The libraries provide public access to a wide range of material, including online exhibits, digitized collections, archival finding aids, our catalog, online articles, and a growing range of materials in many media.

When possible, we provide rights information in catalog records, finding aids, and other metadata that accompanies collections or items. However, it is always the user's obligation to evaluate copyright and rights issues in light of their own use.

Minerals Yearbook

**U.S.
DEPARTMENT
OF THE
INTERIOR**

**BUREAU OF
MINES**

1989

UNITED STATES DEPARTMENT OF THE INTERIOR • Manuel Lujan, Jr., Secretary

BUREAU OF MINES • T S Ary, Director

As the Nation's principal conservation agency, the Department of the Interior has responsibility for most of our nationally owned public lands and natural resources. This includes fostering the wisest use of our land and water resources, protecting our fish and wildlife, preserving the environmental and cultural values of our national parks and historical places, and providing for the enjoyment of life through outdoor recreation. The Department assesses our energy and mineral resources and works to assure that their development is in the best interests of all our people. The Department also has a major responsibility for American Indian reservation communities and for people who live in Island Territories under U.S. administration.

Foreword

This edition of the Minerals Yearbook discusses the performance of the worldwide minerals industry during 1989 and provides background information to assist in interpreting that performance. Content of the individual Yearbook volumes follows:

Volume I, Metals and Minerals, contains chapters on virtually all metallic and industrial mineral commodities important to the U.S. economy. A chapter on advanced materials also has been added to the Minerals Yearbook series beginning with the 1989 volume. In addition, a chapter on survey methods used in data collection with a statistical summary of nonfuel minerals and a chapter on trends in mining and quarrying in the metals and industrial mineral industries are included.

Volume II, Area Reports: Domestic, contains chapters on the minerals industry of each of the 50 States and Puerto Rico, Northern Marianas, Island Possessions, and Trust Territory. This volume also has a chapter on survey methods used in data collection including a statistical summary of domestic nonfuel minerals.

Volume III, International Area Reports, contains the latest available mineral data on more than 150 foreign countries and discusses the importance of minerals to the economies of these nations. Beginning with the 1989 review, Volume III is presented as six reports: Mineral Industries of the Middle East, Mineral Industries of Africa, Mineral Industries of Asia and the Pacific, Mineral Industries of Latin America and Canada, Mineral Industries of Europe and the U.S.S.R., and Minerals in the World Economy. This year's reports incorporate location maps, industry structure tables, and an outlook section previously incorporated in our Minerals Perspectives Series quinquennial regional books, which are being discontinued.

The Bureau of Mines continually strives to improve the value of its publications to users. Therefore, constructive comments and suggestions by readers of the Yearbook will be welcomed.

T S Ary, *Director*

Acknowledgments

Volume I, Metals and Minerals, of the Minerals Yearbook, presents data on about 90 mineral commodities and materials that were obtained as a result of the mineral information gathering activities of the Bureau of Mines.

The collection, compilation, and analysis of domestic minerals industries data were performed by the staffs of the Branches of Ferrous Metals, Nonferrous Metals, and the Industrial Minerals of the Division of Mineral Commodities. Statistical data were compiled from information supplied by mineral producers and consumers in response to canvasses, and their voluntary response is gratefully appreciated. Information obtained from individual firms by means of Bureau of Mines canvasses has been grouped to provide statistical aggregates. Data on individual firms are presented only if available from published or other nonproprietary sources or when permission of the respondent has been granted.

The chapter "Survey Methods and Statistical Summary Nonfuel Minerals" discusses in somewhat greater detail procedures for canvassing the minerals industry and the processing and evaluation of these data.

Other material appearing in the volume was obtained from the trade and technical press, industry contacts, and other sources; this cooperation is gratefully acknowledged.

Statistics on world production were compiled in the International Data Section, Branch of Data Collection and Coordination, Division of Statistics and Information Services, from numerous sources including reports from the U.S. Department of State. U.S. foreign trade data were obtained from reports of the Bureau of the Census, U.S. Department of Commerce. Data on production costs for several commodities were supplied by the Bureau of Mines Minerals Availability System.

The Bureau of Mines has been assisted in collecting mine production data and other supporting information by numerous cooperating State agencies. These organizations are listed in the acknowledgments of Volume II.

Donald G. Rogich, *Chief, Division of Mineral Commodities*

SURVEY METHODS AND STATISTICAL SUMMARY OF NONFUEL MINERALS

By Jeffrey B. Osmint and Stephen D. Smith

Mr. Osmint, a statistician with 13 years of Government experience in surveys, has been with the Bureau of Mines Branch of Statistics and Methods Development since 1983.

Mr. Smith, Mineral Data Assistant in the Branch of Data Collection and Coordination, was assisted in the preparation of the "Statistical Summary" by Sarah P. Guerrino, Chief, Section of Ferrous Metals Data; Imogene P. Bynum, Chief, Section of Nonferrous Metals Data; Barbara E. Gunn, Chief, Section of Industrial Minerals Data; and William L. Zajac, Chief, Section of International Data.

SURVEY METHODS

The Bureau of Mines Information and Analysis Directorate collects worldwide data on virtually every commercially important nonfuel mineral commodity. These data form the base for tracking and assessing the health of the minerals sector of the U.S. economy.

The Bureau's data collection activity was instituted by the 47th Congress in an appropriations act of August 7, 1882 (22 Stat. 329), which placed the collection of mineral statistics on an annual basis. The most recent authority for the Bureau of Mines survey activity is the National Materials and Minerals Policy, Research and Development Act of 1980 (Public Law 96-479, 96th Congress), which strengthens protection for proprietary data provided to the U.S. Department of the Interior by persons or firms engaged in any phase of mineral or mineral-material production or consumption.

Data Collection Surveys

The Bureau begins the collection of domestic nonfuel minerals and materials statistics by appraising the information requirements of Government and private organizations of the United States. Information needs that can be satisfied by data from the minerals industries are expressed as questions on Bureau of Mines survey forms. Figure 1 shows a typical survey form. Specific questions about the production, consumption, shipments, etc., of mineral commodities are structured in the survey forms to provide meaningful aggregated

data. Thus, the entire mineral economic cycle from production through consumption is covered by 169 monthly, quarterly, semiannual, annual, and biennial surveys. After the survey form has been designed, a list of the appropriate establishments to be canvassed is developed. Many sources are used to determine which companies, mines, plants, and other operations should be included on the survey mailing list. Bureau of Mines State Mineral Officers, State geologists, Federal organizations (e.g., Mine Safety and Health Administration), trade associations, industry representatives, and trade publications and directories are some of the sources that are used to develop and update survey listings. With few exceptions, a complete canvass of the list of establishments is employed rather than a sample survey. The iron and steel scrap industry is one of the exceptions where a sample survey is conducted.

The Paperwork Reduction Act requires that any Government agency wishing to collect information from 10 or more people first obtain approval from the Office of Management and Budget (OMB). OMB approves the need to collect the data and protects industry from unwarranted Government paperwork.

Survey Processing

Approximately 26,000 establishments yield more than 50,000 responses to 169 surveys annually. Each completed survey form returned to the Bureau undergoes extensive scrutiny to ensure the highest possible accuracy of the mineral data. The statistical staff monitors all surveys to

ensure that errors are not created by reporting in physical units different from the units requested on the form. Relationships between related measures, such as produced crude ore and marketable crude ore, are analyzed for consistency. Engineering relationships, such as recovery factors from ores and concentrates, are also employed. Internal numerical relationships of column and row totals are validated, and currently reported data are checked against prior reports to detect possible errors or omissions.

For the majority of the surveys, which are automated, the forms are reviewed to ensure that data are complete and correct before entering into the computer. The computer is programmed to conduct a series of automated checks to verify mathematical consistency and to identify discrepancies between the data reported and logically acceptable responses.

The Bureau of Mines is modernizing and automating all of its survey processing and data dissemination functions. Automated commodity data system functions include computerized preparation of statistical tables; the use of desktop publishing to integrate text and tables; and the implementation of a microcomputer bulletin board, known as MINES-DATA, for electronic dissemination of minerals data.

Survey Responses.—To enable the reader to better understand the basis on which the statistics are calculated, each commodity chapter of the "Minerals Yearbook" includes a section entitled "Domestic Data Coverage." This section briefly describes the data sources, the number of establishments

FIGURE 1
HELIUM RECOVERY IN THE UNITED STATES

Kansas Refined Helium Co., Otis, KS; Exxon Company, U.S.A., Shute Creek, WY; and Union Carbide Corp., Linde Div., Bushton, Elkhart, and Ulysses, KS. Linde's helium plant at Elkhart, KS, was shut down in 1988 after modifications at their Ulysses, KS, plant were completed and it was restarted.

CONSUMPTION AND USES

The major domestic end uses of helium were cryogenics, welding, and pressurizing and purging. Minor uses included synthetic breathing mixtures, chromatography, leak detection, lifting gas, heat transfer, and controlled atmospheres. The Pacific and Gulf Coast States were the principal areas of helium consumption.

Bureau sales to Federal agencies and their contractors totaled 350 MMcf in 1989, an increase of about 10% when compared with last year's sales. This increase was due largely to the U.S. Department of Defense Strategic Defense Initiative projects and the National Aeronautics and Space Administration's (NASA) resumption of space shuttle flights, which include associated projects that use large volumes of helium. Sales to the U.S. Department of Energy continue to decline.

The Federal agencies purchase their major helium requirements from the Bureau of Mines. Direct helium purchases by Defense, NASA, Energy, and the National Weather Service constituted most of the Bureau's Grade-A helium sales. All remaining helium sales to Federal agencies were made through Bureau contract distributors, who purchased equivalent volumes of Bureau helium under contracts described in the Code of Federal Regulations (30 CFR 602). Some of the contract distributors also have General Services Administration helium supply contracts. These contracts make relatively small volumes of helium readily available to Federal installations at lower freight charges by using the contractors' existing distribution systems.

STOCKS

The volume of helium stored for
HELIUM MINERALS YEARBOOK—1989

surveyed, the response percentage, and the method of estimating the production or consumption for nonrespondents.

To produce reliable aggregated data, the Bureau employs efficient procedures for handling instances of nonresponse. Failure to return the initial survey form results in a second mailing of the form. If the second form is not returned, telephone calls are made to the nonrespondents. The followup calls provide the necessary data to complete the survey forms and/or verify questionable data entries. Periodic visits to important minerals establishments are also made by Bureau commodity specialists or State Mineral Officers to gather missing data and to explain the importance of the establishment's reporting. By describing the use of the published statistics and showing the impact of nonresponse, the Bureau hopes to encourage respondents to give a complete and accurate reply.

The OMB "Guidelines for Reducing Reporting Burden" stipulates that the minimum acceptable response rate shall be 75% of the panel surveyed. In addition, the Bureau strives for a minimum reporting level of 75% of the quantity produced or consumed (depending on the survey) for certain key statistics. Response rates are periodically reviewed. For those surveys not meeting the minimum reporting level, procedures are developed and implemented to improve response rates.

Estimation for Nonresponse.—When efforts to obtain a response to a survey fail, it becomes necessary to employ estimation or imputation techniques to account for missing data. These techniques are most effective when the response rate is relatively high. Some of the estimation methods depend on knowledge of prior establishment reporting, while other techniques rely on external information to estimate the missing data. When survey forms are received after the current publication has been completed, the forms are edited, necessary imputations are made for missing data, and the survey data base is updated. The revised data are reported in later publications.

Protection of Proprietary Data.—The Bureau of Mines relies on the cooperation of the U. S. minerals industry to provide the mineral data that are presented in this and other Bureau publications. Without a strong response to survey requests, the Bureau would not be able to present reliable statistics. The Bureau in turn

respects the proprietary nature of the data received from the individual companies and establishments. To ensure that proprietary rights will not be violated, the Bureau analyzes each of the aggregated statistics to determine if the data reported by an individual establishment can be deduced from the aggregated statistics. If, for example, there are only two significant producers of a commodity in a given State, the Bureau will not publish that total because either producer could readily estimate the production of the other. It is this obligation to protect proprietary information that results in the "Withheld" or "W" entries in the "Minerals Yearbook" tables. However, if a company gives permission in writing, the Bureau may release data otherwise withheld because of proprietary considerations if the data from other producers in an aggregated cell are protected from disclosure.

International Data

International data are collected by country specialists in the Bureau of Mines Division of International Minerals with assistance from the Section of International Data. The data are gathered from various sources, including published reports of foreign Government mineral and statistical agencies, international organizations, the U.S. Department of State, the United Nations, the Organization of Petroleum Exporting Countries, and personal contact by specialists traveling abroad. Each February an annual "Minerals Questionnaire" is sent through the Department of State to more than 130 U.S. Embassies asking them to provide estimates of mineral production for the host country for the preceding year. Missing data are estimated by Bureau country specialists based on historical trends and specialists' knowledge of current production capabilities in each country.

Publications

The Bureau of Mines disseminates current and historical minerals information through a broad range of printed publications.

The "Minerals Yearbook" summarizes annually, on a calendar-year basis, the significant economic and technical developments in the mineral industries. Three separate volumes are issued each year: Volume I, Metals and Minerals; Volume II, Area Reports, Domestic; and Volume III, International Review. Chapters in these volumes are issued separately as

preprints before the bound volumes are available.

Volume I of the "Minerals Yearbook" presents, by mineral commodity, salient statistics on production, trade, consumption, reserves, and other measures of economic activity.

Volume II of the "Minerals Yearbook" reviews the U.S. minerals industry by State and island possessions.

Volume III of the "Minerals Yearbook" presents the latest available mineral statistics for more than 160 countries with a summary review of the role of minerals in the world economy.

"Mineral Industry Surveys" contain timely statistical and economic data on minerals. The surveys are designed to keep Government agencies and the public, particularly the mineral industry and the business community, informed of trends in the production, distribution, inventories, and consumption of minerals. Frequency of issue depends on the demand for current data. "Mineral Industry Surveys" are released monthly, quarterly, semiannually, or annually.

"Mineral Commodity Summaries," an up-to-date summary of about 90 nonfuel mineral commodities, is the earliest Government publication to furnish estimates covering the previous year's non-fuel mineral industry data. It contains information on the domestic industry structure, Government programs, tariffs, 5-year salient statistics, and a summary of international mining news.

"State Mineral Summaries" provides estimated data and summaries of mineral activities at the State level for the previous year. These summaries have been prepared in cooperation with State geological surveys or related agencies.

"Minerals Today," published bimonthly, provides readers with the latest information about developments, trends, and issues concerning the mining, processing, and use of minerals and materials.

"Information Circulars" are primarily concerned with Bureau economic reviews and interpretative analyses. The series also includes surveys of mining and operating activities, guides to marketing of mineral commodities, and compilations of historical information and statistical and economic data on minerals.

To purchase Volumes I, II, and III of the "Minerals Yearbook" and "Minerals Today," contact the Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402. For free

copies of individual chapters of the "Minerals Yearbook," the "Mineral Industry Surveys," the "Mineral Commodity Summaries," the "State Mineral Summaries," and "Information Circulars," contact Publications Distribution, Bureau of Mines, Cochrans Mill Road, P.O. Box 18070, Pittsburgh, PA 15236.

Electronic Data Dissemination

In addition to the Bureau's printed publications, current "Mineral Industry Surveys" for several commodities and selected chapters from the "Minerals Yearbook" are now available through the Bureau's MINES-DATA computer bulletin board. Using this system, the public may obtain information up to 4 weeks before published copies of the reports would arrive in the mail. The MINES-DATA system may be accessed by calling (202) 634-4637 using a modem set to 1200 or 2400 baud, 8 data bits, no parity, and one stop bit.

Further information on how to use the MINES-DATA system may be obtained from the system operator by calling (202) 634-9632.

STATISTICAL SUMMARY

This chapter summarizes data on crude nonfuel mineral production for the United States, its island possessions, and the Commonwealth of Puerto Rico. Also included are tables that show the principal nonfuel mineral commodities exported from and imported into the United States and that compare world and U.S. mineral production. The detailed data from which these tables were derived are contained in the individual commodity chapters of Volume I and in the State chapters of Volume II of this edition of the "Minerals Yearbook".

Although crude mineral production may be measured at any of several stages of extraction and processing, the stage of

measurement used in this chapter is what is termed "mine output." It usually refers to minerals or ores in the form in which they are first extracted from the ground, but customarily includes the output from auxiliary processing at or near the mines.

Because of inadequacies in the statistics available, some series deviate from the foregoing definition. For copper, gold, lead, silver, tin, and zinc, the quantities are recorded on a mine basis (as the recoverable content of ore sold or treated). However, the values assigned to these quantities are based on the average selling price of refined metal, not the mine value. Mercury is measured as recovered metal and valued at the average New York price for the metal.

The weight or volume units shown are those customarily used in the particular industries producing the commodities. Values shown are in current dollars, with no adjustments made to compensate for changes in the purchasing power of the dollar.

¹Production as measured by mine shipments, sales, or marketable production (including consumption by producers).

²Recoverable content of ores, etc.

³Content of ore and concentrate.

⁴Data may not add to totals shown because of independent rounding.

⁵Grindstones, pulpstones, and sharpening stones; excludes mill liners and grinding pebbles.

⁶Excludes abrasive stone and bituminous limestone and sandstone; all included elsewhere in table.

TABLE 2
NONFUEL MINERALS PRODUCED IN THE UNITED STATES AND
PRINCIPAL PRODUCING STATES IN 1989

Mineral	Principal producing States, in order of quantity	Other producing States
Abrasives ¹	AR, IN, OH.	
Antimony (content of ores, etc.)	MT.	
Aplite	VA.	
Asbestos	CA and VT.	
Barite	GA, NV, MO, TN.	IL, MT.
Bauxite	AR, AL, GA.	
Beryllium concentrate	UT.	
Boron minerals	CA.	
Bromine	AR.	
Calcium chloride (natural)	MI and CA.	
Cement:		
Masonry	FL, PA, IN, MI.	All other States except AK, CT, DE, LA, MA, MN, NV, NH, NJ, NC, ND, RI, VT, WI.
Portland	CA, PA, TX, MI.	All other States except CT, DE, LA, MA, MN, NH, NJ, NC, ND, RI, VT, WI.
Clays	GA, WY, FL, TN.	All other States except AK, DE, HI, RI, VT, WI.
Copper (content of ores, etc.)	AZ, NM, UT, MT.	CA, CO, ID, IL, MI, MO, NV, TN.
Diatomite	CA, NV, WA, OR.	AZ.
Emery	(²)	
Feldspar	NC, CA, CT, GA.	ID, OK, SD.
Fluorspar	IL and NV.	
Garnet (abrasive)	ID and NY.	
Gold (content of ores, etc.)	NV, CA, UT, SD.	AK, AZ, CO, ID, MI, MT, NM, OR, SC, WA.
Graphite (natural)	MT.	
Gypsum	TX, IA, MI, OK.	AR, AZ, CA, CO, IN, KS, LA, MT, NM, NV, NY, OH, SD, UT, VA, WA, WY.
Helium	KS, WY, TX, NM.	
Iodine	OK.	
Iron ore (includes byproduct)	MN, MI, MO, UT.	CA, MT, NM, NY, SD, TX.
Iron oxide pigments (crude)	GA, VA, MI, MO.	AZ.
Kyanite	VA.	
Lead (content of ores, etc.)	MO, ID, CO, AK.	AZ, IL, MY, NM, NY, SD, TN.
Lime	MO, OH, PA, AL.	All other States except AK, CT, DE, FL, GA, HI, KS, ME, MD, MS, NH, NJ, NM, NY, NC, RI, SC, VT.
Lithium minerals	NC and NV.	
Magnesite	NV.	
Magnesium compounds	MI, CA, FL, DE.	TX, UT.
Magnesium metal	TX, WA, UT.	
Manganiferous ore	SC.	
Marl (greensand)	NJ.	
Mercury	NV, CA, UT.	
Mica (scrap)	NC, GA, SC, SC.	CO, PA, SD.
Molybdenum	CO, AZ, NV, ID.	CA, MY, NM, UT.
Nickel	OR.	
Olivine	NC AND WA.	
Peat	MI, FL, MN, IL.	CO, GA, IA, IN, MA, MD, ME, MT, NC, ND, NJ, NY, OH, PA, SC, WA, WI.
Perlite	NM, AZ, ID, CA.	CO, NV.
Phosphate rock	FL, NC, ID, UT.	MT, TN.
Platinum-group metals	MT.	

See footnotes at end of table.

TABLE 2—Continued

**NONFUEL MINERALS PRODUCED IN THE UNITED STATES AND
PRINCIPAL PRODUCING STATES IN 1989**

Mineral	Principal producing States, in order of quantity	Other producing States
Potassium salts	NM, UT, CA, MI.	
Pumice	CA, OR, NM, ID.	HI, KS.
Pyrites (ore and concentrate)	AZ.	
Rare-earth metal concentrate	CA and FL.	
Salt	NY, OH, LA, MI.	AL, AZ, CA, KS, NM, NV, TX, UT, WV.
Sand and gravel:		
Construction	CA, TX, OH, AZ.	All other States.
Industrial	IL, CA, TX, NJ.	All other States except AK, DE, HI, IA, ME, NH, NM, ND, OR, SD, VT, WY.
Silver (content of ores, etc.)	NV, ID, MT, UT.	AK, AZ, CA, CO, IL, MI, MO, NM, NY, OR, SC, SD, TN, WA.
Sodium carbonate (natural)	WY and CA.	
Sodium sulfate (natural)	CA, TX, UT.	
Staurolite	FL.	
Stone:		
Crushed	PA, FL, VA, GA.	All other States except DE, ND.
Dimension	VT, IN, GA, SD.	All other States except AK, DE, FL, HI, KY, LA, MS, NE, NV, NJ, ND, OR, RI, UT, WV, WY.
Sulfur (Frasch)	TX and LA.	
Talc and pyrophyllite	MT, VT, TX, NC.	AL, AR, CA, GA, NY, OR, VA.
Tin	AK and AZ.	
Titanium concentrates	FL and CA.	
Tripoli	IL, OK, AR, PA.	
Tungsten (content of ores, etc.)	CA.	
Vanadium (content of ores, etc.)	CO, ID, AR, UT.	
Vermiculite (crude)	SC, MT, VA.	
Wollastonite	NY.	
Zinc (content of ores, etc.)	TN, MO, NY, CO.	AK, ID, IL, MT, NM.
Zircon concentrate	FL, NJ, AL.	

¹Grindstones, pulpstones, and sharpening stones; excludes mill liners and grinding pebbles.

²No production reported.

TABLE 3

VALUE OF NONFUEL MINERAL PRODUCTION IN THE UNITED STATES AND PRINCIPAL NONFUEL MINERALS PRODUCED IN 1989

State	Value (thousands)	Rank	Percent U.S. total	Principal minerals, in order of value
Alabama	\$462,752	22	1.43	Stone (crushed), cement (portland), lime, and sand and gravel (construction).
Alaska	213,352	36	.66	Gold, sand and gravel (construction), zinc, and silver.
Arizona	3,040,368	1	9.41	Copper, sand and gravel (construction), molybdenum, cement (portland).
Arkansas	381,909	26	1.18	Bromine, stone (crushed), cement (portland), sand and gravel (construction).
California	2,854,116	2	8.83	Sand and gravel (construction), cement (portland), boron, gold.
Colorado	453,990	23	1.40	Molybdenum, sand and gravel (construction), cement (portland), gold.
Connecticut	113,217	41	.35	Stone (crushed), sand and gravel (construction), feldspar, sand and gravel (industrial).
Delaware ¹	6,201	50	.02	Magnesium compounds, sand and gravel (construction), gem stones.
Florida	1,608,263	4	4.98	Phosphate rock, stone (crushed), cement (portland), sand and gravel (construction).
Georgia	1,387,295	8	4.29	Clays, stone (crushed), cement (portland), stone (dimension).
Hawaii ¹	92,051	44	.28	Stone (crushed), cement (portland), sand and gravel (construction), cement (masonry).
Idaho	366,310	28	1.13	Phosphate rock, silver, molybdenum, gold.
Illinois	633,361	17	1.96	Stone (crushed), cement (portland), sand and gravel (construction), sand and gravel (industrial).
Indiana	434,115	24	1.34	Stone (crushed), cement (portland), sand and gravel (construction), stone (dimension).
Iowa	282,702	33	.87	Stone (crushed), cement (portland), sand and gravel (construction), gypsum (crude).
Kansas	318,131	31	.98	Salt, cement (portland), stone (crushed), helium (Grade-A).
Kentucky	330,659	30	1.02	Stone (crushed), lime, cement (portland), sand and gravel (construction).
Louisiana	379,722	27	1.18	Sulfur (Frasch), salt, sand and gravel (construction), stone (crushed).
Maine	64,654	46	.20	Sand and gravel (construction), cement (portland), stone (crushed), stone (dimension).
Maryland	342,050	29	1.06	Stone (crushed), cement (portland), sand and gravel (construction), cement (masonry).
Massachusetts	144,126	39	.45	Stone (crushed), sand and gravel (construction), stone (dimension), lime.
Michigan	1,598,971	5	4.95	Iron ore (includes byproduct material), cement (portland), sand and gravel (construction), stone crushed.
Minnesota	1,438,135	7	4.45	Iron ore (includes byproduct material), sand and gravel (construction), stone (crushed), stone (dimension).
Mississippi	107,610	42	.33	Sand and gravel (construction), clays, cement (portland), stone (crushed).
Missouri	1,050,056	11	3.25	Lead, cement (portland), stone (crushed), lime.
Montana	599,239	18	1.85	Copper, gold, platinum-group metals, molybdenum.
Nebraska	103,817	43	.32	Sand and gravel (construction), cement (portland), stone (crushed), lime.
Nevada	2,319,068	3	7.18	Gold, silver, sand and gravel (construction), molybdenum.
New Hampshire ¹	33,240	47	.10	Sand and gravel (construction), stone (dimension), stone (crushed), clays.
New Jersey	248,883	34	.77	Stone (crushed), sand and gravel (construction), sand and gravel (industrial), zircon concentrates.
New Mexico	1,124,592	10	3.48	Copper, potassium salts, sand and gravel (construction), silver.
New York	745,168	14	2.31	Stone (crushed), salt, cement (portland), sand and gravel (construction).
North Carolina	581,568	19	1.80	Stone (crushed), phosphate rock, lithium minerals, sand and gravel (construction).
North Dakota	13,660	48	.04	Sand and gravel (construction), lime, clays, peat.
Ohio	699,156	15	2.16	Stone (crushed), sand and gravel (construction), salt, lime.
Oklahoma	219,031	35	.68	Stone (crushed), cement (portland), iodine, sand and gravel (construction).
Oregon	185,556	37	.57	Stone (crushed), sand and gravel (construction), cement (portland), lime.
Pennsylvania	1,000,669	12	3.10	Stone (crushed), cement (portland), sand and gravel (construction), lime.
Rhode Island ¹	11,072	49	.03	Stone (crushed), sand and gravel (construction), sand and gravel (industrial), gem stones.
South Carolina	425,297	25	1.32	Stone (crushed), gold, cement (portland), clays.
South Dakota	284,358	32	.88	Gold, cement (portland), sand and gravel (construction), stone (dimension).
Tennessee	638,407	16	1.98	Stone (crushed), zinc, cement (portland), clays.
Texas	1,462,453	6	4.53	Cement (portland), magnesium metal, stone (crushed), sulfur (Frasch).
Utah	1,290,450	9	3.99	Copper, gold, magnesium metal, cement (portland).
Vermont	88,902	45	.28	Stone (crushed), stone (dimension), sand and gravel (construction), talc and pyrophyllite.
Virginia	509,130	20	1.58	Stone (crushed), sand and gravel (construction), lime, cement (portland).
Washington	480,879	21	1.49	Sand and gravel (construction), magnesium metal, gold, stone (crushed).
West Virginia	125,498	40	.39	Stone (crushed), cement (portland), salt, sand and gravel (industrial).
Wisconsin ¹	185,277	38	.57	Stone (crushed), sand and gravel (construction), sand and gravel (industrial), lime.
Wyoming	827,361	13	2.56	Sodium carbonate (natural), clays, helium (Grade-A), sand and gravel (construction).
Undistributed	9,043	—	—	
Total ²	32,316,000	XX	100.00	

XX Not applicable.

¹Partial total, excludes values that must be concealed to avoid disclosing company proprietary data. Concealed values included with "Undistributed" figure.²Data may not add to totals shown because of independent rounding.

Lead:		
Ore and concentrate (lead content) metric tons	57,038	23,516
Pigs, bars, cathodes, sheets, etc. (lead content) do.	33,877	44,204
Scrap (gross weight) do.	59,909	26,165
Magnesium, metal and alloys, scrap, semimanufactured forms, n.e.c. (gross weight) do.	56,631	170,374
Manganese:		
Ore and concentrate short tons	57,191	5,014
Ferromanganese do.	9,014	7,310
Silicomanganese do.	5,858	4,068
Metal do.	5,667	10,632
Mercury: metal metric tons	221	1,874
Molybdenum:		
Ore and concentrate (molybdenum content) thousand pounds	112,946	283,371
Molybdates (gross weight) do.	3,067	16,947
Molybdenum, unwrought (gross weight) do.	558	3,216
Molybdenum, wrought (gross weight) do.	743	8,219
Wire (gross weight) do.	751	10,868
Powder (gross weight) do.	1,399	3,846
Ferromolybdenum (gross weight) do.	165	615
Nickel:		
Primary (unwrought commercially pure, cathodes, ferronickel, pellets, briquettes, shot, powder and flakes) short tons	2,327	XX
Wrought (bars, rods, angles, shapes, sections, plates, sheets, strip; tubes, pipes, blanks, fittings, hollow bar; wire)		
Stainless steel scrap (nickel content) do.	21,871	XX
Compound catalysts and waste and scrap do.	6,736	34,875
Platinum-group metals:		
Platinum kilograms	8,414	135,469
Palladium do.	13,005	72,849
Rhodium do.	1,156	28,519
Iridium, ruthenium, and osmium do.	507	4,232
Waste and scrap do.	15,046	157,040
Rare-earth metals:		
Rare-earth metals, including scandium and yttrium do.	424,837	4,801
Ores and concentrates metric tons	776	560
Cerium compounds kilograms	1,432,672	7,026
Selenium do.	372,126	3,429
Silicon:		
Silicon metal short tons	5,561	84,074
Ferrosilicon do.	54,056	40,842

See footnotes at end of table.

TABLE 8—Continued

U.S. EXPORTS OF PRINCIPAL MINERALS AND PRODUCTS, EXCLUDING MINERAL FUELS

Mineral		1989	
		Quantity	Value (thousands)
METALS—Continued			
Silver:			
Ores and concentrates	kilograms	607	\$166
Waste and scrap	do.	770,788	145,340
Dore and precipitates	do.	78,664	15,478
Bullion, refined	do.	430,110	77,812
Tantalum:			
Ore, metal, other forms (gross weight)	thousand pounds	366	\$26,315
Powder (tantalum content)	do.	211	21,451
Tin:			
Ingots, pigs, bars, etc.	metric tons	904	8,915
Tinplate and terneplate	do.	178,884	101,279
Titanium:			
Ore and concentrates	do.	19,832	5,900
Sponge	do.	136	910
Scrap	do.	5,474	22,909
Ingot, slab, sheet bar, etc.	do.	3,875	63,772
Other articles of titanium	do.	3,857	110,511
Pigments and oxides	do.	212,197	437,645
Tungsten (tungsten content):			
Ore and concentrate	do.	203	1,539
Carbide powder	do.	1,360	27,209
Metal powder	do.	762	15,554
Vanadium:			
Pentoxide, anhydride (gross weight)	thousand pounds	8,248	35,204
Ferrovandium (gross weight)	do.	1,087	5,299
Zinc:			
Slabs, pigs, or blocks	metric tons	7,955	14,433
Waste and scrap (zinc content)	do.	108,086	75,947
Powders and flakes (zinc content)	do.	8,137	13,861
Ore and concentrate (zinc content)	do.	78,877	64,224
Zirconium:			
Ore and concentrates	do.	48,176	33,159
Metal and scrap	do.	242	5,997
INDUSTRIAL MINERALS			
Abrasives (includes reexports):			
Industrial diamond, natural or synthetic:			
Powder or dust	thousand carats	78,235	124,180
Other	do.	2,755	33,248
Diamond grinding wheels	thousand wheels	761	9,896
Other natural and artificial metallic abrasives and products		XX	126,810
Asbestos:			
Exports (includes reexports):			
Unmanufactured	metric tons	27,004	7,690
Products		NA	153,081
Barite: Natural barium sulfate	metric tons	9,709	1,622
Boron:			
Boric acid	thousand metric tons	42	32,613
Sodium borates	do.	646	\$361,000

See footnotes at end of table.

Mineral		1989	
		Quantity	Value (thousands)
INDUSTRIAL MINERALS—Continued			
Bromine:			
Compounds (contained bromine)	thousand kilograms	28,998	\$24,093
Elemental	do.	3,557	3,165
Calcium chloride	metric tons	20,316	5,695
Cement: Hydraulic and clinker	thousand short tons	512	25,561
Clays:			
Kaolin and china clay	thousand metric tons	2,337	370,919
Bentonite	do.	671	52,946
Other	do.	748	126,478
Diatomite	do.	137	41,290
Feldspar, leucite, nepheline syenite	short tons	10,283	829
Fluorspar	metric tons	5,134	694
Gem stones (including reexports):			
Diamonds	thousand carats	1,050	1,243,700
Pearls		NA	7,300
Other		NA	222,200
Graphite, natural	metric tons	11,452	7,421
Gypsum:			
Crude	thousand short tons	108	2,286
Plasters	do.	106	15,914
Boards	do.	97	25,140
Other	do.	NA	16,972
Helium	million cubic feet	796	33,830
Lime	short tons	32,241	3,893
Lithium compounds:			
Lithium carbonate	kilograms	9,045,732	28,214
Lithium hydroxide	do.	4,691,991	17,914
Lithium metal	do.	537,557	NA
Magnesium compounds:			
Caustic-calcined and unspecified magnesia	metric tons	20,218	11,476
Compounds, includes magnesium hydroxide, magnesium peroxide, magnesium chloride, and magnesium sulfate	do.	14,851	6,100
Crude magnesite	do.	10,380	8,299
Refractory and fused magnesia	do.	22,525	10,685
Mica:			
Powder	do.	3,628	1,634
Waste	do.	1,224	555
Unworked	do.	60	156
Worked	do.	415	7,227
Mineral-earth pigments, iron oxide, natural, and synthetic	do.	9,966	15,700
Nitrogen compounds (major):			
Fertilizer materials	thousand short tons	13,569	NA
Industrial chemicals	do.	192	150,813
Phosphate rock (ground and unground)	thousand metric tons	8,323	288,990

See footnote at end of table.

METALS—Continued		
Antimony—Continued		
Antimony and articles thereof, including waste and scrap		
metric tons	10,621	\$21,143
Antimony oxides	12,041	19,770
Arsenic:		
Arsenic trioxide	28,348	13,526
Acid	48	67
Sulfides	2	19
Metallic	928	2,150
Bauxite, crude	10,666	NA
thousand metric tons		
Beryllium ore	601	\$655
metric tons		
Bismuth, metals and alloys (gross weight)	1,880,321	21,586
kilograms		
Cadmium metal	2,787	30,161
metric tons		
Chromium (gross weight):		
Chromite ore and concentrate	525,044	43,949
do.		
Metals and alloys:		
Chromium metal	4,202	27,590
do.		
Chromium ferroalloys	343,732	330,427
do.		
Chemicals	12,895	23,677
do.		
Pigments	5,963	13,355
do.		
Cobalt:		
Metal (estimated cobalt content)	5,444	91,960
do.		
Oxide and hydroxides (estimated cobalt content)	273	6,598
do.		
Salts and compounds (estimated cobalt content)	75	1,426
do.		
Unwrought cobalt alloys (gross weight)	90	3,301
do.		
Other cobalt: Matte, waste, and scrap (gross weight)	364	5,054
do.		
Wrought cobalt and cobalt articles (gross weight)	84	3,627
do.		
Columbium ore (gross weight)	4,891	7,649
thousand pounds		
Copper (copper content):		
Ore and concentrate	46,515	50,744
metric tons		
Matte	2,252	5,232
do.		
Blister	77,217	236,129
do.		
Refined copper	300,110	846,609
do.		
Semimanufactures, copper and copper alloy	100,254	398,605
do.		
Scrap	31,578	87,253
do.		
Ferroalloys not elsewhere listed, including spiegeleisen		
short tons	2,578	7,737
Gallium	15,284	5,665
kilograms		
Germanium	40,105	23,789
do.		
Gold:		
Ore and concentrates	2,426	7,103
do.		
Wastes and scrap	39,952	115,685
do.		
Dore and precipitates	13,159	157,952
do.		
Bullion, refined	96,967	1,198,734
do.		
Hafnium: Waste and scrap	4	976
metric tons

EXCLUDING MINERAL FUELS**

Mineral		1989	
		Quantity	Value (thousands)
METALS—Continued			
Indium	kilograms	26,813	\$8,944
Iron ore (gross weight):			
Nonagglomerated:			
Concentrates	thousand metric tons	371	7,760
Coarse ores	do.	662	15,566
Fine ores	do.	11,629	297,913
Agglomerated:			
Pellets	do.	5,628	175,728
Sinter, briquettes, and miscellaneous agglomerates	do.	1,186	23,251
Roasted iron pyrites	do.	121	2,045
Iron chemicals (gross weight):			
Chlorides	metric tons	1,116	494
Sulfates	do.	7,554	1,429
Iron and steel:			
Direct reduced iron	short tons	188,038	22,621
Pig iron	do.	488,175	73,184
Iron and steel products (major):			
Steel mill products	thousands	17,333	7,590,841
Other products	do.	2,378	2,884,328
Scrap, including tinplate and terneplate	thousand short tons	1,120	149,109
Lead:			
Ore and concentrates (lead content)	metric tons	5,122	1,975
Base bullion (lead content)	do.	5,782	4,538
Pigs and bars (lead content)	do.	115,681	79,863
Reclaimed scrap, including ash and residues (lead content)	do.	677	286
Wrought lead, all forms, including wire and powders (gross weight)	do.	6,068	9,076
Magnesium:			
Metal and scrap	do.	7,652	20,229
Alloys (magnesium content)	do.	3,829	14,702
Sheets, tubing, ribbons, wire, other forms (magnesium content)	do.	808	2,928
Manganese:			
Ore (20% or more contained manganese)	do.	638,524	43,794
Ferromanganese	do.	476,063	246,540
Ferrosilicon-manganese	do.	255,391	151,241
Metal	do.	16,147	22,283
Mercury: Metal, waste and scrap	do.	131	1,247
Molybdenum:			
Ore and concentrate (molybdenum content)	thousand pounds	—	—
Waste and scrap (gross weight)	do.	386	1,701
Metal:			
Unwrought (molybdenum content)	do.	102	2,391
Wrought (gross weight)	do.	111	3,311
Ferromolybdenum (gross weight)	do.	3,108	9,062

Mineral	1989	
	Quantity	Value (thousands)
METALS—Continued		
Material in chief value molybdenum (molybdenum content) thousand pounds	524	\$1,791
Compounds (gross weight) do.	4,976	12,106
Nickel:		
Cathodes, pellets, briquets, and shot short tons	100,448	114,861
Plates, bars, etc. do.	911	16,511
Powder and flakes do.	11,572	127,118
Ferronickel do.	12,650	117,630
Oxide do.	5,550	3,052
Platinum-group metals:		
Platinum kilograms	49,238	801,728
Palladium do.	51,135	263,790
Rhodium do.	7,105	270,466
Ruthenium do.	2,883	7,512
Iridium do.	688	6,565
Osmium do.	58	605
Waste and scrap do.	2,159	30,944
Ores do.	12	83
Rare-earth metals:		
Monazite metric tons	974	674
Metals, intermixed or interalloyed kilograms	294,236	4,181
Cerium compounds do.	250,806	1,940
Rare-earth oxides, except cerium oxide do.	501,898	6,986
Other rare-earth compounds or mixtures do.	1,402,448	8,086
Other rare-earth oxides or other rare-earth chlorides do.	7,390,689	30,709
Ferrocium and other pyrophoric alloys do.	244,271	1,690
Rhenium:		
Metal including scrap pounds	8,345	4,197
Ammonium perrhenate (rhenium content) do.	2,089	949
Selenium and selenium dioxide (selenium content) kilograms	417,095	8,934
Silicon:		
Silicon metal short tons	47,615	80,388
Ferrosilicon do.	196,096	131,631
Silver:		
Ore and concentrates kilograms	7,013	2,301
Waste and scrap do.	90,753	96,254
Dore and precipitates do.	142,739	27,943
Bullion, refined do.	3,061,548	578,781
Tantalum ore (gross weight) thousand pounds	3,850	52,762
Tellurium (gross weight) kilograms	42,871	3,249
Thallium do.	1,173	123
Tin:		
Tin ores and concentrates, containing by weight less than 5% lead (tin content) metric tons	216	1,938
Metal do.	33,988	288,118

MINING AND QUARRYING TRENDS IN THE METALS AND INDUSTRIAL MINERALS INDUSTRIES

By Arnold O. Tanner

Mr. Tanner, a physical scientist with the Bureau of Mines for 4 years and a geologist with the U.S. Geological Survey for 6 years, has been the Mining and Quarrying Trends specialist since 1986. Domestic survey data were prepared by Stephen D. Smith, mineral data assistant.

The domestic mining industry continued to be strengthened and revitalized in 1989. The healthy conditions and the industry comeback that began in 1987 continued to spread and became more established for many commodities. Relatively comfortable and stable commodity prices, still found predominantly in the metals sector, reinforced other operational factors in bringing vitality to the mining and mineral processing industries. New streamlined business practices, mine and plant modernizations, and the progressive use of new technologies successfully helped lower operating costs and increase efficiency during the past 5 to 7 years. An element common to these three factors of industry renewal and growth was the ever-increasing infusion of and growing dependence on constantly advancing computer technology applications. This trend of increasing computerization was occurring throughout the mining and mineral processing business while it similarly was in most facets of modern business and culture. Some commodities and companies still struggled to outlive sluggish prices and other unstable market conditions or to modernize their businesses, but increases in productivity and profits were more common. A trend toward increased mechanical excavation in nonsoil materials was beginning to surface as a substitute for standard cyclic mine development techniques, such as drill-and-blast and surface shovel-and-truck routines. More continuous mechanical excavation offered the potential for increased production, fewer people at the working face, better ground control, and generally improved safety. The main limitation was rock hardness. The construction industry had already recognized the benefits of tunnel-boring machines for long underground drives and mechanical planers for pavement removal. The Colorado School of Mines held a short course

during the year entitled, "Mechanical Excavation Techniques in Mine Development and Production," which was attended by nearly 100 engineers from 12 countries. The consensus of attendees was that for the most efficient use of these machines and techniques, new mining plans needed to be developed beyond the simple adaptation of those excavators to existing mine plans.¹

MINING HIGHLIGHTS

Production Overview

Raw nonfuel minerals produced in the United States during 1989 had an estimated value of about \$31.8 billion, an increase of about \$1.8 billion over the final 1988 value. This was the seventh consecutive year that the value had increased. Except for a decrease in 1982, the value had increased each year since 1971. The estimated value of raw metals production increased a healthy 14% from \$10.2 billion in 1988 to \$11.6 billion in 1989. Growth in this sector was slower than in recent years but still followed the same positive trend. The same value increased 38% in 1988 and 28% in 1987, the year that industry rebounded from the depressed post-1981 years. Industrial minerals value also increased, but at a flatter 2% rise to \$20.2 billion, following a 5% increase in value in 1988. Overall, the value of materials produced from these domestically mined, raw nonfuel minerals rose to an estimated \$315 billion, a 5% increase over that of 1988.

Trends in domestic metal mine production showed significant increases for gold, molybdenum, certain rare earths (the lanthanides), and silver. Moderate increases occurred for copper, magnesium, platinum-group metals, titanium, tungsten, and zinc, with smaller increases for bauxite, iron ore, lead, and silicon.

Production of cadmium, germanium, and selenium decreased a small amount while beryllium experienced a moderate decrease. Industrial minerals with significantly increased production included iodine and sulfur, while moderate increases occurred in bromine, phosphate rock, pumice, and quartz crystal production. More modest increases occurred for calcium chloride, fluorspar, gypsum, perlite, and potash, and small gains were made in clays, feldspar, dimension stone, gem stones, lime, lithium, industrial sand and gravel, salt, soda ash, and talc. Cement, crushed stone, diatomite, fixed nitrogen, vermiculite, and zircon held fairly even. Small decreases occurred for asbestos, boron, magnesium compounds, mica, construction sand and gravel, and sodium sulfate, and production of barite and peat dropped off moderately.

Because of the increased competitiveness of many companies and more profitable prices, many of the base metal markets continued to be very active, as they had been in 1988, following many years of lackluster performance. The generally strong commodity prices in 1989 provided incentive for increased production of most major metals. Copper maintained its position as the metal with the highest production value, followed by gold. But gold continued to be the strongest and most aggressively sought commodity overall in both domestic and international mining, as had been the case for a number of years. The main change for gold in 1989 was that softer prices moderated new growth somewhat, compared to the boom of the previous several years. Gold production continued to increase and was substantially the result of new and expanded mining operations where heap leaching was instrumental in developing low-grade ore deposits. An estimated 37% of total U.S. gold production was the result of heap leaching, and in Nevada, the largest gold-producing

State, it accounted for about 42% of the output. An increasing number of companies were processing their sulfide and refractory ores using new, expensive autoclaves, or by employing roasting methods or other newly developing processes. A few operations continued the development and adaptation of bioleaching methods to preoxidize their sulfide gold ores, which were previously often labeled "waste" by some operations. Until recently, commercial applications of bacterial leaching had been mostly limited to copper and uranium.

Gold output in the United States increased from about 6.46 million troy ounces in 1988 to almost 8.6 million troy ounces in 1989, about a 33% increase. This followed 1988's 31% rise, 1987's similar 33% rise, and 1986's 45-year record increase of 54%. Nevada was responsible for much of this increase. In 1989, Nevada produced just under 5 million troy ounces, slightly more than 58% of total U.S. gold production. Since overtaking Canada in 1986, the United States remained the third largest primary gold producer in the world, behind the Republic of South Africa and the U.S.S.R. Gold bullion imports, following a fall of 25% to 1.8 million troy ounces in 1988, rose 73% to 3.12 million in 1989. Exports of bullion increased 364% to 8.44 million troy ounces in 1988 over 1987 totals because of large sales from company inventories. In 1989, U.S. gold bullion exports moderated, totaling 3.97 million troy ounces, less than one-half that of 1988. However, the current increasing trend, which followed a large drop in 1982, continued. This was a 93% increase over that of 1987 and an 11% increase over that of 1986, the year closest in bullion export total. Interest in precious metals as bullion and commemorative coins remained strong but slower in the United States when compared with that of recent years. Interest in platinum and palladium coins increased in several countries.

Preliminary estimates showed that the United States surpassed world-leading Mexico in silver production in 1989, and the Washington, DC-based Silver Institute projected that this would likely continue through 1992. U.S. production totaled more than 64.6 million troy ounces versus preliminary estimates of 63.5 million troy ounces for Mexico and almost 56 million troy ounces for Peru, the other world leader. The pickup in

U.S. production and optimistic future projections were largely the result of increased silver production as a coproduct with gold and copper production and the opening of several major silver and zinc-lead-silver U.S. mining operations. The Institute reported that lower production from Mexico and Peru was in part the consequence of labor problems.

Equipment Sales

The value of shipments by the U.S. mining machinery industry, measured in constant dollars, rose an estimated 2.8% in 1989, relatively the same as the 3% increase of 1988. Comparatively high levels of industrial production and of investment in capital equipment in the United States continued to stimulate both mine production and sales of mining machinery. Many U.S. mines continued to make new investments in plant and other equipment to be more competitive in world markets. These purchases included equipment for in-pit crushing and high-capacity conveyor systems to replace costly vehicle haulage systems. New electrochemical mineral processing equipment was employed to economically exploit lower grade ore deposits. Computers were increasingly used to track equipment and machinery maintenance requirements to extend equipment operating life and reduce costs. Nevertheless, about one-half of the total demand was projected to be for parts and attachments. U.S. exports of mining machinery were valued at about \$430 million, a 3% increase over a revised 1988 level of \$418 million. The International Trade Administration estimated that U.S. imports of mining machinery grew to about \$380 million in 1989, almost a 50% increase over the 1988 level. In 1988, these imports rose only 6.4% following a 26% increase in 1987.²

East-West Technology Venture

Signs of cooperation between the Communist and the non-Communist world had been on the increase for a number of years. This was partly evidenced by a growing number of scientific and educational information exchanges and cooperative ventures of various sorts. A radical softening of past highly structured political and societal policies in the U.S.S.R., both toward its own people and especially toward the Eastern European bloc

nations, provided a setting for further and more relaxed future exchanges. One concrete example of this in the mining industry was a joint venture that was officially formed late in the year between a very large Soviet gold mining association and an Alaskan company. The two, Severovostokzoloto (Russian for "Northeast Gold"), the largest gold mining association in the Soviet Far East, and Bering Straits Trading Company of Anchorage, AK, joined together to combine and market mining technology developed on both sides of the Bering Strait. The partners' new organization, SVZAL, planned to combine the best aspects of their distinctive technologies in developing safer and more efficient mines in both countries. The Soviets were reported to have more advanced permafrost technology and specialized techniques and equipment for large-scale placer operations. The U.S. company had more extensive automation technology and a different management style that was of interest to its Soviet counterpart.³

LEGISLATION AND GOVERNMENT ACTIONS

Issues important to the mining and mineral processing industries were the subjects of many often strongly debated bills prepared by both the House of Representatives and the Senate of the U.S. Congress. Revision of the Mining Law of 1872, amendments to the Clean Air Act of 1970, proper controls on mine and mineral processing waste, and a number of wilderness, environmental, and public land bills were frequently on Congressional agendas. Mining law issues drew considerable attention. A mineral leasing system for mining on public lands was proposed in lieu of the current claim and patent system in conjunction with stricter environmental protection and land reclamation requirements for those companies seeking to mine on Federal lands. The Western Governors' Association (WGA) at yearend approved a resolution endorsing the Mining Law of 1872. At the same time, it recognized problems with the present system and directed its staff to review allegations of reported abuses. WGA stated that abuses such as nonmining uses of public lands could not be tolerated and should be prohibited by

Western State laws if they were not subject to administrative solutions.⁴ The clean air laws and conflicting information on acid rain also drew much active investigation and debate while major proposals containing an environmental emphasis were presented by the Administration. Substantial wilderness areas in Nevada were protected by one bill's passage, but in terms of legislation that completed the entire circuit through to the President's signature, the year was relatively quiet. Active continuation of most of this legislation was anticipated for the upcoming 1990 session. Legislation to order eventual replacement of the \$1 bill with a copper coin and a palladium bullion coin bill were among coin bills proposed but not completed by yearend.

Statutory Changes

National Defense Stockpile.—The National Defense Authorization Act for Fiscal Years 1990 and 1991 (Public Law 101-189) included amendments to the in-place National Defense Stock Piling Act. The stockpile manager was authorized to dispose of stated quantities of 11 specified stockpile materials during the 2 years, with the disposal limited to \$180 million each year. In turn, \$180 million was to be spent each year for acquisitions and upgrades of stockpile materials, with at least \$30 million yearly to be obligated for new upgrade programs not already required by law. Another provision of the law instructed the President to encourage the development of domestic sources for appropriate strategic and critical materials. This was to be done to the extent that the President determined such action was required for the national defense.

Strategic and Critical Material Availability.—The Defense Production Act (DPA) was extended until August 10, 1990, as Public Law 101-137. The DPA was designed to place heavy emphasis on maintaining a continuing level of industrial and economic preparedness in the eventuality of a national defense emergency. The DPA previously had an exclusive emphasis on mobilization preparedness. In recent years, it had been oriented more toward providing a way to respond to adverse actions occurring outside the country. Such actions included those that could result in nonavailability or serious shortages of strategic and critical materials with serious effect on the

national defense preparedness of the United States. The U.S. Department of the Interior is charged under DPA with responsibility for emergency readiness plans and programs for all nonfuel mineral materials. Under the Act, the Bureau of Mines, as a result of its continual monitoring of mineral supply and demand and its technological competence, has the organizational framework needed to discharge priorities, allocations, and supply expansion responsibilities. To facilitate coordinated Government action in the event of an emergency, the Bureau maintains 96 standby interagency mineral commodity committees, which would be called upon as needed in an emergency, as well as a unit of the National Defense Executive Reserve.

Wilderness Protection.—In December, the President signed into law the Nevada Wilderness Protection Act of 1989 (Public Law 101-95), which established 733,400 acres of wilderness in 13 areas on national forest lands in Nevada to be administered by the Secretary of Agriculture. In addition to setting aside wilderness areas, the bill's passage released about 2.4 million acres of land back into multiple-use status. This land had been tied up for years in wilderness study areas pending passage of a wilderness bill.⁵

Deep Seabed Funding.—The Deep Seabed Hard Mineral Resources Act (Public Law 101-178) was reauthorized and funded through 1994 with an annual funding level set at \$1.5 million. Exclusive exploration licenses could be issued to applicants on a first-come-first-served basis, with the potential for future conversion to a permit for commercial recovery in the area covered. This law was renewed partly in anticipation of more comprehensive future legislation.

State Tax Legislation.—According to a survey of 24 mining States by the Mining Cost Service of Spokane, WA, tax legislation specifically favorable to the mining industry was passed only by Montana. Two States, Kentucky and Nevada, passed legislation increasing taxation of the mining industry, while four others—California, Minnesota, Missouri, and North Dakota—passed tax laws that impacted mining but were not specifically directed at mining. Montana reduced its personal property tax rates for mining equipment and passed a local

government severance tax to replace property taxes on coal mine proceeds. Under State supreme court order, Kentucky raised its property tax rate on unmined coal. The court deemed the then-current rate to be so low that it amounted to an unconstitutional exemption from taxation. Nevada completed passage of a constitutional amendment that effectively raised the tax on the net proceeds of its mines.⁶ In another State action, the New York State government encouraged investment in precious metals by exempting precious-metal bars and bullion coins from New York State sales tax effective September 1, 1989. Platinum products, which were often previously too expensive to purchase; gold and silver bars; and low-premium bullion coin sales of \$1,000 or more became exempt. Exceptions to this exemption included coins from the Republic of South Africa and those being manufactured, processed, assembled, fabricated, or used for an industrial, professional, esthetic, or artistic purpose.⁷

Court Rulings

Increased Arizona Mining Royalties.—The U.S. Supreme Court upheld a 1987 Arizona supreme court ruling that invalidated a State law that allowed the Land Department to charge a maximum 5% royalty for mineral development on the State's 9.6 million acres of trust land. Under the Enabling Act of 1910, the Federal law under which Arizona became a State, mineral lease royalties from State trust lands were to go into a fund for schools with the interest used to pay for education in Arizona. This Act also required the legislature to obtain the highest possible worth for trust lands it chose to lease. The Federal Court ruled that the 5% cap deprived the State of its fair share of the minerals' value, but stopped short of invalidating current mineral leases. If that had been done, Arizona would have stopped receiving royalties while the issue awaited resolution. The Court added that the leases' validity was on shaky ground, having been issued under a mineral leasing law now considered invalid. An Arizona trial court was ordered to resolve the question of current lease validity and decide whether retroactive royalties to the State were to be collected. The specific case, *Asarco v. Kadish*, was initiated by State

education groups and involved royalties received from such operations as Asarco's Mission Mine, south of Tucson, AZ. The copper and molybdenum mine was situated on both Indian territory and Arizona "trust land."⁸

States Allowed Development Taxes on Indian Lands.—Several weeks previous to the Asarco case, the U.S. Supreme Court had ruled in favor of a State's right to tax mineral development on Indian lands in two separate State cases. In the case of *Cotton Petroleum v. New Mexico*, the Court ruled that tribal sovereignty did not prohibit States from imposing taxes on mineral production (in this case oil and gas) from reservations or tribal lands. The decision applied to non-Indian lessees of tribal resources.⁹ In a case brought by Peabody Coal Co. against the State of Arizona, the Court upheld, without comment, a decision by Arizona courts that State "transition privilege" taxes must be paid by Peabody Coal for coal mines it operated on Navajo and Hopi reservations in Arizona. Peabody had been paying taxes under protest since 1980. Of concern to Indian tribes and companies alike was double taxation, by State and tribes, on the same property. Both claimed that mineral extraction should be exempt from State tax levies because of tribal sovereignty. Indian officials contended that double taxation was unfair and that economic development programs on reservations would be hurt by continued State taxation privileges on their lands. Indian tribes from other States, including Colorado, Utah, and Wyoming, expressed concern to the U.S. Senate following the rulings. Tribal representatives stated that the double taxation placed reservations at a disadvantage in trying to attract new oil and gas and other mineral development and was at present threatening the continued operation of some existing facilities. Mineral production tax revenues were necessary to the tribal economies, the tribal representatives insisted.¹⁰

Workplace Health and Safety.—In another U.S. Supreme Court case, the Court let stand a unanimous decision made by the Illinois supreme court earlier in the year that allowed States to file criminal charges against employers accused of neglecting the health and safety of workers. It agreed with Illinois that Federal workplace regulations did not bar

State prosecutions. Corporate officials could be prosecuted for knowingly exposing their employees to hazardous chemicals and unsafe conditions. Defendants argued that criminal charges brought by the State should not be valid because the Federal Government preempted State prosecutions when it enacted the Occupational Safety and Health Act of 1970. They argued that Federal officials were more experienced and knowledgeable and would use more uniform and national workplace safety standards than some local prosecutors and juries which could be less informed and less consistent.¹¹

Federal and State Placer Claim Dispute.—In a case before the Alaska supreme court involving conflicting State and Federal claims to the same placer deposits, holders of several unpatented Federal placer claims lost to State claimants. The problem was caused by (1) Federal Public Land Orders in 1972 and 1981, which withdrew selected public lands from mineral entry, giving their elective control to the State of Alaska, and (2) complicated claim histories, which included some gaps in the mandatory annual labor requirements for the properties. The supreme court affirmed one previous lower court judgment and reversed another, holding that a successor-in-interest to Federal mining claims could not cure his predecessor's failure to perform annual labor after land encompassing claims were withdrawn from mineral entry.¹²

EXPLORATION

The 28th International Geological Congress, with participants from 107 countries, was held in the early summer in Washington, DC. The world supply of minerals was a major focal point of discussion. Money and motivation available for mine development and exploration was of more concern than the size of the world's supply. This was less the case for developed countries such as the United States than for developing countries. They were supplying much of the world's minerals with too little of their own money to invest in such work. On the other hand, these Governments were viewed as becoming less hostile to foreign investors and private mining operations, thereby opening the door to a new and

potentially lucrative style of mine development.¹³

Overview

Mineral exploration in the United States continued to show signs of renewed interest. The pursuit of gold, and less so other precious metals, remained strong in 1989, but with slightly less intensity than in 1988 because of relatively low and somewhat prolonged, soft gold prices. Some companies were reported to be diversifying away from a singular emphasis on gold. Geochemistry plays an important role in gold exploration because gold often occurs in submicron-size grains, especially in hydrothermal deposits. In geochemical surveys, gold remained as the most actively sought commodity, but modest exploration projects were undertaken for other commodities, such as copper, lead-zinc, platinum-group elements, and rare-earth elements (the lanthanides). Generally strong base metal prices helped fuel some increased interest in these materials, but base metals were largely sought in conjunction with precious metal-enriched massive sulfide or porphyry-type deposits.¹⁴ Exploration activity for gold (with some interest in copper and zinc) increased in the States of Idaho, Montana, both North and South Carolina, Oregon, and Washington. Titanium was actively pursued in North Carolina and southeastern Virginia, especially by foreign companies, as well as in southern California. Exploration activity for some industrial minerals was also reported. Among these were sulfur in Texas and the Gulf of Mexico, kaolin in Minnesota, high-grade lime and boron in California, and a diamond deposit in Arkansas. While exploring for gold in southern Nevada, one company discovered a high-grade wollastonite deposit, after which it shifted emphasis to defining and testing the quantity and quality of its wollastonite showings. Wollastonite had an increasing potential for use as an asbestos replacement and as reinforcement fillers in plastics and resin systems.

With support from the Bureau of Mines and the U.S. Geological Survey (USGS), the Society of Economic Geologists (SEG) conducted its annual Mineral Exploration Statistics Survey to gauge the levels of current nonfuel mineral exploration in the United States and Canada. SEG results indicated a definite

need for more investment in base metal exploration in both countries, although more so in the United States. The Society noted a lack of adequate exploration for lead-zinc resources conducted in the United States through early 1989. Because of this, the U.S. ore reserve base was diminishing, with little replacement reserve base being added through exploration. SEG reported copper exploration to be sluggish, but it stated that the lead-zinc situation was more serious because of the geological setting in which the deposits occur. Copper deposits generally have low-grade mineralization adjacent to presently mined ores. However, lead-zinc deposits generally have distinct geologic cutoffs, with little adjacent low-grade mineralization to process when more economically desirable, higher grade reserves are depleted.

Some areas of interest to those exploring in the United States were (1) several areas in Kansas, Missouri, Oklahoma, and Wisconsin for copper, gold, iron, lanthanide, silver, and uranium ores; (2) northern Minnesota for deposits of gold, platinum, and silver; (3) Alaska for gold and rare-earth deposits; and (4) placer gold occurrences along the Georgia-Alabama Fall Line. Minnesota's State Executive Council encouraged metallic-mineral exploration with a lease sale in October. It awarded 65 leases, covering 25,775 acres, to 9 companies primarily interested in gold and platinum-group metals.

Convenient Position Fixing

A handheld Global Positioning System (GPS) receiver called the Magellan GPS Pro¹⁵ was developed through the cooperative efforts of a number of Australian companies and subsequently manufactured at Magellan Systems Corp. of Monrovia, CA. The unit was designed to enable field exploration personnel to precisely fix their position to within 5 to 7 meters (m), by latitude and longitude or specified map grid. The Pro model reportedly incorporated features initially requested by the Australian minerals industry, including standard and user definable datums, computer interface, and navigation features. The GPS used a network of 21 satellites plus three optional backups, circling the earth twice daily in 6 fixed planar orbits. The company claimed that in a country such as Australia, which has a high level of

satellite availability, the unit could be operated virtually without time restriction in most parts of the country in daylight hours. The mineral exploration industry model incorporated a communications package that allowed survey information to be processed by a data logger or personal computer.¹⁶

Airborne Data Collection

Remote Sensing.—The use of remote sensing as an exploration tool has steadily grown. Not only were technologies emerging to identify rock types and the location of minerals and ore deposits, but the location of structural features evident on some processed images were used to assist in determining the safest approach to mining an ore body. A property under consideration could be evaluated for the likelihood of mining difficulties attributable to geologic structural weaknesses, thereby lessening an adverse economic impact on the project and increasing the safety factor. Satellite imagery was useful in detecting special spectral signatures in vegetated areas. A large body of evidence was accumulating indicating that metal anomalies in soils are expressed as anomalies in the overlying vegetation. Such data could be useful as an aid to prospecting and to environmental monitoring of soil chemistry.

Numerous systems were undergoing development for conventional airspace and earth orbital applications, but the workhorse of the geological remote sensing industry remained the Landsat satellite. Federal Government Agencies' support of the two existing Landsat earth-watching satellites 4 and 5 was continued when the President approved funding through fiscal year (FY) 1991. Included in the approved plan was the launching of Landsat 6, tentatively scheduled for mid-1991. Landsat 6 was planned to provide an updating of technology, some of which was as much as 15 years old. Landsat imagery was costly, but it was the least expensive method that was available for conducting regional surveys.¹⁷ The State of Oklahoma used satellite scanning to detect erosion, and single images cost more than \$3,000 each. Nevertheless, scientists expected remote sensing to become increasingly popular, especially if environmental problems and the need to more closely monitor them continued current increasing trends.¹⁸ In addition to the Landsat program, sensor systems

for satellites were being developed by other countries with a variety of spatial and spectral characteristics. On the international scene, remote sensor systems included the French SPOT satellites, Soviet Soyuzkarta, Europe's ERS-1, Japan's JERS-1, Canada's Radarsat, and the international polar platform.

Following the discovery via satellite imagery of a zone of silicate minerals containing ammonium, a scientist from the USGS postulated a substantial potential for gold and silver deposits in the Cedar Mountains in southern Utah. The large size of the ammonium-bearing zone—up to 100 times the size of other known occurrences—made the Cedar Mountain locality unique. Ammonium-bearing minerals had been found at major gold-producing areas in the United States, including the McLaughlin gold mine in California and in gold deposits along the Carlin Trend in Nevada.¹⁹ In Brazil, the use of Landsat imagery and side-looking airborne radar preceded the finding of cobalt, copper, lead, nickel, and zinc mineralization and high bismuth, gold, and silver mineralization. Other areas in Brazil revealed the occurrence of colored granites useful as ornamental stone. In these studies, costs of remote sensing exploration were estimated at about 1% of conventional black and white aerial photography and field mapping at a 1:100,000 scale.²⁰

Economical Geophysical Survey.—Before 1989, the Dinguiraye Gold Mine Ltd. (DGM) mining concession in the Republic of Guinea in western Africa began comprehensive geophysical mapping of a small African bush area with high gold mineralization potential. Outcrops on the heavily laterized landscape could not be used to support any geological model or reasoning for the selection of worksites, and DGM wanted to find more targets. A standard aircraft and crew were too costly because of the small size and remoteness of the exploration area. The company used a microlight aircraft configured with modern sensing equipment and on-the-spot data processing with microcomputers. The location and mapping of a shear zone, a known major tectonic feature, was essential to interpreting the area and selecting further geochemical testing sites. This zone was a site of magma rise, where deepwater convection had redistributed various

elements, including gold. The survey also revealed smaller structures, such as faulted mafic dikes and certain specific faulting patterns, which were especially important for the location of stockwork and placer deposits. DGM's success with this low-level airborne geophysical survey suggested its potential as a future exploration tool in remote areas. This exploration project led to a 50-50 partnership between DGM and the Guinean Government for mineral exploitation and continued exploration programs in 1989.²¹

Drilling Technologies

Diamond Drill Bits.—Two new matrix-diamond impregnated drill bits with differing methods of improving performance were produced, one by Boart Exploration Services of South Africa and the other by Christensen Mining Products, based in Salt Lake City, UT. Boart launched its new "Series 9" core bit, which utilized a new reactive matrix. The matrix reportedly provided improved diamond retention and hence more effective utilization of the diamond in service. The innovative matrix technology necessitated the development of a new manufacturing process, which included further development and use of a sophisticated vacuum furnace. Boart claimed that this addition allowed better process control and consistent product quality, a wider range of processing conditions, and the evaluation of more exotic materials and different production methods. The bit was said to have given impressive results in exploratory underground drilling in a variety of quartzites, providing longer life and improved productivity, particularly on high-speed, medium- to high-powered hydraulic machines.²²

Christensen Mining developed its new "Gold" bit. The new bit combined friable diamonds with a new matrix, which was designed to continually expose the diamonds so that they sharpened but did not polish themselves as they slowly broke down. Christensen claimed a more consistent cutting surface along with more consistent penetration rates, and minimal polishing. In ultrahard, dense, consolidated formations, typical of many gold deposits in the Western United States, other comparable bits could become polished and penetration rates eventually fall off to zero. The new Gold bit was designed to cope more effectively with these conditions. Tests were conducted on many demanding formations

throughout the United States and reportedly demonstrated an overall average increase in hard-rock drilling production of between 15% and 20% and an almost 20% increase in bit life.²³

Hammer Drill.—Entec Industries Ltd., based in Northern Ireland, United Kingdom, developed a new down-the-hole (DTH) reverse circulation hammer specifically for geologic sampling. The Samplex drilling system incorporated independent internal flushing. The patented design created suction at the bit face to promote high-volume recoveries, which Entec claimed contained no contamination, a common DTH drill sampling problem. A continuous airflow was passed through the flushing jet into the sample tube, maintaining flushing whether the drill piston was in operation or not. Sample recovery started immediately when drilling commenced, and the penetration speeds were equivalent to conventional standard DTH hammers. The bit could produce large chip sizes suitable for rock identification in the field and laboratory thin-section analysis. There reportedly was no loss of circulation in voids and fractures with continuous sampling through varying geologic conditions.²⁴

Reduced Drilling Downtime.—Because of the harsh conditions under which drill pipe is required to operate, including the presence of water and highly abrasive particles, difficulties in breaking down the drill stem occur. A South African exploration company approached this problem by having the screw pieces on its drill pipe treated with a coating of nickel phosphorous, chosen for its friction-reducing capabilities. Reportedly, the compound eased pipe detachment and benefitted the tightening process as well and attracted interest from, among others, Australian and Canadian mining firms. Equipment longevity increased, and there was also a significant reduction in downtime during exploration drilling operations. A nickel teflon compound was used on swage lock-type fittings to allow for their reuse after detachment.²⁵

DEVELOPMENT

The rate of development of new mining properties other than those for gold remained moderately slow in 1989. As in recent years, gold mine openings headed

the list. Most were low-grade ore gold mines using heap leaching to recover precious metals. Though not harshly affecting the industry, the relatively low and fairly consistent soft gold prices contributed to the suspension of operations of some marginal gold-mining operations and relegated some other operations to marginal status. As has been the recent pattern, expanded operations and modernization of existing properties, reopening of mines closed during the past several years, and redevelopment of previously mined properties took precedence over the development of new mining ventures. Gold again was the commodity that had the highest number of mine projects to come on-line. More than two dozen new gold mines began production in 1989, while the capacities of many other gold mines were expanded. Six new and reopened zinc-producing mines, several producing significant amounts of lead, began production in 1989. A gold and industrial sand operation in North Carolina commenced production of a mixed heavy-mineral sands concentrate consisting primarily of monazite, a principal ore of the rare earths, with lesser amounts of zircon and the yttrium-rich mineral xenotime. The deposit was the first domestic source known to have produced commercial quantities of xenotime.

Alaskan Production Commences

Largest U.S. Silver Producer.—The Greens Creek lode-silver-gold underground mine on Admiralty Island, 18 miles southwest of the capital city of Juneau, began operations in February. In its first year, it became the largest silver-producing mine in the United States, extracting 6.4 million troy ounces [198,066 kilograms (kg)], and the second largest lode-gold mine in Alaska. Significant quantities of zinc and lead, almost 10% and 4% of the ore, respectively, also were produced. Following milling and flotation, all concentrates were shipped to smelters in western Europe, Japan, and South Korea. Preliminary figures showed that the overall value of mineral production in Alaska increased 27% in 1989, and this was mainly attributed to the metal concentrate production at Greens Creek. Mine development costs amounted to about 40% more than original 1986 estimates, and that rise was attributed to poor weather, safety investigations, breakdowns, and equipment adjustment. In the spring, secondary

explosions hot enough to melt ventilation tubes occurred within seconds of blasting on two separate occasions. Fortunately, no serious injury occurred, but the high-grade ore zones were closed for 6 weeks to solve the problem. Use of a sprinkler system to saturate the mine walls and the ambient air during blasting operations apparently solved this unusual problem not reported in a U.S. mine since 1941. The puzzling explosions were determined to be caused by the buildup of fine-grained sulfide dust after blasting in the massive sulfide ores. The primary ore extraction method was drift-and-fill, and cut-and-fill techniques were used in steeply dipping areas. Mine life based on proven reserves was estimated to exceed 10 years.²⁶

Red Dog Gearing Up.—The Red Dog open pit mine in remote northwest Alaska began somewhat abbreviated production in late November. The zinc-lead-silver deposit was the largest known zinc reserve in the United States and, according to Cominco, was the third largest zinc deposit ever discovered. The milling complex was completed, and the first concentrate was produced on schedule. However, some plant deficiencies, including a concentrator operating at one-half of capacity, and work slowdowns at the mine owing to early winter weather slowed down the anticipated startup pace. Mine development was on schedule with full operation expected by the end of March 1990. Production was expected to reach full capacities of 560,000 tons [508,000 metric tons (mt)] of zinc and 120,150 tons (109,000 mt) of lead concentrate per year in 1992. Development costs were relatively high, totaling about \$420 million, but that was considered worthwhile because of (1) the high ore grade, 17% zinc and 5% lead; (2) a very low average overburden-to-ore strip ratio, 1:1 or less; and (3) known reserves indicating a mine life of 50 years at about 6,600 tons (6,000 mt) per day. Greens Creek and Red Dog were the first major base metal mines to be developed in Alaska since the 1930's.²⁷

Low Budget and Efficient

Amax Gold Inc. commenced production at its Wind Mountain gold-silver heap-leach project in western Nevada in the spring. The low-grade, abrasive (highly silicious) gold deposit, passed up by several companies because of ore grade and location, was developed with a minimum

of contractors. The company chose to use its own personnel from such projects as its productive Sleeper surface gold mine to the north and completed construction of Wind Mountain in about 4 months. Much attention was paid to detail, planning, cautious selection of a significant amount of used equipment, and selection of skilled, industrious personnel in making the marginal near-surface project profitable. The total size of two equal heap-leach pad areas was about 3 million square feet, the majority of which was leached by the increasingly popular drip method. Cash production costs for 1989 were in the range of \$265 per troy ounce of gold and silver combined. Wind Mountain had an anticipated 4.5-year mine life with an annual output of 42,000 troy ounces (1,300 kg) of gold and 7.5 times as much silver. Close to 70% of the gold was sold up to 4 years ahead of time to add some security to the \$17 million project. The Wind Mountain property was close to the prehistoric Lake Range Quarries, where early human beings mined materials to make tools. Amax funded an archeological study of the area from which a Bureau of Land Management archeological team acquired significant amounts of data as well as some artifacts.²⁸

Return to Historic Mining District

The last major gold rush in Nevada and the first made by automobile occurred partly in southern Nevada's Bullfrog Mining District. Substantial precious-metal development returned to the area with the opening of the Bullfrog open pit gold mine. Bond International Gold, Inc. expected average yearly gold production to be 220,000 troy ounces (6,800 kg) with almost as much silver during its first 2 full years of operation. Greater annual production was anticipated thereafter during a 5- to 7-year mine life from approximately 1.8 million troy ounces (55,700 kg) of proven and probable reserves of gold. The company completed construction of the mine and conventional processing complex in 11 months and commenced production on September 1st. Unlike Amax, Bond hired a contractor to do the mining, freeing the company from purchasing its own equipment. Bond personnel did all ore beneficiation, electrowinning, and electrefining to produce doré and neared full production levels by yearend. Ongoing

exploration indicated more reserves and a potential for future underground mining.

Bond paid close attention to the mine's impact on the environment and the local community. The Bullfrog Mine was near the historic Nevada mining camp of Beatty, and it was directly adjacent to the remains of the old gold-mining boom town of Rhyolite, where one-half dozen people still lived in a few remaining buildings. A major local highway leading to Death Valley National Monument, CA, strategically separated the mine and processing complex from the tailings pond area. If a heap-leach pad was ever to be built, it would probably be constructed next to the pond because of the perfect slope, size, and lay of the land. Also, Bullfrog was situated close to the tourist town of Beatty, NV. Among other projects, Bond increased the quantity and quality of the town's water supply by drilling a new well, and it provided funds for expansion of the Beatty school system. Bond drew from the valuable past experience of developing the Colosseum gold mine in an environmentally sensitive area of California. (See Mining and Quarrying Trends chapter in the 1988 Minerals Yearbook.) Control of dust was crucial at Bullfrog. The company controlled dust by continuously spraying water at the mine, on the haulage roads, and in the covered ore conveyors. All ore, even low-grade ore not economical for conventional processing at then-current prices, was stored in buildings to control the dust. These buildings were painted in appropriate colors to blend in with the desert landscape as naturally as possible.²⁹

Instrumentation

Microcomputers and Modeling.—Since about 1984 mining industry professionals, such as geologists, mining engineers, and metallurgists, progressively increased their use of the microcomputer in their day-to-day work. Besides speeding up general office duties, this relatively new tool of the trade was used to store drill-hole data and equipment and flowsheet information as well as perform calculations on this same data. With specialized software, a computer can generate maps and other graphics, such as three-dimensional views and interactive design of mine plans and flowsheets. Another use was that of modeling geological and geophysical data throughout the entire life of a mine from exploration

and development through reclamation of the land. Modern microcomputers were powerful enough to handle the vast numbers of calculations and cross calculations between different sets and types of data that only larger computers could handle not too many years before. Three-dimensional descriptions of a deposit were routinely generated. Mining and mineral processing methods could be tested or computer-simulated and optimized. The performance of many mining and metallurgical operations could be "optimized" in a variety of ways, such as in the selection of the best pit scheduling, the best maintenance plan, or the best size plant equipment. A growing number of methods were being adapted to deal with such factors. Microcomputer simulations of a process or method were similar to conducting a pilot project, but at much lower cost. In mining, simulations consisted of testing alternative equipment and methods on models that represented the ore body or the operation of the mine or mill. Another example of the application of modeling was found in inversion methods. If looking for an ore body with a density of at least 3.2, inversion methods could be applied to gravity data to determine if this was possible, and if so, what was the shallowest possible depth.³⁰

Vibration Measurement and Control.—Microchips and microcomputers have contributed many sophisticated advancements in the blasting industry in the form of electronic timers, accurate caps, complicated blast delay timing schemes, laser face measurements, and nonelectric firing systems, among others. A new technique using miniature computerized seismographs, called the Iso-Seismic System, was developed by Geosonics Inc. of Warrendale, PA, to measure vibration transmission through the subsurface in much greater detail than had previously been practical to do. All vibration data was collected with 100 or more miniature seismographs, called micro-seis units, each of which was a self-contained computer recording device. Following proper operational programming of all units while plugged into a large main board, the units were removed and distributed from 100 to 1,000 feet (30 to 305 m) from the blast site. After recording 1 to 20 separate detonations, this information from the units was downloaded through the main board to a master computer. Specialized software was used to analyze recorded data and the units' exact locations along with

appropriate local data, such as the locations of local significant structures and the mining operation perimeter on a pre-established coordinate grid. Results were displayed on a series of two- and three-dimensional topographs, similar to geologic, equal-elevation, contour maps. The vibration topographs represented areas of equal particle velocity or frequency, vibration intensity differences between two separate blasts, or the percentage of the Bureau of Mines recommended vibration limits that were encountered.

Geosonics noted several potential benefits of the system. With the knowledge gained from each analyzed blast, mine operators could map and understand subsurface anomalies that amplified or attenuated vibrations in specific directions to assist in planning future blasts. Presentation of this scientific information to zoning boards, regulatory agencies, and planning commissions could help to illustrate the effect blasting was having or would have on a community. Often such assessments had previously been dependent on individual seismograph readings and/or the subjective perceptions of various observers or local property owners. Greater control over the vibration effects during blasting could reduce a variety of problems and improve relations with neighbors.³¹

Vertical Borehole Direction Control.—An automatic steering device that gave a reported $\pm 0.1\%$ accuracy during field testing was developed in a joint project between Bergbau-Forschung and Schwing Hydraulik Elektronik GmbH & Co. of the Federal Republic of Germany. The ZBE 3000 directional drilling device utilized concurrent rotary drill stem action to provide power for its built-in generator. The internal inclinometer was designed to detect deviations down to 1 minute of arc from the vertical, and the device was claimed to be effective to a depth of 600 m. The inclinometer generated an automatic correction signal in its control circuitry which, in turn, activated hydraulic clamping cylinders. The cylinders pushed steering runners against the side of the borehole until true vertical direction was restored. To monitor the system's position and log data, the ZBE 3000 utilized the drilling fluid as the data transmission medium. At 5-minute intervals, information was transmitted as pressure pulses by means of an electronic transmitter. Resultant pulses were fed into a differential pressure receiver, converted back into electronic signals,

and sent to a data terminal for decoding, logging, and visual display. Among other applications, the company claimed that the device was particularly useful for pilot-holes before shaft boring where truly vertical holes were essential. Geosonics continued work on the development of a multidirectional version of the device for straight hole drilling at an inclination to the vertical or in the horizontal plane.³²

UNDERGROUND MINING

Mechanized Tunneling

The National Research Council of Canada provided partial funding for a joint venture headed by the Canadian mining company Falconbridge Ltd. to design a new, fast and efficient tunnel boring machine (TBM) specifically for the mining applications. The Compact Underground Borer (CUB) machine was the result. The CUB's initial customer was Falconbridge's Fraser nickel-copper mine, near Sudbury, Ontario, where it was needed to economically speed up the advance rates of the mine's underground drifting. The other design requirement for the CUB was that it be capable of rapid assembly and disassembly to enable quick movement from one job to the next. Disassembled, its components were small enough to traverse shafts and openings of less than 6 feet (2 m) in width. In operation, the machine's overall compactness allowed it to bore curves down to a radius of 85 feet (25 m). In its first application, the 8-foot (2.5 m) diameter cutter head, including 20 special 18-inch [450 millimeter (mm)] diameter rock disc cutters, was to be used to bore through hard rocks of up to 45,000 pounds per square inch uniaxial compressive strength, as are found in many Canadian mines. The high density of the cutter arrangements was combined with a thrust of reportedly more than 1.1 million pounds (1/2 million kg). With the addition of a second gripper module behind the standard cutter module, the CUB was said to be capable of performing as a boxhole or raise borer. It could cut steep raises such as inclined ventilation openings, decline ramps, and inclined conveyor drifts. The designers projected a normal advance rate of a little more than 3 feet per hour (1 m) and anticipated that it would prove to be well suited to many civil engineering applications.³³

The Stillwater Mining Co. (SMC) also decided to use a TBM to speed up the development of footwall drifts at its platinum-group metals mine in the Bear-tooth Mountains near Nye, MT. In 1986, mining commenced at this mine, the first and only primary platinum-palladium producer in the Western Hemisphere. To fulfill recent ambitious expansion plans, the mining company chose mechanized tunneling for developmental drifts over the slower conventional drill-and-blast method previously used. A used 4-m diameter Robbins TBM with its original cutterhead was selected. After cutting two successful drifts while the mine personnel were learning the use of the new equipment, a third drift was cut using a new cutterhead designed more specifically for the hard, mafic gabbro, norite, and anorthosite rocks of the mine. The fairly good performance already achieved improved considerably. A new development drive by a second TBM on the opposite end of the mine was soon to open up a larger mine section with 2,000-ton-per-day (1814 mt) ore production, double that of the present mine. Stillwater professed many advantages of its choice of TBM's. The mechanical underground tunneling of footwall laterals was costing one-third less than traditional drill-and-blast methods. Less rockbolting was necessary on the smoother surfaces of machine-bored tunnels. The round smooth-surfaced tunnel profile improved tunnel ventilation. Even more important to Stillwater, the overall development of the mine was taking much less time than similar work had previously taken them. The second tunnel, 5,000 feet long (1,524 m), was driven in 3 month's time.³⁴

Computerized Equipment Dispatching

During the past decade, Modular Mining Systems Inc. of Tucson, AZ, had been a major developer of computerized dispatching systems for surface mining operations. Acceptance of this type of technology was growing. Modular had completed one-half of its total of 25 system installations in the past 2 to 3 years. With complete real-time knowledge processed through a central computer, appropriate mining equipment, such as excavators, loading shovels, haul trucks, and crushers, could be monitored and controlled. Work duration times for individual tasks and current equipment locations were communicated and proper scheduling executed via digital data radio.

The result reportedly was completion of the normal tasks at hand in a most efficient and safe manner. The company claimed that its surface systems were responsible for mine production increases ranging from 10% to 23%. Recently, Modular completed development of a computerized dispatching system for underground mining applications. The system was designed to allow the mine manager to control ore-mining and ore-hauling equipment from a control console on the surface. The company planned installation of what it said was the world's first underground computerized dispatching system at the Finch Mine in the Republic of South Africa during 1990. Political difficulties had slowed down the contracting process, and arrangements were made through an intermediary company instead of the mine owner, DeBeers Consolidated Mines Ltd.

Continuous Haulage

Finding a continuous automated alternative to the traditional drill-and-blast mining methods has been an ongoing area of research and development efforts for many years. The softer, flatter, and more uniform the material, the easier the mechanization of mineral extraction machines becomes. Coal is usually a relatively soft and brittle material and can be followed more easily than more typical winding and disjointed mineral ore bodies because coal is relatively flat bedded and of uniform thickness. Hence, coal mining is well suited for the development of such machines as continuous miners and longwall shearers. Other minerals, which for similar reasons may be appropriately recovered by continuous mining technologies, are potash, salt, and trona. Applications of continuous mining equipment for mining these industrial minerals have been continually increasing, supported by the same technological advancements that have occurred in the coal sector. Developing a continuous haulage system to complement the new and innovative machines was as much a challenge as designing the continuous excavation machines themselves. In recent years, a number of mobile and semi-mobile continuous conveyors and haulage systems had been developed and successfully installed at mining operations. Although often costly, these initial developments were helping to bring automated mining closer to the totally continuous ideal.

Mobile-Bridge Conveyors.—New Mexico Potash Co. added a system of bridge and mobile-bridge conveyors to continuous miners at its underground potash operation in New Mexico by linking the conveyor beltheads directly to its mining machines. The Full Dimension Continuous Haulage System was developed by Long-Airdox Engineering Co. of Mount Vernon, KY, and this mine was the first noncoal application of the system in North America. This system did not introduce new technology so much as demonstrate the harmonious adaptation of the equipment to a new mining situation. Long-Airdox had installed a similar system in a bauxite mine in Italy four years before. A train of highly mobile, crawler-mounted chain conveyors replaced New Mexico's fleet of shuttle cars. The chain-type system was chosen over a similar belted system because it was more reliable and sturdy, though noisier, and it could break up jams better in the potash, which was harder and more dense than coal. The new system provided a continuous, uninterrupted flow of material from the face direct to an artery of the main conveyor haulage system, which then flowed to the surge bins at the production shaft.

Although application of this technology was relatively new, the miners found that the continuous miner became more the limiting factor. Initial use of the system reportedly increased productivity 30% to 60% over that of traditional shuttle cars, which forced a halt to face advance with each shuttle car change. Further comparative tests showed that a small continuous miner working with a bridge system would out-produce a larger continuous miner working with diesel shuttle cars. Personnel levels and ventilation requirements for the two different systems were about the same. Elimination of diesel pollutants was compensated for by the added heat generated by the continuous miners working long headings without stopping. Ambient air temperature was 78°F in the underground workings, which were 1,650 feet (503 m) below the surface. New Mexico Potash operated 10 days straight with two production shifts and one maintenance shift per day, followed by 4 days off with no maintenance except major work.³⁵

Continuous Trona Production.—Stauffer Chemical Co.'s Big Island trona mine in Wyoming added a continuous haulage system to its continuous mining

faces in 1988. The annual percentage of ore mined by the continuous miners increased from 2.4 % in 1984 to 13.9% in 1988. The company was accelerating its transition to the modernized mining system and was aiming to achieve 100% of its annual ore production with continuous mining methods by 1992. The company claimed that its successful use of continuous miners with the added continuous haulage was the result of well-controlled implementation, supportive equipment manufacturer assistance, and a willingness by mine employees to learn and improve on novel mining methods and technology. This last factor has often been cited by mining professionals in this age of new technologies as one of the most critical yet toughest with which to deal. Although new technology, especially in the form of large fast-moving machinery, can be attractive and challenging to miners, it can be very threatening to the average worker. Stauffer claimed that success with the three factors previously listed had led to constantly rising production standards and a more efficient operation. The company believed that the potential for using continuous mining methods and equipment in similar deposits had been realized in its mining operation.³⁶

Longwall Mining of Trona

Longwall shearers also are technological advancements that owe much of their origin to the coal mining industry. Longwall had become the chief mining system used throughout Europe for mining underground coal deposits. It also accounted for about 30% of deep mined coal from almost 100 installations in the United States. FMC Wyoming Corp. in Green River, WY, the largest producer of trona (sodium sesquicarbonate) in the world, continued its innovative approach to mining at its southwestern Wyoming trona operation. Trona ore is the natural material that is processed into soda ash, versus soda ash that is synthetically produced. Soda ash is a raw material of major importance in the manufacture of detergents and glass products. In the spring, FMC reinstituted longwall mining of trona in the Green River basin area. This method was added to the already aggressive use of mechanized, continuous borer and fixed-drum mining machines in its room-and-pillar operation and to FMC's solution mining of some of its deeper ore deposits.

FMC chose the all-electric EDW 450/1100-L double-ended ranging drum shearer. It was supplied by Eickoff Corp., based in Pittsburgh, PA, from the parent manufacturing company in the Federal Republic of Germany, and was the largest and most technically advanced shearer that the company built. The EDW 450 was capable of cutting seams from 7.5 to 11 feet (2.3 to 3.5 m) thick and this permitted FMC to significantly increase production in its high (thick) ore seams. The electric cutting machine rolled along on a 410-foot (125-m) conveyor and was controlled by one miner using a handheld remote radio device. Whereas FMC pioneered the solution mining of trona, FMC engineers were not the first to introduce longwall technology to the Green River area. They were basically reintroducing it and replacing an old and less powerful machine that became uneconomical to operate several years before. That past longwall experience with the tough trona material led the company to obtain the maximum weight and power output combination that they could buy and still receive good service support from the manufacturer in the United States.³⁷ Longwall equipment was initially a more expensive capital investment than conventional mining machinery, but this was normally offset by higher yields and increased safety. Ore extraction could be more than 80% efficient compared with as low as 50% by room-and-pillar methods.³⁸

Underground Safety and Comfort

Among products developed by manufacturers to make mine conditions better and safer for the individual underground miner was a new miner's cap lamp. The lamp, promoted as giving 60% brighter illumination than conventional krypton-filled bulb lamps, was offered by MSA International of Pittsburgh, PA. The Ultralight cap lamp system used a tungsten halogen bulb and a computer designed reflector to maximize light output. More than 90% of the light was focused into an extremely tight prefocused beam. MSA claimed that it consumed less battery power and ensured brighter output over a full shift without any reduction in bulb life, rated at 300 hours service life. Halogen bulbs, which had become common in the everyday nonmining world, had brighter light than conventional bulbs, and MSA claimed that they would provide better illumination of the

workplace and reduce the eye strain of the miner.³⁹

SURFACE MINING

Novel Electric Detonation

Preferential use of safer nonelectric initiation when blasting continued to be increasingly popular, but electric detonation remained very common because of its significant benefits, such as the ability to check the continuity of the blasting circuit. This benefit helps ensure miners of no or fewer hole misfires but always causes concerns about radio-frequency radiation or stray currents inadvertently causing premature detonations. Nobel Explosives Co. Ltd. of Ayrshire, Scotland, the United Kingdom, developed a new way of stringing together electric initiation systems for multihole blasting. Its Magnadet system, in a modified version, was being used in eight surface mines in the United States, following previous applications in European and South African mines. The system used the electromagnetic property of electric flux, the basis for the functioning of transformers. Any change of current in an electric circuit produces an alteration in the magnetic field around it, and the accompanying change in flux sets up an electromotive force in any circuits nearby. The Magnadet detonators were actually small, frequency-selective transformers, which could only be activated effectively by an alternating current blasting machine set within a specific range of high-frequency currents. The company reported that a standard direct current or the standard 60-hertz alternating current used for main power in the United States would not work. The company also claimed that the detonators were immune to radio frequency radiation and could withstand high electrostatic energy discharges, such as those that could be built up on a poorly grounded ammonium-nitrate-fuel oil explosive truck. Circuit checks were conducted with a standard blasting ohmmeter. According to some of the U.S. users, the Magnadet system was fairly simple to set up, resulting in overall blasting costs being comparable with other systems.⁴⁰

Excavation Equipment

Hydraulic Face Shovels and Excavators.—A Norwegian company, Brown

Engineering (Bryne) A/S, introduced several hydraulic face shovels and excavators, which they redesigned for more efficient and economical operation. Brown used the prior proven superstructure, powerplant, hydraulic systems, and boom arrangements of its wheeled face shovel machines and propelled them on new tracked undercarriages for greater overall stability as well as digging stability. A new speed-sensing power control hydraulic system was the adaptation which, the company claimed, considerably increased the hydraulic efficiency of the newly tracked machines. Also, its dual speed range control system made it possible to change between high- and low-speed ranges while in full operation. Brown claimed that savings of up to 50% had been recorded, compared to machines of a similar production capacity. A tracked backhoe version was offered with hard-rock capabilities, and the new machines followed the current trend toward increased automation with fully automatic centralized lubrication systems for easier and more reliable maintenance.⁴¹

Largest Shovel Dipper.—An all-cast manganese steel power shovel dipper, believed to be the world's largest, was recently produced by the New Jersey-based Amalloy Corp. The dipper weighed 97,000 pounds (214,000 kg) and had a nominal capacity of 34 cubic yards (26 cubic m). The initial unit was produced by Amalloy's Amsco foundries in Quebec and Manitoba, Canada, and was in use at a southwestern U.S. copper mine. Three more were in production at the Quebec plant. According to the company, new design refinements, including a wider lip, revised lip angle, shorter lip-to-door distance, and a reduced back angle, increased power shovel efficiency. Other features, such as an arched back and an unloading door opening that was larger than the front opening, reportedly increased the effective maximum load capability of the dipper. Amalloy maintained that the new design changes reduced or eliminated empty spots, allowed more rapid emptying, and increased the unit's anticipated wear life.⁴²

Steep Incline Conveyor

Several newly developed high-angle and versatile ore conveyance systems were brought on the market in the past few years. In some instances, they were

developed to fulfill the demands of steeper open pit operations, more cramped surroundings (land relief or existing buildings), or other situations calling for a curvy and rolling route to the dropoff point. Many mining operations shifted to the increasingly popular and commonly more economical practice of in-pit crushing. Much more finer grained material than before had to be moved to the grinding mill and processing plant, and conveyors, overall, were the least expensive route. Various innovative concepts had been used in their development, such as wide belts progressively enveloped by idlers into an enclosed pipe structure and doubled "sandwich" belt systems that could convey materials at angles of up to 90° vertically.

One of the newest steep-angle conveyor systems, the Hurise system, was developed by Huwood Conveyors of the United Kingdom. The system was designed to operate between a 20° and 70° inclination uphill or downhill and had a rated capacity of 800 metric tons per hour of material sized at one-third belt width. According to the company, the design incorporated two new concepts in material handling of this sort—a moving bed chain elevating conveyor and a torsion bush chain design. The system consisted of a troughed conveyor belt joining in parallel operation with a chain conveyor at the feed section. Scoops or paddles attached to the chain conveyor were profiled to the shape of the troughed belt, and when running in unison the paddles propelled the material up the conveyor or held it in place when running downhill. The main haul section could be lengthened or shortened by adding or removing 5-m modular design structure sections. Before discharge, the two conveyors parted company on a normally flat to shallowly inclined section (up to 18°), after which the main troughed belt section continued to the discharge point. Runback was prevented by using a series of intermediate brakes, and loading could take place on the incline as well as at any place along the system's length. Huwood added the extra touch of fully remote-controlled operation.⁴³

The increasing use of remote control by addition to standard machinery, as well as more research into complete remote operation of various mining procedures, were evergrowing trends in efforts to develop new technologies and advanced mining methods. Use of remote

control had both production and miner health and safety benefits. In mining as well as in most other vocations, the new science of ergonomics (engineering and design influenced by human factors) was going well beyond the art of designing comfortable office chairs. Ergonomics conscious companies were recognizing the importance of designing sophisticated equipment to fit the cognitive, psychological, and sensory requirements of its users. Removing the miner from the many dangers associated with mining was a priority. These dangers and problems included loud noise, small quantities of respirable dust, and simple tension-producing vibrational discomforts, as well as the more dramatic fire, roof falls, and unsafe mechanical equipment.

Growth of In-Pit Crushing

Approximately 140 mobile and semi-mobile in-pit crushing units for surface mines and quarries were installed or put on order from 1956 through 1987, and interest in them continued to grow. The first mobile crushers were introduced in the limestone-cement industry in the 1950's in the Federal Republic of Germany, and even in the late 1980's most large-scale, mobile and semimobile crushing plants were designed or built by West German manufacturers. Krupp Industrietechnik and O&K Orenstein & Koppel dominated the market. The vast majority of all installations were in quarries producing limestone for cement or other rock products. Interestingly, some 16 of the total installations had throughput capacities in excess of 3,500 mt per hour, and they were almost exclusively in coal and metal mines for crushing ore and overburden. Most large units were semimobile, only 2 of the 16 largest being fully mobile. In the previous 2 years, many of the important new or soon-to-be-completed installations worldwide were in copper or gold hard-rock open pit mining operations. Crushing units potentially could be gyratory, impact, twin-roll, or jaw crusher systems, but all of the recent installations previously referred to used or would use large gyratory crushers. Gyratory crushers were normally selected for big installations because of an unrivalled capacity for crushing the hardest rock, but, in softer overburden and coal, the increasing use of roll crushers was anticipated.⁴⁴

Sizer-Style Roll Crusher.—New design principles were expected by some experts to play an increasing role in in-pit crushing machines. A size-reduction principle was used in a new roll crusher introduced by Mining Machinery Developments (MMD) of England, United Kingdom. MMD incorporated some functions of a sizer machine into a roll crusher and obtained size reduction by a combination of shear and tensile forces. This resulted by applying more precisely directed breaking forces and fewer indiscriminate forces typical of similar machines. Rock was crushed by means of twin, inwardly rotating shafts. On these were mounted a series of toothed rings fitted with less costly, replaceable wear caps. Large-size teeth in special configurations were rotated at low speeds to reduce wear and facilitate the handling of wet and sticky materials without buildup or stalling. The tooth and roller units were designed to require no prescreening of undersized material and to act like a rotating screen to direct passage of that material through the machine. Material to be broken was introduced to the teeth in such a manner as to take advantage of the low tensile strength of rock. The company claimed that higher capacities and reduced power consumption was the result. Roll crushers, because of their relatively small weight and size, were well suited to mobile or semimobile installations, and output from them was considered respectable. After first being introduced in rock quarries, they were also used in several open pits, including coal mines in Australia and in crushing kimberlite in diamond mines in the Republic of South Africa.⁴⁵

Mobile Crushing and Conveying.—Semimobile, cellular constructed, in-pit crushing units, have brought primary crushing stations to the mine site and helped streamline many open pit and quarrying operations. However, as the mine faces advance farther away from the unit, ore haulage distances to the crusher eventually necessitate moving the unit. The smaller the mine the more critical the purchase or relocation of such equipment can be. The execution of such moves, though usually well-planned and kept to a minimum, requires an expensive delay in the running of an operation that includes constructing suitable foundations for new semifixed installations. Lokomo Crusher Works of Finland developed its line of Lokotrack crushers to address this problem. The result was

an innovative, self-propelled in-pit crusher, that could be easily moved to the broken ore on its tracked chassis, and after crushing be backed away from the new mine face for subsequent blasting. When linked to a series of mobile conveyors, the need for a fleet of haul trucks was eliminated. One such operation was working successfully in the United Kingdom at ARC Ltd.'s Silverdale stone quarry in Cumbria, England. ARC reached the point of excessive haulage costs with its fixed primary crusher and had related expansion problems resulting from environmental restrictions. Lokomo's local subsidiary, Lokotrack, Nordberg (U.K.) Ltd.; the English mobile conveyor manufacturer, B&W Mechanical Handling Ltd.; and ARC together developed a system that they believed had the potential to cut operating costs by up to 40%. The system comprised a Lokotrack model 125, which was a track-mounted, diesel-powered primary crushing unit with a capacity ranging from 250 to 400 mt per hour. The unit discharged directly to a pair of B&W self-propelled mobile conveyors developed specifically for the Silverdale operation. These were conventional except for their wheel arrangements which, with 270° rotation capability, allowed a high degree of mobility. The wheel technology used in large loading conveyors at shipping ports made this possible. At Silverdale, the total time taken for placement of the crushing and conveying equipment was about 20 minutes in each direction. In the first 9 months of operation, ARC reported operating cost savings of about 8%. Primary units could be equipped with either impact or jaw crushers, and secondary and tertiary gyratory crushers could be added to the system. Since first developed in 1985, Lokomo had supplied more than 100 Lokotrack units to operators in different parts of the world. A fully remote-controlled model was under development that would enable the operator of the loading machine also to supervise the operation of the crusher.⁴⁶

Microwave Remote Control

A microwave communications system was used to tie a programmable logic controller (PLC) to its remote input/output (I/O) modules at the large open pit copper mine of Phelps Dodge Morenci Inc. in Morenci, AZ. The microwave system was needed to permit a centrally located PLC to communicate over rough terrain to the I/O regulating panels. These units

controlled mine water distribution from storage sites large distances from each other. Use of this remote-controlled system was claimed to be the first such application of the developing communications technology in a mining situation. Microwave was chosen over cable because of the constantly changing mine contour, the distances which needed to be covered, and past experiences with wireline equipment that was repeatedly damaged by lightning. Additionally, a pole line carrying coaxial cable around the pit would need to be more than 15,000 feet long, and this was beyond the maximum range of the regulating I/O driver regulating equipment. In one segment, a single 5,900-foot-long transmission medium was needed to reach across a corner of the extensive pit. The PLC I/O system automated, in a series arrangement, water distribution from the mine's three storage sites to suit the mine's raw water needs. Communications reliability was essential because of limited water supplies that served the needs of the extensive mining operation. For example, one of the three water storage sites only provided 4 to 6 hours of the normal daily mine consumption, so proper scheduling of water transfers from the three sites was necessary. Phelps Dodge Morenci instrumentation electricians, using available components, designed and installed the system.⁴⁷

REMOTE MINING

Government Research

In Situ Leaching.—The Bureau of Mines proceeded with work on a variety of new and advanced mining methods to make underground mining safer, to make economic those ore bodies that were previously of too low a grade or too deeply buried, and to increase productivity in a time of growing worldwide competitiveness. The Bureau continued work on two methods that offered the most promise for significant success: in situ leaching, and a variation of the same, underground stope leaching. For more detail, see the Mining and Quarrying Trends chapter in the 1988 Minerals Yearbook.

Beyond initial applications to uranium mining, the majority of recent research and pilot project work, both public and private, had been on copper deposits. During 1989, the Bureau initiated a research project to investigate the technical

and economic feasibility of applying in situ leaching technology to the mining of domestic manganese deposits. Laboratory column leaching experiments were conducted using iron-manganese ores in which manganese recoveries ranged from 70% to 90%, while removing only 10% to 30% of the iron. The ores started as 18 to 50 weight percent iron and 5 to 18 weight percent manganese. Experiments were also conducted on several ore types from domestic manganese deposits in Arizona, Minnesota, and Nevada. Better definition of the dissolution and complexation reactions were to be sought for each ore type. These experiments provided input for the development of an in situ mining process for manganese oxide ores. Work was to continue in 1990 with drill cores and site-specific field data from two manganese deposits.⁴⁸

Ongoing Automation Research.—A fully automated continuous miner or other mechanized mining process was believed to be at least 20 years in the future. The removal of the miner from the dangers of the mine concurrently with the development of cost-effective, efficient, and more productive and profitable mining procedures were the ultimate goals. Novel technologies brought into the mine gradually meet with less resistance than quick introductions because of the sometimes slow pace of human acceptance of the new. The similar rate of current technological progress would likely ensure that new technology would not be introduced any more quickly. The Bureau of Mines progressed with projects in computer control and automation of continuous miners and roof bolters, the development and application of expert systems, and the development of various machine guidance systems. Computer systems and software would be the means of emulating the human operator's capabilities. Bureau scientists took a practical approach to advanced automation. A machine operator's tasks were examined to identify the research and development topics critical to the development of an intelligent mining machine. Researchers observed that an operator had to *guide* a cutting *machine* tool *within* an *ore* seam or body following a *plan* that could be *altered* by local conditions and events. Those key words, *guide*, *machine*, *within ore*, *plan*, and *altered* provided guidance for automation development work. Tying all these functions together was the challenge that scientists faced, and this data gathering and information

processing would likely be accomplished by a complex computer system.

Continuous miner guidance work was divided into lateral and vertical systems. Lateral referred to positioning the machine laterally within the open space of an entry, and vertical referred to keeping the machine within the coal or ore body. Lateral navigation, most important in the face area, required sensing systems to rapidly provide machine location coordinates, machine heading, and also the location of obstacles, such as ribs, face, and corners. The machine guidance system under development used multiple laser-based scanners for determining position and heading angle. The range of the laser scanner could be increased by using a more powerful laser and more sensitive detectors. The laser system, with gyroscopes and a flux-gate compass, both mounted on the continuous miner, were being individually evaluated for performance and accuracy. Control and analysis software was also being developed. Ultrasonic ranging techniques were being investigated for determination of rib and concave-convex corner positions. A thorough investigation of ultrasonic ranging transponders was completed that indicated response levels to real mine surfaces. Because of known limitations in the individual sensor systems, future sensor-based machine guidance would require data integration between all of a machine's systems and the utilization of the most accurate readings to update references used by other systems. Vertical control developments centered around the detection of fundamental properties of the strata. Sufficient advances had occurred in technologies used to discriminate between differing electrical signals, such as those generated by accelerometers that measure machine vibration or seismic variations between coal or ore body and the adjoining strata. The Bureau was investigating whether the differences in these vibrational signals were significant and consistent enough to allow detection of the adjoining strata and subsequently signal the machine to make adjustments in cutting height.

Another area of active investigation was in the use of an infrared camera that displayed in different colors differences in temperatures at the cutting surface. Recent experiments had shown that there could be a detectable difference in cutting-bit and dust temperature even with the use of water sprays. A system to constantly monitor video images could

be used with such a system to control the cutting. Researchers believed that, in the long run, multiple sensor systems would be needed and that data would require computer filtering to indicate the best estimate of either the location of adjoining strata or coal or mineral deposit thickness.⁴⁹

Dredging

Throughout the world, long-established gold alluvials were being reworked, and, in many countries, small-scale miners were using basic, rudimentary methods. Although gold was the most glamorous placer associated with placer mining, it was by no means the only one. All the world's mineral sands came from alluvial deposits as did much of the world's tin. Alluvial material mining methods were also used to mine phosphate, potash, salt, and other industrial minerals. Alluvial mining was essentially a low-grade and high-capacity business, and the dredge was its workhorse.⁵⁰

Dredger Control System.—Among several sophisticated monitoring and control systems for dredgers was the Survey and Dredge Control System (SDC), developed by Meconaut Ltd. of the United Kingdom. The system was designed to fully integrate survey information and resultant positioning and functional control for ore-layer dredging with bucket-wheel dredgers. The company maintained that the SDC could accurately and automatically control the dredging of soil layers as defined by the survey system that it incorporated. Meconaut produced four systems of increasing performance range that were designed for cutter dredgers but could be applied to cuttingwheel and bucketwheel machines as well. The system used a standard hardware-software survey package installed on a survey launch to produce bathymetric charts and cross-sections of the underwater area being excavated. Borehole data could be integrated with this data to determine ore layers. When dredging, all necessary data were used by the dredge control computer to guide the cutting wheel over the selected path and dredging profile using the machine's positioning system. One of the most sophisticated versions included the Automatic Wheel-dredger Controller (AWC), which could adapt its control to varying soil and other irregular conditions. It monitored all functions, displayed them on a screen with setpoints, and could be manually overridden. System design features

included the capability to calculate the quantity of energy used for each cubic meter of dredged material and the total energy used during a chosen time period.⁵¹

Deepwater Dredge.—An interesting development in deepwater dredging came from Alluvial Mining Ltd., United Kingdom, in the form of the Tramrod, a remote-controlled seabed dredging vehicle capable of operating at depths of 100 m or more. A prototype was used in 1988 to level the seabed around an oil platform in the North Sea. The company reported that in 1989 the same machine, with modifications, had begun successful experimental trials of seabed mineral mining in the United States. Tramrod was a tracked vehicle that was designed to scour and clean up bedrock in conditions where standard cutter dredges could not operate. It reportedly could negotiate rough terrain and slopes greater than 45°. The vehicle was controlled from the surface, and its progress was monitored by two or three underwater television cameras. The suction head consisted of a special jet pump that sucked material from the seabed and pumped it to the surface. Alluvial claimed that Tramrod could handle solids of up to 250 millimeters in diameter at throughputs from 40 to 200 cubic meters per hour, depending on the materials.⁵²

BENEFICIATION

Developments in Comminution

New Technologies-Larger Mills.—In recent years, steady progress had been made in the development of more advanced milling machinery. Technological developments in basic design, adaptations of large wraparound motors, and new manufacturing techniques resulted in the building of ever-larger mills. The world's largest mill, an 11.25-megawatt, 36-foot-diameter by 15-foot-long (10.97-m by 4.57-m), semiautogenous grinding (SAG) unit was being installed in the El Teniente copper processing plant in Chile. Other recent similar installations included three 34-foot-diameter SAG mills of equal length at the Bingham Canyon Copper Mine in Utah and two of the world's largest ball mills at a plant in the U.S.S.R. These new mills were being designed and manufactured to far more stringent reliability standards than those that preceded

them. The cost of downtime for such a large mill was significantly greater than that of one of two smaller machines. Some of the benefits of larger mills were lower capital costs per unit of throughput and, in the case of autogenous (AG) and SAG mills, the elimination of secondary and tertiary crushing. Overall, maintenance costs and media consumption were lower, and generally, fewer operators were required. Operating-cost savings were reported to be as high as 30%. AG and SAG milling reportedly was gaining in popularity, both for high-tonnage operations and increasingly for moderately sized plants of 3,000 metric tons per day or less, especially where wet, sticky, high-clay ores were encountered.⁵³

There were disadvantages to the large machines. Their enormous size meant that they needed to be optimally (amply) loaded to take full advantage of their economies of scale and produce the most consistent product. Less than optimal loading results in varying throughputs with possible attendant changes in ore hardness and sizing. Variations in throughput and product size could have additional deleterious effects on downstream processing. With AG and SAG mills, far greater adjustment of feed tonnage was necessary to avoid overgrinding of soft ores and undergrinding of hard ores as grindability changed. Proper circuit control was important to managing these problems and crucial to sending the most suitable feed to downstream separation steps. The simplest controls adjusted feed rates and water additions to maintain an optimum throughput, but more sophisticated controls were being designed to calculate economic recoveries. With sophisticated controls, an operator could determine the interaction of throughput, recovery, concentrate grade, and sales relationships to arrive at a combination of throughput and grind sizing within the operating constraints that would maximize revenue.

Development of expert systems was still in its infancy, but some initial systems were making their debut. Unlike their predecessors, "black box" microprocessors, the systems were designed to be interrogated at any time, enabling the operator to follow the decisionmaking process and test and alter the control strategy while this accumulating work experience was being stored into memory. Thus, interaction between operator and machine allowed the control logic to

progressively improve at the same time as knowledge did. Expert systems had been implemented at the copper-molybdenum Brenda Mine in British Columbia, Canada, and Outokumpu Oy's Pyhasalmi concentrator in Finland, where they had enhanced efficiency and standardized operating procedures for different operators and shifts. For large mills, controls based on grinding models and expert systems were thought likely to increase in importance. Computer design techniques and gearless wraparound motors were instrumental in dealing with two old constraints over building larger mills: certain restricting mechanical factors and the large amount of power that needed to be applied.⁵⁴

Comminution Symposium.—The Camborne School of Mines of Cornwall, United Kingdom, sponsored the International Comminution Symposium⁵⁵ at which some of the field's latest developments and future needs were presented. A variety of new technologies were discussed along with some concerns about the direction in which research was headed. Despite its importance, comminution generally was still regarded as a relatively inefficient process consuming much energy and materials and often generating an abundance of untreatable fines. One of the major aims of current research and development work in this field was to reduce the high operating costs of comminution. The energy needed for the grinding circuits of base metal concentrating plants was estimated to be about 50% of the total cost.

Another concern at the symposium was the limited focus of ongoing research and Development on comminution processes. According to one view, mineral industry research too often sidestepped a most important objective of comminution: to liberate minerals from each other at their boundaries, as well as to reduce ore to the desired particle size with limited fines. Relatively few current efforts were said to be aimed in this direction. Conventional methods separated one mineral from another relatively inefficiently, if at all in many cases, owing to the indiscriminating breakage process. A few notable exceptions were presented in papers, including one called the Snyder process and several other methods involving electric and ultrasonic energy that were attempting to concentrate the breakage energy at the mineral crystal boundaries. The Bureau of Mines had shown

that microwaves could produce thermal stresses in ores, forming microcracks between mineral grains. Microcracking at these interfaces improved the liberation of mineral values from host rock, which could significantly reduce costs, but use of microwaves in processing was not expected to reach commercial application before the turn of the century. Some of these innovative processes had not been accepted by industry because of their high capital and operating costs and the difficulty so far in adapting them to high throughput continuous operation. Inadequate mineral liberation leads to higher energy consumption, because finer grinding is necessary to achieve an adequate degree of liberation. Another undesirable outcome of finer grinding is the production of ultrafine slime particles, which may not be recovered in the downstream concentration process. This was reported to be a particularly serious problem in the hard-rock tin ores, such as those found in Cornwall, United Kingdom, where up to 30% of the mined tin mineral cassiterite was sometimes lost as fines.

Rare-Earths Processing.—Late in the year, the University of Australia, in cooperation with the Australian companies Carr Boyd Minerals and Ashton Mining Ltd., claimed that an innovative process for the refinement of the lanthanides (rare earths) had been developed. Through a university research program, the developers used mechanical means to process high-purity metal oxides as opposed to traditional, expensive treatments using chemicals. The new process reduced oxides directly to metals and alloys without any heating or melting. Metals and alloys were milled from their respective raw oxide state in a high-energy ball mill. According to the university, the process was much cheaper than conventional chemical techniques (which require careful blending and high temperatures), and yielded a purer product. Carr Boyd, with exclusive world licensing rights to the process, owned a majority share in the Western Australia Mount Weld Mine Project, one of the richest rare-earth deposits in the world, with a preliminary resource of 6.2 megatons grading 17% rare earths and yttrium, including 1.7 megatons grading a full 26%.⁵⁶

Computer Simulation.—One of the major advances in comminution was observed to be in the computer control and computer simulation of comminution

circuits. Considerable research was being done on the simulation of machines and circuits as an aid to design and optimization, and simulation was viewed as being possibly the most important future use of the computer in mineral processing. Expert systems, as previously noted, were undergoing development in various mineral industry applications, including comminution, although practical applications were still limited.⁵⁷ Before actual plant control, expert systems first had to be proven by means of computer simulation runs. An expert supervisory system prototype was developed by one group of scientists to use in simulating the operation of a mineral crushing plant. The "intelligent" supervisor extended the limits of the automatic plant operation in most of the situations where the operator formerly took control of the plant and guided it manually. The supervisor was designed with modular characteristics to allow improvements in future stages of control, including modification of the existing heuristics (a machine's "self-adjusting" problem-solving techniques based on previous decisions or steps), improvements in the knowledge base, and powerful interfacing of alternative information.⁵⁸

Separation

Superconduction Technology.—In 1986, the J.M. Huber kaolin processing plant in Wren, GA, was the first commercial user of superconduction technology in its high-gradient magnetic separator (HGMS) system, installed by Eriez Magnetics of the United Kingdom. Because the production capacity and ease of use exceeded their expectations, Huber had a second machine with double the capacity installed in 1989 and a third one ordered for 1990 delivery. The superconducting HGMS was very efficient because it avoided the incremental energy costs of conventional water-cooled systems and reportedly used no electricity to maintain the magnetic field after startup. The new HGMS superconductor could be powered up to its full 20,000 gauss in 60 seconds, which meant there was less downtime between batches than with similar conventional systems. Eriez continued research efforts to find other successful applications for the new energy-saving technology. Potentially, any process where the removal of paramagnetic impurities was critical could be an application for a similar device.⁵⁹

Sound Wave Separation.—Acoustical methods were being used in the U.S.S.R. to develop a new process for cleaning gravel. Acoustical enclosure devices or "belts" were used to encircle a slurry pipeline using the sound waves to loosen clay particles clinging to the individual gravel bodies.

Flotation

Column Flotation.—The absence of column flotation cells at many mineral concentrating facilities was partly the result of the physical difficulty of accommodating the tall though very efficient columns. Successful trials with a new, small prototype column flotation unit were completed at the Mount Isa lead-zinc-silver mine in Australia. The inventor, a professor from Australia's University of Newcastle, in conjunction with MIM Holdings Ltd., Australia, subsequently completed development of an innovative column flotation unit called the Jameson cell. In addition to marketing the unit, MIM planned installations at several of its lead-zinc mines and a fine coal recovery operation. Although almost twice the height of original design, the new Jameson cell was only 2 m high, and total pulp retention time was reported to be a mere 2 minutes. Because of the small size, installation cost savings were projected for foundation preparation and building height needs. Air was "induced" rather than blown into the pulp, and the total power requirement for the elevation and injection of feed pulps was claimed to be only about 50% of that required for all purposes on tall columns. MIM professed that the Jameson cell had significantly lowered cleaning cell flotation costs more than any other cell they had found available.⁶⁰

Spray Flotation.—Application of a spray flotation system from AFT Inc. of Cleveland, OH, was expanded beyond its initial use with coal recovery from coal waste into other mineral separations where selectivity and recovery of fine minerals was important. The Sprayfloat cell system was an alternative to conventional subaeration flotation cells and, according to the company, required less than one-half the plant floor space of an equivalent capacity subaeration system at about one-half the horsepower. The process began with the primary feed being sprayed onto the surface area of the primary product recovery section of the

cell. Particles that did not float initially were drawn out and sent back to a second recycle spray, which created secondary bubble generation and provided a second chance for product flotation. Particles that did not float were directed to the tailings discharge as waste or on to a rougher cell, and the cleaned product was directed to a froth collection tank. The system could be operated with companies' existing chemistry packages and feed solid streams. It was initially tested in the laboratory with success on minerals such as copper, gold, molybdenum, nickel, and phosphates. Further development and field testing indicated that the system was applicable to a variety of other minerals. A Sprayfloat mobile pilot plant was being transported to various existing concentrators, such as a placer gold operation in British Columbia, Canada, to determine potential applicability to commercial concentrate streams. Significant success was claimed when AFT's system was applied to feed streams that contained very fine particles or agglomerated materials.⁶¹

Modular Design

On-Site Cyanide Production.—By some latest estimates, Nevada accounted for about 55% of U.S. sodium cyanide consumption, about 100 million pounds (45,359,240 kg). Though not yet disruptive, a progressively growing supply shortage had considerably escalated the price of cyanide. Much of this need was the result of extensive growth in the mining of surficial low-grade gold ore deposits, brought on by advances in heap-leaching technologies and fair to good gold prices. A process designed to lower costs was developed by the firm Kappes, Cassidy, & Associates (KCA), of Sparks, NV. The company claimed that the process would allow end users to manufacture their own cyanide on-site as required at a substantially lower cost than manufacturers were charging. KCA's first new modular cyanide-producing plant was completed near Reno, NV, before year-end and was reportedly capable of producing 1,000 pounds (455 kg) of sodium cyanide daily for use in heap leaching in the recovery of precious metals. Another similar but larger plant was undergoing construction by other companies in the active gold-mining area near Winnemucca, NV, with the expectation that the new plants would lessen the supply shortage.

Portable Processing.—KCA was not new to modular plant design. It was one of several companies worldwide that produced small "self-contained" gold processing plants. KCA had introduced a line of portable carbon adsorption recovery plants for the processing of gold-bearing solutions, incorporating the most recent process technology, 2 years previously. These plants were trailer-installed and could be made operational in a short time. Additionally, these modular units could be joined together to handle larger flow rates. This type of plant was advantageous for short-term, low-capital projects and would possibly retain value because of portability. Additionally, KCA designed its plants to be operated in remote areas.⁶²

HEALTH AND SAFETY

Safety Data

Preliminary injury and employment statistics compiled by the Mine Safety and Health Administration (MSHA) for 1989 showed that mine fatalities in the Nation's metal and industrial mineral mines hit a historic low of 48 deaths. This was 1 less than the previous record low of 49 that occurred in both 1986 and 1988. All pre-1989 numbers are final tabulations. The same data showed that the average number of employees increased by about 3.55%, less than the 5.57% average increase in 1988, but almost twice that of the 1.86% increase of 1987. In another preliminary survey, respectable gains in metal mining employment was shown to be partly offset by a slight decline in the industrial minerals mining sector. From the MSHA data, employee hours were shown to increase by an early estimate of 1.5% after 1988's strong upward turn of 6.42%. Total reported injuries increased for the fourth consecutive year, climbing to about 7.76 per 200,000 employee hours, up from a 7.57 rate for 1988 and 6.32 in 1987. The rate of nonfatal injuries requiring lost worktime was virtually the same. Almost 4.35 of such injuries occurred per 200,000 employee hours in 1989 versus 4.33 for 1988. All figures include independent contractors.

Microseismic Activity Monitoring

A new monitoring system, the Automated Microseismic Monitoring System

(AMMS), was developed by the Bureau of Mines Denver Research Center. It was designed to concurrently detect, record, and locate energy release relative to long-wall mining operations. Following more extensive use in the field and the accumulation of data and inherent resulting data patterns, the system had the potential to be used to provide a warning to miners at the face of imminent rock bumping or bursts before they could occur. The AMMS continuously monitored signals received via cable from up to 16 geophones. These were mounted along the headgate and tailgate entries of the long-wall panel and continuously moved with the advancing face. The system evaluated regions of intense microseismic activity to quickly locate or anticipate bumps and bursts. The system was installed at a western coal mine and was undergoing field evaluation and further development aimed at functionally improving it. A real-time graphical display for overlaying sources of microseismic activity on mine maps was being programmed, and a method of generating graphical hardcopy from more accurate digital geophones was being developed. Waveforms captured during monitoring were to be analyzed for indications of the type of physical action creating the seismic source. Also, intentionally generated active seismic sources would be used in conjunction with tomographic analysis to try to delineate anomalous ground structures and stress concentrations in and surrounding the active mining areas.⁶³ Overall, the Bureau's microseismic research program had three goals: (1) to acquire a basic understanding of burst mechanisms and precursors to events; (2) to improve failure forecasting prevention and control capability; and (3) to archive and interpret microseismic data.

Safe Air Underground

Innovative Ventilation Control.—Sometimes a relatively simple and practical solution can be most effective when dealing with a serious problem. A simple air control device based on fundamental pressure principles was developed by research scientists at the Bureau of Mines Pittsburgh Research Center for maintaining adequate escapeway ventilation during mine fire evacuation. During a fire that occurs by the working sections, such as in a beltway, air intake escapeways can quickly become contaminated with smoke and fumes and endanger human

life. There is little to stop significant amounts of air from leaking back into the stoppings, especially with erratic air currents that the fire's heat can help to generate. Scientists compared this to water running through a hose with small cuts in it. Relatively low water pressure occurred at the leaking holes until the end was capped. If in a similar manner fresh intake air could be strategically blocked, air pressure might be raised high enough at the ends of adjacent drifts to "deflect" contaminated air down the return airway. Researchers took a specially sewn 20-foot-diameter parachute and attached it to the roof of a mine air intake tunnel. The parachute was rolled out of its pack downwind to let the incoming air inflate the chute. The chute became a quick-erect check curtain that leaked much less than conventional curtains. Air pressure in the intake quickly climbed, and it was sufficient in the adjacent airways to stop or greatly reduce migration of smoke and fumes into the air intake. The simple and inexpensive pressure curtain chutes were highly effective in field testing at four underground coal mines. In every instance, the intake pressure went up substantially, and the pressure-raising effect of the chute persisted for a distance of about 4,000 feet (1,220 m). Further field tests and a formal report were planned.⁶⁴

Personal Air Monitor.—In many underground fire situations, such as when miners have not learned of additional fire locations, they do not know when to don self-rescuers to protect themselves from hazardous quantities of toxic gases such as carbon monoxide (CO). Usually miners do not carry the instrumentation necessary to detect toxic, colorless, and odorless CO. For this purpose, a personal-size CO alarm prototype called Pemcoal was developed by the Bureau of Mines. The small Pemcoal unit could be carried on a miner's belt, had a flashlamp visual alarm and a disk sensor that changed color with reaction to CO. Pemcoal was tested to concentrations of 1,000 parts per million of CO, from 5° to 40° C, in conjunction with several potential mine gas interferents. The unit alarm times were sufficiently fast to warn miners before exposure to hazardous quantities of CO could occur.

Another belt-worn personal air monitor was developed by Neotronics Ltd. of the United Kingdom. The Exotox was an electronic instrument, weighing just over 1.5 pounds (0.68 kg), that was designed to simultaneously detect up to five gases

and measure temperature and relative humidity. The unit could measure oxygen and inflammable gas concentrations as well as the toxic gases: CO, hydrogen sulfide, sulfur dioxide, chlorine, and nitrogen dioxide. Depending on which of several models was used, presentation of results ranged from immediate on-unit liquid crystal display to future viewing of the data with a programmed analysis of it on a personal computer after transfer of data stored in the unit's electronic memory. Up to 30 hours of continuous exposure for all measured gases could be recorded and evaluated. Two of the models could be programmed to sound alarms when various instantaneous, threshold limit and short-term exposure limit values were reached.⁶⁵

Respirable Dust Detection.—Electronics again provided the means for several innovative, compact dust monitoring devices. One was the 1.5 pound (0.68 kg) HFM-1 dust meter, made by GSA Gesellschaft of the Federal Republic of Germany. It was designed to instantaneously measure dust levels in the range of 0.1 to 100 milligrams per cubic meter, depending on dust type, and subsequently show the results on its light-emitting diode (LED) display. The HFM-1 made use of sophisticated microprocessors combined with infrared light scattering techniques. The company claimed that use of this device in mine dust surveys could reveal the real sources of dust problems and show how effective current dust control measures were without the use of slower, bulkier traditional equipment such as sample pumps. The unit was convenient and could pinpoint equipment, systems, or operations that were causing the major increases in dust levels. Up to 1,600 dust level measurements could be stored for later recall on the LED display or for direct transfer to a personal computer for further analysis or comparative studies with previous dust surveys.⁶⁶

Bergauforschung GmbH, also from the Federal Republic of Germany, developed a continuous long-term recorder for respirable fine dust and aerosol concentration logging. Measurement was based on the photoelectrical measurement of light scattered by respirable dust-size particles at defined angles and optical wavelengths. Environmental (room) light did not affect readings owing to the instrument's optical and electronic filtering systems. The unit could be integrated into the control system of

dust producing processes for direct measurements.⁶⁷

Cleaner Diesel Research.—In the spring, the Department of Energy saw tests by major diesel manufacturers in the United States and Switzerland, which showed that coal-fueled diesel engines produced less than one-half the nitrogen oxides that resulted from conventional diesel engines. The Department committed over \$4 million to several companies including Caterpillar, Inc., of Peoria, IL, to develop a coal gas-fired diesel engine. The Department's Energy Technology Center said that an acceptable coal-fueled diesel would likely be ready for use in trucks, trains, and factories by 1993.⁶⁸ Caterpillar's version involved the installation inside a locomotive of several gasifier-like vessels which would process about 35 pounds (16 kg) of coal per minute to fuel the gas-fired diesel. After being subjected to high pressures but moderate gasification temperatures in the vessels, the coal would react with steam and air to produce a modified ignition-assisted diesel engine.⁶⁹

Spontaneous Combustion Protection

A range of infrared thermal imagery cameras were adapted by Osprey Electronics Ltd., of Scotland, United Kingdom, to detect heat buildup and spontaneous combustion sources in underground mining operations and coal stockpiles. The cameras were also used to locate electrical and mechanical faults in process plant and other equipment. In the latter regard, the United Kingdom certified camera was intended to augment other machine condition monitoring devices currently in use in mines. The equipment was designed to detect very small temperature differences that show loss of insulation, heat buildup in rotating machinery, and overheating in process modules. It was intended for use in pre-maintenance monitoring checks of machinery in motion to help reveal incipient faults.⁷⁰

Health and Safety Training Via Satellite

MSHA began televised transmission of its safety and health programs through the Agency's Mine Health and Safety Academy in Beckley, WV. This provided mining industry personnel who had satellite reception capabilities access to unscrambled, satellite-delivered, interactive broadcasts of appropriate miner training programs with no user fee or site license fee charges. MSHA believed the

broadcasts were an effective tool for companies and others to use in improving their accident, injury, and illness prevention programs. The interactive features gave viewers an immediate forum for their questions. They could call a displayed toll-free number during each broadcast to ask questions of participants. Those interested needed a satellite dish, receiver, television monitor, and telephone. One of several shows during the year covered employee wellness programs and back injuries and was presented by the West Virginia University School of Medicine, Institute of Occupational Health and Safety. Another was presented by the Bureau of Mines Technology Transfer Program, entitled "Ground Control and Fire Protection for Underground Mining." This program highlighted the latest results of research work performed by Bureau scientists in efforts to improve ground control technology in underground mines and develop more efficient, effective fire protection, suppression, and detection systems for underground use.⁷¹

¹Revised.¹This table is a compilation of previous Mineral Yearbook issues tables 17 and 18. In addition a breakout of data for "construction work" and "All other purposes" is included.²Some quantities of this use are included with "All other purposes" to avoid disclosing company proprietary data.³Includes some quantities from "Coal mining," "Metal mining," "Quarrying and nonmetal mining," and "Construction work."⁴Estimated from correlation patterns between explosives sales and end-use sectors were developed from Bureau of Mines time series data and leading indicators of industrial production and economics as reported by the Department of Energy, Federal Reserve Board, Department of Transportation, and Bureau of the Census.⁵Some quantities of this use are included with "Ammonium nitrate: fuel-mixed and unprocessed" to avoid disclosing company proprietary data.⁶Data for 1985-88 are not comparable to data for prior years. Higher strength blasting agents classification was discontinued. Blasting agents formerly in that classification are now included in "Water gels and slurries."⁷Includes some quantities from "Other high explosives," and "Water gels and slurries."

ABRASIVE MATERIALS

By Gordon T. Austin

Mr. Austin, a physical scientist with over 30 years of industry and Government experience, has been the commodity specialist for abrasive materials since 1986. Mr. William Field, mineral data assistant, prepared the domestic data tables.

The combined value of production of natural abrasives, which includes tripoli, special silica stone, garnet, staurolite, and emery, increased about 21% in 1989. The increase in the value of staurolite and tripoli production was the result of an increase in the quantity of materials produced and an increase in the unit value. Emery decreased due to the significant decline in the volume of the material produced. Special silica stone experienced both a decrease in unit value and quantity produced. Garnet showed a small increase in quantity, but a decrease in unit value.

The silicon carbide industry saw a slight decrease in the quantity produced and a 12% increase in the value of

production. The fused aluminum oxide industry showed a 5% decline in the quantity produced, but enjoyed a 15% increase in the value of production. Combined production for both industries decreased 4% in quantity but increased 13% in value compared with those of 1988.

The metallic abrasives industry experienced a decline of 6% in quantity and 5% in value after 4 consecutive years of sales increases in both quantity and value. The industry includes the primary producers of steel, chilled and annealed iron, and cut wire shot and grit, and shot and grit reclaimed by primary producers. Shipments in 1989 were about 9% below the 239,619 metric tons¹ of 1979.

The United States continued as the largest single manufacturer, exporter, importer, and consumer of synthetic industrial diamond in the world. The estimated apparent U.S. consumption of industrial diamond stones rebounded from the 48-year low in 1987 with an increase of 185% to 3.9 million carats in 1988.

DOMESTIC DATA COVERAGE

Domestic production data for abrasive materials was from seven separate voluntary Bureau of Mines surveys. Of the 61 operations producing natural

¹ Includes grindstones, oilstones, whetstones, and deburring media. Excludes grinding pebbles and tube-mill liners.

² Primary garnet; denotes first marketable product.

³ Includes Canadian production of crude silicon carbide and fused aluminum oxide and shipments of metallic abrasives by producers.

⁴ Excludes the United States and Canadian production and value of aluminum-zirconium oxide.

⁵ Bureau of the Census.

and manufactured abrasives canvassed, all responded, representing 100% of the total production shown in tables 1, 5, 6, 8, 14, 15, and 16.

FOREIGN TRADE

The total value of abrasive materials, exports plus reexports, was \$300.9 million, an increase of 16% compared with the 1987 value. The average total value for the last 10 years was \$237.9 million per year with the high of \$300.9 million in 1988 and the low of \$196.8 million in 1982. The last 3 years have each shown a significant increase in total value compared with the essentially level period of 1983-85.

The total value of abrasive materials imported was \$420.9 million, a decrease of 16% compared with the 1988 value. The average total value for the past 10 years was \$362.2 million per year, with the high in 1988 of \$501.7 million and the low of \$245.0 million in 1982. Abrasive material imports had, until the 1989 decrease, increased at a compounded rate of slightly less than 13% per year for the last 6 years.

The United States has shown a trade deficit in abrasive materials for every year of the past 10 years. The trade deficit averaged \$109.2 million per year for the past 10 years and averaged \$173.8 million per year for the past 5 years. The deficit increased 23% to a record high of \$200.8 million in 1988.

TRIPOLI

The category of tripoli includes not only tripoli, but other fine-grained, porous silica materials that have similar properties and end uses. It does not include fine grained or porous silica materials included in other Minerals Yearbook chapters, such as pumice.

Production

Processed tripoli, sold or used, decreased 6% in quantity and 5% in the value, but the value per ton increased slightly. The quantity of crude tripoli produced increased after 5 consecutive years of decline. The average production for the past 10 years was 104,786 tons per year with a high of 112,928

Source: Bureau of the Census.

tons in 1984 and a low of 97,368 tons in 1981. Production in 1989 was 105,230 tons, valued at \$2.5 million. The significant increase in the value of crude produced was the result of a change in the reporting methodology.

Six firms produced tripoli in four States. Malvern Minerals Co., Garland County, AR, produced crude and finished material. American Tripoli Co., produced crude material in Ottawa County, OK, and finished material in Newton County, MO. Illinois Minerals Co. and Tammsco Inc., both in Alexander County, IL, produced crude and finished amorphous (microcrystalline) silica. Keystone Filler and Manufacturing Co. in Northumberland County, PA, processed rottenstone, a decomposed fine-grained siliceous shale, produced by B. J. Ulrich & Sons, also in Northumberland County, PA.

Consumption and Uses

Because tripoli grains lack distinct edges and corners, it has unique abrasive uses. It is the mild abrasive in toothpaste and toothpolishing compounds, industrial soaps, metal and jewelry polishing compounds. The automobile industry uses it in buffing and polishing compounds in lacquer finishing. The largest use of the mineral was as a filler and extender in paint, plastic, rubber, and enamel. The use of tripoli as an abrasive declined for the sixth consecutive year. Over this 6-year period consumption declined about 29%. The average annual consumption of abrasive tripoli for the past 10 years was 31,971 tons, with a high of 37,024 tons in 1984 and a low of 26,192 tons in 1989. The 1989 consumption was the lowest since 1953, when only 22,680 tons were sold or used.

After 5 consecutive years of growth from 1982 to 1987, the amount of tripoli used as a filler declined 4% in 1988 and an additional 8% in 1989. The average consumption of filler-grade tripoli for the past 10 years was 60,741 tons per year, with a high of 71,160 tons in 1987 and a low of 55,180 tons in 1982. Bureau of Mines data show that tripoli use in the United States is greater as a filler than as an abrasive.

Prices

The average reported value of abrasive tripoli, sold or used, in the United

³ Partly estimated.

States was \$121.11 per ton. The average annual value reported for abrasive tripoli for the past 10 years was \$96.95 per ton, with the high value in 1989 of \$121.11 and the low in 1980 of \$74.00. The value of abrasive tripoli has increased over the past 10 years at an annual compounded rate of 10% per year. The increase has been continuous; the annual rate of increase from 1985 to the present was significantly lower than the annual rate of increase from 1980 through 1984.

The average reported value of filler tripoli, sold or used, in the United States was \$145.61 per ton. The average annual value for the past 10 years was \$112.90 per ton, with a high of \$145.61 per ton in 1989 and a low of \$74.00 per ton in 1980. The value increased at an annual compounded rate of 9% for the past 10 years.

SPECIAL SILICA STONE PRODUCTS

Special silica stone products include hones, whetstones, oilstones, stone files, grindstones, grinding pebbles, tube-mill liners, deburring media, and certain specialty products. Manufacture of these products was from novaculite, quartzite, or other microcrystalline quartz rock.

Production

Plants manufactured oilstones, hones, whetstones and files in Arkansas, New Hampshire, and Indiana, and cuticle stones and coaster stones in Indiana. Additional production includes grindstones in Ohio, deburring media in Arkansas and Wisconsin, and grinding pebbles and mill liners in Minnesota. Production of the crude materials was in the same State in which the products were manufactured, except for the oilstones in New Hampshire. The novaculite for the New Hampshire oilstones was produced in Arkansas. The process for estimating the production of crude material changed in 1981 and again in 1987. Because of the two changes in the way of estimating production, 10-year averages and other production trends would be of no practical use.

The quantity of oilstones, hones, whetstones, files, and grindstones produced was only slightly greater than the 10 year low in 1988 at 377 tons and had essentially the same value at \$5.5 mil-

lion. The average annual production of the products for the past 10 years was 522 tons, with a high of 647 tons in 1982 and a low of 37 tons in 1988. The average value of annual production for the past 8 years was \$5.5 million, with a high of \$7.4 million in 1987 and a low of \$3.8 million in 1983. In the past 10 years, two distinct and different trends in the value of production appeared. One was from 1980 through 1984, when the average value of production was \$4.1 million per year. The other was 1985 through 1989, when the value of production was 54% greater at an average value of \$6.3 million a year. During (1985-89), the average annual quantity of production was less than the 10-year average, 473 tons versus 522 tons. During the same period the average annual value of production was 13% greater than the 10-year average. The change in average annual value was the result of a significant increase in the value per ton of manufactured products, starting in 1985.

The industry manufactured four main grades of whetstone. They ranged in grade from the high-quality Black Hard Arkansas Stone down to the Washita Stone. The Black Hard has a porosity of 0.07% and a waxy luster; Washita Stone has a porosity of 16% and resembles unglazed porcelain. The four main types were as follows:

Trade name	Use
Black Hard Arkansas Stone	Polishing the most perfect edge possible.
Hard Arkansas Stone	Polishing blades to a very fine edge.
Soft Arkansas Stone	General purpose.
Washita Stone	Rapid sharpening.

Arkansas accounted for 96% of the value and 98% of the total quantity of special silica stone products reported as sold or used by U.S. producers.

Consumption and Uses

The domestic consumption of special silica stone products resulted from a mixture of residential, industrial, leisure, and craft uses. The major residential uses were the sharpening of knives and other cutlery such as scissors, shears, and lawn and garden tools. Major industrial uses were the sharpening and honing of cutting surfaces, polishing of metal surfaces, and the deburring of metal and plastic castings. The manufacture, repair and modification of guns also make use of stone files. The recreational uses were the sharpening of sports knives, arrowheads, spear points, fish hooks and other recreational items. Craft applications included uses in wood carving, gun engraving, jewelry making, and other engraving work. Estimated value of U.S. apparent consumption was \$1.3 million.

Prices

The value of crude novaculite suitable for cutting into finished products varied from a low of \$0.33 per kilogram to as much as \$2.75 per kilogram. The low value was for Washita grade and the high value for Black Hard Arkansas grade. The manufacture of deburring media or special-purpose crushed stone is from material not suited for making oilstones, hones, or whetstones. The value of these materials ranged from \$39 per ton to more than \$300 per ton. The average value in 1989 of oilstones, hones, whetstones, and grindstones, sold or used by U.S. producers, was \$14,443 per ton or about \$14.44 per kilogram. The average annual value of the same items for the past 8 years was \$11,102 per ton, with a high of \$14,443 per ton in 1989 and a low of \$6,411 per ton in 1984. In the past 10 years, the unit value of special silica stone products followed two distinct negative trends plus the significant increase in 1989. The first trend, a gradual decrease, occurred during the period 1980 to 1984. The value per ton averaged \$7,227, with a high of \$8,284 and a low of \$6,411. The lowest value occurred in 1984. A second trend began in 1985 when the

value per ton more than doubled from \$6,411 to \$13,361. The average annual value per ton for the period 1985 to 1988 was \$13,006, with a high of \$14,113 in 1986 and a low of \$12,229 in 1988. One possible explanation for the series of step-ramp trends is the introduction of new high-value products by a single manufacturer. The product then encounters significant price competition from other producers in subsequent years. Because the special silica stone products industry is not high technology, new products can be duplicated by competitors. This very quickly results in short-term price pressures.

Foreign Trade

The value of exported special silica stone products was \$6.2 million, an increase of 148% compared with that of 1988. The average annual value of exports for the past 10 years was \$2.7 million, with a 10 year high of \$6.2 million in 1989 and a low of \$2.0 million in 1987. The annual value of exports over the past 10 years did not appear to have established a trend. Instead, the value drifted between \$2.0 million and \$2.6 million with as many increases as decreases until the significant increase in 1989.

The value of imported products was \$1.8 million, an increase of 13% compared with the 1988 value, but essentially the same compared with those of 1985 and 1986. The average annual value of imports for the past 10 years was \$1.2 million, with a high of \$1.8 million in 1985 and 1989, and a low of \$0.3 million in 1980. The trend for products imported to the United States was generally upward with some occasional decreases. The United States continues to be a net exporter of special silica stone products. A portion of the finished products imported was from crude novaculite produced within the United States and exported for processing.

In 1989, the trade surplus in special silica stone products was \$4.4 million, an increase of about 389%. During the past 10 years, the United States has enjoyed an average trade surplus of \$1.5 million per year with a high of \$4.4 in 1989 and a low of \$0.4 million in 1985. The trend for the past 10 years has been one of declining surpluses until the significant increase in 1989. The average annual surplus for the previous 4 years had been only \$0.6

million or about 40% of the 10-year average.

GARNET

High-quality U.S. industrial garnet is a mixture of almandine and pyrope that breaks under pressure into sharp chisel-edged plates. Industry uses this garnet as an abrasive powder and in the manufacture of coated abrasives. Low-quality industrial garnet found uses primarily as an airblasting or hydroblasting media and as filtration media.

Production

The United States continued to be the largest garnet producer and consumer, accounting for about 45% of the world's production and 40% of the consumption. Four domestic producers operated five plants, three in New York and one each in Idaho and Louisiana.

The quantity and value of crude garnet concentrates produced were 42,605 tons worth \$4.4 million, essentially the same as those of 1988. The average annual production for the past 10 years was 31,225 tons, with a high of 42,605 in 1989, and a low of 23,089 in 1981. Over the past 10 years, production increased about 75%, or at an annual compounded rate of about 6% per year. The production trend for the past 10 years has been one of continued long-term growth with occasional downward adjustments.

Consumption and Uses

The quantity of garnet sold or used by producers was 41,320 tons, essentially the same as in 1988, but the value decreased about 12% to \$9.8 million. The average annual quantity of garnet sold or used for the past 10 years was 29,973 tons, with a record high of 41,896 tons in 1988 and a low of 23,150 tons in 1981. The trend for the past 10 years was one of steady annual growth, except for 4% decreases in both 1981 and 1984. The growth rate averaged about 8% compounded annually.

Much of the growth in the use of garnet was the result of new regulations. These regulations established new limits on leachable minerals and free silica content in hydroblasting and airblasting media. These changes made garnet the preferred blasting media in some work

environments.

The major industrial use for high-quality, high-value garnet since before 1880 has been as material for free-abrasive machining in such applications as optical lens grinding and plate-glass grinding. In recent years its applications included the high-quality, scratch-free lapping of semiconductor materials and other metals. The finishing of wood, leather, hard rubber, felt, and plastics often require the use of garnet-coated abrasive papers and cloths.

The aluminum aircraft and shipbuilding industries in California and the Pacific Northwest use lower quality, lower cost alluvial garnet, primarily from Idaho, for sandblasting. Similar uses in the Eastern U.S. are for the cleaning and conditioning of aluminum and other soft metals and for cleaning of metal by structural steel fabrication shops. Mixed-media water filtration, using a mixture of sand, anthracite, and garnet, has displaced older filtration methods because it is more reliable, and gives a better quality of water. Demand for this use has greatly increased. The manufacturers of nonskid floor paint also use alluvial and other low-cost garnets.

Garnet has obtained an intermediate place in the coated-abrasive field between low-cost quartz sand and more-costly synthetic abrasives (silicon carbide and fused alumina). Garnet is reportedly more efficient based on unit production costs than quartz sand. It also produces a more desirable finish on items made of wood, leather, hard rubber, felt, and plastic.

Garnet, especially the lower grades, cannot compete with synthetic abrasives for most metalworking applications requiring substantial metal removal because of its friable nature and lower hardness.

TABLE 8

GARNET SOLD OR USED BY PRODUCERS IN THE UNITED STATES

Year	Quantity (metric tons)	Value (thousands)
1985	27,791	\$6,102
1986	28,899	6,748
1987	35,812	7,744
1988	41,896	11,144
1989	41,320	9,768

Prices

The average value per ton of crude garnet concentrates was \$103, a 7% decrease compared with the 1988 average. The average value for the past 10 years was \$95 per ton, with a high of \$113 in 1987 and a low of \$78 per ton in 1980. During the past 10 years, the overall trend for the value of crude concentrates was a net increase with decreases in some years. The 1989 value was 132% of the 1980 value.

The average value per ton of garnet sold or used was \$236, a decrease of 11% from that of 1988. The average value for the past 10 years was \$227 per ton, with a high of \$266 in 1988 and a low of \$205 per ton in 1980. Excluding the highest and two lowest values, the difference between the highest value and lowest value in the remaining 7 years was only 6.5%. The price trend of garnet sold or used during the past 10 years has been stable with very minor changes, except the 23% increase from 1987 to 1988.

Foreign Trade

Garnet exports, as reported by producers to the Bureau of Mines, were about 9,716 tons, an increase of 22% compared to 1988. Export data on garnet were not available from the Bureau of Census. Producers have reported exports to the Bureau of Mines for the past 3 years; before that, the Bureau estimated garnet exports. Trend analysis beyond the past 3 years would be of limited value because of the large number of estimates included with the data. According to reports by producers, exports increased significantly during the past 10 years.

Mineral brokers and other garnet importers reported to the Bureau about 5,000 tons of imported garnet, unchanged from 1988. Import data for garnet also were not available from the Bureau of the Census. Bureau of Mines data, which are available for only 3 years, showed a significant increase in garnet imports each year. The United States was a net exporter of garnet in 1989; exports exceeded imports by 114%.

World Review

The United States was the dominant world producer and consumer of garnet, accounting for approximately 45% of the estimated world output and

¹ Includes capacities of operating plants as well as plants on standby basis.

nearly 40% of estimated world consumption. Target Mines Ltd. continued to produce at near capacity from its Australian garnet sand operation. During 1989, Target sold a 50% interest in the operation to Barton Mines, a U.S. garnet producer. The Chinese mines continued to increase production of garnet for the export market. Yet, to date, the quality of the garnet routinely has not met requirements for the U.S. market. Two mineral-sand mining operations in India continued to produce garnet as a byproduct of mineral sands production. Samples of the garnet were tested for applications in the United States, but, to date, the major market for the Indian garnet has been Japan. Norway, Turkey, and the U.S.S.R. primarily produce for local markets.

Outlook

The U.S. production and consumption of industrial garnet over the next 5 years will be a function of the installed capacity. Currently the industry is operating at or near capacity. If capacity can be added, production and consumption will increase to approximately 60,000 tons per year by 1995. If garnet were not available, other abrasives could be used in its place, but

often with some sacrifices in work volume, quality of work, or cost.

Substitution of other natural and synthetic material is present to some extent for all major end uses of garnet. Fused alumina and staurolite compete with garnet as a sandblasting material in the transportation equipment industries. Ilmenite and plastics compete as filtration media. Diamond, corundum, and fused alumina compete for lens grinding and for many lapping operations. Finally, sand, silicon carbide, and fused alumina compete for grinding and finishing of plastics, wood furniture, and other products.

Background

Definition, Grades, and Specifications.—Garnet is a general name for a family of complex silicate minerals having similar physical properties and crystal form, the most common being the magnesium-aluminum silicate (pyrope) and the iron-aluminum silicate (almandite). Almandite is the most important type of industrial garnet. It ordinarily has a hardness of 7.5, an average specific gravity of 4, and a melting point of 1,315° C. It has a color of various shades of red, a chemical composition of $\text{Fe}_3\text{Al}_2(\text{SiO}_4)_3$, and a cubic crystal structure.

Each domestic producer has distinctive products. The Barton Mines Corp. garnet is a mixture of almandite and pyrope, and is at the top of the garnet hardness range. It occurs as large crystals and exhibits incipient lamellar parting planes that break under pressure into sharp chisel-edged plates. It retains this chisel-edged shape even when crushed to a very fine size. The NYCO and International Garnet Abrasive garnet is a mixture of andradite and grossularite and the crude garnet concentrate may contain diopside/hedenbergite ($\text{Ca}[\text{Mg.Fe}]\text{Si}_2\text{O}_6$). The Idaho garnet is an alluvial material with rounded small-to-medium grains.

Consumers purchase crushed, ground, and graded to size material, depending on the intended end use. The sale of garnet for sandblasting and water filtration is by screen size. Some popular mesh sizes are minus 7 plus 12, minus 7 plus 20, minus 20 plus 40, minus 30 plus 50, minus 50 plus 94 and minus 120 plus 230.

Descriptions of testing methods for materials to be used in coated abrasives

manufacture are in American National Standards Institute (ANSI) Specification B74.18-1977² and other sources.³ Data on other graded sizes are in another ANSI Specification B74.12-1976.⁴

Industry Structure.—Currently four firms produce garnet from five plants in three States. Barton Mines Corp., Warren County, NY, produced garnet for use in coated abrasives, glass grinding and polishing, and metal lapping. The NYCO Div. of Processed Minerals Inc., Essex County, NY, recovered garnet as a byproduct from its wollastonite operation. It sold both crude garnet concentrate for additional refining and refined garnet for use as blasting and filtration media. International Garnet Abrasives Inc., Clinton County, NY, produced garnet for use as blasting and filtration media. Emerald Creek Garnet Milling Co. continued to operate six mining operations, two jigging plants, and a single mill in Benewah County, ID. Blasting and filtration media was the primary uses of the garnet. International Garnet Abrasives also operated its garnet reclaiming plant in Jefferson Parish, LA. The petroleum industry used the garnet as blasting media. Abrasive garnet production in the United States began in 1878 at the Gore Mountain site of Barton Mines, near North Creek, Warren County, NY. During the first year, production was less than 100 tons. It was used in coated abrasives, both paper and cloth.⁵ Barton Mines Corp. mined and processed the abrasive-grade garnet on Gore Mountain until the company moved the mining operation and processing plant in 1982 to the adjoining Ruby Mountain. The same family has owned Barton Mines since its formation. Reported past domestic garnet production was from California, Connecticut, Florida, Maine, New Hampshire, North Carolina, and Pennsylvania.⁶

Nine manufacturers at 10 plants produced garnet coated abrasive papers and cloths. The locations of the plants are the following: New York and Virginia, two each; Massachusetts, Michigan, Minnesota, Mississippi, Ohio, and Pennsylvania, one each.

Geology-Resources.—Members of the garnet group are common accessory minerals in a large variety of rocks including granites, gneisses, schists, mar-

bles, serpentine, and peridotite. The geographical areas in which it may be found are enormous both in extent and in number. Commercially attractive industrial garnet occurrences are not common. Many garnets that occur in deposits of economic size degrade during processing because of internal stresses. These stresses developed in the garnet crystal during formation and cooling. Stress relieving is not economical; therefore, these deposits have no commercial value as a high-grade abrasive material source.

The best abrasive garnets are of the almandine variety but andradite, grossularite, and pyrope also are used. All varieties of garnet have been mined for gem stones. The garnet occurrence near Rangeley, ME, is very unusual. Some classify the host rock as metamorphic, but others, as igneous. The ore exhibits characteristics of both classifications. Because it has a very high garnet content, 50% to 80%, some geologists argue that the ore is a garnet granofel of metamorphic origin. Others contend that the ore is igneous in origin because of the lack of foliation and other textural considerations. In any case, the rock is similar to granite, an igneous rock, except that garnet crystals replace the quartz crystals, a major constituent of granite.

New York and Maine have the only known high-quality garnet reserves in the United States. A rough estimate suggests that more than 600,000 tons of high-quality garnet can be recovered from Barton Mines Corp. deposit on Ruby Mountain in New York. Other similar deposits occur in the area. The estimate of reserves in the igneous rock deposit near Rangeley, ME, are over 1.8 million tons of garnet. The quantity of garnet-bearing gravels reported at Emerald Creek and Carpenter Creek in Idaho is large. A minimum of 450,000 tons of garnet is available in the Emerald Creek Garnet Milling Co. deposits.

There can be little doubt that tremendous reserves of garnet similar to the lower priced materials can be located as needed.⁷ Also, the production of byproduct garnet from many current mining operations is possible if demand increased.

Reserves are significant in Australia, India, and the U.S.S.R. but accurate data are not available. Huge inferred and undiscovered resources are likely to exist throughout the world.⁸

Technology

Mining.—At the Barton Mine in New York, garnet occurs in a metamorphosed igneous rock. The Ruby Mountain ore body covers approximately 4.1 hectares, which is nearly the entire mountain. The estimated total depth of the deposit is 50 to 60 meters. The ore benches in the mine are about 9 meters high. A drop ball breaks the large pieces, and power shovels load trucks to haul the ore to the crusher at the mill, about 0.4 of a kilometer away.

At Emerald Creek and Carpenter Creek, Benewah County, Idaho, stripping 1 to 2 meters of overburden exposes the garnetiferous gravel. Mining is done with a dragline dredge.

Wollastonite mining at Willsboro, NY, produces a byproduct concentrate containing garnet, diopside/hedenbergite and minor amounts of wollastonite. The ore at the NYCO mine contains 60% wollastonite, 30% garnet and 10% diopside. After blasting and loading, the ore is transported 22 kilometers to the plant for separation of the wollastonite from the garnet/diopside.

Beneficiation.—Today, practically all grade-grain abrasive garnet is heat treated as a processing function, not to improve its inherent abrasiveness. Impurities picked up during processing stick to the garnet particle surfaces. These impurities destroy the cleanliness and capillarity needed in later processing to give adhesion for bonding. In the early 1960's, scientific investigations determined that heat treating only cleaned the particle surfaces and that too high a temperature could destroy the abrasive quality of garnet. In the mid-1960's, the coated abrasive industry accepted uniform color standards. These standards assured the cleanliness of the grain surface and a color most closely approaching the natural red color of abrasive garnet. The heat treatment needed to do this is the RT treatment.⁹

At Barton Mines Corp., separation of garnet from other minerals is by combinations of crushing and grinding, screening, tabling, flotation, magnetic separation, water sedimentation, drying, heat treating, and air separation. Sometimes, the same process will do both sizing and removal of gangue minerals, but usually it requires consecutive processes. Particle size control is difficult.

At Emerald Creek, sizing of the garnetiferous gravel is by trommeling and then treatment with jigs and concentrating tables. The garnet concentrate is dried, crushed, and screened. The maximum product grain size is 46 millimeters.

At NYCO, the processing and beneficiation of the wollastonite/garnet ore involves two stages. The first stage includes drying, crushing, screening, and recrushing the feed to minus 16 mesh. In the second stage, the minus 16 mesh raw material passes over a battery of screens to attain minus 16, minus 20, minus 40 and minus 60 mesh splits. Then a battery of magnetic separators removes the garnet fraction from these splits. The final product includes four sizes bagged for shipment.

EMERY

Emery is an impure corundum containing magnesium-aluminum silicates. It is used as an abrasive aggregate for nonskid, wear-resistant floors, pavements, and stair treads, as tumbling or deburring media, and, also, in the manufacture of coated abrasives.

Production

A single firm, Oregon Emery, Albany, OR, produced emery in 1989. Production from the historical producer near Peekskill in Westchester County, NY, stopped in 1988.

Consumption

The Bureau estimated that the United States consumed approximately 12,000 tons of emery in 1989. Imports from Greece and Turkey accounted for most of the material consumed. Four firms processed and distributed emery for domestic consumption: Washington Mills Abrasives Co.; Emeri-Crete Inc.; Oregon Emery; and General Abrasives Co.

Foreign Trade

The United States did not export emery in 1989, nor has it exported emery in the past 10 years. During the past 10 years, the U.S. may have reexported a small amount of emery. The Bureau of the Census reports emery exports and reexports in mineral group categories; thus, exact data on emery are not available. The Bureau of the Census also reports emery imports in a

mineral group category; therefore, data on emery imports are not available. The Bureau estimated Turkey exported approximately 10,500 tons of emery to the United States. Greece, the second largest producer, exports very little emery to the United States because of the high cost of the material.

World Review

Turkey, with production of approximately 21,000 tons, was the world's largest producer of emery. The second largest producer was Greece, with a total production of about 8,500 tons.

STAUROLITE

Staurolite is a naturally occurring, complex, hydrated aluminosilicate of iron having a variable composition. The mineral most commonly occurs as opaque, reddish-brown to black crystals. It has a specific gravity ranging from 3.74 to 3.83 and Mohs' hardness of between 7 and 8.

Production

Georgia, North Carolina, and Virginia produced mineral specimen staurolite crystals. The crystals were in the cruciform twinned form commonly called "fairy crosses." E.I. du Pont de Nemours & Co. Inc. produced industrial grade staurolite in Florida. Production industrial staurolite increased 117% in quantity and 41% in value compared with those of 1988.

Industrial staurolite was a byproduct of heavy-mineral concentrates recovered from a beach sand in Clay County, north-central Florida. Electrical and magnetic separators remove staurolite from the concentrates after scrubbing, washing with caustic, rinsing, and drying. About 77% of the resulting material was cleaned, rounded, and uniformly sized grains of staurolite, with minor amounts of tourmaline, ilmenite and other titanium minerals, kyanite, zircon, and quartz. The nominal specification for the composition of the material was 45% aluminum oxide (minimum), 18% ferric oxide (maximum), 5% silica (maximum), and 3% zirconium dioxide (maximum).

Consumption and Uses

Shipments of staurolite increased

117% in tonnage and 40% in value. Staurolite, marketed under the trade name Biasill, was used as molding material in nonferrous foundries because of its low thermal expansion, high thermal conductivity, and high melting point. Its low softening temperature often restricts its use to nonferrous casting. The major use of staurolite was as an abrasive for impact finishing of metals and sandblasting of buildings. The blasting media trade names were Starblast (80 mesh) and Siasill (90 mesh). A coarse grade (55 mesh) also was used as an abrasive. Some portland cement formulations consumed a minor amount. As regulations limiting the amounts of free silica in airblasting media became more stringent, the demand for staurolite increased.

Foreign Trade

Neither the Bureau of the Census nor the staurolite industry reported any exports or imports of staurolite. Given the limited market and the price per ton, no international market for staurolite is anticipated in the near term.

World Review

India continued to produce small amounts of staurolite for local consumption. Other countries sometimes produce small amounts of staurolite as a byproduct of mineral sands or gem stone production.

INDUSTRIAL DIAMOND

Industrial diamond is natural diamond that does not meet the standards of gem diamond because of its color, size, or other imperfection. Or it may be a synthetic diamond that is tailor-made for industrial applications.

Government Programs

The National Defense Stockpile for industrial diamonds, as of December 31, 1989, had a goal and an inventory of 22 million carats for crushing bort. The goal for industrial stones was 7.7 million carats and the inventory was 7.78 million carats. There were no sales of industrial diamonds from the stockpile during 1989. Currently, there is legislative authority for disposal of 2,355,150 of industrial stones, but there were no disposals during the year.

The inventory of small diamond dies was 25,473 pieces, compared with a goal of 60,000 pieces, but no purchase authorization was issued.

Production

The United States was the world's largest producer of synthetic industrial diamond. This made the United States independent of foreign sources for crushing bort or similar diamond except the grit sizes larger than about 20 mesh. Having no production of natural diamond, it was dependent on other countries for its natural diamond supply.

Three domestic firms produced synthetic industrial diamond in the United States: Du Pont Industrial Diamond Div., Gibbstown, NJ; General Electric Co., GE Superabrasives, Worthington, OH; and Megadiamond Industries Inc., a subsidiary of Smith International Inc., Provo, UT. A fourth company, U.S. Synthetics Corp., Orem, UT, manufactured polycrystalline diamond from purchased synthetic diamond grit. U.S. Synthetics had the capability to manufacture synthetic industrial diamond grit, but chose not to for economic reasons. Domestic production did increase significantly. The United States continued to be the largest single producer of synthetic industrial diamond, a role it has enjoyed since 1957. Over the past 10 years, production increased at an average rate of 9% compounded annually.

U.S. secondary production of industrial diamond was from the following five firms: Industrial Diamond Laboratory Inc., Bronx, NY; Industrial Diamond Powders Co., Pittsburgh, PA; International Diamond Services Inc., Houston, TX; Keenkut Inc., Keene, NH; and National Research Co., Fraser, MI. The firms reclaimed a total of about 3.6 million carats from used drill bits, diamond tools, and wet and dry diamond-containing waste, a decrease of 50% compared with that of 1988.

Consumption and Uses

The United States continued to be the largest single consumer of industrial diamond. The Bureau of Mines estimate of apparent consumption of industrial diamond was approximately 79 million carats, a decrease of about 8% compared with 1988 consumption. Average annual consumption for the

past 10 years was about 59.6 million carats. During this period, two different trends for consumption occurred. The average annual consumption for 1980-1984 was 43.2 million carats, and that for 1985-1989 was 76% greater or 76.1 million carats. The second trend was the result of the strong movement to industrial diamond by U.S. manufacturers. This was because of the economic advantages in removing material and finishing surfaces using industrial diamond and diamond tools and wheels. Additionally, the continued economic growth of the U.S. industrial sector increased demand for most types of industrial diamonds.

Diamond is far harder than any other natural or artificial abrasive material. It was essential for some uses and much more efficient than other abrasives for many others. The primary uses for industrial diamond stones were in drilling bits and reaming shells, single- or multiple-point tools, saws, and wiredrawing dies. Miscellaneous uses for stones include engraving points, glasscutters, bearings, surgical instruments, hardness testers, radiation counters, and other instruments and special tools.

Mineral, oil, and gas exploration were the primary uses of drilling bits and shells. Foundation testing for dams, buildings, and other construction also used diamond bits and shells, as did masonry drilling in buildings for conduits and access, testing of concrete in various structures, and other similar applications. The primary uses of diamond tools were for dressing and trueing grinding wheels and for cutting, machining, boring, and finishing metals. Beveling automobile glass windows also was a use. Cutting dimension stone, ceramics, and concrete in highway reconditioning were the major uses of diamond saws. The forming of refractory shapes for furnace linings also uses diamond saws. Diamond wire dies were essential for high-speed drawing of fine wire, especially from hard, high-strength metals and alloys.

Diamond grit, powders, and fragmented bort go into diamond grinding wheels, saws, impregnated bits and tools, and loose abrasives compounds for lapping and polishing.

The three major types of grinding wheels—resinoid, metal, and vitrified bonds—were made in many shapes and sizes designed for specific applications.

The sizes range up to 1 meter in diameter for very large industrial wheels. Sharpening and shaping of carbide machine tool tips, grinding of dies, edging of plate glass, and optical grinding were among the primary applications of diamond grinding wheels. Very thin saws sliced wafers from brittle metals and crystals for use in electronic and electric devices.

Finishing optical surfaces, jewel bearings, gem stones, wiredrawing dies, cutting tools, and metallographic specimens were the primary uses of polishing and lapping powder and compounds. Hundreds of other important items made from metals, ceramics, plastics, and glass also were finished with diamond compounds.

Changes in technology and conventional wisdom resulted in an increased use of synthetic industrial diamonds and polycrystalline diamond shapes (PDS) and compacts (PDC) for many of the uses listed above. In the past 3 years, the use of PDS, PDC, and matrix set synthetic diamond grit increased in drilling bits and reaming shells. The manufacture of single- and multiple-point tools use PDS and PDC. Many manufacturers of diamond wire-drawing dies use PCD. Diamond saws, diamond wheels, and diamond abrasive grit and powder still are made almost exclusively from synthetic diamond.

Prices

The Bureau of Mines does not collect price data on industrial diamonds. The Bureau did track the average import value of various classifications of industrial diamonds. The average value of U.S. imports of natural grit and

Year	Quantity	Value
1985	46,222	127,191
1986	45,991	110,648
1987	48,877	95,559
1988	71,147	130,300
1989	70,342	105,295

Source: Bureau of the Census.

powder, synthetic grit and powder, and industrial stones was \$0.63 per carat, \$0.74 per carat, and \$6.94, respectively. The average annual value of imported natural grit and powder for the past 10 years was \$1.43 a carat. The high value was \$2.86 in 1980 and the low was \$0.63 in 1989. The average value of natural grit and powder, in current dollars, declined every year since 1980. The 1980 average value was 452% greater than that of 1988.

The average annual value of imported synthetic grit and powder for the past 10 years was \$1.41 a carat. The high value was \$1.86 a carat in 1981 and the low was \$0.74 in 1989. The average value of imported synthetic grit and powder decreased every year since 1981. The 1989 value declined 60% compared with 1981, and the decline from 1988 to 1989 was 31%. During the last 10 years, a major change occurred in the relationship of the average value of natural grit and powder to the average value of synthetic grit and powder. In 1980, the average value of natural grit and powder was 65% greater than the average value for the synthetics. In 1989, the average value for the synthetics was 17% greater than that for natural material. Natural grit and powder declined in value at a much greater rate than did synthetic grit and powder.

The average annual value of imported industrial diamond stones for the past 10 years was \$9.92 a carat, with a high value of \$13.93 in 1981 and a low of \$6.94 in 1989. The trend for the value of industrial stones was mixed for the past 10 years. There was a 23% decrease in the average value. The period started with 2 years of increasing values, followed by 3 years of lower values. Values over the final 5 years were alternating decreases and increases. The 1989 average value was 5% less than the 1988 value, 27% less than the 1981 high, and 23% less than the 1980 value.

Foreign Trade

The United States was the largest exporter of industrial diamond grit and powder in the world. The United States exported and reexported a record 78.2 million carats of natural and synthetic grit and powder. The material was worth a record \$119.1 million. Additionally, the

U.S. exported and reexported approximately 2.8 million carats of industrial stones, valued at \$33.2 million.

Six countries received approximately 76% of the total U.S. exports of synthetic grit and powder. The countries and the percentage of exports they received were: Japan, 30%; Federal Republic of Germany, 21%; Ireland, 6%; Italy, 7%; Belgium, 7%; and Republic of Korea, 5%. Six countries received about 74% of the total U.S. exports of industrial stones. The countries and the percentage of exports they received were: Ireland, 30%; Belgium, 17%; Federal Republic of Germany, 27%; Japan, 10%; Canada, 4%; and France, 2%.

The average annual exports plus re-exports of natural and synthetic grit and powder for the past 10 years was 46.0 million carats, with an average value of \$85.9 million. The highest level of exports plus reexports during the past 10 years was 78.2 million carats valued at \$119.1 million in 1989. The lowest was 28.5 million carats in 1980 and 1981, and valued at \$65.8 million in 1981. The trend of exports plus reexports for the past 10 years was one of continued growth. There was an increase of 178% over the period or an annual average compounded growth rate of just under 12%. The increase from 1988 to 1989 was about 5%, less than one-half of the 10-year average rate.

The average annual exports plus re-exports of industrial stones for the past 10 years were 3.0 million carats a year, and the average value was \$31.9 million. The high was 3.6 million carats in 1980 and 1986, and the low was 1.9 million carats in 1982. There was no distinct trend for the past 10 years. Exports plus reexports of about 2.8 million carats were 7% less than in 1988, but 22% less than in 1980. The 1989 exports plus reexports were 22% less in quantity than the 10-year high in 1980 and 1986.

The average annual imports of natural diamond grit and powder was 7.3 million carats a year for the past 10 years. The high was 13.0 million in 1988 and the low was 3.3 million in 1982. Imports as measured in carats were about 7% less than 1988 and 235% greater than 1980. The trend for the quantity of natural grit and powder imported over the past 10 years was one of significant increases. Yet,

during this period, the quantity of natural grit and powder decreased from 23% to 20% of total grit and powder imports. During 1989, four countries supplied 79% of U.S. imports of natural grit and powder: Ireland, 49%; the United Kingdom, 13%; U.S.S.R., 11%; and Japan, 6%. The U.S.S.R. was the only producer of natural diamonds in this group.

The average annual imports of synthetic diamond grit and powder were 26.8 million carats a year for the past 10 years. The high was 50.7 million carats in 1988 and the low was 10.9 million carats in 1981. Imports in 1989 were about 3% less than in 1988 and 311% greater than in 1980. The trend of synthetic grit and powder imports over the past 10 years has been one of an early decline of about 8% over 2 years followed by continued strong growth until the slight decline in 1989. The average annual compounded growth rate for the 10 years was about 17%; but the average annual compounded rate of growth from the low in 1981 through 1989 was about 21%. The level of imports in 1988 and 1989 indicated that the growth trend has begun to increase at even a greater rate. Four countries furnished 82% of the synthetic diamond grit and powder imported into the United States in 1989: Ireland, 59%; Japan, 10%; U.S.S.R., 8%; and Romania, 5%.

The 10-year average for imports of industrial diamond stones was 6.9 million carats a year, with a high of 9.4 million in 1985 and a low of 3.9 million in 1987. Imports of industrial diamonds lacked a distinct trend during the period; the quantity imported in 1989 was about 42% greater than the quantity imported in 1980. The 1989 imports were about 27% greater than 1988 imports, but 1988 imports were less than the 10-year average.

The United States was a net exporter of diamond grit and powder and a net importer of industrial diamond stones. The U.S. was a net exporter of industrial diamond based on the total quantity and total gross value. The excess trade balance in industrial diamonds was about 10.8 million carats and \$47.2 million.

World Review

Botswana and the Republic of South Africa were the largest producers of

good-quality industrial diamond stones. Australia and Zaire were the world's largest producers of natural industrial diamond, and were the primary sources of natural crushing bort as well as substantial producers of industrial stones. Estimates suggest that the U.S.S.R. was the third largest producer of natural industrial diamond but reliable data were lacking.¹⁰ The next largest, in order of volume, were

Botswana and The Republic of South Africa. Other smaller but significant producers were China, Brazil, Venezuela, Angola, and Ghana.¹¹ Total world output of natural industrial diamond in 1989 was approximately 51.8 million carats, a slight increase over 1988.

Outlook

Diamond grit and powder should experience substantial increases in do-

mestic demand for every end use over the next 5 years. The increases for synthetic grit and powder are expected to be greater than the increases for natural. The constant-dollar prices of these materials, especially the synthetic diamond products, should continue to decrease or at least remain constant, because planned production increases should make them more cost effective. The greatest increases will occur in the

contract construction industry, because large quantities of saw-grade diamond will be required for the tools used in highway and bridge repair and replacement. Large increases also are expected in the dimension stone industry as a cutting and polishing media. The stone, clay, and glass industries will increase their uses in cutting, shaping, and polishing media. Additionally, polycrystalline synthetic diamond compacts and shapes will continue to displace natural diamond stone and tungsten carbide drill bits in the mineral services sector. The probable average annual growth rate in U.S. production is about 6%, based on estimates by U.S. producers. Domestic production of synthetic material is sufficient to supply U.S. diamond grit and powder demand. The United States also will continue to be a major exporter.

The major domestic end use for industrial stones in the next 5 years will continue to be in the oil, gas, and mineral industry. These stones are natural and cannot yet be manufactured commercially. Polycrystalline synthetic diamond compacts and shapes have had a major negative impact on the natural industrial diamond stone markets. This will limit the growth of U.S. demand for stone over the next 5 years. U.S. consumption should average between 6 and 7 million carats a year for the next 5 years. Approximately 50% of the potential natural stone applications will be replaced by the synthetic compacts and shapes by the year 2000.

Background

Definition, Grades, and Specifications.—Natural industrial diamond is diamond that, because of color, structure, size, or shape, is unsuitable for use as gem stones. Major categories are industrial stones (die stones, tool stones, and drilling stones), crushing bort, and grit and powder. The distinction between stone and grit is not well defined; generally, the dividing line is a range of sizes. Stones usually are particles larger than 16 to 20 mesh, grit from 16–20 mesh to 325–400 mesh, and powder as particles smaller than 325 to 400 mesh. These categories are subdivided further into over 100 groups.¹²

Bort is natural diamond that occurs in finely crystalline aggregates and usu-

ally is crushed into finer material. Originally, the term was the name for all crystalline diamonds not usable as gems; later it designated those diamonds not usable as gems, tool stones, die stones, or drill stones. Currently, the term refers to low-grade industrial diamond suitable only for use in a fragmented form.

Most synthesized diamond marketed to date is 20 to 30 mesh and smaller. Recently, producers began to make synthetic stones of 2 carats or larger. Engineered pieces of this material are marketed rather than the entire stone. Polycrystalline synthetic diamond compacts and shapes can replace some larger stones. There are several types of synthetic diamond. They range from very friable material with a highly irregular shape to blocky, regular shapes with excellent crystal structure. The manufacture of industrial diamond stones is not commercially viable.

The metric carat, 0.2 gram, is the unit of measure for industrial diamond. One pound contains 2,268 carats, and 1 kilogram contains 5,000 carats. The carat is equal to 100 points. Diamond grit and powder sizes are identified by U.S. standard screen classifications, by American National Standards Institute (ANSI) Specification B74.16–1971,¹³ ANSI Specification B74.20–1981,¹⁴ and by a proposed standard developed by the Industrial Diamond Association¹⁵ for subsieve micron sized diamond or cubic boron nitride powders. The terms “sand,” “grit,” and “powder” also describe decreasing orders of fine diamond.

Machine-shop waste containing diamond is sludge if obtained from wet grinding, and swarf if obtained from dry grinding.

Industry Structure.—The original discoveries of diamond in India, Borneo, and Brazil, and later in the Republic of South Africa, were due to chance finds by local inhabitants. Certain desirable characteristics in diamond were noted first in India and led to active searches by open pit workings and concentration by hand methods.

The first industrial use of diamond was probably as diamond powder for polishing gem diamonds and other precious stones. The art of diamond cutting and polishing was known in India,

^e Estimated. ^p Preliminary. ^r Revised. W Withheld to avoid disclosing company proprietary data.

¹ Table includes data available through May 16, 1990. Total diamond output (gem plus industrial) for each country actually is reported except where indicated by a footnote to be estimated. In contrast, the detailed separate production data for gem diamond and industrial diamond are Bureau of Mines estimates in the case of every country except Australia (1985-87), Botswana (1987), Brazil (1987), Central African Republic (1985-88), Guinea (1985-89), and Liberia (1985-86), for which source publications give details on grade as well as totals. The estimated distribution of total output between gem and industrial diamond is conjectural, and for most countries, is based on the best available data at time of publication. Estimated distribution figures have been revised as necessary to correspond to reported total production figures.

² Includes near-gem and cheap-gem qualities.

³ Includes all synthetic diamond production.

⁴ Reported figure.

⁵ Figures are estimates based on reported exports and do not include smuggled diamonds.

⁶ Figures do not include smuggled artisanal production.

⁷ Includes estimates for artisanal production.

⁸ Revised to zero.

⁹ Other De Beers' Group output from the Republic of South Africa includes Kimberley Pool, Koffiefontein Mine, and the Namaqualand Mines.

probably well before 1400. Glasscutting was an early application of diamond in industry. It was the most important use of industrial diamond until the 1860's. England issued a patent in 1819 for drawing wire through a diamond die. Diamond wiredrawing dies gave close dimensional accuracy to wire, even after long periods of use.

The use of diamond for metalcutting began in the 1860's, but the high price of diamond tools was a drawback to their acceptance. As the economic advantages of using diamond tools became known, demand increased rapidly.

The use of the first diamond drill was in 1864. The discovery of diamond in The Republic of South Africa in 1867 provided ample supply for the new and growing demand for diamond drill bits.

With the introduction of cemented tungsten carbide cutting tools during World War I, industrial diamond use increased. The cause of the increase was that diamond was the most effective agent in grinding tungsten carbide. Requirements for industrial diamond expanded tremendously because of World War II, when demand increased for grinding wheels, die stones, tool stones, drill bits, dresser stones, and polishing dust. The apparent supply of industrial diamond decreased rapidly following World War II.

In 1955, General Electric Co. announced the development of a process for the manufacture of diamond at its Schenectady, NY, laboratories. Commercial production started in 1957 at its plant in Detroit, MI. In 1969, production moved to Worthington, OH. In 1959, De Beers Consolidated Mines Ltd., announced the manufacture of industrial diamond at its laboratory in Johannesburg, Republic of South Africa. Since these two announcements, the production of synthetic diamond by General Electric, De Beers, and others continued to increase. Today it exceeds the production of natural diamond worldwide about five times.

Geology.—The major source of in-place diamond is kimberlite, an altered, dark-green basic rock of igneous origin. Throughout the world there are approximately 1,000 occurrences of kimberlite, but most do not contain diamonds or do not contain diamonds in economic quantities. The term "diamond pipe" refers to

an occurrence of kimberlite large enough and sufficiently diamondiferous to be mined. The size and shape of these pipes depend on the manner in which molten kimberlite passed through the country rock. They may be columnar, tabular, or irregular in shape. Where mining is deep, the diamond pipe always decreases in area and assumes a dikelike habit. The diamond may contain inclusions of many minerals, and many of these minerals have inclusions of diamond. These accessory minerals include olivine, garnet, diopside, ilmenite, magnetite, rutile, and phlogopite. Every mine has some diamond that is typical of it, but most diamond is indistinguishable from that of other mines.

Currently, about 40% of diamond is from alluvial deposits. These may be alluvial placers, recent or elevated marine beach placers, or glacial deposits. Often the distance of transport has been great. In many areas, the diamond-bearing, alluvial placers were deposited in former drainage systems unrelated to any present system.¹⁶

Technology.—Mining.—Currently the United States has no commercial deposits of diamond. In other countries, mining methods range from very crude hand mining and panning to block caving of kimberlite pipes. Large-scale surface mining operations in Australia, Zaire, Angola, Namibia, and Sierra Leone¹⁷ use modern equipment, such as continuous bucket-wheel excavators, power shovels, draglines, scraper-loaders, and motor trucks to remove overburden and to mine and transport the diamond ore.

Processing.—The type of ore, size of operation, and other factors decide the types of processing equipment used. Crushing, where necessary, is done mostly with gyratory and roll crushers to avoid impact to diamond stones. Additional grinding is done with attrition and ball mills to further separate the gangue from diamond stones. Clayey ore may require the uses of log washers. Diamond washing pans, jigs, heavy-medium separators, or hydrocyclones collect the primary or intermediate concentrates. Depending on the types, shapes, and sizes of diamond present, various final treatments are used. They include the use of grease

tables and grease belts, electromagnetic separators, electrostatic separators, optical sorters, X-ray sorters and other devices. In all processing plants, hand sorting is the final recovery process.¹⁸

Reclaiming industrial diamond stones from drill bits and grit from the wastes generated in grinding, sawing, and other operations is common. This is because of the high unit value of diamonds. Reclamation processes include physical methods such as distillation to remove coolants and lubricants, followed by electrostatic, magnetic, or flotation separation. Reclamation also uses chemical methods including combustion, acid treatment, and fusion with alkalis.¹⁹ The treatment used depends primarily on the contaminants present.

Commercial production of synthetic diamond grit is by two basic methods. Currently, the primary method used involves the application of ultrahigh pressure and high temperature to carbon-metal catalyst mixtures by powerful hydraulic presses. This method uses pyrophyllite and other materials for the reaction vessel. Pyrophyllite for this purpose is from the Republic of South Africa, where the local name for it is wonderstone. The major user of the method now uses synthetic reaction-vessel materials, alleviating the dependency on foreign sources for pyrophyllite. The material used for these replacement reaction vessels is proprietary. The other method employs explosive shock to the carbon-metal catalyst mixtures.

Industrial diamond particles of good quality up to 20 mesh and perhaps larger are produced. The shape and other characteristics can be controlled by proper manipulation of the variables, pressure, temperature, time, and catalyst type. Only micrometer-size particles are presently available from the explosive process. Other methods of diamond synthesis exist, but none are in commercial use in the United States. Other countries produce diamond grit; all apparently use the ultrahigh-pressure, high-temperature method involving hydraulic presses.

Polycrystalline synthetic diamond compacts are a laminated structure of synthetic diamond powder bonded to a cemented carbide substrate. Their production is by a proprietary high-pressure, high-temperature process that gives the product excellent uniform physical properties.²⁰

The polycrystalline synthetic diamond shape is a dense, nonporous, fully intergrown product that is thermally stable to 1,200° C. The producer uses a proprietary high-pressure, high-temperature process using a special binder phase that is retained as an integral part of the product and results in high resistance to shock loading.²¹

MANUFACTURED ABRASIVES

Manufactured abrasives include silicon carbide, fused aluminum oxide, alumina-zirconia oxide, metallic shot and grit, and cut wire shot and grit. Production data reported for silicon carbide, fused aluminum oxide, and alumina-zirconia oxide were for the United States and Canada. Data for metallic and cut wire shot and grit were for only the United States.

Fused Aluminum Oxide

Government Programs.—The National Defense Stockpile, as of December 31, 1989, contained 226,676 tons of crude fused aluminum oxide and 46,179 tons of abrasive-grain fused aluminum oxide. There is no National Defense Stockpile goal for fused aluminum oxide. The crude and abrasive-grain fused aluminum oxide is held as

an offset against a goal of 344,053 tons of abrasive-grain bauxite.

Production.—At yearend, four firms produced fused aluminum oxide at eight plants in the United States and Canada. Production of regular-grade fused aluminum oxide decreased 5% to 164,226 tons. The average annual production for the past 10 years was 138,331 tons. The high was 172,157 tons in 1988 and the low was 105,893 tons in 1982. The production trend for the past 10 years was one of sharp decline, 27% in 3 years, followed by up and down years to full recovery. The 1989 production was 14% greater than 1980 production.

Production of high-purity fused aluminum oxide decreased 7% to 30,634 tons. The average annual production for the past 10 years was 25,511 tons. The high was 33,569 tons in 1981 and the low was 13,468 tons in 1982. The production trend for the past 10 years began with a very sharp decline, 56% between 1980 and 1982. Then production swung between about 14,000 and 28,000 tons until the major increase of 82% in 1988. The 10-year period ended with production essentially unchanged from that of 1980. Total 1989 production of 194,860 tons was 5% less than 1988 production and 63% higher than the low of 119,361 tons in 1982 and 11% higher than the 1980 production of 175,121 tons.

Prices.—The Bureau did not collect

data on the prices of various grades of fused aluminum oxide. It did collect data on the value of fused aluminum oxide production. The average value of regular-grade fused aluminum oxide, as reported by producers, was approximately \$380 a ton. The average annual value for the past 10 years was \$358 a ton, with a high of \$387 in 1983 and a low of \$324 in 1988. In 1989, the average value of high-purity fused aluminum was a 10-year high at \$635 a ton. The average annual value of the past 10 years was \$538 a ton, with a low of \$476 a ton in 1988. The average value of all grades of fused aluminum oxide in 1989 was a 10-year high at \$420 a ton. The average annual value for the past 10 years was \$382 a ton, with a low of \$348 in 1988. The trend for fused aluminum oxide values for the past 10 years was a general upward trend from 1980 to 1983, then a general downward trend from 1983 to 1988. The 1989 average value increased about 21% compared to that of 1988 and 15% to that of 1980.

Foreign Trade.—The quantity of exports plus reexports of fused aluminum oxide increased 11% to 17,207 tons; the value of exports plus reexports decreased 24% to \$19.2 million. The average value of a ton of fused aluminum oxide exported or reexported decreased 33% to \$1,115. During the past 10 years, exports plus reexports have averaged 14,710 tons a year with an average annual value of \$18.4 million and an

Do.	Cap-de-la-Madeleine, Quebec, Canada	Silicon carbide.
		Fused aluminum oxide (regular and high-purity) and aluminum-zirconium oxide.
Do.	Chippawa, Ontario, Canada	
Do.	Shawinigan, Quebec, Canada	Silicon carbide.
Superior Graphite Co.	Hopkinsville, KY	Do.
Washington Mills Ltd.	Niagara Falls, Ontario, Canada	Fused aluminum oxide (regular).

average value per ton of \$1,314. The largest quantity of material exported in a single year in the past 10 years was 26,638 tons in 1982, and the smallest amount was 9,915 tons in 1986. Over the past 10 years no trend developed in the export and reexport of fused aluminum oxide. Quantities increased and decreased randomly, and the period ended in 1989 with exports about even with those of 1980.

Imports were 98,000 tons, a 10-year low, and the value of imports decreased 15% from \$73.7 million in 1988 to \$62.8 million in 1989. Average annual imports for the past 10 years were 135,525 tons, with a high of 170,589 tons in 1981 and a low of 98,000 tons in 1989. The trend of fused aluminum oxide imports for the past 10 years was one of general decline, with 1989 import at 60% of the 1980 level.

Silicon Carbide

Government Programs.—The National Defense Stockpile, as of December 31, 1989, contained 52,990 tons of silicon carbide and the goal was 26,308 tons. During the past year, 12,167 tons of silicon carbide was disposed of from the stockpile; existing legislation authorizes disposal of an additional 26,082 tons in the future.

Production.—Four firms produced silicon carbide at six plants in the United

States and Canada in 1989. Production of abrasive-grade material increased about 4% to a 10-year high of 53,454 tons. Average annual production for the past 10 years of abrasive silicon carbide was 45,865 tons, with a low of 36,193 tons in 1983. Production of metallurgical-grade silicon carbide decreased about 4% to 62,189 tons. Average annual production of metallurgical-grade silicon carbide for the past 10 years was 57,828 tons, with a high of 71,010 tons in 1980 and a low of 38,374 tons in 1983. Production of refractory and other grades of silicon carbide decreased 48% to a 10-year low of 980 tons, which was only 8% of 1986 production and only about 0.3% of 1980 production. The average annual production of refractory and other grades of silicon carbide for the past 10 years was 14,601 tons, with a high of 36,445 tons in 1980. Total production of silicon carbide decreased slightly in 1989 to 116,623 tons, compared with a 10-year average annual production of 118,300 tons. The high was 154,241 tons in 1980, and the low was 98,973 tons in 1983. The 10-year production trend for all grades of silicon carbide was one of sharp decline, 36% in 4 years, and then slow growth and recovery to 76% of the 1980 production level by 1989.

Prices.—The Bureau did not collect price data on the various grades of silicon carbide. Data were available on the value of production of the various

grades. The average value per ton of abrasive-grade silicon carbide, as reported by producers, was \$509; metallurgical-grade averaged \$460; refractory and other grade material averaged \$608; and the average value of all grades was \$484. The average value per ton of abrasive-grade material for the past 10 years was \$497, with a high of \$626 in 1982 and a low of \$414 in 1980. Metallurgical-grade silicon carbide averaged \$420, with a high of \$460 in 1989 and a low of \$389 in 1980. Refractory grade was \$535, with a high of \$644 in 1988 and a low of \$442 in 1986. For all grades the average was \$461, with a high of \$535 in 1982 and a low of \$417 in 1980 and 1985. The trend for the value of all grades of silicon carbide for the past 10 years was one of sharp increases, 28% in 2 years, followed by a general decrease and then generally stable with 3 years essentially unchanged at 103% of the 1980 value. Then, in 1989, there was a significant increase of 13% compared to the average value of the past 3 years.

Foreign Trade.—Exports plus reexports of silicon carbide increased 79% to 8,452 tons. The total value of silicon carbide exported plus reexported increased 27% to \$10 million, and the value per ton decreased 29% to \$1,178. The average annual exports plus reexports for the past 10 years were 6,620 tons, with a high of 12,392 tons in 1980 and a low of 3,859 tons in 1986. The average annual value per ton of exports plus reexports for the past 10 years was

\$1,435, with a high of \$1,865 in 1986 and a low of \$1,068 in 1981. The value of exports plus reexports decreased 25% during the past 10 years.

Imports of silicon carbide in 1989 decreased 4% in quantity to 98,000 tons and increased 7% in total value to \$64.6 million. The average value per ton increased 11% to \$659. The total value was a 10-year high. The average annual imports for the past 10 years were 76,932 tons, with a high of 101,600 tons in 1988 and a low of 56,250 tons in 1985. The average value per ton for the period was \$577, with a high of \$659 in 1989 and a low of \$497 in 1980. The trend of silicon carbide imports for the past 10 years was one that generally decreased to a low in 1985, followed by continuing increases until 1988 and then the decreased in 1989.

Alumina-Zirconia Oxide

One firm produced fused alumina-zirconia oxide in two plants, one each in the United States and Canada. Abrasive applications accounted for all the production. Output increased in both tonnage and value compared with 1988. Export and import data were not available.

Metallic Abrasives

Production.—Eleven firms produced metallic abrasives in 12 plants in the United States. At yearend, a firm purchased a closed plant and announced plans to put the plant into operation in 1989. Quantity, value, and average

value per ton of steel shot and grit production was essentially the same as for 1988 at 206,278 tons, \$79 million, and \$383 per ton, respectively. The average annual production for the past 10 years was 175,600 tons, with a high of 206,278 tons in 1989 and a low of 135,843 tons in 1982. The average value per ton during the period was \$355, with a high of \$402 in 1982 and a low at \$310 in 1987. The trend of steel shot and grit production for the past 10 years was one of decline to the low in 1982 and then general continued recovery. The 1989 production was equal to about 110% of the 1980 production level. Michigan, Ohio, Pennsylvania, Virginia, Maryland, and Indiana, in decreasing order of quantity, supplied the production of steel shot and grit.

Two companies, one each in Indiana and Ohio, produced chilled and annealed iron shot and grit. Additionally, two firms, one in Michigan and one in New York, reported production of cut wire shot. Production and value of chilled and annealed iron and cut wire shot and grit was essentially the same as 1988 at 17,452 tons and \$10.6 million. The average value per ton was essentially unchanged at \$605. The average annual production of these types of shot and grit for the past 10 years was 18,136 tons, with a high of 27,891 tons in 1980 and a low of 13,352 tons in 1986. The average value per ton for the past 10 years was \$440, with a high of \$612 in 1988 and a low of \$307 in 1980.

Consumption.—The quantity of steel shot and grit sold or used decreased 6% to 202,424 tons, the total value decreased 6% to \$81.3 million, and the average value per ton was essentially unchanged at \$401. The average annual quantity of steel shot and grit sold or used for the past 10 years was 174,791 tons. The high was 214,787 tons in 1988 and the low was 133,275 tons in 1982. The trend for sold or used steel shot and grit for the past 10 years was one of fluctuating decreases and increases. The 1989 sold-and-used value was 4% greater than the value in 1980.

The quantity of chilled and annealed iron and cut wire shot and grit sold or used decreased 5% to 16,826 tons. The value was essentially the same as for 1988 at \$11.5 million. The average value per ton increased 6% to \$681. The average annual quantity of these shot and grit sold or used for the past 10 years was 17,367 tons, with a high of 28,699 tons in 1980 and a low of 9,152 tons in 1985. The trend for the sold and used value for the past 10 years was one of large individual increases and decreases. Changes were as much as 50% in a year, with the low in 1985. Since then, continued growth resulted in the 1989 value equaling 120% of the 1980 level.

The estimated apparent consumption of all types of metallic shot and grit decreased 4% in quantity to 214,772 tons, slightly in total value to

\$89.6 million, and increased 3% in average value per ton to \$418. The formula to calculate U.S. estimated apparent consumption is U.S. sold or used plus imports minus exports. The average annual estimated apparent consumption of metallic shot and grit for the past 9 years was 186,615 tons, with a high of 224,216 tons in 1988 and a low of 144,986 in 1982. The average value per ton for the same period was \$400, with a high of \$432 in 1985 and a low of \$375 in 1987. The trend of apparent consumption for the past 9 years was one of rapid increases and declines until 1985. This was followed by general growth until consumption in 1988 was 13% greater than that of 1981. Even with the decline, 1989 consumption was 8% greater than 1981.

Foreign Trade.—U.S. exports of metallic shot and grit decreased 27% to 8,646 tons. The total value of exports decreased 35% to \$6.3 million, and the average value per ton decreased 11% to \$728. The average annual tonnage of metallic shot and grit exports for the past 10 years was 9,363 tons, with a high of 14,146 tons in 1980 and a low of 6,334 tons in 1986. The average value per ton for the past 10 years was \$750, with a high of \$948 in 1987 and a low of \$616 in 1980. The trend for metallic abrasive exports for the past 10 years was one of general decline from 1980 through 1983, followed by fluctuating increases and decreases. The 1989 exports were still 40% below the level of 1980 exports.

U.S. imports of metallic abrasives increased 18% in quantity to 4,168 tons, was essentially the same in total value at \$3.4 million, and decreased 15% in value per ton to \$822. The average annual imports for the past 9 years were 4,257 tons, with a high of 8,509 tons in 1984 and a low of 2,699 tons in 1987. The average value per ton for the period was \$607, with a high of \$965 in 1988 and a low of \$280 in 1984. The trend for the quantity of imports for the past 9 years was one of up-and-down fluctuations resulting in a general decline; 1989 imports were only about 87% of those of 1981.

The United States was a net exporter of metallic abrasives in 1989, a position it has enjoyed by a 2.2-to-1 ratio for the past 10 years.

TABLE 19
PRODUCERS¹ OF METALLIC ABRASIVES IN 1989

Company	Location	Product (shot and/or grit)
Abrasive Materials Inc.	Hillsdale, MI	Cut wire, steel.
Chesapeake Specialty Products	Baltimore, MD	Steel.
Durasteel Abrasive Co.	Pittsburgh, PA	Do.
Ervin Industries Inc.	Adrian, MI	Do.
Do.	Butler, PA	Do.
Globe Steel Abrasives Co.	Richland, OH	Do.
Metaltec Steel Abrasives Co.	Canton, MI	Do.
National Metal Abrasive Co.	Wadsworth, OH	Do.
Pellets Inc.	Tonawanda, NY	Cut wire.
Steel Abrasives Inc.	Hamilton, OH	Chilled and annealed iron and steel.
U.S. Abrasives Inc.	Tippecanoe, IN	Do.
The Wheelabrator Corp.	Bedford, VA	Steel.

¹ Excludes secondary (salvage) producers.

ADVANCED MATERIALS

By Charles A. Sorrell

Dr. Charles A. Sorrell, Program Manager, Advanced Materials Technologies, has more than 32 years of experience and has been with the Bureau of Mines for the past 8 years.

Advanced materials are those developed during the past 30 years or so that are being developed at an accelerating rate at present. They all exhibit greater strength, higher strength/density ratios, greater hardness and wear resistance, and one or more superior thermal, electrical, optical, or chemical property when compared with traditional materials. Advanced metals, ceramics, and polymers, including composites, offer the promise of decreased energy consumption, better performance at acceptable cost, and less dependence on imports of strategic and critical materials. New electronic, magnetic, optical, and chemical devices are creating a revolution in communications, data analysis, chemical and structural analysis, medical technology, and industrial processing. These promise dramatic changes in manufacturing and human lifestyle.

The decade of the 1980's saw advanced materials become recognized as critical to future technologies by the industrialized nations, with the United States, Japan, and the European Community (EC) being the major competitors. All three have identified communications technologies (including all aspects of information, computation, and solid-state electronics and optics), biotechnology, and advanced materials as the keys to future industrial leadership. The closing decade of the 20th century is expected to be an era of rapid development and restructuring. Enormous challenges are posed to the position of the United States in the world economy: (1) the progress of EC '92, the effort to develop uniform standards and remove trade barriers in Western Europe; (2) the determination of Japan to commercialize advanced structural ceramics, alloys, composites, and superconductors; (3) the emergence of developing countries as major suppliers of commodity materials and their increasing interest in moving into advanced technologies; (4) and the recognition by

other industrialized but smaller nations—such as Australia, Canada, and the Republic of South Africa—of the need to move from the status of commodity mineral and materials suppliers to full participants in advanced industrial technologies.

The decade was one of rapidly increasing internationalization of industry, with greatly accelerating foreign investment in the United States and the recognition that financial, structural, and cultural barriers must be overcome if the Nation is to maintain a competitive position.

New materials developments have occurred throughout human history. Until recently, new materials such as aluminum, copper, plastics, and steel were discovered and applied to existing processes and products, resulting in improvements in performance, durability, reliability, or manufacturing efficiency and cost. It was customary for designers and engineers to select from a limited number of commodity materials, whose properties were well understood and measurable, and to design products and fabrication processes within the property limits of those materials. Modern mass production developed in the 20th century on the basis of the property and processing reliabilities of commodity materials, leading to unprecedented manufacturing efficiencies and standards of living for the industrialized nations. Progress came, however, at the price of increasing energy consumption by the manufacturing sector and the mobile consumer and the increasing environmental effects of that energy use.

During and immediately following World War II, a new perspective began to take shape, prompted by the need for new materials with superior properties for improved performance. Development of electronic and sonic detection devices, improved armor and antiarmor technology, nuclear weapons and fission reactors, and high-performance jet engines required new materials with improved properties specifically tailored to applications. At

about the same time, a revolution in computation and analysis began, with the discovery of the field effect transistor in 1947, leading to the first large-scale integrated circuit in 1953. By the late 1960's, electronic computational devices, detection systems, and analytical instrumentation had developed to the point that understanding of the relationships between structures and properties of materials had reached a very high level, and available techniques for synthesis had increased markedly. It became possible to think in terms of making a material with specified properties rather than limiting design, manufacturing, and performance to available commodity materials.

The energy crises of the second half of the 1970's resulted in low economic growth or recession on a global basis and indicated the extent to which the industrial health and economic well-being of the EC, Japan, and the United States were dependent on suppliers of energy, minerals, and commodity materials around the world. The need for more energy efficiency and reduction of reliance on other nations for raw materials became adequate motivation for development of structural materials with higher strength-to-weight ratios, greater resistance to high temperatures, better corrosion resistance, greater durability, and more reliability. The candidates for new structural materials—metal alloys, engineering polymers, advanced structural ceramics, and composites of these—have become subjects of intense research, development, and commercialization and constitute one of the major areas of international competition.

The intrinsic properties of structural ceramics, including high strengths, hardness, wear resistance, corrosion and oxidation resistance, and stability at very high temperatures, make them prime candidates for a wide variety of applications. They can replace metals and plastics in many existing systems to provide better performance and durability and are enabling

components in new technologies. Their potential, which has been recognized for more than a decade, has been slow to develop, however, because of technical and economic factors. It is fair to say that advanced structural ceramics are yet in their infancy, but certain to become increasingly important as problems are solved and new applications require their superior properties.

Advanced polymer matrix composites (PMC), consisting of a wide variety of commodity or engineering plastics reinforced with continuous fibers, filaments, or tapes or with short, discontinuous fibers, whiskers, or particles, also hold great promise for a variety of structural applications. Their superior strengths, strength-to-weight ratios, corrosion resistance, and potential for reduction of the numbers of parts to be assembled in a given system ensure that applications will increase. Use of PMC's as replacements for metals, glass, or ceramics requires, however, essentially different plants and equipment, necessitating large capital expenditures and development of automated equipment. For these reasons, PMC's are finding rapidly increasing applications in defense, aerospace, and sporting goods where improved performance justifies the higher costs. They have been slow to find extensive applications in the automobile industry because they are generally not cost-competitive with metals. However, new fuel consumption standards, rising fuel costs, more stringent exhaust emission standards, and demand for improved durability and performance are adequate incentives for automobile manufacturers to plan for eventual retooling to use new materials.

DOMESTIC DATA COVERAGE

The structure of the ceramics and plastics industries of the United States is diverse in terms of the wide variety of products and the kinds of companies engaged in manufacturing. Unfortunately, no systematic data collection on the structure of the advanced materials industry or production of materials has been done. Between Bureau of Mines data on commodity minerals and metals and the Bureau of the Census data on commodities and finished products, the flow of processed materials through the various value added steps between commodity and product is not covered. The Bureau of Mines is in the process of developing data acquisition methods

to cover advanced materials production but presently must rely on data from existing sources. The accuracy and completeness of these data, most in highly aggregated form, permit only broad generalizations about the current status of new materials, and virtually no historically valid trends can be discerned.

The publishers of Ceramic Industry magazine, over the past 8 years, have conducted the only systematic survey of the industry, relying on voluntary reporting of sales figures and their own estimates of those of nonreporting companies. Most of the information on ceramics reported here is from the results of the Ceramic Industry surveys of 1986,¹ 1987,² 1988,³ and 1989.⁴ The data for 1989 were generously provided in advance of publication by Ms. Patricia Janeway, Editor-in-Chief and Associate Publisher. Similarly, data on production and costs of PMC's are from the open literature.

LEGISLATION AND GOVERNMENT PROGRAMS

Growing awareness of advanced materials as enablers of new technologies was evidenced in 1989 by reorganization of the Office of Science and Technology Policy (OSTP) in the Executive Office of the President. The Director of OSTP, who is also the Science Advisor to the President, designated communications technology, biotechnology, and advanced materials as the essential elements of technical and industrial competitiveness. He linked materials to manufacturing by assigning responsibility for materials policy to the Associate Director for Industrial Policy. The Federal Coordinating Council for Science, Engineering, and Technology (FCCSET), chaired by the Science Advisor, has Assistant Secretary level participation by all agencies having responsibilities in materials research and development. The newly formed President's Council of Advisors on Science and Technology (PCAST), also chaired by the Science Advisor, has industrial and academic members with knowledge of, and interest in, advanced materials. Both FCCSET and PCAST report directly to the President. The Science Advisor was also named to the chairmanship of the National Critical Materials Council (NCMC); the other members named were the Director of the Bureau of Mines and an Assistant

Secretary of Energy. NCMC has begun working closely with OSTP on policy matters dealing with advanced materials.

The National Competitiveness Technology Transfer Act of 1989 (Public Law 101-189) was signed by the President in November. The law is designed to link industry, universities, and national laboratories to accelerate commercialization of new technologies, including advanced materials. The law makes provisions allowing national laboratories to enter into cooperative research and development agreements; negotiate licensing agreements for inventions; exchange personnel, services, and equipment with industry and universities; waive rights to inventions and intellectual property; streamline the processing of agreements. It also assigns a technology transfer mission to the nuclear weapons laboratories. The Secretary of Commerce reported to the President that, by the end of 1988, 111 cooperative research and development agreements (CRADA) had been signed under the provisions of the Federal Technology Transfer Act of 1986, the predecessor to the 1989 act. Many of the CRADA's were for new materials development.

The Department of Commerce established a new Office of Technology Administration in 1989. The Undersecretary for Technology is to work closely with the President's Science Advisor to help coordinate strategies and programs in the Federal agencies. The focus will be to remove barriers and provide incentives for rapid commercialization of technology in the United States. Advanced materials are essential components of all new technologies and are to receive increased attention.

Two bills addressing advanced technologies and materials were introduced in the Congress in 1989 but had not been enacted by year's end. The American Technology Preeminence Act of 1990 (House Resolution 4329) provides appropriations to strengthen the role of the National Institute of Standards and Technology (NIST, formerly the National Bureau of Standards) in assisting private industry in commercialization and marketing of new technologies and processes needed to remain competitive in the global marketplace. The funds are to be provided to the Commerce Department Advanced Technology Program, to be administered by NIST.

A bill (S. 1978) introduced in the Senate proposes reorganization of the Department

of Commerce into the Department of Industry and Technology. An Undersecretary for Industry would handle economic development matters, export promotion, and statistical analysis. An Undersecretary for Technology would be in charge of all science and technology offices currently in Commerce along with a new Advanced Civilian Technology Agency that would fund technology development deemed essential to the Nation.

ADVANCED STRUCTURAL CERAMICS

Production and Consumption

Sales of the major categories of ceramics by U.S.-owned companies, derived from the Ceramic Industry surveys for 1986-89,⁵ are listed in table 1. Though these data do not include many important ceramic products, including abrasives, pigments, cements, etc., they do provide a perspective from which to view advanced ceramics (which include porcelain insulators, electronic, optical, and magnetic materials). With approximately steady sales over the 4-year period at about \$4.3 billion, advanced ceramics constituted only 12.6% to 15.2% of the total. Glass, including plate, container, automotive, and specialty glasses, has consistently made up 55% to 60% of the total market, with other segments holding roughly equal shares.

Table 2 shows sales of advanced ceramics in six categories for the years 1986-89. Advanced structural ceramics (listed as engineering ceramics in table 2) made up 23.4%, 22.3%, 18.8%, and 20.9% of the total for the 4 consecutive years. Because low-voltage and high-voltage electrical insulating porcelain are generally not considered advanced materials in the sense that new structural and electronic materials are, table 3 has been prepared to include only two categories, engineering ceramics and combined electronic, optical, and magnetic ceramics. Table 3 shows that total sales of advanced ceramics, as so defined, have remained nearly constant over the past 4 years at about \$3 billion and that advanced structural ceramics has remained at about 30% of the total. Their economic importance, moreover, as shown by sales as a percentage of total ceramics sales, has apparently been decreasing.

The data in tables 2 and 3 may be misleading, however, because the surveys do not include significant production of

advanced structural ceramics in the United States by foreign-owned companies.

Unfortunately, there are insufficient data to indicate that production. It is likely, however, that total production has actually been increasing in the past several years. There is confidence within the industry that advanced structural ceramics will continue to grow in importance as technical barriers to manufacturing are overcome and economies of scale come into play.

Production data for individual advanced ceramic powders are not available from a single consistent source. This is owing in part to the proprietary nature of the information and also because the production

levels are, in many cases, a small part of the individual company's total production.

In the case of alumina, there are so many different applications that designating what portion of total production goes into advanced electronic or structural materials is virtually impossible. The Bureau of Mines estimates that about 104,000 metric tons of calcined alumina are produced annually worldwide. Of that, 50% is used for refractories, 20% for abrasives, 15% for white wares and spark plugs, and 5% (5,200 metric tons) for miscellaneous applications. High-purity ceramic alumina powder constitutes part of the 5,200 metric tons, but an accurate estimate is not possible.

The West's market for special aluminas is supplied primarily by Aluminum Company of America (Alcoa), Aluminum Company of Canada (Alcan), and LaRoche Chemical Inc., in North America; PUK, Martinswerk (Alusuisse), Alcoa Chemie-Nederland and GmbH, Vereinigte Aluminum-Werke (VAW), and British Aluminum Co. (BACO) in Europe; Alcoa Industrial Chemicals-Asia and Alcoa Industrial Chemicals-Australia, Nippon Lightmetal, Showa Denko, and Sumitomo Chemicals in Asia; and Alcoa-Brazil and Alcan in South America.

The Bureau of Mines estimates total production of silicon carbide in the United States and Canada was 115,540 metric tons in 1989, most of it for abrasives and refractories. High-purity "green" silicon carbide production for advanced structural ceramics is primarily for research and development use and is produced in-house for those purposes or is imported from Japan and Western Europe.

Silicon nitride and sialons (silicon aluminum oxynitrides) have no use other than for advanced structural ceramics. Reliable figures for production are unavailable; it appears that the only U.S. production is by manufacturers for their own use, and there is no domestic supplier of high-purity powder. Powder can be purchased from sources in Canada, the Federal Republic of Germany, Japan, Sweden, and the United Kingdom. Worldwide production is estimated at about 400 metric tons. Production data for the various forms of zirconia for advanced structural applications are also unavailable. A rough estimate, based on conversations with major producers in the United States, is that 1,000 to 2,000 metric tons is currently produced.

Though no reliable data are available, it can be reasonably assumed that production of advanced ceramic powders is a very small percentage of total ceramic production and that materials availability is not an issue.

Industry Structure

As stated previously, the structure of the ceramic industry of the United States is diverse in terms of the wide variety of products and the kinds of companies engaged in manufacturing, and no systematic information has been gathered, except on a highly aggregated basis. The following is a synthesis of information available for calendar year 1989, derived from the

Ceramic Industry survey⁶ and compared with data for 1986, 1987, and 1988.⁷

Table 4 shows the size distribution, in terms of sales volumes, for the 80 largest U.S. advanced ceramics companies in the Ceramic Industry survey for 1989.

The largest producers are Corning Inc., Corning, NY, a major manufacturer of glass, glass ceramics, and other commodity ceramics, whose major advanced products are ceramic honeycomb for automotive catalyst carriers and optical fiber; and Cooper Industries, Houston, TX, which recently acquired the Champion Spark Plug Co. Reported sales for Corning were \$869.9 million and for Cooper Industries were \$512.9 million. Within the \$200 to \$500 million range are General Motors Corp., whose AC Spark Plug and GM Hughes Electronics Divs. accounted for \$454.5 million in sales of spark plugs and defense electronics; AVX, New York, NY, with \$408.0 million in sales of electronic ceramics and a variety of structural ceramics; GTE, Stamford, CT, whose Precision Materials Div. reported sales of \$382.2 million in a variety of products associated with lighting; and Allied Signal, Morristown, NJ, whose Autolite Div. posted spark plug sales of \$211.7 million.

Among the top 10 advanced ceramics producers with sales of more than \$50 million dollars, all but one are primarily manufacturers of spark plugs, optical fiber, electronic components, and porcelain insulators. Only Coors Ceramics Co., Golden, CO, with sales of \$108.8 million, is a major producer of structural ceramics, including alumina and partially stabilized zirconia. Even Coors derives a significant portion of its income from electronic substrates and packaging.

The smaller companies with sales of less than \$50 million, as tabulated in table 4, are the major producers of advanced structural ceramics. As evident in table 4, many of these are privately held entrepreneurial companies. Ownership of these small companies over the past 4 years has been changing rapidly through mergers and acquisitions, many with and by foreign companies. It should be noted that the Ceramic Industry survey is of U.S.-owned companies and does not include some large foreign companies such as Kyocera America Inc., which employs an estimated 12,000 workers in 9 locations in the United States. The parent company, Kyocera Corp. of Kyoto, Japan, one of the largest Japanese producers of commodity and advanced ceramics, has been expanding rapidly in the United States and Europe. Among significant changes in industry structure during 1989 were several changes in ownership, mainly acquisition by Japanese and European buyers, and some expansion of production capacity.

AVX Corp., New York, NY, with 3,000 employees and sales of \$408 million announced a merger with Kyocera Corp. involving an exchange of stock. Later it was announced that AVX would sell all its stock to Kyocera and become a totally owned subsidiary, with no change in AVX management.

Carborundum purchased the Specialty Products Div. of Ceradyne Inc., a maker of high-performance silicon carbide. Carborundum is a U.S. operation of BP Industries of the United Kingdom.

Coors Ceramics Co., announced plans to locate a facility in Oak Ridge, TN, to produce high-precision complex configurations of ceramic materials. Coors also

announced that it had acquired a "significant financial interest" in Cercom Inc., Vista, CA, and would relocate some of the activities of Cercom to the Oak Ridge facility. Cercom, with 34 employees, produces silicon nitride, silicon carbide, titanium diboride, boron carbide, and alumina ceramics for the aerospace and defense industries, industrial wear applications, and electronics industry. Advanced Composite Materials Corp. (ACMC), Greer, SC, entered into an agreement with MB Group, P.L.C., United Kingdom, to develop and commercialize its high-performance silicon carbide whisker-reinforced alumina material in a new generation of tooling systems. ACMC is a totally owned subsidiary of Tateho America Inc., a Japanese company.

Sony USA Inc., a subsidiary of Sony Corp. of Japan, reached an acquisition agreement for Materials Research Corp., Orangeburg, NJ, offering a reported \$58.5 million for MRC shares. Alcan Aluminum Corp. of Canada, acquired Technical Ceramics Labs Inc. (TCL), Alpharette, GA. TCL has proprietary techniques for injection molding ceramics, including oxides and carbides, as well as composites with ceramic whiskers or fiber preforms. Terms were not disclosed.

Carborundum Co., Niagara Falls, NY, received a subcontract for \$5.8 million from Rockwell International to produce the armor protection system for the U.S. Air Force 11 AC-130U gunship aircraft. The system uses Carborundum's sintered silicon carbide affixed to a high-performance fiber board.

In summary, 1989 was an active year in terms of mergers, acquisitions, and cooperative agreements with the most notable trend being toward expansion by some U.S. companies, notably Coors Ceramics Co. and Corning Inc. Acquisition by foreign companies interested in expanding capacity for production of advanced ceramics and developing new markets for these materials continued.

Current Research

The importance of advanced materials to the economic future of the United States has been underlined in a number of assessments and reports over the past 3 years. The Office of Technology Assessment, at the request of the Congress, prepared a report⁸ on the importance of advanced ceramics, engineering polymers, and composites and summarized the

technical and commercial impediments to successful commercialization of these structural materials. The NCMC of the Executive Office of the President prepared a program plan for advanced materials⁹ for submission to the Congress in accordance with the National Critical Materials Act of 1984. Though not a "plan" as such, the report summarized the status of materials development, the barriers to commercialization, and the steps already taken by legislation and Executive order to remove legal barriers and impediments to assist industry.

The National Research Council (NRC) released a major report,¹⁰ 5 years in preparation, that emphasized that there has been inadequate attention paid to synthesis and processing of new materials, and to manufacturing in general, by Federal research establishments, the academic community, and industry. Shortly thereafter, the NIST published a more detailed version of the contribution of Panel 3 of the NRC Committee.¹¹ The report is a very thorough assessment of the relative positions of the industrialized nations, the national policies, and programs for science and technology in general and materials science and engineering in particular.

The Bureau of Mines, at the beginning of this year, published the widest ranging report on new materials yet available. The two volume report¹² summarizes the status of new materials markets, economic and policy issues, and science and technology, including technical constraints on commercialization of new materials. The Bureau report, unlike others, gives adequate attention to recent and potential developments in metal alloys, with emphasis on improved processing for better physical properties in metal systems. The importance of structural and functional materials to military security was also indicated by the U.S. Department of Defense in a "Critical Technologies Plan."¹³ The technologies identified include not only those of strictly military importance but those important to the industrial base in general, upon which the civilian economy also depends.

A good indication of the recognition of advanced materials as essential to future industrial competitiveness is the recent summary¹⁴ of technological challenges and comparative policies relevant to advanced materials in the member nations of the Organization for Economic Operation and Development. Given the emphasis by the Japanese on new materials and the success of Japan in the financial and trade arenas,

it is no surprise that other countries, industrialized and developing, are attempting to position themselves to compete. A sizeable portion of research and development (R&D) in advanced structural ceramics is conducted or sponsored by the U.S. Government, as in the following summary. No reliable data are available for estimating research, development, and pilot plant operations in industry. Most estimate that industrial effort is on a par with, or perhaps twice as much as, the Federal effort.

As shown in table 5 (from the Committee on Materials, OSTP), total support for structural ceramics R&D in Fiscal Year 1989 was almost \$86 billion, or about 8.5% of the total materials budget. The budget for Fiscal Year 1990 shows a slight decrease in absolute dollars, and the President's request to the Congress for Fiscal Year 1991 shows a considerable cut, about 5% over that of Fiscal Year 1990. It should be pointed out, however, that for the past several years Congress has seen fit to provide add-on funding for materials research and development (R&D) in general and, barring sizable cuts in defense spending, it is likely that the Fiscal Year 1991 budget will be comparable with the previous 2 years.

The U.S. Department of Energy (DOE) funds 51.7% (\$44.441/million) of Federal materials R&D, 72% of which is conducted in the DOE National Laboratories, 24% of which is provided in grants to universities, and 4% of which is given to industry. DOE's interests cover the entire range of ceramic science: processing and synthesis; deformation, fracture, and cyclic fatigue; stress corrosion; electronic structures; microstructure, defects, and dislocations; surfaces, interfaces, and grain boundaries; radiation effects; toughening mechanisms; and superplasticity. Of particular note are the efforts of the Office of Transportation Technology to develop applications for advanced ceramics in gas turbines, advanced heat engines, and other ground transportation systems. Total funding over a 5-year period is more than \$38 million.

The Department of Defense funds a wide variety of structural ceramics R&D, with the major emphasis on development and rapid application to military systems. Total funding for Fiscal Year 1989 was \$21.508 million, 25% of the total. The research is accomplished partly in-house, in such laboratories as the Army Materials Technology Laboratory, the Naval Research Laboratory under the Office of Naval Research (ONR), the materials laboratories of the Wright Research and

Development Command, and the Naval Surface Warfare Center. The remainder is conducted by universities and industry through funding by the Army Research Office-Durham, ONR, the Air Force Office of Scientific Research, and the Defense Advanced Research Projects Agency. Of interest to Defense are all aspects of structural and electronic materials, including processing and synthesis of ceramics and composites for ultrahigh strength, high-temperature capabilities, and corrosion resistance for use in aircraft and missiles, armored vehicles, naval vessels, gas turbine engines, and weapons systems. R&D for the Strategic Defense Initiative ("Star Wars") is not included in the totals in table 5.

The National Aeronautics and Space Administration spends about \$10 million per year, mainly on in-house research on toughened and fiber-reinforced ceramics, coating of fibers and composites, fatigue and fracture studies, structural mechanics,

tribology, nondestructive evaluation, and design methodology. Major materials efforts are devoted to the National Aerospace Plane, the space station, and the high-speed civilian transport plane.

The National Science Foundation, which is an independent organization chartered and funded by the Federal Government, funds basic research only by way of grants. These are to universities through the Materials Research Laboratories, the newly established Engineering Research Centers, small research groups, and individual principal investigators. The emphasis is on processing science, mechanical behavior, and characterization.

The Bureau of Mines through the Div. of Minerals and Materials Science, has a research budget of about \$24 million. About \$15 million is devoted to minerals research—extraction, beneficiation, etc.—with the remaining \$9 million devoted to materials research. Only \$3.1 million goes

to structural ceramics research at the Tuscaloosa Research Center (TURC), the Albany Research Center (ALRC), and the Idaho National Engineering Laboratory (INEL). The latter is a DOE laboratory where research of interest to the Bureau of Mines is conducted with Bureau funds. At present, TURC research is in processing and structure-property relationships; ALRC research is in vapor phase synthesis of nitrides; and INEL research is devoted to oxynitride compositions and nondestructive evaluation.

NIST spends \$3 million in appropriated funds on processing science, mechanical behavior, and characterization of advanced structural ceramics at the Materials Science and Engineering Laboratory. NIST has been quite successful over the years in leveraging research funding by conducting contract research for other Agencies, through a visiting scientist program, and the Research Associates Program. The added funding and support-in-kind from industry effectively doubles the support for many NIST programs.

Outlook

There is no shortage of projections of advanced structural ceramics production; however, estimates for the year 2000 currently published vary by more than an order of magnitude. Given the lack of data gathering capability and the proprietary caution of producers, this is not surprising. The only general statement that can be made is that production and consumption will increase and that, by the year 2000, advanced structural ceramics will be economically significant.

A synthesis of various estimates has been offered by R.N. Katz,¹⁵ who used a number of sources, including data from the U.S. Department of Commerce, the Long Term Credit Bank of Japan, and trade publications, as well as private discussions. The estimates, shown in table 6, do not include present or projected military applications, which could be significant.

Background

Definitions, Grades, and Specifications.—Ceramics are solid inorganic, nonmetallic materials and/or products made from mineral particles by processing in one or another of a variety of ways at high temperatures. Processing may involve melting and rapid cooling, as is the case with glass; partial melting, as with porcelain and porcelain enamel; melting,

casting, and recrystallization, as with glass ceramics; or solid-state reaction (sintering), as with alumina (Al_2O_3) or zirconia (ZrO_2). A small quantity of liquid may be formed during solid-state sintering if a component is added as a sintering aid to accelerate reaction and densification. In any case, a ceramic is made by using high temperature to form a solid body by changing the state of aggregation, forming new chemical compounds, or both. Ceramic technology as described previously originated in prehistory and remains today, though with ever improved processing efficiency and property development. The past decade, however, has produced some new methods for ceramic fabrication that promise to improve both processing and properties. These include chemical and physical vapor deposition, plasma spraying to form coatings or fine powders, sol-gel formation, and organic precursors for powder synthesis.

In the broadest sense, ceramics includes all processed inorganic, nonmetallic materials: glass, porcelain and other pottery and dinnerware, porcelain enamels for coating metals or ceramics, whiteware (bathroom and kitchen fixtures), refractories, construction brick, tiles, clay pipe, abrasives, pigments, cements, limes, plasters, and a wide variety of specialty products.

Advanced ceramics are generally classified as having a structural function—i.e., they must retain their physical integrity in harsh environments, at high stresses, at high temperatures, or under chemical attack—or an active function—i.e., their properties are essential to the functioning of an electronic, optical, or magnetic

device or system. The two classes are commonly referred to simply as structural or functional ceramics; that convention will be observed here. The following discussion is restricted to structural ceramics, with emphasis on those materials still in the R&D stage or early stage of commercial development.

A summary of important advanced structural ceramics, their uses, fabrication, and important properties is given in table 7.

The number of chemical compositions and processing variables is quite large; however, the potentially important materials for large-scale application are limited. These are alumina (Al_2O_3), silicon carbide (SiC), silicon nitride (Si_3N_4), sialons (solid solutions of silicon nitride and alumina), and various forms of zirconia (ZrO_2). Attention is focused on these, with brief mention of other materials and their uses.

Alumina (aluminum oxide), though one of the most abundant oxides in the crust of the Earth, is for practical purposes obtainable only from bauxite, a complex mixture of hydrated aluminum oxides. Bauxite must be refined to produce anhydrous oxide suitable for use as feedstock for reduction to aluminum, refractory grain, or other specialty products. Alumina is used for a wide variety of ceramic products, including refractory brick, cements, and castable refractories. High-purity aluminas, those with 75% to 100% Al_2O_3 , are high-value materials used because of their electrical resistivity for semiconductor and integrated circuit substrates, high-frequency insulators, holders and spacers for printed circuits, and spark plug insulators. The high strength and hardness of alumina make it suitable for seal surfaces for rotary pumps, nozzles for a variety of applications, cutting tools, nonlubricated roller bearings, grinding media, and a host of other applications requiring strength, hardness, and wear resistance. Alumina retains about 90% of its mechanical strength up to 1,100° C, though its high coefficient of thermal expansion results in poor thermal shock resistance, which limits its use in applications involving rapid temperature changes. A promising new material is transformation toughened alumina, with 8 to 15 percent by volume of ZrO_2 included in the ceramic body. Cracks that develop during rapid cooling are prevented from growing and causing catastrophic failure by the transformation in ZrO_2 , which is discussed later. A family of fibers of alumina, targeted for use as reinforcement

of a variety of composites, is now commercially available. These are spun from solutions or slurries of alumina-containing precursors, followed by heat treatment. They are available as woven preforms, papers, and mats.

Boron carbide (B_4C) is harder than all known materials, other than diamond and cubic boron nitride. It has found use, therefore, as an abrasive, abrasion-resistant components, and ceramic armor. Because of the high neutron cross-section of boron, both boron and boron carbide have been used as reactor control elements, radiation shields, and moderators.

Silicon carbide (SiC), has been used for nearly 100 years as an abrasive and for manufacture of electrical heating elements and, more recently, as a super-refractory. High-purity silicon carbide, with less than 1.2% impurities, is a prime candidate for many structural applications requiring high strength at high temperatures and good wear resistance, such as in automotive engines. High strength fibers of silicon carbide have been produced by chemical vapor deposition; platelets and whiskers have also found use as reinforcements for ceramic, metal, and polymer composites.

Silicon nitride (Si_3N_4) exhibits excellent corrosion and oxidation resistance over a wide temperature range and retains its high strength up to 1,100° C. Because of these properties and high hardness, it has been under evaluation for use as components in gas turbine engines and heat engines, as high-temperature bearings, cutting tools, industrial wear parts, and ceramic armor. Sialons, oxynitrides of silicon and aluminum, are similar in structure and properties to silicon nitrides. They are being used as lubrication-free bearings, rocket nozzles, and gas shrouds for orbital welders.

Zirconia (ZrO_2), produced from the mineral zircon (ZrSiO_4) or less commonly from baddeleyite (ZrO_2), exists in three different structural forms, depending on temperature and amounts of other oxides (magnesia, MgO ; lime, CaO ; or yttria, Y_2O_3) included in the crystal structure during synthesis. By incorporation of several percent of the stabilizing oxide, a mixture of cubic and tetragonal forms can be produced. Stress applied to the materials, by external mechanical force or resulting from rapid temperature change, causes transformation of the tetragonal form to the low-temperature monoclinic form. This results in an increase of 3% to 5% in the volume of the crystal, effectively blocking crack

TABLE 7
STRUCTURAL CERAMICS

Materials class	Chemistry and form	Processing methods	Critical properties	Uses or potential uses
Monolithic: Oxides	Al ₂ O ₃ ; partially stabilized ZrO ₂ (PSZ); tetragonal zirconia polycrystal (TZP); BeO; cordierite; SiO ₂ ; mullite; Al ₂ TiO ₅ ; Y ₂ O ₃ ; ThO ₂ .	Prepared as submicron powders; formed by pressing; sintered at high temperatures with or without pressure.	Heat resistance; strength; wear resistance; corrosion resistance.	Turbine blades; adiabatic engine components; heat exchangers; cutting tools; bearings; catalyst carriers; mechanical seals; nozzles; RF crucibles; nuclear shielding.
Nonoxides	SiC, Si ₃ N ₄ , Sialons, B ₄ C, AlN, hexagonal BN, cubic BN, TiB ₂ , ZrB ₂ , TiN, TiC.	Prepared as submicron powders; formed by cold or hot pressing, with or without sintering aids; sintered at high temperatures, with or without pressure.	Heat resistance; oxidation resistance; strength at high temperatures.	Turbine blades; adiabatic engine components; heat exchangers; cutting tools; bearings; catalyst carriers; mechanical seals; nozzles; RF crucibles; nuclear shielding.
Composites	Matrices of oxides and nonoxides; reinforcements of C, SiC, Si ₃ N ₄ , Al ₂ O ₃ , aluminosilicate fibers; SiC whiskers; PSZ particulates.	Processing not yet developed; fiber prepreps treated with slurry; chemical vapor deposition.	Heat resistance; improved fracture toughness; "graceful" fracture.	All the applications of monolithic ceramics.
	Carbon matrix-carbon fiber composites.	Continuous fiber prepreps; CVD carbon matrix.	Heat resistance; strength; low density (needs protection from oxidation).	National Aerospace Plane skin; rockets and missiles; space structures.

Source: Bureau of Mines.

growth and total fracture of the ceramic body. This phenomena is called transformation-toughening because the impact resistance is increased many fold. Zirconias containing both cubic and tetragonal zirconia are called partially stabilized zirconia (PSZ). Those containing only tetragonal zirconia are called tetragonal zirconia polycrystal (TZP). Ceramics with added zirconia are called transformation-toughened ceramics (TTC); transformation-toughened alumina (TTA) has found application as a grinding and cutting material.

Other ceramics used or being evaluated in advanced applications include aluminum titanate, Al₂TiO₅, stable to 1,865° C, for use as shock-resistant materials in catalytic converters and diesel engine components; and cordierite, Mg₂Al₄Si₅O₁₈, with a low thermal expansion coefficient, in similar applications.

Technology.—Processing.—One of the key features of the new materials is that the structures are controlled to obtain optimum properties. In addition to controlling the

crystal structures, it is essential that the microstructure, the way in which the crystals are arranged, be controlled. For many materials the level of understanding of the relationships between structures and properties is inadequate, and the relationships between these and processing parameters are only generally understood. Accordingly, a large portion of current research is in this area.

New materials do not lend themselves to assembly line use for several reasons: control of properties during processing is not well understood; the materials cannot be made using existing assembly line equipment; and the low production volumes do not justify large capital expenditures, at least in the early stages of commercialization. Hence, new structural materials will not be widely adopted until fully integrated design and manufacturing processes and a high degree of automation are developed. It will be necessary, moreover, to begin the process even before all the relevant structure-property-processing relationships are fully understood so that the opportunity

to learn by error will be available. Improvements in processing and properties of new materials will be, of necessity, an incremental process.

To assemble the components of a piece of complex machinery or device, it is normally necessary to bond dissimilar materials, such as ceramic to metal, different alloys to each other, or polymer to metal. Because of differences in chemistry and coefficients of thermal expansion, this can be a formidable task. If welding, soldering, or brazing media are used, the bond is likely to be the weak point in the structure, nullifying much of the advantage of the new material. If direct bonding between the new materials is possible, the bonding process itself may alter the properties of one or both components. Much research will be needed to overcome these problems. New design concepts will also have to be developed so that mechanical fits can be used to the maximum.

There are technical constraints specific to advanced structural ceramics in addition to the general constraints summarized

previously. The major impediment to successful application of structural ceramics, with their very high strengths, hardness, and corrosion resistance at high temperatures, is their brittleness. Fracture in a ceramic material originates at flaws—voids, scratches, or inclusions—and proceeds to total failure very rapidly. Much research has been done, and considerable progress has been made in controlling flaws. Still, the rejection rate is very high, as much as 80%, and the range of measured strengths in many samples from the same production run is very wide. The dependability and consistency required for mass production has not been attained in most cases.

The problem of critical flaw density cannot be solved by overdesigning, as with metals, because only one critical flaw is necessary for failure; the larger the component is, the more likely it will have a critical flaw. A second major problem with ceramic materials is that the very properties that make them useful, hardness and strength, also make them difficult to fabricate to close dimensional tolerances. Net shape production is difficult because shrinkage during sintering must be uniform and closely controlled. This requires very precise control of processing parameters. They cannot, moreover, be machined to final size and shape by conventional methods. These areas of concern are being actively researched at present, but solutions, which must be found for these materials to be competitive, appear to be several years away.

All three classes of composites—metal matrix, ceramic matrix, and polymer matrix—are handicapped by inadequate understanding of the forces operating between the matrix and the reinforcing materials (fibers, whiskers, or particles). Much research will be required to maximize the effects of reinforcement. Fabrication is complicated by the requirement for uniform, predictable, and controllable distribution of the reinforcing phase and by the labor intensive nature of the layup of materials. Considerable research is needed to make it possible to control and vary curing times so that a range of forming methods can be used for a given material and production rates can be accelerated.

Testing.—Large-volume commodity materials such as sheet steel, copper wire, and so forth, are selected for a particular application on the basis of well-measured

and well-understood properties. It is relatively easy to match these materials to specifications because physical property data are readily available. Advanced materials are fundamentally different because they are, in general, engineered for particular designs and applications for which no commodity materials are available. Consequently, physical property data bases, from which a designer or process engineer can select a material with correct specifications, are unavailable. The situation is complicated even more in some cases because two apparently identical materials from different suppliers may not be equally suited for a given manufacturer's needs. Much effort is expended, therefore, in locating a suitable material, and it is necessary for the materials supplier and the manufacturer to work together to develop that material. This situation will be improved only when structure-property-processing relationships are adequately understood. Then many advanced structural materials will be cost-competitive with commodity materials in mass production. Standardization of processing and compilation of property data bases need to be given a very high priority in the R&D arena.

Standardized tests for properties of commodity materials have been devised by the American Society for Testing and Materials and can be used worldwide to provide reliable comparisons of competing materials. Such tests are not yet available for many of the new materials. In fact, the only criterion for acceptance of a new material in many cases is successful performance. It is expensive to proof test each component in simulation tests or actual use, so these materials will not be competitive with commodity materials until standard testing methods are developed. Nondestructive evaluation methods are urgently needed, particularly for materials such as structural ceramics in which critical flaws are difficult to prevent and to detect. It is likely that nondestructive evaluation will be needed for each component made of such materials.

All materials will, in general, suffer from deterioration of critical properties during use. The long-term effects of stress, flexure, exposure to corrosive environments, exposure to radiation, and so forth, cause cumulative damage to materials, causing them ultimately to fail. Methods of assessing cumulative damage and predicting remaining usefulness have not been developed for the new materials.

It is essential that methods be devised, perhaps for continual monitoring during use, before manufacturers will have enough confidence in the new materials to adopt them.

POLYMER MATRIX COMPOSITES

Production and Consumption

A polymer composite is a combination of a matrix, formed by polymerization of an organic resin, and a reinforcing material in the form of continuous fibers in a variety of patterns and weaves or short fibers, whiskers, or particles. Generally only polymers reinforced with continuous fibers are considered advanced polymer composites (APC); that convention is followed here. Matrix resins may consist of thermosets such as epoxies, phenolics, polyesters, vinyl esters, or urethanes, or thermoplastics such as polyphenylene sulfide, polysulfones, polyetheretherketone, polyarylenes, or imides. In general, the important physical properties of APC's are determined by the properties of the fibers rather than the matrix, so a myriad of polymers, blends, and alloys may be used. Many of these are widely used as commodity plastics. For these reasons, and to place the production levels and values of APC'S into perspective, an overview of plastics production in the United States precedes that for APC's. The data are provided by Modern Plastics magazine¹⁶ and are compiled from data from the Committee on Resin Statistics of the Society of the Plastics Industry.

Table 8 provides U.S. resin sales, including exports, for 1988 and 1989 by major resin types. Sales for 1989 were less than 0.5% higher than for 1988, compared with gains of 5%, 9%, and 4% for the previous 3 years. The slower growth was attributed to buildup of inventory because of a slower economy in which construction and automotive applications were sluggish.

Eight major market segments, as shown in table 9, accounted for approximately 60% of total sales, with packaging and building applications comprising the major portion and showing slight declines in 1989. These data are for sales of feedstock resins only and do not reflect the total value of products of those industry sectors.

Table 10 provides production data and overall value of advanced polymer composites, compiled by Kline and Co.,

highly significant. The United States produces about 60% of world supply, and projections are that the percentage will remain nearly constant through 1998. Kline and Co. report that the world market consists of 50% for aerospace applications; 25% for recreational products, 15% for industrial use, mainly for composite tooling; and less than 2% for automotive use. For matrix resins, epoxies account for 95% of total production.

The only available data for reinforcing fiber and prepreg have been compiled by the Suppliers of Advanced Composite Materials Association (SACMA) and are given in table 11. Production by individual countries is not available.

According to Kline and Co.,¹⁷ carbon fibers make up 60%, aramid makes up 25%, and high-strength glass fibers make up about 13% of the total. The remaining 2% consists of developmental fibers such as silicon carbide, ultrahigh molecular weight polyethylene, boron, and quartz.

SACMA has provided production data by volume and dollar value, employment data, and breakdowns by market segment and region (table 12). Though the production levels are comparable with those of Kline and Co., the estimates of dollar value differ by a factor of almost four, and SACMA's projections for world production in the year 2000 (90,000 metric tons) are well ahead of those of Kline and Co. in 1998 (36,300 metric tons).

The structure of the advanced polymer composites industry is indicated by table 12, which lists the member companies of SACMA,¹⁸ who accounted for 95% of world production in 1989. In addition to these major corporations, many small companies have found niche markets as weavers, prepreggers (assemblers of resin

impregnated fibers aligned in a unidirectional tape or in a woven preform), or fabricators that provide their services to the major composites producers.

Fibers represent a \$500 million world business and resins about a \$200 million business. Materials costs, however, make up only about 18% of the cost of a finished part, so the future of the industry will depend not on the cost of high-strength fibers so much as on cost-efficient automated process development.

Prices

Because advanced polymer composites are not mass produced commodity materials; because there are almost unlimited possibilities for combination of various polymers, blends, and alloys with different fibers; and because APC's are designed and engineered for each individual application, there is no established price structure. The cost of constituent materials—polymer matrix and reinforcing fiber—makes up, on average, only about 18% of the cost of a finished component¹⁹ so the final price is dependent on design, engineering, tooling, and fabrication costs. These costs will remain high until capital

investment in automated, flexible manufacturing has been made and increased applications permit economies of scale.

Prices of carbon fibers, made either from pitch or polyacrylonitrile precursor, range from \$20 to \$60 per pound, though very high-performance fibers may cost as much as \$1,000 per pound. Aramid fibers (DuPont Kevlar) are priced at \$10 to \$20 per pound, and high-strength fiberglass costs less than \$5 per pound. Commodity polymers, thermosets, and thermoplastics cost only \$1 to \$5 per pound, with high-strength, high-temperature engineering polymers ranging to perhaps as much as \$100 per pound.

Even the average prices of finished APC components are not agreed upon; Kline and Co.²⁰ places average prices at \$125 to \$140 per pound while SACMA²¹ estimated the average price at \$33.60 per pound in 1988.

Current Research

The level of research effort in polymers, not only for structural applications but also for electronic, optical, magnetic, and medical uses, is very high in the Federal, industrial, and academic sectors. Thousands of technical papers are published each year, and proprietary research is certainly extensive. It is impossible, therefore, to present an adequate summary except in the broadest terms. Much of the effort is driven by the defense and aerospace industries,²² where about 60% of advanced polymer composites were used in 1989 and likely will be for many years to come. A few major research areas are summarized here.

New Matrix Materials.—About 95% of polymer matrix composites manufactured in 1989 were composed of an epoxy matrix reinforced with carbon fiber or high-strength glass fiber. This is a result of two factors. First, at the time, about 10 to 15 years ago, when property and performance specifications were written for current aerospace systems, epoxy was the only matrix material sufficiently developed and understood to be used successfully. Second, epoxy composites are relatively easy to fabricate because the resin-catalyst mixture has a low viscosity, suitable for a variety of prepregging and forming operations. Epoxies, moreover, wet fibers effectively to produce a strong bond and possess the strength, stiffness, corrosion resistance, and high-temperature stability needed for many applications.

Epoxies have some disadvantages, however. Though strong, they also do not have high fracture toughness, i.e., they are brittle and do not resist high impacts. Because epoxies are thermosets, formed by irreversible chemical reactions, they do not soften or melt but decompose, making repair or recycling difficult. Thermoplastics, on the other hand, though not as heat resistant as epoxies, have high fracture toughness and can be melted and reformed. The difficulty with thermoplastics is high viscosity, which cause problems with fiber wetting and infiltration and limits the possible fabrication methods.

Current research to develop new matrix materials is aimed at overcoming these difficulties. A number of blends of epoxies and thermoplastics, with greater fracture

toughness than epoxies and lower viscosity than thermoplastics, are being formulated and evaluated. These materials, with potentially better impact resistance, will, nevertheless, be difficult to repair or recycle. A wide variety of commodity polymers, blends, alloys, liquid crystal polymers, and engineering polymers are also being evaluated as matrix materials to optimize strength, stiffness, fracture toughness, corrosion resistance, reparability, and recyclability.

New Fibers.—The effectiveness of fibers as reinforcements in advanced polymer composites depends on their intrinsic strengths, surface condition (failure is initiated at surface flaws), and the strength of the interfacial bond with the matrix. An enormous effort is being made to improve processing of fibers to improve their strengths by eliminating surface flaws through sol-gel formation, better control of molecular orientation, chemical vapor deposition methods, and surface treatments. A variety of silica, aluminosilicate, boron, silicon nitride, silicon carbide, and organic fibers is also being developed and evaluated as potentially stronger or less costly reinforcements.

Improvement of the bond between fiber and matrix is being sought by development of surface treatments to improve fiber wetting and adherence. Improved bonding may result from development of increased fiber surface area by means of extrusion of fibers with crenulations, i.e., with asterisk-like cross sections.

Joining Methods.—Though the number of component parts in a system is generally less with polymer composites than with metal parts, particularly in aerospace systems, parts must still be assembled with fasteners or adhesives. Obviously, if the strength of the joint is less than that of the composite parts, much of the advantage of the composite is nullified. Joining methods are, therefore, receiving a great deal of attention. Improved metal and polymer materials for use as bolts and rivets are being sought, and high-strength adhesives and direct bonding methods are under investigation. Perhaps more importantly, new computer-aided design methods have been developed to predict stress levels within the composite and at the joints of assemblies. This enables engineers and designers to develop structures in which stresses are minimized in critical areas.

Nondestructive Evaluation.—Fiber breakage during fabrication, poor fiber-matrix adherence, and existence of voids and inclusions in polymer composites are potential causes of failure in service and are not readily detectable by visual inspection. Methods for inspection of each component prior to incorporation into a finished assembly are being tested as nondestructive evaluation methods. These include ultrasonic inspection, infrared thermography, thermographic stress analysis, X-ray tomographic microscopy, eddy current measurement, acoustic emission measurement, fluorescence spectroscopy, scanning capacitive and induction probe methods, magnetic resonance imaging (MRI), and pulsed nuclear magnetic resonance (a variation of MRI).

Any structural material under stress deteriorates with use because of formation of microcracks, weakening of the fiber-matrix bond, and fiber breakage. Environmental conditions, such as exposure to chemical agents, ultraviolet radiation, heat, monatomic oxygen (in space), and ionizing radiation, also contribute to degradation of the properties of materials. Because of the lack of experience in longtime use of advanced polymer composites and the variability of properties and structures resulting from lack of uniformity in processing, much effort is being expended to evaluate new materials for deterioration in use. Nondestructive evaluation methods are being developed for periodic inspection of components during use, but the most promising methods being investigated at present are based on continual monitoring during service. Two methods presently under development involve incorporation of pressure sensitive detectors (piezoelectric or light emitters), coupled with wires or optical fibers to transmit data to a computer system or sound detectors to receive acoustic emissions from critical points in the component to be transmitted to an analyzing computer.

Processing.—Synthesis and processing have been identified by the NRC²³ as a problem area in commercialization of new materials, resulting from inadequate recognition of the relationships among design, materials properties, and processing. In the case of polymers, this has not been as great a problem as with other materials because the wide variety of materials and processing methods has required attention by polymer engineers and manufacturers from the beginning of the industry.

Outlook

Two of many projections for production of advanced polymer composites are provided in tables 10 and 12. The United States has a dominant position in what is a truly international industry, as indicated by table 13, and is likely to remain in that position. This is because of strong research effort in materials development, processing research, and rapidly developing capabilities in computer-aided design, computer-aided manufacturing, automated flexible manufacturing, and robotics. As in 1989, future growth will be mainly in defense, aerospace, and recreational equipment where the high costs of advanced polymer composites are justified by improved performance and durability. Very large-scale production of composites in automobiles and many other consumer products cannot be realized until the costs of these materials can be justified by their performance characteristics. Automobile makers appear to be convinced, nevertheless, that large-scale substitution of polymer composites for structural metals is inevitable. A consortium was formed by Chrysler Corp., Ford Motors Co., and General Motors Corp. during 1989 to evaluate polymer composites on a precompetitive basis. New fuel efficiency and environmental regulations will likely contribute to acceptance of the higher costs of these materials. After capital investment has been made to convert manufacturing operations to the new materials and processing methods, however, unit costs should decrease dramatically.

Background

Definitions, Grades, and Specifications.—Polymers are composed of thousands to millions of identical units, called monomers, linked together by strong covalent bonds into linear chains, linear chains with branches protruding at intervals, or networks, with cross linking between chains. The process of linking monomers together, called polymerization, can be accomplished by addition, simply by mixing components or with the aid of a catalyst, or by condensation, which results in linkage of monomers with release of a simple molecule such as water.

Thermosets are those polymers that form by irreversible chemical reaction and consist of strongly cross linked chains. Thermosets cannot be remelted and reformed but, rather, decompose at elevated temperatures. Because of the cross linking, thermosets are strong and heat resistant but tend to be brittle. Examples of thermosets are epoxies, phenolics, vinyl esters, polyesters, and urethanes. Thermoplastics are polymers, with less cross linking, that can be remelted and reformed. They tend to be less brittle (tougher), more flexible, and stronger in the direction across the strongly linked chains than between. Consequently, if the chains are aligned, the polymer is much stronger in one direction than the others. Details of the polymerization process and variations thereof have been described by Catherine Kilgore (Reference 10, pp. 8.1-8.57). Figure 1 illustrates the materials flow from the

major feedstocks to production of the major classes of polymers. The percentages below each of the feedstocks in figure 1 indicate the relative usages of the feedstock materials. Ethylene, for example, comprises 54.5% by weight of the total feedstocks used for polymer production. Table 14 shows the broad classification of thermoplastic polymers according to use, price, and volume.²⁴ As indicated, the performances and prices of the materials are directly related. In the case of advanced polymer composites, the materials of interest are the engineering and high-performance thermoplastic polymers and epoxies. The latter presently are used in about 95% of composites while performance polymers are still being evaluated for use as polymer matrices. Table 15 shows comparative thermal stabilities for representative commodity, engineering, and performance polymers.

Detailed definitions, grades, and specifications for the hundreds of polymer materials are beyond the scope of this work but are readily available in the *Plastics Encyclopedia*.²⁵ As stated previously, specifications for the composites themselves are not written as with commodity materials; the specifications are written for each individual application.

Products for Trade and Industry.—The number of products utilizing polymer materials, better known in most cases as plastics, is too great to list. They are ubiquitous and are being used in more

applications each year. Advanced polymer composites, however, because of cost, have relatively few uses, most notably in defense, aerospace, and sporting goods. In defense and aerospace they are used in helicopter rotors, blades, and tail assemblies and in weapons systems as rocket motor cases on missiles and space vehicles. They are finding increasing use in secondary aircraft structures such as control surfaces (flaps, rudders, and stabilizers) or fairings (streamlining covers for aerodynamics) and more recently as primary structures such as wing, tail, and fuselage sections. Composites use in McDonnell Aircraft's military planes, for example, has increased from about 2% in the F-15 to 27% on the AV-8B *Harrier* currently in production.²⁶ Boeing Co. is teamed with Bell Helicopter to manufacture the V-22 tilt rotor aircraft and with Sikorsky Aircraft to make the new LH helicopters, both with airframes and skins largely constructed of epoxy-carbon composites.

For commercial aircraft, the major manufacturers are planning to increase use of polymer composites in new generation planes. Boeing, for example, plans to increase the composite content of its highly successful 757 line from the present 3% to 24.5% during the 1990-2000 timeframe.²⁷

In sporting goods, the desire for better performance regardless of cost has created a market for fiberglass and carbon reinforced polymers in tennis racquets, golf club shafts, skis, sleds, and toboggans; fishing poles; and bicycles.

In the industrial market, the primary use of polymer composites is in tooling, but many other applications are developing. Robot arms, for example, with less inertial mass than metals, contribute to greater speed and lower systems costs in automated manufacturing.

Technology.—Processing.—Current technology in advanced polymer composites processing has been well summarized by the Bureau of Mines (Kilgore, reference 12). Fabrication methodologies, prototyping, testing, and redesign are all important steps in development of processing; the many methods of fabrication need not be repeated here.

Testing.—Performance standards and testing methods are summarized by Kilgore²⁸ and by Modern Plastics²⁹ in great detail. The reader may refer to those works for specifics on the many materials, properties, tests, specifications, and performance standards.

Recycling.—During 1989, the issues of waste disposal and recycling received increased attention in response to heightened awareness of environmental problems and the realization that the landfills of the United States are approaching their capacities. Even though plastics constitute only about 6% to 8% by weight of municipal waste,³⁰ the volume is somewhat more, and the stability of plastics in a landfill environment creates the perception that they are more of a threat than other materials. The

TABLE 14
CLASSIFICATION OF THERMOPLASTIC POLYMERS

Category	Processability	Maximum use temperature	Price	Production volume	Examples of polymers
Commodity	Very high temperatures not required, generally forgiving and versatile.	70° C to 110°-120° C	Low	Over 1 million tons per region.	Polyvinyl chloride, low-density polyethylene, high-density polyethylene, polypropylene.
Engineering	High-temperature equipment required, process technology limited.	130°-140° C to 200° C.	Medium	40 to 100 thousand.	Polyamides, polyacetals, modified polyphenylene oxide, polycarbonates, PET, PBT, ABS. ¹
High performance	Very high-temperature equipment, often made of special resistant materials; precise processing techniques required.	Above 200° C	High to very high.	0.1 to thousand tons per region.	Polyphenylene sulfide, polyimide, polysulfone, polyether sulfone, polyetherimide, polyamide-imide, PEEK, ¹ liquid crystal polymers.

¹Polymers with only a glass-transition are without crystallinity. Below the glass-transition temperature they are stiff; above it they are very viscous fluids.

²Semicrystalline polymers have a glass-transition temperature, at which noncrystalline areas develop, and a melting temperature, at which the polymer becomes fluid.

Source: Eric Baer.

major producers of commodity plastics have initiated planning programs for designing products for recycling, opened recycling centers, and intensified research on degradable materials. Increased policy and legislative attention is now being paid to these problems by Federal, State, and local organizations and is likely to intensify.

Unlike metals, discarded plastic items generally lack unit value or recyclability and tend to become environmental problems or hazards. In 1990, the total U.S. resin production will reach about 54 billion pounds, and about 38 billion pounds will be discarded as waste.³¹ In the case of APC's, the problem is how to separate the fiber from the resin and reuse them economically. Recycling APC scrap may be economically feasible because of the high cost of carbon fibers. Because the matrix materials currently used are predominantly epoxy resins, studies have been conducted for that type of material.³²

In the uncured condition, epoxies are soluble in organic solvents such as acetone or methyl ethyl ketone. After the epoxy is dissolved, the recovered carbon fiber can be reused. After curing, however, epoxies are insoluble, so this procedure can only be used for prompt scrap and rejects.

Epoxies can be decomposed thermally below 400° C and the fiber may be recovered

the fiber surface, however, is affected so that lower fiber-matrix adhesion is observed in new products. Fiber breakage may be sufficient to render fibers useful only as discontinuous reinforcement. To date, the only satisfactory use for epoxy scrap is as finely ground filler for virgin resins.

As the volume of polymer composites increases, the greatest growth is likely to be in thermoplastic-fiber materials, as in automotive applications, and then recycling, incineration, and disposal will become part of the overall commodity plastics problem.

ANTIMONY

By Thomas O. Llewellyn

Mr. Llewellyn is a physical scientist with the Branch of Nonferrous Metals. He has covered antimony for 3 years. Domestic survey data were prepared by Elsie Isaac, Nonferrous Metals Data Section; and international data were prepared by William L. Zajac, Geographic Data Section.

Production of primary antimony was mostly as a byproduct or coproduct of primary ores of other metals such as lead and silver. Output increased compared with that of 1988, but one antimony refining facility was closed during the year. Antimony oxide exports increased considerably, while total imports of antimony materials decreased sharply from those of 1988. Increased reported industrial consumption was due mainly to the continued strong market for antimony trioxide in flame-retardant applications. The development of high-technology applications for antimony continued in 1989.

LEGISLATION AND GOVERNMENT PROGRAMS

On December 22, 1989, the U.S. Department of State reviewed the list of minerals certified on January 7, 1987, according to section 303(a)(2) of the Comprehensive Anti-Apartheid Act of 1986, as amended. Based on that review, antimony was retained among the revised certified list of strategic minerals now imported from the Republic of South Africa, which are essential for the economy or defense of the United States and are unavailable from other reliable and secure suppliers.

STRATEGIC CONSIDERATIONS

Antimony was included in the National Defense Stockpile (NDS) because of its strategic uses in flame-retardant compounds, camouflage paint, ammunition components, friction bearings, and batteries.

The Government stockpile goal for

antimony was set at 32,659 metric tons in April 1980. No inventory acquisitions or sales were made during the year, and, as of December 31, 1989, the stockpile inventory was 32,658 metric tons of antimony metal.

The metric system is the official system of measurement of most countries. The Bureau of Mines, in an effort to provide statistical data on antimony that are consistent with international usage, will henceforth report data in kilograms and metric tons unless otherwise noted.

PRODUCTION

Mine Production

Sunshine Mining Co. produced antimony as a byproduct of the treatment

of tetrahedrite, a complex silver-copper-antimony sulfide ore, from the Coeur d'Alene District of Idaho.

Smelter Production

Primary.—In July 1989, Amspec Chemical Corp. completed a project to increase its antimony trioxide plant capacity. The company added a new furnace to its plant at Gloucester City, NJ. The new furnace has a production capacity of 10,000 tons per year of antimony oxide compared to about 6,000 tons per year for the old furnace. Amspec did not plan to operate both furnaces simultaneously at full capacity; instead, the old furnace may be used as a backup or to make certain specialty oxides.¹

The producers of primary antimony metal and oxide products were ASARCO

Secondary.—Old scrap, predominantly lead battery plates, was the source of most of the secondary antimony output. New scrap, mostly in the form of drosses and residues from various sources, supplied the remainder. The antimony content of scrap was usually recovered and consumed as antimonial lead.

CONSUMPTION AND USES

Increased reported domestic consumption of primary antimony, compared with that of 1988, reflected the continued strong market for fire-resistant textiles and plastics. Lead-antimony alloys were used in starting-lighting-ignition (SLI) batteries, ammunition, corrosion resistant pumps and pipes, tank linings, roofing sheets, solder, cable sheaths, and antifriction bearings. In 1989, the Battery Council International reported a 1.5% increase in the total shipments of replacement automotive SLI batteries in the United States compared with those of 1988.

Antimony compounds were used in plastics both as stabilizers and as flame retardants. Antimony trioxide in an organic solvent was used to make textiles, plastics, and other combustibles flame retardant. Antimony was used as a decolorizing and refining agent in some forms of glass, such as special

optical glass. The largest end use for antimony compounds was in flame retardants.

PRICES

The New York dealer metal price, published by Metals Week, started the year ranging from \$1.00 to \$1.03 per pound, held steady until early March, and decreased to a range of \$0.95 to \$0.99 per pound by mid-May. In June, during the height of the political crisis in China, the antimony price range firmed back to what it was at the beginning of the year. However, shipments from China were not interrupted, and stocks in warehouses were plentiful. By mid-July, the price range slipped to \$0.95 to \$1.00 per pound, and at the end of December was \$0.81 to \$0.84.

Asarco's published price for high-tint antimony trioxide in lots of 40,000 pounds was \$1.43 per pound at the beginning of the year, and remained constant for the rest of 1989. Other domestic producers adjusted their prices to about the same level to remain competitive.

European price quotations for antimony ore and concentrates, published by the Metal Bulletin (London), held steady during the first 4 months of the year, and followed a downward trend for the rest of 1989. At yearend, the published price-range quotations were as follows: clean sulfide concentrates, 60% antimony content, \$15.50 to \$18.50 per metric-ton unit; and lump sulfide ore, 60% antimony content, \$16.50 to \$19.00 per metric-ton unit.

FOREIGN TRADE

Exports of antimony oxide were about 51% higher than the previous year. Total imports of antimony materials decreased about 16% from those of 1988. China supplied about 60% of the total imported materials in 1989.

WORLD REVIEW

Capacity

The data in table 12 represent rated annual production capacity for mines and refineries on December 31, 1989. Rated capacity was defined as the maximum quantity that could be produced on a normally sustainable long-term operating rate, based on the physical equipment of the plant and routine operating procedures for labor, energy, materials, and maintenance. Capacity included both operating plants and plants temporarily closed that, in the judgment of the author, could be brought into production within a short period of time with minimum capital expenditure.

Mines and refineries rated capacity of antimony was estimated based on discussions with some officials from private industry, past and present production rate, and published capacity data.

Bolivia

On January 7, 1989, antimony producers from Bolivia and China signed an agreement with the intent of coordinating their policies on antimony production and trade. The representatives agreed to introduce a joint quarterly producer price for concentrate (60% antimony), which is being published in

the Metal Bulletin of London, United Kingdom.²

In November, Empresa Nacional de Fundiciones (ENAF), the state-owned smelting and refining company, resumed production at its Vinto antimony smelter after being closed for more than 5 years. The 4,000-ton-per-year Empresa Metalurgica de Vinto smelter never operated at full capacity since its completion in December 1975. ENAF officials did not provide information on anticipated production output.³

Canada

In December 1989, Dominion Explorers Ltd., closed its antimony mine and milling operations at Lake George, New Brunswick. The mine closed once before in 1981 when proven ore reserves were exhausted, but reopened in 1984 when a new zone of antimony-bearing ore was discovered near the existing mine. However, there were not enough proven ore reserves to justify reopening mining operations. The closure was attributed to continuing low metal prices and two consecutive years of revenue losses.⁴

Japan

Antimony trioxide production, main-

ly from imported materials, was 10,327 tons, a decrease of 3% compared with 1988 production. Antimony metal production also decreased from 185 tons in 1988 to 173 tons in 1989.⁵

CURRENT RESEARCH

Scientists at Boeing High Technology Center, Seattle, WA, achieved a significant advancement in solar cell efficiency using a two-layer cell system. The top layer in the new solar cell was composed of a standard gallium arsenide (GaAs) cell, and gallium antimonide (GaSb) was the material used as the secondary cell. Boeing's solar cell converts more than 31% of available solar energy to electricity. The previously verified record was about 22% set by Variant Associates Inc., using a standard GaAs solar cell.⁶

Following the energy crisis of 1973, Congress passed Public Law 94-413, the Electric and Hybrid Vehicle Research, Development and Demonstration Act of 1976. This Act supported research and development of electric and hybrid vehicles, required an organizational entity to conduct the management responsibilities, and established the

submission of an annual progress report to Congress on the program. In February 1989, the 12th annual report to Congress for fiscal year 1988 was published by the U.S. Department of Energy (DOE). The report contained a description of the program activities during 1988 on battery and propulsion systems developed, a list of company and university participants in electric and hybrid vehicle research and development, and concluded with a list of publications resulting from the DOE program.⁷

OUTLOOK

Mining, beneficiation, and metallurgical procedures for antimony have changed little in the last three decades. No new major technological developments that would affect productivity are foreseen for the near future.

The oversupply of antimony products from China that saturated the market in 1989 could not be absorbed by the lower domestic and rather flat world demand. Therefore, producers were forced to lower prices significantly in order to preserve their share of the world market. The market weakness will probably continue through 1990 and 1991, unless the Chinese policy of offering discounts from the world market price changes.

The prospects for western antimony trioxide producers, for the next 2 years, are not good. China has increased its antimony trioxide output and sales, and supplied 42% of the total U.S. trioxide imports for 1989 compared with 32% the year before.

Industry sources indicate that the projected growth of antimony trioxide demand for the next 2 years will be in the range of 2% to 4% per year. But the demand for antimony metal, during the same period, will continue declining and may do so at a rate of about 2% per year through 1991.

BACKGROUND

The natural sulfide of antimony, stibnite, was known and used in Biblical times as medicine and as a cosmetic for eyebrow painting. A vase found at Tello, Chaldea, reportedly cast in me-

tallic antimony indicates that about 4000 B.C., the Chaldeans knew the art of reducing the sulfide to metal.

Definition, Grades, and Specifications

Antimony is seldom found in nature as native metal because of its strong affinity for sulfur and the metallic elements such as copper, lead, and silver. Antimony in its elemental form is a silvery white, brittle, crystalline solid that exhibits poor electrical and heat conductivity properties.

The National Stockpile Purchase Specification P-2a-R4, June 10, 1980, covered two grades of refined antimony metal in ingot form. Grade A has a minimum antimony content of 99.8%

and the following impurity maximums: arsenic 0.05%, sulfur 0.10%, lead 0.15%, and other elements (copper, iron, nickel, silver, and tin) 0.05% each. Grade B material is composed of 99.5% antimony as a minimum with maximum impurity levels of 0.1% arsenic, 0.1% sulfur, 0.2% lead, and 0.1% each of other elements.

Chemical-grade ore is that which is sufficiently pure to be used directly in producing the oxide, chloride, or other industrial chemical compounds. For chemical-grade sulfide ore, total impurities, including arsenic and lead, must not exceed 0.25% and no single metallic impurity can exceed 0.1%.

Antimony oxide, the most important

of the antimony compounds, is used in flame-retarding formulations for many materials. Most commercial grades of antimony trioxide contain between 99.2% and 99.5% antimony trioxide with varying amounts of impurities such as arsenic, iron, and lead. Commercial suppliers offer various grades of antimony trioxide based on the relative tinting strength of their product, which is related to average particle size. In general, the tinting strength increases as the particle size decreases.

Industry Structure

Antimony was produced from ores and as a byproduct of the smelting of base metals ores in about 23 countries. China, the world's leading producer, has a marketing advantage because its facilities are Government owned. The other major producing countries, Bolivia, Mexico, the Republic of South Africa, the U.S.S.R., plus China, accounted for about 84% of the total world estimated mine production during 1989.

Mine production in the United States during the last decade supplied less than 5% of the yearly domestic demand. The remainder was furnished by imported materials and old scrap. Because of its association with lead, secondary antimony has only met about 50% of the total domestic industrial demand. However, this percentage has decreased in recent years owing to a decreasing average antimony content of the scrap lead source material (automotive batteries).

Antimony metal and oxide producers in the United States are forward integrated companies with a wide scope of activity in the marketing and manufacturing of base metals and chemicals. A few producers and processors of antimony have interests in foreign operations. Essentially all are purchasers of raw materials from mine operations either directly or through dealers.

Geology-Resources

Estimates of the abundance of antimony in the Earth's crust range from 0.2 to 0.5 parts per million. Antimony is chalcophile, occurring with sulfur and the heavy metals, copper, lead, and silver. Over a hundred minerals of antimony are found in nature. However, stibnite (Sb_2S_3) is the predominant ore mineral of antimony.

Simple antimony deposits consist principally of stibnite, or rarely, native antimony in a siliceous gangue, commonly with some pyrite, and in places a little gold and small amounts of other metal sulfides, principally silver and mercury. Antimony ores commonly are associated with igneous activity and have common genetic associations with such intrusives as granite, diorites, and monzonites. The mineralogy of the veins and their almost invariably shallow depth suggest a low temperature of formation at near-surface positions, possibly related to the configuration of the water table at the time of deposition. Most of these geologically simple stibnite deposits do not individually contain more than several thousand tons of ore. Deposits of this type are found in the world's most productive antimony districts including those of Bolivia, China, Mexico, and the Republic of South Africa.

Complex antimony deposits consist of stibnite associated with pyrite, arsenopyrite, cinnabar or scheelite, or of antimony sulfosalts with varying amounts of copper, lead, and silver, as well as the common sulfides of these metals and zinc. Ores of the complex deposits generally are mined primarily for gold, lead, silver, tungsten, or zinc.

Most of the antimony produced in the United States is from complex deposits. The tetrahedrite ores found in the Coeur d'Alene district of Idaho are outstanding examples of complex deposits.⁸

Principal identified world antimony resources, at about 5 million tons, are in China, Bolivia, the U.S.S.R., the Republic of South Africa, and Mexico. United States resources are mainly in Idaho, Nevada, Alaska, and Montana.

Technology

Antimony deposits are seldom explored in advance of actual mining, because the deposits are generally small, irregular, and difficult to appraise.

Many of the typically small mines contain irregular and scattered ore bodies that cannot be readily exploited by large-scale mining methods. Mining methods used in mines that recover metalliferous ores, of which antimony is a minor constituent, are designed for producing the principal metals such as lead, silver, or gold.

The antimony content of ores determines the method of recovery. In general, the lowest grades of sulfide ores 5% to 25% antimony, are roasted; 25% to 40% antimony ores are smelted in a blast furnace; and 45% to 60% anti-

mony ores are liquated. At some mines in Bolivia and the Republic of South Africa, the high-grade sulfide ore is concentrated by hand-cobbing and sold as lump sulfide ore, 60% antimony content. As higher grade deposits have become depleted, increasing emphasis has been placed on upgrading these low-grade ores by flotation.

Roasting of the ore to yield a volatile trioxide or the stable nonvolatile tetroxide is the only pyrometallurgical procedure suitable for low-grade ores (5% to 25% antimony content). The sulfur is oxidized and removed from waste gases, and the volatilized antimony oxide is recovered in flues, condensing pipes, a baghouse, precipitators, or a combination of the above. The temperature and quantity of available oxygen determine the kind and quantity of the oxide produced. The oxide produced by this method is generally impure and can be reduced to metal. However, careful control of volatilization conditions will produce a high-grade oxide that can be sold directly to consumers.

Water-jacketed blast furnaces are used in several plants to reduce ores containing 25% to 40% antimony. Oxides, sulfides or mixed ores, residues, mattes, slags, and briquet fines or flue dusts can be used as blast furnace charges. A high smelting column and comparatively low air pressure are used, and the slag and metal are sepa-

rated in the hearth.

Antimony sulfide can be separated from the gangue of sulfide ores by melting in a reverberatory furnace. A reducing atmosphere is kept to prevent oxidation. The solidified product is called liquated or needle antimony, and may be used as sulfide or converted to antimony metal by iron precipitation.

Some complex ores can be treated by leaching and electrowinning to recover the antimony. A typical process uses an alkali hydroxide or sulfide as the solvent. The filtered leach solution containing sodium thioantimonate, Na_3SbS_4 , is electrolyzed in a diaphragm cell using an iron or lead anode and an iron or mild-steel cathode. The cathode metal obtained is 93% to 99% pure antimony.⁹

Antimony metal is also produced as antimonial lead, which is an important

product of the secondary lead smelter. A blast furnace charge containing used or discarded battery plates, type metal, and bearing metal is reduced to a lead bullion. The bullion is refined in reverberatory furnaces and melting pots to meet specifications.

Byproducts and Coproducts

Most of the domestic primary antimony production is a byproduct or coproduct of mining, smelting, and refining other metals and ores that contain relatively small quantities of antimony. In 1989, domestic production of antimony was mainly a byproduct of the treatment of tetrahedrite, a complex silver-copper-antimony sulfide ore. An undisclosed amount of antimony was also recovered as a byproduct of the processing of lead ores.

The antimony deposits of the Republic of South Africa contain gold. High-grade Bolivia antimony ores contain variable and minor values of gold and tungsten and objectionable amounts of lead, copper, and arsenic in some deposits. Chinese ores contain some tungsten.

Economic Factors

Antimony and antimony trioxide are taxed under the new Superfund Amendments and Reauthorization Act of 1986, Public Law 99-499. The taxes, to be collected from producers and importers, were \$4.90 per ton of antimony metal and \$4.13 per ton of antimony trioxide. The taxes end on December 31, 1991.

Antimony producers are granted a depletion allowance of 22% on domestic production and 14% on foreign production.

Under the new Harmonized Tariff Schedule of the United States, which took effect January 1, 1989, antimony ore and concentrates imports from both most favored nations (MFN) and non-MFN were duty free. Antimony and articles thereof, including waste and scrap, and antimony oxide, were duty free for MFN. However, from non-MFN a statutory duty of 4.4 cents per kilogram was imposed.

Operating Factors

Environmental and ecological problems associated with the treatment of antimony metal and ores are minimal because emissions and effluents are controlled at the processing plant.

The major conservation practice of the antimony industry is the recycling of the metal in used storage batteries, type metal, and babbitt. Antimony metal and antimonial lead from intermediate smelter products such as slags, drosses, flue dusts and residues generated at copper and lead smelters are recovered at lead smelters.

Energy requirements for the production of antimony metal and antimony trioxide from stibnite ores are 163 million British thermal unit (Btu) per net ton of antimony metal and 186 million Btu per net ton on antimony trioxide.¹⁰

An estimated 130 persons are employed in the domestic production of antimony ores and in the conversion of antimony ores and raw materials to antimony metal and compounds.

ARSENIC

By J. Roger Loebenstein

Mr. Loebenstein is a physical scientist with the Branch of Nonferrous Metals. He has covered arsenic for 3 years. Domestic survey data were prepared by Evangeline Hemphill, Nonferrous Metals Data Section. International data were prepared by Virginia Woodson, International Data Section.

Small amounts of arsenic trioxide were shipped in 1989 from remaining stocks at ASARCO Incorporated's closed plant at Tacoma, WA. Shipments of arsenic metal from China were halted at yearend and the price for metallurgical-grade arsenic metal increased from about 60 cents per pound in December to about \$4.00 per pound in January 1990.

ISSUES

The former Asarco plant at Tacoma, WA, was a Federal Superfund site designated for environmental cleanup. In addition, soil in residential areas in the town of Ruston, adjacent to the former smelter, was contaminated with arsenic. As a remedy, Asarco proposed cleaning up two playgrounds near its closed plant and creating a trust fund to be administered by the Tacoma-Pierce County Health Department for cleanup work it deemed necessary. Asarco and the Environmental Protection Agency (EPA) continued to negotiate on the extent of Asarco's cleanup efforts.¹

EPA issued an emergency cleanup order requiring the former and current owners of the Bunker Hill smelter in Kellogg, ID, to clean up hazardous materials at the site. The 350-acre designated Superfund site is contaminated with high levels of arsenic and other heavy metals as well as asbestos and PCB's. The cleanup operation was to be supervised by EPA and carried out by contractors hired by the companies involved.²

CONSUMPTION

All arsenic consumed in the United States was derived from imported sources. Apparent demand for arsenic continued to increase in 1989, as shown in table 1. The

TABLE 1

industrial chemical sector, specifically the wood preservative industry, accounted for about 70% of domestic demand. The wood preservative industry converted imported arsenic trioxide to arsenic acid, an intermediary used in the production of the wood preservative, chromated copper arsenate (CCA).

The glass industry used arsenic acid as a fining agent. The wood preserving industry supplied some of the arsenic acid used by the glass industry.

In February 1989, Hickson Corp., a subsidiary of Hickson International PLC, United Kingdom, purchased the wood preservative operations of Koppers Co. Inc., Conley, GA. In addition to the Conley, GA, plant, Hickson operated wood preservative plants in Hickory Grove, SC, Valparaiso, IN, and Kalama, WA. LaPorte PLC, United Kingdom, produced arsenical wood preservatives through its U.S. subsidiary, CSI. CSI operated wood preservative plants at Valdosta, GA, Harrisburg,

NC, Gilmer, TX, and Laramie, WY. Another company, Osmose Corp., produced wood preservatives at plants in Memphis, TN, Tangent, OR, and Rock Hill, SC. Hickson, CSI, and Osmose accounted for most of the arsenical wood preserving industry.

A zinc producer in Illinois used arsenic trioxide as a flotation reagent to separate zinc from copper, cobalt, and nickel. This was the only zinc producer known to use arsenic in its process.

Source: Bureau of the Census.

The major agricultural chemical use for arsenic was as arsenical herbicides, monosodium methanearsenate (MSMA) and disodium methanearsenate (DSMA). Arsenic acid was used as a cotton leaf desiccant. The major producer of DSMA and MSMA was Fermenta ASC Corp., Mentor, OH. Atochem Corp., Bryan, TX, was the major producer of arsenic acid for use by cotton growers and wood preservative companies.

Commercial grade arsenic metal, 99% pure, was used in lead- and copper-based alloys as a minor additive (about 0.01% to 0.5%) to increase strength in the posts and grids of lead-acid storage batteries and to improve the corrosion resistance and tensile strength in copper alloys.

Relatively small quantities of high-purity arsenic metal, 99.99% pure or greater, were used in electronics. Arsenic metal was used in gallium arsenide for a variety of electronic devices and in selenium-based xerography. Gallium arsenide crystals are grown in a highly controlled process that eventually results in gallium arsenide cylinders, generally from 2 to 4 inches in diameter. The cylinders are doped, sawed into wafers, and polished to create semiconductor devices, used in optoelectronic devices.³

PRICES

The average price for arsenic trioxide, imported from Mexico, declined slightly in 1989. The average price of arsenic metal, imported from China, declined sharply in 1989 to 47 cents per pound. However, in December 1989, Chinese producers stopped delivering arsenic metal to lead alloyers, causing the intermerchant price of arsenic metal to rise from 60 cents per pound to \$1.50 per pound in 1 week.⁴ By January 1990, the price of arsenic metal had soared to \$4.00 per pound because of the halt in shipments. China is the only country in the world that produces arsenic metal for use in nonferrous alloys.

WORLD REVIEW

Arsenic was recovered as arsenic trioxide in about 20 countries from the smelting or roasting of nonferrous metal ores or concentrates. Annual arsenic trioxide refinery production capacities for the three leading countries were as follows: Sweden, 11,000

metric tons; France, 10,000 metric tons; and the U.S.S.R., 10,000 metric tons. Arsenic metal, which accounts for only 3% of world demand for arsenic, was produced by the reduction of arsenic trioxide. Commercial-grade arsenic metal, 99% pure, which accounted for the majority of arsenic metal production, was produced only in China. High-purity arsenic, 99.99% pure or greater, for use in the semiconductor industry was produced by about 10 companies. Furukawa Electric Co. Ltd. in Japan and Preussag AG in the Federal Republic of Germany were believed to be the world's largest producers, with reported capacities of 30 and 15 metric tons per year, respectively. Other high-purity arsenic producers included: Johnson Matthey Electronics, in Canada; Mitsubishi Metal Corp. and Rasa Industries Ltd., in Japan; and Johnson Matthey Ltd. and MCP Electronic Materials Ltd., in the United Kingdom.

CURRENT RESEARCH

Hazen Research Corp., Golden, CO, completed pilot plant testing of the

Cashman Process to convert arsenic contained in flue dusts to an insoluble form. The Cashman Process was developed by Artech Recovery Systems Inc., Redmond, WA. The Hazen testing program demonstrated that the process could be operated successfully on a continuous basis. Artech hoped that ARCO Coal Co., owner of the flue dusts, would select its technology to construct a commercial plant at Anaconda, MT, the site of a former Anaconda Co. copper smelter. In the Cashman Process, arsenic is converted into an insoluble residue that meets EPA's standards for safe disposal.⁵

OUTLOOK

The major market for arsenic is its use in wood preservatives. The future for arsenic consumption is therefore tied to new housing starts, where wood decks containing arsenical preservatives have become almost standard items in recent years. People adding decks to existing houses also use treated wood. Over the next 5 years, the growth of wood preservatives is expected

¹Including calculated arsenic trioxide equivalent of output of elemental arsenic and arsenic compounds other than arsenic trioxide where inclusion of such materials would not duplicate reported arsenic trioxide production.

²Table includes data available through May 25, 1990.

³Austria, China, Czechoslovakia, the German Democratic Republic, Hungary, the Republic of Korea, Spain, the United Kingdom, and Yugoslavia have produced arsenic and/or arsenic compounds in previous years, but information is inadequate to make reliable estimates of output levels, if any.

⁴Output of Tsumeb Corp. Ltd. only.

⁵Output of Empresa Minera del Centro del Peru (Centromin Peru) as reported by the Ministerio de Energia y Minas.

⁶Based on arsenic trioxide exported plus the arsenic trioxide equivalent of the output of metallic arsenic exported.

⁷Reported figure.

to average 3% to 5% per year, much less than previous years. No major environmental problems associated with the use of arsenicals in wood preservatives are anticipated because of the small amounts of arsenic used, and the fact that arsenic does not leach from treated wood.

The use of arsenic in agricultural chemicals has been under close scrutiny by the Environmental Protection Agency (EPA) for many years. Many pesticide uses for arsenical chemicals have been banned by EPA. The use of arsenicals, DSMA, MSMA, arsenic acid, and cacodylic acid, on cotton is expected to remain stable or decline over the next 5 years.

Gallium arsenide components have long competed with silicon components in electronic applications. Gallium arsenide components are faster, but silicon components are cheaper. Advances in computer technology have led to the move from linear to parallel arrangement of processors, thus minimizing the relative slowness of silicon. For this reason, it is unlikely that gallium arsenide will replace silicon in most electronic applications, despite growth in gallium arsenide production capacity.⁶

Gallium in 1989. Mineral Industry Surveys, Annual Review.

ASBESTOS

By Robert L. Virta

Mr. Virta, a physical scientist with 14 years Bureau of Mines experience, has been the commodity specialist for asbestos since 1986. Domestic survey data were prepared by Michael McTootle, mineral data assistant; and international data tables were prepared by Harold Willis, international data coordinator.

The most noteworthy event within the industry was the enactment of a regulation by the Environmental Protection Agency (EPA), after 3 years of review, that phases out the use of asbestos in most products by 1997. Health and liability issues also continued to adversely affect the industry. The number of firms that produce asbestos-containing products declined dramatically in the past few years in response to these issues. Domestic asbestos consumption decreased 22% from that of 1988, continuing a 16-year decline from 800,962 tons in 1973 to 55,306 tons in 1989. Only two companies in California and Vermont mined asbestos in the United States. Approximately 97% of the asbestos consumed in the United States was imported from Canada. Domestically, asbestos was consumed in roofing products, 34%; friction products, 23%; asbestos-cement pipe, 15%; packing and gaskets, 8%; and other, 20%.

DOMESTIC DATA COVERAGE

Domestic production data for asbestos are developed by the Bureau of Mines by means of a voluntary industry survey. Of the two canvassed operations to which a survey request was sent, both responded, representing 100% of the total production data shown in table 1.

LEGISLATION AND GOVERNMENT PROGRAMS

EPA issued a final rule banning the manufacture, importation, processing, and distribution of most asbestos-containing products on July 12, 1989. The ban will be implemented in three stages. The first stage, effective August 27, 1990, bans asbestos-containing floor-

ing and roofing felt, pipeline wrap, asbestos-cement corrugated and flat sheet, vinyl asbestos floor tile, and asbestos clothing. The second stage, effective August 25, 1993, bans asbestos-containing gaskets, transmission components, and original equipment drum and disk brake components. The third stage, effective August 26, 1996, bans asbestos-cement pipe, commercial and corrugated asbestos paper, roll board and mill board, asbestos-cement shingle, asbestos-containing roof and non-roof coatings, brake blocks, and after-market drum and disk brake components. The sale and distribution of asbestos-containing products, product labeling, exemptions from the ban, and record keeping are covered by provisions in the regulation.¹ The Asbestos Information Association of North America, Asbestos-Cement Pipe Producers Association, the Asbestos Institute, and several other organizations have petitioned the courts to review the EPA ban.

¹ F.o.b. mine.

² Production, plus imports, minus exports, plus adjustments in Government and industry stocks.

The Mine Safety and Health Administration issued proposed revisions to its existing standards for air quality and chemical substances, including the lowering of permissible exposure levels to asbestos from 2.0 fibers per cubic centimeter (f/cc) to 0.2 f/cc.² The Occupational Safety and Health Administration extended an administrative stay through November 30, 1990, on the regulation governing exposure to the nonasbestiform varieties of actinolite, anthophyllite, and tremolite and continued to study the economic impact of the regulation on the mining and construction industries.³

EPA proposed changes in the national emission standard for hazardous air pollutants. The proposed revisions require daily monitoring of visible emissions for milling, manufacturing, and fabricating operations, weekly inspection of air-cleaning devices, and record keeping. Notification requirements for demolitions and renovations are revised and record keeping is required for asbestos waste disposal.⁴

EPA proposed changes in the national primary and secondary drinking water regulations. The proposal covers 30 organic chemicals and 8 inorganic chemicals, including asbestos. The proposed maximum contaminant level goal for asbestos is 7 million fibers (longer than 10 micrometers) per liter.⁵

STRATEGIC CONSIDERATIONS

A wide variety of asbestos-containing civilian products also have military applications. Examples include friction materials (brakes and clutches), electrical and thermal insulations, packings and gaskets, asbestos-reinforced plastics, etc. for use on military vehicles, ships, rockets, missiles, and in military construction. During World War II and the Korean war, strict controls were placed on the export of asbestos because the United States was dependent on foreign sources for about 90% of its requirements of all grades of asbestos. The United States was totally dependent on foreign sources for low-iron, spinning-grade chrysotile. Since that time, equipment components have been redesigned, new products have been introduced, and substitutes for asbestos are being used more frequently.

Crocidolite	—	33	33	33
Total	18,144	40,591	40,592	40,592

Source: Department of Defense.

Many of the asbestos-containing civilian products that are used by the military will be eliminated because of the EPA-mandated phaseout of asbestos. Because of the trend toward lower asbestos consumption, the Department of Defense has authorized the disposal of 6,155 tons of chrysotile, 15,427 tons of amosite, and 33 tons of crocidolite and is currently considering the removal of these materials from the stockpile of strategic and critical minerals.

ISSUES

Environmental and liability issues continue to affect the asbestos industry. EPA enacted a regulation that phases out the use of asbestos in most products by 1997 because of concerns over the risks of low-level exposures. The regulation is controversial because it assumes that there is no threshold level of exposure to asbestos beyond which there is no risk. Industry representatives maintain that there are insufficient data available to support this assumption, that environmental risks posed by asbestos are far less than many of those encountered in everyday living, and that stricter control of asbestos can reduce the risks even further.

PRODUCTION

Asbestos was produced in the United States by two companies, KCAC Inc., San Benito County, CA, and Vermont Asbestos Group Inc. (VAG), Orleans County, VT. Domestic production was limited to chrysotile, one of six com-

mercial varieties of asbestos. KCAC operated a mine in a highly sheared serpentinite composed of matted short fiber chrysotile and unfractured serpentinite (also referred to as a mass fiber deposit). The ore was stripped and wet processing was used to beneficiate the fiber. VAG operated an open pit mine in a serpentinite containing cross-fiber veins of chrysotile. Dry milling was used to process the fiber. While the California company produced only short fiber chrysotile, the Vermont company produced a wide range of chrysotile grades.

Domestic production decreased slightly in 1989. The two domestic producers were able to maintain production levels despite the EPA ban and phaseout because export markets remained strong.

CONSUMPTION AND USES

Asbestos was used in a wide variety of products because of its high tensile strength, chemical and thermal stability, high flexibility, low electrical conductivity, and large surface area. Products made from asbestos were more heat resistant (and often incombustible), more resistant to chemical attack (particularly for alkalis), stronger (asbestos acted as a physical reinforcer), less conductive (asbestos had a low dielectric constant), more viscose (asbestos stiffened compounds and coatings), faster setting (asbestos hastened water drainage in asbestos-cement pipe production), and more cost efficient than many nonasbestos products.

U.S. consumption of asbestos decreased 22% in 1989. Approximately 93% of the asbestos consumed domes-

⁴ Does not include "Amosite" and "Other" category in total.

⁵ Less than 1/10 unit.

tically was chrysotile, 1% was crocidolite, less than 1% was amosite, and 6% was an unspecified fiber type. Approximately 74% of the chrysotile consumed in the United States was grade 7, followed by grades 4, 5, 6, 3, 2, and 1.

The construction industry is the major consumer of asbestos fiber in the form of asbestos cement pipe, asbestos cement sheet, coatings, compounds, packings, and roofing products. These end uses accounted for 71% of the asbestos consumed in the United States.

Consumption has declined dramatically from 800,962 tons in 1973 to 55,306 tons in 1989 in response to environmental and liability issues. There is a continuing interest among manufacturers of both organic and inorganic fibers in acquiring portions of the asbestos market. Product manufacturers gradually have been replacing asbestos with substitute materials, redesigning old products to eliminate the need for asbestos, or designing new products which require neither asbestos nor asbestos substitutes. Economic, manufacturing, performance, and/or

technical difficulties were considered before asbestos was replaced by a substitute material or product.

Examples of materials substituted for asbestos include aramid fiber, calcium silicate, carbon fiber, cellulose fibers, ceramic fiber, clay, fibrous glass, fumed silica powder, graphite flake and fiber, limestone, mica, polyacrylonitrile fiber, polybenzimidazole fiber, polyethylene fiber, polypropylene fiber, polytetrafluoroethylene fiber, steel fibers, talc, and wollastonite. Examples of alternative products include aluminum, vinyl, and wood siding; aluminum pipe and sheet; asphalt coatings; ductile iron pipe; fiberglass sheet; polyvinylchloride pipe; prestressed concrete and reinforced concrete pipe; semi-metallic brakes; urethane coatings; and vinyl composition floors.

PRICES

The average unit value of domestically produced asbestos increased

slightly in 1989. Unit values for imported asbestos ranged from \$141 per ton to \$3,728 per ton and averaged \$234 per ton. Unit values for exported asbestos ranged from \$128 per ton to \$2,158 per ton and averaged \$285 per ton. Customs unit values of imported crude chrysotile decreased 74% because high valued crude chrysotile from Zimbabwe was not imported under this import category in 1989. The unit value of imported spinning chrysotile decreased 49% because the change to the Harmonized System for import reporting resulted in the inclusion of lower valued chrysotile fiber in the "chrysotile, spinning" category.

FOREIGN TRADE

Beginning in 1989, the Bureau of the Census adopted the Harmonized System for reporting commodity imports and exports. Asbestos import categories under the Harmonized System were unchanged from those of previous years.

TABLE 4
CUSTOMS UNIT VALUES OF IMPORTED ASBESTOS
(Dollars per metric ton)

	1985	1986	1987	1988	1989
Canada:					
Chrysotile:					
Crude	576	547	610	635	167

South Africa, Republic of:					
Amosite	830	—	—	—	3,728
Crocidolite	569	582	572	609	631

Source: Bureau of the Census.

Asbestos export categories under the Harmonized System were considerably different from those of previous years. Export categories that were used prior to 1989 overlap under the Harmonized System and many of the Harmonized System categories were not exclusive for asbestos (i.e., included cellulose pipe and sheet and nonasbestos friction materials).

The total value of asbestos fibers and asbestos products exported and reexported from the United States was \$160,771,000. This is a 21% decrease

from 1988 and reflects a lower volume of asbestos and asbestos products being exported in 1989. Exports and reexports of brake linings and disk pads accounted for 83% of the value of all manufactured asbestos products. Canada remained the largest importer of unmanufactured fibers and manufactured products, followed by Japan, Mexico, Brazil, and the United Kingdom.

Canada provided 97% of the asbestos imported into the United States, and the Republic of South Africa provided 2%. Several other countries pro-

vided minor amounts. Approximately 93% of the asbestos fiber imports were chrysotile.

WORLD REVIEW

Canada continued to be the largest market-economy producer of asbestos, followed by Brazil, the Republic of South Africa, and Italy. The U.S.S.R. was the world's largest producer of asbestos. Canada and the U.S.S.R. accounted for 77% of the world production. Canada continued to be the largest exporter of asbestos.

Capacity

The data in table 8 are rated annual capacity for mines and refineries as of December 31, 1989. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants

temporarily closed that in the judgment of the author can be brought into production within a short period of time with minimum capital expenditure.

Canada

Developmental work continued on the underground portion of Cassiar Mining Co.'s McDame asbestos mine in British Columbia. The mine is expected to become operational in March 1990. Reserves in the open pit are sufficient to continue operation through late 1990.⁶

South America

Swiss Eternit Group (SEG) planned to

divest itself of asbestos cement operations in Brazil, Colombia, and Bolivia and its holdings in SA Mineracao de Amianto (SAMA), a chrysotile operation in Brazil. SEG will begin to focus on the use of asbestos substitutes.⁷

CURRENT RESEARCH

Fifteen fiber-cement products that are used commercially in place of asbestos-cement products were tested for accelerated absorption, aging, color stability, combustion, density, flexural strength, humidity, impact resistance,

porosity, thermal conductivity, warping, and the degree to which a product was waterproof. The fiber-cement products tested performed exceedingly well in the impact resistance test and poorly in the combustibility tests. Mixed results were obtained for the other tests. The study concluded that the overall performance of asbestos-cement products exceeded that of the fiber-cement products.⁸

The Asbestos Information Association (AIA) compiled the results of its third survey of worker exposure to asbestos. Surveys were sent to 32 countries and 26 responded. The survey covered 45,696 workers in mining (30%), asbestos-cement production (39%), friction materials production (22%), textile production (5%), and other asbestos industries (4%). Less than 2% of the workers covered in the survey were exposed to concentrations of more than 2 f/cc. Over 90% were exposed to concentrations of less than 1 f/cc. The bulk of the exposures over 2 f/cc were in the textile industries.⁹

OUTLOOK

Domestic markets will continue to decline because of the EPA ban and phaseout of asbestos and consumer demand for asbestos substitutes. Asbestos mining was not banned under the new EPA regulation so domestic producers will be able to continue to export asbestos fiber. Foreign markets for asbestos fiber should remain strong for several years because of the high demand in Southeast Asian and developing countries for proven, low-cost construction materials.

The prospects for the domestic asbestos manufacturing industry are poor because of the EPA mandated phaseout of most uses of asbestos within 7 years. Asbestos consumption probably would continue to decline even if the EPA ban and phaseout of asbestos were rescinded in favor of stricter regulations because of the continuing concern over environmental, health, and liability issues.

BARITE

By Sarkis G. Ampian

Mr. Ampian, a physical scientist with more than 36 years experience, has been the commodity specialist for barite since 1981. Domestic survey data were prepared by Bruce Baltas, mineral data assistant, and international tables were prepared by Virginia A. Woodson, international data coordinator.

Domestic production of barite decreased more than 28% to 290,000 metric tons (data in metric units, unless noted), while the value decreased nearly 20% to \$13 million. This decline continues the downtrend in barite production, except for 1987, which has persisted since 1981 when the record high of 2.5 million tons was produced. Production from Nevada, the leading producing State, decreased about 18%. Imports for consumption of crude barite decreased nearly 13%, while ground barite imports more than trebled. Imports of barite exceeded domestic production for the eighth consecutive year, but the import figure of 990,000 tons for 1989 was about 1.1 million tons below the record-high tonnage of 1982. Ground barite imports, except for the drilling boom years of the late 1970's and early 1980's, have been negligible. The principal use for barite, as a weighting agent in oil- and gas-well-drilling fluids (muds), accounted for about 90% of U.S. consumption. Chemical, glass, and filler and/or extender uses accounted for the remaining 10%.

Weak demand for barite by the oil- and gas-well-drilling industry carried over from the third quarter of 1988 and persisted for the entire year owing to volatile oil prices and softening of the overall economy. The downturn in demand has been largely due to the decrease in the number of offshore and onshore drilling rigs, thereby lowering the demand for barite-bearing muds. Overproduction by major oil-producing countries during the last quarter caused crude oil prices to decline, which in turn depressed the demand for barite drilling muds. U.S. mine production of barite continued, although still depressed. Producers were encouraged by declining rail rates, which increased the competitiveness of domestic ores in the gulf coast and midcontinent areas. Barite grinding capacity, despite numerous closures, mergers, and acquisitions, remained sufficient to meet present and future requirements.

DOMESTIC DATA COVERAGE

Domestic production data for barite are developed by the Bureau of Mines from a voluntary survey of U.S. operations. Of the 65 operations to which a survey request was sent, all responded, representing 100% of the total crushed and ground production sold or used shown in table 1.

PRODUCTION

The term "primary barite" denotes the first marketable product and includes crude run-of-mine barite, flotation concentrates, and material concentrated by other beneficiation processes such as washing, jigging, or magnetic separation. Run-of-mine barite, the lowest cost primary barite sold or used by producers, representing

43% of total production, was unchanged from 1988; the remaining 57% was flotation concentrate and other beneficiated material. The lower cost crude barite and jigged beneficiated materials were used chiefly in drilling muds; the higher valued floated and other beneficiated material was used mostly in chemical and glass manufacturing and in filler applications.

Reported primary production declined nearly 28% from 404,000 in 1988 to 290,000 tons. Nevada and Georgia remained the two leading barite-producing States. Other producing States, in descending order, were Missouri, Tennessee, Montana, and Illinois. Illinois produces barite as a coproduct of fluorspar mining and milling; in all other States, barite is the primary product.

The leading domestic barite producers were M-I Drilling Fluids Co., a Dresser-Halliburton Co.; Milpark Drilling Fluids, a Baker Hughes Inc. company with mines

in Nevada; and Baroid Drilling Fluids Inc., a division of NL Petroleum Services Inc., with mines in Missouri and Nevada.

In domestic barite news, New Riverside Ochre Co. (NRO), of Cartersville, GA, purchased Baroid Corp.'s, formerly NL Baroid, Sweetwater properties in Tennessee. The properties, amounting to about 1,100 and 1,200 acres, respectively, of fee simple and mineral rights lands. Baroid last worked the barite deposits for both the drilling and nondrilling markets. A. J. Smith Co. Inc. built a washer-jigging plant on the property to feed NRO's complex in Cartersville, GA. NRO is the mining arm of Chemical Products Co. (CPC), Cartersville, GA, and produces barium chemicals from the local barite residuum. Both NRO and CPC are wholly owned subsidiaries of Dellinger Management Co., also of Cartersville. In another action, NRO completed the installation of the Kingston washer plant at midyear, purchased from DeSoto Mining Co. Inc., Richlands, MO, at its nearby Emerson, GA, location to treat local and Sweetwater barite. In drilling mud news, American Barite Corp. completed a barite grinding facility at Morgan City, LA, and Milpark Drilling Fluids Inc. added two additional jigs to its existing Argenta, NV, jigging plant. In corporate news, the shareholders of NL Industries Inc. voted on December 22 to spinoff NL Baroid into a separate entity, Baroid Corp.

The recovery of the domestic barite industry that began in midyear 1987 and continued into the last quarter of 1988 failed to reappear during all of 1989, when overproduction by oil-producing countries caused crude oil prices to decline. During this downturn, volatile but lowering oil prices decreased drilling activity. The slowdown of the growing overall economy did little to spur recovery. The yearend oil glut depressed barite demand by the exploration and development segments of the industry. The decline in production rates in 1989 reversed the near level output in 1971-88 by returning to the trend of declining barite output that had begun after 1981, the high production year (2.8 million tons). Production data indicate that competitive rail rates to the gulf coast and midcontinent areas, based on unit trains and guaranteed-tonnage contracts, combined with a tight barite supply early in the year and attendant price increases, permitted modest domestic mining campaigns.

Nevertheless, the persistent oil glut, exacerbated primarily by overproduction,

caused price volatility, lowered energy rates, and continued to temper or limit any major upturn in drilling activity. Another factor depressing the domestic marketplace was the overcapacity of the drilling-fluids producers. The slowly recovering domestic barite industry, the world's largest, continued to be threatened by imports of crude and ground barite. Rising ocean freight rates, in part due to higher bunker fuel costs and limited availability of bottoms, helped reduce competition by foreign ores early in the year.

Most mining and grinding operations continued to be either suspended or operated on minimal production schedules to address the industry's excess capacity. Many of the additions to mining, milling, and grinding capacity were largely to reduce operating costs to remain competitive in a firming but volatile market situation. Many ongoing and planned projects, including exploration programs, were indefinitely deferred.

The International Trade Commission/Import Administration, U.S. Department of Commerce, terminated an antidumping administrative review of barium chloride from China.¹ Earlier in the year, the Department published preliminary results of its administrative review of the antidumping duty order on barium chloride from China.² The review covered one manufacturer and/or exporter of this chemical to the United States from the periods April 6, 1984, through September 30, 1984, and October 1, 1985, through September 30, 1986. The margins for the first period were stipulated at 27.70% and 60.84% for the second. A cash deposit estimated antidumping duty of 60.84% was required for all shipments from this one source. These cash deposit requirements were effective for all shipments for Chinese barium chloride entered or withdrawn from warehouse for consumption on or after the date of publication of the notice and remained in force by the Customs Service until the termination decree.

The Environmental Protection Agency proposed to grant the petitions to exempt barium sulfate from the reporting requirements under the category "barium compounds" on the list of toxic chemicals under Section 313 of the Emergency Planning and Community Right-to-Know Act of 1986 in recognition that barium sulfate is an insoluble and inert dust.³ The Department of Labor, Mine Safety and Health Administration, proposed to revise its existing standards for barite air quality and

chemical substances at coal and metal-nonmetal mines to a threshold limit value (TLV) of 10 milligrams per cubic meter (mg/m³).⁴ The preproposal draft specified a limit for barite, a barium sulfate compound, of 0.5 mg/m³. The same limit was placed on other soluble and reactive barium compounds by the American Conference of Governmental Industrial Hygienists (ACGIH).

CONSUMPTION AND USES

Consumption of crushed and ground barite decreased nearly 17%, from 1.6 million tons in 1988 to 1.3 million tons in 1989. This decrease resumes the decline in total barite consumption, except for the past 2 consecutive years of 1987 and 1988, prevalent since 1981 when the record high of 4.7 million tons of crushed and ground barite was set. The decrease reflects a downturn not only in barite requirements for oil well drilling, which still accounts for about 90% of total sales, but also in the overall economy. The oil and gas-well-drilling industry completed nearly 21,000 wells and drilled about 102 million feet of hole;⁵ these figures were 16% and 18% lower, respectively, than in 1988.

Total drilling footage exceeded 6 million feet in four States: Texas, 37.7 million feet; Oklahoma, 11.6 million; Louisiana, 9.7 million; and Kansas, 6.5 million. Generally, the deeper a hole is drilled, the more barite is used per foot of drilling. Among the four leading States, Louisiana had the highest average well depth, over 7,900 feet, and Kansas the shallowest, about 3,400 feet. Wyoming, absent from the top States this year in well footage drilled and the perennial leader in the highest average well depth, recorded only 7,300 feet. The U.S. average decreased to nearly 4,900 feet, a 4% reduction. Barite consumption decreased accordingly with the 15% reduction in the number of wells drilled despite the upturn in operating offshore rigs in the Gulf of Mexico and California at the expense of shallower drilling onshore varieties elsewhere. Most of the onshore wells were in the Overthrust Belt in Wyoming and Anadarko Basin in Oklahoma, both deep-drilling areas. There was nearly a 43% decrease in the amount of barite used per foot of drilling, from 63.02 pounds in 1988 to 36.08 pounds in 1989.

Another barometer of drilling activity, the Baker Hughes rig count, showed the

²Includes flotation concentrates.

average number of operating domestic rigs in 1989 decreased 7% to 869.⁶ This decline in rigs reestablishes the downward trend that, except for 1984 and 1988, has seen the number of rigs fall from the 1981 record high of 3,974. The 1989 average rig count of 869 is the fourth time since 1971 (976 rigs) that the count was below 1,000. The estimated rig count during the year ranged from 737 to 1,079. The low count of 737, recorded the week of May 21, was the second lowest since World War II. The high, 1,079 rigs, was registered the week of December 24.

PRICES

Price quotations in trade publications for barite remained unchanged. These prices may serve as a general guide but do not reflect actual transactions.

The reported average value per ton of domestic barite, based on reported value or direct-ship, beneficiated, and floated material, increased 12%, f.o.b. plant, from \$38.40 per ton in 1988 to \$43.53. This increase in value for domestic concentrate is

attributed to a smaller percentage of lower valued drilling-mud-grade material in the total. The average reported value per ton of ground drilling-mud-grade barite from Louisiana and Texas was \$76.77; the average value of that from California, Nevada, and Utah was \$64.81. The value of the Louisiana and Texas ground material, in direct response to steadily rising costs of imported crude, rose about 15%. Material from the other major grinding States, supplied largely by domestic mines, rose slightly. The average customs value of barite exported to Canada and Mexico ranged between \$200 and \$400 per ton; the customs value of material exported to Latin America was under \$200 per ton.

FOREIGN TRADE

Exports of natural barium sulfate or barite increased markedly from about 200 tons to more than 9,700 tons. This increases the modest rebound in barite exports for the previous 3 of 4 years, 5,800 to 9,700 tons, and ends the downward pattern that saw exports plummet from the record high

of 109,000 tons in 1979. Export and import data provided by the Bureau of the Census did not indicate the grades of barite traded; however, based only on the value of individual shipments, from more than \$50 to \$5,000 per ton, drilling-, pharmaceutical-, chemical-, filler-, and glass-grade were all exported. Drilling-mud-grade barite appeared to make up about 75% of the export percentage. Historically, barite exports were predominantly ground drilling-mud-grade material with less than 5% of the tonnage specialty ground barites. Minor amounts of witherite (natural barium carbonate), precipitated barium carbonate, barium sulfate (blanc fixe), and barium chlorides, anhydrous and hydrous oxides, and nitrates also were exported. Crude barite was not exported. Canada and Mexico traditionally either first or second among export recipients of U.S. ground barite, were replaced by Venezuela and Colombia, in decreasing order. These two countries were the leading buyers of U.S. ground barite and accounted for about 55% of the total exports. Exports to Canada and Mexico, major oil-producing countries, declined to less than 2,000 tons from a high of 18,000 tons in 1983. Both Canada and

Mexico continued to rely more on domestic production. During the year, the strengthening U.S. dollar had little effect on this trade because of continuing Canadian and Mexican fiscal problems.

Imports for consumption of crude barite decreased about 13%, from 1.132 million tons in 1988 to nearly 990,000 tons. The 1989 barite import figure was nearly 50% below the record high of 2.32 million tons

set in 1982. The c.i.f.⁷ value of this material resumed its downward trend by declining about 10% to \$40.27 per ton. Except for 1988, the value of imported material has declined for 9 of the previous 10 years. The 1989 decrease indicates that prices of foreign ores lowered in response to oversupply and lower ocean shipping rates. Earlier cutbacks in foreign production in 1988, notably in China and India, because of an absence of forward commitments, saw a firming of both crude barite prices and shipping rates, which carried only into the first quarter of 1989. The 25% increase in imports of Indian ores in 1989 was caused primarily by slippages in delivery schedules that carried over into the first part of the year. Softening worldwide crude oil prices and its resultant lowering of oil- and gas-exploration drilling activity combined to lessen domestic demand for most of the year. Domestic producers and consumers in the gulf coast area, still faced with relatively high rail rates from domestic drilling-quality barite mines in Nevada, continued to take advantage of the lower priced foreign ores to meet their demands. Based on average value per ton of material shipped, the principal source countries, in descending order, were China, \$40.85; India, \$40.27; Mexico, \$38.84; Peru, \$36.37; and Chile, \$33.25. The high-priced Mexican material was chiefly crude filler and extender-quality barite. The high-quality barite, generally material with a specific gravity greater than 4.2, is usually blended during grinding with lower grade ore, foreign or domestic, to meet American Petroleum Institute specifications for 4.2 drilling-mud-grade barite. Most of the crude barite entered through customs districts along the gulf coast for delivery to grinding plants in the area. The import distribution by customs districts in 1989 (1988) was New Orleans, LA, 65% (74%); Houston, TX, 31% (23%); and Laredo, TX (Port of Brownsville, TX), 31% (13%). Small amounts were also received, in decreasing order, in Great Falls, MT; Pembina, ND; and Cleveland, OH.

Imports of ground barite more than tripled to nearly 47,000 tons from about 14,000 tons in 1988; of this, Canada (17%) and Mexico (80%) supplied about 97%. Before 1984, ground barite imports had been limited to premium-quality pharmaceutical grades, which were unavailable domestically. In recent years, this market has been dwindling because certain medical X-ray diagnostic procedures employing barium

¹Includes imports.

compounds have been largely replaced with computer-assisted tomography (CAT) scanners or imaging techniques. Sources of medical-grade barite were Belgium-Luxembourg, Canada, France, the Federal Republic of Germany, and the Netherlands. The average c.i.f. value of imports from Canada, Czechoslovakia, and Mexico ranged from \$51 to \$314 per ton, suggesting that this ground barite is probably destined for the domestic filler and/or extender markets that usually are supplied by U.S. producers. The continued imports of ground filler- and extender-grade barite into this mature market will probably cause concern among domestic producers. The value of imports from other countries, \$400 per ton, indicates that these ground materials are either an ultrahigh-purity pharmaceutical-grade material.

Imports for consumption of barium chemicals and unwrought and/or waste and

scrap barium metal are no longer reported by the Bureau of the Census.

WORLD REVIEW

Capacity

The data in table 13 are rated capacity for mines as of December 31, 1989. Rated capacity is defined as the maximum quantity of product that can be produced on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed, that, in the judgment of the author, can be brought into production within a short period with minimum capital expenditure.

Mine capacity for domestic barite production was aggregated from data voluntarily supplied by the producers. The rated capacity data for the foreign mines were estimated from the previous year's production in cooperation with the Division of International Minerals.

Brazil

A São Paulo-based company, Mineracão Matheus Leme Ltda. (MML), was evaluating a barite deposit in the State of Goiás for the Uruguayan paint market.⁸ MML, a diversified industrial mineral filler, was contemplating the engine gasket markets for its anhydrous mineral filler line.

Burma

The Government expects barite production to increase from the present total of about 20,000 tons per year to more than 40,000 tons per year because of new oil explorations.⁹ Barite production is near Maymyo, Kyaukse, and Taunggyi in Central Burma.

China

A directive issued by The Ministry of Geology and Mineral Industry called for greater efforts to locate exportable economic mineral reserves in the coastal regions.¹⁰ Industrial minerals specifically targeted include barite. Apparently, 100 small- and medium-sized mines under consideration, largely in rural areas, were currently being evaluated.

France

The Bureau de Recherches et de Participations Minières reported a new sulfate deposit in the Lyon District with the capability of yielding byproduct barite.¹¹ Preliminary tests were directed toward a 330,000-ton-per-year treatment rate with an unannounced recovery of both sulfides and barite. A joint-venture scheme for financing was reportedly under consideration. Capitalization was in the order of 300 million francs.

Nigeria

Milpark Drilling Fluids Inc. started construction of a new barite grinding facility at Port Harcourt. The facility was scheduled to be on-stream by midyear.

Pakistan

The Government has allocated two large grants to Saindek Integrated Mineral Development Project, in Chaghai District, Baluchistan, and the other to the Geological Survey.¹² Future growths in production were noted for many industrial minerals, including barite.

United Kingdom

A new barite deposit at Cluniemore, approximately 8 kilometers north of the Foss Barite Mine, was announced by Magcobar Minerals-Eimco, a subsidiary of Dresser Industries Inc. The new deposit has estimated reserves of more than 15 million tons of barite. The Foss Mine and the new deposit are strategically important to the North Sea offshore drilling efforts that consume 200,000 tons of barite per year. Chinese and Moroccan barites are the main competitors for this market.

CURRENT RESEARCH

An indepth review was published on the industrial minerals of Brazil, which includes detailed sections on barite, local geology, reserves, mineralogy, mining and milling flowsheets, indigenous mining methods, and markets.¹³ The report also highlighted the Brazilian mining laws and barite production statistics by region and State. A noteworthy feature on the individual barite mining companies and their long-term goals was of particular interest. A technical article on drilling for oil and gas in the U.S. Gulf of Mexico was published.¹⁴ This publication stressed the importance of the Gulf of Mexico to the U.S. oil and gas production, the geology of deep-water versus shallow water exploration, and the structure of the drilling fluids industry not only in the gulf but also nationally. A highlight of the work was the tables listing the minerals used in drilling fluids, their average consumption rates, technical rationale for use, and the general classification methods for water-, salt-, and oil-base systems employed in drilling.

A review of Canadian barite beneficiation schemes was outlined.¹⁵ A map pinpointing Canada's barite mines and tables summarizing beneficiation techniques, principal flotation parameters, collector concentration data for rougher flotation, reagent facts, and analyses of heads and concentrates were features of the publication. Brief sections on mineralogy,

gravity concentration, flotation, physicochemical considerations for collectors, absorption, and depressant mechanisms were noteworthy additions to the barite mineral dressing literature.

The chemical properties and origin of high-temperature oxide superconductors, generally Ba₂YCu₃O₇, yttrium barium copper oxide and its analogs, were reviewed.¹⁶ This theoretical study reveals the dependence of copper-bearing or cuprate superconductors on the barium ions not

only for charge considerations but also for the superconducting mechanism to function.

OUTLOOK

Domestic demand for barite is expected to recover slowly at an annual rate of between 1% and 2% through 1995. Primary barite production should approach 500,000 tons per year by 1995 and the apparent consumption of barite in this period should be in the vicinity of 2.0 million tons.

The atmosphere for the past 10 years has seen volatile crude oil prices depress oil- and gas-exploration drilling activity. Little gas and oil reserves have been added to the national inventory. Principal drilling areas continue to be offshore rigs in the Gulf of Mexico and California. Most of the onshore wells are in the Overthrust Belt in Wyoming and the Anadarko Basin in Oklahoma. Drilling activities in these areas, however, appear to have focused in the past few years on the search for gas reserves at the expense of oil because of its economic uncertainties. Recent statistics¹⁷ show in the past 3 years, 1987-89, gas-well-drilling footage has increased from about 50% to 80%. The domestic

oil- and gas-exploration industry has not enjoyed the steady economic growth the Nation has enjoyed for the past 8 years. In addition, the uncertainty of alternate fuels as a political solution to national air pollution standards has clouded the future of the oil industry. It is anticipated that inroads of alternate fuels, such as alcohol and electric-power systems, will be challenged by the belatedly introduced newer and cleaner generation of petroleum products by the major oil companies. These two systems, if left to competitive market forces, will probably be resolved to the advantage of the new generation of petroleum products.

BACKGROUND

Definitions and Specifications

The term "primary barite," as used in this report, refers to the first marketable product and includes crude barite, flotation concentrate, and other beneficiated material such as washer, jig, heavy media, table, or magnetic separation concentrate. Most primary barite requires fine grinding before it is used for drilling muds. This grinding may or may not be done at the mine site.

^cEstimated. ^PPreliminary. ^rRevised.¹Table includes data available through May 23, 1990.²In addition to the countries listed, Bulgaria also produces barite, but available information is inadequate to make reliable estimates of output levels.³Data are for fiscal year beginning Mar. 21 of that stated.⁴Data are for fiscal year beginning Apr. 1 of that stated.⁵Reported figure.⁶Barite concentrates.⁷Sold or used by producers.

Barite is the mineralogical name for barium sulfate and was derived from the Greek word "barus," meaning heavy. In commerce, the mineral is often referred to as "heavy spar" or "barytes."

Specifications for barite vary according to its different uses. Material for weighting muds must be finely ground, heavy, and chemically inert; consequently, barite for this purpose must have a specific gravity of 4.2 or higher, it must be free of soluble salts, and 90% to 95% of the material must pass through a 325-mesh screen. A small percentage of iron oxide is not objectionable. In chemical manufacturing, purity is the principal concern, and a maximum of 1% each of ferric oxide (Fe_2O_3) and strontium sulfate (SrSO_4) and a trace of fluorine usually are specified, with a minimum of 94% barium sulfate (BaSO_4). If the mineral is to be used in the production of lithopone, the SrSO_4 content may be somewhat higher. Mesh size is important to chemical manufacturers; if the material is too fine, dust is lost, and if it is too coarse, mixing with carbonaceous material is poor. Most chemical manufacturers specify a size range of 4 to 20 mesh; some purchase lump barite and grind it to their own needs.

Glass manufacturers usually require a minimum of 95% BaSO_4 with a maximum of 2.5% silicon dioxide (SiO_2) and 0.15% Fe_2O_3 . The particle size range generally preferred is -30 to +140 mesh. Fine ground barite can be substituted when crushed material is not available.

Products for Trade and Industry

The principal use for barite, as a weighting material in well drilling muds, accounted for 90% of total U.S. consumption in 1989. Drilling muds have five main functions: (1) Transport drill cuttings to the surface, (2) control formation pressures, (3) maintain borehole stability, (4) protect producing zones, and (5) cool and lubricate the bit and drill string. The principal function of the barite constituent is as a weighting agent to suppress high formation pressures and prevent blowouts. As the well is drilled, the bit passes through various formations, each with different characteristics. The deeper the hole, the more barite is needed as a percentage of the total mud mix.

The use of barite as a filler or extender and other uses accounted for less than 10% of total U.S. consumption in 1989. Barite has a high specific gravity, low oil absorp-

tion, easy wettability by oils, and good sanding qualities. Unbleached barite may be substituted for bleached barite when brightness is not a factor. In painting automobiles, barite is used as a filler for the primer coats. The barite contributes to the gloss of the topcoat. When the primers are applied by the electrodeposition process, the body structure is dipped into a tank containing water and paint primer. The method eliminates one of the primary coats, thus reducing the quantity of barite used.

Barite is also used as a filler or extender in some plastic and rubber products. Processors of polyurethane foam use barite in manufacturing such products as floor mats and carpet-backings to increase density and improve processing qualities. Barite is used in white sidewalls for tires; sidewalls consist mainly of rubber, zinc oxide, and a small quantity of barite.

Other industries use small quantities of barite fillers. In the paper industry, the white and dense barite coatings serve as a base for the sensitized layers in photographic prints. In the printing industry, barite is used in inks.

In glassmaking, barite is added to the glass melt to flux the heat-insulating froth that forms on the melt surface, thus saving fuel, and to act as an oxidizer and decolorizer, making the glass more workable and increasing its brilliance.

Minor uses include ballast for ships, heavy concrete aggregate for radiation shielding and pipe-weighting in low-lying areas, and applications in foundries.

Barite is also a raw material for barium chemical manufacturing. The major barium chemicals are the carbonate, chloride, oxide, hydroxide, nitrate, peroxide, and sulfate.

The most important barium chemical is precipitated barium carbonate, which is a raw material for production of many of the other compounds. It is also used in brick and tile manufacturing to control scum caused by gypsum or magnesium sulfate in the clay and to diminish porosity and prevent discoloration in brick. Other uses are in television picture tubes, optical glass, ceramic glazes, porcelain enamel, ferrites, and miscellaneous ceramic products.

Blanc fixe, chemically precipitated barium sulfate, is used as a white filler in paints, rubber, inks, and other material where a degree of purity higher than natural barite is required. Lithopone, formerly manufactured in large tonnages for use as a white pigment in paints, has been largely replaced by titanium dioxide.

Barium chloride is used in case-hardening and heat-treating baths, in leather and cloth, in making magnesium metal, in preventing scum on brick, in water treatment, and as a laboratory reagent. Fused barium chloride may be electrolyzed to produce barium metal.

Barium metal is also produced by reduction of barium oxide. It is used as a "getter" to remove traces of gas from vacuum tubes. It also is used in alloys for spark plugs and electronic emission elements in electronic tubes.

Barium nitrate is used in green signal flares, tracer bullets, primers and detonators, and enamels. Barium oxide is used in electric furnace ferrous metallurgy to increase the life of acid furnace linings, to give a quieter and steadier arc, to reduce the sulfur content of the iron, and to lower the slag viscosity. Barium peroxide is manufactured from barium oxide.

Barium hydroxide prevents scumming in ceramics and is used in lubricating oils and to recover sugar from molasses by the barium saccharate process. Barium titanate finds use in miniature electronic and communication equipment.

Industry Structure

Domestic barite production began in 1845 in Fauquier County, VA. About 5 years later, production was begun in Missouri. In 1880, Tennessee became the third barite-producing State, and 1901 and 1903 saw Georgia and Kentucky, respectively, become producers. California came into production in 1914, Nevada in 1916, and Arkansas in 1941.

Barite's first use was as a filler in white paints; however, in 1842, with the advent of the domestic lithopone (a white pigment composed of a mixture of barium sulfate, zinc sulfide, and zinc oxide) industry, a second important market was opened. In 1908, Chicago Copper Refining Co. (now Chicago Copper & Chemical Co.) began manufacturing barium chemicals at Blue Island, IL. The first washers and jigs used in the industry were installed in Georgia and Tennessee in 1914-16 and in Missouri in 1923-24. A fourth market for barite came into existence in 1916 when a patent was obtained on the use of barite as a weighting agent in rotary drilling muds; today this is the largest consumer of barite. In 1941, the deposit of barite at Malvern, AK, was opened when Magnet Cove Barium Corp. successfully separated barite from associated minerals by flotation. In

1977, IMCO Services Co. completed a multimillion dollar plant at Mountain Springs, NV, that produced barite concentrate using jigs, concentration tables, and flotation. This combination of beneficiating methods was unique in the barite industry.

Geology

Barite is the only commercial source of barium and barium compounds. Witherite (BaCO_3) was formerly produced from the Settlingstones Mine in England. Pure barite has a specific gravity of 4.5.

Barite varies considerably in appearance depending on source and treatment. It is a moderately soft crystalline material with a Mohs' hardness between 3 and 3.5. In residual deposits, it ranges in size from large boulders to fines. Shades of white to dark gray and black, depending on impurities and surficial coating, are common in commercial deposits.

Vein and cavity-filling deposits are those in which barite occurs along faults, joints, bedding planes, and other solution channels or sink structures. These deposits are found most often in limestone. Most of the vein deposits in the Western States are postulated to be of epithermal origin. The Eastern and Midwestern vein deposits are thought to be of hydrothermal or telethermal origin.

In central Missouri, barite occurs in circular deposits in karst or collapse and sink structures. These ores are rich, but the deposits are generally small in overall extent. These deposits are also important as the source of the residual ore upon weathering.

Residual barite deposits are formed by weathering of preexisting deposits. The principal residual deposits are found in southeastern Missouri; the Appalachian region; Sweetwater, TN; Cartersville, GA; and in the Rio Grande area of Texas. A concentration of at least 100 to 300 pounds of barite per cubic yard is required in a commercial deposit. In Washington County, MO, the residuum is 10- to 15-foot thick, while in Cartersville, GA, the ore is 150-foot thick in some spots. This form of deposit has been of considerable economic significance.

The most important commercial deposits are of bedded barite. These are principally in Arkansas, California, and Nevada.¹⁸ The barite in these areas is generally dark gray to black and has a characteristic fetid odor when struck with a hammer. The beds, which vary in thickness from several

inches to more than 50 feet, occur interbedded with dark chert and siliceous siltstone and shale. In most of the deposits, the barite is laminated. In some areas, barite nodules and rosettes make up a large part of the beds. Many of the beds contain 50% to 95% barite. Originally it was thought that these deposits were the result of the replacement of carbonate rocks; however, current thought is that the deposits are of sedimentary origin. The actual environment of deposition has not been established, but theories range from submarine volcanic emissions to hydrothermal solutions to recycling of barite from preexisting rocks.

Technology

Exploration.—In the past two decades, geological exploration has led to the discovery of bedded barite deposits in Canada, India, Mexico, and the United States. Bedded deposits as yet have not been sought in many parts of the world. As the search for barite expands in the coming years, it is likely that more bedded deposits will be discovered.

Mining.—Residual deposits of barite are generally mined by draglines in open pits after removal of overburden by conventional methods using elevating scrapers, trucks, dumpers, bulldozers, and front-end loaders. The ore is then beneficiated in washer plants equipped with rotary breakers, log washers, trommel screens, and jigs to separate barite from other material. Fine barite in the overflow from the log washers is recovered by tabling and flotation while the jig concentrate is magnetically separated.

Bedded and vein deposits may be mined by open pit or underground methods depending on local conditions. The bedded deposits of Arkansas have been mined by both methods. The ore is crushed and ground for beneficiation by flotation. Bedded barite in Nevada is mined by open pit methods using a combination of bulldozers with ripping teeth and conventional blasting. The ore is picked up by front-end loaders and hauled in dump trucks to a processing plant. In some deposits, the ore is of sufficient grade to be either screened and direct shipped or washed, crushed, screened, and shipped to a grinding plant; however, much of the ore requires beneficiation by jiggling or flotation.

Quantities of barite have been recovered by underwater mining off Castle Island

near Petersburg in southeastern Alaska. The ore is blasted, recovered by a crane equipped with a special digging bucket, and loaded into barges.

Barite grinding is usually accomplished by heated airswept Raymond mills; however, ball mills are used when iron contamination is not important, as in drilling muds. Barite is ground either wet or dry. For use in well drilling, barite is ground dry; if it requires upgrading by flotation, it is ground wet. Also, barite to be bleached for filler use is ground wet; impurities are subsequently removed by treatment with sulfuric acid. The bleached barite pulp is then settled and separated, washed, dried, sized, and bagged.

Barite is converted into an intermediate soluble form before its use in the manufacture of lithopone. Crushed barite is roasted with coke in a kiln at about 1,200° C to reduce the barium sulfate to the more soluble compound, barium sulfide, commonly called black ash. The sulfide is leached from the clinker with hot water.¹⁹ By adding zinc sulfate to the leach liquor, an intimate mixture of barium sulfate and zinc sulfide called lithopone is precipitated.

The leach liquor is also a precursor of a number of barium chemicals. Addition of sodium sulfate precipitates barium sulfate (called blanc fixe). Barium carbonate is precipitated by either carbonating or adding sodium carbonate to the leach liquor. Hydrochloric acid added to the leach liquor produces a solution of barium chloride. Barium carbonate and barium chloride are the starting compounds for the manufacture of many other barium chemicals.

BAUXITE, ALUMINA, AND ALUMINUM

By Errol D. Sehnke and Patricia A. Plunkert

Mr. Sehnke is a physical scientist with 16 years industry and Bureau of Mines experience. Domestic survey data for bauxite and alumina were prepared by Shonta E. Osborne, mineral data assistant, Nonferrous Metals Data Section; and international data tables were prepared by Harold D. Willis and Virginia A. Woodson, International Data Section.

Ms. Plunkert, a physical scientist with 21 years Bureau of Mines experience, has been the commodity specialist for aluminum since 1987. Domestic survey data for aluminum were prepared by Regina R. Coleman, mineral data assistant, Nonferrous Metals Data Section; and international data tables were prepared by Audrey D. Wilkes, International Data Section.

BAUXITE AND ALUMINA

World production of bauxite and alumina rose during 1989 to record high levels in response to a strong but moderating demand for primary aluminum metal. Mine production of bauxite was reported from 26 countries. Domestic consumption of bauxite increased significantly, with the majority of the increase driven by metal market requirements for primary aluminum. Within the specialty materials area, consumption of abrasive grade bauxite was comparable with 1988 usage, but bauxite consumption by the chemical and refractory industries declined in 1989. Demand for alumina was strong but weakened at the end of the year, easing the tight supply situation that had developed in the past several years. U.S. production and shipments of cell-grade alumina increased, while specialty alumina production and shipments declined sharply during the year. Alumina was produced in 25 countries.

Legislation and Government Programs

On September 1, 1989, the Environmental Protection Agency (EPA) presented its final rule on the list of specific solid wastes from ore and mineral processing that would remain within the Bevill exclusion amendment to the Resource Conservation and Recovery Act (RCRA) as special wastes. Red and brown muds generated in the bauxite refining process were among five processing waste streams that were found to satisfy all of the special waste criteria for exclusion from regulation as hazardous wastes under subtitle C of RCRA.¹

The EPA proposed to delete nonfi-

berous aluminum oxide from the list of toxic chemicals contained in the Superfund Amendments and Reauthorization Act passed by Congress in October 1986; final removal of the toxic chemical designation was expected to occur in early 1990.

The National Defense Stockpile (NDS) goals for bauxite remained unchanged at 21.3 million metric tons of Jamaica-type and 6.2 million tons of Suriname-type metallurgical grade bauxite. Goals for calcined refractory grade and abrasive grade bauxite were 1.4 million and 1 million tons, respectively. The Defense Logistics Agency, manager of the NDS, listed an inventory of 12.7 million tons of Jamaica-type and 5.4 million tons of Suriname-type metallurgical grade bauxite. The NDS contained 279,000 tons of calcined refractory grade bauxite and no stocks of abrasive grade bauxite at the close of 1989.

Production

Bauxite was produced from surface

mining operations in Alabama, Arkansas, and Georgia. At Bauxite, AR, the Aluminum Co. of America (Alcoa) mined bauxite for use in the manufacture of proppants for the petroleum industry and processed crude ore at the company's local alumina plant to produce specialty aluminum oxides and hydroxides. Alcoa announced that its mining and refining operations in Arkansas were scheduled for permanent closure in 1990, but that the alumina chemical products production would continue at this location using alumina feedstocks from other company facilities. Harbison-Walker Refractories Div. of Dresser Industries Inc. shipped bauxite from mines in Alabama to its local calcining plant and to Carbo Ceramic Co.'s proppant plant in Eufaula, AL. Mullite Co. of America (Mulcoa) mined bauxite in Alabama and Georgia, which was shipped to Mulcoa's processing plant in Andersonville, GA, for the production of refractory materials.

land of St. Croix in the U.S. Virgin Islands was purchased in April by Clarendon Ltd., an aluminum trading group based in Switzerland. Damage caused by Hurricane Hugo hampered efforts to restart the facility, which had been idle since 1985. The new owners announced that the refinery, renamed Virgin Islands Alumina Inc. (Vialco), should be operational in the first quarter of 1990.

Reynolds Metals Co. announced plans to spend approximately \$50 million over the next 2 years to increase the efficiency of its 1.7-million-ton-per-year alumina plant near Corpus Christi, TX.

Consumption and Uses

A continued strong demand for cell-grade alumina propelled consumption of crude and dried metallurgical grade bauxite to a level well above that of 1988. Most of this increase was supplied from imports. Consumption of bauxite by the abrasive industries was essentially unchanged during 1989, while consumption by the chemical and refractory industries decreased for the year. About 90% of the bauxite consumed in the United States was refined to alumina, and an estimated average of 2.31 tons of dried bauxite was required to produce 1 ton of calcined alumina. Twenty-two primary aluminum smelters reported consumption of 8 million tons of calcined alumina in 1989. An estimated 97% of the alumina shipped by U.S. refineries went to domestic primary smelters for metal production. Consumption in various forms by the abrasives, chemicals, refractories, and other industries accounted for the balance of the alumina usage.

Prices

Contract terms for the purchase of metallurgical grade bauxite and cell-grade alumina in world markets are not normally made public, and, consequently, prices for these commodities are not published by trade journals. Price quotes are generally limited to certain specialty forms of bauxite and alumina for nonmetallurgical uses.

In 1989, the Bureau of Mines estimated the average value of domestic crude bauxite shipments, f.o.b. mine or plant, to be \$16 per ton. The average value of calcined domestic bauxite was estimated to be \$132 per ton. Base

prices quoted by Industrial Minerals magazine and independent sources for imported calcined refractory grade bauxite were as follows: Chinese, typical 85% alumina (Al_2O_3), f.o.b. barge, Burnside, LA, \$90 to \$130 per ton; and Guyanese, f.o.b. rail car, Baltimore, MD, or f.o.b. barge, Gulf Coast, \$164.28 per ton. Abrasive grade bauxite, minimum 86% Al_2O_3 , c.i.f. main European port, was priced at \$95 to \$108 per ton. Base prices were subject to adjustment for various grain-size specifications, size of order, and fuel

cost factors.

The average value of domestic calcined alumina shipments was estimated to be \$310 per ton. Trade data released by the Bureau of the Census indicated the average value of imported calcined alumina was \$280 per ton, f.a.s. port of shipment, and \$295 per ton, c.i.f. U.S. ports.

and Canada 1,900 tons. Exports of all other grades of calcined bauxite (chiefly abrasive grade) amounted to 12,900 tons for the year. Canada received 8,600 tons and Venezuela 4,200 tons. Specialty aluminum compounds exported included 940 tons of aluminum sulfate, 17,200 tons of aluminum oxide abrasives, and 34,300 tons of various fluoride-based compounds of aluminum, including synthetic cryolite and aluminum fluoride.

Imports for consumption of crude and dried bauxite increased from 1988 receipts, and the three traditional primary suppliers, Guinea, Jamaica, and Australia, in order of shipments, provided most of the total. Brazil's shipments to the United States increased sharply, and it greatly strengthened its fourth place ranking.

World Review

World production of bauxite and alumina continued the upward trends that began in the mid-1980's. Twenty-six countries mined bauxite in 1989, and the total world production of bauxite reached a record 105 million tons, an increase of 7% over 1988 produc-

tion. Australia, Guinea, Jamaica, and Brazil, in order of volume, accounted for 70% of the total bauxite mined during the year. The corresponding world output of alumina rose to nearly 39 million tons, also a new production record, and was 6% greater than the 1988 production level. Three countries, Australia, the U.S.S.R., and the United States, contributed nearly 50% of the total world production.

Note: Total U.S. imports of crude and dried bauxite (including the U.S. Virgin Islands) as reported by the Bureau of the Census were as follows: 1987—9,827,818 tons; 1988—10,498,913 tons; and 1989—11,346,182 tons.

Source: Bureau of the Census and The Jamaican Bauxite Institute.

Capacity.—A slight increase in the annual rated capacity of plants producing alumina helped to alleviate the shortages of cell-grade alumina required for the production of primary aluminum that had developed in recent years.

Australia.—In 1989, the world's largest bauxite and alumina producing country achieved new production records for the seventh consecutive year.

The Comalco Ltd. mining opera-

tions at Weipa, Queensland, operated at full annual rated capacity during the year and produced about 9.7 million tons of bauxite. Comalco announced that, in addition to the main production based on standard metallurgical grade bauxite and about 250,000 tons a

year of abrasive grade product, trial shipments of cement grade, chemical grade, and trihydrate bauxite were made to markets in the United States and Europe. The Queensland Alumina Ltd. alumina plant at Gladstone reported that it was expanding its capac-

ity from 3 million to 3.3 million tons per year of alumina by "sweetening" the refining process with trihydrate bauxite from Comalco's Weipa operations, the sole source of the refinery's bauxite feed.

The Gove bauxite-alumina project in the Northern Territories, managed by Nabalco Pty. Ltd., produced 6 million tons of bauxite and 1.45 million tons of alumina in 1989. Participants in this project released plans to increase the alumina plant capacity at Gove by 150,000 tons per year.

Alcoa of Australia Ltd. announced that it planned to proceed with the second stage of its Wagerup alumina plant expansion in Western Australia. The 630,000-ton expansion would double the capacity at the refinery and was part of a two-stage program to increase the total alumina output at Alcoa's three Australian refineries (Wagerup, Kwinana, and Pinjarra) from 5.5 million to 6.1 million tons per year.

The U.S. International Trade Commission determined on March 21, 1989, under Section 735(b) of the Tariff Act of 1930, that U.S. industry was not materially injured or threatened with material injury by imports of calcined proppants from Australia that were found to have been sold in the United States at less than fair market value.²

Brazil.—Mineração Rio do Norte S.A. (MRN), the world's third-largest bauxite producer and exporter, reported it had begun an expansion program at its Trombetas mining operation in Pará State that would increase mine capacity from 6.5 million to 8.5 million tons per year. MRN indicated that the main focus of this program was the transfer of its existing ore-crushing and -washing facilities to sites within the proximity of active mine workings, plus the construction of a new system for tailings thickening and disposal.

The state-owned mining company Cia. Vale do Rio Doce announced preparation of a feasibility study for a new bauxite mining operation at Jabuti in the Paragominas region of Pará State.

Mineração Santa Lucrecia S.A. (MSL) indicated that the new refractory bauxite beneficiation plant it was installing at its Caracuru mine in the Almeirim district of Pará State would have a capacity of 200,000 tons per year of green bauxite product. MSL stated

that construction had also commenced on a 60,000-ton-per-year production capacity rotary calciner near the Jari River port of Munguba, and the plant was expected to be operational in early 1990.

Companhia Brasileira de Alumínio (CBA) announced that the new alumina and aluminum plants it was installing near its existing complex at Sorocaba, in São Paulo State, would utilize bauxite supplied by the company's 850,000-ton-per-year Poços de Caldas mines in Minas Gerais. CBA indicated that it planned to rely on the newly discovered bauxite reserves near Cataguazes in Rio de Janeiro State to supply the Sorocaba operations following the depletion of the ore reserves at Poços de Caldas.

Canada.—Alcan Aluminium Ltd. announced that a solar drying method of red-mud disposal was introduced at its Vaudreuil alumina plant in Quebec to provide a more environmentally compatible method for handling these mineral processing wastes.

Germany, Federal Republic of.—In mid-1989, Vereinigte Aluminium-Werke AG (VAW) announced its withdrawal from tabular alumina production in the Federal Republic of Germany.

Guinea.—Compagnie des Bauxites de Guinée (CBG) produced about 11.2 million tons of the total bauxite mined. CBG reportedly achieved this production despite infrastructure problems due to working beyond normal rated capacity.

Hydro Aluminium A/S of Norway announced that it bought a 20% share in Frialco, the 51% owner of the bauxite and alumina company, Frigua. The new shareholder structure for Frialco was reported as follows: Pechiney 30%, Noranda 30%, Alcan 20%, and Hydro 20%.

A modernization project, financed by the European Community, was reportedly started by Frigua at its Kimbo bauxite-alumina complex.

Guyana.—The decline in bauxite production recorded for 1989 was partially due to a 7-week strike by bauxite workers at the state-owned Guyana Mining Enterprise Ltd. (Guymine).

The Government of Guyana and

Reynolds International Inc., a wholly owned subsidiary of Reynolds Metals, reported the signing of an agreement to mine and market bauxite from deposits at Aroaima in the Berbice region of Guyana.

Norway's Hydro Aluminium and Kaiser Aluminum & Chemical Corp. of the United States reportedly participated in a feasibility study conducted for the state-owned Bauxite Industry Development Corp. to determine what would be required to reopen the Linden alumina plant that had been closed since 1982. It was reported that an estimated \$106 million would be required to restart the idled refinery.

The U.S. firm Green Mining Inc. announced that it began work under an 18-month contract with the Government to remove 1.3 million cubic meters of overburden and mine approximately 800,000 tons of metallurgical grade bauxite at Linden. Green Mining reported that it had delivered its first shipment of bauxite to Guymine in mid-September.

At yearend, Alcan Aluminium announced the signing of an agreement to study the feasibility of renovating Guyana's bauxite production and marketing operations at Linden.

India.—Bharat Aluminium Company announced the closure of its bauxite mining project in the Gandhamardhan Hills, Orissa State, because of strong environmental opposition by the local population. Heightened environmental awareness prompted the Indian State-owned National Aluminium Co. to publicize the environmental preservation and restoration programs developed for their bauxite mining areas.

Italy.—Clarendon Ltd. reportedly bought an 18% interest in Eurallumina SpA the owner-operator of the 720,000-ton-per-year alumina plant at Porto Veseme, Sardinia. This reduced the share of ownership held by the State-owned Allumina SpA from 62.5% to 52.1% and that of the Australian-owned Comalco from 37.5% to 29.9%.

Jamaica.—The Alumina Partners of Jamaica (Alpart) alumina plant at Nain, owned by Kaiser Aluminum (65%) and Hydro Aluminium (35%), restarted operations in April after being closed since 1985.

Plans to increase the capacity of the

Jamalco alumina plant in central Jamaica, jointly owned by the Government and Alcoa, were reportedly delayed by technical problems following a strike and 2-week shutdown in July and August.

Suriname.—The Suriname Aluminum Co. mining operations at Moengo reportedly experienced a brief shutdown in October due to civil strife and ethnic violence associated with the continuing political conflict and insurgent rebel action that had troubled the country in recent years.

Sweden.—On March 27, 1989, the U.S. International Trade Commission determined there was no reasonable indication that U.S. industry was materially injured or threatened by imports of dry aluminum sulfate from Sweden that had been allegedly sold within the United States at less than fair value.³

Venezuela.—The U.S. Department of Commerce reported on October 18, 1989, that aluminum sulfate imports from Venezuela had been subsidized and sold in the United States at less than fair market value.⁴ In December, the U.S. International Trade Administration determined that U.S. industry was materially injured by the imports of aluminum sulfate from Venezuela and these imports were liable for assessment of antidumping and countervailing duties.⁵

Current Research

Exploratory research by the Bureau of Mines on high-temperature structural materials for new and emerging technologies demonstrated that hard, dense composite materials can be produced from metallic nitrides such as titanium or zirconium when combined with alumina (Al_2O_3) and aluminum nitride (AlN). Of these nitrides, titanium nitride (TiN) has shown the best results for meeting the high-performance demands placed upon this new class of advanced materials, and investigations have been conducted to characterize the physical properties of various combinations of ceramic particulate composites made from the system TiN- Al_2O_3 -AlN.⁶

The Ames Research Center of the National Aeronautics and Space Administration reported the development of a rigid, fibrous refractory compos-

¹ Table includes data available through June 13, 1990.

² Reported figure.

³ Dry bauxite equivalent of crude ore.

⁴ Less than 1/2 unit.

⁵ Dry bauxite equivalent of ore processed by drying plant.

⁶ Bauxite processed for conversion to alumina in Jamaica plus kiln-dried ore prepared for export.

⁷ In addition to the bauxite reported in the body of the table, the U.S.S.R. produces nepheline syenite concentrates and alunite ore as sources of aluminum. Nepheline syenite concentrate production was as follows, in thousand metric tons: 1985—1,615; 1986—1,638; 1987—1,660; 1988—1,640; and 1989—1,600 (estimated). Estimated alunite ore production was as follows, in thousand metric tons: 1985—615; 1986—620; 1987—625; 1988—625; and 1989—600. Nepheline syenite concentrate grades 25% to 30% alumina, and alunite ore grades 16% to 18% alumina; these commodities may be converted to their bauxite equivalent by using factors of 1 ton of nepheline syenite concentrate equals 0.55 ton of bauxite and 1 ton of alunite equals 0.34 ton of bauxite.

ite material called "alumina-enhanced thermal barrier" (AETB) that extends the high-temperature capability of insulating materials.⁷ This improved fibrous ceramic tile material had a composition of 14% aluminoborosilicate fibers, 66% silica fibers, and 20% alumina fibers. Although it was intended primarily for use in the heat shield of the Space Shuttle orbiter, the new material had obvious potential for indus-

trial usage in kilns, furnaces, heat engines, and other applications for which lightweight and high operating temperature are major requisites.

An improved method for the removal of iron from Bayer process solutions was developed for mixed gibbistic-boehmitic or boehmitic bauxites.⁸ The removal of the iron oxide was achieved by passing the pregnant alumina plant liquors through a bed of activated sand

(washed and heated coarse red mud) that had a high iron oxide content, which promoted precipitation of iron from the solution.

Outlook

Known world bauxite reserves are sufficient to meet cumulative world demand well into the 21st century. Considering the high probability of discovering additional bauxite deposits and assuming reasonable energy costs, the added possibility of using lower grade bauxite deposits and other alternative sources of alumina, world resources of aluminum are adequate to meet demand for the foreseeable future.

As the costs of imported bauxite and alumina increase, alternate domestic sources of alumina may appear to be-

² Table includes data available through June 13, 1990.

³ Reported figure.

⁴ Hydrate.

come economically more attractive. On the other hand, high fuel prices tend to make nonbauxitic materials less competitive because the processes for treating alternate materials require considerably more energy than Bayer-processed bauxite. It therefore appears evident that nonbauxitic sources of aluminum would become viable only within the context of a prolonged national emergency or international embargo extending over a period of several years.

In the future, the structure of the aluminum industry was expected to see a continued shift of alumina production facilities from the aluminum-producing industrial countries with high energy costs, in North America

and Europe, to the bauxite-producing countries of the world. Imports of primary aluminum metal from countries with low electrical energy costs and secondary production from recycled aluminum was likely to be used in ever-increasing proportions to meet the domestic demand for aluminum.

ALUMINUM

Most primary aluminum smelters operated close to and, in some cases, above rated capacities during the year. Exports of aluminum in 1989 increased significantly for the second successive

year to a level that was more than twice that of 1986. A record 49.4 billion used beverage cans (UBC) were recycled in 1989, equivalent to more than 60% of the aluminum can shipments for the year. Prices decreased during the year as world supply and demand came into a more balanced position. World production of primary aluminum approached a record 18 million tons for the year.

Legislation and Government Programs

The U.S. Department of Transportation issued a notice of proposed rule-making to regulate materials that are transported at elevated temperatures. The proposed changes to the Hazardous Materials Regulations (49 CFR 171-179) would communicate the hazards of these elevated temperature materials by means of marking, shipping papers, and placarding, and would prescribe package requirements. Molten aluminum was one of the materials that would be covered by these proposed changes.⁹

The Office of the U.S. Trade Representative published lists of materials that were under consideration for negotiations with the Canadian Government for accelerated tariff elimination

under the United States-Canada Free-Trade Agreement Implementation Act of 1988. These lists included some articles of aluminum for which acceleration of tariff elimination had been requested in petitions submitted either to the Government of the United States or to the Government of Canada.¹⁰

Production

Primary.—Domestic primary aluminum production was the highest annual production level since 1984. Most smelters operated at or above their rated capacity levels during the year.

In September, a power outage, caused by Hurricane Hugo, damaged the Alumax Inc. 181,000-ton-per-year primary aluminum smelter in Mount Holly, SC. The outage froze metal in the smelter potlines, but company officials reported that structural damage to the plant was not extensive. The company estimated that it would be 20 weeks before full production could be resumed at the plant. However, by the end of the year, a full 10 weeks ahead of schedule, the company announced that repairs had been completed and the plant was back in full production.

Ravenswood Aluminum Corp. announced plans to restart a fourth pot-

line at its smelter in West Virginia, raising the rated capacity of the plant to 166,000 tons per year. This potline had been shut down since April 1981.

Alumax and the United Steelworkers of America (USWA) completed early contract negotiations covering workers at the Frederick, MD, and Ferndale, WA, smelters. In March, a new contract, scheduled to expire on October 1, 1992, was signed by workers at the Frederick, MD, smelter, replacing the previous contract, which was set to expire on October 24, 1990. In November, workers at the Ferndale, WA, plant ratified a new 3-year contract that was scheduled to expire on September 30, 1993. The new Ferndale smelter contract replaced the previous contract that was scheduled to expire at the end of September 1990.

In April, Alcan Aluminum Corp. and the Aluminum, Brick, and Glass Workers International Union (ABG-WIU) announced the ratification and signing of a new labor contract covering workers at the Sebree, KY, smelter. This contract took effect immediately and replaced the previous contract that was not scheduled to expire until October 28. The new contract reportedly included an initial pay increase of 4.25%, plus increases of 3.5% in 1990, and 3% in 1991. Additional cash bonuses were also reported to be included in this new contract that was scheduled to expire on October 28, 1992.

Workers at Noranda Aluminum Inc.'s New Madrid, MO, smelter walked off their jobs on September 1, after the previous labor contract expired. The company reported that production levels at the plant would be maintained by salaried personnel. While negotiations continued between the USWA and management, workers returned to their jobs in December without ratifying a new contract.

Alcan Aluminum announced the purchase of Jarl Extrusions Inc., a maker of custom aluminum extrusions. Jarl reportedly operated five presses and a remelt, billet casting center at Elizabethton, TN, and two presses at its facility in Franklin, NH.

Alcan Rolled Products Co., a division of Alcan Aluminum, announced plans to upgrade its sheet rolling facility at Oswego, NY. The \$175-million program was reported to include a modernization of the hot rolling mill, a

² Shipped to domestic industry.

new melting and casting center, a pusher furnace-preheat facility, a high-speed precision slitting line, and a new roll grinder.

Alcan Aluminum also announced plans to construct an aluminum cable plant in Roseburg, OR. The plant reportedly would be completed by 1991 and would produce transmission and distribution conductor cable as well as aluminum building wire.

Kaiser Aluminum announced plans to build an aluminum forgings plant in Greenwood, SC. The company reported that it would enlarge an existing building on the site and would produce aluminum forgings primarily for the automotive market. Kaiser Aluminum expected production to begin by the end of the year.

Reynolds Metals reported the purchase of Conductor Products Inc., a cable plant in Marshall, TX. The plant manufactured overhead cable and insulated underground cable products.

Reynolds Metals also announced plans for a \$30 million expansion and modernization of aluminum plate capacity at its McCook, IL, rolling mill. The company anticipated that the 2-year program, which targeted larger shares of the aircraft and aerospace markets, would increase aluminum plate capacity by 16% to 80 million pounds per year and increase machining capacity for wing skins by 50%.

Logan Aluminum Inc. announced a major two-stage expansion program for its aluminum can stock mill in Logan, KY, that would double the plant's capacity. The first phase of the program included a 90-inch high-speed cold mill, a coating line, a slitting line, two ingot preheat furnaces, and an ingot scalper. The second phase reportedly included another cold mill plus a fourth stand added to the hot mill. Logan Aluminum was jointly owned by Atlantic Richfield Co. (Arco) and Alcan Aluminum.

Columbia Aluminum Corp., which owns a primary aluminum smelter in Goldendale, WA, announced several acquisitions of fabrication facilities. Columbia Aluminum reported the purchase of an extrusion plant in Rockwall, TX, from Alumax; extrusion facilities in City of Industry, CA, and City of Commerce, CA, from Indal Ltd.; and an extrusion plant in Modesto, CA, from Pacific Aluminum Corp.

¹ Northwest Aluminum Corp. signed a lease-purchase agreement for The Dalles smelter with Martin Marietta Corp. in 1986.

² Purchased from MAXXAM Inc. in Dec. 1988.

VAW of America Inc. reported the purchase of Easco Corp.'s aluminum extrusion plant in Phoenix, AZ. The plant produced extrusions and pipes for the construction, building products, and consumer goods markets.

National Intergroup Inc. (NII), the parent company of National Aluminum Corp., announced the sale of its aluminum rolling and extrusions divisions. NII reported that Noranda had purchased a foil rolling mill in Newport, AR; a light-gauge foil mill in Salisbury, NC; and some laminating facilities in Ohio and Massachusetts. R. D. Werner announced the purchase of NII's custom extrusion plant in Aniston, AL.

Secondary.—According to a survey conducted by the Aluminum Association, the Institute of Scrap Recycling Industries, and the Can Manufacturers Institute, a record 49.4 billion aluminum UBC's were recycled in 1989, surpassing by almost 7 billion the number of UBC's recovered in 1988. The percentage of aluminum cans recycled in the United States increased from 54.6% of aluminum cans shipped in 1988 to 60.8% of can shipments in 1989.

Alcan Aluminum announced the opening of its new UBC recycling plant in Berea, KY. The company anticipated that the production from the 120,000-ton-per-year plant would be sent to the company's can sheet rolling mills in Henderson, KY, and Oswego, NY.

International Mill Service Inc. (IMS) reported that its UBC recycling plant in Hauser, ID, was operational. The plant reportedly had the capacity to convert at least 80 million pounds of UBC's and 40 million pounds of aluminum scrap per year into secondary metal, which could then be transported to Kaiser Aluminum's rolling facility in nearby Trentwood, WA. In addition, the IMS plant reportedly had the capability of processing 50 million pounds of aluminum dross annually.

Golden Aluminum Co. announced plans to construct a new continuous casting and rolling mill in San Antonio, TX. The plant reportedly would convert UBC's into 200 million pounds per year of beverage can body stock.

Secondary Aluminum Smelters Inc. announced the opening of a new 36-million-pound-per-year secondary smelter in Chattanooga, TN. Culp Indus-

tries Inc. announced the sale of its secondary smelter in Steele, AL, to Legett & Platt Inc., a producer of aluminum die-cast components for the home furnishing industry. In December, Apex International Alloys Co., a secondary aluminum smelter in Cleveland, OH, reported that the company had filed under Chapter 11 of the U.S. Bankruptcy Code.

American Recovery Technology Systems Inc. announced the completion of a closed-loop system for recycling secondary aluminum dross and salt cakes. Capacity of the system was reported to be 6 million pounds per month. The company said that the facility was designed to recover the salt flux and produce an exothermic flux for use by the steel industry and remelt secondary ingot producers.

Metal Mark Inc. announced plans to startup an aluminum dross processing plant late next year. The new company, to be located near Chicago Heights, IL, and to be named Columbia Aluminum Recycling Ltd., would reportedly become the fifth plant owned by Metal Mark.

Alcan Aluminium reported the development of a process for recycling aluminum dross that reportedly elimi-

nated the use of salt fluxes employed in conventional treatment methods. The process reportedly used plasma-torch technology provided by Plasma Energy Corp. of Raleigh, NC. Alcan Aluminium announced that the company would begin industrial-scale testing of this process at its plant in Jonquiere, Quebec, in 1990.

Consumption

The container and packaging industry remained the largest domestic consumer of aluminum products. The Can Manufacturers Institute reported that about 83 billion aluminum beverage cans were shipped in 1989, representing almost 97% of the total metal beverage can shipments.

Reynolds Metals announced plans to begin commercial marketing of aluminum composite panels for use by the architectural industry. The panel combined a solid thermoplastic compound core with two sheets of aluminum. The panel reportedly was intended to serve a wide range of architectural applications, including designs where fire resistance was critical. The panel, called Reynobond, would be produced at the company's architectural products plant in Eastman, GA.

TABLE 22
U.S. CONSUMPTION OF AND RECOVERY FROM
PURCHASED NEW AND OLD ALUMINUM SCRAP,¹ BY CLASS

¹ Includes inventory adjustment.

² Includes other die-cast alloys and other miscellaneous.

³ No allowance made for melt-loss of primary aluminum and alloying ingredients.

Topy Corp., which has been manufacturing steel wheels since 1986, announced the completion of a new manufacturing facility for aluminum wheels. The new facility reportedly would have an annual production capacity of 800,000 units. Topy was the U.S. subsidiary of Topy Industries Ltd. of Japan.

A-Mold Corp., a newly established U.S. subsidiary of Ube Industries Ltd. of Japan, announced plans to construct an aluminum wheel manufacturing plant in Mason, OH. The company expected the plant to have an annual production capacity of 1 million units and to be completed in 1991.

Stocks

Inventories of aluminum ingot, mill products, and scrap at reduction and other processing plants, as reported by the U.S. Department of Commerce, decreased from the revised figure of about 1.88 million tons at yearend 1988 to about 1.82 million tons at yearend 1989.

Prices

The monthly average U.S. market price for primary aluminum ingot trended downward during the year as supply and demand came into a more

balanced position. The London Metal Exchange (LME) and New York Commodity Exchange (COMEX) prices for aluminum futures followed the same general trend as the U.S. market prices. In January 1989, the LME changed the basis of its price quotes for aluminum ingot from standard-grade (99.5%-pure aluminum) to high-grade (99.7%-pure aluminum). This change more accurately reflects the material traded in the world market.

The following table summarizes various average monthly and annual aluminum prices during the year, in cents per pound:

	COMEX 1 ¹	COMEX 2 ¹	COMEX 3 ¹	LME (cash)	U.S. market	U.S. transaction
1988: Annual average	111.13	106.57	88.13	² 115.88	110.09	112.24
1989:						
January	106.91	107.67	94.23	108.75	107.73	108.89
February	96.32	97.40	89.61	99.02	99.58	100.95
March	92.15	93.05	84.06	94.06	95.78	97.53
April	93.70	93.70	85.90	96.42	96.38	97.61
May	97.15	96.27	88.76	102.48	97.80	99.18
June	88.74	86.34	81.82	86.83	87.66	89.30
July	82.55	80.78	77.85	79.65	80.40	81.45
August	81.28	80.78	79.07	81.57	81.37	82.34
September	78.23	78.18	76.75	77.92	78.30	79.05
October	79.23	78.64	78.43	82.56	79.76	80.30
November	76.16	75.70	75.85	78.75	75.81	76.25
December	72.85	73.30	73.98	74.08	73.56	74.22
Annual average	87.10	86.82	82.19	88.51	87.84	88.92

¹ COMEX delivery positions: 1-within 1 month; 2-within 3 months; and 3-within 12 months.

² Average for 11 months.

Source: Metals Week.

Purchase prices for aluminum scrap, as quoted by the American Metal Market (AMM), also decreased during the year. The purchase price for mixed low-copper-content aluminum clips, which began the year near 80 cents per pound, closed at a low 50-cent-per-pound level. Purchase prices for old sheet and cast aluminum, as well as clean, dry, aluminum turnings, decreased from the mid 60-cent-per-pound level to a mid 40-

cent-per-pound level by the end of the year.

Prices for UBC's fluctuated during the year but also followed a general downward trend. Aluminum producers' buying prices for processed and delivered UBC's decreased from a range of 74 to 77 cents per pound in late January and early March to a price range of 50 to 53 cents per pound at the end of the year.

TABLE 25
U.S. APPARENT ALUMINUM SUPPLY AND CONSUMPTION

(Thousand metric tons)

	1985	1986	1987	1988 [†]	1989
Primary production	3,500	3,037	3,343	3,944	4,030
Change in stocks: ¹ Aluminum industry	+ 312	+ 108	+ 341	+ 11	+ 61
Imports	1,420	1,967	1,850	1,620	1,470
Secondary recovery: ²					
New scrap	912	989	1,134	1,077	1,043
Old scrap	850	784	852	1,045	1,011
Total supply	6,994	6,885	7,520	7,697	7,615
Less total exports	908	753	917	1,247	1,613
Apparent aluminum supply available for domestic manufacturing	6,086	6,132	6,603	6,450	6,002
Apparent consumption ³	5,174	5,143	5,469	5,373	4,959

[†] Revised.

¹ Positive figure indicates a decrease in stocks; negative figure indicates an increase in stocks.

² Metallic recovery from purchased, tolled, or imported new and old aluminum scrap expanded for full industry coverage.

³ Apparent aluminum supply available for domestic manufacturing less recovery from purchased new scrap (a measure of consumption in manufactured end products).

Secondary aluminum ingot prices, as quoted by AMM, also followed a downward trend. The yearend price ranges for selected secondary aluminum ingots were as follows: Alloy 380 (1% zinc content), 73 to 76 cents per pound; alloy 360 (0.6% copper content) and alloy 413 (0.6% copper content), 78 to 80 cents per pound; and alloy 319, 76 to 78 cents per pound.

Changes in aluminum metal prices from 1850-1988 and a brief analysis of the factors that influenced the changes were included in a Bureau of Mines report on nonferrous metal prices.¹¹

Foreign Trade

For the third consecutive year, exports of all forms of aluminum from the United States increased substantially from those of the previous year. Total exports in 1989 were more than double those of 1986. Japan and Canada continued to be the major recipients of U.S. aluminum materials in 1989. Japan received three-fourths of the U.S. exports of crude metal and about one-half of the total exports of aluminum materials during the year. Exports of UBC's, which were included in the scrap category, totaled 17,354 tons in 1989, more than 4 times the quantity exported in 1988. Japan continued to be the principal destination of UBC's exported, accounting for more than one-half of the total in 1989.

Imports for consumption of aluminum decreased slightly compared with those of 1988. Canada remained the major shipping country to the United States, supplying three-fourths of the total U.S. imports in 1989.

U.S. tariff rates in effect in 1989 for selected aluminum products from countries with most-favored-nation status were as follows:

Item	HTS No.	Import duty
Unwrought metal (in coils)	7601.10.30	2.6% ad valorem.
	7601.20.30	Do.

¹ Tariff Schedules of the United States Annotated.

² Harmonized Tariff System of the United States.

Source: Bureau of the Census.

On January 1, 1989, the Harmonized Tariff System went into effect. This system was designed to bring the trade classifications used in the United States closer to those used in the rest of the world. Tables 29 and 32 provide listings of the tariff codes used by the Bureau of Mines to prepare trade data before January 1 and those that were used under the new Harmonized System.

World Review

World aluminum demand slowed from levels reached during the past few years but remained strong. Inventories in market economy countries increased slightly over last year's levels but remained at historically low levels. Many of the world's producers of aluminum continued to operate their primary smelters at or near rated capacity levels.

Primary aluminum inventories held by members of the International Primary Aluminium Institute (IPAI), which represent the bulk of stocks held outside the centrally planned economy countries, increased slightly from 1.482 million tons at yearend 1988 to 1.576 million tons at yearend 1989. IPAI reported that total metal inventories, including secondary aluminum, increased from 3.085 million tons at yearend 1988 to 3.231 million tons at yearend 1989.

Capacity.—The data in table 35 are rated annual capacity for plants producing primary aluminum metal as of December 31 for the years shown. Rated capacity is defined as the maximum quantity that can be produced on

a normally sustainable long-term operating rate, based on the physical equipment of the plant and given acceptable routine operating procedures for labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Greenfield smelter expansions were planned for areas of the world that had low energy and/or labor costs, most notably Canada and the Persian Gulf area.

Algeria.—A Dubai-based consortium, Industrial Development Corp. of Dubai, and the Algerian Public National Enterprise announced plans to build a 220,000-ton-per-year smelter and related facilities, including a powerplant and port, on the western coast of Algeria. Work on the facility, to be named Medial, was expected to start in late 1990 and take 3 years to complete. Members of the consortium were reported to be Caradel Investments Inc., George Wimpey Plc., Asea Brown Boveri, and the Marc Rich organization.

Australia.—Kaiser Aluminium announced the sale of its 20% interest in

the Boyne Island smelter at Gladstone to Austria Metall AG.

Tomago Aluminium Co. Pty. Ltd. announced that it was investigating the possibility of constructing a third potline at its 230,000-ton-per-year smelter in New South Wales that would increase capacity to 360,000 tons per year. Startup of the additional potline reportedly depended on the signing of a power contract with the New South Wales Electricity Commission.

Comalco announced that a prefeasibility study for a 198,000-ton-per-year expansion at the Boyne Island smelter had been completed. Comalco reportedly was investigating the possible purchase of the Gladstone power station to ensure the power required for the planned expansion.

Bahrain.—Kaiser Aluminum announced the sale of its 17% interest in Aluminium Bahrain (Alba) to the Government of Bahrain. The sale increased the Government's share in the 205,000-ton-per-year primary smelter to 75%. Alba also announced expansion plans for the smelter that would increase capacity to 460,000 tons per year by 1992.

Brazil.—Reynolds Metals announced the sale of all but a 35% interest in

TABLE 30

Latasa, its aluminum can manufacturing plant that came on-stream this year, to three Brazilian banks.

Canada.—A six-member consortium announced the signing of an agreement to construct a 215,000-ton-per-year primary smelter at Sept Iles, Quebec. The members of the consortium were VAW, 20%; Austria Metall, 20%; Hoogovens Groep BV, 20%; Société Generale de Financement, 20%; Kobe Steel Ltd., 13.3%; and Marubeni Corp., 6.7%. The smelter to be called Alouette reportedly was scheduled to come on-stream in 1992.

Alumax announced plans to construct a 215,000-ton-per-year greenfield aluminum smelter at Deschambault, Quebec. Completion of the project was scheduled for 1992.

Reynolds Metals announced plans to add a 120,000-ton-per-year potline to

its smelter at Baie Comeau, increasing capacity to 400,000 tons per year. The company expected the potline to be fully operational by 1991. In June, workers at the Baie Comeau smelter ratified a new 3-year labor contract that was set to expire on June 30, 1992.

Alcan Aluminium announced the purchase of a 20% stake in Moli Energy Ltd. of Vancouver, British Columbia, and the signing of an agreement to blend the technologies of Alcan's aluminum-air battery and Moli's rechargeable lithium battery. Alcan reported that the joint venture could lead to the development of a lightweight power source for an electric vehicle that could also involve the company's aluminum-structured-vehicle technology.

China.—The Government announced plans to add 80,000 tons per year of capacity to its 110,000-ton-per-year smelter at its Guizhou complex. Officials expected the expansion to be completed by 1991.

The China International Trust & Investment Corp. reportedly canceled the contract to buy a mothballed smelter in Sakata, Japan, from Sumitomo Metal Industries Ltd.

Dubai.—Dubai Aluminium Co. (Dubal) announced that construction had begun on a new potline that would increase the smelter's capacity to 235,000 tons per year by 1991.

Indonesia.—The Asahan Development Authority announced plans to build a second hydroelectric power-plant for the Inalum smelter in Sumatra. The plant, with a capacity of 180 megawatts, reportedly was scheduled for completion in 1990.

Korea, Republic of.—Aluminium of Korea Ltd. announced plans to build a 100,000-ton-per-year rolling mill. The company planned commissioning of the plant in 1992.

Netherlands.—Hoogovens Groep BV announced that it would merge its aluminum operations into a new subsidiary, Hoogovens Aluminium BV.

Norway.—Soer-Norge Aluminium A/S announced plans to expand capacity at its 66,000-ton-per-year smelter at Husnes to 100,000 tons per year. The

company noted that the project, which could take 3 to 5 years to complete, hinged on the signing of power supply contracts.

Saudi Arabia.—The Minister of Industry and Electricity reported that approval had been granted for the construction of a 220,000-ton-per-year primary smelter at Yanbu. Alujain Corp., formed by Saudi interests, reportedly would hold a 60% interest in the smelter. Gove Aluminium Ltd. reported the signing of an agreement with Alujain to supply 100,000 tons per year of alumina to the smelter. The Alusa smelter was expected to begin production in 1992.

South Africa, Republic of.—General Mining Union Corp. Ltd. (Gencor) announced that it had purchased a 30.7% interest in the Alusaf Pty. Ltd. primary aluminum smelter at Richards Bay.

Switzerland.—Swiss Aluminium Ltd. (Alusuisse) announced that the company would be renamed Alusuisse Lonza Holdings effective January 1, 1990.

Taiwan.—Ball Corp. of Muncie, IN, and Hong Kong-based Lam Soon Ltd.

announced the formation of a joint venture to construct an aluminum beverage can plant in Hsin Chu County, south of Taipei. Ball reportedly would own 30% of the venture called Lam Soon-Ball International. The company expected the plant to be operational early next year and to produce 1,600 cans per minute for the local beer and soft drink market.

U.S.S.R.—Reynolds Metals, Fata European Group of Italy, and a group of U.S.S.R. organizations announced plans to build an aluminum foil production and converting operation in Siberia. The plant was expected to have a capacity of 47,000 tons per year and to be located in the town of Sajanogorsk. Six U.S.S.R. entities would own 70% of the plant, while Reynolds Metals and Fata would each own 13.5%, and the remaining 3% would be held by the San Paolo Bank of Italy.

United Kingdom.—British Alcan Aluminium Plc. announced plans to build a UBC recycling plant at Latchford Locks in northwestern England.

The company expected the plant to have an annual capacity of 50,000 tons and to come on-stream in 1991.

Venezuela.—Aleaciones Ligeras SA (Alisa) reported the signing of an agreement with Davy McKee for the construction of a 120,000-ton-per-year primary aluminum smelter. Alisa is a wholly Venezuelan-owned project. Corporacion Venezolana de Guyana (CVG) reportedly owned 30% of the project, and Ripesa, an investment group, held the remaining 70%. The new startup date given by the company was 1993.

Current Research

Golden Aluminum published a brief description of the continuous cast process used by the company to produce can body stock at its Fort Lupton, CO, facility. The paper described chemical composition control, surface quality, internal structure, gauge, and casting parameters, as well as the operating practices required to obtain these quality levels.¹²

The Bureau of Mines studied the effects of aluminum additions on the sulfidation resistance of iron-chromium-nickel (Fe-Cr-Ni) alloys. A series of Fe-Cr-Ni alloys with and without additions of 4% aluminum were tested in a wet sulfur vapor atmosphere at 677° C. Aluminum-containing alloys formed a compact, tightly adherent layer of scale that reduced corrosion rates by a factor of 3 to 10 compared with that of aluminum-free alloys. The thin, adherent aluminum-containing scale limited inward diffusion of sulfur and oxygen to the base metal and outward diffusion of nickel from the base metal.¹³

Outlook

World supply and demand should be in fairly good balance over the next few years. Growth in world aluminum demand has slowed from the rapid growth rates of the late 1980's but should show an average growth rate of about 2% per year over the next few years. Increased attention, both domestically and abroad, to waste disposal problems should provide steady growth in the secondary aluminum industry.

^P Preliminary. ^r Revised.

¹ Detailed information on the individual aluminum reduction plants is available in a two-part report that can be purchased from Chief, Division of Finance, Bureau of Mines, Bldg. 20, Federal Center, Denver, CO, 80225. Part 1 of "Primary Aluminum Plants, Worldwide" details location, ownership, and production capacity for 1985-92 and sources of energy and aluminum raw materials for foreign and domestic primary aluminum plants, including those in centrally planned economies. Part 2 summarizes production capacities for 1985-92 by smelter and country.

BACKGROUND

Definitions, Grades, and Specifications

Bauxite is a heterogeneous material composed chiefly of the aluminum oxide minerals gibbsite ($\text{Al}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$), the trihydrate, and boehmite and diaspore ($\text{Al}_2\text{O}_3 \cdot \text{H}_2\text{O}$), the monohydrates.¹⁴ Domestic bauxites and those imported from Brazil, Guyana, and Suriname are of the trihydrate gibbsitic type. Imports from the Sangaredi deposits of Guinea and the north coast of Jamaica are predominantly gibbsitic, but they also contain 4% to 10% of the monohydrate mineral boehmite. In most European and northern Asian bauxite deposits, boehmite is the principal alumina mineral. Recovery of the aluminum oxide in boehmite requires a higher temperature and higher caustic concentration than is needed in processing gibbsite. Major impurities in bauxite ores include iron oxides, silica, aluminum silicates, and titanium oxides.

Free moisture in crude bauxite, as mined, may range from 5% to 30%. In dried bauxite, most of the free moisture

is removed by heating crude bauxite in rotary drying kilns at about 315° C. Calcined bauxite is produced by heating bauxite to 925° to 1,040° C to reduce total volatile matter, including chemically combined water, to less than 1%. About 2 tons of crude ore is required to produce 1 ton of calcined bauxite.

Aluminum metal has a relatively low density, high electrical and thermal conductivity, good resistance to corrosion, and good malleability. It is non-magnetic, nonsparking, and highly reflective. It may be alloyed and treated to yield a high strength-to-weight ratio.

Ingots are a cast form of primary or secondary metal that is convenient to handle and store and is suitable for fabricating or remelting. Commercial size ingots normally weigh about 30 pounds; however, some ingots weigh up to 9 tons. A significant portion of both primary and secondary metal is sold and transported in molten form.

Commercially pure aluminum usually contains about 99.7% aluminum. In the annealed condition, it has low strength and is relatively soft. However, it is available in strain-hardened conditions of higher strength and reduced ductility. Metal with more than 99.7% and up to 99.85% aluminum is available at higher costs than standard commercial metal. Superpurity aluminum contains a minimum of 99.99% aluminum.

Aluminum alloys have been developed that, after cold rolling, heat treating, annealing, or age hardening, have strengths approaching those of mild steels. More than 100 commercial alloys are available, and several new alloys are developed each year. The alloys offer a wide variety of combinations of mechanical strength, ductility, electrical conductivity, and corrosion resistance.

Aluminum alloys are generally divided into two major groups: wrought and casting. The Aluminum Association uses a code to designate the purity and alloy content of wrought alloys and to register the composition of casting alloys and ingot. The range of compositions of wrought aluminum alloys and selected aluminum casting ingot alloys is given in table 39.

New aluminum-base scrap, generated in the production of intermediate and end products of aluminum metal, may be pure (unalloyed), segregated (one alloy type), or mixed (two or more alloys). It

^e Estimated. ^p Preliminary. ^r Revised.¹ The Bureau of Mines defines primary aluminum as "The weight of liquid aluminum as tapped from pots, excluding the weight of any alloying materials as well as that of any metal produced from either returned scrap or remelted materials." International reporting practices vary from country to country, some nations conforming to the foregoing definition and others using different definitions. For those countries for which a different definition is given specifically in the source publication, that definition is provided in this table by footnote. Table includes data available through May 23, 1990.² Reported figure.³ Primary ingot.⁴ Excludes high-purity aluminum containing 99.995% or more as follows, in metric tons: 1985—4,783; 1986—8,140; 1987—12,099; 1988—13,628; and 1989—15,600 (estimated).⁵ Primary unalloyed ingot plus secondary unalloyed ingot.⁶ Primary unalloyed metal plus primary alloyed metal, thus including weight of alloying material.

includes solids, such as new casting scrap; clippings or cuttings of new sheet, rod, wire, and cable; borings and turnings from the machining of aluminum parts; and residues, drosses, skimmings, spillings, and sweepings.

New scrap is further defined as either "runaround" (home) scrap or purchased scrap. Runaround or home scrap is new scrap that is recycled by the same company that generates it; such scrap by definition never leaves the company generating it and, therefore, is never marketed as scrap. Purchased scrap is new scrap that is purchased, imported, or treated on toll by secondary smelters, the original aluminum product suppliers, or others. New aluminum scrap that is purchased from manufacturers of end products may be referred to as consumer scrap. Purchased scrap is sometimes referred to as prompt industrial scrap.

Old scrap, all of which is considered as purchased, comes from discarded, used, and worn out products. It includes aluminum pistons or other aluminum engine or body parts from junked cars, aluminum UBC's and utensils, and old wire and cable. Sweated pig is scrap that has been sweated or melted into a pig or ingot form for convenience and economy in shipping and storage. Obsolete scrap is new, unused, but technologically obsolete aluminum end products, outdated inventory materials, production overruns, and spare parts for machines and equipment no longer being used. In the United States, both sweated pig and obsolete scrap are considered old scrap.

Geology-Resources

Bauxite is formed by the weathering of aluminum-bearing rocks under conditions conducive to the chemical breakdown of minerals in the parent rock. In the weathering process, the aluminum is retained as hydrated aluminum oxide minerals and other constituents are leached from the parent rock. Conditions favorable for the formation of bauxite existed in areas and geological periods that provided warm wet climates, parent aluminous rocks with high permeability and readily soluble minerals, good subsurface drainage, and long periods of tectonic stability that permitted deep weathering and preservation of land surfaces.

The major deposits in central Arkansas were formed by weathering of

nepheline syenite intrusives during late Paleocene and early Eocene time.¹⁵ The predominant aluminum oxide mineral in the bauxite is the trihydrate form, gibbsite. Some deposits are residual on the igneous rock and clay, while others are the result of transportation and accumulation of eroded deposits. Most of the deposits were subsequently covered by sand and clay beds. Bauxite ore ranges in thickness from a few feet to 65 feet and is overlain by a 40- to 150-foot overburden. The composition of the ore mined in Arkansas varies widely within a range of 40% to 52% Al₂O₃, 7% to 17% SiO₂, and 6% to 12% Fe₂O₃.

The bauxite deposits in the coastal

plain of Alabama and Georgia are found as lenses within flat-lying beds of kaolinitic clay, which are overlain by sand and clays of early Tertiary age. Average ore thickness is 10 feet, though locally 33-foot ore has been encountered. Overburden, especially in the Alabama sinkhole deposits, can exceed 120 feet in thickness. The grade of the bauxite is 48% to 56% Al₂O₃, 12% to 16% SiO₂, and less than 2.5% Fe₂O₃. The low iron oxide content permits this ore to be used in refractories and chemicals.

In Jamaica, the bauxite deposits fill sinkholes and channels and blanket uneven depressions in the karst surface of a limestone of middle Tertiary age. Individual ore bodies range from pock-

ets containing a few hundred tons of bauxite to basins containing millions of tons. The soil overburden is only 1 to 2 feet thick. Jamaican bauxite is largely gibbsitic, although mixtures containing up to 20% monohydrate alumina occur. Ore grade is 45% to 49% Al₂O₃, 0.8% to 8% SiO₂, 17% to 22% Fe₂O₃, and 2.5% TiO₂. The bauxite deposits in the Dominican Republic and Haiti are similar in grade, age, and genesis, and are identified as "Jamaica-type" bauxites.

Bauxite deposits in Suriname and Guyana are scattered throughout a narrow belt extending along the contact between the Precambrian crystalline rocks of the Guyana Shield and the sedimentary beds of Tertiary or later age that form the coastal plain. These deposits usually rest on kaolinitic clay and range from exposed outcrops to ore bodies overlain by as much as 200 feet of sand and clay, although the average overburden is around 60 feet. Other deposits of bauxite and laterite occur in these countries at higher elevations south of the coastal belt. The alumina mineral is gibbsite and the ore is high grade; typically 55% to 60% Al₂O₃, 2% to 5% SiO₂, and less than 3% Fe₂O₃. Both countries have been exporters of refractory and abrasive-grade bauxite.

In the large deposits discovered in northern Brazil since 1967, the bauxite occurs as a residual capping on dissected plateaus several hundred feet above the Amazon or other nearby rivers. The ore has developed on unconsolidated Tertiary sediments and is covered by 12 to 30 feet of kaolinitic clay. Ore thickness averages about 16 feet. The approximate grade after washing is 55% Al₂O₃, 3.5% SiO₂, and 11% Fe₂O₃. Bauxites in northern Brazil and Venezuela are of the gibbsitic type and contain little monohydrate alumina.

The Weipa bauxite deposit in Queensland, Australia, occurs in the upper portion of a flat-lying laterite that extends for more than a hundred miles along the west coast of the Cape York Peninsula. The bauxite ranges in thickness from a few feet to 30 feet and is covered by a soil overburden 1 to 3 feet thick. Average ore thickness is about 14 feet. The ore is basically gibbsitic, but some of the alumina is also present in the form of boehmite. The deposits are associated with Tertiary kaolinitic

sands, from which they were probably derived. The grade of the beneficiated bauxite is 53% to 58% Al_2O_3 , 4% to 7% SiO_2 , and 12% Fe_2O_3 .

The Darling Range bauxite deposits in Western Australia occur as a residual capping on Precambrian granites, gneiss, and intrusive crystalline rocks. A thin 1.5-foot blanket of soil mixed with loose pisolites covers the deposits. The top of the ore is characterized by a ferruginous hardcap about 6 feet in thickness. The deposits are characterized by a low alumina and a high quartz sand content; however, the reactive silica is typically less than 2%. General composition is 38% to 46% Al_2O_3 , 10% to 23% SiO_2 , 11% to 16% Fe_2O_3 , and about 4% TiO_2 .

In Guinea, the large Sangaredi bauxite deposits occur as laterite caps on

inland plateaus at elevations of 900 feet or more above sea level. The deposits have been dissected by stream valleys. Most of the bauxite is believed to have formed through weathering of schists and sandstones of Devonian or Post-Devonian age. The thickness of the Sangaredi bauxite ore averages more than 65 feet and exceeds 130 feet in some places. Overburden, where present, consists of a thin topsoil. Typical ore contains 57% to 60% Al_2O_3 , less than 1% SiO_2 , and 2% to 4% Fe_2O_3 . The upper zone of the Sangaredi deposit contained only a few percent boehmite, but mining has progressed to lower benches where the monohydrate content has increased to nearly 10%.

Many of the European bauxite deposits are associated with pockets and

depressions in the karst weathering surface of Mesozoic limestone beds that have been buried, folded, and faulted subsequent to the development of the bauxite. European bauxites are composed predominantly of monohydrate alumina minerals, although some gibbsitic deposits are mined in Hungary and a few other countries.

Historically, the commercial production of primary aluminum has been based almost entirely on the use of bauxite. However, deposits containing aluminum in the other mineral forms are widespread and virtually inexhaustible. The average aluminum content of the Earth's crust has been estimated at 8.3% (15.7% on an Al_2O_3 basis), and deposits containing more than 13% aluminum (25% Al_2O_3) are common.

resources varies from reports based on thorough exploration for some deposits to reports giving only a total quantity estimate based on unspecified field-work for other deposits. The reserve and reserve-base estimates in table 40 are the result of evaluating data and information obtained from many sources. The quality of bauxite deposits cannot be assessed by the alumina content alone because the mineralogical form in which the alumina occurs, its extractability in the Bayer process, the quantity of reactive silica present, iron content, including the ratio of ferric to ferrous iron, and other chemical and physical properties all affect the process cost and the alumina recoverable from a given bauxite. The classification of undeveloped bauxite deposits as either reserves or subeconomic resources also is a matter of judgment because many factors other than grade influence the economics of mining, transporting, and processing the bauxite to alumina. The definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals."¹⁶

Past estimates of world bauxite reserves were about 1 billion metric tons in 1945, nearly 3 billion tons in 1955, 6 billion tons in 1965, and about 21 billion tons in 1985. In 1989, they were estimated at about 22 billion tons. Guinea and Australia together have about one-half of the world's reserves. More than 25% occurs in the Western Hemisphere, principally in Brazil, Jamaica, Guyana, and Suriname. Estimates of additional bauxite classified as subeconomic, hypothetical, or speculative resources bring the total world resources of bauxite to 55 to 75 billion tons. Growth in reserves has roughly paralleled the expansion of world bauxite production capacity. Major new discoveries are the primary factor in reserve increases; however, production economies resulting from technological advances and large-scale operations have also permitted the inclusion of lower grade bauxite previously considered subeconomic.

The principal domestic deposits of bauxite are in central Arkansas, where reserves are estimated to be about 33 million metric tons. An additional 2 to 5 million tons of bauxite reserves in Alabama and Georgia are the source

of domestic refractory and chemical bauxites.

The resources of bauxite in the United States, other than the present reserves, are chiefly in (1) large low-grade deposits containing substantial quantities of clay minerals and deeply buried and thin deposits in Arkansas, Alabama, and Georgia; (2) ferruginous bauxite deposits in Oregon and Washington; and (3) deposits of low-grade ferruginous bauxite in soils and weathered basalts on Kauai and Maui, Hawaii. Inclusion of these low-grade resources increases the total estimated bauxitic resource in the United States to 300 to 325 million tons. The mining of some of these deposits may be restricted or prohibited because of environmental considerations such as their proximity to populated or scenic areas.

Nonbauxitic aluminum-bearing deposits in the United States that have received the most attention as potentially economic sources of aluminum include kaolinitic clays, anorthosite, and alunite. Other types of clays, shales, schists, nepheline syenite, and sapprolite are also potential aluminum raw materials. In addition, the production of certain other minerals yields aluminous materials that may be considered potential sources of metal. These include coal ash and coal mining refuse, copper leach solutions, aluminum phosphate rock, and dawsonite if produced in conjunction with the mining of oil shales.

Technology

Exploration.—The first stage of planning a bauxite exploration program usually entails a thorough study of regional geology, physiography, and any previous reports on exploration or mining operations within the area of interest. The initial regional appraisal should include a review of topographic maps (rarely available for remote tropical areas), aerial photographs, satellite images, and mosaics prepared from aerial side-looking radar (SLR) surveys. In the Amazon Basin of Brazil, where the dense rain forest canopy completely masks stream valleys, scarps, and plateaus, SLR methods have proven effective in revealing the hidden topography. Geobotanical techniques using real or false color air photos and satellite images have been used to identify vegetation types associated with alu-

minous laterites. Airborne radiometric surveys are useful in delineating exposed laterites by their typically evaluated levels of radioactivity.

After specific target areas have been

defined, reconnaissance by helicopter or fixed-wing aircraft can provide valuable logistics information. Surface prospecting for float samples in stream valleys has long been a reliable guide in the discovery of bauxite deposits. Vertical channel sampling of indurated resistant outcrops exposed in stream valleys can often provide the first positive identification of the presence of bauxite. Detailed evaluation and development require drilling, pitting, or trenching to provide samples for chemical analysis. Surface mapping is essential to document drill collar and pit locations and elevations.

Bauxite minerals are difficult to identify visually and require sophisticated laboratory techniques for quantitative analysis. Because of this requirement, exploration samples and development samples are often shipped to the company's main laboratory for analysis. The most important determinations are for alumina and silica content. Both "total alumina" and "available alumina" (alumina recoverable by both low- and high-temperature Bayer processes) are normally determined. In addition to "total silica," it is important to analyze for "reactive silica" because the latter combines with alumina and soda in the Bayer process to form sodium aluminum silicates that are lost in the red mud wastes. Iron oxides, titania, and loss on ignition are also routinely determined.

Mining.—Open pit mining accounted for all of the bauxite mined within the United States in recent years and for about 95% of the world bauxite production. Restoration of the land surface of depleted bauxite mines is being practiced in many areas of the world by preserving the topsoil after stripping for later replacement.

In Arkansas, draglines, scrapers, shovels, and trucks are used in stripping operations. Stripping ratios as high as 13 feet of overburden to 1 foot of ore have been employed, and some surface pits in Arkansas have reached depths of about 200 feet. The pit walls of unconsolidated sand and clay are relatively stable; however, some slumping does occur. In the past, a deeper flat-lying ore was recovered by room-and-pillar mining along a retreating cave line. Underground bauxite mining ceased in 1976, and the remaining surface mining operations in Arkansas are scheduled for permanent

closure in 1990.

In Jamaica, the bauxite deposits lie closer to the surface, and the overburden of vegetation and topsoil is easily stripped. The ore usually requires no blasting. Shovels, draglines, and scrapers are used to load the ore. Haulage is by truck, railroad, or aerial tramline to the alumina plants and port facilities. In Suriname and Guyana, up to 200 feet of overburden is stripped by draglines, scrapers, bucket wheel excavators, or hydraulicking. The ore is broken by blasting and loaded into ore cars or trucks with power shovels, backhoes, or draglines.

At Weipa, Australia, bulldozers and scraper loaders remove the few feet of overburden. Front-end loaders, each mining in excess of 500 tons per hour, then load the uncemented pisolitic ore into trucks for a short haul to a beneficiating plant for sizing and washing. At the deposits in the Darling Range of Western Australia, forest clearing of vegetation and overburden removal are followed by blasting of the hardcap that comprises the top few feet of the bauxite deposits. Front-end loaders load dump trucks for haulage to a mobile crushing plant. Bauxite is carried from the crusher to an alumina plant by conveyor belt.

The deposits mined for the Boké project in Guinea have little overburden, but require blasting. Loosened ore is loaded by electric shovels directly onto railcars for shipment 85 miles to a treatment plant and port at Kamsar.

Underground mining accounts for much of the Greek, French, and Hungarian bauxite production and is widely used in other parts of Europe, including the U.S.S.R. Room-and-pillar and various stoping methods are used. Underground water problems are common—especially in the Hungarian mines where bauxite deposits are associated with the weathering of limestone. Here dewatering of underground workings accounts for 10% to 15% of the mining cost.

Beneficiation.—Bauxite treatment is usually confined to crushing, washing, and drying operations. Most of the bauxites that are mined do not require the more costly beneficiation techniques used on some other metal ores. Moreover, most impurities such as iron, silicon, and titanium are frequently so

finely dispersed in the bauxite that they cannot be readily separated by physical methods. Many bauxites are upgraded, however, by washing or wet screening to remove sand and some of the clay minerals.

Metallurgical and chemical grades of bauxite that must be transported appreciable distances are normally dried before shipment. Drying facilitates the handling of some bauxites, and the degree to which a specific bauxite is dried depends in part on its handling and dusting characteristics. Because crude bauxite may contain 10% to 30% free moisture, drying results in savings in freight that may more than offset drying costs. Suriname and Guinea bauxite is dried to 3% to 6% moisture, whereas Jamaican bauxite is shipped with about 15% moisture. Bauxite for use in refractories and abrasives is calcined to remove both free moisture and chemically combined water.

Alumina Production.—Virtually all commercially produced alumina from bauxite is obtained by a process patented by Karl Bayer in 1888 (German Patent 43,977), although research on aluminum extraction from other mineral raw materials has continued for many years. The Bayer process involves a caustic leach of the bauxite at elevated temperature and pressure, followed by separation of the resulting sodium aluminate solution and selective precipitation of the aluminum as the hydrated aluminum oxide ($\text{Al}_2\text{O}_3 \cdot 3\text{H}_2\text{O}$).

The actual processing conditions such as the leach temperature, holding time, and caustic concentration, as well as the costs, are influenced by the type of bauxite to be processed. As a result, a Bayer alumina plant is designed to treat a specific bauxite and, in general, cannot use a bauxite that is too different from the one the plant was designed to use without major plant modifications.

The Bayer process is initiated by mixing crude bauxite with preheated spent leach solution. Lime is added during this initial step to control the phosphorus content and to increase the solubility of alumina. The resulting slurry, containing 40% to 50% solids, is pumped with additional caustic leach solution to pressurized digesters where high-pressure steam is used to raise the temperature. Alumina and some of the silica are dissolved during this step,

soluble sodium aluminate is formed, and a complex sodium aluminum silicate is precipitated.

Digestion, in tanks 10 to 15 feet in diameter and up to 90 feet high, takes up to 5 hours. Leaching temperatures range from about 105° C to about 290° C, with corresponding pressures ranging from about 60 pounds per square inch (psi) to more than 1,000 psi. The lower temperature ranges are used for bauxites in which nearly all of the available alumina is present as gibbsite. The higher temperatures are needed to digest bauxite having a large percentage of boehmite. Caustic concentration of the spent leach solution, expressed as grams per liter of sodium carbonate (Na_2CO_3), averages about 200 grams per liter for gibbsitic bauxite and about 300 grams per liter for bauxites with a high-boehmite content.

The resulting slurry of sodium aluminate solution and insoluble red mud from the digesters is cooled to atmospheric boiling temperature, and a coarse sand waste fraction is removed by gravity separators or wet cyclones. The fine solids in the red mud are then separated by decantation of the overflow in settling tanks measuring about 15 feet in depth and 50 to 125 feet in diameter. A flocculant such as starch is added to increase the settling rate of the red mud particles. The overflow from the settling tanks containing the alumina in solution is clarified by filtration and placed into precipitating tanks ranging in size from 25 to 30 feet in diameter and up to 80 feet high.

The clarified sodium aluminate liquor is cooled until it becomes supersaturated, then seeded with fine crystals of alumina trihydrate. The alumina is precipitated as the trihydrate, separated by sedimentation or filtration, and washed. The spent leach solution containing caustic soda is regenerated in the precipitation step, and together with the alumina remaining in solution, is recycled to the digesters. The filtered and washed alumina trihydrate is calcined for use in making metal. A portion of the washed alumina may be left in the trihydrate form for chemical uses or it may be further processed under controlled conditions to produce a variety of chemical aluminas, such as activated or tabular alumina for uses other than metal production.

Two forms of calcined alumina are

used to produce aluminum. European Bayer plants have traditionally produced a fine-grained, highly calcined, floury alumina while North American Bayer plants have always produced a coarser grained, porous, sandy alumina that has not been totally calcined to the alpha alumina stage (artificial corundum). The relatively large surface area of the sandy alumina particles compared with the floury alumina particles permits their use as an absorbent in dry scrubber units at the smelter. Fluorine in the gases emitted by the potlines is trapped by the alumina and is later recycled when the alumina is used as feed for the cell. Pressure from environmental regulations and improved economics through recovery of fluoride have been important factors in the conversion of world alumina plants to produce a sandy rather than a floury alumina product.

The red mud contains Fe_2O_3 , TiO_2 , the sodium aluminum silicate complex, and small quantities of other metal oxides. Because the complex represents a loss of both alumina and soda, a low reactive silica content in the bauxite is desirable. Reactive silica contents of more than 8% are usually uneconomic for treatment by the Bayer process because approximately 1.1 units (weight unit) of alumina and 1.2 units of soda are lost for each unit of reactive silica in the ore. The loss of soda is made up by adding caustic soda or soda ash and lime to the spent leach solution to bring it up to the appropriate caustic concentration before it is recycled.

Bauxite with 8% to 15% silica may be treated by the combination process developed by Alcoa. In this process, the bauxite is first subjected to a Bayer leach. The resulting red mud, containing sodium aluminum silicate, is sintered with limestone and soda ash and then leached with water to recover alumina and soda. Alumina produced by the combination process is of relatively high purity and commands a premium price. The insoluble residue (brown mud) resulting from leaching the sintered materials has a composition somewhat similar to that of portland cement.

The upper limit of silica for use in the combination process is about 15%. However, in practice, bauxite containing some clay and as much as 25% silica is mined and blended with low-

silica ore in proportions that will give a feed material approximately 12% to 13% silica. The combination process is currently used in one plant in Arkansas, which has been scheduled for permanent closure in 1990, and reportedly in several plants within the U.S.S.R.

In the U.S.S.R., alumina is extracted from nepheline $[(\text{Na},\text{K})\text{AlSiO}_4]$ flotation concentrates and other nonbauxitic materials containing about 30% alumina. Nepheline syenite has been mined at Belogorsk in Siberia and obtained as a byproduct of apatite recovery from syenite deposits in the Kola Peninsula. The process used involves sintering the nepheline with lime followed by leaching. Alumina reportedly is also produced from alunite $[\text{KAl}_3(\text{OH})_6(\text{SO}_4)_2]$ in the Azerbaijan S.S.R.

Historically, a small tonnage of alumina has been extracted commercially in Norway from high-iron bauxites by the Pedersen process. In this process, bauxite, limestone, coke, and iron ore are smelted in an electric furnace to produce pig iron and calcium aluminate slag containing 30% to 50% alumina. The slag is leached with sodium carbonate solution, and alumina trihydrate was precipitated by carbon dioxide. During World War II, the process was also used at a Swedish plant to treat andalusite (Al_2SiO_5).

Smelting

Primary Aluminum Production.—

Primary aluminum is produced by the reduction of alumina by electrolysis in a molten bath of natural or synthetic cryolite (Na_3AlF_6), which serves as an electrolyte and as a solvent for the alumina. The reduction cells or pots containing the bath are about 10 to 15 feet wide, 20 to 40 feet long, and about 3 to 4 feet deep, lined with carbon, and connected in electrical series of 100 to 240 cells to form a potline. From 800 to 3,000 pounds of aluminum are produced per day in each pot. The carbon lining is in contact with the molten aluminum metal and serves as the cathode. It usually must be replaced after 3 to 4 years.

Cryolite and aluminum fluoride are added to the electrolyte to maintain the desirable ratio of sodium and aluminum fluoride and to replace fluorine lost from the cell in pot linings or

through volatilization. The melting point of the bath is lowered by the addition of small quantities of fluor-spar or, in some instances, lithium compounds. The carbon anode, which is consumed during the operation, is replaced using the Soderberg continuous method or the prebaked method.

In the Soderberg method, a reinforced rectangular steel shell, approximately 3 to 5 feet high and open at the top and bottom, is suspended above the furnace. The carbon mass of paste or briquets of coke and pitch within the shell forms the anode and is added periodically as the anode is consumed. Current enters the anode through rows of pins inserted into the carbon mass either vertically or horizontally. The heat of the bath and the heat resulting from the electrical resistance of the carbon bake the anode mass so that it becomes a hard monolithic mass from the surface of the electrolyte to a point approximately 20 inches above the bath. As the carbon anode is consumed and additional carbon descends through the rectangular steel shell and is consumed, the lowest pins are withdrawn and replaced at higher levels in the carbon mass. The optimum anode-cathode distance is maintained by raising or lowering the cathode mass via the pins, which become baked into the lower part of the carbon block.

In the prebaked anode system, sets of 16 to 24 prebaked carbon blocks are used for the anode. The size of the blocks varies from plant to plant; typical blocks are about 20 inches wide, about 30 inches long, and 12 to 18 inches high. They weigh 400 to 600 pounds. Steel stubs or rods, which suspend the block in the bath and conduct the current to the carbon, are sealed in the anode block by pouring molten iron around the rod and allowing it to solidify. The blocks are raised or lowered separately to maintain proper position with respect to the bath and are replaced individually as they are consumed.

The Soderberg system requires less labor and, except for moving the steel pins, is a continuous method of feeding anode carbon. The prebaked system results in better electrical efficiency in the reduction cell but requires separate anode fabricating and rodding facilities not required in the Soderberg system. The prebaked system permits efficient collection of the cell offgases for subsequent

treatment to remove fluorine; the off-gases from a Soderberg cell are difficult to collect, necessitating fluorine recovery from a larger volume of gas than that required in prebaked systems.

The molten bath or electrolyte may be as deep as 14 inches, but the anode is usually only 2 inches from the pad of molten aluminum collecting on the carbon cathode. The optimum operating temperature is between 950° to 985° C. At this temperature range, the alumina content of the bath ranges from 3% to 10%. When the alumina concentration drops to about 2%, the electrical resistance of the cell increases sharply, chiefly because of a gas film that envelops the anode, and the voltage drop across the cell increases from 5 volts to 30 to 40 volts. The phenomenon is known as the "anode effect," and as soon as it occurs, the crust of frozen cryolite on top of the bath is broken and more alumina is added to the cell, which then returns to normal operating condition.

Every 1 or 2 days the molten aluminum is removed from the bottom of the cell by a vacuum siphon technique. Thermally insulated cast-iron pots with airtight lids and downward-sloping spouts are used to withdraw the molten metal. The pot is evacuated, and the molten metal is sucked into the cast-iron pot. The molten metal is blended in a holding furnace with other batches and alloyed and cast into various solid forms or transported molten to fabricating plants as far as 300 miles away.

Utilizing direct current, cells operate at 65,000 to 150,000 amperes; the majority of plants have 80,000- to 100,000-ampere cells. Anode current densities range from 600 to 800 amperes per square foot. The voltage drop across a single cell is 4.5 to 5.0 volts; across a potline, it may be as high as 1,000 volts.

The larger cells require less labor per pound of aluminum produced, but special problems are encountered in cells designed to operate at 100,000 or more amperes. The larger currents cause powerful magnetic fields in the molten aluminum metal and the bath, resulting in violent agitation. This agitation causes aluminum to be dispersed in the bath, increasing the possibility of reversing the reduction reaction. Another detrimental effect is that the molten metal piles up toward the negative leads, causing a variation in the anode-

cathode spacing. Moreover, localized thermal effects may distort the carbon lining.

Production cells normally have current efficiencies ranging from 85% to 93%. Metal losses are principally caused by reoxidation of aluminum in the electrolyte and by physical loss of metal through vaporization from the bath or spillage. The resistance of the bath is sufficient to maintain the operating temperature. However, heat energy is lost by radiation, thermal conductance through electrode connections, in exhaust gases and tapped metal, and in electrodes removed from the cells.

To prevent atmospheric pollution, fumes evolved from the cells during electrolysis are removed from plant off-gases by a collection and wet-scrubbing system or by a dry process whereby the fluorine is absorbed by alumina and recycled.

Superpurity Aluminum Processing.—

The production of superpurity aluminum, 99.99+ % purity, requires special procedures, such as a continuous electrorefining of commercially pure aluminum in a Hoopes cell. This cell employs three molten layers of metals or bath materials of different densities. The bottom layer is the anode, a relatively impure aluminum alloyed with copper to increase its density. The intermediate layer is molten cryolite electrolyte with alkaline earth metal fluorides added to give the desired density, always greater than pure aluminum. The top layer, which serves as the cathode, is the molten superpurity aluminum that floats on the electrolyte layer.

Recycling.—In recycling, aluminum-base scrap is usually melted in gas- or oil-fired reverberatory furnaces of 30,000 to 100,000 pounds capacity, sometimes with primary ingot metal. The furnaces have one or two charging wells separated from the main bath by a refractory wall that permits only molten metal into the main bath. The principal refining of aluminum-base scrap is the removal of magnesium by treating the molten metal with chlorine or with various fluxes such as aluminum chloride, aluminum fluoride, or mixtures of sodium and potassium chlorides and fluorides. To facilitate handling, a significant proportion of the old aluminum scrap, and in some

cases new scrap, is simply melted to form a solid ingot called "sweated pig," which must be further treated to produce specification-grade ingot.

Aluminum drosses containing about 30% metallics are usually crushed and screened to bring the metallic content up to about 60% to 70%. They are then melted in a reverberatory furnace, with the molten aluminum metal collecting on the bottom of the furnace. Salt slags containing less than 30% metallics may be leached with water to separate the metallics.

Economic Factors¹⁷

Aluminum production costs at aluminum mining and primary processing facilities were affected by internal factors such as variations in bauxite type and quality, stripping ratios, caustic soda consumption rates, and energy and alumina costs. In addition, external factors such as foreign exchange rates, inflation, and world market prices for products affected aluminum producers. The Bureau's Minerals Availability Program (MAP) monitors these factors to determine variations in the industry and changes in the cost competitiveness of major aluminum producing countries.

Table 41 summarizes the principal production costs of aluminum for selected countries in average 1988 U.S. dollars. The wide spread in electric power costs among primary aluminum operations was a principal reason for large variations in aluminum ingot production costs among producing nations. As a result, many energy-intensive plants have closed since 1980, and operating facilities have implemented energy-conserving technology. Countries with lower energy costs appeared to have a cost advantage over other producers.

Extreme variations in inflation relative to foreign exchange rates were another factor affecting production costs

in countries such as Brazil. Although energy was abundant and labor and supply costs in Brazil traditionally have been low, extreme inflation in 1988 and 1989 made Brazil a higher-cost producer when costs were reported in U.S. dollars.

In terms of relative costs competitiveness in 1988, Australia and Canada were the lowest cost aluminum producers, principally because of low-cost energy and lower alumina and supply costs. Latin American countries such as Brazil have traditionally been low-cost producers; Brazil's costs, in the midcost range, reflected the high inflation rates present in that country in 1988. The U.S. aluminum industry also fell in the middle of the cost range, indicative of the domestic aluminum industry's recent efforts in cost reduction and restructuring. European aluminum producers appeared to be the highest cost operations.

BERYLLIUM

By Deborah A. Kramer

Ms. Kramer is a physical scientist with the Branch of Nonferrous Metals. She has covered beryllium for 6 years. Domestic survey data were prepared by Ruth A. Hough and Lura M. Nightlinger, Nonferrous Metals Data Section. International data were prepared by W. Zajac, International Data Section.

Softness in the defense, semiconductor, and computer markets resulted in lower domestic beryllium production and consumption. Concern about health hazards associated with beryllium oxide ceramic components resulted in a decrease in their use in some defense applications. Although total beryllium demand decreased, beryllium alloys, such as Alloy 174, gained new uses in automotive electronics components, and new alloys were introduced for use as molds for injection-molded plastics.

Brush Wellman Inc. remained the sole U.S. mine producer of beryllium ores and the only company with the facilities to process ore into alloys, metal, and oxide. Because of a drop in profits, the company planned to consolidate or sell some of its metals businesses to reduce costs.

LEGISLATION AND GOVERNMENT PROGRAMS

The National Defense Stockpile (NDS) acquired 6 metric tons of hot-

pressed beryllium billets in 1989, under a contract awarded to Brush Wellman in 1988. Of the 27 tons purchased and delivered under the 1988 contract, 21 tons must be tested before it is accepted in the NDS. Total NDS inventories and goals for beryl ore, beryllium-copper master alloy, and metal are shown in table 2.

In September, the Environmental Protection Agency issued a final ruling on the criteria to evaluate mineral processing wastes for exclusion from regulation under subtitle C of the Resource Conservation and Recovery Act (RCRA). Barren filtrate, raffinate, and bertrandite thickener sludge from primary beryllium processing operations were candidates for exclusion under the original criteria established in 1988. To be excluded from regulation under RCRA, waste streams must pass high-volume and low-toxicity criteria established in the final ruling. Barren filtrate and raffinate waste streams did not pass the high-volume criteria and were no longer excluded from RCRA. Bertrandite thickener slurry was reclassified as a beneficiation waste and was to be regulated under the subtitle D+ program.¹

TABLE 2

STOCKPILE STATUS, DECEMBER 31, 1989

(Metric tons, beryllium content)

Material	Goal	Inventory
Beryllium ore	653	653
Beryllium-copper master alloy	287	268
Beryllium metal	363	269

The U.S. Department of Commerce planned to investigate reports that Degussa AG of the Federal Republic of Germany shipped a small quantity of high-purity beryllium metal to India without obtaining an export license. International shipment of beryllium metal is strictly controlled because of the metal's applications in nuclear weapons. Commerce officials indicated that an application for shipment of beryllium would have been denied because India did not sign the nuclear nonproliferation treaty.

PRODUCTION

Mine shipments of beryllium concentrates declined, continuing a 2-year trend. Production of beryllium metal, beryllium oxide, and beryllium-copper master alloy also decreased. Brush Wellman remained the sole ore processor in the United States, treating bertrandite, imported beryl, and small quantities of domestically produced beryl at its plant in Delta, UT.

To provide faster service to customers with small orders, Brush Wellman completed a \$5 million expansion program at its beryllium-copper rolling facility in Reading, PA. New equipment installed at the plant included a 10-inch-wide cluster mill with computerized feed control, a

strand annealing furnace, and a chemical cleaning line. The company expected to provide its customers with shorter response times, larger coils, and improved thickness control.

Late in 1989, Brush Wellman announced that it would consolidate and sell a few of its metal businesses to reduce costs and streamline operations. Specifically, the company planned to sell the unrelated custom rolling business of its subsidiary, Metals Engineering Co., and consolidate the remainder of its metals systems operations at the Lincoln, RI, location of its Technical Materials Inc. subsidiary. In addition, Brush Wellman planned to seek a partner or buyer for its clad metal systems business in Japan because of losses in 1988 and 1989. The company expected that the restructuring plan would affect about 10% of Brush Wellman's 2,200 employees.²

CONSUMPTION AND USES

Because of softness in defense, semiconductor, and computer markets, demand for beryllium products declined in 1989. In addition, concern about the potential health hazards of beryllium oxide ceramic components led to a decline in their use in some defense-related applications.

Although overall beryllium demand decreased, the use of Alloy 174, a lower cost beryllium-copper alloy, continued to increase in automotive electronics. Brush Wellman also introduced two new beryllium-copper alloys for use as molds for injection-molded plastics for automotive, industrial, and consumer applications.

PRICES

Metals Week quoted a price of beryllium ore at a range of \$78 to \$85 per short ton unit (20 pounds) of contained beryllium oxide throughout 1989. At yearend, American Metal Market quoted the following prices, in dollars per pound, for beryllium and beryllium alloys; beryllium-copper master alloy was quoted in dollars per pound of contained beryllium:

Vacuum cast ingot, 98.5% pure	\$225
Metal powder, in 1,000- to 4,999-pound lots and 98.5% pure	196
Beryllium-copper master alloy	160
Beryllium-copper casting alloy	\$5.52- 6.30
Beryllium-copper in rod, bar, wire	9.85
Beryllium-copper in strip	8.90
Beryllium-aluminum alloy, in 100,000-pound lots	260
Beryllium oxide powder	65.65

Changes in beryllium metal prices from 1932 to 1988 and a brief analysis of the factors that influenced the changes were included in a Bureau of Mines report on nonferrous metals prices.³

FOREIGN TRADE

In 1989, the United States implemented the Harmonized Tariff System (HTS), which resulted in changes in classifications for some materials. Some data that were aggregated under one category in the Tariff Schedule of the United States (TSUS) classification system were separated under the HTS, and some data that were separated in the TSUS system are aggregated in the HTS. Consequently, trade data that can be identified specifically with one commodity may have changed, and data for 1989 were not comparable to that of 1988 and previous years. For beryllium, data on exports of metal and waste and scrap in 1989 were not exactly comparable to 1988 export data, and import data for beryllium metal and compounds differed from those in previous years.

Exports of beryllium-copper alloys could not be separately identified in the Bureau of the Census data. The Journal of Commerce Port Import/Export Reporting Service (PIERS) provided some information on these exports. According to PIERS, 300,678 kilograms (gross weight) of beryllium-copper alloys was exported from the United States, with almost 80% of the material shipped to France. In addition, 29,508 kilograms (gross weight) of beryllium-copper master alloy was exported, with 63% shipped to France, 33% to the Federal Republic of Germany, and 4% to Brazil.

WORLD REVIEW

Capacity data for beryllium mining operations are presented in table 7. Beryl mining operations outside the United States employ manual labor to separate beryl crystals from the host rock, and capacity data for such operations represent average production figures. Output from many operations, particularly those in Africa, was dependent largely on the economic and political situation within the country.

Hecla Mining Co. announced that it would withdraw from its joint venture with Highwood Resources Ltd. to develop a beryllium-containing deposit in the Northwest Territories, Canada. Although a processing design was developed, the company encountered difficulties in marketing the product. Highwood Resources planned to assess other alternatives for the project.

OUTLOOK

Although total beryllium demand has declined each year since 1987, this trend is not expected to continue over the next few years. The consumption of beryllium is influenced largely by the requirements for beryllium-copper alloys, which represents more than one-half of the total demand. Increased use of beryllium alloys in automotive electronic components was expected to be an important factor in alleviating the downturn in demand. In addition, applications for Alloy 174 were expected to expand because of its lower cost compared with traditional beryllium-copper alloys, and its superior performance relative to the materials it can replace.

BACKGROUND

Products For Trade and Industry

A wide variety of applications use beryllium in one of three forms—metal, oxide, and alloys. Beryllium-copper alloys are the principal form, averaging about 65% of annual consumption on a beryllium metal equivalent basis. These alloys, most of which contain approximately 2% beryllium, are used because of their high electrical and thermal con-

ductivity, high strength and hardness, good corrosion and fatigue resistance, and nonmagnetic properties. Beryllium-copper strip is manufactured into springs, connectors, and switches for use in applications in automotive, aerospace, radar and telecommunications, factory automation, computer, home appliances, and instrumentation and control systems. The principal use of large-diameter beryllium-copper tubing is in oil and gas drilling equipment and bushings and bearings in aircraft landing gear and heavy machinery. Connectors in fiber optic telecommunications systems are the main application for beryllium-copper rod, and small plug-gable sockets for joining integrated circuits to printed circuit boards is the main use for beryllium-copper wire. Beryllium-copper bar and plate are used in resistance-welding parts, components for machinery and materials-handling systems, and for molds to make metal, glass, and plastic components.

Beryllium also is used in small quantities in nickel- and aluminum-base alloys. Miniature electronic connector components that operate at high temperatures are the main use for beryllium-nickel alloys. Beryllium-aluminum alloys are used as castings in the aerospace industry. Addition of small quantities of beryllium to magnesium alloys inhibit oxidation. Beryllium metal, which averages about 20% of annual domestic demand, is used principally in aerospace and defense applications. Its high stiffness, light weight, and dimensional stability over a wide temperature range make it useful in satellite and space vehicle structures, inertial guidance systems, military aircraft brakes, and space optical system components. Because metallic beryllium is transparent to X-rays, it is used in X-ray windows. In nuclear reactors, beryllium also serves as a canning material, as a neutron moderator, in control rods, and as a reflector. The metal has been used as a triggering device in nuclear warheads. Other applications for metallic beryllium include high-speed computer components, audio equipment components, and mirrors. In the U.S. space shuttles, several structural parts and brake components used beryllium.

Beryllium oxide (beryllia) is an excellent heat conductor, with high hardness and strength. This material also acts as an electrical insulator in some applica-

Beryllium oxide or hydroxide	2825.90.1000	3.7% ad val.	25.0% ad val.

tions. Beryllium oxide, averaging about 15% of U.S. demand, serves mainly as a substrate for high-density electronic circuits for high-speed computers, automotive ignition systems, lasers, and radar electronic countermeasure systems. Because it is transparent to microwaves, microwave communications systems and microwave ovens may use beryllium oxide.

Because of its high cost compared with that of other materials, beryllium is used in applications in which the properties are crucial. Steel, titanium, or graphite composites substitute for beryllium metal in some applications, and phosphor bronze substitutes for beryllium-copper alloys, but these substitutions would result in substantial loss in performance.

Industry Structure

Although beryllium is a constituent of over 90 minerals, only 2 are exploited commercially for their beryllium content. Bertrandite ($4\text{BeO} \cdot 2\text{SiO}_2 \cdot \text{H}_2\text{O}$) is the principal ore mined in the United States, and beryl ($3\text{BeO} \cdot \text{Al}_2\text{O}_3 \cdot 6\text{SiO}_2$) is the principal ore mined in the rest of the world.

The United States is the only market economy country that can process beryllium ore and concentrates into beryllium products. Brush Wellman mines bertrandite and converts this ore, along

with beryl, to beryllium hydroxide at its facility in Delta, UT. Beryllium hydroxide is shipped to the company's plant in Elmore, OH, where it is converted into beryllium alloys and metal. Brush Wellman also produces beryllium oxide from the hydroxide at a plant in Tucson, AZ. At a plant in Reading, PA, NGK Metals Corp. produces beryllium alloys from beryllium hydroxide produced by Brush Wellman, under a tolling agreement.

Production from labor-intensive beryl mining operations outside the United States is sporadic, except for the largest producers, Brazil, China, and the U.S.S.R. Two properties being developed in North America may provide additional beryllium ore supplies. A bertrandite mine near El Paso, TX, is being developed by Cyprus Minerals Co., and a deposit containing phenacite (a beryllium mineral) and rare-earth minerals is awaiting development by Highwood Resources Ltd.

Technology

Outside the United States, where the principal beryllium mineral mined is beryl, the main method used is pick-and-shovel mining of weathered pegmatites. After mining pegmatite ore, beryl crystals are hand-picked from the waste material.

In Utah, Brush Wellman mines ber-

trandite by open pit methods. Unlike beryl, in which the mineral can be identified by color and crystal structure, bertrandite mineralization cannot be recognized with the naked eye. Consequently, Brush Wellman conducts a geological and geochemical evaluation on a specific area, followed by a drilling program to determine if an economic ore body exists.

After delineating an ore body, overburden is removed within 7 feet of the ore body by a local earth-moving contractor during the winter and spring. This stripping operation requires about 9 months for completion. In the 7-foot cover remaining, drill benches are con-

¹ In addition to the countries listed, China produced beryl and Bolivia, Namibia, and Nepal may also have produced beryl, but available information is inadequate to formulate reliable estimates of production. Table includes data available through Apr. 27, 1990.

² Includes ornamental and industrial products.

³ Reported figure.

⁴ Less than 1/2 unit of measure; for Madagascar, production for 1988 and 1989 was 3 kilograms and 3 kilograms (estimated), respectively and for the Republic of South Africa, production for 1987 and 1988 was 135 kilograms and 72 kilograms, respectively.

⁵ Revised to zero.

⁶ Includes bertrandite ore, calculated as equivalent to beryl containing 11% BeO.

structured on 25-foot centers to take samples of the ore body at 2-foot intervals. Information obtained from analyzing the samples allows cross-sectional and contour maps to be produced. These maps are used to plan the mining and processing operations.

After the maps are prepared, the remainder of the overburden is removed, and the ore is mined, typically with a self-loading scraper. Because of the irregular ore-grade distribution in the ground, the ore is mined from predetermined areas and placed in a stockpile in layers to obtain a homogeneous blend. Drilling, sampling, and assaying the stockpiled ore generate a map that identifies ore-grade distribution throughout the stockpile. Stockpiled ore is trucked to the mill, which is about 50 miles away, for further processing.

Beryllium is commercially recovered from two ores—bertrandite and beryl. Brush Wellman is the only company in market economy countries with facilities to extract the beryllium values from both ores. Because of the difference in beryllium content of bertrandite and beryl, the ores are treated separately until the beryllium is dissolved, then the two solutions are combined.

Bertrandite is crushed, screened, and

then leached with a sulfuric acid solution at about 95° C to dissolve the beryllium, forming a beryllium sulfate solution. In contrast, after crushing, beryl ore is heated to 1,700° C and quenched rapidly in water to form a frit. Heat treating the frit at 1,000° C, crushing, and then leaching with a concentrated sulfuric acid solution dissolves the contained beryllium, forming a beryllium sulfate solution.

After separating the solids from both beryllium sulfate solutions, the sulfate solutions are combined. Solvent extraction is used to remove additional impurity elements that were extracted with the beryllium. In solvent extraction, the beryllium sulfate solution contacts an organic solution, which does not mix with water. Beryllium is selectively dissolved in the organic solution, which is then mixed with an ammonium carbonate solution to form an ammonium beryllium carbonate solution.

In addition to beryllium, the solvent extraction step dissolves iron, aluminum, and fluoride. Hydrolysis with steam removes most of these impurities. Two additional hydrolysis steps to remove the ammonia and carbon dioxide result in the formation of beryllium hydroxide, the intermediate product

used for production of beryllium metal, oxide, and alloys.

To produce beryllium-copper master alloy, beryllium hydroxide, electrolytic copper, and carbon are combined in an electric arc furnace. The resultant melt containing about 4% beryllium is cast into ingots. Remelting master alloy ingots with additional copper and other alloying elements yields the desired beryllium-copper alloy, which is then cast into slabs or billets. Slabs of beryllium-copper alloys are further processed to strip or plate, and billets are extruded into tube, rod, bar, and wire products.

Beryllium oxide powder is produced by dissolving beryllium hydroxide in sulfuric acid. The resulting beryllium sulfate solution is concentrated by evaporation and cooled to yield beryllium sulfate tetrahydrate crystals. Calcining these crystals at temperatures up to 1,430° C yields beryllium oxide powder.

To produce beryllium metal, beryllium hydroxide is dissolved in an ammonium bifluoride solution and evaporated to yield an ammonium beryllium fluoride salt. Decomposing the salt at 700° C to 900° C produces molten anhydrous beryllium fluoride, which is reacted with magnesium to produce metallic beryllium and magnesium fluoride. Cooling the mixture produces a solid cake that contains beryllium metal pebbles, magnesium fluoride, and unreacted beryllium fluoride. Crushing this mixture followed by water leaching, yields beryllium metal and magnesium fluoride. After separating the magnesium fluoride, which is recycled, the pebbles are vacuum melted to remove any slag trapped in them and cast into ingots.

Vacuum-cast ingots may be further processed into a powder produced by machining the ingot into chips. Grinding in a ball mill, impact grinding, or attrition grinding reduces the size of the chips. Each of these methods produces a different particle size powder. Beryllium powder is formed into billets by vacuum hot-pressing, hot-isostatic pressing, or cold isostatic pressing, depending on the end use of the material.⁴

Because of the toxic nature of beryllium dust and fines, the industry must maintain careful control on the cleanliness of the workplace. Personal protection equipment for the workers, medical monitoring programs, and source collection of dust, fumes, and mists are

BISMUTH

By Stephen M. Jasinski

Stephen M. Jasinski is a physical scientist with the Branch of Nonferrous Metals. He has been the bismuth commodity specialist for 2 years. Domestic survey data were prepared by Tony E. Morris, Nonferrous Metals Data Section. International data were prepared by Harold Willis, International Data Section.

Owing largely to reduced use in alloys and steel, domestic consumption of bismuth declined. Bismuth was produced in the United States as a byproduct of lead refining. One company accounted for all primary production. Pharmaceutical and industrial com-

pounds and pigments continued as the major chemical uses. Fusible alloys and additives to aluminum, malleable iron, and steel were the major metal uses. U.S. dealer prices for bismuth fell during the year due to the increased availability resulting from record-high imports and lower consumption.

LEGISLATION AND GOVERNMENT PROGRAMS

In April, a Department of Defense study recommended reducing the goal for bismuth in the National Defense Stockpile from the current 997,903 kilograms to 480,808 kilograms over an 8-year period. If approved, disposal would begin at 57,924 kilograms annually in 1990 and 1991. The stockpile inventory on December 31, 1989, was 944,087 kilograms.

DOMESTIC PRODUCTION

Production at the ASARCO Incorporated refinery in Omaha, NE, decreased slightly in 1989. Data are not published to avoid disclosing company proprietary information. Several firms produced small quantities of secondary bismuth, primarily from fusible alloy scrap.

CONSUMPTION AND USES

The use of bismuth in metallurgical additives fell due to reduced production of free-machining steel. Chemical usage rose and accounted for almost one-half of total domestic consumption for the first time since 1986. Major chemical uses included compounds for treating digestive tract ailments, pearlescent pigments for cosmetics and plastics, and varistors and ceramic capacitors.

PRICES

The range of dealer price quotations for bismuth, as reported in Metals Week,

decreased gradually throughout the year from a high of \$6.75 to \$6.85 per pound in January to \$4.40 to \$4.50 per pound in December. The decline in price was mainly attributed to excessive world stock levels.

FOREIGN TRADE

U.S. imports for consumption of bismuth metal reached a record level, up 15% from 1988. Belgium was the largest source of refined bismuth.

Effective January 1, 1990, the import duty for bismuth articles, including waste and scrap (Harmonized code 8106.00.0000), was free for most favored nations (MFN) and 7.5% ad valorem for non-MFN.

WORLD REVIEW

Bismuth was recovered mainly as a byproduct of processing lead and copper ores and only in Bolivia was it mined as the principal product. World mine and refinery production remained nearly the same as 1988. Mexico led in both mine and refinery production for the third consecutive year.

TABLE 4

	1988	1989

The United States and Japan were the largest consumers of bismuth and were also the only countries for which published data on end uses were available. The demand for bismuth has been growing rapidly in Japan since 1987, mainly for varistors and ceramic capacitors, although reported consumption dropped slightly in 1989.

CURRENT RESEARCH

An organic bismuth compound was developed that makes plastics detectable to X-rays. The compound, triphenylbismuth, is heat-stable, moisture-resistant, and flame-retardant. Plastic explosives and weapons containing the additive would be detectable in airport security systems.¹

The Bismuth Institute Information Center (47, rue de Ligne, B. 1000—Brussels, Belgium) collects detailed information on the uses of bismuth. It publishes a bulletin several times a year with articles on current research and lists new patents issued in the world involving bismuth.

OUTLOOK

World reserves and production capacity are sufficient to meet foreseeable demand for bismuth into the next century. Domestic consumption is expected to grow slowly in the next decade. Bismuth has the advantage of being nontoxic. It is expected to remain important in pharmaceutical applications and as a substitute for lead in free-machining steel and pigments.

¹ Table includes data available through Mar. 30, 1990. Bismuth is produced primarily as a byproduct of other metals, mostly lead, and only in Bolivia is it mined for itself.

² In addition to countries listed, Brazil, Bulgaria, the German Democratic Republic, Greece, and Namibia are believed to have mined and/or refined bismuth, but available information is inadequate for formulation of reliable estimates of output levels.

³ It is believed that bismuth-rich residues were stockpiled at the mine site during the period 1983-85 and released into the world market in subsequent years.

⁴ Figures listed under mine output are reported in Canadian sources as production of refined metal and bullion plus recoverable bismuth content of exported concentrate.

⁵ Mine output figures have been estimated based on reported metal output figures.

⁶ Less than 1/2 unit.

⁷ Reported figure.

BORON

By Phyllis A. Lyday

Mrs. Lyday has covered boron for 11 years. Domestic survey data were prepared by Pamela Shorter, mineral data assistant, Industrial Mineral Data Section. International data prepared by G. Jacarepaqua, international data assistant, Geographic Data Section.

U.S. production and sales of boron minerals and chemicals decreased during the year. Domestically, glass fiber insulation was the largest use for borates, followed by sales to distributors, textile-grade glass fibers, and borosilicate glasses.

California was the only domestic source of boron minerals. The United States continued to provide essentially all of its own supply while maintaining a strong position as a source of sodium borate products and boric acid exported to foreign markets.

Supplementary U.S. imports of Turkish calcium borate and calcium-sodium borate ores, borax, and boric acid, primarily for various glass uses, continued.

DOMESTIC DATA COVERAGE

Domestic data for boron are developed by the Bureau of Mines from two separate, voluntary surveys of U.S. operations. Of the three operations to which a production survey request was sent, all responded, representing 100% of the total boron sold or used shown in tables 1 and 7. A Bureau canvass of the three U.S. producers also collected data on domestic consumption of boron minerals and compounds shown in tables 2 and 3.

LEGISLATION AND GOVERNMENT PROGRAMS

The House of Representatives introduced legislation to provide a separate tariff classification and a temporary duty suspension on opal borosilicate glassware imported from Mexico and distributed nationwide by Crisa Corp.

of Laredo, TX. The proposed legislation would permanently reduce the duty to 7.2% and temporarily suspend the duty entirely on opal borosilicate glassware imported in sets. Opal borosilicate glassware is sold exclusively door-to-door to low- to moderate-income consumers. At yearend, no action had been taken on the proposal.¹

The House Mining and Natural Resource Subcommittee, on June 23, 1987, held an oversight hearing on how well the Mining Law of 1872 serves the Nation and the mining industry. Sodium borate minerals, which are excluded from the Law, are included under the Mineral Leasing Act of 1920, as amended and supplemented.

⁴ Boron oxide (B₂O₃) content. In addition, borax imports from Turkey were 4,356 tons in 1987, 8,165 tons in 1988, and 7,257 tons in 1989.

ISSUES

Boron mining in the southwest desert areas could be adversely affected by the recent declaration of the Fish and Wildlife Service granting "emergency endangered status" for the Mojave desert tortoise.²

PRODUCTION

The majority of the boron production continued to be from Kern County, CA, and the rest was from San Bernardino County.

American Borate Co., a wholly owned subsidiary of Owens-Corning Fiberglas Corp., continued sales of ul-exite from storage at Dunn, CA.

Kerr-McGee Chemical Corp. operated the Trona and Westend plants at Searles Lake, in San Bernardino County, to produce refined sodium borate compounds and boric acid from the mineral-rich lake brines. At the Trona plant, a differential evaporative process produced borax with potash as a byproduct. Boric acid was produced by solvent extraction. The Westend plant continued production of sodium borates by a carbonation process. Brines used in the process were pumped to the Argus plant to produce sodium sulfate.

United States Borax & Chemical Corp., a part of RTZ Borax Ltd. of the RTZ Corp. PLC of London, United Kingdom, continued to be the primary world supplier of sodium borates. U.S. Borax mined and processed crude and refined sodium borates, their anhydrous derivatives, and anhydrous boric acid at Boron, in Kern County, CA.

A second plant at Boron used a proprietary process to produce technical-grade boric acid from U.S. Borax's extensive kernite ore reserves. The boric acid was produced to compete with imported colemanite used in glass manufacture. The majority of material was shipped to U.S. Borax's storage, Wilmington, CA. Products made at Wilmington included ammonium borates, potassium borates, sodium metaborates, and zinc borate.

During 1989, U.S. Borax signed a 15-year contract with Mojave Pipeline Company for 100% of the natural gas

used in the co-generation operations. The 386-mile pipeline is proposed from the Arizona-California border to Kern County.³

Corona Corp. purchased the remaining 20% interest held by Mountain States Mineral Enterprise Inc. in the Fort Cady colemanite property in California and renamed the project the Fort Cady Minerals Corp. This gave Corona 100% control of the project. Corona was in the process of negotiating with a number of commercial banks for \$85 million of production financing. The design production of 81,000 tons of boric acid per year was planned. The metric system is the official system of measurement of most countries. The Bureau of Mines, in an effort to provide statistical data on bromine in units most consistent with international usage, will henceforth report data in kilograms (kg) and metric tons (mt) unless otherwise noted. An engineering contract was awarded to Kilborn International Ltd. Canada. Plant construction was expected to be completed in 1992. Reserves were estimated at 147 million tons of ore grading 6.4% boron oxide.

CONSUMPTION AND USES

U.S. consumption of borates decreased. Glass fiber insulation and glass fiber primarily used as reinforcement for plastics continued to be the largest consuming industries.

The use of borates in glass fiber thermal insulation, primarily used in new construction, was the largest area of demand for borates, but decreased over that reported in 1988. Cellulosic insulation, the seventh largest area of demand, increased.

During 1989, PPG Industries Inc. sold its 50% interest in Fiberglas Canada for \$200 million to its partner Owens-Corning Fiberglas. Fiberglas Canada produced fiberglass mainly for insulation, but PPG's interest in the material was for use in plastic reinforcements and circuit boards. Fiberglas Canada had six plants near the Canadian border.⁴

The second major market for borates, manufacturing high-tensile-strength glass fiber materials for use in a range of products, showed a decrease in demand.

A fiberglass reinforced wheel utiliz-

ing a vinyl ester compound won an award in 1989 for the most innovative use of plastics. The award was given to Chrysler Motors Corp. by the Society of Plastics Engineers.⁵

The construction of the first glass-fiber, wide-band digital cable was across the Atlantic Ocean. The ocean cable can transmit more than 30,000 telephone calls and communication services at the same time. The cable stretches from Tuckerton, NJ, on the East Coast of the United States, some 6,000 kilometers across the Atlantic to Denmark, France, and Widemouth, England.⁶

Consumption of borates in borosilicate glasses remained the third major end use, and demand decreased. Boron added to glass reduced the viscosity of the melt and assisted with fiber formation during processing and allowed for thermal expansion.

After almost 16 years of research and design and 5 years of construction, the U.S. Department of Energy was close to finishing the Nation's largest and most technically complex nuclear-waste processing plant. The \$930 million Defense Waste Processing Facility at the Savannah River Plant in Aiken, SC, will convert high-level nuclear waste from weapons production into solid forms from a glass process used in France since 1978. The facility planned to immobilize 34 million gallons of highly radioactive liquid, sludge, and salt that have been accumulating in carbon steel storage tanks since 1954. An in situ salt treatment involves adding a boron compound to salt tanks to separate radioactive cesium. The waste cesium in a molten glass mixture is poured into a stainless steel canister 2 feet in diameter and 10 feet high.⁷ The canisters will be stored in a waste-storage building. Because of delays in the Nevada repository, a second storage building will be built at the Savannah River site.

Boron compounds in cleaning and bleaching were the fourth major end use. Oxygen systems may replace chlorine systems. In the oxygen system, activators produce acids in the wash water. These acids can react with sodium perborate to generate a bleach. Lever Bros. (USA) and Kao Corp. (Japan) are working with perborate activators that also generate softeners. Proctor & Gamble's Tide With Bleach

is the only major commercial U.S. detergent to use a boron activator system and is the first multifunctional detergent on the U.S. market.⁸ About 60 million pounds of perborates are consumed in detergent applications as compared with about 90 to 100 million pounds 20 years ago. Europe consumed about 1 billion pounds annually because of the higher temperature used in wash water.⁹

Boron compounds continued to find application in the manufacture of biological growth control chemicals for use in water treatment, algicide, fertilizers, herbicides, and insecticides. Boron can be applied as a spray, and incorporated in herbicides, fertilizers, and irrigation water.

Boron compounds were also used in metallurgical processes as fluxes, shielding slag in the nonferrous metallurgical industry, and components in electroplating baths. Small amounts of boron and ferrobore were constituents of certain nonferrous alloys and specialty steels, respectively. Steel containing less than 4.75% boron can be forged, and steels with up to 6% boron can be cast. An addition of boron to low-carbon steels reduces the amount of nickel, chromium, or molybdenum required. Boron-containing steels do not require some of the heat-treating steps required in other alloys, which results in significant energy savings. Boron can also be diffused into the surface of metal (boronizing) to make a corrosion- and abrasion-resistant metal.

Boron is used in neodymium-iron magnets to give a one-directional crystal structure that provides the magnet with one-directional strength. There are two basic methods for manufacturing NdFeB magnetic material: sintering and melt spinning.¹⁰

Allied Signal Inc. began production of a rapid-solidification amorphous metal ribbon, Metglas. The ribbon was produced at a site in Conway, SC, with capacity of 60,000 tons per year. Transformers made from Metglas, a boron, iron, rare-earth material, offer utilities energy savings of up to 70%.¹¹

Experiments by the Australian Defense Science and Technology Organization's Aeronautical Research Laboratories in Melbourne, Australia, have used boron fibers surrounded by an epoxy matrix to repair metal structures since about 1975. The material supplier is Textron Specialty Materials, formerly Avco

Specialty Materials, which has been supplying boron material for use on military aircraft, for 20 years. Annual sales are reported at about \$20 million worth of boron a year. The technique, originally developed for use on military aircraft, is being considered for repair of civil applications. Boron-epoxy patches are about five times stronger and six times stiffer than aluminum alloys. The patches can be applied in thinner layers to achieve the same amount of reinforcement, which is important on aerodynamic surfaces.¹²

Union Carbide Corp., Advanced Ceramics Division, Cleveland, OH, offered a titanium diboride powder for use in ceramic armor, cutting tools, bearings or bearing liners, and crucibles. The new compound can be sintered to more than 97.5% of theoretical density without pressure.¹³

Modern manufacturing techniques and higher volume production have lowered the cost of boron nitride. Hexagonal boron nitride is synthesized into low purity powder. Further processing via chemical or thermal techniques yields larger crystals of higher purity and greater stability. Hexagonal boron nitride powder is a raw material for producing cubic boron nitride. The powder is heated under pressure in the presence of a solvent and catalyst.¹⁴

¹Includes imports.

PRICES

Prices for domestic borax compounds and colemanite increased significantly. Industrial Minerals Magazine (London) reported Turkish colemanite c.i.f. to Europe was \$290 to \$325 per ton. Prices obtained often vary widely according to type, source, quality, quantity purchased, and application. Hence, the quotations can only serve as a guide to prices by producers and dealers. Boron compounds and ore were also sold under contracts negotiated between buyer and seller. Price quotations do not necessarily represent prices at which transactions actually occurred, nor do they represent bid and asked prices. They were quoted here only to serve as a guide to year-end price levels.

Prices for European borates published by Metal Bulletin 1989 per ton were as follows: Anhydrous borax \$1,000 to \$1,204; decahydrate borax, \$550 to \$762; pentahydrate borax, \$510 to \$846; and boric acid \$846 to \$1,354.

FOREIGN TRADE

The majority of material from the U.S. Borax facility in Boron, CA, was

³American Borates Co.

shipped to storage, loading, and shipping facilities at Wilmington, CA. A large part of the output was exported to Western Europe from Wilmington to Botlek, Netherlands.

Exports to the United States from Turkey for 1988, as reported by the Istanbul Minerals Exporter's Union, of boron material or minerals and value were as follows: Colemanite 97,000 tons, \$19 million; ulexite 11,000 tons, \$15 million; boric acid 24 tons, \$3,000; and refined borax 12,000 tons, \$3 million.¹⁵

WORLD REVIEW

Capacity

The data in table 7 are rated capacity for mines and refineries as of December 31, 1989. Rated capacity was defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that in the judgment of the author can be brought into production within a short period of time with minimum capital expenditure.

Any restrictions to capacity utilization related to legal, political, or environmental restraints have been footnoted.

Mine capacity for boron was based on rated capacity as reported by the company, by another Government agency, or another published source. Capacity outside of the United States was limited by the availability of loading and transportation equipment and market demand, rather than limitations of ore grade.

Argentina

Borax production exceeded 200,000 tons during 1988. Production at Boroquímica S.A.M I.C.A F., a subsidiary of RTZ Corp., at a tincal deposit at Tincalayu, north-central Salar del Hombre Muerto in Salta Province, was 30,000 tons of boron oxide equivalent.¹⁶ Industrial Químicas Baradero S.A. also had significant production. Installed processing capacity of 37,700 tons was at plants in Campo Quijano and Tincalayu, in the Province of Salta. Exports reached 26,500 tons in 1988.¹⁷

Boro Sur S.A. operated a boric acid plant in Buenos Aires Province approximately 25 kilometers from Buenos Aires. Production was reported as 120 tons monthly with a planned increase to 160 tons in the first quarter of 1990. Production of 300 tons per month was

planned by yearend 1990. The ore is colemanite from a mine in Salta Province.¹⁸

Bolivia

Lithium Corp. of America (Lithco) signed a preliminary agreement with the Ministry of Mines to explore and produce lithium and other elements from brines in the Salar de Uyuni. Under the same contract, Lithco was authorized to mine ulexite found within the salt crust and clay sediments bordering the river Rio Grande of Lipez.¹⁹

Chile

Jacobs Engineering Group Inc., CA, was awarded the feasibility study on the development of 30,000 tons per year of boric acid at the Salar de Atacama. The contract award was made by Sociedad Minera Salar de Atacama Ltda. (Minsal), a consortium of AMAX Exploration Inc. (63.75%), Corfo (25%), and Molibdenos y Metales (Molymet, 11.23%).

Commercial production from the \$300 million project was scheduled for mid-1992. The Salar de Atacama is one of about 74 arid salt basins in the Chile-Bolivia-Argentina border region. The salt nucleus covers more than 1400 square kilometers of which the top 40 meters is porous and filled with concentrated brine.

At capacity, the project will also produce 500 tons per year of potassium chloride, 230 tons of potassium sulfate, and up to 14 tons of lithium salts. The availability of more than 1 million tons per year of sulfuric acid from the Chiquicamat copper smelter will enhance the economic viability of the project.

Minsal products would be transported from the plant by rail to a ship bulk-loading dock at Jejillones. Containers of boron and lithium could be shipped from Antofagasta.

AMAX was developing a financial package and negotiating the use of debt-equity exchanges with the Government before deciding to proceed with the project.²⁰

Reserves are adequate for 30 years of production. The reserves contain about 47 million tons of potassium chloride equivalent, 117 million tons of lithium, and 4 million tons of boric acid equivalent. Brine products can be separated and recovered without further processing. Two sets of evaporation pans will

receive high potassium and high sulfate brine, respectively. Sequential precipitation will produce sodium chloride, mixed sodium, potassium chlorides, lithium, and sulfates in a variety of compounds. Boron will remain in solution until extraction before discharge back into the salt basin.²¹

Chile's National Geological and Mining Service studied a large deposit at Salar de Surire, Arica Province, northern Chile. Surveys of the area

revealed 34.5 million tons of ulexite ore bearing more than 4.5% boron. Brines containing lithium and potassium were also part of the deposit.

Minero del Boro had produced ulexite concentrates and boric acid since 1984. Deposits mined were Salar de Pintados, the Salar de Cariquima, and the Salar de Quillagua, in Tarapaca Province. The company had recently completed an expansion in capacity and further expansion was planned.²²

Quimica e Industrial del Borax Ltda. (Quiborax) had completed a \$3 million plant to treat 1,000 tons per month of ulexite to produce boric acid at Lluato. Mined production was from the Salar de Surire in Arica Province. Quiborax also owned the mineral rights to another ulexite deposit in the Salar de Ascotan, which is north of Salar de Surire.

China

The Ministry of Chemical Industry mines and processes minerals used as chemical feed-stocks, such as borates. The processing of boron as the mineral Szaibelyite in Lioning Province was estimated to be 100,000 metric tons per year. Many minerals of high unit-value, including boron, are of current or potential importance in world trade. China has a rich and varied mineral resource base and all the requisite conditions that tend to stimulate production and utilization of industrial minerals: a large, growing population, rapidly increasing living standards, an

expanding industrial base, a growing need for export earnings, facilities for rail and water transport, and abundant low-cost labor.²³

Netherlands

Botlek can receive 10 40,000-ton shipments per year from the United States. Bulk carriers unload over a 5-day period at the rate of 8,000 tons per day. European consumption of borates is about 350,000 tons per year. At Botlek, bulk products from U.S. Borax that are not required in bulk are packed into 50-kilogram bags or 1-ton "super-bags." Specialty products from Wilmington are usually repackaged into 25- or 50-kilogram paper bags which are then stretch-wrapped.²⁴

Peru

Production of ulexite used to produce boric acid was estimated at 2,000 tons of boron oxide equivalent.²⁵

Turkey

Turkey's boron operations are under the control of the Government corporation, Etibank, that mines boron from major deposits at Bigadic, Kirka, and Emet. Etibank operates refining facilities to produce refined sodium borates and boric acid from tincal concentrates at Bandirma. Boron minerals and compounds are shipped from the port of Bandirma on the Sea of Marmara and Izmir on the Aegean Sea.

Borate deposits are in two different zones in northeast-southwest-trending basins in Turkey. In the Bigadic district, borate minerals formed in two distinct lower and upper zones separated by thick volcanic beds. Colemanite and ulexite are predominant in both zones. Other borates, including howlite, probertite, and hydroboracite, are found in the lower borate zone; whereas inyoite, meyerhofferite, pandermite, terschite, hydroboracite, howlite, tunellite, and rivadavite are found in the upper borate zone. The average colemanite and ulexite ore grades are 30% and 20%, respectively.²⁶

United Kingdom

Borax Holdings Ltd. changed its name to Borax Consolidated Ltd. Borax Consolidated Ltd. was formed as an Anglo-American joint venture. Borax Consolidated purchased the remaining borax interest in 1913. The

Borax group joined RTZ Corp. PLC in a merger in 1968. The name change was to reflect the more active role of borax in the production and marketing.

Borax celebrated its 90th year of operation and was actively making improvements during 1989. Five small refining operations in Europe were merged into one large automated facility in Coudekerque, northern France. Capacity was expanded at the bulk terminal and depot in Botlek, near Rotterdam, Netherlands. New warehousing was brought into operation in Humberside, United Kingdom, and two new facilities in Valencia and Castellon, Spain, were scheduled to open in 1990.

Borax's European network now incorporates Borax Francais SA, Deutsche Borax GmbH, Compagnie des Borates SA, Borax NV, and La Productora de Borax y Articulos Quimicos SA.²⁷

CURRENT RESEARCH

Air Products and Chemicals Inc., under a Department of Energy, Office of Industrial Programs grant of \$366,000, was working to improve the process economics and energy efficiency of glass melting.²⁸

Chemists at Kyoto University, Japan, have developed new boron-containing polymers. Boron is a neutron absorber used in nuclear-shielding applications that could benefit from the new process. The research also included a description of the group's conversion of polyboranes to polyalcohols and polyketones.

In addition, a combination of organic boron compounds produced a polymer of steadily increasing molecular weight until the polymer gelled. A polymer of molecular weight of 24,000 was produced. Unlike pure boranes, which are explosive, the resins produced were completely stable in air. The polyborane resins could be decomposed to low-molecular-weight products by bubbling air through their solutions in organic solvent, thus making borane processing safe.²⁹

Chemists announced the preparation and characterization of the first example of boron-containing compounds named boratirenes. The compounds were prepared by the photochemical rearrangement of metal salts of a bo-

rate ion. The compound exhibits a yellow to orange color even in solution.³⁰

Boron-doped synthetic diamond layers is believed to be a very useful material for electronics. A process for the deposition of boron-doped semiconducting diamond by a depositional process was demonstrated by Case Western Reserve University. Natural diamond crystals containing small amounts of boron are generally blue. The famous Hope diamond is an outstanding example of this type of diamond. Boron is responsible for the color and the semiconducting properties. The properties of high-temperature stability, low dielectric constant, and high electrical-field breakdown voltage make doped diamond a good material for high frequency, high-power semiconducting devices. Research is continuing toward electronic applications of diamond technology.³¹

General Electric Co. developed a resin that can be produced in powder form and packed into a carbon or glass matrix that varies fabrication process time. The powder triggers a catalyst upon heating that causes the molten resin to harden. The process allows the resin to fill all voids, thus increasing the strength of the composite.³²

OUTLOOK

Production and consumption of boron minerals and compounds have decreased between 1980 and 1989. There

are several factors that may give to misleading outlooks in consumption. One is that production and imports reported in 1 year may be utilized over a period of years. In addition, environmental concerns may change the demand for boron significantly in a short period. The regulation of the use of fire retardants in products has resulted in changes in boron usage as a fire retardant.

Agriculture

Boron usage in agriculture declined to a low in 1982 and has declined during the last decade. The primary reason for the decline was attributed to the decrease in the number of operating farms during this period. Farming exports were showing increased strength, and demand for boron usage in agriculture was expected to increase 8% per year for the next 5 years.

Ceramics and Glass

Boron usage in ceramics and glass increased over the decade, reaching a peak in 1984 that was a 36% increase over the prior year. This spike was probably a demand to balance the sharp 41% decline in 1982. Ceramics and glass have both faced competition with polymers. Consumption was expected to continue to increase at the rate of 4% per year for the next 5 years.

Coatings and Plating

Boron usage has experienced a decline as a protective coating for steel products and as a glazing on ceramic tiles. This decline was a result of the demand for polymers that substituted for boron in

the coatings and platings. Demand was expected to remain at 1988 levels.

Fabricated Metal Products

Boron usage decreased in metal products during the last decade. Many traditional metals products that require soldering now are produced from polymers as one piece. Usage in specialized metal was expected to increase at the rate of 2% per year.

Soaps and Detergents

This usage has declined, primarily as chlorine bleaches and cold water washes have replaced boron soap powders. Recent concern for environmental effects of chlorine have reversed that decline. Perborate bleaches have returned to name brand soap products. The usage of boron in soaps and bleaches was expected to increase by 4% per year for the next 5 years.

BACKGROUND

Definitions, Grades, and Specifications

Few of the many minerals that contain boron are commercially valuable. Only colemanite and ulexite minerals, primarily imported from Turkey, are marketed in the United States. The boron oxide content of both minerals as marketed is usually in excess of 40%.

Tincal, kernite ore, and brines are the U.S. source of refined borate chem-

ical compounds. The most common refined borates, borax pentahydrate and its derivative anhydrous borax, are marketed in technical and agricultural grades. Lesser quantities of borax decahydrate are produced in technical, United States Pharmacopeia, and special quality grades. U.S. Borax discontinued the production of a "crude" borax pentahydrate for foreign customers, but began production of textile-fiberglass-grade (TFG) boric acid for domestic use.

Boric acid is a white, odorless, crystalline solid sold in technical national formulary and special quality grades as granules or powder. Boron oxide is a hard, brittle, colorless solid resembling glass that is ground and marketed most often under the name anhydrous boric acid.

Elemental boron is a dark-brown powder in the amorphous form and a yellowish-brown, hard, brittle solid in the monoclinic crystalline form. Boron is marketed in grades from 90% to 99% purity.

Ferroboration is a name given to a variety of boron-iron alloys, containing 0.2% to 24% boron, used primarily to introduce small quantities of boron into specialty steels.

The boron hydride series contains diborane, a gas; pentaborane, a liquid; and decaborane, a solid. These compounds range from 31,200 British thermal units (Btu) per pound for diborane to 27,850 Btu per pound for decaborane. Sodium borohydride is marketed

in powder or pellet form and in sodium hydroxide solution.

Boron nitride, a soft, white, highly refractory solid resembling graphite can withstand significant oxidation to temperatures up to 650° C. Boron nitride produced in fibrous form equals glass fibers in strength and modulus of elasticity, but is lighter in weight and more resistant to high temperature. When subjected to extremely high pressure and temperature, boron nitride forms cubic crystals that rival the hardness of diamond.

Boron carbide, produced by the reaction of carbon and boric acid, is a highly refractory material and one of the hardest substances known. Most commonly used for both abrasive and abrasion-resistant applications as well as nuclear shielding, boron carbide is marketed in technical and high-purity grades.

Byproducts and Coproducts

More than four-fifths of U.S. production comes from mineral deposits mined only for their boron content. The remainder is produced from lake brines, which also supply sodium carbonate, sodium sulfate, potassium sulfate, and potassium chloride. Turkish colemanite, ulexite, and tincal ores are worked only for their boron content. Most U.S.S.R. borates are also mined only for their boron content, but the Gulf of Kara-Bagaz-Gol and the Sivash (lagoon) borates are extracted with coproduct chloromagnesium from brines. South American boron has been mined from ores and also has been produced as a coproduct of nitrate and iodine production.

Economic Factors

Costs.—Energy costs are especially high for producing anhydrous products. The anhydrous products were originally introduced to decrease freight costs per ton of contained boron oxide. Both domestic producers now use cogeneration facilities to reduce the cost of energy for processing and supplying excess electricity for sale.

Depletion Provisions.—The domestic and foreign depletion allowances for boron are 14% of gross income, and may not exceed 50% of net income without the depletion deduction.

TABLE 9

BORON MINERALS OF COMMERCIAL IMPORTANCE¹

Mineral	Chemical composition	B ₂ O ₃ weight percent
Boracite (stassfurtite)	Mg ₆ B ₁₄ O ₂₆ Cl ₂	62.2

Operating Factors

Toxicity.—Naturally occurring boron compounds have relatively low toxicity for man and other mammals. Sodium borates, boric acid, and boron oxide are not present to any significant degree in air and are placed in the same hazard category as general dust. Ingestion in quantities greater than 20 grams by an adult can cause nausea and skin rashes.

In the 1950's, when the boranes (B_xH_y), a class of manufactured boron compounds, were undergoing research

as high-energy aircraft fuels, a few cases of acute poisoning through inhalation occurred in industrial workers. Boranes are highly toxic and produce severe irritation to the central nervous system. Boron trifluoride presents a hazard to workers.

Because small quantities of boron are essential for all plant life, it is added in trace levels to fertilizers; however, quantities well below concentrations affecting man and animals are so extremely toxic to vegetation that boron compounds are also used commercially as herbicides. Concentrated boric acid is used to control certain insects, and in dilute solutions as a preservative to control the growth of bacteria.

BROMINE

By Phyllis A. Lyday

Mrs. Lyday, a physical scientist with the Bureau of Mines, has been the commodity specialist for bromine for 11 years. Domestic survey data were prepared by Gail Mason, mineral data assistant; and international data tables were prepared by Peter Roetzel, international data assistant.

Of the 423 million kilograms of bromine produced worldwide in 1989, the United States produced 41%, followed by Israel, 28%; the U.S.S.R., 15%; the United Kingdom, 6%; and other countries, 10%. The metric system is the official system of measurement of most countries. The Bureau of Mines, in an effort to provide statistical data on bromine in units most consistent with international usage, will henceforth report data in kilograms (kg) and metric tons (mt) unless otherwise noted. The U.S. portion of world production has decreased steadily since 1973, when the United States produced 71% of the world supply. The decrease in world share has been a result of environmental constraints and the emergence of Israel as a major producer. The quantity of bromine sold or used in the United States was about 175 million kilograms valued at \$189 million. Exports of bromine compounds amounted to 29 million kilograms. The price of elemental bromine in bulk was 95 to 101 cents per kilogram. Primary uses of bromine compounds were in flame retardants, as a scavenger for lead in gasoline, and in oil and gas well fluids. International concern over the use of halons brought 44 countries together, including the United States, to agree on proposals to protect the Earth's ozone shield from destruction.

DOMESTIC DATA COVERAGE

Domestic production data for bromine was developed by the Bureau of Mines from a voluntary survey of U.S. operations. Of the six operations to which a survey request was sent, two responded, representing 47% of total elemental bromine sold or used. The

other operations were estimated by using quantity of brine produced and estimated bromine concentration.

LEGISLATION AND GOVERNMENT PROGRAMS

The Underground Injection Control (UIC) program was established under Part C of the Safe Drinking Water Act to protect underground sources of drinking water from endangerment by subsurface emplacement of fluids through wells.

The Environmental Protection Agency (EPA) was required to identify a list of States for which UIC programs may be necessary, to approve or disapprove programs submitted by the listed States, and to develop programs and regulate injection activities in States that do not have approved UIC programs.

Of the 57 States and jurisdictions identified, 35 have primary enforcement authority, or primacy, over all injection practices; 5 share primacy with EPA; and 17 have federally administered programs. In 1987, approximately 300,000 injection wells were regulated nationally by UIC

programs. Seventy-three percent of these wells are regulated by States with primacy programs. Arkansas reported 66 wells as Class V and Michigan reported 2,941.¹ A well used to reinject spent brine into the same formation from which it was drawn after production of bromine, is included as a Class V well (text table below).

The EPA incinerated all leftover stocks of the pesticide fumigant ethylene dibromide (EDB). The disposal included 328,000 gallons of EDB stored at various locations around the country.

In July, the first restrictions on the manufacture of fully halogenated chlorofluorocarbons (CFC) went into effect. Output of halons, which are fluorocarbons that can contain bromine, was to be limited in 1992 to 1986 levels. The EPA set up a quota system that allocates future production of the controlled chemicals based on each U.S. producer's share of the 1986 market for halons. Halons 1211, 1301, and 2402, which are used in fire extinguishers, are included in the quota system. New information identifies chlorine and bromine from CFC as primary factors in the seasonal loss of ozone at the South

INJECTION WELL CLASSIFICATION

Class I:	Wells used to inject hazardous wastes or dispose of industrial and municipal fluids beneath the lowermost Underground Sources of Drinking Water (USDW).
Class II:	Wells used to inject fluids associated with the production of oil and natural gas or fluids/compounds used for enhanced hydrocarbon recovery. These wells normally inject below the lowermost USDW except in cases where the USDW is hydrocarbon producing.
Class III:	Wells that inject fluids for the extraction of minerals.
Class IV:	Wells that dispose of hazardous or radioactive wastes into or above a USDW (BANNED).
Class V:	Wells not included in other classes generally inject nonhazardous fluid into or above a USDW.

If a well does not fit into one of the first four Classes and meets the definition of an injection well, it is considered a Class V well. It should be noted that not all Class V wells are used for disposal. Examples of Class V practices which are not disposal related include: Aquifer Recharge, Fossil Fuel Recovery, and Mineral Recovery.

³ Bureau of the Census.

⁴ Bureau of the Census. Includes methyl bromine and ethylene dibromide.

Pole known as the Antarctic "ozone hole." The fate of halon is uncertain, although the output of halons is small compared with CFC.²

At yearend, a law was passed to raise \$5.6 billion in new revenues for fiscal 1990, including \$489 million from taxes on five chlorofluorocarbons and three halons, namely, halons 1201, 1301, and 2402. The tax rates are based on the potential for depleting the ozone layer, compared with halon 1100, fluoromethane.³

The EPA amended the regulations for hazardous waste management under the Resource Conservation and Recovery Act for methyl bromide. Two wastes generated during the production of methyl bromide were also listed. The regulation would become effective on April 6, 1990.⁴

The U.S. Department of Agriculture was granted a Section 18 exemption by the EPA for methyl bromide used in pest control on imported chayotes, melons, and plantains. The exemption expires on April 17, 1992. The EPA stated that long-term toxicity data were being developed for methyl bromide and future exemption requests will depend upon the outcome of these studies.⁵

A relabeling of the bromine compound, Bromoxynil, produced by Rhône-Poulenc Inc. was approved by the EPA. Rhône voluntarily canceled and recalled the formulation because of high skin absorbent rate. New labeling would be required on all Bromoxynil containers.⁶

The EPA sought to limit the land disposal of certain hazardous wastes listed in 40 Code of Federal Regulations (CFR) 268.12. Seven hydrocarbon wastes containing bromine were included.⁷

The Interagency Testing Committee, a consortium of 15 Federal agencies, issued a report adding 13 chemicals to the list of substances under the Toxic Substances Control Act. These should be given priority consideration to promulgating test rules. The additions to the list included several bromine compounds.⁸

The Department of Health and Human Services performed toxicology and carcinogen studies on rats using tribromomethane, a chemical intermediate and solvent. Under the 2-year studies, there was some evidence of carcinogenic activity.⁹

On January 19, 1989, the Occupational Safety and Health Administration published amendments to its Air

Contaminants Standard, 29 CFR 1910.1000. The new standard includes a new Table Z-1-A to replace the Permissible Exposure Limits. An index alphabetically lists the 428 substances discussed. Bromine and several bromine compounds were included.¹⁰

Ethylene dibromide and dibromochloropropane were 2 of 17 pesticides and 21 other compounds added to the EPA drinking water contaminants list. The proposal to regulate drinking water contaminants was authorized by the 1986 amendments to the Safe Drinking Water Act, which was originally passed by Congress in 1974. The EPA standards generally apply to any water-supply system serving more than 25 people.¹¹

STRATEGIC CONSIDERATIONS

Firefighters and safety engineers in Alaska were alarmed that halons may be banned by Congress. Halons were used to suppress explosions and extinguish fires at the eight pipeline pumping stations. Automatic halon systems installed at wells throughout Alaska's massive North Slope can extinguish fires in a fraction of a second.¹²

Allied-Signal Inc. reported that the U.S. Navy began substituting a fluoride compound in discharge testing of halon systems installed on approximately 275 ships. Although the compound is not a fire-extinguishing agent, it is a practical alternative for reducing halon emissions during testing of the system. Another 150 ships planned to install similar halon systems.¹³

PRODUCTION

Ethyl Corp. and Great Lakes Chemical Corp. produced and marketed bromine chemicals from plants in Arkansas. Small amounts of unpurified bromine were produced as a byproduct of magnesium production in Michigan. The Arkansas plants accounted for about 97% of U.S. elemental bromine capacity at yearend 1989 and 100% of bromine sold or used. Elemental bromine plant capacity did not reflect production capacity, which was dependent upon brine sup-

plies, concentration of the bromine in the brine, and individual plant extraction processes. In Arkansas, one supply and one disposal well were required for each 4.5 million kilograms per year of bromine produced.

Bromine concentrations in the brine decrease as waste brine depleted of bromine is returned to its source. New wells must be drilled to provide adequate reserves to insure future demands of elemental bromine. Each supply well requires an investment in excess of \$1 million and has an average life of about 10 to 15 years.

During 1989, the Arkansas Oil and Gas Commission reported that 63 bromine producing wells were in operation. A small amount of bromine produced as a byproduct of wells in Michigan was not of commercial quality and was reprocessed before consumption.

CONSUMPTION AND USES

The U.S. International Trade Commission (ITC) publication "Synthetic Organic Chemicals, 1988" reported that the Dyes & Pigments Div. of Mobay Chemical Corp. produced Pigment Red 168, dibromoanthranthrone orange. Red 168 was used in automotive metallic applications because of its transparency.

Demand for EDB, primarily as a

gasoline additive, was about 18% of total consumption. The ITC's "Synthetic Organic Chemicals, 1988" listed Great Lakes and Ethyl as the only producers of EDB used in gasoline additives during 1988.

Ethyl reported that 70% of the production of sodium bromide is produced from virgin bromine and hydrogen. The remaining 30% is produced as a coproduct from a new purification system completed in 1988 to recycle bromine.

Unusual circumstances occurred during 1987 and 1988 that affected the company's ability to enter large volume contracts with service companies for the sale of clear brine fluids, including sodium bromide. In 1987, Ethyl signed a consent decree with the Department of Justice requiring a large volume of inorganic bromides to be placed in reserve to supply Tetra Chlor Inc., a subsidiary of Tetra Technologies Inc.¹⁴

Fire retardants were estimated to be about 30% of consumption, primarily as tetrabromobisphenol-A and decabromodiphenyl oxide. About 25% of bromine consumption was in clear brine drilling fluids used in work-over and completion fluids. Agricultural uses, primarily as methyl bromide, were about 15% of consumption, principally as methyl bromide used as a soil fumigant. Bromine was also used in water treatment as a slime and biocidal control product and other uses accounted for an estimated 15% of consumption.

¹ Actual production capacity is limited by brine availability.

² Bromine produced at this plant is reprocessed in Arkansas.

³ Data do not add to total shown because of independent rounding.

PRICES

Bromine was sold under contracts negotiated between buyer and seller. Price quotations do not necessarily represent prices at which transactions actually occurred, nor do they represent bid and asked prices. They were quoted here to serve only as a guide to yearend price levels.

FOREIGN TRADE

In October, the ITC held a hearing concerning the withdrawal of the generalized system of preferences for imports of sodium bromide from Israel. Israel received duty-free treatment on its bromine products in all major world markets except the United States where duties are paid on three significant bromine products.

WORLD REVIEW

A 3-day conference titled "Saving the Ozone Layer" was held in London during March. The basis for the concern was CFC's and halons that are attributed to depletion of the ozone layer in

Product	Value per pound (cents)	Value per kilogram (cents)
Ammonium bromide, National Formulary (N.F.), granular, drums, carlots, truckloads, free on board (f.o.b.) works	131	289

the stratosphere. Another meeting was held in Helsinki in May of the 44 countries that signed the Montreal protocol. The Montreal protocol that went into effect January 1, requires that production of CFC's be reduced to

50% of 1986 levels by mid-1990 and that halon output be limited to 1986 levels. There was support of an agreement to eliminate CFC's by the year 2000. There was disagreement concerning the fate of essential uses of halon.¹⁵

³ Reported figure.

⁴ Sold or used by producers.

Capacity

The data in table 4 are rated capacity for mines and refineries as of December 31, 1989. Rated capacity is the maximum quantity of product that can be produced in a period based on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period with minimum capital expenditure.

Mine capacity for bromine is based on rated capacity as reported by the company, by another Government agency, or another published source.

France

Mines de Potasse d'Alsace, Mulhouse, a producer of bromine from the bitterns of potash production, resumed

production following a strike that lasted a month. The workers feared the collapse of international potash prices would lead to closure of the mines.¹⁶

Israel

Israeli Chemicals Ltd. (ICL) controlled 25 active subsidiaries, including 89% of Dead Sea Bromine, the second largest producer of bromine and bromine compounds in the world. A decision to sell a 50% portion of ICL, the Government's wholly owned subsidiary, was under consideration. The sale was to be handled by First Boston, an investment bank.

U.S.S.R.

The U.S.S.R. took the position, during the Helsinki meeting of May 1988, concerning the Montreal protocol, that all halon uses are essential. There was agreement of the need to eliminate CFCs by the year 2000.¹⁷

United Kingdom

Great Lakes completed a purchase of 52% of Ocel Associates and its operating company, The Associated Ocel Co., Ltd., for \$180 million. The shares were purchased from BP Petroleum Development Ltd., Texaco Oil Co., and Mobil Oil Corp. with 36.5%, 10.65%, and 5.3%, respectively. The acquisition gave Great Lakes more than 30% of the global bromine compounds market. Ocel was the largest producer of tetraethyl lead in the world. Total sales in 1988 were \$400 million. Shell Oil Co. and Chevron Oil Co. retain 36.7% and 10.65%, respectively, in the company.¹⁸ Ocel Associates, headquartered in London, employed approximately 3,000 people throughout Europe. Directly or through affiliated companies, Ocel had interest in manufacturing plants in France, the Federal Republic of Germany, Italy, and the United Kingdom. Ocel sold its products to about 270 refineries in over 90 countries worldwide.

Ethyl established a sales office in Bracknell, Berkshire, at Ethyl Petroleum Additives Ltd. The office provided sales of industrial chemicals and bromine chemicals sold in the United Kingdom, including "Saytech" brand flame retardants and bromine derivative chemicals.¹⁹

CURRENT RESEARCH

Tetra Technologies Inc., Woodlands, TX, purchased the clear brine fluids portion of Dow Chemicals Co. in 1988. Tetra, a diversified chemicals and waste management company founded in 1981, obtained funding from such sources as T. Rowe Price and the Environmental Fund.²⁰ During 1989, Tetra was examining the possibility of selectively precipitating a zinc hydroxide from a heavy metal waste stream. If the process is successful, the zinc hydroxide could be used to produce zinc bromide for use in Tetra's oil well brine fluids business.²¹

OUTLOOK

Sales of bromine, primarily in compounds, has increased about 23% since 1969. This represents an annual rate of increase of about 1.1% per year. These increases have been attributed to increased use of bromine in fire retardants, sanitizers, and well-drilling fluids. Bromine is expected to increase in demand at the same 1.1% rate through the next 5 years. Demand as a fire retardant will offset any decreases in petroleum. Bromine usage in well-drilling fluids was expected to remain depressed.

Petroleum

Demand for bromine as a gasoline additive has declined each year since the EPA issued regulations in the 1970's to reduce the lead in gasoline. Bromine in the form of ethylene dibromide is used as a "scavenger" for the lead to keep the lead from depositing in the engine. In 1979, the amount of bromine sold reached a peak of 225 million kilograms. The rapid decline to 141 million kilograms in 1986 was a direct result of the limits on lead in leaded gasoline. The European Economic Community continued discussions to reduce lead levels in gasoline.

Sanitary Preparations

Bromine has found usage in swimming pools, hot tubs, and whirlpools. The sanitary preparation field is an area where bromine has been found to be safer than its substitutes. The use of

bromine will continue to grow in this area closely following the gross national product in real growth.

Fire Retardants

Federal regulations covering flammability of private and public building materials and furnishings have required greater amounts of fire retardant chemicals to be used in these materials and furnishings. The costs and/or benefits of fire retardants versus environmental hazards in the United States is expected to grow as organic materials replace metals in transportation, infrastructure, and packaging. Several State governments continue to support strong consumer laws that protect State resi-

dents from hazardous products produced in other States.

Other

Usage of calcium bromide and zinc bromide in well-drilling fluids decreased during the 1980's as the domestic petroleum industry suffered a severe recession. Federal laws enacted to encourage alternative forms of power in automotive engines are likely to have a depressive effect on increases in petroleum demand. Senate bill 1630, the Clean Air Act, has an amendment that will require mobile sources, such as cars and trucks, to use the most effective technology possible to control toxicants.

BACKGROUND

Definition, Grades, and Specifications

In the elemental form, bromine is a very dark, reddish-brown liquid. Bromine is the only nonmetallic element that is liquid at ordinary temperature and pressure. The natural form of bromine is a solution of sodium bromide in natural brines, saline deposits, salt lakes and seas, and oceans.

Elemental bromine was marketed in a "purified" grade. Specification for this grade are as follows: specific gravity not less than 3.1 at 10° C to 20° C; bromine, not less than 99.7%; iodine, none; and chlorine, not more than 0.1%

Specifications for the various grades of bromine compounds include technical bromine, 99.5% pure, with the chief impurities consisting of chlorine, traces of moisture, and organic matter. Specifications of the United States Pharmacopoeia and the American Chemical Society Committee on Analytical Reagents allow 0.3% chlorine, 0.05% iodine, 0.0002% sulfur (0.006% as sulfate), and no more organic matter in 1 milliliter than will saturate 50 milliliters of 5% sodium hydroxide solution. The term "chemically pure" signifies a minimum of impurities.

Geology-Resources

Bromine is widely distributed in the Earth's crust, but in small quantities. By far the largest potential source of bromine in the world exists in the oceans. At a concentration of only 65 parts per million, an enormous amount of water must be processed to obtain the bromine.

Arkansas brines contained about 5,000 parts per million at depths of 7,500 feet in limestone of the Smackover Formation of Jurassic age. In Michigan, brines containing about 2,600 parts per million of bromine occur in the Sylvania Sandstone Formation of the Detroit River Group of Devonian age.

In Israel, bromine was produced as a byproduct of salt, sodium chloride, and potash production. The waste brines contain 14,000 parts per million bromine.

Technology

The Arkansas Geological Commission reported three east-west bromine-rich brine fields. Wells are drilled down to the brine level and a submersible pump was lowered to pump the liquid to the surface. Brine is separated by gravity from any residual gas at the surface and was pumped to one of six processing facilities.

At the processing facility, bromine was separated from the brine by a steaming-out process. The brine was pumped into the top of a tower constructed of granite that was filled with ceramic packing. As the brine falls through the packing material, it reacts with chlorine and steam that were injected at the bottom of the tower. One pound of chlorine is required to yield 1 kilogram of bromine. About 95% of

the bromine, or about 0.7 to 0.8 kilograms of bromine per barrel of brine, is recovered if the raw brine was first acidified to a pH of 3.5. The chlorine replaces the bromine in the brine and the gaseous bromine rises with the steam out of the top of the tower; there it was condensed to a reddish-brown liquid. Bromine was separated from gases because it is heavy and can be tapped out of the bottom. The bromine liquid can be further purified or reacted with other materials to form bromine compounds. Bromine vapor, a little chlorine, and water vapor are captured at the top of the tower. Hot bromine-free liquor emerges from the bottom of the tower. After neutralizing with lime, the waste liquor was pumped through a heat exchanger to a waste pond. Brine from the pond was reinjected into the same producing zone to maintain hydrostatic pressure.

Seawater contains about 60 to 70 parts per million (ppm) of bromine as sodium bromide or magnesium bromide. Production of bromine from seawater uses the blowing-out process. Raw seawater is acidified by adding sulfuric acid and then chlorine. Air was drawn into the base of the tower and passes countercurrent to the descending brine. Air containing bromine passes to the absorption tower. In the absorption tower, bromine reacts with sulfur dioxide to form a hydrogen bromide. The bromine is separated by adding acid to the solution and is distilled by steam. The gaseous bromine was condensed, separated, and purified.

Economic Factors

Cost.—Chlorine is the largest cost factor, representing about 30% of the manufacturing cost of bromine. Other cost factors include brine (22%), operating cost (15%), utilities (14%), overhead (12%), and other (7%).

Taxes.—During 1989, brines produced in Arkansas required the payment of \$2 per 1,000 barrels in severance taxes and capital equipment was subject to the payment of property taxes. Bromine produced in the United States was subject to Superfund taxes of \$4.45 per ton. Bromine was manufactured using chlorine, which was also subject to a Superfund tax of \$2.70 per ton of chlorine.

^cEstimated.

Depletion Provisions.—Bromine producers (domestic and foreign) are granted a 5% depletion allowance under the Federal Income Tax Law on the value of bromine produced from brine wells. The depletion allowance can be calculated by the actual cost method.

Operating Factors

Environmental Requirements.—Some bromine-bearing brines contain hydrogen sulfide gas. This gas has a disagreeable odor, is highly toxic, and when burned, will oxidize to sulfur dioxide, an acid-producing gas. Hydrogen sulfide gas is chemically removed from the incoming brine and converted into elemental sulfur or other nontoxic sulfur-containing compounds.

Toxicity.—Bromine is highly toxic and corrosive and must not be allowed to escape into the atmosphere. Many bromine compounds are also poisonous or irritating and must be packaged in leak-proof containers to avoid per-

sonal injury. If bromine is spilled on paper, rags, wood shaving, etc., it will generate considerable heat, which may lead to spontaneous combustion. Bromine will react with living tissue and must be removed immediately to avoid serious injury.

Bromine vapors are hazardous to the eyes and lungs. Any concentration above 1 ppm in the air for an 8-hour exposure is considered a health hazard. Bromine can be detected by its odor even at this level. Exposure to concentrations of 500 to 1,000 ppm for as little as one-half hour is lethal. The Occupational Safety and Health Administration regulates the working conditions of bromine plants.

When handling bromine, a person should use safety goggles, face shield, rubber gloves, rubber boots, and under some conditions, a self-contained breathing apparatus. Bromine spills can be neutralized with a solution of sodium thiosulfate. Gaseous bromine may be neutralized with controlled amounts of gaseous ammonia. All metal, such as electrical switches and connections, that may be exposed to bromine vapors should be made of corrosion-resistant materials and/or completely sealed from contact with the room air.

Employment.—The U.S. chemical industry employs directly an average of 20 personnel for each \$1 million of sales. These employees are working in

production, packaging, transportation, marketing, product and process development, quality control, and administration. More than two-thirds of these jobs are concentrated in Union and Columbia Counties of south Arkansas.

Energy Requirements.—The manufacturing cost of bromine is heavily dependent on chlorine and brine cost. Of the total brine cost, 46% is power related and 53% is maintenance cost. Brine cost is dependent on well maintenance cost and energy cost associated with well pumping. Approximately 14% of the bromine manufacturing cost is energy related.

CADMIUM

By Thomas O. Llewellyn

Mr. Llewellyn is a physical scientist with the Branch of Nonferrous Metals. He has covered cadmium for 3 years. Domestic survey data were prepared by Lura Nightlinger, Nonferrous Metals Data Section. International data were prepared by Giovanni Jacarepaqua, International Data Section.

Domestic production of cadmium metal decreased in 1989. Four companies operating four plants produced all of the domestic cadmium. Imports for consumption of cadmium metal increased, but exports decreased significantly compared to the level of 1988. The New York dealer-price range of cadmium metal, at \$8.45 to \$8.65 per pound at the beginning of the year, declined to \$5.25 to \$5.35 per pound by yearend.

LEGISLATION AND GOVERNMENT PROGRAMS

The Agency for Toxic Substances and Disease Registry published a final version of "Toxicological Profile for Cadmium," required under section 110 of the Superfund Amendments and Reauthorization Act of 1986 (Public Law 99-499).¹

In October 1989, the Environmental Protection Agency (EPA) denied a petition submitted by SCM Chemicals Inc. requesting removal of cadmium sulfide (CdS) and cadmium selenide (CdSe) from the list of toxic chemicals under 313 of the Emergency Planning and Community Right-To-Know Act of 1986. SCM contended that CdS and CdSe were not toxic and did not meet the section 313 criteria for listing; however, EPA's decision was based on available cancer data on CdS and other cadmium compounds.²

STRATEGIC CONSIDERATIONS

Cadmium was included in the National Defense Stockpile (NDS) because of its importance in specialized military applications such as plating where substitutes may be in short supply or unsatisfactory.

The NDS goal for cadmium metal was at 5,307 metric tons, unchanged since 1980. At the end of 1989, the NDS cadmium inventory was 2,871 tons.

DOMESTIC PRODUCTION

Primary cadmium was produced by ASARCO Incorporated, Denver, CO; Big River Zinc Corp., Sauget, IL; Jersey Minière Zinc Co., Clarksville, TN; and Zinc Corp. of America, Bartlesville, OK.

CONSUMPTION AND USES

In 1989, nickel-cadmium batteries were the principal market for cadmium, surpassing both coating and plating application, for the second consecutive year. Based on production, trade, and stock data, the apparent domestic consumption of cadmium in 1989 was higher

than two and one-half times the price range quoted at the beginning of 1988. The range of cadmium metal prices followed a steep downtrend and by the end of August were quoted at \$3.40 to \$3.80 per pound. The price decline was attributed to slower growth of the nickel-cadmium battery industry, particularly in Japan. However, the U.S. cadmium price market improved during September and by the end of the month the price range was \$5.95 to \$6.25 per pound. The prices for cadmium metal during the last quarter of 1989 trended downward and closed the year in the range of \$5.25 to \$5.35 per pound.

FOREIGN TRADE

Exports of cadmium metal and cadmium in alloys, dross, flue dust, residues, and scrap decreased considerably from those of 1988, but imports of cadmium metal increased in 1989.

The Bureau of the Census reported that the United States imported 137 million nickel-cadmium batteries in 1989. Japan, Hong Kong, and Mexico supplied approximately 92% of the total battery imports.

Under the new Harmonized Tariff Schedule of the United States, which was in effect January 1, 1989, cadmium sulfide and pigments and preparations based on cadmium compounds from most favored nations (MFN) were subject to a 3.1% ad valorem duty; for non-MFN a 25% ad valorem duty was retained. Imports of unwrought cadmium, waste and scrap, and powders, were duty free for MFN, whereas a statutory duty of 33 cents per kilogram was imposed on these materials for non-MFN.

WORLD REVIEW

Industry Structure

In 1989, the U.S.S.R. was thought to be the largest producer of refined cadmium, followed by Japan, Belgium, Canada, the United States, Mexico, the Federal Republic of Germany, and Australia. These eight countries accounted for an estimated 67% of the world's refined cadmium production. Because cadmium is recovered mainly as a byproduct of zinc ore processing, many producers of zinc and zinc compounds produce primary cadmium as an integral part of their operation. Cadmium is also recovered from flue dust generated at lead and copper smelters, and at steelmaking mini-mills; however, the amount of production from these sources is not known.

Capacity

The data in table 7 represent rated annual production capacity for mines and refineries on December 31, 1989. Rated capacity was defined as the maximum quantity that could be produced on a normally sustainable long-term operating rate, based on the physical

equipment of the plant and routine operating procedures for labor, energy, materials, and maintenance. Capacity included both operating plants and plants temporarily closed that, in the judgment of the author, could be brought into production within a short period of time with minimum capital expenditure.

Cadmium is principally a byproduct of zinc production. Therefore, cadmium mine capacity was estimated based on zinc mine capacity, and cadmium refinery was estimated based on rated zinc refinery capacity, discussions with officials from private industry, past and present production rates, and published capacity data.

Reserves

Cadmium reserves were obtained by applying an average recovery factor of 0.36% to zinc reserve data. On this basis, the domestic reserves of cadmium were estimated at 72,000 tons. Total world reserves were estimated to be about 530,000 tons. The world's largest reserves of cadmium were located in the United States and Canada.

France

Société d' Accumulateurs Fixés et de Traction (SAFT) of France bought from SAB-NIFE, a Swedish battery company, the rights to use its technology for recycling industrial wastes and

discarded nickel-cadmium batteries. SAFT installed a recycling plant at its Nersac facility, near Angoulême, France. The plant capacity for cadmium recovery was rated at about 300 metric tons per year.³

Japan

Sanyo Electric Co. Ltd. planned construction and installation of a new nickel-cadmium sealed battery plant at Kokushima, Japan, during 1990. The plant's designed production capacity of 10 million batteries per month will increase Sanyo's production to 40 million sealed batteries from the current 30 million units per month.

CURRENT RESEARCH

The Cadmium Association, England; Cadmium Council Inc., New York; and the International Lead Zinc Research Organization Inc., North Carolina, held the Sixth International Cadmium Conference in Paris, France, April 19-21, 1989. Major topics of

¹ This table gives unwrought production from ores, concentrates, flue dusts, and other materials of both domestic and imported origin. Sources generally do not indicate if secondary metal (recovered from scrap) is included or not; where known, this has been indicated by a footnote. Data derived in part from World Metal Statistics (published by World Bureau of Metal Statistics, Ware, United Kingdom) and from Metal Statistics (published by Metallgesellschaft Aktiengesellschaft, Frankfurt am Main, Federal Republic of Germany). Cadmium is found in ores, concentrates, and/or flue dusts in several other countries, but these materials are exported for treatment elsewhere to recover cadmium metal; therefore, such output is not reported in this table to avoid double counting. Table includes data available through Mar. 30, 1990.

² Includes secondary.³ Reported figure.

discussion covered various aspects of cadmium applications technology. Papers were presented in five categories: Regulating Cadmium; New Technologies and Markets—the Essential Uses of Cadmium; Health Effects I—Cadmium and the Kidney; Health Effects II—Cadmium and Cancer; and Controlling Cadmium in the Environ-

ment. Sponsoring organizations expected to have the conference proceedings published by mid-1990.

Developments in cadmium technology during the year were abstracted in Cadscan, a quarterly publication available through the Cadmium Association, 34 Berkeley Square, London, W1X 6AJ, England.

OUTLOOK

Most uses of cadmium are dissipative, therefore little scrap is generated. Exceptions are scrap generated during the recycling of some cadmium bearing alloys and storage batteries. Currently, cadmium is recovered from waste batteries in Sweden, France, Japan, and the Republic of Korea. In the next 3 to 5 years, recycling of nickel-cadmium batteries was expected to become an integral part of many battery manufacturing industries in Europe and North America, because of environmental and economic reasons.

The short-term demand for cadmium in the United States was expected to fall marginally below the level of 1989. This decline was expected to be the result of continuing lower demand for cadmium in coating and plating, pigments, and plastics and synthetic products during the next 2 to 5 years. There was a strong possibility that the world demand for primary cadmium will follow the same trend, for the reasons mentioned above and also due to slower growth of the nickel-cadmium battery industry.

CALCIUM AND CALCIUM COMPOUNDS

By M. Michael Miller

Mr. Miller, a physical scientist with 12 years of minerals experience with the Department of the Interior, has been the commodity specialist for calcium and calcium compounds since 1989. Domestic survey data were prepared by Joseph C. Daniels, mineral data assistant.

In 1960, an International System of Units was adopted by the 11th General Conference of Weights and Measures. This system is called the MKS system or metric system, and most countries of the world have adopted it as their official system of measurement. The Bureau of Mines, in an effort to provide statistical data on calcium and calcium compounds in units most consistent with international usage, will henceforth report data in kilograms (kg) and metric tons (mt) unless otherwise noted.

Calcium, the fifth most abundant element in the Earth's crust, is chemically very active and is found in a host of minerals that occur in nearly every geologic environment. The Bureau of Mines publishes reports for a variety of calcium-containing minerals and compounds because of their commercial significance and contribution to the quality of human life. Calcium fluoride is sold as fluorspar; calcium sulfate as gypsum or anhydrite; calcium oxide and hydroxide as lime; calcium phosphate as phosphate rock; and calcium carbonate as either limestone, marble, calcareous marl, or shell. Information on these commodities can be obtained in the Bureau of Mines Minerals Yearbooks reports entitled "Fluorspar," "Gypsum," "Lime," "Phosphate Rock," "Crushed Stone," and "Dimension Stone." Other calcium compounds are discussed in the Yearbook reports concerning the element with which calcium is combined; for example, calcium bromide is covered in the "Bromine" report in the Minerals Yearbook. This "Calcium and Calcium Compounds" Minerals Yearbook report includes calcium metal, calcium chloride, and various other calcium compounds not covered elsewhere.

DOMESTIC DATA COVERAGE

The Bureau of Mines develops domestic production data for calcium chloride from a voluntary survey of U.S. operations entitled "Calcium Chloride and Calcium-Magnesium Chloride." Of the 10 operations polled, 9 responded, representing less than 35% of the total production shown in table 1. Production for the nonrespondent was estimated using published plant capacity and contacts within the industry.

STRATEGIC CONSIDERATIONS

Calcium metal was used to reduce uranium dioxide, a fuel in some types of fission reactors. The nuclear applications of calcium metal gave it strategic significance; the U.S. Department of State would not permit sales to countries not signatory to the United Nations Nuclear Nonproliferation Treaty.

PRODUCTION

Pfizer Inc. produced calcium metal at Canaan, CT, by the Pidgeon process, in which high-purity calcium oxide (produced by calcining limestone) and aluminum powder are compacted into briquets and heated in vacuum retorts. The vaporized calcium metal product collects as a "crown" in a water-cooled condenser.

Pfizer produced commercial-grade 98.5% calcium in eight shapes and high-purity redistilled 99.2% metal in

three shapes; other shapes were available on request. They produced an 80%-20% calcium-magnesium alloy, a pure calcium wire used in the steel industry to modify inclusions, and a 73%-27% calcium-aluminum alloy or unalloyed calcium-aluminum briquet. Elkem Metals Co., a Norwegian-owned company with headquarters in Pittsburgh, PA, produced a calcium-silicon-barium-aluminum alloy at its plant in Niagara Falls, NY, and imported several other calcium alloys.

Michigan was the leading State in natural calcium chloride production; California was a distant second. The Dow Chemical Co. and Wilkinson Chemical Corp. recovered calcium chloride from brines in Mason and Lapeer Counties, MI. Dow's Ludington plant produced calcium chloride pellets and flake; Wilkinson marketed calcium chloride solutions only. National Chloride Co. of America, Cargill's Leslie Salt Co., and Hill Brothers Chemical Co. produced calcium chloride from dry-lake brine wells in San Bernardino County, CA. Hill Brothers Chemical also produced from a second operation near Cadiz Lake, CA.

Allied Signal Inc. recovered synthetic calcium chloride as a byproduct at its Baton Rouge, LA, plant using hydrochloric acid and limestone. Texas United Chemical Corp. produced synthetic calcium chloride for 2 months in 1989 from purchased hydrochloric acid and limestone at its plant near Lake Charles, LA. This plant was sold to the Tetra Chemicals Division of Tetra Technologies, Inc. on February 28, 1989. Tetra Chemicals produced calcium chloride from this plant and their liquids plant at Norco, LA. Occidental Chemical Corp. manufactured calcium chloride at Tacoma, WA, using limestone and hy-

drochloric acid.

Precipitated calcium carbonate (PCC) was produced by Pfizer Inc. at its lime plant in Adams, MA, and at 10 satellite plants for use at adjacent paper mills. Mississippi Lime Co. produced PCC at a facility adjoining its lime plant in Ste. Genevieve, MO. Continental Lime Inc. produced PCC at Tacoma, WA. In late 1989, Continental Lime Ltd., parent of Continental Lime Inc., sold the assets and technology for PCC production to Georgia Kaolin Co. They have been reorganized under a new company called GK Carbonate.

Calcium hypochlorite was produced by Olin Corp. at Charleston, TN, and PPG Industries Inc. at Natrium, WV. Sales were flat in 1989 due to a rainy summer. Total domestic calcium hypochlorite capacity was 96,600 mt.

was to melt snow and ice from roads. Calcium chloride was also used to control dust, to stabilize road bases, to thaw coal and other bulk materials, in oil and gas drilling, for concrete-set acceleration, as tire ballasting, and in miscellaneous other uses. Calcium chloride when used for deicing is more effective at lower temperatures than rock salt and was used mainly in the Northern and Eastern States. Because of its considerably higher price, it was used in conjunction with rock salt for maximum effectiveness and economy.

Precipitated calcium carbonate was used as a pigment for brightness and opaqueness in premium-quality coated papers and as a filler in uncoated papers. In coated paper, PCC was used in the coating to improve paper brightness and print clarity. In uncoated papers, it

bactericide, deodorant, water purifier, disinfectant, fungicide, and bleaching agent.

Calcium nitrate was used as a concrete additive to inhibit corrosion of steel reinforcement bars, accelerate setting time, and enhance strength.

Calcium carbide and calcium-silicon alloy were used to remove sulfur from molten pig iron as it was carried in transfer ladles from the blast furnace to the steelmaking furnace.

PRICES AND SPECIFICATIONS

The published price of calcium metal changed infrequently. According to the Metal Bulletin, the yearend published price range for calcium metal, minimum 98% purity, was \$3.05 to \$3.45 per pound, U.S. free market.² This was equivalent to \$6.70 to \$7.60 per kg. Calcium metal was sold on a contract basis, and the contract price may vary greatly from the published price. The published price range only serves as a guide to the prices obtained by dealers and producers.

Calcium metal was usually sold in the form of crowns, broken crown pieces or nodules, or billets, which were produced by melting crowns in an argon atmosphere. The metal purity in these forms was at least 98%. Higher purity metal was obtained by redistillation. Calcium metal was usually shipped in polyethylene bags under argon in airtight steel drums. Grades of calcium are shown in the text table.

Typical specification, parts per million					
Commercial		Melted		Redistilled

CONSUMPTION AND USES

Calcium metal was used in the manufacture of maintenance-free and sealed lead-acid batteries, as an aid in removing bismuth in lead refining, and as a desulfurizer and deoxidizer in steel refining. It was used to reduce oxides of the rare earth neodymium and boron for alloying with metallic iron for use in neodymium-iron-boron permanent magnets. It was used as a reducing agent to recover many of the less-common metals such as hafnium, plutonium, tungsten, vanadium, uranium, thorium, and the rare earths from their oxides or fluorides. Some minor uses were in the preparation of vitamin B and chelated calcium supplements, and as a cathode coating in some types of photoelectric tubes.

The principal use of calcium chloride

was used as a filler and extender in the paper to improve the optical, physical, and price-performance characteristics of the paper. The plastics industry used a fine and ultrafine grade of PCC to lower raw material costs, increase impact resistance, improve surface smoothness, and enhance color stability. Its major use was in polyvinyl chloride (PVC), but it was also used in such polymers as polystyrene, polypropylene, and polyethylene. The paint industry used it as a replacement for expensive TiO₂ pigment and to control flow properties, provide body, and maintain dispersion.¹

Calcium hypochlorite was used to disinfect swimming pools, which accounted for more than 85% of domestic demand, and in other municipal and industrial bleaching and sanitation processes. It was used as an algicide,

tiated and usually discounted, yearend 1989 published prices and specifications are shown in the text table.

calcium metal imports have increased. The majority of shipments came directly from China, the U.S.S.R., and France.

Source: Chemical Marketing Reporter. V. 237, No. 1, Jan. 1, 1990, p. 33.

FOREIGN TRADE

U.S. exports of calcium chloride increased by nearly 20% in 1989. A substantial portion of the increase went to Canada. The United States exported nearly 24,900 mt of commercial calcium hypochlorite in small quantities to 78 countries for an export value of more than \$32,400,000. Nearly 1,490 mt of calcium carbide was exported to 20 countries for an export value of more than \$730,000. Exports of 134 mt of calcium cyanamide went to Canada, Mexico, and Barbados.

Imports of calcium metal increased by slightly more than 2% from 1988. This was the fourth straight year that

WORLD REVIEW

Calcium metal was produced in China, France, the U.S.S.R., and the United States. Total world production was estimated to be 2,300 to 2,700 mt, and world production capacity was estimated to be as much as 5,500 mt. This excess capacity was due to the fact that some calcium metal plants were originally designed to produce magnesium metal in substantially greater quantities than current calcium metal production.

Although output was unknown, China was believed to be the world's largest producer of calcium metal in 1989. As in the past, China's pricing practices have had an unsettling effect

on world calcium markets. They were reported to have sold calcium at 20% to 30% below the yearend published price of \$6.71 to \$7.60 per kg (\$3.05 to \$3.45 per lb). Both Pfizer Inc. and Timminco, the Canadian calcium alloy producer, reported poor years due to excessive price cutting by China.

Canada was a major producer of synthetic calcium chloride in 1989. General Chemical Co., which operated the former Allied Signal plant at Amherstburg, Ontario, had a production capacity of 270,000 mt with both liquid and solid capabilities. General Chemical was the last remaining North American producer of synthetic calcium chloride as a byproduct of the Solvay process for synthetic soda ash production. Byproduct calcium chloride was produced in Eastern and Western Europe, where in many cases it was treated as a waste product. The calcium chloride brine from many facilities was dumped into rivers and estuaries. This practice, because of increased pressure from Government agencies and environmental groups, is expected to be severely curtailed.

OUTLOOK

The major end uses of calcium metal were in the lead industry, primarily in maintenance-free and sealed lead-acid batteries; in the steel industry; and as a reducing agent for permanent magnet manufacture. These three areas each account for roughly one-third of domestic calcium metal consumption. The majority of the maintenance-free and sealed lead-acid batteries went into the U.S. starter battery market. Based on projections made for the battery industry, it is estimated that calcium metal consumption in this market segment will grow by only 2% to 3% annually over the next 5 years.³ Industry estimates for consumption by the steel industry call for annual growth of 5% to 10% annually. The steel industry is finding that despite the high raw material cost, using calcium metal lessens the final costs by producing a better product with fewer rejects. Conservative estimates for consumption in the permanent magnet market call for an annual growth of 5% to 10%, while optimistic estimates forecast growth of

25% to 30% annually.

The outlook for calcium chloride consumption over the next 5 years is tied to its major use in deicing and dust control. Due to changing environmental and economic policies, annual consumption for deicing is projected to be static or decreasing. Problems with rust and corrosion and the high cost compared to rock salt have caused government agencies to seek alternatives. Consumption for dust control is expected to remain steady.

The outlook for precipitated calcium carbonate consumption is primarily dependent on the pace of conversions to alkaline sizing by the paper industry. Pfizer Inc. announced that in 1990 it will be signing contracts for, building, or starting up 10 to 11 new satellite PCC plants. GK Carbonate announced plans to build two satellite PCC plants in 1990. The North American market has the potential for 35 to 40 satellite plants. One industry estimate sees alkaline papermaking capturing 60% of the total domestic paper market in the next 3 years.⁴ Overall, during the next 5 years the outlook for PCC consumption in the paint and plastics industries is good, and exceptional in the paper industry.

BACKGROUND

Technology

Calcium Metal.⁵—In 1808, Davy produced elemental calcium as a mercury amalgam by the electrolysis of calcium chloride in the presence of a mercury cathode. He and others were only marginally successful in attempts to isolate the pure metal by distilling

the mercury. In 1855, Bunsen and Matthiessen attempted to produce calcium metal by the electrolysis of a mixture of calcium, strontium, and ammonium chlorides to lower the electrolyte melting point but produced only finely divided calcium alloys. Over the next 50 years this process was slowly improved. By 1904, Rathenau had obtained calcium by the electrolysis of molten calcium chloride held at a temperature above the melting point of the salt but below the melting point of calcium metal. An iron cathode just touched the surface of the bath and was raised slowly as the relatively chloride-free calcium deposited on its end. This process accounted for virtually all calcium metal production from 1904 to 1940.

Prior to 1939, calcium was manufactured exclusively in France and Germany. However, with the outbreak of World War II, an electrolytic calcium plant was constructed at Sault Ste. Marie, MI, by the Electro Metallurgical Corp. Large quantities of calcium were required as the reducing agent for uranium production. In addition, the U. S. Army Signal Corps used calcium to produce calcium hydride, which could easily be transported to remote areas and used as a source of hydrogen for meteorological balloons. To satisfy these needs, an aluminothermic reduction process was developed. Tried earlier on a laboratory scale in 1922, the process was improved and commercialized by the New England Lime Co. in Canaan, CT, which later became a division of Pfizer Inc.

The aluminothermic process, or Pidgeon process as it is sometimes called, begins with quarried high-calcium limestone calcined to form calcium oxide. The calcium oxide is ground to a small-particle size and dry-blended with the desired amount of finely divided aluminum. The mixture is compacted into briquets to ensure good contact of reactants. The briquets are placed in horizontal metal tubes, called retorts, made of heat-resistant steel and heated in a furnace to 1,100° to 1,200°

C under high vacuum, and the calcium oxide is reduced to calcium metal. The calcium metal vapor is collected in the water-cooled condenser section of the retort at about 700° C. After the reaction has proceeded for about 24 hours, the vacuum is broken with argon, and the condensed blocks of 98%-pure calcium metal, called "crowns," and the calcium aluminate reaction product are removed.

For certain applications, greater than 98% purity is required. This is achieved by redistillation. Crude calcium is placed in the bottom of a large vertical retort equipped with a water-cooled condenser at the top. The retort is sealed and evacuated to a pressure of less than 6.6 pascal (0.05 mm Hg) while the bottom is heated to 900° to 925° C. The calcium quickly distills to the condensing section leaving behind the bulk of the less volatile impurities. Subsequent processing must take place under exclusion of moisture to avoid oxidation. Redistillation does not greatly reduce the impurity level of volatile materials such as magnesium.

Calcium Chloride.⁶—Domestic calcium chloride is produced from natural brines and by reacting hydrochloric acid with limestone. Most U.S. production is natural and comes from brine wells in Michigan and dry lakebeds in California.

Initial efforts to stimulate the development of Michigan salt and brine deposits took place in 1859. The State Legislature passed a bill authorizing payment for Michigan salt. By 1870, saw-mill operators were augmenting their income by using waste lumber as fuel to evaporate brines. In 1882, solution mining of rock salt began, and Michigan soon became the leading salt-producing State.

By 1914, an integrated process was developed to extract the various brine components. Bromine was extracted first in an electrolytic cell, and the debrominated brine was then processed through a heated vacuum evaporator.

This process precipitated the sodium chloride, which was used to produce chlorine, hydrogen, and sodium hydroxide. The remaining brine was sent to another evaporator where magnesium chloride was precipitated out. The remaining brine from the second evaporator went to a third evaporator, which produced precipitated hydrates of calcium chloride and a 38% calcium chloride product.

Today, the process has been expanded and improved to extract, in sequence, iodine, bromine, magnesium chloride, and calcium chloride. The calcium chloride is derived from the brine left over after processing the magnesium chloride into magnesium hydroxide. This brine is about 25% calcium chloride, and it is processed through double- or triple-effect vacuum evaporators to make a 32% to 45% solution. Unwanted alkali chlorides are precipitated here and can be removed by settlers and centrifuges. The brine undergoes further evaporation to attain an anhydrous product of 78% to 94% calcium chloride concentration.

CEMENT

By Wilton Johnson

Mr. Johnson, a minerals industry specialist with 28 years of industry and Bureau of Mines experience, has been the commodity specialist for cement since 1983. Domestic survey data were prepared by Howard L. Sullivan, mineral data assistant; and international survey data were prepared by Audrey D. Wilkes, international data assistant.

U.S. demand for cement declined slightly for the second year following five consecutive years of growth. Housing starts declined 8%, and the value of new construction put in place also declined slightly. Cement shipments increased to four of the nine Census regions. California continued to lead all States in the amount of cement consumed.

Domestic cement production increased slightly for the first time following two consecutive years of decline. Shipment of domestically produced cement from domestic mills increased slightly, while the amount of imported cement shipped by producers declined 23%. Total imports declined for the second year, making up 17% of apparent consumption compared with 19% experienced in the record year of 1987.

Cement prices increased for the first time in 6 years, reaching their highest level since 1985.

for new plant construction or capacity modernization and expansion. Foreign import penetration into coastal markets and regional competition among domestic producers have combined to reduce the profitability of the U.S. industry. The lack of domestic investment capital has opened the door for foreign investors who now own more than two-thirds of U.S. cement production capacity.

PRODUCTION

One State agency and 49 companies operated 127 plants in 39 States. In addition, two companies operated two plants in Puerto Rico, manufacturing hydraulic cement. The production data obtained are arranged by State or groups of States that form cement districts. A cement district may represent a group of States or a portion of a

State. The States of California, Illinois, New York, Pennsylvania, and Texas are divided to provide more definitive marketing information within those States as follows:

California, Northern.—Points north and west of the northern borders of San Luis Obispo and Kern Counties and the western borders of Inyo and Mono Counties.

California, Southern.—All other counties in California.

Chicago, Metropolitan.—The seven Illinois counties of Cook, DuPage, Kane, Kendall, Lake, McHenry, and Will.

Illinois.—All other counties in Illinois.

New York, Western.—All counties west of a dividing line following the

DOMESTIC DATA COVERAGE

Domestic production and consumption data for cement are developed by means of the portland and masonry cement voluntary survey. Of the 127 cement manufacturing plants to which an annual survey collection request was made, 125 responded, representing 98.4% of the cement production and consumption data shown in table 1. Estimates were made for nonrespondents using monthly survey data and data received from previous annual surveys.

ISSUES

The primary issue facing the cement industry is a lack of capital investment

⁶ Adjusted to eliminate duplication of imported clinker and cement shipped by domestic cement manufacturers.

eastern boundaries of Broome, Chenango, Lewis, Madison, Oneida, and St. Lawrence Counties.

New York, Eastern.—All counties east of the above dividing line, except Metropolitan New York.

New York Metropolitan.—The five counties of New York City (Bronx, Kings, New York, Queens, and Richmond) plus Nassau, Rockland, Suffolk, and Westchester Counties.

Pennsylvania, Eastern.—All counties east of the eastern boundaries of Centre, Clinton, Potter, Franklin, Huntingdon, and Potter Counties.

Pennsylvania, Western.—All other counties in Pennsylvania.

Texas, Northern.—All counties north of a dividing line following the northern borders of Burnet, Crockett, Jasper, Jeff Davis, Llano, Madison, Mason, Menard, Milam, Newton, Pecos, Polk, Robertson, San Jacinto, Schleicher, Tyler, Walker, and Williamson Counties.

Texas, Southern.—All counties south of the above dividing line.

Clinker Production

Clinker production in the United States, excluding Puerto Rico, was essentially the same at 69.3 million tons. California continued to lead all States in clinker production, accounting for approximately 14% of the total. More than two-thirds of the clinker came from eight plants in the southern part of the State. Texas followed with about 10% of total production. Pennsylvania ranked third, with most of the clinker produced at plants in the eastern part of the State, followed by Michigan and Missouri. Together these five States accounted for 46% of total U.S. clinker production.

By yearend, multiplant operations were being run by 25 companies. The size of individual companies, as a percentage of total U.S. clinker production capacity, ranged from 0.3% to 6%. The 5 largest producers provided 29% of total clinker production; the 10 largest producers provided a combined 50%. The 10 largest companies, in decreasing order of size of clinker production, were Lafarge Corp., Southdown Inc.,

Lone Star Industries Inc., Lehigh Portland Cement Co., Ideal Basic Industries Inc., Dundee Cement Co., Blue Circle Inc., Ash Grove Cement Co., Gifford-Hill and Co., and CalMat Co.

Portland Cement

Portland cement production increased slightly to 73.9 million tons. This was the first production increase following two consecutive years of decline. The increase was attributed to less reliance on imports of finished cement to satisfy demand primarily in Eastern markets. The closing of plants in Alabama, Texas, Utah, and Washington reduced operating capacity slightly to 98.1 million tons. The capacity utilization rate increased to 75.3%.

The industry operated 122 plants, including 8 grinding facilities to produce various types of finished hydraulic cement, compared with 126 plants in 1988. California continued to lead all States with 15% of production, followed by Texas with 10%, Michigan with 7%, and Pennsylvania East and Missouri with 6% each. Together these five States accounted for 44% of total U.S. cement production.

The size of individual companies, as a percentage of total U.S. finished cement production capacity, ranged from 0.01% to 7.0%. The top 10 producing companies, in declining order of production, were Lafarge Corp., Southdown Inc., Lone Star Industries Inc., Lehigh Portland Cement Co., Ideal Basic Industries Inc., Dundee Cement Co., Ash Grove Cement Co., Gifford-Hill and Co., Blue Circle Inc., and CalMat Co.

Masonry Cement

Production of masonry cement declined 8% to 3.3 million tons. At yearend, 81 plants were manufacturing masonry cement in the United States. Two plants producing masonry exclusively were Chaney Lime & Cement Co., Algood, AL, and Riverton Corp., Riverton, VA.

Aluminous Cement

Aluminous cement continued to be produced by Lehigh, Buffington, IN; Lone Star Lafarge, Chesapeake, VA; and Aluminum Co. of America, Bauxite, AR.

Fuel Consumption

The industry's energy efficiency for production of clinker and finished cement continued to improve. Average energy consumption per ton of clinker produced was 3.8 million British thermal units (Btu), slightly lower than that required in 1988. The consumption of electrical energy remained at the equivalent of 1.1 million Btu per ton. Average fuel consumption for kiln for firing plus electricity for grinding was 4.9 million Btu per ton. Fuel used in wet-process plants was 4.5 million Btu per ton, 36% higher than the dry process of 3.3 million Btu per ton. Approximately 67% of clinker was produced by the dry process method. The industry reported 67 suspension and 10 grate preheaters in use during the year. Kilns without preheaters averaged 4.5 million Btu per ton, those with suspension preheaters averaged 3.3 million Btu per ton, and those with grate-type preheaters averaged 4.9 million Btu per ton. Coal accounted for 93% of kiln fuel consumption, natural gas accounted for 4%, and oil and waste fuel accounted for the remainder.

Corporate Changes

Dundee Cement Co., a subsidiary of Holderbank Financiere Glaris SA, purchased the Mason City, IA, cement plant of Northwestern States Portland Cement Co. Ideal Basic Industries, also a subsidiary of Holderbank, acquired Allied Cement Co.'s Birmingham, AL, plant and began using it as a distribution terminal. National Portland Cement Co. of Florida sold its remaining 59% interests to a group of Spanish producers: Cementos Molins, S.A.; Uniland Cementera, S.A.; and Asland S.A. The group initially purchased 41% interest in National in 1988. Lafarge Corp. acquired controlling interest in the Swiss firm Cimentia Holdings S.A. Cimentia owns two U.S. cement plants—Davenport Cement Co. in Buffalo, IA, and Missouri Portland Cement Co. in Sugar Creek, MO. Riverside Cement Co., a subsidiary of Gifford-Hill and Co., formed a joint venture with the Republic of Korea's Ssangong Cement Industrial Co. to operate a bulk storage facility at the port of Stockton in Northern California. Ash Grove Cement Co. purchased the Leamington, UT, cement plant from Martin Marietta.

¹ Includes Puerto Rico and white-cement-producing facilities.

² Calculated on individual company data; 365 days, minus average days for maintenance, times the reported 24-hour capacity.

³ Includes production reported for plants that added or shut down kilns during the year.

⁴ Data may not add to totals shown because of independent rounding.

CONSUMPTION AND USES

Consumer demand for cement in the United States, excluding Puerto Rico, declined 2.8% to 90.7 million tons. This was the second year of decline following 5 consecutive years of growth after the 20-year low experienced at the depth of the recession in 1982. According to U.S. Department of Commerce data, housing starts declined 8% to 1.4 million units. The value of new construction put in place declined 1% to \$414 billion. The value of residential construction put in place declined 1% to \$138 billion, primarily in single-unit structures. The value of nonresidential construction put in place increased 2% to \$97 billion. The increases were primarily in industrial buildings, hotels and motels, hospitals, and religious and educational institutions. Public construction experienced the biggest increase, 10%, caused primarily by increases in spending for highways and streets, military facilities, and sewer systems.¹

Among the consuming States, California continued to lead all areas in the amount of portland cement consumed, followed by, in order of shipments received, Texas, Florida, Illinois, Pennsylvania, and New York. Together, these States consumed 43% of total U.S. tonnage.

Cement shipments increased to four of the nine Census regions. Because of the sustained level of construction activity in southern California, the Pacific region continued to lead all other regions of the country with an 8% increase in consumption. Only marginal increases in consumption of 2% or less were registered in the East North Central, West South Central, and Mountain regions. Shipments to all other regions declined with New England registering a 21% decrease in shipments. The Middle Atlantic suffered a 7% decline in consumption, while the South Atlantic declined 6% and the South East Central region decreased 7%. The West North Central region was down slightly.

Shipments of domestically produced cement from U.S. mills increased slightly; however, the amount of imported cement shipped by producers decreased by 23%. All imported cement shipped by producers and inde-

¹ Includes imported cement.

² Data may not add to totals shown because of independent rounding.

pendent distributors declined for the second consecutive year with imports accounting for 17% of apparent consumption compared with 19% in 1988.

The end-use distribution pattern for portland cement was essentially the same as that of recent years. Ready-mix concrete producers were the primary

consumers, accounting for about 74% of the total, followed by concrete product manufacturers with 11%. Smaller amounts were consumed by highway and other contractors; building material dealers; Federal, State, and other government agencies; and a variety of other miscellaneous users.

TRANSPORTATION

The pattern of cement transport did not differ significantly from that of recent years. U.S. shipments of portland cement to consumers were primarily in bulk, 95%; by truck, 90%; and made directly from cement manufacturing plants (rather than from distribution terminals), 61%.

With respect to shipments of cement from plants to terminals, the preferred modes of transportation were railroads, 40%, and waterways, 42%; transportation by truck accounted for 16%. Cement used at producing plants accounted for the remaining 2%.

PRICES

The average mill value of portland cement increased slightly for the first time in 5 years. The increase can be attributed to higher production levels and a reduction of imports. Import prices remained at \$48.19 per ton, while domestically produced cement increased slightly to \$48.41 per ton. The average value of masonry cement improved slightly to \$68.93 per ton compared with \$68.25 per ton in 1988. The average value of cement as reported by Engineering News-Record (ENR) declined slightly to \$62.52 per ton. The ENR prices are based on an average per ton value of cement delivered to 20 cities. The prices ranged from a low of \$42.00 in Dallas, TX, to a high of \$78 in New York.²

FOREIGN TRADE

According to trade data reported by the U.S. Department of Commerce, Bureau of the Census, cement imported for consumption into the United States and its possessions and territories was 10% lower than in 1988. This was the second year of decline following 3 consecutive years of record-high imports. The decline corresponded to the marginal decrease in total demand resulting from reduced construction activity, primarily in the eastern regions of the United States. Canada, Japan, and Mexico were the principal import

sources, accounting for more than 65% of the total. The industry continued to find it more economical to import finished cement instead of clinker for grinding. Clinker accounted for 11% of total imports compared with 32% reached in the peak year 1985. This was the fourth consecutive year that clinker imports declined, reaching its lowest level since 1983. The value of foreign cement delivered to American ports averaged \$38 per ton, up 9% from that of 1988, primarily because of increased shipping costs.

Florida led all States in the amount of imports received, accounting for 23% of the total. Sixty two percent, or 2.2 million tons, of the Florida imports was shipped through the Tampa Customs District. Imports made up about 49% of Florida's Portland cement consumption, compared with 17% of consumption nationally. Los Angeles was the second largest recipient of imported cement, receiving 2.2 million tons or 14% of the total.

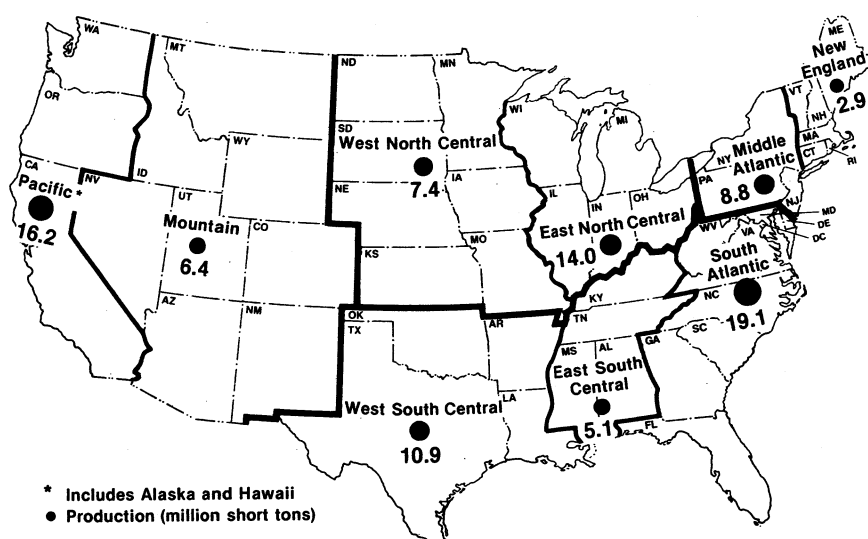

Exports of hydraulic cement and clinker as reported by the Bureau of the Census increased more than 400% to 512,000 tons. Cement was shipped to 42 countries, with Canada receiving 87% of the total.

In other trade developments, the International Trade Commission (ITC) was petitioned by cement producers from Arizona, Florida, New Mexico, and Texas alleging that cement from Mexico was being sold in these areas at less than fair value. The ITC conducted a preliminary antidumping investigation and determined that there was a reasonable indication that the industry was materially injured. A final determination was expected to be made by August 1990.

WORLD REVIEW

World cement production was essentially unchanged at 1.2 billion tons. China continued to lead all nations with 18% of production, followed by the U.S.S.R. with 12%, Japan with 7%, and the United States with 6%. Countries with excess capacity continued to export cement to the United States. In 1989, 29 countries exported cement to the United States, essentially the same as in 1988. The amount of

FIGURE 1
SHIPMENTS OF CEMENT BY GEOGRAPHIC REGION OF
DESTINATION IN 1989

cement imports declined by 10% because of increased demand within exporting countries and because of a reduction in demand in certain coastal markets of the United States.

There was considerable activity in plant modernization or expansion by industry throughout the world. The international issue of Rock Products magazine describes individual plant activities of the cement-producing nations.³

Capacity

The data in table 23 are estimated and were obtained from a number of different sources, including Government representatives, cement associations, producers, consultants and the Cembureau World Cement Directory. Capacity is defined as the maximum quantity of cement that can be produced in a period of time on a normally sustainable basis taking into consideration downtime required for maintenance and repair. Capacity includes operating plants and plants temporarily closed that can be brought into production within a short period of time with minimum capital expenditure.

During 1989, clinker-producing plants

² Includes data for grinding plants.

in an estimated 132 countries had a combined annual capacity of about 1.4 billion tons. Of the top 10 producing countries, China led in clinker production capacity, followed by the U.S.S.R., Japan, the United States, India, Brazil, the Federal Republic of Germany, Italy, Spain, and the Republic of Korea. Together these countries control 60% of the world's clinker production capacity.

In the United States, 44% of the clinker production capacity was concentrated in five States: California, Michigan, Missouri, Pennsylvania, and Texas. At yearend, 225 kilns at 114 plants were being operated, excluding Puerto Rico. The average downtime experienced by the industry for maintenance was 53 days, slightly less than in 1988. The average annual kiln capacity increased 2% to 369,560 tons. The average annual plant capacity increased 7% to 729,395 tons as the trend continued toward development of fewer but larger capacity plants.

Australia

Cement demand in Australia continued to flourish with production reaching 7.2 million tons in 1989. Imports

from Indonesia, Japan, and The Republic of Korea continued to penetrate the Australian market, prompting the filing of antidumping petitions to curtail imports.

Canada

Canadian cement production declined 2% to 13 million tons. Canada remained the second largest supplier of cement to the United States, supplying markets primarily through ports in 15 custom districts from Anchorage, AK, to St. Albans, VT.

China

China continued to be the world's largest producer of cement. Its production continued to increase at a dramatic rate, reaching an estimated 228 million tons in 1989. Chinese cement is expected to become a bigger player on the international market when several of its plant construction and modernization projects are complete.

Greece

Cement production in Greece as reported to the Bureau of Mines increased slightly following three consec-

utive years of decline. Greece was the fifth largest supplier of cement to the United States, although the volume of imports declined 38% from that of 1988. The decline was attributed to increased consumption at home, to other European Community countries traditionally served by Greek producers, and to a drop in cement demand in the U.S. eastern seaboard markets.

India

The Indian cement industry continued to aggressively expand its production capacity through new plant construction, modernization, and expansion activities. Cement production in India reached an alltime high of 46 million tons. This was the seventh consecutive year of production growth. India is not a major exporter of cement; however, that situation could change when capacity expansion projects currently in various stages of development are complete.

Japan

Japan continued to maintain its position as the third highest cement producer in the world, producing nearly 90 million tons, or 5% more than in 1988.

W Withheld to avoid disclosing company proprietary data; included with "Foreign countries."

¹ Includes cement produced from imported clinker and imported cement shipped by domestic producers, Canadian cement manufacturers, and other importers. Includes Puerto Rico.

² Excludes cement (1987—305,000 tons, 1988—318,000 tons, and 1989—183,935 tons) used in the manufacture of prepared masonry cement.

³ Has no cement-producing plants.

⁴ Less than 1/2 unit.

⁵ Data may not add to totals shown because of independent rounding.

⁶ Direct shipments by producers to foreign countries and U.S. possessions and territories; includes States indicated by symbol W.

⁷ Includes cement produced from imported clinker by domestic producers.

⁸ Imported cement distributed by domestic producers, Canadian cement manufacturers, and other importers. Origin of imports withheld to avoid disclosing company proprietary data.

Japanese exports to the United States increased 37% to 2.4 million tons in 1989. Of Japanese exports to the United States, 67% was shipped to the Los Angeles area.

Korea, Republic of

The Republic of Korea's cement production increased 49% during the past 5 years to 34 million tons in 1989. Internal cement consumption in Republic of Korea has increased steadily, reducing the amount of production available for export. Korean exports to the United States declined 59% in 1989, and further declines were expected. Exports to the United States were shipped primarily to the Los Angeles area.

Mexico

Cement production in Mexico con-

tinued to grow, reaching about 26 million tons in 1989. Mexico was again the biggest supplier of cement to the United States, accounting for 28% of total imports. Eighteen of the 36 customs districts reported receiving Mexican cement. The Tampa, FL, Customs District was the largest recipient of Mexican cement with 1.2 million tons, or 28% of the total.

CURRENT RESEARCH

The Bureau of Mines concluded research on the use of lightweight concrete for ground support in underground mining. The objective of the research was to develop concepts for new, innovative continuous liners and

other support systems for metal and nonmetal underground mines having soft, caving, and squeezing ground conditions. Field and laboratory tests demonstrated the feasibility of using lightweight concrete in lining systems. The innovative concepts developed by this research will aid mine operators by decreasing capital and maintenance costs and by improving productivity in soft, caving, squeezing or bursting ground conditions found in deep mines.⁴

The Construction Technology Laboratories (CTL) of the Portland Cement Association reported development of a new concrete using lightweight aggregates. According to CTL, the new concrete is lighter and has better insulating properties than conventional concretes. Unit weights can range from 120

pounds per cubic foot (pcf) to as low as 20 pcf, compared with 140 pcf to 150 pcf for normal weight concretes. CTL also claims that the product offers a broad range of compressive strengths and thermal and fire resistances. The materials are particularly suited for constructing high- and low-rise buildings, bridges, religious facilities, sports arenas, floor slabs, roof decks, and fire barriers.⁵

OUTLOOK

The demand for cement in 1990 is expected to remain essentially unchanged from 1989, driven primarily by continued weakness in the multifamily residential and nonresidential building construction markets. Gradual increases in demand are anticipated after 1990 as the economy improves. The Portland Cement Association estimates that cement demand will reach 100 million and 101 million tons by 1994 and 1995, respectively.⁶

There has been considerable attention given to repairing or rebuilding the Nation's infrastructure. These cement consumption forecasts could be altered dramatically depending on the level of spending authorized for this undertaking.

Imports will continue to be a significant source of supply. The trend toward increased world consumption of cement, however, could impact the amount of cement available for export to U.S. markets, particularly given the political and economic changes taking place in Eastern Europe.

Cement prices could benefit from a restricted supply of foreign cement. The price of foreign cement will also rise as water freight rates continue to increase and as more complaints are filed by domestic producers alleging that the industry is being injured by dumping.

BACKGROUND

The science of making cement is ages

old. During construction of the Great Pyramid about 2600 B.C., the Egyptians made cementing material by calcining impure gypsum containing calcium carbonate. The Greeks were probably the first to calcine limestone for mortar, about 185 B.C. Portland cement was first produced and patented by Joseph Aspdin in 1824. The name "portland" was chosen because the set cement resembles a building stone quarried from the Isle of Portland off the southern coast of England. The first cement plant in the United States was built in Pennsylvania where David O. Saylor obtained a patent for creating a cement equal to the portland cement made in England.

Definitions, Grades, and Specifications

Section 4 of the Annual Book of the American Society for Testing and Materials (ASTM) publishes standards, test methods, definitions, recommended practices, classifications, and specifications for cement, lime, and gypsum.⁷ The National Institute for

Total ^{4 5} or average	86,738	4,232,814	48.80	84,229	4,121,558	48.93

¹ Includes Puerto Rico.² Mill value is the actual value of sales to customers, f.o.b. plant, less all discounts and allowances, less all freight charges to customer, less all freight charges from producing plant to distribution terminal if any, less total cost of operating terminal if any, less cost of paper bags and pallets.³ Includes waterproof, low-heat (Type IV), and regulated fast-setting cement.⁴ Data may not add to totals shown because of independent rounding.⁵ Does not include cement consumed at plant.

Standards and Technology establishes and the General Services Administration issues Federal specifications for hydraulic cements used in Federal construction projects. Following is a brief discussion of various types of hydraulic cements and the materials from which they are made.

Clinker.—Clinker is produced by heating a properly proportioned mixture of finely ground raw materials containing calcium carbonate, silica, alumina, and iron oxide in a kiln to a temperature of about 2,700° F at which partial fusion occurs. The fused material, which ranges from fine sand grains to walnut size, is ground with small amounts, 3% to 5%, of calcium sulfate, usually gypsum or anhydrite, to make portland cement.

Portland Cement.—ASTM specifications C-150 covers five types of portland cement: (1) Type I, for use when special properties specified for other types are not required, (2) Type II, for general use, more especially when moderate sulfate resistance or moderate heat of hydration is desired, (3) Type III, for use when high early strength is required, (4) Type IV, for use when a low heat of hydration is desired, and (5) Type V, for use when high sulfate resistance is required. ASTM specifications also include Type IA, Type IIA,

TABLE 17
AVERAGE MILL VALUE, IN BULK,
OF CEMENT IN THE UNITED STATES¹

(Per short ton)

Year	Portland cement	Prepared masonry cement ²	All classes of cement
1985	51.30	66.64	51.87
1986	50.10	65.68	50.73
1987	¹ 48.79	70.55	¹ 49.70
1988	¹ 48.55	68.48	¹ 49.36
1989	48.93	69.08	49.71

¹ Revised.² Includes Puerto Rico. Mill value is the actual value of sales to customers, f.o.b. plant, less all discounts and allowances, less all freight charges from producing plant to distribution terminal if any, less total cost of operating terminal if any, less cost of paper bags and pallets.³ Masonry cement made at cement plants only.

and Type IIIA for the same uses, but with the addition of air entraining compounds to protect concrete against freeze-thaw damage.

White Cement.—White cement is made from iron-free materials of exceptional purity, usually limestone, china clay or kaolin, and silica. The clinker is burned with a reducing flame in the kiln and rapidly quenched in a water-spray to keep any iron in the ferrous state to avoid coloration by ferric ions. The clinker is then ground with high-

purity white gypsum using ceramic balls and liners in grinding mills. White cement is used in decorative concrete, including terrazzo, highway lane markers, and architectural concrete.

Masonry Cement.—Masonry cement is a hydraulic cement used in mortars for masonry construction. It contains one or more of the following materials: portland cement, portland-pozzolan cement, slag cement, or hydraulic lime, usually with hydrated lime, limestone, chalk, calcareous shale, talc, slag, or clay inter-

ground for plasticity. ASTM designation C-91 contains specifications for masonry cement.

ASTM designation C-595 covers the following four kinds of blended hydraulic cements, each with an optional provision for air entraining.

Portland-Blast Furnace Slag.—This is essentially an intimately interground mixture of portland cement clinker and granulated blast furnace slag, or an intimate and uniform blend of portland cement and fine granulated blast

furnace slag in which the slag constituent ranges between 25% to 70% of the total weight of the cement.

Portland-Pozzolan Cement.—Portland-pozzolan cement is produced by intergrinding portland cement clinker and pozzolan, by blending portland cement or portland-blast furnace slag cement and finely divided pozzolan, or a combination of intergrinding and blending in which the amount of the pozzolan is between 15% and 40% of the total weight of the cement.

Pozzolan-Modified Portland Cement.—The constituents in this type of cement are the same as those for portland-pozzolan cement, and the methods of production are also the same. However, pozzolan makes up less than 15% of the total weight of the blended cement.

Slag Cement.—Slag cement is a finely divided material made from a uniform blend of granulated blast furnace slag and hydrated lime. The slag constitutes at least 70% of the total weight of the blended cement.

Pozzolan.—Pozzolan is a siliceous and aluminous material that in itself possesses little or no cementitious value but will, in a finely divided form and in the presence of moisture, chemically react with calcium hydroxide at ordinary temperatures to form compounds possessing cementitious properties. Fly ash is a pozzolanic material obtained from flue gases produced by coal combustion. Natural pozzolans are naturally occurring materials such as diatomaceous earths, opaline cherts and shales, tuffs, volcanic ash, and pumicites. ASTM C-618 covers fly ash and natural pozzolans.

Oil-Well Cement.—Oil-well cement was developed to seal oil and gas wells under pressures up to 1,800 pounds per square inch and temperatures up to 350° F. This cement must remain fluid up to about 4 hours to be effective.

Expansive Cement.—Expansive cement is a hydraulic cement that tends to increase in volume after setting during the early hardening period. There are three types of expansive cements, Types K, M, and S. Expansive cements are used primarily in shrinkage-compensating

concrete. ASTM specification C-845 covers all expansive cements.

Aluminous Cement.—Sometimes known as calcium aluminate cement, high alumina cement, or "Ciment Foundu," aluminous cement is a hydraulic nonportland cement. Special applications of aluminous cement are based on its rapid hardening qualities, resistance to sulfate action, and refractory properties when used as "castable refractories" and mortars for furnaces and kilns.

Concrete.—Concrete is a proportioned mixture of coarse mineral aggregates of sand and gravel or crushed stone, bound together by a paste of hydraulic cement and water. Volume 04.02 of ASTM standards covers concrete and aggregates.

Products for Trade and Industry

Portland cement composes 96% of the total domestic output; the remainder is mostly masonry cement. About 92% of total portland cement production in 1989 comprised Type I and II cement, 4% was Type III, and 1% was oil-well cement. Cements produced in quantities comprising less than 1% each were portland-pozzolan and portland-blast furnace slag, Type IV, Type V, white, expansive, and waterproof cements. A small quantity of regulated set cement was produced. Each product requires either a change in proportion of raw materials mixed for kiln feed or additives to the clinker.

Industry Structure

The industry is composed of 130 cement producing plants in 40 States. Multi-plant operations were being run by 23 companies. Because of overall poor financial performance by the industry during the 1980's, many companies have left the cement business or closed plants and began importing finished cement or clinker for grinding into finish cement. Fifteen independent importers have constructed terminals to receive foreign cement for markets near coastal areas. The industry has also undergone dramatic changes in ownership. At yearend, foreign investors controlled approximately 65% of U.S. production capacity.

Resources

Primary raw materials required for cement clinker production are, in order of importance, limestone, clay and shale, and iron ore. In instances where essential chemical components are not present in the primary raw material in the required amount, other mined materials or industrial products may be used as additives to correct these deficiencies. Gypsum is added during the clinker grinding process to make finished portland cement.

Although raw materials for cement manufacturing have not been quantified, they are abundant in most countries. Some countries deficient in raw materials meet their requirement by importing. Many domestic companies have reported reserves of raw materials exceeding 100 years supply.

Technology

Principal steps in manufacturing portland cement consist of crushing, grinding, mixing, and burning raw materials and grinding the resultant clinker. About 1.8 tons of raw materials is required to make 1 ton of cement.

Raw Material Grinding.—Both dry and wet grinding are used to obtain a fineness that may range from 75% to 90% passing through a 200-mesh sieve. In wet-milling, water is added with the mill feed to produce a slurry containing about 65% solids. The raw material is then dried and ground for burning.

Burning.—Burning is the most important operation in manufacturing cement because fuel consumption is a

See footnotes at end of table.

major expense, plant capacity is measured by kiln output, and strength and other properties of cement depend on the quality of the clinker. Burning takes place in a rotary kiln that is a refractory-lined steel cylindrical shell. It rotates on an axis inclined at $\frac{3}{8}$ to $\frac{1}{2}$ inch per foot toward the discharge end. U.S. kilns range in size from 116 to 760 feet long and 8 to 24 feet in diameter.

Byproducts and Coproducts

There are no major byproducts and coproducts in manufacturing hydraulic cement in the U.S. Flotation, a method of beneficiation used by some companies to remove undesirable constituents from raw materials to increase the calcium carbonate content of the kiln feed, produces waste such as silica sand, or mica fines which may be marketed. Waste rock quarried in selective mining of usable raw material has been sold for riprap and fill materials or crushed and sold as aggregate for concrete or for road base. Some kiln dusts with high alkali content have been collected and used as fertilizer or processed to recover potash.

Economic Factors

Prices.—Cement prices are greatly influenced by local or regional markets and the availability of energy and raw materials required for cement manufacturing. Discounts for cash and large quantity purchases, absorption of freight charges, and the cost of paper bags and pallets add to the complexity of cement price patterns. Extreme competition among producers and stiff competition from imports are primary contributors to depressed prices, which severely limit investment dollars available for capital improvement or expansion.

Costs.—Cement production costs are determined by such factors as plant location, plant age and level of modernization, type of production process used, the availability of raw materials, and labor. Energy represents by far the largest portion of production costs, accounting for 40% of the total. The industry has had considerable success in stabilizing production costs by undertaking modernization projects that not only conserve energy but increase production capacity.

^c Estimated. ^p Preliminary. ^r Revised.¹ Table includes data available through June 27, 1990.² In addition to the countries listed, Cameroon produces cement, but available information is inadequate to make reliable estimates of output levels.³ Less than 1/2 unit.⁴ Data are for the year ending June 30 of that stated.⁵ Reported figure.⁶ Excludes natural cement.

Tariffs.—For countries with most-favored-nation status, duties are imposed only on white cement in the amount of 22 cent per ton, including the weight of containers. Other hydraulic cement and clinker are duty free. The statutory import duty for countries without most-favored-nation status is \$1.76 per ton and \$1.32 per ton for all other types of cement and clinker, respectively.

Operating Factors

Environmental Requirements.—Since the 1970's, the U.S. cement industry has been required to make substantial capital investments to comply with environmental restrictions. The biggest source of pollution associated with cement production is controlling dust from kilns and clinker coolers. That requires the instal-

lation of dust collectors such as bag houses and electrostatic precipitators, both of which add considerably to operating costs without improving production. In addition to meeting air quality standards, the industry must also comply with water quality, land use, health and safety, and noise requirements. It has been estimated that capital costs for meeting these requirements can account for 20% to 25% of the capital expenditures for new plants and major additions.⁸

Employment.—In the U.S. cement industry in 1989, there were approximately 19,900 workers, including individuals employed in mining and milling operations. Employment in the industry has continued to decline primarily because automated process control technology permits greater productivity with fewer employees.

Energy Requirements.—The U.S. cement industry is one of the largest users of energy, consuming about 275 trillion Btu's during 1989. Substantial energy savings have been achieved since the Federal Government implemented the voluntary energy conservation program in 1972. The installation of improved raw material grinding and processing technology, the use of preheater-precalciner systems for burning raw material, the conversion from wet to dry process, and the conversion from oil and gas to coal for kiln firing all contributed to improved energy efficiency. Further improvements in energy consumption will result as technological and institutional barriers to the use of municipal, industrial, and hazardous wastes for kiln firing are removed.

CHROMIUM

By John F. Papp

Dr. Papp, a physical scientist with 19 years Bureau of Mines experience, has been the commodity specialist for chromium since 1983. Domestic survey data were prepared by the Branch of Data Collection and Coordination, Division of Statistics and Information Services. Chromite world production data by country were prepared by Audrey D. Wilkes, international data coordinator, Geographic Data Section, Division of International Minerals. Cost of production data were prepared by the Minerals Availability Field Office, Division of Resource Evaluation.

In 1989, reported chromium material consumption was 377,726 metric tons, gross weight. All tonnages are in metric tons unless otherwise specified. The reported consumption of chromite by the chemical and metallurgical industry increased while that of the refractory industry decreased. Metallurgical industry chromite consumption includes material consumed as part of the National Defense Stockpile (NDS) program to convert chromite to ferrochromium. Imports of chromite and chromium ferroalloys decreased compared with those of 1988.

United States supply consisted of recycled and imported chromium materials. The United States recycled about 594,000 tons, gross weight, of stainless steel scrap and imported about 894,000 tons of chromium ore, ferroalloys, chemicals, and pigments valued at about \$430 million. The United States exported about 26,000 tons of chromium materials valued at about \$31 million.

LEGISLATION AND GOVERNMENT PROGRAMS

In accordance with the President's November 1982 directive and Public Law 99-591, the Defense Logistics Agency (DLA) continued to upgrade NDS chromium ore to high-carbon ferrochromium. DLA reported conversion of chromium ore to ferrochromium on a calendar year contract basis. DLA signed a contract with Macalloy Corp., Charleston, SC, to upgrade NDS chromium ore into high-carbon ferrochromium. The contract period covers the years 1990 through 1994, the last 2 years of which are optional for DLA.

Contract year	Ore converted (metric tons)	High-carbon ferrochromium produced (metric tons)		Cost (millions)
		Gross	Content	
HISTORICAL PERFORMANCE				
1984	113,968	45,590	30,180	\$22.3

¹ High-, medium-, and low-carbon ferrochromium plus ferrochromium-silicon.

² Includes chromium metal, exothermic chromium additives, and other miscellaneous alloys.

³ As reported in the Ferroalloys chapter.

DLA made a contract with Elkem Metals Co., Marietta, OH, to upgrade NDS nonspecification grade low-carbon ferrochromium into electrolytic (vacuum melting grade) chromium metal. The conversion of NDS non-specification-grade low-carbon ferrochromium to vacuum melting grade electrolytic chromium metal is a new program. Elkem was awarded the \$7.2 million contract to convert 2,129 tons of low-carbon ferrochromium to about 1,043 tons of chromium metal over a 1-year period starting in December 1989.

DLA initiated a 26-month program to evaluate plasma smelting technology. DLA planned to select a smelting method, plan a test program, construct a test furnace, conduct a test program, and employ the program's results to design a commercial-scale smelting furnace. The program was being carried out by South Carolina Research Authority, Macalloy Corp., Massachusetts Institute of Technology, Clemson University, and Arthur D. Little Inc.

The Department of State reviewed the status of chromium with respect to the Comprehensive Anti-Apartheid Act (Public Law 99-440). In January 1987, the Department of State found chromium (including ferrochromium) to be a strategic mineral essential for the economy or defense of the United States, unavailable from reliable and secure suppliers. The Department of State continued this classification of chromium (including ferrochromium) as a result of its review.¹

The Occupational Safety and Health Administration (OSHA) reviewed health, risk, and feasibility evidence for chromium metal, chromic acid and chromates, and chromyl chloride. As a result of their review, OSHA decided to retain the previous exposure limit for chromium metal (8-hour time-weighted average value of 1 milligram per cubic meter) and chromic acid and chromates (ceiling exposer limit of 0.1 mg/m³). OSHA decided to make rules for chromyl chloride exposure.²

Congress authorized the President to revise the goal for refractory-grade chromite ore in the NDS to 630,000 metric tons as part of the National Defense Authorization Act for Fiscal Years 1990 and 1991. At yearend, the authorized change had not been adopted.³

STRATEGIC CONSIDERATIONS

Supply Security

There is no primary production of chromium in the United States, and primary consumption of chromium by U.S. industry is by companies that use chromite to produce refractories, chromium chemicals, and ferrochromium, and chromium metal producers that use ferrochromium or chromic oxide. Long-term chromium supply is abundant. However, supply sources are few and remote from the United States, making supply vulnerable to disruption. The problem for the United States is one of national security. Ferrochromium is essential to stainless and alloy steel production, which are in turn essential to both the domestic economy and to the production of military hardware.

Stockpile

The NDS primarily contains chromium source material in the form of chromite ore, chromium ferroalloys, and chromium metal. The purpose of the NDS is to supply military, essential civilian, and basic industrial needs of the United States during a national defense emergency and by law cannot be used for economic or budgetary purposes. In addition to private and Government stocks, there exists a large unreported inventory of chromium contained in products, trader stocks, and scrap. The amount of these stocks varies with demand and price of the material.

Under severe price pressures resulting from primary chromium shortages, recycling of consumer materials could add to the supply.

Chromite ore must be converted to ferrochromium before it can be used to make steel. Prompt response during a national defense emergency requires that conversion be carried out by domestic industry. However, domestic ferrochromium production capacity is not adequate to meet anticipated domestic demand under mobilization conditions. To ensure prompt response to a national defense emergency using the NDS, the President chose to convert stockpiled chromite ore to ferrochromium. (See Legislation and Government Programs section of this report.)

ISSUES

Ferrochromium production capacity in 1989 increased significantly. Strong demand for ferrochromium, resulting from high levels of stainless steel production worldwide in 1987-89, resulted in ferrochromium plant expansions and new plant construction. Since 1970, the trend has been for ferrochromium production capacity to move from major stainless steel-producing countries (Japan, Western Europe, and the United States) to major chromium ore-producing countries (the Republic of South Africa, Zimbabwe, Turkey, Philippines, and Finland). This has occurred through

Source: Defense Logistics Agency.

the creation of new plants or furnaces in chromium ore-producing locations and the closure of furnaces in geographic areas where ferrochromium production was formerly strong. The expansion of world annual gross weight production capacity by about 530,000 tons in 1989 has continued that trend. This expansion represented in the range of 10% to 15% of world capacity of the previous year and continues the historic trend. The largest addition to national annual capacity was in the Republic of South Africa where 290,000 tons, about 20% to 25% of that country's capacity in the previous year, was added. Three-fourths of the new capacity was located in chromium ore-producing countries. An additional 400,000 tons of annual ferrochromium production capacity had been anticipated to be brought into production in 1990, all of which was to have been in chromium ore-producing countries. An additional 400,000 tons of annual production capacity has been planned for 1991 or later. The supply shortage was estimated to have been about 200,000 tons in 1988 or about 5% of 1988 world production capacity. Stainless steel is the major chromium end use. With stainless steel production growing at a long-term average annual rate of 3% to 4%, it is estimated that it will take about 5 years for demand to catch up with 1989 and 1990 added capacity. Experience shows that short-term variations in chromium consumption and production can be significantly larger than long-term trends.

PRODUCTION

The major marketplace chromium materials are chromite ore and chromium metal, ferroalloys, and chemicals. In 1989, the United States produced chromium metal, ferroalloys, and chemicals, but no chromite ore.

Chrome Corp. of America (previously called Chrome Corp. International), a subsidiary of Boulder Gold (Australia), entered a joint venture with Dynamic Capital Corp. (Canada) to conduct a feasibility study of mining chromite from the Stillwater Complex (Montana) and producing ferrochromium. The study was planned to be completed in 1991. Chrome Corp. estimated that production could start in 1993.

Macalloy Corp. won a contract from the DLA to convert NDS chromium ore into high-carbon ferrochromium. (See Legislation and Government Programs section of this report.) Production at Macalloy's Charleston, SC, plant was interrupted by Hurricane Hugo. The plant did not suffer significant damage; however, electrical energy supply was interrupted for several days.

Elkem Metals Co. won a contract from the DLA to convert NDS non-specification-grade low-carbon ferrochromium into chromium metal. (See Legislation and Government Programs section of this report.) Elkem started a second furnace with a capacity of 17,000 tons per year. Excess supply of ferrochromium by yearend resulted in Elkem closing down both of its ferrochromium-producing furnaces.

CONSUMPTION AND USES

Domestic consumption of chromite ore and concentrate was 560,711 tons in 1989. Of the total chromite consumed, the chemical and metallurgical industry used 516,931 tons, and the refractory industry, 43,780. Much of the chromite consumed and ferrochromium produced by the metallurgical industry were part of the NDS conversion program. (See Legislation and Government Programs section of this report.)

Chromium has a wide range of uses in the three primary consumer groups. In the metallurgical industry, its principal use in 1989 was in stainless steel. Of the 360,962 tons of chromium ferroalloys, metal, and other chromium-containing materials reported consumed, stainless steel accounted for 78%; full-alloy steel, 9%; and other end uses, 13%. The primary use of chromium in the refractory industry was in the form of chromite to make refractory bricks to line metallurgical furnaces. Chromite consumption by the refractory industry decreased to 43,780 tons.

The chemical industry consumed chromite for manufacturing sodium bichromate, chromic acid, and pigments. Sodium bichromate is the material from which a wide range of chromium chemicals are made.

⁴ Includes structural and hard-facing welding material.

⁵ Includes cutting materials and magnetic, aluminum, copper, nickel, and other alloys.

⁶ Includes estimates.

⁷ Includes 4,676 tons of chromium metal.

⁸ Includes 640 tons of chromium metal.

STOCKS

Reported consumer stocks of chromite in the United States increased from 389,621 tons in 1988 to 392,273 tons in 1989. Chemical and metallurgical industry stocks increased, as did refractory industry stocks. Producer stocks of chromium ferroalloys, metal, and other materials increased from 8,831 tons in 1988 to 20,475 tons in 1989. Consumer stocks decreased from 30,425 tons in 1988 to 19,945 tons in 1989. At the 1989 annual rate of chromium ferroalloy and metal consumption, producer plus consumer stocks represented about a 6-week supply.

PRICES

The price of chromite increased steadily until December when it declined slightly. The published price of South African Transvaal chromite, 44% Cr₂O₃ (no specific chromium-to-iron ratio), increased from a range of from \$50 to \$56 per ton, f.o.b. South African ports, to a range of from \$60 to \$66 in March, to a range of from \$68 to \$72 in September, where it remained until December when it declined to a range of from \$60 to \$65. The published price of Turkish ore increased from a range of from \$150 to \$180 per ton, f.o.b. Turkish ports, to a range of \$230 to \$255 in April, then decreased to a range of from \$185 to \$200 in September, followed by a further decrease in December to a range of from \$175 to \$185.

The published price of domestic high-carbon (50% to 55% and 66% to 75% chromium), low-carbon (0.025% and 0.05% carbon), and simplex low-carbon ferrochromium remained unchanged. The price of chromium metal increased from \$3.75 per pound to \$3.95 per pound in August, where it remained through December.

The price of imported high-carbon (50% to 55% and 60% to 65% chromium) and low-carbon (0.05% carbon) ferrochromium decreased almost monthly following 2 consecutive years of rising imported ferrochromium prices. The published price of high-carbon ferrochromium (50% to 55% chromium) de-

¹ Wrought and unwrought and waste and scrap in 1987-88. Articles thereof and waste and scrap in 1989.

² Includes high-, medium-, and low-carbon ferrochromium and ferrochromium-silicon.

³ Contained 2,488 tons of chromium.

⁴ Contained 4,845 tons of chromium.

⁵ Contained 5,647 tons of chromium.

⁶ Chromic acid in 1987-88.

⁷ This category is not applicable before 1989. As a result of conversion to the Harmonized Tariff Schedule in 1989, this category was introduced.

⁸ Included sodium chromate in 1987-88.

⁹ Included potassium chromate in 1987-88.

Source: Bureau of the Census.

In Finland, Outokumpu Oy, a major share of which is state-owned, owns and operates chromite mining, ferrochromium production, and stainless steel production facilities, making it completely vertically integrated. In the Republic of South Africa, Barlow Rand, an investment company, owns chromite mining operations (Rand Mines) and ferrochromium and stainless steel production facilities (Middelburg Steel and Alloys), making it the only completely vertically integrated chromium producer in the Republic of South Africa. Gencor, an investment company, owns chromite mining operations and ferrochromium production facilities through South Africa Manganese Amcor Ltd. (Samancor). Samancor owns chromite mining operations through its subsidiary Cromore and owns ferrochromium smelters (Tubatse and Ferrometals). Associated Ore and Metals Corp. owns chromite mining operations through Rustenburg Development Corp. and operates a ferrochromium smelter (Feralloys). Anglo

American, an investment company, operates a ferrochromium smelter, Consolidated Metallurgical Industries (CMI), through Johannesburg Consolidated Investment Co. Two other companies in the Republic of South Africa, Chromecorp Technology and Purity Minerals, have chromite mining and ferrochromium production operations. Bayer AG (Federal Republic of Germany) owns a chromite mining and chromium chemical production operation. Refractory chromite operations are also vertically integrated from chromite production through refractory material production. In the Republic of South Africa, the chromium-related companies are privately owned. Typically, major shares of a company are owned by other companies, and the remainder, if any, are openly traded. In Brazil, the mining and smelting of chromium is vertically integrated, but stainless steel production is independent of the mining-smelting operations. The major mining companies are subsidiaries of Cia. de Ferro Ligas da

Bahia S.A. (FERBASA), Pajuca, Bahia. Stainless steel is produced by Companhia Aços Especiais Itabira, Itabira, Minas Gerais. Other chromite operations in Brazil are also vertically integrated. Bayer AG (Federal Republic of Germany) owns a chromite mining and chromium chemical production operation. Refractory chromite operations are also vertically integrated from chromite production through refractory material production. In the U.S.S.R., chromite mining, ferrochromium production, and stainless steel production are state-owned.

Capacity

The data in table 15 are rated capacities for major countries that mine chromium ore, produce ferrochromium, primary chromium chemical, and chromium metal as of December 31, 1989. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equip-

ment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Since not all countries or producers make production capacity information available, historical chromium trade data has been used to estimate production capacity.

Reserves

The United States has no chromium ore reserves. However, the United States has a reserve base and resources that

could be exploited. (For further information on reserves, reserve base, and resources internationally, see Geology-Resources section of this report.)

Albania

Albania increased its chromium ore reserves as a result of surveys conducted in 1988. A new chromite deposit was discovered near the Alarup Mine in the Pogradec district, near Pojska about 115 kilometers southeast of Tirana. Albania commissioned the Lucana Mine and two others in the 11 Heronjte mining complex in the Mat district. Albania operated the Prenjas Mine in the Librazhd district and mines in the Kukes district. Construction continued on the chromium ore processing

plant at the Bulqiza Mine in the Dibra district.

A new ferrochromium smelter, under construction at Elbasan, was planned to have three electric furnaces and to have an annual production capacity of about 38,000 tons. At full production the plant would consume about 100,000 tons of chromium ore. Ore for the plant was planned to come from the Librazhd and Pogradec districts. Albania continued to operate its ferrochromium smelter at Burrel.

Albania and Gesellschaft für Electrometallurgie (GfE) of Federal Republic of Germany made a long-term marketing agreement. GfE had used Albanian ore along with Turkish ore to produce high- and low-carbon ferro-

chromium at its Electrowerk Weisweiler smelter. In exchange for the right to market a minimum amount of Albanian ferrochromium annually in the Federal Republic of Germany, GfE was expected to provide technical advice to Albania in setting up its new ferrochromium smelting facilities.

Albania made trade agreements with Bulgaria to supply chromium ore concentrates, with China to supply chromium ore and concentrates, and with Yugoslavia to supply chromium ore.

Australia

Dragon Resources Ltd. continued to develop its Range Well chromium in laterite deposit near Cue in Western

Australia. The company sought a joint-venture partner to conduct reconnaissance exploration to confirm the deposit and develop it. Dragon Resources reported that smelting tests demonstrated 96% to 98% chromium recovery.

Brazil

Companhia Auxiliar de Empresas de Mineração (Caemi) created a subsidiary holding company, Caemi Mineração e Metalurgia, which will own Cia. Ferroligas de Amapá, its ferrochromium-producing operation. The new structure permits Caemi to obtain foreign investment.

Magnesita S.A., a chromite producer in Goiás State, started chromite pro-

duction in Bahia State. Caemi's Vila Nova mine started producing chromite in Amapá territory. The Vila Nova mine had reserves of 4.49 million tons with 34% average Cr₂O₃ content.

Cia. Ferroligas do Amapá continued construction of its ferrochromium smelter at Porto de Santana. Upon completion in 1990, the smelter was to have a ferrochromium production capacity of 19,000 to 20,000 tons. Ferrochromium production would be interchangeable with ferromanganese production.

FERBASA planned to invest \$140 million in Bahia State to construct four hydroelectric plants. Construction of two plants had received Government approval. FERBASA planned to have

¹ This category is not applicable before 1989. As a result of conversion to the Harmonized Tariff Schedule, this category was introduced.

² Includes wrought and unwrought and waste and scrap before 1989.

³ Contained 2,827 tons of chromium.

⁴ Contained 3,885 tons of chromium.

⁵ Contained 2,756 tons of chromium.

⁶ Called chromic acid before 1989.

⁷ Includes material reported as chromium oxide green or hydrated chromium oxide green before 1989.

⁸ Included chromates before 1989 that are reported under other in 1989.

⁹ Includes material reported under chrome green, chromium oxide green, hydrated chromium green, or strontium chromate before 1989.

Source: Bureau of the Census.

these two hydroelectric powerplants operating by mid-1992. Electrical energy costs had been increasing rapidly in Brazil. Projections of electrical energy demand and supply showed a significant shortfall in production by the year 2000. Either private investment or accelerated Government-financed production capacity will be required to meet projected demand. Higher electrical energy prices have been suggested as

a means to raise the capital necessary to construct new plants.

Burma

Burma exported chromium ore containing 48% Cr₂O₃, having a chromium to iron ratio of 1:3, and sized between 1 and 6 inches. The development of chromium ore resources was being studied.

Canada

Canada studied the development potential of its chromium resources. Federal and Provincial governments studied the potential of producing ferrochromium or stainless steel from chromite resources in Manitoba, which produces nickel and has relatively low-cost hydroelectric power available. Canada is 100% import dependent for ferrochromium. The Manitoba chromium resource was

¹ United States-Canada Free Trade Agreement. These tariff values were to become effective Jan. 1, 1990.

² A Generalized System of Preferences. E Caribbean Basin Economic Recovery Act. IL United States-Israel Free Trade Area Implementation Act of 1985.

considered an alternative supply source should current Canadian supply be interrupted. Federal and Provincial governments started to evaluate the feasibility of recovering chromium from a chromium-platinum deposit in Coleraine Township, Quebec. The resource was estimated at 1.36 million tons of ore graded at 4.5% Cr₂O₃.

Sherwood Metallurgical Corp. continued development of its low-carbon ferrochromium smelter in Vancouver, British Columbia. A construction site was selected and a Federal-Provincial environmental review process was begun. The environmental review was ex-

pected to be completed in June 1990. Plant construction was expected to be completed in 1992.

China

China reported 6.4 million tons of high-grade chromite resources in Tibet Autonomous Region.

Finland

Outokumpu Oy continued expansion of chromium ore beneficiation and sintering facilities. The expanded concentrator facilities at the Kemi Mine and the new sintering plant at the ferrochromium works started operation by year-

end. As a result of the plant expansions, Outokumpu was expected to increase ferrochromium production capacity to about 200,000 tons per year. Outokumpu also planned to reorganize its chromium-related operations. Effective January 1, 1990, the chromium ore mining operations and the ferrochromium production facilities were to come under Outokumpu Chrome Oy, an wholly owned subsidiary of Outokumpu Oy. Outokumpu reported 1989 production of 0.8 million tons of chromium ore excavated (down from 1.1 million tons in 1988), 169,000 tons of ferrochromium (up from 156,000 tons

in 1988), and 192,000 tons of stainless steel slabs (down from 206,000 tons in 1988).

France

Chromeuropa S.A. started production from its second furnace. This furnace has a power rating of 16 megavolt amperes and a production capacity of about 25,000 tons per year. Plant capacity was about 36,000 tons per year with the new furnace. Chromeuropa is a subsidiary of Ferroaleaciones Españolas S.A. (Spain).

Greece

Hellenic Ferroalloys SA increased its concentrator capacity to accommodate additional chromite from new mining operations in the Rizo area. The concentrator is near Skoumtsa. The new mining operation was expected to produce about 150,000 tons per year of chromium ore compared with 170,000 tons provided in 1988 by current mining operations in the Kozani area. From the 170,000 tons of run-of-mine chromium ore produced in 1988, Hellenic Ferroalloys produced 31,750 tons of concentrate graded at 49% Cr_2O_3 and 44,147 tons of high-carbon ferrochromium. Fimisco, a refractory company, produced 15,000 tons of refractory grade chromite ore from mines at Eretria.

India

Summary.—India was making major developmental changes in its chromium industry. New chromium ore mining capacity, beneficiation plants, ferrochromium smelters, and electrical power generating plants were being planned, constructed, and put into operation. In recent years, India has been the world's fourth or fifth largest chromium ore producer. Should India utilize about 300,000 tons of planned and developed capacity expansion, Indian chromium ore production would be about 1 million tons annually. At this level of production, India would displace Albania as the third largest chromium ore producer, after the Republic of South Africa and the U.S.S.R. New ferrochromium production capacity was coming into production and more was planned. Major ferrochromium producers installed or were installing captive electrical power generation plants to offset supply shortages from

the State power company. India brought 65,000 to 71,000 tons of annual production capacity into production through new furnace construction (Indian Charge Chrome Ltd.) and furnace conversion (Nav Bharat Ferro Alloys Ltd.). India had under construction or planned an additional annual ferrochromium production capacity of about 240,000 tons. This ferrochromium would be produced in small producers through new plants, expansion of existing ferrochromium plants, or the expansion of ferroalloy producers into ferrochromium production. Should all of this planned capacity be constructed, India would increase its annual ferrochromium production capacity by about 140% over that of 1988 and would move from being the world's fifth largest production capacity country to second to the Republic of South Africa, passing Zimbabwe, the U.S.S.R., and Japan.

Chromium Ore.—Major chromium ore producers in India included: Tata Iron and Steel Co. (TISCO), Orissa Mining Corp. Ltd. (OMC), and Mysore Minerals Ltd. (MML). TISCO and OMC produced in Orissa and exported through the port of Paradip. MML produced in Karnataka and exported through the port of New Mangalore.

TISCO had reserves of about 9,460,000 tons of over 40% chromic oxide ore down to 60 meters. TISCO practiced mechanized mining and hand sorting. Annual production capacity was about 300,000 tons, with historical production by financial year of 132,000 tons in 1985, 165,000 in 1986, 157,000 in 1987, and 200,000 in 1988. TISCO was constructing a beneficiation plant, to begin operation in 1990, that could add about 100,000 tons to its annual production.

TISCO developed its chromite and ferrochromium production capacity by expanding its mining operations and installing a beneficiation plant to upgrade chromium ore fines containing 20% to 30% Cr_2O_3 to about 50% Cr_2O_3 . The beneficiation plant was planned to start operation in March 1990. Mine production was to be expanded from a rate of about 200,000 tons per year of friable and lumpy market chromite ore to about 350,000 tons per year. The beneficiation plant was to process about 300,000 tons of run-of-mine ore to about 105,000 tons

of marketable product. When the beneficiation plant is fully operational, marketable chromite output was expected to be about 455,000 tons per year. TISCO planned to convert one of its two 9-megawatt furnaces, used for ferromanganese production at its ferroalloy plant in Keonjhar District, Orissa, to a 15-megawatt furnace capable of producing 15,000 tons of high-carbon ferrochromium annually. It was planned to convert the second 9-megawatt furnace, subject to successful conversion of the first one. Conversion of the first furnace was planned to be completed by the end of 1990.

OMC had ore reserves of about 14,400,000 tons of over 40% chromic oxide ore down to 100 meters. Annual production capacity was about 300,000 tons, with historical production of 212,000 tons in 1985, 213,000 in 1986, and 300,000 in 1987. OMC was building a beneficiation plant, to begin operation in 1991, that could add 90,000 tons to its annual production.

OMC Alloys, a subsidiary of Orissa Mining Corp., operated a ferrochromium plant at Bamnibal, Orissa, producing high-carbon ferrochromium with an annual production capacity of about 50,000 tons. Owing to limited power supply, OMC produced only at about 50% of its rated capacity. OMC continued construction of a beneficiation and briquetting plant for completion in 1990. The beneficiation plant was planned to have an annual production capacity of about 80,000 tons, the briquetting plant, 50,000 tons. OMC planned to build a 16-megawatt electric powerplant composed of two 8-megawatt diesel-powered generators. The power plant was planned for completion in 1990 at a cost of about \$12.5 million.

MML, with an annual production capacity of about 54,000 tons, produced from a reserve measuring several hundred thousand tons.

Ferrochromium.—Ferro Alloys Corp. Ltd. (FACOR) operated a domestic-oriented ferrochromium plant at Shree-ramnagar, Andhra Pradesh, and an export-oriented plant at Randia, Orissa. FACOR also operated chromite mines in Orissa. FACOR continued construction of three 10-megawatt diesel-powered electric generators at its Shree-ramnagar plant. One generator was tested. The

generators were expected to become operational in 1990. FACOR planned the construction of two 10-megawatt diesel-powered electric generators at its Randia plant. The new powerplant was expected to be constructed by MAN B&W (Federal Republic of Germany) with a completion date of late 1990 or 1991.

Indian Metals and Ferro Alloys Ltd. (IMFA) operated a domestic-oriented ferrochromium plant at Therubali, Orissa, and was constructing an export-oriented ferrochromium plant, Indian Charge Chrome Ltd. (ICCL) at Choudhar, Orissa. ICCL completed construction of its electrical power generation plant, briquetting plant, and electric furnace for ferrochromium production. The powerplant used coal to produce steam from four boilers that drove two turbines rated at 54 megawatts each and started operation in February. The powerplant also supplied power to IMFA's ferrochromium plant at Therubali. The electric furnace was rated at 48 megavolt amperes and 60,000 to 65,000 tons per year production capacity.

Industrial Development Corp. Ltd. (IDC) operated a ferrochromium plant at Jaipur Road, Orissa. IDC produced low-carbon ferrochromium with an annual production capacity of about 10,000 tons. IDC planned to install a 12-megawatt furnace for the production of high-carbon ferrochromium and to build a 9.5-megawatt electrical powerplant. IDC's planned annual high-carbon ferrochromium capacity was 15,000 tons. IDC was licensed for an annual ferrochromium production capacity of 15,000 tons.

Srichrome, a ferrochromium producer in Andhra Pradesh with annual production capacity of about 6,000 tons, started exporting its production. Srichrome operated two 3.6-megawatt furnaces.

Nav Bharat Ferro Alloys Ltd., a major ferrosilicon producer in India, set up a ferrochromium plant in Madhya Pradesh. The plant's annual capacity was 5,000 to 6,000 tons.

Ispat Alloys Ltd., an Indian ferroalloy company, planned to enter the ferrochromium production business. Ispat planned to build a chromium ore pelletizing plant and a ferrochromium smelter in Balasore District, Orissa, to produce high-carbon ferrochromium and charge-grade high-carbon ferrochromium. Ispat planned a pelletizing

plant using Outokumpu Oy (Finland) technology to produce about 160,000 tons per year of pellets. The planned annual capacity of the ferrochromium smelter was 15,000 tons of high-carbon ferrochromium and 22,500 tons of charge-grade high-carbon ferrochromium. Ispat sought to raise about \$80 million to finance these plans. The company was licensed for an annual production capacity of 15,000 tons.

Baroda Ferro Alloys planned to build a ferrochromium plant in Gujarat State with an annual production capacity of about 4,000 tons. Baroda raised \$48.5 million⁴ in Indian money markets for this purpose.

VBC Ferro Alloys Ltd., a ferrosilicon producer in Medak District, Andhra Pradesh, requested an Indian Government license to produce 15,000 tons per year of high-carbon ferrochromium. VBC ordered a 16.5-megawatt furnace from V/O Thermoexport (U.S.S.R.) and started operation of three 2.27-megawatt diesel-powered electrical generators.

Misrilal Mines Ltd. planned to build a low-carbon ferrochromium plant that would use its own ore production and a captive powerplant. Misrilal was licensed to build an electrical powerplant and a ferrochromium smelter with an annual ferrochromium production capacity of 15,000 tons.

In addition to those listed above, eight other companies were licensed by the Indian Government to produce ferrochromium. Those companies, annual production capacities, and locations are as follows: Kamini Steel, 25,000 tons in Maharashtra State; Jindal Strips, 15,000 tons in Madhya Pradesh; Vinod Kumar Garg, 15,000 tons in Madhya Pradesh; Kamal Kishore Shard, 15,000 tons at Madhya Pradesh; Ridhi Sidhi, 15,000 tons in Andhra Pradesh; B C Ferro Alloys, 15,000 tons at Andhra Pradesh; A D Monteiro, 15,000 tons in West Bengal; and S N Mishra, 15,000 tons at West Bengal.

Indonesia

PT Ispat Alloys, a subsidiary of Ispat Alloys Ltd. (India), planned to build a bulk ferroalloys plant that would include ferrochromium production. Ispat selected a site and identified raw material; electrical power, water, and equipment were completed. Construction was expected to begin in 1990. The plant was expected to cost

about \$34 million, produce 50,000 tons per year of ferroalloys including ferrochromium, ferrosilicon, and ferromanganese, and to export about 65% of its production.

Iran

Iran operated three major chromite mines: the Faryab and Esfandagheh, Kerman Province, which are export-oriented, and the Sabzevar in Khorasan Province, which supplies the domestic chemical industry. Iranian chromium exports were interrupted by the revolution and the subsequent Iran-Iraq war. The country resumed exporting chromium ore following the cease fire in the Iran-Iraq war.

Italy

Italcromo, a member of the Schlax group of companies, received approval for financing through GEPI, a state-owned financing company. Italcromo planned to borrow \$15.9 million⁵ to build a high-carbon ferrochromium plant with an annual production capacity of 100,000 tons at Termoli, Molise region. Ore was to be obtained from Albania. Shipping time was 4 to 6 hours across the Adriatic Sea from Albania to Termoli. Italcromo negotiated with the local electrical power supplier over electrical power cost.

Japan

Japan continued to operate its two-level stockpiling program. The Japan Rare Metals Association operated the stockpile under the Metal Mining Agency of Japan, a part of the Ministry of International Trade and Industry. Japan built a second warehouse, adjacent to the first, at Takahagi City, north of Tokyo.

Japan reported stainless steel production of about 2,711,000 tons in 1989. Its ferroalloy industry reported production of about 356,000 tons of ferrochromium. Japan reported imports of 1,043,000 tons of chromium ore, 477,000 tons of ferrochromium, and 818 tons of chromium metal. High-carbon ferrochromium imports had increased their market share from about 40% in the early 1980's to about 60% in 1987-88. Over the same time period (early 1980's to late 1980's), the value of the yen strengthened relative to the U.S. dollar, making Japanese-produced ferrochromium less competitive on the

world (and Japanese) market. Japanese ferrochromium producers benefited from the worldwide short supply of ferrochromium in 1989, increasing their share of the Japanese market from 41% in 1988 to 43% in 1989.

The president of Nippon Denko Co. became chairman of the Japan Ferroalloy Association. He noted that the number of workers employed in the Japanese ferroalloy industry has been reduced from a range of 7,000 to 8,000 in previous years to about 3,400 in 1989. His goals for the ferroalloy association were to stabilize prices and improve the competitiveness of Japanese producers.

Japan Metals and Chemicals Co. Ltd. (JMC) operated two ferrochromium producing plants: one at Kyushu, Fukuoka Prefecture, and one at Oguni, Yamagata Prefecture. A third plant, at Sakata, Toyama Prefecture, produced ferrochromium until 1987, when it was idled. JMC shifted from production of ferrochromium-containing chromium in the range of 60% to 65% to ferrochromium-containing chromium in the range of 50% to 55%. The shift was a cost saving measure. The price of high-grade chromium ore increased significantly in 1989 because of high demand for ferrochromium worldwide in 1988 and 1989.

NKK Corp. operated one ferrochromium-producing plant at Toyama, Toyama Prefecture, typically operating with one furnace in production and one idle. NKK started its second furnace. High demand for ferrochromium in 1989 and the ability of the company to transfer skilled workers from its Niigata ferroalloy plant made production from the second furnace possible.

Madagascar

Kraomita Malagasy (Kraoma), the company that mines chromium ore in the Andriamena region, celebrated its twentieth anniversary in 1989. Madagascar exported 95,000 tons in 1987, and 130,000 tons in 1988. Exports in 1989 were expected to be about the same as those of 1988. Kraoma was investing about \$8 million to improve mine and beneficiation plant production. The project was expected to be completed in 1990 or 1991. Madagascar sought a contractor to perform a final feasibility study and basic engineering. The study was to have started by yearend 1989.

Mexico

Compañía Minera Autlán S.A. de C.V., the only ferrochromium producer in Mexico, was taken over by its creditor, Mexico's Government development bank—Nacional Financiera. The foreclosure resulted from Autlán's failure to make a scheduled payment on its loan.

New Caledonia

Chromical, the chromium ore mining company that operates the Tiebaghi Mine in New Caledonia, planned to close its mining operation from October 1989 until 1991. During the closure, Chromical planned to prove new reserves. The Tiebaghi Mine had been in operation since 1982, producing about 450 tons per day of run-of-mine ore containing a range of from 20% to 50% Cr_2O_3 , which was beneficiated to 52% Cr_2O_3 . Annual production of beneficiated ore was about 80,000 tons per year.

Norway

Norsk Ferrokrom AS began production of high-carbon ferrochromium at Mo i Rana. Norsk Ferrokrom is a new company owned 51% by Norsk Jern Holdings (Norway), 33% by Ferralloy Consulting Establishment, a subsidiary of Macalloy Corp. (United States), and 16% by Fesil KS (Norway). Norsk Ferrokrom planned to produce ferrochromium containing 60% to 65% chromium from two furnaces previously used by Norsk Jernwerk to produce pig iron. Each furnace was rated at about 25 megavolt amperes and could produce about 45,000 to 50,000 tons per year of high-carbon ferrochromium. One furnace was started in September but startup of the second furnace, planned for December, was delayed because of declining ferrochromium prices.

Oman

The Ministry of Petroleum and Minerals of Oman initiated a 2-year, \$982,000 program for exploration of the Batinah coastal region in the north of Oman. Chromite deposits were to be sought in the Rajmi-Fizh and the Far-Hilti areas. A chromite deposit with reserves of about 180,000 tons was being developed in Ghashabi. Oman hoped to prove reserves of 1.6 million tons in the northern part of the coun-

try. Oman considered building a ferrochromium plant with an annual production capacity of 25,000 to 50,000 tons to process its domestic resources, should such an operation be feasible.

Philippines

The Philippines developed chromite resources and ferrochromium production facilities. High demand for ferrochromium in 1988 and 1989 resulted in high ferrochromium production in the Philippines and a short supply of chromium ore.

Under an agreement between the Philippine Government and the United Nations (U.N.), the United Nations Revolving Fund for Natural Resources Exploration conducted a resource identification program consisting of compiling existing data, geological mapping, trenching, gravimetric surveys, and preliminary drilling on Palawan and Dinagat Islands. Dinagat is a major chromite mining area. The U.N. proved 500,000 tons of reserves graded at 50% Cr_2O_3 on Dinagat Island. Major mining deposit operations on Dinagat include Acoje-Masdang, Velore Mining, and Malayan Wood (currently idle). Numerous small mines also operated in the area. Resources were thought to be in the millions of tons. The Philippines planned to find a developer for the deposit quickly. Malayan Wood planned to restart production from its Ledond chromite mine at the annual rate of 20,000 tons of lumpy ore and 5,000 tons of concentrate. The product was to be sold to Ferrochrome Philippines Inc., a local ferrochromium producer. Merlin Mining N.L. (Australia) acquired interests in three operating chromium mines: Filipinas, Matalisbong, and Gloria. All are on Dinagat Island.

Ferro Chemicals Inc., Mindanao Island, started operation of its second furnace in 1988, achieving an annual ferrochromium production capacity of 30,000 tons. Ferro Chemicals converted one of its furnaces to silicomanganese production in 1989, owing to unavailability of chromium ore and declining price of ferrochromium.

Ferro Chrome Philippines Inc., a subsidiary of Voest Alpine Stahl Linz GmbH (Austria), operated its high-carbon ferrochromium plant on Mindanao Island. The plant's annual production capacity was about 55,000 tons.

Integrated Chrome Corp. started production and shipments of charge-grade high-carbon ferrochromium. Integrated converted a 20-megavolt ampere furnace, previously operated by Electro Alloys Corp. for the production of silicon, to the production of ferrochromium at an annual capacity of about 26,000 tons. Integrated is a joint venture between Nippon Denko Co. Ltd., a Japanese ferrochromium producer, and Kaschrome, a Philippine chromium ore producer. Integrated planned to raise money through the sale of stock for the purpose of purchasing mechanical equipment and developing chromium ore resources.

Qatar

Qatar, along with Pennant Holdings (Australia) and Vitkovice (Czechoslovakia) started a study to determine the feasibility of constructing a ferroalloy plant at Umm Said. The planned \$300 million, 230,000 ton ferroalloy plant was planned to produce 60,000 tons of ferrochromium. The plant would include a captive 180-megawatt electrical powerplant that would convert natural gas associated from the North Field gas reserve to electrical energy.

South Africa, Republic of

Anglovaal Ltd. purchased the Grootboom Chrome Mine from Lavino SA (Pty.) Ltd. for \$31.06 (R77.655) million. The mine is located at Lydenburg, near Steelpoort, Transvaal province. With an annual production capacity of about 400,000 tons, the Lavino Mine is one of the Republic of South Africa's major chromium mines. Lavino was sold by American International Minerals Corp. (AIMCOR) of the United States. AIMCOR was to continue as exclusive sales agent for Lavino's ore for 5 years.

CMI, a subsidiary of Johannesburg Consolidated Investment Co. Ltd., worked on the construction of a third 32.5-megavolt-ampere furnace at its production facilities at Lydenburg, Transvaal province. With construction nearly complete by year end, CMI planned to start the furnace in February 1990. The additional furnace was expected to increase CMI's annual production capacity to 200,000 tons.

ChromeCorp Technology continued operation of their two 30-megavolt-

ampere furnaces, reaching an annual capacity production rate of 60,000 tons per furnace. ChromeCorp started construction of a third furnace, due for completion in 1990. With the new furnace, ChromeCorp's annual production capacity was expected to reach 180,000 tons.

Middelburg Steel and Alloys (Pty.) Lt. (MS&A) expanded transformer capacity on its direct current transferred arc plasma furnace at Krugersdorp from 16 megavolt amperes to 40 megavolt amperes. Operating power of the furnace was being steadily increased. Upon reaching full power operation, the plasma furnace annual production capacity was expected to increase from about 20,000 tons to about 50,000 tons. Full power operation was not expected before 1990. The 40-megavolt-ampere transformer capacity was achieved by using two 20-megavolt-ampere transformers with a third 20-megavolt-ampere transformer acting as a spare. MS&A continued construction of a kiln and associated housing and materials handling equipment to produce ferrochromium via a chromium direct reduction (CDR) process. The CDR process was being developed by MS&A and Krupp Stahl AG (Federal Republic of Germany). MS&A anticipated ferrochromium production via the CDR process to start in 1990.

Tubatse Ferrochrome (Pty.) Ltd., a subsidiary of Samancor, started production from its fourth furnace. The new furnace had an annual production capacity of 60,000 tons, bringing Tubatse's production capacity from 180,000 tons to 240,000 tons. Tubatse started construction on a fifth furnace, which was to be completed in 1990. Upon completion of this furnace, Tubatse planned to have an annual production capacity of 300,000 tons.

Samancor and Gencor rationalized their interests in Cromore, the group responsible for mining, and Tubatse. The net effect of the changes was to make Cromore and Tubatse subsidiaries of Samancor. Samancor made improvements to increase productivity of its chromium ore mining operations. In the eastern Transvaal, a new shaft was put in at the Mooihoek Mine, and the Jagdlust Mine was reequipped. In the western Transvaal, the plant at the Waterkloof Mine was modified to increase production and improve quality. Re-

treatment plants were established at the Mooinooi, Waterkloof, and Tweefontein Mines to recover ore from the slimes dams.

Purity Minerals was developing a chromite mine and a ferrochromium smelter near Rustenburg, Transvaal province. The mine and smelter were to be completed in 1990. Purity's chromite mine was expected to produce about 30,000 tons per month run-of-mine ore that was to be concentrated to 21,000 tons per month of product from a reserve of 7.2 million tons in the lower group chromitite seam number 6 (LG6) and lower group chromitite seam number 6A (LG6A) chromite seams of the Bushveld Complex. The product was to be moved by truck 10 kilometers from the mine site to the smelter. The smelter was to consist of two 33-megavolt-ampere furnaces with annual production capacity of 60,000 tons each.

Spain

Prereducidos Integrados del Suroeste de España (Presur) requested the Ministry of Industry to import a 2-megavolt-ampere plasma furnace tax free for the purpose of producing ferrochromium. Presur planned to produce 2,000 to 3,000 tons per year of ferrochromium at Frangel de la Sierra, Badajoz province.

Swaziland

Royal Swaziland Chrome Corp. was a joint venture being planned among Australian Overseas Mining Ltd. (Australia), 35%; German Mines Ltd. (Australia), 20%; International Metals S.A. (Luxembourg), 10%; Swaziland Government, 15%; Boulder Gold N.L. (Australia), Chrome Corp. of America (USA), 10%; and Luxembourg Alloys Co. (Luxembourg), 10%. They proposed to use Krupp's Codir prereducion process to produce ferrochromium in Swaziland using chromite from Lebowa homeland South Africa and local coal. Negotiations started with the Swazi Government in April 1989.

Sweden

SwedeChrome AB operated a ferrochromium plant at Malmö having a production capacity of about 50,000 tons per year. Production capacity had been increased from about 30,000 tons per year in 1988 and was increasing to a target capacity of 80,000 tons per year. SwedeChrome planned to close its

plant in 1990. The plant was to be closed because of the declining price of ferrochromium, an unfavorable cost position owing to the Swedish embargo toward South African chromite, and, to a lesser degree, uncertainty of electrical power rates. With Swede-Chrome out of production, Sweden was expected to be left with one ferrochromium producer, Vargön Alloys AB. Vargön produced high-carbon ferrochromium with an annual capacity of about 160,000 tons.

Turkey

Etibank General Management operated several chromium mines and two ferrochromium plants. The Antalya plant produced low-carbon ferrochromium with an annual capacity of about 10,000 tons. The Elâzig plant produced high-carbon ferrochromium. Construction continued at the Elâzig plant where construction of two electric furnaces of 30-megavolt-ampere electrical capacity and annual high-carbon ferrochromium production capacity of 50,000 tons of each were under development. One of these two furnaces was completed and began production, increasing the plant annual production capacity to 100,000 tons. The second furnace was expected to be completed in 1990, increasing the plant's annual production capacity to 150,000 tons. Etibank operated the Kefdag, Guleman, and Soridag chromite mines in Guleman Province to supply the Elâzig ferrochromium smelter. These mines produce about 250,000 tons of chromium ore annually. Upon completion and operation of the new furnaces at Elâzig, Etibank expected to convert all of its ore and ore purchased from local independent producers to ferrochromium. A new chromium ore deposit was identified in the Adana area, about 75 kilometers west of Iskenderun. Turkey planned to develop mining and ferrochromium production based on the deposit.

Kromsan Birlesik Sanayi ve Ticaret S.A., the chromium chemicals producer, was being sold as part of Turkey's industrial privatization program. The plant, located at Mersin (near Elâzig, Guleman province), produced sodium dichromate: 26,800 tons in 1987, and 27,500 tons in 1988.

United Arab Emirates

The Al Fujayrah Emirate evaluated

its chromite resources, and found that Al Fujayrah had a chromite reserve of about 100,000 tons of chemical- or metallurgical-grade ore. The Emirate sought chromite resources useful for the production of refractories for use by its cement industry.

U.S.S.R.

The Donskoye Ore Mining and Enrichment Combine, located in the northwestern part of Kazakhstan, is the major chromium ore mining area in the U.S.S.R., accounting for about 95% of the U.S.S.R.'s chromium ore production. The U.S.S.R. is the leading centrally planned economy chromium ore producer and accounts for about 40% of world chromium ore production. The collection of ore bodies mined by the Donskoye Combine are collectively called the Yuzhno-Kempirsayskiye (or Donskiye) deposits. The Donskoye Combine operated four surface mines and one underground mine. The surface mines include Yuzhniy, 40 Years of the Kaz-SSR, Obyedinenniy, and Mirnyy. Molodezhnaya, the underground mine, started operation in 1982 and produced about 1.1 million tons in 1987 with an annual design capacity of 2 million tons. Tsentral'naya was a second underground mine under development to be operated by the Donskoye Combine, starting in 1991. In 1987, about 24% of production came from the underground operations. These operations have been developed to compensate for the depletion of high-grade ore available from the surface operations. It was planned that all production would ultimately come from underground operations. Donskoye Combine operated two crushing and grinding mills to process high-grade ore and two concentrators to process lower grade ores. The first concentrator started operation in 1975, and, in 1989, had an annual output capacity of about 615,000 tons. The second concentrator started operation in 1987 with an annual output capacity of 600,000 tons. The West Kazakhstan Geological Association reported the discovery of additional chromite reserves in the Donskoye Complex.

Venezuela

Central de Ferroleaciones de Venezuela C.A. (Cefeca) planned to produce ferrochromium at Puerto Ordaz. Export oriented chromium ferroalloy annual

production capacity of about 180,000 tons was planned for 1992. Cefeca is owned by PT Investment Alloy, Corporación Venezolana de Guayana (Government owned), GT Administración y Participación S.A., Italmagnesio S.A. (Brazil). The project was planned to take advantage of inexpensive electrical power available from the Guri Dam on Venezuela's Caroni River.

Vietnam

Vietnam sought to develop its chromite resources. Vietnam has been producing small quantities of chromite, but sought to develop its mining by granting mining rights to Covictory Investment Ltd. (Australia) in exchange for investment. The Nui Nua chromite mine is located about 150 kilometers (km) south of Hanoi in Thanh Hoa province. The alluvial chromite deposit was thought to vary in thickness from 6 to 35 meters, to be about 3 km wide by 12 km long, and to contain about 30 million tons of ore containing 1.5% to 5% Cr₂O₃. Up to 80% of the chromite grains were between 70 and 280 microns in size. Feasibility studies were being done on the deposit.

Zimbabwe

Zimbabwe reported that foreign exchange earnings from ferrochromium exceeded those of gold in 1988. Zimbabwe Mining and Smelting Co. started production from its remelting furnace. The 3-megavolt-ampere furnace remelts below commercial size ferrochromium resulting from crushing operations with an annual production capacity of about 15,000 tons. The Government of Zimbabwe, Union Carbide (owner of Zimbabwe Mining and Smelting), and Zimbabwe Alloys were developing technology to mechanize the recovery of chromite from the narrow seams in the Mutorashanga area of the North Dyke. The objective was to make that chromite recovery economic, thereby creating an estimated 500 million tons of chromite reserves for the country. The group will acquire and operate an Atlas Copco-Eikhoff (Federal Republic of Germany) roadheader on a narrow North Dyke chromite seam to test the feasibility of using such technology. Owing to a lack of economic recovery methods for narrow seam chromite mining, only the Middle and Southern sections of the Great Dyke chromite are now mined.

^e Estimated. ^p Preliminary. ^r Revised.

¹ Table includes data available through Apr. 3, 1990.

² In addition to the countries listed, Bulgaria, China, and North Korea may also produce chromite, but output is not reported quantitatively and available general information is inadequate for formulation of reliable estimates of output levels. Figures for all countries represent marketable output unless otherwise noted.

³ Figures are sum of (1) crude ore sold directly for use and (2) concentrate output, both as reported in Brazilian sources. Total run-of-mine crude ore (not comparable to data for other countries) was as follows, in thousand metric tons: 1985—727,125; 1986—763,000; 1987—830,000 (revised, estimated); 1988—810,000 (revised, estimated); and 1989—810,000 (estimated).

⁴ Direct-shipment lump ore plus concentrates and foundry sand.

⁵ Exports of direct-shipment ore plus production of concentrates.

⁶ Reported figure.

⁷ Revised to zero.

⁸ Includes production by Bophuthatswana, which was as follows, in metric tons: 1985—358,000; 1986—454,000; 1987—508,000; 1988—450,000 (estimated); 1989—350,000 (estimated).

CURRENT RESEARCH

Bureau of Mines research provides fundamental scientific and technical information essential for advancing mineral science, processing technology, and conserving and developing domestic mineral resources. This research is conducted in support of the Strategic and Critical Materials Stock Piling Act of 1946 as amended, the Defense Production Act of 1950 as amended, the Mining and Minerals Policy Act of 1970, and the National Materials and Minerals Policy, Research and Development Act of 1980.

Recent research related to chromium includes the study of chromium alloys with the objective of reducing chromium content and the recycling of chromium containing materials.

The Bureau of Mines studied heat-resistant steels containing 8% chromium as a substitute for Type 304 stainless steel, the most popular stainless steel grade, that contains nominally 18% chromium. Tests found that the new alloys were very susceptible to room-temperature, deformation-induced martensitic transformations. At higher temperatures, tensile strengths and workability of several of the alloys were

comparable to that of Type 304. Some of the alloys had superior oxidation resistance.⁶

The effect of aluminum additions on sulfidation resistance of some iron-chromium-nickel alloys was studied. Alloys containing 4% aluminum were found to form thin adherent scales in a wet sulfur vapor atmosphere by a mechanism different from that of aluminum-free alloys. It was found that if the sulfur-containing environment could be modified by the injection of water to an oxidizing environment, then aluminum addition dramatically improves corrosion resistance.⁷ The Bureau studied the prediction of microstructure in low-chromium substitutes for stainless steel. Relationships were developed to predict the microstructure for iron-base alloys containing 4% to 12% chromium.⁸ The Bureau also studied the structural stability and oxidation resistance of these alloys.⁹

The Bureau studied impact spalling of high-chromium white cast-iron balls that are used in the milling of minerals. Spalling and abrasive wear tests were conducted and reported on numerous alloys with varying heat treatments.¹⁰ The Bureau also studied NiHard 4 with the objective of improving its impact resistance. The NiHard 4, a 9% chromium-containing alloy, could then be used as an alternative to an alloy containing 15% to 30% chromium. Alloys were developed that achieved comparable impact and abrasion resistance under moderate conditions at only marginally higher cost.¹¹ The Bureau studied an iron-nickel-chromium electrodeposition process which, in combination with heat treatment, could produce stainless steel coatings. A ferrous nickelous electroplating bath containing 3-micrometer-diameter chromium particles was used to produce 250-micrometer-thick coatings that were homogenized by heat treating. Coating corrosion rates approximated that of Type 304 stainless steel.¹²

The Bureau of Mines studied the recovery of chromium from zinc-treated superalloy scrap. Mixed and contaminated superalloy scrap was pyrometallurgically and hydrometallurgically treated to separate and recover metal values. More than 98% of chromium could be leached from zinc-treated or atomized scrap.¹³ An X-ray fluorescence analysis method to promptly analyze the superal-

loy leach liquors using thin-film techniques was also developed.¹⁴ The Bureau studied the recovery of chromium from hard-face alloy grinding waste. The process involved deoiling the grinding waste followed by chloride-based dissolution of the deoiled material. The final raffinate was chromic chloride solution.¹⁵ The Bureau tested tannery sludge for chromium recovery potential. Thermal treatment residues were tested for leachability and to help conceptualize a chromium recovery process.¹⁶

The Department of Defense studied the erosion of chromium plated tank gun barrels. Metallurgical examination found that microcracks originally present in the coating resulted in spalling which, in turn, resulted in erosion.¹⁷

The Council for Mineral Technology (MINTEK) of the Republic of South Africa developed a method to improve prereduction of chromite and evaluated the progress and trends in the substitution for chromium in steels. MINTEK studied the chromite prereduction process. They found that by using coated and fluxed chromite pellets, reduction in the presence of carbon dioxide of 70% of the chromium and 90% of the iron could be achieved. Application of this technique could result in greater productivity and lower electrical energy consumption for existing ferrochromium-producing plants and reduced capital investment cost without sacrificing annual production capacity for new plants.¹⁸ MINTEK found that substitutes for Type 304 stainless steel, the most common grade, in general had inferior corrosion resistance, poorer mechanical properties, and a higher cost than Type 304 stainless.¹⁹ The mechanism of chromite reduction under varying physical conditions was studied.²⁰

Private industry conducted research to improve product quality or to develop more economic production and utilization processes. Ferrochromium production by top- and bottom-blowing converter, direct current plasma, and plasma heater furnaces have been studied. In order to replace energy supplied by the use of expensive electricity in traditional smelting technology with less costly coal combustion, ferrochromium was produced in a top- and bottom-blowing converter. The smelting reduction process was demonstrated technically feasible in furnaces of 100 kilo-

gram and 1 ton capacity.²¹ One direct current plasma arc has been applied to ferrochromium production since 1983. The furnace was found to process less expensive raw materials, achieve greater chromium recovery, and permit freedom in selecting slag composition. However, the furnace was also found to consume more electrical energy than its alternating current submerged-arc counterpart and to produce a higher carbon-containing product.²² The chemistry and metallurgy of metal and slag contained in the direct current plasma furnace was studied.²³ Production by the Plasmachrome process was studied. It was found that energy recovery was an important economic factor and that the chromium content of the ferrochromium product could be adjusted by diluting high chromium-to-iron ratio ore with iron ore. Energy recovery was about 4.5 kilowatt hours per ton of ferrochromium product.²⁴

OUTLOOK

On the average in the United States, about 75% of chromium is consumed by the metallurgical industry, and about 75% of metallurgical industry chromium consumption is for stainless steel production. Thus, stainless steel production accounts for about one-half of the chromium consumed in the United States. The remainder is consumed in the production of other ferrous and nonferrous alloys, chemicals, and refractories. Some of the chemical and refractory products are consumed in the steel production process. The outlook for chromium consumption in the United States is the same as that for stainless steel. Stainless steel is estimated to be the major end use for chromium worldwide. Thus, stainless steel industry performance determines chromium industry demand worldwide.

The trend to supply chromium in the form of ferrochromium by chromite mining countries is expected to continue. The rate at which new ferrochromium plants come into production is expected to diminish now that all major chromite producers have such facilities. With new, efficient ferrochromium production facilities and excess capacity in chromite-producing countries, both

production and capacity are expected to diminish in traditional producing countries, except where domestic industries are protected by quotas and tariffs. Further upward integration of the chromium industry is expected as chromite-producing countries expand current or develop new stainless steel production capacity.

BACKGROUND

Definition, Grades, and Specifications

United States industry chemically and physically specify chromium materials through the American Society for Testing and Materials (ASTM). Other organizations also specify chromium materials. DLA in cooperation with the Department of Commerce maintains purchase specifications for chromium materials contained in the NDS. The Treasury Department, in cooperation with the Department of Commerce and participants in the General Agreement on Tariffs and Trade, maintains definitions of chromium materials for the purpose of recording trade and applying tariff duties.

For the purpose of importation, chromium ore and concentrates made therefrom are classified by their chromic oxide content. Ore and concentrates are divided into three categories: containing not more than 40% chromic oxide, containing more than 40% and less than 46% chromic oxide, and containing 46% or more chromic oxide. Producers of chromium ore and concentrate typically specify chromic oxide content, chromium-to-iron ratio, and iron, silica, alumina, magnesia, and phosphorous contents. They also specify the size of the ore or concentrate. Typically, chromic oxide content ranges from 36% to 56%, with values in the 40% to 50% range being most common. Chromium-to-iron ratios typically range from about 1.5:1 to about 4.0:1, with typical values of about 1.5:1 to 3.0:1. In trade, the chromium ore is also called chromite ore, chromite, chrome ore, and chrome.

For the purpose of importation, chromium ferroalloys are classified as ferrochromium and ferrochromiumsilicon. Ferrochromiumsilicon, also called ferrosiliconchromium and chromium silicide, is not further classified. Ferro-

chromium is classified by its carbon content as containing not more than 3% carbon, more than 3% but not more than 4% carbon, or more than 4% carbon. Producers of ferrochromium typically classify their material as low- or high-carbon or charge-grade ferrochromium. Charge-grade ferrochromium is also called charge chrome. Producers of chromium ferroalloys typically specify chromium, carbon, silicon, phosphorous, and sulfur contents, and material size. Ferrochromiumsilicon typically contains 24% to 40% chromium, 38% to 50% silicon,

and 0.05% to 0.1% carbon. Ferrochromium typically contains 50% to 72% chromium and 0.05% to 8% carbon. Low-carbon ferrochromium typically contains 55% to 75% chromium and 0.02% to 0.1% carbon. High-carbon ferrochromium typically contains 60% to 70% chromium and 6% to 8% carbon. Charge-grade ferrochromium typically contains 50% to 55% chromium and 6% to 8% carbon.

Products for Trade and Industry

Chromium is primarily used in the metallurgical industry as an alloying

element. Small quantities of chromium are alloyed with (i.e., added to), a base metal to achieve certain desired properties not attainable with the base metal alone. Before its use as an alloying element, chromium was used predominantly as a pigment, a plating material, and a refractory material. As a pigment, chromium provided color to many end products and corrosion protection to ferrous metals. As a plating material, chromium provided a lustrous or a hard finish, and corrosion protection to the substrate metal. As a refractory, chromite found major use in

blast furnace iron production. The decline in use of this process has resulted in a corresponding decline in chromite refractory use. Environmental concern over hexavalent chromium contamination has resulted in reduced use or increased expense of chromium use in pigments and plating. Chromium is traded primarily as chromium ore or as ferrochromium. Substantial amounts of chromium chemicals, pigments, and metal are also traded.

Industry Structure

Stainless steel was developed in about 1900. Since then, stainless steel has grown to become the major end use of chromium. Chromium is used in stainless steel production in the form of ferrochromium, a product of smelting chromite ore with a carbonaceous material (chemical reductant) and silicious material (flux material). The production of stainless steel evolved in association with the major steel-producing centers. The production of ferrochromium developed in conjunction with the production of stainless steel at those steel-producing locations.

In a trend toward vertical integra-

tion, chromite-producing countries have been developing ferrochromium and stainless steel production capacity. This trend has worldwide impact. Formerly, ferrochromium was produced mainly by the United States, Europe, and Japan, the major steel producers. The U.S. trend to obtain chromium in the ferroalloy form is a result of the world trend to produce ferrochromium in chromite-producing countries.

The structure of the chromium industry from a material processing perspective begins with mining of chromite ore. Once mined, the ore is beneficiated. The resulting chromite ore or concentrate made therefrom may be consumed in the refractory, chemical, or metallurgical industry. Chromite ore is consumed in the refractory industry for its chromite mineral content. The chromite is typically crushed, ground, and sized. It is then mixed with magnesite to make chrome-magnesite bricks that are subsequently consumed in the steel, glass, or cement industry. The chromite refractories are used to line steelmaking furnaces, cement kilns, or heat exchangers associated with glass production.

Chromite ore consumed in the chemical or metallurgical industry is processed to extract the chromium from the chromite mineral. Chromite ore consumed in the chemical industry is kiln roasted, and the chromium is leached out in the form of sodium bichromate. The sodium bichromate is further processed to make chromic acid and other chromium chemicals and pigments. Chromic oxide is a chemical industry product. Chromite ore consumed in the metallurgical industry is smelted to produce ferrochromium. In effect, the oxygen is removed from the iron-chromium-oxygen mineral leaving an iron-chromium alloy, ferrochromium. Ferrochromium is produced to meet a variety of chemical and physical specifications. Several variations of the ferrochromium production process are practiced; the submerged electric arc furnace is central to each process. Ferrochromium is the source of chromium units for alloys, especially ferrous alloys. When nonferrous alloys require chromium and the iron is undesirable, chromium metal is used. Chromium metal is produced from ferrochromium by an electrolytic process or from chro-

mic oxide by an aluminothermic process.

The major vertical structure of the chromium industry is mining-smelting-stainless steelmaking. In some instances, the ownership of mining operations, smelters, and stainless steel production facilities are integrated. In many other cases, integration is limited to mining and smelting or to smelting and stainless steelmaking. Often the ownership of operations is shared. Major mining, smelting, or stainless steel production facilities are typically privately owned by large companies or groups of companies.

Geology-Resources

The geology of many chromium deposits has been characterized.²⁵

The data in table 15 are rated reserves and reserve base for major chromium ore producing countries.²⁶ The data on chromite reserves and resources are categorized according to a general U.S. Bureau of Mines-U.S. Geological Survey classification system applicable to all minerals. The definition of reserves and reserve base are published in Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals." The distribution of chromite deposits into reserves, reserve base, and resources categories is determined by the physical and chemical nature of the ore and by mining and market economies. The reserve base is the in-place demonstrated (measured plus indicated) resource from which reserves are estimated. The reserve base includes those resources that are currently economic, marginally economic, and some of those that are currently subeconomic.

Reserves are that part of the reserve base that could be economically extracted or produced at the time of determination. Reserves include only recoverable materials. Reserve values are included in reserve base values.

The term "reserves" is commonly used with a variety of definitions. Even when the definition given here is used, the quantitative value of reserves will vary owing to differing physical and economic criteria applied to a deposit by different analysts.

Technology

Mining.—A wide variety of mining technology is applied to the surface and

subsurface mining of chromium ore. Most ore comes from large mechanized mines. However, small labor intensive mining operations contribute to world supply.

Beneficiation.—The amount of ben-

eficiation required and the techniques used depend on the ore source and end-use requirements. When the chromite is clean, only hand sorting of coarse material and gravity separation of fine material may be required. When the ore is lumpy and mixed with host rock,

heavy media separation may be used. When the chromite mineral occurs in fine grains intermixed with host rock, crushing may be used in conjunction with gravity separation and magnetic separation.

Smelting.—The smelting of chromium ore to produce ferrochromium requires electric arc furnace technology. Early electric furnaces having power ratings in the kilovolt-ampere range have developed in modern furnaces

having power ratings of about 50 megavolt amperes. Covered and partly covered electric arc furnaces replaced open ones when pollution control became a factor of production. Industry is developing new production technologies using high-temperature plasmas or using alternatives to electrical energy power supply. The new production technologies are expected to be more cost competitive than traditional production technology.

Technological change in stainless steel production permitted the replacement of expensive high-chromium, low-carbon ferrochromium by less expensive low-chromium, high-carbon ferrochromium. This change permitted the use of low chromium-to-iron ratio ore for smelting to ferrochromium, which is subsequently alloyed to produce stainless steel. The Republic of South Africa is the most abundant and low-cost source of such ore. Unfortunately, this ore is friable (breaks easily into small pieces), and the finer fractions of such ore are blown out of a furnace before it can be smelted. Agglomeration technology has been developed to permit the use of fine chromium ore in the electric arc furnace. Both briquetting and pelletizing are practiced. Efficient production technology uses prereduced and preheated pelletized furnace feed. Advanced smelting technologies have been designed to use fine ore.

Recycling.—Recycling is the only domestic supply source of chromium. Stainless steel and superalloys are recycled, primarily for their nickel and chromium contents. As much as 50% of electric furnace stainless steel production can result from recycled prompt and purchased stainless steel scrap. Advanced stainless steel production technology like continuous casting reduces prompt scrap generation and permits a higher product yield per unit of raw material feed.

Byproducts and Coproducts

Chromium is mined as a primary product. Chromium is not a byproduct or coproduct of the mining of any mineral, nor are there byproducts or coproducts associated with chromium mining. Chromium has the potential of becoming a byproduct of platinum mining in the Republic of South Africa or a byproduct of lateritic nickel mining. Platinum and chromite are both present

in the UG2 seam of the Bushveld complex in the Republic of South Africa. At present, most platinum mining is from the Merensky Reef. However, as platinum mining from the UG2 seam continues and as new mining operations that exploit the UG2 seam are developed, chromium-containing tailings will continue to grow. The feasibility of utilizing these resources has been demonstrated, and new ferrochromium production facilities under development by Middelburg Steel and Alloys are designed to permit the use of these resources. It appears to be only a matter of time before economic conditions dictate the use of those tailings, thereby making chromium a byproduct of some platinum operations.

Economic Factors

Prices.—Inadequate supplies of ferrochromium resulted from strong demand for stainless steel in all three major producing regions: the United States, Japan, and Europe. Inadequate ferrochromium supply resulted in increasing ferrochromium prices until mid-1989, when supply exceeded demand and prices began to decline. The price of chromite rose in 1989 following the steady rise in ferrochromium prices since mid-1987. In 1989, new ferrochromium plants and plant expansions were under construction or being completed. U.S. stainless steel production declined 12% from that of 1988. Although declining, U.S. stainless steel production remained strong. Reduced stainless steel production permitted ferrochromium producers, traders, and consumers to rebuild stocks after about 3 years of generally increasing production. Reduced demand for ferrochromium, resulting from decreased stainless steel production, and increased supply of ferrochromium, resulting from producer expansions and new plant construction, have resulted in declining ferrochromium prices. Ferrochromium production capacity increased about 300,000 tons contained chromium (10% to 15% of 1988 world capacity) in 1989. A similar expansion was anticipated in 1990.

The historical value of chromium ore by grade, ferrochromium by grade, and chromium metal imported to the United States is shown in tables 21 and 22. These values show that, as chromium

ore is processed to ferrochromium and to chromium metal, the added value is quite large. On a per-unit-of-contained chromium basis, the value of ferrochromium is about seven times that of chromium ore; the value of chromium metal is about 30 times that of chromium ore. Variations of the value of ore are shown to follow those of ferrochromium, indicating values of chromium ore change in response to demand with ferrochromium value first to reflect demand changes.²⁷ Ferrochromium values show greater variation than those of chromium ore. The unit value of chromium materials has increased by 10% to 15% per year in actual value since 1963.

Costs.—Operating and transportation

are the two major components of chromium ore cost in the market place. Operating cost includes mining (the production of run-of-mine ore) and beneficiation (the production of marketable chromium ore or concentrate from the run-of-mine ore). Mining cost typically runs from 75% to 80% of operating cost, but may exceed 90% in some cases. Labor cost is the major component of production and of beneficiation cost. Labor cost typically runs from 20% to 60% of mining cost and from 25% to 80% of beneficiation cost, but can be higher.

Electrical energy and labor cost are the major components of high-carbon ferrochromium production cost. Electrical energy cost runs from 20% to 55% of production cost, whereas labor

cost runs from 10% to 30% of production cost.

Tariffs.—Import tariffs are typically imposed to protect domestic industry. Where there is no domestic industry, such as chromium ore production in the United States, there is no tariff. (See Foreign Trade section of this report for U.S. tariff duties on chromium materials.) In some cases, such as ferrochromium imports to the European Community, import tariffs are used along with import quotas. That is, a duty-free quota is allocated to member countries. The quotas may be revised as

necessary to meet the needs of domestic consumers and producers. Only in a few cases, such as ferrochromium exports from China and certain grades of chromium ore exports from India, are export duties applied.

Operating Factors

Environmental Requirements.—Chromium releases into the environment are regulated by the Environmental Protection Agency. Workplace exposure is regulated by the OSHA.

Toxicity.²⁸—The toxic effect of an

element depends on its chemical form and concentration and on the conditions and duration of exposure. At about 200 parts per million, chromium is the sixth most common element in the Earth's crust; at 1 to 2.5 parts per billion, the 15th most common element in sea water. Chromium is ubiquitous. Chromium is generally recognized to be essential to human health. Hexavalent chromium compounds are generally recognized as toxic. The toxic status or trivalent valent chromium compounds is not clear. However, trivalent chromium compounds are less toxic than hexavalent chromium compounds. Chemical compounds containing chromium in lower valence states are generally recognized as benign.

Energy Requirements.—Ferrochromium production is an energy intensive process, requiring about 3800 kilowatt hours per metric ton of product. Currently available technology can reduce the electrical energy requirement to about 2000 kilowatt hours per ton by thermal energy recovery and recycling. Traditional technology uses electricity to supply the energy required to smelt chromium ore. Advanced production technology permits the use of liquid or gas fuel to substitute for part of the energy required. Alternative production technology is being developed which would permit nonelectrical energy sources to supply a significant fraction of the energy required to smelt chromium ore.

Transportation.—Chromite ore is typically transported by trackless truck or conveyor belt from the mine face to storage or processing facilities on the mine site. From there, it is transported by truck from the mine site to local railhead. It is then usually transported by rail to ports or to smelters. Smelters that do not have associated ship loading and unloading facilities transport their product by rail to ports. Following transport by ship to consumer countries, chromium materials are typically barged or hauled by truck to end users who have no ship loading and unloading facilities.

CLAYS

By Sarkis G. Ampian

Mr. Ampian, a physical scientist with 37 years of experience, has been the commodity specialist for clays since 1972. Domestic survey data were prepared by Sarkis Ampian and Rosa McGee, supervisory mineral data assistant. The international tables were prepared by Peter Roetzel, Harold Willis, and Virginia Woodson, international data assistants.

Total quantity of clays sold or used by domestic producers decreased about 5% in tonnage while increasing over 8% in value to a new record high of \$1.52 billion. This decrease in production reverses the upward trend in clay output that had occurred for 6 of the previous 7 years. Clays in one or more of six classification categories, ball clay, bentonite, common clay and shale, fire clay, fuller's earth, or kaolin, were produced in 44 States and Puerto Rico during 1989. Clay production was not reported in Alaska, Delaware, the District of Columbia, Hawaii, Rhode Island, Vermont, or Wisconsin. The leading seven States, in descending order, were Georgia, Ohio, Texas, North Carolina, California, Wyoming, and Alabama. The cost of fuels, such as coal, gas, and oil, were still a major concern to clay producers and manufacturers trying to reduce operating costs in the highly competitive marketplace. Industrywide efforts to economize and modernize were prevalent during the year. Environmental restrictions and associated costs combined with increasing capital cost began to affect production.

Production of common clay and shale was decreased because the downturn in construction, which resulted from rising interest rates, offset an otherwise mixed demand attributed to a slowing domestic economy. Building rates continued to decline because of a soft economy in the oil-producing States of the Southwest. However, firming oil prices for the first three quarters of the year not only increased drilling activity for gas and oil but also slightly improved the overall business atmosphere.

Increases in production for all of the specialty clays—bentonite, fire clay, and kaolin—except for ball clay and fuller's earth, resulted from an improvement in the mixed economy overall and a continued strong export demand. The steel, oil and gas exploration, and foundry industries, all major consumers of specialty clays, had adjusted to lower levels of production and

were experiencing increasing demand by foreign and domestic consumers.

Kaolin accounted for 21% of clay production but more than 67% clay value. Kaolin production of 9.0 million tons and exports of 2.34 million tons were record highs. A record high was also posted for fuller's earth.

DOMESTIC DATA COVERAGE

Domestic production data for clays are developed by the Bureau of Mines from one voluntary survey of U.S. operations. Of the 1,080 operations covered by the survey, 1,026 responded, representing 95% of the total clay and shale production sold or used shown in table 1.

ISSUES

Clay mining has an environmental impact because overburden is moved and a hole is excavated. State laws requiring

reclamation are being enacted. A minimum requirement usually includes leveling or recontouring the disturbed area and planting trees or grasses to prevent or minimize erosion. For processing, the impoundment of slimes and dust control are usually required. The rules for disposal of coarse tailings are similar to or included with those laws governing reclamation of the mined area.

Many local zoning boards are zoning clay producers out of business or forcing them to search for new and usually more distant deposits. This in turn increases costs to the community for these products because of increased transportation charges.

Although domestic clay resources are more than adequate and clay is a mature industry, the average price for clays is expected to rise steadily. These prices, somewhat reflecting the higher quality requirements for the specialty clays, are for the most part associated with land acquisition, severance taxes, land rehabilitation, and environmental and energy factors.

These rising prices, if unchecked, will have an adverse affect on the clay industry by making competing materials more socioeconomically attractive.

PRODUCTION, PRICES, AND FOREIGN TRADE

Kaolin

Domestic production of kaolin was relatively unchanged at 9.0 million tons while its reported value increased more than 9% to \$1.02 billion. Both the reported output and value, for the fourth consecutive year, reached record highs. Kaolin, in general, and filler grades, in particular, have enjoyed steady growth for most of the past 17 years, with output increasing from 6.0 million tons in 1973 to the record-high tonnage this year of slightly more than the 9.0 million reported last year. The unit value of kaolin rose more than 9% to \$113.95 per ton, with filler- and refractory-grade kaolin leading the way in higher reported values. Kaolin was again produced in 13 States, with Georgia (84%) and South Carolina (7%) accounting for 91% of total production. Georgia accounted for more than 92% of the posted values. Georgia produced all grades of kaolins: filler, refractory, chemical and water-washed, air-floated, and unprocessed. South Carolina produced only the latter two. Arkansas, Minnesota, California, Texas, Alabama, and North Carolina were the other six major production States. Arkansas and California produced refractory- and chemical-grade kaolins. Kaolin producers reported major domestic end uses for their clay as follows: paper-coating, 35%; paper-filling, 21%; refractories, 11%; fiberglass and insulation, 6%; face brick and rubber, 4% each; paint and chemicals, 3% each.

Kaolin production was slowed by the slowdown in the overall economy, particularly in the downturn in paper production. Softer demands for paper-, catalyst-, plastic-, and paint-calcined grades, were offset by a strong export demand because of a continued weak U.S. dollar, keeping production unchanged from 1988. The strong inroads of calcium carbonate, both ground and precipitated, as substitutes for kaolin in the paper-filling markets has yet to manifest itself in the statistics. Apparently the growing demand for coated paper has masked the calcium carbonate inroads. Capacity increases in water-washed and calcined grades started in the past few years

were gradually coming on-stream to meet the projected demand of catalyst, paint, paper, and plastic manufacturers. The anticipated excess capacity and slowdown in economy is expected to cause a downward pressure on prices. Kaolin refractory sales were steady for the first three quarters. Increased demand for high-alumina, kaolin-base refractory bricks and specialties by the foundry and steel industries was mostly responsible. Sales to cement manufacturers, a major consumer, were restrained during the year because of continued lower construction rates. The refractory industry, which became acclimated to lower levels of production brought about by changes in steelmaking and refractories technology and imports, was put in an enviable position of meeting the unexpected upsurge in demand. Production of the three paper-grade kaolins increased in 1989 from less than 5.9 to slightly more than 5.9 million tons. Water-washed production increased 2% while low-temperature calcined and delaminated production decreased 11% and 1%, respectively.

All Georgia and South Carolina kaolin filler-extender-pigment producers, both air-floated and water-washed, continued to modernize, to reduce unit operating costs, and to produce higher valued products. Emphasis continued to be placed on energy related costs and expanding the production capabilities for calcined pigment lines used chiefly by the growing paper, plastics, paint, rubber, and catalyst industries. The major enlargements of calcined clay capacity in Georgia by Engelhard Corp.'s Pigments and Additives Div., Anglo-American Clays Corp. (a subsidiary of English China Clays (ECC) America Inc.), Georgia Kaolin Co. (a subsidiary of Combustion-Engineering Inc. (C-E), J.M. Huber Corp., and Nord Kaolin Co. (a subsidiary of Nord Resources Corp.) were all completed by yearend. All the major water-washed kaolin producers now have a calcining capability. In noncalcining kaolin development, J.M. Huber Corp. was more than half way through its plans to add another 250,000 tons of nameplate spray-drying capacity at Huber, GA, by early 1990. Huber also successfully completed installation of reportedly the world's largest superconducting high-gradient magnetic separator (HGMS) system. The HGMS system, a 120-inch diameter and 500-ton unit, operates continuously with power consumption at the magnet reduced to zero. Two major expansions in air-float capacity and operations were also completed dur-

ing the year. Wilkinson Minerals Inc., Gordon, GA, the marketing affiliate of Wilkinson Kaolin Associates Ltd., added sufficient capacity to triple its production to an estimated 250,000 to 300,000 tons per year (tpy). Evans Clay Co., Summit, NJ, doubled its storage and loading capacity at McIntyre to accommodate both bulk and large ton bags on a 24-hour basis.

In development work, the Minnesota State Legislature authorized \$75,000 per year for 2 years to research bringing about a local kaolin industry based on the clays found in the southwest sections of the State. The work will stress test drilling on public lands to determine the kaolin reserves in the promising areas that proponents claim are insufficient on which to base a viable industry because of company confidentiality.

In acquisitions and divestitures, C-E of Stamford, CT, and ABB Asea Brown Boveri Ltd. of Switzerland agreed to a definitive merger in which ABB will purchase all the outstanding shares of C-E. C-E is the parent company of Georgia Kaolin Co., a world class producer of a full line of water-washed and air-floated kaolins in Georgia. Another subsidiary, C-E Minerals Co., in Georgia at Andersonville is the world's largest refractory calcine and/or grog producer. Hecla Mining Co., Coeur d'Alene, ID, in another kaolin move, finalized an agreement to purchase the kaolin operations and assets of Cyprus Minerals Co.'s clay division. The acquisition included kaolin mines and air-float plants at Deepstep and Sandersville, GA, and Aiken, SC. The purchase allows Hecla to offer ceramic grades of kaolin to complement its ball clay lines supplied by its subsidiary, Kentucky-Tennessee Clay Co., (K-T) Mayfield, KY. The Georgia and South Carolina operations will be operated by K-T. In another air-float acquisition, Evans Clay Co. purchased the air-float business of J.M. Huber Corp's Clay Div. in Huber, GA. The deal allows Evans Clay to acquire only Georgia crude clay reserves and the rights to tradenames on four air-float products. No employees or plant equipment were involved. These products will be formulated by Evans at its McIntyre, GA, plant. Clayburn Industries Ltd., Abbotsford, British Columbia, Canada, a producer of refractory-grade kaolin calcines at Bovill, near Moscow, ID, was acquired by IXL Industries Ltd., Medicine Hat, Alberta, Canada. The dead-burned clay is fired at Bovill and shipped to Abbotsford for refractory-brick and monolith specialty manufacturing.

Despite strong foreign competition and a fluctuating U.S. dollar, exports of kaolin, reported as clays by the U.S. Department of Commerce, increased more than 9% to 2.34 million tons valued at \$371 million. The unit value of the exported clay increased to \$158.70 per ton or about 2% more than that of 1988, indicating that a higher percentage of premium-quality grades was shipped. Kaolin, including calcined material, was exported to 67 countries, 2 more than in 1988. The two new countries were mostly small importers. The major recipients, in descending order, were Japan, Canada, Italy, the Netherlands, Finland, and Mexico. Exports to Finland decreased about 15% to 159,056 tons. Since 1985, Finnish imports of U.S. kaolin rose from only 21,000 tons to the high watermark of 187,000 tons in 1988. Finnish imports in the past, destined for their large domestic papermaking industry, have been largely from the United Kingdom. Kaolin producers reported end uses for their exports as follows: paper-coating, 68%; paper-filling, 18%; rubber, 5%; paint, 2%; and other, including ceramics and refractories, 7%.

Kaolin imports for consumption decreased about 60% to 3,106 tons valued at \$1.3 million. The unit value rose about 60% to \$412.05 per ton, reflecting the continuing strong worldwide demand for premium-quality kaolin. No Chinese imports were noted for the year.

Kaolin prices quoted in the trade journals generally advanced during the year. Chemical Marketing Reporter, December 29, 1989, quoted prices in short tons as follows:

Water-washed, fully calcined bags, carload lots, f.o.b. Georgia per ton	¹ \$323.00
Calcined, paper-grade, same basis, per ton	470.00
Paper-grade, uncalcined, bulk, carload lots, f.o.b. Georgia, per ton:	
No. 1 coating	110.00
No. 2 coating	87.00
No. 3 coating	85.00
No. 4 coating	82.00
Filler, general purpose, same basis per ton	64.00
Delaminated, water-washed, uncalcined, paint-grade, 1-micrometer average, same basis, per ton	284.00
Dry-ground, air-floated, soft, same basis, per ton	52.00
National Formulary, powder, colloidal, bacteria controlled, 50-pound bags, 5,000-pound lots, per ton	273.00

¹Average of quoted prices.

Ball Clay

Production of domestic ball clay decreased almost 9% to about 1.0 million tons valued at about \$41 million. Tennessee supplied 71% of the Nation's output, followed by, in descending order of production, Kentucky, Mississippi, Texas, and California. Production increased in all the major producing States. The continuing growth in

demand for water-slurried Tennessee ball clays, combined with the number of producers, allowed the publication of additional production statistics. The principal ball clay market was ceramics, mostly dinnerware, pottery, sanitaryware, and wall tile. Domestic producers continued to enjoy a strong export market, usually about 15% of total production. The domestic industry was slowed during the year because

of a sluggish overall economy and rising mortgage interest rates that depressed construction rates and housing starts. The slowdown in the overall economy continued from the last quarter of 1988.

Increased production capacities, modernization, and/or new plant construction proceeded slowly during the year while acquisitions, divestitures, and/or mergers were prevalent. Ball clay producers were either concentrating on increasing their capabilities to produce, store, and ship (mostly by slurry-tank rail car) water-slurried ball clay for ceramic markets, chiefly sanitaryware, or developing this capability. The divestiture of Cyprus' clay division was again of considerable interest during the year (see Kaolin section of this chapter). Hecla's attempt last year to also acquire Cyprus' ball clay assets was thwarted by the Federal Government's regulatory agencies. Watts, Blake, Bearne & Co. PLC (WBB), Devon, United Kingdom, on March 31 acquired the same assets through its American operating subsidiary, United Clays Inc., for \$7.3 million. This purchase is strategically important to WBB because it establishes the group with a base in its core activity, largely clays, in North America. United Clays, based in Gleason, TN, produces ball clays comparable with WBB's Devon clays that it mines in the United Kingdom. The assets include extensive reserves in Mississippi and Tennessee, as well as permanent and mobile extraction and processing facilities.

The average unit value for ball clay reported by domestic producers increased 6% to \$45.21 per ton. Chemical Marketing Reporter, December 29, 1989, listed ball clay prices, per short ton, unchanged from those of 1988, as follows:

Domestic, air-floated, bags, carload lots, Tennessee, per ton	\$49.00
Domestic, crushed, moisture-repellent, bulk carload lots, Tennessee, per ton	24.00

Ball clay exports decreased approximately 16% to 157,000 tons valued at \$6.8 million. Unit value declined slightly to \$43.62 from \$44.54, reflecting a smaller percentage of higher valued clays. Shipments were made to 25 countries, 1 more than in 1988. The major recipients, in descending order, were Mexico (51%), Canada (38%), and the remaining countries (11%). The expanding Mexican ceramic markets continued to be supplied largely with domestic clays because of international financial difficulties. Mexican ceramic exports, mostly

to the United States, are made chiefly with U.S. and domestic clays.

Ball clay imports for consumption, almost entirely from the United Kingdom, also decreased 8% to 1,483 tons valued at

\$373,911. The unit value of these clays increased more than 40% to \$252.13 per ton, indicating an increasing percentage of the higher valued beneficiated varieties than in previous years.

Fire Clay

Fire clay sold or used by domestic producers increased about 4% in production and 12% in value over that of 1988. This increase in production coupled with the reported increase in 1988 marks only the third major upturn in production in more than 10 years. The increase was attributed chiefly to expanding exports and the recovering smokestack industries, which consumes the bulk of manufactured fireclay refractories and clays. Fireclay production declined from the record highs of the early 1970's, approximately 4 million tons, to about 2 million tons in the early 1980's, and eventually to the low of 592,000 tons in 1986.

Industrywide expansions and modernizations, previously canceled or deferred until economic conditions improved, were cautiously being started again. Manufacturing plants and production lines that were operational were working at full capacity and/or throughput. The increased demand for higher quality fireclay-base product lines was further exacerbating a difficult situation by their slower kiln throughput compared with the lower quality lines.

The clay refractory industry had been in a period of low production because of decreased demand brought about by technological changes and lower consumption levels by its major users—steel, nonferrous metals, ceramics, glass, and minerals processing industries. The technological changes in steelmaking, away from integrated pig iron systems and toward electric furnaces and/or minimills, further compounded the problem by employing shapes and specialty refractories requiring less fire clay.

A world leader in refractory materials production, Didier Refractories Ltd., signed a letter of intent offering to acquire all the remaining outstanding shares of North American Refractories Co. (NARCO), Cleveland, OH, not already owned by Didier. Last year Didier obtained a 35% minority interest in NARCO. The offer is contingent on the approval of greater than 80% of non-Didier shareholders, Didier's board, and regulatory agencies. NARCO is expected to retain its name, management, and operating autonomy. In another move, East Rock Partners Ltd. Partnership, a New York investment partnership, announced a 7.3% stake in A.P. Green Industries Inc., Mexico, MO, common shares outstanding, and East Rock intends to make a bid for

the company. A.P. Green, a former unit of USG Corp., was spun-off to USG shareholders in February 1988. A.P. Green, an acquisition of its own, acquired Detrick Refractory Fibers Inc. from M.H. Detrick Co. Ltd. The new addition makes vacuum-foamed refractory fiber's for the glass, ceramic, metal, and petrochemical industries at a facility in Ellisville, MS. This acquisition gives A.P. Green a new product line in one of the fastest segments of the refractories industry.

Fireclay production was again from mines in 11 States. Missouri, Ohio, and Alabama, in descending order of volume, accounted for more than 92 % of the total

domestic production. Output increased in every producing State, except Ohio, and continued in Colorado.

Exports of fire clay increased about 12% to 284,000 tons. The unit value of exported clay increased about 14% to \$84.54 per ton, indicating that the trend of shipping a larger percentage of premium-quality material continued. Fire clay was exported to 34 countries, 2 more than in 1988. The major recipients, in descending order, were Mexico, Belgium-Luxembourg, Japan, the Netherlands, and Australia. Fireclay imported from three countries amounted to 149 tons valued at \$77,000.

The unit value for fire clay, reported by

producers, ranged from about \$60 to \$40 per ton, indicating a valued fire clay was being recovered and processed.

Bentonite

Bentonite production increased more than 8% to about 3.1 million tons while the value rose 17% to \$125.1 million. This increase marked the second major upturn in production since the record-high year of 1981 when output was 4.4 million tons. The 1987 production figure of 2.5 million tons was the lowest reported figure in the past 17 years. Wyoming, the largest producing State, increased production slightly. Production also continued in Montana. Wyoming and Montana are traditionally the first and second largest swelling bentonite producing States, respectively. Domestic consumption for three major end uses, drilling mud, foundry sand, and iron ore pelletizing, excluding foundry sand, increased modestly in response to improvements in the overall smokestack industries.

Bentonite was produced in 13 States. The high-swelling or sodium bentonite continue to be produced chiefly in Wyoming. The low-swelling or calcium bentonite continued to be produced in the other States, mostly east of the Mississippi River. Calcium bentonite production in Alabama and Mississippi, the major producing States, is suitable for the production of absorbent, acid-activated, and foundry products.

The major and captive producers of bentonite continued to expand their product lines in new marketing areas and restructured to minimize problems associated with industry overcapacity. In addition, no acquisitions, mergers, or divestitures were noted during the year. In a major announcement, Laporte Industries Ltd. of the United Kingdom established a North American marketing and technical service organization to promote its "Laponite" line of synthetic hectorite-type clays suitable for rheological control in paints, cosmetics, and various industrial and pharmaceutical suspensions. In a related Government action, the Food and Drug Administration amended food additive regulations to provide for the safe use of chemically modified bentonites and hectorites in foodstuffs.¹

On December 29, 1989, Chemical Marketing Reporter quoted domestic sodium bentonite, 200-mesh bags, carload lots, f.o.b. mines, at \$30.50 per ton. The average unit value reported by domestic

¹Includes catalyst (oil-refining); fiberglass; glazes, glass, and enamels.²Includes crockery and other earthenware; fine china and dinnerware.³Includes animal feed; asphalt emulsions (1989); asphalt tile; pesticides and related products; rubber; wallboard (1989); other uses not specified.⁴Includes electrical porcelain; firebrick, block and shapes; high-alumina brick and specialties.

producers increased 8% to \$40.19 per ton. Per ton values reported in the various producing States ranged from \$8 to \$75, but the average values reported by the larger producers were near the Wyoming average of about \$34.48.

Bentonite exports increased more than 18% to 671,000 tons valued at \$52.9 million. The unit value of exported bentonite decreased about 7% to \$78.86 per ton. This decrease was attributed to the shipment of lower percentages of the costlier drilling mud and foundry grades shipped rather than the lower cost iron ore pelletizing grades exported mainly to Canada. Domestic bentonite producers, although benefiting from an erratically declining U.S. dollar and rising foreign oil

and gas exploration activities, continued to face increased competition in foreign markets from lower quality Greek material, particularly in the Canadian iron ore markets. In overseas drilling areas, Mediterranean bentonites continued to make inroads into areas also traditionally served by domestic producers.

Bentonite was exported to 76 countries, 11 more than in 1988. The five major recipients, in descending order, were Canada, Japan, Singapore, Taiwan, and Australia. Domestic bentonite producers reported their exports were foundry sand and others, 34% each, and drilling mud, 32%.

Bentonite imports for consumption consisted mostly of untreated bentonite clay (15%) and chemically or artificially acti-

vated materials (85%). Total bentonite imports increased more than 8% to nearly 16,000 tons. The chemically activated category, that slowly increased in quantity for most of the past several years, except for 1988, increased more than 17% to 13,000 tons valued at \$6.3 million. Imports from Mexico, the largest source, increased from 14% to more than 90% of the total. Mexican imports usually made up more than 75% of the total activated clay imports. The Federal Republic of Germany, a former major supplier, furnished only 237 tons, and China recorded its second import of this clay to the United States with another exploratory 6-ton batch. The chemically activated bentonite was imported from 12 countries (3 more than last

year), with Mexico supplying 92%; Canada, 33%; the Federal Republic of Germany and the Philippines, 2% each; and the remaining countries, 1%.

Fuller's Earth

Production of fuller's earth increased 5% to almost 1.90 million tons valued at \$166

million, a record high. The previous high was 1.79 million tons in 1988. This increase in production, except for declines in 1984 and again in 1986, continued the upward trend in production that the industry has enjoyed for more than a decade. A general increase in absorbent-grade clay output in Florida and Georgia was largely responsi-

ble. The average unit value increased 10% to \$88.06 per ton, indicating that an increasing percentage of higher valued gelling grades, produced mostly in Florida, are included in the total. Production was reported in nine States. The two top producing States, Florida and Georgia, accounted for over one-half of domestic production. All States, except Nevada and South Carolina, showed gains in production. Increases in consumption occurred in every major absorbent product line, with pet waste and oil and grease adsorbents leading the way.

Production from the region that includes Attapulgus, Decatur County, GA, and Quincy, Gadsden County, FL, is composed predominantly of the lath-shaped amphibole-like clay mineral attapulgite. Most of the fuller's earth produced in other areas of the United States contains varieties of montmorillonite and/or other clays.

Industrywide, enlargements, modernizations, acquisitions and/or mergers, and new product development were slowed during the year. In a major expansion, Englehard Minerals and Chemical Corp., a major attapulgite producer, announced plans to invest an initial \$2.5 million to upgrade its Attapulgus works in Georgia. The first phase includes new mining and ancillary equipment to start a statistical process quality control program, new packaging, and a more centralized warehouse operation. A major feature of the packaging improvements will involve new air jet milling schemes that will positively influence the particle sizes of the specialty gelling grades. Generally, the absorbent-producing companies enjoyed a good year while the gel-grade producers experienced a mixed year.

Attapulgite, a fuller's earth-type clay, finds wide application in both absorbent and gelling and/or thickening areas. The thixotropic properties of attapulgite clays provide the important thickening and viscosity controls necessary for suspending solids. Mineral thickeners are used in such diverse markets as paint, joint compound cement, and saltwater drilling mud.

Exports of fuller's earth went to 26 countries, 2 less than last year, and the quantity decreased almost 14% to 96,000 tons. The unit value of exported fuller's earth rose about 5% above that of 1988 to \$88.03. The increase was attributed to a larger percentage of high-cost gelling and drilling-mud grades shipped. The major recipients were again Canada (62%) and the Netherlands (23%). A minor amount of

decolorizing fuller's earth was imported from Canada.

Common Clay and Shale

Domestic sales or use of common clay and shale decreased 8% in tonnage and 3% in value to 26.7 million tons and \$141 million, respectively. Output of the 10 major producing States rose in California, Michigan, and Ohio and declined in Alabama, Georgia, Missouri, North Carolina, Pennsylvania, Texas, and Virginia. Common clay and shale represented about 63% of the quantity but only 9% of the value of total domestic clay production.

Domestic clay and shale are generally mined and used captively to fabricate or manufacture products. Less than 10% of the total output is usually sold. The average unit value for all common clay and shale produced in the United States and Puerto Rico increased 5% to \$5.26 ton. The reported unit value ranged from \$5 per ton to \$40 per ton.

Increased production capacities, new plants, and modernizations were either deferred or proceeding cautiously during the year. Mergers and/or acquisitions of domestic heavy clay producers were quite active. The construction industry, the largest consumer of heavy clay products such as brick, lightweight aggregate, portland cement, sewer pipe, and tiles generally experienced soft sales the entire year. The large inventories traditionally accumulated during the slack winter months were worked off during the first quarter, and by the end of the second quarter, inventories were beginning to climb again. The slack demand was brought on by the continuing combination of rising interest rates, slowdown in the overall economy, and wet weather in the south and eastern part of the country. The slack demand was also largely attributed to the continuing construction downturn, which lowered the demand for heavy clay products. In an attempt to boost sales, many brick manufacturers were again actively seeking sales

outside of their traditional marketing areas by offering highly competitive pricing. Building rates in the oil-producing States of Colorado, Louisiana, Oklahoma, and Texas continued to be depressed. Generally, brick sales in the east were depressed while sales in the Midwest and on the west coast were strong.

In building brick acquisitions, Ibstock Johnson PLC of the United Kingdom, through its subsidiary Glen-Gery Corp., Reading, PA, purchased Midland Corp's three brick manufacturing sites, two in Iowa and one in Missouri. The \$18 million transaction involves mines and plants capable of producing upward of 100 million bricks per year. Current production was about 80 million bricks per year. The largest facility in Missouri is capable of manufacturing 50 million bricks per year while the Iowa plants have respective capacities of 20 million and 30 million units yearly. All operations produce a full line of residential and commercial bricks for the midwestern markets. With Midland's

Operations, Glen-Gery will be the fourth largest U.S. brickmaker with a capability of about 700 million bricks per year. Before acquiring Midland, Glen-Gery had already expanded into the firming mideast area's by starting a greenfield brick operation at Caledonia, about 50 miles north of Columbus, OH. The 50-million-brick-per-year Ohio unit should be in full production early in 1990. In another English acquisition, Steetley PLC added Harmer Brick Inc., Pittsburgh, PA, to its group of domestic brick producers, which include Victor Cushwa and Sons Inc., in Maryland, and K-F Brick Inc. in Connecticut and Massachusetts. This purchase will bring Steetley's American brick producing capacity to 200 million bricks per year.

A notice of final results of a countervailing duty review by the International Trade

Administration on bricks from Mexico on December 27, 1989, revoked the duty order effective August 24, 1986.²

CONSUMPTION AND USES

The manufacture of heavy clay products, including: (1) building brick; sewer pipe; and drain, roofing, structural, terra cotta, and other tile; (2) portland cement clinker; and (3) lightweight aggregate accounted for 32%, 18%, and 8%, respectively, of total domestic consumption. In summary, 58% produced was consumed in the manufacture of these clay- and shale-base construction materials.

Kaolin has many industrial applications, and many grades are specifically designed

for use as a filler in paper, paint, rubber, plastics,³ and ceramics.⁴ New uses are constantly being developed. Kaolin is a unique industrial mineral because it is chemically inert over a relatively wide pH range, is white in color, has good covering or hiding power when used as a pigment or extender in coated films and filling applications. It is also soft and nonabrasive, has low conductivity of heat and electricity, and costs less than most materials with which it competes. Fillers and extenders must meet very rigid specifications such as particle size, color, brightness, and viscosity.⁵

Ball clays are extremely refractory and their use, largely in whitewares, imparts a high green strength as well as plasticity to the bodies. Although white-firing ball clays are preferable, fired products that range to

FIGURE 3

FULLER'S EARTH SOLD OR USED BY DOMESTIC PRODUCERS FOR SPECIFIED USES

cream or buff colors do not generally impair the quality of the whiteware products.

Fire clays are used mostly in commercial refractory products such as firebrick and block of many shapes, insulating brick, saggars, refractory mortars and mixes, ramming and gunning mixes, grog and crude aggregates, and many other products. Fire clays are also added to common clays to increase the vitrification range of sewer pipes and bricks.

The swelling sodium bentonites are used largely in drilling muds, in foundry sands, and in pelletizing taconite iron ores. The nonswelling or calcium bentonites are used mostly in conjunction with the swelling bentonites in foundry sand mixes in which the sodium bentonites provide dry strength and the calcium bentonites provide high green strength. The fuller's earth or calcium bentonites also find application in decolorizing and purifying mineral, vegetable, and animal oils. By and large, however, the fuller's earths, both the attapulgite and montmorillonite types, are used for their absorbent properties, especially as a pet waste and oil and grease absorbent. In processing animal or vegetable oils, the clays are usually activated by acid treatment, which leaves a highly absorbent sieve-like structure. The attapulgites are also used in drilling muds in lieu of sodium bentonites for drilling saltwater formations. The sodium bentonite

"breaks the emulsion" or flocculates in brine, thereby destroying the gel-like colloidal suspension required for drilling.

Construction

Common clays and shales are used to manufacture a wide variety of construction materials such as structural clay products, cement, and expanded aggregates.

Structural Clay Products

Structural clay products such as building brick, drain tile, and vitrified sewer pipe are used in building construction, for sewer systems, to drain farmer's fields, and for many other uses. Other clays, such as kaolin, fire clay, or ball clay, could in many cases be used to produce equally suitable "heavy clay" products, but they are generally more refractory and valuable for other uses. Of the total clay produced, about one-third is consumed in the manufacture of these structural products.

Hydraulic Cement

The portland cement industry requires alumina and silica as constituents in the manufacture of portland cement. Common clays provide a low cost source of these materials.

Expanded Clay and Shale

For this purpose, certain bloating qualities and strength are required.

Lightweight concrete blocks, floors, walls, and other shapes made using this material allow reduction in overall weight, which in turn allows savings in design of the supporting framework. Also, these products have better insulating qualities than equivalent products made with sand and gravel and crushed stone aggregates.

Refractories

Refractories require strength at high temperatures, resistance to corrosion, low coefficient of expansion, and many other physical and chemical properties, depending on application. Clays with physical properties most suitable for general refractory use have been classed as fire clays. The current trend is for refractories designed for a specific use and castable mixes containing refractory aggregates and calcium aluminate cements.⁶

Paper Products

Demand for clays for use as filler and coater in paper has followed the rapid increase in demand for paper. Kaolin is the principal clay used.

Other Uses

Pottery and related products require good ceramic qualities, including plastic formation, desirable firing temperatures, color, etc. The principal clays meeting these and other specifications are ball clay and kaolin. Kaolin also is used as a raw material feed in formulating bottle and plate glass batches. Drilling mud is a scientifically designed mixture of several items, generally including, in addition to bentonite or attapulgite, ground barite for its high specific gravity.⁷ Demand for bentonite in iron and steel production is based on its ability to form strong iron ore pellets from fine-grained taconite concentrates. Easily handled hard pellets are essential for efficient blast furnace operation.

Many foreign countries are dependent for specialty clays on sources outside their own borders. Consequently, foreign exploration for deposits is active and so is research directed toward developing substitutes and upgrading available clay deposits.

The United Kingdom, second to the United States in the world's kaolin production, is the biggest exporter of kaolin (china clay) and is also one of the world's largest producers and exporters of ball clay. The United States has been and still is a good

W Withheld to avoid disclosing company proprietary data; included with "Other."

¹Includes Puerto Rico.

²Includes Idaho, Minnesota, New Hampshire, and North Dakota.

Heavy Clay Products

The value reported for shipments by the Bureau of the Census for heavy clay products decreased 7% to about \$1.8 billion. The million standard brick count for building or common face brick decreased 14%. Shipments of clay floor and wall tile increased 12% while vitrified clay and sewer pipe fittings decreased 19%. Decreases in common clay and shale used in building brick manufacturing occurred in most States, with total domestic production decreasing 16%. Decreases were largely under 15% with an average State downturn of about 7%.

Lightweight Aggregates

Consumption of clay and shale in the manufacture of lightweight aggregate decreased about 11% to more than 3.4 million tons. The downturn in overall construction of commercial buildings and highway resurfacing was largely responsible for the decrease in demand. Concrete block, the largest category, (61% of total production), declined 11% while the second biggest consuming area, structural concrete (23% of total production), increased markedly. The third largest segment, highway surfacing (10% of production), also declined significantly. The other category, the smallest segment consisting essentially of new market areas such as recreational and horticultural uses, rose 30%.

Refractories

All types of clay, except for fuller's earth, were used in manufacturing refractories. Kaolin, bentonite, and fire clay accounted for 30%, 23%, and 27%, respectively, of total clay used for this purpose. The remainder, ball clay and common clay and shale, was used chiefly as bonding agents. Bentonite, both swelling and nonswelling, was used as a bonding agent in proprietary foundry formulations imparting both hot- and green-strength to the sand.

The tonnage of clays used for refractories increased 7% and constituted 6% of total clay produced. The continued use of high-alumina clay-base refractories, mostly calcined kaolin grogs in monoliths, and the upturn in demand for the more conventional refractory bricks and shapes were largely responsible. The major refractory consuming industries—cement, foundry, glass, and ferrous and nonferrous metals—continued to undergo major changes in technology and production levels for their products.

customer for these high-unit-value clays. However, the United States had changed from a net importer of these two high-quality clays in 1949 to a substantial net exporter by 1969. During the 10-year period 1979-89, U.S. exports increased almost

110% from 1.1 million tons to 2.3 million tons.

The world's fuller's earth needs are supplied from relatively few areas. The United States is both the world's largest producer and user.

¹Includes extruded and other brick.

²Extruded brick only.

³Other brick only.

⁴Includes 1.5 million tons used in other brick production.

⁵Data may not add to totals shown because of independent rounding.

Filler

Bentonite, fuller's earth, and kaolin are the principal filler clays. Kaolin, either air-floated, water-washed, low-temperature calcined, and/or delaminated, was used in the manufacture of adhesives, paint, paper, plastics, and rubber. Fuller's earth was used primarily in pesticides and fertilizers. Clays were in pesticides and fertilizers as either thickeners, carriers, diluents, or prilling agents. Bentonites were used mainly in animal feeds.

Of the total clay produced, 13% was used in filler applications; of this, kaolin

accounted for 89%; fuller's earth, 5%; bentonite, 2%; and ball clay, common clay and shale, and fire clay, the remaining 4%. Kaolin consumed as fillers increased 2% to 4.9 million tons. An approximate 3% and 5% increase in paper-coater and paper-filler, respectively, which together constitute 84% of the total filler and extender category, was largely responsible. The rubber-grade kaolin increased 27% while the other filler and extender components that constitute the remaining 16% of this group's demand were mixed in ups and downs. The total quantity of fuller's

earth used in pesticides and related products such as fungicides decreased more than 20% from that of 1988.

Absorbent Uses

Absorbent uses for clays accounted for almost 1.9 million tons or 4% of total clay consumption. Demand for absorbents increased 10%. Fuller's earth was the principal clay used for absorbent purposes, and this application accounted for 71% of its entire output. Demand for clays in pet waste absorbents, representing 55% of absorbent uses, increased slightly. Use in floor or oil and grease absorbents, chiefly to absorb hazardous oily substances, accounted for another 16% of the absorbent demand, which decreased from that of 1988. Increases in the use of pet waste absorbents were largely responsible for the upturn.

Drilling Mud

Demand for clays in rotary-drilling muds increased slightly to about 882,000 tons and accounted for 2% of total clay production. This slight increase reverses the downward trend, except for the increase noted in 1984, begun in 1982 when a combination of excess oil production and economic uncertainties resulted in lower oil- and gas-well-drilling activities, which depressed bentonite demand. Oil- and gas-well drilling activity was mixed during the year but generally trended upward by the end of the year because of firmer oil prices brought about by Middle Eastern difficulties. Swelling-type bentonite remained the principal clay used in drilling mud mixes, although fuller's earth, used mostly in saltwater drilling techniques, and nonswelling sodium-activated bentonites were also used to a limited extent. Bentonite and fuller's earth accounted for almost 100% of the total amount of clay used in this category. Small amounts of kaolin were used in specialized formulations.

Floor and Wall Tile

Common clay and shale, ball clay, kaolin, fuller's earth and fireclay, in order of volume, were used in manufacturing floor, wall, and quarry tile. This end-use category accounted for 1% of the total clay production. The rising interest rates for most of the year, while lessening the demand for more attractively appointed tiled homes, spurred the remodeling markets.

Pelletizing Iron Ore

Bentonite continued to be used as a binder in forming indurated iron ore pellets. Demand increased 14% to about 554,000 tons. Inroads of inexpensive foreign bentonites into the Great Lakes markets traditionally served exclusively by U.S. bentonite producers, lower production levels, metal imports, and changing technology all combined to reduce the long-term demand for domestic bentonite in this category.

Ceramics and Glass

Total demand for clay in the manufacture of pottery, sanitaryware, china and dinnerware, and related products (excluding clay flower pots) accounted for 3% of the total clay output. This demand, principally ball and kaolin clays, decreased 4% to 1.37 million tons. The downturn in new residential housing construction, large consumers of whiteware and sanitaryware, was partial-

ly offset by the strong demand for these products in the remodeling areas.

WORLD REVIEW

Capacity

The data in tables 27, 28, 29, and 30 are rated capacity for mines as of December 31, 1989. Rated capacity is defined as the maximum quantity of product that can be produced on a normally sustainable long-term operating rate based on physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Mine capacity for domestic clay production was aggregated from data voluntarily supplied by producers. The rated capacity data for the foreign mines were estimated from previous years' production, in cooperation with the Division of International Minerals.

Australia

The South Australian Department of Mines and Energy supervised an exploration and sampling program on a weathered pegmatite deposit containing high-grade kaolin southeast of Penneshaw on Kangaroo Island.⁸ The irregular weathering and limited size of the deposit may restrict its potential as a large world-class kaolin source.

The diversified Australian group, CSR Ltd., and British-based building products group, Redland PLC, announced their intentions to acquire as a joint venture the business and assets of PGH Bricks and

W Withheld to avoid disclosing company proprietary data. XX Not applicable.

¹Heat short of fusion; volatile materials are thus driven off in the presence of chemical changes, giving more stable material for refractory use.

²More or less plastic brick and materials that, after the addition of any water needed, are rammed into place.

³Materials for domestic use as finished refractories and all exported material.

⁴Includes calcined clay, ground brick, and siliceous and other gunning mixes.

⁵Molten cast refractories are made by fusing refractory oxides and pouring the molten material into molds to form finished shapes.

⁶Completely melted and cooled, then crushed and graded for use in a refractory.

⁷Includes shipments to refractory producers for reprocessing in the manufacture of other refractories.

Pipes Ltd. and Zacuba Ltd. from BTR Nylex Ltd.⁹ The joint venture will be owned 51% by CSR and 49% by Redland, which will also include all of the local businesses of Redland Monier Ltd.

PGH is one of the leading brickmakers in Australia with 12 plants in New South Wales, Queensland, and South Australia. On completion of the acquisition, the benefits of PGH's large clay reserves and

Monier Redland's expanding roofing tile businesses should lead to considerable cost savings. Redland's roof tile operations in Japan, Thailand, and Indonesia are not part of the joint venture. Redland and CSR are already linked in nonclay joint ventures in the United Kingdom and the United States.

The country's leading refractory producer, Heat Containment Industries Pty. Ltd. (HCI), Unanderra, New South Wales,

announced a new a \$1 million expansion for a new fully automated plant to produce a full line of clay and alumina monolithic refractories.¹⁰ The plant's production capacity is to be in excess of 20,000 tpy and is expected to be commissioned at yearend. HCI, in addition to domestic markets, expects to serve the cement, glass, heavy clay, and alumina markets in Southeast Asia and the other Pacific Rim nations. In kaolin

ing upward of 25 million bricks per year.¹³ The production is targeted largely for domestic consumption except for some export to the Republic of South Africa. The new plant, if on schedule, is anticipated to be on-stream during 1992 using about 75,000 tpy of an indigenous red burning clay described as a semishale. The Overseas Private Investment Corp. (OPIC) has agreed to make a minimal investment to cover about 20% of the total cost. OPIC's interest in the Botswana project peaked during a spring visit by American companies eager to encourage the use of private capital and know-how in friendly and developing countries. OPIC has a \$30 million working budget to enhance businesses in Africa and is considering

Rivers in the Almeirim Region within the rain forest.¹⁴ The reserves of the kaolin deposits are in the order of 400 million tons and compare favorably with American clay and that produced by a nearby competitor, Caulim da Amazonia. Further geological work and feasibility tests are planned by CVRD to move the project along. A 50,000 tpy pilot plant was assigned a high priority for further evaluation and testing.

Canada

Western Canada's leading facebrick manufacturer IXL Industries Ltd., Medicine Hat, Alberta, expanded into the refractory brick business by acquiring Clayburn Industries Ltd.'s assets.¹⁵ Clayburn, based in Abbotsford, British Columbia, operates open pits in the United States and Canada and an underground mine in Canada. The clay mined in America is exported to Abbotsford for further processing.

Chile

Sociedad Legal Minera Macarena (SLMM), the country's only calcium bentonite producer, planned to double its plant capacity to about 6,000 tpy.¹⁶ Currently, SLMM's entire production is sold to the fishmeal industry where it is used as a pellet binder. The new production is intended for use by the power generation industry.

China

A directive by the Ministry of Geology called for greater efforts to locate exportable economic mineral reserves in the Coastal Regions.¹⁷ Industrial minerals specifically targeted include kaolin. Apparently, 100 small- and medium-sized mines under consideration, largely in rural areas, were being evaluated. Watts, Blake, Bearne & Co. PLC joint venture, Clay Orient, concentrating on sanitaryware, ceramic tile, and dinnerware markets has been making slow but steady progress in meeting its near-term production and marketing goals.

France

The Devon-based WBB, Europe's leading producer of ball clays, purchased the assets of Pornon et Cie SRL, including extensive reserves and an open pit mine north of the Central Massif in Diou Department Allier.¹⁸ The company plans to let its West German subsidiary, Fuchs'sche Tongruben GmbH & Co. KG, operate the quarry and expand its production to upward of 15,000 tpy, mostly for the Western European markets. These clays are said to complement Fuchs'sche's famous Westerwald clays and are ideally situated to serve the growing demand for early vitrifying and fast-firing systems in southern France, Spain, and Italy by the excellent West German transportation network.

New Zealand

The Australian building products group, Monier PGH, a joint venture between CSR Ltd. (51%) and Redland RLC (49%), acquired the New Zealand Brickmakers (NZB) operations for an undisclosed amount of cash from its parent company, Ceramco Corp. Ltd.¹⁹ Ceramco has been on a divestment policy for a number of years. NZB recently completed a NZ \$8 million upgrading of its Auckland plant, which solidified its position as one of New Zealand's largest brick manufacturers.

Nigeria

The Government cited the need for investments and technical expertise in exploiting the nation's largely underdeveloped mineral wealth.²⁰ Large reserves of industrial minerals, including bentonite, were touted as most promising by its geological survey.

Pakistan

The Government has allocated two large grants to the Saindek Integrated Mineral Development Project, in Chaghai District, Baluchistan, and the other to the geological survey.²¹ Future growths in production were noted for many industrial minerals, including china clay, as the principal justification for the project.

South Africa, Republic of

A new 6,000 tpy sulfuric acid-activation plant was commissioned by G & W's Base and Industrial Minerals (Pty.) Ltd. to be located at Koppies in the Transvaal.²² The new plant is using bentonite from its nearby Ocean deposit as a plant feed to supply local markets with a wide array of vegetable and mineral oil refinery clays. Exports, because of a weakened Rand, are also contemplated. G & W's new plant will compete directly with a joint venture, West Germany's Sud-Chemie AG and the local Cullinan Minerals Ltd. (CML). It is unclear whether the local demand is sufficient to accommodate both plants. CML, in another bentonite action, was spending more than R\$500,000 on modernizing its mine and mill complex at Heidelberg in the Cape Province.²³ The project was to include a new rotary kiln for improved quality control. In refractory clay, the flint clay and Chamotte operations of Chamotte Holdings (Pty.) Ltd. were acquired by ECCA Minerals (Pty.) Ltd., which now makes ECCA the largest domestic chamotte pro-

ducer.²⁴ Chamotte Holding's mines and calcining plant are also at Bronkhorstspuit in the Transvaal. The acquisition will bring ECCA's existing total raw and calcined flint clay production capacities to 85,000 tpy and 56,000 tpy, respectively.

Spain

The Zaragosa-based sepiolite producer, Sociedad Anonimia de Minería y Tecnología de Arcillas (MYTA), announced it bought SEPCO SA, an attapulgitite producer near Segovia in central Spain.²⁵ The SEPCO plant, northwest of Madrid, has a production capacity of 50,000 tpy and is presently producing about 15,000 tpy. MYTA's plant in the same area, operational since 1987, has a production capacity of about 150,000 tpy. Current sales are about 65,000 tons of pet waste absorbents and 10,000 tons of other products, mostly for exports within Europe. MYTA and SEPCO products are also sold into the industrial absorbents, animal feed, agricultural chemicals, and insecticide carrier markets. MYTA and SEPCO are part of the Luengo group of Aragon, with diversified interests in mining, predominantly in subbituminous coal. The group apparently has identified further clay deposits for exploration, including an excellent kaolin property.

U.S.S.R.

A brickworks with an annual capacity of 60 million standard bricks started production in Tokmak in Kirghizia.²⁶ The plant was built with Bulgarian assistance and imported production line equipment. Another ceramic production line was augmented at the Angren ceramics complex in Tashkent to supply the construction needs of the earthquake devastated areas in Armenia and Tajikistan.²⁷ The new production capacity of the Tashkent facility was stated to be its full design capacity of more than 200,000 square meters of facing tiles.

United Kingdom

In environmental affairs involving fuller's earth (calcium bentonite), the application of Laporte Earth Ltd. for permission to mine clay from deposits at Waterhouse Farm, Bletchingley, and Jackass Lane near Tandridge in Surrey was denied by the Secretary of State for the Environment.²⁸ Laporte, although disappointed, does not intend to press the issue even though industry reserves for Laporte and Steetley

PLC, the other domestic producer, at current production rates, would last about 5 years. The Secretary of State also suggested that cat waste absorbents and exports to foreign facilities were not a valuable use of scarce natural resources. In a related event, Steetley agreed to purchase via its subsidiary, Steetley Minerals Ltd., the Absorbent Products (AP) Div. of Lawrence Industries PLC based in Metcham, Surrey.²⁹ AP is a major supplier of imported material, including Danish molar earths, attapulgite, fuller's earth, sepiolite, and other materials for cat litter and other industrial absorbent markets. This buy-out expands Steetley's similar Flixborough, South Humberside, bulk storage and packaging facility that also serves export markets. This acquisition not only makes Steetley more formidable in the growing domestic absorbent marketplace but also positions itself for the future in the event of continuing reluctance on the part of Government officials to approve domestic mining permits. A joint venture, Abbey Chemicals, between NL Chemicals-Europe and Steetley Minerals Ltd., planned to raise the production capacity of its bentone organoclay rheological additives plant in Livingston, Scotland, United Kingdom, by 50%.³⁰ The plant manufactures the additives from NL's American hectorite and bentonite clays for use not only in the paint and surface coatings industries but also for plastisols, ink, grease, and cosmetics and in thickening, antisetling, antisagging, and flow-control markets. In fireclay news, Hepworth Ceramic Holdings PLC purchased British Steel's 22% minority holding in the Hepworth subsidiary, GR-Stein Refractories Ltd., a major international refractories manufacturer.³¹

The EC announced two kaolin actions during the year. The first was another new research facility in St. Austell, Cornwall, to be completed by yearend 1991 and the divestiture of its 21% stake in a competing kaolin and ball clay producer, WBB, for £13 million to a syndicate consisting of Sablieries et Carrieres et Compagne Belge des Silicas Reunies SA (Sibelco) of Antwerp, Belgium, and Quarzwerke GmbH of Frenchen, West Germany.³² The EC apparently felt uncomfortable with its minority ownership in a major competitor. In brick expansion news, Ibstock Johnsen PLC implemented a new tunnel kiln and automated brick marshaling equipment at its Leicester manufacturing facility.³³ A new £1 million brickworks at St. Ives, Cambridgeshire, capable of producing up to 20

million bricks per year, was opened by ARC Powell Duffryn Brick Ltd. (APDB) to serve the Cambridge and East Anglia markets.³⁴ The new works will extend APDB's brick range into a full line of specialties indigenous to the area. Baggeridge Brick PLC fired its first kiln at the recent completed Waresley factory near Kiddenminster.³⁵ The new Lingl kiln, Europe's largest, has the capacity to produce upward of 2.5 million bricks weekly with initial production of 1 million bricks per year of its special line. Base material for the bricks is the West European Upper Triassic clay and Keuper marl mined adjacent to the plant. Baggeridge also manufactures bricks at Kingsbury and Hartlepool, which recently have undergone expansions. London Brick Co., The United Kingdom's largest brick producer, announced production cutbacks amounting to 15% to accommodate the slump in house building activity.³⁶ London Brick, owned by the giant conglomerate Hanson PLC, closed five kilns at two of its plants in the southern region. The kilns were to be refurbished for an anticipated upturn in the construction industry. Increased sales to commercial and industrial construction partly offset the slump in the housing demand. Cutbacks and postponements in ongoing enlargements were also announced by Butterby Brick Ltd., Britain's second largest brick producer at its Desford, Leicestershire plant.

TECHNOLOGY

Indepth reviews were published on the industrial minerals of Belgium,³⁷ Brazil,³⁸ Guyana,³⁹ South Africa,⁴⁰ and Namibia,⁴¹ which include sections on clay, local geology, reserves, mineralogy, mining and milling flowsheets, indigenous mining methods, company profiles, and markets. The Belgian paper covered the lightweight expanded clay aggregates and kaolinitic sand producers while the Brazilian report also highlighted the Brazilian mining laws and clay production statistics by region and State. A noteworthy section on the individual Brazilian kaolin mining companies and their longterm production and marketing goals was of particular interest. A similar but lesser treatment was afforded the Brazilian bentonite and acid-activated manufacturers. The Guyanese study stressed the large kaolin deposits that underlie the presently producing extensive

bauxite horizons. An excellent section underscored the technology of characterizing these indigenous deposits to form a basis of a major ceramics development in the Caribbean. The comprehensive South African manuscript, a first of two articles, highlighted its attapulgite, bentonite, kaolin, acid-activated, and refractory clay producers, including flints. A map showing the clay-producing areas and chemical analyses of white calcined and standard chamotte products was a high point of the clays section. The Namibian paper stressed the industrial minerals potential of the country, with an eye toward future independence. The geological presentation included technical descriptions of areas considered to be promising for future specialty clay production. The specialty clays were targeted largely for export while the common clays were designated for local consumption. A similar exhaustive study on the Australian kaolin clays was also published.⁴² This excellent work not only summarized the country's major kaolin producers and districts, but also presented the clay's complete chemical analyses along with appropriate physical and chemical properties required by the filler and extender, and ceramic industries in the Pacific Rim. A noteworthy inclusion was a detailed map locating the major producing areas.

A scientific article on drilling for oil and gas in the U.S. Gulf of Mexico was published.⁴³ This article stressed the importance of the Gulf of Mexico to U.S. oil and gas production, the geology of deep water versus shallow water exploration, and the structure of the drilling fluids industry not only in the Gulf, but also nationally. A high watermark of the work was tables listing the minerals, including attapulgite, bentonite, and organoclays, in drilling fluids. These included consumption rates, technical rationale for use, and the general classification methods for water-, salt-, and oil-base systems employed in drilling. A discussion on the quality requirements for bentonites used in drilling fluids was the topic of another drilling related work. The paper showed the suitability of non-Wyoming and South Dakota area clays as well as Oregon clays to meet American Petroleum Institute (API) specifications for nontreated bentonites. The API specifications and its bentonites tests were most informative.⁴⁴

A timely review article dealt with the current technical and financially driven decisions by U.S. papermakers in assessing the various quantities and qualities of minerals to be used in their formulations

¹Excludes centrally planned economy countries, some of which presumably produce fuller's earth, but for which no information is available. Table includes data available through July 25, 1990.

²In addition to the market economy countries listed, France, India, Iran, Japan, and Turkey have reportedly produced fuller's earth in the past and may continue to do so, but output is not reported, and available information is inadequate to make reliable estimates of output levels.

³Reported figure.

⁴Estimates made by British Geological Survey of marketable production based on reported crude production, in metric tons, of: 1985—292,000; 1986—248,000; 1987—NA; 1988—NA; and 1989—NA.

⁵Sold or used by producers.

to achieve optimum grades. This work emphasized technical paper terminology, minerals (in particular kaolin and its substitutes), quality and specifications, other mineral possibilities, and the outlook for North American papermakers. The rationale for calcined kaolin and/or lightweight papers and the kaolin, calcium carbonate, both ground and precipitated, along with talc were featured.⁴⁵ The detailed report addressed the mining and marketing of primary and secondary Minnesota kaolins found in four southwestern countries near the Iowa border.⁴⁶ An excellent section compares these northern clays and their mining and refining methods with the more conventional sources and flowsheets practiced in the Georgia and South Carolina kaolin areas.

An article critically reviewed the technology developed by European research projects that are continually being undertaken in the tile, tableware, and sanitaryware industries on the Continent.⁴⁷ The many advances made during the past decade, such as in automation, energy efficiency, quality optimization, and cost effective production, were condensed to only seven fundamental steps: body preparation, including raw materials selection of ball clay, kaolin, and calcined clays; shaping; drying; decorating; firing; and final treatment and inspection. The sections on high-pressure dry pressing, shaping, fast-firing, along with body preparation systems and their flowsheets, commonplace in Europe, were highlights of the report. The trend in the clay and whiteware industries to use shortened expensive firing cycles for wall tiles was the subject of another investigation.⁴⁸ The research revealed that kaolin-bearing lead and lead-free fast-fired wollastonite wall tiles showed acceptable properties when compared with conventionally fired tiles.

A new generation of technically sophisticated refractories, including high-alumina clay-base bricks and monoliths developed for the steelmaking industries, was covered in an article.⁴⁹ Although the work stressed the role of fluxes in steelmaking, its influence on refractory consumption by the different steelmaking processes was exemplary. Another article provided an overview of major pyroprocessing techniques used for selected minerals, including clays.⁵⁰ The technology of rotary and tunnel kilns in manufacturing refractory aggregates from aluminosilicates such as kaolins was examined in depth. The major thrust of

another article was to familiarize the reader with an overview of popular pyroprocessing techniques.⁵¹ The technology, market position, future availability of high-alumina kaolin clay specialty calcines and refractory minerals were explored. The paper compared the different mullite-based refractories made from sillimanite group minerals—andalusite, kyanite, and sillimanite—with its clay-derived counterparts.

An overview on fine-grinding techniques, including wet, dry, and classifications schemes, currently used to meet the demand for finer and finer particle sizes was published.⁵² The technology of attrition grinding mills, used largely by the kaolin industry, including sections on media for attritors and agitators, and media used for milling were covered in detail. Similar treatment was given to fluid energy and roller milling schemes. Diagrams of the equipment, specifications, and a graph of typical working ranges for the different mill types were high points of the report.

Research indicated that bentonite and/or montmorillonite clays specifically treated with a one- or two-step modification process soak up and immobilize carcinogens such as dioxin, polychlorinated biphenyls (PCB), and other toxic organic compounds.⁵³ The clays treated with a cationic inorganic polymer hydroxy aluminum proved to be far less expensive than conventionally activated carbon absorption systems. If further research proves out this new approach, it should go a long way in inexpensively removing selected toxins from industrial wastewaters, municipal sewage treatment plants, and chemical and/or municipal waste dumps.

OUTLOOK

U.S. clay demand during the past decade, 1979-89, has rebounded slowly from the recessionary years of 1981-82 to about 42 million tons or 5 million below the prerecessionary period high in 1979. The decade before witnessed a decrease in construction activity in the public, private, and commercial sectors. Large declines in the manufacture of bricks, lightweight aggregates, portland cement, and other heavy products were responsible, and this demand has never fully recovered. Higher mortgage rates in the late 1980's, as in the late 1970's, coupled with the limited availability of affordable housing and funds for public and

business ventures is again reasserting itself in slowing down the overall economy. This pattern, if not offset by lower interest rates and increased availability of capital, will again not only depress construction activities, but also spread into the overall economy. The specialty clays used in more diversified applications and industries held up better than their common clay and shale counterparts. Demand for these clays, which include kaolin, ball clay, fuller's earth, fire clay, and bentonite, generally fared better during the preceding decade and are expected to repeat this behavior. In addition, the weakening U.S. dollar in the latter part of the decade has encouraged specialty clays, led by kaolin, to expand its share of export markets. This performance in exports is expected to continue well into the next decade and possibly the next century.

Imports of clays, except for English china and ball clays and acid-activated bentonites, are minor. The English clays enjoy a small prestige-dictated market while the activated clays are confined to use in the southern and northern States. Exports of domestic clays, mostly kaolin, bentonite, ball clay, and fuller's earth, are restricted to the higher valued specially treated varieties for use in drilling muds, paper-coating, and iron ore pelletizing and by the foundry industry.

BACKGROUND

Definitions, Grades, and Specifications

Clays are classified in six groups in Bureau of Mines publications. These are kaolin, ball clay, fire clay, bentonite, fuller's earth, and common clay and shale. The definitions listed in this work for the high-alumina clays, kaolin, ball clay, and fire clay are similar to those in Bureau of Mines Information Circular 8335.⁵⁴

Kaolin, or china clay, is defined as a white, claylike material approximating the mineral kaolinite. It has a specific gravity of 2.6 and a fusion point of 1,785° C. The other kaolin-group minerals, such as halloysite and dickite, are encompassed. Specifications are based on the method of preparation (crude, air-separated, water-washed, delaminated, air-dried, calcined, slip, pulp, slurry, or water suspension) and on specific physical and chemical properties.

Ball clay is a plastic, white-firing clay used principally for bonding in ceramicware.

These clays are of sedimentary origin and consist mainly of the clay mineral kaolinite, sericite micas, and organic matter. Ball clays are usually much finer grained than kaolins and, in general, set the standards of plasticity. Specifications for ball clays are based on methods of preparation (crude, shredded, air-floated, water-washed, or slurry) and pertinent physical and chemical tests, which are much the same as those for kaolin.

Fire clay is defined as detrital material, either plastic or rocklike, containing low percentages of iron oxide, lime, magnesia, and alkalies to enable the material to withstand temperatures of 1,500° C or higher. Fire clay is basically kaolinite but usually contains other clays such as diaspore, burley, burley-flint, ball clay, and bauxitic clay and shale. Fire clays commonly occur as underclay below coal seams and are generally used either for refractories or to raise vitrification temperatures in heavy clay products. The fired colors of fire clays range from buff to grays. Specifications are based on pertinent physical and chemical tests to determine the properties of the clays and of products made from them.

Bentonite consists essentially of smectite minerals (montmorillonite group according to some usages). The swelling-type has a high-sodium ion concentration and will increase materially in volume when wetted with water, whereas the nonswelling types are usually high in calcium. Standard grades of swelling bentonite increase from 15 to 20 times their dry volume. The specifications are also based on pertinent physical and chemical tests, particularly those relating to particle size and swelling index.

The term "fuller's earth" is derived from the first major use of the material, which was for cleaning textiles by fullers. The term has neither a compositional nor a mineralogical connotation, and the substance is defined as a nonplastic clay or claylike material, usually high in magnesia, that has adequate decolorizing and purifying properties. Fuller's earths are composed predominantly of the distinct needle- and/or lath-shaped amphibole-like clay mineral attapulgite or varieties of montmorillonite. Fuller's earths containing opal or other forms of colloidal silica are also produced. Specifications are based on physical and chemical tests to determine the properties of the products. Sepiolite-type clays are also included for statistical convenience.

Common clay is defined as a clay or claylike material that is sufficiently plastic to permit ready molding. Its vitrification point is usually below 1,100° C. Shale is a consolidated sedimentary rock composed chiefly of clay minerals that has been both laminated and indurated while buried under other sediments. The common clays and shales are chiefly illitic or chloritic. The materials may also contain some kaolins and montmorillonites and are usually higher in alkalies, alkaline earths, and ferruginous minerals, but much lower in aluminum than the high-quality kaolins, fire clays, and ball clays. The presence of iron usually imparts a reddish hue after firing. There are no specific recognized grades based on preparation and very little terminology based on its usage, although such a clay may sometimes be referred to as common, brick, sewer pipe, or tile clay. Clay and shale are used in the manufacture of structural clay products such as brick, drain tile, portland cement clinker, and expanded lightweight aggregates.

Although many specifications have been established by the American Society for Testing and Materials, American Foundrymen's Association, American Oil Chemists' Society, American Petroleum Institute, Technical Association of the Pulp and Paper Industry, and other national organizations, many producers and consumers rely on their own tests and specifications applicable to their specific needs. The tolerance limits of mineralogical composition, particle size, and other physical and chemical properties also are determined largely by individual requirements. Detailed data on specifications have been published by the Bureau of Mines.⁵⁵

Products for Trade and Industry

Clay goes into a variety of products; consumption is weighted heavily in favor of fired materials. Various methods are used in clay treatment before final use that alters the form, but except for calcining and cation exchange, these methods do not appreciably alter the chemical or mineralogical characteristics.

In manufacturing finished products, the previously mentioned equipment plus a kiln for fired or dried products is usually all that is needed. Kaolins for special use as paper coating may be bleached and further delaminated by grinding, deflocculation, and elutriation to special sizes; a final

ultraflotation or wet magnetic separation treatment may be used to remove iron- or titanium-bearing minerals to provide a whiter product. Common bricks as well as tile, pet litter, lightweight aggregate, etc., require firing in a kiln. The kiln firing or drying operation produces a finished manufactured product.

Because of the many types of clay and different qualities within each type, the consumption pattern and hence the products for trade and industry are constantly changing. Consumption of kaolin in refractories has been growing since 1970 because of the increasing popularity of castable, ramming, gunning, and plastic mixes that use calcined kaolin aggregates (grog) in their formulations.⁵⁶ Calcined kaolin grogs have also made inroads in refractory brick manufacturing, replacing imported calcined refractory-grade bauxite grogs. Bentonite production has been moving away from iron ore pelletizing lines and redirected toward the drilling mud and foundry uses that command premium prices. Bentonite products for waterproofing and sealing in construction and reservoir uses have also gained in popularity.

Attapulgite-type fuller's earth production, like bentonite, is finding increasing applications in the premium drilling mud industry.

Industry Structure

An estimated 350 companies operating more than 1,000 clays pits or mines reported production in 1989; of these, 50 companies, most with multiple operations, accounted for approximately 50% of the tonnage and 80% of the value for all types of clay produced and sold or used. Clay production was reported in all States and Puerto Rico except Alaska, Delaware, Hawaii, Rhode Island, Vermont, and Wisconsin and also the District of Columbia.

Although most clays are mined by open pit methods, a few underground mines exist. In 1989, less than 2% of U.S. clay output was from underground mines. Pennsylvania, Ohio, and West Virginia accounted for the bulk of the underground materials, which consisted mostly of underclays associated with coal and suitable for refractory uses. States leading in output were Georgia, 9.8 million tons; Ohio, 3.5 million tons; Texas, 2.4 million tons; North Carolina, 2.3 million tons; California and Wyoming, 2.2 million tons each; and Alabama, 2.0 million tons.

Most of the large kaolin producers have principal operations in Georgia. In 1989, three large diversified firms accounted for about 60% of total domestic kaolin output. Altogether, 42 firms operated 130 mines in 13 States. Georgia, the largest producing State, accounted for 84% of the total output.

The ball clay industry is small, with 7 producers operating 24 mines in 5 States in 1989. Three of these were large diversified firms with widespread foreign and domestic mineral interests. Tennessee ball clay production represented almost 71% of the total output.

Fireclay producers were mostly refractories manufacturers that used the clays in firebrick and other refractories. Almost 70 mines were operated in 1989 by 26 firms.

Firms producing bentonite operated 220 mines in 13 States. Four were large diversified firms with international mineral operations; three of the firms had interests in other types of clay in the United States. Wyoming was the leading State, accounting for 70% of the total output.

Bentonites are composed essentially of minerals of the montmorillonite group. The swelling-type is high in the sodium ion. Currently, the swelling-type is produced chiefly in Wyoming and Montana while the nonswelling-type is from mines in Mississippi and Texas. The United States is the world's largest producer and exporter of bentonitic clays.

Nine of the 17 fuller's earth producers and 12 of the mines were in the attapulgite-fuller's earth areas of Florida and Georgia. These two States accounted for 57% of domestic production. Production, mostly small scale, was reported from seven other States in 1989. Most producers were small independent firms, but three were large diversified corporations with international mineral interests. The world's fuller's earth needs are supplied from relatively few areas. The United States is both the world's largest producer and user.

Firms producing common clay and shale in 1989 were manufacturers of structural clay products, clay pipe, lightweight aggregates, and cement. Essentially all were integrated to the extent of owning or leasing and operating the deposits of clay used in making their products. Private mining contractors and haulers were beginning to make inroads into many of these operations. A few of the producers were diversified firms having interests in metals and other nonclay products. Some companies owned and operated several clay pits and plants located to cover a large market area.

The economic radius for shipment of common clay or shale products is usually 200 miles or less. This promotes the existence of many local ownership companies, or in case of a large firm, the ownership and operation of several strategically located pits and associated fabricating plants.

Geology-Resources

Clay is a product of the mechanical and chemical breakdown of parent rocks. The products from these weathering reactions consist of mixtures of particles of different sizes and differing physical, chemical, and mineralogical properties. The nonplastic portion consists of altered and unaltered rock products (grit), which are usually quartz, micas, feldspar, and iron oxides. The plastic clays are usually high in clay content and low in grit. Clays may be further designated as residual or sedimentary. Residual clays are those occurring in the same location in which they were originally formed. Sedimentary clays are those that have been transported, usually by water, and deposited elsewhere.⁵⁷ Further alteration and classification are common during transportation. The Georgia and South Carolina kaolins are sedimentary; the North Carolina and the English china or kaolin clays are residual.⁵⁸ The Kentucky and Tennessee ball clays and the Missouri fire clays are sedimentary types. Most bentonites, montmorillonites, and fuller's earth in North America and elsewhere were formed in place from volcanic ash or tuff. The attapulgite-type fuller's earth deposits of Florida and Georgia were probably formed differently. Geologists have never found any evidence of volcanic materials associated with these deposits.⁵⁹

The definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals," which is reprinted in the introduction of Mineral Facts and Problems, 1985 edition.

Common clays and shales are indigenous to most countries. In 1989, U.S. production was reported from 43 of the 50 States and Puerto Rico. Resources are enormous, but not all material is located ideally with respect to the potential market, nor are individual deposits necessarily suitable for a specific use. Most common clay or shale deposits are usable for manufacture of common brick, but the color or strength may not meet the requirements of the local market. Relatively few deposits are com-

mercially suitable for manufacture of lightweight aggregate. Even with these limitations of location and use, the statement "virtually unlimited" is used to describe resources of common clay and shale.

U.S. reserves of clays, other than common clay and shale, which are virtually unlimited, owned or controlled by domestic producers are estimated to total about 700 million tons in the following categories: kaolin, 400 million; ball clay, 30 million; fire clay, 100 million; bentonite, 120 million; and fuller's earth, 60 million.

Georgia contains large quantities of high-quality kaolin suitable for paper-coating and paper-filler. A small area in Georgia and Florida contains sizable reserves of attapulgite-type fuller's earth. Bentonite for iron ore pelletizing and oil-well-drilling muds is chiefly from Wyoming. Fireclay deposits are widespread, such as those found in Missouri, but currently exploited deposits of highest quality fire clay are nearing depletion. Only a few States, namely Tennessee and Kentucky, have sizable deposits of ball clay.

Technology

Exploration.—As with other minerals, exploration for clays begins with an understanding of the geologic occurrence of deposits in question, followed by periods of sampling, testing, and appraisal. Once deposits have been located, they are either auger or core drilled, both to obtain sufficient samples for testing and storage and to delineate the size and quality of the deposits. The evaluation of bentonites and fuller's earth is handicapped by the absence of standard testing procedures or specifications. Generally, these two clays are produced to meet the purchaser's specifications. Kaolin samples are usually evaluated for filler applications by either wet or air-float processing and for ceramic uses. The grit, particle size, brightness, and leachability are all determined. Air-floated clays normally require only grit and brightness determinations. The kaolins, ball clays, and fire clays destined for ceramic and/or refractory uses are analyzed for grit, brightness, green and dry strengths, fired color, and iron and alumina contents. The common clays and shales are usually tested for the intended end use, such as bricks, structural-drain tiles, or lightweight aggregates. Usually, prepared specimens are tested for plasticity, green strength, shrinkage, vitrification temperature range, etc., and for lightweight aggregates, the bloating range.

Mining.—Most clays are mined either totally or selectively from open pits using modern surface mining equipment such as draglines, power shovels, front-end loaders, backhoes, scraper-loaders, and shale planers. Some kaolin is extracted by hydraulic mining and dredging, and a few clay pits are operated using crude hand-mining methods. A small number of clay mines—principally in underclays in coal mining areas—are underground operations employing mechanized room-and-pillar methods. Truck haulage from either the pits or blending areas to the processing plants is the most common; other methods involve use of rail transport, conveyor belts, and pipelines in the case of kaolin. Recovery is almost 100% of the minable beds in most open pit mines and perhaps 75% in underground operations. The waste-to-clay ratio is highest for kaolin, about 7:1, and lowest for common clay and shale, about 0.25:1.

Beneficiation.—Processing of clays ranges from very simple and inexpensive crushing and screening required for some common clays to very elaborate and expensive methods necessary to produce paper-coating clays and high-quality filler clays for use in rubber, paint, plastic, and other products. Significant processing losses are involved only with kaolin and fuller's earth where about 40% and 30%, respectively, of the material delivered to the processing plants is discarded. Waste material from processing consists mostly of off-grade clays and minor quantities of quartz, mica, feldspar, and iron-bearing minerals.

There are several principal processing methods for the various types of clay.

Kaolin.—Processing includes any one or a combination of crushing, blunging with dispersant, rough sedimentation, water fractionation, magnetic separation, ultraflotation, acid treatment, calcination, air floating, and attrition grinding, slurring, and delaminating.

Ball Clay.—Processing includes drying, shredding, pulverizing, air floating and slurring.

Fire Clay.—Processing includes crushing, calcining, and blending.

Bentonite.—Processing includes weathering, drying, grinding, sizing, granulation, and additives for cation exchange.

Fuller's Earth.—Processing includes lunging, extruding, drying, crushing, grinding, sizing, and dispersing.

Common Clay and Shale.—Processing includes crushing, blunging, extruding, and drying.

Imports of clays, for the most part, are precluded because transportation costs would then be noncompetitive.

Processing costs for clays range from a few cents per ton for some common clays to more than \$400 per ton for some special paper-coating clays and high-quality clays that require very elaborate and expensive treatments.

Price schedules, although not complete, are available and are published regularly in the Chemical Marketing Reporter.

Federal tax laws allow clay producers a depletion allowance on both domestic and foreign gross income not to exceed 50% of net income with depletion deduction. Depletion allowances are as follows: ball clay, bentonite, kaolin or china clay, sagger clay, and clay used or sold for purposes dependent on its refractory properties, 14% domestic and 14% foreign; fuller's earth, 14% domestic and 14% foreign; clay used for extraction of alumina or aluminum compounds, 22% domestic; clay used or sold for use in manufacturing drainage and roofing tile, flower pots, and kindred products, 5% domestic and 5% foreign; clay and shale used for making brick, tile, and lightweight aggregate, 7.5% domestic and 7.5% foreign.

Severance taxes are levied by some producing States.

BYPRODUCTS AND COPRODUCTS

One firm each in Texas, California, and Florida produces silica glass sand as a coproduct with kaolin. Byproduct flake mica is mined by one kaolin producer in North Carolina, and coproduct bauxite is mined by kaolin producers in Georgia and Alabama. Clay and limestone for cement manufacture are often produced from the same property and reported as coproducts or byproducts even though they are usually mined separately from different formations or beds. Sand, gravel, and stone aggregates are occasionally produced together with common clays.

ECONOMIC FACTORS

Economic factors affecting clays vary in importance with type, quality, and intended

end use. Transportation costs are critical for common clays and very important for most fire clays. The other clays, being less abundant and higher in unit value, can be marketed at greater distances from production centers. For example, paper-coating clay is produced domestically in Georgia, attapulgite-type fuller's earth is produced in Florida and Georgia, and the bentonite used for iron ore pelletizing is produced in Wyoming and Montana. Consumers have little choice but to use those clays even though in many cases the shipping costs exceed the value of the clay at the mines or processing plants.

Because most clays are relatively low cost materials in the crude state, mining costs must be kept as low as possible. Cost of the crude clays ranges from less than \$3 per ton for some common clays to above \$20 per ton for some of the higher quality materials.

Import duties on clays have little impact on the amount of clays imported. A small but dedicated demand for certain prestigious English clays persists.

OPERATING FACTORS

In manufacturing finished clay products, the previously mentioned equipment plus a kiln for fired or dried products is usually all that is required by the energy intensive clay industry. Many clay producers, having successfully converted to coal from oil firing and gas firing, are not exploring the practicality of augmenting coal with wood chips as a fuel. The conversion to coal and/or wood as a kiln fuel is gaining in popularity where feasible in heavy clay and refractory products manufacturing and in bentonite processing.

Losses in mining are extremely small, except in underground mining where recovery will average about 75%. Processing losses for material receiving, crushing, grinding, mixing, shredding, blending, and drying also are insignificant. Losses from washing, sizing, etc., reach 30% or 40%.

Clay mining lacks many of the hazards inherent in mining because few deposits require use of explosives and most are merely open pit earth-moving operations. Domestic mine employment in 1983 was reported to be approximately 2,000. Processing plants preparing the product for use or sale required about 10,000 workers or approximately five times the personnel in the mines.

COBALT

By Kim B. Shedd

Ms. Shedd, a physical scientist with more than 10 years Bureau of Mines experience, has been the commodity specialist for cobalt since 1988. Domestic survey data and trade data were prepared by the Ferrous Data Section; international production tables were prepared by W. L. Zajac, Chief, International Data Section.

U.S. reported consumption of cobalt decreased slightly from consumption reported for 1988. For the second year in a row, domestic consumption exceeded cobalt imports, resulting in a reduction in industry stocks. The 1989 cobalt market was characterized by stable prices. Significant events included the Defense Logistics Agency (DLA) contract to upgrade cobalt metal in the National Defense Stockpile (NDS) and Brazil's initial production of electrolytic cobalt.

cobalt for higher grade cobalt from other sources. On September 22, DLA awarded the contract to Sherritt Gordon Ltd. of Toronto, Canada. Under the contract, Sherritt was to supply 186 metric tons (410,394 pounds) of cobalt from Norway at a price of \$3.27 per pound in exchange for stockpile cobalt. The two other bidders were La Générale des Carrières et des Mines du Zaïre (Gécamines), which offered to supply its own cobalt from Zaïre, and The Hall Chemical Co., which offered Zambian cobalt. Although Sherritt's bid

milligram per cubic meter (mg/m³) of air to 0.05 mg/m³. In addition, OSHA established 8-hour time-weighted average limits of 0.1 mg/m³ for cobalt carbonyl and cobalt hydrocarbonyl. OSHA had no former permissible exposure limits for the latter two compounds.¹

On April 28, 1989, the Environmental Protection Agency published proposed amendments to the effluent limitations and standards in the Secondary Tungsten and Cobalt Subcategory of the Nonferrous Metals Manufacturing Point Source Category of the Clean Water Act.² The proposed amendments were the result of settlement agreements with companies affected by the regulations. The amendments would increase the allowable amount of cobalt in various wastewater streams in the Secondary Tungsten and Cobalt Subcategory, but would not affect effluent limitations and standards in the Primary Nickel and Cobalt Subcategory.³

LEGISLATION AND GOVERNMENT PROGRAMS

The NDS goal of 38,737 metric tons of cobalt metal remained in effect during 1989. The actual yearend stockpile inventory reported by the DLA was 24,088 metric tons. In July, the DLA solicited bids to upgrade 515 metric tons (1,135,985 pounds) of NDS cobalt. The solicitation required that the cobalt provided met NDS Purchase Specification P-13-R6 grade B, and included the option to exchange NDS

was higher than bids from the other companies, Sherritt won the award because of a clause citing the Buy American and Trade Agreements Acts. This clause provides top preference to domestic material over foreign material, followed by preference to material produced in countries designated under the Trade Agreements Act of 1979. Norway was a designated nation, but Zaïre and Zambia were not.

On January 19, 1989, the Occupational Safety and Health Administration (OSHA) revised the permissible exposure limit for cobalt metal, dust, and fume from an 8-hour time-weighted average of 0.1

STRATEGIC CONSIDERATIONS

Cobalt is considered a strategic and critical metal because of its many industrial and defense-related uses and because the United States is highly dependent on imports for its supply. The United States is the world's largest consumer of cobalt. In 1989, the United States consumed nearly 30% of estimated world production. There was no domestic production, so demand was met primarily from imports, with the exception of about 17% from secondary sources (scrap). To ensure an adequate supply in case of a national emergency, cobalt metal is included in the NDS.

World cobalt production is concentrated in a limited number of geographic areas. More than half of the world's supply of refined cobalt comes from Sub-Saharan Africa, primarily Zaïre and Zambia. Most of the cobalt produced in Zaïre is

transported through the Republic of South Africa. Cobalt produced in Zambia was formerly transported through the Republic of South Africa, but has been exported through Tanzania in recent years. The United States prohibits imports of products "produced, manufactured by, marketed, or otherwise exported by a parastatal organization of South Africa" under section 303(a) of the Comprehensive Anti-Apartheid Act of 1986 (Public Law 99-440). The U.S. State Department has certified cobalt as a strategic mineral so that it is exempt from this prohibition.

PRODUCTION

There was no domestic mine or refinery production of cobalt in 1989. In September, Blackbird Metals Inc. signed agreements with Noranda Minerals Inc. and M. A. Hanna Co. for the sale of the Blackbird cobalt mine in Lemhi County, ID. The sale, which was dependent on several undisclosed conditions, was not closed by yearend.

U.S. cobalt supply included secondary cobalt from the recycling of superalloy and other forms of scrap. Cobalt was recovered from spent petroleum catalysts at the AMAX plant in Braithwaite, LA, and at Gulf Chemical and Metallurgical Corp. in Freeport, TX. Extra-fine cobalt metal powder was produced in the United States at two locations. Carolmet, owned by Metallurgie Hoboken-Overpelt S.A. (MHO) in Belgium, produced extra-fine powder from imported primary metal. GTE Products Corp. produced extra-fine powder from recycled materials.

Domestic chemical processors produced 2,197 metric tons of inorganic and organic cobalt compounds in 1989, as compared with 1,865 metric tons in 1988. Shipments (defined as sales, transfers, or consumption to make other compounds) were 1,904 metric tons, as compared with 1,816 metric tons in 1988. Production and shipments of extra-fine cobalt metal powder are withheld to avoid disclosing company proprietary data.

CONSUMPTION AND USES

Reported domestic consumption of cobalt decreased slightly in 1989 following 3 consecutive years of increases. Consumption in superalloys, the largest end use for cobalt, also showed a slight decrease.

However, cobalt use in superalloys in the past few years has remained high, with only a small decrease since the record level reported for 1986.

An estimate for the cemented carbide industry was introduced to supplement reported data in the "cutting and wear-resistant materials" category. Because of

the addition of the estimate, cobalt consumption in cutting and wear-resistant materials increased to 9% of total consumption. In addition to cemented carbides, this category also includes sintered and cast carbides, diamond bit matrices, and wear-resistant alloys. The data were revised back to 1985 (tables 2 and 3).

³Data not comparable with those before 1985 because of the addition of an estimate for the cemented carbide industry.

⁴Data before 1986 not comparable because of the addition of statistical canvass coverage of the superalloy recycling industry.

⁵Data may not add to total shown because of independent rounding.

Apparent consumption, as calculated from net imports, consumption from recycled scrap, and changes in Government and industry stocks decreased 8% to 7,164 metric tons. Imports are the single largest component in the calculation of cobalt apparent consumption. U.S. imports of cobalt in 1989 decreased 18% from those in 1988. This decrease coincided with the conversion to the Harmonized Tariff Schedule (HTS). In comparing data spanning a change in reporting procedures, it is often difficult to distinguish actual trends in the data from differences resulting from changes in classification. The HTS is discussed in more detail in the Foreign Trade section of this chapter.

STOCKS

Industry stocks of cobalt metal and cobalt compounds decreased for the second year in a row. Stocks held by consumers and chemical processors were equivalent to those before the stock buildup in late 1987 (table 4).

PRICES

The producer price of \$8.40 per pound of electrolytic cobalt established in November 1988 was maintained during 1989. The market price of electrolytic cobalt reported in Metals Week was stable, with a weighted average of \$7.64 per pound for the year. Prices for these and other cobalt-containing materials are presented in table 5.

FOREIGN TRADE

Effective January 1, 1989, the United States adopted the HTS for reporting trade data. The HTS replaced the Tariff Schedules of the United States Annotated (TSUSA) system. Classification of cobalt-containing materials under the HTS differs from classification under the TSUSA, so trade data may not be directly comparable with data reported before 1989. For example, the TSUSA system had one category

for cobalt metal imports in which both unwrought cobalt and cobalt waste and scrap were reported. The HTS has four categories for cobalt metal imports: unwrought cobalt; unwrought cobalt alloys; cobalt mattes and other intermediate products of cobalt metallurgy, waste and scrap; and wrought cobalt and cobalt articles. Changes in classification for imports of cobalt metal and chemicals are reflected in tables 6, 7, and 8. Import duties on cobalt materials were not affected by the change to the HTS. A full listing of cobalt-containing imports under the HTS and their duties are given in table 9.

The United States-Canada Free-Trade Agreement took effect January 1, 1989. Duties on cobalt chemicals, unwrought cobalt alloys, and wrought cobalt and cobalt articles originating in Canada were scheduled to decrease over a 5-year period (table 10).⁴ Other cobalt materials originating in Canada were already duty free.

U.S. imports of unwrought cobalt and cobalt contained in chemicals decreased to an estimated 5,793 metric tons, valued at \$100 million. This is not directly comparable with imports in 1988, which included waste and scrap.

The net import reliance as a percentage of apparent consumption was estimated to be 83%. The net import reliance would be 100% if no cobalt were recovered from secondary sources (scrap). Fifty-nine percent of U.S. cobalt imports were from ores originating in the south-central African countries of Zaire and Zambia. This includes significant amounts of cobalt imported from Belgium, where electrolytic Zairian cobalt is processed into metal powder, oxides, and salts by MHO. Thirty-one percent of U.S. cobalt imports in 1989 were from Canada and Norway.

In 1989, the United States exported an estimated 889 metric tons of unwrought cobalt and cobalt contained in chemicals, valued at \$17.2 million. Major recipients were Mexico (18%), France (12%), and Canada (11%). The remainder was shipped to 40 other countries. Exports of unwrought cobalt, waste and scrap, increased 64% as compared with those of 1988.

Exports also included more than 171 metric tons, gross weight, of wrought metal and cobalt articles, valued at \$7 million. The majority of these materials was sent to four countries: Canada (31%), Japan (16%), France (15%), and the United Kingdom (13%). The remainder was shipped to 18 other countries. In addition, 28 metric tons, gross weight, of material was

exported under the category entitled, "Cobalt ores and concentrates." Canada was the major recipient of this material.

WORLD REVIEW

World refinery production decreased slightly from that of 1988. Sales from primary Western producers to Western consumers were estimated at 21,450 metric tons, relatively unchanged from 21,050 metric tons in 1988.⁵ The balance of Western World demand was met from industry stocks.

Capacity

The data in Table 12 are rated capacity for refineries as of December 31, 1989. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily

closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Albania

Trial production was reported at the nickel-cobalt refinery at Elbasan, southeast of Tirana. The plant was built by the

Federal Republic of Germany firm Salzgitter Industriebau GmbH, with technical assistance from Inco Tech Ltd., a subsidiary of Inco Ltd. Cobalt oxide was to be produced from domestic nickeliferous iron ore.

Australia

Nickel-cobalt sulfide and cobalt sulfide were produced as a byproduct of nickel

mining and refining by Western Mining Corp. in Western Australia and Queensland Nickel Pty. Ltd. in Queensland, respectively. Minor amounts of cobalt oxide were produced as a byproduct of zinc production by Pacific Smelting and Mining Co. Ltd. in Risdon, Tasmania.

Queensland Nickel signed long-term contracts for lateritic nickel ore from Indonesia and New Caledonia. The ore was to replace feed from the Greenvale deposit, which was expected to be depleted within a few years. Cobalt sulfide produced at the Yabulu nickel refinery in Townsville, Queensland, was refined by Outokumpu Oy in Finland.

MIM Holdings Ltd. worked on developing a method to recover cobalt from its Mount Isa copper concentrate at the company's Hydrometallurgical Research Laboratories in Brisbane. During the year, a pilot plant was being built to test the method. The process was reported to involve flotation and bacterial leaching, followed by precipitation of cobalt sulfate. Production of cobalt metal was to be considered.

Resolute Resources Ltd., of Perth, reportedly planned to develop its nickel deposit at Bulong, near Kalgoorlie in Western Australia. Based on a preliminary feasibility study, the company could process 1 million metric tons of ore per year with a sulfuric acid leaching process, from which an estimated 13,000 metric tons nickel and 800 metric tons cobalt in a sulfide precipitate could be produced. Total indicated reserves reportedly were more than 100 million metric tons ore.⁶

Botswana

The quantity of metal produced in copper-nickel-cobalt matte by BCL Ltd. decreased from the record high established in 1988. Production of nickel, copper, and cobalt in 1989 was reportedly 39,025 metric tons, of which 207 metric tons was cobalt.⁷ The drop in production was attributed primarily to depletion of high-grade concentrates stockpiled during a furnace overhaul in 1987. During the year, the company developed a new copper-nickel mine in the Selebi North deposit, with the intention of maintaining current ore production levels into the future.

Brazil

Cia. Niquel Tocantins, a Brazilian nickel producer, started production of electrolytic cobalt at its nickel plant in Sao Miguel Paulista, Sao Paulo State. This represented

the first production of cobalt metal in Brazil. Before installation of the cobalt circuit, cobalt carbonate from Tocantins' nickel refinery was sent to Falconbridge Nikkelverk in Norway to be refined. At yearend, the cobalt circuit was reported to be producing 20 metric tons of cobalt per month. The company hoped to increase capacity to 600 metric tons per year by 1991 or 1992. The cobalt was expected to replace imports for domestic consumption, with some also possibly available for export.

Canada

Falconbridge Ltd. changed ownership in September when it accepted a joint offer from Noranda Inc. of Canada and Sweden's Trelleborg AB to purchase all outstanding common shares. Noranda and Trelleborg planned to own and manage the company on an equal basis. Falconbridge's 1989 cobalt production from mines in Sudbury was 740 metric tons, down from 840 metric tons in 1988. An additional 500 metric tons of cobalt was produced in 1989 from custom feed smelting.⁸

Inco Ltd. produced 1,510 metric tons of cobalt in 1989, as compared with 1,410 metric tons in 1988.⁹ Inco's 1989 cobalt deliveries, including cobalt contained in alloys and engineered products, were 1,456 metric tons, an 8% decrease from deliveries in 1988.¹⁰

Sherritt Gordon produced 613 metric tons of cobalt, 34% less than production in 1988.¹¹ The decrease was attributed to a cutback in production to balance demand for the company's cobalt products and to decreased production as a result of unexpected arsenic impurities in the nickel-cobalt feed. A 10-year feedstock contract between Inco and Sherritt expired at the end of 1989. During 1988 and 1989, Sherritt arranged contracts for feed from the Namew Lake Mine in Manitoba, and the Redstone Mine near Timmins, Ontario. At yearend, the company continued to pursue additional sources of nickel-cobalt feed. In September, Sherritt won the contract for the NDS cobalt upgrading program (see Legislation and Government Programs section of this chapter.)

Geddes Resources Ltd. continued exploration at its Windy Craggy copper-cobalt-gold-silver deposit northwest of Haines, AK, in northwestern British Columbia. According to the company's annual report,¹² the proven and probable reserves at a 1% copper cutoff grade were estimated at 113.8 million metric tons averaging 1.92% copper, 0.08% cobalt, 0.2 gram per ton gold, and 3.7 grams per ton silver. Additional possible reserves were estimated at 51.6 million metric tons averaging 1.82% copper, 0.08% cobalt, 0.2 gram per ton gold, and 4.3 grams per ton silver. Because the reserve estimates did not take into account mining dilution, they were considered "geological reserves" by the company. Metallurgical, engineering, and economic studies were performed in 1989, and an environmental baseline study was submitted to the British Columbia Government. During 1989, Northgate Exploration Ltd. increased its interest in Geddes to 37%, and Cominco Ltd. purchased a 17% interest.

Finland

Outokumpu Oy's production of cobalt products increased 14% in 1989 to 1,295 metric tons contained cobalt.¹³ Outokumpu's Keretti Mine in southeastern Finland was closed in May 1989. Since its opening in 1913, an estimated 30 million metric tons of ore had been mined, producing concentrates containing 60,000 metric tons of cobalt.¹⁴

France

The French Government tendered several 30 to 80 metric ton lots of Government stockpile cobalt during 1989. Gécamines purchased some of the stockpiled cobalt, reportedly to maintain market stability.

Japan

Cobalt metal was one of seven materials included in Japan's rare metals stockpile. The Metal Mining Agency of Japan reported a supply of 51 days in the stockpile at the end of fiscal year 1989 (April 1, 1989 through March 31, 1990), 35.7 days in the Government stockpile, and 15.3 days in the private stockpile. Stockpile goals, to be achieved by March 1992, were 60 days of Japanese consumption, divided into 42 days in the Government stockpile and 18 days in the private stockpile.

Japanese cobalt consumption in 1989 was reported to increase 11% to 2,585 metric tons compared with that of 1988. Cobalt use by industry as compared with that of 1988 was as follows: catalysts increased 35% to 373 metric tons; hard metal tools increased 18% to 302 metric tons; special steels increased 17% to 787 metric tons; tubes, plates, rods, and wire increased 17% to 333 metric tons; magnetic materials decreased 7% to 555 metric tons; and other uses decreased 3% to 235 metric tons.¹⁵

Norway

Cobalt production at the Falconbridge Nikkelverk refinery was 1,946 metric tons, almost equal to production in 1988 at 1,951 metric tons.¹⁶ Feedstock for the refinery was in the form of matte, mostly from Sudbury in Canada (60%), BCL Ltd. in Botswana (25%), and Noril'sk in the U.S.S.R. (10%).¹⁷ Cobalt from Falconbridge Nikkelverk was to be supplied to the NDS under the cobalt upgrading program (see Legislation and Government Programs section of this chapter.)

Philippines

At yearend, ownership of the Nonoc Mining and Industrial Corp. nickel production facility remained with the Philippine Government's Asset Privatization Trust in spite of attempts to sell at auctions and through negotiations during the year. The facility, located in Surigao del Norte, Nonoc Island, was one of the state-owned mining companies the Government intended to privatize.

South Africa, Republic of

Cobalt was produced as a byproduct of the platinum industry in the Transvaal Province by Rustenburg Platinum Mines Ltd., Impala Platinum Ltd., and Western Platinum Ltd.

The Zinc Corp. of South Africa Ltd. (Zincor) investigated methods of improved cobalt removal during zinc processing. Increased cobalt levels were the result of treating concentrates from Black Mountain. A design and feasibility study for a cobalt recovery plant was completed in 1988. However, no decision was made in 1989 on whether to proceed with building a plant for byproduct production of cobalt.

Zaire

Gécamines was the world's largest cobalt producer, providing more than one-third of the estimated world refinery production. The company's cobalt production decreased 6% from that of 1988. Gécamines stated that it planned to continue producing at levels that will maintain a balance with demand, and intentionally reduced its large inventories during 1988 and 1989.¹⁸ Insufficient overburden removal and ore extraction from the open pit mines had also been reported as a contributing factor toward decreased production.

A comprehensive review of copper and cobalt production in Zaire was published by a former Gécamines engineer.¹⁹ Geology of the deposits and operations at the mines, concentrators, and metallurgical plants were described.

Zambia

Zambian production data for 1985-88 in tables 13 and 14 have been revised based on information from Zambia Consolidated Copper Mines Ltd. (ZCCM) annual reports. The data now represent production during the ZCCM fiscal year (fiscal year 1988 was from April 1, 1988 to March 30, 1989). The content of concentrates in table 13 is derived from reported cobalt content of concentrates, when available, and cobalt content of ore milled and percentage of cobalt recovery to concentrates, for plants not reporting content of concentrates. These figures were formerly estimated from metal production figures assuming a 75% recovery from concentrate to metal.

ZCCM closed its Chambishi cobalt refinery and its Nkana cobalt refinery in Kitwe for a period during May and June for routine maintenance. As a result, cobalt production for that quarter was down 20% to 863 metric tons, as compared with 1,079 metric tons produced during the same quarter in 1988.²⁰ Production of refined cobalt metal from January through December 1989, as reported by the Mines

Development Department of the Zambian Ministry of Mines, was 4,488 metric tons.²¹

The addition of ion exchange columns to the electrolyte circuit of ZCCM's Chambishi cobalt refinery in 1988 was reported.²² Nickel contents of cobalt metal produced at Chambishi were decreased to about 0.06 to 0.08%.

A preliminary study on the modernization of ZCCM's Nchanga concentrator was undertaken.²³ The focus of the study was on options for replacing the many small flotation cells used in the plant. The study concluded that column flotation was not recommended for the roughing circuit, but could be investigated for the sulfide cleaning circuit. Further investigation for the roughing circuit was to be directed toward the use of large flotation cells.

Zimbabwe

Delta Gold NL, an Australian company, considered mining a portion of the Great Dyke, a 500-km precious metals and chromite deposit that crosscuts Zimbabwe north to south. Minor amounts of cobalt would be contained in nickel-copper matte produced as a byproduct of platinum group metal and gold production. The matte was to be toll refined in Zimbabwe.

CURRENT RESEARCH

The Bureau of Mines received an R&D 100 Award from Research & Development Magazine for a process developed to recover cobalt from copper leach solutions. The ion exchange/solvent extraction/

¹Table includes data available through May 30, 1990. Figures represent recoverable cobalt content of ores, concentrates, or intermediate products from copper, nickel, platinum, or zinc operations. Morocco was the only country where cobalt was mined as a primary product.

²In addition to the countries listed, Bulgaria, China, the German Democratic Republic, Indonesia, and Poland are known to produce ores that contain cobalt, but information is inadequate for reliable estimates of output levels. Other copper, nickel, platinum, or zinc producing nations may also produce ores containing cobalt as a byproduct component, but recovery is small or nil.

³Calculated from reported and estimated weight of nickeliferous ore.

⁴Figures represent quantities of cobalt contained in intermediate metallurgical products (cobalt oxide and nickel-cobalt sulfide). Cobalt content of lateritic nickel ore, nickel concentrate, and zinc concentrate was as follows, in metric tons: 1985—3,036; 1986—2,914; 1987—2,715; 1988—2,775 (estimated); and 1989—2,375 (estimated).

⁵Reported cobalt content of pelletized nickel-copper matte.

⁶Figures represent total cobalt content of all products derived from ores of Canadian origin, including cobalt oxides shipped to the United Kingdom for further processing and nickel-copper-cobalt mattes shipped to Norway for further processing.

⁷Reported figure.

⁸Determined from reported nickel-cobalt content of granular and powder oxide, oxide sinter, and sulfide production.

⁹Cobalt content of concentrates.

¹⁰Revised to zero.

¹¹Series represents estimated recovery from ores and intermediate metallurgical products exported from New Caledonia to France and Japan. The estimated cobalt content of total ores mined is as follows, in metric tons: 1985—5,186 (revised); 1986—5,000; 1987—5,800; 1988—6,000; and 1989—6,000.

¹²Year beginning Apr. 1 of that stated. Cobalt content of ore milled was as follows, in metric tons: 1985—10,539; 1986—8,656; 1987—11,198; 1988—10,687; and 1989—10,000 (estimated).

¹³Estimated cobalt content of ore.

¹Table includes data available through May 30, 1990. Figures represent cobalt refined from ores, concentrates, or intermediate products and do not include production of downstream products from refined cobalt.

²In addition to the countries listed, Belgium, Czechoslovakia, and the Federal Republic of Germany may recover cobalt from imported materials, but production is not reported and information is inadequate to make reliable estimates of production.

³Reported figure.

⁴Fiscal years beginning Apr. 1 of that stated.

⁵Revised to zero. Material previously listed under Zimbabwe in this table was a semifinished product that was shipped elsewhere (e.g. to Norway) for refining.

⁶Excludes Finland for 1985 and 1986; included with "Unspecified."

electrowinning process uses feed material currently produced on a large scale and readily available industrial equipment. All process streams are recycled or used for product recovery, minimizing the potential for environmental damage.

The Bureau of Mines researched a continuous flotation process to recover a bulk sulfide concentrate from Missouri lead ore tailings. It was estimated that up to 50% of the cobalt originally present in the ore reports to the tailings during processing for lead and other metals. Reprocessing of these tailings produced a final concentrate containing more than 50% of the cobalt in less than 10% of the original tailings weight.²⁴

Results of a study comparing two methods for recovering cobalt, molybdenum, nickel, and tungsten from spent hydro-

processing catalysts were reported by the Bureau of Mines.²⁵ Both the anhydrous chlorination process and the caustic-acid leaching process appeared to be technically feasible. Preliminary economic evaluation favored the chlorination process.

The Bureau published a study on the separation and recovery of metals from mixed, contaminated superalloy scrap.²⁶ The objective of the research was to maximize recovery of cobalt and nickel. Of the many methods studied, oxygen pressure leaching of zinc-treated or atomized scrap with hydrochloric acid was preferred. Chlorine gas could be substituted for hydrochloric acid if processing zinc-treated scrap.

The Cobalt Development Institute of Slough, United Kingdom, published

abstracts on cobalt research, articles on selected cobalt uses, and annual and semiannual data on cobalt production by Institute members in quarterly issues of Cobalt News.

OUTLOOK

Future trends in cobalt consumption are dependent on the performance of a variety of industries. The largest single use of cobalt is in superalloys, which are used primarily in aircraft turbine engines. Relatively high demand for cobalt in superalloys is expected to continue as a record backlog of orders for commercial aircraft is filled in the next 3 to 5 years.

BACKGROUND

Definitions, Grades, and Specifications

Cobalt is a metallic element. It is silvery gray in color, hard, ductile, somewhat malleable, and magnetic. Other properties include atomic number, 27; atomic weight, 58.93; melting point, 1,493° C; boiling point, 3,100° C; and Curie temperature, 1,121° C. Cobalt-60 (⁶⁰Co) is produced by irradiating cobalt metal in a nuclear reactor. This radioactive isotope is used in radiation therapy and sterilization of medical supplies.

Currently there are no internationally recognized specifications for cobalt metal. The two leading Western World producers, Gécamines and ZCCM, have recently proposed specifications for five grades of cobalt.²⁷ The U.S. Government has purchase specifications for NDS cobalt. The current NDS specification, P-13-R6, provides physical and chemical requirements for three grades of refined cobalt metal. Grades A and B must be in the form of electrolytic cathode; grade C can be either cathode or granules. Chemical requirements specify the weight percentage, in order of abundance, of cobalt, nickel, iron, and manganese, as well as maximum levels of 26 impurities.

Products for Trade and Industry

About 60% of the cobalt used in the United States is consumed as primary cobalt metal. This is either in the form of cathode (electrolytic cobalt or flakes), granules (shot), or metal powder. Secondary cobalt metal, or scrap, constitutes

about 15% of U.S. consumption. Cobalt oxide (about 7% of cobalt consumed) can be either gray oxide, with 75% to 78% cobalt content, or black oxide, with 70% to 74% cobalt content. The percent cobalt content in the oxides depends on the relative amounts of cobalt(II)oxide and cobalt(II)dicobalt(III)tetroxide present. The remainder of the cobalt used is in the form of cobalt chemical compounds. Commercially available inorganic cobalt compounds include carbonate, chloride, hydroxide, nitrate, and sulfate (either as heptohydrate or monohydrate). Most of the inorganic compounds are sold in crystalline form, but some are also available in solution. A variety of organic cobalt compounds are also available.

Industry Structure

U.S. mine production of cobalt ceased at the end of 1971, and the sole U.S. cobalt refinery discontinued processing imported nickel-cobalt matte in late 1985. In 1989, Zaire was the world's leading producer of refined cobalt, followed by the U.S.S.R., Zambia, Canada, Norway, and Finland. These six countries represented more than 90% of world cobalt refinery production. Zairian and Zambian production was from domestic ores. The U.S.S.R. and Canada produced cobalt from both domestic and imported raw materials. Cobalt was produced in Norway and Finland from imported raw materials. World producers of refined cobalt and producers of intermediate cobalt-containing products are listed in tables 15 and 16.

Byproducts and Coproducts

Cobalt is rarely produced as a primary product from a mining operation. Most of Western world cobalt supply is produced as a byproduct of copper production in Zaire and Zambia. With the exceptions of Morocco, where small amounts of cobalt are produced as a primary product, and the Republic of South Africa, where cobalt is produced as a byproduct of the platinum industry, cobalt production in most other countries is a byproduct of nickel production.

Operating Factors

Environmental Requirements.—The Environmental Protection Agency regulates releases of cobalt into the environment under various programs. OSHA regulates workplace exposures by setting permissible exposure limits for cobalt metal, dust,

COLUMBIUM (NIOBIUM) AND TANTALUM

By Larry D. Cunningham

Mr. Cunningham, a physical scientist with 10 years of research and commodity experience with the Bureau of Mines, has served as the commodity specialist for columbium and tantalum since 1983. Domestic survey and trade data were prepared by Mss. Cheryl M. Jackson and Robin A. Johnson, mineral data assistants; and columbium and tantalum world production data, by country, were prepared by Mrs. Audrey D. Wilkes, international data coordinator.

The United States remained dependent on imports of columbium and tantalum materials, and the net trade deficit for these minerals was at the highest level since 1981. Most columbium price quotations rose slightly, whereas tantalum concentrate prices declined significantly.

Overall reported consumption of columbium in the form of ferrocolumbium and nickel columbium was down, in line with a decline in steel production and a soft superalloy industry. The overall tantalum industry, which had showed signs of some improvement in recent years, was also down. Factory sales of tantalum capacitors were at the lowest level since 1986. However, much interest was being generated relating to tantalum's use in certain armor-piercing penetrator weapon systems.

Fansteel Inc., a pioneer in and a major domestic processor and producer of tantalum, announced the sale of certain inventory and equipment pertaining to its tantalum product lines.

LEGISLATION AND GOVERNMENT PROGRAMS

Under the offset concept for the National Defense Stockpile (NDS), 57% of the goal for columbium concentrates and 37% of the goal for tantalum minerals were met (table 3). The Report to the Congress on NDS requirements, presented by the Secretary of Defense in April 1989, recommended that goals for the columbium group be increased by 7.67 million pounds of recoverable columbium, that stockpile columbium metal powder and ferrocolumbium be upgraded to 42,000 pounds and 200,000 pounds of high-purity columbium metal, respectively, and that stockpile tantalum metal powder be upgraded to 40,000 pounds of

high-purity tantalum metal. The recommendations were based on the U.S. Department of Defense findings concerned with military requirements for strategic and critical materials. Additionally, Defense's planned targets of opportunity for fiscal year 1990 included the purchase of 200,000 pounds of tantalum oxide contained in tantalum minerals and 600,000 pounds of high-purity ferrocolumbium.

STRATEGIC CONSIDERATIONS

Many of the applications for columbium and tantalum are either directly

or indirectly defense-related because of their uses in the aerospace, communications, energy, and transportation industries. Thus, both metals are classified as strategic and are part of the NDS.

The high degree of import reliance for columbium and tantalum is a principal strategic problem faced by the United States. In the case of both columbium and tantalum, there has been no significant mining since the 1950's. Domestic columbium and tantalum resources are of low grade, some mineralogically complex, and most are not currently commercially recoverable. To ensure a supply of columbium and tantalum during an emergency, goals for both materials have been es-

established for the NDS. However, inventories for both materials are substantially under set goals. The United States will continue to depend on foreign sources of supply, and present supply patterns are expected to continue. Consequently, a degree of vulnerability exists. Most of the foreign sources are not strategically located for the United States, and some have questionable stability.

ISSUES

At the start of the 1980's, there were four major processors of columbium- and tantalum-bearing source materials (feedstocks). One of the operations was shut down in 1985, and another shut down its processing operation at yearend 1989. Of the remaining two companies, one is dedicated solely to the processing of columbium materials, whereas the other company processes both columbium and tantalum materials. The NDS goals and inventory for both columbium and tantalum are mostly for source materials. Thus, it is assumed that the United States would have on hand in an emergency adequate processing capacity for conversion of the material to an upgraded form and quality required by the critical end uses. However, the United States has become more reliant on the processing capability of foreign sources and the availability of intermediate products from those sources.

PRODUCTION

Unreported quantities of columbium- and tantalum-bearing concentrates were produced and shipped from a mine and milling operation in Rockford, AL. There were three processors of columbium- and tantalum-bearing source materials that were integrated from raw material processing to columbium and tantalum end products. They were Cabot Corp. and Fansteel Inc. for columbium and tantalum processing, and Shieldalloy Metallurgical Corp., dedicated solely to columbium processing. NRC Inc. was a major producer of tantalum products, and Reading Alloys Inc. and Teledyne Wah Chang Albany

were major producers of high-purity columbium products. Kennametal Inc. was the major producer of columbium and tantalum carbides.

In December, Fansteel, North Chicago, IL, reported the sale of certain inventory and equipment pertaining to its tantalum product lines to NRC, Newton, MA. Fansteel also sold all of its majority stock interest in V Tech-Fansteel Inc., a Japanese producer of tantalum capacitor powder, to Hermann C. Stark Berlin KG. Additionally, operations at Fansteel's columbium and tantalum source material processing plant in Muskogee, OK, were shut down. Fansteel withdrew from the production of tantalum products and elected to use its resources to remodel its specialty metals business to serve markets that offer superior growth opportunities.¹

CONSUMPTION AND USES

Overall reported consumption of columbium as ferrocolumbium and nickel columbium was down by 8% compared with that of 1988. Consumption of columbium by the steelmaking industry decreased by 7%, affected by a small decrease in raw steel production. There was also a slight decrease in the percentage of columbium usage per ton of steel produced. Demand for columbium in superalloys was down by 14% to the lowest level since 1982. However,

that portion used in the form of nickel columbium increased by about 10% to more than 400,000 pounds.

Overall tantalum demand was down as reflected in the 29% decrease in tantalum shipments reported by the Tantalum Producers Association, with shipments declining more than 50% from the peak-year shipments of 1979. However, shipment data for tantalum carbide in 1989 were not available. Industry sources attributed much of the downturn in demand to a weak electronics industry, a buildup in inventories by capacitor manufacturers, and the continuing improvements in the efficiency of tantalum capacitor powders.

Factory sales of tantalum capacitors declined by 20% to the lowest level since 1986, as reported by the Electronic Industries Association. Weak demand for tantalum capacitor products in the automotive and computer components markets contributed to the decline. In April, the Black & Decker Corp. acquired Emhart Corp., including its subsidiary Mallory Capacitor Co. with its tantalum capacitor business. However, Black & Decker reportedly will dispose of several Emhart businesses, including capacitor manufacturing.² Sprague Technologies Inc., a major manufacturer of tantalum capacitors, initiated a restructuring plan. This included the company's decision to exit certain unprofitable product lines and to concentrate on its passive component businesses of tantalum and aluminum

capacitors, networks, and hybrids.³

An application that could increase future domestic tantalum demand is its use in advanced weapon systems. Because of its ductility, density, and physical properties, tantalum was being considered as a substitute for depleted uranium, tungsten, and copper in certain armor-piercing penetrator systems.

PRICES

The Metals Week published price for pyrochlore concentrates produced in Canada, quoted since December 1985 at \$2.60 per pound of contained columbium pentoxide (Cb_2O_5), f.o.b. Canada, for concentrates with a nominal content of 57% to 62% Cb_2O_5 , was discontinued in February. In June, the published price of regular-grade ferrocolumbium containing 63% to 68% columbium increased from \$6.00 to \$6.58 per pound of contained columbium, f.o.b. shipping port, where it remained through December.

The Metals Week published price for high-purity ferrocolumbium containing 62% to 68% columbium closed from a range of \$16.00 to \$17.50 per pound of contained columbium, f.o.b. shipping point, to \$17.50 in April, where it remained through December. The published spot price for columbite ore rose from a range of \$2.00 to \$2.50 per pound of contained Cb_2O_5 and tanta-

lum pentoxide (Ta_2O_5), c.i.f. U.S. ports, to a range of \$3.00 to \$3.50 in July, where it remained through December. At yearend, the price for nickel columbium had closed from a range of \$17.50 to \$19.50 per pound of contained columbium to \$19.50, the published price for columbium oxide was \$7.64 per pound of oxide, and the published price for columbium metal was at a range of \$30 to \$50.

The Metals Week published spot price for tantalite ore, on the basis of 60% combined Cb_2O_5 and Ta_2O_5 , c.i.f. U.S. ports, began the year at \$49 to \$51 per pound, fell to \$35.00 to \$37.50 by midyear, and continued to fall to finish the year at \$26 to \$28. The Metal Bulletin published price for tantalite fell progressively from \$47 to \$52 per pound of contained Ta_2O_5 to \$29 to \$35 by yearend. The Metal Bulletin published price for tantalite produced by Greenbushes Ltd. of Australia, on the basis of 40% contained Ta_2O_5 , rose from \$47.50 per pound to \$50 in February, where it remained through December. A published price for tantalite from the Canadian producer, Tantalum Min-

ing Corp. of Canada Ltd. (TANCO), was not available. Tantalum capacitor-grade powder was reportedly selling in the range of \$120 to \$130 per pound, and tantalum carbide was reportedly selling at around \$80 per pound.

FOREIGN TRADE

On January 1, the United States adopted the tariff schedules nomenclature of the internationally established Harmonized System, as required by the Omnibus Trade and Competitiveness Act of 1988 (Public Law 100-418). The new nomenclature, TSUS codes, and rates of duty for 1989 are shown in

table 10.

Net trade for columbium and tantalum continued at a deficit and was at the highest level since 1981. Overall trade volume and value for imports were up more than 40% and 60%, respectively.

Imports for consumption of columbium concentrates rose by more than 30% to the highest level since 1980. Imports were estimated to contain 2 million pounds of columbium and a small quantity of tantalum at an average grade of approximately 58% Cb_2O_5 and less than 1% Ta_2O_5 .

Imports for consumption of tantalum mineral concentrates increased substantially. Imports were estimated to contain 1.1 million pounds of tantalum and 680,000 pounds of columbium at an average grade of approximately 35% Ta_2O_5 and 25% Cb_2O_5 .

Imports for consumption of synthetic tantalum-columbium concentrates continued to decline: 170,000 pounds valued at \$2.2 million compared with 263,000 pounds valued at \$1.5 million in 1988. These figures are not included in the salient statistics data.

WORLD REVIEW

Industry Structure

Brazil and Canada were the major producers of columbium raw materials feedstock, while tantalum raw materials were produced mainly in Australia, Brazil, Canada, and in Thailand in the form of high-grade tantalum-bearing tin slags. Synthetic concentrates, produced from low-grade tin slags, from the Federal Republic of Germany were an additional source of columbium and tantalum raw material supply. Principal world raw material and product producers are shown in tables 11 and 12, respectively.

Capacity

The data in table 13 are rated capacity for mines and mills as of December 31, 1989. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operat-

ing plants and plants temporarily closed that, in the judgement of the author, can be brought into production within a short period of time with minimum capital expenditure. Mine capacity for columbium and tantalum is based on published reports, maximum production statistics, and estimates where capacity information is either incomplete or unavailable.

Australia

For its fiscal year, Greenbushes reported that the company's production of tantalite fell short of budget by approximately 30,000 pounds of Ta₂O₅ content with unit cost of production higher than anticipated. Treated ore increased more than 30% to 2.4 million tons, with tantalum oxide produced in tantalite concentrates increasing to 269,100 pounds. The chemical plant, which operated on a one shift basis, produced 32,700 pounds of Ta₂O₅ and 11,800 pounds of Nb₂O₅. Tantalum oxide contained in tantalum glass (slag) production rose by 70% to 82,600 pounds. Greenbushes' tailings re-treatment plant was recommissioned, and this operation produced 67,900 pounds of Ta₂O₅ contained in tantalite.

Centamin Ltd., a Perth-based gold producer, reportedly will restart tin and tantalum production at its Moolyella deposit in the Pilbara region of Western Australia in early 1990. The deposit, which was purchased from Endeavour Resources Ltd., had been placed on care and maintenance in recent years. Known reserves reportedly will permit the production of more than 600 tons of tin and more than 60 tons of tantalum in concentrates per year for up to 5 years.

The Pan West tantalum project in Pilbara, Western Australia, jointly owned by Pancontinental Mining Ltd. and Goldrim Mining Australia Ltd., was nearing startup. When fully operational, the Wodgina mine is expected to have a production capacity of about 200,000 pounds of contained Ta₂O₅ in concentrate annually. Pancontinental was reported to have discovered a tantalum deposit at Mount Farmer in the Murchison region of Western Australia. The initial find was estimated to contain minable ore resources of more than 15,000 tons with an average grade of about 0.29% Ta₂O₅. Further exploration at the site was planned. Additionally, drill testing at Caitlin Creek

near Ravensthorpe, Western Australia, confirmed ore resources containing about 275,000 pounds of Ta₂O₅. Pancontinental reportedly has an 80% interest in this exploration project.

Brazil

Cia. Brasileira de Metalurgia e Mineração (CBMM) reportedly completed construction of a 40-ton-per-year columbium metal plant at its Araxa complex in Minas Gerais State. CBMM had been producing columbium metal on an experimental basis in a venture with the State-owned Fundacao de Tecnologia Industrial at Lorena, Sao Paulo State.

Paranapanema S.A. Mineração Indústria e Construção, Brazil's largest tin producer, was nearing completion of a plant at its Pitinga tin property in the Amazonas State to produce columbium- and tantalum-bearing concentrates. When construction is completed, the concentrates produced at the plant will be shipped to Paranapanema's processing plant in Sao Paulo State for conversion to columbium and tantalum oxides. Planned annual production at the processing plant reportedly will be about 2 million pounds and

200,000 pounds of columbium and tantalum oxides, respectively.

Canada

As reported by Teck Corp. and Cam-bior Inc., production of Cb_2O_5 at the Niobec Mine at St. Honoré, Quebec, a 50-50 joint venture, was a record 7.7 million pounds, attributable to additional tonnages milled and a better recovery. Ore milled was 883,000 tons, as the mill operated on the average of 2,418 tons of ore per day. Average recovery was 61% with Cb_2O_5 grade of concentrate at 71%. Yearend ore reserves were virtually unchanged at about 12 million tons assaying 0.65% Cb_2O_5 .

India

Sartin, a subsidiary of Saru Smelting of Delhi, commissioned India's first tin smelter near Cuttack in the Orissa State, with plans to provide 10% of the country's tin needs. Sartin reportedly

was created to take advantage of Government funding that encourages development of domestic tin deposits by Madhya Pradesh State Mining Corp. Ltd. (MPSM). MPSM's production of tin concentrates had been minimal because the Government had decided that the slags and tin concentrates are strategic materials to be stockpiled and not sold or exported. Tin slags produced by the smelter have a combined columbium and tantalum oxide content of 30%. In 1986, MPSM had planned to build a tantalum treatment plant, but the plan was canceled because of prevailing low tantalum prices.

Japan

Production of ferrocolumbium rose to 812 tons from the 715 tons produced in 1988. Columbium ore imported for ferrocolumbium production fell to about 900 tons, with Canada providing more than 90% of the total. Ferrocolumbium imports rose to 3,957 tons

from the 3,704 tons reported in 1988. The bulk of the imports came from Brazil.

Thailand

Renovations of the Thai Pioneer Co. Ltd. tin smelter reportedly were nearing completion with startup of tin production anticipated by yearend. The 4,000-metric-ton-per-year smelter, closed since midyear 1982 because of a lack of feed material and financial difficulties, also produced tantalum-bearing tin slags. The new tin concentrate supply was expected to be secured from tin mine operations in central and northern Thailand.

OUTLOOK

Columbium

Columbium is used principally as an additive in steelmaking, which has accounted for about 80% of the re-

ported consumption in the United States in recent years. No significant change to this trend is expected in the near term for there are few other growth outlets for the use of columbium. Thus, future columbium demand growth will continue to be directly related to the worldwide performance of the steel industry. A boost for columbium consumption in steelmaking could be the drastic escalation in price in recent years for competing ferroalloys of titanium and vanadium. Some steel companies reportedly have initiated projects for the substitution of columbium for titanium and vanadium in steelmaking. Domestic columbium consumption in the production of superalloys is currently around 15%. Future growth for this end use will be affected mainly by

the demand for columbium-containing superalloys from the aircraft industry, which has an up and down cyclical history. The major components of U.S. supply-demand relationships for columbium in 1979-89 are given in table 15.

Tantalum

During the 1980's, more than 60% of the tantalum consumed in the United States was used to produce electronic components, mainly tantalum capacitors, with major markets in recent years being computer and communication systems. However, overall tantalum demand growth in this sector has been slowed because of the industry's continued emphasis on higher capacitance powders and the miniaturization of electronic components resulting in less tantalum used per unit. A similar situation exists for tantalum in cemented carbide use. Tantalum demand in this market has been affected by the growing use of mixed carbides, coated cutting tools, improved tool life, and the down-sizing of components. Additionally, the demand and price for tantalum has had a cyclical and somewhat volatile history. Thus, the future growth for tantalum will depend not only on the fortunes of the electronic and carbide industries but also on tantalum's price stability. The major components of U.S. supply-demand relationships for tantalum in 1979-89 are given in table 16.

BACKGROUND— COLUMBIUM

Columbium and niobium are synonymous names for the chemical element with the atomic number 41; columbium was the first name given, and niobium was the name officially designated by the International Union of Pure and Applied Chemistry in 1950. The metal conducts heat and electricity relatively well, has a high melting point (2,480° C), is readily fabricated, and is highly resistant to many chemical environments. Columbium has the special property of exhibiting superconductivity, which is the virtual loss of electrical resistance at very low temperatures (about 9° K).

Definitions, Grades, and Specifications

Columbium pentoxide (oxide) is a stable, white- to buff-colored compound that is produced in metallurgical, ceramic, and optical grades. Purity of oxide generally exceeds 99%.

American Society for Testing and Materials (ASTM) Specification A550 covers three grades of ferrocolumbium, designated as low-alloy steel grade, alloy and stainless steel grade, and high-purity grade. For all grades, the composition is approximately 65% columbium, with the balance iron; principal impurities are aluminum, silicon, and tantalum. Nickel columbium, the other main columbium additive, typically contains 63% columbium, with the balance being nickel. Aluminum, iron, silicon, and tantalum are the principal impurities. Columbium carbide is available as a powder containing about 87% columbium and the balance as carbon.

Columbium metal is available in virtually any form and shape. Purity of unalloyed metal is usually more than 99%, with attention mainly given to iron, tantalum, and zirconium as metallic impurities and carbon, oxygen, nitrogen, and hydrogen as interstitial impurities. Alloys with hafnium, tantalum, tungsten, titanium, and zirconium are of most commercial importance. Chemical and physical standards for columbium and columbium alloy mill shapes are given in ASTM Specifications B391-B394, B652, and B654-B655.

Products for Trade and Industry

Columbium, in the form of ferrocolumbium, is used worldwide, principally as an additive to improve the strength and corrosion resistance of steels. These high-strength and corrosion resistant steels are used in applications such as high-strength linepipe, structural members, lighter weight components in cars and trucks, and exhaust manifolds. Additionally, appreciable amounts of columbium in the form of high-purity ferrocolumbium and nickel columbium are used in nickel-, cobalt-, and iron-base superalloys for applications such as jet engine components, rocket subassemblies, and heat-resisting and combustion equipment. Columbium-base alloys are also used in aerospace applications such as rocket nozzles. Columbium carbide is

^c Estimated. ^p Preliminary. ^r Revised. NA Not available.¹ Excludes columbium- and tantalum-bearing tin slags. Production of tantalum contained in tin slags was, in thousand pounds: 1985—877; 1986—623 (revised); 1987—543; 1988—1,145; and 1989—799, according to data from the Tantalum-Niobium International Study Center. Table includes data available through June 30, 1990.² In addition to the countries listed, China, the U.S.S.R., and Zambia also produce, or are believed to produce, columbium and tantalum mineral concentrates, but available information is inadequate to make reliable estimates of output levels.³ Data on gross weight generally have been presented as reported in official sources of the respective countries, divided into concentrates of columbite, tantalite, and pyrochlore where information is available to do so, and reported in groups such as columbite and tantalite where it is not.⁴ Unless otherwise specified, data presented for metal content are Bureau of Mines estimates based, in most part, on reported gross weight and/or pentoxide content. Metal content estimates are revised as necessary to reflect changes in gross weight and/or pentoxide data.⁵ Reported in and/or by official country sources.⁶ Less than 1/2 unit.

used in cemented carbides to modify the properties of the cobalt-bonded tungsten carbide-base material. It is usually used with carbides of metals such as tantalum and titanium. Columbium oxide is the intermediate used in the manufacture of high-purity ferro-columbium, nickel columbium, columbium metal, and columbium carbide.

Geology-Resources

Columbium is almost always found in nature as an oxide in association with other minerals, but not in elemen-

tal form nor as a sulfide. Columbium has an overall crustal abundance estimated as 20 parts per million and a strong geochemical coherence with tantalum. Pyrochlore and bariopyrochlore (also known as pandaite), its barium analog, have become the main sources of columbium. The minerals are quite low in tantalum, having a columbium oxide-to-tantalum oxide ratio of 200:1 or greater. Pyrochlore and bariopyrochlore are commonly found in the interior parts of alkalic rock complexes, frequently in association with minerals

of such other elements as titanium, thorium, uranium, and those of the rare earths. Columbite, the columbium-rich member of the columbite-tantalite isomorphous series, is normally found in intrusive pegmatites and in biotite and alkalic granites. However, because most such deposits relatively high in columbium content are small and erratically distributed, most columbite has been obtained as a byproduct of mining for other commodities, mainly tin.

Reserve and reserve base data for columbium are shown in table 17 and

are based on a judgmental appraisal of current information. Reserve base is defined as the in-place demonstrated (measured plus indicated) resource from which reserves are estimated. The reserve base may encompass those parts of the resources that have a reasonable potential for becoming economically available within planning horizons beyond those that assume proven technology and current economics. Reserves are defined as that part of the reserve base that could be economically extracted or produced at the time of determination.

Technology

Exploration.—Columbium deposits of economic interest are most likely to be found in alkalic rock complexes and associated carbonatites. Aerial photography and geological mapping can be used to reveal alkalic complexes, which

frequently occur with circular geometry and concentric rock arrangement. Test pitting and panning can be used to explore placer deposits for columbium by virtue of the high specific gravity of columbium minerals. The columbium content of samples can be determined rapidly by means of truck-mounted spectrographic equipment and X-ray fluorescence spectroscopy.

Mining.—Pyrochlore has been mined mainly by mechanized open pit, underground stoping methods, or a combination of both. Currently all mining for pyrochlore in Brazil is open pit, whereas in Canada, underground mining is being done via a large-diameter blasthole method. Ore, with host rock, is usually dislodged from a working face with explosives. Beneficiation of the ore, after it has been finely ground, is achieved primarily by various flotation procedures combined with magnetic separation to remove iron miner-

als. A chloridizing and leaching process can also be employed to lower lead, phosphorus, sulfur, and barium contents. Methods used to mine columbite have ranged from simple hand operations in small pegmatite mines to hydraulic monitors and dredges at placer deposits.

Beneficiation.—Pyrochlore concentrates are used solely in the manufacture of ferrocolumbium for steelmaking. Aluminothermy, the process being used for making steelmaking grade ferrocolumbium from pyrochlore concentrates, is carried out in batches. As practiced by CBMM in Brazil, a mixed charge of concentrate, iron oxide (as hematite), fine aluminum powder, and slagging agents is reacted to produce ferrocolumbium in a refractory-lined, cylindrical steel shell open at the top and resting upon a lined silica sand bed. Also, processes have been developed for production of columbium ox-

ide through treatment of ferrocolumbium produced from pyrochlore concentrates. This technology is being used to produce commercial quantities of columbium oxide suitable for the manufacture of high-purity ferrocolumbium, nickel columbium, and columbium metal.

In the extraction of columbium from other mineral concentrates and tin slags, modern technology makes use mainly of digestion with hydrofluoric acid followed by liquid-liquid extraction with methyl isobutyl ketone (MIBK). This procedure efficiently recovers both columbium and tantalum in the form of separate streams that then can be further processed individually into oxides and metal. Columbium oxide is precipitated from the columbium stream by ammonia and then purified and calcined.

Columbium oxide is aluminothermically reduced batchwise to produce high-purity ferrocolumbium, nickel columbium, and columbium metal. Aluminothermically produced columbium metal is commonly purified to remove aluminum and other contaminants by remelting it in an electron-beam furnace. Several remelts may be required before the desired level of purity is reached and a ductile ingot has been produced. The basic method for production of columbium carbide is reduction of columbium oxide by carbon at high temperature under vacuum or a protective atmosphere.

Recycling.—Columbium used in steel-making and in superalloy manufacture is essentially a dissipative use, and little is reclaimed. However, when strict scrap segregation practices are followed, small quantities of columbium-bearing superalloy scrap are recycled. Aside from sales to alloy melters, columbium metal scrap has not been recycled to any extent other than in-house as home scrap by processors.

Economic Factors

Prices.—The price of columbium contained in concentrates, in terms of actual prices and in constant 1982 dollars, has been relatively stable for the period shown in table 18. Actual prices reported are based on historical price quotations, or best available information from producers. Additionally, prices for products based on columbium concentrates have been stable over the past decade. At yearend 1989, the published price for columbium oxide was \$7.64 per pound of oxide, the published price for regular-grade ferrocolumbium was \$6.58 per pound of contained columbium, the published price for high-purity ferrocolumbium was \$17.50 per pound of contained columbium, and the published price for nickel columbium was \$19.50 per pound of contained columbium.

Depletion Provisions.—U.S. columbium-producing companies are granted a depletion allowance of 22% for domestic production of columbium minerals and 14% on foreign production.

BACKGROUND— TANTALUM

Tantalum is a refractory metal that is ductile, easily fabricated, has a high melting point (2,996° C), is highly resistant to corrosion by acids, and is a good conductor of heat and electricity.

TABLE 18

^c Estimated.

It combines readily with other refractory metals such as tungsten and hafnium to form alloys having high-temperature strength and stability. Tantalum forms highly stable anodic films and exhibits a rectifying, or electronic valve, action in an electrolyte. Tantalum is twice as dense as steel with a specific gravity of 16.6.

Definitions, Grades, and Specifications

Metallic forms of tantalum are produced chiefly in unalloyed form or alloyed with up to about 10% tungsten. Unalloyed metal and alloys with tungsten are available as ingot, plate, sheet, strip, bar, rod, wire, and tubing, in accordance with ASTM Specifications B364, B365, and B521. Allowable impurity levels do not exceed 0.3% in most cases; the main impurities are columbium and oxygen, plus tungsten in the case of unalloyed tantalum. Purity of tantalum metal powder is usually about 99.9%. Depending on powder usage, impurities that must be controlled consist mainly of calcium, carbon, columbium, iron, nickel, nitrogen, oxygen, silicon, and sodium. Commercial tantalum carbide usually contains about 93% tantalum and about 6.3% carbon.

Products for Trade and Industry

The major end use for tantalum, as tantalum metal powder, is in the production of electronic components, mainly tantalum capacitors. Applications for tantalum capacitors include computers, communication systems, and instruments and controls for aircraft, missiles, ships, and weapon systems. The tantalum capacitor exhibits reliable performance and combines compactness and high efficiency with good shelflife. Because of its high melting point, good strength at elevated temperatures, and good corrosion resistance, tantalum is combined with cobalt, iron, and nickel to produce superalloys that are employed in aerospace structures and jet engine components. Tantalum carbide, used mostly in mixtures with carbides of such metals as columbium, titanium, and tungsten, is used in cemented-carbide cutting tools, wear-resistant parts, farm tools, and turning and boring tools. Because of its excellent corrosion resistant properties, tantalum mill and fabricated products

are used in the chemical industry in applications such as heat exchangers, evaporators, condensers, pumps, and liners for reactors and tanks.

Geology-Resources

The principal source of tantalum is an isomorphous series of minerals containing columbium, iron, manganese, and tantalum oxides. Tantalum and columbium have strong geochemical affinity and are found together in most rocks and minerals in which they occur. Tantalite-columbite occurs mainly as accessory minerals disseminated in granitic rocks or in pegmatites associated with granites. The microlite-pyroxene mineral series is also a source of tantalum. These minerals consist essentially of complex oxides of calcium, columbium, sodium, and tantalum in combination with hydroxyl ions and fluorides. Microlite occurs mainly in the albitized zones of granite pegmatites, often associated with tantalite or columbite. Struverite is a low-grade source of tantalum recoverable from tin mining wastes in Southeast Asia. Struverite is a variation of the titanium mineral rutile. Tantalum is also obtained through byproduct recovery from tantalum-bearing tin slags, principally from smelters in Brazil and Southeast Asia.

Reserve and reserve base data for tantalum are shown in table 19 and are

based on a judgmental appraisal of current information. Reserve base is defined as the in-place demonstrated (measured plus indicated) resource from which reserves are estimated. The reserve base may encompass those parts of the resources that have a reasonable potential for becoming economically available within planning horizons beyond those that assume proven technology and current economics. Reserves are defined as that part of the reserve base that could be economically extracted or produced at the time of determination.

Technology

Exploration.—Exploration for tantalum is generally pursued on the basis of its known frequent association with tin and certain other elements in pegmatite environments, some features of which can be distinguished by aerial photography. Application of X-ray fluorescence analysis techniques has been helpful in measuring tantalum at the low concentrations at which it occurs. The high specific gravity of tantalum minerals makes it possible to reveal their presence in placer deposits by test pitting and panning.

Mining.—Mining developments generally are small, relatively high-cost in-

termittent operations that depend on the recovery of byproduct or coproduct minerals for economic viability.

Both alluvial and residual tantalum and tantalum-containing tin deposits are normally mined by hand, by hydraulic monitors, by dredges, or by mechanized open pit mining. The mining of pegmatite deposits, which may be either open pit or underground, is carried out by blasting, transporting, and crushing the rock to free the tantalum and associated coproduct minerals. The materials are then concentrated by wet gravity methods (sluices, jigs, spirals, and tables) and finally separated from associated minerals by gravity and electrostatic and electromagnetic processes.

Tantalum is recovered from slags produced at tin smelters located throughout the world. Tantalum content varies in tin slag depending on ore and smelting practice.

Beneficiation.—Tantalum mineral concentrates and tin slags are the predominant feed materials for preparation of tantalum metal and compounds. Both raw materials usually contain recoverable amounts of columbium as well. Depending on circumstances, tin slags may be used directly for extraction of tantalum, or they may be first upgraded. Upgrading is typically performed by means of an electric furnace process that yields a synthetic concentrate.

In the extraction of tantalum from these source materials, technology makes use mainly of digestion with hydrofluoric acid followed by liquid-liquid extraction with MIBK. This procedure efficiently recovers both tantalum and columbium in the form of separate streams that then can be further processed individually into salts, oxides, and metal. The two streams are produced by a series of countercurrent extractions that also remove impurities. The tantalum product stream is a fluo-tantallic acid solution from which either potassium fluotantalate (K-salt), by addition of potassium chloride or fluoride, or tantalum pentoxide, by addition of ammonia, can be precipitated. Reducing K-salt by sodium is the standard commercial method for making tantalum metal. The product of sodium reduction is a powder that is consoli-

dated by a pressing, vacuum sintering, and melting sequence.

Tantalum carbide can be manufactured by several methods, the most common being solid-state reaction between tantalum oxide and carbon. Tantalum carbide can also be made by reacting metallic tantalum directly with carbon.

Recycling.—Recycling of tantalum largely takes place within the processing and producing industry and is mostly runaround or home scrap that is consumed internally. In addition, quantities of tantalum are recycled indirectly in the form of used tantalum-bearing cutting tools and high-temperature alloy melting scrap.

Economic Factors

Prices.—Time-price relationships for tantalum contained in concentrates in terms of actual prices and in constant 1982 dollars are shown in table 20. Actual prices reported are based on historical price quotations or best available information from producers. The prices show large swings between the high and low in response to market conditions, with recent year pronounced maximums occurring in 1980 and 1988. A 7-year trend of declining price, 1967–73, was followed by a trend of rapid price increase that was sustained through midyear 1980. The record price levels during this period were attributed in part to a state of panic buying influenced by anticipated greater tantalum demand, amidst concerns at the time of a shrinking world tantalum supply. The high prices brought about substitution for tantalum and more widespread search for and development of new tantalum sources. However, prices began declining by yearend 1980, and by midyear 1986, were the lowest since first quarter 1977, hastened by a weak tantalum

COPPER

By Janice L. W. Jolly and Daniel L. Edelstein

Mrs. Jolly is a physical scientist (geologist) with more than 30 years in the mining industry, including 16 years with the Bureau of Mines. She worked as a research geologist with the U.S. Geological Survey and Roan Consolidated Mines, Ltd., of Zambia and as a consultant on mineral affairs with the U.S. House of Representatives Armed Services Committee and the World Bank. Mrs. Jolly is currently the copper specialist for the Bureau of Mines, a position she has held since 1983.

Mr. Edelstein is a physical scientist (geologist) with more than 15 years of combined experience working for the Bureau of Mines in minerals processing research, process evaluation, and mineral commodities. He has been a copper commodity specialist for 7 years as well as the specialist for the copper byproduct metals, selenium and tellurium.

Domestic survey data were prepared by Stephen Hayes, Lisa Conley, and Lisa Christian, mineral data assistants, and Imogene Bynum, mineral data supervisor.

World production of copper from primary and secondary sources was higher than in 1988 and nearly in balance with the record 10.9 million metric tons of copper consumed. Copper consumption grew largely owing to increased consumption by the semifabricating plants of Asia and Europe. Copper demand by U.S. wire and brass mills remained at about the same level. Copper mine supply was constrained by disruptions in Africa, Canada, Mexico, and Papua New Guinea. Most of the production gains reflected continued expansions at mines in Chile and the United States. At yearend, visible refined inventories increased slightly to an estimated 634,000 tons, slightly less than 4 weeks of market economy countries (MEC) consumption.¹ The U.S. producers' delivered price averaged \$1.31 per pound, which offered considerable profits for most producers, who were benefiting from cost-cutting of the recent past.

With higher prices and funds available for investment, announcements of new projects and intentions to reopen older mines were commonplace. Exploration expenditures for copper were at the highest level in several decades, particularly in Canada, Chile, and the United States. Rationalization of the industry continued with mines and plants changing owners and companies adapting marketing strategies to the changing international flow of copper.

LEGISLATION AND GOVERNMENT PROGRAMS

Copper Study Group

During a negotiation session in Geneva, Switzerland, February 20-24, an agree-

ment was reached on the terms of reference for the formation of an International Copper Study Group. Formation of the study group had been initiated more than 2 years previously by the United States. According to the terms of reference, the organization could come into existence if a sufficient number of countries, accounting for at least 60% of world trade in copper, notified the United Nations Conference on Trade and Development of their intention to join the group by June 30, 1990. However, if the trade represented by those signifying their intent to join fell short of 60%, the interested countries could decide among themselves to inaugurate the study group anyway. The agreement also provided for 3-year temporary or provisional memberships, which allowed interested countries to join without making an initial long-term commitment.

State Legislation

Following months of debate, Nevada State Legislature approved the first mined lands reclamation laws in the State's history. Assembly Bill 958, passed on June 24, gave enforcement responsibility to the Nevada Div. of Environmental Protection and created several funding mechanisms to support administration of the program. One fund would pay the cost of administering the abandoned mines hazard abatement program, which would be the responsibility of the Nevada Department of Minerals. The bill required that the mining industry pay for all of the State's costs associated with administering and enforcing reclamation laws.²

The U.S. Supreme Court upheld a lower court ruling that found a 5% cap on royalties paid by companies in Arizona to

mine State trust lands deprives the State of its fair share of minerals value. The ruling was expected to result in Arizona passing new mineral leasing laws that would order higher royalty payments for minerals mined on nearly 10 million acres of land granted to the State by the Arizona Enabling Act of 1910.

Montana State Bill 410 was expected to end the longstanding differences of opinion between mining companies and the State Department of Revenue. The bill proposed to increase the gross proceeds and metal mines license tax. Instead of a sliding-scale based on gross value of metals produced, currently ranging from 0.5% to 1.5%, the tax would be raised to a flat 1.8% rate. Mines would no longer pay a separate fee into the Resource Indemnity Trust (RIT) Fund, but a portion of the flat fee would go into the RIT account. Instead of the General Fund getting two-thirds and the Hardrock Trust getting the remainder, the revenue would go 61.5% to the General Fund, 8% to the Hardrock Mining Impact Trust Account, 15.5% to RIT, and 15% to the area of production. The bill reportedly had broad industry support.³

Trade Legislation and Actions

In an official exchange of letters with the United States, the Commission of the European Community (EC) agreed not to propose renewal of quotas on the export of scrap and waste of copper and copper alloys. As a result, all quotas and systems of licensing associated with scrap exports expired on December 31, 1989. In return, the United States agreed to end a General Agreement on Trade and Tariff (GATT) grievance that had been filed in response to a November 1988 petition by the U.S.

⁶Estimated. ⁸Preliminary. ¹Revised. W Withheld to avoid disclosing company proprietary data.

¹Includes production from foreign ores and concentrates.

²Includes primary copper produced from foreign ores, matte, etc., to avoid disclosing company proprietary data.

³Includes copper content of alloy scrap. Export and 1989 import copper content of alloy scrap were estimated from gross weight.

⁴High-grade prior to 1988.

Copper and Brass Fabricators Council (CBFC). The CBFC charged that the EC scrap quotas were a violation of GATT and were having adverse impacts on domestic producers.

In response to an industry petition by the Non-Ferrous Metals Producers Committee, the U.S. Trade Representative, and the Department of Commerce in a joint decision, determined that both the primary cop-

per and lead industries should be identified under Section 409(b) of the 1988 U.S.-Canadian Free Trade Agreement Act of 1988. In the decision, it was found that these industries may face increased imports of subsidized copper and lead products from Canada once tariffs were lowered according to the Free Trade Agreement, and that deterioration of the competitive position could occur. Based on 409(b) iden-

tification, the industry could ask for assistance under the trade laws.

ISSUES

Mine and Plant Labor

Productivity at all mines that produced copper as a principal product was 19.6

worker-hours per ton of recoverable copper produced by open pit, underground, and leach methods. Average productivity, including mine, mill, and leach operations was 41 worker-hours per ton for five operating underground mines and 17.7 worker-hours per ton of recoverable copper for 15 open pit mines. Total workers at U.S. mines and mills averaged 12,400 in 1989. Arizona (8,514 workers) led in average number of mine and mill workers, followed by New Mexico (1,487 workers) and Utah (1,084 workers).

The number of union members in the U.S. nonferrous metals industry, including the copper industry, decreased in recent years. The ties of workers to unions were weakened by frequent mine closings, wage concessions, and effects of a poor economy over long periods of time. When mines were acquired by new owners, such as at the Sierrita Mine in Arizona and the Continental East Mine in Montana, new working systems were set up with the workers opting not to reinstate union rules. Job classifications at both mines were reduced from several hundred to fewer than 15, and workers were offered raises for learning multiple jobs. Small group seminars emphasized healthy working relationships, and at regular meetings, managers sought employee advice. At many mines, management layers were streamlined and managers became multidisciplinary, as did workers.⁴ At some mines, employees participated in profit-sharing plans, such as at Montana Resources Inc.'s Continental East Mine, where it amounted to 10% of pretax net profits. Otherwise, a unified salary rate of \$9.73 per hour (about \$20,000 per year) prevailed for the Continental East workers.

In May, workers at the Troy Mine, MT, voted not to accept the United Mine Workers of America (UMWA) as their collective bargaining agent. The UMWA won certification in 1987, but efforts to negotiate a contract with ASARCO Incorporated failed. Late in 1988, an employee group mounted a petition calling for a new election and Asarco withdrew its recognition of the union and stopped contract talks. The National Labor Relations Board ruled against UMWA charges that Asarco unlawfully withdrew union recognition.

Labor contracts with Magma Copper Co. and Asarco were set to expire July 1, 1989, but both were replaced with new agreements that increased base wages and various benefit plans. Asarco and the United Steel Workers union settled on a new 3-year contract covering 1,600 em-

ployees that included wage increases of \$1.85 per hour over 3 years; an increase in pension payments of \$4.00 per month for each year of service; and additional death and dismemberment insurance. Although the wages were slightly higher than before the pay was slashed in 1986, the cost-of-living clause in the contract remained suspended. Magma agreed to increase the weighted average base wage for 3,100 hourly employees by \$1.00 per hour in the first year and 25 cents in the second and third years. A premium of 0.6% was to be added to base wages as copper prices varied in 5 cent increments above 95 cents per pound, capping at \$1.70 per pound.

Although statistics show that many metal companies were tying employee wages to incentive bonuses as a means of rewarding higher production when profits were high and limiting costs during slow periods, some copper producers reportedly seemed to be reluctant to institute such plans.⁵ It was estimated that 75% of all gain-sharing plans in the U.S. mining industry had been installed in the past 5 years. A variety of factors was used to calculate bonuses. Production was most often used in determining bonus size, but safety, ore grade, development advance, cost savings, profits, commodity price, and housekeeping were also used. Penalties were commonly included to encourage safety. Magma arranged to give its employees bonuses linked to copper prices and established production targets; even so, the company eventually found this plan placed Magma in the position of being among the highest cost of U.S. producers.

Magma and labor unions attempted to resolve disputes concerning interpretation of the bonus rules that were part of the 1986 contract. In 1986, the unions had accepted large cuts in wages and benefits in exchange for certain productivity-based bonuses. Although Magma insisted that the production requirement only related to production arising from Magma's own operation, the union contended that ore processed by Magma for Cyprus Minerals Co. should have been included in the calculations for fulfilling production quotas. The bonuses were linked to the copper price and meeting 80% of Magma's production quotas. Magma announced that it would not pay fourth quarter 1988 and second quarter 1989 bonuses to its unionized workers because production and sales quotas under the plan were not met. An independent arbitrator ruled in favor of the company and determined that no bonus was due for the

fourth quarter of 1988; arbitration of the 1989 bonus had not been settled.

Bonuses averaging \$1,500 per person were paid in December 1989 to about 680 hourly employees at Cyprus Miami Mining Corp.'s copper operations. The bonuses were about equal to those paid in May 1989. The December bonuses were in recognition of achieving a record-breaking year in 1989. Cyprus Minerals announced that as of January 1, 1990, Cyprus Miami employees with at least 20 years of service would receive an additional week of vacation. Cyprus Miami had a total of about 1,020 workers.⁶

Cost of Production

The weighted-average cash cost, including byproduct credits and taxes but excluding depreciation, of producing refined copper in the United States was estimated to have increased slightly to about 54 cents per pound in 1989, according to Bureau of Mines Minerals Availability System estimates. Including recovery of capital, the average production cost was 60 cents per pound.

Asarco reported that the cost to produce copper was higher in 1989 compared with that of 1988.⁷ Startup difficulties with its new milling and concentrating facilities at the Mission complex in Arizona resulted in reduced production and higher costs. Production rates at the Hayden, AZ, smelter also did not meet expectations, thereby increasing costs.

Cyprus Minerals reported that inflation, especially in mining and processing costs, and increased costs and taxes resulting from Federal and State legislation and regulation, were making cost reduction more difficult.⁸ The company planned major capital investments for plant and equipment modernization in 1990 to increase operation efficiency. Cyprus' mine production costs, including depreciation, averaged 68 cents per pound for the year, compared with 65 cents in 1988, according to the company annual report. The increase in 1989 was caused partly by price sensitive costs, such as employee incentive compensation plans and service costs associated with acquisitions, and partly by Cyprus' efforts to maximize production during the year. Average mine production costs reached a high of 76 cents per pound during the fourth quarter as a result of reduced recoveries at Twin Buttes Mine. Milling difficulties resulted from blending ores from four pits. Not only did the mill

recovery fall and costs rise, but more importantly, they were not able to produce copper for sale when prices were high. Recoveries at Miami were reduced because of mining in an area that contained a lower grade of oxide ore.

Cyprus Minerals also faced increased electricity costs at two of its operations. In a hearing held by the Arizona Corporation Commission, Cyprus Sierrita protested the full rate increase that Tucson Electric Power was seeking. The rate increase would cost the company an additional \$7 million per year. It took 19 kilowatt hours of electricity to grind 1 ton of ore, and the mine processed about 30 million tons of ore annually. In addition, Cyprus Miami faced increased electricity charges from the Salt River Project with which the company had a long-term contract. The Salt River Project board voted in July to increase Cyprus Miami's fuel cost adjustment factor, causing it to increase by \$285,000 per month. The fuel cost adjustment factor rose or fell with the price of fuel. The electrical contract was negotiated before Inspiration built the electric furnace at its smelter to comply with air quality standards.⁹

At Magma, costs were above budget as a result of mining lower grade ore to take advantage of the higher copper prices and an expanded development program. The company restarted limited development of the Kalamazoo ("K") ore body, which would extend the life of the mine, increase extraction tonnage, and improve overall mining costs. The new column cell technology used at the San Manuel concentrator proved cost effective, reducing energy and maintenance costs by 9.5% over the year. Cost efficiency was further improved through complete reinstrumentation of the concentrator for better process control.¹⁰

Phelps Dodge Corp. completed a \$48 million in-pit crushing and conveying project at Morenci, AZ, which significantly reduced haulage costs in the pit. Expansions to the Morenci (\$44 million) and Tyrone (\$20.5 million) solvent-extraction and electrowinning (SX-EW) plants were also completed during the year. Costs at these plants were reported to be less than 30 cents per pound of copper. The corporation's average production costs for copper in 1989 were reported to be marginally higher than those of 1988 largely because

of increased supply costs, total material mined, depreciation, and costs that derived principally from increased capital expenditures.¹¹

At the White Pine Mine, MI, gains in efficiency were achieved through a 29% reduction in the work force over that of 1981 levels. As productivity increased, production costs dropped from a 2-year average in the early 1980's of 99 cents per pound, to 62 cents per pound mined and processed, before silver byproduct credits. Meanwhile, the ore grade dropped from 1.46% in 1979 to about 1.1% in 1989. Company efforts focused on modernizing equipment and mining methods. Over the next few years, about \$5 million per year was to be provided annually for new underground equipment. New cost targets were set at or below 60 cents per pound.

Industry Restructuring, Investments, and Earnings

U.S. copper mining companies continued to report record profits during the year. Ownership changes and company restructuring continued. With more money

available, interests shifted toward reinvestment, expansion, opening of closed mines, and renewed exploration efforts. Phelps Dodge, the largest producer, reported a net income of \$267 million, including a write-down in the fourth quarter of certain non-producing assets. The assessed valuation of operating copper mines in Arizona reportedly increased 43% compared with 1988, to more than \$860 million.¹²

Asarco reported an operating income of \$206 million from the sales of copper. Over the past 4 years, Asarco concentrated on acquisition and ore reserve development to shift from being a custom smelter and refiner for others to being a fully integrated producer. In 1989, the company announced a \$270 million project to expand production at Mission and Ray Mines by 40%

with financing to come from company funds. Asarco acquired a 49.9% interest in Montana Resources Inc., a partnership that owned and operated the Continental East Mine in Montana, for \$100 million and purchased the Pima, AZ, mill for about \$6 million. Asarco also acquired a significant share in Mexicana de Cobre S.A. through its 34% share of Mexico Desarrollo Industrial Minero S.A. de C.V. (MEDIMSA). MEDIMSA acquired Mexicana de Cobre for \$1.36 billion.

In May, Metall Mining Corp. of Toronto purchased the Copper Range Co. for \$83 million. Each of the 1,000 workers received about \$65,000 for their shares in the company. In addition, each employee will gain an additional \$18 per share if the mine meets the 5-year production and efficiency

goals set by Metall. It was announced that the Copper Range name, which originated in 1899, would be retained to preserve the historical significance of the company. Copper Range became the first wholly owned mining operation of Metall, which also held minority interests in several Canadian and Papua New Guinea operations. Metall Mining's parent company, Metallgesellschaft AG, based in the Federal Republic of Germany, retained a 62% interest in the Toronto company.

Cyprus Mineral's record earnings of \$250 million after taxes was more than the combined earnings of the past 3 years, largely as a result of increased copper production and higher prices. Since the July 1985 spinoff from Amoco Minerals Co., Cyprus had made more than 20 acquisi-

tions, including coal, copper, lithium, molybdenum, talc, and silver mines. Early in 1989, Cyprus acquired the Warren-ton Refining Co., a Missouri producer of copper ingot and wirebar from scrap. By yearend, Cyprus had made arrangements to purchase MCR Product Co.'s copper rod mill in Chicago, IL.

Rio Tinto Zinc (RTZ) Corp. completed its acquisition of British Petroleum PLC's (BP) minerals group for \$3.6 billion on June 30, 1989. The name Kennecott Corp. was restored as the official title of the properties. The primary asset of Kennecott was its Utah Copper Corp. Bingham Canyon Copper mine, smelter, and refinery in Utah. In 1989, Kennecott's expenditures were \$200 million, of which \$76 million was spent at Utah Copper. Plans for a second \$227 million construction project at Bingham Canyon were announced. Construction was to begin in June 1990, with completion scheduled for the last half of 1992.

Magma had a record net income of \$58.5 million. Earnings were stronger because of lower labor costs and higher copper prices. Magma's earnings included a \$3.5 million pretax write-down of assets in the fourth quarter, related to the closure of the company's MCR Products' rod casting facility in Chicago, IL. A change in sales strategy toward increased cathode sales resulted in just 53% of Magma's 1989 production being sold as rod, compared with 93% in 1988. Of equal importance was the change in arrangements for procuring smelter feedstock, which now would include increased toll and purchased concentrates. The company was restructured into four operating divisions: the San Manuel Mining Div., Pinto Valley Mining Div., Superior Mining Div., and the Smelting and Refining Div.

Plexus Resource Corp., in a property exchange with Cyprus Minerals acquired the rights to the Bornite Project, a copper-gold-silver property about 45 miles east of Salem, OR. Cyprus acquired the rights to develop the Lyon property in Nevada, as well as a 2% share of the net proceeds from Bornite. Rio Gold Mining Ltd., a Canadian company, acquired the Hillsboro-Copper Flat Mine in New Mexico from Inspiration Development Co., the owner, and from Cobb Resources Inc., the lessee.

Mine Environmental Issues

Several sites in Montana continued to be the focus of environmental concern during the year. The Montana Water Quality

Bureau received a report about high concentrations of metals in water from seepage at a tailings impoundment site at Asarco's mine near Troy. A local environmental group reported an average of 0.0036% copper in water at several sites.¹³ Atlantic Richfield Co. (ARCO) filed a motion in the U.S. District Court protesting the limitless cost responsibility for cleaning mine and smelter wastes located between Butte and Milltown Dam, just east of Missoula. ARCO wanted the court to dismiss a Federal lawsuit filed last June by the Environmental Protection Agency (EPA) to recover \$6.3 million spent replacing the arsenic-polluted water supply at Milltown, relocating families at Mill Creek, and demolishing the Anaconda Smelter. ARCO reportedly had spent about \$20 million in reclamation costs in Montana, mostly in the Butte area. The 6-year, \$25 million cleanup of the site, which stretched from Silver Bow Creek in Butte to Milltown Reservoir near Missoula, was considered to be the country's largest and among the most controversial of the Superfund cleanup efforts.

Late in the year, Cyprus protested the proposed inclusion of two tracts, the Upper and Lower Burro Creek, into the Arizona wilderness system. Withdrawal of these two areas from development would have a significant impact on its \$24 million expansion project and drastically reduce the Bagdad Mine's projected 30-year life. The New Mexico State Environmental Improvement Div. approved the Cyprus plan, estimated to cost \$1 million, for revamping and reopening the Deming concentrator. Originally built as a custom concentrator for small regional mines, the plant also treated lead-zinc ores from the old Groundhog Mine. The plant was to be used for processing Pinos Altos ores.¹⁴ According to the company annual report, Cyprus spent more than \$28 million on environmental protection measures in 1989.

The U.S. Forest Service awarded a \$3.1 million contract to a Port Angeles, WA, firm for cleanup of 8 million tons of tailings at Holden, WA. The tailings covered a large part of the valley near Holden Village, about 12 miles above Lake Chelan. The Holden Mine, the only major copper producer in Washington at the time, closed in late 1956 because of poor markets.

Smelter Environmental Issues

According to the company annual report, Asarco received notice from EPA that it

and numerous other parties were responsible, under CERCLA, for correction of hazardous substance releases at the following locations on the dates indicated: The Commencement Bay area in Tacoma, WA (1982); Pitcher Mining Field in Oklahoma (1982); YAK drainage tunnel in Leadville, CO (1983); the Tacoma Smelter site (1984); southeastern Cherokee Co. in Kansas (1985); the East Helena Smelter (1987); and the Ruston, WA, area (1988). In 1987, part of an Asarco subsidiary's (Federated Metals Co.) former scrap processing plant in Houston was listed on the Texas Superfund Registry. Asarco was also involved in litigation under CERCLA and State law involving alleged hazardous substance releases at the company's former Perth Amboy, NJ, smelter site and at its Globe Plant in Denver, CO. Asarco had established financial reserves for these programs, spending \$13.4 million in 1989, \$13.7 million in 1988, and \$19.2 million in 1987 on environmental compliance. Asarco had spent more than \$12 million to clean up the Tacoma, WA, smelter since it closed in 1985. The demolition of the 565-foot-tall stack was expected to cost about \$3 million. Because of the contaminants, EPA had declared the smelter site a Federal Superfund Site for cleanup, one of 36 in the Pacific Northwest.

PRODUCTION

Mine Production and Reserves

Copper was mined in 13 States during 1989, with Arizona maintaining its lead with 60% of the total, followed by New Mexico and Utah. There were 68 copper-producing mines, up from 65 mines in 1988. Of these, 22 were copper mines, and 46 were mines from which copper was produced as a byproduct or coproduct of gold, lead, silver, or zinc. Total U.S. operating mine capacity, in terms of recoverable copper per year, was estimated to be 1.79 million tons in 1989, compared with 1.62 million tons in 1988. The increase was largely the result of improvements at operating mines, although some new mines were brought on-stream during the year. Annual SX-EW capacity was expanded by about 50,000 tons to 358,000 tons and by 1992 was expected to reach 434,000 tons. Some companies' reserves were reevaluated in light of higher copper prices, and the mill-head grade decreased at some mines as lower graded ore became economic to mine.

As a result of sustained higher copper prices, interest was being shown in reopening several long-closed U.S. copper mines. Among those planned for production were the Centennial No. 6 Mine near Kearsarge, MI; the Continental and Copper Flat Mines in New Mexico; an SX-EW project at the Yerrington Mine in Nevada; several small mines near Butte, MT; and the Superior Mine, the Oracle Ridge copper-silver property, the Johnson Camp Mine, and the Emerald Isle Project, all in Arizona. A tentative agreement was reached for the restart of the Arbiter electrowinning plant in Montana. Anaconda Enviro-Refining Co. planned to convert copper and other metal concentrates into finished metals at the Arbiter plant.

Cyprus signed a letter of intent with Sharon Steel Corp. in August to consider a joint venture at the Continental Mine in New Mexico after it had completed evaluating the geology, assets, and accounts. Production would be limited to the open pit mine at first, which had a 4,500-ton-per-day concentrator. The underground mine and its 2,700-ton-per-day concentrator would not be operated. In addition, the nearby Hanover Mountain deposit was reported to have reserves of 9 million tons of mixed oxide and sulfide mineralization that averaged 0.63% copper. Portions of this property reportedly could be used for leaching and SX-EW recovery.¹⁵

Magma approved a plan for the rehabilitation of the Superior Mine, AZ, which closed in 1982 because of low copper prices. Expenditures for this project were expected to be \$12 million, with production at the rate of 12,700 tons per year scheduled for late 1990. The mine life was estimated to be about 8 years. The mine was about 1 mile deep and had been flooded to about 3,000 feet. In addition, two promising vein structures to the south of the present workings were being explored. The new project would require a new shaft and concentrator. In 1989, Magma resumed development of a small part of the Kalamazoo ore body, which had been suspended during the fourth quarter of 1988. The company planned to mine at the 2,950-foot level using high-performance work teams for cost reduction. Ore production from this section of the mine was expected to begin in the third quarter of 1990.

Rio Gold Mining Ltd., a new company from British Columbia with headquarters in Denver, CO, announced intention of reopening the Copper Flat Mine, NM, which closed in 1982; and the mill was

dismantled and sold. Once financing of the \$37 million project was secured, the mine was expected to be commissioned within 1 year. Production was expected to be about 18,000 tons of copper, 12,000 ounces of gold, 300,000 ounces of silver, and 386 tons of molybdenum per year. At a cutoff grade of 0.25% copper, a minable reserve of 48 million tons averaging 0.45% copper was reported.

An \$8 million loan with Chemical Bank of New York was approved for Michcan to reopen the Centennial No. 6 Mine in Michigan. Michcan, a group of investors that included Peninsula Copper Industries (PCI) of Hubbell, MI, also received a \$350,000 loan to assist in dewatering the 5,000-foot mine shaft. PCI produced copper oxide, which was used in wood preservatives and automobile safety airbag propellants. The 4,000 tons per year production from the Centennial Mine would be used for copper oxide production. Copper oxide production was to be expanded from 8 to 11.5 million pounds annually. PCI held 29.5% of Michcan, with American Chemet Inc. and a New York investment group holding the rest.

In addition to reopening older mines, increased interest also was shown in exploration for and development of new projects. Exploration expenditures were increased by Phelps Dodge, which reported spending \$50 million on exploration, advanced mine evaluations, research, and development. Nearly 80% of the 1989 exploration expenditures were in the United States with emphasis on copper, mixed base metal sulfides, and precious metals. In addition to its acquisitions program, Cyprus also expanded its exploration efforts in 1989 to include copper with funds increased to \$15.2 million, up \$7 million over that of 1987. Exploration efforts were conducted in Australia, Canada, Chile, Mexico, New Zealand, and the United States. Cyprus Northshore Mining Corp. was exploring the former Minnamax copper-nickel property adjacent to its Babbitt taconite mine. The property was partially developed in the 1970's by Amax Inc. with shaft sinking and underground work.

Chevron Minerals Co. was reported to have sold the Bald Mountain Mine in Maine to Boliden International Mining. Ore reserves at Bald Mountain were sufficient to support a 15-year mining operation. Two mining companies, Crown Butte Mines Inc. and Noranda Minerals Corp. reportedly were considering the development of a copper and gold mine located 2 miles north of Yellowstone Park. Sunshine

Mining and Noranda sought \$150 million to further finance exploration and development of the Montanore, MT, property, which was expected to be in production by 1992. Western World Mining Co. had petitioned the planning commission of Yuba County, CA, for a permit to operate a copper mine in Big Oak Valley. Mine plans called for the open pit removal of 1.4 million tons of copper-zinc ore, averaging 2% copper, over a 6-year period. However, local public opposition prevented the permit from being granted. The project had been started in 1971 by Superior Oil Co. Plexus Resource Corp. planned to expedite development of the Bornite Project, OR. The deposit was estimated to contain 2.54 million tons of ore grading 2.49% copper in a bornite-rich breccia pipe, extending to a depth of 800 feet.

RTZ indicated that development of Kennecott's North Ore Shoot Extension in Utah could begin in 1990. The deposit contained a minable reserve of 11.2 million tons of ore grading 2.9% copper within a resource of 118.5 million tons of ore. Production at the annual rate of 25,000 tons of copper and 31,000 ounces of gold could begin as early as 1993. The company's Flambeau deposit in Wisconsin was scheduled to commence production in 1992.

Expansions at established operating mines also continued during the year. Asarco announced a 3-year expansion program to improve its mining, milling, and smelting capacity. At the Ray Mine, about \$130 million would be spent to install an in-pit crusher and new mill and concentrator. An 18-mile pipeline was to be built to pump slurry from the new mill to tailings ponds. Asarco estimated that output at Ray would be boosted by about 20,000 tons of ore per day. The entire plan would boost Ray Mine output by 37,000 tons of copper per year. The Pima mill and concentrator would be reopened and refurbished for about \$94 million.

Cyprus reported total copper production of about 270,000 tons in 1989.¹⁶ With a \$21 million expansion at the Bagdad Mine, the company production target was 295,000 tons in 1990. Bagdad was to be expanded by 10% to 104,000 tons of copper in concentrate per year by adding a fifth grinding line. Cyprus' ore reserves (table 4) were based on a long-term copper price projection of 75 cents per pound and reevaluation of Bagdad ores. This was offset in part by the reclassification of Twin Butte's reserves from copper to copper-molybdenum reserves, according to the company annual report.

^aAdditional reserves in and around shaft pillars and in lowest mine levels, not included in stated mine plan in 1989. Active reserves based on 70 cents per pound. Pinto Valley undeveloped reserves are peripheral to the current reserves and in the mine plan for beyond 2006 when current reserves are depleted.

Copper Range expected to spend about \$30 million on larger scale replacement equipment that would boost the copper production to about 60,000 tons per year over the next 3 to 4 years. In addition to improvements underground, the mill was to be expanded.

Kennecott redefined the Bingham Canyon reserves to incorporate lower grade material and announced plans to increase production by about 32,000 tons of ore per day. The new project included an expansion of the coarse ore stockpile facility, addition of a fourth grinding line, a new flotation circuit with 21 3,000-cubic-foot flotation cells, expansion of the molybdenum plant at the Copperton concentrator, and installation of a fourth filter press at the smelter. As a result, mill capacity would increase from 70,000 tons to 102,000 tons of ore per day, in addition to the ore that continued to be processed through the older Bonneville and Magna concentrators. Total copper production would be about 245,000 tons per year.

Magma completed its expansion of Pinto Valley Division's Miami Unit SX-EW plant. Production began during the year from the tailings leach project associated with the plant expansion. According to the company annual report, Pinto Valley's total production included 260,000 tons of concentrate and 9,500 tons of electrowon copper cathode.

New Butte Mining PLC conducted limited underground mining near the Missoula Horsetails, which were relatively

untouched parts of the heavily mined main Lexington vein in Butte, MT. New Butte was operating under a small-miners exclusion that permitted only a limited (about 32,600 tons) amount of ore to be mined each year. Once the Montana Department of State Lands approved its mining permit, the company planned to expand production. After the Missoula Horsetails and Chief Joseph vein systems, the Gray Rock area was to be the next production site.

In 1989, Phelps Dodge invested \$217.4 million in copper mining expansion and improvement projects. About \$112 million was allocated to the expansion of the Morenci, AZ, SX-EW operations. New capacity of 63,500 tons per year was to come on-stream in mid-1991. The expansion also involved development of the Northwest Extension adjacent to the Morenci Mine. A \$48 million, in-pit crushing and conveying project was completed during the year. According to the company annual report, Phelps Dodge had a record production of 534,967 tons of copper from its Morenci, AZ, and Chino and Tyrone, NM, operations, including 106,322 tons from electrowinning.

Smelter Production

Total U.S. smelting capacity was 1.8 million tons, a slight increase compared with 1988. Cyprus Lakeshore, AZ, roaster was included. At Lakeshore, concentrates

from other mines were roasted before treatment in a vat-leach, SX-EW system. Nine primary plants, including the Lakeshore roast-leach plant, operated during the year with a total capacity of 1.35 million tons of copper. Five secondary smelters operated with a combined capacity of 416,000 tons of copper anode.

Asarco announced plans to retrofit its El Paso reverberatory furnaces with Contop flash smelting units at a cost of \$30 million. The retrofit was expected to improve sulfur capture, improve quality of sulfuric acid recovered, and reduce production costs by about 17%. At its Hayden, AZ, plant, Asarco installed a new electric slag cleaning furnace in the third quarter.

A flashback at Cyprus' Miami, AZ, smelter occurred in September, closing the smelter for 2 weeks and injuring one worker. Cyprus settled a concentrate contract dispute with Magma and entered into a new smelting and refining agreement. The Magma smelter, Cyprus' Miami smelter, and the Casa Grande roast-leach plant were anticipated to meet Cyprus' current smelting needs. In 1989, Cyprus sold 78,000 tons of concentrates overseas, according to the company annual report. Copper concentrates from Cyprus' newly refurbished Deming mill were to go to the Asarco El Paso smelter for toll smelting. Sales of siliceous flux products from the Pinos Altos Mine to copper smelters in the region would not continue because the flux ore body at Pinos Altos was depleted during the year.¹⁷

According to the company annual report, Magma's smelter treated 853,000 tons of concentrate. In 1989, Magma significantly increased the amount of purchased concentrates. The smelter was able to achieve its installed capacity of about 1 million tons of concentrate per year. In addition to the new Cyprus concentrate contract of about 272,000 tons per year, Magma also secured a 140,000-ton-per-year, multiyear concentrate purchase contract with Compania Minera de Cananea S.A. of Mexico.¹⁸

Texas Copper Corp., a consortium of Mitsubishi Metal Corp. (51%) and four other Japanese companies, announced that the design capacity of its intended Texas City smelter would be 182,000 tons per year of copper. The smelter was expected to operate on a toll basis with each shareholder providing concentrates according to their percentage of ownership. The majority of concentrates was expected to come from South America. About 12,000 tons of total copper production was expected to be from scrap. The proximity to the Florida sulfuric acid market and ease of concentrates transport were important factors in selecting a gulf coast location. Construction of the \$200 million smelter could begin in 1991, depending on the progress of environmental permitting.

Refinery Production

Ten electrolytic, six fire refineries, and twelve SX-EW plants were operating at yearend. Increased refinery production resulted from the continued expansion at electrowinning plants, startup of the Lakeshore roast-leach process, and electrolytic refinery expansion at Magma and Kennecott facilities. Two secondary plants also expanded capacity during the year. Total U.S. refinery capacity at primary and secondary plants was 2.42 million tons, up by nearly 10% over that of 1988. Of the total, 636,000 tons of capacity was at secondary electrolytic and fire-refining plants.

At the end of October, the American Telephone and Telegraph Co. (AT&T) announced that its Nassau Metals Corp. operations, including its electrolytic copper refinery and wirerod plant, were for sale. Nassau's facility, one of the largest secondary copper processing plants in the United States, was constructed in 1978 and provided Western Electric with between 40% and 45% of its copper.

According to the company annual report, Magma had a record electrolytic cathode production of 243,000 tons, including

66,200 tons refined for others. Production from the company's SX-EW plants accounted for 22% of refined cathode produced, with the San Manuel Div. producing 77.4% of the SX-EW production. Magma operated three SX-EW plants with the following capacities: San Manuel oxide plant, 68,000 tons per year; Pinto Valley waste leach, 7,260 tons per year; and the Miami in situ leach plant, 9,000 tons per year. Four new sections were added to the San Manuel electrolytic refinery during the year that will enable the plant to produce more than 272,000 tons of cathode per year.

Magma announced the closure of its MCR Products Co. (Chicago) rod mill as of January 1, 1990. The move reflected basic changes in Magma's marketing plans. Magma was to continue to supply rod from its San Manuel rod plant, which had a capacity of 164,000 tons of rod per year. MCR had a capacity of 127,000 tons per year of rod.

This was the first full year of operation for Phelps Dodge's 40,000-ton-per year SX-EW plant at the Chino Mine, NM. In December, a 100% expansion of the Morenci, AZ, SX-EW plant was completed, raising the capacity to about 91,000 tons of cathode per year. The company's Tyrone plant had a capacity of 50,000 tons per year. The company was anticipating SX-EW production to comprise about 50% of its total production over the long run. Phelps Dodge reported that it was the world's largest producer of copper rod. Its U.S. facilities, located at Norwich, CT, and El Paso, TX, were capable of producing about 380,000 tons per year of rod. The El Paso refinery also initiated a \$9 million modernization program that was to improve production costs.

Copper Sulfate Production

Copper sulfate was produced from copper scrap, blister copper, copper precipi-

tates, electrolytic refinery solutions, and spent electroplating solutions. U.S. production of copper sulfate was a little lower than in 1988, while imports increased significantly. In October, Kocide Chemical Corp. discontinued production of copper precipitates from in situ leaching at the Van Dyke property, AZ. Closure reportedly was the result of technical problems, including a buildup of soluble iron and diminished flow rates. Precipitates had been used for production of copper sulfate at the company's Casa Grande Plant. Data supplied by domestic producers for 1989 indicated that 64% of their shipments were for agricultural uses, 24% for industrial uses such as wood preservatives, and 12% for water treatment. In agriculture, copper sulfate was used principally as a fungicide for treatment of citrus and vegetable crops.

Copper Powder Production

Copper powder production and consumption were at about the same level as in 1988, which was about one-half that of 1979. Copper powder consumption was highly dependent on the automobile industry, which comprised the largest single end-use market. Copper powder used to manufacture self-lubricating bearings accounted for about 70% of the granular powder used. Pure copper powder was also used in the electrical and electronic industries. Copper flakes were used for antifouling paints, decorative and protective coatings, and printing inks. Nonstructural applications included brazing, cold-soldering, mechanical planting, metals and medallions, metal-plastic decorative products such as floor tile and epoxy resins, and various chemical and medical applications. American Metal Market commercial-grade copper powder prices ranged from \$1.64 to \$1.80 per pound, reflecting the higher refined copper prices.

TABLE 5

COPPER SULFATE PRODUCERS IN THE UNITED STATES IN 1989

Company	Plant location
CP Chemicals Inc.	Sewaren, NJ, and Sumpter, SC.
Kocide Chemical Corp.	Casa Grande, AZ.
Madison Industries Inc.	Old Bridge, NJ.
Phelps Dodge Corp.	El Paso, TX.
Southern California Chemical Co.	Santa Fe Springs, CA, Union, IL, Garland, TX.
Tennessee Chemical Co.	Copperhill, TN.

Granular copper powder can be produced by a number of methods, including atomization, electrolysis, hydrometallurgy, and solid-state reduction.

Sulfuric Acid Production

Sulfuric acid was produced as a byproduct of copper smelting. Seven copper smelters produced a total of 3.1 million tons of sulfuric acid; in addition, some sulfuric acid was produced at Cyprus' Lakeshore concentrate roaster. Copper Range does not produce sulfuric acid at its smelter. According to the company annual report, Magma's new smelter produced 744,250 tons of sulfuric acid and was largely responsible for the significant increase in acid production over that of 1988. About 280,000 tons was used in Magma's leach operations and 464,000 tons was sold. Magma reported that the smelter captures greater than 97% of the input sulfur.

CONSUMPTION

U.S. apparent and reported demand for copper, which trended upward since 1983, were essentially unchanged in 1989. However, the trend for an increasing domestic self-sufficiency for copper continued. Domestic production of primary refined copper and copper recovered from old scrap accounted for about 93% of domestic demand. Imports of brass mill products, as reported by the CBFC, declined by 7%.

Refined copper or directly melted scrap was consumed at about 20 wire-rod mills, 40 brass mills, and more than 1,000 foundries, chemical plants, and miscellaneous manufacturers. According to Bureau of Mines estimates, 72% of the copper, as a percentage of apparent consumption, was consumed in electrical applications; 15% in construction; 6% in machinery; 3% each in transportation and miscellaneous uses; and 1% in ordnance. Copper used in electrical wiring and devices in all end uses, except ordnance, was included under electrical applications.

Although demand for unwrought copper (refined plus direct-melt scrap) was stagnant, demand for copper semifabricates declined. According to Copper Development Association estimates, mill shipments to domestic markets declined by about 3%. Much of the decline in total shipments was accounted for by a decline in imports of brass mill products. Shipments to the

building construction, industrial machinery and equipment, and transportation equipment sectors declined by about 2%, 6%, and 7%, respectively. According to Copper Development Association, building construction was the largest end use sector, accounting for 41% of shipments, followed by electrical and electronic products, 24%; industrial machinery and equipment, 13.5%; transportation equipment, 11.5%; and consumer and general products, 10%.

While demand in most industry sectors was weak, the brass tubing market was undergoing restructuring, and several new plants were announced. Water tubing demand was negatively impacted by the housing slump, but demand for thin-walled and inner-grooved copper tubing used in air-conditioning and refrigeration was strong and supply was tight. At least two major domestic air-conditioning manufacturers who switched to aluminum reversed their position and returned to copper tubing. A decline in imported air-conditioning units and a decline in imported tube boosted demand for domestically produced air-conditioning tube. Domestic mills announced a series of expansions to boost their production of air-conditioning and refrigeration tube. Kobe Copper Products Inc. announced plans to boost air-conditioning and refrigeration tube capacity from 400 tons per month to 1,000 tons per month at its Pine Hall, NC, plant. The plant, adjacent to Halstead Industries' tube mill, was a joint venture among Kobe Steel, Halstead, and three other Japanese companies. American Brass increased capacity at its Franklin, KY, plant to 30,000 tons per year, and Wolverine Tube was constructing a new redraw mill at Booneville, MO. Cerro Copper Products, which completed a second expansion of its redraw capacity in Selbina, MO, announced plans to build a new fully integrated tube plant.

Several other expansions or new plants were announced during the year. PMX Industries, a subsidiary of Poongsan Corp. of the Republic of Korea, announced plans to open an 80,000-ton-per-year sheet mill in Cedar Rapids, IA. Some of the plant equipment was to be purchased from Canada's Arrowhead Metals, which closed its brass mill during the year. Other announced plant expansions included Plume and Atwood's Connecticut mill and MRM Industries, who relocated expanded facilities from Connecticut to Sikeston, MO. North Coast Brass and Copper, formerly Chase Brass and Copper Co.,

announced its intent to close its 60,000-ton-per-year sheet mill in Ohio.

PRICES

The average annual price for copper was at a record-high level in 1989. Industry stocks remained near the low level established during the second half of 1988. At the prevailing rates of consumption, stocks represented only about an 18-day supply. With stocks at such a low level by historical measure, prices were volatile and sensitive to real or perceived changes in supply availability. The Commodity Exchange of New York (COMEX) spot price fell by almost 10 cents per pound over a 2-day period in March. The decline coincided with economic indicators showing a potential softness in the market, a rise in exchange stocks, and cancellation of a planned 3-day strike in Peru. On average, prices declined throughout the first 7 months of the year, having reached record levels in December 1988.

Copper prices rose during the third quarter. The COMEX spot price peaked at \$1.42 per pound in mid-September. The price rise coincided with strong industry demand, a decline in COMEX stocks, and the announcement of an additional production setback in Chile. To insure an orderly expiration of its September copper contracts, COMEX raised its margin requirement for all September contracts to 100% of their value. A slight increase in refined copper inventories, uncertainties about sustaining the strong demand for copper, and the prospect for increased primary production in 1990 contributed to a fourth quarter decline in prices. Yearend prices were at the lowest point of the year.

December 27 was the last trading day for the standard-grade copper contract on the COMEX. Beginning January 1990, only the high-grade contract, first introduced in July 1988, was traded. COMEX delisted the remaining inventory of standard-grade copper, causing reported stocks between the end of December and the beginning of January to decline by 7,000 tons. Standard-grade stocks were expected to be withdrawn from warehouses by contract holders during the first half of 1990. Prices on COMEX remained in backwardation during most of the year with forward contracts trading at a discount to spot purchases. A normal or contango market, where forward contracts sell at a premium

to spot purchases, briefly returned in July and August for 3-month forward contracts. Copper prices were at the low point for the year. However, 12-month forward contracts remained in backwardation throughout the year. The market backwardation was attributed to industry expectation that new primary copper production would lead to supply surplus and lower prices.

Producer prices for refined copper closely tracked that of COMEX prices, because domestic producers had adopted a COMEX-based pricing system. Producer premiums to COMEX ranged between 4 and 5 cents per pound throughout the year, but generally declined slightly with lower prices. Though copper scrap prices generally tracked refined copper prices up and down, the spread in price between refined prices and scrap prices was more of an inverse relationship. High prices for refined copper generally attracted more scrap to the marketplace, depressing its price relative to refined prices. For example, during the September price surge, the spread between the price refineries paid for No. 1 copper scrap and the producer price for refined copper was more than 20 cents per pound. This narrowed to only about 13 cents at yearend. Thus, when prices rose, processing margins increased for secondary smelters and for brass mills, who adjusted product prices to reflect the refined value of contained copper.

Though the average annual delivered producer price for copper cathode, as reported by Metals Week, was \$1.31 per pound, the price realized by producers varied depending on their pricing, delivery charges, and sales policies. The average price realized by Asarco for the year was \$1.28 per pound, compared with \$1.17 in 1988, according to the company annual report. Magma, on the other hand, reported average sales prices of \$1.22 and \$1.14 for 1989 and 1988, respectively, in its annual report. Some of the realized price difference between the two companies was ascribed to guaranteed forward sales contracts made the previous year by Magma in anticipation of lower copper prices. Cyprus, which reported a 1989 realized price of \$1.27 per pound, implemented price protection strategies in 1989 in the advent of a decline in copper prices. About 30% of Cyprus' anticipated 1990 production was reportedly sold forward at prices ranging from \$0.80 to \$1.00 per pound. Magma entered into contracts to supply cathode to fabricators in Asia, selling forward about one-third of the company's

anticipated production at prices that averaged \$1.02 per pound over 1990 and 1991. Similarly, Copper Range sold forward contracts covering 45,000 tons of copper at a minimum average price of \$1.00 per pound for 1990 and \$0.98 per pound for 1991, according to Metall Mining's annual report.

WORLD REVIEW

Despite an increase in world refined production, the close balance between the supply and demand for refined copper that prevailed during 1988 continued throughout 1989. World consumption kept pace with the growth in production, and total stocks of refined copper changed only slightly throughout the year. However, with stocks representing only 4 to 5 weeks of supply, extremely low by historical standards, the price of refined copper was sensitive to even small changes in availability. Though total estimated world stocks remained unchanged during the first quarter, commodity exchange stocks rose by more than 50%. Coincidentally, copper prices declined steadily during the first half of 1989. Prices had risen to historic high levels in December 1988. In addition, several disruptions to the production of primary copper, which had threatened availability during the traditional yearend 1988 buying season, were resolved during the first quarter of 1989. A renewed price rise during the third quarter of 1989 coincided with strong industry demand and additional disruptions to supply. Prices declined to the lowest levels of the year when both exchange and industry inventories rose slightly and some supply disruptions were settled.

Industry Structure

Consumption.—While total world consumption of refined copper rose, consumption in the United States remained at about the same level. Weak demand in Canada from the depressed U.S. automobile market and the closure of a major Canadian brass mill was balanced by increased Mexican demand. The increase in Mexican demand was ascribed to an overall economic recovery. Demand for refined copper in Europe, according to the World Bureau of Metal Statistics, rose by about 4%, buoyed by strong demand in France, the Federal Republic of Germany, Italy, and Spain. The growth in the Federal Republic of Germany

was attributed to strong domestic and export demand for sheet products; in France to strong domestic and export demand for wire mill products; and in Italy and Spain to a boom in construction demand for wire, tube, and sheeting. In Asia, an overall demand increase of about 10% was fueled by strong demand in Japan and Taiwan. In Japan, increased consumption resulted from a boom in construction and domestic automotive and consumer electronic consumption. Demand in Taiwan increased along with increased exports.

Supply Disruptions.—Though world mine and refined production increased, an anticipated copper surplus failed to materialize owing to sustained strong demand and significant disruptions to production. In January, an explosion at Corporacion Nacional del Cobre de Chile's (CODELCO-Chile) new flash smelter at Chuquicamata, resulted in an estimated 20,000 tons of lost production. In September, CODELCO-Chile suffered a month-long setback at its El Teniente underground mine, where a landslide cut production by about 25%. Repeated acts of sabotage throughout the first half of the year led to production curtailments at the 170,000-ton-per-year Bougainville mine in Papua New Guinea. Bougainville Copper imposed a force majeure on June shipments of concentrates following closure of the mine in mid-May. At yearend, the mine remained shuttered and near-term prospects for reopening the mine were poor. In June, a 3-week strike at the Metallurgie Hoboken-Overpelt S.A. (MHO) Olen refinery in Belgium led both MHO and La Générale des Carrières et des Mines du Zaïre (Gécamines) to declare a force majeure on shipments. Gécamines had a toll refining agreement with MHO. A 107-day strike at Highland Valley, Canada's largest copper producer, began in July and also led to declaration of a force majeure. The strike resulted in the loss of about 56,000 tons of copper in concentrate compared with 1988 production.

The Government of Mexico, failing in its attempt to sell its interest in Cia Minera de Cananea S.A. to private investors, declared Cananea to be bankrupt and, on August 20, shut down the mine and dismissed the workers. It was not until the end of October that an agreement was reached with the unions to allow the reopening of the mine. The agreement called for a 25% reduction in the work force and a 33% increase in

wages for remaining employees. Though less severe than the previous year, strikes continued to impact Peruvian production. Production by Centromin in Peru was affected by strikes in February and sabotage in July. A nationwide strike by the National Federation of Mining Unions closed Southern Peru Copper Company's (SPCC) Toquepala and Cuajone Mines in August, as well as Minero Perú's Ilo refinery and Cerro Verde Mine.

In the Philippines, mine production fell by more than 13% compared with 1988. Atlas Consolidated Mining and Development reported significant losses because of heavy rains in January, February, and June; typhoons in August; labor problems in the second half of the year; and disruption of its new underground conveyor system by a landslide. Water saturation of the mine and a 26-day shutdown of the mill reduced output by Philex Mining Corp. Production by Lepanto Consolidated Mines fell by 50% during the first half of the year owing to closure of its roasting plant. Benguet Corp.'s Dizon Mines also reported lower output for 1989.

Mine Expansions.—Despite setbacks, mine production in Chile increased significantly. CODELCO-Chile invested \$410 million dollars in capital projects, resulting in production increasing by 111,000 tons to 1,218,000 tons of copper.¹⁹ The largest gain was at the Chuquicamata Div. where a 51,000-ton-ore-per-day concentrator expansion was completed in March. Production at Chuquicamata rose to 660,000 tons of copper in 1989. Expansions of smelting, refining, and sulfuric acid plants were also underway. Production at the Salvador Div., which began processing relatively high-grade slag from the Chuquicamata smelter, rose by about 50% to 130,000 tons of copper. In addition, production from the Quebrada "M" open pit, which began during the second half of the year, and an expansion of the Porterillos smelter was partially completed. The above gains in production more than offset production declines of 7,000 and 26,000 tons at the Andina and El Teniente Mines, respectively. Andina and El Teniente suffered from declining ore grades, and El Teniente also suffered severe mine stability problems.

In Canada, eight copper and copper coproduct mines with a combined annual capacity of about 75,000 tons of copper started production during the year. Minnova Inc. began production from its Ansil copper-zinc mine in Quebec and the

Samatsum silver-zinc-copper mine in British Columbia. Noranda reopened the Gaspé Mine, closed in 1987 owing to a major underground fire. Other reopened mines included the Mobrun Mine, the Shebandowan nickel-copper mine, the Heath Steele and adjacent Stratmat zinc-lead-copper mines, and the Callinan zinc-copper mine at Flin Flon. In addition to the above new or reopened projects, steps were taken to extend mine life at the Gibraltar Mine, the Similkameen Mine, and BHP-Utah Mines Ltd. open pit on Vancouver Island. With the relocation of the former Highmont mill to the Lornex millsite, Highland Valley Copper increased its mill capacity by about 10,000 tons per day.²⁰

Samincor's Neves Corvo Mine in Portugal was brought into production early in the year, and by yearend, was operating at or near its projected annual capacity of 120,000 tons of copper in concentrate. Ore grades at the underground massive-sulfide mine were reported to average between 8% and 11% copper. In Australia, production rose significantly owing to expanded production from the large Olympic Dam copper-uranium-gold project, the Selwyn Mine, and the Horseshoe Lights Mine, all of which began production in 1988. Production also increased from the Gecko copper-gold mine, which reopened in 1988.

New Mine Projects and Investments.—

The sustained high price for copper projected declines in ore grades and reserves, and a long-term outlook for a copper supply deficit stimulated investments in new copper production and in expansions of existing facilities. In Chile, development of the Sur open pit at Andina began during 1989, and partial production was expected to begin in 1990. At El Teniente, development of the Mina Sur and Mina Norte extensions continued. A 2-stage, 24,000-ton-ore-per-day expansion of the Colon concentrator was planned for completion in 1991. While production from the State-controlled Empresa Nacional de Minería (ENAMI) and the private sector only rose by a combined 20,000 tons in 1989, numerous expansions and new mine developments were underway, which could boost non-CODELCO capacity by as much as 750,000 tons of copper by 1992. Most notable was La Escondida Mine, where development was running ahead of schedule and under budget. Production startup was now projected for yearend 1990. The long-term production rate was

expected to be 320,000 tons of copper per year in concentrates. Exxon Minerals International Inc. signed an investment agreement with the Chilean Government that included \$400 million for expansion of its Los Bronces Mine from 49,000 tons of copper per year to 130,000 tons per year by 1992. Other smaller projects that were underway included the joint development of the 40,000-ton-per-year Quebrada Blanca sulfide and oxide leach project by Cominco Resources and ENAMI; the 20,000-ton-per-year Los Pelambres underground sulfide flotation project owned in part by the Midland Bank and Anaconda Chile SA; the 40,000-ton-per-year Cerro Zaldívar sulfide flotation project, acquired by Outokumpu Resources in 1989; and numerous smaller oxide leaching projects with a combined capacity in excess of 60,000 tons of copper per year.

In Indonesia, expansion of Freeport-McMoRan Copper Co.'s mine and concentrator from 20,000 tons of ore per day to 32,000 tons was initiated early in the year. In August, further expansion of the facilities to 52,000 tons of ore per day was approved. The expansions were to accommodate production from the Grasberg copper-gold deposit discovered in 1988, about 2.5 kilometers from their existing Ertzberg operation. Production from Grasberg was to begin in 1990.

In Canada, Geddes Resources Ltd. continued exploratory drilling and was proposing to develop a 120,000-ton-per-year copper mine on its Windy Craggy property in the northwestern corner of British Columbia. The company reported proven and probable reserves of 114 million tons of ore grading 1.9% copper. The company was proceeding with the environmental permitting process. Numerous other Canadian deposits, including the Louvicourt Township property and the Estrades property in Quebec, the Duck Pond property in Newfoundland, the Hanson Lake property in Saskatchewan, and the Mount Milligan property in British Columbia were being considered for development.²¹ Other new projects included a 20,000-ton-per-year mine in Burma, mill expansions at RTB Bor's mines in Yugoslavia scheduled for completion by 1992, and modernization and expansion of the Erdinet Mine in Mongolia.

Smelting and Refining Production.—

World smelter and refinery production during 1989 rose with increased availability of copper concentrates. Refined copper

production from scrap, which had increased markedly in response to higher prices during 1988, remained high in 1989 at about 2 million tons and comprised about 22% of refined copper production. Production increases of secondary refined copper in the United States were tempered by the static secondary recovery in Europe, the largest producer of refined copper from scrap. According to Bureau of Mines estimates, the Western European countries produced about 710,000 tons of refined copper from scrap, compared with only 540,000 tons for the North American countries. The increase in smelter production lagged behind that of both mine and refinery production. The expansion of world SX-EW production, which bypasses the smelting step, helped to boost primary refined production.

Increased concentrate production, smelter setbacks, and a decision by Japanese smelters to maintain their relatively low operating rate led to a surplus of copper concentrates. Consequently, treatment and refining charges rose significantly during the first quarter of the year. A tight supply of concentrates, which had prevailed over the past several years, had led to low treatment and refining charges. According to Commodity Research Unit Ltd. of London, United Kingdom, combined spot treatment and refining charges rose by 45% during the first half of the year to about 29 cents per pound of copper. However, by yearend, charges had returned to 1988 levels. Disruptions to mine production and increased smelter utilization rates again led to a tight supply in the custom concentrate market. However, refined copper production was not affected by the return of tight supply. Stocks of concentrate, accrued by smelters earlier in the year, were able to supplement new production.

Limited surplus primary smelter capacity and expanding mine production served to stimulate numerous smelter expansion plans. In Chile, several smelter projects were being considered at yearend. In addition to the ongoing expansion of the Ventanas smelter and refinery, expansion of the Paipote smelter was planned, and construction of two new ENAMI smelters was being considered. In the Philippines, the Philippine Associated Smelting and Refining Co. (PASAR) announced plans to expand its smelter by 34,000 tons per year to 172,000 tons per year, and in Thailand, Padaeng Industry Co. planned construction of a 100,000-ton-per-year smelter by 1995. In addition to the new smelter planned in

the United States, Mitsubishi announced plans to retrofit its Naoshima smelter with a new smelter, equal in capacity to its existing two smelting furnaces. In Mexico, startup of the Santa Rosalia smelter was delayed until 1990 owing to delays in refurbishing the shuttered smelter. In June, Finland's Outokumpu Oy and a consortium of Portuguese companies initiated a feasibility study on constructing a major smelter in Portugal. Other potential sites for new smelters included Brazil and Indonesia.

Capacity

Compared with that of 1988, world mine capacity increased by 6%, smelter capacity by 3.3%, and refinery capacity by 1.5%. Copper mine, smelter, and refinery capacity for 1989 is shown in table 6. World capacity utilization (82%) at mines continued to be low in 1989 owing to the extensive disruptions at mines, discussed in the previous section. Since 1974, average annual world mine production has ranged between 79% and 85% of available capacity, being highest during periods of peak demand and low available capacity, such as existed in 1987, a year of high-capacity (85%) utilization.

The data in table 6 are rated annual production capacity for mines, smelters, and refineries as of December 31, 1989. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Capacity at mines represents the potential copper production contained in concentrates for many producers, but for some major producers—such as Chile, the United States, and Zambia—it represents copper recoverable at the smelter level, based on known recovery factors. SX-EW capacity is counted as smelter-level capacity only when the material must be further refined. It is otherwise counted as mine and refinery capacity, bypassing the smelter level. Past and present production potential are taken into consideration when rating a mine, especially where an engineering

estimation is not available or seems inappropriate in the case of decreased ore grades. Generally, the rated capacity is based on 360 days per year and two to three shifts per day. For new facilities, capacity is prorated for the year in which it started, but the full capacity is used for the year in which a facility closes. Mines and plants generally are not counted if they are not operating at any time during the year, except where it may be reasonably expected that a shutdown may be temporary, i.e., usually less than 2 years.

OUTLOOK

Trends in Consumption

U.S. demand for refined copper from 1950 to 1989 rose an average of 1.3% per year and was anticipated to remain less than 2.3 million tons per year through 1991. World demand increased at about 3.6% per year over the same period. Demand rates for select periods within the 1950-2000 time span have varied significantly, as shown in table 7 and in figures 1 and 2. Particularly noticeable in the United States are the lower growth rates that have existed since 1980. Growth in other countries during this same period was more robust, accounting for the higher 1963-89 average growth rate of 2.5% per year for market economy countries (MEC).

In general, copper demand is largely dependent on economic growth. High demand for copper products is associated with a high standard of living and increased electrical uses. The growth of plastics, fiber-optic cable, and aluminum as competing materials continued to impact several copper markets, but the outlook remains positive for growth in copper consumption, which has related historically to industrial growth. In the United States, a high degree of correlation since 1960 (R^2 value of 0.90) between the Gross Private Domestic Investment (GPDI) and the demand for copper in electrical uses indicates the strong tie between copper demand and economic growth.

Copper consumption has been increasing in the electrical sector as a share of end-use markets since 1960, so that in 1989 this sector comprised more than 70% of U.S. copper demand. Statistical projections provided by the Bureau of Mines Branch of Economic Analysis indicated that, by using an independent forecast for the GPDI as a comparative basis, copper consumption

in electrical uses alone could reach 2.29 million tons by the year 2000 in the United States.

Although the correlation is high between total U.S. copper consumption and the GPDI, it is not as high as for electrical

uses. The GPDI correlates very poorly with copper consumed for other end-use sectors. One explanation has been the increased U.S. consumption of imported manufactured goods containing copper, which were not reflected in the measure of

copper consumed at U.S. semifabricating plants, but which were included in the dollar-valued GPDI. Another reason is that the impact of substitution has been higher in other sectors. Shearson Lehman Hutton also found a high historical correlation with

Trends in Supply

World mine production has grown steadily since World War II, interrupted only by short periods of severe depression or long-term labor strikes. Financial investment in expanding capacity at new and existing mines has exceeded \$10 billion since 1987. Much of the new capacity developed in the 1980's and 1990's stems from a more intensive prospecting and reserve development period that took place during the 1950's and 1960's. The long period of poor profits for the copper industry through much of the 1970's and 1980's lent credence to a perception that exploration in nonferrous metals was a poor investment. In addition, although many large deposits already had been discovered, the large sums of money required for further development were not available. The location of some of the largest deposits further increased financial risks. Political and economic stability was poor in some nations with large copper resources. In other countries, such as the United States, environmental and other licensing procedures made new mine development costs prohibitive in some areas. Although new arrangements for investment sharing and methods of financing are possible among mining companies, banks, and Governments, sufficient capital to develop some of these deposits may be a future problem.

The direction of mine supply growth, forecasted from 1989 to the year 2000, is shown in table 8. Also shown is the amount of capacity still in exploration stages that has been incorporated in the country forecasts for the latter part of the 1990's. Although speculated for possible initiation during the latter half of this period, no firm development plans had been made for these projects, and their implementation, therefore, was speculative.

Copper and copper alloy scrap is also a major source of copper. Although the potential supply of world scrap is significant, the rate of old scrap recovery is limited by copper's long life in its essential uses. The historical recovery of old scrap has averaged an estimated 18% of world copper consumption. Although old scrap recovery has been higher in the United States, it seldom has exceeded 22% of world consumption.

TABLE 7
COPPER CONSUMPTION TRENDS

Period	United States	Market economy countries	World total

Forecast Supply and Demand Trends

Copper demand is forecast to grow at a 1.9% rate in the United States and at a 2.7% rate in the world between 1989 and the year 2000. While consumption in the United States, Europe, and Japan was expected to increase at a relatively lower rate, other countries were expected to surpass these rates as their economies develop. Significant increases in world copper demand could be driven by economic recovery in the centrally planned economy (CPE) countries and by increased domestic consumption in the less developed countries (LDC) and newly industrialized countries. Rejuvenation and building of new plants, equipment, and infrastructure in these countries could consume major amounts of copper. However, the problems of some African, Southeast Asian, and South American countries could continue or could deteriorate further. Consumption in these countries, therefore, was expected to exhibit minimal growth.

The projected balance between supply and demand forecasts is shown in figures 1 and 2. Estimated MEC refined inventories are compared with projected average monthly MEC consumption in figure 1, and world consumption is compared with primary (mine) supply in figure 2. Both illustrations indicate the potential for tight copper supply in the latter part of the 1990's. Historically, when inventories were less than 1 month's supply at prevailing rates of consumption, price pressures

became significant. Supplies are anticipated to be impacted negatively during 1990 and 1991 by the continued shutdown of the Bougainville Mine, Papua New Guinea. A significantly positive supply influence will result from the anticipated early 1991 startup of the large Escondida Mine in Chile. Although some inventory surpluses are anticipated through 1993, it is not anticipated that the depressed market conditions of the middle 1970's and early 1980's will reoccur, causing inventories to accumulate to 4 months or more of supply.

BACKGROUND

Definition, Grades, and Specifications

Copper is traded in many forms that relate to different stages of processing. For example, at the mine copper may be sold as ore, concentrate, or precipitate. Copper ore may contain as little as 0.40% copper or more than 10% copper, depending on its source. Copper concentrates are produced by milling and concentrating copper ore and may contain between 18% and 40% copper. Copper precipitate or cement copper is recovered from leach solutions by chemical precipitation with scrap iron and may contain as much as 90% copper.

Smelter products include copper matte, blister, slag, and anode. Slag is the waste formed in smelting through the combination of a flux, such as limestone and silica, with the gangue or waste portion of the ore

and, although it may contain small amounts of copper, is high in silicon and iron. Copper matte contains between 15% and 65% copper, together with much of the sulfur and other nonferrous and precious metals. The newer flash smelting technologies result in a much lower sulfur content in the matte than was possible in the reverberatory furnaces. Copper matte is transferred to a converting furnace where the sulfur is oxidized and removed as sulfur dioxide, and the enriched copper melt is poured as blister copper. Blister contains 97% to 98.5% copper. The blister is then fire refined by oxidizing the impurities in a reverberatory furnace, followed by removal of the excess oxygen by a process called poling. Poling may be done by insertion of green logs or a reducing gas into the melt. The blister is then cast into anode shape and further treated in an electrolyte bath to form refined copper cathode through electrolysis, transferring the copper ions of the anode by electrical current to the negatively charged cathode. Impurities in the copper anode such as gold, selenium, and silver are collected at the bottom of the electrolytic tank for recovery in a later process. Cathode copper may also be obtained from an electrowinning process. In this process, cathode copper is plated directly from copper-bearing solutions obtained from leaching copper-bearing ore, matte, scrap, or other material and enriched by solvent extraction methods. An alternative to electrolytic refining is fire refining of blister or of scrap, in which case, the fire-refined product is cast into ingots, bars, billets, or cakes and is not processed electrolytically.

Refined copper cathode, which contains greater than 99.3% copper, is the predominant form traded. Tough-pitch copper is refined copper cast into shapes. Oxygen-free copper, which is preferred for special electrical uses, is refined copper melted and recast in a deoxidizing atmosphere. Deoxidized copper is refined copper treated with deoxidizers to reduce cuprous oxide and remove oxygen. Normal refinery shapes cast from cathodes and fire-refined copper are wire bars, billets, slabs, ingots, and bars. Since the late 1970's, the continuous cast wire rod nearly has eliminated the wire bar as an intermediate shape used for making wire rod from refined copper. Wire rod is used to make wire of all types. Wire bar currently comprises less than 1% of the copper market. Billets made from refined copper, scrap, or alloys are large cylindrical shapes used for extruding tubing or

sometimes wire rod. Slabs are the precursors to flat products such as sheet. Ingots are small shapes that are usually remelted and used for making alloys.

There are more than 370 copper and copper alloys divided into broad categories of wrought and cast metals. A unified numbering system (UNS) for metals and

materials was developed by the American Society for Testing and Materials (ASTM) and the Society of Automotive Engineers. This system designates each alloy by five digits preceded by the letter C. The UNS is administered by the Copper Development Association and is widely used by ingot-makers, brass mills, and foundries in

the United States. The major classes are coppers that contain greater than 99.3% copper; high-copper alloys, which contain at least 94% copper; brasses, which contain zinc as the dominant alloying agent; bronzes, which normally contain tin as the dominant alloying agent, but which also may contain such other metals as aluminum,

lead, phosphorus, and silicon but only small amounts of zinc; copper-nickels, which contain nickel as the principal alloy metal; nickel silver, which contains copper, nickel, and zinc as the principal metals; leaded coppers, which are cast alloys containing 20% or more of lead, but no zinc or tin; and special alloys, which are copper alloys with compositions not covered in the above groups. Master alloys and hardeners are copper-based alloys cast with a high alloying element content and are used in producing copper alloys. Hardeners and master alloys not only permit closer composition control than possible by addition of pure metals, but also permit easier introduction of a deoxidizer, such as phosphorus. Beryllium copper master alloy, containing 7% to 10% beryllium, and phosphor copper, containing 10% to 14% phosphorus, are examples. The ASTM specifications for refined copper are designated in part 6, section B5-77 of the ASTM specifications, and are under the jurisdiction of ASTM Committee B-5 on copper and copper alloys.

Products for Trade and Industry

At least four physicochemical properties, singly or in combination, account for the widespread use of copper and its alloys. Foremost among these is electrical conductivity. Among the electrically conductive metals, copper is second in conductivity only to silver. Electrical uses, which account for about 70% of copper demand, include electrical power transmission, motors and generators, housing and industrial wiring, automotive and appliance wiring, telecommunications, electronic circuit boards, specialized electronic equipment, and numerous other electrical and electronic applications.

The chemical stability and workability of copper are among the reasons that copper and its alloys have been extensively used in tubing and valves for systems carrying potable water, saltwater, and other aqueous fluids. Because of its good thermal conductivity, again being second only to silver in thermal conductivity, copper and its alloys were extensively used as materials of construction for heat exchangers used in motor vehicles, refrigeration, air-conditioning units, and numerous other applications. Because of its resistance to salt, copper was widely used in marine environments and automotive brake components.

Copper also was used widely, for other than electrical conductivity, in industrial

machinery and transportation equipment. Because of its aesthetic appeal and resistance to weathering, copper was used in construction for roofing, flashing, decorative hardware, and guttering and downspouts. Miscellaneous uses of copper included ammunition, industrial and agricultural chemicals, pigments, fine instruments and watches, jewelry, cooking utensils, decorative items, and coinage.

Electrical uses of copper have accounted for an increasing market share over the past 20 years. Growth in consumer and business electronics and building wire demand have contributed to electrical demand growth, while materials substitution in plumbing, automotive radiators, coinage, etc., and increased imports of copper-containing manufactured goods such as automobiles, machinery, and air-conditioning units have reduced or stabilized demand for other uses. The growth in electrical demand has occurred, despite the substitution of aluminum in overhead power transmission lines; development of microwave, digital, and fiber-optic technologies for telecommunications; and downsizing of motors and switch gear. Specialty alloys, such as beryllium copper used for electronic connectors, have experienced strong growth in demand. The growth in electrical uses and the shift from wire bar technology to continuous cast wire rod has increased the demand for electrolytic copper at the expense of fire refined material. In 1989, only one domestic secondary refinery produced fire refined wire bar.

Industry Structure

Copper smelting operations have been traced back to at least 5000 B.C., but modern history and growth in demand for copper began with the discovery and commercial development of electricity in the latter part of the 19th century.²³ World copper production was estimated to be only about 50,000 tons in 1850. However, by the turn of the century, it reached an estimated 500,000 tons per year. By 1912, world mine production had reached 1 million tons. World production continued to grow, almost uninterrupted, to almost 9 million tons in 1989. More than 90% of cumulative world mine production has occurred since 1900; 60% since 1960.

In 1989, copper was mined in about 60 countries. The top 13 producing countries accounted for 85% of production. The United States and Chile were the leading producers, each accounting for about 17% of production. Copper was smelted in 40

countries and refined in 42 countries. Industrialized countries in Europe and the Far East, which lacked sufficient raw materials, encouraged mine production in the LDC's to assure supplies. These countries have long dominated world smelting and refining capacity. Thus, in 1989, Japan was second only to the United States in smelter and refinery production despite having only nominal mine production. To assure its supply of concentrates, Japanese smelters and refiners invested heavily in world mine capacity, particularly in Chile, but also in other countries. In 1989, Japanese companies owned a 15% and 33% interest, respectively, in the Chino and Morenci Mines in the United States.

European smelting-refining companies, similarly lacking in copper resources, invested in mines in Africa, Asia, and Oceania. The new Escondida Project in Chile, slated to come on-stream at the beginning of 1991, was owned by a consortium of Australian, British, and Japanese companies and, in exchange for concentrate supply contracts, financed in part by interests in Japan, Finland, and the Federal Republic of Germany. Similarly, U.S.-based Freeport-McMoRan Inc., owners of Freeport Indonesia Inc., secured a \$500 million loan package to expand its concentrator and develop its Grasburg, Indonesia, deposit from banks in eight countries, one-half of which will receive Freeport concentrates.

However, in recent years the concentrate exporting countries have sought to increase their local smelting and refining capacities to supply growing domestic demand for refined copper and to maximize foreign exchange earnings. Traditional copper concentrate exporting countries with expanded smelting capacity included Australia, Chile, Mexico, and the Philippines. The PASAR smelter and refinery was commissioned in 1983 and subsequently expanded. To assure supplies to the Philippine Government-controlled (60%) operations, Philippine mines were ordered to ship a minimum of 30% of their concentrates to PASAR despite its high smelting and refining charges. In addition, newly industrialized countries such as the Republic of Korea have added capacity to meet their growing demand for refined copper. Similarly, Brazil became an exporter of brass mill products and major new brass mills were being constructed in the Republic of Korea, Philippines, and Taiwan.

In the 1950's, eight privately owned U.S. and Western European companies controlled three-fourths of world copper

[†]Revised.

¹Copper Development Association (CDA) categories have been redistributed on a copper content basis (the alloy component has been subtracted). The electrical component has been extracted from all end-use categories except electrical and ordnance. Adjustments were also made for the new scrap component, which was subtracted. Ordnance data reflect U.S. Department of Commerce ACM military shipments to 1983; estimated data, thereafter, reflect CDA data for 1989.

²Includes wire and other forms used in electrical, communications, and other special uses.

production outside the U.S.S.R. By 1983, many mines in the less developed countries had been partially or totally nationalized so that more than 50% of the world's copper mine production was from Government-owned corporations. Most notable of the state-controlled mining companies that came into existence during the 1960's and 70's were the following: CODELCO-Chile, the world's largest copper producer; Zambia Consolidated Copper Mines Ltd. (ZCCM), which was formed in 1982 through the merger of state-owned Nchanga Consolidated Copper Mines Ltd. (NCCM) and Roan

Consolidated Mines Ltd. (RCM), and was accountable for all of Zambia's mine production; La Générale des Carrières et des Mines du Zaïre (Gécamines), which, in 1987, acquired Japanese and state-owned Société de Développement Industriel et Minière du Zaïre (Sodimiza) to account for all of Zaïre's production; and Empresa Minera del Centro del Perú (Centromin Perú), Empresa-Minera del Perú (Minero Perú), and Empresa Minera Especial Tintaya S.A. (Tintaya), which combined accounted for about one-third of Peru's mine capacity.

Since 1983, state control of copper production has declined slightly to about 50% of world capacity owing to contraction of some state-controlled operations and capacity growth in the private sector. All of the greenfield copper projects that came on-stream since 1983 or were slated to come on-stream over the next several years were privately owned.

Following the supply-demand imbalance in 1982, which led to accumulation of massive world refined copper inventories, copper prices were severely depressed. The fall-off in copper revenues resulted in

sustained economic losses by some copper producers and mine closures. In some countries, such as Chile and the Philippines, price support mechanisms were instituted to aide the private mining sector.

Significant restructuring by both state-controlled and privately held copper producers occurred in efforts to rationalize production and reduce operating costs. In Zaire, Gécamines, which operated about 1 dozen mines in three geographic regions along the Copperbelt of Central Africa, launched a 5-year, \$870 million rehabilitation project in 1985, including plans for a new refinery. In Zambia, ZCCM began a 5-year plan in 1986 to streamline and rationalize production to stem the decline in annual output. The decline was ascribed to low equipment availability owing to a shortage of spare parts, insufficient skilled labor, an exodus of engineering staff, unreliable transportation to African ports, and a shortage of sulfuric acid for expanded leach operations. As part of the revitalization, the Chambishi Mine was closed, new reserves at Mufulira were developed, the worker training budget was increased 16-fold, and various national economic policies were adopted to ensure capital.

In the Philippines, most of seven mining companies continued to sustain losses, even after the recovery of copper prices in 1987. Atlas Consolidated Mining Development Corp., the largest Philippine producer, closed several open pit operations but was expanding high-grade underground operations and developing a new open pit to replenish reserves.

In Mexico, the two State-controlled mining companies, Mexicana de Cobre S.A., which operated the La Caridad Mine, and Cia Minera de Cananea S.A., which operated the Cananea Mine, together accounting for about 98% of production in Mexico, were offered for sale in 1988 in an effort to reduce Federal debt by selling nonstrategic assets. Cananea remained unsold through 1989.

In Chile, capital investments in excess of \$2 billion and devaluation of currency helped to halve operating costs at CODELCO-Chile's four divisions over the decade ending in 1985, to make it one of the world's lowest cost copper producers. CODELCO-Chile, which operated the world's largest open pit (Chuquibambilla) and underground (El Teniente) mines, continued to invest heavily to maintain and expand production in light of rapidly declining ore grades. In 1988, CODELCO-Chile

announced a \$1.25 billion, 5-year investment program that was projected to boost production by 200,000 tons to 1.38 million tons. Despite these investments, production by CODELCO-Chile remained nearly constant between 1986 and 1988, with most of Chilean production increases over that period coming from the private sector. However, production in Chile rose significantly in 1989, owing to capacity increases at Chuquibambilla.

In the United States, major rationalization and ownership changes, restructuring, labor concessions, and major capital investments revitalized the copper industry and reduced average production costs from more than 80 cents per pound in 1982 to less than 60 cents per pound in 1989. Production rose from 1.04 million tons in 1983 to 1.5 million in 1989, just slightly short of the record production level set in 1973. Foremost in technology changes were expansion of lower cost SX-EW technology, in-pit crushing and conveying systems, and flash smelting technology. By 1989, with the sale of Kennecott to RTZ, oil companies, which in the late 1970's had seen domestic copper companies as attractive acquisitions, had divested their domestic copper holdings.

Though about 20 different companies operated a total of more than 60 copper-producing mines in the United States, 4 companies, Phelps Dodge Corp., Cyprus Minerals, Asarco, and Magma accounted for 90% of domestic capacity. Major industry ownership changes occurred as companies sought to raise capital for production increases and become more self-sufficient through vertical integration of mines, smelters, refineries, and rod mills.

Several companies, including Inspiration Resources, Noranda, and AMAX, totally divested their U.S. copper holdings. In 1986, Kennecott, the largest domestic producer (then owned by BP Minerals), in exchange for labor concessions, agreed to reopen its shuttered Bingham Canyon Mine and invest \$400 million in modernization of its Utah operations. To raise capital, it sold its Chino and Ray Mines. Phelps Dodge emerged as the largest and lowest cost domestic copper producer following the purchase of Chino, restructuring of its labor force, major investments in electrowinning capacity, and investment in in-pit crushing and conveying technology.

Magma invested \$200 million in a new flash smelter and acid plant at San Manuel. The new smelter provided the sulfuric acid necessary to develop open pit and in situ

copper oxide reserves and to lower overall production costs. Asarco acquired the Ray Mine, full control of the Mission Complex reserves and other properties, switching from a custom smelter to an integrated producer. Between 1986 and 1989, Cyprus Minerals also acquired several properties from other companies.

The U.S. primary smelting industry underwent significant contraction with the coincidence of depressed copper prices and a year-end 1987 compliance deadline with the clean air regulations. Between 1983 and 1986, 7 of 13 primary smelters, most of which were noncompliance reverberatory smelters operating under interim compliance orders, were permanently closed. Insufficient smelting capacity for processing its concentrates prompted the acquisition of the Inspiration smelter and Lakeshore roast-leach plant by Cyprus Minerals and Chino smelter by Phelps Dodge. With the recovery of copper mine production, the United States became a significant exporter of concentrates.

The erosion of U.S. ownership of world copper production, which has been the case since the nationalizations of the 1960's, took on a new dimension in the 1980's, with foreign companies investing in domestic mines. In addition to foreign ownership of Kennecott, first by BP and later by RTZ, and Japanese investment in the Chino and Morenci Mines, Copper Range sold its mine, smelter, and refinery in White Pine, MI, in 1989 to a Canadian subsidiary of Metallgesellschaft AG. of Germany. Mitsubishi Metals of Japan planned to construct a copper smelter in Texas.

While companies tended to integrate their unwrought copper production facilities, the 25-year-old trend away from the strong ties between downstream processors and mine producers continued. In 1986, Anaconda sold its American Brass divisions. Ownership of Chase Brass, which had been reorganized in 1986 into separate operating divisions along product lines, remained partially with BP Minerals America when RTZ purchased Kennecott. Phelps Dodge sold or closed much of its wire production facilities. Where the brass industry was dominated by a few full-line mills, it evolved into four distinct industries with mills having single or limited product lines: Strip, sheet, and plate; plumbing and commercial tube; alloy wire and rod; and unalloyed copper wire rod for electrical wire production. Only the copper wire rod mills retained their association with the primary producers. Low processing margins

and increased import competition during the period of low copper prices hastened the trend toward sell-off or closure of unprofitable operations and specialization of product line.²⁴ Imports of semifabricated products doubled over a 10-year period, reaching their peak in 1984 of more than 260,000 tons. Though still high by historic standards, import penetration has declined slightly owing to successful antidumping suits filed by the domestic industry, restructuring of the domestic industry, and a weakened U.S. dollar.

Production and consumption of brass and bronze ingot in the United States declined markedly between the late 1960's and early 1980's owing to the substitution of plastics and aluminum for brass and bronze castings, increased import penetration, and more stringent environmental regulation being applied to ingot makers and foundries. Over that time period, domestic production of alloy ingot fell by 40%, and more than one-half of the approximately 40 ingot makers were closed. The foundry industry underwent a similar contraction, with alloy ingot consumption falling by a commensurate amount. However, since about 1985, domestic production and consumption of alloy ingot stabilized at about 180,000 tons per year.

Geology—Resources

According to their mode of origin, copper deposits may be grouped in the following broad genetic classes: (1) porphyry copper deposits and their associated skarn, hydrothermal veins, and replacement breccia deposits; (2) deposits associated with ultramafic, mafic and alkaline ultrabasic, and carbonatite rocks; (3) volcanogenic and metavolcanogenic deposits; (4) sedimentary and metasedimentary deposits; and, (5) veins and replacement bodies associated with metamorphic sequences, not otherwise classified. As a percentage of total world capacity, the predominant type mined was that of the porphyry copper and associated deposits (59%), followed by stratiform sedimentary replacement and metasedimentary deposits (23%), volcanogenic massive sulfide deposits (7%), veins and replacement bodies (7%), and ultrabasic massive sulfide and carbonatite deposits (4%). Though the massive sulfide and vein and replacement deposits were much more numerous than the porphyry and stratiform sedimentary deposits, they tended to be smaller in both capacity and reserves, but generally contained a wider

variety of other mineral coproducts. In the United States, porphyry copper deposits made up about 93% and stratiform sedimentary and metasedimentary deposits about 6% of established mine capacity.

In recent years, plate tectonic theory has been emphasized in defining copper deposits as they relate to the Earth's lithospheric plates, their edges, subduction zones, and spreading axes in space and time. For example, deposits of the porphyry copper type occur mainly in magmatic, volcanic arc, and back-arc regions of plates overlying subduction zones; hence, their predominant location along areas such as the continental edges of North and South America. Copper deposits found in ultramafic sequences are characteristic of oceanic plate settings and ophiolite rock groups. Alkaline ultrabasic rocks and carbonatites intrude stable continental cratons and are presumed to have come from mantle-derived magmas contaminated with crustal rocks. At Palabora, the Republic of South Africa, a carbonatite is host to a copper deposit; as a significant producer of copper, this is a unique occurrence. Sedimentary copper deposits generally occur in rocks typical of passive continental margin and interior environments and intracontinental rift systems. In addition, these deposits may have been redistributed by later diagenetic or metamorphic hydrothermal systems, but retain their stratiform identity. Stratiform applies to a layered mineral deposit of any origin. Stratibound refers to a deposit confined by a single stratigraphic horizon.

Copper occurs in about 250 minerals; however, only a few are commercially important. The most common are chalcopyrite (CuFeS_2), covellite (CuS), chalcocite (Cu_2S), bornite (Cu_5FeS_4), enargite (Cu_3AsS), and tetrahedrite ($\text{CuFe}_{12}\text{Sb}_4\text{S}_{13}$). Metals may be leached out of the rock above the water table by circulating ground water, oxidized, and enriched in the underlying supergene zone. The supergene capping of an ore body often contains the highest concentration of copper as chalcocite or as various copper oxide and silicate minerals. Native copper also occurs in the oxidized or supergene zones.

The definitions for reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals." In this system, the reserve base is the measured plus indicated (demonstrated) resource from which reserves are estimated. Reserves are that part of the reserve base

thought to be economically recoverable with existing technology at operating or developing properties. Among individual countries, Chile had the largest share (22%) of the reserve base, followed by the United States (16%), the U.S.S.R. (9.7%), and Australia (7.3%). Peru, Zaire, and Zambia also had large copper reserves with about 5% each. More than 90% of U.S. copper reserves was in five States—Arizona, Michigan, Montana, New Mexico, and Utah. The U.S. Geological Survey (USGS) estimated total world land-based copper resources, comprised of the reserve base and a larger body of less well characterized resource, was about 1.6 billion tons.

Copper reserves reported at operating or developing properties were sufficient to meet a projected cumulative demand of nearly 130 million tons of primary copper through the year 2000. In addition, some of the material already identified in the reserve base, which was presumed to be uneconomic to mine, may become economic with new technology and/or higher copper prices. However, the rate of increase in the reserve base has declined since 1976. The world reserve base, including measured and indicated ore, increased by about 140% from 1965 to 1976, corresponding to a 56% growth in world production and 48% growth in consumption over the same period. Since 1976, however, the reserve base has increased by only 23% and production by only 17%, while consumption grew by an impressive 36%. Since the late 1970's, the preoccupation with gold exploration and general neglect of base-metal exploration led to a significant decline of reserves in Canada, Peru, the Philippines, and other countries. Unless substantial new discoveries occur immediately, some countries' output will decline by the late 1990's. According to a recent Canadian analysis, to maintain 1988 Canadian production, each mine approaching exhaustion must be replaced by a new operation, based on a discovery some 6 years earlier.²⁵ Canadian copper production is forecast to fall off sharply by 1994 because mine reserves would be exhausted. The large reserves of copper in Canada were discovered during the period of high base-metal exploration that existed through the late 1950's to the early 1970's.

place in potential areas within which the anticipated copper deposit is masked by postore cover in the form of alluvium and volcanic or sedimentary rock. Following discovery of a potential deposit by geophysical and chemical means, successively and increasingly intensive drilling campaigns to characterize and quantify the deposit are undertaken before a decision is made to bring a deposit into pro-

duction. Continued drilling programs to extend identified reserves may continue throughout the production life of the deposit. Copper exploration was seriously lacking through most of the 1970's and 1980's, but has received renewed vigor since the high prices of the late 1980's. In the United States, recent exploration and development has focused on oxide ores suitable for processing by low-cost, leaching SX-EW technology and on the stratiform ores of Montana.

Studies of the geologic environments of identified deposits may lead to a basis for predictive metallogeny of other parts of the same area. For example, the USGS considered the Midcontinent rift area of the United States as a particularly important geologic environment for certain types of mineral deposits. The rift structure extends for 2,000 kilometers from Kansas, northeast through the Lake Superior region, and bends southeast into Michigan. A new USGS project was designed to characterize the rift and provide metallogenetic analysis of types of minerals deposits that may be expected. Identified occurrences included the copper-nickel sulfides of the Duluth complex, stratiform deposits of the Keweenaw Peninsula, MI, and copper-molybdenum bearing breccia pipes of Ontario.²⁶

Mining and Beneficiation.—Since the turn of the century, the evolution of technology for large-scale mining, milling, and concentrating low-grade ores has resulted in a continued shift away from mining small, high-grade, massive sulfide deposits by labor-intensive underground methods. Today, open pit mining accounts for almost 60% of MEC production and more than 80% of domestic production. Open pit mining requires a relatively shallow deposit with typical waste-to-ore stripping ratios between 1:1 and 2:1. A typical surface copper mine uses rotary blasthole drills and a shovel-truck combination for the loading and hauling operation. Underground mining methods vary with the geophysical nature of the ore and host rock, but typically have lower waste-to-ore ratios and higher grades and employ some form of large-scale block-caving such as that employed at San Manuel in the United States and El Teniente in Chile.²⁷ Following extraction, run-of-the-mine ore is milled (successively crushed and ground) to liberate the copper sulfide minerals and beneficiated or concentrated via froth flotation to produce a concentrate containing

about 30% copper suitable for modern smelting.

Faced with higher energy costs, deeper mines with longer haul distances, high labor rates, and lower ore grades, the domestic industry has fought to maintain and subsequently lower production costs over the past few decades. Major improvements in energy use and labor management in mining and milling technology have been made in recent years through improved strategies of materials transport, grinding, and concentration. Technological improvements include in-pit crushing and conveying systems to replace truck-haulage to the mill; semiautogenous and autogenous grinding circuits; column and cyclone flotation cells; increased equipment scale, including trucks and flotation cells; computer-controlled truck dispatch systems; and improved on-line sampling and automated reagent control in the mill.

An important factor in domestic mine cost savings has been the development and rapid expansion of SX-EW technology for the treatment of acid soluble oxide or chalcocite ores. In this process, dilute sulfuric acid is percolated through the ore, either in dumps, pads, or in situ. The copper-bearing solution (leachate) is collected and processed through solvent extraction to concentrate the copper in solution. Copper is recovered from the concentrated solution by electrowinning where copper is plated directly from solution onto a starter cathode. The resultant electrolytically pure copper bypasses the traditional smelting and refining steps. Recent advances in the organic extractants and in electrowinning have improved the economics of this process. In addition to processing oxidized ores, mines have realized tremendous cost savings by leaching existing waste and ore dumps and by adjusting cutoff grades to the concentrator upward, with lower grade material being processed by SX-EW.

Growth in SX-EW capacity has been rapid since the mid-1970's. In the United States, SX-EW capacity increased from only 37,000 tons in 1974 to 358,000 tons of copper in 1989. Similarly, SX-EW capacity for the world, which was estimated to be 910,000 tons of copper per year in 1989, was expected to exceed 1.3 million tons by 1995.

Smelting.—Most copper concentrates are processed through three-stage smelting to produce anode suitable for electrolytic refining. Concentrate is processed in the primary smelting reactor to produce a

copper and iron sulfide matte containing up to 60% copper. The matte is oxidized in a converter, forming iron oxides that are removed in the slag and blister copper containing in excess of 98% copper. Sulfur is removed as sulfur dioxide in the gas streams. Blister copper is fire refined in an anode furnace to remove oxygen and other impurities. The anodes are interspersed with either copper, stainless steel, or titanium starter sheets in an electrolytic cell or tank, and copper is plated from the anode to the cathode. The resulting cathode is 99.9% pure and suitable for most electrical applications of copper. Valuable impurities, including the precious metal values, collect as sludge in the bottom of the electrolytic cell.

In 1970, environmental constraints and energy costs became a prime concern of the domestic smelting industry. Through the late 1970's and mid-1980's, domestic smelters were able to use interim methods such as tall stacks and intermittent operation to meet sulfur dioxide emissions standards. However, by the 1987 compliance date, most remaining smelters had abandoned traditional reverberatory smelting and had adopted one of the various oxygen enriched smelting furnaces (Outokumpu flash, Noranda, Inco flash, Mitsubishi continuous). These furnaces generally required lower energy input and provided a more concentrated sulfur dioxide gas stream, which allowed for sulfuric acid production as a means of sulfur dioxide capture. The byproduct sulfuric acid has provided a readily available, inexpensive source of acid for expansion of the SX-EW capacity.

Flash smelting involves the blowing of concentrate, flux, and oxygen into a hot furnace. The sulfur and iron in the concentrate react rapidly (flash) with the oxygen, and release a tremendous amount of heat. Flash processes using oxygen or oxygen-enriched air are generally autogenous, requiring no external fuel input. In 1988, Magma commissioned the world's largest single furnace Outokumpu flash smelter. The majority of new smelters constructed worldwide since 1970 were Outokumpu flash smelters. However, in the United States, two new Inco furnaces, at Hayden, AZ, and Hurley, NM, were commissioned since 1980. The Noranda process smelter, installed by Kennecott, was not autogenous but had the advantage of being able to process larger size material, including scrap, and produce a higher grade copper matte.²⁸ Cyprus operated the only domestic electric furnace, the Copper Hill smelter,

having shutdown in 1987. Though electric furnaces require a large electrical energy input, they produce a low-copper slag suitable for direct disposal and can process a variety of materials.

Asarco, which operated one of the two remaining reverberatory smelters at its El Paso smelter, announced plans to install a Contop (Continuous Top-Blowing process) flash smelter. In this newly developed, autogenous process, concentrate is continuously melted in a cyclone furnace located on top of a large settling chamber. The high temperature of the flash smelting, combined with top blowing of the slag in the settling chamber, volatilizes most of the impurities such as lead, arsenic, etc., and is well suited to ores having high-impurity levels. It also provides for a low-copper slag that can be dumped without further treatment. Also, because of its relatively low capital requirement and compact size, it was reportedly well-suited for retrofit installation.²⁹

The rapid advancement in continuous cast technology for rod and sheet since the middle 1970's and the increasing dominance of the electrical end-use market has promoted the need for high-purity forms of copper. Technical improvements at the refinery level have included the use of permanent stainless steel or titanium starter sheets, improved solution chemistry, and automated system control leading to greater current efficiency and reduced impurity levels. As a result of reagent and production refinements, almost all domestic SX-EW production is high-quality cathode, which does not require further refining. The increase in continuous cast wire rod capacity has rendered the wire bar, an intermediate cast shape, almost obsolete and has effectively shifted intermediary casting from the refinery to the mill. Though it has not replaced deep-well casting of intermediate, cake slab, and billet, continuous casting technology also has been developed for the sheet and tube sectors.

Recycling.—The Institute of Scrap Recycling Industries Inc. (ISRI), recognized more than 50 classes of copper and copper alloy scrap. Although there were several grades of scrap within each, the major unalloyed scrap categories were No. 1 copper, which contained greater than 99% copper and often could be simply remelted, and No. 2 copper, which contained between 94.5% to 99% copper and usually had to be rerefined. In recent years, about 1.6 million tons of copper-base scrap,

containing an estimated 1.3 million tons of copper, was consumed annually in the United States. The largest scrap categories were as follows: No.1 copper, 26%; No. 2 copper, 25%; yellow brass, 21%; cartridge cases, 9%; automobile radiators, 7%; low-grade ashes and residues, 4%; red brass, 3%; and refinery brass, 2%. A wide variety of alloys made up the remaining 3%. Brass and copper tube mills consumed 65% of No. 1 copper and most of the cartridge cases and yellow brass, while the secondary smelters and ingot makers consumed 85% of the No. 2 scrap and most of the auto radiators and red brass scrap. With a few exceptions, U.S. wire rod mills did not consume scrap directly. One U.S. wire rod producing company constructed a continuous-process scrap refining and wire rod casting plant in which it processed No. 1 return scrap from making wire in its own plants.

Scrap was classified into two general categories called old scrap and new scrap, depending on its origins. New scrap, or manufacturing scrap, was generated during the fabrication of copper products and was returned to the mill for reprocessing (return scrap) or sold; it was not considered a new source of copper supply by the Bureau of Mines. New scrap was termed "run-a-round" or home scrap when it was generated internally at the plant consuming it.

Old scrap was generated from wornout, discarded, or obsolete copper products and was considered to be a reservoir of recoverable copper, and thus, was a source of supply. Since World War II, the ever-increasing reservoir of copper products in use, much of which was eventually recycled as "old" copper, provided annually between 19% and 33% of U.S. apparent demand and, on average, provided about 18% of world copper demand. It was estimated that the world copper reservoir of items in use or abandoned in place from which old scrap can be recovered exceeded 173 million tons. The U.S. old scrap reservoir was estimated to exceed 66 million tons or 38% of the world's total.

The rate of old scrap recovery was limited by copper's long life and its essential uses. On average, the rate of old scrap recovered in the United States, as a percentage of total scrap consumption, declined from 50%-60% in the 1940's to about 40% in the 1980's. The decline in the old scrap component, relative to new scrap consumed, could be correlated not only to an increasing manufacturing base from which

to generate new scrap, but to a changing demand pattern in which electrical uses became more dominant. Essential electrical uses, which now form greater than 70% of the market, were less likely to be scrapped. The long service life for utility and building cable, among other reasons, results in a practical limit to the amount and rate at which old scrap from this source can be recovered. The average life for old copper items has been estimated at about 20 years. Historically, old scrap recovery not only improved during periods of high refined copper prices, but also increased at any time that primary supplies became scarce, including the deep depression years of the 1930's.

In the United States, about 44% of total annual copper consumption was from copper in old and purchased new scrap. A similar percentage, 36%, was consumed in the EC, which collectively comprised one of the largest sources of copper scrap in the world. The intensity of scrap consumption varied in different parts of the copper industry. For example, scrap made up nearly all of the copper raw material for ingot makers, who made specialty alloy ingot for use in foundries. The same was true for mills producing yellow and leaded-yellow brass rod and for many copper tube mills. In both Europe and the United States, many of the smelters and refiners used scrap as feed, a trend that had been increasing. In recent years, about 40% of refined copper produced in Western Europe and about 24% of refined copper in the United States was derived from copper scrap. Copper scrap provided an average of about 19% of the world's refined copper annually. Direct melt copper and copper alloy scrap, used mostly by brass mills and foundries, was more than double that used to make refined copper.

Economic Factors

Prices.—Each copper product, including scrap, from mine through refinery has a distinct pricing mechanism linked, for the most part, to its copper content and the market price for refined copper. For example, copper concentrates, which contain between 20% and 30% copper, were purchased on the basis of recoverable copper content and anticipated smelter and refinery charges for processing.

Copper concentrates were sold under long-term contracts and included provisions for the delivery of specified quantities and the formula by which the price paid

was to be calculated. Contracts tended to be for periods as long as 10 years, though various terms were renegotiated at shorter intervals, and thus provided smelters with secure sources of materials. Without such contracts, new mines would find development financing difficult. Contracts provided for two types of charges. A treatment charge was assessed for every ton of concentrate by the smelter, and a refining charge was assessed for every pound of recoverable copper contained. There was generally a provision for the smelter to participate in copper price rises. There also were penalties for undesirable impurities, such as antimony, arsenic, and bismuth, and credits or additional payment for precious metals in the concentrates. Anticipated material losses were figured into credit terms.

Refined copper prices varied according to its form and purity. Historically, the price for refined wirebar was the "bellwether" price for refined copper, because this was the dominant form traded. With the advent of continuous casting for wire rod, however, high-grade cathode became the dominant form traded. In 1989, wirebar comprised less than 1% of refined copper trade. Copper wire rod prices were based on the refined copper cathode price plus a processing premium. In the case of scrap, the spread between the purchase price of scrap and refined copper must be sufficient to allow for processing costs.

Refined prices not only reflect the refined shape and its quality, but also to the manner in which it was priced, i.e., through producer's annually negotiated contracts or through the London Metal Exchange (LME) or COMEX. Trading in copper began on the LME January 1, 1877, and on the COMEX May 15, 1929. Futures contracts changed gradually over the years to correspond to the most active markets. The LME dropped its wirebar and standard cathode contracts and beginning January 1989, traded only the Grade A (high-grade) cathode contract. Similarly, COMEX converted to the high-grade cathode contract on January 1, 1990. The spot, or first position, price is most often quoted for the exchanges. To this price, however, various premiums and other charges were added to determine the actual price paid by the buyer.

Historically, the U.S. copper producers' price series was related to annually negotiated contract sales with price changes occurring at periodic intervals. When quoted, this price normally included a charge for delivery and insurance. Most

U.S. producers abandoned classic producer pricing during the 1970's and 1980's when inventories accumulated on the exchanges and the COMEX price became more influential and have adopted the first position COMEX price as a basis for contract pricing. During tight markets, however, such as that which has existed since late 1987, the speculative influence of a COMEX-based pricing system can prove to be less than satisfactory for the consumer. The conventional producer pricing system tended to provide less volatility in the market. Periods of speculative interest have usually been brief, however. The long period of stock surpluses since 1982 dampened speculative interest until the end of 1987. Since that time, both producers and consumers increasingly used futures contracts and the newly introduced copper options to hedge their sales and purchases and protect themselves against fluctuations in the market.

Table 11 gives average U.S. producers' copper price by decade in both constant 1987 dollars and current dollars. Based on constant dollars, one must look to the depression era of the 1930's to find prices as low as those occurring in the 1979-88 decade. Since that time, current dollar prices have approached the long-term 1901-89 constant dollar average of \$1.32 per pound.

¹Bureau of Mines. Nonferrous Metal Prices in the United States through 1988. Special publication, 1989, p. 33.

Copper prices not only responded to changes in the world economy but also to large copper inventory accumulation, copper cartel actions to restrict production, which were most effective before World War II, and from time to time to speculative influences on the commodity exchanges. The relationship of copper prices to U.S. supply levels are shown in figure 3. Significant events affecting copper supply and demand, prices, and inventory levels have been described in a recent paper by the Bureau of Mines.³⁰

Surplus refined copper inventories not only have accumulated in response to periods of economic recession, but also as a result of U.S. Government purchases for, and release from, the National Defense Stockpile. High commercial inventory levels had a depressing effect on prices when these surplus supplies were released onto the market to compete with newly mined copper. In addition, whenever commercial refined copper stocks, for whatever reason, fell below 1 month's supply at prevailing consumption rates, prices took a sharp upward climb. Trends in U.S. copper inventories since 1955 are shown in table 12.

Governmental Monetary, Trade, and Other Policies.—Government policies to control prices, levy tariffs, impose import quotas and export controls, provide price supports, lend monies for expansion and exploration, guarantee production purchases, levy taxes, and expand or contract the money supply all have had significant impact on copper supply and demand. In the United States, nearly all of these mechanisms were applied at one time or another. For example, prices were controlled at the end of World War I, during and after World War II, during the Korean war (1950-53), and near the end of the Vietnam war (1971-74).

U.S. export controls on copper and copper scrap were implemented during World War II and off and on through much of the 1950's and 1960's owing to recurring supply shortages during this period. On November 17, 1965, the U.S. Government announced a four-point program to reduce inflationary pressures on the price of copper that might impair the defense effort in Vietnam. The program called for release of material from the National Defense Stockpile, control of exports of copper and copper scrap for an indefinite period, legislation to suspend the 1.7% per pound import duty on copper, and the imposition of higher margin require-

Sources: Bureau of Mines; Aug. 1990.

ments on copper trading by COMEX to lessen speculation in the metal. Export controls on copper products were terminated finally in September 1970 as a result of the dramatic reversal in supply balance that year from shortage to surplus.

Many other countries also have had export controls on copper products. The EC imposed export controls on scrap from 1971 to yearend 1989. Some countries, such as Taiwan, used import or export licensing mechanisms to enforce trade restrictions. Because of pollution problems at the Tafa Industrial District, imports of pollution-prone materials such as insulated electric wire or cable have been banned by Taiwan's Environmental Protection Administration since October 1989. Sweden maintained export restrictions on copper waste and scrap. Japan has maintained restrictions on copper waste and scrap since 1965. After June 1986, scrap export from Japan was possible only through a license granted by the Agency for National Resources and Energy. Australia also maintained an export prohibition on copper and copper alloy scrap. New Zealand maintained export restrictions on copper ores, concentrates, matte, unwrought copper, and copper waste.

In addition, New Zealand had discretionary import licensing on copper bars and rods.

Most developed countries had most-favored-nation (MFN) duties on copper and copper products. Although copper ores and concentrates were frequently MFN duty free, duties often increased with various stages of processing. Most countries applied tariffs on wrought copper products and copper chemicals. All developed countries also granted duty-free or preferential rates under the 1974 Trade Act, Generalized System of Preferences (GSP) schemes for developing countries.

The U.S. GSP was started on January 1, 1976, and provided for duty-free treatment for up to 10 years on a wide range of articles, including copper, imported directly from any developing country designated as a beneficiary developing country. There were program limitations to GSP status based on the value of the imported article. The EC scheme for GSP granted duty-free access to imports of copper semimanufactures and manufactures from 89 developing and 38 least developed countries. The EC also granted duty free treatment to members of the Lome Convention and Mediterranean countries,

including Yugoslavia. Imported copper ores and concentrates enjoyed duty-free MFN status in Japan and accounted for about 70% of total Japanese imports. MFN rates for matte and copper scrap were also zero. Other unwrought copper was subject

to MFN rates ranging from 3.2% to 7.3% on the value. Imports of copper manufactures were subject to even higher rates.

In recent years, some countries sought to promote copper production through temporary guaranteed price-support systems,

as in Brazil, Chile (small- and medium-size mining sector), and the Philippines. Some countries used protective tariffs to aid domestic copper industries, as in Japan and the Republic of Korea; import restrictions, as in Brazil; and direct financial aid through loan guarantees and assumptions of company debt, as in the Philippines. In addition to drastic devaluations of currencies, these policies were effective in maintaining production in the face of falling dollar-denominated prices.

U.S. monetary policies have had a significant effect on the "real" price of copper, as well as on the general economic well-being and international competitiveness of the U.S. copper industry. The stable gold price following the Gold Reserve Act of 1934 had a general stabilizing effect on most industrial metal prices. Beginning with the monetary arrangements of the Bretton Woods Agreement of July 1945, which established the World Bank and the International Monetary Fund, a number of events had significant effect on the value of copper. One of the reasons for the extreme variability and inflation in copper prices since the 1960's was the destabilization of monetary arrangements that followed the U.S. Coinage Act of 1965, the cessation of silver certificates in 1967, the elimination of the gold reserve requirement in 1968, and the abandonment of fixed exchange rates in 1973. International debt reached record heights as a result of the Vietnam war and extensive borrowing done by the less developed countries in pursuit of economic expansion during the 1960's and early 1970's. These debts were compounded by the Organization of Petroleum Exporting Countries cartel action to increase the price of petroleum in 1974 and again in 1978. Oil shortages, inflationary prices, and economic downturns began to adversely affect world markets. Many of the developing countries adopted austerity measures because of heavy debt burdens, including devaluation of currencies by as much as 600% against the U.S. dollar. When inflationary pressures built up in the United States, the Federal Reserve Board restrained the money supply and increased interest rates.

The sustained strength of the U.S. dollar through the mid-1970's and 1980's and the series of devaluations by other countries to improve their balance of payments severely impacted the competitiveness of the U.S. copper industry. The effects of a strong dollar, high interest rates, and of high energy, labor, and environmental compliance

costs combined with the effect of copper surpluses and a depressed world market proved to be insurmountable for some mines. In response, the U.S. industry implemented innovative technology and productivity measures to cut costs. Considerable financial restructuring that often involved ownership changes also was necessary to gain sufficient capital to carry out the changes.

Operating Factors

Costs.—Production.—In recent years all domestic and most world producers endeavored to cut production costs in an effort to remain competitive through periods of prolonged depressed prices, such as that experienced during the mid-1980's. Domestic producers adjusted mine plans, reduced stripping ratios, and raised cutoff grades. Large capital investments were made in new in-pit crushing and conveying systems and on mill and concentrator expansions or replacements. Lower cost SX-EW capacity was expanded to process both oxidized ores and the higher grade waste dumps resulting from increased cutoff grades. Consolidation of assets through ownership changes improved operating efficiencies. Overall labor costs were reduced through improved employee productivity and wage and work-rule concessions by union and nonunion miners. Productivity at mines, in terms of worker hours per ton of copper produced, declined from more than 40 hours in 1980 to 28 hours in 1983 to an average 18 hours in the 1985-90 period. Similar cost savings were realized through smelter renovations and renegotiation of smelter contracts.

Byproduct values and the combined affects of inflation, Governmental monetary policy, and exchange rates also affected operating costs. A study prepared by the Minerals Availability Field Office, Bureau of Mines, Denver, CO, compared operating cost factors for 89 mines operating in both 1981 and 1987. Table 13 shows the impact that technical factors, byproduct values, and the combined affects of inflation and exchange rate (I/ER) had on production costs. In the United States, technological improvements overcame a competitive disadvantage from shifting byproduct credits and I/ER. Conversely, devaluation of the kwacha and improved byproduct prices allowed Zambia to remain competitive despite deteriorating technical factors.³¹

TABLE 13
FACTORS AFFECTING COPPER PRODUCTION COSTS FOR MAJOR
MEC COPPER PRODUCERS¹

(U.S. dollars per pound of copper)

	Production costs at common mines, 1981	Cost changes, 1981-87			Production costs at common mines, 1987

¹Porter, K. E. and P. R. Thomas. International Competitiveness of U.S. Copper Production, 1981-87. Bureau of Mines, Mineral Issues 1989, Table 2—3, p. 14.

²A decrease in byproduct prices between 1981 and 1987 results in an increase in production costs.

³Represents the combined effect of changes in inflation and exchange rates. A negative value reflects an over devaluation of local currency in relation to local inflation.

⁴Included are the impacts of changes in stripping ratios, feed grades, smelting and refining charges, labor force and wage rates, technology, and other changes that were implemented to reduce costs and improve competitive positions. It was not possible to disaggregate this category into individual factors.

Capital.—An analysis of total development costs for 60 new mine projects in Australia, Brazil, Botswana, Burma, Canada, Chile, Indonesia, Pakistan, Panama, Papua New Guinea, Peru, the Philippines, Portugal, Turkey, and the United States indicated an average of \$8,100 per ton of copper capacity must be invested to bring a new mine on-stream. Mine expansions at established mines, on the other hand, averaged \$3,200 per ton of copper capacity. A new SX-EW plant cost an average of \$2,400 per ton and a new smelter an average of \$1,800 per ton of copper to construct. New mine costs varied widely with location, size, and type of mine; for example, the 300,000-ton-per-year Escondida open pit mine in Chile was estimated to cost about \$3,200 per ton of copper, whereas the proposed Geddes underground mine in British Columbia and Olympic Dam Mine in Australia were around \$10,000 per ton, according to published estimates.

Total project financing also varied with location, size, and type of mine. Financing required for expansion at an existing mine ranged from \$48 million for the Morenci, AZ, expansion to \$500 million for the Chuquicamata, Chile, expansion. Of the total 60 projects analyzed, the average new mine would cost \$300 million to develop. Of 11 new mine projects in Peru, the average cost was about \$400 million. Some

individual projects, such as the Escondida Mine were to cost more than \$1 billion to bring into production. The average of 19 SX-EW projects was \$63 million, including expansions at existing plants.

Environmental Requirements.—The many environmental protection laws and regulations that have been promulgated in the United States since the late 1960's have impacted the copper industry in many ways. Most of the cost of compliance with environmental regulation was incurred at the smelter level. Although some regulations have resulted in offsetting costs through production of an additional salable product, such as sulfuric acid and reduced operating costs in modernized smelters, the net effect has been to increase total operating costs.

Laws and regulations in force that affect U.S. copper operations include those promulgated under the Federal Clean Water Act, the Clean Air Act of 1970, the National Environmental Policy Act of 1969, the Solid Waste Disposal Act (RCRA) of 1976, the Federal Surface Mining Control and Reclamation Act, the Toxic Substances Control Act, CERCLA, and numerous State laws concerned with mining techniques, reclamation of mined lands, air and water pollution, and solid waste disposal. Transportation of mineral and hazardous substances is also regulated. Ground water

regulations in Arizona were being developed and could have a greater impact on the copper industry than surface water quality. The new Arizona Aquifer Protection Permit program was expected to have important impact by 1990. Arizona already had a Groundwater Protection Permit Program.³²

Under the 1980 Bevill Amendment to RCRA, solid wastes from the extraction, beneficiation, and processing of ores and minerals were temporarily exempted from regulation as hazardous wastes under subtitle C, pending a comprehensive study to determine potential hazard and feasibility of treatment. EPA published an interim interpretation that placed wastes from exploration, mining, milling, smelting, and refining within the exclusion pending completion of a report to Congress. Acting under a court-ordered deadline, in 1986 EPA issued its regulatory determination in which it concluded that subtitle C regulation was not warranted at that time for mining and beneficiation wastes.

However, EPA's determination of the scope of the Bevill exclusion was challenged in court, and in October 1988, the court found that the intent of the Bevill exclusion was to include only those wastes from processing ores that met a special waste criteria of high volume and low hazard. In compliance with the court, on October 20, 1988, (see 53 FR 41288) EPA published a proposal to define the scope of the exclusion and listed 15 wastes it believed met the necessary criteria. On April 17, 1989, (see 54 FR 15316) the agency published a revised list containing 6 wastes that it believed met all the necessary criteria, and an additional 33 wastes that they proposed to conditionally retain pending further study. EPA felt that these 33 wastes met the high-volume criteria but that they had insufficient data to determine if they met a low-hazard criterion, established, for the first time, in the April proposal.

On September 1, 1989, (see 54 FR 36592) EPA published a Final Rule for Bevill exclusion criteria and proposed a final list of 5 wastes to be temporarily retained within Bevill, including slag from primary copper processing, as well as a reduced list of only 20 mineral processing wastes for conditional retention. Four wastes, including acid plant and scrubber blowdown from primary copper processing, were permanently removed from the Bevill exclusion. Two other copper associated wastes, bleed electrolyte from primary copper refining and wastewater

from primary selenium production, were omitted for further consideration of exclusion. This final rule contained a modified definition of "processing of ores and minerals" that incorporated leaching operations and roast leaching operations and a modified definition of "large volume." On September 25 (see FR 39298), EPA narrowed the list of conditionally retained wastes to only 13.

On January 23, 1990, EPA issued a final rule that retained 15 wastes, in addition to the 5 retained in the September 1 notice, within the exclusion pending preparation of a final report to Congress and subsequent Regulatory Determination. In addition to copper slag, the copper processing wastes retained were calcium sulfate wastewater treatment plant sludge from primary copper processing and slag tailings from primary copper processing.³³

The major thrust to the Clean Water Act (an amalgam of numerous acts and amendments, including the Federal Water Pollution Control Act of 1972 and Clean Water Act of 1977 and some 23 amendments) and its legal interpretations is through its elimination of pollutant discharge into navigable waterways through the National Pollutant Discharge Elimination System (NPDES), which provides for a permitting system to cleanup discharge of process wastewater, mine drainage water, storm-water runoff, and nonpoint sources. At U.S. copper mills, processing plants, and semifabricating plants most process water was reclaimed and reused, particularly in the southwest where there is a chronic water deficit. Mine water discharge problems usually occur when a mine and mill shuts down, largely because there is no place, such as a mill, to use the continuously discharging mine water.³⁴

Energy Requirements.—Open pit mining may extend to as much as 1,500 feet below the rim, and the energy required for hauling rock from such depths becomes an important cost factor. Hauling by truck was estimated to consume as much as 54% of total processes in the pit, including drilling, blasting, loading, hauling, and ancillary processes. Grinding and concentration consume about 45% of the energy used in the milling. The lower the ore grade, the more ore that must be processed and the finer the grinding required and thus, more energy consumed.

Major improvements in energy use in mining and milling have been made in recent years through improved strategies in

grinding, concentration, and ore transportation. The use of larger flotation cells has improved process efficiency and also lessened energy usage. Hydrometallurgical processes for copper recovery, such as the SX-EW recovery of copper, required more energy than pyrometallurgical processes. Electrowinning consumes 21 to 24 million British Thermal Units (Btu) per ton of cathode, or almost 20% of the total required from mine to refining stages. The in situ extraction of copper was the least energy consuming process, despite the low (50%) recovery. Energy consumption in dump leaching was higher owing to pumping requirements for leachate circulation and cementation. The combined total energy required for dump leaching, cementation, and refining is about 94 million Btu per ton of cathode copper.³⁵

Flash furnace technology and the Noranda and Mitsubishi continuous smelting technologies have resulted in energy savings. Energy consumption in millions of Btu per ton of refined copper recovered were reported as follows: Outokumpu flash smelting (18.92 million Btu), Inco flash smelting (21.25 million Btu), Noranda continuous smelting (24 million Btu), Mitsubishi continuous smelting (19.16 million Btu), and Oxy Fuel Reverberatory smelting (26.62 million Btu).³⁶

TABLE 27—Continued

**STOCKS AND CONSUMPTION OF PURCHASED COPPER SCRAP IN THE UNITED STATES IN 1989,
BY CLASS OF CONSUMER AND TYPE OF SCRAP**
(Metric tons, gross weight)

Class of consumer and type of scrap	Stocks, Jan. 1 ¹	Net receipts	Consumption			Stocks, Dec. 31
			New scrap	Old scrap	Total	
Cartridge cases	15,973	126,241	125,235	988	126,223	10,874
Automobile radiators (unsweated)	3,981	94,140	629	95,766	96,395	1,726
Bronze	2,575	20,675	7,247	13,665	20,912	2,505
Nickel silver and cupronickel	2,716	23,258	19,858	3,703	23,561	2,289
Low brass	3,128	22,105	19,844	2,348	22,192	2,231
Aluminum bronze	801	2,711	1,419	1,277	2,696	816
Low-grade scrap and residues ⁴	27,981	133,600	58,273	84,510	142,783	18,798
Total	115,864	1,611,997	943,501	673,258	1,616,759	100,725

¹Revised from 1988 closing stocks.²Brass and wire-rod mill stocks include home scrap; purchased scrap consumption is assumed equal to receipts, so lines in "BRASS AND WIRE-ROD MILLS" and "GRAND TOTAL" sections do not balance.³Of the total shown, chemical plants reported the following: unalloyed copper scrap, 342 tons new and 1,687 tons old.⁴Includes refinery brass.

TABLE 28

**CONSUMPTION OF COPPER AND BRASS MATERIALS IN THE
UNITED STATES, BY ITEM**
(Metric tons)

Item	Brass mills	Wire- rod mills	Foundries, chemical plants, miscellaneous users	Secondary smelters- refiners	Total
1988: ¹					
Copper scrap	1757,042	W	64,320	784,479	1,605,841
Refined copper ²	493,215	1,667,190	47,412	2,607	2,210,424

^eEstimated. ^pPreliminary. ^rRevised.

¹Data represent copper content by analysis of concentrates produced except where otherwise noted. Table includes data available through June 27, 1990.

²Reported figure.

³Less than 50 tons.

⁴Copper content of pelletized nickel-copper matte produced in smelter.

⁵Anode copper recovered in Canada from domestic concentrates plus exports of payable copper in concentrates and matte.

⁶Recoverable copper content by analysis of concentrates for export plus nonduplicative total of copper content of all metal and metal products produced indigenously from domestic ores and concentrates; includes leach production for electrowinning in Chile and Portugal.

⁷Copper content of cement copper.

⁸Recoverable content.

⁹Copper content by analysis of ore mined.

¹⁰Includes electrowon from concentrates roast-leached.

¹¹Data are for fiscal years beginning Apr. 1 of year stated. Zambian-mined copper reported recovered during smelting and electrowinning.

^eEstimated. ^PPreliminary. ^rRevised.¹This table includes total production of copper metal at the unrefined stage, including low-grade cathode produced by electrowinning methods. The smelter feed may be derived from ore, concentrates, copper precipitate or matte (primary), and/or scrap (secondary). To the extent possible, primary and secondary output of each country is shown separately. In some cases, total smelter production is officially reported, but the distribution between primary and secondary has been estimated. Table includes data available through June 27, 1990.²Argentina presumably produces some smelter copper utilizing its own small mine output together with domestically produced cement copper and possibly using other raw materials including scrap, but the levels of such output cannot be reliably estimated.³Reported figure.⁴Data include electrowon production; estimated to be 35,000 to 45,000 metric tons per year that is fire refined and cast into wirebars; detailed data are not available.⁵Figures for U.S. primary smelter production may include a small amount of copper derived from precipitates shipped directly to the smelter for further processing; production derived from electrowinning and fire refining is not included. Copper content of precipitates shipped directly to smelter are as follows, in metric tons: 1985—90,938; 1986—89,122; 1987—71,173; 1988—49,356; and 1989—34,485.⁶For fiscal years beginning Apr. 1 of year stated. Electrowon is based on total primary production and represents metal that is further refined; also includes a small amount of leach material from the Chanobie Mine. Smelter production also includes toll material processed for Zaire.⁷Refined figure; unrefined data not available. Includes production from low-grade electrowon cathodes produced in nickel processing.⁸Data may not add to totals shown because of independent rounding.

^eEstimated. ^pPreliminary. ^rRevised.

¹This table includes total production of refined copper, whether produced by pyrometallurgical or electrolytic refining methods and whether derived from primary unrefined copper or from scrap. Copper cathode derived from electrowinning processing is also included. Table includes data available through June 27, 1990.

²Reported figure.

³Data may not add to totals shown because of independent rounding.

⁴May include secondary.

⁵Data are for fiscal year beginning Apr. 1 of that stated.

⁶Electrowon covers only presumably high-grade cathodes reported as "finished product leach cathodes." Other, in addition to electro-refined cathodes, includes "finished product refined shapes" presumably cast from electro-refined cathodes, high grade electrowon cathodes or any blister/anodes and low-grade electrowon cathodes that were fire-refined.

⁷May not include copper-nickel matte (copper content more than 6,000 tons per year) imported from Botswana for toll refining in 1986-89.

DIATOMITE

By Lawrence L. Davis

Mr. Davis, a physical scientist with 34 years of industry and Bureau of Mines experience, has been acting commodity specialist for diatomite since 1989. Domestic survey data were prepared by Blanche S. Hughes, mineral data assistant; the international data table was prepared by Giovanni Jacarepaqua, international data assistant.

U.S. sales of processed diatomite decreased slightly to 617,000 metric tons valued at \$137 million. Seven companies processed diatomite at 11 plants in 5 States. California continued to be the leading State followed by Nevada, Washington, Oregon, and Arizona. Major domestic producers were Manville Products Corp., with operations at Lompoc, CA; Grefco Inc., Dicalite Div., at Lompoc and Burney, CA, and Mina, NV; Eagle-Picher Minerals Inc. at Sparks and Lovelock, NV, and Vale, OR; and Witco Corp., Inorganic Specialties Div., at Quincy, WA. Other producers were Whitecliff Industries, Mammoth, AZ; CR Minerals Corp., Fernley, NV; and Oil-Dri Production Co., Christmas Valley, OR.

CONSUMPTION AND USES

Apparent domestic consumption of processed diatomite decreased slightly to 481,000 metric tons. The major use of diatomite is in filtration to separate suspended solids in liquids. In 1989, domestic and export sales of filter-grade diatomite were 441,000 tons, slightly more than in 1988. Sales of diatomite as a filler, the second largest use, were 90,000 tons, about 15% less than in 1988.

PRICES AND FOREIGN TRADE

The average unit value of sales for processed diatomite was \$222 per ton. This

was slightly less than in 1988. U.S. exports of processed diatomite were 137,000 tons, about 7% less than in 1988. Average unit value was \$302 per ton compared with \$268 per ton in 1988. Diatomite was exported to 67 countries. The following four countries combined received 37% of the total exported: Japan, 16,600 tons; Australia, 12,600 tons; the Federal Republic of Germany, 11,100 tons; and the United Kingdom, 10,100 tons. U.S. exports represented 22% of domestic production. Imports of diatomite were 838 tons, of which 84% was supplied by Mexico.

WORLD REVIEW

World production was estimated to be 1.8 million tons in 1989. The United States remained the world's leading producer followed by Romania, the U.S.S.R., and France. These four countries accounted for 75% of world production.

FELDSPAR, NEPHELINE SYENITE, AND APLITE

By Michael J. Potter

Mr. Potter, a physical scientist with 23 years industry and Bureau of Mines experience, has been the commodity specialist for feldspar since 1976. Domestic survey data were prepared by Linder Roberts, mineral data assistant; and international data table was prepared by Virginia Woodson, international data assistant.

Total U.S. feldspar production in 1989, including soda, potash, mixed feldspar, and feldspar-silica mixtures, was 720,000 short tons with a value of \$28 million. Imports of nepheline syenite were an estimated 334,000 tons with a total value of \$12.3 million.

FELDSPAR

Domestic Data Coverage

Domestic production data for feldspar are developed by the Bureau of Mines by means of a voluntary survey. Of the 14 active operations, 11, or 79%, responded, representing an estimated 83% of the total production data for feldspar shown in table 1. The remaining 17% was estimated from prior year data adjusted to current industry levels.

Legislation and Government Programs

According to provisions of the Tax Reform Act of 1969, which continued in force throughout 1989, the depletion rate allowed on domestic and foreign feldspar production was 14%.

Production

Feldspar or feldspar-silica sand was mined in seven States, led by North Carolina and followed in descending order by Connecticut, California (estimated), Georgia, Oklahoma, Idaho, and South Dakota. North Carolina accounted for 67% of the total. Twelve U.S. companies operating 14 beneficiating plants and 1 grinding plant produced feldspar or feldspar-silica mixtures for shipment to more than 31 States and foreign countries, including Canada and Mexico. Of the 12 companies, 3 produced potash feldspar, and the remainder produced soda or mixed

feldspar or feldspathic sand mixtures. North Carolina had six plants, California had three, and Connecticut, Georgia, Idaho, Oklahoma, and South Dakota each had one. The grinding plant was located in South Carolina.

The Bureau of Mines uses a criterion of 8% minimum K₂O content in collecting data for potash feldspar.

California Silica Products Co. withdrew from glass sand supply at the end of 1988 and was to concentrate on the recreational and construction sectors. Beginning in January 1989, Corona Industrial Sand Co. (CISCO), Corona, CA, and Unimin Corp., Emmett, ID, were added as producers of feldspar silica sand.

Consumption and Uses

Of the total feldspar sold or used in the United States, 54% went into glass-

making, including container glass and glass fiber, and 45% was used in pottery. Fewer housing starts in 1989 resulted in decreased feldspar usage in plumbing fixtures and tile compared to the previous year.

Processed feldspar is added to glass-making formulas for its alumina and alkali contents. Alumina enhances the workability of molten glass and improves the finished product by giving it better chemical stability. The increased workability facilitates the operation of automatic machines for shaping jars and bottles. Greater chemical stability broadens the usefulness of the containers. Feldspar is used in ceramic mixtures, such as those for the making of vitreous china and porcelain enamels, principally as a flux. It fuses at a temperature below the melting point of most of the other ingredients. It also

performs as a vitreous binder to cement particles of various crystalline substances present in ceramic mixtures. Feldspar serves advantageously in abrasives and scouring soaps. It forms a mild abrasive but is soft enough to avoid injury to the article being cleaned. Feldspar is also used as a filler in paint, foam rubber, and plastics. The raw materials most often substituted for feldspar in a number of end uses are aplite and nepheline syenite. Aplite, which contains plagioclase (lime-soda) feldspar, is mined in Virginia and used mostly in glassmaking. Nepheline syenite is a coarse crystalline rock resembling granite but consisting

principally of feldspathoid minerals—sodium-potassium feldspars and nepheline—with little or no free quartz. All of the nepheline syenite consumed in the United States in the manufacture of glass and ceramics and in filler applications is imported from Ontario, Canada.

Other materials that can serve as substitutes for feldspar in the glass and ceramics industries include talc, pyrophyllite, electric-furnace slag, and Cornwall stone.

The quantity of potash feldspar sold or used in 1989 was 80,500 tons with a value of \$6.4 million.

Prices

Industrial Minerals (London), listed the following prices for feldspar, per short ton, f.o.b. plant, bulk:

Producing States	1988	1989
Ceramic grade:		
Middleton, CT, minus 200 mesh	\$53.25	\$67.50
Monticello, GA, 200 mesh, high potash	73.50	82.50
Spruce Pine, NC, 170-250 mesh	44.00	50.00
Glass grade:		
Middleton, CT, 96% plus 200 mesh	39.00	45.00
Monticello, GA, 92% plus 200 mesh, high potash	54.00	64.75
Spruce Pine, NC, 97.8% plus 200 mesh	30.75	32.50

World Review

Capacity.—The data in table 9 are rated capacity for mines and refineries as of December 31, 1989. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Because actual capacity data were not available, recent peak production during the past 5 years for the United States and foreign countries was considered to be equal to rated capacity.

Ethiopia.—A feasibility study and engineering design were being prepared for the production of 4,400 tons per year each of kaolin, feldspar, and quartz. These products would be used as raw materials for the Ceramics Manufacturing Complex to be established at Awassa. The kaolin and feldspar deposits were 267 miles from Addis Ababa. Laboratory tests on feldspar from the Kenticha deposit showed that the material was suitable for use in ceramics and glass. Development of the

industrial minerals sector is the responsibility of the Industrial Minerals Division of the Ethiopian Mineral Resources Development Corp.¹

Turkey.—Laboratory research was performed on feldspar ore, from Simav in western Turkey, containing 98% feldspar and quartz, 1.5% micas and 0.5% accessory minerals such as garnet, tourmaline, magnetite, and hematite. The research, done at the Technical University of Istanbul, included geologic, petrographic, and mineral processing studies. The optimum mineral processing scheme included size reduction, classification, and flotation.²

NEPHELINE SYENITE

Nepheline syenite was produced by Indusmin Ltd., a division of Falconbridge Ltd., from two operations at Blue Mountain, and Nephton, Ontario, Canada. Output in 1988, the latest year for which information was available,

was at least 660,000 tons. The largest market for the mineral has been the glass industry. Applications were being pursued in the adhesives, rubber, and plastics industries.³

In Norway, nepheline syenite was produced at the Elkem Nefelin A/S, underground mining operation on the arctic island of Stjernøy. Output was 287,000 tons in 1988. Sales were largely to markets in Western Europe.⁴

Prices for Canadian nepheline syenite listed in Industrial Minerals (London), December 1989, were \$22 to \$28 per ton for glass grade, 30 mesh, bulk, carlots-trucklots, depending on iron content; \$67 per ton for ceramic grade, 200 mesh, bagged, 10-ton lots; and \$79 to \$91 per ton for filler-extender grade, bagged.

In China, 14 nepheline syenite bodies with a total area of approximately 0.4 square miles have been found, mainly in southwestern China. Because of its high iron content, the nepheline syenite's application is limited. Another nepheline ore, apatite ore, is found only in Sichuan province. This ore is

characterized by high contents of K₂O plus Na₂O, Al₂O₃, and nepheline, and low iron content. The ore can be beneficiated by crushing, grinding, and magnetic separation, yielding a product that can be used in glass and ceramics.⁵

APLITE

Aplite is a feldspar mineral that has more than one geological definition. However, aplite from the one active U.S. operation contains primarily lime-soda feldspar. Aplite, usually unsuitable for use in ceramics, has been used in the manufacture of glass when it is sufficiently low in iron.

Aplite of glassmaking quality was produced in the United States by The Feldspar Corp. near Montpelier, Hanover County, VA.

Domestic output decreased compared with that of 1988. The data are company proprietary and cannot be released for publication. Aplite traditionally has a somewhat lower price than feldspar. Industrial Minerals (London), December 1989, gave a value of \$25.75 per ton for glass grade, bulk, 100% plus 200 mesh, f.o.b. Montpelier, VA.

With an annual production of 500,000 tons to 580,000 tons, Japan has been the world's largest producer of apelite. Italy is the world's largest producer of feldspathic materials, including feldspar and apelite; published figures did not give the relative breakdown of the two minerals.

OUTLOOK

The outlook for the near future is for feldspathic demand to remain generally at 1989 levels. Continued competition from imported nepheline syenite, as well as increased use of recycled glass (cullet) and lightweighting of glass containers, will reduce the demand for feldspathic materials in glass manufacturing.

If housing starts rebound moderately from 1989 levels, requirements for feldspathics in plumbing fixtures, tile and glass fiber for insulation will be maintained. This should offset the drop of feldspathic usage in glass demand.

BACKGROUND

Definitions, Grades, and Specifications

Feldspar is the general term used to designate a group of closely related minerals, especially abundant in igneous rocks and consisting essentially of aluminum silicates in combination with varying proportions of potassium, sodium, and calcium. The principal feldspar types are orthoclase or microcline, both K₂O·Al₂O₃·6SiO₂, and anorthite, CaO·Al₂O₃·2SiO₂. Specimens of feldspar closely approaching these ideal compositions are seldom encountered in nature, however, and nearly all potash feldspars contain significant proportions of soda feldspar. Albite, or soda feldspar, and anorthite are the theoretical end members of a continuous compositional series known as the plagioclase feldspars, none of which is ordinarily without at least a minor admixture of potash. Commercially speaking, "potash spar" is feldspar containing 10% or more K₂O; "soda spar" contains 7% or more Na₂O.

Perthite is the name given to material consisting of orthoclase or microcline and containing crystals that are intergrown with crystals of albite. Most of the feldspar of commerce can be classified most correctly as perthite.

Alaskite is a relatively coarse grained, granite-like feldspar ore which occurs in the Spruce Pine district of North Carolina. The principal mineral ingredients of this ore are approximately: plagioclase, 45%; quartz, 25%; microcline, 20%; and muscovite mica, 10%. Minor amounts of other minerals are also present.⁶ Beneficiated feldspar from alaskite comprises a major portion of total U.S. feldspar output.

Feldspar for glass manufacturing, ordinarily ground to 20 to 40 mesh, usually contains 4% to 6% K₂O, 5% to 7% Na₂O, and approximately 19% Al₂O₃. Material for this purpose may be sold as a feldspar concentrate low in free quartz or else in the form of a mixture containing feldspar and quartz with harmful impurities removed. In glass-grade feldspar, the iron content, expressed as Fe₂O₃, is approximately 0.08% for high-quality clear glass. Typically, 150 to 200 pounds of ground feldspar is used to produce 1 ton of container glass.

Feldspar with a high potash-to-soda ratio is often preferred for pottery making, and spar for this purpose is usually ground to minus 200 mesh. Potash spar ground to 120 or 140 mesh is usually specified for use in porcelain enamel, and even traces of such impurities as garnet, hornblende, tourmaline, and biotite mica ordinarily are not tolerated. Both potash and soda feldspars, ground to minus 200 mesh, are used in glazing.

Pottery-grade feldspar for whiteware and similar ceramic products may range from 5% to 14% in K₂O content and usually is ground to 200 mesh or finer. Limitations on iron content may be even

more stringent than for glass grade; Fe₂O₃ content may be 0.07%. Feldspar for use in filler applications, such as for foam rubber products, may be similar to pottery spar in fineness of grind and chemical composition, although more free quartz is often accepted; sometimes material for this purpose may be held to particle-size specifications expressed in micrometers.

Industry Structure

Among the largest U.S. feldspar producers in 1989 were The Feldspar Corp., with operations in Connecticut, Georgia, and North Carolina, and Indusmin Inc. and Unimin Corp. in

North Carolina. Feldspar, aplite and imported nepheline syenite from Canada compete against each other, especially in the eastern United States. Shipping costs play a big role in determining the market radius of each of the three feldspathic products.

Feldspar was produced in more than

40 other countries in 1989. Italy has reportedly had the highest output of feldspathic materials in recent years; much of that country's production is believed to be aplite (lime-soda feldspar). Other significant feldspar producers in Western Europe included France and the Federal Republic of Germany. Norway is the only other producer of nepheline syenite in the Western World besides Canada. There has been considerable trade in feldspathic materials in Western Europe because of the close proximity of the countries involved. International trade in other parts of the world is somewhat limited.

Geology-Resources

Feldspar, one of the most abundant minerals in the Earth's crust, is found in significant amounts in some sedimentary strata and in nearly all igneous formations. Workable deposits of feldspar are probably widely distributed throughout most of the world, and the total quantity of the mineral potentially available is very large.

It has been estimated that feldspar constitutes 60% of all crystalline igneous rocks. Granted sufficient demand and economic incentive, the mineral could be extracted from the world's granite, a source that is extremely large.

Data are not available on the quantity of feldspar in either domestic or foreign deposits. However, U.S. reserves are estimated to be quite large in the Spruce Pine district of North Carolina alone.

Feldspar concentrations of potential economic interest exist in many pegmatites, granites, and other granitic rocks, and as accumulations of certain residual sands on ocean beaches or river banks.

Pegmatites are masses of coarsely crystalline rocks of igneous origin. Pegmatite bodies may range in size from small pods to extensive formations measuring hundreds or even thousands of feet. The principal feldspar ore bodies of pegmatitic type currently being exploited in the United States are located in Connecticut, North Carolina, Georgia, and South Dakota. Potentially exploitable pegmatite bodies are known to exist in other areas.

The only feldspathic sand deposits now being mined in the United States are in California, Idaho and Okla-

TABLE 10—Continued
FELDSPAR: WORLD PRODUCTION, BY COUNTRY¹
 (Thousand short tons)

Country ²	1985	1986	1987	1988 ^P	1989 ^c
Yugoslavia	54	53	50	39	39
Zambia	(⁷)	(⁷)	(⁷)	(⁷)	(⁷)
Zimbabwe	3	2	3	4	4
Total	^r 4,452	^r 4,430	4,769	5,150	5,155

^c Estimated. ^P Preliminary. ^r Revised.

¹ Table includes data available through Apr. 18, 1990.

² In addition to the countries listed, Czechoslovakia, Madagascar and Namibia produce feldspar, but output is not officially reported and available general information is inadequate for the formulation of reliable estimates of output levels.

³ Series excludes production of leucite and sodalite; data consist only of that material reported by Brazil under the heading of "Feldspar." Data represent the sum of (1) run-of-mine production for direct sale and (2) salable beneficiated product; total run-of-mine feldspar production was as follows in thousand short tons: 1985—109; 1986—116; 1987—109; 1988—154; and 1989—150 (estimated).

⁴ Reported figure.

⁵ In addition, the following quantities of aplite concentrate were produced in thousand short tons: 1985—517; 1986—504 (revised); 1987—514 (revised); 1988—580; and 1989—625 (estimated).

⁶ Revised to zero.

⁷ Less than 1/2 unit.

⁸ Revised to less than 1/2 unit.

⁹ Excludes nepheline syenite.

¹⁰ Includes pegmatite.

TABLE 11
U.S. IMPORTS FOR CONSUMPTION OF NEPHELINE SYENITE

Ground	2529.10	2.8% ad valorem.	30% ad valorem.

homa. Other accumulations of feldspathic sands in the United States offer possibilities as future sources of feldspar supply.

Granites are widely distributed igneous rocks of plutonic origin. Granites are present as major components of whole mountain ranges, and the dimensions of granite bodies can often be stated in miles. The important constituent minerals in granites are much the same as those in pegmatites, although there are likely to be significant differences in the respective proportions. Because of economic and technologic considerations, commercial utilization of granite in the United States as a source of feldspar is not presently taking place.

Technology

Most feldspathic rocks can be quarried by open pit procedures. High-grade, selectively mined feldspar from pegmatites may be dry processed, passing consecutively through jaw crushers, rolls, and pebble mills before being subjected to high-intensity magnetic or electrostatic treatment to bring the iron content down to an acceptable level.

The customary procedure applied to most massive deposits, such as alaskite, begins with drilling, blasting, and drop-ball breaking at the quarry, followed by primary and secondary crushing and fine grinding in jaw crushers, cone crushers, and rod mills, respectively. The sequence typically continues with acid-circuit flotation in three stages, each stage preceded by desliming and conditioning. The first flotation step typically depends on an amine collector to float off and remove mica, and the second uses sulfonated oils to separate iron-bearing minerals, most notably garnet. The third step, flotation with another amine collector, leaves behind a residue that consists chiefly of quartz. Sometimes the third step is bypassed, leaving a feldspar-silica mixture, which can be used with little or no additional processing as furnace-feed ingredients in the manufacture of glass.

The flotation-cake feldspar or feldspar-silica mixture is dewatered in filters or drain bins and dried in rotary driers for use as glass-grade feldspar. Some material is further ground in pebble mills as pottery spar and for other uses.

Byproducts and Coproducts

Feldspar was obtained as a coproduct in 1989 from two companies mining and processing lithium ores and one company treating weathered pegmatite ore containing mica and kaolin. Coproduct recovery of mica and silica sand was reported by some feldspar processors.

Economic Factors

Feldspar is largely sold in bulk and moved by rail hopper cars. Transportation can comprise 50% or more of the total delivered cost. Some shipments are by truck. Most feldspar products are shipped less than 1,000 miles. An exception is premium-grade high-potash feldspar.

FERROALLOYS

By Clark R. Neuharth

Mr. Neuharth, a physical scientist with 7 years Bureau of Mines experience, has been a commodity specialist since 1986 covering silicon initially and ferroalloys currently. Domestic survey data were prepared by Jo-Ann Sterling and Elizabeth Voyatzis, mineral data assistants, and Mr. Neuharth; the international data tables were prepared by Peter Roetzel, international data assistant.

Overall domestic demand for ferroalloys and related metals declined approximately 5% compared with that of 1988 owing to decreased production of iron and steel. Free market prices for most ferroalloys dropped throughout most of the year, stabilizing somewhat at yearend. World production was essentially unchanged.

LEGISLATION AND GOVERNMENT PROGRAMS

The South Carolina Research Authority, a public corporation created by the State's government to promote high-technology industries, received seed funding from the Defense Logistics Agency (DLA) to support a research project aimed at utilizing plasma arc smelting technology in the production of ferrochromium. Macalloy Corp., Arthur D. Little, Clemson University, and the Massachusetts Institute of Technology, are principals in the project. In the first stage of the project, Macalloy was to build a pilot scale (2,000-kilowatt) smelter that would produce about 1,000 pounds of ferrochromium per hour at the company's plant in Charleston, SC. Site preparation was nearly complete at yearend; assembly of the furnace was scheduled to be completed by April 1990.

STRATEGIC CONSIDERATIONS

Ferroalloys are essential in the production of iron and steel, making their continued availability a matter of strategic importance. Silicon metal is consumed in the aluminum industry as an alloying agent and in the chemical industry as a raw material in silicon-based chemicals. The domestic

ferroalloys industry has been in a state of decline since its peak years in the mid-1970's owing to competition from low-priced imports. Since that time, most of the producers of chromium- and manganese-containing alloys have quit producing those materials or gone out of business altogether.

Security of Supply

The U.S. dependence on foreign sources for most ferroalloy materials has risen steadily over the past two decades. Net import reliance for chromium-, manganese-, and silicon-containing materials was estimated to be 78%, 100%, and 23%, respectively, in 1989. Commercially, the United States is 100% dependent on foreign sources for chromium ore (chromite) and manganese ore used to make ferroalloys containing those elements; however, some of these ores and their respective alloys, along with materials containing columbium and tungsten, are held in the National Defense Stockpile (NDS). Supplies of raw materials necessary to produce silicon-containing ferroalloys and metal are readily available domestically, but the capacity to produce these materials has declined in recent years.

Stockpile

DLA renewed contracts for the upgrading of ferroalloy materials in the NDS. Macalloy was awarded a contract to convert 126,053 short tons of chromite to high-carbon ferrochromium in 1990 and an additional 126,341 short tons in 1991 at a cost of approximately \$30 million per year. The contract included an option to convert a total of 264,791 short tons in 1992 and 1993. Elkem Metals Co. was awarded a contract to convert 132,861 short tons and 132,244 short tons of manganese ore to high-carbon ferromanganese in 1990 and 1991, respectively, at a total cost of approximately \$82 million. The manganese con-

tract also included a third and fourth year option in which an additional 264,791 short tons of manganese ore would be converted to high-carbon ferromanganese. Elkem also was awarded a contract for the conversion of low-carbon ferrochromium to vacuum melting-grade electrolytic chromium metal. The conversion will yield 1,150 short tons of chromium metal at a cost of \$7.2 million.

TABLE 1
GOVERNMENT INVENTORY
OF FERROALLOYS,
DECEMBER 31, 1989

(Thousand short tons of alloy)

Alloy	Stock- pile grade	Non- Stock- pile grade	Total
Ferrochromium:			
High-carbon	640	1	641
Low-carbon	300	19	319
Ferrochromium-silicon	57	1	58
Ferrocolumbium (contained columbium)	.3	.2	.5
Ferromanganese:			
High-carbon	812	—	812
Medium-carbon	29	—	29
Ferrotungsten (contained tungsten)	.4	.6	1
Silicomanganese	24	—	24

ISSUES

The Office of the United States Trade Representative (USTR) denied the U.S. Ferroalloys Association's 1988 request to end the duty-free status under the Generalized System of Preferences (GSP) for imports of silicon metal (99.00% to 99.99% purity) coming from Argentina and

Yugoslavia. The duty on this product would be 5.3% ad valorem without GSP status. Both of these countries were considered by the U.S. industry to be longtime producers of silicon metal; however, individually, they did not meet the criterion for GSP removal, which is to account for more than 25% of total imports of a product. Imports of the 99.00%- to 99.99%-pure silicon metal from the two countries combined accounted for about 30% of all silicon metal imports into the United States over the past few years. The USTR did reject GSP status for import of ferrosilicon in the 55% to 80% silicon range (above and below 3% calcium) and ferrosilicon-manganese from Brazil.

As part of the United States-Canadian Free Trade Agreement, duties on imports of all forms of ferromanganese, silicomanganese, silicon-containing ferroalloys, and ferrochromium silicon from Canada were lifted effective January 1, 1989. For some other manganese materials and silicon metal of Canadian origin, scheduled stages of reduction were established in which some duties would be reduced to zero by January 1, 1993, and others by January 1, 1998.

PRODUCTION

Domestic production of ferroalloys and related metals overall decreased 2% compared with that of 1988. Shipments overall were unchanged from those of the previous year. Production of silicon-containing ferroalloys and silicon metal overall increased 2% compared with that of 1988, but near the end of the year, major producers were facing cutbacks because of oversupply, low prices, and much needed maintenance. SKW Alloys Inc. Elkem, and Globe Metallurgical Inc. were among the silicon producers that announced significant maintenance programs and/or production cutbacks. Elkem was the only producer of ferromanganese and silicomanganese. Elkem and Macalloy continued to produce high-carbon ferrochromium. Macalloy's ferrochromium smelter was shut down for a few weeks owing to erratic power supplies following Hurricane Hugo. Ferronickel was produced domestically for the first time in 3 years as Glenbrook Nickel Co. poured its first ingot on August 12.

Shieldalloy Metallurgical Corp. purchased Frankel Metal Co. (Detroit, MI), a titanium scrap processor. Shieldalloy of

ficials said the acquisition would broaden its base as a supplier of titanium-bearing materials. Shieldalloy also concluded its purchase of Affiliated Metals and Minerals Inc.'s 20% interest in a joint-venture vanadium project to be situated in Pittsburgh, PA; Shieldalloy already owned the remaining 80% of the venture. The plant was scheduled to be operational by mid-1990. The process would involve the conversion of vanadium-bearing residues to an intermediate step for the eventual production of ferrovanadium.

Strategic Minerals Corp. (Stratcor), Danbury, CT, completed expansion and renovation of its Niagara Falls, NY, facility. The expansion included new furnace operations that were to increase the company's worldwide output of nitrogen-bearing vanadium ferroalloy, trade-named Nitrovan. In the past, Stratcor had produced Nitrovan only in the Republic of South Africa.

The Glenbrook Nickel operation, which was previously owned and operated by the M.A. Hanna Co., started production in August at Riddle, OR. Universal Consolidated Co. initiated the venture when they bought the property from M.A. Hanna in 1988. Universal Consolidated then sold the project to Cominco American Resources (a wholly owned subsidiary of Cominco Resources International Ltd.) and USA Investments in April of 1989. In June, the operation was supplied power by the Bonneville Power Administration after the installation of a new transformer at the power substation. The plant began producing ferrosilicon, which is consumed in the ferronickel process, and upgrading stockpiled nickel ore in July, and tapped the first ferronickel the following month. In November, USA Investments' interest in the project was sold to Cominco Resources International. Although stockpiled ore (6 million short tons containing 0.7% nickel) that had accumulated over 30 years while M.A. Hanna operated the smelter was being used for feed initially, the company was facing either reopening the Riddle Mine or importing ore as a means of lowering production costs. The company's goal of producing 1 million pounds of nickel contained in ferronickel per month was not met in 1989, but was expected to be reached sometime in 1990.

Globe Metallurgical Inc., Cleveland, OH, purchased Materials & Methods Ltd. (London) to broaden its European presence in the worldwide marketing of foundry processes and ferroalloys. Globe expected to double its current European revenue (5%

of total sales) as a result of the deal. This was Globe's first major acquisition since its management buyout in 1987. In July, Globe terminated its 34-year-old relationship with Pickands Mather & Co., a subsidiary of Cleveland-Cliffs Inc., and formed an internal sales force in what company officials said was an attempt to increase the quality of service and technical support to its customers. In November, Cleveland-Cliffs announced that it was selling the metallurgical sales business it had acquired with the purchase of Pickands Mather in 1986.

American Alloys Inc. began producing silicon metal during the third quarter at its Graham, WV, facility (previously operated by Foote Mineral Co.).

In December, Boulder Gold NL (Australia) entered into an agreement with DCC Equities Ltd. (Canada), which includes as its shareholders Dynamic Capital Corp., Placer Dome Inc., Corona Corp., and the Canadian, Imperial Bank of Commerce, to finance a feasibility study of the planned Mountain View ferrochromium project near Columbus, MT. Chrome Corp. of America, Boulder Gold's U.S.-owned subsidiary, would manage the project during the feasibility stage. The project, if determined feasible, would utilize the Coal Ore Direct Iron Reduction process for chromite developed by Krupp Industrietchnik (Federal Republic of Germany). Smelter feed for the operation initially could come from an existing 600,000-ton chromite stockpile at Columbus; however, continued operation would require reopening of the Mouat chromite mine, which is estimated to have a life of about 20 years.

The Ferroalloys Association reported that its member companies consumed approximately the same amount of electricity in 1989 as in 1988, 5.3 billion kilowatt-hours.

CONSUMPTION AND USES

The iron and steel industry consumes most of the ferroalloys produced; however, other alloy systems, although relatively small in volume, represent substantial and growing markets with respect to value. Some examples are (1) silicon for alloying aluminum, principally the casting varieties; (2) nickel and cobalt-base alloys; and (3) titanium alloys.

Overall domestic demand for ferroalloys and related metals decreased about 5% compared with that of 1988 owing to

TABLE 2
U.S. FERROALLOY PRODUCTION¹ AND SHIPMENTS²

^rRevised.

¹Does not include alloys produced for consumption in the making of other ferroalloys.

²Gross sales (including exports) minus purchases.

³Includes all regular and specialty grades of ferrosilicon, excluding silvery pig iron.

⁴Includes ferroaluminum, ferrobore and other complex boron additive alloys, all chromium-containing ferroalloys and chromium metal, ferrocolumbium, all manganese-containing ferroalloys and manganese metal, ferromolybdenum, ferronickel, ferrotitanium, ferrovanadium, and silvery pig iron.

decreased production of iron and steel. The steel industry was very strong during the first half of the year; however, overall production of steel (i.e., raw steel production) dropped significantly during the second half, ending the year down 2%. Production of stainless grades decreased 5%, lessening the demand for nickel- and chromium-containing ferroalloys. Shipments of iron and steel castings from U.S. foundries decreased significantly. Compared with that of 1988 demand decreases for both chromium- and silicon-containing materials were 5%; demand for manganese-containing materials increased slightly.

Functions of the Elements

Manganese is required in virtually all steels and cast irons to counteract the harmful effects of sulfur. Manganese is also a mild deoxidizer, but is supplemented generally by stronger deoxidizers such as silicon and aluminum. Chromium provides corrosion resistance to stainless steels.

PRICES

Prices for most ferroalloys and related materials fell throughout 1989, owing to decreased demand by consuming industries. The price for imported ferro-manganese containing 78% manganese was much more stable than that of most other alloys and actually ended the year up \$25 per long ton of alloy at a range of \$620

to \$645. The yearly average, \$620, was nearly 25% higher than that of 1988. The price for imported charge chrome (ferrochromium containing 50% to 55% chromium) on January 1 was quoted at a range of 88 to 93 cents per pound of contained chromium and fell to a low range of 52.0 to 55.5 cents by the end of the year. The yearly average was 75.7 cents per pound, about 10% lower than that of 1988. The silicon price swing was by far the most drastic. The price of imported 75% ferrosilicon was quoted at a range of 66 to 69 cents per pound of contained silicon on January 1 and fell to a 2-year low range of 34.0 to 35.5 cents per pound in November before rebounding slightly at the end of the year. The average yearly price was 49 cents, 12% lower than that of 1988. Prices for molybdenum-, nickel-, and vanadium-containing ferroalloys also fell during 1988.

FOREIGN TRADE

The trade deficit for ferroalloys and related metals overall was \$977 million, a 7% increase over that of 1988. A trade deficit of \$26 million was recorded for related metals, compared with a surplus of \$52 million in 1988.

Exports of ferroalloys and related metals overall increased 19% compared with that of 1988; however, the associated value of those materials decreased 35% compared with that of the previous year. The rise in exports overall was fueled primarily by a 63% increase in the exports of alloys con-

taining chromium, manganese, and silicon. Exports of other ferroalloys decreased 5% and those of ferroalloy metals decreased 44%.

Imports for consumption of ferroalloys and related metals overall were supplied by 44 countries and decreased 10% and 18%, respectively, compared with those of 1988. Geographic sources and their respective share of total U.S. imports of ferroalloys and related metals overall were Africa, 35%; Europe, 25%; the Western Hemisphere, 22%; Asia, 9%; Oceania, 6%; and the Mideast, 3%. The Republic of South Africa continued to be the main source of U.S. imports of those materials, accounting for 30% of the total. Of the imported chromium- and manganese-containing alloys, the Republic of South Africa supplied 40% and 36% of the respective totals. The second leading suppliers of those materials were Zimbabwe (17%) for chromium and France (20%) for manganese. Imports of ferrosilicon decreased 18% compared with those of 1988. The principal sources of ferrosilicon imports were Brazil, 25%; the U.S.S.R., 19%; Venezuela, 15%; and Canada, 15%. Imports of silicon metal overall decreased 23%. The principal sources of silicon metal were Brazil, 36%; Canada, 18%; China, 17%; and Argentina, 16%.

Tariffs

Tariff schedules for ferroalloys and related metals can be found in the respective individual commodity chapters of this yearbook.

TABLE 3
PRODUCERS OF FERROALLOYS IN THE UNITED STATES IN 1989

WORLD REVIEW

The Chromium Association and the Chromium Centre announced the merger of their organizations into a single unit, the International Chromium Development Association, effective January 1, 1990. The new group was charged with promoting the use of chromium in both traditional and new markets. The Manganese Centre, which was formed in 1975 to promote the use of manganese and its alloys, changed its name to the International Manganese Institute. The organization's address will remain 17 ave. Hoche, 75008 Paris, France.

Capacity

The data in table 8 are rated capacities for major countries that produce ferroalloys

containing chromium, manganese, and silicon, as well as silicon metal as of December 31, 1989. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Because not all countries or producers make production capacity information available, historical production and trade data have been used to estimate production capacity in some cases.

Albania

Status of the new ferrochromium smelter, which was to be located at the Elbasan steel and metallurgical complex, was uncertain. Initial plans called for the facility to produce 38,000 metric tons per year of HC material with startup scheduled for 1990; however, in recent years, the country had encountered difficulties with chromite and ferrochromium operations because of water and electrical power shortages.¹ Albania and Gesellschaft für Electrometallurgy (GfE) of the Federal Republic of Germany entered into a marketing agreement in which GfE would provide technical advice to Albania in setting up new ferrochromium smelting facilities in exchange for the right to market a predetermined amount of Albanian ferrochromium in the Federal Republic of Germany annually.²

Australia

Late in the year, Barrack Mines Ltd. started operation of its newly commissioned silicon metal production facility in Western Australia. The plant, utilizing two 18-megawatt electric furnaces, had a planned capacity of 24,000 metric tons per year, but it was expected that production could reach 30,000 metric tons per year once both furnaces were fully operational. Barrack had secured contracts to export material to Asia, Europe, and North America.³

Brazil

Overall ferroalloy production increased 6%, compared with that of 1988 to a new record high of slightly more than 1 million metric tons, despite significant increases, 12% to 18%, in electric power rates, according to Anuario da Industria Brasileira de Ferroligas (ABRAFE). The most significant production increases were those of ferrosilicon and silicon metal, 7% and 47%, respectively. Total production of silicon-containing materials was 436,793 metric tons. The production of manganese-containing ferroalloys also increased by 4% to 388,930 metric tons. Of the ferroalloy production overall, nearly one-half was exported.

The largest production increase, that of silicon metal, was attributed to five new furnaces; two were started in late 1988 by Camargo Correa Metais S/A, two by Rima Electrometallurgia S/A in 1989, and one by Cia. Ferroligas Minas Gerais in 1989.⁴

After several years of rapid expansion, many of Brazil's ferrosilicon and silicon producers canceled or postponed plans for

further growth as world silicon prices dropped to preboom levels, and that country was struck with power shortages and increased power rates. One company, Cia. di Ferro Ligas da Bahia, also considered switching ferrosilicon capacity to that of silicomanganese. However, one ferrosilicon expansion project that had not been delayed at yearend was Eletrovale SA Industria e Comercio, a Brazilian-Japanese joint venture that began construction of a 31-megavolt-ampere (MV·A) furnace at the Nova Era Works, Minas Gerais State. The expansion was expected to double the output of 75% ferrosilicon from 24,000 to 50,000 metric tons per year.⁵

Cia. Ferroligas do Amapá continued construction of a 20,000 metric-ton-per-year ferrochromium smelter at Porto de Santana, with completion scheduled for 1990.⁶

Finland

Chromium producer Outokumpu Oy continued the expansion of its chromium operations. Expansion of its concentrator facility and construction of a new sintering plant were complete by yearend. Future plans included an increase in annual ferrochromium capacity from 60,000 metric tons to 250,000 metric tons sometime in 1990.⁷

France

Chromeuropa S.A., a subsidiary of Ferroleaciones Espanolas S.A. of Spain, started its second high-carbon ferrochromium furnace, a 16-MV·A unit. The company began production at its new Dunkirk facility with a 12-MV·A unit in 1988. The combined planned output of the two furnaces was to be 36,000 metric tons per year.⁸

India

Major developments were occurring in the ferroalloy industry. New ferrochromium and ferrosilicon smelters and electrical-power generating plants were being planned, constructed, and put into operation. Potential for significantly increased ferrochromium production capacity existed as the Government issued letters of intent (i.e., license agreements) to 11 domestic companies to produce at least 15,000 metric tons per year of ferrochromium each.⁹ This amount of expansion, along with a number of smaller new operations that would not require licensing,

would nearly double the country's ferrochromium production capacity over the next several years.¹⁰ Ferrosilicon producer Nav Bharat Ferro Alloys announced plans to increase ferrosilicon production capacity from 30,000 metric tons per year to 40,000 metric tons per year with the addition of a new furnace. The company also planned to build a new plant and install two 16.5-MV·A furnaces to produce 40,000 metric tons per year of silicomanganese.¹¹

Indonesia

Ispat Alloys Ltd. (India) planned to build a new bulk ferroalloy production facility to be operated as PT Ispat Alloys. Construction was expected to begin in 1990, and overall planned capacity was to be approximately 50,000 metric tons per year.

Italy

Italcromo planned to build a 100,000-metric-ton-per-year high-carbon ferrochromium plant at the site of a closed steel mill in Termoli. The company, a member of the Schlax group, received approval for initial financing through GEPI, a state-owned financing company.¹²

Japan

Steelmaker NKK Corp. divested its interest in ferrosilicon producer Yakushima Denko Co. Ltd. The sale was based on a decision by NKK to rely on imports from Brazilian ferroalloy producer Ferro Ligas Assofon SA, of which NKK held a 27% portion of ownership. Yakushima Denko said it would continue production at the same level and sell to other outside customers.¹³

Norway

BHP-Utah Minerals International, a subsidiary of Broken Hill Pty. Co. Ltd. (BHP, Australia) and Elkem A/S, announced plans to form a 50-50 joint venture involving the Bell Bay ferroalloy smelter of Tasmanian Electro Metallurgical Co. Pty. Ltd. in Tasmania and the Beauharnois, Quebec, plant of Elkem Metals Canada Inc. Details of the agreement were expected to be worked out sometime in 1990. The two companies have been doing business involving Elkem technology and BHP raw materials since the mid-1970's.

Norway's first ferrochromium project started production in September. Norsk Ferrokrom, a joint venture involving Norsk Jern Holding, the FESIL group, and

Macalloy Corp. (United States), consists of two furnaces with a total capacity of 100,000 metric tons per year in Mo I Rana, Norway. Only one of the furnaces had been operated at yearend, but company officials said the other could be started with very short notice. Macalloy will be responsible for North American marketing, while FESIL will control sales for the rest of the world. Another ferroalloy joint venture between Norsk Jern and FESIL was started at Mo I Rana. This project involved the conversion of two electric furnaces to produce 70,000 metric tons per year of ferrosilicon.

Late in the year, Elkem announced that it would cut ferrosilicon production 8% to 10% worldwide in 1990. During the period of reduced production, some extensive overhauls and maintenance would take place in Norway and North America. FESIL also planned cutbacks in production. The cuts were considered by industry representatives as "timely," in that prices were not favorable and demand had softened, helping to bring balance to the market.

Elkem and Tinfos Jernverk A/S were granted an extension of their Government's approval to continue importing manganese ore from the Republic of South Africa until 1991, as the country's two manganese ferroalloy producers were unable to secure other sources of manganese ore.¹⁴

Philippines

Integrated Chrome Corp. started production of ferrochromium with its newly converted 20-MV·A furnace. The furnace, which could produce 30,000 metric tons per year ferrochromium, previously had been used to produce silicon by Electro Alloys Corp. Integrated Chrome is a joint venture, between Nippon Denko Co. Ltd., a Japanese ferrochromium producer, and Kaschrome, a Philippine chromium ore producer.¹⁵

Ferro Chemicals Inc. completed the conversion of one of its ferrochromium furnaces to silicomanganese production. As a result of the conversion, Ferro Chemicals' ferrochromium production was expected to decrease by 50%.¹⁶

Maria Cristina Chemicals Industries (MCCI), along with Korean interests, Sangyong Co. Ltd., Pohang Iron and Steel Co. (Posco), and Dongil Chungong Co. Ltd., planned the construction of a 13,000-metric-ton-per-year ferrosilicon production facility. MCCI would have a 60% interest in the venture, which was scheduled for startup in 1990.¹⁷

Portugal

After 2 years without ferroalloy production, the Brazilian Italmagnesio group planned to restart idled Portuguese ferrosilicon, ferromanganese, and silicomanganese capacity through its new subsidiary, Novos Fornas de Beira Alta Lda. (Forbel). The plan involved eight electric furnaces, previously owned by Cia Portuguesa de Fornos Eletricos S.A.R.L., with combined capacity of 30,000 metric tons per year 75% ferrosilicon, 20,000 metric tons per year manganese alloys, and 24,000 metric tons per year calcium carbide. Italmagnesio, which had previously experienced antidumping problems in the European Community, hoped the new subsidiary would give the company a better sales position in the European market;¹⁸ however, only one of the furnaces had been started at yearend and was reported to be producing either 75% ferrosilicon or inoculants.¹⁹

South Africa, Republic of

Several ferrochromium expansion projects included ChromeCorp Technology's startup of a 30-MV·A furnace;²⁰ construction of a 32.5-MV·A furnace at CMI's facility in the Transvaal province;²¹ 16-MV·A to 40-MV·A transformer capacity expansion on a direct current transferred arc plasma furnace at Middelburg Steel and Alloys (Pty.) Ltd., potentially increasing output from 20,000 metric tons per year to 50,000 metric tons per year; and Purity Minerals' development of a new 120,000-metric tons per year ferrochromium smelter near Rustenburg, Transvaal Province. Tubatse Ferrochrome (Pty.) Ltd., a subsidiary of Samancor, started production from its fourth furnace. The new furnace had an annual production capacity of 60,000 metric tons, bringing Tubatse's production capacity from 180,000 metric tons to 240,000 metric tons. Tubatse also started construction on a fifth furnace, which was to be completed in 1990.²²

Turkey

Etibank General Management started a third high-carbon ferrochromium furnace at its Elazig plant and was scheduling start-up of a fourth sometime in early 1990. The existing electric furnaces at the Elazig facility, two 17-MV·A units, were capable of producing 50,000 metric tons per year; the addition of the third and fourth furnaces, 30 MV·A each, was expected to

raise total production capacity to 150,000 metric tons per year.²³

Venezuela

The State development body, Corporacion Venezolana de Guayana (CVG), was involved with a number of joint-venture ferroalloy projects. These projects were being developed primarily to take advantage of Venezuela's abundant electricity available from CVG's Guri Dam near Puerto Ordaz. Joint ventures included Rima Electrometallurgical SA (Brazil), Italmagnesio (Brazil), C.V.G. Ferrosilicio de Venezuela CA, Central de Ferroaleaciones de Venezuela CA, and Venezuelan PT Investment Alloy.²⁴

Zimbabwe

Zimbabwe Mining and Smelting Company (ZIMASCO) completed construction of its 3-MV·A remelting furnace for ferrochromium fines generated from its crushing operations. ZIMASCO planned to process 15,000 metric tons per year with the new furnace, increasing its total ferrochromium capacity to 190,000 metric tons per year.²⁵

OUTLOOK

Production

In recent years, a shift of production from major ferroalloy consuming countries to countries that possess significant ore reserves and low-cost electric power has occurred. For example, a number of expansions and new operations have been underway in chromite producing countries (e.g., Finland, the Philippines, the Republic of South Africa, Turkey and Zimbabwe). Some of the projects came on-line in 1989, increasing world ferrochromium capacity by more than 10%. Further ferrochromium capacity expansion, another 10% to 15%, is expected over the next several years. It is expected that this trend will continue in the future, not only for chromium-containing ferroalloys, but for those of manganese and silicon as well, as more traditional producers of ferroalloys (i.e., countries with well-established steel industries such as the United States and Japan) continue to decrease ferroalloy production capacity.

Trends in Usage

In most cases, consumption of chromium, columbium, manganese, nickel, silicon,

vanadium, and the rareearths as ferroalloys relates either directly or indirectly to the production of iron and steel. Demand forecasts for steel and the major ferroalloy elements are given in the individual commodity chapters.

BACKGROUND

Ferroalloys impart distinctive qualities to steel and cast iron and serve important functions during iron and steel production cycles. The principal ferroalloys are those of chromium, manganese, and silicon. Manganese is essential to the production of virtually all steels and is also important to the production of cast iron. Manganese is used to neutralize the harmful effect of sulfur and as an alloying element. Silicon is used primarily for deoxidation in steel and as an alloying element in cast iron. Boron, chromium, cobalt, columbium, copper, molybdenum, nickel, phosphorus, titanium, tungsten, vanadium, zirconium, and the rare earths are among the other elements contributing to the character of the various alloy steels and cast irons. Most of these elements are normally added to the molten metal as a ferroalloy. This chapter considers the ferroalloy industry as a whole and its role as a supplier of ferroalloys to the iron and steel industries.

Definitions, Grades, and Specifications

Ferroalloy is defined by the American Society for Metals and the Bureau of Mines as "an alloy of iron that contains a sufficient amount of one or more other chemical elements to be useful as an agent for introducing these elements into molten metal, usually steel." However, in practice, the term is used loosely to include master alloys containing little iron, employed to introduce reactive elements to nickel- and cobalt-base aluminum and titanium-base, and other alloy systems.

The bulk ferroalloys are produced in a variety of grades distinguished by (1) carbon level, (2) silicon level, (3) or aluminum level. Thus, ferromanganese is classified into three carbon ranges (high, medium, and low carbon), but further subclassifications exist in the high- and low-carbon categories. Generally, ferrosilicon is classified by broad silicon ranges, but it is further classified by aluminum and calcium contents. Altogether, there are scores of different specifications applying to the ferroalloys or "addition agents" used in the

^eEstimated. ^PPreliminary. ^rRevised. W Withheld to avoid disclosing company proprietary data; included with "Other."

¹Table includes data available through June 20, 1990.

²To the extent possible, ferroalloy production of each country has been separated according to the furnace type from which production is obtained; production derived from metallurgical operations is included with electric furnace production.

³To the extent possible, ferroalloy production of each country has been separated so as to show individually the following major types of ferroalloys: spiegeleisen, ferromanganese, silicomanganese, ferrosilicon, silicon metal, ferrochromium, ferrochromium-silicon, and ferronickel. Ferroalloys other than those listed that have been identified specifically in sources, as well as those ferroalloys not identified specifically but which definitely exclude those listed previously in this footnote have been reported as "Other." For countries for which one or more of the individual ferroalloys listed separately in this footnote have been inseparable from some other ferroalloys owing to the nation's reporting system, such deviations are indicated by individual footnotes. In instances where ferroalloy production has not been subdivided in sources and where no basis is available for estimation of individual component ferroalloys, the entry has been reported as "Undistributed."

⁴Reported figure.

⁵Data for year ending Nov. 30 for 1985 and 1986; calendar years thereafter.

⁶Data may not add to totals shown because of independent rounding.

⁷Includes silicomanganese.

⁸Although furnace type has not been specified for any ferroalloy production for China, North Korea, and the Republic of South Africa, all output of these countries has been included under "Electric furnace" (and metallurgical) output except for their production of ferromanganese, which is reported separately.

⁹Includes ferrochromium-silicon, if any was produced.

¹⁰Revised to zero.

¹¹Includes ferrochromium-silicon and ferronickel, if any was produced.

¹²Includes silicospiegeleisen.

¹³Includes ferronickel, if any was produced.

¹⁴Series excludes calcium silicide.

¹⁵Includes calcium-silicon, ferrotungsten, ferromolybdenum, ferrovanadium, ferrocolumbium, and other ferroalloys.

¹⁶Less than 1/2 unit.

¹⁷Estimated figures based on reported exports and an allowance for domestic use.

¹⁸Ferrovanadium only; other minor ferroalloys may be produced, but no basis is available for estimation.

¹⁹U.S.S.R. production of electric furnace ferroalloys is not reported; estimates provided are based on crude source material production and availability for consumption (including estimates) and upon reported ferroalloy trade, including data from trading partner countries.

²⁰U.S. production of ferronickel cannot be reported separately to conceal corporate proprietary information.

²¹U.S. output of ferromanganese includes silicomanganese and manganese metal.

²²U.S. output of ferrochromium includes ferrochromium-silicon, chromium briquets, exothermic chromium additives, other miscellaneous chromium alloys, and chromium metal.

²³Includes ferronickel.

²⁴Spiegeleisen for the Federal Republic of Germany is included with "Blast furnace ferromanganese."

²⁵Includes silicospiegeleisen for France.

²⁶Ferromanganese includes silicomanganese and manganese metal for U.S. and silicomanganese (if any was produced) for countries carrying footnote 7 on "Ferromanganese" data line.

²⁷U.S. production under "Other."

²⁸Ferrochromium includes material listed in footnote 22 for the United States and ferrochromium-silicon (if any was produced) for countries carrying footnote 9 on "Ferrochromium" data line.

²⁹Includes ferronickel production for France, Norway, and the United States.

manufacture of steel and cast iron. Perhaps the most varied assortment of alloys is associated with silicon. These include silicon metal, with varying amounts of iron; five ranges of silicon in ferrosilicon; and magnesium ferrosilicon alloys and other inoculant-type alloys involving controlled additions of barium, calcium, zirconium, and rare-earth elements, with or without magnesium, in alloys where silicon is the dominant element. The majority of the specialized alloys involving another element or two elements in addition to silicon is utilized by the iron-casting industry. In the United States, the most complete set of accepted ferroalloy specifications are those of the American Society for Testing and Materials.

Industry Structure

The ferroalloy industry is closely associated with the iron and steel industries, its largest customers. World production of the ferroalloys and silicon metal was estimated to be 18.66 million short tons in 1989. U.S. ferroalloy shipments in 1989 were 985,000 short tons valued at \$928 million. Domestically, 28 companies produced ferroalloys and/or silicon metal, although 5 of those produced only ferrophosphorus as a byproduct of elemental phosphorus production. The U.S. industry can be divided into three sectors according to the alloys produced, with only a few companies operating in more than one sector.

The first sector produces the tonnage or bulk ferroalloys of manganese, chromium, and silicon, and their respective metals. Except for manganese metal, chromium metal, and some specialty alloys, these products are made in submerged-arc electric furnaces, and to a limited extent, the companies can switch their production among these products according to market conditions. Since 1977, there has been no blast furnace production of ferromanganese in the United States, and currently no ferroalloys are produced domestically within a steel plant. One primary aluminum company operates a captive plant to produce silicon metal for alloying aluminum. Authors and publishers usually include silicon metal among the ferroalloys

because its production process (i.e., electric furnace) is very similar to that of most ferroalloys.

The second sector of the industry comprises companies producing the remaining ferroalloys other than ferrophosphorus. These companies are either vertically integrated and produce alloys such as ferromolybdenum or ferronickel using ores from their own mines, or produce relatively low-tonnage but high-unit-value ferroalloys such as ferrovanadium or ferrocolumbium from purchased raw materials.

The third sector of the industry produces ferrophosphorus as a byproduct of elemental phosphorus production.

Most countries with well-established steel industries also produce ferroalloys, but a definite shift in the location of ferroalloy production has occurred in more recent years toward countries with relatively low energy costs. These include Brazil, Norway, and Venezuela, as well as countries possessing substantial quantities of high-grade ferroalloy ores such as India and the Republic of South Africa. Development of a large export potential in countries such as these has decreased economic viability of small-scale ferroalloy production in some areas, particularly where stringent pollution abatement requirements have been established and power costs are high. Japan's ferroalloy industry, not unlike the United States, has been in a state of decline in more recent years because of high power costs. The Japanese ceased silicon metal production at the end of 1982 and have cut back the production of some other ferroalloys.

Resources

The reader is referred to the respective commodity chapters for complete discussions of ore reserves and potential sources of ferroalloy raw materials. The U.S. ferroalloy industry is dependent on imports for most of its primary supply of chromium, cobalt, columbium, manganese, and nickel. The United States has large reserves of molybdenum and raw materials for ferroboron, ferrotitanium, and the rare-earth additives. It also produces a substantial percentage of its vanadium requirements from domestic raw materials.

Technology

High-carbon ferromanganese, spiegeleisen, and silvery pig iron (containing 10% to 20% silicon) are produced in several countries in the type of blast furnace used

to produce pig iron. However, since 1977, U.S. production of alloys containing manganese, silicon, and chromium has been in electric-arc furnaces exclusively. Most of these alloys are smelted in submerged-arc furnaces (i.e., the electric arc is kept submerged within the charge of raw materials). Ores are smelted with carbon from coke, coal, or wood chips as reductant. The high temperature and added energy needed for the reaction are provided by the electric arc. Unlike the operation of electric furnaces in steelmaking, that of the submerged-arc furnace is continuous, with raw materials being fed from above and molten alloy and slag (if produced) being tapped through holes in the side of the furnace. For some grades, such as low-carbon ferromanganese and low-carbon ferrochromium, two or three processing steps are involved and open-arc as well as submerged-arc furnaces are used.

Modern ferroalloy electric furnaces evolved from calcium carbide furnaces, which became important in the 1920's. Initially, ferroalloy plants had several furnaces of small size that provided flexibility in producing a limited volume of a variety of alloys. The trend has been toward fewer but larger furnaces, with transformer ratings now up to 100 MV·A, and with some new plants consisting of just one or two furnaces. The larger furnaces are designed more for specific alloy production, and the use of the furnace for other alloys may require physical modification. Modern furnaces are equipped with automated materials handling equipment to reduce labor requirements and with computerized control systems to maintain more efficient production.

Some ferroalloys are produced in the electric furnace by metallothermic reduction. The reductant may be aluminum or silicon (often as ferrosilicon). The reactions are generally self-sustaining, but heat may be added by an electric arc to keep the molten alloy liquid until the slag can be separated.

Economic Factors

Prices.—Demand for ferroalloys is determined by the level of activity in the iron and steel industries, and prices for ferroalloys tend to vary, sometimes widely, with changes in demand or supply. For example, in 1987 and 1988, bulk ferroalloy prices rose steadily and, in some cases, more than doubled as U.S. steel produc-

tion and that of stainless grades headed toward their highest levels in nearly 10 years. In 1989, as steel production fell slightly, most bulk ferroalloy prices also fell.

Costs.—Principal elements in the cost of ferroalloy production are (1) delivered costs of the ore, (2) energy cost, (3) cost of reductant coke or low-ash coal, (4) cost of iron in the form of steel scrap, and (5) labor. The cost of all of these elements, and particularly the cost of energy, increased rapidly since 1970. In addition, new capital costs for pollution control equipment were added.

Energy costs are a dominant factor in the cost of producing ferroalloys in submerged-arc furnaces. Silicon alloys require the highest energy input, followed by chromium- and manganese-containing alloys. In the United States, energy costs account for about 40% of the cost of silicon-containing ferroalloys. In addition, many national Governments are favoring less power intensive industries by allocating power. Thus, countries with an adequate technology base, economy of large-scale operation, and assured low energy costs will be favored to become larger factors in the ferroalloy industry. The United States will be in an intermediate energy cost position. However, energy costs and ore reserves continue to favor expansion in production of (1) chromium alloys in Albania, Greece, India, the Philippines, the Republic of South Africa, and Turkey; (2) manganese alloys in Brazil, Mexico, and the Republic of South Africa; and (3) silicon alloys in Australia, Brazil, and Norway. At the same time, such growth will tend to dampen growth in steel-producing countries such as the United States, Japan, and many Western European countries.

Operating Factors

Environmental Requirements.—Air pollution is the principal environmental problem in the production of ferroalloys. Most ferroalloy furnaces in the United States use baghouses to control air pollution. Wet scrubbers and electrostatic precipitators are also in use.

Most developed countries, particularly Japan and the countries of Western Europe, have stringent environmental controls. In other countries, such as Brazil, environmental controls are not always required by the Governments; but ferroalloy producers are generally equipping new

furnaces with the most modern equipment commercially available to effect substantial removal of objectionable emissions.

Energy Requirements.—Bulk ferroalloys produced in submerged-arc electric furnaces are extremely power intensive, especially silicon metal and the silicon-containing alloys, which can require up to 12,000-kilowatt-hours of electric energy per ton of silicon contained in the final product. Standard ferromanganese is the least power intensive of the major ferroalloys, requiring approximately 2,500 kilowatt-hours per ton of alloy produced.

To buy power at low cost, many ferroalloy companies have long-term contracts with use of pay conditions that may restrict the companies' operational flexibility. Contracts that specify a high minimum charge limit the amount that costs can be reduced by cutting production during periods of weak demand. Under interruptable contracts, power can be cut off during power shortages.

FLUORSPAR

By M. Michael Miller

Mr. Miller, a physical scientist with 12 years of minerals experience with the Department of the Interior, has been the commodity specialist for fluorspar since 1989. Domestic survey data were prepared by Gail D. Mason, mineral data assistant; and international data tables were prepared by Gio Jacarepaqua, international data assistant.

In 1960, an International System of Units was adopted by the 11th General Conference of Weights and Measures. This system is called the MKS system or metric system, and most countries of the world have adopted it as their official system of measurement. The Bureau of Mines, in an effort to provide statistical data on fluorspar in units most consistent with international usage, will henceforth report fluorspar data in metric tons (mt) unless otherwise noted.

In the United States, fluorspar was shipped by one major producer and by one small producer that supplied less than 10% of the Nation's requirements. Supplementing fluorspar as a domestic source of fluorine was byproduct fluosilicic acid production from some phosphoric acid and hydrofluoric acid (HF) producers. Imports of fluorspar, which

continued to supply most of the United States requirements, decreased nearly 5% from 1988. HF imports were nearly 4% lower than reported in the previous year.

The fluorspar industry witnessed some important events in 1989. In July, the first phase of cutbacks in chlorofluorocarbon (CFC) production, mandated by the Montreal Protocol on Substances that Deplete the Ozone Layer (Montreal Protocol), went into effect, freezing CFC production at 1986 levels. Pennwalt Chemical Corp., parent of domestic fluorspar producer Ozark-Mahoning Co., was purchased by the French chemicals giant, Société Nationale Elf Aquitaine. An international meeting was held in Monterrey, Mexico, in April to discuss fluorspar production and markets and to assess how developments are shaping the industry.

DOMESTIC DATA COVERAGE

Domestic production and consumption data for fluorspar were developed by the Bureau of Mines from voluntary surveys of U.S. operations. Surveys were conducted to obtain fluorspar mine production and shipments and fluosilicic acid production. Of the four fluorspar mining operations to which a survey request was sent, 100% responded. Production statistics in table 1 are withheld to protect company proprietary data. Of the seven fluosilicic acid producers surveyed, 100% responded, representing 100% of the quantity reported. The consumption survey was sent to approximately 88 operations quarterly and to 39 additional operations annually. Of the operations surveyed quarterly, 70% re-

sponded. Of the operations surveyed on an annual basis, 36% responded. Together, quarterly and annual responses represented 87% of the apparent consumption data shown in table 1.

LEGISLATION AND GOVERNMENT PROGRAMS

At yearend, the National Defense Stockpile fluorspar inventory was unchanged from yearend 1988 and remained well below the stockpile goals of 1.4 million short dry tons (about 1.27 million mt) for acid grade and 1.7 million short dry tons (about 1.54 million mt) for metallurgical grade. Revised goals were authorized in 1989 of 900,000 short tons (about 816,000 mt) for acid grade and 310,000 short tons (about 281,000 mt) for metallurgical grade. The revised goals had not been implemented by the end of the year. Depletion allowances against Federal taxes of 22% and 14%, respectively, remained in effect for domestic and foreign production by U.S. companies.

In September 1987, the United States and 22 other nations signed the Montreal Protocol. The protocol, under the auspices of the United Nations Environmental Program, mandated a freeze in CFC production at the 1986 level by July 1989, followed by a 20% reduction by mid-1993 and an additional 30% reduction by mid-1998. The United States complied with the July 1989 date for reduction of CFC production to 1986 levels. In December 1989, an excise tax was levied on the production of CFC's that are subject to the Montreal Protocol. The tax was included as part of a deficit reduction bill, which set a base tax rate for CFC-11 of \$1.37 per pound in 1990 and 1991. The rate increases to \$1.67 in 1992, \$2.65 in 1993 and 1994, and an additional 45 cents per pound per year thereafter. Tax rates for CFC-12, CFC-113, CFC-114, CFC-115, and halon-1201, halon-1301, and halon-2402 will be calculated based on their ozone layer depletion potential relative to CFC-11.¹

ISSUES

The total phaseout of CFC's by the

end of the century is likely to generate large costs. About one-half of CFC consumption consists of foam production, solvents, and firefighting applications. Non-CFC replacements for foam production and solvents can be developed without significant costs. Although there are no replacements for the halons used as firefighting agents, emissions can be greatly reduced by the strict control of operating practices. Large costs will occur in replacing the CFC's used for refrigeration and air-conditioning. Replacement costs for new equipment in net present value may range from \$6.4 billion to as much as \$12.5 billion by early next century. If CFC's were to become unavailable in 10 years, the costs of premature obsolescence of equipment could be as high as \$13 to \$23 billion in net present value. Automobile air conditioners would account for 75% of these costs. Additional costs would ensue from a slight decline in energy efficiency of equipment that formerly used CFC's.² These cost projections were made before passage of the excise tax on CFC production and do not take into account impacts of the tax.

PRODUCTION

Illinois remained the leading producing State, accounting for over 98% of all U.S. shipments. Data on shipments of fluorspar by State and grade are withheld to avoid disclosing company proprietary data.

Ozark-Mahoning Co., the Nation's largest fluorspar producer and now a subsidiary of Atochem North America Inc., operated three mines and a flotation plant in Pope and Hardin Counties, IL. Ozark-Mahoning also dried imported fluorspar to supplement its production. Seaforth Mineral & Ore Co. Inc., dried imported fluorspar at its facilities at Cave-In-Rock, IL, and East Liverpool, OH, for sale primarily to consumers in the ceramic industry. J. Irving Crowell, Jr., & Son produced and shipped a small amount of metallurgical-grade fluorspar from its Crowell-Daisy Mine in Nye County, NV.

Ozark-Mahoning reopened the former Inverness Mining Co. Minerva #1 Mine, acquired from Seaforth, in De-

cember 1988. Ozark completed the rehabilitation of the mine in late December 1989 and planned to start production in January 1990.

Eleven plants processing phosphate rock for the production of phosphoric acid and one plant producing HF sold or used 46,565 mt of byproduct fluosilicic acid, which was equivalent to 90,700 mt of fluorspar.

CONSUMPTION AND USES

Acid-grade fluorspar, containing greater than 97% calcium fluoride (CaF_2), was used primarily as a feedstock in the manufacture of HF. Ceramic-grade fluorspar, containing 85% to 95% CaF_2 , was used for the production of glass and enamel, to make welding rod coatings, and as a flux in the steel industry. Metallurgical-grade fluorspar, containing 60% to 85% or more CaF_2 , was used primarily as a fluxing agent by the steel industry.

Reported domestic consumption by the HF industry decreased by less than 3%; consumption by the steel industry remained essentially unchanged. According to the American Iron and Steel Institute (AISI), domestic production of raw steel decreased slightly from 90.1 million mt in 1988 to 88.4 million mt in 1989. A comparison of the AISI data with fluorspar consumption data collected by the Bureau of Mines from the U.S. steel industry shows that aver-

age fluorspar consumption per ton of raw steel has remained relatively constant during 1986-89. The industry average for all furnace types is shown below:

Fluorspar consumption (kilograms per metric ton)			
1986	1987	1988	1989
1.37	1.34	1.34	1.39

In the ceramic industry, fluorspar was used as a flux and as an opacifier in the production of flint glass, white or opal glass, and enamels. Fluorspar was used in the manufacture of glass fibers, aluminum, cement, and brick, and was also used in the melt shop by the foundry industry.

Three companies reported fluorspar consumption for the production of HF. The U.S. Department of Commerce, Bureau of the Census, reported that, based on their monthly survey, anhydrous, technical, and aqueous HF, 100% basis, "produced and withdrawn from the system," was over 177,148 mt for 1989, compared with the 1988 quantity of 195,777 mt.

The largest use of HF was for the production of a wide range of fluorocarbon chemicals including fluoropolymers and CFC's. CFC's were produced by five companies. According to data from the U.S. International Trade Commission, production of trichlorofluoromethane (CFC-11) decreased over

13% to 87,657 mt; dichlorodifluoromethane (CFC-12) increased slightly to 177,604 mt, and chlorodifluoromethane (HCFC-22) remained essentially unchanged at 148,413 mt, compared with 1988 figures.

As a consequence of the adoption of the terms of the Montreal Protocol, CFC-11 and CFC-12 production will probably decrease continuously for the next 10 years and may be phased out completely when adequate substitutes are developed and tested. Because HCFC-22 is not a fully halogenated CFC and is broken down in the lower atmosphere, it was not included in the list of ozone-depleting substances covered by the Montreal Protocol.

The chemical industry is pursuing research into replacement compounds for the CFC's that are to be phased out. The CFC producers are developing substitutes called hydrochlorofluorocarbons (HCFC's) that have ozone-depletion potentials of about 5% that of CFC-11, CFC-12, and CFC-113, which in total account for over 90% of CFC consumption. Other substitutes are called hydrofluorocarbons (HFC's), which have no ozone-depletion potential, since they contain no chlorine atoms. So far, the most likely candidates to replace controlled CFC's are HCFC-22, for use in home air conditioning and plastic foams; HCFC-123, a potential substitute for CFC-11 in plastic foams and refrigeration; HFC-134a, a potential substitute for CFC-12 in refrigeration and auto air conditioners; and HCFC-141b, a potential substitute

for CFC-11 in plastic foams. Only HCFC-22 is currently in commercial use, although several companies have announced plans to build commercial-scale plants to manufacture the other compounds. These plans are not without risk, since the compounds have to pass inhalation and toxicity tests before commercial sales are allowed.³

The manufacture of synthetic cryolite and aluminum fluoride for use in aluminum reduction cells was a major use of HF. An estimated 40 to 60 pounds of fluorine was consumed for each ton of aluminum produced. Aluminum fluoride was used by the ceramic industry for some body and glaze mixtures and in the production of specialty refractory products. It was used in the manufacture of aluminum silicates and in the glass industry as a filler.

HF was consumed in the manufacture of uranium tetrafluoride that was used in the process of concentrating uranium isotope 235 for use as nuclear fuel and in fission explosives. It was also used in stainless steel pickling, petroleum alkylation, glass etching, oil and gas well treatment, as a cleaner and etcher in the electronics industry, and in the manufacture of a host of fluorine chemicals used in dielectrics, metallurgy, wood preservatives, herbicides, mouthwashes, decay-preventing dentifrices, plastics, and water fluoridation.

Fluosilicic acid was used primarily in water fluoridation, either directly or after processing to sodium silicofluoride, and to make aluminum fluoride for the aluminum industry.

¹ Includes glass and fiberglass, enamel, welding rod coatings, primary aluminum, primary magnesium, other chemical products, other ceramic products, and other primary metals.

STOCKS

Fluorspar consumer stocks increased substantially for the second straight year. Consumer stocks were 79,347 mt, up 42% from the level reported in 1988. This approached the level reported in 1986. Government stockpiles of fluorspar remained unchanged and contained 891,957 short dry tons (809,171 mt) of acid grade and 294,045 short dry tons (266,753 mt) of metallurgical grade.

TRANSPORTATION

Fluorspar products are transported to customers by truck, train, barge, and ship. Most acid-grade fluorspar is shipped in the form of damp filter cake containing 7% to 10% moisture to facilitate handling and reduce dust. Types of transportation available to producers influence the economic viability of an operation to a certain extent. The Republic of South Africa must transport its products over long distances from the mines in the Transvaal area to the port of Durban. Fortunately, the Republic of South Africa has an extensive rail network that serves a large number of mineral producers in the Transvaal area. The port at Durban is highly mechanized and can load and unload ships faster and more efficiently than most ports in the world, allowing shipments to be cost competitive with other less distant producers.

In contrast, Mexico has a less efficient rail and highway network, and the port facilities at Tampico are older; these are disadvantages that are overcome by short rail and water transport distances to major markets along the U.S. gulf coast. However, the cost competitiveness becomes strained for more distant consumers.

In the United States, after the products have cleared the port, they are transported to consumers by barge, rail, or truck. Truck and rail costs are much higher than barging costs, and many consumers are located near ports or along major rivers in order to take advantage of the lower costs that are provided by proximity to water transportation.⁴

PRICES

According to prices published by Industrial Minerals (Metal Bulletin PLC), the price of domestic acid-grade fluorspar was unchanged. Foreign producer prices at yearend had increased by about \$15 per metric ton compared with 1988 prices.

Yearend price quotations from the Chemical Marketing Reporter (CMR) were unchanged at \$0.6875 per pound for anhydrous HF and up \$3.00 at \$52.00 per 100 pounds for aqueous HF, 70%, in tanks. These quotations were equivalent to about \$1.52 per kilogram (kg) for anhydrous HF and \$114.64 per 100 kg for aqueous HF, 70%, in tanks. The CMR yearend price quotation for fluosilicic acid, 100% basis, in tanks, was up at \$340 per short ton (about \$375 per metric ton), and for cryolite was unchanged at \$550 per short ton (about \$606 per metric ton).

The impact of the Montreal Protocol was evident in the price increases reported for CFC compounds. The CMR yearend price quotations increased from \$0.64 to \$0.90 per pound for CFC-11, from \$0.74 to \$1.04 per pound for CFC-12, from \$0.935 to \$1.22 per pound for CFC-113, and from \$1.08 to \$1.41 per pound for CFC-114.

FOREIGN TRADE

According to the Bureau of the Census, U.S. exports of fluorspar increased by 64% and had an average value of \$135 per metric ton. Synthetic cryolite exports decreased to 6,103 mt representing 7,360 mt of 92% equivalent fluorspar, valued at \$3.2 million. In descending order of the quantity exported, the most important importers of U.S. produced synthetic cryolite were Canada, Turkey, and Japan. Ac-

Source: Bureau of the Census.

cording to the reported data, the average export value for synthetic cryolite was \$522 per metric ton.

Imports for consumption of fluorspar decreased by nearly 5% with Mexico remaining the most important supplier, followed by, in descending order of the quantity imported, China, the Republic of South Africa, Canada, Morocco, and Spain. The average unit value, in dollars per metric ton, was \$127 for acid grade and \$93 for subacid grade. U.S. import duties remained in effect for all grades of fluorspar. The duty was \$1.875 per short ton for acid grade (\$2.07 per metric ton) and 13.5% ad valorem for ceramic- and metallurgical-grade material.

Imports for consumption of HF decreased nearly 4% to a quantity equivalent to approximately 172,000 mt of fluorspar. Imports of synthetic and natural cryolite were essentially unchanged representing 10,200 mt of 92% fluorspar equivalent.

WORLD REVIEW

World fluorspar consumption and production increased compared with 1988. China, Mexico, Mongolia, the U.S.S.R., and the Republic of South Africa were the major producers. International prices increased despite market pressures caused by a massive Chinese presence in the export market.

Capacity

The data in table 8 are rated capacity for mines and beneficiation plants as of December 31, 1989. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Normal production practices for many underground fluorspar operations are two-shift-per-day mining operations with one shift for blasting and ventilation; associated milling operations are continuous with two or three shifts per week

leading producer and exporter. U.S. imports from China continued to grow dramatically, especially in acid-grade fluorspar. The United States doubled its acid-grade imports from the previous year, from 79,000 mt to over 159,000 mt.

Namibia

Although the presence of fluorspar occurrences in Namibia (formerly Southwest Africa) has been known since the 1920's, production has only occurred briefly in the 1950's and 1970's. In early 1988, development by Okorusu Fluorspar (Pty.) Ltd. began at the site of the largest fluorspar outcroppings in the Okorusu Mountain area, which is 50 to 60 kilometers north of Otjiwarongo and over 400 kilometers from Walvis Bay, the nearest port of shipment. By the end of 1989, production capacity had reached about 40,000 mt per year. Shipments were made to the Federal Republic of Germany and to the United States.

OUTLOOK

There are three major components in fluorspar demand: consumption of metallurgical grade and briquets by the steel industry, consumption of acid grade by the aluminum industry for production of aluminum fluoride, and consumption of acid grade by the chemical industry for production of hydrofluoric acid.

Consumption of fluorspar by the steel industry has declined dramatically since the introduction of the basic oxygen furnace and the gradual obsolescence of the open-hearth furnace. Twenty years ago, the domestic steel industry produced 119 million mt of steel and consumed 519,000 mt of metallurgical-grade fluorspar. In comparison, in 1989, the steel industry produced 88 million mt and consumed approximately 140,000 mt of metallurgical-grade fluorspar. That is a decrease in steel production of 26%, with a much larger corresponding decrease in fluorspar consumption of 73%. Unless there is a large increase in domestic steel production, it is estimated that overall consumption of metallurgical-grade fluorspar will continue to decrease over the next 3 to 5 years.

dedicated to maintenance and cleaning.

Brazil

Brazil's fluorspar reserves are located in the southern part of the country. The majority of reserves are in the States of Paraná, Santa Catarina, and Rio de Janeiro. In 1989, Mineração Del Rey Ltda. opened a new mine and beneficiation plant at Mato Preto, in Paraná State. This subsidiary of E. I. du Pont de Nemours & Co. is expected to produce about 60,000 mt per year of acid grade and 10,000 to 20,000 mt of metallurgical grade. The acid-grade material is in-

tended for export and to supply the domestic aluminum industry; the metallurgical-grade material is intended for the domestic steel industry.⁵

China

Fluorspar exports from China continued to increase with reported exports of 912,000 mt in 1988 and 1,180,000 mt in 1989. Based on reported export data and estimates of domestic consumption, it is estimated that China produced 1.7 million metric tons in 1989. This would be nearly twice the production of Mexico, which has been historically the world's

Source: Bureau of the Census.

The domestic aluminum industry is currently operating at or above rated capacity. No expansion of capacity is anticipated in the next few years, and the consumption of fluorspar by the aluminum industry is expected to remain at current levels over the next 3 to 5 years.

Consumption of acid-grade fluorspar by the chemical industry for the production of HF is the largest market for fluorspar. Approximately 70% of HF production is used in the manufacture of CFC's, while the rest is used in chemical intermediates, glass and metal processing, petroleum alkylation, and other small uses. Most end uses of HF are expected to follow the trend of the economy and grow with the projected Gross National Product. However, the CFC situation is difficult to analyze. Some industry analysts see large increases in HF consumption for production of replacement HCFC's and HFC's. The new replacements contain more fluorine than present CFC's and are expected to reach the marketplace between 1991 and 1994. Other analysts predict any gains in HF consumption for HCFC's and HFC's will be offset by overall decreases in CFC usage, as nonfluorine replacements for some current uses are developed. HF producers are currently operating at about 90% of capacity and are studying possible expansions. Despite the uncertainties, during the next 3 to 5 years the outlook for consumption of acid-grade

fluorspar is good in the short term and excellent in the long term.

BACKGROUND

Definition, Grades, and Specifications⁶

Technically, pure fluorspar, or the mineral fluorite, contains 51.1% calcium and 48.9% fluorine. Natural fluorite is commonly associated with other minerals such as quartz, barite, calcite, galena, siderite, celestite, sphalerite, chalcopryrite, sulfides, or phosphates. It tends to occur in well-formed isometric crystals, in massive and earthy forms, and as crusts or globular aggregates with radial fibrous texture. In crystalline form, it can be colorless or may exhibit a wide range of colors, including yellow, blue, purple, green, rose, red, bluish and purplish black, and brown. It has a hardness of 4 on the Mohs' scale, a specific gravity ranging from 3.01 to 3.60, and a melting point of 1,378° C.

Three principal grades of fluorspar are available commercially: acid, ceramic, and metallurgical. Although the specifications for individual grades are generally well defined, some variation is permitted to satisfy the requirements of individual consumers.

In the United States, acid-grade fluorspar (acidspars) contains at least 97% CaF₂. Some manufacturers of hydroflu-

^e Estimated. ^p Preliminary. ^r Revised.

¹ Table includes data available through Apr. 25, 1990.

² In addition to the countries listed, Bulgaria is believed to have produced fluor spar in the past, but production is not officially reported, and available information is inadequate for the formulation of reliable estimates of output levels.

³ An effort has been made to subdivide production of all countries by grade (acid, ceramic, and metallurgical). Where this information is not available in official reports of the subject country, the data have been entered without qualifying notes.

⁴ Reported figure.

⁵ Year beginning Mar. 21 of that stated.

⁶ Data for 1985–1987 were provided by the Instituto Mexicano de la Fluorita. Data for 1988 were provided by the Mexican Chamber of Mines, from the Secretaria de Energia, Minas y Industrial Paraestatal (Semip). Data for 1989 were provided by industry sources.

⁷ Revised to zero.

Moisture content of the dried material is preferably 0.1% or less. Particle size and distribution are sometimes specified for proper control of the rate of chemical reaction and stack losses. Very few reserves in the world can be used to produce acid-grade fluor spar without flotation processing.

Ceramic-grade fluor spar is generally marketed as No. 1 ceramic, containing 95% to 96% CaF₂, and No. 2 ceramic, containing 85% to 90% CaF₂. An intermediate grade of about 93% to 94% CaF₂ is also available. Specifications on impurities vary but may allow a maximum of 2.5% to 3.0% silica, 1.0% to 1.5% calcite, 0.12% ferric oxide, and trace quantities of lead and zinc. Shipments of ceramic-spar are usually tailored to the specific need of individual consumers.

Metallurgical-grade fluor spar (metspar) contains a minimum of 60% effective CaF₂. In the United States, metspar is usually quoted in terms of effective CaF₂ units, obtained by subtracting 2.5 times the silica content of the ore from its total CaF₂ content. The term “metspar”

is usually used to refer to material with a maximum CaF₂ content of 85% but sometimes is used for material as high as 96%, which includes what is technically ceramic grade. Other countries may require a minimum of 80% CaF₂, which allows larger quantities of silica, usually a maximum of 15%, and other contaminants. Metspar is often traded as a lump or gravel that must pass a 1- to 1½-inch screen and contain less than 15% of material passing a 1¼-inch screen.

In the domestic steel industry, various shapes and sizes of briquets or pellets are being used. Generally made to consumer specifications, briquets contain varying quantities of fluor spar mixed with binders, fillers, and fluxing agents. Typically made on roll presses and ranging in size from that of a peach seed to a 5-centimeter square, briquets contain 25% to 90% CaF₂ and steel mill waste ingredients, such as mill scale, flue dust, shredded scrap, iron ore fines, and manganese ore fines. The most popular binders are molasses and lime, which do not require baking ovens. Imported briquets are often made

from fines accumulated during metspar preparation and from flotation concentrates. U.S. producers use imported acid grade to take advantage of its lower tariff. Pellets have been made on balling machines using sodium silicate binder.

Geology—Resources⁷

Fluor spar occurs in a wide variety of geological environments, which indicates that deposition takes place in a number of different ways. From an economic standpoint, seven of the most important modes of occurrence are as follows:

1. Fissure vein deposits commonly occur along faults or shear zones and are the most readily recognized form of fluor spar occurrence in the world. Although the vein structure may be persistent, the fluor spar mineralization commonly occurs as lenses or ore shoots separated by barren zones. Fissure veins occur in igneous, metamorphic, and sedimentary rocks.

2. Stratiform, manto, or bedded deposits occur as replacements in carbon-

ate rocks. Some beds are replaced adjacent to structural features such as joints and faults. In frequent instances, there is a capping of sandstone, shale, or clay.

3. Replacement deposits in carbonate rocks along the contact with acidic igneous intrusives are another common type of deposit. Deposits do not have to be the result of contact metamorphism, but may be introduced later, following the contact zone as a conduit and replacing the limestone.

4. Stockworks and fillings in shear and breccia zones are another form in which fluor spar occurs. The Buffalo deposit in the Transvaal consists of a network of fluor spar veinlets in sill-like bodies that are inclusions in the granite of the Bushveld complex.

5. Carbonatite and alkalic rock complexes may have fluor spar at their margins. Fluor spar grades are not usually sufficient to be economic, but the Okorusu deposit in Namibia is made up of a number of bodies of fluor spar in limestones, quartzites, and related rocks that have been intruded and metamorphosed by an alkaline igneous rock complex.

6. Residual deposits of fluor spar are formed in clayey and sandy residuum that results from surficial weathering of fluor spar veins and replacement deposits. These deposits may be the sources of metallurgical-grade fluor spar. They include detrital deposits blanketing the apex of veins and the upper portions of the veins themselves that have been deeply weathered to depths of 30 meters or more.

7. Fluor spar may also occur as a major gangue mineral in lead and zinc veins. Two operations in the Parral area of Mexico have treated the tailings of lead-zinc mines to recover fluor spar from previously discarded gangue minerals.

Identified world fluor spar resources are approximately 365 million metric tons of contained fluor spar. As might be expected, the countries with the highest production have the largest fluor spar reserves, although their production ranking does not necessarily mirror their reserve ranking. World resources of equivalent fluor spar from phosphate rock are approximately 325 million metric tons, which includes about 32 million metric tons from domestic phosphate rock.

³ The reserve base includes demonstrated resources, reported in terms of 100% CaF₂, that are currently economic (marginal reserves), and some of those that are currently subeconomic (subeconomic resources).

Technology

Mining.—Mining methods vary according to geologic conditions at individual deposits around the world. Deep deposits usually require underground techniques, while wide, shallow deposits employ open pit methods. If the ground is unable to support underground mining, open pit methods may be used even though overburden removal

might be substantial. In some cases, open pit methods are used until the depth requires moving underground.

Narrow vein mining is often done by shrinkage stopping and open stopping where strong walls occur, while stratiform or bedded deposits use room and pillar patterns. Replacement and fissure vein deposits are mined with shrinkage stopping or cut-and-fill methods if they are deep, narrow occurrences. They may also be mined by open pit or strip mining techniques where they are near the surface and have competent sidewalls. The replacement and stockwork deposits in the Republic of South Africa, the carbonatite deposit in Namibia, and most of the fissure veins in Thailand are all mined with open pit methods. However, replacement deposits in Mexico are extracted by stopping or cut-and-fill methods.⁸

Beneficiation.—Most fluor spar must be upgraded for marketing. Metspar is often produced by hand sorting of high-grade lump crude ore, followed by crushing and screening to remove most of the fines. In the case of fluor spar ores of lower grade and/or ores with relatively coarse interlocking of minerals, gravity concentration processes are used based on the specific gravity of over 3.0 for spar and less than 2.8 for most gangue minerals.

Heavy-media cone and drum separators are particularly effective in the 1½- by ¾-inch size range, either for producing metallurgical gravel or for preconcentrating the crude ore for flotation feed. For the finer sizes, the heavy-media cyclone process is frequently used. The high capacity and low operating cost of heavy-media methods give very satisfactory results. Ores as low as 14% CaF₂ are being preconcentrated to yield a flotation feed of 40% CaF₂ or more. Lead and zinc sulfides and barite concentrate with the fluor spar to enrich the flotation feed with these valuable minerals. In some cases, washing plants are also used prior to flotation to remove clay or manganese oxides (wad).

Ceramic and acid grades of fluor spar are produced by multistage froth flotation. Ore from the mine is crushed and ground to proper size; care is taken not to overgrind and cause fluor spar to be lost in the slimes. If lead and zinc sulfides are present, they are preferen-

tially floated off with xanthate collector. After this process is completed, all the easy floating fluorspar is removed in a quick pass through a flotation circuit and sent on to the cleaner circuit. The tailings are discarded. The middling product is reground to separate the more finely interlocked grains of fluorspar and gangue, and passed through one or more cleaner circuits. The final products generally comprise an acid-grade concentrate and, in some cases, one or more concentrates of lower grade, which are sold as ceramic grade, or pelletized and sold as metallurgical grade. Fatty acids are used as collectors for the fluorspar. Quebracho or tannin is used to depress calcite and dolomite; sodium silicate is used to depress iron oxides and silica; and chromates, starch, and dextrin are used

to depress barite. Cyanide is used to depress any remaining sulfides. Lime, caustic, or soda ash can be used for acidity control. Flotation temperatures range from ambient to 80° C.⁹

GALLIUM

By Deborah A. Kramer

Ms. Kramer is a physical scientist with the Branch of Nonferrous Metals. She has covered gallium for 6 years. Domestic survey data were prepared by Lura Nightlinger, Nonferrous Metals Data Section.

Gallium demand in the United States declined in 1989, principally because penetration of gallium arsenide (GaAs) devices into commercial applications did not occur as rapidly as expected. This also resulted in the closure of two large U.S. GaAs manufacturers and the decision of a Canadian firm to withdraw from its gallium recovery and purification businesses. In addition, two companies in the United Kingdom ceased or significantly reduced their activities in GaAs manufacturing.

Despite the gallium consumption downturn, world gallium production capacity increased significantly as a large gallium recovery plant began operation in Australia in 1989. Also, a U.S. firm planned to reopen a gallium and germanium recovery plant in Utah in 1990. Substantial research and development on new GaAs-based devices and novel fabrication techniques was continued, funded by both Government and private industry.

DOMESTIC PRODUCTION

Hecla Mining Co. purchased the gallium-germanium mine and processing plant in St. George, UT, from St.

George Mining Corp. early in 1989 for about \$5.5 million. St. George Mining had filed for bankruptcy in 1988, and the plant had been idle since 1987. Using solvent-extraction technology, developed by Cominco Ltd., Hecla planned to reopen the mine and plant in early 1990 and recover a sodium germanate concentrate and 99.99%-pure gallium metal. Annual plant capacity was estimated to be 7,000 kilograms of gallium metal and 20,000 kilograms of sodium germanate.

Eagle-Picher Industries Inc., Quapaw, OK, recovered and refined gallium from both imported and domestic materials. Recapture Metals Inc., Blanding, UT, recovered gallium from scrap materials.

CONSUMPTION

The growth of commercial applications for integrated circuits apparently slowed and led to the closure of two GaAs wafer manufacturing facilities in 1989. Morgan Semiconductor Div. of Ethyl Corp. closed its plant in Garland, TX, in June, and Spectrum Technology Corp. closed its plant in Holliston, MA, in December. Texas Instruments Inc. bought the assets of Morgan Semiconductor. Spectrum Technology agreed

to sell some of its assets and inventory to M/A-Com Inc., another large GaAs wafer manufacturer.

Several companies participating in the U.S. Department of Defense Microwave/Millimeter Wave Monolithic Integrated Circuits program (Mimic) developed new GaAs-based integrated circuits for use in defense applications. Texas Instruments Inc. and Raytheon Co. shipped GaAs amplifier devices to the military for use in high-speed anti-radiation missiles early in 1989. This was believed to be the first use of devices produced under the Mimic program in an actual product. Manufacturing the integrated circuits from GaAs was expected to increase performance of the devices.

Harris Microwave Semiconductor Div. of Harris Corp. had several monolithic microwave integrated circuit (MMIC) products incorporated into military electronics systems. These systems were included in the Advanced Medium-Range Air-To-Air Missile, the B-1B bomber, and the Combined Altitude Radar Altimeter. In addition, Harris Microwave worked with General Electric Co. and Hughes Aircraft Co. to develop airborne and ground-based phased-array radar systems. Harris Microwave produces about 50,000 MMIC and 400,000 microwave devices annually.¹

Honeywell Inc. and Magnesys Corp. reportedly signed an agreement to put bubble memory systems, manufactured by Magnesys, into a portable battlefield communication terminal. This represented the first high-volume application for a bubble memory system in a production model military computer. Initial orders were for 575 terminals containing more than \$1 million in bubble memory systems. Additional purchases of 3,200 units were planned over a 3.5-year period. Bubble memories store information in small magnetic domains that form in a garnet epitaxial layer over a gallium-

¹ Includes gallium metal and gallium compounds.

PRICES

Quoted prices of gallium metal have not changed since 1986. Yearend prices for gallium quoted in the American Metal Market were as follows, in dollars per kilogram:

Gallium metal, 99.9999%-pure, 100-kilogram lots	\$525
Gallium metal, 99.99%-pure, 100-kilogram lots	435
Gallium metal, 99.9999%-pure, imported	\$460- 490
Gallium oxide, 99.99%-pure	435
Gallium oxide, 99.99%-pure, imported	400- 420

FOREIGN TRADE

Gallium export data were combined with data for other metal exports by the Bureau of the Census and could not be separately identified. The Journal of Commerce Port Import/Export Reporting Services (PIERS) provided some information on gallium materials exported by ship. According to PIERS, about 300 kilograms of gallium in scrap materials was exported in 1989, principally to Belgium.

WORLD REVIEW

The average value of gallium imports into the United States in 1989 was \$371 per kilogram.

Changes in 99.9999%-pure gallium prices from 1960 to 1988 and a brief analysis of the factors that influenced these changes were included in a Bureau of Mines report on nonferrous metals prices.³

Gallium production was estimated to be about 50,000 kilograms in 1989. Most gallium was recovered in the Federal Republic of Germany, France, and Japan. With the opening of Rhône-Poulenc S.A.'s gallium recovery facility in Australia, it is expected that Australia will become one of the leading gallium producers in the next few years.

Australia

Rhône Poulenc's 50,000-kilogram-per-year gallium extraction plant opened in April near Pinjarra, Western Australia. Crude gallium produced at the plant was shipped to Rhône-Poulenc's refinery in France for production of 99.9999%- and 99.99999%-pure gallium. Feedstock for the Australia plant comes from Alcoa of Australia Ltd.'s alumina refinery nearby.

Canada

In June, Alcan Aluminium Ltd. announced that the company was withdrawing from its gallium operations. Alcan owned a 10,000-kilogram-per-year gallium purification plant in Switzerland and a 10,000-kilogram-per-year gallium scrap recycling facility in Kingston, Ontario. The company also had planned to construct a 4,000-kilogram-per-year gallium recovery plant in Jonquière, Quebec.

United Kingdom

Imperial Chemical Industries Ltd. (ICI) announced that it would sell its Wafer Technology subsidiary, which processed GaAs. The company cited the slow progress in developing applications for GaAs because of its cost and the manufacturing complexity. Earlier in 1989, Plessey PLC, another GaAs producer, significantly reduced its activities in the technology.

CURRENT RESEARCH

IBM Corp. reportedly demonstrated two experimental GaAs integrated circuits for sending and receiving data over fiber optic lines at speeds of 1 billion bits per second. These components, which contain 50 times more electronic and optical components than previously assembled on 1 chip, were designed as precursors to high-speed optical links between computers. Many new computer applications, including national economic forecasts and aircraft simulations, would be suited for the new technology because they create images composed of billions of data bits. Sending these images from one place to another would require new data transmission techniques.⁴

Scientists at SRI International announced that they fabricated a GaAs laser diode that emits multiple lasers

from a single diode. Instead of creating mirrorlike edges when the diode is cut from the wafer, the multiple laser diode uses a specialized waveguide that is 1/500th of the width of a human hair. This technique allows diodes to be made with tightly packed lasers that produce a stronger beam. The new diodes may allow integrated circuits in high-speed computers to relay information with light instead of wires.

A new transistor that can do the work of more than 20 conventional devices was developed at American Telephone & Telegraph Co.'s (AT&T) Bell Laboratories. Two very thin layers of indium gallium arsenide (InGaAs) clad with 2 aluminum indium arsenide layers, each 25 atoms thick, creates a quantum structure. Although commercial manufacture of quantum devices is years away, AT&T has used the new transistor in complex circuits to detect transmission errors in digital telephone systems. Normally this task requires 24 conventional transistors, but because the AT&T transistor can operate in multiple states, it can function as a parallel processor, doing several tasks at once.

Engineers at the University of California at Santa Barbara reported that they constructed and tested a lattice of quantum wires constructed of GaAs

bounded by an insulation of aluminum arsenide. These wires are so tiny, 6 million of which would equal the width of a human hair, that they behave as if they only have two dimensions—length and width. These are precursors of a new family of components that would lead to even greater miniaturization of computer components and electronic equipment, although commercialization of the devices is likely more than 15 years away. A review of quantum technology outlines some of the recent U.S. developments.⁵

Ferranti Instrumentation Ltd. of the United Kingdom announced the development of an optical communications system for use in battlefield radio communication. The new system, based on the use of GaAs laser diodes, would allow users to communicate without fear of revealing their position, and the system also resists jamming. Testing of the communications system was performed on a military helicopter, and the company claimed that there may be applications in land- and sea-based military equipment.

Spire Corp. received several contracts from Government agencies in 1989 to develop new GaAs-based components. The company received a contract from the National Aeronautics & Space Administration to develop an InGaAs photodetector that is capable of detecting wind-shear conditions and would be incorporated into a system that can be carried on airplanes to monitor air turbulence. The U.S. Air Force awarded two contracts to Spire. One contract was to develop a long-wavelength GaAs-gallium aluminum arsenide (GaAlAs) superlattice photodetector for infrared imaging applications. The second contract was for the development of lighter, more radiation-resistant GaAs solar cell assemblies. In addition, Spire also received a contract from the Naval Weapons Support Center for development of GaAs complementary heterojunction bipolar technology.

Varian Associates Inc. reported the development of a terrestrial solar cell with a 27.6% solar-to-electric-power conversion rate, which was the highest rate ever reported. The new solar cell was made with layered GaAs and GaAlAs. Varian also received a \$2.6 million contract from the U.S. Air Force to develop three-junction cascade solar cells with a 30% conversion rate.

The unit would consist of GaAs sandwiched between GaAlAs and InGaAs and would be designed to operate at 75° to 100° C.⁶

Scientists at the University of California's Lawrence Berkeley Laboratories announced the development of a new method of GaAs crystal growth that significantly reduces crystal defects. GaAs crystals were grown in a completely sealed crucible that uses microprocessors to control temperature gradients and growth rates. Using an advanced vertical freeze technique, the researchers produced 2-inch-diameter crystals with 5 to 10 times fewer defects than crystals produced by conventional methods. Fewer crystal defects should result in increased GaAs device yields from the crystal.

Scientists at Bell Communications Research reported using a technique called epitaxial lift-off to produce thin layers of GaAs that can be separated from the substrate on which they are grown and transferred to another material. In normally produced GaAs optoelectronic devices, over 90% of the device is present to mechanically support the thin active layer. By separating the active layer from the support, GaAs optical devices can be combined with silicon-based integrated circuits, virtually eliminating difficulties surrounding the growth of GaAs on a silicon

substrate. In the new technique, a dissolvable film of aluminum arsenide is deposited directly on a GaAs substrate, then the active layers are deposited on the aluminum arsenide surface. Treatment with hydrofluoric acid dissolves the aluminum arsenide layer, and the active layers can be separated from the substrate, which can be reused. The active layers can then be transferred to a smooth surface such as a polished silicon wafer.

OUTLOOK

Nearly all the gallium consumed in the United States, and throughout the world, is used as gallium compounds, particularly GaAs, for optoelectronic devices and integrated circuits. The technology to produce these devices is still developing and a significant portion of the funding for research and development is provided by the Department of Defense. If total defense funding is cut back, as has been anticipated in view of recent world events, it is likely that funding for GaAs device development will be reduced. With slower technological advancements, penetration of GaAs devices into new applications would be greatly reduced, and consumption would remain flat or may decline.

At the same time, GaAs components are still undergoing "head-to-head" competition with silicon components in markets in which GaAs had expected to replace silicon. Continued developments in silicon production technology have led to the development of more powerful devices that can compete with GaAs devices in these applications and are much less costly. This factor also would lead to flat or reduced gallium consumption.

Although many companies are working to reduce the cost of GaAs device production, improve materials yields, and develop devices for large-scale commercial applications, it is likely that U.S. gallium demand over the next few years will remain at about the same level as that in 1989.

GEM STONES

By Gordon T. Austin

Mr. Austin, a physical scientist with over 30 years industry and Government experience, has been the gem stones commodity specialist since 1986. Mr. William Field, mineral data assistant, prepared the domestic production survey data.

The value of production of natural gem materials in the United States during 1989 decreased slightly to \$42.9 million. The materials produced included faceting rough, lapidary rough, carving material, specimen material, natural and cultured freshwater pearls, mother of pearl, agatized coral, and coral.

The reported combined production value of synthetic and simulant materials was \$18.8 million, about a 15% increase over that of 1988. Synthetic gems are manmade and have essentially the same optical, physical, and chemical properties and the same appearance as the natural gem that they represent. Synthetic gem materials produced in the United States include alexandrite, coral, diamond, emerald, garnet, lapis lazuli, quartz, ruby, sapphire, spinel, and turquoise. Simulants are manmade gem materials that have an appearance similar to that of a natural gem material but have different optical, physical, and chemical properties. The gem simulants produced in the United States include coral, cubic zirconia, lapis lazuli, malachite, and turquoise. Additionally, certain colors of synthetic sapphire and spinel, used to represent other gem stones, would be classed as simulants. Colored and colorless varieties of cubic zirconia are the major simulants produced.

Wholesale and retail outlets, gem and mineral shops, gem and mineral shows, cutting factories, and jewelry manufacturers were the major purchasers of domestic gem materials.

DOMESTIC DATA COVERAGE

The Bureau of Mines estimates of U.S. production were from the "Natural and Synthetic Gem Material Survey," a vol-

untary survey of U.S. operations, and from Bureau estimates of unreported production. Of the approximately 358 operations surveyed, 82% responded, accounting for about 95% of the total production, 92% of the natural production, and 100% of the synthetic and simulant production.

The 358 operations surveyed in 1989 were an increase of about 19% compared with the number of operations surveyed in 1988. The response rate was essentially the same as that of 1988. The Bureau estimated the production by nonresponding operations, by professional collector, and by amateur or hobbyist collectors. The basis for these estimates were information from published data, conversations with gem and mineral dealers, analyses of gem and mineral shows and sales statistics, and from information informally supplied by collectors. The Bureau is totally dependent on the cooperation of the producers, brokers, dealers, and collectors for the formal voluntary survey and the informal surveys. Individuals and companies have been very cooperative and forthcoming with information. The Bureau is very appreciative of this cooperation.

PRODUCTION

Each of the 50 States produced at least \$1,000 worth of gem materials. Ten States accounted for 95% of the total value of natural gem material produced. The States, in order of declining value of production, with their 1988 standing shown in parenthesis, were Tennessee (1), Arkansas (4), California (2), Arizona (3), Montana (5), Nevada (12), Oregon (6), North Carolina (7), Maine (16-17), and Utah (10). Certain States were known for the production of a single gem material (i.e.,

Tennessee for freshwater pearls and Arkansas for quartz). Other States produced a variety of gem materials. Arizona produced the greatest variety of gem materials. Production included agate, amethyst, antlerite, azurite, chrysocolla, fire agate, garnets, jade, malachite, obsidian, onyx, peridot, petrified wood, precious opal, shattuchite, smithsonite, and turquoise. California, Idaho, Montana, and North Carolina also produced a variety of gem materials. North Carolina was the only State to have ever produced all four of the major gems: diamond, emerald, ruby, and sapphire.

The average production value of natural gem materials for the past 10 years was \$12.5 million a year, with a high of \$43.5 million in 1988 and a low of \$6.9 million in 1980. The value of production for the past 10 years must be separated into two trends. The first trend was the period between 1979 to 1985, during which time approximately 24 operations reported production. Production averaged \$7.5 million a year and was generally level. During the second trend, 1986 to the present, production averaged \$24.2 million and was the result of an increase of 1,392% in the number of producers surveyed.

The reported production value of synthetic and simulant gem materials was \$18.8 million in 1989. The reported value of production increased 15%; however, the quantity of materials produced was significantly greater. A shift in the types of materials produced, primarily a change from colored cubic zirconia to colorless cubic zirconia, resulted in the production of lower valued material. Thirteen firms, five in California, four in Arizona and one each in Massachusetts, Michigan, New Jersey, and Ohio, produced synthetic and simulant gem material. The six States, in order of declining value of production were Massachusetts, California, New Jersey, Michigan, Ohio,

and Arizona.

Dia Em Resources Ltd. and LKA International Inc. completed the evaluation of their Rist and Ellis Emerald Mines at Hiddenite, NC, in 1988, and disposed of the property in 1989. LKA's plans to sell the two largest emerald crystals ever found in the United States, the 1,438-carat Stephenson and the 1,686.3-carat LKA crystal, have not been successful to date.

Crystal Exploration Inc. of Denver, CO, a subsidiary of Restech International Ltd. of Sydney, Australia, continued exploration for diamonds on mineral leases in Michigan. It purchased the leases from Dow Chemical Co. in 1988. Crystal took advantage of the north-central U.S.'s cold winter weather to explore for diamonds on the frozen grounds of swamps in Michigan and Wisconsin.

Amselco Exploration Inc., a subsidiary of British Petroleum Co. of Canada, and Exmin Corp., a subsidiary of the Belgian company Sibeka (Societe d'Entreprises et d'Investissements S.A.), continued exploration for diamonds on leased lands in Michigan and Wisconsin. Exmin also continued diamond exploration efforts in Minnesota.

Three firms continued their diamond exploration project in the State Line district on the Colorado-Wyoming border.

The Arkansas State Parks, Recreation, and Travel Commission voted 12 to 0 to enter a cooperative agreement with four mining companies to undertake a testing program at Crater of Diamonds State Park. Their vote enacted the recommendation of the Diamond Mining Task Force. The program will decide if commercial diamond mining at the park would be feasible. The four companies will pay for the testing, plus any litigation costs. Each firm also will appoint a representative to a technical advisory team that will manage the testing. The four firms are (1) Continental Diamonds, a joint venture between Continental Diamonds Inc. and Galactic Resources Ltd., (2) Diamond Development Co., a equal ownership joint venture between Sunshine Mining Co., Rhombus Inc., Exdiam Inc., and Boule Partnership, (3) Capricorn Diamonds Ltd., and (4) Kennecott Inc. The testing would cost about \$350,000 and would include drilling about 30 core holes. Two environmental groups, the Sierra Club and

Friends of the Crater of Diamonds, have promised to sue to stop the testing.

In June, the U.S. Forest Service held the first ever bid opening for quartz mining parcels in the Ouachita National Forest. A total of 76 bids, worth more than \$25,000, were received on 84 parcels. The successful bids covered only 46 of the 84 parcels, representing about 522 hectares (1,289 acres) valued at \$18,464. The parcels ranged in size from about 4 hectares (10 acres) to about 32 hectares (80 acres). A successful bidder will be issued a 5-year contract on the parcel and will be required to pay an annual fee to retain the contract. The revenues generated by the program, bids, and annual fees will be divided equally between the Federal and State Governments. The State plans to return its share to the county containing the lease parcel.

Mines in southern Oregon continued to produce a large amount of gem Labradorite. Production included both material that contained schiller, commonly known as sunstone, and non-schiller material, called helidorite by some. The Ponderosa Mine furnished the material to cut an extremely fine bright red color stone of over 10 carats. The mine at Opal Buttes in Morrow County continued to produce several varieties of very high-quality opal.

Hobbyist and commercial production of sapphire in Montana increased significantly during the year. Improvements in the techniques for heat treating the material and better commercial acceptance of the Montana sapphires were the major reasons for this increase. The increase in production occurred at all three of the major producing areas, the Missouri River, Rock Creek, and Yogo Gulch.

Plumbago Mining Corp. of Rumford, ME, mined amethyst for the entire permitted mining season, June through September, at the Sweden, ME, property of the Saltman family. Gems & Gemology reported production was about 2,270 kilograms, of which most was specimen quality. An officer of Plumbago reported the cutting of a 12-carat stone from material from the mine and that some material recovered would yield stones as large as 20 carats.

Sugar Hill Minerals reported the recovery of the largest gem morganite ever found in North America. The rose col-

ored beryl was found at the company's Bennett Quarry near Buckfield, ME. The large crystal produced about 23 kilograms of varying sized blocks of gem rough for the company's gem inventory.

American Pearl Farms of Tennessee completed its third significant harvest of cultured freshwater pearls. American currently has five pearl farms under operation and purchased additional water acreage for a sixth farm to be established during 1991. The new farm will be nine times larger than the existing farms.

Pala International reported the discovery in May of the largest gem pocket found at the Himalaya Mine during the past 12 years. The pocket was approximately 0.7 by 1 by 3.7 meters and yielded about 500 kilograms of tourmaline. Approximately 50% of the material was suitable for carving or cabochons, with less than 1% suitable for faceting. The Himalaya Mine is in the Mesa Grande District of San Diego County, CA.

CONSUMPTION AND USES

Consumption of domestic gem material production was in the commercial and amateur manufacture of jewelry, for exhibit in gem and mineral collections, and for decorative purposes in statuettes, vases, and other art objects. Some industrial applications requiring clean homogeneous stones used low-quality gem diamond.

Industrial uses of tourmaline include a simple laboratory instrument to show the polarization of light, as a material to measure the compressibility of fluids, and in gages for measuring high pressures. Mortar and pestle sets, knife edges for balances, textile rollers, and spatulas are some nongem uses of agate. The manufacturing of jewel bearings for timing devices, gages, meters, and many other types of instruments requiring precision elements used natural gem material. These uses are now mostly supplied by artificial and synthetic crystalline materials.

The uses of synthetic and simulant gem crystals include applications in frequency controllers, polarizers, transducers, radiation detectors, infrared optics, bearings, strain gages, amplifiers, lasers, lenses, crucibles, and many more. A

recently developed use is as connectors for optical fibers.

The estimated value of U.S. apparent consumption was a record high \$3,711 million, but only a slight increase over that of 1988. The average annual estimated consumption for the past 10 years was \$2,737 million, with a high of \$3,711 in 1989 and a low of \$1,642 in 1982. The trend for estimated consumption for the past 10 years was one of continued growth with about 199% total increase or an annual compounded growth rate of about 13%.

The value of U.S. estimated apparent consumption of diamonds increased slightly to \$3.1 billion. The average annual value of apparent consumption of diamonds for the past 10 years was \$2,158 million, with a high of \$3,115 million in 1989 and a low of \$1,642 million in 1982. The trend for the value of apparent consumption for the past 10 years was one of significant increase. The value of apparent consumption of diamonds increased 216% over the period.

The 1989 estimated apparent consumption of colored stones, led by emerald, ruby, and sapphire, was valued at \$406.9 million, an increase of 31%. The annual average value of consumption of colored stones for the past 8 years was \$316.0 million, with a high of \$406.9 million in 1989 and a low of \$252.4 million in 1982. The trend for apparent consumption of colored stones for the past 8 years was one of fluctuating increases and decreases, but the general trend was one of increased consumption.

The estimated apparent consumption of pearls—natural, cultured, and imitations—was \$146.9 million, a decrease of about 18% from 1988. The value was about 53% greater than the 8-year low in 1982, but was about 18% less than the 8-year average of \$178.9 million a year.

Estimated apparent consumption of synthetic and imitation gem materials decreased about 49% to \$43.7 million. Average apparent consumption of synthetic and imitation gem materials for the past 8 years was \$50.3 million per year, with a high of \$109.1 million in 1987 and a low of \$13.9 million in 1982. The trend for apparent consumption for the past 8 years was one of generally strong growth until the significant decrease in 1989. Even with the 1989 decrease, annual apparent con-

sumption increased about 214% over the 8 years.

Estimates of U.S. diamond jewelry sales by jewelers were \$11.6 billion during 1989, up slightly from the \$11.3 billion in 1988.

PRICES

Demand, beauty, durability, rarity, freedom from defects, and perfection of cutting determine the value of a gem stone. But the major factor in establishing the price of gem diamond is the control over output and prices as exercised by the Central Selling Organization's (CSO) Diamond Trading Co. Ltd. The CSO is a subsidiary of De Beers Consolidated Mines Ltd.

The average U.S. wholesale asking price of the top 25 grades (D-H color

and IF through VS2 clarity) of a 1-carat diamond fluctuated between \$7,256 and \$7,202 and was \$7,044 at yearend. The average value per carat of all grades, sizes, and types of gem-quality diamond imports was \$408, a 9% increase compared with that of 1988. The average value of diamond imports for the past 10 years was \$407 a carat, with a high of \$541 in 1980 and a low of \$353 in 1984. The trend for the average annual value of diamonds imported for the past 10 years was one of general decline from the 10-year high in 1980 to stable prices in 1986, 1987, and 1988, followed by the 1989 increase.

The average yearend wholesale purchase price of a fine-quality 1-carat ruby, paid by retail jewelers on a per stone or memo basis, was \$3,500, unchanged from 1988. The average value of ruby imports increased 9% to \$33.75 a carat. The average annual value of

⁴ Jeweler's Circular-Keystone V. 159, No. 2, Sept. 1989.

ruby imports for the past 8 years was \$25.33 per carat, with a high of \$34.04 in 1982 and a low of \$16.42 in 1984. The trend for the value of ruby imports for the past 8 years was one of rapid decline, 52% for the period from 1982 to 1984. This was followed by a steady, moderate increase of 16% per year.

The average yearend wholesale purchase price of a fine-quality 1-carat sapphire, paid by retail jewelers on a per stone or memo basis, was \$1,400, unchanged from 1988. The average value of sapphire imports increased 5% to \$24.28 per carat. The average annual value of sapphire imports for the past 8 years was \$23.43 per carat, with a high of \$27.97 in 1987 and a low of \$18.50 in 1984. The trend for the value of sapphire imports for the past 8 years was one of fluctuating increases and decreases. The 8-year period ended with the 1989 value slightly below the 1982 value.

The average yearend wholesale purchase price of a fine-quality 1-carat emerald, paid by retail jewelers on a per stone or memo basis, was \$2,750, an increase of 6%. The average value of emerald imports decreased 23% to \$61.00 per carat. The average annual value of emerald imports for the past 10 years was \$56.47 per carat, with a high of \$78.79 in 1988 and a low of \$35.06 in 1984. The trend for the value of emerald imports for the past 10 years was one of fluctuating increases and decreases from 1980 through 1984. A steady moderate growth followed, re-

sulting in the 1989 average value being about 55% greater than the 1980.

FOREIGN TRADE

The export value of gem materials increased 17% to \$1,180 million, a record high. The quantity of diamonds exported increased 17% to 692,588 carats, and the value of diamond exports increased about 20% to \$1,086.6 million. The average annual quantity of diamonds exported for the past 10 years was 369,264 carats, with a high of 590,412 in 1988 and a low of 184,871 in 1982. The trend for the quantity of diamonds exported for the past 10 years was one of moderate decline, 13%, during the first 4 years, followed by significant growth, 219%, from 1982 to 1989. The average annual value of diamond exports for the past 10 years was \$521.6 million, with a high of \$908.9 million in 1988 and a low of \$292.8 million in 1982. The trend for the value of diamond exports for the past 10 years was one of significant decline, 113%, over 4 years, followed by a moderate growth of 32% in 3 years, and then a significant growth of 136% over the last 3 years. This resulted in record exports in 1989.

The export of other precious stones, cut but unset and other than diamonds and pearls, decreased about 36% to \$43.6 million. The average annual export value for the past 8 years for these

natural gem stones was \$39.4 million, with a high of \$68.5 million in 1988 and a low of \$27.7 million in 1984. The 8-year trend for the value of exports for these types of gem materials was one of increases and decreases, but ultimately resulting in a significant total increase of 131% for the period.

Exports of synthetic gem material increased by 667%, to \$46.0 million. The average annual value of exports for the past 8 years was \$15.6 million, with a high of \$46.0 million in 1989 and a low of \$6.0 million in 1987 and 1988. The 8-year trend for the value of exports was one of extreme decline, 52%, for 1982-83, followed by steady moderate growth of 62% over the next 5 years and showing a significant gain in the last year.

Export of natural, cultured, and imitation pearls, not set or strung, increased about 55% to \$3.4 million.

Reexports of gem material decreased 24% to \$293.2 million. The quantity of diamonds reexported decreased about 77% to 0.4 million carat, the lowest amount in the past 10 years. The value of diamonds reexported decreased about 51% to \$157.1 million. The average annual quantity of diamonds reexported for the past 10 years was 1.8 million carats, with a high of 3.0 million carats in 1981 and a low of 0.4 million in 1989. The 10-year trend for the quantity of diamonds reexported was highly mixed. The period started with 2 years of extreme increase, 171%, followed by 3 years of moderate decline, 37%, followed by 3 years of essentially stable reexports, and then the most recent declines in 1988 and 1989. The average annual value of reexported diamonds for the past 10 years was \$285.0 million, with a high of \$412.8 million in 1981 and a low of \$157.1 in 1989. The 10-year trend for the value of reexports was one of increase, 4%, for 1980-81, moderate decline, 55%, the next 4 years, followed by 3 years of significant increase, 72%, and then the major decrease in 1989. The value of 1989 reexports was 61% less than that of 1980.

The reexport of natural gem materials, cut but not set, other than diamonds and pearls, decreased about 92% to \$4.6 million, a record low for the 8-year period for which data were available. The average annual value of reexports for the past 8 years was \$33.0

TABLE 2
PRICES OF U.S. CUT COLORED GEM STONES, BY SIZE¹

Gem stones	Carat weight	Price range per carat in 1989 ²	Average price per carat ²	
			Jan. 1989	Jan. 1990
Amethyst	1	\$6- \$18	\$8.00	\$13.00
Aquamarine	1	100- 250	175.00	175.00
Emerald	1	1,900-3,500	2,400.00	2,750.00
Garnet, tsavorite	1	500- 800	950.00	650.00
Ruby	1	3,000-4,000	3,000.00	3,500.00

Tanzanite	1	250- 350	354.00	300.00
Topaz	1	6- 12	7.50	9.00
Tourmaline, red	1	60- 125	92.50	92.50

¹ Fine quality.

² Jewelers' Circular-Keystone V. 161, No. 3, Mar. 1990, p. 190. These figures represent a sampling of net prices that wholesale colored stone dealers in various U.S. cities charged their cash customers during the month for fine quality stones.

million, with a high of \$55.1 million in 1988 and a low of \$4.6 million in 1989. The 8-year trend for the value of reexports was one of alternating decreases and increases.

The reexport of natural gem materials not cut or set, other than diamonds and pearls, increased about 473% to \$127.3 million. The extremely large increase was most likely the result of reexporting colored stones to worldwide cutting centers for cutting and reexport to the United States as finished gems. The average annual value of reexports for the past 8 years was \$25.0 million, with a high of \$127.3 million in 1989 and a low of \$1.3 million in 1987. The 8-year trend for the value of reexports was one of extreme increases and decreases, with the value over the period increasing 1,575%.

Reexports of natural, cultured, and imitation pearls and synthetic gem materials were \$3.9 million and \$0.4 million, respectively.

The value of gem materials imported increased slightly to a record high of \$5,115 million. The value of imported gem diamonds accounted for about 85% of the total. The average annual value of gem material imports for the past 10 years was \$3,661 million, with a high of \$5,115 million in 1989 and a low of \$2,384 million in 1982.

The value of imported gem diamonds increased slightly to a record high of \$4,358 million. The 10-year trend for the value of diamond imports was one of generally steady continuous growth with an increase of 94% for the period. During the period, the value of imported uncut diamonds decreased 44%, while the value of cut stones imported increased 203%.

The imports of cut diamonds increased slightly in quantity and value to 8.9 million carats and \$3,805.5 million, respectively. The average annual quantity of cut diamonds imported was 6.3 million carats, with a high of 8.9 million in 1989 and a low of 1.3 million carats in 1980. The trend for cut diamond imports for the past 10 years was one of continued increases; the period ended with imports 246% greater than at the beginning of the period. The average annual value of imported cut diamonds was \$2,549.6 million, with a high of \$3,805.5 in 1989 and a low of \$1,256.0 million in 1980. The trend for the value of imported cut diamonds for

the past 10 years was of strong growth and increases. The value at the end of the period was 203% greater than at the beginning.

The value of imports of other gem materials, led by emerald, ruby, and sapphire, was \$756.4 million, about the same as those of 1988. Emerald imports increased about 19% to 207.5 million. The average annual value of emerald imports for the past 10 years was \$149.8 million, with a high of \$207.5 million in 1989 and a low of \$120.8 million in 1982. The 10-year trend for the value of emerald imports was one of fluctuating increases and

decreases resulting in a 44% increase for the period.

The value of ruby imports increased 16% to 83.4 million, the fourth highest value for the past 10 years. The average annual value of imports for the past 10 years was \$75.8 million, with a high of \$93.8 in 1981 and a low of \$58.7 in 1987. The 10-year trend for import values was one of extreme fluctuations. The period ended with values having increased 42% from the 10-year low, but still 11% below the high for the period.

The value of sapphire imports increased 23% to \$100.0 million, the high

value for the past 10 years. The average annual value of sapphire imports for the past 10 years was \$78.7 million, with a high of \$100.0 million in 1989 and a low of \$50.3 million in 1980. The 10-year trend for the value of imports was one of extremely fluctuating increases and decreases. The period ended with the value 96% greater than

at the beginning and at the high for the period.

The value of imported gem materials other than diamond, emerald, ruby, and sapphire decreased 15% to \$365.5 million. The average annual value of imports was \$314.7 million, with a high of \$429.5 in 1988 and a low of \$110.6 in 1980. The 10-year trend for the value

of imports was one of fluctuating increases and decreases resulting in a total increase of 230% for the period.

WORLD REVIEW

Diamond sales by De Beers Consolidated Mines Ltd.'s CSO in the second half of 1989 were \$1.77 billion. This was 24% less than the \$2.32 billion for the first half of 1989 and 10% less than for the second half of 1988. Total diamond sales by the CSO were \$4.09 billion in 1989, about 2% less than the 1988 record high of \$4.17 billion. According to diamond dealers, the reduced sales were most likely the result of a sagging U.S. demand. Estimates of the annual world market for diamond jewelry are approximately \$40 billion. The U.S. share of this market dropped in 1989 from the historical level of about 33% to 29%. The three largest consumers are Japan (30%), the United States (29%), and Europe (18%). The amount of diamonds in the pipeline between the CSO rough sales and the retail purchaser is of equal importance to the CSO sales. Estimates of the material in the pipeline in 1989 were about \$15 to \$18 billion, measured at wholesale polished prices, or 2.5 years of sales. Sales of colored gem stones remained very strong.

Natural diamond production occurs in Africa, Asia, Australia, and South America. The principal producing localities are as follows: in Africa—Angola, Botswana, Namibia, the Republic of South Africa, and Zaire; in Asia—the U.S.S.R. (Northeastern Siberia and in the Yakut, A.S.S.R.); in Australia; and in South America—Venezuela and Brazil.

Foreign countries in which major gem stone deposits (other than diamond) occur are Afghanistan (beryl, kunzite, ruby, tourmaline); Australia (beryl, opal, sapphire); Brazil (agate, amethyst, beryl, kunzite, ruby, sapphire, tourmaline, topaz); Burma (beryl, jade, ruby, sapphire, topaz); Colombia (beryl, sapphire); Kenya (beryl, garnet, sapphire); Madagascar (beryl, rose quartz, sapphire, tourmaline); Mexico (agate, opal, topaz); Sri Lanka (beryl, ruby, sapphire, topaz); Tanzania (tanzanite, garnet, ruby, sapphire, tourmaline); and Zambia (amethyst, beryl).

Angola

Endiama, the Government-owned and operated diamond mining company, sold over 1 million carats of diamonds in 1989 valued at about \$200 million. But when diamonds taken in UNITA raids and smuggling are considered, the country's production was most likely nearly double the official sales. UNITA representatives recently offered \$10 million worth of rough for sale on the U.S. market.

De Beers signed a declaration of intent with Endiama to help in developing Angolan diamond deposits. The agreement, worth \$180 million annually, is for co-operation in prospecting, mining, and marketing. Further discussions and technical studies, leading to the establishment of a joint venture, are underway. Endiama may start marketing a "significant proportion" of production through the CSO in 1990, moving toward an exclusive agreement as production increases. It is also the intentions of the parties to build a diamond sorting building in Luanda in which to sort Angolan production before its sale to the CSO.

Australia

Poseidon Exploration Ltd. purchased Freeport Bow River Properties Inc., the joint venture of Freeport-McMoRan Australia Ltd. and Gem Exploration and Minerals Ltd. The joint venture owned and operated the Bow River alluvial diamond project. Production from Bow River averages 20% gem quality, 70% near-gem quality, and 10% bort.

Argyle Diamond Mines Pty. Ltd.'s annual diamond production from the AK-1 pipe was essentially unchanged at about 34.4 million carats. Argyle's annual production accounted for about 37% of the world's production of natural diamonds.

Many firms continued their diamond exportation efforts. Gem Exploration Ltd. reported success in a sampling program for the Kununurra Project in Western Australia, and Terres Resources NL also worked in the Kununurra area. Poseidon-Trian Minerals continued to explore in the Phillips Range in Western Australia, as did the Capricorn Resources, Copperfield, and Moonstone joint venture. Auridiam-Afro-West worked on its project at Mount Wynne in Western Australia, as

on either side of the Ord rivermouth. Quicksilver Resources was seeking investors to finance the exploration of three diamond prospects in Western Australia, the Byro Project, Mount Edith, and Tier Range. The Mount Gipps Ltd. and Reedy Lagoon Corporation NL joint venture will begin drilling for diamonds in the Reedy Lagoon region of South Australia during 1990.

Australia held its first culture pearl auction in October at Darwin. Long the leading producer in the quantity of cultured South Sea pearls, it was time also to claim the title of number one in quality. For this reason, the nine pearl farms that account for an estimated 80% of the production decided to sell the bumper pearl crops at home instead of in Japan. The auction was a large success with 60 firms worldwide spending \$33.5 million. The Japanese were the largest purchaser, buying about \$23 million.¹

A new form of gem orthoclase, named Rainbow Lattice Sunstone, was discovered in an area known as the

Mud Tank Zircon Field in the Harts Range of the Northern Territory. The material was named for the unique lattice pattern of aventurescence it displays. Inclusions of ilmenite and hematite oriented on the crystal lattices causes this effect.²

Heavy rains during the month of March severely disrupted opal production from Coober Pedy, Mintabie, and Andamooka. The rains collapsed mine shafts and flooded tunnels and opencut mines. It will take 6 months, and in some cases a year, to get back into full production. The lost production will result in an increase in the price of Australian opal.

Brazil

Glencairn Explorations Ltd. received a positive feasibility study on the Feijao Cru diamond deposit in Bahia. It was estimated that production would be 42,000 to 84,000 carats annually and would average 80% gem quality. The

original discovery was made by Mineracao Piracicaba Ltd., a Brazilian company. Glencairn can earn 50% interest in Piracicaba by investing an additional \$250,000. There are about 25 small mines operating in the Chapada Diamantina region of Bahia.

Mineracao Te jucana, the joint venture between Sibeka's wholly owned Sibradium Participacoes Ltda. and Union Miniere, produced more than 34,000 carats of diamonds and 107 kilograms of gold from its dredging operations on the Jequitinhonha River. The joint venture operated four dredges on the Lamarao flat and a fifth dredge was located outside of the main production area.

A discovery of tourmaline of unusual colors was made in Paraiba. The material, called "Paraiba" tourmaline, ranged in color from a highly saturated medium bluish green to medium dark blue-green and to a dark blue to violetish blue. The saturation and depth of

color is outstanding. The stones demand a high price with 30 to 50 point stones selling for as much as \$150 per carat and 5-carat stones going for as much as \$2,500 per carat.

Canada

Cameco and Uranerz Exploration and Mining reportedly found seven kimberlite pipes on their joint-venture Fort a la Corne property east of Prince Albert, Saskatchewan. Microdiamonds were found in one pipe. The two firms have staked 170,000 hectares for exploration in the Fort a la Corne area. Additionally, Uranerz is acquiring land to the north in the Choiceland-Snowden-Smeaton area for exploration. The race to claim land for diamond exploration in Saskatchewan is growing. The staking of a 200,000 hectare parcel between Prince Albert and Saskatoon increased the total amount of land held for diamond exploration to 647,000 hectares. Monopros, the Canadian exploration arm of De Beers, started the staking rush in 1988.

Corona Corp. discovered kimberlite rocks on the Sturgeon Lake exploration property of Claude Resources. A drill intersected kimberlite at a depth of 37 meters and was still in kimberlite at 111 meters. To date, there is no indication that the kimberlite contains diamonds; additional work will be necessary to determine if diamonds are present. The property is located north of Prince Albert, Saskatchewan.

Central African Republic

A joint venture, founded in 1987 between Osborne & Chappel Goldfields and Societe d'Enterprise et d'Investissements SA, continued their diamond exploration program with encouraging results. The joint venture has exploration rights for alluvial diamonds along a 170-kilometer stretch of the Mamber River. To date, reconnaissance drilling, geophysical testwork, and small-scale bulk sampling has been completed.

China

The production of colored gem stones increased about 30% in the past year. The five most commonly mined gem stones were aquamarine, tourmaline, sapphire, topaz, and nephrite jade. Other gem materials produced include amazonite, amber, amethyst, andalusite, aventurine, azurite, bowen-

ite, diopside, garnets, jet, kunzite, malachite, peridot, quartz, ruby, turquoise, and zircon.³

Ashton Mining Ltd. of Australia was granted exclusive exploration, mining, and marketing rights for diamonds in the Hunan Province. The company will share equally in any production, processing, and sale of diamonds with the provincial government. A cutting factory will be established in Hunan when diamond production begins.

In Laioning Province, the Wafandian diamond deposit, potentially the largest in China, is being developed for mining and is scheduled to begin operation in late 1990. Production is forecasted to be 118,000 carats per year. The Wafandian Mine would be China's fifth diamond mine, joining the Bin-Hai also in Laioning Province, and the Chang Ma, Tao Cheng, and Linshu Mines in Shandong Province.

Columbia

At the Muzo emerald mine in Boyaca, two major leaseholders, Tecminas and Coesminas, have begun using shafts and underground tunnels in addition to strip mining to recover emeralds. The relative flatness of the Muzo mining area and the accumulation of hundreds of years of mine tailings resulted in limiting access to some areas for production and exploration. The shafts and tunnels may allow the producers to relocate some of the old production veins and to discover new productive areas. The tunnels have encountered problems both with ground support and the inflow of water.⁴

Finland

The Finnish Geological Survey (GSI) reported the discovery of a 2,250-carat emerald. The totally transparent gem was estimated to be valued at approximately \$250,000. The GSI drew up plans to intensify the exploration work in a 2-hectare area.

Guinea

A 255.61-carat diamond, recovered from the Aredor Mine, was purchased for slightly more than \$10 million. At \$39,300 per carat, it was not the highest per carat price ever paid for a rough diamond; a 181.77-carat rough diamond from Aredor sold for \$47,400 per carat in 1988. However, the total purchase price was the highest ever paid

for a rough diamond. In February, Aredor was granted a 405-square-kilometer extension to its mining lease. The new ground is believed to contain high-quality alluvial reserves.

India

During fiscal year April 1, 1988, to March 31, 1989, the value of finished diamonds exported increased 75% to \$2.95 billion. The value was the greatest for any country and accounted for about 28% of the value of diamonds and 70% of the stones used in diamond jewelry. The increase was the result of a general increase in demand for diamonds, a depreciation of the rupee, falling labor costs, and favorable Government policies aimed at boosting exports. India plans to increase its share of the market to near 50% of the value within 2 years. The diamond industry employs approximately 1 million skilled and semi-skilled workers.

The Indian Minerals Exploration Corp. Ltd. and the French BRGM company entered into an agreement to explore for diamonds and develop any commercial deposits discovered in the Pana, Krishna, and Vajnakarur areas.

Israel

Diamond imports and exports increased for the year. Imports increased about 6% to \$2.6 billion and exports were approximately \$2.7 billion, an increase of over 7% compared with that of 1988. Approximately 43% was exported to the United States and about 35% to the Far East.

Dov Riger of Israel and Tasaki Shinju of Japan opened a joint-venture automated polishing factory at Beit Shean, in northern Israel. The factory employs 30 workers using automatic piermatic polishing machines. The entire output of the factory is committed to the Japanese parent company. Tasaki Shinju has annual sales of about \$200 million.

Namibia

Consolidated Diamond Mines of South-West Africa (CDM), the De Beers Consolidated Mines, Ltd. subsidiary that controls the majority of the diamond mining concessions in Namibia, began development of two new diamond operations. The Elizabeth Bay operation will recover about 250,000 carats per year of small stones from windblown depos-

its. The mine is located about 30 kilometers south of the town of Luderitz and will mine and process about 4 million metric tons per year during its projected 10-year life. Production is scheduled to begin in March 1991. The Auchas Mine along the Orange River will recover about 40,000 carats per year of large stones. The mine is scheduled to begin production in July 1990. CDM also is undertaking offshore diamond recovery research at depths of up to 90 meters in its offshore concessions.⁵

The Namibian West Coast Diamond Co. started a major exploration program in the deep-sea area of its concession. The concession starts about 2 kilometers offshore, continues to about 10 kilometers, and is roughly 90 kilometers long. A 250-ton survey and research vessel was purchased to survey, test, and map the deepwater area. In the past 2 years, the company has recovered about 26,000 carats of diamonds from the concession. However, it is estimated that large-scale commercial mining of the concession is still 10 years in the future.

It was reported that in Swakopmund, fake diamond octahedra and imitation tsavorite garnet rough were being sold to gem stone buyers. The fake diamonds were made from cubic zirconia and the tsavorites from cut green bottle glass.

Sierra Leone

In January, the Ministry of Mines began issuing export licenses to private firms and individuals for the export of diamonds. The Ministry granted 26 licenses for diamond exporting, 11 of which were granted to foreign individuals or companies. Applicants must pay a fee for the licenses, a fixed fee and/or a royalty, post a performance bond of \$500,000, and must achieve a performance goal of exporting 250,000 in diamonds monthly, or forfeit the bond. The new regulations eliminate the diamond dealers and recognizes only two legal players in the diamond fields—the miners and the exporters. The Ministry believes that privatization will increase diamond production as well as increasing diamonds sold or exported through official markets.

South Africa, Republic of

The Kim Diamond Cutting Works, currently under construction, will pro-

ess 30,000 carats of rough a week. The cutting factory will employ at least 1,280 workers. Using local rough, it will process stones from 1 to 30 points for the overseas market. The factory is scheduled for completion by the end of April 1990.

A new open pit diamond mine, the Samanda, is being developed in the Orange Free State Province. The mine is forecasted to begin production in the second quarter of 1990. The developer is apparently a private concern.

De Beers announced that, in cooperation with Saturn Mining Ltd. of the Anglovaal group, it will open a new diamond mine on the Venetia farm in The Transvaal. The mine will cost approximately \$280 million and will be the largest investment De Beers has ever made in a single mine. The mine is scheduled to begin production in the second half of 1990 at a rate of about 4 million carats per year.

Gemgold Mining Ltd. commenced mining diamonds from an open pit mine in the Cape Province. The company expects to produce about 40,000 carats in 1990 and 100,000 carats in 1991.

Tanzania

Williamson Diamonds Co. received a \$4.7 million loan from Willcroft Co. Ltd. The funds will be used to modernize Williamson's diamond treatment plant, which has been in operation for over 30 years. The condition of the treatment plant has adversely affected Tanzania's diamond production for a number of years.

Zaire

In April, the Government of Zaire enacted new regulations on the purchase and export of diamonds. The purchasers of artisanal diamonds, called *comptoirs*, were required to pay a license fee and deposit of \$300,000, compared with the old fee and deposit of \$100,000. Additionally, *comptoirs* were allowed to purchase diamonds in Kinshasa if stones were offered for sale. Because Kinshasa is not an official buying location, there are not the same controls that are present in the interior where representatives from the National Evaluation Center are required to be present at all transactions.

Pilfering and smuggling from the diamond-producing areas was rampant according to the *Societe Miniere de*

Bakwanga (Miba). Miba estimated that illegal mining and trafficking of diamonds in the two Kasai provinces cost the Government somewhere between \$140,000 and \$350,000 every month. Tough security measures are difficult to enforce because state security men connive with the smugglers, giving them protection as they go about their business. The law allows Zairian nationals the freedom to mine industrial diamonds anywhere in the country as long as the diamonds are sold through Miba. The system is no longer working because of access to better markets outside of Miba.

A substantial diamond deposit was reportedly discovered at a rubber plantation owned by the Amcit Blattner family at Kaparata. The plantation was sealed off by soldiers, which denied the owners access. The Blattners may enter into an agreement with a well-known diamond firm to exploit the deposit. It is possible that local residents are digging diamonds after gaining access by bribing the soldiers that are guarding the plantation.

Zambia

The Government of Zambia centralized the future marketing of emeralds by allowing the export only of cut and polished stones. Gem-Impex Ltd. of Zurich, Switzerland, was appointed the sole distributor of emeralds cut and polished in Zambia to implement the centralization. Gem-Impex will market Zambian emeralds worldwide for the state-owned Zambian Emerald Industries Ltd. Zambian Emerald, which operates a 50-cutter factory in Ndola, has the exclusive right to cut and polish emeralds produced in Zambia. Production from the Ndola factory was about 5,000 carats per month in a variety of shapes and sizes.

CURRENT RESEARCH

Mr. Zvi Yehuda of Ramat Gan, Israel, developed a new diamond enhancement process. The process improves the apparent clarity of diamonds by filling surface-reaching cleavages and fractures. The process replaces the air that normally fills the cleavages and fractures with a transparent material that has an index of refraction near that of diamond.

The result is that the cleavages and/or fractures are less visible and thus the appearance and apparent clarity of the diamond is improved. The treatment can be detected using a standard darkfield-equipped gemological microscope. The orange and blue flash effects, flow structures, and flattened, trapped gas bubbles evident in the filled areas are easily detected. Yehuda also has founded a firm in the United States that uses a similar procedure to improve the appearance and apparent clarity of emeralds.⁶

The technology to improve the apparent color of diamonds in the very light to light yellow color ranges has been used occasionally to increase the value of a stone. The addition of a grayish or bluish material to the surface of "J" or "K" color stones can give the stone the appearance of a "G" color. This deceptive treatment could affect the value of a 1.00 carat "VS1" "K" stone by as much as \$1,600 by changing its appearance to that of a "VS1" "G." The coating may be a fluoride compound similar to that used for lens coating in optics. The coating generally can be detected by careful examination under 30 to 45 power magnification.

Miners from Santa Terezinha de Goias, Brazil, developed a new process for treating rough and cut emeralds to improve their appearance, similar to the use of oil and Canada balsam on emeralds in the past. The treatment is based on the filling of the fractures that reach the surface of the stones. The stones are cleaned, dried, heated, and then treated with a synthetic fracture sealant marketed under the trade name Opticon. Individuals in the United States have improved and expanded upon the process to include treating stones, primarily cut emeralds, with Opticon in a heated vacuum vessel.

OUTLOOK

World demand for gem diamond can be expected to rise because of the rising average personal income of the population of the United States and other industrialized countries. Demand is expected to increase because of highly effective promotional campaigns. These promotions are changing social customs in many Far East countries, particularly in the use of diamond engagement rings.

^c Estimated. ^P Preliminary. ^r Revised. W Withheld to avoid disclosing company proprietary data.

¹ Table includes data available through May 16, 1990. Total diamond output (gem plus industrial) for each country actually is reported except where indicated by a footnote to be estimated. In contrast, the detailed separate production data for gem diamond and industrial diamond are Bureau of Mines estimates in the case of every country except Australia (1985-87), Botswana (1987), Brazil (1987), Central African Republic (1985-88), Guinea (1985-89), and Liberia (1985-86), for which source publications give details on grade as well as totals. The estimated distribution of total output between gem and industrial diamond is conjectural, and for most countries, is based on the best available data at time of publication. Estimated distribution figures have been revised as necessary to correspond to reported total production figures.

² Includes near-gem and cheap-gem qualities.

³ Includes all synthetic diamond production.

⁴ Reported figure.

⁵ Figures are estimates based on reported exports and do not include smuggled diamonds.

⁶ Figures do not include smuggled artisanal production.

⁷ Includes estimates for artisanal production.

⁸ Revised to zero.

⁹ Other De Beers' Group output from the Republic of South Africa includes Kimberley Pool, Koffiefontein Mine, and the Namaqualand Mines.

The changes are resulting in significant growth in the diamond market.

Demand for other precious gems will continue to grow as diamonds become more expensive and the popularity and acceptance of colored stone increases. Demand for synthetic and simulant gem materials for both personal and industrial consumption is expected to increase. The diversity of sizes, types, uses, and values of gem materials precludes any meaningful forecasting of future demand.

BACKGROUND

The history of production and preparation of gem stones begins with the wearing of items for personal adornment in prehistoric times. This preceded even the wearing of clothes. Amber was mined in the Baltic countries for use as a gem material before 25000 B.C. Later, the Phoenicians in their writings described trade routes to the Baltic for amber and to areas in Asia and Africa for other gem materials. The voyages of Columbus brought increased interest in gem deposits, especially emerald, in South America. The discovery of diamond in Africa in 1859 focused major interest on Africa. More recently, the discovery of diamond in Western Australia in 1967 has resulted in the development of one of the largest deposits in the world.

Commercial mining of gem materials has never been extensive in the United States. Although more than 60 gem minerals and materials have been produced commercially from domestic sources, most of the deposits are relatively small. In many instances, production rests in the hands of the numerous hobbyists and members of mineralogical and lapidary clubs. The Crater of Diamonds State Park near Murfreesboro, AR, is open to the public on a daily fee basis. Many gem-quality stones are found there each year.

Definitions, Grades, and Specifications

Select rocks, certain varieties of mineral specimens, and some organic materials such as pearl, amber, jet, and coral are included in gem stones data. Customarily, diamond, ruby, sapphire, and emerald are considered the major gems.

The designation "gem stone" refers to a material appropriate for personal adornment. The most important qualities of gem stones are beauty, durability, uniqueness, and rarity. Beauty, indicated as splendor, purity, or attractiveness, is judged mainly according to the taste of the beholder and includes such appearances as luster, transparency, brilliance, and color. Luster of a mineral or stone is independent of color and is the surface appearance in reflected light. Apart from materials that have a metallic luster, the chief contributors to luster are transparency and refractive index. The perfection of polish enhances the luster of a stone. Visible imperfections impair the luster of transparent stones. However, defects, described as "jardens" or "inclusions," may enhance the beauty and value of natural rubies, sapphires, and other gem stones and may be used to identify the country of origin and even the mine. Durability is measured by the resistance of a stone to abrasion, pitting, chipping, or splitting. Resistance to abrasion is correlated with relative hardness, but intrinsic brittleness and toughness indicate resistance to wear in other aspects. Rarity is an essential qualification and is more important for some stones in determining their value than their physical characteristics.

Of the 1,500 mineral species, only about 100 possess all of the attributes required in gems. Silicates furnish the greatest number, including such minerals as beryl, topaz, tourmaline, and feldspar. Oxides such as corundum (ruby and sapphire) and quartz (amethyst, agate, etc.) comprise the second largest group. Sulfides, carbonates, and sulfates are of small importance; the phosphates yield only turquoise and variscite. An exception is pearl, essentially calcium carbonate, which is ranked high as a gem. Diamond, the best known gem stone, is an isometric crystalline form of the element carbon.

In general, gem materials are classified the same as minerals, that is, into group, species, and variety. Group refers to two or more gem materials that are similar in crystal structure and physical properties but have different chemical properties. Each individual member of the group is called a species. Varieties of species have similar crystal structure and chemical characteristics but differ in color. An example of this would be the hessonite variety of the

grossular species of the garnet group.

Products for Trade and Industry

Cutting and polishing of gem materials are done to obtain the most effective display of the material. No significant change is made in the fundamental properties, and the preparation is intended to enhance the desirable characteristics that are present initially. Gem materials are cut into gem stones in three main styles; cabochons, baroque, and faceted.

Cabochons are cut in four operations: sawing, grinding, sanding, and polishing. Sawing, the initial step in cutting, is customarily done with a diamond saw to obtain a slab or slice of the desired size and thickness from the rough gem material. The cabochon outline is scribed onto a flat surface, most often using a template for making a standard size for jewelry mountings. Rough grinding of the stone may be by metal-bond diamond, silicon carbide, or aluminum oxide wheels or coated abrasive disks. In grinding, the hardness of the gem material determines the grit and hardness of the abrasive used. Multiple grinding steps starting with 80- to 100-mesh (grit) through 600-mesh abrasives are normally used. The scratches left by grinding are removed by progressively finer grinding and sanding. Disk or belt sanders use bonded to cloth abrasives, waterproof reinforced paper abrasives, or cloth charged with abrasive pastes. The final polish is obtained by using hard felt, wood, or leather laps, with various polishing agents such as fine diamond compound, tin oxide, tripoli, chromium oxide, cerium oxide, alumina, and rouge.

Polished irregular shapes are called baroque gems. An inexpensive method of polishing baroque gems consists of tumbling them in rubber-lined drums, using a grinding and polishing medium with or without water.

Facet cutting is employed ordinarily on transparent gem stones to increase brilliancy and appearance and is generally confined to the harder materials. Softer materials may be faceted, but extreme care must be exercised in cutting and polishing the stones and in their use in jewelry. The "round brilliant" cut, most commonly used in faceting, has 58 facets, 33 above the circle "girdle" and 25 below it, arranged in eightfold symmetry. The

FIGURE 1

PRINCIPAL FORMS OF CRYPTOCRYSTALLINE AND CRYSTALLINE GEM STONE CUTS

"round brilliant" and some other common cuts are illustrated in figure 1.

Industry Structure

The world market for diamonds is controlled by De Beers Consolidated Mines Ltd. It is by far the most strictly controlled of the world's commodity markets. An estimated 80% to 85% of gem and natural industrial diamond is marketed by De Beers' wholly owned subsidiary, the Diamond Corp. Ltd. The marketing is done through the CSO by the Diamond Trading Co. Ltd. and the Industrial Distributors Ltd., divisions of the CSO. The CSO sells uncut gem diamonds on behalf of De Beers and most other major producers at sights (approved bidder viewings) in London, England; Lucerne, Switzerland; and Kimberley, Republic of South Africa.

Diamonds reach the CSO sights through three channels. First, South African and Namibian production goes directly to the Diamond Producers Association. The principal members of this association are De Beers, the South African Government, and the Namibian administration. Second, contractual sales by foreign producers are handled by the Diamond Corp. Ltd., which represents the foreign producers on the Diamond Producers Association. Third, open-market competitive sales and West African sales go directly through the Diamond Trading Co.

The Diamond Producers Association funnels the production of the first two groups into the Diamond Purchasing and Trading Co. (50% held by De Beers), part of the CSO. From this point, the diamonds go through the Diamond Trading Co. The Diamond Trading Co. markets diamond to South African cutters at a 10% discount on world prices; and, through its branch in London, diamonds are sold at sights on world markets. The third group's production is handled directly by the Diamond Trading Co.'s London Branch.

The CSO has been extremely successful at maintaining the rough diamond market for about 100 years. In modern times there has never been a decrease in CSO's price of rough diamonds. Table 9 illustrates the timing and the amounts of the average CSO price increases for rough gem diamonds from 1949 until the present. The compounded effect of these increases is a price increase of

about 1,800% over the approximate 41.5 years. Thus, a piece of rough that sold for \$100 in August 1949 would sell for about \$1,800 in April 1990.

For more than 30 years, the major diamond cutting and polishing centers of the world were located in Belgium and Israel, with a certain amount of the larger stones being cut in the United States. Today there is estimated to be over 450,000 cutters as the result of the development of a large cottage industry in India that started in the early 1980's. This has had a major impact on world diamond trade. Indian consumption of most of the world's small-gem, cheap-gem, and near-gem rough material in the manufacture of small stones resulted in annual cut-stone exports of almost \$3 billion from April 1, 1988, to March 31, 1989. These small stones averaged less than one-fifth of a carat (0.20 carat). The availability of small inexpensive stones resulted in substantial changes in the design of jewelry. The utilization of small cut diamond stones (usually 0.07-0.14 carats each called melee) to create a pavé effect (set close together to conceal the metal base) is but one example. Cutting and polishing of colored, synthetic, and simulant gem stones is centered in Thailand, India, Hong Kong, and Brazil, where cheap labor and favorable export laws ensure the lowest total costs for finished gems.

Geology-Resources

Gem materials occur in a large variety of igneous, metamorphic, and sedimentary rocks and mineral deposits, usually as a small fraction of the total deposit. The origins are as varied as the occurrences. Principal formation of

gem materials is by precipitation from watery solutions, by crystallization from molten rock, and by metamorphic processes. Approximately one-third of gem minerals are composed of silicate minerals, about one-fifth of alumina-silicates, and nearly one-seventh of oxides. The remaining compositional groups include the sulfides, phosphates, borosilicates, carbonates, and, in the single case of diamond, an element. The composition of selected gem materials is included as one of the items in table 10.

The United States has no defined large resources of major gem materials. Emerald deposits are known in North Carolina, as are ruby and sapphire. Historically, sapphires have been mined in Montana, and commercial mining once again is underway. Numerous other domestic deposits of gem minerals are known and have been mined for many years. However, no systematic evaluations of the magnitude of these deposits have been made, and no positive statements can be made about them.

Occasional finds of diamond have been made, but no great diamond pipes or alluvial deposits similar to those of Africa have been reported. Several companies are involved in diamond exploration in the Colorado-Wyoming State Line area, in Michigan, Minnesota, Wisconsin, and Arkansas. Diamond-bearing kimberlites have been located, and bulk samples have been processed for diamond recovery. Results have not been made public.

World resources of gem materials are nearly all unevaluated. However, world gem diamond reserve is estimated to be about 300 million carats, including

near-gem and cheap-gem qualities. Nearly all of the reserves are in Australia, Africa, and the U.S.S.R. (Siberia). The estimates for diamond reserves are of limited value because data needed for reliable estimates are not available from the producers. Reserve data on other gem materials are even less available than for diamond.

Technology

Synthetic Gems.—The first synthetic gem produced was ruby, and later, by various melt techniques, sapphire, spinel, rutile, strontium titanate, and cubic zirconia. The Verneuil flame-fusion process, developed in 1902, consists of growing a single crystal in a simple, downward-impinging oxyhydrogen blow-pipe flame. In manufacturing synthetic gems, pure oxides of aluminum and titanium, and as needed, moderating and coloring oxides, are charged at the top of a small furnace and melted as they pass through an oxygen-hydrogen flame. The molten material is solidified on a fire-clay peg as a carrot-shaped single crystal known as a boule, usually ½ to 1 inch in diameter, 2 to 4 inches long, and weighing 75 to 250 carats. After cooling, the

boule is heat treated and tapped at one end to relieve the internal strain that causes the boule to split into two vertical halves. The halves are then cut and polished into gems. Other melt techniques used are the Czochralski pulled-growth method for ruby, sapphire, spinel, yttrium-aluminum-garnet (YAG), gadolinium-gallium-garnet (GGG), and alexandrite; the Bridgman solidification method for sapphire; and skull melting for cubic zirconia and sapphire.

Solution techniques for manufacturing synthetic gems include flux methods for emerald, ruby, sapphire, spinel, YAG, GGG, and alexandrite; hydrothermal methods for emerald, quartz, and the colored varieties of quartz such as smoky, yellow, citrine, and amethyst; and the high temperature ultra-high-pressure presses used in the manufacture of synthetic diamond in which a molten metal is used as the solvent.

Other techniques involve solid- or liquid-state reactions and phase transformations for jade and lapis lazuli; vapor phase deposition for ruby and sapphire; ceramics for turquoise, lapis lazuli, and coral; and others for opal, glass, and plastics. However, the Verneuil, Czochralski, and skull melting

processes are the melt techniques most often used for gem materials. The various synthetics and the method of production are shown in table 11.

Enhancement of Gem Stones.—

Enhancement of all types of gem materials through chemical and physical means has become much more commonplace and in the past few years has included a wider variety of gem materials. Irradiation by electromagnetic spectrum (X-rays, gamma rays, etc.) and by energetic particles (neutrons, electrons, alphas, etc.) is being used to enhance or change the color of diamonds, topaz, tourmaline, quartz, beryl, sapphire, zircon, scapolite, and pearls. Blue topaz is normally irradiated, but this does not imply that all of these gem materials are regularly irradiated.⁷

A number of gem materials can be enhanced by chemical treatment or impregnations. The treatments may alter the bulk of the gem material or only penetrate the surface. This includes bleaching, oiling, waxing, plastic impregnations, color impregnations, and dying. The treatments that alter only the surface of the gem material include

TABLE 11

surface coatings of various types, interference filters, foil backings, surface decoration, and inscribing. Chemical treatment is more widespread than the common dying of quartz, treatment of turquoise, and oiling of emeralds. Chemical treatment and impregnations have been used to enhance chalcedony, coral, ivory, pearl, tiger's eye, emerald, lapis lazuli, opal, ruby, sapphire, turquoise, beryl, quartz, jade, diamonds, and amber.⁸

The oldest and most common method of gem material enhancement is heat treating. Heat treatment of gem materials was used in Greece and Rome well before the Christian Era. Heat treatment can cause color change, structural

change, and improve clarity. In the past, heat treatment was common for quartz and gem corundum. Today, materials that are heat treated to enhance their appearance include sapphire, topaz, beryl, tourmaline, quartz, zircon, amber, diamond, and zoisite.⁹

Mining

Gem materials mining operations can range from the most primitive to the most sophisticated. In hard rock, at shallow depths, an operation by one, two, or three persons may be mined by prybar, pick, shovel, and baskets for carrying material. A larger operation may include drilling, blasting, and minimum timbering. Mechanized hauling

and hoisting is done only at the larger mines.

Diamond mining in the kimberlite pipes of Africa and the U.S.S.R. and the lamproite pipes of Australia represent the ultimate in that huge quantities of ore must be mined to extract small quantities of diamond produced at as low a cost as possible.

Placer mining for gem stones ranges from small-scale, simple procedures to huge complicated operations. In some areas, digging is by hand and sorting and recovery is by panning, screening, or sluicing. Diamond miners in the larger placer operations use bucket dredges and heavy-duty excavating equipment, as, for example, in Australia, Brazil, Namibia, the Republic of South Africa, and the U.S.S.R.

Processing

Most gem stone material is broken or crushed where necessary and concentrated by various combinations of hand picking, washing, screening, or jigging. In large-scale operations, mineral beneficiation methods employ mechanization and the latest technology in all steps from primary crushing and screening to the final recovery processes. Diamond recovery, in particular, makes use of standard gravity methods, grease belts, electrostatic separation, skin-flotation, magnetic separation, separation by X-ray luminescence, and separation by optical sorting.

GERMANIUM

By Thomas O. Llewellyn

Mr. Thomas O. Llewellyn is a physical scientist with the Branch of Nonferrous Metals. He has covered germanium for 3 years. Domestic survey data prepared by Lura Nightlinger, Nonferrous Metals Data Section.

The estimated domestic refinery production and consumption of germanium decreased compared with the levels of 1988. Infrared systems and fiber optics continued to be the major end uses. The domestic fiber-optic market for germanium decreased for the fourth consecutive year and consumption for this application was about 25% less than that of 1988.

DOMESTIC DATA COVERAGE

Domestic refinery production and consumption data for germanium are estimated by the Bureau of Mines based on discussions with domestic producers.

LEGISLATION AND GOVERNMENT PROGRAMS

In September, the Defense Logistics Agency (DLA) contracted to purchase 9,000 kilograms of germanium metal in two separate and equal solicitations. DLA scheduled the first lot for delivery starting July through November 1990 and the second lot for the period between September 1990 and January 1991. The contract price for both lots was \$609 per kilogram. DLA rejected bids ranging from \$559 to \$582 per kilogram received from European and African producers and selected Eagle-Picher Industries Inc. The main reason for the selection was a clause in the solicitation that indicated the agency may be required to follow a "Buy American" policy for the acquisition of strategic and critical materials that are mined and refined in the United States (Amendment No. 7, Public Law 98-473, October 12, 1984).¹

STRATEGIC CONSIDERATIONS

The Federal Emergency Management Agency (FEMA) established the importance of germanium as a strategic and critical material on July 6, 1984, and an initial National Defense Stockpile (NDS) goal of 30,000 kilograms of germanium metal. Based on the U.S. Army's estimates for actual emergency conditions of mobilization, FEMA established a new goal of 146,000 kilograms on July 24, 1987.

Some of the metal inventory acquisitions made in 1988 were delivered in 1989 and, as of December 31, the stockpile inventory was 38,282 kilograms of germanium metal.

DOMESTIC PRODUCTION

The Bureau of Mines estimated domestic refinery production from both primary and secondary materials at 20,000 kilograms, a decrease of 5% compared with that of 1988.

Hecla Mining Co. bought the assets of St. George Mining Corp. of St. George, UT, for \$5.5 million. St. George, a subsidiary of the Canadian company Musto Explorations Ltd. recovered and mined germanium and gallium as principal products until 1987 when it closed its operation. The new owners expected to resume mine and refinery production during the first quarter of 1990 and reach full production levels before yearend.

CONSUMPTION AND USES

The Bureau also estimated that consumption of germanium decreased

about 10% compared with the level of 1988. The estimated consumption pattern by end use of germanium in 1989 was as follows: infrared systems, 65%; fiber optics, 6%; gamma-ray, X-ray, and infrared detectors, 8%; semiconductors, 8%; and other, 13%.

The largest end use for germanium continued to be in infrared optics, mainly for military use in guidance and weapon-sighting systems. Germanium containing lenses and windows transmit thermal radiation similarly to visible light transmission by optical glass. Germanium glass was also used for nonmilitary surveillance and monitoring systems in fields such as satellite systems and fire alarms.

The U.S. fiber-optic market for germanium continued the downward trend of the previous 3 years, and consumption of germanium in this application decreased about 25% compared with that of 1988. Germanium is used as a dopant in the core of many optical fibers employed in telecommunications. The decline resulted from the development of new manufacturing processes that achieved more efficient use of germanium.

American Telephone & Telegraph Co. (AT&T) of Morristown, NJ, and Kousai Denshin Denwa of Japan completed installation of a 8,271-mile underwater fiber-optic cable system that links the Guam, Japan, and the United States. This system, known as the Pacific Link, is capable of carrying 40,000 phone calls simultaneously. The underwater cable from Point Arena, CA, goes to an undersea branching unit offshore of Japan. At this point the cable splits, and one branch goes to Tanguisson, Guam, and the other to Chikura, Japan.²

AT&T and Zenith Electronic Corp. signed a joint agreement to develop a system for high-definition television (HDTV). This application was poten-

tially a large market for fiber-optic applications in transmission network.³ Although not used in all fiber-optic systems, germanium is an important constituent in many fiber-optic cables.

Two of the U.S. Navy's guided-missile cruisers were outfitted with fiber-optic cable systems that transmit several voice and data functions, including combat system displays and a damage control sensor system. Fiber-optic cable for shipboard communications offered a dramatic advantage in terms of weight and immunity to electromagnetic interference compared to coaxial copper cable. As an example, a 750-foot coaxial cable for an advanced 3-D radar system weighing about 7 tons and measuring 18 inches in diameter can be replaced by a 40-pound fiber-optic cable measuring less than 1 inch in diameter. More information on the present market for fiber-optic components and their applications were described in the study "U.S. Navy Market for Fiberoptic Components," available from Kessler Marketing Intelligence, 31 Bridge Street, Newport, RI 02840.⁴

PRICES

Throughout 1989 domestic producer prices for germanium metal and dioxide, published by *Metals Week*, remained at the levels established in late 1981 (\$1,060 and \$660 per kilogram, respectively). However, discounting by producers was evident during 1989 because of competition from imported material.

The Belgian producer price for germanium metal, published by *Metal Bulletin* (London), remained throughout the year at about \$754 per kilogram.⁵

FOREIGN TRADE

A comparison of the value per kilogram of imported germanium material with the published foreign producer price for germanium metal was used to estimate the germanium content of imported materials. In 1989, the estimated germanium content of total imports was calculated to be approximately 33,000 kilograms.

TABLE 1
U.S. IMPORTS OF GERMANIUM,¹ BY CLASS AND COUNTRY

Class and country	1988		1989 ²	
	Gross weight (kilograms)	Value	Gross weight (kilograms)	Value
Unwrought and waste and scrap:				
Australia	100	\$33,960	—	—

WORLD REVIEW

World refinery production was estimated at 82,000 kilograms. Primary germanium was produced by Metallurgie Hoboken-Overpelt S.A. (MHO), Belgium; Johnson Matthey Electronics, Canada; Société Minière et Métallurgique de Peñarroya S.A., France; Preussag AG and Otavi Minon AG, Federal Republic of Germany; Società Mineraria e Metallurgica di Pertusola Sud S.A., Italy; and Nippon Denshi Kinzoku and Sumitomo Metal Mining Co. Ltd, Japan. Germanium refineries also were in China and the U.S.S.R.

Capacity

The data in table 2 represent rated annual production capacity for refineries as of December 31, 1989. Rated capacity was defined as the maximum

quantity that could be produced on a normally sustainable, long-term operating rate based on the physical equipment of the plant and routine operating procedures for labor, energy, materials, and maintenance. Capacity included both operating plants and plants temporarily closed that in the judgment of the author could be brought into production within a short period of time with minimum capital expenditure.

Refineries rated capacity of germanium was estimated based on discussions with some officials from private industry, past and present production rates, and published capacity data.

Brazil

Telebras, Brazil's state-owned telecommunications company, ordered 35,000 kilometers of optical fibers from Philips Optical Fiber, Eindhoven, the Netherlands. The optical fibers will

be used by several Brazilian companies to manufacture fiber-optic cables, in great demand by the communications industry.⁶

Canada

Canstar Communications, a division of Canada Wire & Cable Ltd. of Toronto, Canada, was awarded a contract by the New York City Transit Authority to supply and install a fiber-optic communications network. This network will interconnect 107 transit stations in the Bronx, Brooklyn, Manhattan, and Queens. The project, using 800 kilometers of fiber-optic cable, will be completed by 1992. Fiber-optic cable and accessories for this network will be manufactured in Canada and the United States.⁷

Japan

Germanium metal production was 3,346 kilograms, a decrease of about 20% compared with 1988 metal production levels. Dioxide production also decreased from 13,883 kilograms in 1988 to 13,302 kilograms in 1989.⁸

Poland

Installation of an underwater fiber-optic cable between Poland and Denmark was started by Nordiske Kabel &

Traadfabriken A/S of Denmark. The cable will connect the Danish island of Bornholm in the Baltic Sea with the settlement of Mielno near Koszalin, Poland. The 150-kilometer network system was scheduled for completion by 1990 and was expected to greatly upgrade Poland's communication capacity with the United States and Canada through Denmark via the United Kingdom. Total project cost was estimated at \$4.5 million and will be jointly financed by Poland and the telecommunications authorities of Denmark, Finland, Norway, and Sweden.⁹

OUTLOOK

Abundant supplies of germanium materials on the market through 1989 could not be absorbed by a rather stagnant demand. Producers were forced to lower prices to maintain their share of the market. Germanium supplies are likely to remain high for the next 2 years, owing to larger availability of concentrates from Canada and resumed mining operations by Hecla Mining Co. at their recently acquired gallium-germanium Apex Mine in Utah.

Domestic short-term demand for germanium metal probably will fall below the 1989 level. A reduced spending rate for strategic programs, as a consequence of recent events in Eastern Europe, could have a negative impact on germanium consumption for infrared systems for conventional weaponry.

BACKGROUND

Germanium was recovered as a minor byproduct of the refining of base metal ores, and the potential supply of this metal, which was dependent on the level of zinc production, has historically exceeded demand.

Invention and development of the germanium transistor opened the path for the solid-state electronic field and, from 1950 through the early 1970's, provided an excellent market for germanium. Despite the continued growth of the electronics industry in the 1970's, germanium demand for transistors, diodes, and rectifiers declined.

This decline was caused mainly by the increasing use of electronic-grade silicon, which was replacing germanium. However, the reduced demand for germanium in the electronics field was offset by a dramatic increase in demand for germanium in both infrared night vision systems and fiber-optic communication networks.

Definition, Grades, and Specifications

Germanium has a metallic appearance and is grayish white in color, lustrous, hard, and very brittle. It is a semiconductor, with electrical properties between those of a metal and an insulator.

The National Stockpile Purchase Specification P-114-R, December 16, 1989, for intrinsic germanium metal specifies an electrical resistivity of 50 ohm-centimeter at 20° C (40 ohm-centimeter at 25° C) over the entire ingot length.

Germanium is available commercially as a tetrachloride and high-purity oxide and in the form of zone-refined ingots, single-crystal bars, castings, doped semiconductors, optical materials, optical blanks, and other specialty products.

Industry Structure

Most germanium occurs as a minor constituent of certain base metal ores and coal deposits. Those producers that currently recover primary germanium for the most part depend on germanium-rich residues, mainly from zinc derived from past or present base metal smelting operations.

In the United States, Eagle-Picher's Quapaw, OK, Specialty Materials Div. has the capability of recovering primary germanium from zinc smelter residues. Eagle-Picher also reprocessed scrap. Kawecky Berylco Industries Inc., a division of Cabot Inc. in Revere, PA, and Atomergic Chemetals Co., Plainview, NY, produced germanium from reprocessed scrap and semirefined foreign material.

The Jersey Minière Zinc Co. in Clarksville, TN, continued to produce germanium-rich residues as a byproduct of processing zinc ores from its Gordonsville and Elmwood Mines. These residues were shipped to MHO in Belgium for germanium recovery and refining.

Little information was available on

the financial structure of U.S. and world germanium industries. Germanium refiners usually were involved in the production and sale of many different metals and specialty products.

Geology-Resources

Minerals in which germanium is concentrated are germanite, a sulfoarsenite of copper, iron, and germanium with an average of 5% germanium; argyrodite, a double sulfide of germanium and silver containing 5% to 7% germanium; renierite, a complex sulfide of copper, iron, germanium, tin, zinc, and arsenic with 6% to 8% germanium; and several other minerals such as canfieldite, utrabasite, itoite, and stottite. Primary germanium minerals are normally formed in sulfide mineralization processes at low-to-intermediate temperatures, and secondary varieties may result from supergene alteration of sulfide ore deposits.¹⁰

Currently, there are two major reserves of germanium in the United States. The largest is the recoverable germanium that occurs as a minor constituent of zinc sulfide ores in the middle Tennessee zinc district. The other major reserve of germanium is in southern Utah. Here the germanium is found in the iron oxide ore zone of a depleted copper mine.

There are no reliable germanium assay data available for many areas of the world. The U.S. and world resources could be expanded if germanium were to be recovered from ash and flue dusts resulting from the burning of certain coals for power generation.

Technology

Germanium is obtained commercially as a byproduct of base metal refining and extracting. Improvements have been developed, but the basic processes have remained virtually unchanged.

Regardless of the source, germanium raw materials are reacted with concentrated hydrochloric acid to form germanium tetrachloride, which is then purified by fractional distillation. The purified germanium tetrachloride is hydrolyzed with water to produce germanium dioxide, which is removed by

filtration and dried. The dried germanium dioxide is reduced with hydrogen at about 760° C to a germanium metal powder, which is then melted and cast into metal bars. These bars are then zone-refined to produce intrinsic grade metal. This high-purity metal is mainly used for electronics and infrared optics. Zone refining produces polycrystalline germanium.¹¹

Certain applications of germanium, such as gamma-ray detectors, require single-crystal germanium. Single crystals are produced by two methods, the horizontal pulling process or the vertical pulling process, also known as the Czochralski method.

More than 50% of the metal used during the manufacture of most electronic and optical devices is recycled as new scrap. As a result of the low unit use of germanium in microelectronic devices, very little germanium returns as old scrap.

Economic Factors

Table 3 shows import duties for germanium products, which became effective in January 1, 1989, under the new Harmonized Tariff Schedule of the United States.

Domestic producers are granted a depletion allowance of 14% on both domestic and foreign production of germanium.

Operating Factors

Germanium has little or no effect upon the environment because it usually occurs only as a trace element in some ores and carbonaceous materials. The small quantities used in commercial applications also pose no threat to the environment. Germanium com-

pounds generally have a low order of toxicity, except for germanium tetrahydride which is considered toxic.

Based on a 1976 report, the energy requirements for the production of zone-refined germanium metal from zinc sulfide concentrates and scrap is 2,145 million British thermal units (Btu) per net ton of germanium ingot.

GOLD

By John M. Lucas

Mr. Lucas, a geologist with 29 years of Federal, State, and foreign and domestic mineral industry experience, has been the Bureau of Mines commodity specialist for gold since 1980. Domestic survey data were prepared by Eraina C. Dixon, Lisa P. Conley, and Stephen L. Hays, Nonferrous Data Section. International data tables were prepared by Giovanni P. Jacarepaqua, International Data Section.

Gold production by the domestic and international mining industry continued at record levels during 1989. With production rising more than 33% over that of 1988, the domestic industry completed its 10th successive year of growth. Nevada continued as the Nation's principal gold-producing State, having increased production nearly twentyfold since 1979. The overall demand for gold for use in fabricated products in the market economy countries exceeded the record level set in 1988. Jewelry was again the dominant end-use sector. Hoarding of gold bars, exclusive of North America and Europe, surpassed the record level reached during the previous year.

LEGISLATION AND GOVERNMENT PROGRAMS

On June 14, under legislation approved in 1988, gold and silver coins commemorating the Bicentennial of the U.S. Congress (1789–1989), were struck on four 7-ton coin presses mounted temporarily in front of the U.S. Capitol. The ceremony marked the first time since 1792 that official U.S. coins were struck outside of a U.S. Mint facility. The enabling legislation provided for surcharges from the sale of the coins to go to the U.S. Capitol Preservation Commission to maintain and restore the Capitol. Up to 2,239 kilograms (kg) (72,000 ounces¹) of gold and 33,090 kilogram (1.064 million ounces) of silver will be used in minting the coins.

In 1989, legislation affecting gold was enacted by a number of States. Laws regulating the use of cyanide in gold and other mineral processing operations were enacted in Montana and South Dakota. A new Montana law requires that small placer or dredge mining operations that disturb 0.8 or

more hectares (2 or more acres) must comply with the State's general mine reclamation requirements. In a special election held in May, Nevadans approved a tax on gold mining. The measure amended the State constitution and increased the net profits tax on all mineral production from about 2% to 5%. In June, the Governor of Nevada signed into law that State's first program for reclamation of mined lands. The law requires that all public and private lands disturbed by mining or exploration activities be reclaimed in an economically and technically practical manner to a safe, stable condition capable of supporting a productive post-mining land use.

A law exempting the sale of precious metal bars and bullion coins from a 4% State sales tax became effective in New York on September 1. To be eligible for the exemption, the sale must be for \$1,000 or more, with the price being based on the item's metal content, not its aesthetic value. Coins produced by the Republic of South Africa, with coins and bars produced for noninvestment purposes, were not eligible for the exemption. Texas and Ohio passed similar legislation during 1989.

In June, the U.S. Forest Service announced that, effective May 1, 1990, it will require certification of its examiners who investigate and evaluate unpatented mining claims located on National Forest System lands. Under the certification program, mineral examiners will have to be mining engineers or geologists and have had training in mineral examination, experience in mining claim validity examinations, surface use determinations, or mining law-related actions. The new certification process pertains only to Forest Service employees. Private mining consultants wishing to perform mineral examinations on the National Forest lands will have to meet the same qual-

ifications as a Certified Forest Service Mineral Examiner before being awarded a contract to work on National Forest System land.

STRATEGIC CONSIDERATIONS

Gold is not a National Defense Stockpile item; however, the Treasury had stocks of bullion amounting to about 8,146 metric tons (262 million ounces) at yearend 1989. Large quantities of gold are also held as commercial and private bullion stocks. Therefore, the availability of gold in times of national emergency appears to be ensured.

One strategic aspect of the domestic gold mining industry that is infrequently considered is that the industry constitutes a valuable pool of experienced personnel, including chemists, geologists, engineers, and metallurgists as well as miners, machinists, and heavy equipment operators. In the event of a national emergency, these skills may be readily directed toward the discovery, development, and production of strategic materials.

PRODUCTION

Of the 266 metric tons of gold (8.5 million ounces) produced in the Nation, 75% was attributed to the 25 leading producers. The average recoverable gold content of precious metals ores processed from lode mines was 1.37 grams per metric tons (0.04 ounce per short ton), while placer gravels yielded an average of 1.23 grams per cubic meter (0.03 ounce per cubic yard) of material washed.

The individual company production and performance data in this chapter

Alaska

Gold was the most valuable mineral product, accounting for 39% of total mineral production revenues. According to a Summary of 1989 Mineral Activity prepared by the Alaska State Div. of Geological and Geophysical Surveys (DCGS), gold production was reported from 222 operations; 217 placer mines and 5 lode mines.² The total number of operations in 1988 according to DCGS was 211. Gold production in Alaska of 5,756 kg (185,055 ounces) was reported to the Bureau of Mines by 17 operations. However, an informal annual survey by the DCGS suggested that 8,852 kg (284,616 ounces) was produced.

Alaska's largest gold producer in 1989, the Valdez Creek Mining Co.'s placer operation east of Cantwell, produced 2,237 kg (71,942 ounces) of raw unparted gold during the 1989 operating season. The Alaska Gold Co. operated its two onshore gold dredges at Nome while offshore of Nome Western Gold Exploration and Mining Co. Ltd. Partnership (WestGold) recovered about 899 kg (29,000 ounces) of gold with its mining vessel, the *BIMA*.

Five lode mines reporting production during the year were: the new Greens Creek Mine near Juneau, the State's second largest gold producer, the Ryan Lode Mine, the Grant Mine, and the Democrat Mine, all located near Fairbanks, and the old Independence Mine near Hatcher Pass.

Following a trend established in recent years, funds expended by corporations exploring for precious metals accounted for nearly 92% of the \$46 million spent in 1989. Of funds expended, 59% was on three advanced gold exploration projects: the Fort Knox Mine project of Fairbanks Gold Ltd. near Fairbanks and Echo Bay Mines Ltd.'s two advanced projects—the rejuvenation of the old A-J Mine at Juneau and the Kensington Mine project at Berners Bay, 80 km (50 miles) north of Juneau.

The relaxation of tensions between the U.S.S.R. and the United States resulted in an exchange during 1989 of visits by scientific personnel from both countries. Gold Mines in the Magadan Oblast region of neighboring Siberia were visited by personnel from the Bu-

² These figures, reported to the Bureau of Mines, probably understate production. Data collected by the State indicate production to have been as follows, in kilograms: 1985—5,910; 1986—4,977; 1987—7,154; 1988—8,258; and 1989—8,852.

³ Less than 1/2 unit.

reau of Mines and by representatives from Alaskan State, educational, and industrial organizations.³

A brochure on Placer Mining in Alaska prepared by the U.S. Bureau of Land Management was published in 1989. The brochure provided an overview of placer mining methods used on public lands in Alaska and offered suggestions for avoiding or reducing the environmental effects of placer mining and for reclamation of placer mining sites.⁴

Arizona

At Arizona's largest gold mine, Cyprus Gold Co.'s Copperstone Mine near Quartzite in LaPaz County, underground development was suspended because lower ore grades were encountered. However, the company continued the open pit operation. Copperstone had a productive capacity of nearly 2,200 kg (70,000 ounces) per year.

Several mines produced gold-bearing flux ore that was shipped directly as a flux to copper smelters where the gold values were ultimately recovered as a byproduct of copper refining.

After less than 1 year of operation, mining at the McCabe Mine in Yavapai County was halted in early 1989. The owner, Stan West Mining Corp., later

transferred ownership of the facility to Elders Resource Finance Inc. of Australia.

Exploration for gold continued to be widespread throughout Arizona. Exploration accompanied by drilling was conducted at a number of properties, including the following: the Yarnell Mine in Yavapai County by joint-venture partners ASARCO Incorporated and Norgold Resources Inc. and the Mexican Hat property in Cochise County by venture partners Placer Dome U.S. Inc. and Oneida Resources Inc. Other sites included DRX Inc.'s Commonwealth property and Queenstake Resources Ltd.'s Gold Prince Mine, both in Cochise County; and East West Minerals Inc. at the Clementine Mine, U.S. Borax and Chemical Corp. at the Picacho project, and Westmont Mining Inc. and Aur Resources Inc. at the Newsboy deposit, all in Maricopa County.

California

For the third consecutive year, California has ranked as the Nation's second largest gold-producing State. Three California gold mines, McLaughlin, Mesquite, and Jamestown, were among the top 25 gold producers during 1989.

The McLaughlin Mine of Homestake

Mining Co., located about 113 km (70 miles) north of San Francisco, produced a record 8,823 kg (283,843 ounces) of gold during 1989. A new oxide ore processing circuit commissioned in early 1989 and new cost control measures initiated during the year combined to improve productivity and led to an increase in production of 2,489 kg (80,016 ounces) over that of 1988. California's second largest gold mine, the Mesquite Mine owned by Gold Fields Mining Corp., recovers about 5,750 kg (185,000 ounces) annually using heap leaching. Gold ore, mined from several surface deposits at the Imperial County site, was processed and stacked on the heaps at a rate of about 18,000 metric tons per day.

Improved gold recovery and higher throughput of ore contributed to an increase in gold production to 3,461 kg (111,300 ounces) in 1989 at the Jamestown Mine in Tuolumne County. The large surface mine opened in late 1986 by Sonora Gold Corp. employed flotation methods to produce a gold concentrate. The concentrate was processed for gold recovery at the Buckskin leach plant at Yerington, NV.

Several new mines began production in 1989, and several others were closed. The new Royal Mountain King Mine near Copperopolis, Calaveras County, began open pit mining and milling in February. This new mine, owned by Meridian Gold Co. and Mother Lode Gold Mines Consol., was expected to recover about 1,866 kg (60,000 ounces) of gold annually. In September, the American Girl Mining Corp. poured the first gold at its new open pit heap leaching American Girl Canyon Mine in Imperial County. The Carson Hill Mine at Angels Camp, Calaveras County, closed in October. Leaching of previously mined ore and site reclamation were proceeding at yearend. The Sixteen-To-One Mine in Sierra County was placed on a care-and-maintenance status late in the year.

In September, Bond International Gold Inc. sold its 67% interest in the Yuba dredge placer operation near Marysville, Yuba County, to WestGold. Yuba dredge reportedly recovered 732 kg (23,540 ounces) gold during the fiscal year ending June 30, 1989.

While a dozen or more other mines continued to produce gold in California, other properties undergoing exploration or moving toward production

included the following: Viceroy Resources Corp.'s Castle Mountain property in San Bernardino County, Amax Gold's Hayden Hill property in Lassen County, Centurion Gold Ltd.'s Grey Eagle Mine and American Gold Mineral Inc.'s Siskon Mine in Siskiyou County, and the Long Valley prospect of Royal Gold Inc. and Standard Industrial Minerals Inc. in Mono County.

Colorado

A nearly 33% decline in gold production from the previous year reflected to some extent the closure of two mines and the failure of several new mines to reach production.

The principal producing gold mines were the Summitville Mine in Rio Grande County, the Sunnyside Mine at Silverton, and the combined operations of the Cripple Creek and Victor Mining Co. in Teller County. Several other smaller producers such as the Bessie G Mine in La Plata County were also active during the year.

Mining at Galactic Resources' seasonal Summitville Mine was halted in mid-June following the discovery of an unstable area in the embankment of the leach pad. About 170 employees were laid off and studies to remedy the leach pad problem were initiated. Leaching of previously mined ore continued, and nearly 1,000 kg (32,000 ounces) of gold was recovered. More than twice that amount was recovered during the previous year.

Underground mining operations at the Sunnyside Mine in San Juan County were continued by the mine's operator and owner of a 33% share, Washington Mining Co. Gold production during the year declined about 5% from that of the previous year to about 921 kg (29,612 ounces).

In Teller County, Cripple Creek and Victor Gold Mining Co. recovered nearly 1,100 kg (34,507 ounces) of gold from its Mine Dump Rock and Gold Star Projects and its Portland open pit. Mining of the Portland pit was completed and reclamation of the affected area was being planned at yearend. The company reportedly had several new local exploration projects under study.

Battle Mountain Gold Co. decided in early 1989 to modify its mining plan at its developing San Luis project in Costilla County and thereby limit gold recovery to milling only rather than milling and

heap leaching combined. The decision necessitated the amendment of the company's mining permit and was expected to delay the targeted startup until early 1991. The San Luis project was expected to yield about 1,870 kg (60,000 ounces) of gold per year for at least 8 years.

The Empire (Grace) Mine project that was expected to produce in 1989 was further delayed while the owner, Nevada Goldfields Corp., negotiated a joint venture for further exploration and development. The proposed open pit heap-leaching project is located in Clear Creek County about 64 km (40 miles) west of Denver.

Exploration and development was continued at a number of other Colorado gold properties, including the Platoro gold-silver mine in Conejos County, Levon Resources Ltd.'s Carbonate Hill property in Teller County, and Hendricks Mining Co.'s Cross Mine, an underground mine at Caribou in Boulder County.

Idaho

The number of active exploration projects in Idaho, dominated by interest in precious metals, increased from 68 in 1988 to 82 in 1989 according to a review of State mineral activities prepared by the Idaho Geological Survey.⁵ The State defined an active project as one that had some significant work such as sampling and trenching or drilling, not just claim staking.

Despite the heightened level of exploration that may eventually lead to increased production, total Idaho gold production during 1989 remained near the level achieved during the previous year. Producing gold mines in Idaho during 1989 included Nerco Minerals Co.'s DeLamar Mine in Owyhee County, Pioneer Metals Corp.'s Stibnite-West End and Coeur d'Alene Mines Corp.'s Thunder Mountain Mine, both in Valley County, and Idaho Gold Corp.'s newly opened Champagne Mine in Idaho County. All of these properties were open pit heap-leaching operations, except that DeLamar also employed a vat-leaching recovery system.

Nerco announced that it had begun development of its Stone Cabin deposit, formerly referred to as Florida Mountain. Stone Cabin is adjacent to the DeLamar Mine. The property, reportedly containing more than over 18,000 kg (580,700 ounces) of recoverable gold, was to be developed as a satellite opera-

tion of the DeLamar Mine with mining projected to begin by early 1992. Nerco also signed an agreement with War Eagle Mining Co. Inc. to explore War Eagle's claims on War Eagle Mountain about 6.4 kilometers (4 miles) east of Nerco's DeLamar property.

Hecla Mining Co.'s Yellow Pine unit in Valley County did not operate during the 1989 season. Instead, a new \$4.5 million heap-leach facility was constructed. Startup of the new plant was scheduled for the second quarter of 1990 with an anticipated seasonal output of about 1,900 kg (60,000 ounces). U.S. Antimony (USAC) continued to process ore from its various mining operations at its mill at Preacher's Cove in Lemhi County. The company signed joint-venture agreements with WestGold to further explore USAC's Yellow Jacket Mine and Estes Mountain property, both in Custer County.

Grouse Creek Mining Co., a subsidiary of CoCa Mines Inc. of Denver, moved ahead with development of its Grouse Creek deposit and newly acquired Sunbeam property on nearby Jordan Creek in Custer County. A new milling process was devised that would work with both deposits as well as address concerns of environmentalists. A conventional milling technique with zero discharge was selected and should be operational by 1992.

Interest in the potential for further gold discoveries in the Salmon area in Lemhi County, Southwestern Idaho, were heightened by the 1988 discovery by Meridian Minerals Co. of their large Beartrack deposit. Among the companies reported by the State to be exploring in the Salmon area during the year were AMAX, American Gold Resources Corp., Corona Gold Inc., FMC Gold Corp., GEXA Gold Corp., Hecla, Homestake, Placer Dome, Sovereign Explorations Inc., and many others.

Michigan

In early October, Callahan Mining Corp. of Phoenix, AZ, announced that its Ropes gold mine, near Ishpeming, MI, the Nation's only underground gold mine east of the Mississippi, had been shut down indefinitely owing to the low price of gold and ground control problems near the main production shaft. Nearly 550,000 metric tons of ore bearing 2.33 grams per metric ton (0.069 ounce per short ton) was hoisted and milled during

the 9-month period prior to closure.

Montana

Mining and mineral developments in Montana during the year were summarized in a report prepared by the Montana Bureau of Mines and Geology.⁶ The number of mining plans, most of which included gold, filed with the U.S. Forest Service increased from 246 plans in 1988 to nearly 400 in 1989. Similarly, mineral exploration, again focused primarily on gold, continued to expand. The State reported that 35 new State exploration permits were issued during the year, bringing the total to 210 compared with 192 in 1988 and only 56 in 1982. All mining activity in Montana, whether on private, State, or Federal land, is regulated by the Montana Department of State Lands. Exploration, including drilling, sampling and mapping, was continued at many properties throughout the mineralized areas of the State, and some properties were moved a step closer toward development and production.

Gold production from Montana's active mines increased 27% over the previous year, reflecting in part, improved performance at some operations plus the contribution of newly opened mines, including the Beal Mountain Mine and the Mineral Hill Mine.

The new Mineral Hill Mine at Jardine in south-central Park County opened in September. Mineral Hill, an underground operation and joint venture of American Copper and Nickel Co. and Homestake, was initially expected to produce about 1,300 kg (42,000 ounces) annually.

In June, Pegasus Gold opened its new open pit Beal Mountain Mine at German Gulch Southwest of Butte, Silver Bow County. The new heap-leaching operation was designed to produce nearly 1,100 kg (35,000 ounces) per year over a mine life conservatively estimated at 10 years. Pegasus also operates three other large gold mines in Montana: the Zortman/Landusky Mine in Phillips County; the Montana Tunnels gold, silver, lead, and zinc mine in Jefferson County; and the Basin Creek Mine, formerly known as the Pauper's Dream Mine, in Lewis and Clark County. Other principal gold-producing mines in the State include Placer Dome's Golden Sunlight mine in Jefferson County near Whitehall, the Kendall Mine of Canyon Resources Corp. near Lewistown, and

Blue Range Mining Co.'s Geis Mine, both in Fergus County. Operations at another Fergus County mine, the Spotted Horse, were suspended during the year, reportedly for economic reasons.

Numerous, generally small, intermittent placer operations were active along favorable drainages in Western Montana. In September, Highland Gold Properties Inc., working their placer claims in Cooley Gulch on the Fish Creek drainage in Silver Bow County, recovered an 855 gram (27.495 ounce) nugget; reportedly the largest gold nugget found in Montana during this century.

Nevada

Nevada's percentage contribution to the Nation's total gold production increased yet again over that of the previous year. Fifteen of the Nation's leading 25 gold mines during 1989 were located in Nevada.

Newmont Gold Co. (NGC), with operations generally centered in Eureka and Elko counties near the town of Carlin, was once again the largest gold producer in Nevada as well as in the Nation and in North America. As the largest producer, NGC also controlled the Nation's largest block of gold ore reserves; exploration by the company increased reserve by 27% during 1989 to a total of 640 metric tons (20.7 million ounces) contained in 10 deposits located along a northwest-trending geological structure frequently referred to as the Carlin trend. During the year, NGC produced a record 45,648 kg (1.47 million ounces) of gold from ore mined at six open pits in Eureka and Elko Counties. Newmont also operated five separate mills and four leaching facilities in the same counties. The company's Gold Quarry Mine in Eureka County produced almost as much gold during 1989 as the entire Nation produced in 1980. According to the company, total production costs, including depreciation depletion and amortization, were \$273 an ounce in 1989 compared with \$266 an ounce the previous year. Pursuant to a decision announced the previous year, NGC moved its corporate headquarters from New York to Denver, CO, in 1989.

American Barrick Resources Corp. planned to develop its Betze deposit sulfide reserve and its Post deposit oxide reserves at the company's Goldstrike Mine. Goldstrike, adjacent to NGC's operations on the Carlin trend in north-

ern Eureka County, was one of the leading gold-producing mines in 1989. During 1989, Goldstrike yielded more than 6,446 kg (207,264 ounces), well above its production target of 5,598 kg (180,000 ounces). In June, Goldstrike received the first of six 1,500-ton-per-day autoclaves to be installed to convert the mine's gold-bearing sulfide ores to oxides for subsequent cyanide treatment and gold recovery. Construction and commissioning of the new autoclave was completed near yearend. Exploration by Barrick in the Goldstrike area encountered three new areas of gold mineralization.

Nevada's second largest gold mine and the fourth largest in the Nation, the Jerritt Canyon Mine of Freeport McMoRan and FMC in Elko County, reported gold production of 9,234 kg (296,900 ounces) during 1989 at a production cost of \$166 per ounce. Freeport also holds a majority interest in the nearby Big Springs Mine where 1,882 kg (60,500 ounces) was produced. During the year expansion programs begun the previous year at both mines were completed. New and proprietary ore-roasting facilities became operational in June at Big Springs and in September at Jerritt Canyon. The roasting facilities increased the mines' ore reserve base and production capacities by allowing the milling of previously unacceptable ore.

In Lander County, expansion work on Echo Bay's McCoy-Cove gold and silver mine moved ahead with completion of a new mill in July and the driving of two access ramps, one to 183 meters (600 feet) below the surface at the Cove deposit and another 274 meters (900 feet) below McCoy. Underground mining at Cove began in December. Gold production from both surface and underground workings at McCoy-Cove more than doubled during 1989 to 6,673 kg (214,566 ounces). Underground problems related to poor ground conditions and substantial waterflows at Cove forced the company to modify its planned underground mining rate. A problem related to contaminated samples derived by reverse-circulation drilling below the water table resulted in a substantial negative revision of Cove's ore reserves.

At the nearby Lander County operations of Battle Mountain Gold Co., more than 7,800 kg (251,000 ounces) of gold was recovered during the year

from the company's Canyon Placer Mine and two open pit lode mines, the Fortitude and the Surprise.

The world's largest heap-leach gold mine, the Round Mountain Mine in Nye County, completed a 2 year expansion program in 1989 that effectively doubled its tonnage capacity. Published company data reported gold production during the year at 9,909 kg (318,616 ounces). In January, the mine's owners, Homestake, Echo Bay, and Case Pomeroy & Co., merged Echo Bay's nearby properties, including the Manhattan mill, into the Round Mountain operations, thereby enabling the mine to achieve better recovery rates on its high-grade ore than could otherwise be achieved by heap leaching.

Just west of the town of Beatty in Southern Nye County, Bond Gold Bullfrog Inc. poured its first gold in July at the newly commissioned Bullfrog Mine and mill. Bullfrog was expected to produce more than 6,344 kg (204,000 ounces) in its first full-year of production. Several kilometers to the east the U.S. Nevada Gold Search Joint Venture began production near yearend at its new open pit, heap-leaching Mother Lode Mine.

The mines previously mentioned were only a small portion of the scores of gold properties in Nevada that were in operation during 1989, undergoing design, construction or permitting, expanding production capacity, or in various stages of exploration from claim staking to reserve evaluation.

Oregon

A State-prepared review of mining in Oregon during 1989 listed 10 active gold mines; 2 seasonal lode mines, the Pyx and the Lower Grandview; and 8 placer mines.⁷ Of the 34 active exploration sites and areas in Oregon during the year, only 4 sought commodities additional to gold.

Oregon's total gold production for the year was attributable mostly to the Bonanza Mining Co.'s 46 cubic meter per day (60 cubic yd per day) placer operation on Pine Creek in Baker County. The State reference noted that although stripping and mining progressed in one area of the pit, backfilling and site reclamation was proceeding in another part.

The rush precipitated by the 1988 discovery of the large Grassy Mountain deposit in Malheur County by Atlas Precious Metals Co. accelerated during 1989. Near yearend, close to 8,000 new

claims had been located mostly in northern Malheur County, thus bringing the county total to more than 21,000. Exploration drilling was done on at least 16 properties. In the meantime, at Grassy Mountain, Atlas continued drilling while preparing feasibility studies and collecting supporting environmental and water-quality data. An operating plan calling for the development of two open pits and a heap-leach recovery system was submitted to the U.S. Bureau of Land Management in November.

Also in northern Malheur County, Chevron Resources Co. continued exploration of three different areas, including their Hope Butte and Quartz Mountain properties.

In Lake County, south-central Oregon, Quartz Mountain Gold Corp. formed a joint venture with Pegasus Gold to further explore and develop a mine plan for two large gold deposits discovered in 1986.

South Carolina

Near the town of Ridgeway in Fairfield County, the Ridgeway Mine of Ridgeway Mining Co. completed its first full-year of operation. The first year's performance at the new mine, a joint venture between Galactic Resources Ltd. and the RTZ Corp. PLC, was consistently in excess of expectations, producing 5,365 kg (172,505 ounces) of gold compared with a budgeted production of 4,978 kg (160,064 ounces). According to Galactic Resources, the average production cost during 1989 amounted to \$140 per ounce, significantly lower than the \$167 per ounce expected earlier. The lower cost reportedly reflected high mill throughput, enhanced recoveries, and low reagent consumption.

Despite lower gold prices and production delays attributed to bad weather, Piedmont Mining Co.'s Haile Mine near Kershaw in Lancaster County produced an increased amount of gold compared with the previous year. Gold production at the open pit, heap-leaching operation was 481 kg (15,458 ounces) in 1989 compared with 365 kg (11,738 ounces) in 1988. Surface mining and heap leaching was continued at the Brewer Mine just west of Jefferson in Chesterfield County. The mine, opened in 1987, is owned by Westmont Mining Inc.

In McCormick County, Gwalia (U.S.A.) Ltd., a wholly owned subsidiary of Gwalia International Ltd. of

Perth, Western Australia, conducted exploration and drilling aimed at re-opening the old gold mines around the town of McCormick. The old mines, including the old Dorn Mine, produced gold between the 1850's and 1930's. Gwalia's operation was referred to as the Barite Hill Project.

South Dakota

Gold was produced by five primary gold mines, including the Homestake Mine, the Nation's third largest. All five mines were located in Lawrence County.

The 114-year-old Homestake Mine's production in 1989 was 11,874 kg (381,788 ounces), down slightly from the 1988 record level of 12,134 kg (390,162 ounces). Homestake operated both surface and underground mines at the town of Lead. The surface operation, referred to as the Open Cut, was begun in 1985, on the site of the original 1876 gold strike. During the year Homestake processed about 2.3 million metric tons of ore from both the surface and underground operations. The grade of underground ore declined about 4% to 6.17 grams per metric ton (0.180 ounce per short ton) and, this, combined with slightly higher labor costs, caused production costs to increase slightly to \$301 per ounce. During the year Homestake completed construction of a new plant to process tailings dam water for an expected annual recovery of an additional 218 kg (7,000 ounces) of gold. Exploration, mostly below the 2,073 meter (6,800 foot) level, added about 28,000 kg (0.8 million ounces) of gold to the mine's reserves.

Bond Gold-Richmond Hill Inc. began production in early 1989 at its Richmond Hill Mine located 8 km (5 miles) northwest of Lead. The new open pit, heap-leaching mine was expected to produce about 1,244 kg (40,000 ounces) of gold annually. Wharf Resources (USA) Inc. continued production at its Annie Creek open pit, heap-leaching operation near Terry Peak. A new treatment plant completed in late 1988 was expected to increase Wharf's 1989 production by about 30% over the previous year's level of 1,850 kg (59,500 ounces). Golden Reward Mining Co. began production at its new open pit and heap-leaching Golden Reward Mine in November. The first gold bar was poured in mid-December.

MinVen Gold Corp. completed its first full year at its Gilt Edge Mine located 6.4 km (4 miles) south of Lead. In early 1989, the company submitted a plan to the U.S. Forest Service that, if approved, could quadruple the size of the new open pit, heap-leaching facility. The expansion was aimed at utilizing the mine's sulfide ore deposits adjacent to, and deeper than, the oxide ore presently being mined.

An environmental group based in Rapid City filed a petition in November to place an acreage limit on Black Hills surface mining. The group wants an initiative on the November 1990 general election ballot that would limit to 1,255 hectares (3,100 acres) the amount of

land that could be mined at any one time by large-scale precious metals mining companies in the Black Hills.

Utah

The year witnessed the first full-year of copper and byproduct gold production at the giant Bingham Canyon Mine near Salt Lake City since completion of a \$400 million modernization program begun several years earlier. Bingham Canyon, owned by RTZ and operated by the Kennecott Corp., was the Nation's second largest producer in 1989 of both copper and byproduct gold. The mine was the State's largest producer of both gold and silver. In the fall of the year, Kennecott began

¹ Revised. W Withheld to avoid disclosing company proprietary data; included in "Total."

² Includes old tailings and some nongold-bearing ores not separable, in amounts ranging from 0.15% to 0.25% of the totals for the year listed.

³ Includes some placer production to avoid disclosing company proprietary data.

⁴ Less than 1/2 unit.

gold production at its new Barney's Canyon Mine located 6.4 km (4 miles) north of Bingham Canyon. The new open pit and heap-leaching mine was designed to produce approximately 2,500 kg (80,000 ounces) of gold per year.

Utah's second largest gold mine and the State's largest producer of primary gold, Barrick's Mercur Mine in Toole County, continued to operate at full capacity, producing 3,656 kg (117,536 ounces) of gold during 1989. A new autoclave unit for processing sulfide ore completed its first full-year of operation. Throughput exceeded design capacity of 680 metric tons per day, and the unit reportedly achieved an average recovery rate of 81.4% for the year. Barrick reported that a major increase in gold production resulted from improvements at the mine's dump-leaching facilities and that a third such facility was

under construction at yearend.

Tenneco Minerals Inc., officially began operations in May at its new Goldstrike Mine near St. George in Wash-

ington County. The new open pit and heap-leaching operation has the capacity to produce 1,244 kg (40,000 ounces) each of gold and silver per year.

TABLE 6
GOLD PRODUCED IN THE UNITED STATES BY CYANIDATION¹

Year	Extraction in vats, tanks, and closed containers ²		Leaching in open heaps or dumps ³	
	Ore treated (metric tons)	Gold recovered ⁴ (kilograms)	Ore treated (metric tons)	Gold recovered (kilograms)
1985	18,636,045	48,392	17,290,462	16,578
1986	24,590,938	73,362	34,073,586	31,060
1987	29,408,635	74,807	59,468,094	55,005
1988	¹ 30,784,205	100,817	102,262,904	72,676
1989	40,642,933	121,716	129,830,246	105,513

¹ Revised.

² May include small quantities recovered by leaching with thiourea, by bioextraction and by proprietary processes.

³ Including autoclaves.

⁴ May include tailings and waste ore dumps.

⁵ May include small quantities recovered by gravity methods.

Washington

According to a review of Washington State's Mineral Industry prepared by the State, Washington's largest gold mine, the Cannon Mine at Wenatchee in Chelan County, produced an estimated 4,454 kg (143,200 ounces) of gold and about 9,330 kg (300,000 ounces) of silver during 1989.⁸ Comparable data for 1988 was about 4,510 kg (145,000 ounces) of gold and about 7,775 kg (250,000 ounces) of silver. The mine, a joint venture between Asamera Minerals (U.S.) Inc., the operator, and Breakwater Resources Ltd., is the Nation's second largest underground gold mine. Underground exploration to locate additional reserves was continued by Asamera, especially in the northern and western extensions of the B-4 ore zone, in the B-west ore body, and in the B-north zone. Surface exploration was also conducted in the Wenatchee Heights area 5.6 km (3.5 miles) southeast of the mine.

Washington's second largest gold mine is the underground Republic Unit, or Knob Hill Mine, of Hecla in Republic, Ferry County. On May 26 the 2 millionth ounce (62.2 metric tons) of gold was hoisted from the Knob Hill No. 2 shaft. This 541-meter (1,774 foot) inclined shaft has made over 4 million trips since it was opened in 1940. During 1989, the Republic Unit recovered 2,312 kg (74,335 ounces) of gold and 9,375 kg (301,432 ounces) of silver. Hecla also completed modifications to the mine's 52-year-old concentrator during 1989, raising its capacity from 218 metric tons per day to 245 metric tons per day. Improved gold recovery circuits were also installed during the overhaul.

Development was continued at Echo Bay and Crown Resources Corp.'s Kettle River project. The project located in Ferry County, 18 km (11 miles) north of Republic, includes the new Kettle and Overlook underground mines. Construction of a new 1,260 metric-ton-per-day automated flotation mill, employing carbon-in-pulp and vat-leaching systems, was completed before yearend. Commercial production was begun in February 1990.

The State reported that more than 80 companies and individuals explored for metals in Washington during 1989. Gold, particularly gold in skarn and replacement deposits and epithermal gold-bearing deposits in Eocene-age rock in

^r Revised.

¹ Data are only for those mines that report annually on the Bureau of Mines voluntary survey; there are many more, usually smaller and less well-established operations, mainly in Alaska, that do not report.

² Excludes tonnage of material treated at commercial sand and gravel operations recovering byproduct gold.

³ Includes gold recovered at commercial sand and gravel operations.

⁴ Gold recovered as a byproduct at sand and gravel operations not used in calculating average value per cubic meter.

⁵ Data may not add to totals shown because of independent rounding.

northeastern Washington, was the principal target of this exploration.

CONSUMPTION AND USES

The use of gold in the domestic market shown in table 9 accounts for only part of the overall market for commercial products. An important segment of market demand is also satisfied by imported gold-bearing products in various forms ranging from unfinished, jewelry products, such as gold chain and findings, to electronic equipment containing gold components.

Contracts for gold futures traded during 1989 on the Nation's futures exchanges represented about 31,330 metric tons (1,007 million ounces) compared with the previous year when the equivalent of nearly 30,000 metric tons (962 million ounces) were traded. The New York-based Commodity Exchange Inc. (COMEX) was, as in the previous year, by far the dominant exchange with an equivalent of more than 31,000 metric tons (999 million ounces) of gold traded during 1989.

Sales of newly-minted gold coins by the U.S. Mint declined somewhat from levels established during previous years. The sales program for the Bicentennial of the U.S. Congress Commemorative coins began in June, and the sales program for the 1988 Olympic coins, begun in February 1988, was completed in June 1989. During the fiscal year ending on Sept 30, 1989 about 2,140 kg (68,800 ounces) of gold was used to satisfy various official minting programs.

Gold loan activity between commercial depository banks and gold producers continued to be a popular method of financing new mine development or expansion of existing facilities.

In addition to its age-old usage in jewelry, decorative applications, and dentistry, gold has a number of applications that are important to the functioning of domestic industry, modern high technology, engineering, and defense systems. It is used extensively in a great variety of solid-state electronic devices, in industrial control and monitoring instruments, and in corrosion-resistant chemical process equipment.

Of the strategic and industrial uses of gold, the most important is its use in electronic devices, especially in printed

circuit boards, connectors, keyboard contacts, miniaturized circuitry, and as a dopant in some semiconductors. Modern solid-state electronic devices such as computers employ very low voltages and currents, and thus require connectors, switch contacts, soldered joints, and certain other components that must remain completely free of high resistance tarnish films and that remain chemically and metallurgically stable for the life of the device. Increasingly complex civilian, military, and aerospace electronic systems use gold to ensure dependable operations under a wide range of operating conditions. For example, because of its ability to provide

reliable electrical connections, gold is used extensively in all spacecraft such as the *Hubble Space Telescope* that must function flawlessly over a long period of time in the harsh environment of outer space.

Gold alloys have long been used in certain electrical instruments, for example, as wipers and windings in slide-wire potentiometers, where long-term reproducibility is essential. Gold-palladium alloy wires are used in thermocouples, especially those used to measure high temperatures encountered in some industrial processes and aircraft engines. Gold-containing brazing alloys such as gold-nickel alloy are important to the aerospace industry, especially in the as-

sembly of some military jet turbine engines and high-performance rocket engines. Gold is used as a reflector of infrared radiation in radiant heating and drying devices and heat-insulating windows for large buildings and spacecraft such as the *space shuttle*, which relies upon gold to seal and protect its vital propulsion system from problems associated with hydrogen embrittlement. Gold-coated mirrors are the principal component of infrared jammers used on numerous military aircraft to confuse the guidance instruments of heat-seeking missiles.

Gold, applied as organometallic liquids, is used for the decoration of porcelain and glass dinnerware; gold leaf is used for the decoration of buildings, both inside and outside; and gold alloys are used in rupture discs in chemical process equipment and in the perforated "spinnerets" through which cellulose acetate fibers are extruded. Since 1975, a small amount of gold has been used in the United States each year for medals, small bars, and other similar items having high gold content, purchased primarily as investments.

STOCKS

Stocks of refined bullion held by industrial users at the end of the year were substantially lower than those held at the end of 1988. The sharpest declines in industrial stocks were reported during the first and second quarters of the year and may reflect a withdrawal of material by manufacturers to meet the continuing demand, especially for jewelry products destined for sale later in the year.

Yearend stocks of gold certified for delivery by COMEX, the Nation's largest futures exchange, increased substantially from those held at the end of the previous year.

PRICES

The Engelhard Industries-London daily final price of gold ranged from a low of \$357 per ounce in September to a year's high of nearly \$417 per ounce in mid-December. Despite the strong surge in the price toward yearend, the

average for the year amounted to about \$383 per ounce or nearly \$60 per ounce less than the average for 1988.

FOREIGN TRADE

U.S. exports of gold, though not as large as in the previous year, were nevertheless substantial when compared with many earlier years. Contrary to 1987 and 1988, when Taiwan was the

principal recipient of U.S. refined bullion shipments, exports to that country all but ceased during 1989. Switzerland was instead the principal destination during 1989, receiving large quantities of both refined bullion and doré.

Canada continued to be the Nation's principal source of refined bullion. Imports of gold from Uruguay which began in earnest in 1980 and peaked in 1986, declined in 1989 to roughly their 1980 level. During the 1980-89 period, Uruguay, a country with little or no domestic production and no official

controls on gold trade, became an important conduit for newly mined gold originating in other Latin American nations, especially Brazil where the trade of gold is tightly controlled. The dramatic decline in exports of gold from Uruguay in February 1989 may in part have been related to the discovery and closure there of an international money laundering operation reportedly

involving the export of gold plated lead bars.

WORLD REVIEW

In 1989, for the 10th consecutive year, world gold mine production exceeded that of the previous year. Gold Fields

Mineral Services Ltd.,⁹ continuing the annual statistical survey prepared over the previous 23 years by its predecessor Consolidated Gold Fields PLC, noted that world demand for gold in the market economy countries (MEC) reached another new record, surpassing the previous record set in 1988.

The company began its summary by noting that in addition to the supply of

newly-mined gold and net sales to the MEC from the centrally planned economy (CPE) countries the main addition to the supply was derived from sales to the market by the world's central banks. Central banks, for the first time

since 1984, were substantial net sellers of gold. Net sales by central banks amounted to 225 metric tons (7.2 million ounces), the highest since 1979. Gold releases to the market by investors in North America and especially Eu-

rope continued to be important sources of supply with much of this gold going directly to investors in Asia. Net sales of gold from the CPE Countries increased from 263 metric tons (8.5 million ounces) in 1988 to 296 metric tons

(9.5 million ounces) during 1989. Supplies of old gold scrap declined for the third consecutive year to 304 metric tons (9.8 million ounces).

Fabrication data on gold was assembled by Gold Fields from MEC data describing the trade in gold bullion and its use by industries in the MEC that transform bullion into marketable products. Gold, including gold scrap, fabricated into karat gold jewelry absorbed 1,811 metric tons (58 million ounces) or 23% more than in 1988. The company stated that the new gold component of jewelry manufacturing rose by as much as 30% because of the decline in available scrap. Jewelry fabrication grew steadily in North America and reached record levels in Europe and the Far East. Gold products fabricated for use in electronic applications rose by 3% from the previous year to 138 metric tons (4.4 million ounces) while gold used in other industrial and decorative applications grew by 6% to 62 metric tons (2.0 million ounces). The use of gold in dentistry declined slightly from the 1988 level to 49 metric tons (1.6 million ounces). Gold absorbed in the fabrication of medals and imitation coins rose fractionally to 19 metric tons (614,000 ounces). Gold minted into official coins declined 10% to 123 metric tons (3.9 million ounces); however, sales, at 127 metric tons (4.1 million ounces), were little changed from the previous year. The identified hoarding of gold bars outside of Europe and North America as measured by statistics for cross-border movement rose nearly 13% from 1988 to 516 metric tons (16.6 million ounces) in 1989.

Capacity

Rated annual production capacities for gold mines, as of December 31, 1989, are shown in table 14. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time at a normally sustainable long-term operating rate, based on the physical equipment of the plant and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

A telephone survey of leading do-

mestic producers responsible for 75% of current output was conducted in late 1989. The survey indicated a current capacity utilization rate of better than 97%. Incomplete data on the utilization rate for those mines responsible for the remaining 25% of production suggested that although most are probably operating at a rate comparable with the leading producers, some, for a variety of factors, may be operating at rates low enough to reduce the overall utilization rate to about 96%, as reflected in table 14. This estimated rate was believed to reflect the level of performance in most of the other industrialized nations.

Because of the size, diversity, and explosive growth of primary gold production over the past decade, comprehensive world capacity data that would include all operating units that contribute to national totals are generally not available. Therefore, in the absence of appropriate data, certain broad assumptions must be employed to derive international capacity numbers that are compatible with production data shown in table 15.

Optimum engineering capabilities may be more or less restrained by a combination of factors relating to Government and business attitudes, climate, location, ore grade and hardness, and mineralogy. With these and other considerations in mind, the author derived and applied to annual production data different conversion factors to approximate rated annual capacity for each producing nation.

Production data for individual nations were estimated to reflect a utilization rate from 75% of maximum capacity utilization for some essentially nonindustrialized nations up to a 96% utilization for most industrialized nations.

Reserves

Demonstrated U.S. reserves of gold were about 4,980 metric tons (about 160 million ounces), and the reserve base was 5,480 metric tons (176 million ounces). Most of the U.S. gold reserve base shown in table 14 is confined to 18 states, with about 80% of the total in Alaska, California, Idaho, Montana, Nevada, and Washington. A dominant portion of the reserve base occurs in lode deposits.

Total world reserves shown in the table approximated 42,000 metric tons

(1.4 billion ounces), of which nearly one-half are in the Republic of South Africa. The world reserve base for gold totals about 47,000 metric tons (1.5 billion ounces). Reserves of gold in the U.S.S.R. and China are believed to exceed 6,220 metric tons (200 million ounces).

Estimates of reserves become available only over a period of time. The reserves shown for Australia, Brazil, Canada, and the United States, generally reflect post-1980 data and the success of exploration efforts frequently initiated years earlier in response to rising prices.

Australia

With nearly 202 metric tons (6.5 million ounces) of gold produced during 1989, Australia maintained its position as the world's fourth largest gold producing nation. The Australian gold mining industry, like its U.S. counterpart, has experienced phenomenal growth in recent years, with production rising nearly twelvefold during the period from 1980 through 1989.

The State of Western Australia continued to maintain its dominance as the nation's largest gold-producing State, hosting, during 1989, 14 of the nation's 15 leading gold mines. The State and the nation's largest gold mine, the Bodington Mine located 113 km (70 miles) southeast of Perth, continued producing at or near its recently doubled capacity rate of nearly 12,500 kg (400,000 ounces) of gold per year. Bodington is managed by the Worsley joint venture. Production at Australia's second largest mine, Newmont Australia Ltd. and BHP Gold's large open pit Telfer Mine near Nullagine was setback during 1989 by labor problems and a mid-year collapse of one wall of the open pit. These setbacks, in turn, delayed the owner's plans to initiate the first stage of a planned underground development project designed to expand the mine's annual production rate to nearly 11,000 kg (350,000 ounces) by 1991.

Some other developments in Western Australia in 1989 included the following: In October, Homestake Gold of Australia Ltd. (HGAL) poured the first gold at its new wholly owned Fortnum Mine north of Meekathara. HGAL and Gold Mines of Kalgoorlie Ltd. completed a 50-50 joint-ownership agree-

¹ Estimated as of Jan. 1989. Data may not add to totals shown because of independent rounding.

² Reserves listed for countries other than Australia, Canada, the Republic of South Africa, and the United States may, in some instances, include inferred reserves.

³ The reserve base includes demonstrated resources that are currently economic (reserves), marginally economic (marginal reserves), and some of those that are currently subeconomic (subeconomic resources).

⁴ Excludes China and other centrally planned economies.

ment of Kalgoorlie's famous Golden Mile. The partnership now manages the Consolidated Kalgoorlie operations, including the "Super Pit" and Mount Charlotte, the largest underground gold mine in the country, plus five mills, including the newly commissioned Fimiston Mill. The partner's offsite Gidji roaster also became operational before yearend. Other new mines beginning production during the year included Westralian Resource Projects Ltd.'s Porphyry Mine, Goldconda Minerals NL's Duketon Mine, Aztec Mining Co. Ltd.'s Bounty Mine, and Poseidon Ltd.'s Kaltails project. Kaltails was developed to reprocess the vast gold-bearing tailings accumulated around mines developed along Kalgoorlie's Golden Mile.

The Western Australian Mint opened its new gold refinery in Perth. The mint's companion refinery in Kalgoorlie began operations during the previous year. The two facilities have a combined annual capacity of about 10,500 kg (3.4 million ounces).

In Australia's State of Queensland, the nation's third largest individual gold mine, the Kidston, produced nearly 6,400 kg (205,361 ounces) during 1989, and in September the mine's operator, Kidston Gold Mines Ltd., celebrated the production of its millionth ounce of gold. Several of Queen-

sland's other gold mines, including the Red Dome Mine of Elders Resources Ltd. and the Mount Leyshon Mine of Pan Australian Mining Ltd., announced plans to expand their production capacities.

Canada

Canadian gold production increased for the ninth consecutive year with most of the 1989 increase of nearly 18% attributable to gold mines in the Province of Ontario. New gold mines opened at an average of one per month during the year, thus bringing to 70 the total number of primary gold mines operating in the country. Seven mines were also closed during the year.¹⁰

New mines opened in Ontario during 1989 included Placer Dome's Dona Lake Mine and Flanagan McAdam Resources Inc. and Windarra Minerals Ltd.'s Magnacon Mine in the Mishibishu area of Ontario. In mid-year the Supreme Court of Canada confirmed a 1986 ruling by the Supreme Court of Ontario that the Page-Williams Mine at Hemlo belonged to Corona Corp. The ruling ended an 8-year legal battle between Corona and Lac Minerals Ltd. The Page-Williams Mine, producing nearly 15,400 kg (494,000 ounces) of gold in 1989, was the nation's largest gold producer. The old Kerr Addison Mine at Virginatown and the Surlaga Mine near Wawa were both

closed owing to technical and financial difficulties.

Quebec, Canada's second largest gold-producing Province, accounted for nearly 36,000 kg (1.16 million ounces) of new Canadian gold production during the year. New Quebec gold mines becoming operational during 1989 included the Kierens Mine of Aur Resources Inc., the Beauchastel Mine near Rouyn-Noranda by Augmitto Explorations Ltd., and the nearby Pierre Beauchemin Mine and the Lucien C. Beliveau Mine near Val-d'Or, both opened by Cambior Inc. Several mines were at the final preproduction stage and at least one mine, the Bachelor Lake Mine, was closed.

Three new mines with a planned production rate in excess of 1,000 kg (32,000 ounces) per year began production in British Columbia during the year; they were the Lawyers Mine of Cheni Gold Mines Inc.; the Golden Bear Mine, an open pit, underground operation owned by Chevron Canada Resources Ltd. and Homestake; and the Premier Mine of Westmin Resources Ltd. Exploration and development was continued at a number of gold projects throughout the Province with a lot of the exploration interest focused in the Iskut River-Eskay Creek areas of Northwestern British Columbia.

Gold mining activity in the Maritime Provinces was increased with the opening in September of the new Murray Brook Mine near Bathurst, New Brunswick. Several Gold Mines in Saskatchewan and Manitoba were closed owing to depletion or financial difficulties. Production at gold mines in the Yukon and Northwest Territories increased about 4% from that of the previous year.

Latin America

Gold production in Brazil, Latin America's largest gold-producing nation, was slightly lower than that of the previous year. Factors contributing to the decline reportedly included heavy rains that affected some placer mining areas, increased regulation, higher costs, and declining grades.

In early 1989, the president of Brazil signed a decree prohibiting the use of mercury and cyanide in gold mining unless approved by Brazilian State environmental agencies. The mercury amalgamation process to collect gold concentrated during placer mining operations has

been used for many years by unregulated independent gold miners or "garimpeiros." The States most affected by mercury contamination have been those in the Pantanal and Amazon regions of Brazil.

According to Gold Field's annual review¹¹ production increased in the unregulated mining areas or garimpos of Roraima and Rondonia along the Western frontier near Venezuela. Production decreased in the major garimpos of Alta Floresta and Tapajós to the east, where mining was slowed by heavy rains. Although production at the Serra Pelada Mine declined sharply from the peak production year of 1983, news of a new gold discovery there reportedly caused some garimpeiros who thought the mine was depleted to flood back into the region. The new discovery, in the main street of the minesite boomtown spawned by the original mine, reportedly developed quickly into a pit large enough to threaten the foundations of nearby homes and stores. Police action was required to halt mining until an orderly development plan could be found.

Production by the formal or regulated gold mining sector rose only slightly during the year. The dominant producer, Mineração Morro Velho S.A., maintains interests in gold mines in the Brazilian States of Bahia and Minas Gerais as well as Goiás where, in 1989, the company began production at its new 50%-owned Crixas Mine. Some other large gold mining concerns in Brazil include Sao Bento Mineração S.A., Cia Vale do Rio Doce, and Rio Paracatu Mineração S.A.

Chile's favorable geological potential as well as its increasingly attractive investment climate has encouraged a large number of companies in recent years to explore for gold as well as other commodities such as copper, silver, and zinc. With an estimated 7,000 kg (225,000 ounces) of gold production in 1989, Compañía Minera El Indio was Chile's largest producer. The company produces gold from its EL Indio and nearby Tambo mines in the Fourth Region. Other large mines owned and operated by foreign and/or domestic firms include the Choquelimpie, El Bronce, and El Hueso Mines. About 30% of Chile's gold production was derived as a byproduct of base metal mining while the remainder was attrib-

uted to numerous small lode and placer mines.

In early 1989, Placer Dome and Consolidated TVX Mining Corp. opened their new La Coipa Mine in the Third Region of northern Chile. The mine was expected to produce about 6,220 kg (200,000 ounces) of gold per year by late 1991. Minera Anglo-American Chile also opened its Marte Mine in the Third Region during 1989 and planned to open its nearby Lobo project by 1992. Because of the high number of exploration and mine development projects now under way, Chile's gold production was expected to rise substantially over the next several years.

In some other large gold-producing nations of Latin America such as Bolivia, Colombia, Ecuador, and Peru, the climate for investment in mining may not be as favorable as that in Chile. As a result, much of the gold production may be attributed to the informal sector; that is, as in Brazil, to more or less unregulated miners working individually or in cooperative groups. Exploration for gold and the development of new mines in these areas was also actively pursued by the respective Governments and/or foreign and domestic firms.

Oceania

The high level of activity in gold mining and the development of new mines in many nations of the southwestern Pacific was sustained for another year. For exploration companies, the principal targets continued to be high tonnage, low-grade epithermal gold deposits similar to many recently discovered and/or developed deposits in various Western Pacific nations such as Fiji, Indonesia, Japan, New Zealand, Papua New Guinea, the Philippines, and elsewhere.

Gold production in Papua New Guinea declined about 8% from the previous year's level, reflecting in part the suspension of operations at CRA's 53.6%-held Bougainville copper-gold mine. The Bougainville Mine, on Bougainville Island, was closed on May 15 because of continuing violence stemming from a political movement aimed at gaining the island's independence from Papua New Guinea. As a result of the closure, byproduct gold production from the mine declined to about 7,340 kg (236,000 ounces) from the nearly

14,400 kg (462,400 ounces) produced in the previous year.

In March, Placer Pacific Ltd. opened its new Misima Island gold and silver mine in Milne Bay, thus, to some extent, offsetting the loss in production from the closure of Bougainville. The first gold from the new 12,440-kg-per-year (400,000 ounces) operation was poured in May. To the west, in the highlands of Enga Province, Placer and its three partners moved toward a planned September, 1990 startup of the new Porgera Mine. At Mount Fubilan, about 200 km (124 miles) further west of Porgera, the OK Tedi copper-gold mine, the nation's largest gold mine, reportedly produced about 15,900 kg (495,000 ounces) of gold compared with the previous year's output of about 18,000 kg (581,000 ounces). The decline in 1989 production apparently reflected a combination of both labor and operational problems, plus the expected gradual depletion of the gold-enriched "cap" overlying the principal lower-grade copper-gold ore body.

Other gold-producing mines in the nation included New Guinea Goldfields Ltd.'s nearly depleted deposit at Wau and Niugini Mining Ltd.'s small Mount Victor Mine. A number of promising deposits continued to be evaluated in Papua New Guinea; Niugini Mining and RTZ prepared a final feasibility study of their extensive Lihir Island deposit; CRA was developing its Hidden Valley and Mount Kare deposits.

To the west in Indonesia's Province of West Irian, Freeport Indonesia Inc. continued copper-gold mining at its Ertsberg property while simultaneously moving toward an early 1990 startup of mining at the new Grasberg copper-gold deposit. Ertsberg is Indonesia's largest gold producing mine. In the island provinces to the west, the pace of gold exploration and development moderated somewhat from the previous year's level of activity. In January, the P.T. Ampalit Mas Perdana Mine began production in Central Kalimantan. Several major gold projects under construction or final evaluation included Royal Dutch Shell's Billiton Group's Lerokis Mine under construction on Wetar Island in Maluku Province; CRA's Kelian Gold Project Team moved at yearend to gain Government approval to begin development of its Kelian Project in East Kalimantan.

The recently reopened Martha Hill

Mine at Waihi, New Zealand, was the only lode mine operating in that country during 1989. The startup of several developing mines was delayed until operational or environmental issues could be resolved.

Gold production at the two principal mines in Fiji increased over the previous year because of the mining of higher grade ore at the Emperor Mine and improved efficiency at the newly opened Tavua Basin Mine.

South Africa, Republic of

Despite escalating production costs and steadily declining ore grades, the Republic of South Africa's gold mines continued to dominate the world gold mining scene, collectively producing more than 30% of total world production during 1989.

Most of the 603 metric tons (19.38 million ounces) of gold produced in the Republic of South Africa during the year was produced by the 34 mines that represent the membership of the Chamber of Mines of South Africa. The remainder was produced by several dozen small independent mines or as a byproduct of other mining sectors. The total ore milled by Chamber members, including ore milled by producers of byproduct and coproduct uranium, amounted to nearly 114 million metric tons or about 10 million tons more than the previous year. The average grade of ore milled during 1989 was nearly 5.0 grams per metric ton (0.146 ounce per short ton) compared with 5.13 grams per ton (0.150 ounce per ton) during 1988. Working costs for Chamber members averaged about \$277 per ounce (23,340 rands per kg) and ranged from about \$171 per ounce (14,407 rands per kg) at the East Driefontein Mine to about \$442 per ounce (37,189 rands per kg) at East Rand Proprietary.¹² Production by the six major mining groups was as follows: Anglo American Corp. of South Africa Ltd. (AAC), 253.1 metric tons; Gold Fields of South Africa Ltd. (GFSa), 113.1 metric tons; Gencor Ltd, through its newly created subsidiary General Mining, Metals and Minerals (Genmin), 86.1 metric tons; Rand Mines Ltd., 52.4 metric tons; Anglovaal Ltd., 43.4 metric tons; and Johannesburg Consolidated Investment Co. Ltd. (JCI), 41.5 metric tons.

The largest gold mines in terms of individual output, in metric tons of gold,

^cEstimated. ^PPreliminary. ^rRevised.¹ Table includes data available through May 30, 1990.² Gold is also produced in Burma, Cuba, Czechoslovakia, the German Democratic Republic, Norway, Senegal, Thailand, and several other countries. However, available data are insufficient to make reliable output estimates. Poland annually mines and processes copper ore estimated to contain about 31,000 kilograms of gold. Disposition of the gold byproduct is unknown.³ Reported figure.⁴ Excludes gold in gold ore and concentrate from South Australia.⁵ Only the combined total of gold and silver production is reported, which for this table is estimated to be divided thus: 83.5% gold-16.5% silver, the approximate ratio for combined 1982-83 production.⁶ Officially reported figures are as follows, in kilograms: Major mines: 1985—7,597; 1986—9,348; 1987—13,120; 1988—24,012 (estimated); and 1989—24,900 (estimated). Small mines (garimpos): 1985—22,076; 1986—14,776; 1987—22,660; 1988—55,053 (estimated); and 1989—56,000 (estimated).⁷ Gold purchased by Banco Central from placer deposits and mines; actual production estimated to be at least twice this amount.⁸ Year ending June 30 of year listed.⁹ Does not include undocumented production from small artisanal production¹⁰ Figures include reported mine production of 320 kilograms in 1988 and 1,059 kilograms in 1989. Remainder represents approximate reported sales to Government of artisanal production. Figures do not include artisanal production smuggled out of country.¹¹ Refinery output.¹² Excludes production from so-called people's mines, estimated at 15,000 kilograms per year during 1986-89, but includes gold recovered as byproduct of copper mining.¹³ These figures are based on gold taxed for export and include gold entering Liberia undocumented from Guinea and Sierra Leone.¹⁴ Includes production from Kalana Mine, artisanal production and undocumented gold entering Mali.¹⁵ Data are based on official exports and do not reflect gold moved through undocumented channels.¹⁶ Year beginning Apr. 1 of year listed.

included AAC's Freegold Mine with 110.9, Vaal Reefs with 75.5, Driefontein with 54.4, Western Deep Levels with 40.6, and Hartebeestfontein with 31.2.

In mid-December, Rand Mines poured its first bar of gold at its new Barbrook Mine near Barberton in the Orange Free State (OFS). Barbrook is the first grass-roots mine opened by Rand Mines in many years. In late 1989, Genmin announced plans to pro-

ceed with the development of its new Weltevreden Mine near Orkney in the OFS. The new mine, scheduled to begin production in the second half of 1992, was expected to extract ore from the gold-bearing Vendersdorp Contact Reef. A relatively shallow mine by South African standards, Weltevreden's ore will be extracted using low-cost trackless mining methods operating from 100 to 1,100 meters below the surface.

CURRENT RESEARCH

The Bureau of Mines conducts research into various aspects of the gold mining industry.¹³ Because gold mining is pursued in many nations, the results of this ongoing work may, like the Bureau's earlier work in heap leaching, ultimately benefit a broad segment of the industry worldwide. The Bureau's current research relating to gold mining generally focused on the use of cyanide in the recovery process. Through its work, the Bureau addressed several questions regarding the use of cyanide, its long- and short-term persistence, and effects in the environment. These questions included such topics as the persistence of cyanide, the mass balance of cyanide in the leaching process, the mobility of metals in the heap during heap leaching, and the protection of wildlife.

The Bureau sponsored university research through its mineral industry waste treatment and recovery generic center. A joint Bureau-university-industry effort was recently commissioned to assist in defining future environmental needs relating to gold mining and cyanide use. Six priority areas chosen for research included the following: mine and mill closure, cyanide destruction, seepage, wildlife protection, acid mine drainage, and cyanide alternatives.

Several reports on research relating to gold were issued by the Bureau during 1989.¹⁴

OUTLOOK

As an internationally traded commodity serving not only the industrial and jewelry end use sectors but the investment sector as well, the outlook for gold supply and demand must be viewed from a global viewpoint.

Gold Fields Mineral Services¹⁵ in its annual review of supply and demand, acknowledges the pitfalls of long-term forecasting by limiting its outlook to the immediate future. Gold Fields, in addressing the outlook for prices greater than those achieved near yearend, noted that several underlying factors favoring a higher price were evident. These factors included their forecast for a levelling-off of mine production in the market econ-

omy countries during the early 1990's and a lower level of accelerated supplies from other sources such as the gold loans and forward sales that were featured most prominently during 1988. Gold production in the U.S.S.R. may decline during the present economic crisis while pressure to sell gold to raise foreign exchange will continue. Sales of gold by central banks and sales of bullion coin holdings by European investors may be somewhat less than in 1989 and the amount of scrap entering the market should remain at the present low level.

Gold Fields concluded its supply forecast by stating that, in the absence of exceptional sales from CPE countries, the record supply level of 1989 is unlikely to be repeated in the immediate future. On the demand side, Gold Fields expects that the rate of growth in jewelry demand of the past 3 years may decline as consumer spending slows. Similarly, an expected decline in physical bar hoarding in Brazil and Some Far Eastern Nations may be softened by increased demand from the Republic of Vietnam.

If the price of gold remains at levels acceptable to the domestic mining industry, gold production may be expected to grow, but at a slower rate than that of the past several years. The hectic pace of exploration seen in recent years appears to have peaked or at least shifted somewhat toward the base metals. Many small mines opened in recent years will probably close as their limited ore reserves are depleted. This loss in production will probably be offset by some new mines and especially expanded production at established larger mines where the focus has shifted toward exploiting their large reserves of gold-bearing sulfide ores. Any growth in production must assume, of course, that a relatively stable and predictable regulatory climate will continue to prevail.

On the demand side, the near-term outlook for continued strength in the all-important jewelry sector depends on a number of unpredictable factors such as the continuance of acceptable gold prices, variable fashion trends, and the continued success of industry product advertising to attract new jewelry buyers. Jewelry demand may level off somewhat in the near term as discretionary consumer funds tighten. The use of gold in electronic applications may experience continued growth as

the demand, for sophisticated and more reliable electronic goods expands to match the growth of the gross national product. Gold has a number of unique characteristics that favor its continued usage in dental applications; its usage in dentistry should probably remain at or near the present level despite the continued impact of cheaper substitute materials.

BACKGROUND

Gold lore and the use of gold predates written history. Gold has been considered a precious metal since ancient times, and the search for gold has stimulated world exploration and world trade for more than 60 centuries.

Gold mining in the United States began about 1800 in North Carolina, with Georgia becoming a producer in 1829 and Alabama in 1830; Virginia, Tennessee, and later New Mexico began producing as prospectors moved west. The most important gold discovery, because of its influence on development in the Western United States as well as on the amount of gold produced, was at Sutter's Mill in California in 1848. Later discoveries were made in most other Western States and territories.

Gold mining in Australia began about 1849 as an offshoot of the California gold rush. Russian gold mining had been expanding since the mid-18th century, and by the eve of the California gold rush, Russia was producing nearly two-thirds of the world's gold. Gold mining in the Republic of South Africa started in the 1870's. The last major gold rush began just before 1900 in Canada's Yukon and in Alaska.

Early mining was largely by placer methods with a multitude of miners working stream deposits (placers) by hand mining techniques, a practice that continues to this day in many areas of the world. In the 1860's, the more difficult underground mining of lode deposits—the sources of the placers—became important. Cyanidation, a chemical process for gold extraction, was introduced about 1890. The concentration of finely ground ores by the flotation process, selective adherence of mineral particles to rising bubbles, was first used for gold ores around

1900 and came into general use in the 1930's. Heap leaching, essentially a form of cyanidation, has come into general practice for treatment of low-grade ores only during the past two decades.

Cumulative world production to date is estimated at about 105,000 metric tons (3.4 billion ounces), about two-thirds of it mined in the past 60 years. The total is equivalent to a cube roughly 18 meters (58 feet) on a side. The Republic of South Africa has been the source of about 41% of that gold, but nearly all countries have reported at least some production of gold.

U.S. gold production from its beginning in the 18th century to date totals nearly 11,000 metric tons (353 million ounces). The principal producing States, in declining order of cumulative production are: California, Nevada, Colorado, South Dakota, Alaska, Utah, and Montana; the remainder came from 11 other States. To date, lode gold mining has supplied about 50% of U.S. production, placer mining 35%, and base metal mining 15%. The Homestake Mine at Lead, SD, has accounted for about 10% of all U.S. gold production. Other major sources of past production include the Mother Lode and Grass Valley areas of California, the Comstock Lode and Goldfield areas in Nevada, Cripple Creek in Colorado, and the Fairbanks and Nome, AK, areas.

Most domestic gold mines were closed by Limitation Order L-208 in the early months of World War II so that scarce equipment, supplies, and skilled manpower could be focused on mining essential base metals. Because of increased cost and rehabilitation problems, only a few reopened after the war; however, during the resurgence of gold exploration and mining over the past decade, many deposits affected by L-208 have been reexamined or returned to productive status.

Definitions

Gold has an atomic number of 79 and an atomic weight of 197, occurring naturally as a single stable isotope. Its melting point is 1,063° C and its specific gravity is 19.3. In addition to being highly resistant to corrosion, gold is also extremely malleable and ductile; 31 grams (1 troy ounce) can be beaten into about 250 square feet of gold leaf about four-millionths of an

inch thick while a similar quantity can be drawn into a wire more than 80 km (50 miles) long.

As an illustration of gold's high specific gravity or density, 1 cubic foot of pure gold weighs a little more than 1,200 pounds, one cubic inch of pure gold weighs about 311 grams (10 troy ounces), and a lump or nugget of gold the size of a navy bean weighs about 3 grams (0.1 troy ounce).

The troy system of weights is generally used in the United States for gold and other precious metals; however, to aid in harmonizing world data collection, Government practice now requires the use of the metric system of measure. Thus, outside of the Government, either system may be encountered. The troy weight system is based on the troy ounce of 480 grains or 20 pennyweight. One troy ounce is equivalent to 1.097 ounces avoirdupois. Many nations use the metric system; under this system, the weight of gold may be designated in standard metric terms; gram, kilogram, or metric ton. The metric ton is equivalent to 32,150.7 troy ounces.

Fineness refers to the weight proportion of pure gold in an alloy, expressed in parts per thousand; 1,000 fine gold is 100%-pure gold. Commercially traded gold bullion is usually 995 fine or higher. The term "fine gold" may also be used to designate the particle size of gold in its native state; for example, a placer deposit with gold particles ranging from 0.38 millimeter (mm) to 0.76 mm (0.015 to 0.03 inch) in diameter contains fine gold, whereas a similar deposit with particles more than 1.5 mm (0.06 inch) in diameter contains coarse gold.

The term "karat," like fineness, refers to purity, but is expressed in 24ths; thus 24-karat (24k) gold is 1,000 fine or pure gold, and 10k gold is 10/24, or 41.7% gold. Although there are many 10k alloys, each 10k alloy contains 41.7% gold. Various 10k alloys, for example, differ from each other in the number, identity, and proportions of their other constituent metals. Gold alloys used in jewelry and certain other end uses are referred to as karat golds, whereas alloys used in dentistry and electrical devices are designated more precisely. Yellow, red, and green karat golds are essentially ternary alloys of gold, silver, and copper, often with

additions of zinc and sometimes a little nickel. White karat golds are usually composed of gold, copper, nickel and zinc, although platinum and palladium have also been used as components.

Refined gold bullion bars destined for monetary, investment, and industrial usage are generally designated as "Good Delivery Bars." The unit of trading on the London Gold Market is a bar measuring about 17.8 centimeters (cm) by 9.2 cm by 4.1 cm (7 inches by 3 $\frac{3}{4}$ inches by 1 $\frac{1}{2}$ inches) thick weighing approximately 12.5 kg (400 troy ounces or about 27 pounds), having a minimum fineness of 995, and bearing a weight stamp, serial number, melt number, and the stamp of an acceptable melter or assayer. Smaller bars for use by investors as well as industrial users are also commonly available on the commercial gold market.

U.S. trade practice rules for the jewelry industry, set by the Federal Trade Commission, require that any article labeled gold must contain at least 10k gold, with a tolerance of three parts per thousand for most articles, or if soldered, to seven parts per thousand. Rolled gold plate and gold filled are terms referring to articles made of base metal to which karat gold has been bonded by soldering, brazing, welding, or mechanical means. A marking such as " $\frac{1}{10}$ 10-karat gold filled" means that one or more surfaces are covered with 10-karat gold and the coating constitutes at least 10% of the weight of the entire article covered. No article may be marked "gold filled" if its karat gold surface constitutes less than $\frac{1}{20}$ of the total weight. Thinner coatings are marked "rolled gold plate."

Products for Trade and Industry

Although gold compounds are used in substantial quantities in electroplating, most of the gold sold in the international marketplace for industrial usage is in the form of metal or metal alloys. Many standard metallic forms are available, such as bar, rod, sheet, foil, wire, powder, granule, and shot. Pastes and inks prepared with gold powder are widely employed in the electronics industry. Much jewelry gold is supplied as granules of specified karat content. Semimanufactured items for trade and industry may include gold jewelry findings or unassembled parts such as earring clamps, chain clasps,

pins, etc.; dental findings; and inlaid, clad, and plated metals. Investment products such as bars, coins, and medallions are manufactured and sold by both industry and by governments.

Industry Structure

In the United States during 1989, 89% of domestic production came from gold ore, and most of the remainder was a byproduct of silver or copper and other base metal production. Placer gold production has declined to about 2% of the reported total production in recent years. Sixteen mines accounted for about 61% of domestic output in 1989; 80% came from mines in Nevada, California, Montana, and South Dakota. The leading producer in most recent years, Newmont Gold Co., provided about 17% of domestic output from its surface operations near Carlin, Nevada. The Homestake Mine, a deep underground mine in South Dakota, has been an alternate leading producer for many years. The Utah Copper Division of Kennecott, a major copper producer, has been a significant gold producer in many years since 1979, a year when it was the Nation's largest gold producer. Kennecott's gold is a byproduct of its extensive copper mining operations at Bingham Canyon, UT. Freeport-McMoRan Gold Co.'s Enfield Bell (Jerritt Canyon) Mine, a large open pit operation in north-central Nevada that began production in 1981, was the fourth-largest producer in 1989.

Attracted by the favorable U.S. business climate, foreign investment in domestic firms that produce gold as a principal product or as a byproduct has increased since 1980. This is especially true for mining interests acquired by multinational companies, some of which in turn may be directly linked to foreign governments. The general attractiveness of the United States as a country in which to conduct business has been a principal motive behind these acquisitions. Canadian mining companies have, throughout the history of North American mining, operated mines in the United States, as to a lesser extent, have British and other European companies.

The South African gold mining industry, accounting for about 30% of current world output, consists of about 3 dozen large underground operations

and several dozen smaller mines. In a typical year, the Republic of South Africa's gold industry reportedly mills enough ore to cover 60 city blocks to a height of 20 stories; from this volume is recovered enough gold to fill a small room. These mines are owned or controlled by six corporations, which interlock through directorships and mutual shareholdings and have extensive mineral and industrial investments in many parts of the world. The corporations are; Anglo American Corp. of South Africa, Ltd.; Anglovaal Ltd.; Gencor Ltd.; Gold Fields of South Africa, Ltd.; Johannesburg Consolidated Investment Co. Ltd.; and Rand Mines Ltd.

Geology

The Earth's crust has been estimated to have an average gold content of about 0.0034 gram per metric ton (0.0001 ounce per short ton), or 3.5 parts per billion (ppb). Sedimentary rocks, especially sandstones, tend toward higher than average gold content. In igneous rocks, the content averages slightly higher in darkly colored mafic rocks than in lighter colored felsic rocks. Seawater typically contains about 0.011 ppb gold; however, content varies widely with location and may range from 0.001 to 44 ppb. Numerous attempts have been made over the years to recover gold from seawater; however, none have been commercially sustainable. The gold content in surface and ground waters lies within the range of analyses for seawater, but varies widely depending on source. For instance, waters from gold mines in southern Yakut, U.S.S.R., contain an average of 0.7 to 0.9 ppb. In Colorado, waters draining from gold mining and other areas contain up to 0.15 ppb, but with no distinct differences between gold-enriched and gold-barren areas. Hot-spring waters generally contain more gold than other waters.

Gold deposits are found in many kinds of rock. Hydrothermal deposits appear to be somewhat more common in acidic and intermediate igneous rocks, in silty, laminated carbonate rocks, and in silicious or aluminous sedimentary or metamorphic rocks. The general deposit types include hydrothermal, hydrothermal-metamorphic, metamorphic, replacement (lode, massive, and disseminated), and cavity filling (fissures, stockworks, saddle, reefs, breccias, and conglomerates).

Gold occurs mainly as native metal, alloyed with silver and/or other metals, and as tellurides. A naturally occurring alloy of gold and silver is known as electrum. Other gold minerals are rare. Gold is commonly associated with the sulfides of iron, silver, arsenic, antimony, and copper.

Chemical and mechanical weathering and erosion cause gold in the free or metallic form to be released from lode or primary deposits and to accumulate as nuggets and grains in residual deposits or placer deposits. Although the richest lode gold deposits have been small fissure vein types with quartz gangue, the so-called bonanzas, much larger quantities have been mined from large, medium-grade deposits. U.S. gold ores average about 3.5 grams per metric ton (0.1 ounce per short ton), or less; however, the advent of chemical heap leaching now makes it possible for rock with suitable properties containing considerably less than 3.5 grams per metric ton to be considered ore.

Technology

Exploration.—Although a number of new techniques have come into use in the exploration for gold, the gold pan remains one of the simplest and most efficient low-cost means of finding visible gold and tracing it to its source. Collecting, crushing, and panning quartz samples from geologically favorable areas is a common basic procedure employed in prospecting for bonanza-type lode deposits. Neutron activation analysis and atomic absorption spectroscopy permit relatively fast and reliable gold analyses and have had an important bearing on the ability of field geologists to do geochemical surveys of areas formerly of little interest because of sampling costs and lack of outcrops. The long-established fire assaying technique, however, continues to be the most widely used method for determining the quantity of gold present in samples or market products where precision and accuracy of the results are important. Newmont Gold Co. recently initiated an automatic assay system whereby more than 4,900 laser-read barcoded samples are directed daily through the various laboratory stages with the aid of computers. Geochemical studies have established relationships between gold and other

elements, such as tellurium, mercury, arsenic, and copper, which can be useful trace elements in the search for gold. In recent years computers have proven to be useful in determining the often subtle relationships between trace elements and gold mineralization. Metallogenic studies relating tectonic histories and regional and local geology have given better understanding of where important gold deposits may lie.

Wire-line core drilling and improved percussion drilling methods have reduced the costs and increased efficiencies of exploration and development. Research on sampling through statistical analysis techniques that take into account the distribution and size of gold particles in a sample has shown ways to effectively reduce sampling costs. Computer methods have been useful in defining the extent of pay zones in larger ore bodies, such as those in the Republic of South Africa, and have application to low-grade disseminated deposits. Improvements in mining machinery and procedures and the introduction of new gold leaching methods have combined to lower the economic cutoff limits for gold deposits, providing an impetus for extensive reevaluation of previously mined areas as well as the incentives necessary to encourage the exploration of new, heretofore unproductive, areas.

An issue of continuing concern to domestic gold producers and to producers of other minerals as well is that of mineral land availability. Because the geological forces that form mountains and unique physiographic features are often responsible for producing mineral deposits, exploration for gold and other minerals frequently focuses on these areas of disturbance. The same rugged features that make certain areas attractive to the minerals explorer may also make them less accessible for mining because these areas may be more valued for their undisturbed, or wilderness, qualities than for their mineral potential. In recent years, the trend toward preserving increasingly greater areas of unevaluated wilderness land, on which exploration is prohibited or severely restricted, may lead to a decline in new discoveries as well as jeopardize national security.

Mining.—The technology of gold mining is well established, having

evolved largely over the past century. Much of the world's gold production has come from deep narrow veins or from thin-bedded layers called reefs; these have been difficult to mine (in the Republic of South Africa, for example) because of high underground temperature, humidity, and extreme rock pressure, which often causes dangerous rock bursts. Most domestic gold comes from surface lode mines.

Placer mining was once an important source of gold. Dredging offers the maximum efficiency in large alluvial or marine deposits; dragline, hydraulic, or bulldozing methods are commonly used in smaller, bouldery deposits. Most placer mining requires large quantities of water, but dry operation is also possible, using bellows or other air-blowing equipment for separation. However, recovery efficiency may be lower in dry processing. For large-scale, open pit lode gold mining, computer models have been developed to analyze various production factors and establish optimum pit configurations and extraction efficiencies.

The South African mining industry, a leader in deepmining technology for many years, has evolved new methods of controlling problems relating to rock stress, dust, and stope temperature. Both large and small water-powered

rock drills, large-diameter raiseboring machines, and new types of rubber tired transporters have been developed in recent years to increase the efficiency of mining operations. Also, the South Africans have developed new techniques of shaft sinking, mineral processing, and extraction that are critical to the success of deep mining. At the Vaal Reefs Mine, for example, part of the gold ore is transported to the surface from a depth of more than 2100 meters (7,000 feet) by hydraulic pumps.

Beneficiation.—Milling technology for gold is highly developed, and normal mill recovery rates may range from 92% to 96%. Gold is recovered by cyanide leaching of gold ore contained in tanks or heaped on impervious leaching pads or by amalgamation, flotation, gravity concentration, and smelting, or by a combination of these processes. Heap-leach process components are shown in figures 1 and 2. Increased exploitation of gold-bearing sulfide ores in recent years has led to the development and application of several technologies designed to render sulfide and refractory ores amenable to cyanide leaching; thus, process steps such as autoclaving, biological preoxidation, or fluid-bed roasting have re-

cently been incorporated at a number of milling operations.

Smelting.—Many gold mining operations recover gold from cyanide leach solutions by precipitation with zinc dust, though in recent years, carbon-in-pulp (CIP) recovery technology has been adopted at a number of new mining operations. With CIP, activated carbon made from coconut shells or other durable carbon sources collects gold from the cyanided pulp until it contains 10 to 12 kg (300 to 400 ounces) of gold per ton of carbon. Gold with accompanying silver is desorbed or stripped from the carbon with a strong alkaline cyanide-alcohol solution. The precious metals are recovered from the strip solutions by electrodeposition on a stainless steel wool cathode. The cathode deposit is then refined into bullion or doré, a mixture of mostly gold and silver. The carbon is reused after being screen-sized and reactivated through controlled roasting. Generally, gold recoveries range from 92% to 97% of the feed content. Gold leaching processes in use or under development that do not employ cyanide as the principal lixiviant or dissolution medium include the application of thiourea, iodine, malonitrile, or various bioextraction

FIGURE 1

HEAP-LEACH PROCESS COMPONENTS

techniques. Some of these alternate techniques, unlike the long-established, well-understood cyanide process however, may be accompanied by unacceptable cost or environmental burdens. When gold is associated with copper ores, it travels with the base metal through concentration and smelting to the refining stage. It is eventually separated from the anode slimes that accumulate in electrolytic copper refining cells and is recovered as gold bullion in the precious metals refinery. Gold losses in concentrating copper ores are about the same as for copper, but are negligible in smelting and refining.

Gold is refined by chlorination in the molten state (Miller process) and by electrolysis (Wohlwill process). Generally, gold bullion made by the Miller process is 996 to 997 fine, and bullion made by the Wohlwill process is 999.5 to 999.8 fine.

Recycling.—Because of its high intrinsic value, gold has been recycled throughout the ages. Thus, a modern

article of jewelry containing recycled gold could conceivably contain atoms of gold from a golden earring worn by Helen of Troy or from a nugget of gold used in the year 4000 B.C. to barter for ingots of crude copper or other goods at a Mediterranean seaport.

Precious metals refiners throughout the world recover gold from scrap. In the United States, about 60% of the scrap comes from current manufacturing operations, and the remainder comes from old scrap in the form of items such as discarded jewelry and dental materials, used plating solutions, junked electronic equipment, etc. Gold is so valuable that even the gloves, aprons, and dust masks worn by gold workers and the dust or "sweeps" from their shops may be processed to yield payable quantities of metal. Similarly, a specialized field of secondary gold recovery focuses on gleaning gold from defunct gold processing operations. Most domestic scrap processors are located in the Northeastern States.

The general flow of gold in the secondary industry is shown in figure 3. Refiners receive scrap in a variety of forms and determine processing steps according to batch size, average gold content, and the impurities to be separated. Scrap dealers and semi-refiners may process the scrap and then ship the upgraded product elsewhere, including overseas, for further treatment and refining. Scrap is either purchased outright or treated on a toll basis.

A considerable quantity of scrap is generated in manufacturing operations, but because of tight security controls over waste materials in precious metals plants, nearly all of this "home-generated" scrap is recovered. Some old scrap, on the other hand, is lost because in practice gold cannot be economically recovered from all manufactured products; this is increasingly true as miniaturization of gold-bearing electronic products proceeds. The U.S. Department of Defense recovers a significant quantity of gold from military scrap; other Federal Government agencies either participate in the Defense recovery program or have their own.

Economic Factors

On January 31, 1934, following provisions of the Gold Reserve Act of that year, the official price of gold was

raised by the U.S. Government from \$20.67 per ounce to \$35 per ounce. The value of \$1 was thus established at 28.57 thousandths of a troy ounce, and gold flowed into the United States. By 1949, gold stocks held by the U.S. Department of the Treasury had risen to a peak of 21,708 metric tons (698 million ounces).

During the 1950's and 1960's, foreign central banks vigorously exchanged their large dollar holdings for U.S. gold. Consequently, U.S. stocks declined, with much of the gold accumulating in stocks owned by foreign governments. When the outflow of gold was finally stemmed in August 1971 by a Presidential order ending the convertibility of U.S. dollars into gold, U.S. stocks stood at 9,069 metric tons (291.6 million ounces). Thereafter, U.S. stocks declined somewhat, reflecting gold auctioned by the Department of the Treasury in 1975, 1978, and 1979 and later minting of gold coins and medallions for public sale. At yearend 1989, U.S. Treasury stocks stood at 8,146 metric tons (262 million ounces).

Because of increasingly severe pressures on official gold reserves stemming from attempts by monetary agencies to hold the price of gold down to \$35 per ounce, a seven-nation International Gold Pool established a two-tier price system in March 1968. Under this system, there was an official price of \$35 on monetary transactions, thenceforth restricted to Government-owned gold, and an open market price for other transactions, which could fluctuate with supply and demand. Since then, the free market has flourished, and the price of gold has risen dramatically, while the monetary sector has evolved to the point where most nations conduct gold transactions and value their gold reserves at market-related prices. The United States is the only remaining holder of large gold reserves to value them at the low official price of \$42.22 per ounce. The U.S. dollar was devalued twice in the 1970's, raising the dollar price of gold to \$38 an ounce on May 8, 1972, and then to \$42.22 on October 18, 1973, where it remains today. With the second devaluation, the President was empowered to eliminate regulations on the private ownership of gold, which had been in force since 1934, and these were eventually removed on December 31, 1974. January

2, 1975, was the first day that the general public was allowed to resume holding gold without a licence issued by the U.S. Treasury's Office of Domestic Gold and Silver Operations; the office was closed on July 31, 1975.

Trading in gold futures began in New York and Chicago upon restitution of the right to private ownership of gold. Trading volume has increased nearly sixteenfold since 1975, peaking at nearly 43,000 metric tons (1,380 million ounces) in 1982; the volume in

subsequent years has ranged from about 25,000 to nearly 35,000 metric tons. However, only a small percentage of the gold traded enters the physical market.

Because of gold's monetary role and the fixed \$35-per-ounce price from 1934 to 1968, domestic producers had difficulty maintaining production in the face of rising costs. Gold was particularly attractive as a commercial metal because its price was stable and a dependable domestic supply was pro-

vided to industrial users by the U.S. Treasury until March 17, 1968.

In March 1982, the U.S. Gold Commission, which had earlier convened to consider a renewed role for gold in the U.S. economy, concluded that reintroduction of gold into the current monetary system would probably not serve to alleviate potential economic problems such as inflation. The prospects for a return to a gold standard in other countries would also seem to be uncertain. However, as a so-called "hard cur-

rency," gold may come to enjoy a greater role in world economics, than it has in the recent past. This is especially important as the world economic system adjusts to accommodate rapidly changing political, economic, and trade practices and to address the many issues associated with the rapid growth in world population, dwindling resources, and slower growth in industrial productivity. Small-scale bartering arrangements involving gold continue as they have for centuries, especially in frontier mining areas such as those in South America, Africa, the western Pacific, and remote areas of North America.

An issue of increasing concern to the mining industry as well as Federal, State, and local law enforcement authorities has been the recent growth in telemarketing fraud and investment swindles involving sales of gold bullion and investment in questionable mining ventures. In late 1988, the North American Securities Administrators Association Inc. (NASAA) and the Council of Better Business Bureaus Inc. issued an Investor Alert entitled "Dirt Pile Gold Swindles." The alert was to educate the public regarding the organization, characteristics, and pitfalls of the classic "dirt pile" or "gold-in-the-ground" swindle. The NASAA is composed of representatives from the securities regulatory agencies of all 50 States plus Puerto Rico. Law enforcement authorities and various industry trade groups continue to police against other fraudulent practices such as misrepresented gold quality marks on jewelry and bullion and faked collector coins.

Prices.—The price of gold is a topic of continuing concern and interest to the producer and the consumer of gold alike; where it has been, where it will go, and the reasons behind its wild fluctuations over the past decade or so have been studied from every angle by numerous observers. Apparent causes for the price changes have been presented, and speculation on their future directions have been offered.

Unfortunately, many of these sophisticated econometric models forecasting the price using combinations of economic, political, and social factors that proliferated in the early 1980's had all but disappeared from the public domain by the end of the decade. The

course of future events cannot, of course, be forecast with accuracy, nor can the price of gold. Forecasting gold's price is unusually complicated because gold occupies a unique position among the world's commodities. Gold is both an internationally traded commodity and, at the same time, a long-established, universally acceptable storehouse of value, considered by many people worldwide to be superior to fiat paper currencies with fleeting longevity or fluctuating unpredictable value. Unlike many commodity prices that are more or less tied directly to supply and industrial demand, the price of gold cannot be viewed as one would view the price of other goods or services in a free market. Gold also cannot be viewed strictly from the standpoint of the U.S. market alone, for international, political, and economic events that may impose a positive or negative influence on gold the commodity may be overshadowed by developments perceived to favor gold the medium of exchange. For example, citizens of nations that have been invaded by other countries during the course of their history tend to value the monetary and exchange aspects of gold more highly than countries such as the U.S., where this has not been the case. To them, gold is money or the preferred substance of wealth, and the ownership of even a small amount of physical metal ensures escape or a new beginning. Therefore, many individuals worldwide, as a matter of tradition or simple prudence, continue to hold small quantities of gold in the form of jewelry, coins, nuggets, etc., legally or illegally, as a portable form of universally accepted capital; for some, especially in developing countries, gold may constitute the only available and relatively risk-free form of old age or disaster insurance.

Although the average price has declined from its record 1980 level of \$612 per ounce, it remains considerably higher than the prices of the early 1970's. This high price level, not generally enjoyed in recent years by many other commodities, continues to spark investor interest and lead to an overall sustained increase in the level of funding available to gold producers to invest in exploration and productive capacity. The heightened interest in gold has, as in the past, promoted exploration of

those remote corners of the Earth where exploration for other less valuable minerals could not be justified but where their serendipitous discovery as a byproduct of exploration for gold is likely to eventually contribute to the needs of society.

In the fabrication of gold, particularly in the electronic and electrical industries, the cost of gold used per unit item is still such a small percentage of the total unit cost that the price for gold is often of small significance in pricing the product. Some industrial consumers of gold, however, confronted with unpredictable and potentially ruinous prices, have turned in recent years to the various world futures markets to ensure that their future gold requirements will be available at preselected prices.

Costs.—Costs of mining gold in the United States range upward from costs typical of low-cost placer mining, where dredging or hydraulic operations are conducted profitably on gravels containing less than 0.49 gram per cubic metric (0.01 ounce of gold per cubic yard). Surface lode mining, although considerably more expensive than placer mining, is profitable with some ores containing as little as 0.3 gram of gold per metric ton (0.01 ounce per ton), depending on the stripping ratio, size and type of operation, the characteristics of the ore processed, and the mine's location with respect to the duration of the operational season and the infrastructural requirements. Underground mining for gold is the most expensive mining, but costs vary greatly from mine to mine; nevertheless, some underground mines are able to produce an ounce of gold at costs below those of some surface operation; for example, the average cost to produce an ounce of gold at the 2400-meter-deep (8,000 ft) Homestake Mine in South Dakota, including a small contribution from a new surface pit, during 1989 was \$322. The cost was distributed as follows: mining and treatment, \$287; administrative and general \$16; and taxes \$19.

Costs for processing gold ores can vary widely, depending on the treatment required. Recent advances in heap leaching of gold and extraction with activated carbon may afford lower capital and operating costs than those associated

with conventional cyanidation. One recent advance, for example, is particle agglomeration, a technique developed and patented by the Bureau of Mines to increase the flow rate of leaching solutions through crushed ore. Fine particles in the ore that would otherwise impede solution flow are bound together or agglomerated through the addition of a water-soluble binder such as a cement or lime. Other innovative techniques developed in recent years to improve the efficiency of the heap-leaching process include the use of ore conveyors and stackers, solution heaters, and improved solution distribution and recovery and leak detection systems. Other advantages of heap leaching over conventional milling include shorter plant construction time and greater adaptability to lower-grade ores. A disadvantage of conventional heap leaching is lowered recovery, usually 60% to 80% of the gold present, compared with 88% to 92% or greater recovered by conventional mill treatment. The recovery efficiency of heap-leaching operations where agglomeration technology is employed approaches that of conventional methods.

Some producers, by forward selling of their future gold production, are able to maintain economic production even during periods when their production costs may exceed the existing market price of gold.

Taxes.—Taxes may be levied on mining operations for gold and other minerals at the Federal, State, and local levels. In addition to the usual business, occupation, and property taxes and licence fees required of all business enterprises, mining operations in many States are subject to severance or extraction taxes imposed on the yield or proceeds received from the sale of newly mined products. In 1989, the State of Nevada, for example, increased the net profits tax on State mineral production from about 2% to 5%. In 1986, a new Federal tax, the Customs User Fee, was adopted; it places a 0.22% levy on all imports, including gold and gold-bearing products. The fee was reduced to 0.17% on September 30, 1987.

Most major gold-producing nations impose taxes on domestic mining operations; taxation of the gold mining industry in some countries may be specifically tailored to accommodate a nation's

stated economic and political objectives. For example, in the Republic of South Africa gold mines are taxed in accordance with two basic formulas: one taxes the profits of mines opened before to 1966, while the other formula applies to newer mines. Many major gold-producing nations have also provided tax concessions, subsidies, and others assistance to gold mining. The U.S.S.R. has supported gold mining through administrative fiat. China encourages gold prospecting by both the civilian and military population. Australian mining companies have for decades been exempted from paying taxes on profits derived from gold mining. However, effective January 1, 1991, the Government of Australia will eliminate its six-decade-old tax exemption for income derived from gold production, including byproduct production from copper operations where gold represents more than 40% of the total income.

Operating Factors

Environmental Requirements.—The costs associated with meeting various Federal, State, and local environmental requirements can vary considerably from one mine site to another. At mines utilizing cyanide recovery techniques in their milling or heap-leaching plants, special precautions and monitoring procedures are employed to avoid contamination of the surrounding environment and to reduce the exposure of wildlife or humans to cyanide-laden process streams. In an emergency, chemical breakdown of cyanide can be induced quickly with chlorine gas.

Because of the danger of mercury pollution, the use of mercury amalgamation in domestic gold operations is now virtually nonexistent. The amalgamation process continues, however, to be used in an environmentally detrimental manner in some unregulated frontier mining operations in the Amazon Basin and in the Philippines. Mercury and arsenic can be natural contaminants of gold ores, requiring troublesome or costly extraction processes. Other potential pollutants that may be byproducts from gold mining include antimony, bismuth, tellurium, and thallium. Two iron sulfides, pyrite and pyrrhotite, commonly occur in gold deposits and can be a source of stream pollution as they oxidize to sul-

fates and other soluble compounds. Pollution resulting from some placer operations may be reduced or eliminated through the use of properly designed settling ponds. Waste dumps, mill tailings, and excavations are increasingly subject to public scrutiny, and control costs must be taken into account with other operating factors. Expanded mine safety requirements in recent years are another important cost factor.

Employment.—According to annual data prepared by the U.S. Department of Labor, employment in the Nation's gold mines and mills, exclusive of office employees, more than doubled from nearly 7,000 in 1985 to 15,000 in 1989. The number of jobs available in both surface and underground mines and associated processing plants is not always directly proportional to mine production, reflecting instead variations in development activity, the price of gold, weather, type of mining operation, etc. Citing employment studies for mining in Nevada and South Dakota, the Economics Institute of Boulder, CO.¹⁶ derived an employment multiplier of 19.4 that, when applied to each \$1 million of gold production, gave an estimate for total direct plus indirect employment attributable to gold production of about 51,000.

¹ Ounce refers to troy ounce. One kilogram of gold weighs 32.1507 troy ounces.

GRAPHITE

By Harold A. Taylor, Jr.

Physical scientist, Branch of Industrial Minerals. He has covered graphite for 10 years. Domestic survey data prepared by Joseph Daniels, mineral data assistant, Branch of Data Collection and Coordination. International data prepared by Audrey Wilkes, international data assistant, Geographic Data Section.

Amorphous graphite was mined domestically in 1989. Graphite supplies, particularly of fine crystalline flake, lagged behind industrial demand, which increased substantially from the previous year. Prices of the major imported graphites generally increased from those of 1988. Production of manufactured graphite and graphite fibers decreased slightly and increased by 21% respectively.

DOMESTIC DATA COVERAGE

Domestic production data for synthetic graphite are developed by the Bureau of Mines from a voluntary survey of domestic producers. Of the 33 operations polled, 100% responded. This represented 100% of the total production data shown in table 4.

LEGISLATION AND GOVERNMENT PROGRAMS

No acquisitions or disposal of graph-

ite from the strategic and critical materials stockpile occurred in 1989. However, new and smaller goals were authorized but not implemented, as follows: 12,882 metric tons for Madagascar crystalline flake and 1,751 tons for crystalline graphite other than Madagascar and Sri Lanka. The following amounts of graphite were authorized for disposal: up to 3,298 tons of Madagascar crystalline flake and up to 792 tons of crystalline graphite other than Madagascar and Sri Lanka.

PRODUCTION

United Minerals Co. operated its Townsend, MT, mine in 1989. Output of manufactured graphite decreased slightly to about 270,000 tons, at 30 plants, with a likelihood of some unreported production for in-house use. Production of all kinds of graphite fiber and cloth increased 21% to 2,915 tons. Union Carbide Corp. continued to operate its Puerto Rican graphite electrode plant in 1989, on an interim basis.

TABLE 2

U.S. GOVERNMENT STOCKPILE GOALS AND YEAREND STOCKS OF NATURAL GRAPHITE IN 1989, BY TYPE

(Metric tons)

Type	Goal	National stockpile inventory
Madagascar crystalline flake	18,144	16,171
Sri Lanka amorphous lump	5,715	4,934
Crystalline, other than Madagascar and Sri Lanka	2,540	1,754
Nonstockpile-grade, all types	—	846

Source: General Services Administration, Inventory of Stockpile Materials as of Dec. 31, 1989.

CONSUMPTION AND USES

Reported consumption of natural graphite increased 9% to about 37,400 tons. The three major uses of natural graphite were refractories, lubricants, and foundries, which together accounted for 59% of reported consumption.

Nonclay refractories represent two important use categories of graphite. Standard refractory products, particularly gunning and ramming mixes, accounted for a sizeable part of the demand in the past 5 years, mainly as amorphous graphite. Crucibles, shrouds, nozzles, stopper heads, and retorts, used in hot metal processing operations such as the continuous casting of steel, use significant amounts of crystalline flake. High-purity coarse flake graphite is preferred for crucibles and refractory associated items, but generally it is mixed with some fine crystalline material of lower value. The newest impor
