powders—Their Occurrence and Characteristics: Soap and Sanitary Chemicals, vol. 15, No. 12, December 1939, pp. 24–26, 70; abs. in Canadian Chem. and Process Industries, vol. 24, No. 1, January 1940, p. 16.
[2] Collingridge, George S., Progress in Metal Polishes and Their Raw Materials: Chem. Age (London), vol. 40, No. 1042, June 17, 1939, pp. 448–450.
[3] Collingridge, George S., Work cited in footnote 2.

powder, fuller's earth, china clay, aluminum oxide, chrome oxide, tin oxide, common salt, calcium phosphate, rouges, and heavy magnesium carbonate. The abrasives most used are the silicas and pumicite. Heavy water-base pine-oil polishes require a sharp silica, usually ground quartz. Neutral naphtha-type polishes must use a milder form of silica because they contain nothing to act as a "buffer." Next in popularity to silica flour and pumice as abrasives in metal polishes are tripoli, emery, calcite, and china clay. Precipitated chalk, whiting, rouge, fuller's earth, and diatomite are considered satisfactory for the finer grades of polishes, such as those used for silver and chromium ware. Four leading brands of American silver polishes contained 15 to 19 percent of diatomite as the sole abrasive.

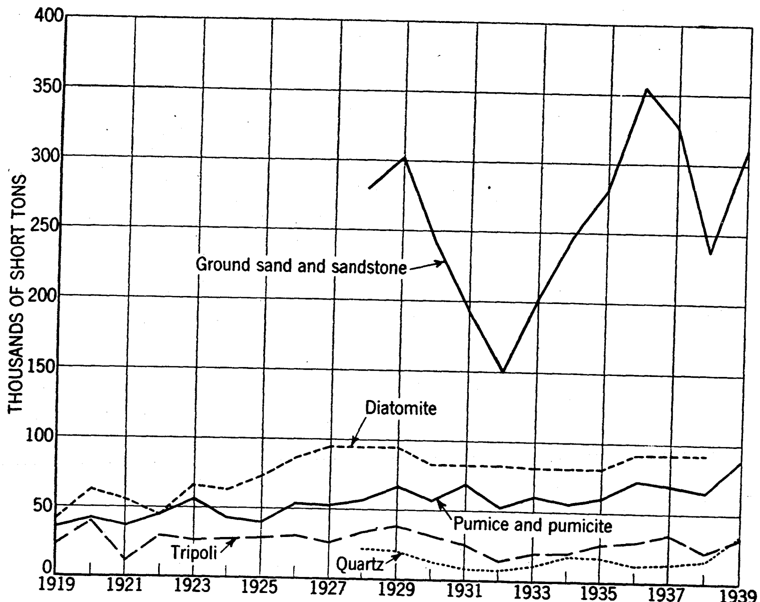

FIGURE 1.—Trends in production of diatomite, tripoli, pumice and pumicite, quartz, and ground sand and sandstone, 1919–39.

The properties of mechanically polished metallic surfaces compared with those of electrolytically polished surfaces were studied by Jacquet.[4] Mechanically polished surfaces show no crystalline properties and, aside from a surficial, probably amorphous layer, have a zone of microcrystals that bear no resemblance to the crystals of the metal. Electrolytic polishing, however, etches the metallic crystal faces and permits study of their properties.

NATURAL SILICA ABRASIVES

Diatomite.—The Bureau of Mines has not been at liberty to publish annual production figures on diatomite since 1926. Production (sales) for 3-year periods, however, may be shown, and these 3-year averages since 1926 are plotted in figure 1. From an all-time peak in 1929

[4] Jacquet, P. A., Comparative Properties of Metallic Surfaces Polished Mechanically and Electrolytically: Jour. Iron and Steel Inst., vol. 136, No. 2, 1937, p. 42A; Ceram. Abs., vol. 18, No. 7, July 1939, p. 169.

sales fell during the following years but totaled 279,645 short tons in the period 1936–38. Sales in 1939, although much higher than in 1938, did not quite equal the 1937 figure.

The principal States producing diatomite are California and Oregon. Other Western States where diatomite was produced in 1939 were Idaho, Nevada, and Washington. Eastern States reporting output of diatomite were Florida, Massachusetts, and New York. Although interest was revived in the Maryland deposits along the Patuxent River, no sales were reported to the Bureau of Mines during 1939. The following table presents such recent data on diatomite sales as the Bureau of Mines may publish.

Diatomite sold or used by producers in the United States, 1933–38 [1]

Year	Short tons	Value	Year	Short tons	Value
1933 / 1934 / 1935	244,342	$3,618,428	1936 / 1937 / 1938	279,645	$4,377,353

[1] Bureau of Mines not at liberty to publish annual figures.

Diatomaceous earths are used principally in polishes and insulation products and as fillers, admixtures, and filter aids. The use of the finely sculptured silica skeletons of diatoms as critical test objects for determining the quality of microscope lenses,[5] although minor, is important to laboratory workers. Uses of diatomaceous earth and patents covering many of its special applications have been listed in the trade press.[6]

The behavior of diatomite as a filter aid was investigated by Carman,[7] who worked with a filter cake of rigid quartz particles and determined that, as with compressible filter cake, increase in permeability after the addition of higher proportions of diatomaceous earth is due solely to the resulting greater porosity of the cake. Efficient filtering action therefore requires that high porosity, the chief property of a filter aid, should not be sacrificed by attempting to obtain high absorptive or high coagulating power.

According to Cummins,[8] the use of diatomaceous earth as a filler in synthetic plastics, a relatively new development, increased nearly 100 percent in 1939 over the average of the previous 4-year period. The material mixes readily with plastic compositions and can be handled satisfactorily in molding operations. It is available as natural or calcined powders of different degrees of fineness and chemical purity. The density of the powder may also be varied, ranging from those that are very light to those of 25 pounds per cubic foot, loose weight. The high resistance to heat, chemical inertness, low moisture absorption, excellent electrical properties, and surface finish imparted by diatomaceous earth make it suitable for use as a filler in many products, including battery boxes, electrical parts, closures, rubber products, parts requiring a good durable surface finish, phonograph records, and sulfur plastics.

Tripoli.—Sales of tripoli (including Pennsylvania rottenstone) in 1939 nearly reached those of 1937; the value of sales, however, was 4 percent higher than in 1937. Sales in 1939 totaled 33,474 short tons valued at $466,380 compared with 22,188 tons worth $329,081 in 1938, an increase over 1938 of 51 percent in tonnage and 42 percent in value. In 1939, as in 1938, tripoli was produced in Arkansas, California, Illinois, Missouri, Oklahoma, and Tennessee. In addition, output was reported from Texas in 1939. Production for many years has centered largely in two small areas—one in Newton County, Mo., and adjacent Ottawa County, Okla., and the other principally in Alexander County, southern Illinois. Pennsylvania produced only rottenstone. Figure 1 shows the trend in sales of tripoli since 1919.

Tripoli (including Pennsylvania rottenstone) sold or used by producers in the United States, 1935–39

Year	Illinois		Other States [1]		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1935	10,001	$113,484	17,374	$269,932	27,375	$383,416
1936	10,981	138,063	17,506	253,815	28,487	391,878
1937	11,647	151,154	23,289	299,416	34,936	450,570
1938	8,141	117,107	14,047	211,974	22,188	329,081
1939	11,134	148,310	22,340	318,070	33,474	466,380

[1] 1935: Arkansas, California, Georgia, Missouri, Oklahoma, and Pennsylvania; 1936: Arkansas, California Missouri, Oklahoma, and Pennsylvania; 1937-38: Arkansas, California, Missouri, Oklahoma, Pennsylvania, and Tennessee; 1939: Arkansas, California, Missouri, Oklahoma, Pennsylvania, Tennessee, and Texas.

Tripoli sold for abrasive uses in 1939 represented 33 percent of the total sales compared with 36 percent in 1938 and 59 percent in 1936. Sales for filler (the second largest use) increased 61 percent over 1938 and were considerably higher than in 1937. Sales of concrete admixture dropped in volume during 1939, but nearly doubled in realization over 1938. Other uses of tripoli include fair-size tonnages for foundry facing and oil-well drilling mud.

Tripoli (including Pennsylvania rottenstone) sold or used by producers in the United States, 1937–39, by uses

Use	1937		1938		1939	
	Short tons	Value	Short tons	Value	Short tons	Value
Abrasives	15,235	$228,373	8,097	$138,807	10,953	$169,370
Concrete admixture	2,126	21,627	2,170	12,634	1,653	24,580
Filler	8,363	108,285	5,584	78,900	9,016	120,284
Other uses [1]	9,212	92,285	6,337	98,740	11,852	152,146
	34,936	450,570	22,188	329,081	33,474	466,380

[1] 1937: Filter block, filtration, foundry facing, oil-well drilling mud, pottery and enameling, and unspecified; 1938: Filter block, foundry facing, and unspecified; and 1939: Foundry facing, oil-well drilling mud, and unspecified.

The Barnsdall Tripoli Corporation, Seneca, Mo., in 1939 replaced its plant, which was destroyed by fire in 1938, with a modern, all-steel 200-ton mill erected at a reported cost of $100,000.[9] Tripoli is obtained from two quarries owned by the company and from purchases in the district.

[9] Pit and Quarry, vol. 31, No. 10, April 1939, p. 23, and vol. 32, No. 7, January 1940, p. 100.

Quartz.—Sales of crude, crushed, and ground quartz from pegmatite deposits, veins, and quartzite beds in 1939 jumped to 34,959 short tons valued at $153,038, an increase of 88 percent in tonnage and 74 percent in value over 1938. The volume of sales was the largest for any year since 1920; however, the average value per ton declined to $4.38 in 1939 compared with $4.74 in 1938 and $5.08 in 1937, continuing a steady downward trend in average realization since 1929 which was broken only in 1934 and 1936. Crude quartz sold or used in 1939 more than tripled, and crushed quartz increased by more than half over 1938. The greater relative importance of sales of crude and crushed quartz in 1939 may be due as much to a growing tendency of consumers to purchase crude or semicrude quartz and grind it with their own equipment as to increased demand from sandpaper manufacturers, metallurgical plants, and other large consumers of the unground product.

Quartz (crude, crushed, and ground)[1] sold or used by producers in the United States, 1935–39

Year	Crude		Crushed		Ground		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1935	[2] 7,586	[2] $26,807	(2)	(2)	9,592	$84,977	17,178	$111,784
1936	[2] 6,281	[2] 24,971	(2)	(2)	6,705	71,621	12,986	96,592
1937	3,252	10,096	5,891	$24,652	3,869	31,293	13,012	66,041
1938	4,493	17,023	9,930	27,941	4,188	43,233	18,611	88,197
1939	13,739	45,785	15,504	49,186	5,716	58,067	34,959	153,038

[1] To avoid duplication, the ground material shown here is only that ground by the original producers of the crude quartz or by grinders who purchase from small miners not reporting their production.
[2] "Crushed" included under "Crude."

Quartz was mined in the same States in 1939 as in 1938, except that no sales were reported from New Hampshire in 1939. All States for which comparisons are available show large increases in sales for 1939 over 1938, especially Arizona-California and North Carolina-Virginia. Other States with consistent production records are Maine, Maryland, New York, Ohio, and Tennessee.

Quartz (crude, crushed, and ground)[1] sold or used by producers in the United States, 1937–39, by States

State	1937		1938		1939	
	Short tons	Value	Short tons	Value	Short tons	Value

[1] California, Missouri, Pennsylvania, Virginia, West Virginia, and Wisconsin.

The largest outlet for sales of ground sand and sandstone for several years has been the pottery, porcelain, and tile industry, which in 1939 absorbed 40 percent of the material reported by the producers according to use (89 percent of the total sales). Cleansing and cleaning preparations and other abrasive use comprised 19 percent, followed by foundry consumption with 17 percent. Sizable tonnages also are consumed in enamel manufacture and for fillers.

Ground sand and sandstone sold or used by producers in the United States in 1939, by uses [1]

Use	Short tons	Value	
		Total	Average per ton
Abrasive:			
Cleansing and scouring compound	52,942	$276,468	$5.22
Other	958	5,790	6.04
Enamel	10,416	57,256	5.50
Filler	5,071	36,797	7.26
Foundry	46,546	269,300	5.79
Glass	1,696	9,075	5.35
Pottery, porcelain, and tile	109,417	730,601	6.68
Other uses	48,380	320,596	6.63
Total reported by uses	275,426	1,705,883	6.19

[1] Data represent 89 percent of the industry.

Abrasive sand.—Abrasive sands have a high silica content and include all natural sands used for abrasive purposes, such as sawing stone, grinding glass, sandpaper manufacture, and sandblasting. Sales dropped sharply in 1938 to 502,328 short tons valued at $754,805 compared with 1,067,178 tons valued at $1,440,736 in 1937. Included in the total for 1938, and undoubtedly contributing largely to the 11-percent increase in average value per ton, were 205,753 tons of blast sand valued at $509,178. Statistics for abrasive sand in 1939 are shown under the classification "grinding and polishing sand" in the chapter on Sand and Gravel in this volume.

SPECIAL SILICA-STONE PRODUCTS

Grindstones and pulpstones.—The total sales value of grindstones and pulpstones made from quarried stone rose in 1939 to $426,375, an increase of $186,369 over 1938. Sales of grindstones increased 70 percent in tonnage and 73 percent in value over 1938, and pulpstones 62 and 86 percent, respectively. Grindstones were quarried in Ohio and West Virginia and pulpstones in Washington and West Virginia in 1939.

Grindstones and pulpstones sold by producers in the United States, 1935–39

Year	Grindstones		Pulpstones		
			Quantity		Value
	Short tons	Value	Pieces	Equivalent short tons	
1935	11,476	$342,864	948	3,111	$162,514
1936	10,703	334,363	685	2,472	163,634
1937	11,617	352,377	761	2,924	220,331
1938	4,653	149,019	417	1,553	90,987
1939	7,917	257,350	672	2,517	169,025

Oilstones and related products.—Sales of natural sharpening stones of various types, including oilstones, whetstones, hones, scythestones, and rubbing stones, were 21 percent higher than in 1938 but were lower than in 1936 and 1937 by a substantial margin. Various States contributed to the total as follows: Arkansas, oilstones and whetstones; Indiana, rubbing stones; New Hampshire, scythestones; Ohio, whetstones, scythestones, lathestones, and holystones.

Oilstones and other whetstones, hones, scythestones, and rubbing stones sold by producers in the United States, 1935–39

Year	Short tons	Value	Year	Short tons	Value
1935	439	$105,589	1938	511	$130,277
1936	752	121,196	1939	620	115,805
1937	810	112,841			

Millstones.—The value of sales of millstones, chasers, and dragstones in 1939 was $11,084—more than triple the low established in 1938. Although this value is the highest since 1930, it is much below the levels of the preceding 50 years. New York, North Carolina, and Virginia were the only States from which millstones were obtained in 1939; no output from North Carolina was reported from 1936 to 1938. In 1939 millstones were produced in the following localities: Ulster County, N. Y. (the "Esopus" stone from the Shawangunk conglomerate); Brush Mountain, Montgomery County, Va. (supplying a fine-grain quartzite known as "Brush Mountain" stone); and Rowan County, N. C., near Salisbury (furnishing granite millstones).

Value of millstones, chasers, and dragstones sold by producers in the United States, 1935–39

Year	New York		Other States [1]		Total	
	Producers	Value	Producers	Value	Producers	Value
1935	8	$4,645	3	$4,885	11	$9,530
1936	6	5,458	3	5,151	9	10,609
1937	6	(2)	2	(2)	8	8,305

[2] Bureau of Mines not at liberty to publish figures.

Flint lining and grinding pebbles.—Although steel balls have largely replaced flint pebbles in grinding ores and other materials, a moderate continuous domestic demand for noncontaminating grinding and lining mediums for pulverizing ceramic raw materials in which a minimum of iron is essential has been supplied partly by one or two domestic producers and partly by imports.

Production of domestic flint liners nearly doubled in 1939 but was still considerably below the 1937 level. The average value per ton also increased. In 1939, as in recent years, the only supplier of domestic mill liners in the United States known to the Bureau of Mines was the Jasper Stone Co., Sioux City, Iowa. The material used is quartzite obtained near Jasper, Minn. Sales of quartzite grinding pebbles by this company in 1939 doubled in volume and increased somewhat in average value compared with 1938; they topped 1937 shipments by a wide margin. The King Solomon Mines Co., Black Bear (near Yreka), Calif., again reported the use of local granite pebbles in ball mills at its gold mill.

Flint liners have been imported largely from Belgium, whereas flint grinding pebbles are imported largely from Denmark and France, although at one time a fair supply was obtained from crude chalk formerly imported in considerable quantities for grinding into whiting. Importations under the classification of "flint, flints, and flint stones unground" were larger in 1939 than in 1938, but shipping and production difficulties occasioned by the present war may curtail future receipts. In addition to the quartzite pebbles and liners quarried by the Jasper Stone Co., near Jasper, Minn., small quantities of true flints were also recovered in former years at Encinitas Beach near San Diego, Calif. Certain companies have utilized pebbles of quartzose ore, granite, or other local rock, and it seems possible that some such natural or artificially rounded material may provide satisfactory substitutes for imported grinding pebbles.

NATURAL SILICATE ABRASIVES

Pumice and pumicite.—Sales of pumice and pumicite in 1939 totaled 89,159 short tons valued at $424,780, a 36-percent rise in both tonnage and value over 1938. The 1939 sales set an all-time high both in tonnage and value; the tonnage was 22 percent greater than in 1936 (72,915 short tons), the previous record year, while the total value was 20 percent greater than in 1929 ($353,064), hitherto the record year in sales realization.

Pumice and pumicite sold or used by producers in the United States, 1935–39

Year	Short tons	Value	Year	Short tons	Value
1935	60,000	$247,076	1938	65,742	$312,886
1936	72,915	328,406	1939	89,159	424,780
1937	71,007	301,936			

Production of pumice in 1939 was reported in California, Kansas, Nebraska, New Mexico, Oklahoma, and Oregon, and that of pumicite or volcanic ash in Kansas, Nebraska, Nevada, and Oklahoma.

Consumption of pumice and pumicite showed large gains for all uses. Cleansing and scouring compounds and hand soaps, still by far the most important outlet, increased consumption to 52,521 short tons, a 12-percent gain over 1938. Sales for concrete admixture and concrete aggregate expanded to 20,719 tons, nearly 175 percent above 1938 and about 50 percent over 1936 and 1937. Sales for acoustic plaster were 77 percent higher than in 1938. (See fig. 2.)

Pumice and pumicite sold or used by producers in the United States, 1937–39, by uses

Use	1937		1938		1939	
	Short tons	Value	Short tons	Value	Short tons	Value
Abrasive:						
Cleansing and scouring compounds and hand soaps	48,608	$193,559	47,013	$188,807	52,521	$227,447
Other abrasive uses	1,442	17,369	938	8,499	(1)	(1)
Acoustic plaster	3,641	54,459	3,080	54,055	5,444	97,181
Concrete admixture and concrete aggregate	13,839	23,650	7,596	18,297	20,719	24,852
Other uses [2]	3,477	12,899	7,115	43,228	10,475	75,300
	71,007	301,936	65,742	312,886	89,159	424,780

1 Included under "Other uses."
2 1937: Asphalt, grading roads, chicken litter, filtering, rock gardens and landscaping, building tiles, floor sweep, and some unspecified uses; 1938: Asphalt, filtering, rock gardens and landscaping, building tiles, and some unspecified uses; 1939: Asphalt, heat or cold insulation, or other abrasive use, insecticide, building tile and blocks, roofing, stucco, and unspecified uses.

Nordberg [10] described the use of lightweight concrete "Basalite" units made from California pumice for residential construction. Pumice also was utilized for acoustical veneer in the walls and for shingles. Trauffer [11] described the pumicite plant of the California Industrial Minerals Co., Friant, Calif., giving a detailed account of

the recovery and processing of this material. The Calsilco Corporation is said to have installed a four-roll Williams mill to prepare pumicite from a new deposit about 40 miles north of Mojave, Calif., for acoustic plaster and insulation material.[12] The Barnsdall Tripoli Corporation also has installed new equipment, including a 6-foot

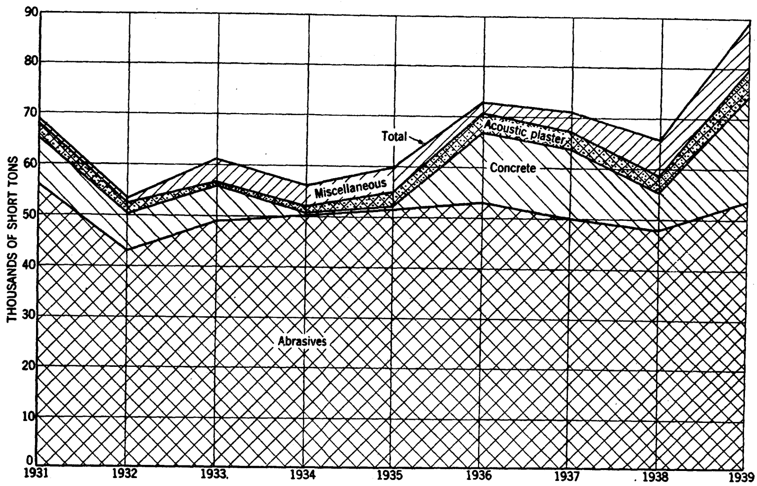

FIGURE 2.—Trend, by uses, of pumice and pumicite sold or used by producers in the United States, 1931–39.

North Creek, Warren County, N. Y.; Davenport Garnet Co., South Danbury, Merrimack County, N. H.; and Celo Mines, Inc., Burnsville, Yancey County, N. C., reported sales during the year. The mines of the Warren County Garnet Mills, Wevertown, N. Y., were idle. Total sales include a small tonnage of combined quartz and garnet produced and sold by the Green Mountain Mica Corporation, Gassett, Windsor County, Vt., for use as an abrasive in sawing marble. No imports of garnet were reported for 1939.

Abrasive garnet sold or used by producers in the United States, 1935–39

Year	Short tons	Value	Year	Short tons	Value
1935	3,060	$256,520	1938	2,669	$191,658
1936	3,820	315,913	1939	4,056	278,534
1937	4,863	382,535			

NATURAL ALUMINA ABRASIVES

Corundum.—No corundum has been mined in the United States in recent years. Imports of corundum ore, largely from the Union of South Africa, totaled 1,964 short tons valued at $104,724, slightly less in tonnage than in 1938 and 1937 and nearly one-fourth less in value. Most of the corundum and emery is imported crude and crushed and graded in this country for domestic consumption. Newly discovered deposits of corundum and garnet are reported in the Union of South Africa.[15]

Emery.—Sales of emery in 1939 were 765 short tons valued at $6,828, the highest in any year since 1933. No sales of domestic emery were made in 1938. Four producers were active in 1939 in the emery district near Peekskill, Westchester County, N. Y., the only locality reporting production in recent years. From the property formerly mined by Smith & Ellis, operated by Gaetano DiRubbo during the first part of 1939 and by the partnership of DiRubbo & Ellis the latter part of the year, shipments were made to the Hamilton Emery & Corundum Co., Chester, Mass. DiRubbo also shipped a carload from another location to the same mill. Joe DeLuca shipped 2 carloads of emery to the Washington Mills Emery Manufacturing Co., North Grafton, Mass., from two locations, one of which was the McCoy mine, well-known as a producer of high-grade emery in former years. The Howard Emery Corporation also mined and sold emery during the year.

Emery sold or used by producers in the United States, 1935–39

Year	Short tons	Value	Year	Short tons	Value
1935	176	$1,606	1938	----------	----------
1936	325	2,900	1939	765	$6,828
1937	320	2,780			

[15] Consul General H. Earle Russell, Johannesburg, November 17, 1938, reported in Bureau of Mines Mineral Trade Notes, vol. 8, No. 2, January 20, 1939, p. 30.

Discovery of an emery vein 50 feet wide and nearly a mile long about 3 miles south of Peekskill was reported by Zodac.[16] The outcrop at one point is 60 feet wide and 30 feet high, and a short distance away it is 60 feet wide and 15 feet high. This is the first large vein located in the Peekskill district where, until the recent discovery of underground veins,[17] all deposits were held to be comparatively small, scattered surface occurrences.

Figure 4 shows trends in domestic sales and imports of emery and corundum since 1924.

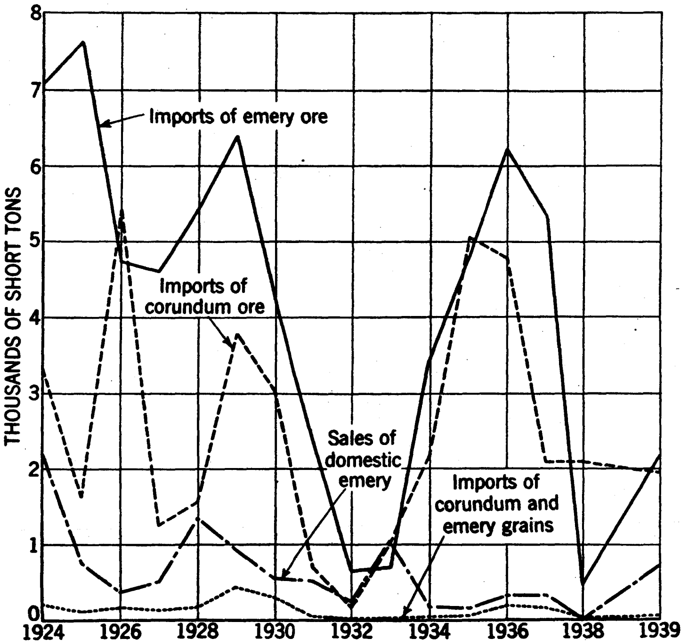

FIGURE 4.—Comparison of sales of domestic emery with imports of emery and corundum in the United States, 1924–39.

NATURAL CARBON ABRASIVES

Abrasive or industrial diamond.—World production of diamonds in 1939, as in 1938, approximated 11 million metric carats, but notwithstanding firmer prices the value of the output declined to about 40 million dollars owing to the larger proportion of industrial stones.

The demand for industrial or abrasive diamonds in the United States is supplied entirely by imports of black diamonds (carbonados), largely from Brazil, and bort, chiefly from the Union of South Africa. The total value of imports of abrasive diamonds in 1939 increased $5,468,875 to $9,764,579. Imports of "glaziers' and engravers', unset, and miners'" diamonds, by far the most important classification, rose

[17] Zodac, Peter, New Emery Strike in Peekskill: Rocks and Minerals, vol. 12, No. 12, December 1937, pp. 372–374.

to 3,568,730 carats worth $9,725,683, more than twice the quantity and value reported for 1938 and 89 percent greater in quantity and 49 percent greater in value than 1937 receipts. Imports of bort increased 20 percent in quantity and 80 percent in value. The average value of bort in 1939 rose sharply to $25.07 a carat compared with $16.67 in 1938, although the average value of "glaziers, and engravers', unset, and miners'" diamonds declined to $2.73 a carat from $3.02 in 1938 and $3.47 in 1937.

The substitution of borts for carbonados and the use of smaller and smaller diamonds for industrial purposes continues. One innovation is the employment of beryllium-copper, under the trade name Vankolite, for cast-setting diamond core bits and reaming shells. Drill bits using this tougher and harder metal have increased tensile strength and improved qualities owing to the close bond between the metal and the diamonds. Before the advent of mechanical setting methods diamonds had to be placed in the crown laboriously by hand. The newer technique permits proper spacing of several hundred small stones over a comparatively small circular area at negligible cost.

It is claimed that small borts would be preferable to large stones, even if they were more expensive, as small crystals are said to be sounder and harder than large ones. A typical drilling bit contains 178 stones having an aggregate weight of 7 carats or, roughly, 25 stones to a carat. Abrasive wheels are now made by adding even smaller diamonds to powdered metal or bonded compositions and sintering to a solid mass. Because of the wider use of the extremely hard alloys that are difficult to shape, diamond-bearing tools and grinding wheels are much more in demand. Weslow [18] describes the use of a tungsten carbide and cobalt matrix impregnated with bort diamonds for drilling crowns.

In the South African fields high-intensity magnetic separators were introduced early in 1939 to remove garnet and other feebly magnetic minerals from the gravity concentrates, thereby facilitating subsequent treatment on grease tables.

ARTIFICIAL ABRASIVES

Owing to a 63-percent gain in sales of metallic abrasives in 1939, the artificial-abrasives industry increased its total sales to 116,689 short tons valued at $6,504,403, a gain in tonnage of 12 percent and in value of 4 percent over 1938. Production of both silicon carbide and aluminum oxide, however, showed small declines in 1939 compared with 1938.

[1] Bureau of Mines not at liberty to publish data for United States separately.
[2] Includes also material used for refractories and other nonabrasive uses.
[3] Includes value of some grain.
[4] Production.

Production of silicon carbide in the United States centers in the Niagara Falls region in New York and that of aluminum oxide in the Niagara Falls region and at Anniston, Ala. Metallic abrasives are manufactured in several Northern States from New Hampshire to Michigan.

Since 1937 producers of silicon carbide and aluminum oxide have been requested to indicate the approximate percentages of their products consumed for refractory or other nonabrasive uses. Estimates based upon these percentages indicate that about 29 percent of the output of silicon carbide in 1937 was employed for nonabrasive purposes, about 26 percent in 1938, and about 29 percent in 1939; about 4 percent of the output of aluminum oxide in each year was used for nonabrasive purposes.

MISCELLANEOUS ABRASIVE MATERIALS

Besides the materials already discussed many others have abrasive uses. Several oxides, including tin oxide, ferric oxide in the form of rouge and crocus, chromium oxide, magnesium oxide, manganese oxide, and lime, as well as clay, talc, and whiting are used as polishing agents. Silt, clay, and feldspar and other mineral substances also are used as abrasives.

FOREIGN TRADE [11]

The increased consumption of smaller diamonds for industrial uses, chiefly as a result of more efficient drilling made possible with the mechanical, cast-set, and diamond-impregnating methods of preparing drilling and grinding agents is reflected in the much larger imports of diamonds in the last 2 or 3 years, particularly of "glaziers' and engravers', unset, and miners'" diamonds which constitute by far the greater part of the total value of abrasive materials imported.

[11] Figures on exports and imports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Imports of most types of abrasive materials increased in volume, although receipts of hones, oilstones and whetstones, corundum ore, tripoli and rottenstone, and diamond dust decreased. Imports of tripoli and rottenstone were the lowest since the present classification (excluding diatomaceous earth) was adopted in 1930.

Abrasive materials imported for consumption in the United States, 1937–39, by kinds

Kind	1937		1938		1939

[1] Less than 1 ton. [2] Emery included with corundum; not separately classified.
[3] 3,276 reams in 1937; 2,205 reams in 1938, 2,479 reams in 1939; weight not recorded.
[4] Quantity not recorded.

The value of exports of natural abrasive materials in 1939 rose 32 percent over 1938 to $1,415,589; all classes of abrasives shared in the upturn. Although the value of exports of grindstones increased 41 percent, the largest absolute gain in value was in the classification, "all other natural abrasives," which increased to $1,116,711, $280,817 more than in 1938 and 35 percent higher than in 1937. Both grindstones and abrasive wheels (emery and corundum) showed lower values in 1939 than in 1937, the highest year since 1930.

Value of domestic abrasive materials exported from the United States, 1935–39

SULFUR AND PYRITES

By ROBERT H. RIDGWAY AND A. W. MITCHELL [1]

SUMMARY OUTLINE

World production of sulfur declined further in 1939 despite war in Europe and improved business conditions in the United States. World markets are supplied largely from American and Italian mines, and in both countries output was at a lower level than in the preceding year. Italian production, which was relatively low during the early months of the year owing to fires in the Sicilian mines, did not meet the planned program for the fiscal year. Although the Italians encountered further American competition in world markets, stocks of mined sulfur in Italy at midyear reached a new low for this century. The controlling provisions of the international agreement between the Sulphur Export Corporation (American) and the Central Sulfur Sales Bureau (Italian) is inoperative because of war conditions. Spain, Japan, and Norway were the largest producers of pyrites in 1939; but operations in Spain, the largest source, were hampered by the civil war. Of interest in 1939 was the large increase in production and exports of pyrites from Canada.

The domestic sulfur industry reacted to the stimulus of unprecedented expansion of the domestic industry during the last quarter of 1939. This improvement in business conditions, which coincided with the outbreak of war in Europe, was felt in both the domestic and foreign sulfur markets; but as the change came near the end of the year, its effect on the sulfur industry was demonstrated to a greater extent in the rate of shipments rather than in the rate of production. This was due partly to large producers' stocks and partly to the method of extracting sulfur, which is not readily susceptible to change conforming to the market pattern. Thus, although shipments in 1939 increased one-third over 1938, production dropped 13 percent. Most of the increase in shipments went to domestic consumers; but, even though exports of sulfur were only slightly higher in 1939 than in 1938, there was a substantial increase in our foreign business after hostilities were begun abroad. Domestic production for the first three-quarters of 1939 held at the lower rate reached during the latter half of 1938, but in the last quarter there was a sizable increase.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

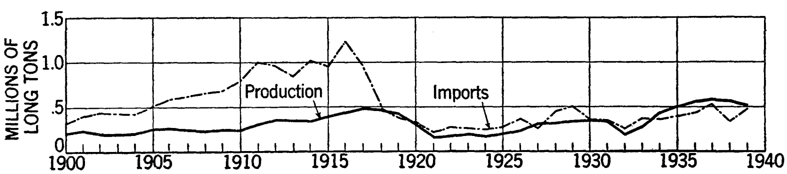

FIGURE 2.—Domestic production and imports of pyrites, 1900–1939.

In connection with its studies on the concentration of economic power the Temporary National Economic Committee held hearings on the sulfur industry on March 14, 1939.[2] During the year the United States Department of Justice, with the full cooperation of the two leading sulfur companies, conducted an investigation of the sulfur industry in connection with its general inquiry into fertilizers and their constituent ingredients. Early in 1940 the Department announced "that in view of certain commitments made by the two principal domestic sulfur companies, the public interest requires no prosecution by the Antitrust Division in the sulfur industry at this time."

[2] Temporary National Economic Committee Hearings; Part 5. Investigation of Concentration of Economic Power: Washington, 1939, pp. 1983–2009, 2200–2275.

The production of native sulfur in the United States up to and including 1939 has totaled more than 45 million long tons. Virtually the entire output has been produced since 1900. The principal trends in the sulfur and pyrites industries are shown in figures 1 and 2.

SULFUR

Domestic production.—Production of sulfur in the United States in 1939 decreased 13 percent from 1938; however, shipments from the mines increased 37 percent over 1938, were only 9 percent below the record total in 1937, and were the third largest of record. About a hundred tons of sulfur-bearing ore used for agricultural purposes were produced in 1939 but are not included in the total for 1939. None of this material was reported in 1938.

Sulfur produced and shipped in the United States, 1935–39

Year	Produced (long tons)	Shipped		Year	Produced (long tons)	Shipped	
		Long tons	Approximate value			Long tons	Approximate value
1935	1,632,590	1,634,990	$29,300,000	1938	2,393,408	1,628,847	$27,300,000
1936	2,016,338	1,968,820	35,400,000	1939	2,090,979	2,233,817	35,500,000
1937	2,741,970	2,466,512	44,300,000				

Eighty percent of the domestic output of sulfur reported for 1939 came from Texas and the remainder principally from Louisiana. California and Utah produced only 2,979 long tons. Thus the first two States produced more than 99 percent of the domestic output. Active mines in 1939 are listed in the following table.

Mines that produced sulfur in the United States in 1939

Operating company	Name of mine	Location of mine
California: Various companies	Crater Group	Bigpine, Inyo County.
	Gulch Group	Do.
Louisiana: Freeport Sulphur Co.	Grande Ecaille	Port Sulphur, Plaquemines Parish.
Texas:

Recovery as byproduct.—Treatment of copper and zinc ores yields large quantities of sulfur, which is recovered at the mills as a pyrites concentrate or at the smelters as sulfuric acid. Production of pyrites concentrate is discussed in the pyrites section of this report. In the smelting of copper and zinc concentrates, sulfur is driven off as sulfur dioxide gas, which is used at many smelters in the manufacture of sulfuric acid. The equivalent of about 155,000 long tons of sulfur was recovered as sulfuric acid annually from this source during the 5 years ended in 1938. Such sulfur is not included in the sulfur-production figures for the United States, but the following table shows the output of byproduct acid at both copper- and zinc-smelting plants. The acid reported is only that made from the sulfur content of sulfide ores but does include the relatively small amount of acid made from pyrites concentrate in Wisconsin.

Byproduct sulfuric acid (expressed as 60° B.) produced at copper and zinc plants in the United States, 1934–38, in short tons [1]

	1934	1935	1936	1937	1938
Copper plants	168,676	160,151	226,738	[2] 291,638	[2] 220,297
Zinc plants	406,984	443,476	505,882	542,356	466,879
	575,660	603,627	732,620	[2] 833,994	[2] 687,176

[1] Figures for 1939 not yet available.
[2] Includes a small amount of sulfuric acid produced as a byproduct in the roasting of high-sulfide gold and silver concentrates.

Purification of manufactured gases—that is, the removal of hydrogen sulfide—has long been accomplished by passing the gases through trays of iron hydroxide, which resulted in the formation of iron sulfide, known as spent oxide. Although this material has been used as a source of sulfur in Europe, it has not been to any great extent a source of sulfur in the United States and has been discarded. During the last decade, however, the removal and recovery of sulfur as a useful byproduct from coke-oven gas, water gas, refinery-still gas, natural gas, and other fuel gases have been expanding in this country as a result of developments in various liquid-purification processes. All such processes are not designed to permit recovery of sulfur as a byproduct, but those that do may be divided into two classes, those that recover elemental sulfur and those that give hydrogen sulfide as an end product. The latter has received increasing attention in recent years. Typically, processes that recover elemental sulfur operate on manufactured fuel gases, while those that recover hydrogen sulfide are applied to refinery-still gas and natural gas, and usually these gases are under high pressure. However, investigation has indicated that the phenolate process, at least, is adapted to the removal and recovery of sulfur from low-pressure, low-sulfur gases,[3] such as coke-oven gas, and commercial application to such gases may be made in the near future.

Most of the elemental sulfur recovered from gas purification results from operations using the Thylox process; only relatively minor amounts are recovered from Ferrox-process or Nickel-process operations. Production in 1939 (reduced to 100-percent sulfur) totaled 4,307 long tons, of which 3,144 tons valued at $115,000 was shipped. Output came from Illinois, Maryland, Missouri, New Jersey, New York, Washington, West Virginia, and Wisconsin, with New York the principal producer. The sulfur is produced and marketed either as a paste containing 30- to 57-percent sulfur or as dried, relatively pure sulfur. The fine particle size of the sulfur makes it valuable as a fungicide and insecticide for agricultural purposes, which absorb most of the shipments; some has been exported for such use. Of the 1939 shipments, 1,740 tons was in the form of paste and the remainder dried sulfur.

The hydrogen sulfide gas resulting as the end product in the second class of sulfur recovery is converted to sulfuric acid or burned for

[3] Powell, Alfred R., Recovery of Sulfur from Fuel Gases: Ind. Eng. Chem., vol. 31, No. 7, July 1939, p. 795.

fuel. The hydrogen sulfide recovered as a source of sulfur in 1939 came from plants using the phenolate and phosphate processes, while that recovered by the Girbotol process is wasted or burned as fuel. In 1939 the output of sulfur in the form of hydrogen sulfide, which was sold or used in the manufacture of sulfuric acid, was 13,000 long tons and came from California, Indiana, and Pennsylvania.

The figures on the byproduct yield of sulfur from gas purification are not included in the sulfur-production figures for the United States.

Stocks.—As shipments exceeded production in 1939, stocks at the mines decreased during the year. Such stocks, however, are still large and on December 31 totaled 4,000,000 long tons.

Price.—Sulfur is not quoted on any commodity exchange, and the sellers issue no list prices or statements of similar character; however, the average quoted contract price for sulfur as reported by trade journals was unchanged at $16 a ton f. o. b. mines throughout 1939. The ex-vessel quotation along the Atlantic seaboard was $20.50 a long ton. According to the Department of Justice actual prices for various grades, as shown by sales invoices, were substantially lower. Higher prices in foreign markets show the result of increased transportation costs.

Consumption.—The apparent domestic consumption of sulfur in 1939 increased 53 percent over 1938 but was 10 percent below the record level in 1937.

Apparent consumption of sulfur in the United States, 1935–39, in long tons

	1935	1936	1937	1938	1939
Shipments	1,634,990	1,968,820	2,466,512	1,628,847	2,233,817
Imports	1,978	729	628	2,603	13,976
	1,636,968	1,969,549	2,467,140	1,631,450	2,247,793
Exports:

Refined	10,916	19,708	13,533	12,707	25,005
	413,299	566,907	688,830	591,814	652,824
Apparent consumption	[1] 1,223,669	[1] 1,402,642	[1] 1,778,310	[1] 1,039,636	1,594,969

[1] Revised figures.

The consumption of sulfur in various industries from 1935 through 1939 has been estimated by Chemical and Metallurgical Engineering as follows:

Sulfur consumed in the United States, 1935–39, by uses, in long tons [1]

Use	1935	1936	1937	1938	1939
Chemicals	555,000	620,000	777,000	484,000	695,000
Fertilizer and insecticides	239,000	266,000	415,000	220,000	370,000
Pulp and paper	204,000	260,000	302,000	174,000	240,000
Explosives	42,000	53,000	68,000	50,000	64,000
Dyes and coal-tar products	39,000	46,000	49,000	40,000	40,000
Rubber	33,000	39,000	37,000	29,000	49,000
Paint and varnish	48,000	54,000	64,000	50,000	49,000
Food products	4,000	4,500	6,000	5,500	6,000
Miscellaneous	68,500	78,000	82,000	47,500	82,000
	1,232,500	1,420,500	1,800,000	1,100,000	1,595,000

[1] Figures for 1937 and 1938 are not truly representative of consumption but rather of shipments to these specified industries. In 1938 consumers carried over large stocks from 1937, so that actual consumption in 1937 was less than the figures indicate and consumption in 1938 was larger than the above total.

Production of sulfuric acid, the chief use of sulfur in the United States, rose in 1939 owing to increased industrial activity during the latter half of the year. Consumption of acid by the largest consumers, the fertilizer and petroleum-refining industries, increased moderately (about 10 percent) over 1938. Production of superphosphate was up moderately in 1939 accounting for the increased consumption of acid in fertilizers. The Tennessee Valley Authority continued its work on calcium metaphosphate, and operation of the first full-size unit was continued during part of the year. The plant yielded a product containing about 60 percent P_2O_5. The unit uses lump rock phosphate, or agglomerated fines, and phosphorus condensed from electric furnace gases. A second process that has been carried through the pilot-plant stage uses phosphate fines instead of prepared agglomerates or the less available rock. Continued progress is being made in the use of electric furnaces in supplying phosphorus for phosphate fertilizers.[4] During 1939 activities in the petroleum-refining industry the second largest consumer of sulfuric acid, increased about 6 percent over 1938 and explained some of the increase in consumption of acid. Use of the alkalation process, which employs sulfuric acid as a catalyst, may reverse the long-time trend toward reduction of requirements in the refining industry. On the other hand, through application of reversible absorbents, the hydrogen sulfide removed in the purification of oil refinery products is being recovered and converted to sulfuric acid. Continued increase in output of titanium dioxide accounted for a large increase in the use of acid in paints and pigments.

Chemical and Metallurgical Engineering has estimated the consumption of sulfuric acid, by industries, from 1935 through 1939 as follows:

Sulfuric acid (expressed as 50° B.) consumed in the United States, 1935–39, by industries, in short tons

Industry	1935	1936	1937	1938	1939
Fertilizer	1,720,000	1,987,000	2,230,000	1,920,000	2,100,000
Petroleum refining	980,000	1,100,000	1,100,000	1,100,000	1,210,000
Chemicals	940,000	955,000	1,020,000	800,000	975,000
Coal products	625,000	770,000	865,000	585,000	740,000
Iron and steel	630,000	770,000	1,100,000	590,000	980,000
Other metallurgical	520,000	560,000	625,000	350,000	570,000
Paints and pigments	400,000	450,000	525,000	430,000	500,000
Explosives	175,000	222,000	180,000	140,000	190,000
Rayon and cellulose film	303,000	330,000	380,000	318,000	400,000
Textiles	90,000	108,000	112,000	90,000	116,000
Miscellaneous	342,000	380,000	450,000	355,000	400,000
	6,725,000	7,632,000	8,587,000	6,678,000	8,181,000

Foreign trade.—Exports of crude sulfur in 1939 were 8 percent above those in 1938 and, except for 1937, the largest since 1929. Exports of treated sulfur in 1939, while relatively minor, were nearly double the 1938 figure. Movement was slow during the first half of the year, but there was a substantial rise during the closing months.

Imports, though small, were higher in 1939 and were received in the Northwestern States from Canada.

Shipments to Canada, normally the principal market for American crude sulfur, showed the largest quantitative increase, while those to Germany, formerly a large market, dropped to only 8,702 long tons. Australia and the United Kingdom again were large takers of American sulfur. Noticeable in 1939 was the large movement of refined sulfur to Greece, which purchased more than any other nation. The foregoing table shows the distribution of exports by countries of destination for 1938 and 1939.

THE INDUSTRY IN 1939, BY STATES

California.—Several operators, all in Inyo County, reported production in 1939. The output consisted of relatively pure sulfur and concentrates containing about 85 percent sulfur. The largest output came from the Crater Group of claims.

The sulfur deposits in Inyo County have been described by Lynton.[5]

Louisiana.—Production of sulfur in Louisiana in 1939 totaled 422,600 long tons and was made by the Freeport Sulphur Co. from its operations at Grande Ecaille, Plaquemines Parish.

Texas.—Texas supplied 80 percent of the domestic sulfur output in 1939. Five operations contributed to the total, but by far the largest output came from the Boling Dome property of the Texas Gulf Sulphur Co. The following table, compiled from information issued by the Texas State Comptroller's Office, shows the quarterly production of sulfur in Texas for 1939.

Sulfur produced in Texas in 1939, by companies, in long tons

Company	First quarter	Second quarter	Third quarter	Fourth quarter	Total
Texas Gulf Sulphur Co.	200,210	152,191	146,123	319,799	818,323
Freeport Sulphur Co.	89,790	95,030	91,565	91,970	368,355
Duval Texas Sulphur Co.	59,800	72,080	81,129	58,122	271,131
Jefferson Lake Oil Co., Inc.	55,463	38,519	53,838	60,156	207,976
	405,263	357,820	372,655	530,047	1,665,785

The Freeport Sulphur Co., the second largest producer, continued operations at Hoskins Mound. Output at Clemens Dome, Brazoria County, which was begun in 1937 by the Jefferson Lake Oil Co., Inc., continued in 1939 but at a lower rate than in 1938. This company explored, by drilling, certain leases on Long Point Dome during the year but was unsuccessful in developing commercial quantities of sulfur. The Duval Texas Sulphur Co. continued production at Orchard Dome, Fort Bend County, and at Boling Dome, Wharton County.

Utah.—Sulfur production in Utah in 1939 came from the Utah Sulphur Industries plant at Beaver, Beaver County.

WORLD PRODUCTION

World production of sulfur in 1939, including elemental sulfur recovered in the treatment of pyrites and as a byproduct from the treatment of gas and gasoline in Germany, is estimated at 2,900,000 long tons. The following table shows the output of native sulfur for the world from 1935 through 1939.

[5] Lynton, Edward D., Sulfur Deposits of Inyo County, Calif.: California Jour. Mines and Geol. Division of Mines, Dept. of Natural Resources, State of California, vol. 34, No. 4, October 1938, pp. 563–590.

World production of native sulfur, 1935–39, in long tons [1]

[1] Sulfur is also believed to be produced in China, Spain, and the U. S. S. R., but the amount produced is unknown.
[2] Data not available.
[3] In addition, the following quantities of sulfur rock are reported: 1935, 4,785 tons (77.5 percent sulfur); 1936, 11,612 tons (40–80 percent sulfur); and 1937, 1,050 tons.
[4] In addition, the following quantities of sulfur rock are reported: 1935, 18,738 tons; 1936, 20,743 tons; 1937 19,793 tons; and 1938, 16,545 tons.
[5] In addition, the following quantities of sulfur rock are reported: 1935, 20,764 tons; and 1936, 31,576 tons. Similar data are not available for 1937–39.
[6] Crude sulfur product.

Canada.—Elemental sulfur is being produced in the treatment of base-metal smelter gas at Trail, British Columbia, by the Consolidated Mining & Smelting Co. The plant has a reported capacity of 150 tons of sulfur per day. Late in 1938 the Aldermac Copper Corporation, Ltd., was reported to have begun construction of a plant for the production of elemental sulfur from pyrite concentrates by the Westcott process. Imports of sulfur into Canada increased to 135,907 long tons in 1939 from 83,658 tons in 1938.

Chile.—Chile is the principal sulfur producer in South America. Production data in 1939 are not yet available, but exports for the first 11 months were 7,135 long tons compared with 9,227 for the same period in 1938. The development of sulfur deposits has been listed by the Government as one of the items to be considered in the general plan of national economic development.

Germany.—Germany does not produce native sulfur, but in recent years the output of byproduct sulfur has been making such rapid progress that the country soon may be self-sufficient. Data on production for 1939 are not available, but increased output is coming from coking plants, low-temperature carbonization plants, and gasoline hydrogenation plants. In the past, nearly the entire German output of elemental sulfur came from desulfurization at coke plants, but most of the gain in production recently has resulted from installation of improved recovery methods at gasoline hydrogenation plants, now the main source of supply. Imports of sulfur into Germany for the first 6 months of 1939 were 25,323 long tons (63,856 tons for 6 months in 1938), of which 23,059 tons came from Italy. Much of the sulfur imported into Germany is transshipped to nearby countries; exports for the first 6 months of 1939 were 23,154 tons. A plant for producing sulfuric acid from gypsum was completed and put into operation at Wolfen in 1939. The annual capacity is reported to be 80,000 tons of acid.

Italy.—Italy, including Sicily, is the world's second largest producer of sulfur, and the output is subsidized with minimum prices to mine operators guaranteed by a central Government sales bureau. The production quota established for the fiscal year ended July 31, 1939, was 393,682 long tons, but only 349,400 tons were placed at the disposal of the sales office; 64 percent came from 99 mines in Sicily and 36 percent from 6 mines in continental Italy. Although continental mines fulfilled their quota, output in Sicily was restricted by the outbreak of fires in several important mines. The guaranteed prices on the grades of sulfur produced in Italy are as follows:

Gialla superiore (guaranteed 99.5 percent of sulfur) 350 lire per metric ton.
Gialla inferiore (guaranteed 99.25 percent of sulfur) 340 lire per metric ton.
Buona (guaranteed 98 percent of sulfur) 328 lire per metric ton.
Corrente (guaranteed 97 percent of sulfur) 318 lire per metric ton.

Prices increased 20 lire per metric ton for the second quarter of 1939

Exports for the first 7 months of 1939 were 144,623 long tons, compared with 135,061 tons for the same period in 1938.

Japan.—Data on the production and exports of sulfur in Japan in 1939, the third largest producer, are not available. Exports were 31,012 long tons in 1938.

Norway.—Production of sulfur in Norway results from the treatment of cupriferous pyrites at the Thamshavn plant of the Orkla Metal Co.; output in 1939 was reported [6] to be about 108,263 long tons. Exports in 1939 were 82,422 long tons compared with 75,425 tons in 1938. Although Norway has exported sulfur since 1932, it continues to import sulfur; imports in 1939 were 9,481 long tons.

Portugal.—Production of elemental sulfur from pyrites at the San Domingos mine was begun in 1935. Output during 1939 was 11,221 long tons compared with 11,059 in 1938; imports in 1939 were 3,157 long tons compared with 3,408 in 1938.

Spain.—The output of native sulfur in Spain is supplemented by elemental sulfur obtained in the treatment of pyrites. Figures for recent years are not available.

Sweden.—Elemental sulfur recovered as a byproduct of smelter gases by the Boliden Co. at Ronskar in North Sweden is the only sulfur produced in Sweden. Output at this plant was 17,512 long tons in 1938. Imports of sulfur for the first 9 months of 1939 were 36,241 long tons compared with 27,531 for the same period in 1938.

PYRITES

Domestic production.—Production of pyrites (ores and concentrates) in the United States in 1939 dropped 7 percent from 1938, but the sulfur content was higher—42.2 percent in 1939 compared with 39.4 percent in 1938—with the result that the available sulfur was nearly the same. Of the 1939 total, only 30,579 tons were lump and the remainder fines; most of the fines were flotation concentrates.

[6] Mining Journal (London), Norway in 1939: Vol. 208, No. 5455, March 9, 1940, p. 147.

Pyrites (ores and concentrates) produced in the United States, 1935–39

Year	Quantity: Gross weight (long tons)	Quantity: Sulfur content (percent)	Value	Year	Quantity: Gross weight (long tons)	Quantity: Sulfur content (percent)	Value
1935	514, 192	39. 5	$1, 583, 074	1938	555, 629	39. 4	$1, 685, 766
1936	547, 236	39. 6	1, 666, 194	1939	516, 408	42. 2	1, 550, 449
1937	584, 166	39. 7	1, 777, 787				

The quantity of pyrites (ores and concentrates) sold or consumed by producing companies totaled 511,739 long tons in 1939 compared with 524,120 tons in 1938. In 1939, 188,712 tons were sold by producers compared with 163,711 tons in 1938. All sales in both years were to domestic consumers. Prices quoted by the trade journals are for imported pyrites and are given in cents per long-ton unit of sulfur, c. i. f. Atlantic ports; quotations, which are nominal, were unchanged at 12–13 cents per long-ton unit throughout the year.

Tennessee was the principal producing State in 1939; other States producing were California, Colorado, Illinois, Indiana, Kansas, Missouri, Montana, New York, Virginia, and Wisconsin.

THE INDUSTRY IN 1939, BY STATES

California.—The Mountain Copper Co., was the only producer of pyrites in California in 1939; output came from the Hornet mine in Shasta County.

Colorado.—The Minnesota Mines, Inc., was the only producer of pyrites in Colorado in 1939. The material is recovered by flotation as an auriferous sulfide concentrate, which is shipped to Denver for manufacture of acid after the gold content has been recovered by cyanidation.

Illinois.—One operator, the Midland Electric Coal Corporation, produced and shipped 13,950 long tons of pyrites (coal brasses) from its coal-cleaning operations at the Atkinson mine in Henry County. The product, which contained about 46 percent sulfur, was shipped to Indiana for the manufacture of sulfuric acid.

Indiana.—The Snow Hill Coal Corporation produced and shipped 4,403 long tons of pyrites (coal brasses) containing 40 percent sulfur from its Talleydale mine in Vigo County in 1939. The product moved to acid plants in the Chicago area. A considerable additional tonnage was wasted.

Kansas.—The Mineral Products Co. produced 9,838 long tons of pyrites (coal brasses) in 1939 at West Mineral, Cherokee County. Shipments averaging 47 percent sulfur were consigned to St. Louis, Mo., where they were used in acid making.

Missouri.—In 1939 three operations produced 32,496 long tons of pyrites containing 47 percent sulfur, the total for Missouri. The largest producer was the Moselle No. 10 mine in Phelps County, operated by Thomas & Williams. Other output came from Cherry Valley mine in Crawford County operated by H. H. Lark and from the Kelsey mine in Franklin County operated by Roy C. Libhart. Shipments moved to acid plants in the St. Louis area.

Montana.—The pyrites produced in Montana in 1939 came from the Anaconda Copper Mining Co. at Anaconda, where it is recovered as a flotation concentrate in copper-plant operation.

New York.—During 1939 the St. Joseph Lead Co. produced 71,176 long tons of pyrites concentrate at its Balmat mill in St. Lawrence County. The pyrites, which ran 49.85 percent sulfur, was produced as a flotation concentrate in the treatment of zinc-bearing ore.

Tennessee.—The pyrites output in Tennessee during 1939 came from the Tennessee Copper Co., Ducktown Basin, Polk County. It is produced as a flotation concentrate but does not enter the market, as all of it is used by the company in the manufacture of acid.

Virginia.—The only pyrites mined in Virginia in recent years has come from the Gossan mine at Cliffview, Carroll County, and the entire output is concentrated by means of air tables for the manufacture of sulfuric acid in the company plant at Pulaski. The new mill, which was placed in operation late in 1938, has increased the tenor of the product shipped.

Wisconsin.—The one company reporting production in Wisconsin in 1939 was the Vinegar Hill Zinc Co. in Grant County which has been recovering pyrites by selective flotation since the latter part of 1938; previously, magnetic separation was employed. The ore is produced from several mines in the Platteville district.

FOREIGN TRADE

Imports of pyrites in 1939 increased 44 percent over 1938. Receipts from Spain, normally by far the principal source, dropped moderately, but the striking increase in shipments from Canada made up the difference. Greece, a new source, also supplied a substantial quantity in 1939.

Pyrites, containing more than 25 percent sulfur, imported into the United States, 1935–39, by countries

Country	1935		1936		1937		1938		1939	
	Long tons	Value	Long tons	Value	Long tons	Value	Long tons	Value	Long tons	Value
Belgium	------	--------	5,290	$29,756	------	--------	------	--------	------	--------
Canada	9,888	$45,965	55,105	200,184	20,558	$74,946	30,064	$135,659	176,804	$470,336
Greece	------	--------	------	--------	------	--------	------	--------	22,800	106,271
Mexico	85	430	------	--------	549	1,473	202	522	------	--------
Portugal	------	--------	59,804	286,974	21,725	109,395	------	--------	------	--------
Spain	387,140	1,266,606	309,114	913,820	481,598	1,158,671	303,968	709,983	282,732	738,439
	397,113	1,313,001	429,313	1,430,734	524,430	1,344,485	334,234	846,164	482,336	1,315,046

Most of the imports of pyrites move into Philadelphia and Baltimore where it is used in the manufacture of sulfuric acid.

Pyrites, containing more than 25 percent sulfur, imported into the United States, 1935–39, by customs districts, in long tons

Customs district	1935	1936	1937	1938	1939

WORLD PRODUCTION

The following table shows world production of pyrites and its sulfur content. The figures are taken principally from official sources of the countries concerned, supplemented by information from publications of the Imperial Institute and other reliable sources.

World production of pyrites (including cupreous pyrites), 1937–39, in metric tons

[Compiled by M. T. Latus]

Country [1]	1937		1938		1939

[1] In addition to countries listed Belgium, China, Japan, Spain, and the U. S. S. R. produced pyrites, but production data are not available.
[2] Data not available.

Canada.—There was a pronounced increase in Canadian production of pyrites in 1939. Of the year's output, 113,464 metric tons containing 55,249 tons of sulfur came from Quebec and 95,634 metric tons containing 48,056 tons of sulfur from British Columbia. Output in Quebec came from the Aldermac mine in western Quebec and at Eustis in the eastern townships; operations at the latter property ceased in July 1939 after nearly three-quarters of a century. The output of

British Columbia came from the Britannia mill, where pyrites concentrate is produced in the treatment of ores for the extraction of copper. Other deposits in British Columbia and northwestern Ontario attracted attention during the year. Exports from Canada rose sharply in 1939, amounting to 99,919 metric tons (sulfur content) compared with 20,057 tons (sulfur content) in 1938.

In addition, sulfuric acid is made from smelter gases at the Trail (British Columbia) and Copper Cliff (Ontario) smelters, and elemental sulfur is recovered at Trail. In 1939, 87,842 metric tons of sulfur were recovered as sulfur or in sulfuric acid manufactured from smelter gases.

Japan.—Japan is one of the principal producers of pyrites, but data on production are not available, owing to a ban on information pertaining to domestic production and consumption. The entire output is consumed locally in the manufacture of sulfuric acid, and Japan is said to be nearly self-sufficient as regards this material.

Norway.—Production of pyrites is one of the principal mining industries in Norway, and in 1939 output exceeded 1,000,000 metric tons for the fourth successive year. Exports were slightly lower in 1939, totaling 653,962 metric tons compared with 654,956 in 1938. Some of the Norwegian pyrites is used locally for the production of elemental sulfur.

Portugal.—Output was at a high rate in 1939, totaling 673,200 metric tons. Exports in 1939 were 432,895 metric tons compared with 456,786 in 1938.

Spain.—Spain is the principal world producer of pyrites, but war conditions undoubtedly affected operations during 1939. Official data for recent years are not available, but unofficial reports indicate that shipments of pyrites from the ports of Huelva, Seville, and La Laja were 2,256,800 metric tons in 1937, 2,331,200 in 1938, and 1,635,200 in 1939. Underground mining methods at Rio Tinto have been described by Julian.[7]

PHOSPHATE ROCK

By Bertrand L. Johnson and K. G. Warner

SUMMARY OUTLINE

Domestic demand for phosphate rock improved slightly in 1939 over 1938, a little more than enough to offset the decline in exports caused partly by the blockade of Germany after the outbreak of war in September. Total shipments of domestic phosphate rock in 1939 (3,757,067 long tons, valued at $12,294,042), although a little greater in tonnage, were less in value than in 1938. Part of the slight gain in mine production over 1938 was added to stocks, which were greater at the end of 1939 than a year earlier. The output in Tennessee and the Western States was greater than in any previous year; but in Florida, by far the leading producing State, it was less than in 1937 or 1938. Imports were even smaller than usual.

Salient statistics of the phosphate rock industry in the United States, 1938–39

	1938			1939

On February 27, 1939, the Department of Justice began a Nation-wide investigation of the fertilizer industry.

The report of the hearings of the Joint Congressional Committee to Investigate the Adequacy and Use of Phosphate Resources of the United States, pursuant to Public Resolution No. 112, was published early in the year.[1] The findings and recommendations of the joint congressional committee were reviewed in a pamphlet entitled "The Facts About the Adequacy and Use of Our National Phosphate Resources," published in April 1939 by the Phosphate Rock Institute of New York City.

Just before the close of Congress in August, the phosphate investigators were granted a $5,000 appropriation to complete their work of determining the extent of domestic resources of phosphate rock and related minerals.

A general paper on phosphate, by F. S. Lodge, of the National Fertilizer Association, presented at the meeting of the Division of Fertilizer Chemistry, American Chemical Society, held at Boston, Mass., September 11 and 12, 1939, was published later in the American Fertilizer.[2]

Production.—Mine production of phosphate rock in the United States in 1939 increased about 128,000 tons over 1938 but did not recover to the 1937 peak. Phosphate rock was mined in Florida, Tennessee, Idaho, and Montana, and apatite was recovered from nelsonite in Virginia. Phosphate rock operations in South Carolina, which had been resumed in 1938 after a lapse of many years, were inactive in 1939.

Phosphate rock mined in the United States, 1930–39, by States, in long tons

Year	Florida	Tennessee	Western States	United States	Year	Florida	Tennessee	Western States	United States
1930	3,361,786	607,814	66,597	4,036,197	1935	2,598,337	[1] 493,501	67,490	3,159,328

[1] Includes small quantity of apatite from Virginia.
[2] Includes small quantity of apatite from Virginia and phosphate rock from South Carolina.

Sales.—The quantity of domestic phosphate sold or used by producers in 1939 was slightly greater than in 1938, but the value of the shipments declined more than half a million dollars from the 1938 figure.

Phosphate rock sold or used by producers in the United States, 1935–39

Year	Long tons	Value at mines		Year	Long tons	Value at mines	
		Total	Average			Total	Average
1935	3,042,381	$10,951,723	$3.60	1938	3,739,238	$12,952,143	$3.46

[2] Lodge, F. S.; Phosphates and Their Utilization: Am. Fertilizer, vol. 91, No. 8, October 14, 1939, pp. 9–11; No. 9, October 26, 1939, pp. 9–11, 26.

Distribution of sales.—Shipments of phosphate rock fall into two distinct groups according to grade—one below 60 percent B. P. L. (bone phosphate of lime) and the other above 68 percent B. P. L. The latter is the larger group, and most of the sales are of the grades between 72 and 75 percent B. P. L. The manufacture of acidulated superphosphate is still the major outlet for domestic rock; however, with development of the use of low-grade material in the production of elemental phosphorus by the electric furnace method, the retreatment of land-pebble wastes by flotation, and the utilization of the low-grade, hard-rock, waste-pond phosphates, the consumption of grades containing less than 60 percent B. P. L. is becoming increasingly important.

The following table, showing the distribution of sales by grades, uses, and classes of consumers, is compiled from reports of domestic producers of phosphate rock.

Phosphate rock sold or used by producers in the United States, 1938–39, by grades, uses, and classes of consumers

[1] Bone phosphate of lime. [2] Figures not available. [3] Less than 0.5 percent.
[4] Included under "Undistributed"; Bureau of Mines not at liberty to publish figures.
[5] Includes grades of B. P. L. content between 68 and 70; 69/66; 68/70; 71; 73/74; 73; 76.55; 78/76; 78; and above 85 percent; also dust, B. P. L. content not known.
[6] Includes some calcined phosphate and phosphatic material used in pig-iron blast furnaces, concrete aggregates, in the manufacture of concentrated fertilizers, as filler in asphalt mixtures, and as foundry facings.
[7] As reported to the Bureau of Mines by producers (exclusive of exports by dealers, etc.).

Consumption.—The apparent domestic consumption of phosphate rock in 1939 (2,811,561 long tons) was about 200,000 tons above the figure for 1938 and 100,000 tons below the 1937 peak. Figure 1 shows a logistic curve fitted to the consumption of phosphate rock in the United States since 1867, the consumption for 1938 and 1939 being added to the same curve shown on page 1171 of Minerals Yearbook, 1938. The data for 1938 and 1939 tend further to confirm the decreasing rate of increase and the sidewise trend in domestic consumption of phosphate rock forecast by the logistic curve, with no indication of greatly increased consumption in the future.

Prices.—Trade-journal quotations for various grades of domestic phosphate rock were changed in January 1939. For Florida land

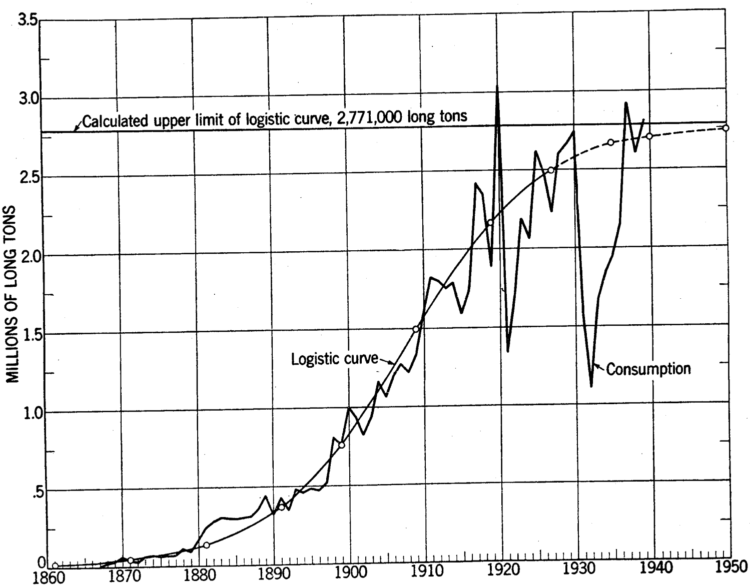

FIGURE 1.—Consumption of phosphate rock in the United States, 1867–1939.

pebble containing 68 percent B. P. L. prices increased slightly ($1.85 to $1.90), but for higher grades quotations were substantially lower. The price of the 70-percent grade was dropped from $2.35 to $2.15, of the 72-percent grade from $2.85 to $2.40, and of the 75-percent grade from $3.85 to $2.90. No further changes occurred during the year.

Reserves.—Mansfield has discussed the phosphate rock reserves of the United States in two recent papers.[3] As of January 1940, he estimated reserves as at least 13,291,543,000 long tons, including all the different grades considered in his study. Of this quantity, 5,306,651,-000 tons are in the Eastern States and 7,984,892,000 tons in the Western States.

REVIEW BY STATES

Florida.—The total tonnage of Florida rock shipped in 1939 was a little less than in 1938, and its value decreased by nearly $900,000. A

[3] Mansfield, George R., Phosphate Deposits of the United States: Econ. Geol., vol. 35, No. 3, May 1940, pp. 405–429; Recent Studies of Reserves of Domestic Phosphate: Amer. Inst. Min. and Met. Eng., Min. Technol., Tech. Pub. 1208, 1940, 10 pp.

slight gain in shipments of land-pebble rock was more than offset by a decline of 22 percent for soft rock and 29 percent for hard rock. Total stocks in hands of Florida producers were higher at the end of 1939 than on December 31, 1938.

In 1939 seven companies produced land-pebble phosphate rock, three companies hard rock, and several small concerns soft rock.

The following seven companies produced land-pebble phosphate rock in 1939:

American Cyanamid Co., 30 Rockefeller Plaza, New York, N. Y. Plant at Brewster.
The American Agricultural Chemical Co., 50 Church Street, New York, N. Y. Plant at Pierce.
Coronet Phosphate Co., 19 Rector Street, New York, N. Y. Plant at Coronet, near Plant City.
International Agricultural Corporation, 61 Broadway, New York, N. Y. Plant at Prairie, near Mulberry.
The Phosphate Mining Co., 110 William Street, New York, N. Y. Plant at Nichols.
Southern Phosphate Corporation, Baltimore Trust Building, Baltimore, Md. Plant at Ridgewood.
Swift & Co. Fertilizer Works, R. F. D. 1, Bartow, Fla. Plant at Agricola.

The following companies mined hard rock in 1939:

J. Buttgenbach & Co., Lakeland, Fla.
C. & J. Camp, Ocala., Fla.
Dunnellon Phosphate Mining Co., Savannah, Ga.

The following companies were reported to have produced soft phosphate rock in 1939:

Colloidal Phosphate Sales Co., Dunnellon, Fla.
The Dixie Phosphate Co., Ocala, Fla.
Lakeland Phosphate & Fertilizer Co., 225 East Main Street, Bartow, Fla.
Loncala Phosphate Co., Ocala, Fla.
M. R. Porter Co., Ocala, Fla.
Soil Builders, Inc., Dunnellon, Fla.
Superior Phosphate Co., Dunnellon, Fla.

[1] Includes material from waste-pond operations. [2] Includes sintered matrix.

The United States Circuit Court of Appeals, sitting at Philadelphia, Pa., in the spring of 1939, in litigation between the Phosphate Recovery Corporation, of New York, and the Southern Phosphate Corporation, of Baltimore, Md., sustained patents owned by the Phosphate Recovery Corporation, an affiliate of the International Agricultural Corporation, on a process for recovery of phosphate rock, at the same time ruling invalid a similar patent owned by the Southern Phosphate Corporation. A cash settlement was made by the Southern Phosphate Corporation, and it again became a licensee of the Phosphate Recovery Corporation.

The Phosphate Mining Co. is reported to have installed in 1939, at Nichols, Fla., a second bowl mill with gravity discharge and a 12-foot mechanical air separator for closed-circuit grinding of pebble phosphate rock, duplicating an installation made late in 1937.

On May 28, 1939, an investigation was ordered by the Secretary of the Interior, Harold L. Ickes, as to the advisability of reserving to the United States the undeveloped phosphate rock deposits in many parts of the public domain of Florida. More than 66,000 acres in 16 Florida counties are reported as already included in the Federal Phosphate Reserve. The new order instructed the Geological Survey to determine the possibilities of additional workable deposits of phosphate rock before the General Land Office disposes of the land under the present public land laws.

Mansfield's[4] study of Florida reserves largely substantiates the figures for land-pebble and river-pebble rock recently given before the joint congressional investigating committee, considerably lowers the figure for hard rock, and points out that the data now available as to the reserves in the Hawthorn formation and certain phosphate marls "are insufficient to justify their present inclusion in reserves, though it is recognized that they are worthy of further consideration and study." He estimates total phosphate reserves in Florida, of all grades, as exceeding 5 billion tons, of which over 2 billion is classified as known, 1¼ billion as probable, and 1¾ billion as possible.

Tennessee.—The quantity of phosphate rock shipped in Tennessee in 1939, including a small amount of apatite from Virginia, was 938,448 long tons, 4 percent greater than the previous all-time high attained in 1938. The shipments consisted almost entirely of brown rock, although a small quantity of blue rock went to the Tennessee Valley Authority. Stocks of phosphate rock in the hands of the producers at the end of 1939 were larger than at similar periods in 1937 or 1938.

Tennessee phosphate rock sold or used by producers, 1935–39

[Includes apatite from Virginia]

[4] Mansfield, George R., Work cited in footnote 3.

In 1939, as in previous recent years, almost the entire output of the State was mined by six companies—Armour Fertilizer Works, Charleston Mining Co., Federal Chemical Co., Hoover & Mason Phosphate Co., International Agricultural Corporation, and the Monsanto Chemical Co.—together with the T. V. A.

The two privately owned electric furnace plants, the Victor Chemical Works, Mount Pleasant, Tenn., and the Monsanto Chemical Co., Columbia, Tenn., and the T. V. A. plant, Muscle Shoals, Ala., were operated during 1939. The elemental phosphorus produced by the Victor Chemical Works and the Monsanto Chemical Co. was shipped in tank cars to Nashville, Tenn., Anniston, Ala., and elsewhere for the manufacture of phosphate chemicals. The elemental phosphorus produced by the T. V. A. was used to make concentrated superphosphate and calcium metaphosphate at Muscle Shoals. Two electric furnaces at the Monsanto plant are reported to have been shut down for a short time in the fall.

The Monsanto Chemical Co., the Charleston Mining Co., and the T. V. A. are reported to have increased their phosphate land holdings during the year. A small washing plant, which was built during 1938 near Gallatin in the Sumner County phosphate rock field for the preparation of phosphate rock for T. V. A. use, began operations late in 1939.

The Victor Chemical Works added two new electric furnaces to its elemental phosphorus plant at Mount Pleasant, Tenn., and a nodulizing plant of sufficient capacity for all three electric furnaces. The company is reported to own large tracts of phosphate-rock land in Tennessee which it has never developed. In recent years it has obtained its supplies of phosphate rock from the Charleston Mining Co. Both its electric-furnace plant at Mount Pleasant, Tenn., and its blast-furnace plant at Nashville, Tenn., were operated during 1939. Several illustrations of these plants, with flow sheets and descriptions, were given in articles published in 1939.[5] A plant for continuous oxidation of elemental phosphorus to phosphoric acid was built by the company at Chicago Heights, Ill.

The plant of the Federal Chemical Co. at Ridley, 1 mile north of Mount Pleasant, was largely rebuilt early in 1939; almost the entire steam plant was replaced with electric motors, and the washer plant was reconstructed. A large four-roll low-side mill is also reported to have been installed for grinding phosphate rock. Operations were resumed late in the summer.

The three completed electric furnaces of the T. V. A. were operated throughout the fiscal year except during the annual shut-down in August, according to the T. V. A. annual report.[6] Output approximated 69,000 tons of concentrated superphosphate, with an average available P_2O_5 content of about 47 percent. Construction of a new electric furnace, different in design and method of handling the gas produced, was nearly completed. Another small experimental electric furnace was operated from time to time to obtain data regarding various operations. The first full-size calcium metaphosphate unit was operated part of the fiscal year ended June 30, 1939, yielding

[5] Chemical and Metallurgical Engineering, How Victor Makes Its Phosphates: Vol. 46, No. 5, May 1939, pp. 269–272; Phosphate Plants Continue Growth: Vol. 46, No. 11, December 1939, p. 684.

[6] Tennessee Valley Authority, Annual Report for the Fiscal Year Ended June 30, 1939; Washington, D. C., 1940, 478 pp.

approximately 4,600 tons of "metaphos" with an average content of about 60 percent available P_2O_5. This unit uses lump-rock phosphate, or agglomerated fines, and phosphorus condensed from electric furnace gases. A second process that has been carried through the pilot-plant stage uses phosphate fines directly instead of prepared agglomerates or the less available rock. A large-scale experimental plant for this process has been designed and partly built.

Work has been done on another material, fused-rock phosphate, which is not so concentrated but is considered promising because T. V. A. studies show that the processing should be relatively economical. After completion of laboratory and pilot-plant tests a full-size unit was built and operated during the fiscal year. Work continued on improvements in the production of concentrated superphosphate by the electric-furnace method, that is, by treating ground phosphate rock with concentrated phosphoric acid resulting from the smelting of phosphate ores in the electric furnace. Improvements were also made in the methods of agglomerating raw phosphate ore for use in the electric furnace which enabled the Authority to process a much larger proportion of its ore than formerly.

Other investigations included blast-furnace studies and research with elemental phosphorus and high-strength phosphoric acids; small-scale experimental work and pilot-plant operations on the production of potassium-calcium metaphosphate; studies to reduce the cost of phosphate fertilizer by greater and more efficient recovery of byproducts such as fluorine and ferrophosphorus; chemical studies of the curing of superphosphate and the elimination of its fluorine; and studies of the corrosion of apparatus. Studies were also made of the phosphate rock from the T. V. A. reserves to determine the most favorable site for a field plant to prepare phosphate rock for furnace use.

Options to purchase were taken on 11 tracts, and commitments were made to acquire 2 in fee simple and to purchase mineral rights on the other 9. The 11 tracts totaled 660 acres. During the fiscal year purchases were consummated on seven properties in Maury and Giles Counties; interests acquired were fee simple title in one instance and mineral rights in the other six, a total of 968 acres. All but two of the Authority's leases on phosphate property were permitted to lapse; one of these was in Maury County and the other in Sumner County.

Several articles were published in 1939 covering T. V. A. phosphate operations.[7]

T. V. A. fertilizers were tested by land-grant colleges in 40 States, by the United States Department of Agriculture in 3 additional States, and on approximately 25,700 farms in 20 States. More than 50,000 tons of T. V. A. concentrated fertilizers were also distributed by the Agricultural Adjustment Administration. In the fiscal year

Junkins, J. N., and Newton, R. H., Instrumentation of T. V. A. Electric Furnace Phosphoric Acid Plant: Instruments, vol. 12, June 1939, pp. 161-165; presented at Carnegie Inst. Technol., Pittsburgh, March 2-3, 1939.

1939 appreciable quantities of metaphosphate entered the test demonstration program, and nearly 4,000 tons were distributed.

During the fiscal year 1938–39 fertilizer having a content of 32,786 tons of available P_2O_5 was shipped from the experimental large-scale production plant. These shipments comprised 30,457 tons (available P_2O_5) of concentrated superphosphate and 2,329 tons (available P_2O_5) of calcium metaphosphate. Most of the concentrated superphosphate was sold to the A. A. A., whereas most of the calcium metaphosphate was used in tests and demonstrations.

Early in 1939 a report by C. R. Ball,[8] describing the work done by the land-grant colleges of the Tennessee Valley in cooperation with the Tennessee Valley Authority, was published.

The estimates of reserves of phosphate rock in Tennessee, as presented in 1938 by the phosphate rock industry to the Joint Congressional Committee to Study the Adequacy and Use of the Phosphate Resources of the United States (totaling more than 5 billion tons, largely phosphatic limestone), were reviewed critically during the year by G. I. Whitlatch,[9] associate geologist, Tennessee Division of Geology, Nashville, Tenn., who concluded, in regard to blue rock that

> Phalen's estimate of approximately 84,000,000 tons of blue-rock phosphate, made in 1916 still remains as the most acceptable current reserve figure, because additional data necessary for its revision are lacking.

He states in regard to the white rock that

> The white fields have never been fully explored, and any estimate of reserves based on present meager data is apt to be in serious error. Barr's figure of 23,000,000 tons, as reported in the Webster estimates of 1938, cannot therefore be accepted without reservations.

Regarding the brown rock reserves Whitlatch says:

> Brown phosphate reserves today are actually and potentially greater than at any time in the history of the industry, owing to the development of processes in which phosphate of grades lower than ever heretofore acceptable can be used. Of chief importance in this phase of development are the sintering and nodulizing processes of the electrothermal phosphorus manufacture introduced in 1937. On the basis of such widened conception of commercial reserves, Webster's figures of 1938 indicate that Tennessee has approximately 100,000,000 tons of available and usable brown phosphate, and this reserve figure is essentially confirmed by data compiled by the writer and by a third independent survey.

The great increase in the phosphate rock industry's 1938 estimate of Tennessee's reserves was in the figure submitted for phosphatic limestone; regarding these, Whitlatch states:

> Phosphatic limestones are, admittedly, a potential future source of phosphate, but present data are too meager to warrant full acceptance of Webster's 1938 estimate of 5,000,000,000 tons of highly phosphatic limestone.

Mansfield [10] places the reserves of phosphate rock in Tennessee at 195,151,000 tons, accepting Whitlatch's figures of 96,918,000 tons for the brown-rock reserves but adding 83,233,000 tons for blue rock and 15,000,000 tons for white rock in accordance with data supplied by the State geologist.

Western States.—In 1939, as in 1938, Idaho and Montana were the only Western States to produce phosphate rock. In Idaho there were

[8] Ball, Carleton R., A Study of the Work of the Land-grant Colleges in the Tennessee Valley Area in Cooperation with the Tennessee Valley Authority: Special comm. on Land-grant College Data and Sub-comm. on Exp. Sec. Data, 1939, 76 pp.

[10] Mansfield, G. R., Work cited in footnote 3.

at least two known producers—the Anaconda Copper Mining Co., which operated its No. 3 mine at Conda, Caribou County, Idaho, shipping more phosphate rock than in any previous year, and the Vassar Produce Co., of Caldwell, Idaho, which shipped phosphate rock from Bennington, Bear Lake County, Idaho. Two other companies, recently organized, hold phosphate rock deposits in Bear Lake County, Idaho—the Teton Phosphate Co., Boise, Idaho, incorporated in 1939 with a reported capitalization of 50,000 shares of $1 each, and the Idaho Grange Phosphate Cooperative, of Nampa, Idaho. No production in 1939 was reported by either company. Montana had two producers—one large and one small. The larger one, the Montana Phosphate Products Co., of Trail, British Columbia, operated the Anderson mine near Garrison, Powell County, Mont., and United States Government Leases Great Falls 076740 and 081920, supplying the requirements of the Consolidated Mining & Smelting Co. of Canada, Ltd., at Trail. The Anderson mill at Garrison, which prepares ground phosphate rock for direct application to the soil, is not known to have been operated during the year. The Mineral Hill Mining Co. shipped less than 2,000 tons from its mines near Avon, in Powell County, Mont.

The Western Phosphate Conference held symposia on reserves, technology, and uses of phosphate rock at the University of Idaho, August 31 to September 2, 1939. The delegates to the conference also visited some of the phosphate rock deposits of the Western States.

Much information regarding the phosphate rock deposits of the Western States and the phosphate industry of that region is contained in the recently published hearings of the joint congressional committee on phosphate.[11]

Mansfield[12] discusses the phosphate reserves of the Western States in detail. As of January 1940, he estimates reserves at 7,984,892,000 long tons, at least in the areas so far studied, with Idaho listed as 5,736,335,000 tons; Utah (including grades down to 40 percent),[13] 1,741,480,000 tons; Montana, 391,323,000 tons; and Wyoming, 115,754,000 tons.

Western States phosphate rock sold or used by producers, 1935–39

Year	Idaho			Montana			Total		
	Long tons	Value at mines		Long tons	Value at mines		Long tons	Value at mines

FOREIGN TRADE [14]

Imports.—Imports of phosphate rock into the United States in 1939 dwindled to only 3,500 tons compared with 7,006 tons in 1938 and 13,400 tons in 1937. All imports in 1939 came from Curaçao in the Netherland West Indies and entered the United States in May. No further imports from this source were received during the year, reportedly because of increased costs and shipping difficulties. Customarily phosphate rock is imported from French Oceania, but no imports were recorded in 1939. No apatite was imported from the U. S. S. R. or Brazil.

Phosphate rock and phosphatic fertilizers imported for consumption in the United States, 1935–39

Fertilizer	1935		1936		1937		1938		1939

[1] Not shown separately; included with "Phosphates, crude, not elsewhere specified" beginning January 1, 1937.
[2] New classification beginning January 1, 1937.

The United States Treasury Department order of February 9, 1928 (T. D. 42577), a finding of dumping with respect to Morocco phosphate rock, was reversed by the Department on September 18, 1939. On the basis of undisclosed new evidence the Treasury Department became convinced that the original order was not justified, and it was vacated as of February 9, 1928, the original date of issue. (T. D. 49964.)

Late in 1939 the Interstate Commerce Commission granted authority for railroads to establish rail rates of not less than $4.70 per ton of 2,000 pounds on carload lots of imported phosphate rock from New Orleans and other Gulf ports to Quincy, Ill., for the duration of the next open season of navigation, from March 1 to November 30, 1940.[15]

Exports.—Exports in 1939 totaled only 949,006 long tons compared

Phosphate rock exported from the United States, 1935–39

Year	Long tons	Value		Year	Long tons	Value	
		Total	Average			Total	Average
1935 [1]	1,104,394	$5,773,506	$5.23	1938	1,140,841	$6,637,638	$5.82
1936 [1]	1,208,951	6,776,917	5.61	1939	949,006	5,233,104	5.51
1937	1,052,802	5,818,231	5.53				

[1] Includes sintered matrix.

[14] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.
[15] Interstate Commerce Commission, Phosphate Rock from Gulf Ports to Quincy, Ill.: 4th Sec. Application 17796, Opinion 22920, 1939, pp. 204–206.

with 1,140,841 tons in 1938 and 1,052,802 tons in 1937. Their value was nearly 1½ million dollars less in 1939 than in 1938. Not only was a smaller quantity exported, but also the average value declined to $5.51 per ton in 1939 compared with $5.82 in 1938. Most of the exports were from Florida, but some were from the Western States.

The quantity and value of exports of both high-grade hard rock and land-pebble rock were less in 1939 than in 1938. The quantity and value of exports of other phosphatic material, including sintered matrix, were also less. The following tables show total exports of high-grade hard rock and land-pebble phosphate rock, as well as shipments of each type of rock to various countries from 1935 to 1939, inclusive.

Phosphate rock exported from the United States, 1935–39, by countries

[1] For statistical purposes, trade with the Sudeten area, as far as ascertainable, is included with Germany, while trade with the other Czechoslovak Provinces occupied by Germany, Hungary, and Poland has been included with these countries since March 18 or 19, 1939. After November 16, 1939, trade with Danzig and that part of Poland occupied by Germany has been included with Germany and trade with that part of Poland occupied by U. S. S. R. has been included with U. S. S. R.

[2] Excludes sintered matrix. [3] Figures cover period January 1 to May 5.

Other phosphate materials [1] *exported from the United States, 1935–39*

Year	Long tons	Value	Year	Long tons	Value
1935	3,984	$154,429	1938 [2]	32,581	$208,550
1936	3,489	165,385	1939 [2]	29,080	192,306
1937 [2]	55,665	466,850			

[1] Includes bone ash, dust, and meal; animal carbon for fertilizer; basic slag; etc.
[2] Includes sintered matrix.

The following table shows exports of high-grade hard rock from the various customs districts. In 1939 most rock of this type went from the hard-rock district of Florida to European countries, but a considerable quantity of phosphate rock from the Western States was shipped from the Montana-Idaho customs district to Canada.

High-grade hard-rock phosphate exported from the United States, 1938–39, by customs districts

Customs district	1938		1939	
	Long tons	Value	Long tons	Value
Buffalo	2	$30	2	$25
Dakota	14	120	23	260
Florida	114,782	753,507	87,821	564,353
Michigan	70	812	251	2,595
Montana and Idaho	67,042	405,445	44,873	273,373
New Orleans	4	48		
St. Lawrence	2	16	13	119
Washington	4	40		
	181,920	1,160,018	132,983	840,725

Exports of phosphate rock have decreased since the British blockade of Germany was established. Shipments for the last 4 months of

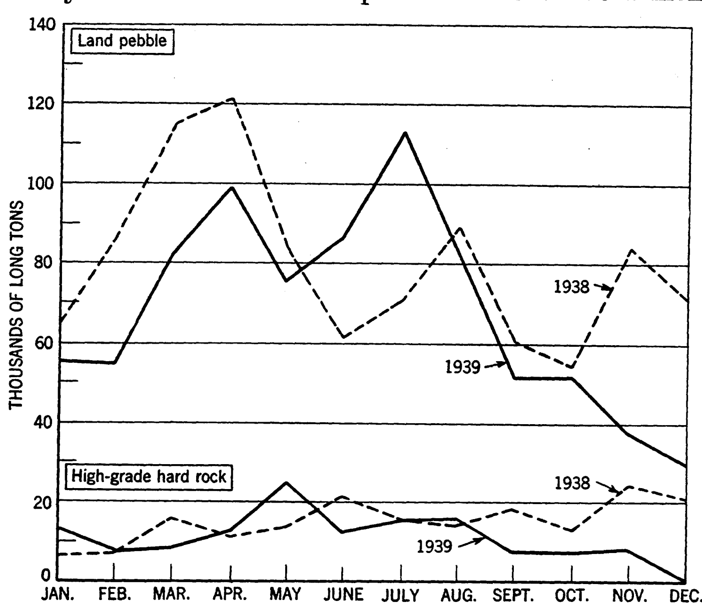

FIGURE 2.—Exports of phosphate rock from the United States, 1938–39. Note drop in exports after outbreak of war in September 1939.

1939, after war broke out in Europe, were below those for the same period in 1938. The last 1939 shipment of Florida high-grade hard rock from the United States to Germany was in August and of Florida land pebble in September. The monthly exports of phosphate rock for 1938 and 1939 are shown in figure 2.

The first seizure of a cargo of phosphate rock as contraband by the British Navy was reported by the British Government on September 14, 1939. The shipment comprised 5,900 tons of Florida land-pebble phosphate, intended for Germany and German-owned, on the American-owned freighter *Warrior*, of the Waterman Steamship Corporation, Mobile, Ala.

Figure 3 gives the sources of Germany's supplies of phosphate rock

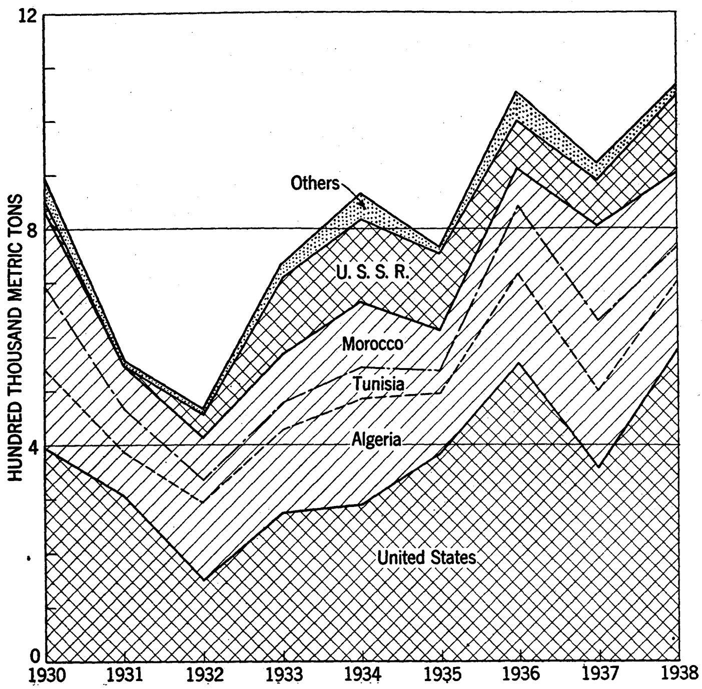

FIGURE 3.—Sources of Germany's supplies of phosphate rock, 1930–38. Data from Phosphate Export Association.

in recent years, based upon reports of the Phosphate Export Association, of New York City.

Figure 4 shows similar data for Japan.

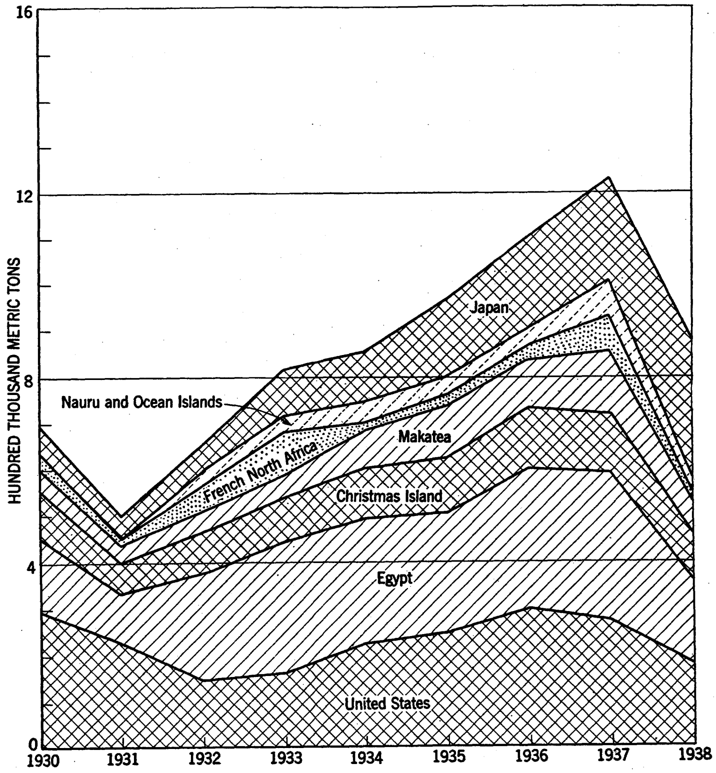

FIGURE 4.—Sources of Japan's supplies of phosphate rock, 1930–38. Data from Phosphate Export Association.

WORLD PRODUCTION

World production of phosphate rock from 1935 to 1939 is given in the following table.

World production of phosphate rock, 1935–39, by countries, in metric tons

[Compiled by M. T. Latus]

Country	1935	1936	1937	1938	1939
Algeria	603,863	530,998	631,148	584,452	[1] 450,000
Angaur Island (exports)	78,112	89,226	90,652	105,578	(2)

United States (sold or used by producers)	3,091,211	3,405,654	4,019,686	3,799,253	3,817,368

[1] Estimated. [2] Data not available. [3] Estimated (Imp. Inst., London).
[4] Including exports as follows: 1935, 1,296,052 tons; 1936, 1,247,923 tons; 1937, 1,484,562 tons; 1938, 1,427,643 tons; 1939, 1,465,673 tons.
[5] Exports during fiscal year ended June 30 of year stated.
[6] Apatite concentrates. Production of apatite ore in 1936 amounted to 2,000,000 tons. In addition, low-grade phosphate rock is produced, but production data are not available.

German trial exploitation of the phosphate deposits in Nassau, in the Lahn River Basin, were abandoned in 1939, the operations being much too costly, even under German conditions of closed national economy, because of the low grade of the deposits and their pockety nature. According to Redecker, the best grades of the phosphate rock in the Lahn region contained only 10 to 13 percent phosphorus.[16] The phosphate rock situation in Germany is described in considerable detail in another report by Redecker.[17]

TECHNOLOGY

The design of a 5,500-kw. electric furnace for smelting phosphate rock is described by Curtis and Heaton [18] of the T. V. A. One of the furnaces now in use is described in detail.

[16] Redecker, S. B., American consul, Frankfort on the Main, Germany, June 7, 1939: Bureau of Mines Mineral Trade Notes, vol. 9, No. 1, July 1939, p. 23.
[17] Redecker, S. B., American consul, Frankfort on the Main, Germany, October 4, 1939: Bureau of Mines Mineral Trade Notes, vol. 9, No. 6, December 1939, pp. 17–20.
[18] Curtis, H. A., and Heaton, R. C., Design for a Phosphate Furnace: Chem. and Met. Eng., vol. 45, No. 10, October 1938, pp. 536–540.

The determination of fluorine in natural phosphates and phosphatic fertilizers is described in considerable detail in a paper by Reynolds and Hill,[19] of the Bureau of Chemistry and Soils, United States Department of Agriculture.

Emmett and Shultz,[20] also of the Bureau of Chemistry and Soils, United States Department of Agriculture, have studied the utilization of carbon dioxide in the oxidation of elemental phosphorus.

The results obtained by a comparative study of methods of determining available phosphoric acid are given in a paper by J. R. Adams,[21] of the Bureau of Chemistry and Soils, United States Department of Agriculture. Ross and Adams [22] present the results of further studies on phosphoric acid.

The development of dipotassium phosphate for use in wool processing has been announced.[23] Cleansing of raw wool now requires large quantities of olive oil, which must be imported. It is reported that the olive oil can be replaced by domestic dipotassium phosphate.

A British patent [24] describes a method for the production of the alkaline phosphates, such as trisodium phosphate, direct from phosphate rock by the treatment of mixtures of crude phosphates and alkalies.

The determination of phosphoric acid in basic slag and in superphosphate is the subject of two articles by W. Spengler.[25]

A new plant has been opened for the manufacture of sodium tetraphosphate by the Rumford Chemical Works at Rumford, R. I.[26] The use of this chemical as a water softener, in cleansing compounds, and in drilling oil wells is reported to be increasing. Ranshaw [27] describes the use of trisodium phosphate in laundries.

The growing scarcity of sulfuric acid for use in the production of superphosphate in Germany, because of its employment for other purposes, has stimulated research to develop improved processes for making phosphate fertilizers with less sulfuric acid or none at all. Four main types of phosphatic fertilizers using less sulfuric acid than before have been developed. These are described in a recent report.[28]

MacIntire and Hardin in a recent article [29] presented the results of a study of the development of citrate insolubility through the formation of fluorphosphate by the reaction between the fluorides of superphosphate and calcined rock phosphate in mixtures of these two compounds.

The results of a study to determine the nature and composition of the products of the reaction of potassium chloride with phosphoric

[30] Madorsky, S. L., and Clark, K. G., Potassium Metaphosphate. A Potential High-analysis Fertilizer Material: Ind. Eng. Chem., vol. 32, No. 2, February 1940, pp. 244–248.

Statistics for 1937 covering international trade in superphosphates and production of superphosphates in various countries were published early in 1939.[31]

A revised definition of superphosphate was adopted in 1939 by the Association of Official Agricultural Chemists at its 55th annual meeting but does not become final until its next meeting. It would include as superphosphate a product made by mixing concentrated phosphoric acid with limestone. This product lacks the gypsum content of ordinary superphosphate. The new definition reads:

Superphosphate is a commercial phosphate, the phosphoric acid content of which is due chiefly to monocalcium phosphate.[32]

In October 1939 the price of superphosphate was advanced from $7.50 to $8.50 a short ton (basis, 16 percent for run-of-pile, in bulk, f. o. b. Baltimore) because of reported increases in the cost of production. The Temporary National Economic Committee[33] calls attention to the absence of any change in the price of either phosphate rock or sulfuric acid, the basic raw materials for the production of superphosphate.

BASIC SLAG

Basic slag is an important competitor of phosphate rock and superphosphate as a source of fertilizer phosphorus in European countries, where most of it is produced and used. The demand in the United States is limited and is met by importation of a small quantity and the annual production of a few thousand tons in the Birmingham iron district of Alabama. Less than 1 percent of the world production comes from the United States.

Production of basic slag, 1935–38, by countries, in metric tons [1]

Country	1935	1936	1937	1938

Basic Bessemer slags supply about 70 percent of the phosphorus for the German fertilizer industry and a considerable proportion comes from German ores. That country has very few phosphate deposits and, in operating the basic Bessemer process, must consider the need of producing a phosphatic slag suitable for fertilizer use along with other metallurgical problems.[35]

Sauchelli [36] discusses the composition of superphosphate and Mehring [37] the various grades of superphosphate sold in the United States.

TALC, PYROPHYLLITE, AND GROUND SOAPSTONE [1]

By Bertrand L. Johnson and K. G. Warner

SUMMARY OUTLINE

Sales of talc, pyrophyllite, and ground soapstone attained a new high in 1939, exceeding the previous 1937 peak by 24,000 tons. (See fig. 1.) Total sales were 253,976 short tons valued at $2,700,834.

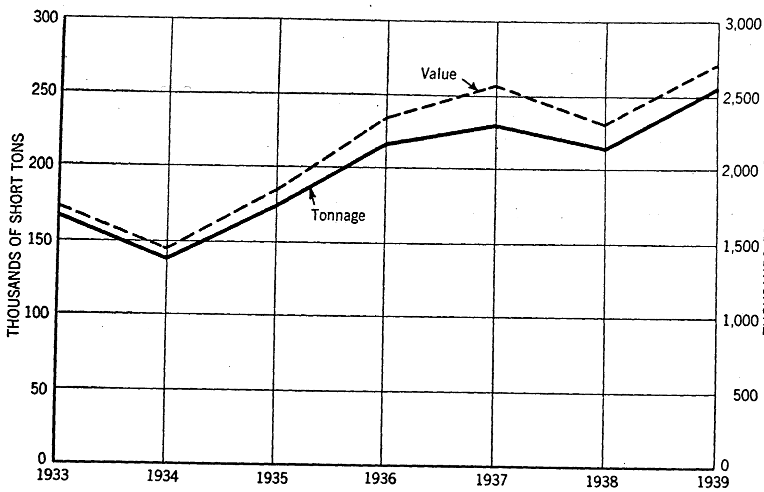

Figure 1.—Sales of domestic talc, pyrophyllite, and ground soapstone, 1933–39.

Sales of crude, sawed and manufactured, and ground materials increased over 1938, but by far the greatest part of the increase—over 38,000 tons—was in sales of the ground products. Imports of crude materials were much smaller than in 1938, but those of manufactured products were appreciably larger. Exports of all classes were greater in 1939 than in 1938.

Pyrophyllite is included in this discussion with talc solely because the custom was established many years ago in these annual reports of the Bureau of Mines. Although pyrophyllite resembles talc in certain physical properties, it is a hydrous aluminum silicate

[1] Soapstone sold in slabs or blocks is included in the chapter on Stone.

($Al_2Si_4O_{10}(OH)_2$) instead of a hydrous magnesium silicate like talc ($Mg_3Si_4O_{10}(OH)_2$). Authorities who have classified pyrophyllite as one of the kaolin minerals were cited in Minerals Yearbook, 1939 (p. 1273). Several analyses of North Carolina pyrophyllite have been assembled by Trice.[2]

Salient statistics of the talc, pyrophyllite, and ground-soapstone industry in the United States, 1938–39

	1938		1939

		1,102,294		1,277,602

1 Quantity not recorded.

In 1939, as in 1938, nine States produced talc, pyrophyllite, and ground soapstone. Seven of these States, which contribute most of the output, are in the East; the other two are California and Washington. Talc, pyrophyllite, and soapstone were reported as produced in California; talc and soapstone in Georgia, Maryland, Virginia, and Washington; talc and pyrophyllite in North Carolina; talc in New York and Vermont; and soapstone in Pennsylvania.

PRODUCTION

The following producers of talc, pyrophyllite, and soapstone in the United States reported to the Bureau of Mines in 1939.

Producers of talc, pyrophyllite, and soapstone in the United States in 1939

SALES

Sales of talc, pyrophyllite, and ground soapstone by producers increased 19 percent in quantity in 1939, totaling 253,976 short tons valued at $2,700,834 compared with 212,775 tons valued at $2,302,560 in 1938. The output exceeded the previous peak of 1937 by 10 percent. Only in 1928, 1929, and 1936–39 have sales of these commodities exceeded 200,000 tons annually. Sales of crude, sawed and manufactured, and ground materials increased in 1939 over 1938. The greatest increase—38,835 short tons or 94 percent of the total increase (41,201 tons)—was in sales of ground products. Sales of ground materials alone in 1939 were greater than total sales of all classes of talc, pyrophyllite, and ground soapstone in any previous year.

Talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1935–39, by classes

Year	Crude		Sawed and manufactured		Ground		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value
1935	10,725	$57,259	841	$63,211	161,150	$1,727,585	172,716	$1,848,055
1936	10,910	59,556	618	90,542	204,663	2,193,073	216,191	2,343,171
1937	11,087	52,750	1,101	111,680	217,811	2,397,323	229,999	2,561,753
1938	13,498	72,845	1,729	70,268	197,548	2,159,447	212,775	2,302,560
1939	15,722	82,188	1,871	77,915	236,383	2,540,731	253,976	2,700,834

Sales by States.—In 1939 increased sales of talc, pyrophyllite, and ground soapstone were reported in all States for which figures can be given. Sales showed the greatest advances in New York and North Carolina and established all-time highs in California, North Carolina, and Georgia. In North Carolina sales gained 34 percent and in Georgia 33 percent. The greatest percentage increase was in Virginia where sales were 58 percent greater in 1939 than 1938. About 39 percent of the total sales in 1939 came from New York.

Talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1938–39, by States

State	1938		1939	
	Short tons	Value	Short tons	Value
California	30,059	$391,456	33,796	$483,839
Georgia	15,117	130,595	20,090	177,881
New York	86,423	1,110,024	99,880	1,252,525

	212,775	2,302,560	253,976	2,700,834

[1] Maryland, Pennsylvania, and Virginia.

MARKETS [3]

The largest markets for talc, pyrophyllite, and ground soapstone are in northeastern United States and along the Pacific coast. Many industries use these minerals, but they are employed principally in paint, ceramics, rubber, roofing, and paper.

Talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1938–39, by uses

Use	1938		1939	
	Short tons	Percent of total	Short tons	Percent of total
Paint	53,506	25	67,859	27
Ceramics	29,590	14	38,407	15
Rubber	25,374	12	31,078	12
Roofing	27,607	13	30,516	12
Paper	27,329	13	30,177	12
Toilet preparations	5,970	3	9,672	4
Foundry facings	2,511	1	3,986	2
Other uses [1]	20,732	10	12,918	5
Use not reported	20,156	9	29,363	11
	212,775	100	253,976	100

[1] Includes crayons, bleaching, insecticides, plaster, textile, and other minor uses.

As indicated by reports from the producers to the Bureau of Mines, the paint industry—the leading consumer of these materials—increased its share of the market to 27 percent in 1939, taking nearly twice as much as the ceramic industry, the next largest user. All industries specified in the foregoing table absorbed larger quantities in 1939 than in 1938; the tonnage increases in consumption were especially notable in the paint, ceramics, and rubber industries.

Most of these materials are sold ground. There are no generally accepted standard specifications, but the largest quantity of talc is sold on the basis of previously satisfactory material or plant tests.[4] Chemical analyses are of interest, but physical tests pertinent to the particular trade, such as size and shape of grain, color, slip, retention, oil-absorption index, bonding strength, melting point, and vitrification range, usually are more significant.

Freight rates on soapstone and talc in the United States were fixed by the Interstate Commerce Commission in 1939 in the widely publicized Southern Governors' case.[5] The findings in this case, as far as soapstone and talc are concerned, are that the rate on higher-grade talc in carload lots shall be 16 percent of the first-class rate and on lower-grade talc 13 percent of the first-class rate. These rates are to apply from points in the South to points in the North. From points in the North to points in the South the carload rate on higher-grade talc is to be 22½ percent and on the lower-grade talc 19 percent of the first-class rate.

PRICES

The selling price of domestic talcs—except grades suitable for toilet preparations, lava, and crayons—usually is between $4 and $20 a ton. The average value of sales of all grades of talc, pyrophyllite, and ground soapstone, as reported to the Bureau of Mines by producers, has been about $11 a ton, ranging between $12.50 per ton, as in 1928, and $10.43, as in 1933; in 1939 it was $10.63. The average values for the past 5 years are given in the following table.

Average value per short ton of talc, pyrophyllite, and ground soapstone sold by producers in the United States, 1935–39

1935	$10.70	1938	$10.82
1936	10.84	1939	10.63
1937	11.14		

Quotations on finely ground domestic talcs, f. o. b. works, carload lots, in April 1940 were as follows: California, $17 to $20; New York, $11 to $19; Vermont, $9 to $14; Georgia, $6 to $8; Virginia, $4.50 to $7. Crude Virginia talc was quoted at $4 a ton. Prices of imported talc ranged from $11.50 to $13 for Canadian, $23 to $60 for French, and $64 to $78 for Italian.

Prices of pyrophyllite are reported to have gained in 1939, but trade-journal quotations in April 1940 for ground pyrophyllite still showed a range from $7.50 to $12 a ton, as in 1938.

DEVELOPMENTS IN THE INDUSTRY

The leading development in the talc industry is its growing use in wall tile and other ceramic bodies, for which purposes New York and Canadian talcs are said to have found favor.[6] Lime-free talcs are reported as wanted for use in highly absorptive bodies employed for electrical heater plates, but for porcelain and particularly for bodies maturing at low temperature talcs containing definite amounts of lime are desired.

The present froth-flotation plant of the Eastern Magnesia Talc Co., at Johnson, Vt., has been described in detail by Trauffer.[7] This company began experiments with froth flotation in 1934 and in cooperation with the Bureau of Mines developed a reclamation process to recover talc from waste material. The present plant is reprocessing both accumulated and current wastes at the rate of 30 tons a day. Froth flotation now makes possible the economical recovery of 95-percent-pure talc from the dry-plant waste, which comprises about 55 percent talc, 35 percent magnesite, and 10 percent other impurities. About 150 pounds of nickel concentrates also are being recovered daily. Recently a market has been found for the high-iron magnesite (breunnerite) which at first was being wasted.

Pyrophyllite originally was utilized mainly as a substitute for talc, and considerable quantities still are used as a filler in various products. Consumption of pyrophyllite in ceramic bodies, however, has been increasing rapidly. According to Tyler,[8] probably 90 percent of the

[6] Tyler, Paul M., Talc: Bureau of Mines Mineral Trade Notes, January 1939, p. 33.
[7] Trauffer, W. E., Froth Flotation Economically Recovers Valuable Material from Talc Waste: Pit and Quarry, vol. 32, No. 4, October 1939, pp. 28–30.
[8] Tyler, Paul M., Pyrophyllite: Bureau of Mines Mineral Trade Notes, January 1939, pp. 32–33.

makers of wall tile have adopted pyrophyllite-talc mixtures to eliminate the crazing that hitherto had been accepted as more or less unavoidable; one formula for wall tile contains 40 percent pyrophyllite and 12 percent magnesia talc (New York or Canadian). Still more recent is the use of pyrophyllite-talc mixtures for dinnerware bodies, a typical formula being 19 percent pyrophyllite and 6 percent talc.

In July 1939 the North Carolina Division of Industrial Hygiene announced pyrophyllite dust as a new industrial hazard. In February 1940 M. F. Trice [9] of that organization presented before the American Institute of Mining and Metallurgical Engineers a detailed study of pyrophyllite dust and its effects, together with suggested methods of control. Thirty-five percent of the workers exposed to the dust for 2 years showed evidence of lung damage. The effective control of dust underground results from the adoption of wet methods and improved ventilation. On the surface, tight housings for machinery and exhaust ventilation have eliminated hazardous concentrations of dust.

Trice [10] has also described some of the present uses of pyrophyllite. He states that it is an excellent refractory, as pure crystalline specimens have a pyrometric cone equivalent of 29; moreover, associated impurities such as quartz and sericite do not appear to affect this coefficient appreciably, as this value has been found to be a fair average for many run-of-mine specimens. Virtually all floor and wall-tile bodies now produced are said to contain pyrophyllite. It reduces the coefficient of expansion and moisture expansion of the tile body and prevents crazing of the glaze, which usually results from the absorption of moisture. Pyrophyllite is also employed in the production of electrical and other porcelains and in the manufacture of tiny insulation elements, such as are used in radios. One company manufactures dry-press pyrophyllite brick for use as refractory furnace lining. Pyrophyllite is employed to some extent in the manufacture of enamels for porcelain enamel products for stoves and refrigerators, and its use in this connection is increasing. Promising results have been obtained from experiments utilizing pyrophyllite, ground to 1,250-mesh, as an extender for paints and as a surfacer for cardboard. An original use for pyrophyllite, which is still important, is for talcum powder. It is also used as a filler in several industries.

Schünemann [11] found that pyrophyllite from Indian Gulch, Calif., on heating to 400° was unchanged; above that temperature H_2O was evolved continuously but was not reabsorbed on cooling. The lattice remained unchanged to 500°; above that there was some indication of a new form, but the scaly structure continued. Pyrophyllite resists attack by NaOH or HCl unless previously heated above 500° and then is affected only slightly unless the heating has exceeded 1,000°. With $MgCl_2$ cordierite is formed; with $CoCl_2$, spinel; with LiF, products of varying composition; and with $NiCl_2$, a bright-green substance of doubtful composition.

Studies by the Bureau of Mines in cooperation with the W. H. Loomis Talc Co. on the fibrous and foliated talc ores of the Gouverneur (N. Y.) district show that these ores may be improved by froth

[11] Schünemann, H., Effect of Heat on Pyrophyllite and Its Decomposition Products with Magnesium and Cobalt Chlorides: Univ. Berlin Inaug. Diss., 1937, 34 pp.; Neues Jahrb. Mineral., Geol. Ref. I, 1938, pp. 309–310; Chem. Abs., vol. 33, No. 8, April 20, 1939, p. 2849.

flotation.[12] Three types of ores were tested—tremolite talc, limy talc, and green talc. The ores are said to have differed in type of talc—foliated and fibrous—and in proportion and kind of impurities—calcite, tremolite, serpentine, diopside, and quartz—and each represented a separate problem in flotation. The ores containing fibrous talc and those containing tremolite and calcite were difficult to separate, whereas those containing foliated talc and quartz were easy to float. Different flotation agents were required for the various ores. Pine oil was suitable for foliated talc, but reagents of the amine type proved more suitable for the fibrous talc. The results indicate that a product of high talc content may be separated from each of the ores. In the talc-tremolite ores nothing need be wasted in consequence of beneficiation, as the tailing, enriched in tremolite, is stated to be suitable for wall tile as it is or blended with the feed.

From values listed by manufacturers and standard references Thurnauer [13] has tabulated the mechanical and electrical properties of porcelain, steatite, cordierite, TiO_2, and lava materials.

Meyer [14] found that ground soapstone pressed to shape and burned to 1,400° gave satisfactory results when used for gas-meter valves, remaining tight in tests lasting 1½ years.

Esme [15] discussed the occurrence and properties of talc and its use in papermaking.

Hendricks [16] treated the crystal structure of both talc and pyrophyllite as determined by X-ray data.

Charrin [17] presented a general discussion of talc.

d. Moraes and Leinz [18] described the occurrence of deposits of pyrophyllite suitable for ceramic use in the Province of Minas Geraes, Brazil. They conclude that the pyrophyllite deposits have been formed from kyanite-rich schists through the agency of pneumatolytic-hydrothermal emanations from the associated granitic bodies.

The mining and milling of pyrophyllite are described briefly by Milliken,[19] who points out that pyrophyllite as a substitute for Cornwall stone in wall-tile bodies gives equal absorption, shrinkage, and modulus of rupture, greater uniformity over the firing range, and lower moisture expansion.

Webb and Ratcliffe [20] discussed the use of talc as an anticraze material.

Attention is called by Tyler and Bowles [21] to a new use of pyrophyllite for a refractory known as "pyroplastic," employed chiefly to patch disintegrated firebrick, thereby obviating costly shut-downs and lengthening the life of furnace linings. They also report that the platy or schistose variety of pyrophyllite is claimed, as a result of recent tests, to make a satisfactory paint filler.

Ralston and others [22] note that the separation of the earthy minerals—talc, pyrophyllite, and clay—has been benefited by attrition scrubbing before flotation. It is thought that attrition produces cleaner concentrates by rubbing off "smears" of the soft mineral from the gangue material.

Flotation tests on two talc ores from California were described by Engel and Shelton.[23]

FOREIGN TRADE [24]

Imports.—Both the quantity and value of total imports of talc, steatite or soapstone, and French chalk were greater in 1939 than in 1938 but did not quite reach the 1937 levels. Imports of crude and unground steatite and French chalk dropped markedly in 1939, but this decline was much more than counterbalanced by the increase in "manufactures."

Talc, steatite or soapstone, and French chalk imported for consumption in the United States, 1935–39

Year	Crude and unground steatite and French chalk		Manufactures (except toilet preparations) wholly or partly finished		Total

	Powders—talcum (in packages), face, and compact	(1)	966,473
1938	Talc, steatite, and soapstone, crude and ground	7,118	124,194
	Powders—talcum (in packages), face, and compact	(1)	978,100
1939	Talc, steatite, and soapstone, crude and ground	9,047	162,426
	Powders—talcum (in packages), face, and compact	(1)	1,115,176

1 Quantity not recorded.

A shipload of talc, consigned to London, England, by the Sierra Talc Co., Los Angeles, Calif., was reported sunk by a German mine.[25]

WORLD PRODUCTION

Although few figures are yet available on the production of talc, pyrophyllite, and soapstone in foreign countries in 1939, the data at hand, coupled with established production trends in the principal

25 Pit and Quarry, vol. 32, No. 8, February 1940, p. 23.

producing countries, indicate that the United States was by far the leading producing nation and that its output exceeded greatly that of other important producers, such as China, France, Italy, British India, Germany, Canada, Norway, and Sweden.

World production of talc and soapstone, 1935–39, by countries, in metric tons

[1] In addition to the countries listed talc is produced in Brazil, Newfoundland, Spain and the U. S. S. R., but data of production are not available.
[2] Data not available.
[3] Excludes soapstone, which is reported only by value and was as follows: 1935, $32,053; 1936, $32,770; 1937, $40,513; 1938, $35,038; 1939, $41,471. Soapstone is sold in the form of both blocks and powder.
[4] Talc, pyrophyllite, and ground soapstone sold or used by producers.

FLUORSPAR AND CRYOLITE

By H. W. Davis and M. E. Trought

SUMMARY OUTLINE

FLUORSPAR

Greatly increased demand for fluorspar by all the chief consuming industries was indicated by the consumption of 176,800 short tons of fluorspar in 1939 compared with 115,100 tons in 1938. As a result of this improved demand, operations were resumed at some inactive mines and operating schedules at many others were increased. In consequence, domestic mine production and shipments were 75 and 127 percent, respectively, higher than in 1938. In fact, so great was the demand for fluorspar that shipments from domestic mines in 1939 were the largest since 1920 and the fourth highest on record. Shipments from Arizona, Kentucky, and Nevada established all-time highs. However, shipments of fluorspar far exceeded consumption, and as a result consumers' stocks at the end of 1939 were abnormally high. Sales of imported fluorspar in the United States were 7 percent less than in 1938.

Much prospecting and development work was done in 1939, which led to discovery of additional ore bodies and the opening of several new properties. In 1939 new mills came into operation at seven mines, and two new plants were under construction. Improvements and refinements were made in the flow sheets at several mills. Additional new mills are contemplated for 1940.

Total sales of fluorspar to consumers in the United States were 198,198 short tons in 1939 (179,795 tons from domestic mines and 18,403 tons from foreign sources) compared with 99,478 tons in 1938 (79,615 tons from domestic mines and 19,863 tons from foreign sources). Total sales to the steel industry increased to 139,060 tons in 1939 (62,196 tons in 1938), while sales to manufacturers of hydrofluoric acid advanced to 31,966 tons (20,976 tons in 1938) and those to makers of glass and enamel increased to 22,018 tons (12,902 tons in 1938).

Despite the improved demand for fluorspar in 1939, the average composite selling price of all grades of fluorspar (both domestic and foreign) delivered to consumers in the United States was 32 cents a ton less than in 1938. The average selling price f. o. b. Illinois-Kentucky mines of fluorspar shipped to steel plants was $18.24 a short ton ($18 in 1938), of that shipped to manufacturers of hydrofluoric acid \$27.34 (\$25.29 in 1938), and of that to makers of glass and enamel \$26.87 (\$27.90 in 1938). The average selling price at seaboard (duty paid) of imported fluorspar shipped to steel plants was \$20.64 a short ton in 1939 (\$20.56 in 1938) and of that shipped to manufacturers of hydrofluoric acid \$29.76 (\$27.54 in 1938).

Salient statistics of the fluorspar industry in the United States, 1938–39

	1938		1939

[1] Revised figures.
[2] Figures not available.

Because of the interest that has centered lately on strategic, critical, and essential minerals from a military standpoint, as well as the fact that fluorspar has been classed by the Army and Navy Munitions Board as an essential mineral, it seems fitting at this time to present historic tables comprising data on production and imports.

The total quantity of fluorspar shipped and imported into the United States from about 1870 through 1939 was about 5,333,000 short tons, including about 80 percent from domestic mines and 20 percent from foreign sources.

The total shipments since the beginning of commercial production (about 1870) in the United States through 1939 was approximately 4,294,000 short tons. Illinois has contributed 57, Kentucky 35, and Colorado 5 percent; most of the remaining 3 percent was supplied by New Mexico. Imports of fluorspar into the United States from 1910 (the first year for which complete data are available) through 1939 were 882,360 short tons and imports before 1910 are estimated at 157,000 tons; thus, total imports have been about 1,039,000 tons, of which the United Kingdom has contributed about 51, Germany 20, and France 12 percent. Africa, 7, and Spain, 4 percent, have furnished the greater part of the remainder.

[1] Imports Aug. 1 to Dec. 31, 1909, 6,971 short tons valued at $26,377; not separately recorded before Aug. 1, 1909. Imports before Aug. 1, 1909, virtually all from the United Kingdom, estimated at 150,000 short tons.
[2] Argentina, Australia, Austria-Hungary, Belgium, China, Czechoslovakia, Mexico, Netherlands, Norway, Tunisia, and Soviet Russia in Asia.
[3] Quantity not recorded. [4] Optical fluorspar.

Production and shipments.—Fluorspar was known to have been produced in 1939 at 106 mines and prospects, and small quantities were recovered at an undetermined number of other prospects and reclaimed from millponds, waste dumps, and old workings of abandoned mines. All operations yielded about 173,000 short tons of merchantable fluorspar compared with about 99,000 tons in 1938. However, in spite of the large number of properties worked in 1939, 28 mines produced 87 percent of the total output.

Shipments of fluorspar from domestic mines in 1939 aggregated 182,771 short tons valued at $3,704,959, increases of 127 percent in quantity and 132 percent in total value over 1938. Shipments in 1939 were equivalent to 146 percent of the average annual tonnages shipped in the 5-year period 1926–30. Of the 1939 shipments, 48,648 tons (an all-time high) were shipped by river or by river-rail for delivery to consumers in Illinois, Kentucky, New Jersey, Ohio, and Pennsylvania. In 1938, 20,862 tons were so shipped.

In 1939, mines operated by or for consumers shipped 36,335 short tons of fluorspar for use in their own plants compared with 13,226 tons in 1938.

The average value of all grades of domestic fluorspar shipped was $20.27 ($0.37 more than the 1938 average). The value recorded for domestic fluorspar is the price paid f. o. b. mine shipping point and excludes cost of containers.

In 1939, an undetermined quantity of optical fluorspar from Illinois was sold for $25.

The following table shows shipments of fluorspar by States and by kinds for 1938 and 1939.

Fluorspar shipped from mines in the United States, 1938–39, by States and kinds

State	1938			1939		
	Short tons	Value		Short tons	Value	
		Total	Average		Total	Average
Illinois	35,368	$751,227	$21.24	75,257	$1,638,693	$21.77

[1] Includes flotation concentrates shipped to hydrofluoric acid, steel, and cement plants and run-of-mine fluorspar shipped to steel plants.
[2] Includes flotation concentrates shipped to glass and enamel trades.

Shipments, by uses.—The predominance of the steel industry as a purchaser of fluorspar is evident from the following table.

Fluorspar shipped from mines in the United States, 1938–39, by uses

Use	1938				1939			
	Quantity		Value		Quantity		Value	
	Percent of total	Short tons	Total	Average	Percent of total	Short tons	Total	Average
Steel	64.67	51,991	$912,111	$17.54	68.59	125,371	$2,234,996	$17.83

	100.00	80,403	1,599,666	19.90	100.00	182,771	3,704,959	20.27

Uses.—As shown graphically in figure 1, the steel industry is the chief consumer of fluorspar in the United States, followed in order by the hydrofluoric acid, glass, and enamel industries. Comparatively small quantities of fluorspar are used in a number of miscellaneous operations, such as production of the finer grades of iron castings,

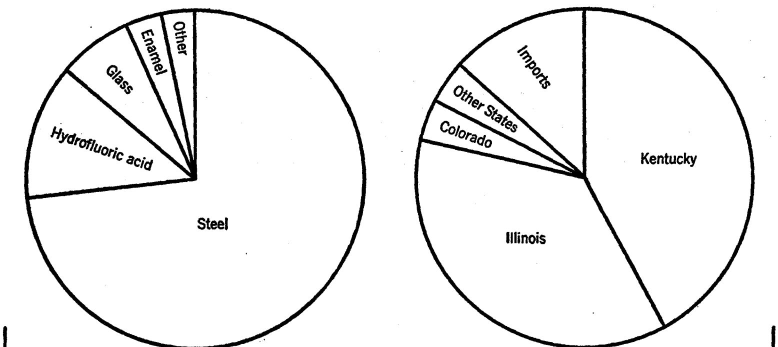

FIGURE 1.—Average annual fluorspar sales in the United States, 1935–39, by consuming industries and by sources.

nickel and Monel metal, cement, ferro-alloys, carbon electrodes, and calcium carbide and cyanamid; reducing aluminum; refining lead and silver; extracting various rare metals from their ores; smelting refractory ores of gold, silver, and copper; as a paint pigment; and as a binder in abrasives.

Chief commercial grades of fluorspar

Name	Chief use	Form	Specifications, in percent		
			CaF_2 (minimum)	SiO_2 (maximum)	Fe_2O_3 (maximum)
Metallurgical	Basic open-hearth steel.	Washed gravel, less than 1 inch and not more than 15 percent of fines.	85	5	
Ceramic	Glass and enamel	Ground: coarse, fine, and extra fine	95	3	0.12
Acid	Hydrofluoric acid	Lump, gravel, and ground	98	1	

Consumption and consumers' stocks.—The following tables give data on consumption and stocks of fluorspar.

Fluorspar (domestic and foreign) consumed and in stock in the United States, 1938–39, by industries, in short tons

[Partly estimated by Bureau of Mines]

Industry	1938		1939	
	Consumption	Stocks at consumers' plants Dec. 31	Consumption	Stocks at consumers' plants Dec. 31
Basic open-hearth steel	73,600	55,000	116,200	69,900
Electric furnace steel	4,000	1,000	7,600	1,400
Foundry	2,000	800	2,400	800
Ferro-alloys	800	400	1,100	400
Hydrofluoric acid	18,900	11,200	26,300	14,100
Enamel	4,000	900	21,400	3,100

Miscellaneous	1,300	900	1,800	700
	115,100	71,800	176,800	90,400

Consumption and stocks of fluorspar (domestic and foreign) at basic open-hearth steel plants, 1935–39

	1935	1936	1937	1938	1939
Production of basic open-hearth steel ingots and castings long tons	30,447,000	43,615,000	46,361,000	25,868,000	43,368,000
Consumption of fluorspar in basic open-hearth steel production short tons	99,600	133,900	138,900	73,600	116,200
Consumption of fluorspar per ton of steel made pounds	6.5	6.1	6.0	5.7	5.4
Stocks of fluorspar on hand at steel plants at end of year short tons	47,500	59,200	71,400	55,000	69,900

The quantity of fluorspar used by individual plants per ton of basic open-hearth steel produced ranges from 1 to 50 pounds—a relatively small proportion of the furnace charge. The average is generally 5 to 8 pounds, but it decreased to 5.36 pounds in 1939 from 5.69 pounds in 1938. It is noteworthy that since 1921—the first year for which these data were collected—the average consumption of fluorspar per ton of basic open-hearth steel made has declined almost steadily from 8.2 to 5.4 pounds. The following table shows the variation in average consumption of fluorspar per ton of basic open-hearth steel over a 5-year period in certain plants that make about 88 percent of the total.

Average consumption of fluorspar (domestic and foreign) per ton of steel, 1935–39, in pounds

1935	1936	1937	1938	1939	1935	1936	1937	1938	1939
13.243	13.187	13.867	12.548	14.079	7.048	6.734	7.360	8.420	6.337
4.182	4.792	5.623	4.457	3.623	9.347	10.495	6.623	11.984	8.506
4.803	4.541	4.376	3.845	3.793	8.168	5.104	4.358	3.831	3.171
8.452	10.519	8.795	8.297	8.095	5.236	5.027	6.619	6.448	6.551
7.027	4.105	3.550	6.843	6.814	6.764	6.357	8.895	8.340	9.370
5.658	5.160	5.275	3.694	3.709	5.257	5.917	5.236	6.195	4.578
6.857	7.416	6.404	6.806	4.958	7.115	6.789	6.816	6.097	6.896

Quoted prices.—In 1939 the quoted price f. o. b. Illinois-Kentucky for fluxing gravel fluorspar ranged from $17 to $22 a short ton for rail delivery and $18 to $22 a ton for barge delivery at Ohio River and tributary landings. Imported fluxing gravel fluorspar (at seaboard, duty paid) was quoted at $21.50 to $27 a short ton.

Stocks at mines or shipping points.—According to reports of producers the total quantity of fluorspar in stock at mines or shipping points at the close of 1939 was 65,365 short tons, or about 22 percent less than in 1938. These stocks comprised about 26,700 tons of crude fluorspar (calculated to be equivalent to 15,000 tons of ready-to-ship fluorspar) and 38,619 tons of ready-to-ship fluorspar.

Stocks of fluorspar at mines or shipping points in the United States, Dec. 31, 1938 and 1939, by States, in short tons

State	1938			1939		
	Crude [1]	Ready-to-ship	Total	Crude [1]	Ready-to-ship	Total

[1] The greater part of this crude (run-of-mine) fluorspar must be beneficiated before it can be marketed.
[2] Revised figures.

Technologic developments.—Further interest in flotation of fluorspar was apparent in 1939. Four new plants—two at Rosiclare, Ill., and one each at Salida, Colo., and Deming, N. Mex.—were completed and put into operation, a new plant is being built at Duncan, Ariz., and two new plants—one each at Lordsburg, N. Mex., and Skyline, Mont.—are planned. The output of flotation concentrates was 22,450 tons in 1939 compared with 10,321 tons in 1938.

The commercial production of fluorspar flotation concentrate for use in the manufacture of hydrofluoric acid, glass, and enamel, which require a finely divided material of high purity, was begun about 11 years ago. The middling product of the flotation process, however, which is not pure enough for the chemical and ceramic trades, is objectionable to steel makers because of its particle size, as such fine material would blow out of the furnace or would not sink into the molten charge. Consequently, during recent years experimenting on agglomeration has been under way; and the Mahoning Mining Co., in cooperation with the Dwight & Lloyd Sintering Corporation, has carried on considerable test work on sintering of fluorspar. In the summer of 1938, 150 tons of minus 100-mesh fluorspar concentrates were sintered on a commercial machine under regular plant conditions. The resulting 150 tons of sinter were divided among three open-hearth steel plants, which found the sinter as satisfactory as the metallurgical gravel fluorspar used ordinarily. Although the sintering of fluorspar has been successfully demonstrated, the Mahoning Mining Co. has not felt justified in installing a sintering plant, because its output of metallurgical-grade concentrates comprises only a small proportion of its total production.

The flotation concentrates produced by the Hillside Fluor Spar Mines will, it is reported, be briquetted and then crushed to gravel size for use in steel plants.

A method of sintering finely divided fluorspar is the subject of United States Patent 2,184,078. According to this patent—

* * * Fluorspar concentrate offers difficulties to sintering for the purpose of increasing its particle size. These difficulties are due to the physical character of the fluorspar concentrates which are of a "sandy" nature. Ordinary moistening and pelletizing processes are ineffective and the charge of concentrate would, therefore, make a dense bed on a sintering machine through which air could not be drawn at a rate sufficient to produce a sintering temperature. This condition is aggravated by the fact that fluorspar has a relatively high fusion temperature so that a higher sintering temperature is required than in the sintering of ordinary materials. Owing to the sandy character of the fluorspar, any pellets formed solely of fluorspar in a pelletizing machine would break down as soon as the charge is exposed to the ignition heat, thus destroying the permeability given to the charge by pelletizing.

In my present invention these difficulties are overcome by forming the fluorspar concentrates into pellets by means of a plastic bonding material which is sufficiently stable during the sintering operation to maintain the pellets of fluorspar concentrates against breakdown until sintered, and which is neutral or unobjectionable in the later metallurgical operations.

In my invention I admix with the fluorspar concentrates, either during or previous to pelletizing, a small quantity of an inorganic bonding material of plastic nature. Such a bonding agent may, for example, be freshly hydrated lime (fresh mason's hydrate), ferrous hydrate, or some ferrous salt, which will form ferrous hydrate in alkaline solution, plaster of Paris, sodium silicate, clay or similar plastics, or any hydrated metal compound compatible with the metallurgical operations in which the fluorspar is to be employed, and having plastic properties such as those of lime or ferrous hydrate. The amount of material thus added may amount, for example, to 5% of the total quantity of fluorspar. During the pelletizing operation in which the fluorspar and the plastic bonding agent in a moistened condition are admixed and tumbled about or otherwise subdivided into pellets, the action of the bonding agent is primarily mechanical, serving to bond and hold the finely divided particles of fluorspar in stable pellet form. A small quantity of fuel may be added either admixed in the interior of the pellets or as a surface coating. This fuel will also be in finely divided condition as, for example, coke breeze or powdered or finely divided coal. In forming the pellets, returns may be employed as is customary in sintering operations.

The pellets are then laid in a bed on a sintering machine to a suitable thickness as, for example, from about 5 inches to 8 inches, and burned with a strong blast of air. As is usual in sintering operations, a down blast of air is used. During the sintering operation the cementing or bonding material may combine or flux with the fluorspar. In the event that lime is employed, the lime will be available for fluxing purposes in the later metallurgical operation. In the event that iron oxide, such as that produced from ferrous sulfate or mill scale, is employed it may also flux with the fluorspar during the sintering, or with impurities such as lime or silica contained in the fluorspar. Inasmuch as the fluorspar is to be used in steel making, the iron oxide thus added may be reduced in the open hearth furnace and replaced by silica or other slag material.

Examples of my invention are as follows:

Example I

Fluorspar concentrate, containing 98% CaF_2, and of the following size—

	Percent
Minus 40 plus 60 mesh	6.8
Minus 60 plus 80 mesh	7.7
Minus 80 plus 100 mesh	19.3
Minus 100 mesh	66.2
	100.0

was mixed with 10% of coke breeze, moistened and mixed in a pelletizer mixer with 5% of freshly hydrated lime and formed into pellets. It was then discharged into a sintering machine on a bed of 5½ inches depth. When ignited and burned with a down draft of air, an excellent sintered product was obtained in about 15 minutes.

Example II

100 pounds of fluorspar concentrate of the characteristics described in example I were mixed with 5 pounds of ferrous sulfate crystals, 2 pounds of freshly hydrated lime and 10 pounds of coke, then moistened and pelletized to form pellets, and sintered on a sintering machine in a bed of 5 inches depth. It ignited readily and sintered in about 10 minutes to an excellent sintered product.

Example III

Fluorspar concentrate such as described in example I was mixed with freshly hydrated lime (mason's hydrate), iron oxide and return sinter fines in the following proportions—

	Pounds
Fluorspar concentrate	100
Mason's hydrate	5
Iron oxide (fine ore)	5
Return sinter fines	40
Coke	10

The mixture was then moistened and pelletized and sintered on a sintering machine as described above. It ignited readily and made an excellent sintered product in about 15 minutes burning time.

The term "pellets" as used herein is not limited to rounded particles or nodules only, but is meant to include also small irregularly shaped masses composed of a number of fine individual particles bonded lightly together in such form that a mass of the pellets, when charged on a sintering machine, will form a bed with interstices between the pellets through which gases may be caused to flow readily. * * *

Engel and Shelton[1] have recorded data obtained in applying flotation to fluorspar mill tailings from Illinois. The results of both batch and pilot-plant tests are given. The object of these tests was to produce "acid-grade" concentrates containing 98 percent fluorspar, less than 1 percent silica, and nearly free from metal sulfides.

United States Patent 2,168,762 covers "improvements in the concentration of ores by flotation and is especially directed to the recovery of fluorspar of a high degree of purity from ores in which it is accompanied by calcareous substances, such as calcite and other forms of calcium carbonate, and/or various mineral sulfides such as galena (PbS) and sphalerite (ZnS)."

Improvements in or relating to methods of extracting fluorine values from fluorspar ores are covered in British Patent 512,005.

[1] Engel, A. L., and Shelton, S. M., Progress Reports—Metallurgical Division. 36. Ore-Testing Studies, 1938-39: Bureau of Mines Rept. of Investigations 3484, 1940, pp. 20-24.

INDUSTRY IN 1939, BY STATES

Arizona.—Production in Arizona in 1939 came chiefly from mines and prospects near Duncan, Greenlee County, and most of it was shipped to the flotation plants at Deming and Lordsburg, N. Mex. Some, however, was shipped to steel plants. Figures on shipments for Arizona in 1939 have been combined with those for New Mexico. The flotation concentrates recovered from the fluorspar, instead of the run-of-mine material produced, have been credited to Arizona in the statistics. Considerable development work was done at the Polly Ann mine in 1939. A flotation plant is being built at Duncan.

California.—At the Big Horn mine in San Bernardino County, some fluorspar was mined in the course of development work, but none was shipped. Some Nevada fluorspar was ground at the grinding plant at West Berkeley and shipped to the ceramic trade in 1939. The ground fluorspar has been credited to Nevada in the statistics.

Colorado.—The effect of reopening the Wagon Wheel Gap mine in Mineral County and of several properties in Chaffee County is shown in the shipments of 7,569 short tons of fluorspar from Colorado in 1939 compared with 1,704 tons in 1938. Most of the 1939 shipments went to steel plants, but some went to iron foundries and to ferroalloy, cement, glass, and hydrofluoric acid plants. Production in 1939 came from Boulder, Chaffee, Jackson, Jefferson, Mineral, and Park Counties, but mines in Chaffee and Mineral Counties supplied 93 percent of the total for Colorado.

A crushing plant was installed at the mines of the American Fluorspar Corporation near Salida. The Colorado Fluorspar Corporation, Salida, completed its new 125-ton combination flotation and jig mill the latter part of 1939. It was operated a short time and produced a small quantity of flotation concentrates. The mill is described and illustrated in a recent article.[2] Fluorspar for the ceramic trade was ground in the mill of the Western Feldspar Milling Co., Denver.

Illinois.—Approximately 128,000 short tons of fluorspar-bearing rock, equivalent to 71,000 tons of merchantable fluorspar, were mined at 25 mines or prospects in 1939 compared with about 75,000 tons, equivalent to 46,000 tons of merchantable fluorspar, mined at 30 mines or prospects in 1938. Of the merchantable fluorspar produced in 1939, 43,000 tons were from mines where the fluorspar occurs in veins, chiefly in fault fissures, and 28,000 tons from mines where the fluorspar occurs in flat-lying tabular masses, locally called blanket formations. Virtually all the output in 1939 came from Hardin County.

Fluorspar-bearing material milled in Illinois in 1939 totaled 147,000 tons, from which 82,000 tons of fluorspar were recovered—a ratio of 1.793:1.

Shipments from Illinois were 75,257 tons in 1939 compared with 35,368 tons in 1938. Of the total, 23,989 tons were shipped by river or river-rail to consumers compared with 13,572 tons in 1938. In 1939, an undetermined quantity of optical fluorspar was sold for $25.

The Argo, Boundary, Crystal, Daisy, W. L. Davis, Hamp, Humm, Lee, Midway, Spar Mountain, Stewart, and Victory mines supplied about 92 percent of the total merchantable fluorspar produced in Illinois in 1939. Most of the remainder came from the Cave in Rock, Dimick, Eureka No. 5, Lacey, and Lead Hill mines.

[2] Pit and Quarry, vol. 32, December 1939, pp. 48-50.

At the Crystal mine near Cave in Rock, a new shaft (No. 3) was sunk 110 feet, and a steam plant was installed at this shaft. In the mill a trommel screen was replaced by a double-decked vibrating screen. The barge loading station at Cave in Rock of the Benzon Fluorspar Co. was purchased by the Crystal Fluorspar Co. in 1939.

The Hillside Fluor Spar Mines completed a flotation plant at Rosiclare. This plant will, it is reported, treat the large tonnage of fluorspar fines from the Hillside mill that have been accumulated over a period of years. The flotation concentrate will, it is understood, be briquetted and then crushed to gravel size for use in steel plants.

The Benzon Fluorspar Co., operators of the Spar Mountain mines, ceased operations in 1939 because its ore reserves virtually were exhausted. The mining property was acquired by a local purchaser. A considerable tonnage of ore was recovered by contractors in mining the remaining pillars. The Spar Mountain mines were opened in 1918 by the Spar Mountain Mining Co., which operated them until 1925, when they were acquired by the Benzon Fluorspar Co. These mines have been important producers of fluorspar in the Cave in Rock district; the output from 1918 through 1939 was about 140,000 short tons.

At the Victory mine, 2,039 feet of diamond core drilling were done; 600 feet of development drifts were driven; a hoist engine was installed at the Carlos shaft; a change house for employees was constructed; and an underground gravity drainage system, consisting of 1,000 feet of ditching, was excavated through the lowest part of the mine to drain the water to the surface through a side hill adit.

Development work was continued by the Rosiclare Lead & Fluorspar Mining Co. on the 800-foot levels on the Daisy and Blue Diggings veins. Although these two veins did not intersect at this level, as was believed, they approach each other closely, being 30 to 40 feet apart. Additional fluorspar was located on the Daisy fault by diamond drilling. The new power plant of the company was completed during the summer of 1939. It consists of two 600-horsepower boilers and a 1,250-kilowatt and a 1,000-kilowatt turbine generator. A stand-by 750-kilowatt generator remains in the old power plant. To dewater the Rosiclare mine, flooded since January 1924, a pump with a 600-horsepower motor and a 620-foot lift and having a capacity of 3,200 gallons per minute will be installed. A 3,000-gallon-per-minute pump was installed in the Rosiclare shaft in 1938.

Core and churn drilling was in progress at the mine of the Cave in Rock Spar Co. In addition to production from its Cave in Rock mine, the company treated considerable purchased ore in its mill on Peters Creek. This company is increasing the capacity of its present mill and building a mill at Cave in Rock.

At the Humm mine near Rosiclare considerable development work was done, and a mill was built on Grand Pierre Creek.

In June the Mahoning Mining Co. put its new flotation plant into operation at Rosiclare. It produces fluorspar, lead, and zinc concentrates by selective flotation. The mill feed comprised tailings from the Benzon mill and ore from the company W. L. Davis mine, which made its initial production in 1939. The ore at this mine occurs in a bedded deposit similar to other Cave in Rock ore bodies, but in addition to fluorspar it carries appreciable quantities of lead and zinc.

Kentucky.—Production of merchantable fluorspar in Kentucky was about 81,000 short tons in 1939 compared with 43,000 tons in 1938; and shipments, which established an all-time high, were 89,563 tons compared with 34,803 tons in 1938. Of the 1939 shipments, 24,659 tons were shipped by river or river-rail to consumers compared with 7,290 tons in 1938.

The output of fluorspar in Caldwell County in 1939 was from the Walker, Eureka, and Crook mines. The Hollowell & Hobby mine, which has been the chief producing mine in Caldwell County in recent years, was nonproductive in 1939. However, the stock of crude ore previously mined was washed, and some was sold.

Production in Crittenden County, amounting to 53,000 tons, came chiefly from the Bachelor, Davenport, Keystone, Lafayette, Pigmy, Pogue, Two Brothers, and Watson (Eagle) mines, which contributed 91 percent of the county output. Production was 15,000 tons in 1938.

At the Watson (Eagle) mine, a fluorspar ore body of high purity was opened during 1939. The Two Brothers mine, inactive for some time, was reopened. The Ada Florence mine, adjacent to the Keystone, was acquired by the Hillside Fluor Spar Mines. A prospect shaft followed by crosscutting and drift driving developed a new ore body at the Pigmy mine. At the Davenport mine, No. 3 shaft was sunk to 260 feet, and a crosscut was driven to the east vein, where a 7-foot ore body was found. A power plant was built and machinery installed at this shaft.

In Livingston County, 28,000 tons of merchantable fluorspar were produced in 1939 compared with 24,000 tons in 1938. The chief producing mines were the C. R. Babb, Klondike, and Nancy Hanks, which supplied 90 percent of the 1939 output of the county.

A jig plant to treat tailings from the Klondike mill was completed and put into operation by John Hughett & Son during 1939.

In 1939 the Faircloth mine near Wilmore, Woodford County, and the Twin Chimney mine near Mundys Landing, Mercer County, shipped small quantities of fluorspar. The fluorspar from the Twin Chimney mine was recovered from an old dump. Veins containing fluorspar and fluorspar associated with barite are being opened in Woodford County.

Montana.—At the Boeing prospect near Austin, Lewis and Clark County, development work was continued, and flotation tests on the ore were in progress. The building of a mill at Skyline is under consideration.

Nevada.—Shipments of fluorspar from Nevada, which were 3,520 short tons in 1939 compared with 2,909 tons in 1938, established an all-time record. Most of the 1939 shipments went to steel mills, but some went to iron foundries and to ceramic and hydrofluoric acid plants.

The chief producing mine in Nevada in 1939 was the Baxter, in Mineral County, which shipped 2,505 tons. The other active mine was the Daisy, in Nye County, which shipped 1,015 tons. Development work at the Baxter mine consisted of sinking the main shaft to 200 feet, drifting 200 feet, and installing a power plant.

New Mexico.—Shipments of fluorspar from New Mexico and Arizona were 6,477 short tons in 1939 compared with 5,159 tons in 1938.

Shipments in 1939 comprised flotation concentrates, which went to ceramic and hydrofluoric acid plants, and metallurgical grade, which went to steel plants.

Production in 1939 was from Catron, Grant, Luna, Sierra, and Valencia Counties. Several new properties were opened and some mines were reopened in New Mexico in 1939. P. L. Grattan completed a flotation mill 1 mile east of Deming to treat ore from the Sadler mine. As a result of mill tests, a small quantity of concentrates was produced. The capacity of the mill is being increased to 50 tons daily. A flotation plant at Lordsburg with a capacity of 75 tons per 24 hours is contemplated by the Fluorspar Milling Co. to treat ore from the reopened Great Eagle mine and purchased ores. Improvements were made in the flotation plant of the Indian Metals Co. at Lordsburg. The flotation plant of General Chemical Co. at Deming operated throughout the year on fluorspar purchased from local producers.

Utah.—Shipments of fluorspar from Utah were 385 short tons in 1939 compared with 370 tons in 1938, all from the Monarch claims in Beaver County; they were consigned to steel plants and iron foundries.

IMPORTS AND EXPORTS [3]

Imports of fluorspar for consumption in the United States in 1939 totaled 16,302 short tons (3,351 tons containing more than 97 percent and 12,951 tons containing not more than 97 percent calcium fluoride) valued[4] at $176,691, compared with 19,622 tons (9,216 tons containing more than 97 percent and 10,406 tons containing not more than 97 percent calcium fluoride) valued[4] at $287,643 in 1938. The value assigned to the foreign fluorspar in 1939 averaged $10.84 a ton. The cost to consumers in the United States also includes duty, loading charges at the docks, ocean freight, insurance, consular fee, and freight from docks to consuming points. The duty on fluorspar containing not more than 97 percent calcium fluoride is $7.50 a short ton and on fluorspar containing more than 97 percent calcium fluoride $3.75 a short ton.

Of the 1939 imports, 73.8 percent was metallurgical gravel fluorspar, 0.8 percent ceramic ground fluorspar, and 25.4 percent acid lump fluorspar. Virtually all the metallurgical gravel fluorspar was imported from France; the ceramic ground fluorspar from France and Germany; and the acid lump fluorspar from Mexico, Newfoundland, Spain, Tunisia, and the United Kingdom. Imports were equivalent to 9 percent of the total shipments of domestic fluorspar in 1939 compared with 24 percent in 1938.

[3] Figures on imports (unless otherwise indicated) compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce; those on exports supplied by the producers. No exports of fluorspar recorded by the Bureau of Foreign and Domestic Commerce.

[4] As defined in sec. 402 of the tariff act of 1930, "The value of imported merchandise * * * is the foreign value or the export value, whichever is higher—that is, the market value or the price at which the merchandise, at the time of exportation to the United States, is offered for sale in the principal markets of the country from which exported, including the cost of containers or coverings and all expenses (including any export tax) incident to placing the merchandise in condition ready for shipment to the United States."

Fluorspar imported for consumption in the United States in 1939, by countries and customs districts

[1] Less than 1 ton.

The following table, compiled from data furnished the Bureau of Mines by importers, shows the quantities of imported fluorspar delivered to consumers in the United States in 1938 and 1939 and the selling price at tidewater (duty paid), irrespective of the year of importation into the United States; it differs from the preceding table, which shows the quantities received in the United States during 1938 and 1939. The quantities in the following table are based upon the actual outturn weights ascertained by sworn weighers and represent the weights on which duty was paid and entries were liquidated. Stocks of foreign fluorspar in the hands of importers in the United States were 466 short tons at the close of 1939 compared with 1,165 tons in 1938.

Imported fluorspar delivered to consumers in the United States, 1938–39

	19,863	475,418	23.93	18,403	423,338	23.00

Producers of fluorspar reported exports of 2,976 short tons of fluorspar valued at $74,443 in 1939 compared with 788 tons valued at $9,061 in 1938. In 1939 all the exported fluorspar went to Canada and the greater part of it was shipped from the Illinois-Kentucky district by rail to Chicago, thence by water over Lakes Michigan, Huron, Erie, and Ontario and the St. Lawrence and Saguenay Rivers to Quebec. Of the 1938 exports, 247 tons went to Canada and 541 tons to Japan.

WORLD PRODUCTION

The following table shows the world production of fluorspar by countries from 1935 to 1939, insofar as statistics are available. Although complete returns for 1938 and 1939 are not yet available, it is evident that the upward trend in world production, which began in 1933, was arrested in 1938 but was resumed in 1939. The greatly increased world production in recent years has been due chiefly to gains in the output of steel and aluminum in many European countries. Despite the fact that fluorspar is produced in about 20 countries, 5—United States 32 percent, Germany 29 percent, U. S. S. R. 13 percent, United Kingdom 9 percent, and France 7 percent—contribute 90 percent of the world total.

World production of fluorspar, 1935–39, by countries, in metric tons [1]

[Compiled by M. T. Latus]

Country	1935	1936	1937	1938	1939
Argentina [2]	403	450	350	1,406	(3)
Australia:

[1] In addition to countries listed, China and Spain produce fluorspar but data of output are not available.
[2] Railway shipments. [3] Data not available. [4] Estimate included in total. [5] Estimated.

Argentina.[5]—Production of fluorspar in Argentina, under the stimulus of demand from Japan, increased from 350 metric tons in 1937 to 1,406 in 1938, of which 1,300 tons were exported to Japan and 10 to Brazil.

Production of fluorspar is confined almost entirely to the Province of Córdoba. It is also mined in the Province of San Luis, but production is small by comparison with that of Córdoba. It is understood that the fluorspar generally averages 97 to 98 percent calcium fluoride, although little sorting or refining is done. The Argentina ceramic industries annually use about 250 or 300 metric tons of the domestic output.

Newfoundland.—Shipments of fluorspar from Newfoundland in 1939 were 12,376 short tons, of which 3,569 tons of acid grade went to the United States and 4,838 tons of special-grade lump (93 to 95 percent CaF_2) and 3,969 tons of fluxing grade went to Canada. Shipments were 9,859 tons in 1938.

The fluorspar deposits in Newfoundland have been described in a recent article by Howse and Fischer.[6]

Union of South Africa.—Production of fluorspar in the Union of South Africa advanced to 11,378 short tons in 1939 from 5,221 tons in 1938. The greater part of the 1939 production was exported to Japan.

At present very little acid-grade fluorspar is available in the Union of South Africa.[7] In the past, fluorspar of this grade has been obtained from freak deposits, but they are now exhausted. A lower grade fluorspar is being mined, however, for metallurgical purposes. The feasibility of raising fluorspar to acid grade by concentration is now under investigation, but the process is still in the experimental stage.

U. S. S. R.—The fluorspar deposits of the U. S. S. R. have been described by the Institute of Economic Mineralogy.[8] Except for a two-page summary in English, from which the following is quoted, the text is in Russian.

> * * * In the geological part particular attention is paid to questions relating to the fluorspar deposits of Eastern Transbaikalia, where such large deposits as the Abagaitui and the Kalangui and a number of much smaller ones are located; they are distinguished by a particularly simple mineralogical composition and relatively low temperature conditions of formation. These deposits of the Turga and Argun groups are characterized by the presence in the ore veins of nearly exclusively fluorspar with the addition of varying relative amounts of quartz, and by the absence of sulfide minerals.
>
> To the same group of deposits belongs the Onon group, including relatively small deposits, of which the Sedlovoie is located near the station of Sedlovaia.
>
> The Solonechnoie deposit, located about 250 km. from those of the Turga and Argun groups, is of a different nature. The fluorspar veins here are composed partly also of very pure fluorite with a greater or lesser amount of quartz; it is characterized as a higher-temperature deposit than the preceding one, according to data of geological and mineralogical investigations.
>
> Mention is made also of the deposits of the Far East region.
>
> The Suenga and other deposits located in Western Siberia have been as yet little studied, both from the mineralogical and petrographical, and from the geological standpoint.
>
> A brief description is given of the deposits located within the region of Southern Kazakhstan and Middle Asia. They are usually distinguished by a complex mineralogical composition which makes their utilization rather difficult. Thus, the Badam deposit is characterized by the content, along with fluorspar, also of

[7] South African Mining and Engineering Journal, vol. 1, pt. 1, April 22, 1939, p. 224.
[8] All-Union Scientific Research Institute of Economic Mineralogy, Fluorspar in U. S. S. R.: Trans. 119, Moscow, U. S. S. R., 1937, 335 pp.

barite, their separation being difficult. The large Khaidarkan fluorspar deposit in Kirghizia is rich in sulfides, among which cinnabar plays the predominant part. The utilization of this large fluorspar deposit is also hampered by the absence of sufficiently developed technological methods.

A characteristic of the Aurakhmat deposit in Kazakhstan is also given; this is distinguished by a relatively low sulfide content and a favorable mode of occurrence of fluorspar ores among limestones, the reserves being large.

Of a quite different nature, as seen from the occurrence in the form of a large thick vein in granite, is the Takob fluorspar deposit in Tadjikistan. The vein intersecting the granite is distinguished by the content of sulfides, mainly galena, partly zinc blende, and—which is characteristic of this deposit—also of products of oxidation of these minerals.

This deposit, as shown by the prospecting works carried out by the Institute of Economic Mineralogy and by the Middle Asia Geological Trust, possesses vast reserves of fluorspar. As a result of the technological works conducted by the Institute simultaneously with prospecting, the deposit has become now one of great economic importance.

In the monograph a brief description is given also of the explored and developed large Kuli-Kolon deposit of optical fluorite, located on the shore of Lake Kuli-Kolon in Tadjikistan.

In addition to a geological description, detailed mineralogical and petrographical characteristics are given for all of the deposits, the chief attention being paid to those studied by the Institute of Economic Mineralogy and to those studied by this Institute but partly, as for example, the large Amderma deposit near the island of Vaigach, etc.

In the technological part of the monograph the results are cited of a study of the methods of concentration of the fluorspar ores from the deposits described in the geological part, chiefly those of Eastern Siberia, of the Amderma deposit and of a number of those in Middle Asia and Kazakhstan. Of particular interest are the results which were obtained in the course of the works of the Institute of Economic Mineralogy dealing with the study of the possibility of concentrating fluorspar ores, containing oxides of lead and zinc, from the Takob deposit. Eng. Eigheles who conducted this work succeeded in obtaining positive results and in establishing the possibility of fluorspar concentration even in the presence of lead and zinc oxides, and of the utilization of particularly poor ores as well.

Data are also presented concerning the lines along which the works are to be conducted on the concentration of fluorspar from different deposits and of diverse mineralogical composition, structure, and origin.

In the third, economic, part of the monograph a discussion is presented of the technical requirements which fluorspar should satisfy, and of its standards, and the questions are summed up concerning the utilization of fluorspars in different industries. The problems of mining, exports and imports of fluorspar by different countries, and the treatment of fluorite ores in various industries, subsequent to their concentration, are also discussed. A detailed review is given of the condition of the fluorspar industry in USSR and in foreign countries.

CRYOLITE

Cryolite occurs in commercial quantity and is mined at only one place—Ivigtut, Greenland. It is used in the metallurgy of aluminum, in the manufacture of glass and enamels, and in insecticides.

Gibbs [9] has described the mine at Ivigtut, grades of ore produced, methods of processing and purification, and various uses of cryolite.

The cryolite mine at Ivigtut is owned by the Danish State, and the mining concession formerly belonged to the A/S Kryolith Mine og Handels Selskabet, Copenhagen, which divided all the raw material between the Pennsylvania Salt Manufacturing Co., Philadelphia, Pa., and the Oresunds Chemiske Fabriker, Kommanditselskake, ved C. F. Jarl, Copenhagen. The mining concession previously in force expired at the end of 1939. The industry has been reorganized and consolidated into a stock company controlled jointly by the State and the private interests concerned.[10] The merger and the formation of the new company, which will be known as the Kryolithselskabet Øresund A/D (Øresund Cryolite Co., Inc.), has been approved by the Parliamentary Financial Committee and will go into effect on January 1, 1940. It is understood the reorganization will not alter the existing world marketing arrangements.

Imports.—The following table shows imports of cryolite into the United States in 1938 and 1939. As cryolite is mined only in Greenland, it is evident that importations credited to countries other than Greenland probably include artificial cryolite.

Cryolite (natural and artificial) imported for consumption in the United States, 1938–39, by countries

Country	1938		1939	
	Long tons	Value	Long tons	Value
Canada			39	$7,426

FELDSPAR

By Robert W. Metcalf

SUMMARY OUTLINE

The output of crude feldspar in the United States rose sharply in 1939, exceeding in quantity that of any year except 1937, but the value was less than that in several earlier years; however, a substantial output of feldspathic material, known as "aplite," produced in Virginia, might have been included in the 1939 totals if it had been possible to do so without revealing confidential information. Even excluding this material, which virtually made its commercial debut in 1939, the average value of the output ($4.39) was less than in 1938, continuing a steady downtrend begun in 1936, when the average sales realization reported by producers was $5.32 a long ton.

Salient statistics of the feldspar industry in the United States, 1938–39

	1938	1939	Percent change in 1939
Crude feldspar:			
Domestic sales:			
Long tons	196, 119	253, 466	+29. 2
Value	$895, 081	$1, 112, 857	+24. 3
Average per long ton	$4. 56	$4. 39	−3. 7
Imports:			
Long tons	7, 651	7, 460	−2. 5
Value	$56, 126	$52, 141	−7. 1
Average per long ton	$7. 34	$6. 99	−4. 8
Ground feldspar sold by merchant mills:			
Short tons	214, 514	259, 194	+20. 8
Value	$2, 466, 252	$2, 862, 278	+16. 1
Average per short ton	$11. 50	$11. 04	−4. 0

Sales of ground feldspar (excluding aplite) advanced to 259,194 short tons valued at $2,862,278 compared with 214,514 tons valued at $2,466,252 in 1938 and the all-time peak of 279,272 tons valued at $3,486,741 in 1937. Although the tonnage was exceeded only in 1937, the value of the 1939 output, while 16 percent higher than in 1938, was less than that in both 1936 and 1937.

Imports of crude spar in 1939, all from Canada, were slightly less than in 1938 and much less than in other recent years except the depression years 1932 and 1933.

Nearly all the States producing crude feldspar shared in the increased activity in 1939. There were increases of approximately 35 percent in Connecticut, New Hampshire, and North Carolina. Output in California and Wyoming in 1939, although still comparatively small, showed large percentage gains over 1938.

DOMESTIC PRODUCTION

In accordance with the usual practice in the industry, crude feldspar is reported in long tons of 2,240 pounds and ground spar in net (short) tons of 2,000 pounds.

Crude feldspar.—Crude feldspar sold or used in 1939 increased to 253,466 long tons valued at $1,112,857 compared with 196,119 tons valued at $895,081 in 1938 and 268,532 tons valued at $1,383,249 in 1937, the all-time record year.

Crude feldspar sold or used by producers in the United States, 1935–39

[Value at mine or nearest shipping point]

Year	Long tons	Value		Year	Long tons	Value	
		Total	Average			Total	Average
1935	189,550	$1,005,021	$5.30	1938	196,119	$895,081	$4.56
1936	244,726	1,303,090	5.32	1939	253,466	1,112,857	4.39
1937	268,532	1,383,249	5.15				

Crude feldspar sold or used by producers in the United States, 1937–39, by States

Undistributed [2]	17,291	105,649	10,465	59,126	8,503	46,582
	268,532	1,383,249	196,119	895,081	253,466	1,112,857

[1] Included under "Undistributed." [2] Includes States indicated by "1."

In 1939 feldspar was mined in 13 States, 1 more than in 1938. After a lapse of a year, Maryland again reported a small output. Wyoming, which first reported sales in 1938, increased its shipments sixfold to a total of 6,726 tons. North Carolina, notwithstanding a 35-percent gain in tonnage over 1938, produced only 30 percent of the national total compared with 29 percent in 1938 and 35 percent in 1937. South Dakota raised its output to 48,328 tons, 14 percent more than in 1938. A 35-percent increase over 1938 ranked New Hampshire ahead of Colorado, which, despite a 9-percent gain over

1938, failed by a wide margin to equal its output in 1937, when it was the second largest producing State. Virginia ranked fifth as a producer of feldspar in 1939.

The downtrend in average values continued in 1939; in several States the decline was caused by larger shipments of lower-grade spar, and in a few States the averages actually increased. A further decline in average values of standard grades is indicated. Sales realizations in South Dakota and Colorado were \$2.77 and \$3.59, respectively, as against \$2.90 and \$3.81 in 1938. In certain Eastern States sales realizations in 1939 were as follows: Maine, \$4.10; New Hampshire, \$4.71; and North Carolina, \$5.18—compared with \$4.94, \$5.31, and \$5.21, respectively, in 1938.

Ground feldspar.—Sales of ground feldspar increased sharply compared with 1938, the tonnage rising 21 and the value 16 percent; however, sales were 7 percent lower in quantity and 18 percent lower in value than in 1937, the all-time record year. Colorado and South Dakota mills furnished 35 percent of the total ground feldspar sold or used in 1939 and 1938 compared with 30 percent in 1937. North Carolina and Tennessee mills, after suffering more than those in other States in the 1938 slump, increased their sales by more than 14,000 tons in 1939 when they supplied 29.2 percent of the total compared with 28.7 percent in 1938 and 32.5 percent in 1937. Three mills grinding imported Canadian feldspar shipped 4 percent of the total sales of spar from United States mills in both 1938 and 1939. In 1937, 6 percent of the total tonnage ground was imported spar.

Shipments of ground spar, from South Dakota, the leading producer in 1939, rose to 49,497 short tons, a record for the State and 16 percent higher than in 1938, the previous high year. Tennessee was second in rank, followed by Colorado and North Carolina. Sales from North Carolina and Tennessee mills in 1939 totaled 75,740 tons, 23 percent more than in 1938. Colorado's output also increased 23 percent to 41,176 tons. New Hampshire, Arizona, and Virginia showed substantial gains over 1938. New Jersey's output rose 35 percent to 18,727 tons.

Ground feldspar sold by merchant mills[1] *in the United States, 1935–39*

Year	Active mills	Domestic			Canadian			Total	
		Short tons	Value		Short tons	Value		Short tons	Value
			Total	Average		Total	Average		
1935	29	189,289	\$2,460,073	\$13.00	10,806	\$199,067	\$18.42	200,095	\$2,659,140
1936	30	222,126	2,884,493	12.99	14,764	270,360	18.31	236,890	3,154,853
1937	31	263,387	3,187,185	12.10	15,885	299,556	18.86	279,272	3,486,741

1939	31	249,889	2,685,473	10.75	9,305	176,805	19.00	259,194	2,862,278

[1] Excludes potters or others who grind for consumption in their own plants.

The average sales value of ground feldspar shipped by merchant mills in the United States declined further in 1939 to \$11.04 a short ton compared with \$11.50 in 1938 and \$12.49 in 1937, reflecting the larger consumption of graphic granite and other lower-grade spar, as well as further shading in the average prices of standard grades.

Average prices in virtually all States were lower and ranged from $6.42 to $18.01 as against $6.55 to $21.09 in 1938. Sales realizations in the Eastern States were as follows: New Jersey, $18.01; Maine, $12.68; and North Carolina-Tennessee, $12.15, compared with average values for Colorado and South Dakota of $6.42 and $6.88, respectively. Sales of ground spar manufactured from Canadian crude averaged $19 per short ton, a reduction of 26 cents from that reported in 1938.

Ground feldspar sold by merchant mills [1] in the United States, 1937–39, by States

[2] Included under "Undistributed."

Minerals Yearbook, 1939 (pp. 1301–1302), listed feldspar grinding mills and their locations. In 1939 there were 31 mills in 13 States operated by 25 producing companies, of which 4 were merely subsidiary corporations of major producing companies. In California the American Radiator & Standard Sanitary Corporation succeeded the Standard Sanitary Manufacturing Co. at Campo, and the Kennedy Minerals Co. took over the Los Angeles plant of Chamberlain Co., Inc. The Coors Porcelain Co., Golden, Colo., was added to the list of producers. The Oxford Mining & Milling Co., West Paris, Maine, and the Tennessee Mineral Products Corporation, Spruce Pine, N. C., former subsidiaries of United Feldspar Corporation, were operated after January 1, 1940, as the Oxford Division and Minpro Division, respectively, of the United Feldspar & Minerals Corporation.

CONSUMPTION AND USES

Crude feldspar.—Most crude feldspar is sold to merchant mills, which obtain material from several mines or localities, store and sort it according to grade and source, blend and grind it to required purity and fineness, and sell the ground product. However, at least two sanitary-ware manufacturers mine and grind spar for their own use, and some enamel and pottery manufacturers purchase part of their feldspar requirements crude and process it as needed with their own equipment. Manufacturers of soap, cleansing, and nonskid compounds also buy crude spar, chiefly from mines in New England and the South, and, after grinding or other processing, utilize it as an abrasive in their products. A small tonnage of carefully selected crude material, commanding a substantial premium over No. 1 grade commercial spar, was reported sold for use in the manufacture of artificial teeth.

Ground feldspar.—For several years the glass industry has taken an increasingly large proportion of total sales of ground spar, but in 1939 this industry consumed only 53.4 percent of the gross sales compared with 54.9 percent in 1938 and 50.9 percent in 1937. If consumption of nepheline syenite, aplite, and other competitive sources of alumina were included with the feldspar sales the importance of this outlet would have continued to grow relatively as well as actually in 1939. The increased consumption of glass spar at the apparent expense of the higher-price pottery grades is a contributing factor in the smaller realization per ton for both ground and crude feldspar in recent years. Pottery makers used about 34 percent and enamel plants 11 percent of the ground feldspar sold in 1939. The rest was shipped for use in soap and abrasives and for miscellaneous purposes, largely ceramic.

Ground feldspar sold by merchant mills in the United States, 1937–39, by uses, in short tons

Use	1937		1938		1939	
	Short tons	Percent of total	Short tons	Percent of total	Short tons	Percent of total
Ceramic:						
Glass	142,028	50.9	117,800	54.9	138,336	53.4
Pottery	102,346	36.6	74,035	34.5	87,209	33.7
Enamel and sanitary ware	25,111	9.0	19,395	9.0	28,356	10.9
Other ceramic uses	6,442	2.3	2,077	1.0	2,132	.8

[1] Not separately reported.

The following table, presented for the first time, shows distribution of ground feldspar by chief consuming States, as reported by grinding mills processing 99 percent of the feldspar ground in 1939. According to these data Ohio was the largest market for ground spar, taking 21 percent of the total. Indiana and Pennsylvania each took 15 percent, New

Shipments of ground feldspar from mills into States [1] in 1939, in short tons

State	Short tons	State	Short tons
California	7,590	Pennsylvania	37,466
Illinois	15,948	Tennessee	5,077
Indiana	38,189	West Virginia	19,188
New Jersey	34,309	Wisconsin	5,134
New York	14,995	Other States [2]	25,463
Ohio	53,410		
			256,769

[1] Data include 99 percent of total ground feldspar.
[2] Arkansas, Colorado, Kentucky, Maryland, Mississippi, Oklahoma, South Carolina, and other States for which shipments cannot be segregated. Small shipments to Canada also included.

Jersey 13 percent, West Virginia 7 percent, and Illinois and New York 6 percent each. Included under "Other States" are sizable tonnages shipped to Maryland, Mississippi, Oklahoma, and South Carolina. One grinder reported small sales to Canada.

NEPHELINE SYENITE

Production of nepheline syenite in Ontario, Canada, continued throughout 1939. The largest company, Canadian Nepheline, Ltd., ships most of the tonnage obtained from its Blue Mountain (Peterborough County) quarry to the grinding mill of its subsidiary, the American Nepheline Corporation, Rochester, N. Y. Although the largest part of the company output is consumed by glass manufacturers, a fine-grinding unit has been installed to prepare material for general ceramic uses. The company mill at Lakefield, Ontario, now supplies the Canadian glass trade. A good general review of the operations of this company, which includes a detailed description and flow sheets of its plant with data as to the product and its applications, was published recently.[1]

Two quarries were operated in a coarse nepheline syenite pegmatite in Dungannon Township, Hastings County, during 1939. The product averages higher in nepheline and consequently higher in alumina than the Blue Mountain material. It was shipped to the processing mills of the Golding-Keene Co., Keene, N. H., and the United Feldspar & Minerals Corporation, Oxford Division, West Paris, Maine, and blended with granular glass spar. Late in 1939 development was begun on a third property to furnish raw material to the Rochester mill of the Consolidated Feldspar Corporation.

The only commercial production of nepheline outside of Canada, of which the Bureau of Mines has information, is in the U. S. S. R. on the far-northern Murmansk coast of the Kola Peninsula. Nepheline tailings or waste from the flotation of apatite at Kirovsk are now being concentrated in a new plant recently put in operation.[2] Other byproducts of the apatite wastes will be soda, potash, and portland cement. The concentrates will be shipped to the Volkhov aluminum plant, which is being equipped to use nepheline in place of bauxite in the manufacture of aluminum oxide. A detailed description of the Kola Peninsula deposits and of nepheline syenites and related rocks in the Urals, Siberia, and Central Asia, with chemical analyses and notes as to origin of the rocks and constituent minerals, has been published.[3 4]

Apparently Canadian nepheline syenite has become firmly established as a ceramic raw material. Shipments were begun in 1936, and annual output now greatly surpasses that of feldspar in Canada. The Bureau of Foreign and Domestic Commerce reported imports of nepheline syenite separately for the first time in 1939, when 26,099 long tons of crude material, valued at $95,453, entered the United States, all from Canada. No ground nepheline syenite was imported in 1939.

In addition to increased demand from glass plants, a recent customs decision, if sustained, may encourage importation of nepheline syenite. The United States Customs Court, Third Division, (C. D. 293) set aside an assessment of 30 percent ad valorem under paragraph 214 of the Tariff Act of 1930 and held nepheline syenite, when ground to the consistency of a sand, to be free of duty under paragraph 775 as manufactured sand.[5]

The addition of nepheline syenite to pottery, semivitreous ware, sanitary porcelain, tile, and structural-clay bodies has certain advantages, according to G. A. Bole,[6] professor of research, Engineering Experiment Station, Ohio State University. The syenite increases fluxing action and lowers fusibility, thus conserving time and fuel. It also increases translucency and reduces warpage and crazing. Additions of 3 to 5 percent of nepheline syenite to structural-clay bodies increase their vitrification and mechanical strength, as its active fluxing properties offset somewhat the greater refractoriness of many domestic clays.

In testing the suitability of nepheline syenite for use in heavy-clay products, additions of 3 percent B-grade Lakefield syenite to fire-clay mixtures lowered the absorption 20 percent according to Chilcote and Koenig.[7] Fluxing of wall-tile and floor-tile bodies with nepheline syenite and feldspar alone and with various mixtures of nepheline, talc, feldspar, and pyrophyllite was studied by Koenig.[8] His conclusions, which largely substantiate Bole's claims,[9] were that the lower fusibility and increased fluxing action of nepheline syenite permit the formulation of bodies maturing at lower temperatures and increase the life of refractories. Direct substitution of nepheline syenite for potash feldspar in wall-tile bodies lowers absorption and moisture expansion and increases shrinkage and mechanical strength. The thermal expansion of both the so-called low and high talc wall-tile bodies is reduced by direct substitution of nepheline syenite for potash feldspar, whereas wall-tile bodies singly fluxed with nepheline syenite have a higher thermal expansion than corresponding bodies singly fluxed with potash feldspar. The greater refractoriness of American clays compared to English clays is compensated for by the increased fluxing action of nepheline syenite.

TECHNOLOGIC DEVELOPMENTS

The search for better and more efficient means of separating feldspar from quartz or other impurities still is active. Lower-grade spars, some feldspathic pegmatitic rocks, and even glacial sands are being tested and studied as sources of substitutes for, or competitors to, feldspar hitherto obtained chiefly from pegmatites. Ordinary gravity methods of concentration do not separate feldspar from quartz and certain other associated minerals. In the sand sizes other methods

of separating the minerals include various electrostatic and allied processes, but the most promising from a commercial standpoint are wet methods that depend upon surface properties; flotation is suitable for fine material and agglomerate tabling for coarse or sand sizes.

Froth flotation of feldspar to rid it of closely combined quartz has been perfected by members of the staff of the Nonmetals Division, Bureau of Mines. The first commercial installation of the process was the Golding-Keene Co. plant at Keene, N. H., where increasing proportions of quartz were being found in mining. The mill was wrecked by the hurricane in September 1938 but was partly rebuilt the following spring and again placed in operation; however, a new body of high-grade feldspar at the mine, with adequate reserve for several years, has now made operation of the flotation plant unnecessary, at least for the present. A second mill for separating feldspar from quartz has been authorized and soon will be under construction at the Erwin (Tenn.) plant of the Consolidated Feldspar Corporation. Similar plants are contemplated by several other companies, according to Oliver C. Ralston, chief engineer, Nonmetals Division, Eastern Experiment Station, Bureau of Mines.

All natural feldspar and quartz mixtures do not behave the same when treated by agglomerate tabling and flotation. Bureau of Mines investigators found that this was due to alteration of the feldspar. This alteration, even when invisible, may so activate the quartz as to make it float with the feldspar. Details of the processes have been described in a recent paper.[10] Cationic reagents, such as have proved useful in the Bureau's work on other acid minerals (chiefly substituted ammonium compounds and nitrogen bases), are suitable collectors, but other chemical additions were required to supplement mechanical methods of cleaning the mineral particles. Best results were obtained with lauryl amine hydrochloride and fluorine-bearing acids or salts in an acid circuit.

Considerable attention also has been given to the recovery of feldspar from various granites and other feldspathic rocks. Some years ago attempts were made in New Hampshire to salvage the feldspar content of the waste from granite quarrying. Recently similar efforts in Missouri have been reported.[11]

A new material that shows promise of commercial use as an important source of mixed feldspars in pottery manufacture is alaskite, composed essentially of quartz and alkali feldspars. The electrotechnical laboratory of the Bureau of Mines at Norris, Tenn., recently has tested a rock of this type occurring near Spruce Pine, N. C.; it comprises chiefly potash and soda feldspar (in about equal proportions) and quartz. This rock, when ground to a fine powder and treated electromagnetically for removal of a small content of ferromagnesian minerals, gives a satisfactory product for use in china sanitary-ware bodies.

During studies having other objectives the Illinois State Geological Survey found that many deposits of glacial sand in Illinois contain

Survey, Bureau of Mines, and Missouri School of Mines, presented at fall meeting of St. Louis section, Am. Ceram. Soc., December 1, 1939; Ceram. Ind., vol. 34, No. 1, January 1940, p. 66.

from 10 to 25 percent feldspar.[12] Investigation is under way to determine the composition and purity of this spar, as well as a practicable commercial method of separation.

An improved method of analysis of potash in feldspars and perhaps other silicates is described by Koenig.[13]

IMPORTS [14]

Notwithstanding the reduction in duty on both crude and ground spar under the Reciprocal Trade Agreement with Canada, effective January 1, 1939, imports of crude feldspar for consumption decreased slightly in 1939 to 7,460 long tons valued at $52,141 (all from Canada) compared with 7,651 long tons valued at $56,126 (1 ton valued at $7 from Brazil and the rest from Canada) in 1938. The average value per ton (foreign market value) dropped to $6.99 from $7.34 in 1938 and $7.09 in 1937.

Two short tons of ground feldspar valued at $54 were imported from the United Kingdom in 1939; no ground feldspar was imported in 1937 or 1938.

Feldspar imported for consumption in the United States, 1935–39

Year	Crude		Ground		Year	Crude		Ground	
	Long tons	Value	Short tons	Value		Long tons	Value	Short tons	Value
1935	8,937	$56,175	1	$106	1938	7,651	$56,126		
1936	10,786	68,198	132	1,276	1939	7,460	52,141	2	$54
1937	12,956	91,885							

Cornwall stone.—Imports of unmanufactured (unground) Cornwall stone in 1939 jumped to 1,684 long tons valued at $17,233, or more than triple the 1938 receipts of 513 tons valued at $4,976. Imports of ground Cornwall stone also increased sharply to 348 long tons valued at $3,965 compared with 233 tons valued at $1,797 in 1938. Imports of crude (unmanufactured) and ground material originated in the United Kingdom in both years.

Cornwall stone imported for consumption in the United States, 1935–39

WORLD PRODUCTION

According to available data, the United States produces far more feldspar than any other country. In normal times important tonnages have come from Norway, Sweden, China, and probably Czechoslovakia. Data for 1939 indicate small decreases both in Canadian output and Norwegian exports. A considerable part of the Canadian spar output is shipped crude to United States grinding mills for processing.

Norwegian and Swedish feldspar generally is exported largely to the United Kingdom, Germany, and other nearby European countries.

Available data on world production of feldspar, 1935–39, appear in the following table.

World production of feldspar, 1935–39, by countries, in metric tons

[Compiled by M. T. Latus]

Country [1]	1935	1936	1937	1938	1939
Argentina (shipments)	495	1,082	1,346	620	(2)

United States (sold or used)	192,592	248,654	272,842	199,267	257,534

[1] In addition to countries listed, feldspar is produced in Czechoslovakia. Official figures of output are not available, but it is estimated that the annual production is approximately 30,000 metric tons (Stat. Comm. Czechoslovak Ceram. Soc.).

[2] Data not yet available.

[3] Includes some china stone.

ASBESTOS

By Oliver Bowles and K. G. Warner

SUMMARY OUTLINE

Sales of domestic asbestos attained an all-time high of 15,459 tons in 1939, an increase of 48 percent over 1938. Their value was more than double that of 1938. Imports also increased greatly. Consumption of asbestos in the United States was 37 percent greater than in 1938 but still was far below the high point of 1937.

The United States leads all countries in the manufacture of asbestos products but in 1939 produced only 6 percent of the quantity and 5½ percent of the value of its domestic requirements. Large tonnages of the better grades of asbestos, used in fabrics and in making magnesia-asbestos insulation and asbestos-cement products, normally are imported from Africa. Although such shipments may be interrupted to some extent owing to the war, it is unlikely that a serious shortage will result because the extensive deposits in Quebec, Canada, situated only about 80 miles north of the Vermont border, have furnished the United States with its major supplies since the industry was organized and doubtless could furnish larger supplies if necessary.

Domestic production of chrysotile asbestos is centered chiefly in the extensive deposits near Hyde Park in northern Vermont. Although production in this region is expanding, the national situation is essentially the same as heretofore; there have been no new developments, and our dependence on foreign supplies is virtually as great as it has been in the past. The Arizona deposits furnish excellent fiber; but mining costs are high, transportation is difficult, and freight rates to eastern markets are excessive. There is no evidence of increasing activity in Arizona.

Small quantities of amphibole asbestos are produced in several States. It is more resistant to chemicals and high temperatures than chrysotile and accordingly is employed chiefly in making special products, such as acid filters.

Unusual attention has been directed toward asbestos during the past year because it has been classed by the Army and Navy Munitions Board as a critical mineral. Asbestos is so classed because it is the chief constituent of brake-band linings and clutch facings and thus is essential to automotive transport and because only a small percentage of the Nation's requirements is obtained from domestic mines.

Synthetic fibers, such as glass wool, mineral wool, and slag wool, are being refined to an increasing degree in manufacture and are competing with asbestos to some extent in the heat-insulation field. Asbestos generally is regarded as an indispensable constituent of automobile brake bands, but a recent patent covering a brake lining of glass fiber bonded with synthetic resin may be prophetic of future developments.

The following table of salient statistics compares 1939 data with those of 1938. A noteworthy feature is the great increase in unit value of domestic sales in 1939. The average sales value of domestic asbestos in 1938 was $23.68 a ton; in 1939 it was about $33. As price quotations of Vermont fiber were the same in both years, the increase in average price can be explained only by the sale of a larger proportion of the better grades.

Salient statistics of the asbestos industry in the United States, 1938–39

[1] Figures of Bureau of the Census (collected biennially for odd years) include value of certain gaskets, packing, and similar products in which little asbestos was employed.
[2] Compiled from the records of the Bureau of Foreign and Domestic Commerce.
[3] Figures not yet available.

The consumption of asbestos depends chiefly on the manufacture of automobiles, on the building trades, and on industrial activity. As stated, automobiles require large quantities for brake bands and clutch facings. Building construction employs many products in which asbestos is an important constituent, such as asbestos-cement shingles and siding, wallboard, and various heat-insulation and fireproofing materials. Asbestos consumption bears a definite relationship to industrial activity because asbestos is used extensively for packings and gaskets in steam and other machinery, as well as for

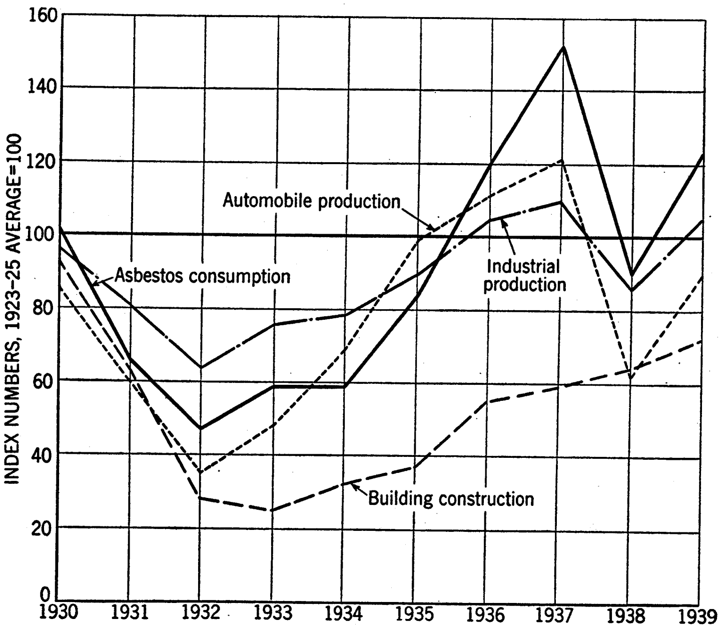

FIGURE 1.—Asbestos consumption compared with automobile production, value of building construction, and industrial production in the United States, 1930-39. Unlike units are reduced to percentages of the 1923-25 average. Statistics on automobiles are from the Bureau of the Census and building contracts and industrial production from the Federal Reserve Board.

boiler lagging and pipe covering. Figure 1 shows the relationship of asbestos consumption to these three major activities for a period of years.

WORLD CONSUMPTION

The following table presents a compilation of data on apparent world consumption of asbestos in 1938, based upon production plus imports minus exports. This table may not give a true picture because stocks held from previous years may be reexported, or material consumed may consist of stocks produced or imported during previous years. The figures are therefore approximate only, but they are the best that can be compiled from the records available. Anomalies are bound to appear in a table compiled upon this basis. For example, the consumption of 3,509 tons by Cyprus, which has virtually no consuming industries, is interpreted as an accumulation of stocks.

World consumption of asbestos in 1938, in metric tons

[1] Compiled by Foreign Minerals Division, Bureau of Mines.
[2] Figures as given in The Mineral Industry of the British Empire and Foreign Countries, Statistical Summary, published by The Imperial Institute, London.
[3] Estimated.

Market conditions.—Markets were disturbed during the spring and summer because of unsettled conditions in Europe and hesitancy of American business. After hostilities were begun the fear of curtailed supplies of asbestos from Africa stimulated a stronger demand for Canadian fibers.

Prices.—All prices for asbestos are quoted on a short-ton basis. Canadian prices are f. o. b. Quebec mines, tax and bags included; Rhodesian, South African, and Russian prices, c. i. f. New York; and Vermont prices, f. o. b. mines, Vermont.

According to quotations in Metal and Mineral Markets, published by the McGraw-Hill Publishing Co., Inc., New York City, prices of Canadian asbestos were constant throughout the year, as follows: Crude No. 1, $700–$750; Crude No. 2 and sundry crudes, $150–$350; spinning fibers, magnesia and compressed sheet fibers, $110–$200; shingle stock, $57–$78; paper stock, $40–$45; cement stock, $21–$25; floats, $18–$20; and shorts, $12–$16.50. Canadian quotations are in American dollars rather than Canadian dollars as formerly.

Rhodesian Crude No. 1 was quoted at $300 and Crude No. 2 at $260 throughout the year.

South African prices were quoted as follows: Amosite: Grade B 1 (white), $140; Grade B 3 (dark), $120. Transvaal Blue: Grade B (long fiber), $450 until August when it dropped to $400 for the remainder of the year; Grade S (short fiber), $140.

Russian Crude AA was quoted at $750; Crude No. 1, $275; Crude No. 2, $240; and shingle stock, $67.50 and up.

Vermont prices were constant throughout the year, as follows: Shingle stock, $57; paper stock, $40; cement stock, $25; and shorts and floats, $12–$18.

NEW DEVELOPMENTS

There were no outstanding new developments in the domestic asbestos industry during 1939, but increasing production in Vermont, a mild revival of activity in anthophyllite production, and a reported occurrence of chrysotile near Lake George, N. Y., are worthy of note. New factors in the asbestos industry abroad include the beginning of production at the important Havelock mine, Swaziland, Africa, initiation of milling on a small scale at the Rahn Lake chrysotile deposit in Ontario, Canada, and development of a deposit of blue asbestos in Western Australia. The year 1939 marked the Diamond Jubilee of asbestos, the seventy-fifth anniversary of the establishment of the organized asbestos industry.

REVIEW BY STATES

Arizona.—Sales of asbestos in Arizona were somewhat smaller in 1939 than in 1938 and were reported by the following companies: Arizona Chrysotile Asbestos Co., Arizona Asbestos Corporation, Emsco Asbestos Co., and Arthur Enders, all of Globe, Ariz.; and Johns-Manville Products Corporation, New York, N. Y. Several other producers sold small quantities to the larger operators.

Georgia.—Limited quantities of anthophyllite were obtained some years ago near Helen, White County, and Hollywood, Habersham County, but recently these districts have been inactive. A small output was reported in 1939 near Dillard, Rabun County, some distance north of the deposits formerly operated.

Maryland.—The Powhatan Mining Co., Woodlawn, Baltimore, Md., continued operation near Pylesville, Harford County. The tremolite obtained is prepared for use chiefly as a filtering medium for chemicals. The company also handles anthophyllite mined in several Southern States. A new mine was opened in this district during 1939.

Montana.—The Montana Asbestos Co. reported small sales of anthophyllite from its property at Gallatin Gateway, Gallatin County.

North Carolina.—A small tonnage of anthophyllite was mined near Greenmountain, Yancey County, in 1939.

South Carolina.—Small shipments of anthophyllite in 1939 from a deposit near Pickens, Pickens County, brought South Carolina for the first time into the list of asbestos-producing States.

Vermont.—Vermont Asbestos Mines, a division of the Ruberoid Co. (address 500 Fifth Avenue, New York, N. Y.), operated continuously with three shifts of workers during the summer of 1939. The extensive deposit worked by the company near Eden, Lamoille County, contains slip-fiber chrysotile in serpentine.

Virginia.—Anthophyllite was mined many years ago near Bedford, Bedford County, and Rockymount, Franklin County. Production of a small quantity of slip fiber was reported in the latter county in 1939.

FOREIGN TRADE [1]

The following table shows imports of unmanufactured asbestos into the United States in 1938 and 1939 by countries and classes. Total imports in 1939 increased 35 percent in quantity and 48 percent in value over 1938. Imports from Africa were nearly twice as great as in 1938 and those from Canada 35 percent greater than in 1938. Substantial shipments of short-fiber chrysotile from Cyprus were renewed, but shipments from the U. S. S. R. declined 50 percent.

Asbestos (unmanufactured) imported for consumption in the United States, 1938–39, by countries and classes

Country	Crude (including blue fiber)		Mill fibers		Short fibers [1]		Total	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value

Venezuela	76	71	(3)	(3)	(3)

[1] In addition to countries listed, a small quantity of asbestos is produced in Madagascar.
[2] Rail and river shipments. [3] Data not available. [4] Less than 1 ton.
[5] Exclusive of sand, gravel, and stone (waste rock only), production of which is reported as follows: 1935, 2,744 tons; 1936, 2,815 tons; 1937, 3,611 tons; 1938, 2,975 tons; 1939, 3,535 tons.

CANADA

The value of sales of asbestos in Canada reached an all-time high in 1939, and the quantity sold was the second highest of any year, being exceeded only in 1937. The mines and mills of the well-known Thetford Mines district of Quebec, where almost the entire production of Canada is mined, were working virtually at capacity throughout the year. Johnson's Co. and Bell Asbestos Mines, Ltd., are changing from open-pit to shaft mining and are planning to introduce the block-caving system.

Activity has been renewed at the Rahn Lake deposit, Bannockburn Township, Ontario. A test shipment of chrysotile comprising 18 tons valued at $720 was made in 1939. This material evidently is not included in the following table of Canadian sales taken from the Preliminary Report on the Mineral Production of Canada in 1939, issued by the Dominion Bureau of Statistics.

Sales of asbestos in Canada, 1938–39

	1938			1939		
	Short tons	Value		Short tons	Value	
		Total	Average per ton		Total	Average per ton
Grade:						
Crudes	2,911	$955,423	$328.21	3,121	$938,718	$300.68
Fibers	163,097	9,710,899	59.54	193,992	12,049,539	62.12
Shorts	123,785	2,223,873	17.97	167,359	2,870,955	17.15
	289,793	12,890,195	44.48	364,472	15,859,212	43.51
Sand, gravel, and stone (waste rock only)	3,279	2,464	.75	3,897	2,930	.75
Total asbestos and waste rock	293,072	12,892,659		368,369	15,862,142	
Rock mined	5,816,368			6,650,416		
Rock milled	4,874,548			5,548,765		

AFRICA

Southern Rhodesia.—The output of asbestos in Southern Rhodesia in 1939 was a little lower in quantity but a little higher in value than in 1938. The following table shows production during recent years:

Asbestos produced in Southern Rhodesia, 1935–39

Year	Short tons	Value	Year	Short tons	Value
1935	42,598	£646,658	1938	58,811	£1,020,921
1936	56,346	836,469	1939	58,313	1,088,782
1937	57,014	840,025			

Union of South Africa.—The output of the Union of South Africa was 5 percent lower in 1939 than in 1938. The following table lists the output from 1935 to 1939:

Asbestos produced in the Union of South Africa, 1935–39, by sources

Year	Short tons				Total value
	Transvaal	Cape Province	Natal	Total	
1935	[1] 20,167	[1] 2,541		22,708	[2]£226,167
1936	21,188	4,048	(3)	[3] 25,236	[2] 337,229
1937	23,921	4,712	(3)	[3] 28,633	[2] 431,212
1938	16,505	6,484	[3] 187	[3] 23,176	[2] 416,401
1939	15,811	6,143	79	22,033	[2] 509,278

[1] Small quantity of blue fiber from Transvaal included under Cape Province.
[2] Value of local sales plus value of exports.
[3] Small production in Natal in December 1936 and in 1937 included in 1938 figures.

The following table states the tonnage of each variety produced from 1935 to 1939. The decline in chrysotile production in the Transvaal to a mere fraction of its former volume reflects the imminent depletion of the Amianthus mine.

Asbestos produced in the Union of South Africa, 1935–39, by varieties and sources, in short tons

Variety and source	1935 [1]	1936 [1]	1937 [2]	1938 [2]	1939 [2]
Amosite (Transvaal)	4,684	4,823	6,531	8,793	11,378
Chrysotile (Transvaal)	15,483	16,149	16,855	[3] 5,573	[3] 582
Blue (Transvaal)	2,541	216	535	2,326	3,930
Blue (Cape)		4,048	4,712	6,484	6,143
	22,708	25,236	28,633	23,176	22,033

[1] Data from Government Mining Engineer, Union of South Africa, Department of Mines, Annual Report.
[2] Data from Union of South Africa, Department of Mines, Monthly Reports.
[3] Includes 187 short tons in 1938 and 79 tons in 1939 produced in Natal.

Swaziland.—The Havelock mine about 12 miles south-southeast of Barberton, which has been under development since April 1937, began producing in June 1939. The shaft, inclined at an angle of 40°, had attained a depth of 850 feet in May 1939. The mine is connected with the railway station at Barberton by means of an overhead cableway 12.6 miles long with a capacity of 7½ tons of bagged asbestos per hour. Production was started in June, and an output of 7,973 short tons was reported for 1939.

CYPRUS

Short-fiber chrysotile is produced in Cyprus. The following table, compiled from the Annual Report of the Inspector of Mines and Labor, shows exports during recent years.

Asbestos exported from Cyprus, 1935–39

Year	Long tons	Value	Year	Long tons	Value
1935	7,513	£50,174	1938	5,578	£88,290
1936	9,506	80,343	1939	(1)	(1)
1937	11,704	126,371			

[1] Data not available.

U. S. S. R.

The following table presents the most recent available statistics on Russian asbestos.

Asbestos produced in and exported from U. S. S. R., 1935–39, in metric tons

Year	Production	Exports	Year	Production	Exports
1935	95,500	[1] 25,109	1938	86,000	(3)
1936	125,117	[1] 26,147	1939	(3)	(3)
1937	125,000	[2] 27,299			

[1] U. S. Bureau of Foreign and Domestic Commerce, Foreign Trade Notes.
[2] Statistics of the Foreign Trade of the U. S. S. R.
[3] Data not available.

AUSTRALIA

A deposit of blue asbestos has been worked in Western Australia recently, and small shipments have been made to the United States. The material is similar to South African blue asbestos. Samples submitted to the Bureau of Mines comprise strong, flexible, dark-blue fibers having a maximum length of 1¾ inches.

BARITE AND BARIUM PRODUCTS

By Bertrand L. Johnson and K. G. Warner [1]

SUMMARY OUTLINE

In response to the intensified demand for crude barite in 1939 new all-time peaks were attained for domestic production (365,870 short tons), domestic crude barite sold or used (383,609 tons), and reported consumption of domestic and imported crude barite (391,683 tons). The apparent new supply (barite sold or used by producers plus imports), however, was less than in 1937, when an exceptionally large quantity of crude barite was imported. The total value of domestic crude barite sold or used by producers also set a new record ($2,344,103), although the average value per ton declined from $6.47 in 1938 to $6.11 in 1939. Increased demands for crude barite came from the glass, lithopone, and barium-chemical industries, but the greater part of the expansion was a consequence of sharply improved demand from lithopone manufacturers. The consumption of crude barite in the production of ground barite decreased slightly. Imports of crude barite in 1939 were less than half those in 1938; the average value declined from $6.09 in 1938 to $4.83 in 1939, owing to the elimination of barite imports from Germany and the increase in imports of lower-price barite from Cuba.

Total sales of barium products in 1939 likewise established a new record of 354,443 short tons, although the value of the sales was exceeded in several recent years. The quantities of ground barite, lithopone, and artificial barium carbonate sold or used by producers in 1939 were greater than in 1938, but sales of blanc fixe (precipitated barium sulfate) and all other barium chemicals were less.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Salient statistics of the barite and barium products industries in the United States, 1935–39

[1] F. o. b. mine shipping point.
[2] Declared value f. o. b. foreign market.
[3] Barite sold or used by producers plus imports.
[4] Includes crushed barite as follows: 1938, 7,121 short tons; 1939, 11,678 tons.
[5] To avoid duplication, the barium chemicals reported here do not include the output of firms that make these chemicals from such products as barium chemicals and imported barite and witherite purchased in the open market.

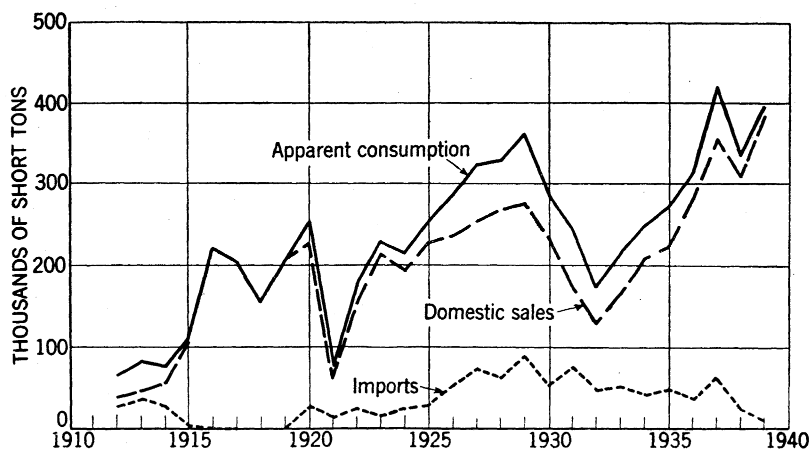

FIGURE 1.—Trends in domestic sales, imports, and apparent consumption of crude barite, 1912–39.

CRUDE BARITE

Production.—Barite was mined in 1939 in 11 States—Alabama, Arizona, California, Colorado, Georgia, Missouri, Montana, Nevada, South Carolina, Tennessee, and Virginia—compared with only 9 States in 1938. No output was reported from Texas in 1939, although this State had produced barite in 1938. Alabama, Colorado, and Montana were among the producing States in 1939, but not in 1938. The California output included witherite as well as barite. Mine production in 1939 totaled 365,870 short tons, a 9-percent increase over that in 1938 (335,433 tons).

Sales.—More domestic crude barite was sold or used by producers in the United States in 1939 than ever before (383,609 short tons), and the total value was higher ($2,344,103).

Missouri continued to be the leading State in sales of crude barite in 1939, with Georgia second; both States reported increases over 1938. The quantity of crude barite sold or used by producers in the nine other producing States was less than half that in Missouri and Georgia combined.

Figure 1 shows trends in domestic sales, imports, and apparent consumption of crude barite since 1912.

Crude barite sold or used by producers in the United States, 1938–39, by States

State	1938		1939	
	Short tons	Value	Short tons	Value
Georgia	64,304	$315,329	86,589	$438,378
Missouri	156,539	1,150,630	171,642	1,163,870
Tennessee	29,898	209,040	57,140	372,348
Other States [1]	58,922	329,522	68,238	369,507
	309,663	2,004,521	383,609	2,344,103

[1] 1938: Arizona, California, Nevada, South Carolina, and Texas; 1939: Alabama, Arizona, California, Colorado, Montana, Nevada, South Carolina, and Virginia.

Prices.—The market quotation for crude barite from Georgia, f. o. b. mines, has remained unchanged at $7 per long ton from 1935 to 1939, inclusive, according to the Engineering and Mining Journal Metal and Mineral Markets. The price of Missouri crude (93 percent barium sulfate, less than 1 percent iron) was $7.50 per short ton during the first half of 1939, dropped to $6.50 to $7.50 f. o. b. mines at the end of June, and remained there until October. Quotations for crude barite (minimum, 90 percent $BaSO_4$) remained at $6 to $6.50 per ton until October, after which only the 95-percent $BaSO_4$ and 93-percent $BaSO_4$ were quoted. Missouri crude (95 percent $BaSO_4$, less than 1 percent iron) was quoted at $6.50 to $7 per ton for the last 3 months of 1939; the 93-percent grade was quoted at $6 to $6.50 per ton for the same period.

The average value, f. o. b. mine shipping point, of crude barite for the entire United States dropped from $6.47 in 1938 to $6.11 in 1939.

Consumption by uses.—Nearly 27,000 tons more crude barite (domestic and imported) were consumed in 1939 than in 1938 by manufacturers of barium products in the United States, raising the reported consumption of crude barite in this country to a new all-time record of 391,683 short tons. The production of crushed barite, lithopone, and barium chemicals required more crude barite than in 1938; the increase was especially marked in the lithopone-manufacturing industry—slightly more than 24,000 tons. About 6,000 tons less crude barite was used in the production of ground barite than in 1938, but the total quantity consumed in this industry remained considerably greater than in the manufacture of lithopone, the leading customer for crude barite before 1938. (See fig. 2.)

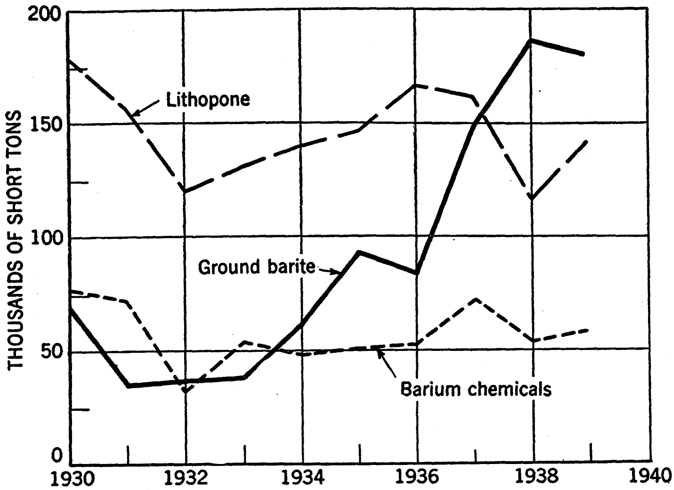

FIGURE 2.—Crude barite (domestic and imported) used in the manufacture of barium products in the United States, 1930–39.

Crude barite (domestic and imported) used in the manufacture of barium products in the United States, 1935–39, in short tons

Year	In manufacture of—			Total	Year	In manufacture of—			Total
	Ground barite	Lithopone	Barium chemicals			Ground barite	Lithopone	Barium chemicals	
1935	93,692	146,164	50,488	290,344	1938	[1] 193,728	117,007	54,250	[1] 364,985
1936	83,990	167,014	52,445	303,449	1939	[1] 192,112	141,556	58,015	[1] 391,683
1937	148,930	162,681	72,371	383,982					

[1] Includes crushed barite as follows: 1938, 7,121 short tons; 1939, 11,678 tons.

Consumption by States.—Crude barite for the production of ground barite, lithopone, and barium chemicals was consumed in 34 plants in 14 States in 1939 as against the same number of plants in 13 States in 1938. The markets for crude barite lie (1) along the Atlantic coast, (2) along the Pacific coast, and (3) in the Mississippi River Valley region where there are three subregions—the West Virginia area, where crude barite is consumed in chemical plants; the Colorado area, where crude barite and witherite are utilized in preparing barium chemicals for use in the sugar industry; and the central valley region of Kansas, Illinois, and Missouri, where ground barite, lithopone, and barium chemicals are produced. Lithopone alone is manufactured in Kansas, ground barite and chemicals in Missouri, and all three products in Illinois. All these products likewise are produced in both the Atlantic and Pacific Coast regions. In the Atlantic Coast region crude barite is utilized for the production of ground barite in Georgia and South Carolina only. In 1939 the Mississippi Valley area was the largest consuming market for crude barite; the Atlantic Coast area ranked second and the Pacific Coast area third.

Crude barite (domestic and imported) used in the manufacture of barium products in the United States in 1939, by States

State	Product manufactured	Plants	Barite used (short tons)
Missouri	Ground barite and chemicals	3	102,218
Delaware, New Jersey, and Pennsylvania	Lithopone and chemicals	5	81,152
California	Ground barite, lithopone, and chemicals	8	57,650
Illinois	do	7	52,761
Colorado	Chemicals	1	
Rhode Island	do	1	
West Virginia	do	2	
Kansas	Lithopone	1	86,224
Maryland	do	1	
Georgia	Ground barite and chemicals	2	
New York	do	2	
South Carolina	Ground barite	1	
		[1] 34	[2] 391,683

[1] A plant producing more than 1 product is counted but once in arriving at State totals.
[2] Includes 11,678 short tons of crushed barite.

Deposits.—A recent report [2] on the Mississippi Valley lead and zinc deposits contains considerable information regarding the distribution and geologic setting of the associated barite deposits of that region. This region, which lies between the southwesterly trending Appalachian Mountains on the east and the southeasterly trending Cordilleras on the west and is bounded on the south by the Southern Highlands, is divided structurally into two parts—the Great Plains and the Central Lowlands—separated by the north-south trending Nemaha-Sioux uplift. The thick Paleozoic and later sediments, which rest on the pre-Cambrian crystalline bedrock, have been flexed into broad domes and basins that constitute the major structural elements of the Mississippi Valley region. Locally, broad, gentle folds are superimposed on the major structural features. Barite deposits occur in both the Great Plains and Central Lowland areas, but only those of the latter region have economic importance at present. In the Great Plains barite has been reported in both the Black Hills uplift of South Dakota and the Llano uplift in Texas. A small quantity of barite has been mined in the latter district.

In the Central Lowland area barite deposits occur on the flanks of the Ozark dome of the Southern Highlands in Missouri; on the Jessamine dome in central Kentucky and the Nashville dome in middle Tennessee—subordinate domes on the Cincinnati geanticline; on the Wisconsin arch of Wisconsin and Illinois; and on a collapsed northeasterly trending dome in the southern part of the Illinois Basin in Illinois and Kentucky. The most important barite-producing district is in Washington County, Mo., on the north flank of the Ozark dome, where the barite is recovered from residual deposits derived from the weathering of barite-bearing veins in the Potosi and Eminence formations of the Cambrian period.

Jewell [3] has described certain barite-bearing veins of probable post-Carboniferous age in the northeastern part of the Central Basin of middle Tennessee. All known veins lie in the Ordovician limestones

and range in width from a few inches to 5 or 6 feet, but most of them are 3 feet or less in width. The more persistent have been traced for 2 or 3 miles in length. They strike from N. 30° E. to N. 70° E., and dip 80° to vertical. The vein filling consists mostly of barite, fluorite, calcite, sphalerite, galena, and locally a little pyrite. Alteration products include calamine, limonite, witherite, and greenockite. Jewell, after discussing the possible origin of the veins, concludes that they are hydrothermal veins of the telethermal type, that therefore they will persist in depth, and that, at some unknown distance below the surface, the igneous rocks occur from which the ore solutions were derived. Various attempts have been made to develop and exploit these veins, and small quantities of galena, barite, and fluorite have

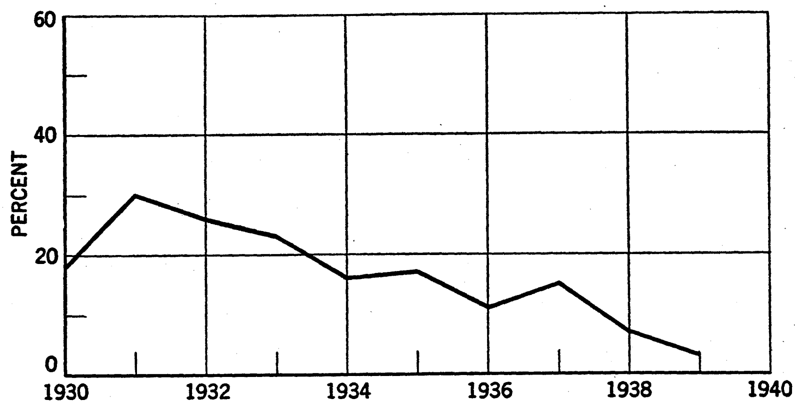

FIGURE 3.—Ratio of imports of crude barite to apparent consumption of crude barite, 1930–39.

been produced. A few carloads of barite were shipped from a deposit in Davidson County in 1934.

Boos [4] describes the occurrence and origin of barite in the form of sand-barite rosettes or "stone roses."

Technologic developments.—The technology of barite is discussed in several recent reports.[5]

Foreign trade.—Imports of crude barite enter the United States chiefly through Atlantic coast ports. In the past imports have consisted largely of German barite that came either from Germany direct or was transshipped from the Netherlands. In 1938, 74 percent of the crude barite imported into the United States originated

in Germany; the rest came from Cuba. In 1939, however, there was a complete reversal in relative importance of these sources; no imports were received in that year either from Germany or the Netherlands. Imports of barite from Cuba, on the other hand, nearly doubled those of 1938 and, except for 51 tons from Algeria and 1 ton from Canada, constituted the entire supply from foreign sources. The total quantity of barite imported in 1939 was slightly less than half as great as in 1938, and the average value of the imports dropped from $6.09 per ton in 1938, when German barite was the dominant material imported, to $4.83 per ton in 1939, when virtually all the barite came from Cuba. With the exception of 1921 the total quantity of barite imported in 1939 was the lowest in any year since the World War period. (See fig. 3.)

Half of the world supply of barite is produced in Germany, and normally more than half of the German output is exported, large quantities of crude barite being shipped to the United States, Great Britain, France, Netherlands, and Belgium. Statistical details of the German barite industry, taken from official German sources, are given in a recent publication.[6]

Italy is one of the larger European producers of barite, and its annual output is exceeded only by those of Germany and Great Britain. In 1933 the United States imported 6,493 short tons of barite from Italy, but since then it has taken much smaller quantities (none at all in 1938 and 1939). The most important barite-producing localities are in the Trento, Carrara, and Milan districts in northern Italy and on the Island of Sardinia. Most of the output comes from the Trento district. Details regarding the various occurrences are given in a recent report of the Imperial Institute.[7]

The barite deposits of Greece,[8] formerly a source of barite imports into the United States, are in Melos, Polivos, and Kimolos Islands in the southern part of the Cyclades Archipelago in the Aegean Sea. The barite occurs as the principal gangue mineral of irregular silver-lead bearing deposits in Tertiary or later lavas and probably is of hydrothermal origin, deposited from solutions related to the associated igneous rocks. Operations, which were begun in 1934, have been confined principally to Melos. The other islands have been little explored. Imports of barite into the United States from Greece reached a maximum of 9,026 short tons in 1937 and then stopped.

Cuba has become an important foreign source of barite for the domestic industry. Barite deposits are known to exist in the Provinces of Oriente and Pinar del Rio.[9] The deposits in Oriente are so inaccessible that no effort has been made in recent years to develop them on a commercial scale. In Pinar del Rio most of the deposits are also inaccessible, and cost of development under present economic conditions is too high to justify exploitation. Only two barite deposits in Pinar del Rio are reported as being exploited at present. These are the deposits of San Luis de Managuacos, the property of the Compañia Marmolera e Industrial del Cangre, S. A., and the deposits of

Abraham Perez at Ysabel Maria. The total output of both of these mines is shipped to the United States. Barite production in Cuba was begun in 1936. Imports into the United States have increased each year from 183 short tons in 1936 to 11,536 tons in 1939.

Canada has started a small barite industry, and in 1939 made an output for the first time since 1933.[10] The production—300 short tons—came from a mine near South Porcupine, Ontario, about 400 miles north of Toronto; it is operated by the Canada Barytes Mines, Ltd., which has an option and lease on the mine and mill of the Canada Night Hawk Mines, Ltd. The property was first developed

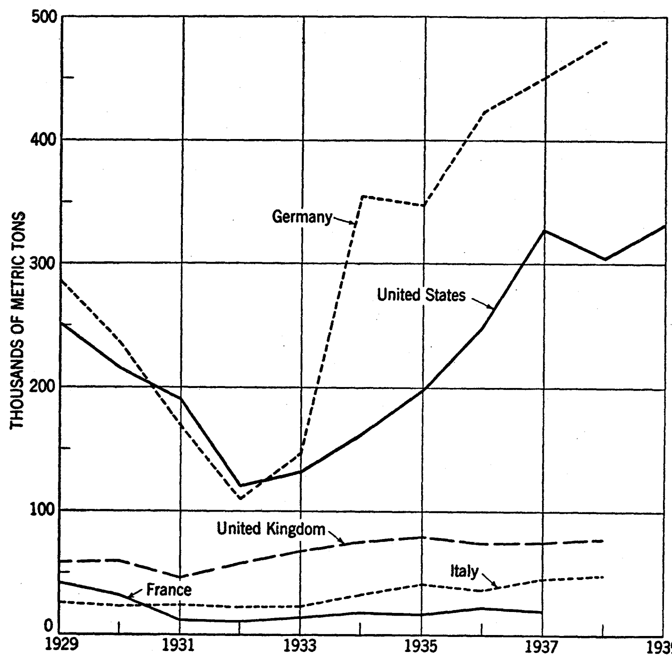

FIGURE 4.—World production of crude barite by countries, 1929–39.

in 1933, when 60 short tons of barite were produced. The shipment of 1 ton to New York, noted in the import statistics, is said to have been a trial order.

Barite has been found in several States of Brazil,[11] particularly in Minas Geraes, where deposits have been exploited to a small extent for local use, largely in paint manufacture. The present output is estimated at about 600 metric tons annually. None has been exported. Development of the barite deposits has been hindered by unfavorable transportation facilities and lack of capital.

Exports of crude barite from the United States are not separately recorded.

Crude barite imported for consumption in the United States, 1938–39, by countries

Country	1938		1939	
	Short tons	Value	Short tons	Value
Algeria	---	---	51	$161
Canada	---	---	1	7
Cuba	6,367	$27,578	11,536	55,817
Germany	4,200	27,188	---	---
Netherlands	14,278	96,469	---	---
	24,845	151,235	11,588	55,985

World production.—Germany and the United States are by far the leading barite-producing countries of the world. (See fig. 4.) Few figures are available for 1939 regarding the barite production of the various barite-producing countries, but in 1937 and 1938 the United Kingdom, Italy, Greece, France, and British India were also important producing nations.

World production of barite, 1935–39, by countries, in metric tons

[1] In addition to the countries listed, barite is produced in Canada, China, Czechoslovakia, Spain, and the U. S. S. R.
[2] Data not available.
[3] Official figures which, it is reported, cover only output of mines included under the mining law.

BARIUM PRODUCTS

Sales.—The quantities of ground or refined barite, lithopone, and artificial barium carbonate sold or used by producers in 1939 were greater than in 1938, in response to marked increases in the demand for all of these barium products. Blanc fixe (precipitated barium sulfate) sold or used by producers, however, decreased for the second consecutive year but did not decline to the 1936 figure. The demand for "other barium chemicals" was less in 1939 than in 1938 but was above that in other recent years. Detailed statistics of barium products during the past 5 years are given in the following table.

Barium products sold or used by producers in the United States, 1935–39 [1]

Product	1935	1936	1937	1938	1939
Ground barite:					
Plants	11	13	12	14	13
Short tons	76,250	69,102	129,777	[2] 161,422	[2] 170,695
Value	$1,407,787	$1,217,818	$2,249,612	[2] $2,786,823	[2] $2,902,973
Lithopone: [3]

Short tons	7,329	11,347	10,755	9,543	12,478
Value	$357,585	$515,624	$511,357	$459,901	$617,799
Other barium chemicals: [4]					
Plants	5	7	6	5	7
Short tons	7,520	8,893	8,632	10,963	9,858
Value	$642,576	$698,942	$796,988	$728,896	$814,170
Total barium products:					
Short tons	268,652	263,810	332,185	[2] 327,102	[2] 354,443
Value	$16,858,413	$16,299,448	$17,242,511	[2] $14,871,835	[2] $15,694,242

[1] To avoid duplication, the barium chemicals reported here do not include the output of firms that make these chemicals from such products as barium chemicals and imported barite and witherite purchased in the open market.
[2] Includes crushed barite.
[3] Does not include cadmium lithopones.
[4] Figures cover chemicals, in order of value, as follows: 1935 and 1937: Chloride, dioxide, sulfide, and hydroxide; 1936 and 1938: Chloride, dioxide, sulfide, hydroxide, and oxide; 1939: Chloride, dioxide, hydroxide, sulfide, and oxide.

Lithopone is used principally in the paint industry. Smaller quantities are consumed by the floor-covering, textile, and rubber industries. Sales of lithopone, 1937–39, by consuming industries, are shown in the following table.

Lithopone [1] *sold or used by producers, 1937–39, by consuming industries*

Industry	1937		1938		1939	
	Short tons	Percent of total	Short tons	Percent of total	Short tons	Percent of total
Paints, enamels, and lacquers	122,915	79.4	101,924	81.1	113,995	79.9
Floor coverings and textiles	20,194	13.1	15,400	12.2	17,429	12.2
Rubber	4,383	2.8	3,148	2.5	3,189	2.2
Other	7,279	4.7	5,274	4.2	8,146	5.7
	154,771	100.0	125,746	100.0	142,759	100.0

[1] Does not include cadmium lithopone.

Data on ground barite sold or used by producers, classified by consuming industries, are given in the accompanying table; this information is available for 1938 and 1939 only.

Ground or refined barite sold or used by producers, 1938–39, by consuming industries

Industry	1938		1939	
	Short tons	Percent of total	Short tons	Percent of total
Well drilling	126,697	78	125,560	74
Paint	8,227	5	9,750	6

[1] Includes crushed barite as follows: 1938, 7,121 short tons; 1939, 11,678 tons.

Prices.—Quotations for ground barite at \$23.65 a short ton in 1939 were the same as in 1938, but by March 1940 they had risen to \$25.65. Prices of ground witherite had a wider range in 1939 (\$41 to \$47 a ton) than in 1938 (\$41 to \$44) and like those of ground barite had risen by March 1940 to \$45 to \$47 a ton. Precipitated barium carbonate quotations remained unchanged from 1938. Lithopone (ordinary) quotations in 1939 showed lower limits than in 1938 (⅜ cent in the lower limits and ½ cent in the upper limits). The upper range in the price of barium chlorate rose to 25 cents a pound in 1939 from 17½ cents in 1938; in March 1940 it was quoted at 20 to 22 cents a pound. Barium chloride prices were unchanged in 1939 from 1938, as were those for barium dioxide. Quotations for high-grade precipitated blanc fixe reached \$80 a ton in 1939 from \$75 a ton in 1938. Pulp-grade blanc fixe quotations were the same in 1939 as in 1938 but in March 1940 had risen from the 1939 quotation of \$40 a short ton to \$50. Barium nitrate quotations also were higher in 1939 than in 1938; in March 1940 they were 9½ to 10½ cents a pound.

[2] 90 percent. [3] Lowest price for pulp grade, highest for high-grade precipitated.

Technology.—Barium-zinc lithopone is the most important single chemical made from barite. A comprehensive description of the process of manufacture of this type of lithopone, with a detailed flow sheet and list of patents, is given in a recent article by Mactaggart.[12] Briefly the process is as follows: Run-of-mine barite is crushed to minus 4-mesh and fed, with coal of similar size, to a rotary furnace heated by gas or pulverized coal. The barite is reduced to barium sulfide. The product ("black ash")—barium sulfide, ash, and unburned coal—is mixed with a weak solution of barium sulfide; the slurry passes into a tube mill and is finely ground; the barium sulfide is leached out of the black ash by a countercurrent leaching system, clarified, and carried to a barium sulfide storage tank. Barium sulfide and zinc sulfate solutions are run separately into a tank and mixed with the help of an agitator. The slurry so formed is treated in a thickener and then passed to a continuous vacuum filter. The filter cake is first dried, then calcined at 750° to 800° C., quenched, and ground in a pebble mill. The ground lithopone passes to classifiers, hydroseparators, thickeners, and filters. This filter cake is dried and disintegrated or ground.

Some cadmium lithopone—that is, lithopone in which the zinc sulfide is replaced by cadmium sulfide—is produced in this country and has been used as a rubber pigment and as a pigment for coloring artificial resin compounds.[13] The cadmium yellows made in the United States are said by Brown [14] to be combinations of cadmium sulfide and barium sulfate, with or without zinc compounds. They are produced in shades ranging from primrose yellow to light chrome orange. Because of their high cost, they are used only for special purposes.

Foreign trade.—Imports of all classes of barium compounds (except barium dioxide, barium hydroxide, witherite, and barium oxide) for consumption in the United States in 1939 decreased in both quantity and value from 1938. Barium dioxide and barium hydroxide imports did not reach the 1936 figures, however, and imports of witherite did not equal those of 1937. There were no imports of precipitated barium carbonate.

Considerable ground barite is exported. An important market is Trinidad, where it is used in oil-well drilling to weight the drilling mud. Imports of barite into Trinidad range from 20,000 to 25,000 tons a year. Germany and the United States have been the principal sources of supplies. Specifications call for barite of not less than 4.25 specific gravity and a fineness of at least 98.75 percent to pass a 300-mesh screen. The barite arriving in Trinidad usually is packed in 120-pound, six-ply paper bags or in double jute sacks. Some of the barite used in the drilling operations is reclaimed from the impregnated mud; the quantity so reclaimed is estimated at about 20,000 tons annually.[15]

The quantity of lithopone exported in 1939 was greater than in any year since 1922—when exports of barium products were first recorded separately—and probably before that date as well, because appreciable quantities of barium products had not been exported; the total value

POTASH

By J. H. Hedges

SUMMARY OUTLINE

During a 20-year period beginning in 1911, various agencies of the Federal Government spent about $2,000,000 searching for sources within the United States from which domestic needs for potash might be economically supplied. Government initiative soon inspired private efforts that led to the founding of a major industry. Now that history is repeating itself in Europe and potash imports again are declining, with the possibility that they may cease altogether, an evaluation of the public benefits derived from this program is in order.

In 1939 American producers supplied 634,000 short tons of potash salts, for which they realized an average of $18.97 per ton at the plants. They may be called upon to deliver an even larger tonnage in 1940, as imports continue to decline. Increased costs may force prices somewhat higher; but no material advance is likely, and any prospective demand can be supplied from domestic sources, if necessary. Contrast this with the situation after the outbreak of the World War. In 1915 the then infant industry produced 4,374 short tons of low-grade potash salts that sold for an average price of $78 per ton f. o. b. plant. In 1916, when importers' stocks were exhausted and imports virtually ceased, the average price obtained at the plant for some 35,700 tons of potash salts produced and sold rose to $119 per ton and did not again drop below $100 until after the war was over. Even at these prices, the maximum output reached was 55,000 tons of K_2O, or about 20 percent of pre-war consumption. At the peak of the potash shortage as much as $500 a ton was paid for muriate on the eastern seaboard. The cost to the ultimate consumer in high prices for certain farm products that cannot be grown successfully without fertilizer was incalculable.

With Europe again at war, no potash shortage now threatens the United States; there is no prospect that the farmer will have to pay exorbitant prices for his potash. This fortunate situation is directly attributable to the foresight that led the Federal Government to pioneer in the search for potash resources and to encourage and foster the building of a domestic industry that now can supply cheaply all the potash required to meet essential needs.

Some measure of the economic significance of these developments may be obtained by applying 1915 prices to prospective 1940 consumption, remembering that with respect to foreign supplies the experience of 1915 is likely to be repeated in 1940. The average price of potash f. o. b. plant was $3.14 a unit of K_2O in 1915 (increased to $4.36 in 1916). In 1939 the average value at the plant was 33 cents a unit, a decrease from the 1915 figure of $2.81 a unit or $281 a ton of K_2O.

Consumption in 1940 may approximate 450,000 tons of K_2O at a total cost approximately $126,000,000 less than for the same quantity in 1915 at the prices then prevailing. Although it would be absurd to claim a direct saving of this amount it is obvious that enormous benefits have accrued to the American people from the discovery and development of domestic resources of potash. By comparison with many other basic industries the potash industry bulks small, but because of its essential character its importance in the national economy is out of all proportion to the dollar value of its products.

Potash is used principally as an ingredient of mixed fertilizers; hence the demand for potash closely follows fertilizer sales, which in turn reflect farm income, although this relationship has been obscured in recent years by farm-benefit payments and crop-control programs. Fertilizer sales continued in 1939 at about the 1938 level; and, if allowance is made for extension of the final delivery date on 1939 discount contracts to January 31, 1940, instead of completing deliveries within the calendar year, as in 1938, a drop of about 3 percent from 1938 sales of potash for consumption in the United States and its possessions is indicated. However, the proportion of total sales that was supplied by American producers rose sharply to establish a new record, although production fell slightly below that in 1938.

During the last 4 months of the year, following the invasion of Poland on September 1 and subsequent events that virtually cut off shipments from Germany, only 52,723 tons of potash fertilizer salts were imported compared with 230,481 tons during the corresponding period in 1938. By virtue of "trading-with-the-enemy" laws the N. V. Export My. was dissolved and its affairs liquidated when war was declared between France and Germany. The French Potash Co., with offices at 30 Rockefeller Plaza, New York City, was incorporated to import and sell French potash salts and the Pioneer Potash Co., with offices at 44 Whitehall Street, New York City, to handle German business. It is reported that all N. V. contracts have been filled from stocks held in this country and at Antwerp and Rotterdam, sizable shipments having been received in January and February 1940; thus the war appears to have had little effect on delivery of the tonnage contracted for during the 1939 discount period, except for delayed completion of some importers' contracts.

Six domestic producers reported a total output in 1939 of 524,986 tons of potash salts equivalent to 307,051 tons of K_2O, a decrease from 1938 of 2 percent in gross tonnage and 3 percent in contained potash. Producers' sales increased 28 percent from 286,437 tons of K_2O in 1938 to 366,287 tons of K_2O in 1939. Sales exceeded production by about 60,000 tons, and stocks were reduced about 66 percent—to 29,440 tons of K_2O. Potash sold by producers and importers for use in agriculture and industry in the United States and its possessions totaled 393,549 tons of K_2O, of which American producers supplied 72 percent (282,487 tons).

Exports of 140,329 tons of salts equivalent to 83,800 tons of K_2O valued at $5,254,840 represented increases from 1938 of 62 percent in bulk, 63 percent in K_2O, and 70 percent in value. Imports of 254,692 tons of salts equivalent to 99,569 tons of K_2O valued at $8,158,334 represented decreases from 1938 of 43 percent in bulk, 49 percent in K_2O, and 40 percent in value. Thus the decline in imports during 1938 continued at an accelerated pace in 1939, influenced in part by the outbreak of hostilities in Europe.

The potential capacity of American producers, without major additions to plants or equipment, has been estimated by the Federal Geological Survey to be approximately 540,000 tons of K_2O per year, considerably more than probable needs. Any deficiency in high-grade salts that might develop can be made up by increased output of manure salts, which can be mined in New Mexico to average around 25 percent K_2O. Some apprehension has been expressed concerning the supply of sulfate, for which this country formerly depended almost entirely on imports; however, this salt now is being produced by three companies at the rate of about 48,000 tons a year, and a new plant for the manufacture of sulfate is expected to begin operations toward the end of 1940. In 1939 approximately 49,000 tons of sulfate of potash and 15,000 tons of sulfate of potash-magnesia were sold for consumption in the United States. Many agronomists believe that sulfate is not essential for some crops to which it customarily has been applied, and its advantages in many instances do not justify farmers in paying the higher price it commands. Hence the demand for sulfate conceivably may decline, and the supply doubtless will be adequate for essential uses. Following the outbreak of war American producers voluntarily restricted export sales of all potash materials to guard against any possibility of a shortage in the American market.

Natural brines and bedded saline deposits were the sources from which nearly 99 percent of the 1939 output of potash was drawn. As in past years, a small tonnage was derived from cement-plant dust and distillery waste. The three major companies (American Potash & Chemical Corporation, Potash Co. of America, and United States Potash Co.) produced 97 percent of the total. Bonneville, Ltd., treating brine from the Salduro marsh at its plant near Wendover, Utah, reported increased production in its second year of operation. As the process employed utilizes solar evaporation, operation of the plant is seasonal, although in that desert region many months of hot, dry weather may be counted upon with considerable assurance. Producers of byproduct potash were the North American Cement Corporation and United States Industrial Chemicals, Inc.

Salient statistics of the domestic potash industry for 1938 and 1939 are summarized in the following table:

Salient statistics of the potash industry (crude and refined potash materials) in the United States, 1938–39

Value	$485, 672	$807, 987

PRICES

The initial price schedule for the 1939–40 fertilizer season, issued by importers May 26, 1939, offered potash salts for prompt shipment from Europe at the base prices of the previous year c. i. f. Atlantic, Gulf, and Pacific ports, subject to 12-percent discount and guaranteed with respect to price reductions. In later schedules issued in June by the importers and the three major producers the price of sulfate of potash (90 percent K_2SO_4) was reduced from $38 to $36.25 per short ton, sulfate of potash-magnesia (48 percent K_2SO_4) from $25.75 to $24.75 per ton, and kainite (20 percent K_2O) from $12.75 to $12.25 per ton, the prices for other salts remaining the same. Quotations c. i. f. Atlantic, Gulf, and Pacific ports were as follows:

Muriate of potash—all grades	53½ cents per unit K_2O.
Manure salts—30 percent K_2O	58½ cents per unit K_2O.
Kainite—20 percent K_2O	$12.25 per ton.
Sulfate of potash—90 percent K_2SO_4	$36.25 per ton.
Sulfate of potash-magnesia—48 percent K_2SO_4	$24.75 per ton.

These base prices were subject to a discount of 12 percent on all orders placed before July 20, for delivery in approximately equal monthly quantities over the period from August 1, 1939, to January 31, 1940, and of 5 percent on orders placed before October 1, 1939, for delivery in approximately equal monthly quantities from October 1, 1939, to January 31, 1940. From October 1 prices were net for the remainder of the season ending May 31, 1940. The only changes from 1938 were decreases of $1.75, $1.00, and 50 cents per ton, respectively, in list quotations for sulfate of potash, sulfate of potash-magnesia, and kainite and extension of the maximum discount period to July 19 instead of June 30 and of the delivery period to January 31 instead of December 31. Extension of the delivery period into 1940 throws out of balance the record of sales in 1939 in relation to sales reported in 1938. To reach a comparable figure, contract deliveries in January 1940, estimated at about 60,000 tons of K_2O, must be added to deliveries reported in 1939.

The following table shows the monthly average prices prevailing during 1939, in accordance with published schedules and discounts:

Average prices per short ton of potash salts in the United States in 1939, by months

Month	Muriate of potash, 50 percent K_2O, in bulk	Sulfate of potash, 90 percent K_2SO_4, in bags	Sulfate of potash-magnesia, 48 percent K_2SO_4, in bags	Manure salts, 30 percent K_2O, in bulk	Kainite, 20 percent K_2O, in bulk
January to April	$26.75	$38.00	$25.75	$17.55	$12.75
May	26.13	36.81	24.98	17.14	12.37
June	23.54	31.90	21.78	15.44	10.78
July	24.26	32.88	22.50	15.92	11.11
August and September	25.41	34.44	23.51	16.67	11.64
October to December	26.75	36.25	24.75	17.55	12.25

CONSUMPTION AND USES

Producers and importers of potash salts sold and delivered approximately 387,000 short tons of potash in 1939 for consumption in the United States and its possessions; 93 percent was for agricultural and

7 percent for industrial use. For comparison with 1938, when deliveries on contracts were completed December 31, about 60,000 tons—representing estimated deliveries in January 1940 on 1939 contracts—should be added to this figure. Thus sales of potash for domestic use in 1938 and 1939, adjusted to a comparable basis, would be 467,000 and 447,000 tons, respectively, indicating a decline in potash consumption in 1939 of about 20,000 tons of K_2O.

The American Potash Institute reports that deliveries by member companies in the United States and its possessions in 1939 totaled 365,049 tons of potash and that 77,675 tons were exported. Importations and sales of all other primary suppliers amounted to 28,500 tons, indicating a total movement of potash of 471,224 tons from primary sources to buyers. Deducting exports of 83,800 tons leaves 387,424 tons delivered to purchasers for consumption in the United States. Apparent consumption calculated by subtracting exports (83,800 tons) from the sum of domestic sales (366,287 tons) and imports (99,569 tons) was 382,056 tons. Adjustment of the total of reported sales to the basis of completed deliveries reduces apparent consumption as calculated above to 367,000 tons and indicates withdrawal from importers' stocks of salts equivalent to about 23,000 tons of K_2O.

Differences in the methods of reporting to various agencies dealing with the statistical position of the potash industry lead to discrepancies sometimes difficult to explain, although in general these differences are compensating over a period of years. Figures published by the American Potash Institute, for example, represent deliveries of material sold in accord with a very precise definition of "deliveries" that is suited to the purposes of the institute and its members. Sales for any one year reported accurately to the Bureau of Mines may differ in greater or less degree from the record of transactions completed within that year as reported by the institute. In 1939, reported sales exceeded recorded completed transactions by about 15,000 tons of K_2O.

The following table gives as accurate a picture of sales for consumption in the United States and for export as can be drawn by combining information derived from numerous sources adjusted to a comparable basis.

Sales of primary potash in the United States for consumption and export, 1938–39, in short tons of K_2O

	1938	1939
Deliveries by member companies, as reported by American Potash Institute—		
In United States and possessions:		
Agricultural	423,977	340,765
Chemical	15,584	24,284
For export	40,843	77,675
	480,404	442,724
Imports, not included above, plus sales of nonmember producers	38,938	28,500
	519,342	471,224
Total exports	51,800	83,800
Actual sales for consumption in United States	467,542	387,424

PRODUCTION AND SALES

The output of marketable salts by domestic mines and plants leveled off in 1939 and continued at about the 1938 rate, although the aggregate tonnage produced in 1939 fell slightly below that of the previous year. The extra tonnage required to satisfy increased sales was drawn from stocks, and no high-pressure efforts were made to operate plants continuously at full capacity. It is believed that the annual output of refined salts by existing plants could be stepped up at least 20 percent, if necessary.

Potash production decreased 3 percent, from 316,951 tons in 1938 to 307,051 tons in 1939. Increased output of the 50-percent grade of muriate, which for some obscure reason is in considerable demand, lowered the average grade from 59.2 percent K_2O in 1938 to 58.5 percent in 1939. Fertilizer manufacturers appear to prefer lower-analysis salts for certain mixtures, notwithstanding the higher unit cost at inland points.

Sales attained a new high, rising 28 percent from 286,437 tons of K_2O in 1938 to 366,287 tons in 1939. Producers supplied about 72 percent of the home market, and about 23 percent of their sales was exported, either directly or through resale by buyers.

Production and sales of marketable potassium salts and stocks in the hands of producers for the last 5 years are summarized in the following table. Only the final weight of marketable salts after refining or mixing is shown. For similar data from the beginning of the potash-producing industry in 1915 to 1934 see the chapter on Potash in Minerals Yearbook, 1935. Data by States and sources cannot be given without disclosing individual reports.

Potassium salts produced, sold, and in producers' stocks in the United States, 1935–39

Year	Production			Sales				Producers' stocks

GOVERNMENT ACTIVITIES

The uncompleted investigation of the potash industry by the Senate Committee on Public Lands, begun in 1936 pursuant to Senate Resolution 274 (agreed to June 18, 1936), was in abeyance throughout 1939. The committee is especially concerned with the extent and implications of foreign ownership or control of American potash companies and the conditions under which deposits belonging to the Government are being exploited. The investigation was pursued vigorously for a year or so, but the committee was not ready to report to the Seventy-fourth Congress as required by the resolution. An extension of 2 years was granted in 1937, and in 1938 the time again was extended to permit submission of the committee's report any time before expiration of the Seventy-sixth Congress at midnight December 31, 1940.

The Department of Justice, which had begun a general investigation of the fertilizer industry in 1936, undertook a special study of the potash industry by its Antitrust Division in February 1939. Material assembled in this investigation was placed before a Federal grand jury in New York, which was reported to have returned a sealed indictment in June that had not yet been officially filed at the end of February 1940. The Department of Justice is understood to be seeking satisfactory ground for a consent decree that would obviate the necessity of prosecuting the reputed indictment and would provide certain changes in pricing and trade practices believed by the Department to be desirable.

In its studies of various industries the Department of Justice on several occasions has sought the advice and assistance of other Departments more intimately acquainted with the organization and functioning of an industry under consideration. Early in 1939, at the suggestion of the Department of Justice, an economic study of the potash industry was undertaken by the Department of Commerce to examine the industry's performance and make such recommendations for changes in practices as might appear necessary in the public interest. Throughout this study the Department of Commerce had the wholehearted cooperation of the three domestic potash companies and the importer. Many conferences were held with the principal executives and attorneys of the companies at which policies and performance of the industry were discussed in detail. Each of the four companies submitted upon request a comprehensive report with subsequent supplementary reports showing full and intimate details of its operations. All data submitted to the Department of Commerce have been made freely available by the companies to the Department of Justice for the information and use of its economic staff. At the close of the year a report was being prepared for submission to the Department of Justice.

Six leases embracing 6,409.6 acres of potash-bearing areas in Searles Lake, San Bernardino County, Calif., were sold to the highest bidders by the General Land Office at public auction in Sacramento, October 19, 1939, at 11 a. m. Four units aggregating 5,969.6 acres were awarded to the American Potash & Chemical Corporation and two units aggregating 440 acres to the West End Chemical Co. For a number of years these two companies have operated plants for the treatment of Searles Lake brines, from which the West End Chemical Co. recovers borax and soda ash and the American Potash & Chemical Corporation extracts directly or prepares by base-exchange methods muriate and sulfate of potash, borax, salt cake, soda ash, and lithium compounds. Bids included bonus payments aggregating $189,156.52. Lessees are required to invest $50,000 each on three of the units in actual development and improvements and $200,000 each on the other three. The Government is to receive a 3-percent royalty on the gross value of all products at the point of shipment and a rental of 25 cents per acre the first year, 50 cents during the next 4 years, and $1 per acre thereafter. It is estimated that royalties from these leases will exceed $50,000 annually.

REVIEW BY STATES

California.—Potash is but one of the products extracted commercially from the complex brine of Searles Lake by the American Potash & Chemical Corporation at Trona. Borax, soda ash, and salt cake likewise are recovered, and in 1938 sodium-lithium phosphate was added to the list. Preparations are now being made to save some of the bromine; the Searles Lake brine contains about 12 times as much as sea water. Brine entering the plant annually carries nearly 10,000,000 pounds of bromine, of which 2,000,000 to 3,000,000 pounds will be recovered in the form of liquid bromine and alkali bromides. Formerly high-grade muriate was the only potash salt produced by this company, but in 1939 the manufacture of sulfate of potash by base exchange with sodium sulfate was begun. The sulfate plant is reported to have a daily capacity of about 100 tons. Leases covering about 6,000 acres of Searles Lake added to the company holdings during the year assure an adequate supply of brine for many years to come.

Maryland.—No new developments relating to potash were reported in operations of the North American Cement Corporation, Hagerstown, or U. S. Industrial Chemicals, Inc., Baltimore, which recover small quantities of potash materials from cement-kiln flue dust and molasses-distillery waste, respectively.

New Mexico.—Operations at the mines of the United States Potash Co. and the Potash Co. of America near Carlsbad continued on approximately the same scale as in 1938. Interruptions incident to unionization of the mines reduced somewhat the total tonnage of ore mined and the output of refined salts. However, stocks sufficed to meet requirements.

A suit filed in 1938 by three Pecos Valley farmers to recover $250,000 from the United States Potash Co. for alleged damage to land and crops by infiltration of brine from the refinery-waste pond into irrigation water was dismissed in June 1939 when it was shown conclusively that owing to structural dip the direction of underground drainage is away from the irrigated areas and the contamination claimed was a physical impossibility.

The Union Potash & Chemical Co., controlled by the International Agricultural Corporation by ownership of nearly 60 percent of the common stock, continued throughout the year development of the potash beds exposed in the shaft that was completed in 1938 to a depth of 925 feet. A large tonnage of commercial-grade material is now assured, and the International Agricultural Corporation has announced plans to invest an additional $2,500,000 in preparing the mine for production and constructing a refinery that will have an annual capacity of 70,000 tons of potassium sulfate and 70,000 tons of 60-percent muriate. It is reported that the mine will be equipped to handle up to 2,000 tons daily and that production will begin late in 1940.

Utah.—Bonneville, Ltd., 540 West Seventh South, Salt Lake City, produced an increased tonnage of potassium chloride from Salduro marsh brine at its plant near Wendover. Solar evaporation is utilized to concentrate the brine, which is then treated to separate potassium chloride from the other constituents. The product is a high-grade salt that appears to find a ready market. No other production was reported from Utah in 1939.

FOREIGN TRADE

Imports.—The drastic decline in imports of potash salts during 1938 continued in 1939 to the lowest point reached since normal shipments from Europe were resumed in 1922 following the World War. Much of the decrease in 1939 doubtless was due to war conditions that disrupted shipping during the last 4 months of the year, when potash imports normally are heaviest. Fertilizer salts contained 94.1 percent of the potash imported and salts for industrial use the remaining 5.9 percent.

The quantity, average grade, and total declared value of the various potash salts imported in 1938 and 1939, the countries from which shipments were made in 1939, and the approximate K_2O equivalent of imports for the past 5 years are shown in the following tables.

Potash materials imported for consumption in the United States, 1938–39

[1] Less than 1 ton.

Exports.—A greater quantity of fertilizer salts was exported in 1939 than ever before, and exports of chemical salts likewise approached in quantity and exceeded in value the previous high record established in 1935. Exports totaled 140,329 tons of material equivalent to approximately 83,800 tons of K_2O, an increase of about 32,000 tons of K_2O (62 percent) from 1938. About 4,000 tons of K_2O were exported by customers of the producers and importers who originally sold this material for consumption in the United States. Japan and Canada, the principal customers for American potash for a number of years, increased their purchases materially, and for the first time substantial sales were made to the United Kingdom.

Potash fertilizer materials exported from the United States, 1938–39, by countries

WORLD PRODUCTION

Publication of production statistics by European governments virtually ceased in the summer of 1939, and no adequate data are available for the latter half of the year. However, reports of production and sales of potash fertilizer salts during the first 6 months of 1939 indicate a definite upward trend in every major producing country except Germany, where output declined slightly owing to labor shortage and transportation difficulties. Mobilization and concentration of civilian manpower in war industries preparatory to and following the outbreak of war virtually closed the French potash mines for a time and doubtless resulted in further curtailment of German production. Rehabilitation of the Spanish mines was in progress; but there was little or no production by the end of the year, and the output of Polish mines, following the German occupation, probably was negligible. Increased operations in Palestine were not significant with respect to world production. The over-all result doubtless was a drop in world output of potash salts that might be as much as 10 percent of the 1938 production figure.

Available official figures of world production for 1935–38 are shown in the following table.

World production of potash minerals and equivalent K_2O, *1935–38, by countries, in metric tons*

FOREIGN DEVELOPMENTS

France.—Production of the French potash mines for the first 8 months of 1939 was reported by the American commercial attaché, Paris, to total 428,100 tons of K_2O, an increase of 45,400 tons compared with the corresponding period in 1938. Production figures for the rest of the year are not available; but it is known that, although the mines are close to the Maginot line, they have continued to operate. Disruption of the administrative and operating staffs by mobilization slowed production for a time, but reorganization soon was accomplished and by the end of the year output was reported approaching the maximum previously attained. Success of the educational campaign to increase the use of potash fertilizers, in which motion pictures have played a prominent part, was indicated by the rise of domestic sales, in spite of firmer prices decreed by the State Potash Mines Administration.

Since the beginning of the war special efforts have been made to continue exports to the United States as a means both of protecting the American market and providing dollar exchange. Potash for export, formerly transported by barge down the Rhine, now must be shipped by rail to Belgian or French ports at much higher cost. The cost is increased further by labor shortage at the mines and by higher ocean freight and war-risk-insurance rates. This situation may hasten development of the deposits in the Department of Landes in southwestern France, less than 100 miles from Bordeaux. Formation of a company with a capital of 16 million francs to develop and equip these properties was announced in 1936, and it was stated at that time that about 5 years would be required to prepare them for production.

French Potash Co., Inc., 30 Rockefeller Plaza, New York City, was organized shortly after the outbreak of war to import and sell French potash in the United States.

Germany.—The following comments on the potash industry in Germany are abstracted from comprehensive reports by Sydney B. Redecker, American consul, Frankfort on the Main.

The virtual cessation of overseas trade as a result of the naval blockade of Germany has limited potash sales to the extensive domestic market and to nearby European countries not cut off from Germany by the war, together with such overseas trade as it may be possible to carry on through neutral countries. Aside from loss in trade for the industry itself, the interruption of shipments of potash to overseas countries is a financial blow to Germany, depriving the nation of badly needed foreign exchange yielded by overseas potash exports, especially as potash is one of the few raw materials of which the country has a large exportable surplus.

To offset losses in export trade the industry has turned its attention to intensive cultivation of the domestic market, especially the recently annexed regions of Greater Germany, and to trade with nearby neutral countries in accordance with the national policy of supplying German products in exchange for foreign foodstuffs and industrial raw materials. The newly annexed territories of Austria, Czechoslovakia, and Poland are believed to offer an excellent field for expansion, as potash fertilizers have been consumed in these regions at a very much lower rate per hectare than in the Old Reich and must be increased to attain the maximum agricultural production essential to the national autarchic program. It is also believed that the countries of southeastern Europe, as well as Italy, Scandinavia, and the Baltic States, are capable of consuming notably increased quantities of German potash and other fertilizers, deliveries of which can be applied toward payment for increased receipts of agricultural products by Germany.

244615—40——89

Remarkable gains have been attained in consumption of potash fertilizer in Germany (Old Reich) in the past few years, stimulated especially by drastic price reductions enforced by the Government in the spring of 1937 for expanding national agricultural production. Consumption rose to 1,156,000 metric tons of K_2O in 1937–38 and is believed to have exceeded this figure in 1938–39. For many years, before 1937, when authentic export statistics were available the domestic market absorbed 70 to 75 percent of the total national turn-over.

Germany's production of potash expanded from 1932 to 1938, rising from 871,354 to 1,861,000 metric tons of K_2O, an output far surpassing that in any previous year except 1937. However, beginning in 1938 difficulties began to be experienced in the further expansion of production owing to increasing shortage of miners coupled with other circumstances, such as flooding of mines, break-down of equipment, delayed deliveries of replacements and new equipment, and shortages of railroad rolling stock. These difficulties were intensified in 1939, so that, for the first time in 6 years, production actually declined somewhat, to 1,090,700 metric tons of K_2O in the first 7 months compared with 1,103,900 tons in the corresponding period of 1938. Although statistics for a later period are not available and quite possibly no further ones will be issued during the war, the prospects are that lessened shipments to overseas countries, coupled with labor shortage and other difficulties hampering productive activities under wartime conditions, may cause further decrease in production in the future.

For several years a substantial part of German potash exports has consisted of consignment shipments, made in accordance with the terms of confidential cartel agreements for the account of foreign potash producers (notably the Spanish mines) that were unable to make the deliveries themselves. The conditions governing these consignment shipments are not publicly known, but it is understood that the producer for whom the shipment is made has the right subsequently to supply, within a stipulated period, a correspondingly increased quantity of potash under the terms of the International Cartel Pact, or to receive certain financial indemnification. Deliveries by the German potash industry for the account of foreign producers reached a maximum of 190,000 metric tons K_2O in 1937 and dropped to 80,000 tons in 1938.

After contracting considerably in 1938 from the high levels established in 1937, Germany's exports of potash expanded markedly in the first 7 months of 1939, doubtless indicating the desire of both German producers and foreign importers to effect early delivery in foreign countries of as large a tonnage as possible, in view of the unfavorable international outlook threatening interruption of Germany's overseas trade.

Faced with the loss of the world monopoly enjoyed before 1914, resulting from the loss of the Alsatian mines to France and the development of extensive potash industries in other countries, the German potash companies in recent years have sought active participation in other industrial spheres, notably petroleum and the mining of nonferrous metals and coal, as a means of developing new outlets for profitable investment of their capital and employment of their technical facilities. The extent to which diversification has been carried is indicated by the fact that in 1933 around 95 percent of the personnel of Wintershall A. G. was employed in potash production, whereas in 1938 only 67 percent of the workers were associated with potash activities. During the same period the total number of employees increased fourfold to 13,340 in 1938; the company has attained an outstanding position in Germany's petroleum industry and has become a major producer of magnesium metal and alloys used in the manufacture of aircraft. Other leading members of the potash industry likewise have entered upon extensive programs of diversification and the development of byproducts to supplement the shrinking profits from their potash operations.

Italy.—The American Embassy at Rome reports that the concessionaire for the Marada Basin in Libya completed its first experimental season in the summer of 1939 with an output of 2,100 metric tons of potash salts. Although hampered by transportation obstacles a minimum production of 25,000 tons is contemplated in 1940. A road is being constructed from Maaten Ciofer to Ras Aali to facilitate movement of potash from Marada to the sea.

Japan.—In anticipation of the possible cessation of imports of potash salts from European countries and the United States the Japanese Ministry of Commerce and Industry and the Ministry of Agriculture and Forestry introduced a joint ordinance on October 3, 1939, requiring official approval for all future sales of potash and authorizing the respective ministers to issue orders for distribution of potash for the manufacture of fertilizers. Details concerning stocks of potash are required to be submitted immediately to the ministries. Japan is reported to be negotiating a trade pact with Spain to exchange Japanese raw silk and camphor for Spanish potash and other raw materials. Japanese interests are said to have purchased 10,000 metric tons of sodium-potassium nitrate in Chile. Imports of potash salts from the United States, which contracted sharply in 1938, were expanded in 1939 to 59,000 short tons, approaching the maximum of 63,000 tons imported in 1937.

Palestine.—According to a report from the American consulate general, Jerusalem, the shift in sources of supply for potash brought about by the conflict in Europe has caused Palestine Potash, Ltd., to accelerate production activities. Exports during the first 9 months of 1939 showed an increase of 35 percent over the corresponding period of 1938. Output for the year might reach 80,000 tons of 50-percent muriate. Palestine, where potash is extracted from salts derived by solar evaporation from waters of the Dead Sea, is the only important source of potash in the British Empire.

Poland.—The steadily rising output of potash from the Polish mines reached 84,585 metric tons K_2O in the crude salts mined in 1938, and sales of commercial grades of crude and refined salts totaled 71,412 tons K_2O in salts averaging 20 percent K_2O, as reported by the American commercial attaché, Warsaw, from production and sales figures compiled by the producer. No information is available relating to 1939 operations. The mines are situated in southwestern Galicia, a former Austrian Province that was incorporated in the Polish State following the World War. The greater part of Galicia, including the potash mines at Kalusz, Stebnik, and Holyn, south of the city of Lwow, was ceded to the U. S. S. R. by Germany following the German conquest of Poland and the Soviet-German alliance and is now occupied by the U. S. S. R.

Spain.—Rehabilitation of the Spanish potash mines in Catalonia was undertaken soon after the close of the civil war. It was hoped that production might be resumed before the end of 1939, but it is doubtful whether this objective was achieved, as the mines were reported to have been badly damaged by the retreating Loyalist troops and the railroad connecting the mines with the port of Barcelona destroyed. However, it is believed that productive operations will approach normal in the near future, and strenuous efforts probably will be made to attain maximum output in 1940 to supply in the world market as much as possible of the deficiency that will result from stoppage of German overseas exports by the naval blockade.

It was reported in September 1939 that 10,000 to 12,000 metric tons of potash salts were on hand at Barcelona and about 30,000 tons at the mines. Before the civil war the Spanish mines were producing about 120,000 metric tons K_2O a year, and their full capacity is said to be around 200,000 tons. The pre-war project to establish a Government-controlled sales agency to handle the distribution of all Spanish potash has been revived, and an organization for this purpose has been established under the title "Potasas Espanolas." The three operating companies are the Union Espanola de Explosivos, a Spanish company financed by British capital; Potasas Ibericas, S. A., controlled by French capital; and Minas de Potasa de Suria, S. A., controlled by Belgian Solvay interests and affiliated with Potasas Reunidas, S. A., a selling organization headquartered in Madrid.

U. S. S. R.—The development of the potash deposits at Ozinki and at Okuz-Bulak in central Asia is being urged by Soviet engineers to supplement production from the Solikamsk mines and to avoid the present long hauls from the northern Urals to central Asia and the Ukraine. Ozinki is in the Urals, but a considerable distance south of Solikamsk. The deposits have been prospected only superficially but are believed to be extensive. Soviet chemists are reported to have obtained crystals containing nitrogen, phosphorus, and potash—presumably a composite salt—that have been tested in the experimental flax fields of an agricultural institute near Moscow with very satisfactory results. Construction of a factory for the manufacture of concentrated fertilizer by this new method is planned.

MICA

By Paul M. Tyler and K. G. Warner

SUMMARY OUTLINE

After improving slowly during the first 8 months of 1939 the demand for mica rose rapidly to record proportions following the outbreak of war in Europe. Consumption of sheet mica and splittings during the last quarter of the year probably exceeded even the feverish pace set during the first half of 1937. The total consumption for the year exceeded the total for 1938 but fell short of a record. Domestic production of sheet mica, notwithstanding increases in several States and the greatly increased activity in all the mining districts in the latter part of the year, failed to equal that of 1938.

Mica is a strategic mineral; mica splittings, radio-tube mica, condenser sheet, airplane spark-plug "cigarette" mica and washers, and magneto condenser films are materials especially needful from a military standpoint—to maintain communications as well as to enable airplanes and all modern mechanized equipment to operate. Other kinds of sheet mica required in electrical machinery and in the manufacture of munitions are obtainable domestically, but the items mentioned have been almost wholly imported, principally from British India.

A Bureau of Mines survey in the early summer of 1939 showed that stocks of splittings and other strategic varieties of mica in the United States were equivalent to more than a year's supply at any previous annual consumption rate. As the European war greatly stimulated sales of manufactured mica products, monthly consumption of several of these items rose above any previous requirement, and simultaneously the normal flow of supplies from India was interrupted. Manufacturers who had been buying raw material on a hand-to-mouth basis were threatened with a shortage of supplies. In December one large consumer exhausted its stock of its most important grade of splittings, and no companies could maintain their customary raw-material inventories. At no time was there any dearth of supplies in Calcutta, but the heavy movement of burlap and other commodities caused a shortage of shipping space. This situation, however, began to improve toward the end of the year as more ships were routed from India to the United States. Early in 1940 a new alarm arose, as word came that all exports of block mica from India might be prohibited because of the British Government's munitions needs, but no real curtailment of shipments was apparent by April 1940. Shipments of amber splittings from Madagascar came under French Government control, and not until the end of 1939 were licenses obtainable for even limited quantities for export to this country. A threatened shortage of cigarette mica was averted by employing selected domestic sheet.

Even before these wartime uncertainties developed shipments of South American mica to the United States began to increase, and domestic mines displayed renewed activity.

Late in the year prices paid for domestic mica advanced much more than those for India mica. Those for Argentine and Brazil sheet mica averaged perhaps 10 percent above the relatively high levels reached in 1938. For India splittings and radio mica sterling prices and freight and war-risk insurance rose sharply, but with respect to bulk lines these increases virtually were offset by the decline in exchange. For more expensive grades of splittings, however, prices increased slightly; No. 5 book-packed splittings, for example, advanced from $1.25 to $1.40 a pound.

Salient statistics of the mica industry in the United States, 1935–39

	1935	1936	1937	1938	1939
Domestic mica sold or used by producers:					
Total uncut sheet and punch:

Value	$908,384	$1,205,568	$2,067,599	$664,419	$1,059,310
Export (all classes of mica):					
Short tons	1,499	1,478	1,795	1,772	1,827
Value	$165,385	$170,011	$216,858	$183,889	$226,364

[1] Includes mica recovered from kaolin and mica schists, as follows: 1935, 6,667 short tons valued at $111,345; 1936, 8,258 tons, $127,343; 1937, 10,536 tons, $149,931; 1938, 6,550 tons, $86,602; 1939, 10,011 tons, $108,899.

[2] Exclusive of a nominal quantity of splittings produced in the United States and South America.

DOMESTIC PRODUCTION [1]

Sheet mica.—The output of sheet mica was less in 1939 than in 1938 owing to a sharp reduction in output of punch mica in North Carolina and New Hampshire and of larger sheet in New Hampshire. Substantial increases were reported in Connecticut and South Dakota and minor increases in Maine, Virginia, and other States. A small output of punch mica, with some scrap mica, was shipped in 1939 from a newly opened feldspar property near Edinburg, Saratoga County, N. Y.; this is the first output of mica reported in that State since 1923, when a little sheet mica was produced in St. Lawrence County.

Sheet mica sold or used by producers in the United States, 1908–39 [1]

Year	New Hampshire		North Carolina		Other States [2]		Total

[4] Exclusive of Connecticut, which is included with New Hampshire.

Production statistics on mica have been published annually since 1880, in which year the output of American mines (all sheet mica) was 81,669 pounds valued at $127,825. After rising to 147,410 pounds valued at $368,525 in 1884 it dwindled rapidly owing to the competition of India mica, which was imported first in 1885. The rapid growth of the electrical industry during the 1890's so increased the demand for sheet mica that in 1898 domestic output once more rose above 100,000 pounds and at the turn of the century jumped to 456,283 pounds valued, however, at only $92,758. By 1906 the output had

[1] Historical tables compiled and readjusted by E. T. Shuey, Bureau of Mines.

grown to 1,423,100 pounds valued at $252,248. In 1910 it attained a peak of 2,476,190 pounds—but this was mostly small mica as the value was only $283,832 whereas the 1,700,677 pounds produced in 1913 was worth $353,517.

In the earlier years some mica miners operated cutting plants; and the value of their finished products, such as stove mica and other more or less standard sizes, was included in the production statistics. Since 1920, however, the production as officially reported is uncut sheet mica alone, although separate figures were also compiled for uncut punch and uncut sheet larger than punch. "Punch mica" is a domestic term not generally used abroad and refers to crystals of book or block mica, usually thumb-trimmed, as opposed to knife- or shear-trimmed, but not large enough to furnish sheets more than about 1½ inches in diameter. Included with punch mica is circle mica, which is somewhat larger, yielding circles up to 2 inches in diameter.

As may be seen in the preceding table of annual production by States from 1908 to 1939, North Carolina has been the leading producing State, although occasionally yielding first place temporarily to New Hampshire and for two years to South Dakota.

[1] Small amount of splittings included with punch.

Scrap mica.—Scrap mica may be defined as material suitable for conversion into ground mica with little or no additional purification. Production from domestic sources in 1939 totaled 24,672 short tons valued at $311,895, of which 10,011 tons worth $108,899 were recovered in washing kaolin or kyanite or by milling schists and the remainder was mine scrap.

Separate statistics covering domestic mine production of scrap mica have been available continuously since 1893, when an output of 156 tons was recorded. In 1900 the output soared to 5,497 tons valued at $55,202, but this was abnormal; the average for the 5-year prewar period, 1909–13, was only 4,043 tons valued at $55,296. Beginning in 1916, mica recovered from schist has been reported first to the Geological Survey and since 1925 to the Bureau of Mines; and in 1925 byproduct mica from kaolin operations first became prominent. For several years these items were not reported in the mica statistics; they were grouped merely as "miscellaneous minerals" or miscellaneous mineral production in summary tables. By 1935, however, the contributions from these sources had become so important that it seemed best to include them in the production figures for "scrap mica" and also those for "ground mica." Readjusted data for earlier years have not been published hitherto and are inserted in the following table for the first time. The revised figures for all years are believed now to be on a comparable basis, as they include available data on mine scrap; production from muscovite, sericite, and chlorite schists; and byproduct mica from china clay and kyanite operations.

Since sales of scrap mica may increase the revenues of sheet-mica mines substantially, it has been contended that mine scrap should be separated from mica of similar use obtained from other sources. Accordingly, the Bureau of Mines in recent years has recorded separately the total mica from other sources, usually in a footnote to the production tables.

Scrap mica [1] and mica recovered from kaolin and schists [2] sold or used by producers in the United States, 1908–39

Ground mica.—The quantity of ground mica sold by domestic producers in 1939 was 30,924 short tons valued at $1,156,333, exceeding by a wide margin the previous record of 27,245 tons valued at $839,812 in 1937. The trend toward increased consumption in wallpaper, paint, and miscellaneous uses, noted in previous Yearbook chapters, continued in 1939, and the increase in sales to the rubber industry was notable. More mica was consumed in roll roofing—still the principal use—than in 1938 but less than in 1937; the percentage of total sales used for this purpose declined to 62 percent compared with 70 percent in 1938 and 79 percent in 1937.

Data for 1923 to 1934 have been adjusted to permit comparison with those for 1935 and later years as now reported; the production of ground mica includes the product made from mine scrap, factory scrap, byproduct mica, and schist mica of all kinds.

	27,086	100	924,554	30,924	100	1,156,333

[1] Includes mica from kaolin and schist.
[2] Includes mica used for molded electric insulation, house insulation, Christmas-tree snow, manufacture of axle greases and oil, annealing, pipe-line enamel, plastic specialties, textiles, coating levee mattresses, and other purposes.

MICA SPLITTINGS

Reflecting the increased activity in the factories producing built-up mica during the last few months of the year, the consumption of mica splittings in the United States was virtually twice as large in 1939 as in 1938, although, owing to the slow recovery during the earlier months the total for the year fell far short of the 1937 peak and failed even to equal the quantities used in 1929 or 1936.

Of the 1939 total (1,712 short tons valued at $1,089,683) 88 percent was India muscovite splittings, 9 percent amber splittings from Madagascar, and 3 percent amber splittings from Canada. An increasing amount of South American mica is being sent to Calcutta to be split and is reexported as "India splittings." Both domestic and imported mica may be converted into splittings in the United States, but the quantity seldom has constituted as much as 2 percent of the domestic consumption and in many years has been virtually negligible.

Stocks of splittings in consumers' hands at the end of 1938 had reached an all-time high, exceeding consumption for any previous 12 months and about 3 years' supply at the 1938 consumption rate; but as imports did not pace withdrawals the total stocks at the end of 1939 were reduced to less than 9 months' supply, and several companies had no more than enough to last them a few weeks when deliveries from India began arriving in substantial volume after November.

Consumption and stocks of mica splittings in the United States, 1935–39, by sources, as reported by the consumers

[1] Exclusive of a nominal quantity of splittings produced in the United States and South America.

BUILT-UP MICA

In 1939 the Bureau of Mines made its first compilation of production of various kinds of built-up mica as part of its investigation of the strategic uses of mica. However, the total output of these products in the United States in certain specified years had been reported by the United States Tariff Commission, as follows:[2]

[2] U. S. Tariff Commission, The Mica Industry: Rept. 130, 2d ser., 1938, pp. 63-64.

	Pounds		Pounds
1927	2,925,941	1933	1,308,924
1929	4,042,478	1934	1,839,888
1931	1,702,938	1935	2,385,623
1932	922,936	1936 (6 months)	1,452,734

Additional data compiled by the Commission for 1935 and 1936 show the quantity and value of major classes of built-up mica produced in the United States, separated according to the type of mica used, and also the percentage of binder used in such products:

Built-up mica produced in the United States in 1935 and January–June 1936, by kinds [1]

[1] U. S. Tariff Commission. [2] Weighted average for both periods combined.

In American factories splittings are assembled on paper or fine-mesh screen and held together with shellac, glyptol, or other suitable binder, which is sprayed or painted over each layer of splittings as formed until the desired thickness is attained up to ⅝ inch. Individual plates, usually 3 feet square, are put into an oven, heated at 250° F. to dry the varnish, and then inspected over a strong light in a darkened room or occasionally by X-ray. Imperfections or thin spots are touched with additional binder or covered with additional splittings as required; if the sheet cannot be repaired the defective part is cut out. The sheets are then put in a press, subjected to a pressure of 1,000 pounds per square inch and a temperature of about 300° for several minutes, and then chilled quickly. When removed from the press they are milled or sanded and finally ground perfectly smooth and to exact thickness. Several plants employ more mechanized methods; the flakes of mica, instead of being dabbed on by hand, fall from a "snowing" tower onto a suction drum or moving screen upon which one or at most three layers are built up before the binder is sprayed over the sheet.

Domestic production of built-up mica comes almost entirely from six companies, although at least two other concerns produce minor amounts. Roughly, half the built-up mica made in the United States is manufactured by large electrical companies for use in their own motors, generators, and all sorts of electrical equipment and appliances. Several other companies, about equally prominent as producers, are not so integrated, although they generally carry their fabricating processes beyond the point of making board, tape, etc. Most of them manufacture tubing, tape strips, V-rings, and—most important from a quantity standpoint—segment plates for the commutators of generators and starting motors of automobiles.

Molding plate is used largely in making commutator V-rings and cones; when heated it becomes flexible enough to be molded into these shapes or bent into troughs or square tubing. As the name implies, flexible plate can be formed cold, although it may be heated slightly when rolled into tubes. Segment plate is used entirely for flatwork, commutator segments (as previously stated) being the chief shapes cut or stamped from it. Heater plate contains even less binder than commutator segments; the bonding material, whether organic or inorganic, must be nonvolatile so that the product can be used in place of pure sheet mica for such purposes as supporting flatiron and toaster heater elements without excessive disintegration. Flexible sheets or ribbons (insulating tapes) are made in a thickness of 0.004 to 0.008 inch, including the paper, cloth, or silk facing; a common form is a "sandwich" made from book-packed splittings between 1-mil layer of Japanese rice paper.

Built-up mica produced in the United States, 1937–39, by kind of product

[1] Figures for value not available.

PRICES

As previously noted, the prices of India mica did not change greatly owing to the break in the English pound sterling from an average exchange value of $4.68 during the summer to less than $4 during the last 4 months of the year.

Trade-journal quotations for domestic mica, after remaining virtually unchanged for about 2 years, began to rise in the early summer and were completely revised before the end of the year. As shown in the following table, the new quotations represented, with fair accuracy, the average prices actually received by producers as reported to the Bureau of Mines. A comparison of the average prices reported shows an increase over corresponding averages for 1938 of 39 percent for clear circle mica and smaller increases for several other items.

Trade-journal quotations and average sales value of domestic uncut sheet mica per pound in 1939

Size	Trade-journal quotations [1]		Average value [2]	
	Dec. 22, 1938	Dec. 14, 1939	Clear	Stained or spotted
Punch	\$0.03-\$0.05	\$0.05-\$0.06	\$0.056	\$0.055
Circle			.143	.188
1½ by 2 inches	.15- .40	.25- .30	.299	.184
2 by 2 inches	.30- .60	.40- .50	.515	.267
2 by 3 inches			.778	.479
3 by 3 inches	.75- 1.20	1.00- 1.20	1.104	.653
3 by 4 inches	1.00- 1.40	1.30- 1.40	1.372	.824
3 by 5 inches	1.25- 1.60	1.60- 1.70	1.767	1.043
4 by 6 inches	2.00- 2.50	2.60- 2.70	2.812	1.284
6 by 8 inches	2.50- 3.50	4.00- 4.50	4.167	1.398
8 by 10 inches	3.50- 5.00	7.50-10.00	7.935	2.071

[1] Engineering and Mining Journal (Metal and Mineral Markets) quotations for No. 1 or No. 2 quality, f. o. b. North Carolina; stained qualities take 25 to 50 percent discount.
[2] Calculated from reports of 1939 sales by domestic producers to the Bureau of Mines.

State geologist H. J. Bryson comments upon the wartime boost to North Carolina mining as follows:[3]

The mica industry is undoubtedly more active in North Carolina now than in the past 10 or 12 years * * * all of the larger mines are operating night and day while more than 200 small mines, many of them little more than holes in the mountain sides, are being operated by the mountaineers, and the mica hauled into washing plants. * * *

Mica that 6 months ago was bringing only \$5 and \$10 a ton is now bringing from \$15 to \$20 a ton and frequently more. The larger mica, large enough for washers and punch purposes, brings from \$150 to \$250 a ton, while mica as much as 4 by 6 inches in size now brings from \$2.50 to \$2.60 a pound.

FOREIGN TRADE [4]

Imports.—The imports of mica in 1939 aggregated 6,280 short tons valued at \$1,059,310 compared with 5,761 tons valued at \$664,419 in 1938 and 11,339 tons valued at \$2,067,599 in 1937. The reduction in imports of scrap and splittings in 1939 was notable compared with 1937.

Imports furnish virtually all the splittings, most of the sheet mica larger than punch, and a variable proportion of the small sheet and scrap mica used in this country. Available data on imports for the period 1909–39 are summarized in the following table compiled by E. T. Shuey, of the Bureau of Mines.

[3] Mining Congress Journal, North Carolina Mining Industry Benefits from Price Advance: Vol. 26, No. 2, February 1940, p. 19.
[4] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Mica imported for consumption in the United States, 1909–39, by classes

[1] "Phlogopite" not separately classified before 1939.

[2] In addition, 4,953 pounds valued at $5,155 of "All manufactures of which mica is the component material of chief value (duty, 40 percent)" were imported; no imports of this class are shown in 1938.

[3] Changes in table, Minerals Yearbook, 1939, p. 1350, are as follows: 18,965 pounds valued at $18,500 of "Mica plates and built-up mica" reported as imported from Canada should be reported as imported from Germany; 169,025 pounds valued at $2,626 of "ground or pulverized" reported as imported from Germany should be reported as imported from Canada.

Exports.—Although production in the United States falls far short of domestic requirements, small quantities of sheet mica are exported every year. Ground mica long has comprised the bulk of the mica exported, although not separately recorded in the official statistics before 1937. It has been estimated that only 15 percent of the quantity and 50 percent of the value of exports formerly classified as "mica and manufactures" consisted of manufactures other than ground. Studies made from time to time by the Tariff Commission have indicated that although important but unreported quantities of mica manufactures are included in domestic exports of radio equipment, motors, generators, and household appliances, the exports of manufactured mica other than ground have consisted of repairs and replacement parts for American-made machinery and electrical apparatus. Draw-back statistics published by the Department of Commerce show $20,000 to $30,000 worth of foreign mica contained in exported goods in certain years; but, as the value of mica embodied in most products is small and often difficult to identify for purposes of obtaining a refund on duties, it is believed that the draw-back statistics afford an inadequate measure of the volume of mica consumed in export goods.

Mica and manufactures of mica exported from the United States, 1910–39

Year	Unmanufactured		Manufactured				Total

[1] Change in Minerals Yearbook, 1939, p. 1352, is as follows: Australia should read Oceania.

DOMESTIC CONSUMPTION OF SHEET MICA

The United States is the largest consumer of mica. Although it normally produces 15 to 35 percent of its requirement of sheet mica, it is virtually 100 percent dependent on imports not only for phlogopite mica and for mica splittings of all kinds but also for condenser mica and certain other specialties. One of the largest uses of sheet mica (excluding splittings) is for radio-tube bridges and supports; and most of such mica is imported, although domestic mica also is used successfully for radio stampings. During the 5 years 1925–29 domestic mines furnished almost 90 percent of the punch and small-sheet mica (1 to 2 square inches) but only 35 percent of the larger sheets and not over 1 or 2 percent of the splittings. In 1939 the percentage contribution of domestic mines was greatly reduced, and the relative importance of foreign mica correspondingly increased even with respect to supplies of punch and circle sizes.

The United States virtually depends on British India for high-grade condenser and spark-plug cigarette mica. An attempt to cover any large proportion of our needs of such mica from domestic or other foreign mines would seem impossible. Even in British India not more than 10 percent of the sheet mica mined satisfies the rigid requirement of such material. Moreover, in India the opportunity for selection is far greater than it would be under American conditions, because in that country the mica is inspected far more carefully at the mines. Skilled labor is cheap, and the small books of mica are handled and examined repeatedly during the laborious process of sorting and manufacturing mica films and splittings. In the splitting operation, as leaf after leaf is removed, stained or spotted laminae are laid bare and can be eliminated and sold separately. In the United States only about one-fifth as much sheet mica is mined as in India, no splitting is done, and even the trimming is far less complete because more irregular pieces can be marketed.

It is almost impossible to account for the total consumption of mica by industries because of the tremendous waste in manufacturing and because block mica from some mines is trimmed much more closely than mica from other mines. Moreover, as imports of uncut block mica are divided according to price rather than size, some assumptions are necessary to calculate apparent supplies of different sizes available each year. However, the Bureau of Mines estimates that the consumption of raw sheet or block mica in the United States in 1937, the most active recent year, totaled about 2,600,000 pounds, which was distributed approximately as shown in the following table.

Estimated consumption of sheet mica in the United States in 1937, by uses

Use	Pounds	Usual quality	Typical size
Transmitter condensers	30,000	Fair-stained or better; films, block.	No. 5½ (mostly), 5, 4.
Trimmer condensers	20,000	Fair-stained films, block	No. 6.
Receiver condensers	105,000	Fair-stained (60 percent); good-stained.	No. 6.
Industrial condensers, magnetos	15,000	Mostly fair-stained	No. 6 (75 percent); 5, 4, 3, 2.
Spark-plug cigarettes and shields	12,600	Fair-stained block, slightly stained films.	No. 4 and larger.
Spark-plug washers—amber	10,000	Phlogopite	No. 5.
Spark-plug washers—muscovite	20,000	Good-stained	No. 5.
Radio-tube parts	750,000	do	No. 6 (85 percent); 5½, 5.
Washers, small stampings	1,127,400	Domestic (75 percent), stained	Punch, circle No. 6.
Electrical appliances, etc	500,000	Domestic (50 percent), stained	Various.
Miscellaneous	10,000	Mostly good-stained or better	Do.
	2,600,000		

Estimates in this table for the first eight items covering most of the high-grade mica are based upon reports from manufacturers and probably are at least 80 percent correct. The last three items are added to account for the total estimated consumption of block mica and thick films as indicated by available data for domestic consumption and imports. Built-up mica and splittings are not covered in this table. In addition, 138,773 pounds of manufactured mica (cut or stamped to dimensions), equivalent to probably 300,000 pounds of block mica, were imported in 1937. In calculating the total apparent consumption as shown by this table the domestic production of punch and circle was reduced by 35 percent and of larger sizes by 10 percent to make it comparable with imports because imported block mica is trimmed more closely.

Of the total apparent consumption of 170,000 pounds of mica in condensers of all kinds, about 40,000 pounds was good-stained (No. 6); the remainder (chiefly fair-stained) comprised 55,000 pounds of No. 6, 35,000 pounds of No. 5½, 30,000 pounds of No. 5, and 10,000 pounds of larger sizes, up to No. 2.

WORLD PRODUCTION

Until 1914 India, the United States, Canada, and German East Africa accounted for virtually all the world output of mica. The World War, by emphasizing the fact that 80 percent of the total supply came from the British Empire, stimulated development elsewhere, but India has managed to maintain its place as the dominant factor; in fact, its position has been better entrenched owing to the greater importance of splittings. In the manufacture of splittings, as previously noted in this chapter, India has a preponderant advantage not only in abundant supplies of mica but also in cheap, experienced labor. Most large consuming countries import supplies; the only important producing countries that consume more than a small fraction of the mica they produce are the United States and the U. S. S. R.

The occurrence and mining of mica in India and in other countries are described in a recent book [5] by Chowdhury, who also discusses marketing and manufacturing.

POSSIBLE SUBSTITUTE

In 1939 definite progress was made in the use of Alsifilm as a substitute for mica. This interesting product, made from bentonite, was described in Minerals Yearbook, 1939, p. 1353, which mentioned insulating tapes as a possible field of use in addition to built-up mica. Although Alsifilm of high tensile strength and material that is flexible or even creaseproof can be produced, it has not been possible to obtain a high degree of flexibility without sacrificing other properties that render the material a competitor of mica. Under the cooperative agreement between the Massachusetts Institute of Technology and the Research Corporation, Dr. E. A. Hauser and his associates investigated in 1939 the properties of films from raw materials from many domestic localities and from foreign sources, finally selecting a variety produced by one of the Wyoming companies as best suited for the process—chiefly because of its higher yield of ultrafine colloidal material. The status of the several developments at the end of 1939 has been summarized as follows:[6]

Aside from fundamental laboratory research, quasi-commercial developments are now being conducted under cooperative arrangements with various companies. One of these companies is investigating the production of a cambric-type insulating tape impregnated with Alsifilm; another is working on a combination of Alsifilm with fiber glass, including both felted fibers and woven fabrics; and still other companies are directing their efforts to the production of substitutes for built-up mica sheet or board. Already commutator segments and other stampings have been made that appear to be acceptable substitutes for mica products. Large V-rings may also be produced, although the material does not seem at present to be universally suitable for molding plate. Experiments in the manufacture of heater plate are quite promising but are not far advanced as yet.

The technique of production of Alsifilm is quite simple. The raw bentonite is made into a 2-percent dispersion with water, which is allowed to settle or is centrifuged to remove the coarser particles. The colloidal material is then either evaporated or concentrated in a supercentrifuge to a 6- to 8-percent gel, which has the consistency of smooth paste and so can be spread over a flat surface and then struck off to an even thickness by passing it under a knife. The moist film is next placed under a bank of incandescent electric lamps with infrared reflectors; films up to 4 or 5 mils thick are dried in this way in about 5 minutes, although thicker films cause difficulty. The final treatment is immersion in a hardening bath that renders the material water-resistant. Experiments have been made with both potassium hydroxide and lead acetate baths. The action is one of base exchange, and although the addition of potash yields a product that more nearly duplicates the chemical composition of the muscovite molecule, lead acetate is employed more commonly. The sheets are now made separately in 3-foot lengths and widths of 18 inches or more. Eventually, however, a continuous sheet may be produced and recovered in the form of a roll. In making commutator segments the next step is to paste these sheets together with shellac or other binder and to compress them in a heated press in exactly the same way as ordinary built-up mica sheets are made. Some difficulty has been experienced in cutting the built-up Alsifilm sheets into strips without breakage; but the stamping operations are conducted without difficulty, this operation being, if anything, easier with Alsifilm than with ordinary built-up mica. When shellac binder is used, the Alsifilm sheets are reported to have dielectric strength equivalent to 800 volts per mil, which is quite satisfactory. Although the individual films are rather brittle the laminated sheets are reasonably strong and will stand ordinary handling.

In addition to its use as a possible substitute for mica Alsifilm is being investigated as a substitute for paper, especially for permanent records. It takes ink well, can be strengthened by the addition of asbestos or other noninflammable fiber, and may be opacified with a dispersed pigment.

SALT

By A. T. Coons and F. E. Harris

SUMMARY OUTLINE

Total domestic production of salt was the largest ever reported to the Bureau of Mines, aggregating 9,277,911 short tons valued at $24,509,680. This quantity exceeded the nearest previous record (that for 1937) by 36,347 tons and thus more than compensated for the million-ton drop in 1938, when production was only 8,025,768 tons valued at $23,242,561.

All three types—rock salt, evaporated salt, and salt in brine—shared in the increase, but salt in brine contributed by far the greatest part, totaling 4,584,177 tons in 1939 compared with 3,694,807 in 1938; evaporated salt was next—2,658,577 tons compared with 2,429,-100 in 1938; and rock salt was last—2,035,157 tons compared with 1,901,861 in 1938.

Salient statistics of the salt industry in the United States, 1931–35 (average) and 1936–39

PRODUCTION

Salt production was reported by 79 plants (65 companies) in 1939 compared with 79 plants (63 companies) in 1938. Minerals Yearbook, 1936 (p. 920), listed producing companies in 1935, location of plants, and class of salt produced. Changes since then have been given in subsequent issues of the Minerals Yearbook. Changes in 1939 are as follows: The General Foods Corporation, Diamond Crystal Salt Division, Lyons, Kans., was taken over by the Carey Salt Co. The E. S. Blackmon operation, Freedom, Okla., is now the Eklund-Blackmon Salt Co. In Puerto Rico the works formerly designated as Ernesto H. Lienau now is the Salinas Del Papayo, Inc., Mayaguez, P. R. The Livestock & Milling Co., Redmond, Utah, reported production in 1939. The California Rock Salt Co., of Los Angeles, Calif., has bought the 40 salt claims that it has oper-

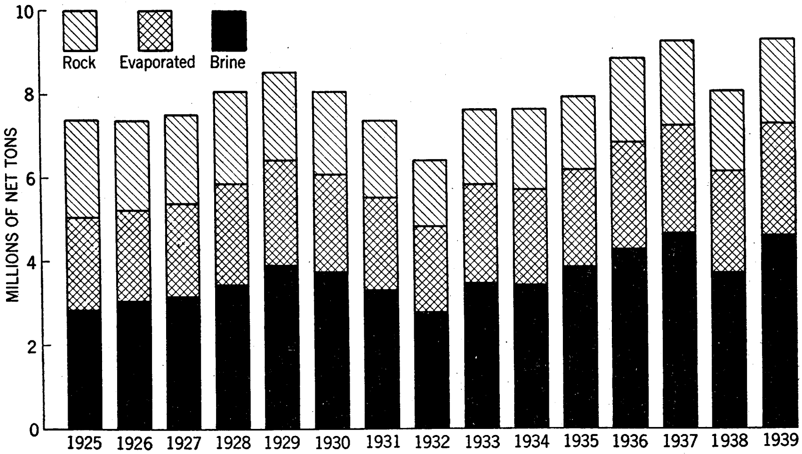

FIGURE 1.—Trends in the quantity of rock salt, evaporated salt, and brine (in terms of salt content) sold or used by producers in the United States, 1925–39.

ated on lease for 18 years at Bristol Dry Lake in the Mojave Desert south of Amboy. The deposits, formerly owned by the Consumers Salt Co., Los Angeles, cover 5,000 acres and are said to have been bought for $50,000. On July 31, 1939, a bill (H. R. 6831) to permit the Metropolitan Water District of Southern California to operate a salt mine on the public domain was passed by the House of Representatives, and to date no other action has been taken. If the bill is passed the water district will obtain from this mine all the salt required in large quantities annually to treat water from the Boulder Reservoir for domestic use. The operations would be confined to the production of salt for water conditioning only and would not permit its output for commercial use or sale. Under the general leasing law a public corporation may not obtain a mineral lease, hence the special bill.

The following tables give statistics on salt sold or used by producers in the United States by States and by methods of manufacture. Because of the small number of producers of salt in brine for chemical manufacture and of rock salt and evaporated salt in some States, it is impossible to show either rock salt or salt in brine separately by States.

Salt sold or used by producers in the United States, 1937–39, by States

Evaporated salt.—Evaporated salt aggregating 2,658,577 short tons in 1939 was produced at 58 plants, either from the original brine of wells and ponds or from brine obtained artificially by forcing the water into beds of rock salt and withdrawing it for processing by one of several methods in use. This total includes 152,121 tons of salt blocks for stock, the output of 19 plants. Solar-evaporated salt from 25 plants comprises 15 percent of the evaporated-salt output and in 1939 totaled 391,287 tons. Most of it comes from California and some from Utah, New Mexico, and Oklahoma.

Evaporated salt sold or used by producers in the United States, 1938–39, by States

State	1938		1939	
	Short tons	Value	Short tons	Value
California	343, 008	$1, 912, 637	396, 479	$1, 943, 698
Kansas	217, 918	1, 724, 635	232, 985	1, 717, 995
Michigan [1]	841, 836	4, 672, 529	922, 645	5, 019, 674
New York	340, 137	3, 378, 167	365, 899	3, 496, 414
Ohio	372, 711	2, 307, 949	395, 913	2, 337, 282

Texas	38, 362	208, 533	39, 096	198, 051
Utah	56, 597	173, 746	62, 177	183, 422
West Virginia [1]	129, 568	721, 490	144, 727	773, 988
Other States [2]	76, 455	404, 836	85, 331	471, 651
	2, 429, 100	15, 566, 439	2, 658, 577	16, 199, 882

[1] Includes a quantity of salt contained in brine for chemical use reported as evaporated salt with value as evaporated salt.
[2] Colorado, Louisiana, New Mexico, and Oklahoma.

Rock salt.—The output of rock salt reported by 21 plants totaled 2,035,157 short tons in 1939, which includes 39,242 tons of blocks produced by 7 plants for consumption by livestock. New York maintained the lead in rock-salt production, followed by Louisiana, Kansas, and Michigan. These four States continue to produce most of the national total.

Rock salt sold by producers in the United States, 1935–39

Year	Short tons	Value	Year	Short tons	Value
1935	1, 759, 242	$5, 510, 413	1938	1, 901, 861	$6, 252, 081
1936	2, 009, 579	6, 003, 054	1939	2, 035, 157	6, 496, 807
1937	2, 030, 432	6, 447, 648			

Salt content of brine.—Notwithstanding the fact that the quantity of salt in brine sold or used by producers was 4,584,177 tons in 1939, 24 percent greater than the 1938 total (3,694,807 tons), production did not reach the peak record of 4,631,580 tons in 1937. Salt in brine was produced at 10 plants in 1939, excluding 2 plants where the product is reported as evaporated salt rather than as salt in brine.

Pressed blocks and salt for livestock.—The quantity of salt consumed by livestock is increasing. Although the sale of pressed-salt blocks slumped in 1935 and 1937, their sale is increasing, as evidenced by the rise in 1938 and 1939. Moreover, not all the salt used by stock is apparent in the production statistics, as a greater quantity (estimated by a Department of Agriculture specialist as two-thirds or three-fourths of total stock salt) is used in the prepared feed for stock and poultry or is added to the feed at the farm. The blocks are suitable for some stock, but others—swine in particular—cannot be allowed to eat it at their discretion, as they are prone to overeat the salt and thus poison themselves. The salt used in the prepared feed is a coarse, granulated size. A convenient way for cattle to get their required salt (and whatever other conditioning mineral is added) is by a newly developed molded plastic dispenser that calls for a cylindrical "block" of salt.

Pressed-salt blocks sold by original producers of the salt in the United States, 1935–39

Year	From evaporated salt		From rock salt		Total	
	Short tons	Value	Short tons	Value	Short tons	Value
1935	126, 005	$900, 040	24, 691	$156, 002	150, 696	$1, 056, 042

[1] Figures not available before Jan. 1, 1939. [2] Less than 1 ton.

PRICES

New York quotations on rock salt were stable in 1939, but those of vacuum common fine salt fluctuated somewhat. The price of bagged rock salt, delivered at New York, was $13.20–$13.80 a ton in carlots; in less than carlots it was $15–$15.60. Bagged common fine salt in carlots delivered in New York cost $15.30 a ton in the first quarter of 1939; in less than carlots it cost $16.30–$21. At the end of the first quarter the quotations dropped to $14 a ton for carlots and $15–$19.70 a ton for less than carlots. These prices prevailed until the last quarter of 1939, when they were changed to $15.30 a ton for carlots and $16.60–$19.70 a ton for less than carlots—quotations that continued through the first quarter of 1940. At the end of this quarter the price for carlots rose to $15.70, the prices for smaller lots remaining the same.

USES

Salt is one of the minerals about which the United States need have no concern as to an ample supply. It is found abundantly in many parts of the country, and new sources are discovered almost daily. The chief problems therefore are distribution and research to develop new uses and efficient methods for converting it into useful commodities. The ingenious use of salt has been an important factor in attainment by the United States of first place in world production of chemicals. Many chemicals are based upon salt, especially the heavy alkalies so important to process and other industries.

A quantitative break-down of salt production into its ultimate as well as immediate uses would be interesting, but so far the sequence has never been followed through. All that can be said is that there are hundreds of uses of salt, many of which are vital to the respective industries employing it. Some of these industries consume only small quantities of salt, but together their consumption aggregates an important volume.

Of the heavy alkalies made from salt, soda ash and caustic soda are used in large quantities by important industries. According to recent statements,[1] 2,964,000 short tons of soda ash and 970,000 tons of caustic soda were consumed in 1939, increases over 1938. The greatest increase in soda-ash consumption was in the glass, pulp and paper, caustic and bicarbonate soda, and other chemical industries. Textile industries also used more soda ash in 1939 than in 1938, and requirements for water softening and petroleum refining were greater. Production of caustic soda rose because the rayon and cellulose industry consumed more in 1939 than 1938, as did the pulp and paper industry. The soap, petroleum-refining, lye, textile, and rubber-reclaiming industries also took more caustic soda in 1939 than in 1938. Exports of both soda ash and caustic soda were larger in 1939 than in the previous year.

The same source of information stated that the indications were that chlorine gas "slightly exceeded its previous high point in 1937, probably by about 2 percent, although the pressure of excessive chlorine demands was relieved in 1938, and neither that year nor 1939 was an exciting one for chlorine."

[1] Chemical and Metallurgical Engineering, February 1940, pp. 70–71.

The European war influenced the chemical market in no small degree. Some markets were cut off from the United States, but others were substituted that had been deprived of their European supply. Moreover, because of the war, chemical requirements were greater.

The effect of the use of common salt on concrete roadways still engages attention. How the salt honeycombs snow and ice was described.[2] The flaking, spalling, and disintegration of concrete surfaces owing to application of salt in icy weather was discussed,[3] and Swedish investigations were reported.[4] This use of salt has no reference to dirt roads on which the use of salt appears to have been successful. Although reported progress is slow the quantity so employed has been increasing steadily in recent years.

Although aggregating a small total, the use of salt in drinking water for those working in hot places is continuing.[5]

The new plastics and rubberlike fabrics in which salt is used as one of the basic ingredients are still in the public eye and their practical features are being shown.

As a novelty, the ceiling of the Rumanian building at the New York World's Fair of 1939 was built of blocks of rock salt mined in Rumania. The blocks in the center of the ceiling were streaked with wide bands of gypsum, while the large blocks around the edge appeared to be of purer quality. All the blocks were crude (just as mined and cut). From below they resembled polished marble. Fans had to be used to keep the salt blocks dry, otherwise they would begin to deliquesce and drip.

A recent bibliography [6] of published reports of experiments on the effect of various minerals on plant growth includes a number of references to the use of salt; these include determination of the salt requirements of tobacco, the plant uptake of potash as induced by salt, the effect of application of common salt upon the yield and quality of sugar beets and upon the sugar content of melons, and other phases of salt action.

Food is the largest market for dry salt. A new food use, although consuming an insignificant quantity compared to the present total, may be mentioned. The canning of Atlantic crab meat for long keeping, not heretofore attempted, has been begun recently. The process employs sodium chloride in a brine to give the meat a protective salt treatment.[7]

TECHNOLOGIC DEVELOPMENTS

The up-to-date methods of mining rock salt at the Jefferson Island Salt Mining Co. in northern Louisiana were described and illustrated in a magazine article.[8] This salt is pure enough to use without

further treatment than crushing, screening, and grading to size after mining.

Fine granulated salt has been the form most favored by many textile factories for industrial use in the past because such salt dissolves more readily than other types. Rock salt costs less, but because it dissolves slowly dissolvers must be used if a plant wants a fairly continuous supply of brine. At a textile show in the South, the Myles Salt Co., of Louisiana, exhibited a small rock-salt dissolving unit, the storage tank of which was nickel-lined to prevent not only corrosion but also contamination of the brine.

The International Salt Co., of New York and Pennsylvania, has equipment called the Lixator [9] which supplies saturated brine for such industrial uses as regenerating zeolites; curing meat, fish, and hides; and dyeing textiles. The brine, free from sediment, is produced from cheap rock salt as needed. The equipment is automatic, except for the necessity of refilling the salt hopper and emptying the sediment from the bottom of the cone. It is made of Monel metal.

A method of purifying rock salt "uses silicate to prevent the floating of soluble crystals in a saturated solution and makes clean separation of insoluble dirt from such a substance as common salt by floating the earthy material on a soapy foam; thus certain rock salts can be purified without the expense of dissolving and recrystallizing." [10]

IMPORTS AND EXPORTS [11]

Although foreign trade in salt is small (and has been for a long time), domestic imports and exports were larger in 1939 than in 1938. Imports increased by only 17 percent, but exports advanced 84 percent. Of the imports the greatest tonnage increase was in bulk salt with a substantial rise in salt in bags, barrels, etc., while the total imported for curing fish declined sharply. The largest tonnages exported went to Canada and Japan; both represented gains over 1938 shipments.

WORLD PRODUCTION

Although production data are still lacking for many countries listed in the accompanying table, doubtless, the United States in 1938 maintained its long-held position as the leading salt producer of the world.

World production of salt, 1934–38, by countries, in metric tons

[Compiled by M. T. Latus]

Country [1]	1934	1935	1936	1937	1938

[1] In addition to the countries listed salt is produced in Bolivia, Gold Coast, Madagascar, and Southern Rhodesia, but figures of production are not available.
[2] Data not available. [3] Exports. [4] Railway shipments.
[5] Output of U. S. S. R. in Asia included with U. S. S. R. in Europe.
[6] Includes Manchuria. [7] Estimated annual production.
[8] Year ended March 31 of year following that stated. The figures do not include output from salt beds which, although situated on Government beach lands, have no fixed areas.
[9] Incomplete data. [10] Year ended June 30 of year stated.

Canada.—A substantial quantity of salt is produced annually in Canada for various uses. At present only the preliminary report for 1939 is available.[12] The final annual reports of the Dominion Bureau of Statistics usually give a break-down of total salt production into uses, by quantity. In 1937 the Dominion Bureau began to itemize separately the quantity of salt used on roads in the Dominion; the quantity of highway salt sold in 1938 was 10,174 tons valued at $34,689 compared with 1,969 tons valued at $6,227 in 1937. Canadian salt beds are discussed in an article [13] on the development of mineral resources. Two occurrences of salt 900 and 1,400 feet thick, which were discovered incident to drilling for gas and oil in New Brunswick, were described.[14]

China.—Salt fields have received a great deal of attention from Japan, according to United States Counsul Frederick W. Hinke, Tientsin, China, who has furnished a comprehensive official report on the needs of Japan for an adequate and continuous supply of salt for its industries and military purposes and on Japan's intense efforts to exploit the Changlu field of China to meet a large part of its requirements. Japan's annual consumption totals about 1,900,000 tons, of which it produces 36, Taiwan 4, and foreign countries 60 percent. Because of the growth of industries in the country its requirements have increased by leaps and bounds. The quantity of salt used industrially by Japan in 1912 was only 3 percent of the total; in 1924, 10 percent; in 1932, 35 percent; and in 1933, 46 percent. In the past 6 years salt consumption in Japan has increased 50 percent. Since the outbreak of the conflict in China it has become increasingly imperative for Japan to obtain salt from nearby sources because of exchange and shipping difficulties. The European war has heightened this urgency, as Japan for the past 7 years has imported an annual average of well over 400,000 tons of salt from Africa whence it is difficult now to obtain a supply. Expectations were that the Changlu field would fill the gap, but this does not seem to be the case. Despite the promising yields of salt early in 1939, output from the Changlu field has suffered set-backs owing to typhoons, increased domestic needs, and lack of shipping facilities. An increase of 190,000 tons in Changlu production was anticipated from 1938 to 1939 but did not materialize, and a further estimated increase of 120,000 tons for 1940 cannot be realized because of typhoon damage.

Germany.—Despite a reduction in exports, salt production in Germany has expanded steadily since 1933.[15] Part of the decrease in exports was due to the German Reich's absorption of countries to which salt was exported previously. In 1939 Germany introduced a new denaturant for (tax-free) salt to be used for industrial purposes. Formerly, heliotropine was the chief denaturant used, but as it has to be imported a new denaturant was introduced which is called Nerolin (also known as Bromelia) and is produced from domestic materials.[16]

Italy.—Chiefly through the aid of the colonies of the Italian Empire, Italy has been striving to increase its exports of salt.[17] The Italian East African salt industry now exports about 250,000 tons a year, which is more than is being exported from Italy.

Palestine.—Although Palestine has huge resources of salt, much of which is in the Jebel Usdum area, the reported output is not large, and it seems difficult to obtain representative statistics. According to an article [18] that describes operations at the southern plant on the Dead Sea, the brine is pumped up to a series of pans exposed to the intense heat of the sun and arranged for a continuous flow downward to the Dead Sea. Common salt is the first of the dissolved salts to be deposited in the pans.

Spain.—It is reported that Spain is endeavoring to reestablish its salt industry and recapture its former markets.[19] For many years Spain was second in the list of salt-exporting countries, and its shipments averaged more than 500,000 tons a year.

Venezuela.—An extension of the salt works at Araya is included in the program for which an additional 26,099,000 bolivares was allotted by the Government under the 3-year public-works plan in July 1939. This salt field was described in a report in 1938.[20]

MAGNESIUM COMPOUNDS, BROMINE, CALCIUM CHLORIDE, IODINE, SODIUM SULFATE, BORATES, AND MISCELLANEOUS SALINES

By PAUL M. TYLER AND A. T. COONS [1]

SUMMARY OUTLINE

Common salt, the most important saline mineral, and potash are discussed in separate chapters of this volume. Available data on other natural salines and on magnesite and other magnesium compounds are reviewed in this chapter, following the arrangement first adopted in Minerals Yearbook, 1939.

Previous annual reviews have stressed the growing interchangeability of sources of magnesium. In 1939 serpentine was added to the list of minerals mined for their magnesium content. As noted in the Minor Nonmetals chapter of this volume, serpentine is being employed as an admixture in the new dolomite-base refractories, both to increase the magnesia content and to convert the lime into a nonslaking disilicate. Early in 1940 it was reported that the Dow Chemical Co. proposed to build a plant on the Gulf of Mexico, utilizing sea water as the source of additional raw material for metallic magnesium. A process for making either Epsom salt or monohydrated magnesium sulfate from North Carolina olivine was investigated; this process also is discussed briefly in the Minor Nonmetals chapter of this volume.

MAGNESIUM COMPOUNDS

MAGNESITE

Domestic production and imports of magnesite increased sharply in 1939. The apparent new supply of dead-burned magnesite was more than twice as large as in 1938 and larger than in any previous year except 1936 and 1937. It exceeded the 1925–29 average by 25 percent and was well ahead of recovery in iron and steel output, which failed to regain its predepression average, thereby tending to confirm the fact that new outlets for magnesite in other industries are offsetting any losses in demand caused by possible substitution of competitive refractory materials in the iron and steel industry.

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

Salient statistics of the magnesite industry in the United States, 1935–39

	1935	1936	1937	1938	1939

Percent domestic	74.6	67.9	59.8	60.8	66.0

[1] Partly estimated; most of the crude is processed by the mining companies, and very little enters open market.
[2] Average receipts f. o. b. mine shipping point.

Although the use of calcined magnesite is barely one-third as large as during the 1923–25 boom, the apparent new supply was larger than in any other year since 1930 except 1937. More crude magnesite was sold in 1939 than in 1938, and imports were unusually large, but the expense of shipping uncalcined material and competition from other sources of magnesia tend to prevent sales from increasing greatly.

Northwest Magnesite Co. (Farmers Bank Building, Pittsburgh, Pa.) operated two to five of its six kilns at Chewelah, Wash., 11 months and closed 1 month. Both the Finch and Allen-Moss quarries were operated in 1939, as in 1938. An experimental flotation plant has been installed.

In California the new sea-water plant of the Westvaco Chlorine Products Corporation (405 Lexington Avenue, New York, N. Y.) was operated virtually at capacity, and its Red Mountain mine 30 miles south of Livermore was reopened during the summer. Before the completion in November of a new kiln at the mine the material was calcined at Patterson where the product of the Robert Hays Smith mine was treated until it was worked out in 1936. The company also continued mining at the Bald Eagle mine near Gustine and the Western mine above Livermore. Water-soluble magnesium oxide for fertilizer use was added to the list of products made from sea water;

a company brochure stated that "Tonnage into four figures had been used by fertilizer manufacturers prior to September 1939."

The Eastern Magnesia Talc Co., Inc. (206 Bank Street, Burlington, Vt.), made a trial shipment of its high-iron magnesite tailing in 1939 in expectation of a contract for regular deliveries in 1940.

Magnesite has been discovered in the vicinity of Llano, Tex., and a prospect is being currently developed by Meramec Minerals, Inc., a subsidiary of Basic Dolomite, Inc., of Cleveland, Ohio.

Fairly heavy shipments of Austrian magnesite were made early in 1939, but this trade dwindled promptly after April when the extra (countervailing) duty of 25 percent was levied against all shipments from Germany and later became virtually impossible because of the British blockade.

Freight rates even from the Orient advanced greatly after the outbreak of the war in Europe. Cargo rates from Dairen to United States Atlantic ports jumped from $10 to $13 a ton, with $20 mentioned as an early possibility. Imports from Manchukuo, which are credited in the United States import statistics as coming from Kwantung, began to increase markedly 2 years ago. This material is not always uniform, but it is usually low in iron (less than 2 percent) and had begun to displace Austrian material even before war was declared. The inclusion of Austria and Czechoslovakia in Greater Germany gave the German Government almost complete control of the Magnesite Cartel, which had influenced production in Hungary and other parts of the former Austro-Hungarian Empire. Shipments can still be made from Yugoslavia but are subject to the handicaps of moving through the Mediterranean and war-infested parts of the Atlantic Ocean. A little Chinese magnesite has been imported into the United States, apparently from areas not controlled by the Japanese. Large deposits of high-grade magnesite have been reported in Chosen, but so far as is known no magnesite from this source has been exported to the United States.

The magnesite deposits at Tashikkiao (Manchukuo) have an annual output of over 300,000 metric tons and are among the most important in the world. About 60 percent of the output is exported to Europe and America and the remainder to Japan. Reserves are estimated at 5 billion tons. Other extensive magnesite deposits are being worked in Southern Manchukuo, although exploitation in this area is handicapped by transportation difficulties. The leading producer is the Nippon Magnesia Chemical Co., which makes brick and calcined magnesia.[2]

[2] The Chemical Age (London), Foreign News: Vol. 42, No. 1080, Mar. 9, 1940, p. 146.

Magnesite imported for consumption in the United States in 1939, by countries and classes

[1] For statistical purposes trade with the Sudeten area, as far as ascertainable, is included with Germany, while trade with the other Czechoslovak Provinces occupied by Germany, Hungary, and Poland has been included with these countries since Mar. 18 or 19, 1939. After Nov. 16, 1939 trade with Danzig and that part of Poland occupied by Germany has been included with Germany and trade with that part of Poland occupied by U. S. S. R. has been included with U. S. S. R.

Price quotations of the Engineering and Mining Journal remained at $22 and $25 a short ton for dead-burned magnesite f. o. b. Chewelah, Wash., and California shipping points, respectively. For other products, its quotations f. o. b. California were nominally: Artificial periclase, 94 percent MgO, $65; 90 percent $35; caustic, 95 percent MgO, white color, $40; 85 percent MgO, no color standard, $37.50 a ton. The base price of magnesite brick (9-inch straight) continued at $67 a ton.

Average values realized on domestic sales in 1939 were somewhat higher on dead-burned magnesite, probably owing to a larger proportion of the more expensive California periclase. The figures for crude, caustic calcined, and dead-burned magnesite, respectively (1938 figures in parentheses), were $14.03 ($13.42), $30.53 ($30.88), and $19.75 ($18.87).

World production of magnesite, 1934–38, by countries, in metric tons [1]

[2] Data not available.
[3] Magnesitic dolomite.
[4] Data for production not available; value reported as follows: 1936, $768,742; 1937, $677,207; 1938, $420,261.
[5] Exports, less imports, of crude and sintered magnesite, the sintered being reduced to crude on the basis of 2.1 tons crude to 1 ton sintered.
[6] Estimated production.

DOLOMITE

In 1939 sales of dead-burned dolomite by domestic producers increased to another new record, 671,561 short tons valued at $5,447,554 compared with 366,626 tons valued at $3,095,355 in 1938 and 617,706 tons valued at $5,217,833 in 1937.

As shown in the table on page 1375 of Minerals Yearbook, 1939, imports of dead-burned dolomite, comprising principally impure Canadian magnesite or "Basifrit," rose from 6,051 tons valued at $152,795 in 1931 to a maximum of 13,928 tons valued at $349,678 in 1936. Basic Dolomite, Inc. (845 Hanna Building, Cleveland, Ohio), acquired the American rights to a similar product in 1938 and is reported to be making it from ordinary dolomite admixed with magnesia obtained from brucite and serpentine. In 1939 imports totaled only 186 short tons valued at $4,260 compared with 2,875 tons valued at $67,340 in 1938.

Dead-burned dolomite sold in and imported into the United States, 1935–39

Year	Sales		Imports [1]		Year	Sales		Imports [1]

[1] Reported as "dead-burned basic refractory material."

BRUCITE

The production of brucite from the deposit near Luning, Nev., increased further in 1939, but the Bureau of Mines is not at liberty to publish the figures separately and the material is included under "Other magnesium compounds." Basic Ores, Inc., a subsidiary of the principal consumer, Basic Dolomite, Inc., is the only domestic producer.

Commercial deposits of brucite were first discovered in Canada in 1937 at Rutherglen in the Nipissing district, Ontario, by M. F. Goudge of the Dominion Bureau of Mines. Subsequent field work has disclosed other deposits in the same area and in the Bryson and Wakefield areas of Quebec, all within easy reach of transportation. The brucite occurs as small crystals or grains comprising 25 to 30 percent of the surrounding limestone. The Bureau at Ottawa has worked out a process of calcination, hydration, and separation that yields calcined brucite granules analyzing 94.4 percent magnesia and only 0.40 percent CaO, the remainder being chiefly water (4.38 percent) and fractions of 1 percent silica, iron, and alumina.[3]

OTHER MAGNESIUM COMPOUNDS

The output of magnesium compounds other than magnesite and dolomite produced from natural sources and sold or used in the United States totaled 85,754 short tons valued at $1,907,944 in 1939 compared with 70,733 tons valued at $1,588,570 (revised figure) in 1938. The principal item is magnesium sulfate, but magnesium chloride is a close second, and brucite (natural magnesium hydroxide) has become an important factor. These figures include a fair amount of carbonate and a little oxide, but the output of the new sea-water magnesium oxide sold for fertilizer by the California Chemical Co. Division of the Westvaco Chlorine Products Corporation is included in the statistics of sales of caustic calcined magnesite. This product carries three times as much magnesium as kieserite but sells for much less than three times the kieserite price. It is bought by manufacturers of mixed fertilizers, especially fertilizers used in magnesium-deficient areas. Not only is it a magnesium carrier, but also it acts as a soil conditioner and sweetener and is reported to improve the physical characteristics of the fertilizer itself owing to the absorption of free acid and excess moisture.

Magnesium compounds imported for consumption in the United States, 1930–34 (average) and 1935–39

Year	Magnesium chloride (anhydrous and n. s. p. f.)		Magnesium sulfate (Epsom salts)		Calcined magnesium sulfate or calcined kieserite (not fertilizer)		Oxide or calcined magnesia

[1] Less than 1 ton. [2] Not separately classified prior to 1936.
[3] Magnesium silicofluoride or fluosilicate included under "magnesium salts and compounds, n. s. p. f."

Imports of most magnesium compounds declined further in 1939, along with other products imported from Germany; but imports of precipitated carbonate, which come chiefly from the United Kingdom, increased greatly after the reduction in duty under the reciprocal trade agreement on January 1, 1939, from 1½ cents to 1 cent a pound. The following notes on imported items are taken from a recent report: [4]

Kieserite, a hydrous magnesium sulfate ($MgSO_4 \cdot H_2O$), has been produced commercially almost exclusively at Stassfurt, Germany, where it occurs abundantly in the potash mines. Formerly it was calcined and used chiefly as raw material for making Epsom salts ($MgSO_4.7H_2O$). Imports of kieserite were reported in official statistics of the United States for many years, averaging 6,455 long tons annually in 1910–14, after which they dropped off and eventually ceased. Kieserite for fertilizer use is exempt from duty under par. 1706 of the Tariff Act of 1930, but imports were probably small or nonexistent until 1935 when they were included in the official statistics along with imports of "other substances used chiefly for fertilizer," amounting to 11,428 long tons valued at $142,902. In 1937 the imports under the latter classification amounted to 10,781 long tons valued at $99,054, and a study by the Chemical Division of the Bureau of Foreign and Domestic Commerce revealed that this was entirely kieserite. In 1938 kieserite was again listed separately in the official statistics, and imports aggregated 14,221 long tons. About one-third of this was imported into New England for use principally on potato fields in Maine, considerably more than one-third was entered at Florida ports for use on citrus fruits, and the remainder was used mainly by tobacco growers in Virginia and the Carolinas. In 1939 shipments diminished along with those of other German commodities, only 2,245 long tons valued at $14,511 being imported during the first 9 months before war conditions cut off further deliveries.

In 1935 the official statistics showed imports of "calcined magnesium sulfate or calcined kieserite (not fertilizer)" of 1,834 short tons valued at $30,291. This material is dutiable at 25 percent ad valorem under par. 5 of the Tariff Act of 1930 as a chemical compound not specially provided for, and according to a study made by the United States Tariff Commission it is used principally by rayon producers in the coagulation of cellulose solutions into filaments. After rising to 4,117 short tons valued at $71,889 in 1937, imports under this classification declined in 1938 and again in 1939.

Epsom salts, magnesium chloride, magnesium carbonate, and calcined magnesia are provided for at specific rates of duty under par. 49 of the Tariff Act of 1930. Imports of magnesium chloride have been small for several years and were further reduced in 1939. An increase occurred in those of precipitated carbonate which arose to a new record, probably as a result of the reduction in duty under the British Reciprocal Trade Agreement which was extended to all countries except Germany. Domestic production of precipitated carbonate was 7,301 tons

[4] Tyler, Paul M., and Bowles, Oliver, Nonmetallic Mineral Industries in 1939: Bureau of Mines Inf. Circ. 7106, 1940, pp. 18–19.

in 1937 as reported by seven producers to the Bureau of the Census, but most of this was technical or basic carbonate used for pipe coverings or other heat insulation, whereas imports are mainly for medicinal or pharmaceutical use.

A process for making synthetic kieserite or magnesium sulfate from olivine was tested in 1939. Parts of a large deposit of olivine at Webster, N. C., are reported to contain 25 to 35 percent MgO and up to 1½ percent nickel, which can also be recovered.

Magnesol, a synthetic silicate of magnesium, recently has been used as a competitor of bleaching clays in a newly patented process of oil refining.

TECHNOLOGIC TRENDS IN MAGNESIA REFRACTORIES

A trend toward still wider use of dolomite in refractories is forecast by successful experiments in overcoming the tendency of the lime content to slack. Pioneer work in this field in Canada is well-summarized in a recent paper [5] released by the National Research Council (Ottawa). The chief Canadian raw material for making basic refractories is the so-called magnesitic dolomite which occurs in large deposits at Kilmar, Quebec. This material contains only 38 percent MgO and 11 percent CaO and corresponds mineralogically to a mixture of 57 percent magnesite, 35 percent dolomite, and 8 percent serpentine. In the production of thermoplastic refractories for open-hearth furnaces blends of various classes of rock and iron ore are made into a material containing roughly 65 percent periclase and 20 percent dicalcium silicate (both of which are extremely refractory), along with 15 percent low-melting calcium aluminate and ferrites. Such material can be burned-in on furnace hearths in much the same way as mixtures of slag and ordinary dead-burned magnesite, but the resulting lining is claimed to be superior. This development is strategically important, as it relieves the British Empire steel industry of all anxiety from unavailability of Austrian magnesite.

Chemically bonded magnesia-base refractories are now being made for use where high burning-in temperatures (3,000° F.) are not obtainable. Preliminary tests with thermoplastic magnesitic dolomite clinker, liquid sodium silicate, and an additional agent to increase strength resulted in failure, but addition of a new chemical has produced a chemically bonded ramming mixture that has been applied successfully in converters, anode furnaces, and reverberatory furnaces in the copper industry and in open-hearth and electric furnaces in the steel industry.

Another development has been production of unburned brick. Owing to the dicalcium silicate in the magnesitic dolomite a strong chemical bond is obtained with or without chrome ore.

Chrome-ore additions are desirable not only for unburned brick but also for nonspalling burned brick, tap-hole blocks, and linings for kraft furnaces. Although chrome ore has proved of enormous advantage in combination with magnesia-bearing minerals, it also has limitations, according to the afore-mentioned authority. To avoid undue absorption of iron oxide, resultant swelling, and possible failure, a pure magnesia brick may be employed. Recent work with Canadian brucite has produced satisfactory brick of this character.

In making magnesite brick American plants have depended mainly on imported grain magnesite, owing less to technologic than to eco-

[5] Lathe, F. E., Basic Refractories in Canada, 1914 and 1939: Trans. Canadian Inst. Min. and Met., vol. 43, 1940, pp. 83-99.

nomic reasons. The plants are situated on the Atlantic seaboard, where overseas shipments do not have to bear the additional expense of railroad transportation. Moreover, the draw-back on duties paid on imported magnesite can be refunded only in respect to export products in which the imported magnesite is actually used and, since the doctrine of substitution of domestic raw materials (applied to manufactures of nonferrous metals) has not been accepted as applicable to magnesite refractory products exported, this factor is important. As much as one-third of the magnesite now used in refractory brick and other shapes may be domestic, and the proportion probably is larger in magnesite-chrome brick. Even straight magnesite brick can be made from domestic magnesite alone without any impairment of quality, although the trend is to use mixed materials in the manufacture of high-heat-duty brick. Virtually all chrome brick now contain a certain amount of magnesite, and according to at least one authority the most satisfactory mixture for general service is 75 percent chrome ore and 25 percent dead-burned magnesite. Owing to displacement of medium-duty by high-duty refractories the total consumption of straight magnesite, straight chrome, and magnesite-chrome brick has increased, but owing to the preferences for mixed materials about twice as much chrome ore as dead-burned magnesite is now consumed in the manufacture of these high-grade products.

BROMINE

Production of bromine in the United States continued to climb much faster even than motor-fuel demand and soared to 18,941 short tons valued at $7,611,400 in 1939 compared with 16,662 tons (revised figure) valued at $6,610,056 in 1938. The use of bromine in the form of ethylene dibromide for making tetraethyl lead compounds for anti-knock motor fuels was begun in 1923 and has been the principal outlet for bromine since 1928, when total sales were only 1,082 tons valued at $649,475.

Bromine is recovered from salt-well brines by five companies in Michigan and five in the West Virginia-Ohio salt area. By far the largest producer is the Ethyl-Dow Corporation, which recovers bromine from sea water at Kure Beach near Wilmington, N. C. The second largest producer is the Dow Chemical Co., which, in addition to its joint interest in the former corporation, recovers large quantities of bromine from its brine operations at Midland, Mich. The third largest producer is the Westvaco Chlorine Products Co., which not only operates in West Virginia but obtains bromine from sea-water bitterns at Chula Vista and Newark, Calif. According to a recent report [6] the American Potash & Chemical Corporation plans to add bromine to the list of products it recovers from Searles Lake brine. Some concentrated products of this brine carry 100 times as much bromine as sea water, and the quantity of brine treated in 1939 carried 10,000,000 pounds. The proposed installation, however, will recover only 2,000,000 to 3,000,000 pounds annually, using the richer liquors.

The foreign market value of imports of bromine or its compounds was only $38,097 in 1939 compared with $277,527 in 1938. Hereto-

[6] Oil, Paint and Drug Reporter, Bromine to be Made by Potash Concern: Vol. 137, No. 5, January 29, 1940, pp. 3 and 37.

fore imports of ethylene dibromide have been a factor in the domestic market, but in 1938, as noted in Minerals Yearbook, 1939 (p. 1379), a countervailing duty of 3.775 cents a pound was assessed on imports of

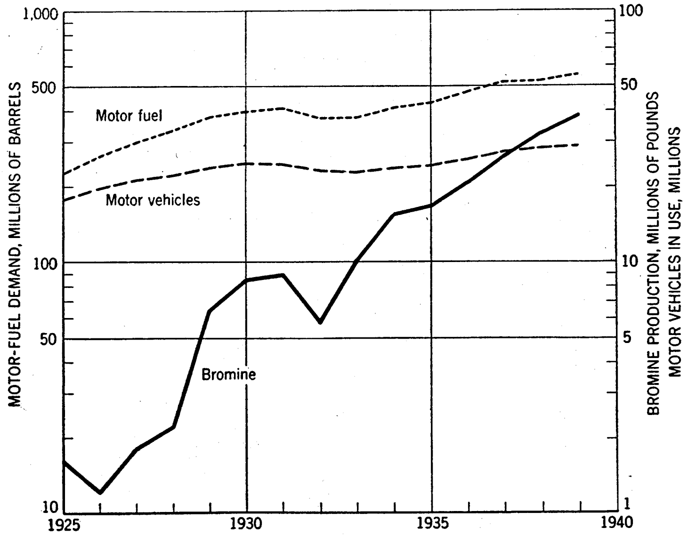

FIGURE 1.—Bromine production compared with motor-fuel demand and motor vehicles in use (July 1) in the United States, 1925–39.

this product, all of which came from Germany, and none was imported in 1939.

CALCIUM CHLORIDE

Production and sales of calcium chloride and mixed calcium-magnesium chloride (basis 75 percent $CaCl_2$) obtained directly from natural brines increased to 108,441 short tons valued at $1,307,717 in

1939 compared with 96,470 tons valued at $1,218,938 in 1938 and 97,142 tons valued at $1,295,403 in 1937. Calcium chloride is also produced as a byproduct of soda ash in the Solvay process, but sales of this material are not included in the Bureau of Mines tables that follow, as the calcium comes from limestone and the chlorine mostly from sodium chloride that is reported elsewhere as salt in brine. The total domestic sales, including byproduct chlorides, have been estimated at 258,000 tons in 1938, of which 39 percent was used for road treatment, 15 percent for dedusting coal and coke, 12 percent for ice

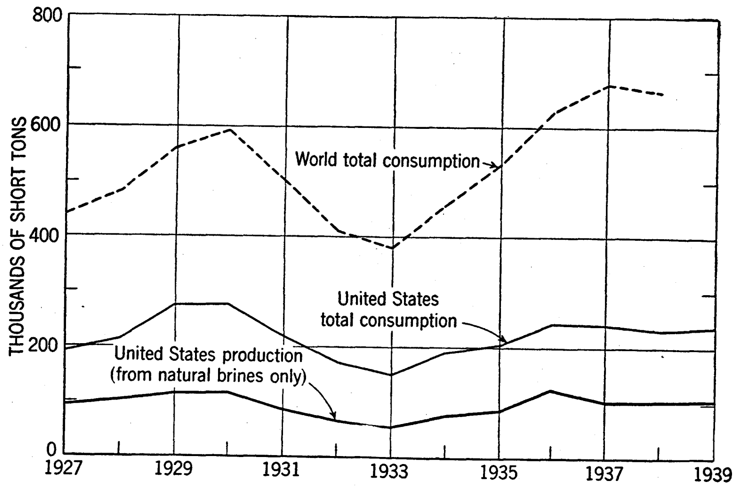

FIGURE 2.—Domestic production of calcium chloride (and mixed calcium-magnesium chloride) from natural brines compared with United States and world consumption, 1927–39.

control, and 6 percent in refrigerating brines; 28 percent was taken by resellers, exports, or minor consuming outlets.

Calcium (calcium-magnesium) chloride from natural brines sold by producers in the United States, 1935–39

IODINE

Domestic production of iodine increased again in 1939. The Dow Chemical Co. is the leading producer, having taken over the business of its subsidiary Io-Dow Chemical Co. on March 31, 1939. The company plant is at Long Beach, Calif. The only other producer is the Deepwater Chemical Co. (plant at Compton, Calif.) which recently has operated under a process patent controlled by Dow. The General Salt Co., Long Beach, Calif., one of the pioneer domestic producers, has been idle for several years and reported no output in 1939.

Imports of iodine (all crude) totaled 200,000 pounds valued at $168,238 compared with 570,532 pounds valued at $464,303 in 1938 and a record quantity of 1,967,148 pounds valued at $1,784,491 in 1937.

The price of crude iodine, after dropping to 81 cents a pound in 1936, rose to $1.02 in 1938, and the average for 1939 sales remained at approximately that figure.

Chile has been the leading producer of iodine for many years, but substantial quantities have been produced also in France, the United Kingdom, Ireland, Norway, Japan, Netherland Indies, and British India. According to a recent study,[7] Japanese exports dropped from 78,708 kg. in the fiscal year 1932–33 to 4,586 in the fiscal year 1937–38, whereas domestic consumption increased from 34,668 to 40,972 kg. Cost of production has increased above the cost of importation as a result of increased wages, and the supply of kelp on Hokkaido Island has diminished. Two companies produce iodine from subterranean brines, but prospecting has failed to develop additional supplies from this source.

Iodine produced in the United States, 1935–39

Year	Pounds	Value	Year	Pounds	Value
1935	245,696	$248,654	1938	(1)	(1)
1936	233,925	212,635	1939	(1)	(1)
1937	299,286	242,422			

1 Bureau of Mines not at liberty to publish figures.

Crude iodine imported for consumption in the United States, 1935–39

Year	Pounds	Value	Year	Pounds	Value
1935	375,819	$420,793	1938	570,532	$464,303
1936	592,217	558,326	1939	200,000	168,238
1937	1,967,148	1,784,491			

SODIUM SULFATE

Sales of natural sodium sulfate jumped 71 percent to 137,479 short tons valued at $1,027,876 in 1939 compared with 80,210 tons valued at $596,812 in 1938, the previous high record. Census data on total production in 1939, including the output of chemical plants, are not yet available, but imports of salt cake increased slightly, and consumption in the United States is believed to have been as large or

7 Bernard, L. M., Le Marché de l'iode au Japon: Chim. et ind., vol. 43, No. 5, March 5, 1940, pp. 439–443.

larger than in 1937, the record year. For 1937 the Bureau of the Census reported a production of 269,177 tons of salt cake, of which 241,347 tons valued at $2,367,616 were for sale.

Synthetic salt cake, a sintered product of soda ash and sulfur in molecular proportions, is a promising substitute for sodium sulfate in its leading use (kraft paper), especially in the South, according to Walter L. Lovell of the Mathieson Alkali Works, Inc.[8] A large plant is to be erected to produce this new-process salt cake on Lake Charles, La.

The large increase in Canadian output of sodium sulfate in recent years is due to its use in smelting nickel-copper matte and in the manufacture of kraft paper. Production in 1939 is reported officially as 71,453 tons valued at $627,941 compared with 63,009 tons worth $553,307 in 1938—all from Saskatchewan. Not included in these figures were 30 tons valued at $186 shipped from deposits in Alberta.

After reaching a peak of 220,176 short tons in 1937, imports of salt cake dropped to 142,429 tons in 1938 and amounted to only 148,794 tons in 1939. Notwithstanding the European war 26 percent of the total imports for the year came in during the fourth quarter, and receipts from Chile which rose to 26,079 tons in 1938 dropped to 1,503 tons in 1939. Germany supplied 103,259 tons, almost as much as in 1938, and 5,111 tons came from Poland and Danzig (before German occupation) and 25,607 tons from Belgium. Imports from Canada increased from 8,262 tons in 1938 to 9,518 in 1939. As usual virtually all the European salt cake imported was entered at South Atlantic or Gulf ports, principally for use in southern kraft-paper mills, which also are served by the recently expanded salt-cake mining industry in Texas.

Sodium sulfate imported for consumption in the United States, 1938–39, by countries

Country	Crude (salt cake)		Crystallized (Glauber salt)		Anhydrous		Total

BORATES

Owing to a large increase in domestic consumption the production (shipments) of borates in the United States increased to 249,976 short tons valued at $5,882,302 in 1939 compared with 219,513 tons valued at $4,570,316 in 1935. In 1937, the peak year, production was 358,898 tons valued at $7,232,897, of which 154,052 tons having a declared value of $4,715,691 were exported. In 1938 exports declined sharply to 77,519 tons valued at $2,642,446, and in 1939 they were 91,139 tons valued at $3,230,304.

The production figures for 1939 include borax and kernite (from California) and small quantities of colemanite (from California) and ulexite (from Nevada).

Salient statistics of the boron-mineral industry in the United States, 1935–39

	1935	1936	1937	1938	1939

Short tons	158,520	211,739	204,846	141,994	158,837

[1] 1935–37: Borax, colemanite, kernite, and boric acid (calculated as borax); 1938: Borax, kernite, and boric acid (calculated as borax); 1939: Borax, colemanite, kernite, ulexite, and boric acid (calculated as borax).
[2] Also 348 pounds of crude valued at $3.

Although borax was used as a flux in fire refining of gold at least as early as the fourteenth century, large tonnages were not employed until new discoveries in California reduced the price to about $30 a ton after 1920. During the last 2 decades the use of borax in the United States has increased approximately three fold, owing partly to its growing employment in enamelware but principally to its use in glass manufacture. Recently boron has been found to be one of the so-called minor elements that stimulate plant growth and inhibit the development of certain plant diseases. Borax already is included in many mixed fertilizers, but the quantities used are so small that only wide recognition of its desirability as a fertilizer constituent will result in any appreciable increase in demand from this source.

Germany, which before 1938 imported as much as 50,000 short tons of crude and refined borax a year, chiefly from the United States, has taken definite steps to reduce consumption, first as a means of conserving foreign exchange and later as a war measure. In April 1939 the use of boron materials was prohibited in the manufacture of leather, finishing agents used by the leather goods and hat industries and in the manufacture of cosmetics, office glue, plywood, casein, and shellac. After war was declared the quantities used in ceramic glazes was limited to a maximum of 10 percent B_2O_3 of the dry mix for primary enamel (and then only for one coat) or to 5 percent for surface enamel. In the glass industry the use of boron was restricted to optical and scientific or technical glass. To replace part of the borax in enamels, which hitherto have been responsible for most of Germany's consumption of imported boron minerals, metallurgical slags have been used successfully, especially those from the smelting of siliceous domestic ores by a newly developed process employing soda ash as a desulfurizing agent.

World reserves of boron minerals are abundant, but known sources are confined to a few countries, chiefly the United States, Chile, Argentina, Peru, Italy, and Turkey, although borax also has been reported in Tibet, Persia, India, and Ceylon. Perhaps the most interesting operations are in Italy where boric acid is a joint product of the utilization of volcanic gases, which also yield ammonia, carbon dioxide, and heat and power from natural steam. The history of the industrial development of the "soffioni" or vapor springs at Laiderello and elsewhere in the Province of Pisa is told in a recent article.[9] A brief but competent review of the industry in the United States, which is by far the leading producer of borax, has been presented in a paper by Kitchen.[10]

SODIUM CARBONATES

Sales of natural sodium carbonates (chiefly soda ash but also bicarbonate and trona) rose in 1939 to an all-time record of 124,743 short tons valued at $1,528,810 compared with 100,010 tons valued at $1,235,328 in 1938 and a previous peak of 104,711 tons valued at $1,191,485 in 1937.

Only a small percentage of the total production of soda ash or sodium sulfate comes from natural resources. According to the annual review in Chemical and Metallurgical Engineering (vol. 47, No. 2, February 1940, pp. 70–71 and pp. 86–87) the total domestic output of soda ash in 1939 was believed to be 2,964,000 short tons, most of which (apart from the small amount of natural soda and 7,000 tons of electrolytic soda produced at pulp mills) was ammonia soda ash. Production of caustic soda in 1939 is estimated as 930,000 short tons, composed of 465,000 tons each of lime-soda caustic and electrolytic caustic, compared with a revised estimate of 420,000 of lime-soda caustic and 415,000 tons of electrolytic caustic in 1938 and the revised census figures of 488,807 tons of lime-soda caustic and 479,919 tons of electrolytic caustic in 1937.

Estimated distribution of soda ash consumed in the United States, 1937–39 by industries, in short tons [1]

Consuming industry	1937	1938	1939
Glass	903,000	660,000	830,000
Soap	180,000	187,000	198,000
Caustic and bicarbonate	751,000	655,000	716,000
Other chemicals	650,000	556,000	640,000
Cleansers and modified sodas	140,000	120,000	137,000
Pulp and paper	104,000	85,000	105,000
Water softeners	32,000	27,000	30,000
Petroleum refining	10,000	10,000	11,000
Textiles	38,000	30,000	43,000
Exports	55,000	51,000	84,000
Miscellaneous	184,000	149,000	170,000
	3,037,000	2,530,000	2,964,000

[1] Chem. and Met. Eng., vol. 47, No. 2, January 1940, p. 70.

Domestic production of natural sodium carbonates has been limited almost exclusively to the output at Searles Lake and at Owens Lake, Calif., where borax and other products help to bear the cost of recovery. Common salt, soda ash or sodium bicarbonate, and possibly small amounts of potash salts and borax could be obtained from the waters of Abert Lake or Summer Lake in southeastern Oregon, but a recent study [11] casts doubt upon the commercial feasibility of working these deposits under existing conditions.

The Geological Survey discovered a large deposit of trona at a depth of about 1,600 feet on Government land in Sweetwater County, Wyo., in 1939. The trona beds were found in cores of an oil and gas well being drilled by a commercial company. Associated with the trona were small quantities of two exceedingly rare minerals, northupite and pirssonite, both complex carbonates. A new mineral in these formations was identified by Fahey,[12] who named it "shortite"; it is a double carbonate of sodium and calcium.

OPERATIONS AT OWENS LAKE, CALIF.

Although operations at Searles Lake have been described frequently, less information has been published on Owens Lake. This lake, in Inyo County between the Sierra Nevada on the west and the Inyo Range on the east, covers an area of about 17.2 square miles and has no outlet. The Owens River, before being diverted in 1937 for the municipal water supply of Los Angeles, entered the basin from the north, and the lake waters were a dense brine containing common salt, soda, borax, and other soluble salts. Subsequently the lake has dried and, like Searles Lake, has become a vast bed of solid salt with only its crevices filled with brine, except occasionally in an unusually wet season when it may be flooded. The following notes on technology originally were published in Bureau of Mines Mineral Trade Notes for September 1939:

The Pacific Alkali Co. has a plant on the west shore of Owens Lake at Bartlett, about 10 miles south of Lone Pine (H. S. Mudd, president, George E. White, general manager, George D. Dubb, superintendent). According to a recent report (Tucker, W. B., and Sampson, R. J., Mineral Resources of Inyo County: Calif. Jour. Mines and Geol., State Mineralogist's Report 34, No. 4, October

[11] Stafford, O. F., Preliminary Report Upon Oregon Saline Lakes: Oregon State Dept. of Geol. and Min. Ind., G. M. I. Short Paper 1, 1939, 4 pp.
[12] Fahey, J. J., New Mineral Discovered: Glass Ind., vol. 20, No. 8, August 1939, p. 300.

1938), this company pumps brine through 2½ miles of 14-inch pipe into three vats, which range from 15 to 50 acres in area. After being concentrated by solar evaporation to 12 to 14 percent soda, the brine is run to storage reservoirs and thence is pumped into 16 carbonating tanks, each 6 feet in diameter and 80 feet in height. Carbon dioxide gas made from dolomite is forced into these tanks, thereby precipitating sodium carbonate, which is drawn off from the bottom as a sludge, centrifuged, and then dried and screened for laundry use or calcined in Herreschoff furnaces into soda ash, which is screened and sacked for shipment. After the soda is removed, the mother liquor is chilled to precipitate borax, passed through an Oliver filter, and returned to the lake. The crude borax cake is redissolved and the solution is treated chemically, clarified in Sweetland filters, and chilled again. The purified borax crystals are recovered in a centrifugal drier, and this liquor likewise goes back to the lake. This plant can produce about 1,000 tons of soda and 2,000 tons of borax per season and employs only 50 men.

Early in 1917 the California Alkali Co., an affiliate of the Great Western Electro-Chemical Co., erected a plant at Cartago on the southwest shore of the lake. This plant operated for 2 years and then closed until 1923, the company meanwhile acquiring the Inyo Development Co. In 1924 the two corporations were merged under the name of the Inyo Chemical Co., and the Keeler plant was leased to the Natural Soda Products Co., which subsequently has operated almost steadily at Keeler. The Cartago operations were discontinued in 1932, and the California Alkali Co. and the Great Western Electro-Chemical Co., which controls it, while retaining ownership, have not operated their properties on their own account since that year.

At Bartlett, which lies north of the original California Alkali Co. plant on the northwest shore, the Chemical Products Co. of Denver, Colo., built a wartime plant with a nominal capacity of 20 tons daily, which operated scarcely 2 months in 1918. The process was a failure, and the property, after being optioned to at least two different lessees, was sold to Boston capitalists, who rebuilt the plant completely and operated briefly under the name of the Clark Chemical Co. After producing soda ash and caustic soda liquor in 1927 and early 1928, this company ceased operations on May 8, 1928, and became bankrupt in 1931. In 1926 the Kuhnert Syndicate built an experimental plant to test its process for recovering borax, and in 1928 it was merged into the Pacific Alkali Co., whose present operations at Bartlett have been described and which has reported a substantial output every year since 1928.

On the east side of the lake, just south of Keeler, the Natural Soda Products Co. recently erected a new plant of 100 tons daily capacity, using a new process, details of which are not divulged. It employs 44 men.

Operations were begun near Keeler by Inyo Development Co. in 1885. For many years the treatment consisted essentially of solar evaporation in clay vats 1 to 20 acres in extent. These were filled with from 6 to 8 inches of brine, and the precipitated trona ($Na_2CO_3 \cdot NaHCO_3 \cdot 2H_2O$) was harvested once a year in the form of crust about three-quarters of an inch thick. The trona was calcined for soda ash in an oil-burning furnace, pulverized in rolls, and sacked. About 3 miles from this site and 2 miles south of Keeler the Natural Soda Products Co. erected a plant about 1915, which produced sodium bicarbonate as well as soda ash and trona. Shortly after the World War this company was making large shipments to Japan and Sweden as well as to domestic consumers, its total output being estimated by the State mineralogist as 10,000 tons of trona a year, employing 100 men and 2,230 horsepower. Carbon dioxide at various times has been obtained from dolomite from the Inyo Marble Co. and from limestone from the Cerro Gordo mine.

Producers of natural salines (other than common salt and potash) in the United States in 1939

Company name and address	Plant site	Product
American Potash & Chemical Corporation, Trona, Calif.	Trona (Searles Lake), San Bernardino County, Calif.	Borax, boric acid, potash (muriate and sulfate), salt cake (also burkeite), soda ash, lithium salts.

Westvaco Chlorine Products Corporation, South Charleston, W. Va.	South Charleston, Kanawha County, W. Va.	Bromine, calcium-magnesium chloride, common salt (brine).

GEM STONES

By Sydney H. Ball[1]

SUMMARY OUTLINE

Retail sales of jewelry in 1939 totaled about $307,000,000, or 10 percent above sales in 1938 ($279,000,000) and only slightly less than those in 1937 ($312,000,000). Diamond rings, watches, and gold jewelry were the principal items. After February sales were better each month than in 1938, and after September monthly sales showed increases over those of 1937. Improvement was progressive in 1939, and the Christmas trade in jewelry was markedly better than that for either of the past 2 years (16 percent over 1938 and 13 percent over 1937); moreover, there was some demand for higher-price articles. Sales in Oregon and Washington and, to a smaller extent, Georgia and South Carolina, made marked progress over 1938. Installment selling is increasing in the trade and is likely to show further gains.

Manufacturers' sales and those of wholesalers were respectively 25 and 20 percent greater than in 1938, and it is evident that both wholesalers and retailers increased their stocks somewhat in 1939 (retailers about 2 percent). Wholesale trade was relatively good, particularly during the last 5 months of the year, and sales of costume jewelry continued to increase.

Fashions in jewels.—Large jewels, flamboyant in color and daring in design, were the mode in 1939. Use of gold (often in two or three colors) and silver, to a smaller extent, gained at the expense of platinum. It is the opinion of many, however, that platinum sets off fine diamonds much more advantageously than gold. The motifs include geometric, classical, Victorian, Georgian, Hindoo, and ancient Egyptian. Jewelry ensembles, each piece set with similar stones, gained in popularity, as did large jewels divisible into several ornaments. Long pendant earrings, rings with large stones, clips, lapel ornaments, and necklaces were much worn. Jeweled flowers increased in popularity.

Colored gems set pavé with countless diamonds are used to a larger extent yearly. The finer gems—diamond (including an unusual number of colored diamonds), ruby, sapphire, and emerald—are most popular; however, aquamarine, moonstone, and topaz are used fre-

[1] One of the consulting engineers, Bureau of Mines. Figures on imports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

quently and many other colored stones from time to time. For men's wear, star sapphires, cat's-eye, and quartz gems predominate.

As a result of the war "mourning jewelry" is likely to be in demand (jet or black-stained onyx alone or with white stones, such as moonstone).

Domestic production.—From the 1909 peak production of gem stones valued at $534,280, the domestic industry dwindled until in 1934 the value decreased to about $3,000. Since then production has increased markedly and in 1939 was valued at $235,000 to $470,000; the first figure is a rough estimate of the amount used in jewelry and the second an estimate of the total, including that treasured by collectors or sold to tourists, mineral collectors, and rock gardeners. Almost 85 percent of the amount used in jewelry comprises stones of the agate family. Gems are produced largely by individuals or small partnerships, and as there are no official production returns exact figures are not available. The revival of the industry is due to three factors: (1) The purchase by automobile and other tourists of souvenirs, (2) the extraordinary increase in gem cutting as a hobby (particularly in Oregon and Washington), and (3) the use of an increasing variety of colored stones in jewelry.

The war has shut off, at least partly, the country's normal sources of supply of colored gems and has engendered nationalistic sentiments; consequently, gems of American origin, notably turquoise, tourmaline, kunzite, benitoite, and hiddenite, should increase in popularity. An important gem-stone industry cannot, however, arise in this country owing to the lack of gem deposits of the first order and the high cost of cutting in the United States. Unfortunately, some unscrupulous dealers sell to tourists and even to their fellow townsmen "American" gems which actually originated in foreign countries and were cut in Germany.

In the Northwest, especially in Oregon, according to correspondence with H. C. Dake, the number of mineral collectors and lapidaries, both professional and amateur, most of whom collect and cut quartz gems, continues to increase markedly. He estimates the value of the material cut in 1939 as follows: Oregon, $300,000; Washington, $90,000; Idaho, $35,000; Montana, $10,000; and Wyoming, $8,000—a total of $443,000. Much of the material remains in private mineral collections. In Oregon the centers of the industry are Portland and Newport. Some 14 lapidary shops in Newport employ from 2 to 10 persons each. For about 75 miles up and down the beach from Newport agate hunters (both amateur and professional) search for the rough material, particularly from February to the beginning of summer after winter storms have uncovered new sources of supply. The mineralogical societies of Lincoln County have protested against the use of local agate-bearing gravels as road material by the State highway commission. Oregon ships some uncut agates to cutters outside the State. In Washington the largest cutting centers are Seattle and Spokane; the principal stone cut is opalized wood from Miocene lake beds. In Wyoming local gem stones, mostly moss agate, are cut at Rawlins and Cheyenne. In Idaho the production was largely opalized wood from the southwestern part of the State and star garnets from Ruby Creek, Latah County.

Numerous collectors are slowly depleting the supplies of moss agate along the Yellowstone River in southeastern Montana from Huntley to northeast of Glendive, a distance of over 200 miles; however, the supply is partly replenished by the spring floods which rework the gravels. The most satisfactory collecting periods are during low water. Billings is the chief cutting center. The better moss agates are valued at $3 to $5 a pound in the rough.

Nevada yielded turquoise valued at about $17,000 in 1939. The principal producers were the Smith mine, Cortez district, Lander County, the Blue Matrix mine near Tenabo, and the "Royal Blue" mine at Royston. The output of the Smith mine was 7,512 pounds in 1939. Considerable turquoise was also produced at Villagrove Colo., and a little in Mineral Park near Kingman, Ariz. Mines in Utah, some about 5 miles west of Fairfield and others about 10 miles south of Grantsville, yielded 1,000 pounds or more of variscite.

A substantial quantity of sapphire was produced in Montana (perhaps 1,000 pounds), but very little of this was gem material, most of it being of industrial grade.

In 1939 it was reported that nephrite was found in place in California and that some had been cut and was on the market. Considerable prospecting for gems was done in North Carolina in 1939, and the local lapidary trade is increasing, thanks largely to tourist demand. Kunzite crystals were discovered in Mitchell County a few years ago.

Other gem stones produced in the United States in 1939 included agatized wood (private lands surrounding Petrified National Monument, Ariz.); amethyst (Townes County, Ga.; Larimer County, Colo.; and New Hampshire); aquamarine (Black Hills, S. Dak., and Maine); kyanite (Upson County, Ga.); garnet (Washington); oligoclase moonstone (North Carolina); rock crystal (Arkansas and North Carolina); rose quartz (Black Hills, S. Dak., and Albany, Maine); ruby (Macon County, N. C.); rutilated quartz (North Carolina); satin spar (Niagara Falls, N. Y.); topaz (Thomas Ridge, Utah; San Diego, Calif.; and New Hampshire); and tourmaline (green—San Diego, Calif., and Maine; red (rubellite)—Black Hills, S. Dak.).

For 60 years the Potter family has cut satin-spar (gypsum) beads and other souvenirs at Niagara Falls. Some of the material is of local and Canadian origin, but most of it is imported from England.

Marble similar to Mexican onyx was produced near Pelican Point on Utah Lake, Utah, by the Onyx Corporation of America and by the Jay Em Onyx & Gem Co., near Hartville, Wyo.

According to information furnished by A. H. Cornelison, the Hawaiian Islands produce a few gems and several decorative stones. Their output of olivines in 1939 was very small, as information regarding the locality of the best prospect was lost with the death of E. Mott Smith. Some clear plagioclase feldspar, locally known as "Hawaiian golden-yellow topaz," was mined, also an interestingly marked jasper and some common opal. The known deposits of "Hawaiian diamonds" (rock crystal) are almost exhausted. Possibly $1,000 worth of local stones were sold in 1939.

Imports.—According to the Bureau of Foreign and Domestic Commerce, imports of precious and imitation stones (exclusive of industrial diamonds) into the United States in 1939 totaled $40,487,-877, an increase of 43 percent over 1938. Details are shown as follows:

	Carats	Value
Diamonds:		
Rough or uncut (suitable for cutting into gem stones), duty free	153,982	$7,956,397
Cut but unset, suitable for jewelry, dutiable:		
Less than 10 stones per carat	60,332	5,107,173
10 or more stones per carat	427,822	22,310,100
Emeralds:		
Rough or uncut, free	36,946	17,531
Cut but unset, dutiable	17,624	361,345
Pearls and parts, not strung or set, dutiable:		
Natural		249,415
Cultured or cultivated		328,250
Other precious stones:		
Rough or uncut, free		111,830
Cut but unset, dutiable		1,937,479
Imitation, except opaque, dutiable		2,018,134
Imitation, opaque, including imitation pearls, dutiable		30,969
Marcasites, dutiable:		
Real		38,860
Imitation		20,394
		40,487,877

Tariff regulations.—Wars in Europe and the East brought about many changes in tariffs.

As soon as war was declared France decreed that licenses are required for the importation of gems and jewelry, and to conserve the country's gold, licenses doubtless will be difficult to procure. Supplies of gold for use in jewelry are controlled, and to prevent hoarding, jewelry containing an abnormal quantity of gold can no longer be manufactured.

At the outbreak of war the British Government placed an embargo on the export of diamonds to prevent industrial stones from reaching its enemies. Committees were set up in Antwerp, Amsterdam, Paris, and possibly also in New York to assist the British Board of Trade in issuing export licenses. The early delays caused by the embargo are now less exaggerated, but the embargo accounts partly for the fall in American diamond imports of uncut and industrial stones after September 1939.

Germany requires that official approval be obtained before precious and rare metals can be fabricated, and jewelers can only sell gold jewelry made of gold furnished by their clients. When Germany absorbed Czechoslovakia the duty on imitation precious stones immediately was increased 30 to 45 percent, as Czechoslovakia had a favored-nation trade agreement. France is supplying part of the shortage.

In Belgium special authorization from the Department of Economic Affairs is necessary to import or export rough diamonds for the duration of the war. In January 1940, Hungary replaced free imports by a regime of permits, and by May permits were virtually unobtainable.

In May 1939 Japan required all residents to report to the Government all gold held and after June 1 no gold articles could be displayed in shop windows. China nationalized all gold (coins, bars, and jewelry) in August, the owners being compensated at official rates.

Ceylon reduced the import duty on diamonds from 15 to 5 percent, or to that of India and Burma. Precious stones can be exported from

Brazil only by registered buyers or dealers after official appraisal. During the year Palestine removed duties on diamonds and unset precious stones.

Effect of war on jewelry trade.—When war was declared certain panicky dealers feverishly replenished their stocks; this buying, with a certain speculation by those outside the trade, raised the price of small cut diamonds 20 or 30 percent and that of large stones less. In reality the supply of diamonds is adequate, and prices should only have been raised enough to cover increased shipping and insurance costs. The price of colored stones also rose some 20 percent. Later higher cutting costs may have to be taken into consideration. Rather large stocks of costume jewelry were purchased, as the war automatically cut off some important sources of imitation and synthetic precious stones. Platinum prices rose (January 1, 1939, \$34.44; December 30, 1939, \$40 an ounce).

Hereafter jewelry probably will be more expensive, but there is no reason to fear a shortage of supply, even if the war becomes a long-drawn-out affair. Obviously the warring nations need dollar exchange.

The American diamond-cutting industry may be stimulated somewhat by the war, but even under war conditions small diamonds doubtless will continue to be cut in Europe, as American cutting costs on such goods are prohibitive.

War and destruction are synonymous, therefore war must hurt industry. Today the Russian and German markets for gem stones are almost nonexistent; France and England are throttled by high taxation; hence the industry must live on the trade of the United States, India, and South America and on such investment buying of fine gems as the citizens of belligerent countries can accomplish.

Gem publicity.—At the New York World's Fair, jewels will again be attractively exhibited in 1940. The House of Jewels will show the beautiful jewelry of five leading Fifth Avenue jewelers and gorgeous diamonds, uncut and cut, of De Beers & Associated Producing Cos. During 1939 De Beers, in a selected group of periodicals, conducted a campaign advertising the beauty, value, and rarity of the diamond.

DIAMOND

The year 1939 was surprisingly satisfactory in the diamond industry in view of the grave political crises and the two major wars. Trade was far better than in 1938, and in some respects was almost as good as in 1937, admittedly a good year. Production of rough stones, which was virtually equivalent to that in 1938, exceeded sales, and for the second successive year stocks increased. All grades of diamonds increased in price. In Europe increases were as follows: Large rough, slight, and small rough, 25 to 45 percent; large cut, 15 to 20 percent; and small cut, almost 100 percent. In America increases were less. Many stones were bought for investment, notwithstanding attempts by various governments to curtail the practice.

Share dealings.—The shares of diamond-mining companies listed on the London Stock Exchange had a restricted market in 1939. Prices were weak during most of the year, although there were sharp recoveries in the last half of July, owing to activity in Wall Street, and after October, owing to news of good sales by the Diamond Trading Co., and smaller recoveries from mid-February to mid-March, early May to mid-June, and late December. During the year five representative stocks lost 17 percent of their value and at the end of the year were 31 percent of their high (1927) and 307 percent of their low (1932). Of the 12 principal mining shares, 7 paid dividends in 1939.

Market.—In 1939 the Diamond Trading Co., which sells about 95 percent of the world output of diamonds, inaugurated a new sales policy. "Sights" are now held fortnightly; buyers, large and small, are urged to attend, and goods are sorted into standard types that will not vary from "sight" to "sight." Sales in 1939 were about £5,865,000—159 percent of those in 1938 but only 64 percent of those in 1937. First- and fourth-quarter sales were particularly satisfactory. Good-quality stones continue to be scarce.

Sales of polished diamonds, while not satisfactory, showed an appreciable gain over 1938. Small sizes were particularly in demand, fine goods being bought when available and mediocre grades at other times. Fine large stones were in demand as investments. Sales of industrial stones were excellent. The market was quiet until May, after which the improvement was progressive, and by August the market was animated. When war was declared, frantic buyers, fearing that their sources of supply would be cut off, purchased in quantity, but in October the market became normal.

Cutting in 1939.—The cutting trade was even worse in 1939 than in 1938; "masters" made little money, and the men were frequently unemployed. During the year the number of artisans decreased from approximately 27,000 to 23,000, owing largely to the shutting down of German shops at the outbreak of war. Both Antwerp and Amsterdam suffered, the first somewhat more than the second. Cutters' wages were raised 15 percent in October.

Imports.—Diamond imports into the United States in 1939, by countries, were as follows:

Diamonds imported into the United States in 1939, by countries

[Exclusive of industrial diamonds]

Country	Rough, or uncut			Cut, but not set		
	Carats	Value		Carats	Value	
		Total	Average		Total	Average
Africa:						
British East Africa	34	$3,091	$90.91			
Union of South Africa	148,001	7,656,408	51.73	1,488	$187,107	$125.74
Belgium				399,806	21,733,478	54.36
Brazil	5,846	292,854	50.09			
France				4,719	699,239	148.18

United Kingdom				3,284	270,600	82.40
	153,982	7,956,397	51.67	488,154	27,417,273	56.17

World production.—World production of diamonds (gem and industrial) in 1939 approximated 11,330,000 carats (2.266 metric tons) worth about $39,270,000. Compared to 1938 this is a decrease of 2 percent (readjusted figure, 11,620,000 carats worth $40,750,000) by weight and 4 percent by value. Of the South African pipe mines only Dutoitspan and Bulfontein operated; world alluvial mines yielded 91 percent of the output by weight and 77 percent by value. The British Empire produced 26 percent by weight and 60 percent by value of the total production; less than one-fifth by weight were gem stones.

The following table gives, as accurately as available statistics permit, world production for the past 5 years.

World production of diamonds, 1935–39, by countries, in metric carats

[Including industrial diamonds]

Country	1935	1936	1937	1938	1939

[1] Estimated.
[2] Exports.
[3] Includes 2,791 metric carats recovered from re-treatment of tailings.
[4] 1935: Borneo, India, Nigeria, and Venezuela; 1936: Borneo, India, New South Wales, Rhodesia, United States (California), and Venezuela; 1937: Borneo, India, Liberia, New South Wales, Rhodesia, and Venezuela; 1938–39: Borneo, India, New South Wales, U. S. S. R., and Venezuela.

In South Africa the output of pipe mines increased, whereas that of alluvial mines continued its decline. Production in Brazil and the new fields of the French African colonies increased, but in Southwest Africa and the Gold Coast it was drastically curtailed. As usual, the Belgian Congo contributed 64 percent, by weight, of the world output, largely industrial stones. New discoveries are reported in the U. S. S. R., Kenya, and Uganda.

Tropical hygiene and diamond production.—Diamond output, more than that of any other mineral product, comes from tropical countries—in the past from India, Borneo, and Brazil; today from Central Africa and to a smaller extent Brazil and British Guiana. The richness of the tropics in gems is a matter of chance, but the scientists of the Middle Ages believed that the hot tropical sun ripened the gems. A century ago 100 percent of the production came from the tropics; in those days tropical diseases decimated the workmen, and jewel buyers felt they were risking their lives in visiting the diamond fields. Of the present world output, approximately 88 percent by weight and 51 percent by value are produced in tropical countries, but today the personnel of the larger companies enjoys a health record comparable to that of mining companies operating in temperate climates. The different records of the two centuries "spotlights" the advance of tropical hygiene.

Malaria no longer saps the vitality of the staff and workmen; the dreaded sleeping sickness is being conquered, and dysentery has become rare. Turn-over in the staff is no longer a detriment to efficient operation. The staff lives in modern camps with proper water supply, sewerage systems, electric lights, and golf courses. Many bring their families, and schools are provided for the children. The villages of native laborers serve as models to be imitated by the bush natives. The Forminière Co., operating in the Belgian Congo, realizing that its future labor supply was menaced by the sleeping-sickness plague for some years, has had a large, mobile medical staff examining the natives of the countryside and giving treatment to infected natives. In 1938 the medical staff examined 129,348 natives for the disease. The scourge is now under control. Throughout the Belgian Congo the number of cases of the dread disease has decreased from 11 per 1,000 in 1908–10 to 2.9 per 1,000.

It may be stated safely that if it were not for tropical medical research and present-day knowledge of sanitation, the diamond production of the world would be at least one-third less than it is.

Industrial diamonds.—In 1939 more industrial diamonds were employed than ever before; larger factory use in the United States and munition-plant use in Europe more than offset decreased use of the diamond drill in Canadian prospecting. Striking features of the 1939 advance were the rapid expansion in use of diamond-impregnated wheels and other abrasive tools (particularly those with a powdered-metal bond), the increased use of very small bort in drilling, and the gain of mechanically set over hand-set diamond-drill bits. Diamond drills are now employed extensively, particularly in Canada, for blast-hole work.

The demand for industrial stones was strong throughout 1939. As it has been for 3 years, the scarcity of fine stones required the use of mediocre grades. Prices of all grades registered marked advances.

Imports of industrial diamonds into the United States during the past 5 years were as follows.

Industrial diamonds (glaziers', engravers', and miners') imported into the United States, 1935–39

Year	Carats	Value		Year	Carats	Value	
		Total	Average			Total	Average
1935	954, 589	$4, 293, 611	$4. 50	1938	1, 396, 247	$4, 213, 412	$3. 02
1936	1, 166, 094	4, 328, 603	3. 71	1939	3, 568, 730	9, 725, 683	2. 73
1937	1, 885, 970	6, 542, 365	3. 47				

The 1939 imports are somewhat misleading, as some shipments were sent here for safekeeping by the countries at war; in addition a number of dealers, forced to leave their homelands, brought with them their stocks of industrial diamonds.

EMERALD, RUBY, AND SAPPHIRE

The increased use of colored stones in jewelry during the past 4 years has caused concern over the source from which supplies are to be obtained in the future. With the State-owned Colombian emerald mines closed, the Burma ruby mines worked only by the natives, and the production of world sapphire mines small, little new rough stone is coming on the market. The jewelers are using largely stones recovered from old jewelry, Spain having furnished many fine-colored stones in the past 2 years. Such a situation, however, cannot last, and eventually old mines must be reopened or new mines found.

The Muzo emerald mine in Colombia has been shut down several years, but the property of the Chivor Emerald Mines, Inc., has been operated under lease from September 15, 1937, to date by the Compañía de Esmeraldas de Colombia. From September 15, 1937, to September 1, 1939, 28,841.22 carats of emeralds of all grades and 73,633.4 carats of moralla were produced. About 100 miners were employed. Since September 1, 1939, the output has been unimportant. The property is to be sold to the leasing company on a royalty basis and a cash payment of $10,000.

The emerald deposits of the Murchison Range, Transvaal (*see* bibliography, Kent, L. E., Emeralds, Murchison Range, Transvaal) were discovered in 1927; altogether there have been 15 producers, most of which are now moribund. Production to the end of 1937 was 664,612 carats, worth £84,294, or 2s. 6½d. per carat. Some of the stones are of fine color, but like most emeralds they usually are flawed (owing to movement after deposition) and often include biotite inclusions. Color zoning is common. Cobra Emeralds, Ltd., has been by far the largest producer. Emeralds occur as well-shaped crystals, distributed sporadically in shoots and pockets in biotite schist near pegmatitic intrusions. The pegmatite contains no emerald but does contain beryl. Near later basic intrusions the emerald has been "baked" to a brownish green. The emerald deposits resemble those of Egypt, the Urals, the Salzburg Alps, and North Carolina. The emeralds were deposited during the "hydrothermal phase" following the intrusion of the pegmatite.

Open-cut methods of mining are used, and the emeralds are separated largely by hand methods. The yearly emerald content has ranged from 2.75 to 3.16 carats per load (approximately a cubic yard). The product is sold directly to London gem buyers. In 1938–39 the Cobra Emerald Mines, Ltd., was shut down, owing partly to the depressed state of the precious-stone market and partly to decreased quality of the stones. N. M. Uspensky believes that although some of the emeralds at the Ural emerald mines near Sverdlovsk, crystallized at 500° C., most of them crystallized below 400° C. and some as low as 200° C.

In 1938 the Mogok or Katha workings, Burma, produced 202,483 carats of rubies, a 29-percent increase over 1937 (157,308 carats).

The subcommittee appointed by the Government of Ceylon to report on marketing and cutting gems in Ceylon, recommended (1) that a Government institute to instruct the natives in gem cutting be set up as part of the Department of Mineralogy, and (2) that a Government salesroom be attached thereto. The Singhalese cutter certainly has much to learn from an up-to-date gem cutter. The report of the committee is an interesting document, describing the three trades concerned (the miner, the cutter, and the dealer), the laws relating to gemming, mining methods, marketing, and other phases of the industry. It is understood that the recommendations of the committee will be acted on favorably.

The sapphire production of the Mogok ruby workings, Burma, has been as follows in the past 3 years: 1936, 172 carats; 1937, 4,392 carats; and 1938, 1,344 carats. Judging from the statistics of the Indian Government, the output of the Kashmir sapphire mines was probably less than 10,000 carats in 1938.

In 1938 gems valued at £2,166 were sold from the Anakie (Queensland) sapphire field (£1,410 in 1937). First blues comprised three-fourths of the sales; other sapphires (green and yellow) and zircons were not in demand. Production came from Rubyvale, Reid's Water Hole, and Mt. Laura. In 1939 a new field is said to have been discovered about 6 miles west of Rubyvale, central Queensland. A 412-carat emerald-green sapphire is reported among the finds. No gem sapphires were produced in New South Wales in 1938, but 132 ounces of industrial stones were produced at Sapphire.

At Mtito Andei, Kenya, patches of fine blue sapphire are found in crystalline corundum, encountered in working asbestos. Several small parcels of sapphires have been shipped.

LESSER GEMS

The Smithsonian Institution put on exhibition a huge topaz weighing 153 pounds, or about 350,000 carats, in 1939. It is pale blue, with a sherry-color interior. The Harvard University Mineralogical Museum also added to its collection a large white topaz weighing 225 pounds. Late in the year the American Museum of Natural History, New York, obtained an even larger topaz weighing 596 pounds. All three crystals came from Minas Geraes, Brazil.

In 1937 the output of aquamarine at Daso, Kashmir, was 6,260 carats (no output in 1935 and 1936).

The total value of the opal production of New South Wales to December 31, 1938, has been £1,627,021. The 1938 output was valued at £4,226 (1937, £3,357); Lightning Ridge produced stones valued at £4,132, Grawin £50, and White Cliff £44. No production was reported from Queensland in 1938.

In 1930 a deposit of lapis lazuli was discovered by G. L. Judin at Ovalle, Pamir Mountains, Badakhshan. Like similar occurrences, it is a contact-metamorphic deposit in marble.

The Katanga copper deposits are the most important present-day producers of malachite. The material is used in cheap jewelry and objets d'art. Recent sales are as follows: 1937, 3½ tons; 1938, 2½ tons; and 1939, 1½ tons.

A little turquoise is produced in northern Baja California, Mexico, not far from Ensenada.

The amber mines at Palmnicken, Samland, Prussia, produced 400 metric tons of amber in 1938 (1937, 328 metric tons). Amber is used as an ornament, and considerable amber oil and amber acid are distilled, as they are employed in the German dye and varnish industries. In 1938 Germany exported 16,400 kilos of amber valued at 229,000 reichsmarks. Most of the amber goes to Danzig for processing and reexport, the major trade being with the Balkan States and the Orient. In Germany the use of amber "German gold" has been increased by nationalistic propaganda and the difficulty of buying other types of jewelry. Laws forbid the sale of imitation amber and synthetic resins resembling it in Germany.

Some gem prospecting is being done in the Grenville limestone near Laurel, Quebec. Clear pale-lilac diopside and honey-yellow vesuvianite occurences may have some gem value. Previously minute blue sapphires were found at Kilmar. As Frank D. Adams has pointed out, the geology of the Laurentian rocks is similar to that of the gem-bearing rocks of Ceylon, but owing to recent glaciations there is no concentration of the gems in stream gravels.

The mining and cutting of jet at Whitby, England, was an important industry 75 years ago. Today, only a few score of people are engaged in it. The present war may revive the trade.

In 1938 Brazil exported 746,872 kilos of rock crystal, 2½ times the average for the preceding 14 years (*see* bibliography, Winslow, Rollin R., Quartz Crystal (Brazil)). Japan in particular, Great Britain, Germany, and to a smaller extent the United States are the principal purchasers. The best-quality crystals are sent to the United States for use in scientific instruments. Bahia is the principal producer, followed by Minas Geraes and Goyaz. The crystal occurs in pegmatite dikes or in detrital or placer deposits derived from them. Mining methods are primitive and usually are carried on by "garimpuros," locally called "crystalleiros"; the open pits are rarely more than 5 meters deep. Most of the exporting firms have their own buyers in Brazil. Rough crystal is worth $0.15 to $18.50 per kilo, according to quality. Reserves of crystal are reported to be large. Optical quartz has been discovered recently in the Mtito Andei district, Kenya.

No other gem except the diamond has a wider variety of industrial uses than rock crystal. It is employed for oscillators in radio transmitters; for quartz-plate resonators at cable and long-distance telephone terminals; and for quartz plates in sound-detecting and sound-locating devices of various sorts and in detonator measurers. Quartz is also the basis of fused quartz employed as tubes, flasks, and fibers for precision instruments. It is used widely in the optical trade, in moderate-priced jewelry and objets d'art, in quartz lamps, and as an abrasive. A glass developed in 1939 by the Corning Glass Works may decrease the use of fused quartz. In December the United States Treasury Department bought 14,800 pounds of Brazilian crystals under its strategic-materials buying program. The price was $98,875, or $6.68 per pound.

San Luis and Mendoza Provinces, Argentina, produced, respectively, 325 and 270 metric tons of greenish yellow translucent marble ("onyx") suitable for decorative purposes in 1937. The United States is the principal purchaser; the rough material is worth $140 to $230 per ton. To obviate flaws, the blocks are cut by hand with chisels, no percussion drills or powder being used. The "onyx" deposits at El Marmol, Baja California, Mexico, produce from 3,000 to 25,000 cubic feet a year. The product is trucked to Santa Catarina, whence it is shipped to the United States.

In 1938 Madagascar exported 453,638.037 kilos of gems and industrial stones. Beryl, tourmaline, colored topaz, opal, sapphire, ruby, garnet, and spodumene totaled 6.81 kilos; feldspar, scapolite, amethyst, and other lesser gems, 263.544 kilos; opaque beryl and garnet, 328,979.208 kilos; rock crystal, 4,693.625 kilos; rose quartz, amazonstone, etc., 6,249 kilos; and industrial rock crystal, 111.763 kilos. France was the principal purchaser, although Germany purchased the finer rock crystal and Switzerland and England certain grades of stones.

There were four producers of precious stones in South-West Africa in 1938. The following table gives productions and exports for 1937, 1938, and the first quarter of 1939.

Production and exports of precious stones in South-West Africa, 1937–38 and first quarter of 1939

	Production			Exports		
	1937	1938	1939 (first quarter)	1937	1938	1939 (first quarter)
Semiprecious stones:						
Aquamarine grams	4,970	270	2,000	4,350	200	
Chalcedony do				119,000	70,000	
Rose quartz do			6,720	54,786	9,720	
Topaz do	4,000	500		3,000	1,000	70
Tourmaline do	37,795	26,248	4,300	507,851	59,508	10,666
Iceland spar pounds	873	3,630	250	309	24	

Germany buys virtually the entire output of aquamarine.

With the possible exception of Ceylon, Brazil is the most important producer of the lesser gems, but figures on its 1939 production are not at hand.

SUMMARY OUTLINE

CARBON DIOXIDE

According to trade reports, more carbon dioxide was consumed in the United States in 1939 than in any previous year, and the production and use of both solid and liquid products increased more than the general consumption of goods and services. The latest available statistics, however, are for 1937 when, as reported by the Bureau of the Census, the output of dry ice was 156,609 tons valued at $4,618,937 and of liquid or gaseous CO_2, 50,358 tons worth $4,939,508.

The ice-cream industry continues to be the main outlet for dry ice, but in 1939 there seemed to be a marked increase in the production of other frozen foods, a trend that may serve somewhat to level off the seasonal slump in demand during winter months. Gassing strawberries and raspberries for 4 to 7 hours in an atmosphere containing 35 to 40 percent CO_2 is claimed to keep them in good condition at least 2 days longer than normal. A recent patent specifies CO_2 as a means of making soybeans more palatable, removing certain odors and flavor elements. A broad research program for carbon dioxide gas storage of foodstuffs has been projected by the American Institute of Refrigeration.[2]

No new wells producing natural carbon dioxide were reported to the Bureau of Mines in 1939, and although natural dry-ice plants have been built in California, Colorado, New Mexico, Utah, and Washington further expansion is likely to be restricted by the various difficulties and losses attendant upon transportation to large consuming centers. Recovery of byproduct gas from lime, cement, and other process plants likewise is largely a matter of geography. At Neville Island, Pittsburgh, Pa., the Frozen Carbonic Corporation installed a new generator which recovers 3 tons of gas and 4¾ tons of lime from 8 tons of somewhat low grade stone. With a purity of 97 to 99 percent CO_2, the normal gas yield is 90 percent, but 98 percent recovery can be

[1] Figures on imports and exports compiled by M. B. Price, of the Bureau of Mines, from records of the Bureau of Foreign and Domestic Commerce.

made if the purity of the gas is lowered.[3] This plant uses Carbofrax retorts and related equipment under the process of the Gillette Kiln Sales Co.

GRAPHITE

Although the graphite needs of the United States still are obtained almost entirely from foreign sources the outbreak of war in Europe in 1939 caused no such serious dislocation as after 1914. During a quarter century the nature of consumption of graphite has altered so that different kinds of graphite are more nearly interchangeable in use. In 1914–18 the most important use was in crucibles, and domestic crucible makers wanted principally Ceylon lump or chip plumbago. In recent years the consumption of graphite in crucibles has declined to rather small proportions, and crucible makers insist upon having Madagascar flake graphite of suitable mesh sizes. Some soft Ceylon lump is required for pencil-lead mixtures, and there are a few other specialties for which Madagascar flake or certain kinds of crystalline Ceylon graphite are desired in preference to qualities obtainable elsewhere. Fortunately, from the standpoint of national security, the tonnage of graphite from these distant sources that can be considered as absolutely essential to military or even to civilian industry is a relatively small fraction of the total now compared to what it was even a dozen years ago.

During the last quarter of 1939 the demand for graphite was unusually active, and the difficulty of getting export licenses for shipment from Madagascar occasioned some inconvenience but no real distress. Supplies of certain grades had to be rationed to discourage speculative purchasing, but prices were held in control and in most instances remained stationary.

There was no revival of graphite mining in the United States in 1939, and apparently the only substantial domestic production of crystalline graphite was by the Long Valley Ore Co., with mines near Pope Mills and a milling plant at Morristown, N. Y. The deposit is said to be extensive and carries 20 to 30 percent carbon. The milling plant probably could furnish 100 tons or more of concentrate a week but has been operated at full capacity only occasionally, owing to market limitations. The product has been used almost exclusively as an addition to foundry facings.

Small amounts of amorphous graphite for paint were produced at Carson City, Nev., by the Carson Black Lead Co. As in former years, some amorphous graphite for foundry facings was shipped from the Rhode Island anthracite mine. A letter to the Bureau of Mines states that it is unlikely that the business will be continued after existing stocks are sold. The mine at Cranston, R. I., has not been worked for a number of years, but equipment is still on the premises and mining could be resumed if demand justified. A moderate tonnage of amorphous graphite was shipped by the Southern Mining & Milling Co., Clarkesville, Ga., as a byproduct of its kyanite operations.

Foreign trade.—Imports of graphite in 1939 totaled 21,950 short tons valued at $425,326, a substantial increase over 17,005 tons valued at $372,039 in 1938 but much less than the 29,593 tons valued at $752,315 in 1937 or even the 24,171 tons valued at $566,662 in 1936.

[3] Trauffer, W. E., Improves Recovery of Carbon Dioxide: Pit and Quarry, vol. 31, No. 12, June 1939, pp. 26–28, 48.

Exports were 976 short tons valued at $109,715 compared with 983 tons valued at $112,443 in 1938 and 1,514 tons worth $163,331 in 1937.

All artificial graphite imported comes from Canada. Recently Mexico has supplied about two-thirds of the imports of natural amorphous graphite. Imports of Ceylon lump and chip have so diminished that they are now included with "dust," imports of which come from Canada and other countries as well as from Ceylon. As usual, most of the flake graphite was from Madagascar or France, the remainder chiefly from Canada.

Graphite imported for consumption in the United States, 1935–39, by kinds

Year	Amorphous				Crystalline					
	Natural		Artificial		Lump and chip		Dust		Flake	
	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value	Short tons	Value

1937 2	1,514	163,331			

1 Crude, refined, and manufactures.
2 Natural.

Prices.—Prices of graphite in 1939 were about the same as in 1938 and 1937, the quotations being roughly the same as those reported in Minerals Yearbook, 1938. Ceylon quotations for some grades were advanced, and freight rates rose sharply after the outbreak of war; however, these increases were at least counterbalanced by the downward course of exchange. For a year or more Japan has been the chief buyer of high-grade Ceylon plumbago, and anticipated increases in shipments to the United States or Europe were offset by the loss of the German market. Actually it seems doubtful whether the present war has done much to increase the consumption of graphite, and although the tone of the market was buoyant at the end of 1939 there was no expectation of sharp price advances in any leading production centers.

World production.—Assuming that the Soviet output has continued at approximately 84,000 metric tons annually (as in 1935, the last year for which statistics have been published) the world output of graphite is around 200,000 tons annually. On this basis the U. S. S. R. furnishes over 40 percent; Germany (including Austria and Czechoslovakia), 25 percent; Chosen, 20 percent; and Mexico, 5 percent. However, the bulk of the product of these countries is low-priced amorphous graphite, much of the European portion being used only locally. Although the tonnage mined in Ceylon and Madagascar seldom exceeds 15 percent of the world total the value of their combined output is probably at least half the world total.

World production of natural graphite, 1915–34 (5-year averages), 1935–37 (3-year average), and 1938, in metric tons

Domestic consumption.—Although graphite no longer is listed by the military establishments of the United States as a "strategic" mineral, it is considered important enough to the national defense program to be included in the "critical" group. In 1939 the Bureau of Mines investigated the consumption of graphite by industries and obtained replies from 48 dealers and consumers, of which all but about a dozen directly consumed substantial tonnages. A strict accounting is fraught with difficulties, not the least of which is the overlapping among materials "used" by one establishment after being "processed for resale" by another. The total tonnage accounted for, even in 1937, was less than the apparent supply as indicated by the import statistics, but the discrepancy is explained largely by the building-up of inventories and to a minor extent by various shrinkages, possible reexports, and errors in classifying and recording imported merchandise. The Bureau canvass, however, greatly exaggerated the apparent consumption of crystalline at the expense of amorphous graphite. According to Department of Commerce import statistics, only 12 percent of the total new supply of natural graphite in 1937 and 11 percent in 1938 was flake or crystalline grades, whereas the replies from consumers indicated 24 and 32 percent for the respective years. This is accounted for only partly by the larger proportion of amorphous graphite that went into stocks in both years. Many consumers probably classed as "crystalline" blended material mixed with even a small proportion of flake or Ceylon plumbago. Moreover, many of them may not have known that in recent years 95 percent of the imports of Ceylon graphite have been classified as "amorphous," whereas formerly virtually all Ceylon graphite was imported as crystalline lump, chip, or dust.

In 1937 the quantity of graphite consumed in the United States was almost the same as in 1913; yet crucibles, which took 55 percent of the total consumed in 1913, required only 8.3 percent of the total in 1937. The quantity of graphite used in foundry facings, core wash, and similar uses rose from 10 percent in 1913 to 38.5 in 1937. Other features were the decline in the quantities used for stove polish and the increase in graphite lubricants. Notable, too, is the recent jump in consumption for dry batteries. A decade ago several large battery makers began using manufactured graphite instead of natural flake. Concurrently the use of batteries declined, as radios were operated by light-socket power; but during the last few years Mexican graphite has been widely accepted for this purpose, and the demand for dry batteries has revived (owing in part to the growing popularity of portable radios and the increasing use of flashlights), so that by 1937 the consumption of amorphous graphite for this purpose had risen to around 5,000 tons a year.

Consumption of natural graphite in the United States, 1913, 1919, 1923, 1924, 1933, 1937, and 1938, by kinds of graphite and by uses

[1] Partly estimated.
[2] Bureau of Mines not at liberty to publish figures.

Market channels.—New York always has been the principal port of entry for foreign graphite, although the tonnage passing through Arizona during the last year or two has exceeded the total even for New York, owing to the large increase of imports of Mexican amorphous graphite. However, as virtually all the higher-priced Ceylon and Madagascar varieties have entered at New York, that port is still far in the lead in values of the material imported. Canadian graphite, of course, comes through border ports, and a portion of the imports from Korea has been landed at San Francisco or Los Angeles. Michigan appears as an outstanding importing point owing to the fact that it is a distributing as well as consuming center for Mexican graphite railed through in bond. Chicago, too, often is listed as the actual port of entry even though much of the consumption in the Middle West is entered, and commonly processed to some extent, in the East. Canadian artificial graphite usually is entered at Buffalo.

The bulk of the graphite imported into the United States passes through the hands of only half a dozen companies, and only three firms import most of the Madagascar flake and Ceylon plumbago received. One of these firms is primarily a consumer of raw graphite, which it uses in making a wide variety of manufactured products. The other concerns, while engaged primarily in the sale of material to other manufacturers, are not merely importers or even merchants, for in addition to carrying extensive stocks for prompt shipment they are processors and blenders. Moreover, as the grinding, sizing, and purification of graphite and blending or otherwise preparing it for use by manufacturers of crucibles, pencils, lubricants, and other commodities result in a great deal of dust and off-grade material, the principal importers have built up manufacturing businesses of their own to utilize these byproduct materials economically in foundry facings and other products. Whereas the Bureau of Mines lists at least 40 companies as buyers of crude graphite, including a dozen or more relatively large consumers, scarcely 5 percent of the crystalline graphite used in this country is handled by ordinary importers. The proportion of amorphous graphite handled by other firms is somewhat larger because most of it requires little or no preliminary processing after arrival in this country, yet much of the amorphous graphite also passes through the same main channels.

Stocks.—The larger importers and dealers generally maintain a year's supply of crystalline graphite, either in warehouse or on order;

there is generally considerably more than a year's supply of Madagascar flake used for crucibles in the hands of manufacturers or their suppliers in this country. Characteristically, purchases are made when material can be bought advantageously. Graphite miners in most countries often are in need of cash; and large American buyers, being well financed, frequently can buy graphite under favorable terms. It follows that on a falling market, when lower prices are anticipated, stocks of graphite in the United States tend to diminish. However, it seldom happens that they dip much below the 12-month margin, and when prices are low the resumption of buying may result in the acquisition of enough graphite to last 18 months or longer.

During the latter part of 1939 the large importers and dealers were faced with the sudden increase in demand, whereas, particularly as regards Madagascar flake, there was difficulty in obtaining deliveries even of graphite that had already been ordered. Notwithstanding this condition, they continued to sell graphite to their regular customers at the old prices.

GREENSAND

In recent years the only commercial production of greensand has been in New Jersey, and it has been consumed almost exclusively in water-softening compounds. A brief review of this industry was published in 1939.[4] Shipments of refined greensand in 1939 totaled 6,466 short tons valued at $150,500 compared with 6,576 tons worth $152,000 in 1938 and an annual average for the 1925–29 period of 12,715 tons valued at $197,200. Valuation figures are partly estimated. The best grade of refined greensand has been quoted nominally at $20 a short ton f. o. b. cars, but most of the output nowadays is processed further by the three leading producers and sold as water softener at prices up to $115 a ton. The yield of finished greensand zeolite averages between 35 and 40 percent of the hand-picked raw glauconite; including overburden, about 5 tons of material have to be moved for each ton of finished product.

Refined greensand produced in New Jersey, 1935–39

Year	Short tons	Value	Year	Short tons	Value
1935	7,589	$219,749	1938	6,576	$152,000
1936	8,368	177,835	1939	6,466	150,500
1937	9,734	210,974			

Processed greensand zeolite comes on the market in the form of hard green granules ranging from 0.25 to 0.8 mm. in diameter—averaging about 0.30 mm. They bulk about 90 pounds per cubic foot, and the exchange capacity usually ranges from about 2,500 to 3,000 grains of $CaCO_3$ per cubic foot, although this can be increased by extra processing. As the softeners can be regenerated indefinitely and the total loss (chiefly mechanical) in active use is only 2 or 3 percent a year, replacement sales are a relatively small factor in this industry.

KYANITE, ANDALUSITE, AND DUMORTIERITE

Domestic kyanite has become a fairly important refractory material. With at least two new producers entering the field in 1939 the production in the United States for that year is estimated at 2,950 short tons valued at $69,000 f. o. b. mines. Although no figures of domestic output are available for earlier periods, the 1939 output is believed to have been twice as large as that of any preceding year. Most of this was used in glass-house refractories, but small amounts are employed in the glass industry also as a constituent of the melt, as well as in various ceramic products. Imports of kyanite, almost all of Indian origin, were 3,881 short tons having a foreign market value of $38,137 compared with 3,964 tons valued at $32,458 in 1938 and 7,674 tons valued at $79,410 in 1937, the first year for which statistics were recorded separately.

Somewhat like kyanite in composition and potential uses are pinite and topaz, which are discussed later in this chapter.

Celo Mines, the pioneer eastern producer of kyanite, has installed flotation equipment for better cleaning of concentrates from schist at its Burnsville (N. C.) plant. The Phosphate Recovery Corporation has used flotation to supplement tabling almost from the beginning of its work on Baker Mountain near Pamplin, Va. This company has also leased kyanite property near Henry Knob, S. C., owned by B. J. Lachmond. At Clarkesville, Ga., the Southern Mining & Milling Co. has three plants, one of which was idle in 1939. E. C. Noble produced and shipped kyanite concentrates from a new Georgia plant, which later was leased by the A. P. Green Firebrick Co., Mexico, Mo. The Vitrefrax Corporation, Los Angeles, Calif. (mines at Ogilby, Calif.), converts most of its product into mullite grains.

The Champion Sillimanite, Inc., a subsidiary of the Champion Spark Plug Co., Detroit, Mich., produces andalusite from White Mountain, Mono County, Calif., and dumortierite from near Oreana, Nev. The Tillotson Clay Products Co., Los Angeles, Calif. (mines in California and Nevada), also produces andalusite. The production of these minerals has been estimated at 2,000 tons or more a year chiefly for use in ceramic spark-plug cores.

According to Edgar Bowles [5] of the Alabama State Geological Survey, a 2- to 4-foot vein of kyanite has been opened up in Alabama on Turkey Heaven Mountain southeast of Heflin, Cleburne County. Until recently the only known occurrence in Alabama was of float material, which has been found in Coosa, Tallapoosa, Clay, Randolph, Chilton, and Cleburne Counties, often in large blocks but never in commercial quantities. In contrast to the usual pockety nature of vein kyanite, the newly discovered deposit may be more or less regular and continuous over a distance of at least 6 miles. An occurrence of gneiss in Iron County, Wis., containing 8 to 10 percent kyanite has been described by Carl Fries in an unpublished report. The kyanite is relatively free of inclusions and of good quality. Garnet (almandite) and biotite also are present in significant amounts. Several years ago, various kyanite occurrences were being prospected in Wyoming, especially in the Encampment district, but no recent activity has been reported in kyanite developments in this State.

As noted in Minerals Yearbook, 1939, andalusite sands are found in South Africa. Sales of 450 short tons worth £675 were reported

[5] Bowles, Edgar, Kyanite in Eastern Alabama: Bull. Am. Ceram. Soc., vol. 18, No. 8, August 1939, p. 316.

during the third quarter of 1939. Consolidated Minerals, Ltd., of Johnannesburg is the sole producer.

A great deal of domestic kyanite can now be had at $15 a short ton in bulk or $17.50 in bags, f. o. b. cars, to which must be added a freight rate of $5 to $7 a ton to consuming points in the North or Middle West. Very-low-iron concentrates are offered at $25 a ton, with intermediate grades at around $20. An extra-low-iron grade (under 0.1 percent Fe_2O_3, 98 percent kyanite) calcined and ground to 325 mesh sells for $78 a ton f. o. b. Burnsville, N. C.

LITHIUM MINERALS

Of interest in 1939 was the increased use of lepidolite in glass making and of spodumene in general ceramic work. Improved methods of concentrating low-grade spodumene ores, abundant in North Carolina, were worked out by the Bureau of Mines in cooperation with the Tennessee Mineral Products Corporation.[6]

In South Dakota, the Black Hills Keystone Corporation (Ingersoll mine) and the Maywood Chemical Works (Etta mine) shipped lepidolite and spodumene, respectively, from Keystone, Pennington County. A small tonnage of spodumene was shipped also from the Ralph A. Smith property, near Keystone. The Black Hills Tin Co., Tinton, S. Dak., made no shipment. The national output (which includes the total for the three South Dakota producers and also that of the American Potash & Chemical Corporation, Trona, Calif.) was 1,990 short tons valued at $97,000 in 1939 compared with 892 tons worth $47,088 (corrected figure) in 1938.

Lithium compounds shipped from mines in the United States, 1935–39

Year	Producers	Short tons	Value	Year	Producers	Short tons	Value
1935	4	1,154	$26,834	1938	4	892	[1] $47,088
1936	6	1,241	34,273	1939	4	1,990	97,000
1937	7	1,357	36,206				

[1] Corrected figure.

Leading foreign countries producing lithium minerals are South-West Africa and Argentina.

A detailed plane-table survey has been made by the Geological Survey of the spodumene deposits in the Kings Mountain district of North and South Carolina, and a pilot plant has been erected at Spruce Pine, N. C., for beneficiation by flotation of spodumene-bearing rock from this district. Tests indicate that a spodumene-microcline product can be obtained that, when used in place of feldspar in whiteware bodies, will lower the fusion temperature several cones, thus conserving time and fuel.

The Black Hills Tin Co. has perfected a flotation process for separating spodumene from quartz. The company property is said to contain a 90,000-ton deposit of spodumene quartz crystallized so finely that formerly it was thought to be feldspar. The concentrate contains 6 percent or better lithium oxide. After operating experimentally for 6 weeks during the summer of 1939 the company proposed to introduce in its present tin-tantalum concentrating mill a spodumene circuit capable of producing several carloads a week.

MEERSCHAUM

Meerschaum, hitherto used exclusively in the manufacture of smokers' articles, has recently shown promise of becoming a useful medicament. Dr. Manfred Kraemer, Newark, N. J., has reported excellent results in both England and the United States from using the powdered mineral as a remedy for stomach ulcers.[7]

World supplies of meerschaum came from Eskishehir, Turkey. Imports into the United States in 1939 were 10,467 pounds valued at $12,191 compared with 3,559 pounds valued at $9,221 in 1938.

MINERAL WOOL

Statistics on mineral wool are not compiled by the Bureau of Mines but are obtained biennially by the Bureau of the Census. Preliminary reports indicate that production in 1939 exceeded that in 1938 but probably failed to reach the 1937 peak; however, there was a boom in the sale of batts and strips, consumption of which has increased rapidly during the last year or two.

The Carney Rock Wool Co., an affiliate of the Carney Cement Co., Mankato, Minn., began producing at a new mineral-wool plant late in 1939. The American Rock Wool Co. is spending $100,000 improving its plant at Wabash, Ind. In August 1939 it was reported that Superior Insulations, Inc., was about to erect a new rock-wool plant at Lagro, Ind. The Kentucky Stone Co. rock-wool plant at Mullins, Ky., was destroyed by fire in February 1939 but it probably will be rebuilt.

No rock wool is manufactured at present in the Southeastern States, and slag-wool plants in this territory are found only in Tennessee and Alabama. According to a recent circular (No. 10) of the State Department of Natural Resources, Division of Mines, Mining, and Geology, Georgia is well-situated geographically, has ample wool-rock resources, and offers other advantages for establishing a plant. Annual consumption of mineral wool in this market is now only 1,000 to 1,500 tons—most of which comes from Indiana, Ohio, and New Jersey—but it might be increased.

MONAZITE

Owing to the declining use of gas mantles as electric lighting became more nearly universal, world production of monazite decreased, slowly at first but later quite rapidly, from the peak of 7,392 short tons in 1909 to less than 100 tons annually. After fluctuating violently for several years a turning point appeared about 1932, and in 1938 the gross output exceeded 6,000 metric tons; owing to the greater purity of recent shipments the actual output in terms of thorium content and perhaps even in content of cerium and other rare metals, may now exceed the pre-war peak.

What actually stimulated the revival in demand for monazite is not generally known. There has been a sizable increase in demand for the metal in radio and X-ray equipment, and there is a small consumption of thoria for highly refractory crucibles and other laboratory utensils. Substantial quantities of monazite are used more or less directly in rare-earth electrodes or carbons for sun lamps and other light-therapy

[7] Science News Letter, vol. 35, No. 20, May 27, 1939, p. 334.

equipment. Nevertheless, these relatively new uses could not begin to offset the decline of around 90 percent in consumption for making gas mantles. Mesothorium is recovered from monazite, but ordinarily only as a byproduct. On the other hand, the manufacture of sparking flints and certain miscellaneous uses for cerium salts have expanded greatly; it is probable, therefore, that some of the increased demand for monazite can be ascribed to an increased demand for cerium and other rare earths. There is the further question, however, since these elements are available in the residues from gas-mantle manufacture, whether current needs cannot still be supplied, at least in part, from accumulated residues. About 100,000 tons of monazite have been consumed in Europe and the United States since 1893, chiefly for gas-mantle making. Roughly 30 percent was cerium oxide, and 30 percent more comprised lanthana, didymia, and other rare-earth oxides. An almost negligibly small fraction of this 60,000 tons of various oxides was needed in the gas-mantle industry. It is not known to what extent these residues have been absorbed by other industries or otherwise dissipated, but it would seem that in the United States the increasing need for cerium salts—chiefly for mothproofing fabrics, for coloring topaz-yellow glass, for opacifying enamels, and for stabilizing the arcs in carbon arc lamps—is being supplied by imports of monazite.

According to Chambers,[8] a recent shipment of Indian monazite from the Quilon area in Travancore analyzed: Thorium dioxide, 8.3; cerium and other rare-earth oxides, 61.7; iron oxide, 0.1; and phosphoric anhydride, about 29.0 percent.

In 1938 British India produced 5,305 metric tons of monazite compared to 3,130 tons in 1937. As recently as 1933 the Indian output was only 141 tons, and in 1930 it dropped to 14. A somewhat similar revival has occurred in Brazil, whose exports virtually ceased after 1933 and were not resumed until 1938 when they were 323 metric tons. Recently the Netherland East Indies has appeared as a new source, furnishing 668 metric tons in 1937 and 393 tons in 1938. Egypt and Ceylon also have produced monazite in the past, although only sporadically and in small amounts. The United States likewise has never been a large producer, and domestic output has been reported in only 1 year (1925) since 1917.

According to an American consular report,[9] the exports of monazite from Brazil totaled 474.68 metric tons in 1938, all from the State of Espirito Santo. Of this quantity, 373.20 tons were shipped to France, 100.02 tons to the United States, and 1.46 tons to Germany. The first discovery of monazite in Brazil was in diamond-bearing river sands of Bahia in 1884, and John Gordon shipped monazite to Europe in 1886. From 1904 to 1910 Brazil shipped an average of 5,000 metric tons annually, but after the Travancore deposits began to be worked in 1910 British India gradually became the leading source of monazite and Brazilian output declined. By 1915 Brazil furnished only 439 tons and India 1,108. It has been stated that monazite sands are found all along the coast of Espirito Santo, but the Guarapary deposits are the only ones worked in recent years. The relative importance of these deposits may be due mainly to their size and to the fact that they are not covered by the sea at high tide, as are so many of the other

[8] Chambers, Gordon H., Zircon, Ilmenite, and Monazite Mining in India: Foote-Prints (Foote Mineral Co.), vol. 12, No. 1, Philadelphia, June 1939, pp. 6–7.

[9] Forsyth, T. Muldrup, American vice consul, Victoria, Brazil, Monazite in the State of Espirito Santo, Brazil: Consular Rept., June 27, 1939, 17 pp. (abstracted in Bureau of Mines Mineral Trade Notes: Vol. 9, No. 2, August 19, 1939, pp. 16–19).

large deposits. Moreover, they are more accessible, since Guarapary has good anchorage for small coastwise vessels. The principal known deposits of monazite in Brazil are on lands belonging to States or to the National Government. Since 1915 the National Government has been adjudicated all deposits situated not more than 33 meters from the mean water level. Contracts for mining on public lands generally have called for a minimum output and payment to the State or to the National Government of a certain percentage of gross income from sales, over and above export taxes. Before 1907, the only concentration was in sluices, the mixed product containing 60 to 65 percent monazite and varying quantities of ilmenite, zircon, garnet, and quartz. Later, however, the Société Minière Franco-Brésilienne installed magnetic separators, which yield a concentrate containing 85 to 92 percent monazite, with zircon and ilmenite as byproducts.

The monazite sand shipped from Espirito Santo to the United States in 1938 was sold for $35 (United States currency) a metric ton f. o. b. Victoria, Brazil. Trade-journal quotations in the United States have remained unchanged at $75 a short ton (basis, 8 percent ThO_2) for several years. This quotation relates to Indian monazite, which is higher grade; a presumably typical analysis of the Guarapary concentrates shows only 6.3 percent ThO_2.

In 1939 the imports of monazite into the United States aggregated 1,560 short tons valued at $52,016; 1,336 tons were imported directly from British India and 54 tons from Brazil. In 1938 the imports were 456 short tons valued at $18,210, of which 339 tons were from British India.

OLIVINE

The North Carolina dunite deposits contain 50 to 100 million tons of olivine and have yielded as much as 600 tons a month. Recently, however, only two quarries have been worked—both in Jackson County, N. C.—and shipments were estimated at 3,000 tons in 1939, only a little more than in 1938. Other domestic deposits of commercial size are found in California and Washington. Those in Norway and the U. S. S. R. (Urals) have been worked on a small scale. Synthetic olivine can be made of talc or serpentine and research along these lines has been done in Germany, Italy, and Japan, as well as Norway.[10]

Magnesium silicate or forsterite refractories do not have a wide market but have become well-established in several specific services. Owing to their remarkable resistance to attack by iron oxide their use in nonferrous metallurgy is broadening, and they are also used to a growing extent in rotary kilns for portland cement and dead-burned dolomite. Relatively small amounts of olivine are used as quarried blocks or cut shapes; the major tonnage goes into manufactured forsterite brick.

Julius R. Gillis and George W. Pawel, Sylva, N. C., have devised a process for making synthetic kieserite or magnesium sulfate from olivine. They propose to employ material from a large deposit at Webster, N. C., which is reported to contain 25 to 35 percent MgO and up to 1½ percent nickel. Southern rayon mills afford the anticipated market for the magnesium sulfate and the nickel also can be recovered.

[10] Mining Journal (London), Development of Refractories: Vol. 208, No. 5445, December 30, 1939, p. 1086.

PINITE [11]

Several secondary minerals derived from alteration of feldspar, nepheline, and certain other silicates are classed as pinite. Essentially a hydrous silicate of alumina and potash, pinite has virtually the same composition as muscovite, and certain varieties resemble sericite in appearance. Massive pinite resembles steatite or pyrophyllite.

A large deposit of pinite on the east side of the Humboldt Range near Rochester, Nev., has been developed, and during the last 2 years approximately 1,200 tons have been shipped to the Stockton Fire Brick Co. at Pittsburg, Calif., for manufacture into firebrick. In a paper presented in August 1939 at the American Ceramic Society meeting in San Francisco, Calif., Page, Raine, and Sullivan of that company listed the important properties of pinite as refractoriness, ease of raw grinding, snow-white color after firing, inversion to mullite at relatively low temperatures (1,125° C.), low and reversible thermal expansion, absence of free silica, extreme hardness and resistance to abrasion of the fired product, low firing shrinkage, high density after firing, and resistance to molten-enamel slags. In the cold zones of rotary kilns and in the coolers that take the discharge from rotary kilns, pinite linings last longer than linings of other materials. It is claimed they have been used in calcining cement clinker, magnesite, and limestone since 1936; in 1939 an installation was made in the new cement plant of the Permanente Corporation at San Jose, Calif.

SERPENTINE

Massive serpentine, neither fibrous (asbestos) nor decorative (verde antique "marble"), has entered the growing list of industrial minerals. Carload shipments were made in 1939 from Nottingham, Pa., for use in dolomite-base refractories.

STRONTIUM MINERALS

The celestite resources of the United States undoubtedly are large; a few domestic occurrences of strontianite have been reported to the Bureau of Mines, but no production of either mineral has been reported since 1918—apart from impure celestite mined near Sweetwater, Tex., and sold by the Mudrite Products Co., of Houston, Tex., for use as oil-well drilling-mud admix.

American manufacturers of strontium nitrate for red flares and other pyrotechnic compounds have employed imported raw materials. As these have come almost exclusively from Germany in recent years the wartime blockade late in 1939 developed some uncertainties, and prices of strontium salts were tending slightly higher.

Strontium minerals and chemicals imported for consumption in the United States, 1935–39

Year	Minerals		Nitrate		Carbonate and oxide	
	Pounds	Value	Pounds	Value	Pounds	Value
1935	2,674,094	$11,595	277,548	$15,716	[1] 21,828	[1] $2,641
1936	3,880,302	14,537	694,696	39,820	52,311	6,056
1937	5,636,570	20,877	609,488	40,243	44,579	4,610
1938	552,868	2,824	364,362	23,921	82,859	8,502
1939	5,645,935	23,136	479,933	32,060	23,148	2,811

[1] Carbonate only; not separately recorded after 1935.

[11] Tyler, Paul M., Pinite—A New Refractory: Bureau of Mines Mineral Trade Notes, vol. 9, No. 5, November 20, 1939, pp. 18–19.

TOPAZ

A carload of fine-grained topaz was shipped in 1939 by the Tennessee Mineral Products Corporation, Spruce Pine, N. C., from the unique deposit at the Brewer gold mine near Jefferson, S. C. The raw material analyzes 50 percent Al_2O_3, 40 percent SiO_2, 0.92 percent Fe_2O_3, and 12.74 percent F_2. (Inasmuch as the analysis totals over 100 percent, it would appear that some of the aluminum is combined with fluorine instead of oxygen.) After calcining, however, it carries 71 percent Al_2O_3 and 29 percent SiO_2, or about the same composition as calcined Indian kyanite. Like kyanite it may be used in special refractories.

VERMICULITE

The production of raw vermiculite in the United States in 1939 was larger than in 1938 but did not attain the 1937 record. Declines in the western output partly canceled an important gain in North Carolina, where there are now two producers, Philip S. Hoyt and Cary Minerals Co., both operating at Franklin, N. C. The latter company is affiliated with expanding plants in Washington, D. C. (Vermiculite Products Co.), and Newark, N. J. (Munn & Steele, Inc.). The two producers at Libby, Mont., merged into a new corporation—Universal Zonolite Insulation Co. (C. W. Kearney, president), Chicago, Ill.—which continues to mine the raw material and to ship cleaned and sized vermiculite to its own and other expanding plants in various cities. The Mikolite Co. (1100 South Mill Street, Kansas City, Kans.), after being optioned to Lehigh Portland Cement Co., resumed operations under the original management, producing—in addition to loose fill—a varied line of insulating, acoustical, and lightweight plasters, cements, and coatings, as well as stucco and textural finishes. Among its newer products is an extender for aluminum paints which, it is claimed, give better results than straight aluminum paint and increase coverage by 25 percent. Vermiculite for this purpose is only 0.00002 inch in diameter, and 1 ounce bulks approximately 5½ ounces by volume. Other uses of this fine powder (98 percent through 325 mesh) are as a coolant and lubricating agent in automobiles, both in the motor and in the transmission and rear end. This company gets its raw material from Wyoming. Vermiculite is mined in Colorado by the Vermiculite Co. of America, 406 Thorpe Building, Minneapolis, Minn.

Vermiculite sold or used by producers in the United States, 1924–39

Year	Short tons	Value	Year	Short tons	Value
1924	2	$68	1932	1,643	$16,950
1925	102	2,818	1933	2,247	21,993
1926	150	3,750	1934	4,746	56,965
1927	51	1,318	1935	7,068	88,445
1928	1,006	38,118	1936	16,933	185,787
1929	982	24,483	1937	26,556	260,664
1930	831	13,682	1938	20,700	192,000
1931	1,256	24,758	1939	21,174	174,587

Freshly exfoliated vermiculite has been reported as being a powerful desiccant, a property that prevented its proposed employment for packing fruit, but a recent investigation [12] indicates that vermiculite that has been exfoliated several months has low capacity and efficiency for the sorption of water vapor. On the other hand, the silica obtained after other oxides are dissolved out with sulfuric and hydrochloric acids has excellent sorbing properties; it has characteristics of a good desiccating agent, although a large volume may be needed owing to its low density.

Retail prices of expanded vermiculite remained firm at 90 cents to $1.35 a 24-pound bag, and prices to building material dealers stiffened. The raw material was worth $7 to $12 a ton, f. o. b. mines.

[12] Hansen, L. A., Samuel, W. S., Jr., and Forni, P. A., Sorption of Water Vapor by Vermiculite and Its Silica: Ind. Eng. Chem., vol. 32, No. 1, January 1940, pp. 116–118.

PART IV. MINE SAFETY

EMPLOYMENT AND ACCIDENTS IN THE MINERAL INDUSTRIES

By W. W. Adams

SUMMARY OUTLINE

Reports from mineral producers to the Bureau of Mines for 1939 reveal widespread recovery of much of the loss in employment noted in 1938. Combined figures covering all main classes of mines and quarries, coke ovens, and metallurgical plants showed more employees working and a larger aggregate number of man-hours worked in 1939 than in 1938.

Increased employment was accompanied by a rise in the number of accidents but not to such an extent as to cause an increase in the accident-frequency rate per million man-hours worked. In fact, as far as may be determined from tentative figures now available, the accident rate for 1939 actually was a little lower than the corresponding rate for 1938.

Reports furnished to the Bureau of Mines are classified into 21 groups; each represents a major branch of the mineral industries and has separate accident and employment figures. Eighteen groups employed more men in 1939 than in 1938, and 18 worked a larger number of man-hours. Nonmetallic-mineral mines reported fewer employees but a gain in man-hours worked, whereas the gold-and-silver group reported a gain in employees but a slight decrease in man-hours. The only two groups reporting a loss both in employees and man-hours worked were those covering miscellaneous metal mines and trap-rock quarries.

This general review of accidents and employment in 1939 is based largely upon reports that had been received from mining companies at the time this chapter was prepared for Minerals Yearbook, 1940. Complete figures are now available for only a few groups—beehive coke ovens, byproduct coke ovens, cement mills and quarries, marble quarries, and slate quarries. Estimates have been made for all other groups.

Figures in the following table show the estimated number of men employed in 1939, the number of men employed in 1938 as shown by reports that are complete and final for all groups except bituminous-coal and metallurgical plants, and the number of men employed in 1937 as shown by complete and final figures for all operations.

Number of men employed in the mineral industries of the United States, 1937–39

	1937	1938	1939
Coal mines:			
Bituminous-coal	490,771	[1] 444,000	[1] 446,000
Pennsylvania anthracite	99,085	96,282	[1] 98,000
	589,856	[1] 540,000	[1] 544,000
Metal mines:			
Iron	22,957	18,006	[1] 20,700
Lead-zinc (Mississippi Valley)	8,466	6,413	[1] 7,000
Copper	21,175	17,582	[1] 18,300
Gold, silver (including lead, zinc, copper)	51,610	47,534	[1] 52,300
Miscellaneous (tungsten, manganese, etc.)	4,204	3,943	[1] 3,800
	108,412	93,478	[1] 102,000
Nonmetallic-mineral mines	10,017	9,526	[1] 9,200
Quarries:			
Cement	27,215	25,520	26,045
Marble	3,647	3,414	3,697
Slate	3,074	2,615	2,833
Trap-rock	2,806	3,141	[1] 2,900
Granite	8,961	8,395	[1] 8,500
Sandstone	3,242	2,907	[1] 2,950
Limestone	24,789	22,352	[1] 22,900

[1] Subject to revision.

The following table shows men employed, man-days and man-hours of employment, and men killed and injured by accidents chargeable to the hazards of their occupations, as well as the yearly fatality and injury rates for mines, quarries, coke ovens, ore-dressing plants, smelters, and auxiliary works connected with ore-dressing plants and smelters.

Employment and accident record of mineral industries of the United States, 1931–39

Year	Men employed	Man-days of employment	Man-hours of employment	Number		Rate per million man-hours	
				Killed	Injured	Killed	Injured
1931	784,347	147,602,799	1,209,270,036	1,707	96,412	1.41	79.73
1932	671,343	110,655,616	900,211,723	1,368	68,717	1.52	76.33
1933	677,722	122,787,658	984,570,160	1,242	72,342	1.26	73.48
1934	739,817	144,566,133	1,081,694,716	1,429	81,660	1.32	75.49
1935	783,139	152,354,170	1,128,808,465	1,495	82,219	1.32	72.84
1936	824,514	177,920,334	1,326,347,029	1,686	92,644	1.27	69.85
1937	859,951	186,790,283	1,381,261,415	1,759	96,484	1.27	69.85
1938 [1]	774,000	144,700,000	1,074,000,000	1,364	73,740	1.27	68.64
1939 [1]	793,000	158,700,000	1,173,000,000	1,359	78,248	1.16	66.69

[1] Subject to revision.

The trends in employment and accidents based upon figures in the foregoing table are shown graphically in figures 1, 2, and 3.

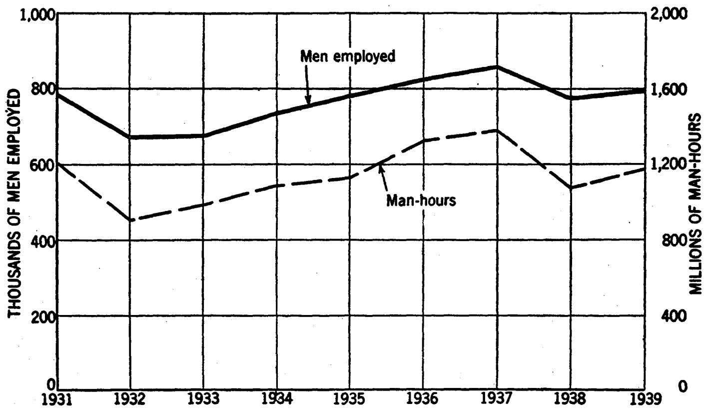

FIGURE 1.—Trend of employment in the mineral industries of the United States, 1931–39.

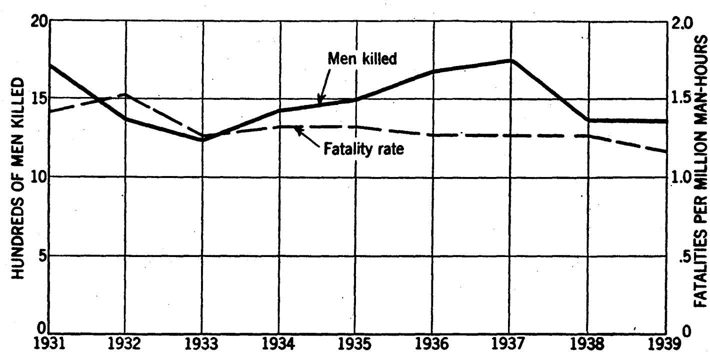

FIGURE 2.—Trend of fatal accidents in the mineral industries of the United States, 1931–39.

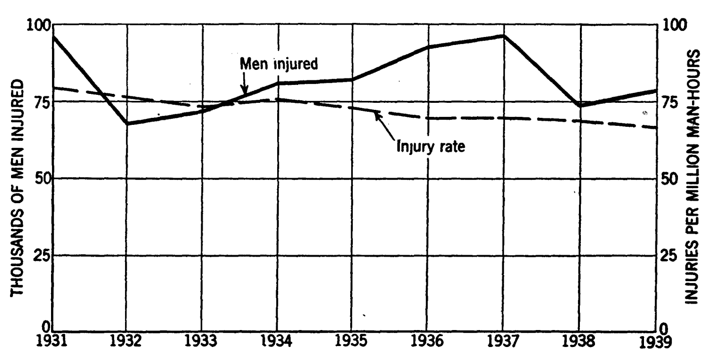

FIGURE 3.—Trend of nonfatal accidents in the mineral industries of the United States, 1931–39.

EMPLOYMENT AND ACCIDENTS

BITUMINOUS-COAL MINES

Employment.—Bituminous-coal mining is by far the largest branch of the mineral industries in the United States. Approximately 60 percent of the total number of men engaged in extracting minerals of all kinds, except oil, sand, gravel, and clay, work in mines that produce bituminous coal. The number of employees at bituminous-coal mines in 1939, as estimated from operators' reports now available, was 446,000 and the total man-hours worked approximately 559 million. The number of employees in 1939 was almost the same as in 1938; however, there was a large increase, amounting to about 10 percent, in volume of labor as measured by man-hours worked. The average working time also increased—from 161 days per man in 1938 to about 176 days per man in 1939.

Accidents.—Accidents increased in number in 1939, but the accident-frequency rate per million man-hours worked was prevented from rising by a proportionately larger gain in man-hours of employment. In fact, information now available indicates that the accident rate probably was a little lower in 1939 than in 1938. The tentative rate, covering both fatalities and injuries, was 75.84 compared with 78.54 in 1938. According to present reports, 890 employees were killed by accidents in 1939. Nonfatal injuries are estimated at 41,500. The tentative fatality rate is 1.59 per million man-hours worked in 1939 compared with 1.72 in 1938. Corresponding rates for nonfatal injuries are 74.25 for 1939 and 76.82 for 1938.

Only one major disaster occurred at bituminous-coal mines in 1939 (a major disaster being defined as an accident causing the loss of five or more lives). The single disaster was a mine explosion on July 14 in Webster County, Ky., in which 28 lives were lost.

ANTHRACITE MINES

Employment.—As referred to in the present discussion, this group of mines covers only the anthracite or hard-coal operations in eastern Pennsylvania. Employment during 1939 was more favorable than in 1938; a few more men were working at the mines, and a notably higher aggregate number of man-hours were worked. Incomplete returns from operating companies indicate a total of 98,000 employees, a slight gain over the 96,282 men employed in 1938. A more significant increase is revealed by the estimated 126 million man-hours worked in 1939 compared with 116 million man-hours worked in 1938. Improvement also was made in 1939 in the number of days of work available per employee; the average was 184, a gain of 12 workdays per man over the average of 172 per employee in 1938.

Accidents.—Accidents were more numerous in 1939 than in 1938. Because of increased employment, however, there was no increase in accident-frequency rate per million man-hours of work done. Tentative figures show a total accident rate of 121.84 per million man-hours for 1939, compared with 127.27 for 1938.

Anthracite mining was free of major disasters in 1939. No such disaster has occurred in an anthracite mine in Pennsylvania since June 2, 1938, when 10 men were killed in a mine explosion in Luzerne County.

IRON-ORE MINES

Employment.—Employment in iron-ore mining recovered sharply to approximately 20,700 men in 1939 from 18,006 men in 1938. Similar recovery was made in man-hours of labor performed, which rose to about 36 million man-hours in 1939 from 28.5 million in 1938. The workyear also was lengthened, as tentative figures indicate 219 workdays per employee in 1939 compared with 197 days in 1938.

Accidents.—Accidents were more numerous in 1939 than in the preceding year, and the accident rate per million man-hours worked also was higher than in 1938. According to present information the death-and-injury rate was 17.68 in 1939 compared with 16.69 in 1938. Although the rate increased in 1939, it was lower and therefore more favorable than the 1939 rate for any other major branch of metal mining in the United States.

COPPER MINES

Employment.—Notable recovery in employment in the copper-mining industry in 1939 compared with 1938 was shown by a 21-percent rise in number of man-hours worked. The number of men employed in and about the mines also increased. Moreover, the average employee had a longer work year in 1939 (285 days per man—a gain of about 39 workdays per man employed), according to reports now available. About 18,300 men were employed in 1939 compared with 17,582 men in 1938. Man-hours worked totaled 41.9 million compared with 34.6 million in 1938.

Accidents.—There was no significant change in the accident-frequency rate for copper mines in 1939 from that reported for 1938, although the actual number of persons injured was larger in 1939. The increase in number of accidents did not cause a rise in the accident-frequency rate owing to the larger number of man-hours worked in 1939. According to preliminary figures, the 1939 accident rate was 60.25 per million man-hours, whereas final reports for 1938 showed a rate of 61.27. Both rates represented an improvement over 1937, when the rate was 95.93.

LEAD AND ZINC MINES (MISSISSIPPI VALLEY STATES)

Employment.—This group includes mines producing lead or zinc in the Mississippi Valley States—including principally Kansas, Missouri, and Oklahoma—and those producing fluorspar in Illinois and Kentucky, where similar accident conditions prevail. The number of men working increased slightly in 1939, and the total man-hours worked gained much more, proportionately. The number of employees was approximately 7,000 compared with 6,413 in 1938. The aggregate man-hours worked at all mines increased about 12 percent in 1939, as reports for the year indicated 11.9 million man-hours worked compared with 10.6 million in 1938. The average employee had 212 days of work, a gain of 5 days over 1938.

Accidents.—Tentative figures based upon reports now available indicate an accident-frequency rate in 1939 of 53.11 injuries and deaths per million man-hours of employment, a more favorable record than that shown by the rate of 58.80 for 1938. Five men were killed by a fall of roof in a mine at Treece, Kans., on January 31, 1939.

GOLD AND SILVER MINES

Employment.—This group includes not only gold and silver mines, but also those producing some copper but operated chiefly for some other metal and those producing lead or zinc elsewhere than in the Mississippi Valley States. Placer as well as lode mines are included.

Mines in this group employed approximately 52,300 men in 1939 compared with 47,534 in 1938. The favorable record shown by the increase in number of employees did not extend to the man-hours worked, which declined from 88.8 million in 1938 to about 87.4 million in 1939.

Accidents.—Accidents increased in 1939 and resulted in higher death and injury rates than in 1938. Tentative figures place the death rate at 0.95 and the injury rate at 105.13 compared with 0.90 and 94.21, respectively for 1938. Reports now available indicate 83 lives lost and 9,187 men injured in accidents at mines in 1939. Final reports for 1938 showed 80 fatal and 8,362 nonfatal injuries.

MISCELLANEOUS METAL MINES

Employment.—This group covers all operations that mine any kind of metallic ores except those produced chiefly for their gold, silver, copper, lead, zinc, or iron; therefore it includes mines that produce ores of tungsten, mercury, manganese, or any of the other metals. The group as a whole contains quite a large number of mines, but many of them are small and employ relatively few men. According to tentative figures now available, the number of employees in 1939 was 3,800, slightly less than the 3,943 men employed in 1938. Total man-hours worked likewise dropped; the total for 1939 was 7.4 million compared with 7.8 million for 1938 and 8.3 million for 1937.

Accidents.—Progress was made in prevention of accidents in 1939, as the tentative accident-frequency rate per million man-hours worked was 51.21 compared with 61.48 for 1938. The 1939 rate was 17 percent below 1938 and 25 percent below 1937.

NONMETALLIC-MINERAL MINES

Employment.—This group covers mines that produce all kinds of nonmetallic minerals except stone, sand, gravel, and clay; therefore it includes mines producing phosphate rock, rock salt, sulfur, gypsum, and many other minerals. The group as a whole employed approximately 9,200 men in 1939, a decrease from 9,526 in 1938. More continuous operation of the mines, however, was reported in 1939, so the aggregate number of man-hours worked increased, the total for 1939 being about 18.4 million and for 1938 17.8 million.

Accidents.—The safety record for nonmetallic-mineral mines as a group was slightly more favorable in 1939 than in 1938. The records for both years, however, were better than in 1937. According to tentative figures the rate for 1939 was 39.20 compared with 41.06 for 1938. The improvement indicated by each of these rates is seen when they are compared with the rate of 48.69 for 1937.

CEMENT MILLS AND QUARRIES

Employment.—A gain in employment was reported for cement quarries and mills in 1939 compared with 1938; the number of men working increased 2 percent and the aggregate number of man-hours worked 7 percent. The total number of workers was 26,045; and man-hours worked, 52 million. An increase of about 17 days per man over the 255 workdays in 1938 was shown.

Accidents.—Accidents were reduced in 1939, notwithstanding an increase in workers and in man-hours of employment. Twelve men were killed and 456 injured in 1939. These figures represent a fatality rate of 0.23 and an injury rate of 8.77 per million man-hours worked by the cement industry as a whole. Corresponding rates for 1938 were 0.29 for fatalities and 9.69 for injuries; thus the record for 1939 was favorable both in accident prevention and employment.

MARBLE QUARRIES

Employment.—More men were employed and more man-hours of employment were available at marble quarries in 1939 than in 1938. The average number of men working at both quarries and finishing plants was 3,697, and the total man-hours worked during the year was more than 7 million. The average number of workdays per employee was 2 more than in 1938, bringing the figure to 236 days per employee in 1939.

Accidents.—No employee was fatally injured in 1939—a favorable record considering that men working at the quarries and finishing plants were exposed to occupational hazards for more than 7 million man-hours. One man was fatally injured in 1938. Nonfatal injuries involving disability of 1 day or more totaled 429 and represented a frequency rate of 60.90 per million man-hours of exposure. This rate was slightly higher than that for 1938.

SLATE QUARRIES

Employment.—Increased employment, both in men working and man-hours of work performed, was reported for the slate-quarrying industry in 1939. Total man-hours worked was 25 percent higher than in 1938 and only 12 percent lower than in 1937. Final figures for 1939 show 2,833 employees and 5.3 million man-hours of work.

Accidents.—Three men were killed and 375 injured by accidents at slate quarries during 1939—more than in either 1938 or 1937. The increase in accidents was proportionately greater than the gain in employment, so that the accident rate for 1939 was higher than for 1938. The rate for 1939 was 70.80 injuries and fatalities per million man-hours worked compared with 57.04 for 1938.

TRAP-ROCK QUARRIES

Employment.—Contrary to the general upward trend in employment in most mineral industries, the number of men employed at trap-rock quarries (about 2,900) was smaller in 1939 than in 1938 but larger than in 1937. The aggregate number of man-hours worked (4.2 million) by the operating plants was less than in either 1938 or 1937.

Accidents.—Although final figures are not available, injuries during 1939 approximated 297, including 4 fatal injuries. The frequency rate, covering both nonfatal and fatal injuries, was 71.46 compared with 62.85 in 1938.

GRANITE QUARRIES

Employment.—The number of men employed in and about granite quarries in 1939 was slightly higher than in 1938, when 8,395 men were employed, but did not differ materially from that figure; however, the aggregate number of man-hours worked in the industry as a whole increased about 5 percent, owing chiefly to a gain of about 14 workdays per man over the average of 214 workdays per man shown by final reports for 1938.

Accidents.—Preliminary data indicate that 592 men were injured, 8 of them fatally. These figures represent an accident-frequency rate of 39.89 per million man-hours of employment or exposure to risk. The rate for 1938 was 42.93.

SANDSTONE QUARRIES

Employment.—About 2,950 men were employed at sandstone quarries in 1939. The number working was a little larger than the 2,907 employees in 1938. During 1939, 4.5 million man-hours of work were performed; the corresponding figure for 1938 being 4.3 million.

Accidents.—From reports so far received, the sandstone-quarrying industry was operated during 1939 without a fatality. Nonfatal injuries totaled 331, a considerable increase over the 252 that occurred during 1938. As a result the accident-frequency rate was higher in 1939, being 73.60 compared with 58.15 in 1938.

LIMESTONE QUARRIES

Employment.—Excluding quarries that produced limestone chiefly for the manufacture of lime, the limestone quarries of the United States employed approximately 22,900 men in 1939, a slight gain over the 22,352 reported for 1938. The number of man-hours of labor performed also increased, from 34 million in 1938 to about 36 million in 1939.

Accidents.—A reduction in accidents, both in number and in relation to man-hours of employment, was shown by operators' reports for 1939. Tentative figures indicate 1,786 injuries in 1939 compared with 1,914 in 1938. The gain in man-hours worked and the more notable reduction in number of injuries lowered the accident-frequency rate to 49.40 in 1939 from 57.12 in 1938.

LIMEKILNS AND QUARRIES

Employment.—Gains in number of workers and in man-hours worked in 1939 compared with 1938 were reported by limekilns and quarries. Tentative figures show 9,600 men employed in 1939 compared with 9,153 in 1938, and total volume of employment was 20.2 million man-hours compared with 18.1 million in 1938.

Accidents.—Tentative figures show that 8 men were killed and 1,054 injured by accidents at quarries and kilns in 1939. The fatality record was better than that for 1938, which included 14 fatal accidents. Nonfatal injuries, on the other hand, were more numerous in 1939 (1,054 compared with 936 in 1938). The accident frequency rate for 1939 was 52.53 compared with 52.51 for 1938. The increase in number of injuries in 1939 did not cause a material rise in the accident rate per million man-hours owing to the increase in man-hours worked during 1939.

BYPRODUCT-COKE OVENS

Employment.—Increased employment in 1939 raised the total number of employees at byproduct-coke ovens to 14,852, a gain of more than 16 percent over 1938 but 17 percent less than in 1937. Volume of employment amounted to 42.2 million man-hours in 1939 compared with 35.5 million in 1938, the gain in 1939 being nearly 19 percent.

Accidents.—Byproduct-coke ovens and one other group, cement mills and quarries, are conspicuous among the various mineral industries for consistently low and favorable accident rates reported from year to year. In 1939 byproduct-coke plants, with an accident-frequency rate of 8.15, established the best safety record of any group canvassed by the Bureau of Mines. The rate for 1939 was not quite as favorable as that for 1938, which was 7.29, but compared favorably with 8.54 for 1937.

BEEHIVE-COKE OVENS

Employment.—Although the number of men working at beehive-coke ovens in the United States has been small in recent years, a marked increase was reported in 1939 compared with 1938. Final reports show a total of 1,757 men working at the ovens, an increase of 67 percent over 1938 when the number was 1,049. Man-hours of work also showed a substantial increase, being 1.54 million in 1939 compared with 1.06 million in 1938.

Accidents.—There were no fatal accidents in 1939 but 62 men were injured, an increase of 33 over 1938. Because injuries increased more in proportion than number of man-hours worked, the accident rate rose to 40.25 in 1939 compared with 27.36 in 1938; however, the rate for 1939 compared favorably with that for 1937—48.49—which represented 158 injuries and 1 fatality that occurred during 3.3 million man-hours of work.

ORE-DRESSING PLANTS

Employment.—At ore dressing and beneficiating plants employees increased about 5 or 6 percent and man-hours worked in 1939, 14 percent compared with 1938. According to tentative figures, 13,100 men were employed and 27.4 million man-hours of work done at all operations in 1939.

Accidents.—Seven fatalities and 745 injuries occurred in 1939. These figures represent an accident-frequency rate of 27.44 per million man-hours worked, which compares favorably with the previous year's rate of 34.93 and the 1937 rate of 35.04, showing the progress in accident prevention during 1939.

SMELTERS

Employment.—The smelting industry, as classified herein, covers the smelting and refining of all metallic ores except iron ore. The smelting of iron ore and the manufacture of steel are not included in accident and employment reports collected by the Bureau of Mines, as such reports have been collected and compiled by the Department of Labor. Reports for all smelters except those treating iron ore show that 16,300 men were employed in 1939. This figure represents a gain over 1938 but a loss compared with 1937. The man-hours worked during 1939 totaled 39.1 million compared with 36.4 million in 1938.

Accidents.—Progress in accident prevention during 1939 was indicated by a reduction in the accident-frequency rate from 19.21 in 1938 to 16.74 in 1939. The rates for both years were more favorable than that for 1937 which was 22.84.

AUXILIARY WORKS AT ORE-DRESSING PLANTS AND SMELTERS

Employment.—Auxiliary works cover all operations at mills and smelters not directly connected with milling and smelting processes. About 12,900 men were so employed in 1939, virtually the same number as in 1938, when the figure was about 12,500. The man-hours worked during 1939 also was virtually the same as in 1938; reports for each year show a total of about 30 million man-hours of labor performed.

Accidents.—Preliminary figures indicate that 523 employees were injured—6 fatally—by accidents during 1939. Based upon this figure, the accident-frequency rate was 17.25 per million man-hours worked, which was nearly identical with the rate of 17.21 in 1938. Each of these rates was considerably better than that of 27.40 reported for 1937.

SUMMARY, 1931–39

Accident and employment data of the Bureau of Mines, except those covering nonfatal injuries at coal mines, first became available for 1911; the figures covered the mining and quarrying industries only. Beginning with 1913, statistics also became available for coke ovens and for ore-dressing plants and smelters, although the early records did not show the number of man-hours worked. After a few years some companies operating metal mines and stone quarries supplied special information, including man-hours worked, and tables based upon these data were prepared from time to time. Nationwide coverage of accidents and employment, including the number of man-hours worked, first became available for coal mines in 1930 and for quarries, coke ovens, metallurgical plants, and all other mines in 1931. Beginning with 1931, therefore, the yearly records of the Bureau of Mines are complete as to fatal and nonfatal injuries, men employed, and man-days and man-hours worked.

The low point of the depression in many branches of mining and quarrying was reached in 1932. In the discussion of accidents and employment in the mineral industry published in Minerals Yearbook, 1939, 1932 was chosen as a base year to show the comparative record of accidents and employment in 1938. However, 1931—the earliest year for which man-hour and other data are complete for all classes of the mineral industry on which annual reports of accidents and employment are compiled—may also be chosen as a base year with which to compare the record in later years, particularly that for 1939.

If, therefore, 1931 is used for purposes of comparison and assigned a base rating of 100, the comparative rating for later years may be clearly seen. Considering the number of men employed in 1931 as being represented by an index of 100, the number of employees fell to its lowest level in 1932 (when the index was 86), reached its highest point with an index of 110 in 1937, dropped to 99 in 1938, and recovered to 101 in 1939. As the trend in employment based upon number of employees does not necessarily parallel that based upon man-hours worked, comparison may be made also on a man-hour basis. With an index of 100 for the number of man-hours worked in 1931, the comparable figure for 1932 (the depression low point) is 74, followed by a rise to a maximum of 114 in 1937, a drop to 89 in 1938, and an increase to 97 in 1939.

The number of fatal accidents in 1931, which was 1,707, also may be represented by an index of 100. Comparative figures show an index of 73 for 1933, the lowest number reported for any year since 1931, and of 80 in both 1938 and 1939. Similarly, if an index of 100 represents the actual number of persons injured in 1931, the smallest number of injuries, which was reported in 1932, may be represented by an index of 71, while the tentative figure for 1938 is 76 and that for 1939 is 81.

The accident-frequency rate per million man-hours of exposure for 1939, covering an estimated 79,607 fatal and nonfatal injuries, was 67.85. The rate was lower and therefore more favorable than the corresponding rate for any year since comparable rates first became available in 1931.
