Minerals Yearbook
1965

Volume IV of Four Volumes

AREA REPORTS: INTERNATIONAL

Prepared by staff of the
BUREAU OF MINES

UNITED STATES DEPARTMENT OF THE INTERIOR • Stewart L. Udall, Secretary

BUREAU OF MINES • Walter R. Hibbard, Jr., Director

Created in 1849, the Department of the Interior—a Department of Conservation—is concerned with the management, conservation, and development of the Nation's water, fish, wildlife mineral, forest, and park and recreational resources. It also has major responsibilities for Indian and Territorial affairs.

As the Nation's principal conservation agency, the Department works to assure that nonrenewable resources are developed and used wisely, that park and recreational resources are conserved for the future, and that renewable resources make their full contribution to the progress, prosperity, and security of the United States—now and in the future.

Foreword

This issue marks the 100th year since the first publication by the Federal Government of a report on the U.S. mineral industries and the 84th year in which the Minerals Yearbook or its predecessors have been issued on an annual basis. The general content of the four-volume edition follows:

Volume I, Metals and Minerals (Except Fuels), contains chapters on metal and nonmetal mineral commodities except mineral fuels. In addition, it includes a chapter reviewing these mineral industries, a statistical summary and chapters on mining and metallurgical technology, employment and injuries, and technologic trends.

Volume II, Mineral Fuels, contains a chapter on each mineral fuel and on such related products as helium, carbon black, peat, coke and coal chemicals, and natural gas liquids. Also included are data on employment and injuries in the fuel industries and a mineral-fuels review summarizing recent economic and technologic developments.

Volume III, Area Reports: Domestic, contains chapters covering each of the 50 States, the U.S. island possessions in the Pacific Ocean, the Commonwealth of Puerto Rico, the U.S. island possessions in the Caribbean Sea, and the Canal Zone, Volume III also has a statistical summary chapter, identical with that in Volume I, and a chapter on employment and injuries.

Volume IV, Area Reports: International, contains 105 chapters presenting the latest available mineral statistics for more than 130 foreign countries and areas. A separate chapter reviews minerals in the world economy.

The 1965 Minerals Yearbook has been redesigned to achieve a more compact volume and to maximize economy and efficiency in its publication. We believe that the short lines of the text improve readability despite use of the smaller type.

The Bureau of Mines' continuous effort to enhance the Yearbook's value to its wide readership can be aided by constructive comments and suggestions of its users. Such comment is particularly invited during the formative years of the new International review volume.

WALTER R. HIBBARD, Jr., *Director*

Acknowledgments

The Bureau of Mines acknowledges the assistance in the preparation of this volume of many foreign mineral agencies and of the official publications on statistical data and other subjects issued in various countries. Many useful data were obtained from publications of the United Nations and from technical publications originating in the United States and many other countries. Information obtained from dispatches from the Embassies of the Department of State the world over is also acknowledged. Particularly useful were routine and special reports received from technical, mineral, and petroleum attachés who usually report on several countries in their respective areas. The attaché services comprise:

Burton E. Ashley, Attaché, Minerals Officer, Canberra, Australia.
W. Charles Bridgett, Attaché, Petroleum Officer, Caracas, Venezuela.
Bryan R. Frisbie, Attaché, Minerals Officer, Lima, Peru.
James G. Henderson, Attaché, Minerals Officer, La Paz, Bolivia.
William F. Keyes, Consul, Minerals Officer, Johannesburg, Republic of South Africa.
Edgar L. McGinnis, First Secretary, Petroleum Officer, London, United Kingdom.
Charles D. Mueller, Second Secretary, Consul, Minerals Officer, Mexico D. F., Mexico.
Roderick G. Murchison, Jr., Minerals Attaché, Accra, Ghana.
Martin Prochnik, Second Secretary, Minerals Officer, Santiago, Chile.
Alfred L. Ransome, Attaché, Minerals Officer, Rio de Janeiro, Brazil.
Charles W. Sweetwood, Attaché, Minerals Officer, New Delhi, India, beginning September 1965.
Clarence A. Wendel, Attaché, Minerals Officer, Ankara, Turkey.
Dawson S. Wilson, Second Secretary, Minerals Officer, Manila, Philippines.

In addition, attaché contributors to this volume included John Burgess, Jr., formerly at Lima, Peru, and Donald F. Campbell, formerly at La Paz, Bolivia. Bryan R. Frisbie, now at Lima, served as Attaché, New Delhi, India throughout most of 1965 and provided some reports on that country.

Basic data on production and trade of minerals commodities appearing in country chapters were in a number of cases supplied by the International Statistics Staff, supervised by Berenice B. Mitchell, and including Corra A. Barry, Agnes M. Chaney, Marjorie L. Cunningham, Bertha M. Duggan, Virginia G. Hugley, Liela S. Price, Joan F. Shaw, Pearl J. Thompson and Virginia A. Woodson.

The individual chapters of this volume were prepared by the staff of the Division of International Activities with contributions from various members of the Foreign Service. These chapters were coordinated and reviewed by Lester G. Morrell and Charles L. Kimbell. The correlation and final checking of the volume were performed in the Division of Minerals, and this assistance, patricularly that of Paul F. Yopes and Kathleen J. D'Amico, is gratefully acknowledged.

The regimes of some of the countries and areas reviewed in this volume are not recognized by the U.S. Government. The information contained herein is technical and statistical and is not to be construed as conflicting with or contradicting U.S. policies toward these countries.

VIRGIL L. BARR,
Chief, Division of International Activities.

Minerals in the World Economy

By Stephen C. Brown [1] and L. Nahai [2]

The major developments of the world's mineral economy in 1965 were the continued rise in production and consumption of practically all major minerals, the sharp increase in output of the fertilizer minerals in response to demands for greater food output, the cutback in new investment for steel capacity in Europe and Japan, Europe's continuing decline as a producer of primary minerals, and the emergence of nuclear power as an economically competitive factor in the energy economies of the United States and Western Europe.

In resource development, discovery of new natural gas deposits in the North Sea and the continued development of Australia's bauxite and iron ore resources, making this country a major source for these commodities, were significant.

In nonferrous metal prices, higher prevailing prices for lead favored marginal producers as in the Federal Republic of Germany, and zinc prices remained fairly stable at a level higher than that of 1964. Introduction of producers' price for zinc in July 1964 may have contributed to narrowing the range of movement in the London Metal Exchange (LME) price of this commodity. World market price of copper in 1965 increased from January to April, declined somewhat between April and midyear as major producers started marketing copper at LME prices, and then increased continuously after mid-year so that yearend prices surpassed those of April.

Substantial progress in the Kennedy Round of tariff negotiations was delayed by the French boycott of the Council Meetings of the European Economic Community (EEC). Following the boycott the organization could not negotiate as a unit, however bilateral negotiations were carried out on industrial commodities.

Continuing expansion of the world economy in 1964 and 1965 raised both production and consumption of practically all major minerals to new heights, but there was a distinct slowing of the rate of growth in 1965 as compared with 1964. In 1965, it was chiefly the sustained growth of the United States economy that maintained the expansive forces in the world economy, as growth rates in Western Europe and Japan lagged behind those prevailing in 1964. The effects of this 1965 decline in growth rates were felt in smaller rates of increase in mineral production, consumption, and trade.

Gross national product (GNP) of the United States, in real terms, increased by 5 percent in 1964 and by 5.5 percent in 1965. In the EEC the corresponding rates were 5.6 percent for 1964 and 4 percent for 1965. The slowdown in the economic growth of the European Free Trade Association (EFTA) dominated by the performance of the British economy, was more than that recorded for the EEC. Increase in production in the United Kingdom was marginal. In Scandinavia, only Norway maintained the economic vigor of 1964. In Japan, the economy was still undergoing a recession phase which, however, did not deteriorate, because of increase in public expenditures. Increase in output dropped from about 14 percent in 1964 to about 3 to 4 percent in 1965. Industrial investment remained low but private consumption increased a little. Indices of industrial pro-

duction in these countries showed parallel changes.[3]

Latin America as a whole had favorable economic development and increased exports; in a number of countries inflation was brought under control. Argentina, Mexico and Brazil had the highest rate of expansion with Bolivia, Chile, and Peru following closely. Nonetheless, the less developed countries though still benefiting from high demand for their exports and (in the case of most minerals) rising export prices, were facing possible restrictions on further growth induced by their increasing burden of debt and the possibility of reduced aid from the industrialized countries arising from the latter's balance of payments problems.[4]

Thus the pattern of development exhibited in the past 2 years showed both the industrialized countries of the free world and the developing primary producing countries recording high but declining rates of economic growth, the former at a rate of about 4.5 percent for the 2 years together and the latter at a slightly lower rate. Yet the pattern also showed evidence of some strains. Among the industrialized countries the major problem seemed to be the control of steadily rising inflationary pressures as rapidly growing output overtook supplies of both manpower and capital resources; one after another the industrialized countries (France and Italy in 1963, the United Kingdom and Japan in 1964, a number of the smaller European countries in 1964 and 1965) were forced to take restrictive measures to slow down economic activity and restrain rises in unit costs of production.

World trade continued to grow in value and volume, rising by about 12 percent in 1964 and 8 percent in 1965, with mineral commodities participating in the increase. The reduced 1965 growth rate in volume of trade compared with that of 1964 resulted from protective measures in a number of countries and efforts to correct balance of payments by direct controls. United Kingdom maintained its surcharge and Ireland put a 10 percent surcharge on most consumer imports. Business slowdown in West Europe also was a contributing factor. Price increases for the major nonferrous metals, continuously rising demand for petroleum in Western Europe and Japan, and the rapid shift of European steel mills to dependence on imported ores improved the economic position of the primary producing countries, and together with rising prices for some other primary commodities helped improve their balances of payments and increase their rate of economic growth. Prices of primary products on the average rose about 5 percent in 1964, and export receipts of primary producing countries rose by about 13 percent in that year; in 1965 primary commodity prices declined somewhat, due chiefly to falling prices for agricultural products, but mineral and metal prices with few exceptions remained at high (and in some cases, rising) levels. Petroleum, iron ore, and steel were the chief causes of weak mineral prices.[5]

PRODUCTION

The index of world industrial production (1958=100), a much more accurate guide to world demand for minerals than changes in gross national product, rose by 14.5 percent from 1963 to 1965; while the production index for the mining and extractive industries rose by 9.4 percent the same period. Mining output in the less industrialized countries rose at about twice the rate of increase in the industrialized countries. Similarly, output of the mineral processing industries rose sharply in the 2 years, but with evidence of a considerable slowing down of the rate of increase between 1964 and 1965.

Production of most metals increased in both 1964 and 1965. In 1965, iron ore output rose by 5.4 percent, pig iron output (including ferroalloys) by 6.3 percent, and

steel output by 5 percent over 1964 levels. Among the nonferrous metals, bauxite production increased by 9.9 percent and aluminum output by 10.3 percent; mine output of copper rose by 4.6 percent, of lead by 5 percent, and of zinc by 7 percent. Among the scarcer metals, tin production (content of ore) rose by 2 percent and silver output by 1.9 percent. Gold production continued its rising trend, increasing by 3.5 percent.

The most notable output increases in 1965 were recorded however by the fertilizer minerals. Potash production rose by 12.5 percent, phosphate rock production by 11.2 percent, and output of elemental sulfur by 9 percent. Of the other major nonmetallics, output of hydraulic cement rose by 4.5 percent.

Crude petroleum production in 1965 was 7 percent greater than in 1964 and natural gas production increased by 6.1 percent, while coal output increased by only 1.7 percent. The output of uranium (a metal, but economically significant as an emerging fuel mineral) declined for the fifth year in a row (by 21 percent), but technological breakthrough in the field of nuclear power and the placing of large orders for power reactors in the United States and Western Europe during 1965 suggested that this trend might be reversed in coming years.

The outlook for increased mineral production is favorable. Copper production capacity is expected to gain by 1.4 million tons per year by 1970 [6] and that for iron ore to increase to 722 million tons per year by 1975. Growth rates of 6 to 7 percent per year for phosphate rock and 5 to 7 percent for potash are predicted. Lead and zinc may have additional mine capacity of 586,000 tons and 849,000 tons per year respectively by 1970.

Significant changes in the geographic distribution of mineral production since 1963 were especially notable in the cases of crude petroleum, zinc, bauxite, lead and iron ore. In the case of crude petroleum, the share of the Western Hemisphere dropped from 48 percent of the 1963 total to 43.8 percent of that for 1965, and the non-Communist European share declined marginally, while the African share increased from 4.6 percent to 7.3 percent, and that for the Middle East and Asia increased marginally. Similar increases in the African share of total output of bauxite and iron ore were recorded, the former rising from 5.8 percent in 1963 to 6.5 percent in 1965,

[p] Preliminary. [r] Revised.
[1] Excludes production, if any, by Albania, Bulgaria, mainland China, Czechoslovakia, East Germany, Hungary, North Korea, Mongolia, Poland, Rumania, U.S.S.R., and North Viet-Nam.
[2] Excludes production by Argentina, Austria, Finland, United Kingdom, and Yugoslavia.
[3] Excludes production by United States; data withheld.
[4] Excludes production by Bulgaria.
[5] Excludes data on output, if any, by one or more countries that have not reported output and for which no reasonable basis for estimation exists; such countries however, are believed to have produced only relatively negligible quantities.
[6] Excludes production by Czechoslovakia, Hungary, Iran, Kenya, and Malaya.
[7] Excludes production by Argentina, Nigeria, North Korea, Rumania, South-West Africa, and Spain.
[8] Excludes U.S.S.R.
[9] Excludes production by Czechoslovakia and Rumania.
[10] Excludes production by Hungary and Rumania.
[11] Excludes production by mainland China and Rumania.
[12] Excludes production by Mexico and U.S.S.R.
[13] Excludes production by Brazil.
[14] Excludes production by East Germany, West Germany, Poland, and U.S.S.R.

and the latter rising from 4.1 percent to 6.4 percent. Africa also increased its share of mine copper output from 20.7 percent to 22.1 percent, of mine lead output from 7.4 percent to 8.3 percent, and of mine zinc output from 6.9 percent to 7.3 percent. The Western Hemisphere increased its share of iron ore, mine lead and mine zinc output, with its share of mine copper output rising marginally and of bauxite declining by a similar small margin. In general, the share of Europe in total primary mineral production declined. Oceania's share of total bauxite output rose sharply, from 1.2 percent in 1963 to 3.2 percent in 1965; its share of both mine lead and mine zinc output declined, however, the former from 16.4 percent to 13.4 percent and the latter from 9.9 percent to 8.1 percent. These shifts were all attributable to changes in Australian production.

In general, the relative shares of non-Communist world producers rose slightly during the period, while that of Communist nations of Europe and Asia declined slightly for most mineral commodities. Significant commodity exceptions to this pattern were gem and industrial diamond, mine and smelter lead, ingot aluminum, phosphate rock, pyrites and coal as shown in table 3.

Most of the changes in geographic distribution can be explained by relative rates of economic growth in the respective regions during the 2 years under review. High rates of growth in the United States and Canada stimulated output of most minerals in the Western Hemisphere, while slower growth rates in Europe (and during 1965, in Japan) tended to depress output elsewhere. The decline of mineral output in Western Europe and the contemporaneous rise in Africa's share, however, reflects more basic shifts in the resource positions of the two continents, resulting in growing European dependence on Africa's resources. Shifts in the relative positions of the other areas in general reflect this fundamental shift rather than declines in actual output.

Similar pressures for reliance on overseas ores and fuel products existed in Japan, but since a large part of its total requirements already were being met from Middle Eastern and Asian sources, this pressure is not reflected in statistics showing changes in a real distribution of production during 1963–65.

Details of production of major commodities by principal producing countries appear in tables 14 to 29.

Table 3.—Approximate percentage distribution of world mineral production by major areas in 1965 [1]

Mineral	Western Hemisphere			Eastern Hemisphere						World [2]

NA Not available, no estimates have been included in computing percentage distribution.

W Withheld to avoid disclosing individual company confidential data. Data however have been used in determining percentages in total column.

[1] Based on production data (including estimates) presented in world production tables in commodity chapters of Volumes I and II. In some cases, revised figures have been incorporated in individual country chapters of Volume IV, thus percentages given here will not necessarily agree with any totals of production based on data in individual country chapters. Regional divisions of totals conform to those used in the Table of Contents of Volume IV except as noted.

[2] Includes Communist countries of Europe and Asia as listed in footnotes 3 and 4 respectively as well as Cuba.

[3] Of the European countries listed in the Table of Contents of Volume IV, the following are included under the heading Communist Europe in this table: Albania, Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, Rumania and the U.S.S.R. Yugoslavia, although Communist, is included in non-Communist Europe for Statistical purposes.

[4] Of the Far Eastern countries listed in the Table of Contents of Volume IV, the following are included under the heading Communist Asia in this table: mainland China, Mongolia, North Korea, and North Viet-Nam.

[5] Distribution of output by non-Communist countries, Yugoslavia and Cuba only; no estimate of production for other Communist countries has been made.

[6] Less than 0.05 percent.

[7] U.S. data excluded.

CONSUMPTION AND TRADE

As in the case of production, consumption of most major minerals (except coal) rose significantly in 1965 but at a slower rate than in 1964. Statistical estimates exist for only a few minerals, however. Indicators of consumption changes for the ferrous group of minerals (iron and ferroalloy ores such as manganese, tungsten, vanadium, and molybdenum) are provided by pig iron and steel production data, which showed increases of 5.4 percent and 5 percent respectively. In the case of nonferrous metals, aluminum consumption continued to show the most rapid rate of increase (9.7 percent) in 1965, while copper consumption expanded by 1.5 percent, lead consumption by less than 1 percent and zinc consumption by 2.6 percent. Tin consumption declined by 1.2 percent. The higher levels of consumption for aluminum, copper, lead, and zinc were chiefly the result of large increases by U.S. consumers; demand in other industrialized areas generally declined. Tin consumption in 1965 declined in all industrialized areas except the United Kingdom. U.S. stockpile releases accounted for significant supplies of copper, lead, zinc, and tin coming on the market in both years. Among the nonmetals, consumption of sulfur, phosphates, and potash rose sharply in 1964 and 1965 as production of fertilizers and sulfuric acid reached new highs. Sulfur markets became especially tight as consumption expanded to the limits of output.

With increasing realization of the urgency of greater food production to meet increasing world needs, it is likely that the sharply rising consumption trend of these minerals will continue. One source gives a growth rate of 7 to 8 percent annually through 1980 [7] stating that if all announced projects go on stream as planned, worldwide capacity and demand by 1970 will be as follows:

Commodity	Million tons	
	Capacity	Demand
Nitrogenous fertilizers (nitrogen content)	34	31
Phosphate rock	80	72
Potassic fertilizers (K_2O equivalent)	21.1	19.7

Producers' stocks of lead declined by 45,000 tons in 1964 but rose by 12,000 tons in 1965, while a 1964 decline of 39,000 tons in producers' stocks of zinc was reversed to a gain of 23,000 tons in 1965.[8]

Estimates of overall stock changes of the nonferrous metals in 1965 show increases for copper, zinc, and tin and a decline of 4,000 tons for lead.

A perhaps significant trend in the world's mineral economy is the slow but steady growth of the developing countries' share of total world consumption of major mineral products. Data provided by UNCTAD (United Nations Conference on Trade and Development) commodity studies show, for example, that the developing countries' share of world pig iron output (a guide to iron ore consumption) rose from 3.6 percent in 1961 to 4 percent in 1965. Their share in consumption of primary aluminum rose from 3.5 percent in 1960 to 4.1 percent in 1964; of refined copper, from 4.4 per-

[4] As reported by International Tin Council.

Source: Yearbook of the American Bureau of Metal Statistics (Forty-fifth Annual Issue for the Year 1965). Data for aluminum, copper, lead and zinc converted from short tons.

cent in 1960 to 5.3 percent in 1965; of refined lead from 6.4 percent in 1960 to 8.6 percent in 1964; of slab zinc from 7 percent in 1960 to 8.4 percent in 1964; of tin, from 8.3 percent in 1953–1955 to 9.5 percent in 1965.[9] In the case of petroleum, the developing countries have maintained their share of consumption at about 14 percent of the total over the period since 1955. In the cases of most of these commodities it was rising consumption in India and a few of the Latin American countries that accounted for the increasing share of the developing countries.

The significance of this, in a period when total world consumption of most minerals has increased rapidly, should not be underestimated. Many of the developing countries are themselves major producers of the minerals they are now beginning to consume in significant quantities and it is logical to expect that the usual economies of locating mineral processing industries in rapidly growing markets for their products will result in the build-up of mineral processing industries in the developing countries, especially when many of them are also major producers of the mineral raw materials. Such a development might well have effects both on trade patterns and (depending on the location and elasticity of mineral supplies) on the terms of trade.

UN data show that world trade in minerals (mineral fuels, metallurgical ores, and scrap metals) expanded by about 6.5 percent in terms of value in 1963 and again by about 13.5 percent in 1964, the latest year for which this analysis is available. As a proportion of total world trade, the share of these commodities fell from 21 percent in 1962 to 20.3 percent in 1963, but increased again to 20.6 percent in 1964. The addition of trade in nonmetals would raise the total trade in minerals, and probably its proportion of total trade, by a significant amount.

In terms of volume only scanty data are available but UN figures indicate that crude petroleum and petroleum products alone accounted for 54 percent of total international seaborne commerce in 1964, while trade in iron ore acounted for another 13 percent of total world trade in that year.[10]

In 1963 and 1964 of the three industrialized areas North America, western Europe and Japan took an increasing proportion of the world's exports of the major minerals, the combined share of the three areas rising from 67.8 percent in 1962 to 68 percent in 1963 and 69.8 percent in 1964. The shares of western Europe and Japan in the total rose, the former taking nearly half (48.7 percent) of total mineral exports in 1964, and the latter 6.4 percent. The share of North America declined from 17 percent in 1962 to 16.6 percent in 1964. These shifts, as well as the rising proportion of the total going to the three areas, in large part reflect sharply rising European and Japanese imports of petroleum and iron ore from other regions.

Data exhibiting the patterns of international trade in individual mineral commodities confirm the growing importance of western Europe and Japan as importing areas and illustrate the effects of transport costs in determining the directions of trade. A third factor, the partial isolation of the United States markets for some minerals and maintenance of prices below world levels by means of quota restrictions and stockpile releases, is probably reflected also to some extent but its effect is not specifically distinguishable. Tables 30 to 45 show trade patterns for iron ore, steel products, bauxite, solid fuels, crude petroleum, and lead and zinc ores and concentrates, for the most recent years available.

INVESTMENT

Except for figures on iron and steel industry investment, data for 1965 investments in the mineral industries are not available on a worldwide basis. There was a sharp decline however in investments in the European and Japanese steel industries as compared with the period from 1960 to 1962.

Much of the recent European and Japanese investment in steel has been for purposes of rationalization and modernization rather than explicitly for new capacity. A large part has gone into conversion to oxygen processes; in 1964 and 1965 no less than 70 percent of steel mill investment in the European Coal and Steel Community was for this purpose.[11]

The shift to oxygen processes is proceeding rapidly in the world's steel industries. In 1965, over 19 percent of ECSC output was produced by these processes; in Japan 55 percent of 1965 production was accounted for by oxygen process plants, while the corresponding figures for the United Kingdom and United States were about 17 percent in each case.

A second area of investment has been in the expansion of iron ore sintering and pelletization plants. In 1964 about 45 percent of world output of iron ore was agglomerated mainly as sinter, while about 50 million tons was pelletized. Pelletizing capacity, mainly in North America, totaled 57 million tons at the end of 1965, with an additional 22 million tons of capacity under construction. The bulk of both sinter and pelletizing capacity is in the developed countries.

The trend towards beneficiation of ores, plus the opening up of large new deposits such as Australia's Hammersley mines, appears likely to keep total world investments in the iron and steel industry at a high level despite the current cutback (except in the United States) in steel industry expansion.

Finally, a trend in developed countries (particularly in Western Europe) towards the construction of new seacoast steel plants to benefit from the advantages of cheap access to high-grade overseas ores may well contribute a second stimulus to investment in the industry.

Data on investment in the nonferrous metal industries are fragmentary and do not permit construction of a worldwide statistical summary, but evidence from the aluminum, copper, lead and zinc industries suggests a rising level of investment expenditures.

Free world petroleum investments were maintained at a high level in 1963 and 1964; estimates for 1965 are not yet available. Chase Manhattan Bank estimates show total capital expenditures in 1963 of $11,150 million, practically unchanged from 1962; a 10 percent increase, to $12,275 million, is shown for 1964. The industry's capital expenditures were divided about equally between the United States and other free world countries in both years. In 1964, 45.3 percent of the total was invested in production, 15.6 percent in transportation facilities, 12.7 percent in refining, and 17.8 percent in marketing.[12]

United States Department of Commerce estimates of U.S. direct investments in the mining, smelting and petroleum industries outside the United States show a rising trend in the period 1962–1966. Perhaps most notable is the sharply rising trend of mining investments in Australia, attributable to U.S. interest in the development of recently discovered bauxite and iron ore deposits. Similarly, the rising trend of mining and petroleum investment in Africa

is noteworthy, while the expansion of petroleum investments in Europe (chiefly in refining and marketing) continued at a more normal rate.

Earnings on United States mineral investments abroad rose sharply in dollar terms from 1963 to 1965 in the case of mining and smelting industries, but were static in the petroleum industry. As a proportion of total capital invested, earnings in the mining and smelting industries rose from 10.6 percent in 1963 to 15 percent in 1965, while earnings of the petroleum industry declined slightly from 13.4 percent in 1963 to 13.3 percent in 1965.

TRANSPORTATION

Changes in transport facilities during 1964 and 1965 centered mainly around the continuing increase in total tonnage and average size of the world's bulk carrier and tanker fleets, and the expansion of pipeline facilities for petroleum and natural gas both in producing areas and in the main product markets (chiefly Europe). Concurrently plans were made in importing countries (again, chiefly in Europe) for deepening channels and harbors and improving cargo handling facilities to accommodate the newer and larger ships. Also in some European countries plans were made to enlarge shipbuilding yards to enable them to compete with Japanese yards, which hitherto have dominated the construction of very large vessels.

In the two years 1963–64 the deadweight tonnage of the world's bulk carrier fleet increased by 32 percent, from 19.9 million tons to 26.4 million tons. The increase in 1964 alone totaled 2.6 million tons, or 11 percent. At the end of 1964, bulk carriers accounted for 12.4 percent of the world's sea-going merchant fleet. In the first half of 1965 bulk carriers with an additional 1,850,700 deadweight tonnage were delivered and an additional 10.5 million deadweight tons of capacity were under construction or on order. The bulk of this new capacity was in vessels of 30,000 tons and over, and more than 40 percent of the total in vessels of 40,000 tons and over.

Tanker tonnage (deadweight) increased by 17 percent in the 2 years, rising to 81.7 million tons, or 40 percent of the world's merchant fleet, at the end of 1964. An additional 4.2 million tons were delivered in the first half of 1965, and a further 19.2 million tons were under construction or on order at mid-year. The average size of new tankers was rising even more rapidly than that of new bulk carriers; of those on order at mid-year 4.5 million tons were of 100,000 deadweight tons or over.[13]

The principal sea-borne mineral products, by volume, are petroleum and its products, and iron ore. In 1964, petroleum and petroleum products accounted for 800 million tons of cargo, and iron ore for 176.4 million tons, out of a total of 1,520 million tons. Other mineral cargoes important on a tonnage basis included other ores (mainly bauxite and alumina) and coal. The growth of sea-borne trade in iron ore has provided a special stimulus for the increase of the world's bulk carrier fleet.

Limitations on the increase in average size of vessels appear to be more restrictive in the case of bulk carriers than in that of tankers, since the former are restricted not only by harbor depths but also to a greater degree by the cargo-handling capacities of ports and terminals. These facilities are better developed for tankers because of the much larger volume of trade involved.

In the past, the maximum depth of the Suez Canal, the principal international waterway for oil traffic, limited the maximum size of tankers. Development of large producing areas west of Suez and routing of supertankers from the Persian Gulf area around Africa have lessened the influence of Suez on tanker size. Another factor is that there has been a substantial increase in the eastward flow of oil from the Persian Gulf; this does not involve international waterways.

Freight rates for dry cargo and tanker vessel moved in opposite directions in 1965 with dry cargo rates (both trip charter and time charter) moving upwards and tanker rates weakening. Tanker owners, a group of whom in 1963 devised a scheme to stabilize rates by laying up idle vessels, (which has become known as the Tanker Recovery Scheme), attempted to revive the

scheme in mid-1965 after it had been dormant since the end of 1964. It was apparently aimed chiefly at stabilizing rates during the summer seasonal slack in trade.

Under the scheme, any tanker of 15,000 deadweight tons and up, built in 1947 or later, is eligible to join; some 7 million tons were said to be eligible at the initiation of the scheme but only about half this tonnage was reported to have joined. Some observers believed that tanker owners relied chiefly on shifting idle vessels to the grain trade in the summer, in which nearly 5.8 million tons of tanker capacity was said to be engaged in August 1965.[14]

The expansion of petroleum and natural gas pipeline capacity continued in 1965, especially in Western Europe. In this area the rapid development of the Netherlands' domestic natural gas network, the commencement of work on gas export lines from the Netherlands to West Germany and Belgium, and expansion of the Mediterranean central Europe crude petroleum lines were the main factors. Work started on the Trans-Alpine pipeline from Trieste, Italy, to Ingolstadt, West Germany, while the line from Genoa to the Danube was completed except for a short section near Lake Constance. Product pipelines in western Europe also continued to multiply.

Meanwhile the Soviet Union continued work on the expansion of its COMECON system to provide petroleum to its East European neighbors. In the producing areas of the Middle East and Africa, additional pipelines for gathering and shipping crude to ports and refineries were planned or under construction.

PRICES

The United Nations export price indexes for minerals (1958=100) rose for the second year in a row, even the index for fuels showing a slight increase. The sharpest rise occurred in the index for metal ores, and within this group, for nonferrous metals.

Table 10.—Minerals export price indexes [1]
(1958=100)

Year	Metal ores	Fuels	Total
1963	96	91	92
1964	104	91	94
1965	110	92	96

[1] United Nations, Monthly Bulletin of Statistics, June 1966, Special Table C II.

As usual, the rise in export prices of all minerals taken as a group benefited the developed countries more than the underdeveloped areas, but the latter benefited significantly from the rise in export prices of nonferrous metals.

The chief features of the metals markets in 1965 were the fluctuations in nonferrous metal prices and the efforts of metal producers and governments of producing countries to manage the prices of these metals. These efforts were particularly notable in

[14] Petroleum Press Service, v. 32, No. 6, June 1965, pp. 219–221; v. 33, No. 4, April 1966, p. 147.

the case of copper, whose price on the free markets fluctuated sharply in response to political events and labor troubles affecting or threatening to affect the availability of supplies, but were also significant in the zinc markets.

Table 11.—Analysis of export price indices [1]

(1958=100)

Year	Developed areas		Underdeveloped areas	
	Minerals	Nonferrous metals	Minerals	Nonferrous metals
1963	99	106	90	116
1964	102	128	92	147
1965	105	143	93	176

[1] United Nations, Monthly Bulletin of Statistics, June 1966, Special Table C III.

The copper market provided an interesting example of the dual price system which had first been introduced by producers in the years of price weakness prior to 1963. During 1965, producers (who supply direct to consumers most of the metal coming on the markets) found it necessary to follow the upward movement of London Metal Exchange quotations for the marginal supplies required by consumers. However, producer prices lagged considerably behind the levels reached by the volatile LME market.

In the case of zinc, producers' price policies were necessarily different. Whereas strong demand and threats of supply interruption led to rising prices of copper on the free markets, with producers' quotations lagging behind, production increases and larger available supplies of zinc caused a downward tendency in zinc prices, and producers adopted a policy of support buying of the metal on the London Metal Exchange, without however attempting to peg prices at a fixed level.

Prices of most other nonferrous metals were firm in 1965. Lead prices showed a rising tendency in the first half but were stabilized at lower levels after U.S. stockpile releases early in the year. Aluminum prices (entirely on a producers' price basis) were relatively unchanged. Tin prices fluctuated within a narrower range than in 1964, but remained at high levels.

One significant fact that became clear during the years 1964 and 1965 was the extent to which the world's reserve stocks of major metals have been held (and of course, financed) by the United States Government through the operation of its stockpiles. In both years these stockpiles were drawn on to a considerable extent to alleviate actual supply shortages in, and to moderate price movements of, copper, lead, zinc and tin, as well as in the case of silver, where releases came from U.S. Treasury rather than stockpile sources.

POLICIES AND PROGRAMS AFFECTING MINERAL PRODUCTION AND TRADE

A Third International Tin Agreement, adopted at a United Nations Tin Conference in April 1965, was open for signature by adhering producer and consumer countries until December 31, 1965. Although Malaysia (the chief producer) at first refused to sign, which would have prevented the Agreement from coming into effect, its Government eventually signed at the last moment. Upon ratification by the required number of adherents the Agreement was to become effective as soon after June 30, 1966 as possible. Seven producing countries and 16 consuming countries signed the Third Agreement, including all members of the Second Agreement except India. The United States did not become a member.

The general provisions of the Third Agreement are similar to those of the Second Tin Agreement, which was to expire of its own terms on June 30, 1966. Although it, like the Second Agreement, provides for a buffer stock, the International Tin Council under the Third Agreement will (at least initially) hold no actual metal, the buffer stock having been exhausted long ago and tin prices in the past 2 years so high as to avoid the necessity of buying for the Council's buffer stock. The new Agreement has a duration of 5 years.

In both 1964 and 1965 the Tin Council consulted with the United States Government regarding the latter's tin stockpile disposal policies.

STATISTICAL SUMMARY OF WORLD PRODUCTION AND TRADE FOR MAJOR COMMODITIES

The 30 tables that follow extend statistical series started in the 1963 edition of this chapter. They are provided both as a supplement to the statistical data within the body of the chapter and as a summary of international production and trade data for major commodities covered in greater detail on a commodity basis in individual commodity chapters of volumes I and II of Minerals Yearbook and on a regional basis in individual country chapters of volume IV. For various reasons, data presented here may not correspond exactly to that presented in the individual country chapters of volume IV. In the case of production tables (tables 14 through 29), the foremost of these reasons is that they are shortened versions of world tables prepared for use in volume I commodity chapters. These source tables in most instances were prepared considerably earlier in the year than the individual country production tables, and as a result, may not include revisions based on later receipt of

data. In the case of the trade tables (tables 30 through 45), differences result primarily from the fact that most of these tables have been obtained from single sources which have already processed a wide variety of official and unofficial trade data to reach the listed aggregates, and in some cases, sources used have not been identical with those used in individual country chapters.

Nevertheless, differences in figures in most cases are small enough that for the purposes of the tables—to indicate relative importance of countries and/or regions—they can be regarded as unimportant.

Table 14.—Leading world producers of bauxite [1]

(Thousand metric tons)

Country	1961	1962	1963	1964	1965 [p]

World total [e]	45,480	[r] 48,280	[r] 51,210	[r] 59,050	65,670

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Includes output of all major crude mineral sources of phosphate, including apatite, guano, and similar materials. Data presented conform with that given in world production table in commodity chapter, volume I. In some cases, revised figures for individual countries have been incorporated in country chapters of volume IV.

[2] Includes a category of material described by the Russians as "sedimentary rock."

[3] Exports.

[4] Derived figure; difference between indicated world total and sum of output of individually listed producers.

Table 25.—Leading world producers of marketable potash [1]

(Thousand metric tons, K_2O equivalent)

Regional Mineral Industry Review of North America[1]

By Lester G. Morrell [2]

For the fifth consecutive year the trend of growth and expansion continued in virtually all major segments of North America's industrial economy. While growth rates of the minerals and mineral products segments in Canada and United States were slightly below overall industrial growth rates in both countries, overall output, as indicated by value of products, established new records. According to United Nations annual index [3] of industrial production, Canada's mining production rose from 144 in 1964 to 153 in 1965 (1958=100). The corresponding rise for the United States was from 116 to 120. The United Nations continental index for mining, manufacturing, electricity, and gas industries was estimated at 153 in 1965 compared with 141 in 1964, both on a 1958=100 base. As the world economy continued to expand, the growing demands of industrial nations for basic raw materials resulted in increased mine output of many mineral commodities and higher prices for several metals. Prices of nonmetals and fuels showed little change in 1965. According to U.S. Department of Labor indexes, wholesale prices in general were up about 2 percent in 1965.

Total gross national product (GNP) for the United States and Canada, in current dollars, was estimated at $729,300 million in 1965, nearly 8.5 percent above that of 1964. National income in the two countries amounted to $594,900 million in 1965, compared with $550,100 million in 1964. Combined total value of mineral products in the two countries amounted to $24,900 million in 1965, compared with $23,600 million in 1964; thus representing a rise of from 3.4 to 3.5 percent of GNP, and from 4.2 to 4.3 percent in output value. Although mineral fuels accounted for more than 60 percent of the North American mineral product value in both years, the greatest percentage gain in 1965 was in metallic materials which, reflecting larger quantities and higher prices, recorded an annual increase of 11 percent. The year's gains in value of nonmetallic minerals (including construction materials) and fuels amounted to 6.4 percent and 3.4 percent, respectively. Gains were recorded in the output of more than 40 of the principal mineral commodities produced in North America during 1965. Bismuth, mercury, molybdenum, tellurium, and pumice showed annual gains of over 25 percent. Cobalt, manganese ore, nickel, platinum-group metals, zinc ore, phosphate rock, potash, salt, sulfur, and vermiculite were up 10 to 25 percent.

United States or Canada led the world in production of more than 30 of the mineral and metal commodities listed in the U.S. Bureau of Mines World Mineral Production tables for 1965. More than half of the world output of magnesium, mica (including scrap), molybdenum, nickel, natural gas, phosphate rock, selenium, sulfur, tellurium, uranium oxide, and vanadium were produced in North America during the year.

The high level of industrial activity throughout 1965 in North America as a whole resulted in increased numbers of employees and lower rates of unemployment. Labor supply shortages, particularly in the

[1] North America, for this purpose, embraces the Dominion of Canada, the United States including Alaska and insular possessions, and the Danish Colony of Greenland. French islands off the east coast of Canada and United States Pacific possessions, including the State of Hawaii, are insignificant in the continental mineral industry.

skilled categories, were common in the mining and mineral processing industries of both countries. Shutdowns due to labor troubles were at a relatively low level. Mining industry wage rates were above industry-wide averages in both countries. Average weekly earnings of mine workers were up approximately 5 percent. Hourly earn-

ings during 1965 averaged $2.76 for a 44-hour workweek in the United States and Can$2.43 for a 41-hour workweek in Canada.

Dominated by demands of U.S. industries, consumption of mineral and metal raw materials in North America, remained at a high level through 1965. The trend of industrial consumption for selected mineral and metal commodities is tabulated in table 2. Although consumption of 23 of the 27 listed materials was at a higher quantitative level in 1965 than in 1964, the North American share of non-Communist world production rose in only 13 materials. Nevertheless, United States and Canada absorbed over half of the year's output of eight metals, in addition to sulfur and natural gas, and absorbed over one-fourth of all listed commodities except cement and anthracite coal.

Canada's abundant resources, administered under progressive government policies have long been looked upon as a favorable area for U.S. industrial investment. At the close of 1965 the value of U.S. direct investments in the Dominion of Canada totaled $15,200 million, nearly one-third of the total U.S. private investment in all foreign countries. U.S. investments in the minerals industries of Canada, including $221 million added during the year, amounted to $5,100 million. Approximately two-thirds of this amount represented holdings in the Canadian petroleum industry. U.S. capital was also prominent in iron ore mines, potash, asbestos, and base metals industries. According to Department of Commerce 1965 summaries, U.S. investments in Canada contributed $692 million to U.S. national income. Of this total, minerals accounted for $232 million, a net annual yield of 4.6 percent on the minerals industry investment.

According to United Nations estimates, North America's external trade in 1965, valued at $31,830 million, represented 18 percent of the world total. However, because Canada and the United States continued to be each other's largest sources of supply and markets, a large part of this trade remained on the continent. During 1965, over 20 percent of U.S. total exports and about 23 percent of total imports crossed the common boundary. Of Canada's total foreign trade, 57 percent of exports went to the United States while about 23 percent came from the United States. As a continental unit, and for both countries individually, the overseas trade of North America has traditionally been favorable. The $24,925 million value of merchandise exported from North American ports in 1965 exceeded imports by $6,062 million, about 32 percent.

As summarized in table 3, Canada supplied about one-fourth of U.S. imports of minerals, metals, and fuels in 1964 and 1965. The bulk of this value was in nonferrous metals, iron ore, and petroleum categories. Shipments from United States to Canada which made up slightly over half of that country's minerals, metals, and fuel imports in 1964 consisted largely of iron and steel semimanufactures and coal.

The Mineral Industry of Canada

By Lester G. Morrell [1]

In 1965, the value of Canada's mineral industry output rose an estimated US$323 million [2] to a total US$3,457 million. This represents an increase of 10.3 percent over the value of the previous year and marks the seventh successive annual increase. During the 1955–65 decade, the physical volume index of Canada's mineral production has more than doubled. Canada, in 1965, was the world's leading producer of nickel, zinc, and possibly asbestos. Canada ranked second after United States in uranium, and sulfur production; third in molybdenum, platinum and metallic aluminum output; fourth in lead production; and fifth in copper and iron ore output.

Again in 1965, metals accounted for more than half of the total value and showed the greatest—13.0 percent—annual gain. In general, quantities were higher, markets were firm to strong, and prices were above 1964 averages. Category percentages and total value of minerals produced in recent selected years were as follows:

Year	Share of total value (percent)			Total value (million U.S. dollars)
	Metals	Nonmetals	Mineral fuels	
1955	56.1	20.8	23.1	$1,660
1960	56.4	20.9	22.7	2,306
1961	53.7	21.0	25.3	2,388
1962	52.6	20.0	27.4	2,637
1963	49.5	20.7	29.8	2,822
1964	50.2	20.3	29.5	3,134
1965 p	51.5	19.6	28.9	3,457

p Preliminary.

Crude petroleum accounted for 19.2 percent, nickel 11.7 percent, iron ore 11.3 percent, and copper 10.4 percent of the total value of Canada's 1965 minerals output. In succeeding order were natural gas and gas byproducts totaling 7.8 percent, zinc 6.7 percent, cement 3.9 percent, asbestos 3.7 percent, gold 3.6 percent, and sand and gravel 3.5 percent. The combined value of the additional 53 mineral commodities that complete the list of Canadian mineral products accounted for the remaining 18.2 percent. According to preliminary estimates, annual gains in value were recorded for more than two-thirds of the individual commodities. Outstanding increases were in molybdenum production which more than tripled; potash output increased 75 percent, and lead production was 62 percent above the 1964 level. Eighteen minerals recorded a decline in value during 1965; however, the amounts were small in all except uranium oxide, nearly US$18 million, and gold, US$8 million below the values of the previous year.

The Provinces of Ontario, Alberta, and Quebec, with respectively 26.4 percent, 21.4 percent, and 18.8 percent of total output value, produced two-thirds of the nation's minerals. Saskatchewan accounted for 8.7 percent, British Columbia 7.5 percent, Newfoundland 5.9 percent, and Manitoba 4.9 percent. With the exception of the Yukon, which fell about US$1.7 million, all Provinces and Territories reported increased value of minerals output in 1965. Lead-zinc ores from the new mine at Pine Point on Great Slave Lake credited Northwest Territories with a fourfold increase (US$50.7 million). Expansion in the nick-

[1] North America-South Pacific specialist, Division of International Activities.

[2] Where necessary, values have been converted from Canadian dollars (Can$) to U.S. dollars at the rate of Can$1 equals US$0.925.

el-copper industries was primarily responsible for the US$78.3 million rise in value of Ontario's 1965 mineral output. Increased production of crude petroleum and natural gas contributed largely to the additional US$58.7 million recorded in Alberta. Production from new base metal mines in New Brunswick and potash operations in Saskatchewan resulted in gains of about US$32 million in each of those Provinces.

Preliminary estimates by the Dominion Bureau of Statistics place the 1965 national mineral production index at 347 compared with 327 and 294 in 1964 and 1963 respectively. (Base 1949=100). The estimated per capita value of minerals produced in 1965 was US$176.63, compared with US$162.87 in 1964. Value of mineral production was equal to 7.8 percent of the officially estimated US$48,096 million gross national product and 10.4 percent of the US$35,907 net national income (at factor cost). Salaries and wages paid to mineral industry workers totaled US$627 million in 1965, approximately 2.6 percent of the national payrolls.

General wholesale price indices for minerals and metal categories for 1965 and for 1964 (the latter in parentheses), compared with the 1935–39 base, were nonferrous metals—217.7 (205.9), iron products—264.4 (256.4), nonmetallic minerals—191.6 (190.9), and chemical products—200.0 (191.2). Average hourly pay of mining industry employees was equivalent to US$2.22 in December 1965, compared with $2.19 for the corresponding month of 1964. Profits, before taxes, reported by mining, quarrying, and petroleum producing companies were US$555 million in 1965 compared with US$559 million in 1964. All Canadian industries reported a total of US$4,810 million in 1965 compared with US$4,459 million in 1964. Investment activity in the minerals industry is indicated in a high level of prices for mineral and metal securities. Total construction and equipment expenditures by the mineral and primary metal industries in 1965 has been estimated at US$578 million.

More than a score of new mines were added to the long list of Canadian producers in 1965, and developments underway aim to bring twice that number on stream by 1970. Sixteen new mills started operation during the year. These developments are distributed across the length and breadth of Canada and their products include lead, zinc, copper, molybdenum, nickel, iron, gold and silver, asbestos, potash, sodium sulfate, and the oil sands of Alberta. The outstanding events of 1965 were the initiation of lead-zinc ore shipments from Pine Point in the Northwest Territories, the startup of two new molybdenum producers in British Columbia, and the passing of the million-ton production milestone for Saskatchewan potash. Despite cutback in uranium mining activities, one company has introduced underground bacterial leaching of uranium ore, another has announced plans to construct a new uranium refinery and has begun commercial production of yttrium oxide, a new product for Canada. Of the many new discoveries announced during 1965, those particularly noteworthy included the rushes to new lead-zinc prospects at Pine Point and Ross River in Northwest Territories and the Yukon. In the Maritime Provinces, lead-zinc-silver and copper discoveries respectively on Cape Breton Island and in the Gaspé Provincial Park, were announced, and sulfur was discovered in deep drilling near Truro, Nova Scotia. Drilling during 1965 at Rainbow Lake in northwestern Alberta has indicated what may prove to be Canada's most prolific oilfield. Construction of a 240-mile pipeline to serve the area was started late in the year.

Exploration activity continued at a rapid pace throughout Canada in 1965, with emphasis on the Precambrian shield area of eastern Canada, and the British Columbia-Yukon Cordillera. In the latter region, private industry's field force was estimated at more than 1,000 prospectors, engineers, and geologists maintained by 75 large companies and 250 smaller ones. During the year the Canadian Geological Survey employed a total of 112 field parties: 49 in Ontario and the eastern Provinces, 12 on the western plains, 38 in the Cordillera, 8 in the Arctic Islands, and 5 on general programs. Their scientific functions included reconnaissance, detail geological investigations, glacial and groundwater studies, and paleontological, geophysical, and geochemical projects. The mineral agencies of several Provincial Governments also conducted similar activities; Ontario Depart-

ment of Mines had 25 parties in the field. In addition, the Canadian Department of Mines and Technical Surveys, in cooperation with Provincial agencies, has continued aerial geophysical surveys on an intensified scale.

Federal budgetary expenditures by the Department of Mines and Technical Surveys amounted to US$61.1 million in 1965, compared with US$53.5 million in 1964. Recent emphasis has been on research in geophysical techniques, metallurgy, and rock mechanics. Payments under the Emergency Gold Mining Assistance Act went to 44 of Canada's 54 gold producers in 1965. Subvention payments to coal producers totaled US$20 million, in the 1964–65 fiscal year. The Prospectors' Assistance Program provides US$55,500 annually to prospectors in Yukon and Northwest Territories, and in 1965 Federal roads and aerodrome assistance programs were increased. A loan fund of Can$3 million was established by Department of Northern Affairs and Natural Resources to provide qualified applicants with up to 40 percent of the cost of exploration for petroleum and other minerals in the Territories.

Developments in Quebec dominated Canada's new minerals legislation in 1965. The Mining Act of 1909 has been modernized under Bill 8 (SQ 1965 Chap. 34) to increase the size of claim areas, the former concession system has been replaced by a leasing schedule, a Mining Court has been provided, and workers' safety provisions have been strengthened. Bill 9 provides for higher duties from mineral producers with credits for ore processing and exploration or development. Under Bill 10 Quebec Mining Exploration Company (SOQUEM) is chartered for 10 years to engage in mining exploration and development of mineral resources.

PRODUCTION

Canada's mineral production in 1965 included a total of 63 minerals; 26 metallics, 33 nonmetallic and construction materials, and 4 categories of mineral fuels. Quantitative increases were recorded in more than half of the products, and total value of minerals output in 1965, continuing the trend of recent years, increased 10 percent above that of 1964. Despite smaller quantities actually produced in 1965, several products, notably lithia, quartz, salt, and certain construction materials, returned a higher total value as a result of increased unit prices. The following tabulation omits a number of mineral items and classes that are not separately reported in Dominion Bureau of Statistics lists but are nevertheless regularly produced in Canada. Among these are abrasives, lightweight aggregates, carbon black, mineral pigments, roofing granules, and helium. Recovery of vanadium from imported crude petroleum was initiated, and tungsten mining was resumed in 1964 after a 5-year period of nonproduction.

TRADE

In 1965, Canada's exports of crude and fabricated minerals and metal products were valued at US$2,573 million, about 35 percent more than that of 1964. The minerals industry thus contributed nearly one-third of the total US$7,884 million value of Canadian merchandise exports. As in previous years, the bulk of exported minerals and products went to the United States. Relative percentages in 1965 were: United States—59, United Kingdom—19, European Common Market—8, Japan—4, and other countries—10 percent. Principal export items included: iron ore and concentrates valued at US$334 million, primary aluminum—US$312 million, crude petroleum—US$259 million, primary nickel—US$186 million, asbestos fiber—US$147 million, and refined copper—US$137 million.

Total value of Canadian imports in 1965 amounted to US$7,986 million, compared with US$7,490 million in 1964. The United States share of 1965 total imports approximates 70 percent, made up mostly of fully manufactured products.

[1] Antimony content of antimonial lead alloys, flue dust, and dore slag.
[2] Refined metal and bullion plus recoverable bismuth content of concentrates exported.
[3] Refined metal from domestic ores plus cadmium content of some exported ores and concentrates.
[4] All forms, excludes the cobalt in nickel sinter shipped to United Kingdom by International Nickel Co., but includes cobalt in Falconbridge nickel-copper matte to Norway.
[5] Refined nickel and nickel in produced oxide and recoverable nickel in matte exported.
[6] Cement shipped or used by producers.
[7] Value including bentonite and products from common, stoneware, fire clay, and other types of clay.
[8] Spodumene concentrates.
[9] Building, ornamental, paving and similar uses of granite, limestone, marble, slate, and sandstone.
[10] Includes sulfur from natural gas and from pyrite, pyrrhotite, and smelting of sulfide ores.

COMMODITY REVIEW

METALS

Aluminum.—Early in 1965 production of primary aluminum by Aluminum Company of Canada Ltd. (ALCAN) [3] was reduced from 94 to 89 percent of capacity to permit reduction of stock inventories and to provide for expansion of facilities at two of the company's plants. As a result, Canada's aluminum output in 1965 was slightly below the 1964 record. Shipments of pri-

[3] Parent company name changed early in 1966 from Aluminum Limited to Alcan Aluminium Limited (in French: Alcan Aluminium Limitée).

e Estimate. NA Not available.

mary refined metal to domestic consumer industries were also down, totaling 145,000 metric tons in 1965, compared with about 164,000 tons in 1964. Exports of aluminum ingots and other primary forms were nearly 13 percent higher in 1965 in response to heavy United States demand.

The six aluminum reduction plants, five operated by ALCAN and the sixth by Canadian British Aluminium Co. Ltd. (CBA), had a total capacity of 831,00 tons at the close of the year:

Company and location:	*Metric tons*
ALCAN:	
Arvida, Quebec	338,000
Beauharnois, Quebec	34,000
Shawinigan, Quebec	64,000
Alma (Isle Maligne), Quebec	104,000
Kitimat, British Columbia	193,000
CBA: Baie Comeau. Quebec	98,000
Total	831,000

Raw materials for the Canadian plants were supplied principally by Alcan Jamaica Ltd. which produced 751,000 tons of alumina and the Demerara Bauxite Co. Ltd., in British Guiana, which produced 284,000 tons of alumina in addition to 2,052,000 tons of crude bauxite in 1965. Both companies are wholly owned subsidiaries of ALCAN, and both supply to other than Canadian consumers. ALCAN fluorspar requirements are met by shipments—102,000 tons in 1965—from the subsidiary Newfoundland Fluorspar Ltd. at St. Lawrence, Newfoundland.

Renovations at the Arvida and Beauharnois smelters in Quebec are expected to be completed early in 1966. New facilities which will add about 22,000 tons to the annual ingot capacity at Kitimat, British Columbia, are scheduled to commence production during the second quarter of 1966. The ALCAN subsidiary alumina plant in Jamaica is being expanded, and by mid-1966 will have an annual capacity of about 830,000 tons of alumina; and in

British Guiana additional equipment to reinforce the mine operations of Demerara Bauxite Company Ltd. is being provided.

In research and development, a temporary setback resulted from failure of certain equipment in the new ALCAN monochloride process refinery. Production by the new process cannot be expected before 1967.

Copper.—The Canadian copper industry has enjoyed a good year owing to the worldwide shortage and resultant rising prices, in part brought about by political crises and strikes in producer countries. Both mine production and output of refined copper rose to record levels in 1965, 4 percent and 6 percent above 1964 levels, respectively.

The Department of Mines and Technical Surveys named more than 50 mine producers of copper in eight of Canada's Provinces and Territories in 1965. An additional score of prospective producers are expected to commence operations in the 1966–69 period. Among the year's newcomers were British Newfoundland Corp. Ltd., which began shipments from its 2,000 ton-per-day operation at Whalesback Pond, Newfoundland, the Lorraine Mining Co. Ltd. (400 tons per day) at Belleterre, Quebec, and Cupra Mines Ltd. (1,000 tons per day) at Stratford Place, Quebec. In Ontario, the McLennan, a new mine of the International Nickel Company of Canada Ltd. was opened at Sudbury, the Coppercorp mine near Batchawana began operations, and Metal Mines Ltd., nickel-copper mine at Gordon Lake began production. Rio Algom Mines Ltd. started its 900 ton-per-day mill near La Ronge, Saskatchewan late in the year. The Texas Gulf Sulphur Co. Inc. continued preparation of the big open pit mine project near Timmins, Ontario. According to a recent announcement, the planned capacity of the concentrator being built at Hoyle to process Texas Gulf Sulphur's ore is to be increased from 6,000 to 9,000 tons per day. This operation is expected to commence late in 1966. Although considered, no commitment was made by the company to provide a smelter; in the meantime, copper concentrates will be processed into anode copper by the Noranda Mines Ltd. smelter. Noranda is expanding the capacity of its wholly owned Canadian Copper Refiners Ltd. plant in Montreal, in anticipation of 100 million pounds additional copper annually from Texas Gulf Sulphur's production beginning in 1967.

On November 22, 1965, the Canadian Government applied export control on various forms of copper as a precautionary measure. Since that date, all offshore shipments to destinations other than United States have required export permits. The control applies to copper ores and concentrates, smelter and refinery shapes, and rolled and mill forms including wire mill products, copper base alloys, secondary copper ingot, and copper and copper base alloy scrap. Established exporters will receive quotas which are to be set on a quarterly basis beginning in January 1966.

Consumption of refined copper by manufacturers was estimated at 194,000 tons in 1965, compared with 183,300 tons in 1964. Usage of primary copper in semimanufactured products in 1962 and 1963 (most recent years for which details are available) were reported by Dominion Bureau of Statistics as follows, in metric tons:

	1962	*1963*
Copper mill products—sheet, strip, bars, rolls, pipe, tube, etc	41,783	47,956
Brass mill products—plate, sheet, strip, rods, bars, rolls, pipe, tube, etc	11,498	6,047
Wire and rod mill products	86,820	99,818
Miscellaneous	1,255	1,043
Total	141,356	154,864

Gold.—The downtrend in gold production continued in 1965, with the year's output about 5 percent below that of 1964. Of the 54 lode gold mines that contributed the great bulk of the Canadian production, 3 were new operations. Eight gold mines closed during the year, principally owing to exhaustion of reserves. Among the closures were the famous old Wright-Hargreaves Mines Ltd., and Lake Shore Mines Ltd., both at Kirkland Lake, Ontario, and both with records of over 40 years' uninterrupted operation.

Approximately 82 percent of the gold produced during 1965 was from lode mines, 17 percent from base metal ores, and the balance from placers. Mines in Ontario, including 29 lode gold producers (of which 5 shut down in 1965) accounted for about 1,926,000 troy ounces. The 14

lode gold mines (including 3 which closed during the year) and 20 base metal mines in Quebec are credited with approximately 923,000 ounces. Five lode mines in the Northwest Territories produced 437,000 ounces and about 300,000 ounces came from mines in British Columbia, Yukon, the Prairie Provinces, and the Maritimes.

Outlook for the Canadian gold mining industry is for continuing decline, as a result of ore exhaustion and general rising operation costs and labor shortages which are particularly acute in the gold camps. The Hollinger Consolidated Gold Mines Ltd., at Timmons, Ontario, one of Canada's oldest and historically largest lode gold mines, is expected to close in 1966, and several others are faced with ore exhaustion in the near future. Emergency Gold Mining Assistance payments went to all but 10 of the 54 producing mines in 1965.

The average price paid by the Royal Mint in 1965 was Can$37.73 (equivalent to US$34.90), down slightly from the Can$37.75 average in 1964.

Iron Ore, Pig Iron, and Steel.—Annual productive capacity of Canada's iron mines reportedly increased from 39.6 million metric tons in 1964 to 46.2 million tons in 1965; however, shipments during 1965 remained at about the same level as that of 1964. Mines in Quebec and Newfoundland, including Labrador, accounted for 71.5 percent of total Canadian shipments in 1965, compared with 73.5 percent in 1964. Ontario's mines accounted for 22.7 percent and British Columbia for 5.8 percent in 1965, compared with 21.2 percent and 5.3 percent, respectively, in 1964. Although 17 mining companies and 5 byproduct producers contributed to the year's output, 2 companies accounted for about two-thirds of the national total. Iron Ore Company of Canada (IOCO), the largest Canadian producer, shipped 7.2 million tons of direct shipping ore (54.2 percent Fe) from Shefferville and 7.1 million tons of concentrates and pellets (63–65 percent Fe) from the IOCO-Carol Pellet Co. operations at Labrador City. Quebec Cartier Mining Co. at Gagnon, Quebec, reported shipments of 8.3 million tons of high-grade (64.5 percent Fe) concentrates in 1965. Wabush Mines open pit mine and concentrator at Wabush Lake, Labrador, rated at 5.4 million tons per year, opened in June 1965. Concentrates are hauled by Quebec North Shore and Labrador Railway to the affiliate Arnaud Pellet Co. plant at Point Noire on the St. Lawrence River. Shipments of pelletized concentrates (65 percent Fe) from the Wabush-Arnaud operations totaled 1.9 million tons during the half year. In Ontario, the new Adams Mine and pellet plant, wholly owned by Jones & Laughlin Steel Corp., produced about 710,000 tons of pelletized concentrate (66 percent Fe) in the first full year's operation.

Continuing the trend of recent years, Canada's annual pellet production capacity rose to 14.6 million tons in 1965. Seven pelletizing plants are in operation, and the three plants currently under construction will provide an additional 2.6 million tons by 1969.

Exports of iron ore, including concentrates and pellets, totaling 31.3 million tons in 1965 went to the usual markets in United States, United Kingdom, Japan, and Western Europe. Shipments of Canadian ores to domestic consumers amounted to 4.2 million tons. The Canadian iron and steel industry also absorbed 4.8 million tons of imported ores, nearly all of which came from United States.

Pig iron capacity of the 15 blast furnaces and 10 electric furnaces in use during 1965 was rated at 7.15 million tons per year. Actual 1965 output represented about 92 percent of capacity. Steelmaking facilities as of December 31, 1965, were rated at 10.70 million tons, comprising 10.21 million tons for ingots and 0.49 million tons for steel castings.

The Department of Mines and Technical Surveys lists 23 iron and steel producers in 1965 with a total capacity of 6.7 million tons of pig iron and 9.7 million tons of steel. In addition, about 26 small companies that produce steel castings have a combined annual capacity of about 180,000 tons. Although the industry operated at about 94 percent capacity, domestic production of ingots and castings was approximately 700,000 tons short of the apparent domestic requirement.

Several major expansion and construction projects were initiated or announced during 1965. New electric furnaces were put in service at the Lake Ontario Steel Co. in Ontario, and Horton Steel Ltd., in British Columbia. Consolidated Mining & Smelting Co. of Canada Ltd., Kimberley, British Columbia, is installing a small bas-

ic oxygen unit that will commence production of steel in 1966 at an annual rate of about 73,000 tons. Dominion Foundries & Steel Ltd. at Hamilton, Ontario, is replacing its 90-ton basic oxygen furnace with one of 150-ton capacity.

New construction plans recently announced include complete steelworks in New Brunswick and Quebec. The Brunswick Mining & Smelting Corp. Ltd. project, based on the pyrite component of base metal ores is aimed at an annual capacity of 230,000 tons of rolled steel. The Quebec Government-sponsored Sidérurgie de Québec (Sidbec) steel plant at Bécancour, expected to cost $300 million, will include blast furnace, basic oxygen steel unit, and mills for rolled products. Its designed capacity is 600,000 to 1 million tons annually.

Lead and Zinc.—Both lead and zinc set new Canadian production records in 1965 with mine output 47 and 25 percent, respectively, above 1964 levels. On a mine basis, Canada strengthened its position as the world's leading producer of zinc and retained fourth place after Australia and United States in lead output. The 1964–65 list of lead and zinc mines by Department of Mines and Technical Surveys includes 28 companies, 19 of which produced substantial quantities of both metals. By areas, mines in Quebec accounted for 31 percent of the 1965 Canadian zinc output, followed by British Columbia—18 percent, New Brunswick—14 percent, and Northwest Territories—10 percent. British Columbia continued as the principal source of lead, producing 40 percent in 1965. However, reflecting output of the new mines at Pine Point and Bathurst, Northwest Territories and New Brunswick rose to second and third places, respectively, with 26 percent and 16 percent of total mine output of lead.

Shipments of lead-zinc ore during 1965 from the new mine of Consolidated Mining and Smelting Co. of Canada Ltd. (COMINCO)[4] at Pine Point, Northwest Territories totaled 330,214 tons to the company's concentrator at Kimberley and the smelter at Trail, and to the Bunker Hill Co. in Idaho. With the completion of the concentrator at Pine Point, concentrate shipments all of which went to Trail, started in December 1965. Pyramid Mining Co. Ltd. reported a new lead-zinc discovery adjacent to the COMINCO holdings in the Pine Point district.

In New Brunswick, operation of the No. 12 mine and 4,000 ton-per-day concentrator of Brunswick Mining & Smelting Corp. Ltd., near Bathurst, continued at capacity throughout 1965. Construction of the sec-

[4] On May 16, 1966, the name "Consolidated Mining and Smelting Company of Canada Limited" was officially changed to "Cominco Ltd." ("Cominco Ltée" in French.)

ond concentrator, which will treat zinc-lead-copper ore from the No. 6 open pit mine, is scheduled to start operation early in 1966. A subsidiary company, East Coast Smelting & Chemical Co. Ltd., which will include a lead-zinc blast furnace and by-product facilities is expected to commence in 1966. Its designed capacity is 27,000 tons of lead and 28,000 tons of zinc annually.

At yearend the Texas Gulf Sulphur Co., Inc., open pit mine at Kidd Creek, near Timmins, Ontario, was nearly ready for production to begin in 1966, and construction of the concentrator at Hoyle, for which design has been raised from 6,000 to 9,000 short tons ore input daily, was proceeding on schedule. The route of the 17-mile connecting railroad spur has been surveyed.

The COMINCO smelter at Trail, British Columbia, the only Canadian lead refiner, reported production of 169,175 metric tons of lead metal in 1965, 23 percent higher than that of 1964. The three zinc refineries, COMINCO, Flin Flon (Manitoba), and Valleyfield (Quebec), produced a total of 325,314 tons of slab zinc in 1965. During the year the annual capacity of the COMINCO zinc plant was raised to 210,000 tons, and Canadian Electrolytic Zinc Ltd. at Valleyfield was in process of expanding its 65,000 tons annual capacity by about 60 percent.

Molybdenum.—As anticipated, Canada became the world's third largest producer of molybdenum in 1965. Of the seven mines that contributed to the year's record production, two in Quebec and two in British Columbia commenced operation during the year. The 9,000 metric ton-per-day operation of Endako Mines Ltd., in north-central British Columbia, and the 900 ton-per-day plant of Noranda Mines Ltd., at Boss Mountain in the Cariboo district of the same Province, both of which started in May, were largely responsible for the increase. Preissac Molybdenite Mines Ltd. and Anglo American Molybdenite Mining Corp., near Cadillac in northwest Quebec, with mills rated 1,200 and 1,000 short tons per day, respectively, also started production about mid-1965.

Production by companies, in 1965, was as follows:

Company and location	Contained Mo (metric tons)
Molybdenite Corporation of Canada Ltd., Quebec	310
Gaspé Copper Mines Ltd., Quebec (byproduct)	224
Preissac Molybdenite Mines Ltd., Quebec	e 360
Anglo American Molybdenite Mining Corp., Quebec	e 140
Bethlehem Copper Corp. Ltd., British Columbia (byproduct)	e 10
Endako Mines Ltd., British Columbia	e 2,500
Boss Mtn. Noranda Mines Ltd., British Columbia	e 720
Total	e 4,264

e Estimate.

Properties in British Columbia being developed and expected to add to Canada's molybdenum production within the next few years include the Kennecott Copper Corp., subsidiary British Columbia Molybdenum Ltd., at Alice Arm, and Torwest Resources (1962) Ltd., near Rossland. Mills of 5,400 and 360 metric tons per day capacity, respectively, are planned for these properties.

The great bulk of Canada's molybdenum was exported in the form of concentrates. However, molybdic oxide, MoO_3 was produced by Molybdenite Corporation, Preissac Molybdenite Mines, and Endako. Masterloy Products Ltd., in Ottawa, produced calcium molybdate and ferromolybdenum.

Nickel.—Canadian production of nickel in 1965 attained a record 15 percent above the previous peak established in 1961. With use of nickel in coinage by more than 100 countries and growing consumption for metallurgical purposes, the world-wide demand has continued at a high rate through 1965. Canada's mine output comprised 60 percent of the world total in 1965; the Soviet Union contributing about 20 percent and New Caledonia about 12 percent.

The Canadian production was from 18 mines in 4 Provinces. The International Nickel Co. of Canada Ltd. (INCO), operated seven mines in the Sudbury district and metallurgical plants near Sudbury and

at Port Colborne, Ontario; and a mine, smelter, and refinery at Thompson, Manitoba. On December 31, 1965, proven ore reserves in Sudbury and Thompson mines were estimated at 278 million tons with a nickel-copper content of 8.4 million metric tons. During the year 18 million tons of ore were mined and deliveries of principal metallic products totaled 223,623 tons of nickel, 125,147 tons of copper, and 510,800 ounces of platinum-group metals. New mines under development by INCO include Totten (which started producing early in 1966), Copper Cliff North, Kirkwood, Coleman, and Little Stobie, all in the Sudbury district, Ontario, and Birchtree and Soab, near Thompson, Manitoba. The company's foreign activities include nickel deposits being prepared for early production in Australia and Guatemala and exploration in Africa, the United States, and certain South Pacific islands. The current $90 million expansion program for INCO operations will raise production capacity of the company's Canadian plants about 10 percent. A new 20,000 ton-per-day mill is to be built at the Frood-Strobie mine and in the smelter, roasting equipment will be modernized, a nickel oxide sinter facility added, and the oxygen plant will be enlarged. A new metallurgical research laboratory (Sheridan Park Ontario Research Community) will be opened in Toronto in 1966. In November 1965 the company agreed to take 70 million pounds of cathode nickel from U.S. Government surplus stocks over a 5-year period, with 28 million pounds to be delivered by June 1966.

Falconbridge Nickel Mines Ltd. operations near Sudbury included six mines (Falconbridge, East, Onaping, Hardy, Fecunis, and North), three mills, and a nickel-copper matte smelter. The matte is refined by Falconbridge Nikkelverk A/S, in Kristiansand, Norway. In 1965, the mills treated 2,126,430 metric tons of ore. The company reported delivery of 33,105 tons of nickel and 15,337 tons of copper. At yearend, proven ore reserves in the several Falconbridge mines were estimated at 50 million tons with a nickel-copper content of 1,054,000 tons. The new Strathcona mine and 5,400 ton-per-day mill in the Sudbury district is scheduled for production in 1967–68. A second blast furnace was blown in at the smelter in January 1966.

The Sherritt Gordon Mines Ltd. mine at Lynn Lake, Manitoba, and chemical refinery at Fort Saskatchewan, Alberta, reported production of 11,698 tons of nickel, 5,621 tons of copper, and 240 tons of cobalt in 1965. Ore mined during 1965 totaled 1,237,015 tons and recalculation of reserves at yearend showed 11.4 million tons averaging 0.84 percent nickel and 0.49 percent copper. The Fort Saskatchewan refinery reported no production from imported nickel matte during 1965. However, late in the year, 13 million pounds of nickel briquets were bought from the U.S. Government stockpiles for resale to regular customers.

Four small mines contributed to the Canadian nickel production during 1965. Lorraine Mining Co. Ltd. in Belletere area, Quebec, opened a 400 ton-per-day mill in March, with concentrates shipped to INCO's Copper Cliff smelter. Marbridge Mines Ltd., operating at about 350 tons per day, continued shipping concentrates to the Falconbridge smelter. Metal Mines Ltd., at Gordon Lake, Ontario, also continued its 700 ton-per-day operation and shipment of concentrates to Copper Cliff. For the year ending September 30, 1965, Giant Mascot Mines Ltd., near Hope, British Columbia, reported recovery of 1,784 tons of nickel and 932 tons of copper in concentrates (from 29,975 tons of ore treated) for shipment to Japan.

Platinum-Group Metals.—Canada ranked third after the U.S.S.R. and Republic of South Africa in production of platinum-group metals. Reflecting a substantial increase in output of nickel-copper ores with which they are coproduced, and a rise in prices for the individual metals, the value of Canadian production of platinum-group metals in 1965, estimated at US$33 million, was 40 percent higher than that of 1964. While virtually all of the nickel-copper ores mined in Canada are known to contain platinum metals, details by producers are not disclosed. Platiniferous sludges produced in the INCO nickel refineries are exported to the company's precious metals refinery in Acton, England. Falconbridge platinum is contained in nickel-copper matte shipped to Norway. Accordingly, Dominion Bureau of Statistics reported total exports of 492,501 troy ounces of platinum-group metals in concentrates, residues, and matte in 1965; of which 471,238 ounces went to the United Kingdom, 16,823

ounces to Norway, and 4,440 ounces to the United States. Return of refined platinum-group metals to Canada in 1965 is indicated in officially reported imports of 229,029 ounces from United Kingdom and 4,574 ounces from United States.

Silver.—The 7-percent increase in Canadian silver production in 1965 reflected higher output from base metal mines as well as a firm demand and sustained high price. According to 1964 lists, 36 companies, many of which operate several mines, account for the national output. Over 80 percent of the total is derived from ores mined primarily for lead, zinc, and copper. Accordingly, the COMINCO smelter at Trail, British Columbia, recovered and refined 6,415,230 ounces in 1965 (compared with 7,347,590 ounces in 1964) from ores and concentrates mined in western Canada. Nearly half of this was from COMINCO mines. The Noranda copper smelter and its affiliate, Canadian Copper Refiners Ltd., in Quebec, reported recovery of 7,669,340 ounces and 9,647,000 ounces, respectively, in 1965. INCO copper-nickel plants at Copper Cliff, Ontario, recovered 1,581,000 ounces in 1965.

United Keno Hill Mines Ltd., in Yukon Territory, and the COMINCO Sullivan mine at Kimberley, British Columbia, have for many years been the leading Canadian silver producers. On an area basis, however, Ontario, which accounted for 34 percent or over 11 million ounces, was again Canada's largest source of silver. In succeeding order, Quebec contributed 16 percent, British Columbia and Yukon each about 14 percent, New Brunswick 9 percent, and Northwest Territories 4 percent. The year's greatest regional increase resulted from shipments of argentiferous lead and zinc ores and concentrates from the new COMINCO mine at Pine Point, Northwest Territories. The first full year's operation by Brunswick Mining & Smelting Corp. Ltd. was instrumental in virtually doubling New Brunswick silver output.

The five industry-owned silver refineries and the Royal Canadian Mint produced 11,268,110 ounces of silver bullion in 1965, compared with 10,583,439 ounces in 1964. During 1964, domestic consumers absorbed 18.8 million ounces of silver; 13.7 million for coinage, 3.1 million in manufacture of silverware and photographic materials, and 2.0 million for electroplating and other purposes. Exports of silver, most of which went to the United States, totaled 23.5 million ounces in 1965. Canadian imports in 1965 (13,413,000 ounces) were approximately double the annual average of the 2 preceding years.

Thorium and Yttrium.—The uranium ores of the Elliot Lake and Bancroft regions of Ontario have long been known to contain appreciable amounts of thorium and other rare earth oxides. Elliot Lake ores average about 0.05 percent and Bancroft ores 0.02 to 0.2 percent thorium dioxide (ThO_2). Total reserves of the two regions are estimated at 74,000 metric tons of thorium. Rio Tinto Dow Ltd. recovered thorium at the Quirke mine from 1959 until its closure in 1961. Since 1961 thorium recovery has been in a new unit at the Nordic mine. Concentrates from these plants have been refined by Dominion Magnesium Ltd., at Haley, Ontario, and the products exported principally to the United States. Although Canadian production data are not published, United States imports in 1964 and 1965 from Canada included respectively 2,900 pounds and 5,000 pounds of thorium metal.

Recovery of yttrium concentrates from uranium ores was initiated by Stanrock Uranium Mines Ltd. at Elliot Lake late in 1965. Commercial shipments were made during the first months of 1966, but quantities have not been reported.

Uranium.—Continuing the downtrend that has been continuous since 1959 when 21 mines shipped over 14,400 metric tons of uranium oxide (U_3O_8), only 4 companies operated through 1965, and the year's output fell below 4,000 tons.

To maintain production capability in the uranium mines and plants, the Canadian Government in June 1965 announced a new purchase program that will permit the established companies to produce a total of about 4,000 tons annually for the next 5 years. At the same time the Government announced that export permits would be issued only on the basis of agreements with importing countries to the effect that the uranium would be used solely for peaceful purposes.

Three mines in the Elliot Lake area, Ontario, produced a total of about 3,000 tons of U_3O_8 in 1965. Denison Mines Ltd. and the Nordic mine of Rio Algom Mines Ltd. accounted for the bulk of Elliot Lake pro-

duction. Stanrock Uranium Mines Ltd. employed underground bacterial leaching to recover 5 to 7 tons U_3O_8 per month. Eldorado Mining and Refining Ltd. in the Beaverlodge area, Saskatchewan, shipped about 900 tons of U_3O_8 in 1965. This company's operation is geared to contractual commitments that extend through 1966.

Despite the current slump in uranium mining, Rio Algom Mines Ltd. early in 1966 announced plans to build a 150 ton-per-day uranium refinery at its Nordic mine, near Elliot Lake. Of interest in the field of nuclear energy, Canadian Deuterium of Canada Ltd. is constructing a heavy waterplant at Glace Bay, and Canadian General Electric Co. Ltd. has announced plans to build a similar plant on the Strait of Canso, both in Nova Scotia. Heavy water is used as a moderator in reactors employing natural uranium fuel.

NONMETALS

Asbestos.—During 1965 a total of 16 asbestos mines, 1 each in Newfoundland, Ontario, and British Columbia and 13 in Quebec, were operated. The year's production was slightly below the record output of 1964, but well above that of any previous year. Department of Mines and Technical Surveys analysts estimate Soviet production in 1965 may have surpassed Canada's longstanding position as the world's leading source of asbestos.[5]

Although Canadian asbestos producers are confronted with growing competition from foreign producers, new properties under development are expected to raise Canadian production within the next few years. At Asbestos Hill in northern Ungava, Quebec, Asbestos Corp. Ltd. is developing a 20-million-ton deposit that is scheduled for 90,000 ton-per-year production beginning in 1970. At Lake Roberge, near Chibougamau, Quebec, a deposit containing more than 150 million tons with a fiber content averaging 4 percent has been outlined by McAdam Mining Corp. Ltd. Canadian Johns-Manville Co. Ltd. is developing a prospect for underground mining operation in Reeves Township, 43 miles southwest of Timmins, Ontario. A test mill was provided at this prospect in 1965. In the Yukon Territory, Cassiar Asbestos Corp. Ltd., is expected to begin production at 36,000 tons per year at Clinton Creek, 40 miles northwest of Dawson, and to double this output by 1970. Ore reserves are estimated at 13 million tons with a fiber content in the 6 to 7 percent range.

Potash.—During 1965 three companies, with a combined refining capacity of 3 million tons of KCl product, contributed to the national output which was 67 percent above that of 1964. The year's achievements constitute a firm start in the long-range plan that is expected to increase annual Canadian production to 12 million tons of crude product (equivalent to 7.5 million tons K_2O) before 1970.

In 1965, International Minerals & Chemical Corp. (Canada) Ltd. (IMC) raised the capacity of its Yarbo plant, near Esterhazy, Saskatchewan, to 2 million tons of product per year, making it the world's largest. The second IMC project, at Gerald, about 6 miles southwest of Yarbo, scheduled for completion in 1967, will start at 1.5 million and later expand to 2.5 million tons per year. Potash Company of America, after a 6-year suspension during which shaft difficulties were overcome and the refinery redesigned, resumed production in 1965 at full 600,000-short-ton annual capacity. The world's first solution-mining of potash, undertaken by Kalium Chemicals Ltd., at Belle Plain, 25 miles west of Regina, was initiated in 1964 and reportedly operated satisfactorily throughout 1965. Plant capacity is estimated at 600,000 tons per year.

In addition to the present producers, four companies were actively developing and several others were being planned. The developers, all in south-central Saskatchewan, include Alwinsal Potash Co. of Canada Ltd. at Lanigan, designed for 1 million tons of product per year; U.S. Borax & Chemical Corp. at Allan, 1.5 million tons per year; and Consolidated Mining & Smelting Co. of Canada Ltd. at Colonsay, 1.2 million tons yearly.

Exports of Canadian potash are not separately disclosed; however, according to United States records, the great bulk of Canadian shipments are to the United States. In past years small shipments have also gone to Japan and other countries

[5] An official of Canadian Johns-Manville Co. Ltd. who supervised installation of US$7.8 million Canadian-made asbestos equipment in U.S.S.R. and toured Soviet mines in 1964 reported Soviet asbestos production capacity at 1.43 million metric tons annually.

Canadian consumption of potash in 1964 amounted to 163,524 metric tons.

Sulfur.—Spurred by a strong worldwide demand and a substantial price increase in 1965, Canadian production of sulfur, all forms, was 8 percent above the previous record established in 1964. In 1965, Canada probably displaced Mexico as the free world's second largest source of sulfur. The great bulk of 1,730,648 metric tons of elemental sulfur sold in 1965 was extracted from sour natural gas produced in Alberta. In addition, the 1965 total included 465,494 tons contained in liquid sulfur dioxide and sulfuric acid derived from smelting metal sulfide ores and about 160,000 tons in shipments of pyrite and pyrrhotite.

During 1965, 17 companies operated 23 sulfur recovery plants with a total rated capacity of 2.5 million tons of elemental sulfur yearly. With the exception of five plants—three in Ontario and one each in Saskatchewan and British Columbia—representing a combined capacity of 178,000 tons per year, all natural gas sulfur was recovered by facilities in Alberta. The Claus process, or modifications thereof, is employed in all 23 plants.

Two new plants, both in Alberta, started during the year; these were the 120,000 ton-per-year plant of Socony Mobil Oil Co. of Canada Ltd., at Wimborne, and the 64,000 ton-per-year plant of Hudson's Bay Oil and Gas Co. Ltd. at Edson. Several existing plants increased capacity. Construction of the Canadian Oil Sands Ltd. oil refinery, close to the border of Northwest Territories, continued through 1965. When completed in 1967, this plant is expected to recover about 110,000 tons of sulfur annually from bituminous tar sands.

Early in 1966, announcement of a discovery of native sulfur in a dome-like structure near Truro, Nova Scotia, resulted in a rush to acquire land rights. The sulfur occurs in anhydrite at a depth of about 400 feet and was found in exploratory drilling for gypsum conducted by the Nova Scotia Department of Mines.

Canadian consumption of sulfur in 1965, including that converted directly to sulfuric acid, was estimated[6] at 1,025,000 tons compared with 950,000 tons in 1964. Most of the elemental sulfur produced in 1965 was exported to the United States, Australia, Japan, Hungary, Poland, U.S.S.R., Republic of South Africa, and other overseas countries.

MINERAL FUELS

Total Energy.—Use of energy, estimated at a total of 53.3 billion therms[7] in 1964, represents an increase of 8 percent over that of 1963 and a virtual doubling of energy usage in the 1954–64 decade. Throughout the 10-year period the share of solid fuels has fallen from 35 to less than 13 percent of the total, and hydroelectric power from 10 percent to about 7 percent. Energy derived from natural gas has risen from 6.5 percent to 27.7 percent. Despite the virtual doubling in quantity, petroleum's role in the total energy picture since 1954 has remained relatively constant at a little over half the total. Summary details for the 1962–64 years, compared with those of 1954, as developed by the Dominion Coal Board are given in the following tabulation:

[6] Gittinger, L. B., Jr. Sulfur. Eng. and Min. J., February 1966, pp. 146–147.

[7] One therm is equivalent to 100,000 B.t.u.

Source	1954	1962	1963	1964

[1] Includes coal coke and briquets.

Coal.—Although production of bituminous coal from mines in the Maritime Provinces, British Columbia, and Yukon declined during 1965, the 408,000-ton higher output from Alberta's subbituminous mines resulted in a national increase of about 2 percent over that of 1964. Production of lignite, all of which is mined in Saskatchewan, also recorded a small increase in 1965. The national coal balance, in million short tons, has been summarized for recent years as follows:

Year	Production	Imports		Total available	Consumption	Exports
		Anthracite	Bituminous			
1961	10.4	1.0	11.1	22.5	21.5	0.9
1962	10.3	.9	11.5	22.7	22.2	.9

1965	11.6	.6	15.6	27.8	26.6	1.2

Source: Dominion Coal Board and Dominion Bureau of Statistics.

Principal statistics for the Canadian coal mining industry in 1964 as summarized by Industry Division, Dominion Bureau of Statistics[8] (corresponding data for 1963 in parentheses), were as follows: number of mines, 94 (97); average number of employees, 9,087 (8,903); value of production, f.o.b. mines US$67.8 million (US$66.4 million); average production per man-day, total 4.90 (4.28) metric tons, from strip mines, 16.81 (14.81), from underground mines 2.97 (2.98).

During the 1964–65 fiscal year (April 1 to March 31), Dominion Coal Board reported subvention payments totaling US$19.98 million on transportation of 4,406,584 metric tons of coal. As in previous years, the major portion of these payments were on Nova Scotia shipments to Quebec and Ontario. Payments amounted to US$2.7 million on 928,627 tons of British Columbia and Alberta coals for export (to Japan) and ships' stores. Other assistance to the Canadian coal industry during fiscal 1964–65 included $197,000 on 389,948 tons converted to coke for use in production of iron and steel, under the Coal Equity Act; and $2.1 million paid under The Atlantic Provinces Power Development Act to the Power Commissions of Nova Scotia and New Brunswick.

Domestic consumption of coal as estimated by the Dominion Coal Board[9] for recent fiscal periods was distributed as follows:

Consumer	1961–62	1962–63	1963–64	1964–65
Total consumption—thousand metric tons	r 20,750	r 21,564	r 21,988	24,265

r Revised.

Coal consumption in recent years has shown several changing trends. Total consumption, reflecting inroads of gas and petroleum, fell from 40 million tons in 1950 to a low of about 20 million tons in 1961. Since 1961, Government subsidies, research programs, and construction of several electric facilities based on domestic coal have been instrumental in reversing the overall decline. Domestic and household usage, which in 1954 accounted for 27 percent of the national total consumption, took only about 12.4 percent in 1965, and consumption by railroads over the same period fell from 19 percent to less than 1 percent.

Coal technological and market research during 1965 has been intensive. The Cana-

[9] Dominion Coal Board. Seventeenth Annual Report 1964–65. Ottawa, 1966, p. 30.

dian Advisory Committee on Coal Research, comprised of representatives from Mines Branch, Geological Survey of Canada, Dominion Coal Board, and Provincial research groups, conducted geological investigations in Alberta, rock mechanics studies in Nova Scotia mines, and coal cleaning and combustion research in various laboratories. Several iron and steel producers combined to form the Canadian Carbonization Research Association to study coking processes in cooperation with Department of Mines and Technical Surveys. Briquetting of coals is being studied at the University of British Columbia. The New Brunswick Government, along with the Dominion Coal Board, has undertaken an economic and sociological evaluation of the Minto Coalfield.

Transportation facilities for coal from Sydney, Nova Scotia, via the St. Lawrence River and Seaway to Ontario Hydro Commission powerplants are to be expanded with the addition of a second self-unloading ore carrier. It is expected to start operation early in 1966 and will supplement the SS *Cape Breton Miner* which completed its first full year of service.

Petroleum and Natural Gas[10].—In 1965, production of liquid hydrocarbons averaged 935,890 barrels[11] per day, an increase of 9 percent over the 1964 average rate. Of this total, daily output of crude petroleum and condensates accounted for 813,698 barrels, and natural gas liquids—propane, butane, and pentanes plus—for about 122,000 barrels per day. Natural gas production at a daily rate of 3,952 million cubic feet increased 5.9 percent over the 1964 level.

Approximately two-thirds of the 1965 crude oil output went to 41 Canadian refineries that operated during the year and one-third was exported, all to the United States. Crude oil imports, mostly from Venezuela and Near East countries, for the year amounting to about 395,000 barrels per day, were required to meet national requirements totaling 966,000 barrels per day. Supply of crude oil and equivalent to the petroleum refineries was substantially in excess of their rated total capacity of 1.1 million barrels per day.

Disposition of marketable natural gas averaged 2,963 million cubic feet per day during 1965. About 53 percent of this was absorbed in domestic sales, 37.4 percent was exported to western United States markets, and 9.6 percent went to distributor storage and other purposes. With the addition of 15 new plants in 1965, at yearend, Canadian gas processing facilities included 100 plants having a total capacity of 5,900 million cubic feet per day.

Regional distribution and capacities of operating oil refineries and processing plants as of December 31, 1966, is summarized in the following tabulation:

Province	Oil refineries		Gas processing plants	
	Number	Capacity (thousand 42-gallon barrels per day)	Number	Capacity (million cubic feet per day)
Alberta	7	93,300	85	5,141.2
British Columbia	6	101,170	5	624.0
Manitoba	3	41,100	---	---
New Brunswick	2	45,300	---	---
Nova Scotia	2	72,000	---	---
Ontario	7	320,400	3	6.5
Quebec	6	351,200	---	---
Saskatchewan	6	69,300	7	138.0
Others	2	10,100	---	---
Total	41	1,103,870	100	5,909.7

Extensions and new discoveries during the year resulted in upward revision of reserve estimates, bringing totals for liquid hydrocarbons to 7,710 million barrels and gas to 44,372 billion cubic feet. Drilling activity in 1965 exceeded that of any earlier year. A total of 16,380,477 feet was drilled in 3,772 completed wells, of which approxi-

[11] The Canadian unit barrel containing 35 imperial gallons is approximately equivalent to the U.S. barrel of 42 U.S. gallons.

mately 5.2 million feet in 1,140 wells was classified as wildcat. By Provinces, 62 percent of the total footage was drilled in Alberta, 27 percent in Saskatchewan, 6 percent in British Columbia, and the balance in Ontario, Manitoba, and the Northwest Territories. During the peak months of survey activity, 75 seismic, 4 gravity, and 13 surface crews were in the field in western Canada.

The bright prospects of the Rainbow Lake field in northwestern Alberta, extending into British Columbia, continued to dominate the Canadian petroleum and gas scene. Since mid-1964 the 10 oil pools and 12 gas pools that have been indicated in this area by seismic work and drilling are looked upon as Canada's major petroleum discovery in recent years. Banff Oil Ltd. and its partners, Aquitaine Co. of Canada Ltd. and Mobil Oil Corp., are the principal operating companies in the area. Rainbow Pipeline Co. Ltd., late in 1965, started laying a 20-inch pipeline 240 miles from Utikuma Lake to connect the Rainbow field with existing lines to Edmonton. The Mitsue field at the southeast end of Lesser Slave Lake had a full year of production, and about 125 wells were completed in 1965. Some 40 miles to the northwest of Mitsue, the new Nipisi field at Utikuma Lake was discovered almost simultaneously by three companies in January. Two competitive pipelines were laid and 30 wells completed by yearend.

A total of about 2,500 miles of new oil and gas pipelines was laid in 1965; the largest single project was the 173-mile, 30-inch oil line link from Carstairs, near Calgary, to the Edson field, 120 miles west of Edmonton.

Helium.—In keeping with Canadian Government policy, production of helium by the single Canadian producer, Canadian Helium Ltd. near Swift Current, Saskatchewan, has not been disclosed. The company recently announced plans to triple plant production capacity by January 1967, to 36-million cubic feet per year. In April 1966, International Helium Ltd. announced its intention to start immediately on design and construction of Canada's second helium recovery plant. An official of International Cryogenics Inc., Hermosa Beach, California, has been retained as consultant-in-charge of design and engineering. The new plant will be in Saskatchewan and will have an annual capacity of 40-million cubic feet.

The Mineral Industry of Greenland

By Lester G. Morrell [1]

During 1965, mining activities in Greenland were limited to extraction of a small quantity of coal and unreported quantities of construction materials for local use. An official of the Greenland Technical Organization reported that the sharp drop in coal output in 1964 and 1965 has been due to lack of stability in the local labor force. Exports of cryolite continued through 1965 from stockpiles accumulated prior to 1963 when the Øresund Cryolite Co., Inc., operation was suspended. On December 31, 1965, remaining stocks of cryolite were calculated at 500,000 to 600,000 metric tons. The lead-zinc orebody mined by Nordic Mining Co., Inc., at Mesters Vig on Kong Oscars, Fjord, was worked out in 1962, and no export shipments of concentrates have been made since that year.

A Danish company, O. Fink-Jensen, recently announced plans to resume mining of marble at Marmorilik, north of Umanak on Umanak Fjord; previous operations there were discontinued in 1940. The company was seeking cooperation of the Greenland Trade Department in solving transportation problems and planned to market its expected small output of marble in Denmark, Sweden, and Germany.

The molybdenum project, that since 1962 has been the subject of intensive study and diamond drilling by Arctic Mining Co. (owned jointly by Nordic Mining Co., of Denmark, and American Metal Climax, Inc.), appeared closer to realization when plans to aim for mining 3 million tons of ore per year which will yield about 7,500 tons of molybdenum concentrate annually was announced. It is anticipated that production may begin in 1972.

The Greenland Geological Survey and the Danish Atomic Research Station in Risø, Denmark, continued research related to uranium occurrences in the Kvane Mountain area near Godthaab. Preliminary estimates indicate at least 4,000 tons of uranium. Prospects for thorium, beryllium, and columbium are also found in this general area. In the coastal region between Godthaab and Sukkertoppen a government concession has been granted to Øresund Cryolite Co., Inc., to prospect for copper, iron, nickel, and chromium.

Early in 1966 a Canadian press article [2] reported two new exploration programs to be undertaken by Canadian mining companies, beginning in June 1966. The Anderson-Greenland Syndicate, headed by Consolidated Mining and Smelting Co. of Canada Ltd., has been granted a 1,000-square-mile concession on the west coast mainland at Umanak Fjord. Deposits of high-grade lead and zinc ore in this vicinity have been known since 1939. The second project involves a concession covering the 3,000-square-mile area of Disko Island, south of Umanak Fjord, granted to New Quebec Mining and Exploration Ltd. and the Anderson-Greenland Syndicate. The existence of nickel, copper, and bituminous coal has long been known on the island.

[1] Quantities shown for 1963 and subsequent years are entirely from accumulated stocks.

TRADE

The value of cryolite, amounting to $2.75 million (18.97 million kroner) accounted for over one-fourth of the $10.49 million (72.49 million kroner) value of Greenland's total exports in 1964. The great bulk of exports is made up of fish products. Total imports, valued at $28.53 million (197.04 million kroner) consisted mostly of fully manufactured products, electrical apparatus, and petroleum fuels. The value of 1964 imports of metal and mineral products listed in table 3 amounted to $4.10 million (28.30 million kroner), more than half of which was in kerosine and diesel fuel.

Regional Mineral Industry Review of Latin America [1]

By Frank E. Noe [2]

Government actions in several of Latin America's more important mineral producing countries dominated industry developments during 1965. Considerable disruption was caused to the world sulfur supply pattern when the Mexican Government restricted exports early in the year.

In Chile, the Government of President Frei battled throughout the year to obtain passage of the Copper Bill, the principal item of the Government's new mining policy. Although passage of the bill had not been completed at yearend, enough of the essential provisions had been approved by November to cause the left-wing-dominated copper union to begin a strike which ultimately caused the loss of 70,000 tons of copper to the world supply.

On the encouraging side, however, Brazil and Bolivia actively undertook the encouragement of private investment, both domestic and foreign. Brazil announced a 10-year master plan to determine the extent and value of mineral resources and to increase production of those minerals most needed by domestic industry. Steps were also taken to attract foreign capital by conclusion of an investment guarantee agreement with the United States and by liberalizing the remittance of profits abroad. The Bolivian Government adapted beneficial measures consisting of a new mining code, new royalty scales for mineral exports, and a new investment code.

Argentina's investment climate appeared more favorable as the Government concluded negotiations with private enterprise on all but four of the petroleum exploration and development contracts abrogated in 1963. At yearend the remaining four were nearing settlement.

The Latin America area's contribution to world mineral supply is summarized in table 1. The region supplied over 20 percent of the world output of antimony, arsenic, bauxite, beryl, bismuth, columbium-tantalum, silver, fluorspar, iodine, natural nitrates, and quartz crystal; it also produced more than 5 percent of world output of an additional 16 mineral commodities.

The principal mineral commodity produced in terms of value was petroleum, and Venezuela supplied about 75 percent of the Latin America output. This country, however, failed to reach the modest target of 3.7 percent increase in production set by the Ministry of Mines and Hydrocarbons. Venezuela maintained first rank among world crude oil exporters. Exports to Western Hemisphere countries continued to rise, but shipments to Europe did not recover from the 1964 decline caused by the competition of lower-priced oil from the Middle East. Among the other Latin countries, Colombia increased petroleum production about 16 percent while minor increases were recorded by Bolivia, Brazil, Ecuador, Mexico, and Trinidad. For a

[1] The term Latin America embraces the Western Hemisphere south of the United States exclusive of U.S. territories and dependencies in the Caribbean. It includes in South America 10 republics and the 3 Guianas: in Middle America 7 republics and 1 British colony on the North American continent (Mexico to Panama), and all the islands, independent and otherwise, of the West Indies other than those belonging to the United States. Cuba has been excluded from statistics for Latin America in this chapter, but has been retained in world totals given.

[2] Acting Chief Latin America specialist, Division of International Activities.

variety of political and economic reasons, crude petroleum output declined in Argentina, Chile, and Peru. Latin America has gradually declined in importance as a world supplier of crude petroleum since 1962 and, as shown in table 2, accounted for only 15.2 percent of the world output in 1965.

Stimulated by regional industrialization programs and the availability of abundant iron ore deposits in several of the countries, iron and steel production in Latin America has been developing at a substantial pace since 1950. Iron ore production has increased from approximately 5.4 million tons in 1950 to about 57 million tons in 1965. Pig iron and sponge iron output totaled about 5.2 million tons during 1965 compared with 1.1 million tons in 1950, an annual growth rate of about 12 percent. Ingot steel production as shown in table 3 reached 8.3 million tons, an increase of 56 percent from 1961, but only 3.2 percent above 1964 output. The abrupt reduction in the rate of increase of production is explained by the fact that in the years between 1961 and 1964 various new plants came into production and expansion programs were completed at others; while in contrast, 1965 was a period for initiating new expansions which will come into production in 1966 and later years.

Despite the industry's rapid growth since 1961, the annual volume of steel imports has remained between 3 million and 3.2 million tons. However, most of the imports are by nonproducing countries or are types of steel as yet not available in the producing countries of Latin America.

p Preliminary.
[1] Data are presented as published by ILAFA and differ in some cases from that reported in individual country chapters of this volume and that presented in the world production table in the iron and steel chapter of Minerals Yearbook, Volume I.

In 1965, the United States exported goods to Latin America valued at $4.2 billion and imported materials worth $4.4 billion. The importance of Latin American production and exports of mineral commodities to the import needs of the United States is outstanding as illustrated in table 4.

Latin America ranked second only to Canada as a recipient of mineral industry investment [3] in 1965. The value of total

direct U.S. investments abroad increased $4,831 million (10.9 percent) to $49,217 million from the end of 1964 to the end of 1965. The largest increases were in manufacturing, up $2,349 million (13.9 percent) to $19,280 million, and in the mineral industries, up $1,211 million (6.7 percent) to $19,114 million. The largest segment of investment in the mineral industries was petroleum, up $986 million to $15,320 million, while mining and smelting advanced $225 million to $3,794 million.

On a geographic basis, although ranking second to Canada in total mineral industry investment, Latin America still led all other areas of the world as a recipient of U.S. investment in petroleum and remained second to Canada in mining and smelting investment. Table 5 indicates the distribution of U.S. investment in Latin America in selected sectors of the mineral industry by geographical segment, and as a percentage of total U.S. world investment.

Venezuela and Colombia were the leading markets in Latin America for U.S. investments in petroleum, while Chile and Peru were the major targets for investment in mining and smelting. Although Venezuela remained the second largest recipient country for U.S. petroleum industry foreign investment funds, total U.S. investment in that country's petroleum industry was reduced $106 million during 1965 in the face of increased tax demands by the Government. Investment in the Mexican petroleum industry was reduced $8 million by U.S. companies. U.S. investment in the mining and smelting industry of Mexico declined $25 million, probably due to the withdrawal of funds following Mexicanization of both the American Smelting and Refining Co. subsidiary and the San Luis Mining Co., plus the acquisition by Mexican investors of the 49 percent American interest in the previously Mexicanized Peñoles Co. Therefore, despite new U.S.

[3] Investment in steel and nonferrous rolling mills as well as fertilizer plants, petrochemical plants and some economically less important mineral processing facilities are not reported separately, but are included in manufacturing, therefore data reported here cover only the mining, smelting, petroleum producing and petroleum refining sectors of the mineral industry.

investment in Peru, Panama, Brazil, Colombia, Chile, and Central America, the net new investment in mining, smelting, and petroleum in Latin America was held to $14 million.

Many Latin American countries are handicapped by small populations and low incomes which limit the demand for industrial products. In an effort to enlarge area markets, two regional groups have been formed which make other countries' markets more accessible to local producers. These two groups are the nine-nation Latin American Free Trade Association (LAFTA)[4] and the five-nation Central American Common Market (CACM).[5] Both have been operating about 5 years but CACM has been more successful than LAFTA in opening national markets to the products of other member countries.

The Mineral Industry of Mexico

By Burton E. Ashley [1]

The mining industry in Mexico showed overall growth in terms of production value during 1965 despite declines recorded in output of some commodities. In relation to the gross national product (GNP) of slightly more than $19 billion,[2] the minerals industry as a whole contributed about 4 percent (mining alone about 1.8 percent), slightly more on a dollar basis than in 1964. However, growth in other industrial sectors tended to overshadow growth in mining, thereby reducing its relative importance to the economy.

Favorable world prices raised production value in cases of certain mineral commodities for which output volume was less than in 1964. Mexico continued to hold top, or near top, world rank as a source of some half dozen minerals—white arsenic, bismuth, fluorspar, silver, strontium, and sulfur.

The taxation structure in Mexico, particularly with regard to levies on exports, caused some disruption in the normal export trade of graphite, zinc, limestone, marble, alabaster, sand, and gravel.

Little was accomplished with regard to ameliorating certain official attitudes toward mining in Mexico. The industry in general felt that many of the regulations were restrictive. At yearend, new amendments to the mining law of 1961 were put into effect; it was reported that the new rules did little but to tighten loopholes in the Mexicanization program while affording some assistance to small and medium-sized mining companies. The new amendments hardly had been in operation long enough to determine what their effect might be.

In August approximately 5 million hectares of land were released from the national minerals reserve in the States of Baja California, Coahuila, Jalisco, Colima, Michoacan, Guerrero, and Oaxaca.

Cía. Minera Asarco, S.A., a wholly owned subsidiary of American Smelting and Refining Co., was Mexicanized in 1965 by the purchase of a 51-percent interest by a group of Mexican financiers; the new name of the company is ASARCO Mexicana, S.A. It was thought in industry quarters that Government plans to bring various relief measures to the mining industry would be speeded up with Mexicanization of this organization. The reasoning behind this idea was that the already large company would become larger if relief measures were put into effect thereby making it even more difficult for domestic capital to be raised for Mexicanization.

At yearend it was reported that the San Luis Mining Co. was Mexicanized with purchase of all the stock at a price of between $60 million to $70 million. The firm, renamed Cía. Minera de San Luis, S.A., was bought by a group of Mexican investors.

American Metal Climax, Inc., sold its remaining 49 percent interest in Metalúrgica Mexicana Peñales, S.A., to Mexican interests. The Mexican organization is reportedly the country's foremost mining company entirely held by domestic capital.

This leaves only one major U.S. mining company to be Mexicanized—Compañía Minera de Cananea, S.A. de C.V., owned by The Anaconda Mining Co.

There are a few smaller U.S. organizations as yet not Mexicanized.

---

[2] Where necessary, values have been converted from Mexican pesos (Mex$) at the rate of Mex$1=US$0.08.

Estimates put the number of persons engaged in the mining, metal, and petroleum industries at about 142,000, including 65,000 in mining, 25,000 in mineral processing, and 52,000 in all aspects of the petroleum industry.

A Canadian study group reported that Mexican mining labor receives $2.24 to $4.80 a day, plus many social benefits.[3] The work week is 6 days, but payment is for 7 days; overtime is paid at double rates, with triple time for holiday work. Total fringe benefits probably amount to 20 to 40 percent of actual wages.

In October 1965, the U.S. Department of Commerce released a publication that gives a clear general picture of the industrial and business guideposts in the country, updating earlier similar reports.[4] Topics covered include Mexican Government policy, rights of aliens, taxation and labor legislation. While not exclusively concerned with the mining industry, the paper would be of value to anyone interested in Mexico from an industrial point of view.

The Mexican Government issued a list of 370 industries which it would like to see developed in the country. Goals for development programs included the maximum use of human and natural resources and the exploitation and conservation of natural resources. Among the listed categories were items of interest to the chemical, petrochemical, iron and steel, ferroalloy, and mineral processing and exploitation industries.

A cooperative mapping venture of the Government of Mexico and the United Nations Special Fund was completed in the State of Sonora. Embracing an area of about 70,000 square kilometers, the survey cost $2.4 million, of which the Special Fund paid $855,700.

It was decided to map an additional 50,000 square kilometers in Sonora with particular emphasis on copper mineralization. The extended survey will cost $531,000, of which the Special Fund will provide $156,200. It was expected that the work would be completed in about a year.

PRODUCTION

Total value of mineral production for 1965 was reported at $768 million. According to the Mexican Mining Chamber, value of mining and metallurgical output was $386.2 million, a rise of 13 percent over that of 1964; the remainder was attributable to the petroleum industry.[5] The gross value figure was 11 percent greater than in 1964. Mexico's increased mineral value was more the result of higher world prices during 1965 than of increased production. Quantity of output was lower for sulfur (9 percent), silver (3 percent), lead (3 percent) and zinc (5 percent) than in 1964. Iron increased 14 percent; copper, 31.7 percent and gold output increased slightly less than 3 percent.

Except for vanadium, for which no production was recorded in 1964, mercury made the most phenomenal percentage rise of the metallic mineral group; quantity of output increased 52.9 percent, while value of output increased nearly 200 percent.

Portland cement output increased in value by nearly 10 percent over the 1964 total, in spite of a decline in output amounting to slightly more than 3 percent. Barite and fluorspar output increased 10 percent and 14 percent, respectively. Graphite, tungsten, and bismuth production also increased while output of cadmium, molybdenum, arsenic, tin, and selenium decreased.

Annual crude oil production was 132.1 million barrels, an increase of 2.6 million barrels over that of 1964; natural gas production also increased by 8.2 billion cubic feet to 493.2 billion cubic feet.

Refinery input was 134.9 million barrels (126.9 million barrels in 1964) with output of 130.1 million barrels. Nearly all categories of products showed output increases; the exceptions were some gasolines, kerosine, and paraffin.

[1] U.S. imports.

[2] Exports.

TRADE

Identifiable statistics of mineral exports showed that the United States substantially increased its already leading position as Mexico's best customer. Indicated gross value of U.S. mineral purchases from Mexico in 1965 was $191.7 million, or nearly 64 percent of the gross export value; in 1964, the United States purchased 54 percent of the export value. West Germany and Japan were other major purchasers.

Principal mineral exports in rounded figures were zinc ($63 million), silver ($38 million), lead ($36 million), sulfur ($34 million), fluorite ($16 million), manganese ($6 million), and copper ($4 million).

Imports of nonmetals—kaolin, diatomite, and feldspar—continued but on a lower scale than in 1964. Bauxite, phosphate, and magnesite imports increased.

The United States also supplied the bulk of Mexican mineral imports. Main categories of such trade were petroleum products, scrap iron and steel, aluminum oxide and metal, mineral fuels, and phosphate rock.

The following table shows the relation of total commodity trade to trade in minerals:

	Value (millions)		Mineral commodities share of total (percent)
	Mineral commodities	All commodities	
Exports:			
1964	$266.3	$1,022.4	26.0
1965	301.0	1,111.0	27.1
Imports:			
1964	15.8	1,492.9	1.1
1965	71.9	1,559.6	4.6
Trade balance:			
1964	+250.5	−470.5	XX
1965	+229.1	−448.6	XX

XX Not applicable.

COMMODITY REVIEW

METALS

Aluminum.—Alumex, S.A., in which American and Foreign Power Co., Inc., and American Metal Climax, Inc., reportedly have an interest, will construct an aluminum sheet plant at Puebla. Initial capacity is planned for 3,500 tons annually.

Gold and Silver.—According to trade journal reports, Sunshine Mining Co. was reopening the Los Pericos gold and silver mine in the Promontorio, Durango area. Crews were retimbering the main drift and repairing the shaft. After the rehabilitation work is finished, geological mapping and sampling will proceed.[6]

Cía. Minera Guazapares was reported to be interested in the Palmarejo mines in Chinipas, Chihuahua. Construction was begun on a 100-ton-a-day flotation mill.[7]

Iron and Steel.—*Iron Ore.*—Despite numerous rumors that the Pena Colorado iron ore deposits would be developed, no substantiation of the reports was forthcoming at yearend. The deposits, located in the State of Colima, are said to contain reserves of around 130 million tons of 60 percent iron ore, carrying 2.4 percent sulfur. Total tonnage of the deposit has been reported as high as 3 billion tons.

Pig Iron, Ingot Steel and Semimanufactures.—Four firms produced about 90 percent of Mexico's steel in 1965, which totaled 2,454,680 tons, up 5.8 percent over the 1964 figure. The firms and their individual output were: Altos Hornos de Mexico, S.A.—1,110,812 tons; Cía. Fundidora de Fierro y Acero de Monterrey, S.A.—448,176 tons; Hojalata y Lamina, S.A. (HyL)—409,657 tons; and Tubos de Acero de Mexico, S.A.—220,296 tons. Altos Hornos, after Brazil's Volta Redonda, was Latin America's second company to produce over 1 million tons of steel a year. This firm expanded operations in 1965 to the extent of some $25 million. Further planned expansion will raise annual capacity to around 1.6 million tons in 1966.

It was also reported that HyL borrowed about $16 million from French sources in order to build a new steel plant at Puebla; French equipment was to be installed. The plant, to cost about $50 million, will have an annual capacity of about 200,000 tons of steel in the form of bars, billets, rods, shapes, and structurals.

According to the National Iron and Steel Chamber, apparent consumption of ingot steel in 1965 amounted to 2.7 million tons, 9.1 percent more than in 1964. Requirements for finished steel products increased

[6] World Mining Magazine. V. 18, No. 2, February 1965, p. 61.
[7] Page 62 of work cited in footnote 6.

to 2 million tons, 9.2 percent above the previous year's level.

In order to protect local industry, the Mexican Government decreed a duty on imports of stainless steel powder early in 1965. The tariff, at 55 percent ad valorem plus $1.20 per gross kilo, reportedly stopped nearly all imports of the material.

HyL put its new electrolytic tinning line into operation in 1965, bringing its annual electrolytic tinplate capacity to 60,000 tons. The company's total annual capacity was 75,000 tons, and Mexican national tinplate output capacity was put at 150,000 tons per year.

HyL also was raising its steelmaking capability by adding one electric furnace to its facilities. Annual capacity for steelmaking and hot-rolling by 1966 should be 750,000 tons, and for cold-rolling 240,000 tons; sponge iron capacity was being increased to 240,000 tons per year.

Manganese.—In order to meet growing domestic requirements for manganese, Cía. Minera Autlan de C.V. planned to expand its production and processing programs. The $22.4 million expansion expenditure will be made over a period of some 2 years. The program called for development of known deposits and for a more vigorous prospecting program. In addition, a new processing complex was to be built at Tlanchinol near Pauchuca. Some tax relief was approved by the State in accordance with the Hidalgo Industrialization Laws.[8]

Mercury.—Demand for mercury put many small sporadic operations back into business in 1965, but details are not available as to which properties may have been affected. However, small mines in the States of Durango, Zacatecas, and Jalisco, which were worked only in times of greater than normal demand, were activated.

Because of Mexico's high export tax on mercury, smuggling mercury out of Mexico became a profitable business. It was reported that the metal was flown into the Southwestern United States and sold at less than east coast prices. Marketing in the United States presented little difficulty, as the U.S. import tax was paid.

Substantiation of smuggling rumors was afforded by confiscation of certain overland shipments in Nogales, and Cd. Juarez by Mexican authorities. It was also reported that nonexistent lots of mercury were being sold to unwary buyers in Mexico from time to time.

Actual mercury output in Mexico increased by more than 50 percent in volume and by nearly 200 percent in value over 1964 levels.

Tin.—Tin ore production in Mexico is only by individual miners working alluvial or relatively shallow lode deposits. No company mines tin, and sales of ore to smelters are made by the individual "gouger."

Four tin smelters were in operation in the country, three in San Luis Potosí and one in Tlalnepantla, Mexico D.F. These facilities processed all domestically produced ore as well as concentrates imported from Bolivia, Burma, and Canada.

Mexico's largest tin smelter was Estaño Electro, S.A. de C.V., in the Mexico City area. This plant, owned by four individuals, had three gas-fired furnaces with a monthly capacity of 80 tons; production was about equal to capacity. Raw materials from domestic sources assaying about 38 percent tin are combined with imported ores from Bolivia and Canada, averaging 53 percent tin. The firm was considering plant expansion to a productive capability of 120 tons per month.

The family-owned Metales Potosí smelter, with a monthly capacity of about 60 tons, produced about 10 to 12 tons of metal monthly in 1965. Equipment consisted of two diesel-fired brick furnaces; an electric furnace of 1-ton-per-day capacity was being installed. Raw material supply was from purchases of domestic alluvial and lode ore, running 40 to 60 percent tin.

Fundadora de Estaño, S.A., a stock company, had a smelter capacity of 50 tons of metal per month, and 1965 output was at the rate of about 35 tons monthly. There were two 1½-ton diesel-fired furnaces, using equal portions of domestic ore containing 40 percent tin and imported ore containing 70 percent tin.

The individually owned Estaños Mexicanos smelter had a capacity of about 30 tons per month, which was being fully utilized. There was a single diesel-fired 2-ton capacity furnace. Raw material came from domestic sources containing 30 to 60 percent tin. Expansion plans called for installation of a 40-ton-capacity furnace.

---

[8] Mining Journal (London). Dec. 31, 1965, p. 482. Engineering and Mining Journal. V. 166, No. 3, March 1965, p. 143.

NONMETALS

Cement.—At yearend 1965, the 23 producing cement plants in Mexico had an installed annual capacity of 5.1 million tons. Despite this potential, output in 1965 fell slightly more than 3 percent below 1964 output. Capacity utilization in 1965 was about 82 percent compared with the 1964 figure of about 94 percent. However, at a reported 1965 price of $20.80 per ton, output was of higher total value than 1964 sales at $18.28 per ton.

Expansion plans for increased production were being contemplated for eight of the existing plants, while at the same time, six entirely new plants were either being built or being planned. If all projects are completed on schedule, annual capacity in 1967 will be 6,798,000 tons with additional annual capacity of 1,170,000 tons becoming available by 1968.

The most commonly produced cements were the types of Portland I, II, and III; in addition, about nine other types were available from domestic plants.

Fertilizer Materials.—The fertilizer industry in Mexico continued to grow rapidly. The Mexican Government has promoted the use of fertilizers through educational extension services and by affording loans for greater fertilizer use. The Rockefeller Institute also has conducted an educational program to promote the use of soil nutrients.

In terms of nutrient units, Mexican production of nitrogen and phosphoric fertilizers increased 56 percent and 33.5 percent, respectively, from 1962 to 1964. Over the same period, imports of phosphate rock (all from the United States) increased nearly 59 percent.

The foregoing is indicative of the growth of the fertilizer industry in Mexico. In addition, it was reported that the Government was consolidating and combining many of its own fertilizer operations in the interest of increased operating efficiency and economy.

Guanos y Fertilizantes de Mexico, S.A. (G. y F.), was building a plant in Coatzacoalcos, Veracruz, with installed capacity of 50,000 tons of ammonium sulfate per year. Another G. y F. plant was under construction at Torreon, Coahuila, with planned capacity of 72,000 tons per year. The G. y F. plant at Cuautitlan was being expanded to produce 73,000 tons per year, while a 250-ton-per-day plant was planned in Chihuahua to produce urea.

G. y F. reportedly had plans to establish production facilities at Guaymas, Sonora, for urea, ammonium sulfate, and ammonium phosphate; at Guadalajara, Jalisco, for ammonium sulfate; and at Leon, Guanajuato, for urea.

Fertilizantes Fosfatados, S.A., was planning a $44 million complex at Coatzacoalcos, Veracruz, to produce about 365,000 tons of phosphatic fertilizers, part of which will be for export. Participants in this company are Pan American Sulphur Co., Kuhn Leob and Co., Carl M. Leob, Rhoades and Co., and the Banco Nacional de Mexico.

Fosfatos del Golfo, S.A., was also planned as a combined private and public venture. Initial investment in this phosphatic fertilizer enterprise was put at $16 million with possible eventual outlay reaching $240 million. Participants were reported to be Nacional Financiera, S.A., Guano y Fertilizantes, S.A., Hooker Chemical Corp., and Martin Garcia Urtiaga. Projected capacity has not been announced.

Projections attributed to Nacional Financiera, S.A., put 1970 consumption of fertilizer, in nutrient tons, at 445,000 for nitrogen and at 167,000 for phosphatic acid. Consumption figures for 1964 were about 300,000 tons and 90,000 tons, respectively.

Surface area upon which fertilizers were used in 1964 amounted to about 3 million hectares; it is expected that about 5 million hectares will be fertilized in 1970.

Fluorspar.—The Bureau of Customs, U.S. Treasury Department, clarified its changed position in sampling and classifying trainload lots of fluorspar imports for tariff purposes. The original procedure of sampling for tariff purposes was to classify such ore on a car-by-car basis. It was found that such a method was not required for proper determination of the shipment. Under the revised procedure, a sample from each car will be combined into a composite sample; the chemical assay thus determined will determine the assay of the entire trainload of ore as a composite shipment. It was expected that the revised method would

cut handling costs, and also tend to insure that the shipments would contain not less than 97 percent CaF_2. Under the U.S. tariff schedule, fluorspar imports containing less than 97 percent CaF_2 are levied at $8.40 per ton, while only $2.10 per ton is payable on imports containing more than 97 percent CaF_2.

Graphite.—For the purpose of levying export taxes on amorphous graphite, the Mexican Government sets an export evaluation. The set evaluation has apparently been unrealistically high and consequently, exporters of amorphous graphite reached the point in mid-1965 where at least some operations would have to shut down for lack of profitable income.

Two U.S.-based companies have been trying to get some tax relief for the industry for a number of years. The Mexican Government had granted no relief by yearend; however, in the face of possible mine shutdowns, with consequent loss of mine jobs and income, indications were that relief would be granted in 1966.

Sulfur.—In April the Government placed quantitative restrictions on the export of sulfur from the Isthmus of Tehuantepec in order to protect reserves and provide for an adequate domestic supply. Export quotas were made dependent on the discovery of new reserves. As a result of this measure, exploration efforts during the year increased sulfur reserves by 11 million tons. Export formulae were issued to the two producing companies and stated export tonnages were assigned.

Additional results were the formation of new companies, predominantly capitalized with Mexican funds, to explore for and exploit sulfur and the formation of projects to promote domestic sulfur-consuming industries such as chemical fertilizer plants.

MINERAL FUELS

Petroleum.[9]—Drilling activity decreased by 43 percent in 1965, with 361 wells drilled during that year compared with 631 in 1964. Of the 361 wells drilled, 222 were development wells and 139 were wildcats; the results were 209 wells capable of producing oil or gas and 152 dry holes. Of the 209 producing wells, 173 were successfully completed for oil and 36 for gas. There were 15 discoveries of new fields and 5 discoveries and 1 extension in or around known pools. Total footage drilled was 2,992,661.

There were 43 exploratory crews in the field, an increase of 4 crews over the preceding year; the exploration crews were made up as follows: Seismic 21; surface geology 17; gravity meter 4; and magnetometer 1.

Seismic methods accounted for the discovery of 11 new fields; subsurface geology and seismic methods combined accounted for 3 new fields; and surface geology and seismic techniques combined accounted for 1 new field.

Proved reserves of oil and gas equivalent as of January 1, 1966, were put at 5,077 million barrels (5,000 cubic feet of gas equals 1 barrel of oil).

Refinery operations showed an overall 5.6 percent increase over those of 1964; the more significant operations in terms of output were asphalt, liquefied petroleum gas, residual fuel oil, and some types of gasoline.

Petroleum storage tanks in Mexico numbered 2,796 with a capacity of 3,671,702 cubic meters. Of the total, 1,147 tanks were at sales agencies, 861 at refineries, and 788 at oilfields.

The Mineral Industry of Central American Areas

By Burton E. Ashley [1]

Contents

BRITISH HONDURAS

The very limited mineral industry in British Honduras produced limestone and sand and gravel, all for local use, with an estimated value of $671,349 [2] in 1965.

While the Government of British Honduras was making a determined effort to invigorate the economy and improve various internal conditions, efforts were directed primarily toward agricultural projects. In plans and hopes enunciated by the Government for raising the gross national product and improving the general welfare, little attention was paid to the development of mineral resources.

Under existing conditions of poor communications and lack of access to much of the interior, little mineral industry development could be expected.

In a geological study of part of the country,[3] attention was drawn to occurrences of zircon, ilmenite, magnetite, tourmaline, tin, and gold. In addition, deposits of limestone, sandstone, clays, and stone suitable for construction purposes are known, and barite occurrences have also been studied. Investigation of various deposits in the past has revealed nothing of economic importance with the exception of some construction materials.

PRODUCTION

Recorded mineral output has been confined to limestone and sand and gravel as follows:

[1] Physical scientist, Division of International Activities.

[2] Where necessary, values have been converted from British Honduran dollars (BH$) to U.S. dollars at the rate of BH$1.40=US$1.

TRADE

Exports of all commodities totaled $23.9 million in 1964, while in 1963 exports were valued at $21.6 million. In terms of 1964 commodity trade, imports of all commodities were valued at $47.5 million, compared with the 1963 level of $38.6 million.

Recorded exports were limited to scrap metal—154 tons in 1963 and 8,698 tons in 1964. In addition, minor reexports of petroleum products and cement were reported. Exports and reexports of cement, metals, and petroleum products were valued at slightly over $400,000 in 1964.

Imports of mineral fuels, mostly petroleum products, were valued at about $2.2 million in 1964. Other mineral commodity imports comprised modest amounts of building materials, salt, steel products, and fertilizer materials. In 1964, the United States was a source of about 38 percent of total British Honduras imports, by value, while slightly over 32 percent of exports were directed to the United States.

COMMODITY REVIEW

Petroleum.—Exploration activity was reinitiated in 1965 after having been suspended for nearly 2 years and seemed to offer the only immediate hope for significant expansion of mineral industry activities. Marine seismic surveys were conducted by British Honduras Shell Petroleum Co., Ltd. (Shell) and Esso Belize, Inc. (Esso). Esso, Shell, and the Phillips Petroleum Co. all held acreage offshore of the British Honduras coast. Belize Chevron Oil Co. was awarded exploration rights over some 4,125 square miles, which comprises much of the northern half of the country.

At yearend Phillips Petroleum Co. held about 1.3 million acres under lease, and Shell held just slightly less.

It was expected that exploration completed in 1965 would lead to a drilling program in 1966.

COSTA RICA

Incomplete returns of mineral output in Costa Rica indicated a minimum production value of $3.8 million[4] in 1965. No reasonable estimate of total value could be made with available information.

The gross national product, estimated at $593 million, rose 7.6 percent over the 1964

[4] Where necessary, values have been converted from Costa Rican colones (C) to U.S. dollars at the rate of C6.65=US$1.

level. It is evident that value of mineral output had little impact on the total Costa Rican economy.

Some interest in mineral investigation was expressed in 1965, but no new production was established. Output of manganese ore and iron ore was considered possible in the near future.

The Government continued to welcome foreign investment, particularly in joint ventures with domestic interests. The Government Department of Geology, Mines and Petroleum actively assisted in exploration work. The U.S. Agency for International Development also provided help for prospectors, and the United Nations was expected to start a program of mineral resource evaluation. However, the planned U.N. program had not received final Costa Rican Government approval by yearend.

It was reported that a road construction program was planned in conjunction with agricultural and forest development. Improved access within the country could well be a spur to mineral prospecting and development.

PRODUCTION

As in previous years, only estimates of volume of building material output were available. Production was in the hands of many small operators, and apparently records were not kept in all cases.

Ordinarily, output figures for cement, salt, and diatomite are considered reliable. The reason for the indicated sharp fall in 1965 salt production is not evident; whether production actually decreased, or returns for 1965 were incomplete, is not known.

[e] Estimate. NA Not available.

TRADE

Total commodity exports in 1965 were valued at $111.8 million, compared with like imports valued at $178.2 million, which created an adverse balance of $66.4 million for the period. This was a significantly higher deficit than was recorded for 1964. In 1965 the United States supplied about 40 percent of Costa Rican commodity imports and was a destination for 50 percent of its exports.

The 1964 estimated value of mineral imports was $20.7 million, and that of mineral exports was $7.1 million.

In 1965, the most valuable mineral imports were manufactured fertilizers, $11.7 million, and petroleum products, $8.7 million.

COMMODITY REVIEW

Metals.—*Bauxite.*—The contract between the Aluminum Co. of America (Alcoa) and the Costa Rican Government for Alcoa to extract bauxitic laterite was validated upon publication of the agreement in the Government's Gaceta of February 10, 1965, Number 32.

Alcoa was continuing its program of exploration and development at yearend.

Gold.—Interest in gold recurred during the year, partly as a result of an article in a popular U.S. magazine and partly because of reports of nuggets said to have been sold to a local bank. The area on which interest was focused was the Isla de Los Violines near the Peninsula de Osa, a region that has been the site of sporadic alluvial gold finds in the past.

Activity and reports of samples in 1965 were viewed cautiously because the romantic lure of gold often interferes with factual reports of finds.

Iron and Steel.—A feasibility report concerning the establishment of a steel mill near Puntarenas was given to the President. Estimated cost of the complex was about $30 million. It was expected that financing would come from local sources supported by U.S. and West German investors.

A consumer tax on iron rods of national and foreign origin was established in mid-1965. The rate decreed was $0.75 per quintal of 46 kilograms. It was expected that the assessment would be added to the price. Armaduras de Acero Ltda. and Aceros Nacionales Ltda., two companies which produced over 90 percent of total domestic requirements for this product, did not believe the tax would affect sales.

Price per quintal (46 kilograms) of rods at the time the tax decree was announced was $7.37 for the local product and $8.12 for imported material.

Metales y Cía., S.A., announced expansion of its galvanizing-line annual capacity by 20,000 tons to a total of 30,000 tons; estimated consumption of galvanized steel sheets in the five countries of the Central American Common Market was 22,500 tons annually. Output will be to USG–22 and USG–37 specifications.

A survey of the magnetite sands along the coastal areas under the auspices of the Costa Rican Geological Survey[5] developed calculated reserves of 3.7 million tons of iron. It was thought that adequate reserves could be established to supply a steel industry for some time.

Manganese.—It was reported in late 1965[6] that a U.S. company planned to build a plant to manufacture dry cell batteries in Costa Rica. Output of the $1.5 million plant was expected to replace U.S. exports to the Central American Common Market.

Another source[7] indicated that a manganese dioxide supply will be developed in Costa Rica.

Nonmetals.—*Cement.*—Industria Nacional de Cemento, S.A., increased production by 261 percent in 1965 over the 1964 level.

Domestic requirements for type I portland were fully met in 1965. Local price was about $1.20 per 42.5-kilogram bag. The only exports were to Nicaragua. Trucks bringing gypsum from Nicaragua to the cement plant were used to ship cement as return cargo thus obtaining a more favorable transportation rate than if the trucks returned empty.

In mid-1965 various industry representatives met in San José to form the Cámara del Cemento del Istmo Centroamericano. Countries represented, in addition to Costa Rica, were El Salvador, Guatemala, Honduras, Nicaragua, and Panama. The object of the Cámara is to promote the use of cement generally in construction projects, and in particular to encourage the Government and municipalities in each country to use concrete in highway construction.

The various member companies planned to cooperate in exchanging ideas and to collaborate in the supply of materials and replacement parts in case of short supply in any of the plants.[8]

Productos de Concreto, S.A., as the leading manufacturer of concrete products in the Central American Common Market area, found that demand for its products had reached the point where expansion was necessary.[9] Therefore, funds were being

raised through a number of sources to carry out a $500,000 expansion and modernization program.

Fertilizer Materials.—Fertica, S.A., reportedly was finding it difficult to meet competition from imported fertilizers.[10] European shippers were able to absorb tariff charges, nullifying any advantage that Fertica, S.A., might have expected to enjoy through such protection.

Abonos Superior, S.A., was producing about 15,000 tons of complex chemical fertilizers annually; it imports fertilizer materials for local mixing.

Mineral Fuels.—At yearend the facilities of Refinadora Costarricense de Petróleo were still under construction, with completion scheduled for 1966.

In September 1965, the Ministry of Industry authorized construction of a petroleum products pipeline from the refinery at Limón to Ochomogo. The cost of the 100-kilometer pipeline was estimated at $3.5 million. It was expected that the 6-inch line would take 18 months to complete. No petroleum exploration activity was reported for 1965.

[10]E&MJ Metal and Mineral Markets. V. 36, No. 28, July 12, 1965, p. 8.

EL SALVADOR

El Salvador's economy in 1965 expanded, with an increase of 6.3 percent in the gross national product over figures from the previous year. Manufacturing was a major contributor to the country's growth, while sustained building activity was responsible for production increases of the few indigenous minerals which are worked.

Various metallic minerals have been reported, and sporadically mined, in El Salvador, but little information is available about 1965 activities. Exports of silver concentrates in 1964 presumably originated within the country.

Crude oil runs to the refinery declined about 8 percent from 1964 levels.

PRODUCTION AND TRADE

Domestic mineral output was virtually limited to salt and a few components used in the construction and ceramic industry.

Output of refined petroleum products declined 7 percent from 1964 levels.

There were some exports of locally mined construction materials and silver ores and concentrates. The remaining exports were largely commodities made from imported raw or semifinished materials, or reexports. An import upon which the duty has been paid becomes a "national article;" if it is subsequently sent out of the country, it becomes an export for statistical purposes.

Table 5.—El Salvador: Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	1964	1965

Total ---do---	---	---	1,785	3,264	3,034

e Estimate. r Revised. NA Not available.

While the value of mineral output is estimated to supply less than 1 percent by value of the gross national product, trade in minerals assumed greater proportions. The trade imbalance, particularly in minerals, is shown in the following table:

	Value (million dollars) [1]		Mineral commodities share of total (percent)
	Mineral commodities	All commodities	
Exports:			
1963	5.6	153.8	3.6
1964	6.5	178.1	3.6
Imports:			
1963	28.0	151.7	18.5
1964	38.3	191.1	20.0
Trade balance:			
1963	−22.4	+2.1	XX
1964	−31.8	−13.0	XX

XX Not applicable.

[1] Where necessary, values have been converted from El Salvadoran colones (C) to U.S. dollars at the rate of C1=US$0.40.

In 1964 the United States supplied about 35 percent of El Salvador's imports and took about 26 percent of its exports.

COMMODITY REVIEW

Metals.—*Iron and Steel.*—Siderúrgica Salvadoreña, S.A., continued production of reinforcing rods ranging from ¼ inch to 1½ inches, and of small shapes. Output in 1963, the latest year for which figures are available, was 2,677 tons.

Nonmetals.—*Cement.*—Cementos de El Salvador, S.A., the country's only cement producer, continued to move its plant from Acajutla to Metapan, where limestone deposits were expected to be adequate for over 150 years' operation. The second kiln, with capacity of 240 tons a day, was moved in 1965. A new Schmidt kiln with a daily capacity of 500 tons was on order at year-end.

Gypsum is imported from Honduras or Guatemala. While the plant was closed because of the move, cinder was imported from Guatemala for local grinding.

Fertilizer Materials.—It was reported that Fertica, S.A., projected expansion of its facilities to produce 150 tons a day of nitric acid and 300 tons a day of ammonium nitrate.

GUATEMALA

Guatemala's economic growth in 1965 continued as the gross national product reached an estimated $1,380 million.[11] Of this figure, commerce accounted for about 30 percent, agriculture nearly 28 percent, and industry 30 percent.

The contribution of the part of the mineral industry based on domestic raw materials remained insignificant, but with two petroleum refineries in operation, mineral industries based on imported raw materials presumably made an increasingly valuable contribution to the local economy as well as to export trade. However, income from the latter source was partly offset by necessary increases in crude oil imports.

Projected development of nickel deposits offered some promise of expanded activities in the field of metal mining and processing.

A mineral survey under the auspices of the United Nations was announced. The project was expected to take about 3 years and cost slightly over $1 million.

Decree Law 342, Guatemala's new mining code, was published on May 4, 1965, and became effective 30 days after publication. The stated object of the law is "to have legislation which gives impetus to the effective development of the nonrenewable natural resources of the country. . . ." [12]

The law annulled all previous mining legislation and Presidential Decrees that were inconsistent with the code.

Minerals found within the national territory or maritime limits were declared property of the State. Regulations for prospecting, exploration, and exploitation rights were defined. Rights may be granted to either foreigners or Guatemalans; however, Guatemalan entities having more than 51 percent national capitalization will be favored in the granting of exploration concessions. Exploitation rights may be granted to foreign-owned corporations formed in Guatemala.

Concession size and time limits for which concessions are effective were stated; license fees and tax requirements were also enumerated. Income tax exoneration under provisions of the Industrial Development Law may be claimed by mining companies which establish installations for processing minerals within the country.

In its entirety, the code is divided into 23 chapters containing 152 articles.

At yearend the law had not been in effect long enough to be appraised in regard to workability, but it was reported that certain aspects of the code were not entirely clear.

PRODUCTION

Crude mineral production in Guatemala remained largely dependent upon cement output, since this is the end use for limestone, clays, and gypsum as well as other components of total production.

Output of refined petroleum products showed a considerable increase; aviation gasoline entered the list of refined products for the first year.

TRADE

Figures pertinent to mineral trade for 1965 were not available, but obviously imports far exceeded exports. In 1964, values of mineral and metal imports were some $27 million higher than export values for similar categories.

In overall commodity trade, Guatemala showed a deficit of about $40 million in 1965.

Preliminary figures for commodity trade for 1964 indicate that Guatemalan exports amounted to $164.3 million compared with imports of $202.1 million. Of the totals, the United States took about 32 percent of exports and supplied 44 percent of imports.

---

[11] Where necessary, values have been converted from Guatemalan quetzales (Q) to U.S. dollars at the rate of Q1=US$1.

COMMODITY REVIEW

Metals.—*Copper, Lead, and Zinc.*—Existence of reserves of shipping-grade ores of copper, lead, and zinc carrying commercial values of silver and gold were reported. While no developmental activity was described, principals were actively seeking solutions to the economics of shipping to custom smelters in the United States.

Iron and Steel.—INTUPERSA, S.A., which manufactures steel pipe and shapes, reportedly increased its capitalization by $600,000.

Galvanizadora Centro Americana, S.A., began operations in Guatemala City in late 1965. Guatemalan, Japanese, and U.S. interests combined in the $1.5 million plant, which was able to produce about 1,000 tons of galvanized sheet steel monthly. Planned production schedules allowed progressive doubling of that capacity.

The iron and steel industry in Guatemala generally has not reecived a great deal of attention. Output in the past has been limited to steel reinforcing rods, nails, tin cans, and some pipe and tubing.

In 1958, the latest year for which statistics were available, 107 firms were engaged in the metal or metallurgical industry, but more than half of them were plumbing or welding shops and few employed more than 10 workers.

Interest in metals manufacturing apparently quickened in 1965, and it was expected that more interest would be taken in supplying the growing local demand.

Nickel—Exploraciones y Explotaciones Mineras Izabal, S.A. (EXMIBAL), held by International Nickel Co. (80 percent) and Hanna Mining Co. (20 percent), was granted 40-year mining rights to about 385 square kilometers in northeastern Guatemala. Under the agreement, the company is to invest a total of $50 million and export at least 25 million pounds of nickel equivalent annually. A plant was planned for the production of ferronickel.

Average nickel content of all ore is reported to be 0.7 percent metal, but initial operations will be based on material containing 1.25 percent nickel. Reserves are considered to be fully adequate for long-term output.

This investment will create one of the largest single private enterprises in the country. In addition to the direct benefit of being a source of foreign exchange, the project will employ about 700 persons and open an important new section of the country for development.

It appeared at yearend that U.S. interests were also becoming interested in nickel-bearing laterite deposits adjacent to EXMIBAL's property.

Nonmetals.—*Mica.*—Mica de Guatemala mines and exports green mica, but output statistics were not available. The firm's chief activities were centered in the Zacualpa area in Quiché Department. Mica deposits of potential value are known to exist elsewhere. Output is exported to Japan and Europe in the form of block and scrap.

Mineral Fuels.—*Petroleum.*—The Abularach No. 1 San José well, reported in Volume IV of the Minerals Yearbook for 1964, suspended drilling operations in May. Casing was run to total depth of 1,727 feet. The test remained inactive for the remainder of 1965.

Esso Standard (Guatemala), Inc., was awarded exploration rights over a 396,968-hectare offshore block on the Pacific Ocean side of the country. Exploration work was initiated immediately.

Texaco, Inc., began operations at its new refinery in early 1965, helping to account for the country's 194 percent increase in refined products for the year. Capacity of the installation is rated at about 8,500 barrels a day, of which about 8,000 barrels is being used.

Refineria Petrolera de Guatemala-California, Inc., was tripling its capacity to 12,500 barrels a day. Upon completion of the planned expansion, total Guatemalan refining capacity will be about 21,000 barrels a day, compared with domestic consumption of some 10,000 barrels daily. Local consumption of products was increasing at 4 to 5 percent annually, which suggests a need for export markets if total refining capacity is to be utilized.

HONDURAS

The small mineral industry of Honduras increased output in terms of both tonnage and value in nearly all commodities in 1965. New industry starts were made in steel rolling and marble quarrying and dressing. An integrated steelmaking facility and a petroleum refinery were being considered.

The economy generally functioned on a rising scale. The 1965 gross national product, an estimated $504 [13] million (at current prices), was more than 9.5 percent greater than in the previous year, while the value of mineral output in 1965 was estimated at $13.7 million.

While only a few mining companies were actually in production in Honduras, 37 mining or petroleum firms were officially reported.

In 1965 about 1,200 persons were employed in mining; salaries were valued at $1.7 million. Taxes paid by mining companies to the Honduran Government amounted to slightly under $1 million.

Although no new laws concerning mining or petroleum were passed during 1965, a useful compendium of laws affecting business was published in English during the year. Included in the volume were translations of the mining law of 1937, amended in 1950, and of the petroleum law of 1962.[14]

PRODUCTION

The increased value of apparent mineral production in 1965, about 24.5 percent over 1964 levels, was accounted for largely by increased output of precious and base metals. Statistics on mineral production and value were incomplete in regard to nonmetals and building materials.

Silver, valued at $4.7 million, accounted for 34.3 percent of estimated total value of mineral production.

[13] Where necessary, values have been converted from Honduran lempiras (L) to U.S. dollars at the rate of L1=US$0.50.

e Estimate. NA Not available.
[1] Production commenced in May 1965.
[2] Exports.
[3] Consumption at El Mochito mine only.

TRADE

Values of mineral imports and exports, as determinable from available sources, were $10.7 million and $8.7 million, respectively, in 1965. Total commodity imports were valued (c.i.f. basis) at $121.9 million and exports (f.o.b. basis) at $126 million.

The United States supplied about 47 percent of total Honduran imports and received 57 percent of that country's exports by value in 1965.

Nonmetallic mineral exports were supplied to neighboring countries, but except for petroleum products, relatively few commodities came from Central American and Caribbean sources.

Honduran trade within the Central American Common Market group is not expected to show much increase until industrial expansion increases within the country.

COMMODITY REVIEW

Metals.—*Cadmium, Gold, Lead, Silver, Zinc.*—Increases in output of all metals mined except cadmium were attributed to expanded operations at El Mochito mine of New York and Honduras Rosario Mining Co. New records were set in tonnages mined and milled and in mill recovery percentages. Metallurgical results for gold and silver recovery were improved by finer grinding and better washing efficiency of pulp in the cyanide circuit.

An expansion plan was furthered during the year to bring milling capacity to over 700 tons daily.

Assured and probable ore reserves as of December 31, 1965, were 1,025,061 tons containing 19.1 million ounces of silver, 20,166 ounces of gold, over 70,000 tons of lead, and more than 71,000 tons of zinc.

El Mochito had 892 employees during 1965, an increase of 47 from the 1964 level.

Iron and Steel.—Aceros Industriales, S.A., commenced reinforcing-rod production at its plant near San Pedro Sula early in 1965. While the plant operated, 2,331 tons of rods was produced. The plant operated on billets imported from Europe. Only 1 shift a day was being worked, but if the planned 3 shifts are put on, monthly output of about 1,200 tons can be expected.

Plans were announced to expand production lines to include angles and shapes.

In April 1965, the Banco Central de Honduras issued a résumé of efforts to establish a local steel plant.[15] Plans at the time the report was made called for a 50,000 ton-a-year facility founded on domestic iron ore, charcoal, and limestone resources.

An iron ore source had been acquired and eucalypt plantations were started on an experimental scale as a source of charcoal. At yearend indications were that the Honduran Government was serious about establishing a domestic steel industry.

Lubricants, including greases	4,465	4,138	United States 4,031.
Paraffin, vaseline, waxes	761	648	Mainly from United States.
Asphalt and coke	449	2,746	United States 1,789.

[1] Less than ½ unit.

Nonmetals.—An unnamed Italian group was nearly ready to start processing local marble in San Pedro Sula. The marble, said to be of excellent quality, will be quarried, cut, and polished for local and export sale.

Mineral Fuels.—*Petroleum.*—Slightly less than 10.5 million hectares were under concession for oil and gas rights during 1965. Concession boundaries must be modified by May 27, 1966, in order to conform to the 1962 petroleum code that limits the

number of hectares in a concession and requires boundaries to bear north-south and east-west.

No geological or geophysical exploration activity was reported in Honduras during the year.

International Geophysical Explorations, Inc., drilled three tests on the north coast about 30 kilometers east of Tela. Two of the tests were less than 1,000 feet in depth and bottomed in igneous or metamorphic basement. Results of the third test were unreported.[16]

It was announced in late 1965 that Gulf Oil Corp. was seeking approval to build a refinery at Puerto Cortés; proposed daily capacity was to be 6,000 barrels to supply local consumption estimated at 5,000 barrels a day.[17] Estimated cost of the refinery was $12 million.

Texaco Caribbean, Inc., was also interested in establishing a refinery in Honduras at the Puerto Cortés site. It was understood at yearend that Texaco had received government approval of its project.

NICARAGUA

The economy of Nicaragua showed sustained growth in 1965 with an increase in the gross domestic product (GDP) of 9.7 percent over 1964 levels,[18] but the mineral industry did not keep pace with this growth rate. Mining, with a contribution of about $7.5 million,[19] accounted for 3.1 percent of the GDP. While the actual value of mining output rose in 1965 by 2.7 percent over that of 1964, the contribution to the GDP declined from the 1964 contribution of 10.8 percent.

No new metal mines were reported to have been put in operation during the year. However, geological surveys for mineral resources were being carried on. Results may be announced in 1966.

The largest part of mining and petroleum refining investment was held by U.S. and Canadian interests.

The Government continued to welcome foreign investment and placed no restrictions on incoming capital. Joint ventures with domestic capital were favored but were by no means obligatory.

Decree 1067 of March 20, 1965, enacted the Special Law on the Exploration and Exploitation of Mines and Quarries.[20] Publication date of the law in La Gaceta was March 24–27, 30, 1965.

The new legislation, consisting of 177 articles, replaced the Mining Code of 1906 and supplemented the General Law on the Exploitation of Natural Resources of 1958.

The newly constituted National Mining Commission was to establish fiscal and performance standards for concessionaires under the new law. Additionally it was to serve as an advisor to the Ministry of Economy on mining matters. The Minister of Economy was to serve as Chairman of the Commission. Other members named were the Minister of Finance, the President of the Central Bank of Nicaragua, and the general manager of the National Development Institute; the mining industry was to be represented by one member chosen by the President of the Republic from a list of five names submitted jointly by mining enterprises in the country. The minority party was to have a member on the Commission.

Under the new law, the Office of the Director General of Natural Resources was to be responsible for inspection and supervision of mining and quarrying operations.

Rules for exploration and exploitation of concessions were laid down, payments of guarantees, fees, and taxes were described, and measures to protect land owners, principals, and the Government were described.

Mines were differentiated from quarries; definitions and rules governing each type of activity were stated.

Industrywide reaction to the new law was not available. One company expected that "operating conditions will be not less favorable than under our present contract with the Government of Nicaragua."[21]

PRODUCTION

Gains of 10 percent and 14 percent were made in copper and silver production, respectively, while declines of 12 percent in gold output and 8 percent in petroleum refinery products were registered.

Preliminary figures published by the Banco Central de Nicaragua[22] put the value of metallic minerals produced at $14.8 million. Of this total, copper accounted for 51 percent, gold for 46 percent, and silver for 3 percent. Nonmetallic mineral output was valued at $5.1 million, and the value of petroleum refinery products was reported at $6.3 million. This figure includes the value of refinery fuel and losses.

TRADE

Preliminary figures for 1965 showed that Nicaragua's net foreign trade balance was a positive $6.3 million. The total value of exports was $143.0 million (f.o.b. basis), and that of imports was $136.7 million (f.o.b. basis). Exports of gold, silver, and copper totaled $11.3 million. There were also minor amounts of nonmetals, zinc, and scrap metals exported for which value was not available. Petroleum refinery activity was reflected in declining imports of selected products.

Metal exports went chiefly to the United States, Canada, and Europe. There were minor mineral exports to neighboring Central American countries.

In 1965 the United States supplied about 45 percent of all of Nicaragua's imports by value and took nearly 23 percent of its exports.

Trade among the Central American Common Market countries continued to increase; various trade advantages for products manufactured within the community provided incentive for manufacturing and fabricating firms to initiate new plants.

COMMODITY REVIEW

Metals.—*Copper.*—Byproduct copper concentrate production began in March at the La Luz gold-silver-copper mine of La Luz Mines Limited. The flotation circuit operated successfully and was reportedly responsible for improvement in silver recovery as well. Operations at Rosita copper mine were maintained at the expense of La Luz during a period of inadequate power.

Copper output for the fiscal year at Rosita showed an 18.8-percent increase over that of the preceding fiscal year; copper production for the calendar year 1965 increased 10.3 percent over that of 1964. Reserves at Rosita as of September 30, 1965, totaled 1.5 million tons averaging 3.91 percent copper and 0.079 ounce of gold per ton, sufficient for 5½ years' operation at plant capacity. The total number of employees during the fiscal year averaged 477.

Gold and Silver.—The tonnage of ore milled by La Luz Mines Limited during the fiscal year ended September 30, 1965, declined 2.5 percent from that milled in 1964. The decline was reportedly the result of lack of power during the dry season, maintenance work on the hydroelectric plant, and failure of the skip hoist motor.

Gold output for the fiscal year was 56,048 troy ounces, and silver output totaled 26,641 ounces.

Positive ore reserves for 1965–66 were put at 3.0 million tons averaging 0.101 ounce of gold; possible reserves were announced at 4.2 million tons averaging 0.096 ounce.

Employment averaged 1,133 persons during the year.

Empresa Minera de El Setentrion, controlled by Noranda Mines Ltd., produced 56,072 ounces of gold and 14,638 ounces of silver.

Production at the Neptune Gold Mining Co. of the American Smelting and Refining Co. was not made public in 1965.

Iron and Steel.—Rheen International, Inc., expected to establish a joint venture with domestic interests for the manufacture of steel drums for lubricants and chemicals.

The Dutch firm of Van Leer also expected to establish a steel drum and cylinder manufacturing facility.

A new firm, Aceros Nacionales, S.A., was established to produce steel rods and angles.

Nonmetals.—*Chemicals.*—A base for establishing a chemical complex in Nicaragua was created in September by the formation of Electro-Quimica Pennsalt, S.A. (ELPESA) and Hercules de Centroamerica, S.A. (HERCASA). ELPESA will produce caustic soda, chlorine, hydrogen, and hydrochloric acid. HERCASA will manufacture chlorinated camphene insecticides. Both firms are joint investments of U.S. and Central American capital, with the latter holding the majority interest.

The Central American Bank for Economic Integration authorized loans of $1.7 million and $1.1 million for ELPESA and HERCASA, respectively.

Nicaragua was granted monopoly status for the caustic soda-insecticide complex by the Central American Common Market in accordance with its Protocol.

The two plants represented an investment of $6.4 million.

Fertilizer Materials.—Interore de Centro America S.A., owned in equal shares by local farmers and the Occidental Petroleum Corp. of Los Angeles, was formed to produce mixed fertilizers. The compounding and mixing plant will be located at Corinto, 144 kilometers from Managua. Initial capacity will be 75,000 tons of mixed fertilizers a year.

Mineral Fuels. — *Petroleum.* — Interest in offshore leasing increased during 1965. Although only 300,000 hectares were held under lease in early 1965, it was reported that at yearend 1.2 million hectares were held in concessions and an additional 1.2 million hectares had been filed upon.

Applications covered the offshore areas on both the Atlantic and Pacific coasts.

Only 2½ party-months of marine seismic work was done in 1965, but it was expected that the various companies involved would start prospecting work as applications were granted.

Esso Standard Oil S.A. Ltd. refined 1.7 million barrels of crude oil in 1965 at its refinery near Managua. Plans were announced to double the plant's refining capacity to approximately 11,000 barrels of crude oil per day. Cost of the expansion was estimated at $4.6 million.

Esso, with the only refinery in the country, supplied the three other distributors, Texas Petroleum Co., Shell Oil Co., and Standard Oil Co. of California (Chevron).

PANAMA

Except for refined petroleum, Panama's limited mineral industry produced only salt, construction materials, and semimanufactures of aluminum and steel. The metals and petroleum refining segments were founded on imported raw materials.

Value of domestic mineral production in relation to the gross domestic product is minuscule.

In August 1965 the Government and the United Nations Special Fund agreed to conduct a minerals survey over 20,000 square kilometers covering the Azuero Peninsula and a belt north to the Caribbean coast. The survey was scheduled to take 3 years and to cost about $1.4 million.[23]

The purpose of the project is to assess mineralized zones in order to outline a mining development plan which, it is hoped, will attract investment. The plan calls for airborne geophysical surveys, regional geological and geochemical examinations, and in-service training of selected staff members of the Panama Department of Mineral Resources.

The Agency for International Development is sponsoring a minerals investigation program to determine the resources of the Santiago-Chitre-Aguadulce area. Exploration will be aimed primarily at agricultural-use minerals for local consumption. The contract was signed in October 1965, but status of the work was not known at yearend.

A consortium of three companies planned a rural cadastral survey. Financing was to be partly provided by the Agency for International Development in accord with an Alliance for Progress Loan Agreement between the Republic of Panama and the United States. While this survey is not aimed primarily at mineral resources, the nature of the work does not preclude discovery.

Some interest in acquiring concessions covering the mining of gold, iron-bearing beach sands, manganese, and copper was reported, but there were no concrete plans for development in evidence by yearend.

Late in 1965, it was announced by Panamanian interests that financing had been arranged for test drilling on oil concessions held in the Provinces of Panama and Darien.

The Government of Panama was trying to promote interest in local bauxite resources. Two U.S. companies examined the deposits some years ago but apparently were not particularly impressed by the results.

There were no significant changes in government mineral legislation or policy.

PRODUCTION

Output of minerals, metals, and petroleum products showed irregular movement for 1965 in comparison with 1964 results. Banner performances on the plus side were shown in volumetric output of cement and petroleum refinery products with increases of 32.3 percent and 12.5 percent, respectively; production of motor gasoline alone increased 19.4 percent over the previous year.

Some new aluminum products were added to the aluminum manufactures, particularly low-pressure cylinders for bottled gas. A widespread market was expected to develop in Central and South America for the cylinders.

In achieving record production in 1965, Cemento Panamá, S.A., reportedly operated at 80 percent capacity. Some thought was apparently given to increasing the plant's capacity by 500 tons per day; this would bring theoretical daily production capability to 1,130 tons.

Expansion was also reported at the locally owned plant of Concreto, S.A. Production statistics are not available, but the firm was the major Panamanian supplier of concrete pipe and forms and ready-mixed concrete.

TRADE

Total imports during 1965 amounted to $208.5 million, compared with total exports of $69.0 million, resulting in a negative trade balance of $139.5 million.

The United States was Panama's best customer, receiving about 61 percent of all exports; Panama imported 42.3 percent of all its goods from the United States. This is in accordance with traditional trade patterns.

---

[23] Where necessary, values have been converted from Panamanian balboas (B) to U.S. dollars at the rate of B1=US$1.

[1] Fabricated or processed from imported raw materials.

[2] Fiscal year ending Oct. 31.

[3] Panama also produces sand and gravel and crushed rock.

[4] Does not include fuel oil consumed in refinery.

Trade in crude petroleum and products comprised the largest part of Panama's overseas business by value. In 1965, value of imported crude and partly refined petroleum was $40.8 million, and that of products was $2.3 million. In the same year, products valued at $23.7 million were exported.

About 96 percent of crude imports came from Venezuela, and Colombia supplied the remainder. Product exports went chiefly to Canada, the Canal Zone, the United States, and the United Kingdom.

Recorded petroleum exports to the Canal Zone must be considered with care and are probably not a true reflection of trade. The reason for this is that ordinarily an undetermined quantity of products is merely stored in the Canal Zone for eventual reentry into Panama. Fuel sold at the airport for international jets is not tabulated as an export.

The following table compares imports of petroleum commodities for 1964 and 1965:

Commodity	Value (thousand dollars) 1964 (f.o.b. basis)	1965 (c.i.f. basis)

COMMODITY REVIEW

Metals.—*Aluminum.*—The name of the only aluminum extrusion plant in Panama, Ingeniera Amado, S.A., was changed to Aluminio de Panamá, S.A., although ownership was retained by the Amado family. In addition to various types of aluminum tubing, frames, bars, and jalousies, the company manufactured corrugated aluminum and galvanized roofing. The roofing segment of the business had sales of about $400,000 in 1965, while sales value of other aluminum products totaled between

$600,000 and $700,000. Over 65 percent of sales were made in the domestic market, with some exports to Costa Rica and Nicaragua. Extrusions are manufactured from imported billets, and roofing sheets are made from imported aluminum and galvanized sheets.

An aluminum anodizing facility was installed during the year.

Sealgas, S.A., jointly owned by Aluminio de Panamá and Tropigas of Miami, Fla., began production of low-pressure aluminum cylinders for the bottled gas trade. Demand for such containers was high, and the value of 1965 production was reported at about $300,000. The cylinders were made from sheet aluminum imported principally from Japan. About one-half of the first year's output was sold in Central American countries.

Iron and Steel.—At yearend, Productora de Acero y Afines Asociada, S.A., was organized to engage in the manufacture of iron and steel products. Ownership reportedly was held by Panamanian, U.S., and Jamaican interests. The proposed plant location was on Las Minas Bay, adjacent to property owned by Refinería Panamá, S.A.; arrangements were made to use the dock facilities of the refinery.

The plant was planned to operate on imported steel ingots (100,000 tons annually) and produce reinforcing rods, beams, angles, and other semimanufactured products. At yearend, there were no reports of plant construction.

Acero Panamá, S.A., the only operating steel establishment in Panama, began the installation of its 3-ton Brown Boveri electric furnace and two Sulzer diesel genera-

tors, which were expected to permit the processing of as much as 24 tons of scrap metal daily. In 1965, the mill worked on ingots principally imported from Belgium. Production of barbed wire, staples, and cyclone fencing was inaugurated during the year, using imported galvanized wire as a base. The company was investigating the possibility of producing drawn wire; a galvanized iron pipe facility was also under consideration, probably to be under a joint-venture arrangement.

The company output of reinforcing rods, small shapes, and other products was 11,000 tons for its fiscal year ended October 1965; this was a slight decrease from the previous year's attainment.

Nonmetals.—*Cement.*—Cemento Atlántico, S.A., which had been expected to enter into production in 1965, did not complete its facilities. Work on the plant and port amenities was still in progress at yearend.

Salt.—Production, refining, and distribution of solar salt is controlled by the Government's Institute for Economic Development. Value of production in 1965 was estimated at about $280,000. Imports of specialized salt forms supplement local output.

Mineral Fuels.—*Petroleum.*—No drilling or exploration activity was reported in 1965. Some petroleum concessions were allowed to lapse during the year, but it was believed that some 2.5 million hectares were held by local companies and individuals.

Refinería Panamá, S.A., the only petroleum refinery in Panama, was jointly owned by the Continental Oil Co. and National Bulk Carriers, Inc. It was reported [24] that Ultramar, Ltd., had begun to exercise an option to acquire a one-third interest in the refinery. When Ultramar completely exercises its option, the three companies will each hold a one-third interest in Refinería Panamá, S.A.

Consumption of petroleum products in Panama continued to rise in 1965. Rough estimates put the increased use of selected fuels over 1964 figures, in terms of percentage, as follows: Aviation gasoline 4, motor gasoline 10, jet fuel 10, and kerosine 3 to 4.

Refinería Panamá, S.A., processed 16.9 million barrels of crude and partly refined oil during 1965.

The Mineral Industry of the Islands of the Caribbean

By Burton E. Ashley [1]

Contents

CUBA

Information on mineral production, processing, and trade of Cuba remained scanty throughout 1965; statistics presented in this chapter are incomplete, estimated, and/or unverified but they are considered it is felt, adequate to make comparisons with mineral industry activities of previous years.

Late in 1966, information relating to production and trade of selected mineral commodities for 1963 and 1964 became available from Cuban Government sources.[2] This was the first official production data available to the Bureau of Mines since about 1960.

In terms of percentage contribution to the State industrial production in 1964, petroleum and derivatives accounted for 9.4 percent, mining 2.5 percent, and construction materials 3.9 percent; metallurgy combined with metal manufacturing contributed a total of 4.5 percent.

The monthly average number of persons at work in the mining industry in 1962, 1963, and 1964 was 16,936, 18,677, and 14,375, respectively; the average monthly salary in the mining industry during 1964 was $161.[3] Average monthly salaries in other industries during 1964 ranged from $151 in textiles and leather to $254 in electrical energy. Petroleum workers averaged $250 monthly, near the top of the wage scale.

PRODUCTION

Production data for 1961 and 1962 are estimates identical to those published in the Minerals Yearbook, volume IV, for 1964; data for 1963 and 1964 are revised from earlier Cuban publications and were taken from official Cuban Government sources; while figures for 1965 are estimates based on January to June output totals released by Cuban sources.

The preliminary total value of State industrial gross production in 1964 was reported as $2,516 million. Part of this total was made up of mining output, $62.4 million; production of petroleum and its derivatives, $236.2 million; construction materials output, $98.1 million; and chemical production, $242.2 million. Output of metallurgical and metal manufacturing facilities reportedly totaled $111.8 million.

Data in the production table for nickel and cobalt are listed as recoverable content in oxides and sulfides. These figures are based on gross weights of nickel and cobalt oxides and sulfides reported by Cuban authorities. The figures for recoverable content were arrived at by using factors of 78 percent combined nickel-cobalt in the

oxide and 55 percent nickel and 5 percent cobalt in the sulfide material (dry basis).

TRADE

No official statistics on Cuban trade are available for 1965; the most recent official trade reports cover 1963 and 1964 but are incomplete. These data indicate that 1964 exports of nickel industry products were valued at about $32.3 million while values for other mineral exports were: Other nonferrous metal products—$7.0 million, petroleum products—$185,723, and nonmetallic mineral products—$4,498.

Table 2.—Cuba: Exports of selected mineral commodities
(Metric tons)

Commodity	1963	1964	Principal destinations, 1964

Source: Junta Central de Planificacíon, Dirección General de Estadística. Comercio Exterior de Cuba. Havana, 1965.

Exports of all commodities from Cuba to non-Communist countries (as measured by import statistics of these countries) went primarily to Morocco, Spain, Japan, the United Kingdom and France, and totaled $123.1 million in 1965. However, in this total, Spain received no minerals, and Japan's receipts were almost entirely iron and steel scrap.

Polish trade publications provide the following data on imports from Cuba for 1964 and 1965 in metric tons. The 1964 data generally correspond to reported Cuban exports but include some materials not reported in Cuban sources.

Commodity	1964	1965
Chrome ore	---	4,223
Copper concentrate	6,489	4,410
Manganese ore	25,015	45,807
Nonferrous concentrates, other	---	299
Phosphatic fertilizers	49,000	54,000

Official Cuban import data for 1963 and 1964 do not provide information on the sources of commodities. However, comparison of data published in Soviet sources indicate that through 1964, the U.S.S.R. was by far the largest supplier of Cuban imports. Moreover, these sources indicate that Soviet shipments of most mineral commodities to Cuba in 1965 exceeded those of 1964. Also, Soviet sources list exports to Cuba of mineral commodities that do not appear in the partial Cuban trade returns.

The value of Soviet mineral exports to Cuba in 1965 as reported in Soviet sources totaled $98 million,[4] slightly more than 9 percent greater than in 1964.

Inconsistencies apparently are due to the time lag between shipments and receipt of the material in question.

In addition to the U.S.S.R., other Communist nations also report exports of mineral commodities to the island. Yugoslavian sources record the shipment of about 1,900 tons of metals valued at $222,000 in 1965, including copper pipe and tube, aluminum sheet and plate, and steel barbed wire and wire netting. Polish sources report exports of 36,000 tons of coal, 5,000 tons of coke, 5,000 tons of salt, and about 800 tons of petroleum products during the two years, 1964 and 1965.

Canada, the United Kingdom, Spain, France, and the United Arab Republic (Egypt) reported total commodity exports valued at $152.1 million to Cuba in 1965. Among these imports were relatively minor quantities of mineral commodities, the most prominent of which were fertilizers, iron and steel semimanufactures, and sulfur.

[4] Where necessary, values have been converted from rubles to U.S. dollars at the rate of 1 ruble =US$1.10.

The value of Cuba's foreign trade (as available) for all commodities is shown in the following table:

	(Million dollars)		
	Communist countries	Other countries	Total
Imports:			
1964	592	285	877
1965	NA	208	NA
Exports:			
1964	416	293	709
1965	NA	185	NA

NA Not available.

Source: International Trade Analysis Division, Bureau of International Commerce, United States Department of Commerce.

Reported administrative changes in Cuban foreign trade involve two new agencies. Cubaexport will deal with all commodities except sugar and tobacco and will work toward increasing exports. Ferriimport will manage the import of all hardware; in addition, this agency will also have the responsibility for domestic distribution of such imports. Whether Cubaexport has replaced Cubametals is not known.

COMMODITY REVIEW

Metals.—*Iron and Steel.*—Expansion of Cuba's iron and steel industry was progressing. In Santa Clara a steel foundry was being built for Fabric Aguilar Noriega. Costing an estimated $700,000, the plant was slated to produce 5,000 tons of steel annually for the fabrication of parts. Equipment for the plant was to be obtained from Poland.[5]

Three other plants, La Antillana de Acero, Cabillas Cubanas, and Aceros Unidos were also reported to be undergoing modernization and expansion. Antillana de Acero's annual capacity will be raised from 80,000 to 350,000 tons. The total program, to be phased over an unspecified period of time, will require investment of $59 million.[6]

Nickel.—Late in 1965 press reports announced that Société Le Nickel of France had made purchases of Cuban nickel. This posed a problem with regard to imports of nickel-bearing materials into the United States from France, as any materials containing Cuban nickel would be barred from U.S. markets. After various discussions between representatives of the French and U.S. Governments, the matter was resolved, and it was agreed that technical and control measures could be satisfactorily applied which would preclude products with Cuban nickel content reaching the United States.

Nickel sinter was produced at Nicaro, and output there was reported to be 14,790 tons in 1963 and 15,701 tons in 1964. Sinter was not reported on the production table in order to avoid duplication.

Nonmetals.—*Fertilizer materials.*—Production of some fertilizer materials was recorded in the Cuban statistics for 1963 and 1964. Output of "complex fertilizers" decreased from 16,989 tons in 1963 to 8,016 tons in 1964. In 1964 fertilizer classified only as "for cane" amounted to 159,036 tons; during the same year, 262,961 tons, also unidentified, were produced for use in "other cultivation."

Mineral Fuels.—Cuba and the U.S.S.R. concluded a treaty to conduct offshore marine seismic surveys to determine possibilities for petroleum production. Toward this end, the Soviet survey ship "Vladimar Obruchev" was reportedly assigned to Cuban waters. The ship is rated at about 800 tons and carries about 70 technicians and crew. It was reported that no Cubans were assigned to the craft. Exploration, not expected to commence until early 1966, will be conducted over a period of 2 years; it was expected that about 500 kilometers of profiles would be recorded during the investigation. Reported estimated cost of the complete job was $1.4 million.

Some onshore drilling was completed during 1965, but seemingly there were no significant discoveries. A years' program of marine exploration work was being conducted by Cuban nationals with Soviet advice and technical help. Three crews, each of 25 to 30 men, were carrying out oil exploration programs on land.

Salary scale for exploration personnel reportedly ranged from $120 to $150 a month for laborers and between $175 and $200 a month for men working on instruments; a geophysicist receives a higher rate.

DOMINICAN REPUBLIC

Incomplete data on mineral commodity production in the Dominican Republic during 1965 showed decreases in nearly all categories. The one bright facet was the nearly 24-percent tonnage increase in bauxite shipments compared with those recorded in 1964. In 1965 the Dominican Republic accounted for about 2.5 percent of world bauxite output. Other minerals were not produced in quantities of world significance, but requirements for mineral construction materials and salt were largely satisfied by domestic production. Lower output levels for such mineral commodities were no doubt attributable to interruptions in output stemming from the civil disturbances which began in April. The increased quantities of bauxite that were shipped indicate that this segment of the industry escaped interruption, probably because of its isolation from the principal areas of disturbances.

Production values of the various mineral and metal commodities have not been available since 1962. However, the contribution of the industry to the gross domestic product, estimated at $700 million in 1965, could not be reckoned as significant.

Late in 1965 an Emergency Fund was established by the Provisional Government to stimulate recovery in the industrial and agricultural sectors that had experienced interruption because of civil disorder. It was reported that applications for a share of these funds had been made by the salt and other unspecified mineral industries.

Yearend 1965 brought the expiration of the law requiring payment of a special duty at the rate of 50 cents a sheet on imports of corrugated iron and galvanized steel. It was expected, however, that this law would be repromulgated.

PRODUCTION

Shipments of bauxite increased nearly 24 percent over those of 1964; actual production figures were not available, and it is expected that shipments will be recorded in the future, but because there is no domestic consumption, shipments are regarded as a reasonable measure for actual salable output.

Figures for salt production during 1964 and 1965 were obviously incomplete. This is particularly evident in respect to 1964 when official trade figures which became available in 1965 recorded salt exports of more than 21,000 tons and no salt imports.

TRADE

The Dominican Republic's total trade is given in the following tabulation for the most recent years for which data are available:

	Value (thousand dollars)		Mineral commodities share of total (percent)
	Mineral commodities	Total trade	
Exports:			
1963	$9,899	$174,136	5.7
1964	9,069	179,383	5.1
Imports:			
1963	31,831	160,285	19.9
1964	26,130	192,373	13.6
Trade balance:			
1963	−21,932	13,851	XX
1964	−17,061	−12,990	XX

XX Not applicable.

Source: Republica Dominicana, Oficina Nacional de Estadística. Comercio Exterior—1964. V. 12, Santo Domingo, February 1966, 323 pp.

Import value of mineral fuels in 1964, the latest year for which statistics are available, amounted to $13.4 million, which was equivalent to about 51 percent of all mineral imports; in relation to total imports, mineral fuels accounted for 0.7 percent of value.

Bauxite, all of which went to the United States, was the largest single mineral export by value and accounted for 97.7 percent of total mineral export value in 1964. In terms of total trade, the United States took 63.1 percent of the country's exports in 1964 and furnished slightly more than 50 percent of all imports.

In regard to petroleum imports, the United States furnished a substantial part of lubricants required; Venezuela and the Netherlands Antilles supplied the bulk of all other products.

Incomplete figures for 1965 indicate the likelihood of a considerable decrease in exports compared with 1964 statistics. It was estimated that total 1965 exports by value might show a decline of about 40 percent from the previous year's level although export sales of bauxite were higher than in 1964 by about $2 million.

COMMODITY REVIEW

Metals.—*Bauxite.*—No change was reported in the bauxite operations of the Aluminum Company of America in the Dominican Republic in 1965; all shipments were consigned to Point Comfort, Tex. The company employed about 375 persons.

Nickel.—Pilot plant operations of Falconbridge Nickel Mines Ltd. subsidiary, Minera y Beneficiadora Falconbridge Dominicana C. por A., were still in progress and experimental production continued. The company reported that unsettled conditions within the country resulted in postponement of plans for a commercial plant, although a decision was made to enlarge the pilot plant. Diesel generators and other unspecified equipment were ordered for the proposed expansion. Shutdowns were necessary in March and December of 1965 for major repairs.

According to various trade magazines, total expenditure to mid-1965 amounted to some $6 million. Estimated daily output was about 1 ton of ferronickel containing about 50 percent nickel.

Metal Manufactures.—The joint project of the Corporación de Fomento Industrial and Camer International, S.A., to establish a complex of seven light industries to manufacture metal products had not been completed by yearend. A portion of the machinery had arrived and some construction had been completed. Project delay reportedly was due to financing problems.

Nonmetals.—*Fertilizer Materials.*—It was reported late in 1965 that Sun Ray DX Oil Co. of Tulsa, Okla., was interested in the possibility of establishing a plant to produce nitrogenous fertilizers in the Dominican Republic. Estimated cost of the proposed plant was between $7 million and $10 million.

Salt.—Gonzales, C. por A. reportedly had plans to increase salt output to supply the domestic market. A loan of $13,000 was requested from the President's Emergency Fund to expand facilities.

Mineral Fuels. — *Petroleum.* — Exploratory oil well drilling, which started in 1964, was suspended early in 1965 because of the outbreak of the civil disturbance; drilling had not been resumed at yearend. La Sorpresa-1, 14 kilometers southeast of La Vega, was shut down at 1,400 feet; Bani-1, 4 kilometers from Bani, had been drilled to 2,487 feet before suspension of operation.

No progress was reported in regard to construction of proposed refinery capacity described in Volume IV of the 1964 Minerals Yearbook. Political and economic conditions in the country during 1965 brought such investment activity to a halt.

HAITI

The mineral industry of Haiti continued to have significance only in relation to the domestic economy. Value and quantity of production made little impact when compared with world figures; as a source of bauxite and copper, Haiti supplied only 0.9 percent and 0.1 percent, respectively, to world markets in 1965.

Haiti's trade in minerals and metals was kept in favorable balance by exports of bauxite and copper although nearly all domestic requirements for mineral industry products were met by imports.

Because of incomplete data, it is not possible to determine the exact contribution of the mineral industry to the Haitian gross domestic product in 1965, but the apparent absence of any great change in the nation's economy leads to the assumption that this was close to the plus 2 percent share that the industry provided in 1964 and 1963.

There were some indications of possible increases in activity in the minerals field. A proposal was made for investment from the United States in marble quarrying. Furthermore, a joint venture was undertaken by three U.S. companies and one Canadian company to carry out a minerals exploration program in northern Haiti. It was also reported that Haitian and Canadian interests were forming an association to develop a gold prospect in northern Haiti.

No progress has been reported on construction of the proposed oil refinery.

PRODUCTION

Output of all reported mineral categories decreased in 1965. Bauxite, Haiti's most valuable mineral export, showed a production loss of 14.1 percent, and copper contained in concentrates decreased 21.3 percent in production. Cement output was nearly 25 percent lower than in 1964.

Available information does not explain the decreased production in any particular case. However, it was reported that during the year, business in general was slow, unusually heavy rains fell, and in some cases, new labor contracts were negotiated; any or all of these factors might have had a slowing effect on mining activities.

Table 8.—Haiti: Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	1964	1965

TRADE

The following table shows the relationship of mineral trade to total commodity trade for Haiti for 1963 and 1964, the latest years for which complete data were available:

	Value (thousand dollars)		Mineral commodities share of total (percent)
	Mineral commodities	All commodities	
Exports:			
1963	$7,478	$43,212	17.3
1964	6,984	37,962	18.4
Imports:			
1963	4,178	36,014	11.6
1964	4,417	35,901	12.3
Trade balance:			
1963	+3,300	+7,198	XX
1964	+2,567	+2,061	XX

XX Not applicable.

Note: Data are for fiscal years ending September 30.

Source: L'Administration Générale des Douanes. Rapport Annuel, pour L'Exercise Octobre 1963-Septembre 1964. Undated. 123 pp.

Bauxite and copper concentrate remained the only mineral commodities produced in Haiti for which exports were recorded. In 1964, value of bauxite exports was listed as $3.9 million and that of copper as $3.0 million. In addition, slightly less than $10,000 worth of scrap iron was shipped overseas. The United States and Japan remained the chief destinations of exports.

Imports to the extent of $4.4 million went to satisfy Haiti's need for minerals and metals in 1964. Of the total, $3.0 million, or 67 percent, was expended on imports of mineral fuels and petroleum. The next largest single category of imports by value was iron and steel semimanufactures. Crude oil and petroleum products came mostly from Trinidad and the Netherlands Antilles while the United States, Belgium, and West Germany supplied most of Haiti's metal requirements.

In terms of 1964 trade, the United States supplied 58.4 percent of all Haitian imports and took 47.4 percent of all exports.

COMMODITY REVIEW

Metals.—*Copper.*—Consolidated Halliwell Limited reported ore reserves as of January 1, 1965, as 285,310 tons, averaging 2.12 percent copper, with an additional possible 54,000 tons averaging 2.2 percent metal. Announcement was made in early 1965 that a combine of four firms would become associated in an exploration program over the northern part of Haiti. Participants in the venture were Guggenheim Exploration Co., Reynolds Metals Co., Cerro Corp., and Consolidated Halliwell Limited. Halliwell's present mining property and an adjacent property are to be excluded from the deal.

Mineral Fuels.—*Petroleum.*—There was no exploration or drilling for oil carried out in Haiti during 1965.

Consumption of refined petroleum products in Haiti has been reported as follows, in 42-gallon barrels:

Products	1963	1964	1965
Aviation gasoline	9,000	10,186	5,699
Aviation jet fuel	NA	NA	16,977
Motor gasoline	235,000	227,453	214,370
Distillate fuel oil	296,000	364,448	295,252
Residual fuel oil	156,000	195,067	151,695
Lubricants	16,000	19,270	11,133
Other	5,000	12,384	[1] 39,307
Total	717,000	828,808	734,433

NA Not available.

[1] Includes kerosine (22,242 barrels).

JAMAICA

Jamaican bauxite mining operations set new production records in 1965, keeping the nation ahead of all other producers and accounting for 23.4 percent of total world output. The island's mineral industry remained undiversified, essentially consisting of bauxite mining and alumina producing, petroleum refining, and a construction materials sector. In total, the output of these operations was valued at $81.0 million [1] in 1965, 12 percent higher than the $72.2 million figure recorded for 1964 output. For comparison, Jamaica's gross domestic product (GDP) for 1965 was valued at $818.7. Of the 1965 mineral product value total, $73 million was attributed to the bauxite and alumina producing sector of the minerals industry.

The petroleum refining industry completed its first full year of production in 1965; as a result, the combined contribution of quarrying and refining sectors rose sharply from $5.0 million in 1964 to $8.0 million in 1965. Increased refinery requirements for crude and partly refined oil were reflected by the increase in value of imports of these commodities from $8.4 million in 1964 to $27.7 million in 1965.

Construction activity maintained a high level in 1965 as reflected in general production gains of construction materials.

Jamaica's general economic situation continued to expand, with the exception of agriculture, but unemployment, estimated at 16 percent, and balance of payments showed no improvement over the previous year. Per capita income in 1965 was $407.68, a rise of about 3.5 percent over the 1964 level.

PRODUCTION

Bauxite output (in net dry tons) reached new records with an increase of 9.6 percent over the 1964 total. Recorded alumina production, however, decreased 0.5 percent from the 1964 figure to 753,000 tons in 1965.

For fiscal years 1964–65, government revenue from bauxite and alumina in the form of royalty and taxes amounted to $18.5 million.

Increased output of cement and construction materials were indicative of sustained construction activity. Local cement sales rose more than 18 percent above 1964 sales.

Esso West Indies Ltd. contributed significantly to the economy by supplying petroleum products for local use, as well as for export.

[1] Where necessary, values have been converted from Jamaican pounds (J£) to U.S. dollars at the rate of J£1 equals US$2.80.

TRADE

The following table compares the value of total trade with trade in mineral commodities and shows the importance of minerals, particularly exports, in the pattern.

	Value (thousand dollars)		Mineral commodities share of total (percent)
	Mineral commodities	All commodities	
Exports:			
1963	$84,864	$201,922	42
1964	100,449	218,096	46
Imports:			
1963	38,905	225,519	17
1964	52,925	281,765	19
Net trade balance:			
1963	+45,959	−23,597	XX
1964	+47,524	−63,669	XX

XX Not applicable.
Note: Conversion of values made at the rate of J£1 equals $2.80.

Source: Jamaica Department of Statistics. External Trade of Jamaica—1964. 1965, 375 pp.

While total commodity trade showed an unfavorable balance, trade in mineral commodities remained favorable because of the 1965 value of bauxite exports, $49.8 million, and alumina exports, $48.7 million. All bauxite exports were directed to the United States; Canada and Norway received the bulk of alumina shipments.

Export sales of gypsum in 1965 totaled $634 million, all of which went to the United States. Other Jamaican mineral products of export importance included cement, fertilizer materials, and petroleum.

Exports of petroleum products, all produced from imported crude oil, showed a substantial increase in 1965. Except for some fuel oil and lubricants consigned to the United States, petroleum product trade was directed to neighboring islands of the West Indies.

Imports of petroleum products, mostly from Venezuela, the Netherlands Antilles, and Trinidad, decreased considerably.

Imports came mostly from the United Kingdom and Canada, but the United States supplied construction materials and some chemicals. Fertilizer materials and some metals came from Europe. In terms of total visible trade, United Kingdom, United States, and Canada received approximately 81 percent of Jamaica's exports and supplied 66 percent of its imports. The United States ranked first among Jamaica's trading partners in 1965 in terms of both exports and imports. Venezuela, supplying $22.1 million worth of crude petroleum in 1965, ranked fourth as a trading partner.

COMMODITY REVIEW

Metals.—*Alumina and Bauxite.*—Alcan Jamaica Ltd., one of the island's four bauxite producers and its only alumina producer, recorded a slight decline in alumina output in 1965, but alumina plant expansion announced in 1964 was well into its second phase by yearend. Construction of three of the five planned precipitator tanks was underway, and work on the new thickener tanks was nearing completion. The company reported that its total annual alumina capacity in Jamaica would be 830,074 tons when construction is completed.

Alcoa Minerals of Jamaica, Inc., attained a production rate in 1965 of 60,963 dry tons of bauxite a month. Shipments, in net dry tons, for the year totaled 727,310 tons, of which 152,616 tons went to the U.S. stockpile.

Kaiser Bauxite Co. mined a record 5,030,083 tons of bauxite (wet) during 1965, of which 48,293 tons of high silica material was destined for use by non-Jamaican producers. The company continued premining development work on its Dry Harbour Mountain property on the north coast. Shipping and rail facilities were still under construction at yearend.

Reynolds Jamaican Mines, Ltd., announced plans for an additional ore conveyor system which could double the present annual shipments of approximately 2 million tons. Proposals call for a 10.4-kilometer conveyor system from the ore driers at Lydford to the port at Ochos Rios; mining and storage facilities will also be expanded.

The four operating bauxite companies in Jamaica were served with a 31-point claim by the National Workers Union, which represents some 5,000 workers. Chief demands were for a profit sharing scheme based on the companies' international position, a cost of living escalation clause, and a 15-percent end-of-project bonus for construction workers. At yearend there had not been any report of action taken.

The Jamaican Bauxite Union called for greater alumina output within the country in order to help the domestic economy.

There were indications of the formation of a consortium to produce additional alumina in Jamaica, but no firm announcement had been made by yearend.

The agreement between Jamaica and the United States under which bauxite shipments to the U.S. stockpile were contracted was fulfilled late in 1965.

Iron and Steel.—The Caribbean Steel Co. purchased a 33-acre plant site for a steel mill at Gilpin, Spanish Town. It was reported that site preparation, access roads, office building and fencing had been completed. Major machinery was ordered and contracts were set for plant erection.

The mill, due for completion in 1966, will operate on scrap; planned annual ingot capacity is 30,000 tons, with rolling mill capacity for 18,000 tons of reinforcing bars. The plant will operate on a one-shift basis. Products will receive protection under the Industrial Incentives Law.

Cost of the plant was estimated at around $2.8 million. Caribbean Cement Co., Ltd., announced that it had purchased one-half of the equity capital. Other financing will come from Jamaican Government sources, and possibly through public subscription in Jamaica.

Nonmetals. — *Cement.* — The Caribbean Cement Co., Ltd., set new production and sales records in 1965. Gross revenue of $8.1 million increased $1.2 million over the 1964 figure. Despite higher sales, earnings of $1.6 million were only the third highest registered by the company as a result of higher wages and depreciation charges as well as increased cost of reconditioning operating equipment.

Clays.—A study and classification of Jamaican clays aimed at increasing the utilization of this resource was proposed but by yearend no concrete action had apparently been taken.

Fertilizer Materials.—It was announced in the press that Albatros Chemical Co. of the Netherlands and Imperial Chemical Industries, Ltd., of Great Britain planned establishment of a facility in Jamaica to produce about 40,000 tons of nitrogenous, potassic, and phosphatic fertilizers annually. Estimated cost of the plant is between $3 million and $4 million.

Mineral Fuels.—Supplementing information published in the 1964 chapter, it has become evident that the lubricating oil plant run in connection with Esso West Indies Ltd.'s oil refinery is strictly a blending facility. Base stocks are imported from the United States for blending and packaging. The plant is not owned by Esso West Indies but rather by Esso Standard Oil, Ltd., S.A., an affiliate of Standard Oil Co. of New Jersey.

No petroleum exploration activity was reported in Jamaica during 1965, nor were any leases held.

H. R. Greiner of the University of New Brunswick, Canada, prepared a report on the gas and petroleum possibilities of the island. According to advance notices, Mr. Greiner's study was to be based largely on the results of previously completed exploration. Publication of the report was scheduled for early in 1966.

THE NETHERLANDS ANTILLES

The economic strength of the Netherlands Antilles continued to depend largely upon the petroleum refining industry: Shell Curaçao, N.V., located on the island of Curaçao, and Lago Oil and Transport Co., Ltd. (Lago) on the island of Aruba. Unemployment was one of the immediate problems of the Netherlands Antilles; it is estimated that a quarter of the country's work force was unemployed in 1965. This situation was aggravated by the decreasing number of jobs available in the petroleum industry, which in 1965 employed some 6,300 persons. This was about one-half of the number of jobs available in 1960. It was expected that this erosion of refinery jobs would continue into 1966.

In 1965, oil refineries made a direct contribution of 24 percent to net national product of $221.5 million.

A new pension plan was put into effect by Lago in 1965. Under the plan, funds are to be contributed by both employer and employee. The new plan was in addition to the previous plan of which the company paid the entire cost.

No expansion of the mineral producing industries was announced during 1965. However, it was announced in 1966 that plans for the erection of an aluminum plant on Curaçao have been abandoned. This was to have been a joint effort involving Société Tréfimétaux, Kaiser Aluminum and Chemical Co., and the Netherlands Government.

It was reported that subsequent to a survey the construction of a $800,000 iron smelting furnace was being considered by the Zoellner Corp. on Aruba, however, no further details were available at yearend.

It was also reported that S.E.L. Maduro and Sons planned to erect a plant to process byproducts from the Shell refinery. Unidentified foreign capital was reportedly slated to participate in the project.

TRADE

Total Netherlands Antilles' imports and exports declined again in 1965, with mineral imports and exports recording an even more rapid decline than the totals, thus mineral commodities were less significant in total trade in 1965 than heretofore. Despite these declines, however, mineral commodities, almost entirely petroleum and its products, retained their position of overwhelming dominance in trade, accounting for 97.8 percent of all exports and 82.8 percent of all imports in 1965 as shown below:

	Value (million dollars)		Mineral commodities share of total (percent)
	Mineral commodities	All commodities	
Exports:			
1963	652.3	658.4	99.1
1964	622.1	629.9	98.8
1965	589.6	602.8	97.8
Imports:			
1963	589.8	695.3	84.8
1964	546.0	647.6	84.3
1965	510.1	616.0	82.8
Net trade balance:			
1963	+62.5	−36.9	XX
1964	+76.1	−17.7	XX
1965	+79.5	−13.2	XX

XX Not applicable.

Source: Statistical Office of the United Nations.

Petroleum and its products accounted for more than 98 percent of total mineral commodity exports and imports in each year from 1963 to 1965 and for more than 96 percent of all commodity exports and 81 percent of all commodity imports in each year for that period.

The United States was the primary destination for petroleum exports, having taken 42.4 percent by value; the United Kingdom, with 7.9 percent, ranked second, and Canada, with 6.9 percent, ranked third as a destination. Petroleum imports valued at $473.4 million were supplied primarily by Venezuela, accounting for slightly more than 94 percent of all petroleum imports.

Exports of phosphate rock in 1965 at 112,152 tons showed a 6.2 percent decrease from 1964 exports. In 1965, exports amounting to 89,798 tons went to the United States, and the remainder to Europe.

COMMODITY REVIEW

Nonmetals.—*Limestone.*—Data on limestone output in 1965 are incomplete; however, 48,626 tons were sold to local consumers, and 10,481 tons were exported.

Nitrogenous Fertilizers.—The Aruba Chemical Industries announced late in 1965 that it was expanding its facilities in order to produce calcium ammonia nitrate using Aruba limestone.

Salt.—Salt output was reported at an estimated 2,000 tons, but the reason for the large indicated increase was not apparent. The 1965 production was reported from Curaçao; the new works inaugurated on Bonaire in mid-1964 was not expected to begin production for some years.

Mineral Fuels.—It was reported that Shell Curaçao N.V. had a modernization program in progress costing an estimated $2 million. A number of old stills were to be replaced with a new crude unit. Overall capacity will remain unchanged.

TRINIDAD AND TOBAGO

The petroleum industry, keystone in the economic arch of Trinidad and Tobago, remained strong in 1965. Of an estimated GDP of $661 million in 1965, the petroleum industry accounted for about 26 percent. The industry further contributed about 85 percent of all exports by value and 35 percent of Government revenues. The industry also provided employment for about 15,000 people.

While crude oil output declined about 2 percent over the 1964 figure, production during the last 3 months of 1965 showed a reversal of the downward trend. The daily production of 141,472 barrels during December 1965 was reported to be the highest attained in the last 2½ years.

According to Trinidad and Tobago Government sources, total refinery throughput for 1965 increased 7.5 percent over that of 1964.

It was reported late in 1965 that the Government was considering introducing new taxes. The result of the proposals, if enacted, would have the effect of putting a tax rate of about 61 percent on foreign investment.

Industrial stability improved following the 1965 enactment of the Industrial Stabilization Act (ISA). The act gave the Government broad powers to control strikes; to review, challange, and otherwise adjust terms and wages of any collective bargaining agreement; to control prices, and where necessary, to examine corporate records.

PRODUCTION

Despite the slight decline in total crude oil output in 1965, increases in daily production during the last quarter suggest that annual production in the immediate future will level off at around the production figures of the last 3 years. Refinery output gained 7.5 percent over that of 1964.

Cement output was nearly 7.5 percent greater compared with the 1964 record; other nonpetroleum commodities indicated some slackness. Sulfur production eased, possibly reflecting the effect of increased imports. Although reported statistics indicate sharply decreased output of sand and gravel, limestone, and diorite for 1965, it is believed that no appreciable decline occurred and that the apparent decline can be attributed to a change in the reporting policy.

Sulfur was produced by Texaco Trinidad Inc. at its Pointe-á-Pierre refinery. About one-half of the output reportedly goes to Federation Chemicals, Ltd.; a small portion is distributed to the sugar industry and minor users, with the remainder consumed in Texaco's refinery operations.

TRADE

Total value of exports and reexports of metals and minerals in 1964 was $350 million, of which nearly 98 percent was accounted for by petroleum, mainly refinery products but including sizable quantities of crude and partly refined oils.

The role of mineral commodity trade in Trinidad and Tobago's total trade in terms of value for 1963 and 1964 is reflected by the following data:

	Value (thousand dollars)		Mineral commodities share of total trade (percent)
	Mineral commodities [1]	Total trade	
Exports:			
1963	320,396	377,000	85
1964	349,982	409,800	85
Imports:			
1963	197,981	379,200	52
1964	236,518	427,700	55
Net trade balance:			
1963	+122,415	−2,200	XX
1964	+113,464	−17,900	XX

XX Not applicable.
[1] Approximate.

Source: U.S. Embassy, Port-of-Spain. A–168, Mar. 8, 1966. A–109, Oct. 22, 1964.

Although complete data on 1965 trade are not available, no significant changes in relationships were believed to have occurred, although trade in petroleum and its products generally increased. Exports of refined petroleum products in 1965 were reported by the Ministry of Petroleum and Mines at 127.9 million barrels, an increase of some 11 percent over the 1964 figure. The Ministry estimated that 4.5 million barrels of crude oil were exported in 1965, a very slight decrease from the 1964 level.

Canada was the principal destination for crude oil and lubricants, including greases. The United States and Europe took most of the remaining exports, there being no significant changes in traditional destinations.

Small-scale exports of scrap metal, fertilizers, and building materials in 1964 were virtually unchanged from those of the preceding year.

The Ministry of Petroleum and Mines announced that 93.4 million barrels of crude oil were imported in 1965; about half came from Venezuela, with Saudi Arabia, Colombia, and the United Arab Republic (Egypt) supplying the remainder. Indonesia, which supplied less than 250,000 barrels in 1964, was not a source in 1965. Crude oil imports for 1965 increased about 12 percent compared with those for 1964.

Imports of refined products in 1965, at 651,751 barrels, increased about 42 percent over those of 1964. The bulk of imports was in the form of unfinished oils; no gasoline or gas oil was imported in 1965. This was a change from the 1964 import pattern.

COMMODITY REVIEW

Metals.—No metal production was recorded for Trinidad and Tobago, and all requirements were again satisfied by imports.

Nonmetals.—Requirements for nonmetallic building materials continued to be satisfied from local sources. Needs for industrial nonmetals, including salt, barite, and sulfur again were largely met by imports. It was reported that Federation Chemicals, Ltd. (a subsidiary of W. R. Grace and Co.) produced 189,601 metric tons of anhydrous ammonia in 1965; in addition, the same company also recorded output of 79,651 tons of ammonium sulfate and 39,281 tons of urea. An additional ammonia plant designed to produce 635 tons per day is expected to be commissioned in 1966.

Mineral Fuels.—*Natural Gas.*—Output of natural gas in 1965 increased over that of 1964, but the rate of increase for the period slackened from more than 11 percent for 1963 to 1964 to less than 1 percent for 1964 to 1965. Gas used as process gas in 1965 increased over that of 1964 by more than 6 percent.

Petroleum.—Total footage drilled in 1965 was 1,057,445 feet, only 1,111 feet more than that drilled in 1964; however, there were 214 well completions recorded in 1965; this is 24 more well completions than were recorded in the previous year. Many of 1965's completions were shallow, and drilling activity measured in rig months was essentially the same in 1964 and in 1965.

Texaco Trinidad Inc. and Trinidad Petroleum Development Co., Ltd., both reportedly increased production in 1965, while other operating companies showed slight decreases. Increased production was accounted for partly by the use of modernized technology and partly as a result of newly drilled wells.

The refining industry continued to grow and expand. Daily throughput at the Pointe-à-Pierre complex of Texaco Trinidad Inc. averaged 323,560 barrels in 1965 compared with 298,500 barrels in 1964. Shell Trinidad Ltd. also raised daily throughput at its Point Fortin refinery from 49,900 barrels in 1964 to 52,000 barrels in 1965.

Source: Government of Trinidad and Tobago. Central Statistical Office. Overseas Trade. Pt. A, 1963 and 1964.

Early in 1965 two new processing plants were placed on stream. Texaco Trinidad Inc. began operating a 1,500-barrel-per-day paraffin plant; products include a range of normal paraffins, which are exported. Shell Trinidad Ltd. commissioned its new hydrotreater-hydrogenerator complex to produce high-octane gasoline and high-quality kerosines.

Costs of the plants were reported as $7.7 million and $3 million, respectively.

Late in 1965, BP (Trinidad) Ltd. completed its natural gas complex to supply gas to Federation Chemicals Ltd. The new 14-inch gasline reportedly delivers 25 million cubic feet of gas a day.

Consumption of petroleum products during 1965 totaled 219,507 barrels. Gas oil and diesel oil made up 48 percent of consumption, and fuel oil 40 percent. International bunkering accounted for 12.3 million barrels, of which 85 percent was fuel oil. The consumption figures given above are subject to revision but are the best ones presently available.

In 1964, 90.7 percent of domestic gasoline supplies came from Texaco's refinery, and 9.3 percent from that of Shell. During the first half of 1965, the market share of gasoline in Trinidad and Tobago was divided as follows: Texaco (Trinidad) Ltd., 35.5 percent; Shell Trinidad Ltd., 27.9 percent; BP Caribbean Ltd., 9.5 percent. The Report of the Commission of Enquiry into the Marketing of Petroleum Products in Trinidad and Tobago was issued in mid-1966 but was largely applicable to 1965. The report was requested by the Governor-General because of a gasoline "price war" that started in December 1964. Part I of the 1965 report was concerned entirely with the aspect of domestic gasoline refining and distribution and went into some detail on the effect of a price war on the individual distributor, the refiner, and the Government. While the scope was domestic in approach, international oil companies were involved. The study appeared to be a good case history that might be generally applicable in other areas with similar conditions.

The Mineral Industry of Argentina

By Charles L. Kimbell [1]

The Republic of Argentina remained relatively unimportant among world producers of both crude and processed mineral commodities in 1965. Moreover, the domestic mineral industry as a whole was only a modest contributor to the nation's economy, with the extractive sector (mining, quarrying, and crude oil production) contributing only about 1.5 percent of the gross national product (GNP), and the mineral processing sector making only a slightly larger contribution, insofar as can be determined. Also, the entire industry (extractive and processing) employed less than 2 percent of the total labor force, which was estimated at 7.3 million in 1965.

The importance of mineral commodities to the nation's economic growth, however, is reflected in the relationship of mineral imports to total imports; in 1964, the last year for which complete data are available, mineral commodity imports with a value of $308.3 million constituted 28.6 percent of total imports, and preliminary figures indicate that this may have exceeded $360 million in 1965.

Salient statistics on the nation's general economy and on value of mineral production are presented in the following tabulation:

	1962	1963	1964	1965
Gross national product:				
National currency, current prices ---- billion pesos	1,409	1,740	2,521	e 3,150
U.S. currency:				
Current prices ---- million dollars	10,440	10,130	11,160	e 12,300
1962 prices ---- do	10,440	10,000	10,840	e 11,750
Exchange rate (free rate) [1] ---- pesos per U.S. dollar	134.1	132.5	150.9	188.5
Value of crude mineral production:				
National currency ---- million pesos	43,411	54,907	r 50,922	[2] 58,003
U.S. dollars, converted at exchange rates above [3] ---- million dollars	r 323.7	r 414.4	r 337.5	[2] 307.7
Percentage distribution of total output value by commodity group:				
Metal ores and concentrates ---- percent	3.6	3.1	4.0	[2] 5.6

r Revised.
[1] As reported by the U.S. Agency for International Development.
[2] Excludes value of 8 commodities that were not reported in 1965 but that in 1964 accounted for only 0.3 percent of total.
[3] Data differs from that reported in Minerals Yearbook, Volume IV for 1964 because of the use of different exchange rates.
[4] Construction materials as reported here include those commodities listed in Argentine sources as "rocas de aplicación"; all clays are included under other.

[1] Physical scientist, Division of International Activities.

Despite the industry's relative unimportance in the sense of its direct role in the economy in 1965, it remained quite diversified, and efforts were being made for expansion of productive capacity so as to better meet anticipated growth in internal demand. Relatively small programs of facility expansions were completed in the steel industry, the petroleum refining industry and the cement industry in 1965, and generally increased production of nonmetallic minerals probably reflected other unreported efforts to increase production.

More ambitious plans for further expansions, some announced in 1964 and others reported for the first time in 1965, were undergoing further study, were being held in abeyance until sufficient capital was available for a start, or were moving into preliminary development stages. Among such projects were a major iron mining venture, a manganese-gold-silver mining project, a sizeable lead-zinc mining expansion, major expansion of the existing integrated San Nicolas steel plant, erection of two new integrated steel plants, erection of a new cement plant, sizeable expansion of mineral fertilizer production facilities, establishment of a significant petrochemical industry, expansion of the borate industry, and overall expansion of the petroleum industry, both crude oil production and refining capacity.

There was also hope that discoveries of porphyry copper resulting from United Nations Special Fund studies and of uranium resulting from exploration by National Atomic Energy Commission technologists would add to the country's economically minable mineral resource, but the commercial feasibility of these deposits had not been positively proven at yearend.

Notable developments in the area of governmental actions, policies and programs included intensification of efforts to settle problems created by annulments of oil exploration and development contracts in late 1963 with the result that by yearend, only 4 of the original 11 disputes remained unresolved, and these were being negotiated. Also of significance were the legislative action to insure maximum use of domestic coal resources; governmental approval of several industrial expansion programs; and continued mineral and petroleum exploration efforts by Government entities on their own and with contracted assistance.

PRODUCTION

Argentina's mineral industry as a whole increased output on a quantitative basis in 1965. Although complete data were not available, value of total output also presumably increased but this value increase was attributable primarily to elements of the processing sector, chiefly the iron and steel industry, the nonferrous metal smelters, the cement industry, and the petroleum refining industry. Despite quantitative increases in production of most commodities by the extractive industry, value of total extractive industry output fell by almost $30 million.

Considering extractive industry output by major commodity sectors, the value decline was attributed entirely to the fuels sector, and was the result of a 2 million barrel decline in crude oil output as well as to a lower unit value for crude oil. Coal production increased marginally but was slated for a greater increase in 1966 in response to government efforts to curtail imports of higher quality coal which enjoyed market preference to the domestic product.

Among metallic commodities, the steel output increase was made possible by increased domestic iron ore output as well as by increased imports of both iron ore and manganese ore, the latter in response to both increased Argentine demand and lower domestic output. Production of lead in concentrates was higher in 1965 than in any year except 1959, and output of zinc in concentrates, although considerably short of the record level of 1959, was higher than in 1963 and 1964. Moreover, the lead and zinc in concentrate output increases were achieved despite the fact that the mine which through 1963 had ranked as the nation's second largest lead producer, approached, if it did not reach, exhaustion of reserves during 1965. Argentine smelter lead and zinc production also reached new highs in 1965, as a result of higher mine output levels and curtailed concentrate exports.

As a result of the gains in metal mine output noted above and increases in a few other minor commodities, the total value of extractive industry metal production increased by over 28 percent, despite declines in gold and manganese output and cessa-

tion of production of concentrates of bismuth, columbium-tantalum and vanadium.

Among industrial nonmetals, higher levels of sulfur and borate production, both derived from deposits in the high Andes, apparently indicated better than average climatic conditions permitting a prolonged mining season. The higher borate output also was a result of expansion of facilities by the nation's principal borate producer. The sizable improvement in salt production also was apparently attributable to better than normal climatic conditions in the principal producing areas of Buenos Aires Province, Chubut Province, and Salta Province. Increases in output of these commodities together with most less-prominent Argentine industrial nonmetals and most major as well as a number of minor nonmetallic construction materials accounted for the 23 percent increase in the total value of crude nonmetallic minerals produced.

5 Converted to barrels and included with other liquid products.

TRADE

Preliminary and incomplete trade returns indicate that the value of Argentina's 1965 mineral commodity exports fell below the 1964 level of $30.6 million, possibly to as low as $20 million, while the value of imports of these commodities unquestionably exceeded the 1964 level of $308.3 million by a sizable amount, perhaps exceeding $360 million in total. Thus, the nation remained a major importer of mineral commodities in 1965 as it was in 1964, when a trade deficit of $277.7 million was recorded for these goods, compared with an overall positive trade balance of $333.2 million as shown in the following tabulation:

	Value, million dollars		Mineral commodities share of total (percent)
	Mineral commodities	All commodities	
Exports:			
1963	33.9	1,365.1	2.5
1964	30.6	1,410.3	2.2
Imports:			
1963	200.4	980.7	20.4
1964	308.3	1,077.1	28.6
Trade balance:			
1963	r−166.5	+384.4	XX
1964	−277.7	+333.2	XX

r Revised.
XX Not applicable.

Source: Statistical Office of the United Nations.

Dominant mineral commodity import groups in 1965 were iron and steel, crude oil, iron ore, distillate fuel oils, and lubricating oils.

Dominant mineral commodity exports in 1965 in terms of value were residual fuel oil, steel semimanufactures, complex tin ores with high silver content, and salt; these commodities together apparently accounted for about 90 percent of total 1965 mineral commodity export value. Residual fuel oil exports nearly doubled those of 1964 on a value basis, while the value of salt exports increased by 5 percent and that of tin ore exports moved upward by 3.6 percent. Steel semimanufacture exports, although remaining the nation's second most important mineral industry export commodity, were 40 percent below those of 1964 on a value basis. Exports of zinc in the forms of concentrates and unwrought metal, which had been the country's third through 1964, fell sharply and their contribution to the 1965 total was quite modest.

Principal destinations for mineral exports in 1965 were not available, but it is presumed that they remained about the same as in 1964, when almost 30 percent of the total on a value basis was destined for the United States, 18 percent for Venezuela, 9 percent for Paraguay, 9 percent for Uruguay, and 8 percent for Brazil.

As is the case with destination data for exports, information on 1965 source countries for mineral imports are not available, but it is believed that there were no radical changes from the 1964 distribution, when the United States ranked first, accounting for 18 percent of the total value, followed by Venezuela with 9.5 percent, the United Kingdom with 9.3 percent, Italy with 9.1 percent, West Germany with 8.9 percent, Trinidad and Tobago with 6.4 percent, and the Netherlands Antilles with 6.0 percent.

COMMODITY REVIEW

METALS

Aluminum.—No significant steps were taken with regard to the establishment of a facility to extract aluminum, iron, and titanium concentrates from Missiones Province lateritic clays. Proposals for such a facility, reported in Volume IV of Minerals Yearbook for 1964, were predicated upon the commercial feasibility of a separation process of Australian design. Reports indicate that otherwise unidentified foreign groups were considering the possibility of further exploring for suitable deposits and obtaining Government authorization to establish production facilities, but no details were given.[2]

Similarly, no positive action evidently was taken with regard to three 1961–62 proposals to establish any of the alumina reduction facilities that were summarized in the 1964 edition of Minerals Yearbook, Volume IV.

Copper.—The United Nations-Fabricaciones Militares (Argentine Government Agency) $3 million exploration program, underway since 1963, began more detailed study of some of the areas delineated for further examination by preliminary geophysical, photogeological and geochemical methods. Of five areas reportedly having some promise, one, at Paramillos, was the site of three reconnaissance drill holes, each about 700 feet deep. The borings here, on a rolling plateau about 10,000 feet above sea level near the paved highway from Mendoza, Argentina, to Santiago, Chile, were claimed to definitely demonstrate the existence of porphyry copper mineralization, however, economic feasibility of exploitation reportedly hinged upon more and deeper drilling. Other areas, not drilled, were near Santa Clara ravine in Mendoza Province and at Leoncito in San Juan Province. At yearend, it was announced that in 1966, the United Nations group expected to subcontract for further drilling work on these porphyry deposits, which have been described as being similar to the type found in Chile and in the Western United States.[3]

According to the original United Nations-Fabricaciones Militares agreement, the latter has the right to reserve to its domain 10 percent of the most promising areas surveyed, while the remainder of the areas would be opened for international bidding.

Elsewhere in Argentina, the Instituto Nacional de Geología y Minería began planned studies in the Provinces of Salta, Jujuy, Catamarca and La Rioja, and by yearend reported a copper discovery of unspecified size and grade in Catamarca. Further results on reportedly promising discoveries during 1964 by The Mineral Department of San Juan Province in that Province and by an unidentified group in Santa Cruz Province were not available.

Iron Ore.—Imported ore continued to be the overwhelmingly dominant source of iron for Argentina's steel industry in 1965, as receipts from abroad increased 2.8 percent to 1,032,519 tons. However, the small domestic iron ore industry recorded a 19 percent gain in output, thus providing slightly over half of the increase in ore availability (gross weight basis) in 1965 as compared to its 1964 performance, when imports cut into domestic ore markets.

The bulk of domestic output again apparently was obtained from the Zapla deposit in Jujuy Province, captive mines which supply ore to the nation's second ranked steel producer, Establecimiento Altos Hornos de Zapla. The large Sierra Grande iron ore deposit of Río Negro Province remained unexploited, although studies relating to its development continued. Data on reserves previously reported have been modified; the latest available source[4] gives the following data based on a study completed in 1964 by a private consulting firm employed by S.A. Minera y Siderúrgica Patagónica Sierra (MISIPA), the private joint stock corporation charged with exploration and development of the deposit: Measured ore—48.35 million tons, indicated ore—30 million tons, inferred ore—15.34 million tons, total ore—93.69 million tons. Ore grade reported was as follows in percent: Iron—58.04, silica—5.95, alumina (Al_2O_3)—4.85, phosphorus—1.43, sulfur—0.44, calcium—3.27.

Tentative studies on this project indicate that establishment of this deposit as a producer of 1 million tons of pellets as blast

[4] Pages 3–4 of work cited in footnote 2.

furnace feed, including mining, beneficiation and pelletizing facilities, will cost between $35 million and $60 million, but at yearend, no detailed economic and financial feasibility study had been carried out. There were indications however, that MISIPA would accept bids for such studies during 1966.

Iron and Steel.—The Argentine iron and steel industry set new production records in 1965 in response to domestic market demand that remained strong until the latter part of the year. Pig iron output, 12.5 percent higher than in 1964, was again obtained from two operating companies: Sociedad Mixta Siderúrgica Argentina (SOMISA) produced 589,600 tons (7.8 percent more than in 1964) while Fabricaciones Militares' Establecimiento Altos Hornos de Zapla produced 73,600 tons (73.5 percent more than in 1964) using only 2 of its 4 furnaces. Altos Hornos Güemes, the nation's only other facility capable of pig iron production, reportedly remained idle during 1965 although there was an indication that production might start again in 1966.[5] Of total pig iron output, 643,400 tons was used for steelmaking; the remaining 19,800 tons was foundry iron.

Crude steel production increased nearly 8 percent in 1965; of total output, SOMISA accounted for 768,955 tons, Zapla for 71,629 tons, and the country's 10 semi-integrated steel companies for 505,637 tons. (In addition, small foundries produced an estimated 22,000 tons of steel castings which are not included in reported steel output). The decline in the growth rate relative to that of past years was due to the fact that no new furnaces were added by any of the producers, the entire gain being attributed to better utilization of existing installations and to relatively minor improvements in these facilities.

Production of semimanufactures, totaling over 1.5 million tons, was 16 percent greater than in 1964, with output of every class of semimanufacture increasing except for hot-rolled strips (down 7.9 percent with respect to the 1964 level) and wire rod (down 8.3 percent). The greatest increase for any single type of semimanufacture was again, as in 1964, in the case of hot-rolled sheets, but the 1965 increase (24.5 percent) was more modest than that of 1964.

SOMISA was the nation's leading producer of semimanufactures, accounting for 30.8 percent of the total. The second-ranked producer of semimanufactures was the partly integrated Industria Argentina de Aceros, S.A. (ACINDAR), with 19.5 percent of the total. The remaining 9 partly integrated plants together produced 24.6 percent of all semimanufactures while two firms engaged only in rolling operations provided 22.2 percent. The Zapla integrated steelworks accounted for the remaining 2.9 percent of 1965 steel semimanufactures output.

Apparent consumption of steel semimanufactures totaled 2.12 million tons, almost 19 percent above that of 1964, and 37 percent greater than recorded production. This calculation of apparent consumption takes into account both direct imports of semimanufactures and the steel semimanufacture equivalent of finished goods imported.[6]

At yearend, the nation's capacity for iron and steel production in general terms was estimated as shown in the following tabulation compared with projected capacity in 1972 under long range plans:

Commodity	Capacity (thousand tons)			
	1965			1972 projected
	Active	Inactive	Total	
Pig iron	744	44	788	3,365
Crude steel	1,689	10	1,699	4,641
Hot-rolled steel	2,310	141	2,451	4,134

[5] Gilberti, Enrique. Argentina. Mining Annual Review 1966. Min. J. (London) May 1966, p. 211.

[6] Centro de Industriales Siderúrgicos. La Siderúrgia Argentina en 1965, p. 30.

Development plans aimed at attaining the 1972 goals included SOMISA's $33 million emergency project that was started in October and that was aimed at raising the firm's crude steel capacity from 850,000 to 1,100,000 tons, mainly by providing for oxygen blast in the open hearth furnaces. Port construction for the SOMISA San Nicolas steel plant also was started in 1965. Aside from these SOMISA projects, several firms (ACINDAR, Santa Rosa S.A., Dálmine Siderca S.A., and La Cantábrica S.A.) reported improvements in their existing steel furnaces aimed at increasing output, but no firms reported major new installations underway through yearend.

The two major projects for new integrated steel plants, that were pending at yearend 1964 remained in that status at yearend 1965. There were indications that at least part of the financial backing required for both the ACINDAR and the Propulsora Siderúrgica plants had been obtained by yearend, but no actual work was underway on either. The ACINDAR proposal calls for a plant to produce 500,000 tons of pig iron and 650,000 tons of steel annually, thereby fully integrating ACINDAR's operations. The Propulsora project calls for facilities to produce 1.4 million tons of pig iron, 1.3 million tons of ingot steel and 1.1 million tons of rolling mill feed.

Lead and Zinc.—Increases in output of lead and zinc in concentrates were apparently entirely the result of expanded operations at the Aquilar mine of Cía. Minera Aquilar in Jujuy Province. This company, the Argentine affiliate of St. Joseph Lead Co. (United States), increased its dominance over the nation's lead-zinc industry in 1965, accounting for 91 percent of total lead concentrate output and nearly 99 percent of total zinc concentrate production, with the entirety of its output coming from the Aquilar property. (In 1964, the Aquilar mine produced about 82 percent of total lead concentrate output and 91 percent of total zinc concentrate output.) In May, it was reported that engineering and design work was underway for an expansion of the Aquilar mine.[7] Preliminary plans called for increasing the capacity of the operation by a minimum of 50 percent and it was hoped that the additional capacity would be achieved in early 1968.

No details were available on activities of other producers, but the decline in production of both lead and zinc concentrates by other firms indicates that output, if any, by the Castaño Viejo mine of the National Lead Co. (United States) affiliate, Cía. Minera de Castaño Viejo, was considerably reduced even from the 1964 level. This mine in San Juan Province, formerly the nation's second ranked source of lead and zinc concentrates, lost its second ranking in lead concentrates during 1964 to the Gonzalito mine in Río Negro Province, and indications at that time were that the Castaño Viejo orebody was virtually exhausted.

Manganese.—Despite the considerable attention that has been directed to the Aqua de Dionisio (or Farallon Negro) manganese ore deposits of Catamarca Province, Argentina's production of this commodity apparently again was largely derived from a few relatively small mines in Córdoba and Mendoza Provinces. There was increased reliance on imported ores as domestic output fell by 8,502 tons from that of 1964. Argentine mine production in 1964 (the most recent year for which exact ore grade data are available) had an average manganese content of 32.9 percent, which significantly exceeded the 12 to 18 percent manganese content that has been reported for the Aqua de Dionisio occurrences. Moreover, recently completed surveys of the deposit indicated lower values of precious metals than had originally been indicated. A total of nearly 1.4 million tons of measured and indicated ore was reported to contain 12 percent manganese, 6 grams per ton of gold and 114 grams per ton of silver. This compares unfavorably with earlier reports indicating as much as 18 percent manganese, 10 to 12 ounces per ton of gold and 200 ounces per ton of silver. In view of the apparent poor competitive position of existing domestic producers of ore containing over 30 percent manganese, it appears questionable that the Aqua de Dionisio property could be developed and enter successfully into a competitive market, despite the precious metal values.

Nevertheless, the Government entity, Yacimientos Mineros Aqua de Dionisio (YMAD) reportedly was continuing exploration work in the northeast part of the Angalgalá area of Catamarca through yearend 1965, and reportedly had prepared a preliminary report for the Argentine President containing conclusions of a detailed technical-economic study of the area. With-

[7] Engineering and Mining Journal. V. 167, No. 5. May 1966, p. 148.

out any indication of the likelihood of such development, it was reported [8] that the development project proposed for the area would involve an investment of 2,200 million pesos spread over 28 months and would include development of the necessary infrastructure such as roads.

There were no indications that any decision was made with regard to some 30 propositions submitted for development of the Aqua de Dionisio deposits under a public auction called by YMAD in 1964 and reported in Volume IV of Minerals Yearbook for that year.

Uranium.—Argentine output of uranium concentrates in 1965 increased 36 percent to 29,604 tons in 1965, reflecting the continuation of domestic interest in the field of nuclear materials. The mine product as sold to the Argentine National Atomic Energy Commission reportedly averaged about 0.16 percent U_3O_8, a roughly comparable grade to that of 1963 and 1964. Output apparently continued to come chiefly from Jujuy Province as it did in 1964, when that area accounted for 99 percent of the total. Other producers in 1964 were located in La Rioja, San Luis and Mendoza Provinces. During 1965, deposits near Cosquín and Los Gigantes in Córdoba Province reportedly were being studied. These deposits, originally discovered in 1958, were undergoing apparently extensive evaluation studies by technologists from The National Atomic Energy Commission. Specific information on exploration results were not reported, but on the basis of drillings to a depth of 65 meters and completion of otherwise undescribed underground works, ". . . the occurrences are said to present tremendous possibilities for the future of mining in this zone." [9]

NONMETALS

Borates.—Broquímica Argentina, the Republic's largest producer of borate minerals, completed a major expansion of its facilities at Campo Quijano, Salta Province, in early 1965, and reportedly had further plans for increases in output. Work completed in 1965 included raising capacity of the plant from 12,000 to 18,000 tons, improvement of the mountain roads from the deposits (some in Jujuy Province) to Campo Quijano, and expanded employee housing. A further increase to 24,000 tons per year was under study.

Despite difficulties of Argentine product in international marketing owing to the high costs of mining the ore in the high Andes and moving the product to consuming centers in the country and to ports for export, producers seemed to feel that demand increases anticipated would justify the expansions completed and projected, including a 2 year, $150,000 exploration program aimed at locating deposits nearer existing rail lines and/or locating sodium borate deposits which could be exploited in lieu of the calcium borate deposits now mined.

Cement.—Argentine portland cement capacity was increased by 45,000 tons in 1965, reaching 4,937,000 tons as the result of modifications and additions to existing plants. These numbered 15 in all, including 1 facility (location not reported) completed in the latter part of 1964 but not reported in Volume IV of the Minerals Yearbook for that year. The development of the portland cement industry in the past 5 years is reflected in the following table of salient statistics:

	1961	1962	1963	1964	1965

[9] Work cited in footnote 5.

On December 31, Government approval of plans for erection of a 16th cement plant was formalized by publication of Decree No. 11884 in the Boletín Oficial. This 100,000-ton-per-year facility is due to be built in Zapla, Neuquén Province, with at least a part of the machinery and equipment to be imported. Under an earlier decree, expenditure of about $2.8 million for imports was authorized.

Fertilizer Materials.—The Republic continued to depend heavily on imports to meet its growing requirements for fertilizer materials in 1965, but expansion of the domestic industry was approaching reality as the Inter-American Development Bank announced approval of a 9½ year, $10,525,000 loan to Petrosur S.A.I.C., a private company established in 1961 to set up a major fertilizer operation in the country. The major shareholders in Petrosur are American and Foreign Power Co., Inc.; Shell CAPSA; Archilnit SRL; and Techint S.A. The company's plant, to be completed in early 1968 at Campana, Buenos Aires Province, will produce ammonia and sulfuric acid both for its own use in the production of urea, ammonium sulfate and compound fertilizers, and for sale to other companies.

In addition to the Petrosur plant, which will have the annual capacity to produce 55,000 tons of urea, 50,000 tons of ammonium sulfate and 30,000 tons of nitrogenous-potassic-phosphatic mixed fertilizers, at least 3 other expansion projects were in the planning stage. The Government entity, Fabricaciones Militares, which in 1965 produced about 12,000 tons of ammonium sulfate, plans a $25 million expansion that will enable it to produce annually 50,000 to 100,000 tons of ammonia, 36,300 tons of ammonium nitrate, 42,900 tons of urea, 15,000 tons of Thomas slag (16 percent P_2O_5) and 59,400 tons of complex fertilizers.

The Government oil operation, YPF, was considering installation of an $11 million ammonia and urea plant at Chapapoyas (90 tons of ammonia and 150 tons of urea daily), and of a $30 million facility at San Lorenzo to produce daily 500 tons of ammonia, 350 tons of nitric acid, 450 tons of ammonium nitrate and 600 tons of complex fertilizers. The latter plant would produce more ammonia than it would need and the balance would be for sale. Phosphate rock for mixed fertilizer production would be imported.

Finally, Impagro, S.A.I.C. reportedly signed a contract with Cooperativas Agrícolas in Bahía Blanca for establishment of a facility to produce annually 100,000 tons of ammonia, 60,000 tons of ammonium nitrate, and 80,000 tons of urea.

These expansion plans are postulated on anticipated growth of domestic demand for fertilizers, in terms of nutrient content indicated as follows:

Nutrient	Metric tons	
	Reported sales 1963–64 crop year	Forecast demand in 1970
Nitrogen (N)	22,116	102,200
Phosphorus pentoxide (P_2O_5)	6,736	75,700
Potassium oxide (K_2O)	5,009	23,800

MINERAL FUELS

Coal.—The Río Turbio property of the Government entity, Yacimientos Carboníferos Fiscales (YCF) remained Argentina's only coal producer in 1965. Output of the mine in western Santa Cruz Province was stepped up in 1965 and plans called for further increases in 1966. Gross production totaled 540,597 tons in 1965, yielding 374,216 tons of washed coal; comparable figures for 1964 were 423,898 tons and 332,007 tons respectively.[10]

The high ash content and low calorific value of the Río Turbio coal continued to mitigate against any marked displacement of imported coals in existing markets, as did the long distance between the coal mine and established producing centers which contributed to even higher costs per unit of heat energy. Principal consumers of Río Turbio coal remained other government owned or controlled entities—powerplants, the railroads, and the SOMISA steel plant.

To attempt to force greater utilization of Río Turbio coal, the Argentine Congress on September 2 passed a law making it obligatory for consumers having appropriate facilities to use domestic coal, and further providing that new installations using coal either as a fuel or as a nonfuel raw material must be of a type that can use domestic coal to a maximum degree.[11] Under the law the percentage of total coal to be obtained from domestic resources will be redetermined

[10] U.S. Embassy. Buenos Aires. Department of State Airgram A–279, Oct. 22, 1966, 10 pp.
[11] U.S. Embassy, Buenos Aires. Department of State Airgram A–228, Sept. 9, 1965, 2 pp.

each year after YCF prepares and submits a report of projected production, transportation and price data, and consumers who do not comply will be subject to fines, the income from which, if any, will be placed in a special fund for YCF's benefit. Although the law was passed in September, implementing regulations were not prepared much before yearend and the law therefore had no effect in 1965. Moreover, it was believed that the limitations of production and shipping facilities at Río Turbio and quality considerations with regard to the coal would moderate the effect on major industrial operations in the near future.

Petroleum.—Declining domestic production and growing internal petroleum product demand led to increased oil imports in 1965. These import increases, however, were confined to crude oil receipts; Argentine refineries, processing both domestic and foreign crude oil, met an increased share of total national requirements and petroleum product imports declined.

Of both national and international significance were the out-of-court settlements during the year between the Argentine Government (through its oil entity, Yacimientos Petrolíferos Fiscales—YPF) and several foreign-controlled private firms that held differing exploration, development operating and drilling contracts with YPF which were annulled by the Government in 1963. By yearend, agreements had been reached with Tennessee Argentina S.A., Union Oil Co. of California, Shell Production Co. of Argentina Ltd., Esso Argentina, Inc., Continental Oil Co. of Argentina-Marathon Petroleum Argentina Ltd., and Transworld Drilling Co. Ltd.[12] In the cases of Tennessee, Union, Shell, and Esso, YPF agreed to refund a total of between $117.9 million and $122 million[13] (in U.S. dollars and British pounds) and an additional M$N228.6 million (in Argentine currency) in repayment of investments, plus interest in amounts of 6 to 6.75 percent of the unpaid balance. The Transworld settlement called for YPF to refund as debit balance $4.5 million in 24 months with 6.25 percent interest on the balance. Under the settlement with Continental-Marathon, the firms, having assumed the mining risk, renounced all reimbursement of expenses and investment in exchange for permission to withdraw any or all equipment and financial assets in Argentina and a provision under which income tax claims against them will be paid up by YPF.

At yearend, Pan American Argentina Oil Co., Argentina Cities Service Development Co., Cía. Argentina para el Desarrollo de la Industria del Petróleo y Minerales S.A. (CADIPSA) and Soc. Azionaria Italiana Perforazioni e Montaggi—SAIPEM (an affiliate of the Italian State oil entity, Ente Nazionale Idrocarburi) were still engaged in negotiations with respect to their contracts. In 1964, Cía. Argentina de Petróleo S.A. (ASTRA) had reached an agreement that provisionally called for payment of about US$16.1 million in Argentine currency.

Exploration, Development, and Reserve.—YPF had 22 seismic crews, 2 gravimetric crews, 5 geological parties and 8 topographic survey parties in the field in 1965, which in all performed 436 party months of work. In addition to these onshore projects, a 2-month marine reflection-seismic study was carried out in the Gulf of San Jorge. Activities of survey parties resulted in completion of 7,330 kilometers of seismic profiles, 94,300 square kilometers of gravimeter surveys, 8,654 square kilometers of gravimeter-magnetometer surveys, 17,520 square kilometers of geological mapping, and the detailing of 240 kilometers of stratigraphic sections.

Exploration and development drilling during 1965 is summarized in the following table:

	Exploration drilling	Development drilling	All drilling
Footage drilled, thousand feet	701	2,184	2,885
Well completions:			
Successful, number	18	419	437
Oil, do	18	419	437
Gas, do	2		2
Dry holes and abandoned, do	58	58	116
Percent success	26	88	79

[12] Contract transferred from Kerr-McGee Oil Industries S.A.

[13] Final amount remained to be fixed in the case of Union and Esso.

Of 16 discovery oil wells listed, the largest producer was rated at about 500 barrels per day; the average was rated at about 235 barrels per day.

YPF's 1966 drilling program announced near yearend called for 323 wells, including 153 in the Huincul area of Neuquén Province, 125 near Comodoro Rivadavia in Chubut and Santa Cruz Provinces and 45 near Viscacheras in Mendoza Province.

Crude oil reserves were estimated at about 2,000 million barrels [14] and natural gas reserves at about 7.06 trillion cubic feet.[15]

Field Production.—Total 1965 crude oil production in five of Argentina's seven producing Provinces was lower than that recorded for 1964. The overall decline in these Provinces, 11.4 million barrels, was only partly compensated by increased output by the other two, totaling 9.4 million barrels, with the result that national production was 2 million barrels less than in 1964. On a company and field basis, the output decline was distributed between most producers; only the Río Negro Province operations of YPF, the Mendoza Province fields operated under contract for YPF by Argentine Cities Service, and the Santa Cruz concessions formerly held by the Argentine private firm, Astra, showed production gains.

The 2 percent decline in crude oil output was exceeded by the 5 percent decline in gross natural gas production in 1965, while output of natural gasoline increased by nearly 30 percent, as shown in the following tabulation:

Province	Crude oil production (thousand barrels)		Natural gasoline production (thousand barrels)		Gross natural gas production (million cubic feet) [1]	
	1964	1965	1964	1965	1964	1965
Santa Cruz	42,535	34,586	----	----	102,928	94,199
Mendoza	21,638	25,421	63	84	2,931	3,097
Chubut	20,327	19,061	29	28	13,952	14,103
Salta	6,017	5,404	800	1,044	95,069	90,432
Neuquén	5,001	4,891	4	4	14,357	13,699
Tierra del Fuego	4,464	3,035	----	----	3,799	2,591
Río Negro	294	5,878	----	----	106	2,796
Total	100,276	98,276	896	1,160	233,142	220,917

[1] Converted from cubic meters at the rate of 1 cubic meter equals 35.38 cubic feet, assuming that cubic meter measurement was on the basis of 1 atmosphere and 15° C.

As shown, only Mendoza, Río Negro and Chubut Provinces showed production gains in 1965 in gas output.

Despite lower total output for the year as a whole, the crude oil production rate increased throughout the last 5 months of the year, and averaged 291,000 barrels per day in December, compared to overall yearly averages of 269,000 barrels per day for 1965 and 275,000 barrels per day for 1964.

Refining.—Most of the nation's petroleum refineries operated at or in excess of their rated capacities in 1965; total crude runs in 1965 were reported provisionally as 122,620,000 barrels, 13,872,000 barrels more than in 1964 and 24,344,000 barrels more than was produced domestically. Refinery capacity at yearend was rated at 333,300 barrels daily [16] of which about 60 percent was in the six refineries owned by YPF and 40 percent was in the nine refineries owned by eight private firms. Several projects were underway at yearend to increase refining capacity.

Consumption and Trade.—Argentine domestic demand for petroleum products reportedly reached a new high of 127.8 million barrels in 1965, 6.8 percent higher than in 1964. Of reported 1965 sales (which totaled 102.9 million barrels), about 38 percent was residual fuel oil, 26 percent was gasoline, 26 percent was distillate fuel oil, 7 percent was kerosine and the remaining 3 percent was all other products.

[14] Data is as of 1964, as reported in Oil and Gas Journal, v. 62, No. 52, Dec. 28, 1964, p. 106, but is believed to have changed but little.

[15] Argentina—Most Private Companies Reach Out-of-Court Settlements. World Petroleum. Mar. 15, 1966, p. 56.

[16] Petroleum Press Service. World Petroleum Report. Mar. 15, 1966, p. 56. Elsewhere, refinery capacity has been reported as high as 370,000 barrels daily.

Preliminary data indicate that imports of refinery products totaled about 9.6 million barrels, or slightly under the 1964 level. These comprised mainly gas oil (about 60 percent), liquefied petroleum gas (about 15 percent) and lubricants (about 10 percent), while exports, totaling about 5.6 million barrels, were almost all residual fuel oil, the one refinery product produced in Argentina in excess of local demand.

Pipelines.—The 1,700-kilometer Pico Truncado-Buenos Aires 30-inch natural gas pipeline, completed in 1964 and rated as South America's largest, was equipped with a $9 million microwave communication system to relay vocal and/or written communications with regard to operations and maintenance of the line and its valve and pumping stations. Line capacity is reported as 175 million cubic feet daily.

The Mineral Industry of Bolivia

By Charles D. Hoyt [1]

Tin continued to be by far the most important of Bolivia's mineral products in 1965. The metal accounted for three-quarters of the value of mineral exports which in that year totaled almost $125 million,[2] 16 percent higher than in 1964.

Other significant minerals produced, in order of decreasing importance, were antimony, lead, silver, copper, gold, tungsten, and bismuth.

Mineral exports continued their overwhelming dominance of the Bolivian export scene. In 1965, they represented 95 percent of the value of all exports compared with 90 percent in 1961.

Mineral exports in Bolivia again were nearly equivalent to production because practically all output is exported. The actual tonnage of minerals exported in 1965 was almost 70,500 tons, an increase of 3.4 percent over that of 1964. The much larger increase in total value of mineral exports was mainly due to the higher average price for tin during 1965.

The mineral industry contributed 14.7 percent of the Gross Domestic Product of $610 million in current dollars; this was divided between mining (11.6 percent) and petroleum (3.1 percent). At yearend there were an estimated 43,000 workers employed in the mining industry of which about 53 percent were employed by the State-owned Bolivian Mining Corp. (COMIBOL) and the remainder were employed by the private mining industry. In addition, there were an estimated 5,000 employees in the petroleum industry, including 4,540 employed by the State petroleum operation, Yacimientos Petroliferos Fiscales Bolivianos (YPFB).

COMIBOL in 1965 produced materials that accounted for 61 percent of the gross value of mineral exports compared with 64 percent for 1964. The private sector produced the remaining 39 percent of the gross value of exports. This sector is divided by the Government into medium-size mines and small mines which produced 22 percent and 17 percent, respectively, of the total value of mineral exports.

The following table presents the distribution of output by commodity among the private (medium-size mines and small mines) and public (COMIBOL) sectors.

[1] Insignificant.

In 1965, for the first time since nationalization in 1953, the COMIBOL mines as a group finally operated at a profit, although a number of individual properties continued to show operating losses. Specifically the corporation showed a profit of slightly over $160,000 for the year and in December 1965 paid $255,300 in export taxes to the Bolivian Government. This contrasted with losses in 1964 of from $6 to $8 million. The reasons for this change were twofold. First, during 1965 substantially higher prices for tin prevailed ($1.78 per pound average New York market) than during the past decade. In 1953, average tin prices on the New York market were at a low of 95.8 cents per pound and then slowly increased to a level of over $1.57 per pound in 1964. The second and equally important reason for COMIBOL operating at a profit was the strong set of measures instituted by the Bolivian Government.

These measures, passed in May, provided reduced labor union domination in the mines (Decree 07171), established discipline in the mines, lowered and standardized wages (Decree 07188), and provided regulations to lease some of COMIBOL's properties to miner's cooperatives or unemployed COMIBOL workers (Decree 07187). The net effect of these regulations was to allow management to finally begin to operate after many years of little or no control over operations.

There was a continuation of negotiations begun in 1964 between the Bolivian Mining Bank (Banco Minero) and the U.S. Agency for International Development (AID) for a development loan. On April 14, a formal application was submitted to AID for a $5.7 million loan. At yearend the approval of the loan appeared to be imminent. It should be mentioned that the new mining code which was implemented in mid-1965 eliminated the virtual monopoly that required the small miners to sell only to the Banco Minero. These mines may now sell to private ore buyers.

A major program of financial assistance to COMIBOL was instituted in August 1961 by the U.S. Government, the Inter-American Development Bank, and the West German Government. This plan is referred to as the "triangular plan" because of the three parties funding the program. This program was divided into two phases and a third phase has been under consideration since early 1964. By December 1965, about $472,000 remained unspent out of more than $43.7 million. Of this latter sum, the United States provided almost 64 percent, the Inter-American Development Bank loaned 21 percent, and West Germany supplied 15 percent. A third phase loan under the triangular plan contemplates an additional $10.1 million to be spent over a 2-year period. It should also be mentioned that Argentina provided $1 million assistance under this plan.

The Government also passed several important Supreme Decrees aimed at providing a stimulus to expand the private mining sector and to attract foreign investment to Bolivian mining ventures. The most important change of this nature in 1965 was the new mining code that became effective July 6, 1965. This Decree (07148) substantially assists the private sector and had already begun to attract needed capital investment by yearend.

Three other Supreme Decrees, passed during 1965, also greatly assisted the private sector. Decree 07150 opened 20 new areas for exploitation by private enterprise. Decree 07360 lowered by 30 percent the export taxes on tin effective November 1, 1965. The last action of this type taken in 1965 was Decree 07447 that lowered the export taxes on all minerals about 40 percent. This decree, effective January 1, 1966, should encourage the mining industry to increase production and to develop new mines.

PRODUCTION

Production statistics represent actual COMIBOL production plus exports by the small and medium-size mines and the smelters except in the case of gold. Since the exports of gold were obviously not representative of production, a more representative figure was obtained by adding the production of South American Placers, Inc. (SAPI), the purchases by the mining bank, the exports of medium mines other than SAPI, and COMIBOL production.

[5] Gross production.
[6] Commercial production, processed for domestic fuel and for export.

TRADE

During 1965 Bolivia did not maintain a favorable balance of trade. The value of total exports was $131.8 million of which minerals accounted for 95 percent. Total imports were valued at almost $133.9 million which provided an unfavorable trade balance of nearly $2.1 million. The United States continued to be the principal source of imports providing almost 44 percent by value of the products. The United Kingdom, Bolivia's main customer for exports, received practically all the tin that was exported. The exported tin was valued at $58.8 million or 44.6 percent of the total value of exports.

Among exports of other minerals (gold, silver, copper, lead, zinc, tungsten, antimony, and bismuth) the United States was the principal buyer and received $56.2 million (42.6 percent) in exports from Bolivia. As in the past, the ultimate destinations for antimony exports were Japan and West Europe, despite the fact that export statistics list the United States as the destination. Other significant customers for Bolivian exports were West Germany, Japan, Belgium, and the Netherlands.

COMMODITY REVIEW

METALS

Antimony.—Higher metal prices resulted in an 8-percent increase in the value of total antimony exports in 1965, despite a 9-percent decline in tonnage exported. As in the past, private mines produced nearly all of the national output; the medium-size mines accounted for about two-thirds of the total output. The single largest antimony producer in Bolivia and the Western Hemisphere continued to be the Empresa Minera Unificada, S.A. (EMUSA) which produced ores and concentrates containing 3,566 tons of metal in 1965, about two-fifths of the country's total production.

Bismuth.—An 8-percent increase in the quantity of bismuth exported coupled with much higher prices for the metal in 1965 resulted in a 62-percent increase in the value of exports. About 97 percent of total bismuth output came from COMIBOL's Tasna mine.

Gold.—Bolivian gold output is estimated to have dropped about 27 percent owing to a 50-percent decrease in production by the leading producer, SAPI. This company operated a dredge which processed almost 2.3 million cubic yards to recover 33,861 ounces of gold in 1965. SAPI reserves were stated to be 26.8 million cubic yards at $0.37 per cubic yard. As in the past, almost all gold production came from the Tipuani and Kaka Rivers in the northeast part of the La Paz Department. On December 22, 1965, a flash flood in the Tipuani gold dis-

trict wiped out two mining camps with a loss of 30 lives. The Cangalli section where the accident occurred is a major gold producer. Therefore, output in 1966 will be affected by this disaster.

In late 1965, a United Nations sponsored Special Fund Technical Assistance project was approved to provide a pilot project for gold mining in the Tipuani River area. This operation is scheduled to begin in early 1966.

At practically all of the existing small gold mining placer operations in the Tipuani area, primitive hand panning methods are used to recover the gold, and estimated recovery is only 20 percent.

Exploration drilling and other work by Tidewater Oil Co. in the Mapiri, Kaka, and Alto Beni Rivers revealed nothing of interest.

Lead.—Exports in 1965 of lead in concentrates declined about 5 percent, whereas metallic lead exports increased over 92 percent compared with those of 1964. Output from the COMIBOL mines declined nearly 11 percent, while the output of lead from small mines in 1965 increased about 9 percent. Nevertheless because of higher lead prices during the year, the total 1965 return from lead exports increased almost 14 percent.

Tin.—Tin remained the dominant mineral in the Bolivian economy. In 1965 tin exports provided more than 70 percent of the country's foreign exchange. Mine production by COMIBOL was down slightly due to serious labor troubles in May and September when troops had to be used to restore order at the mines.

COMIBOL operations in 17 tin-producing mines contributed almost 70 percent of the nation's total tin output. The combined output from six COMIBOL mines was 78 percent of the total COMIBOL production. These mines and their 1965 production of contained tin were: Catavi (4,370 tons), Huanuni (2,256 tons), Unificada (1,985 tons), Colquiri (1,927 tons), The Empresa Minera Quechisla's Chorolque mine (1,235 tons), and San José (1,115 tons). Two of these operations, Quechisla and Unificada, showed profits in 1965, while the remaining four recorded operating losses.

Table 4.—Bolivia: Exports of tin by groups
(Long tons of contained tin)

Group	1963	1964	1965
Tin contained in concentrates:			
Corporación Minera de Bolivia	13,933	14,182	13,673
Medium-size mines	3,223	r 3,512	3,861
Banco Minero (small mines)	3,134	r 2,793	2,887
Smelter products (refined metal and solder):			
Fundición de Estaño de Oruro (Peró)	1,760	2,958	2,923
Metabol	702	652	483
Total	22,752	r 24,097	23,827

r Revised.

In 1965 COMIBOL mined almost 2.7 million tons of various ores with an underground labor force of 8,900 for an average productivity of about 1 ton per man-day underground. Total employment at yearend was 23,000, a reduction of about 8 percent below the total employment of 1964.

The two national smelters continued operations in 1965. One operated by Fundición de Estaño de Oruro (known as the Peró smelter) is affiliated with COMIBOL and refined almost 3,000 long tons of metal in 1965. The other smelter, Metabol, is owned and operated by the Banco Minero and had an output of 483 long tons in 1965.

Despite a number of proposals to expand Bolivian tin smelter capacity, the bulk of the concentrates continued to be exported for smelting.

About 10,000 tons of tin in concentrates are smelted annually in the United Kingdom by Williams Harvey, a subsidiary of Consolidated Tin Smelters, Ltd. Additional tonnages of lower grade concentrates are smelted in the United Kingdom at Capper Pass, Ltd., and in the United States by Wah Chang Corp.

Tungsten.—In 1965 exports of tungsten were down 11 percent compared with those of 1964; yet owing to higher prices, the value increased over 54 percent. Medium-size mines in the private sector produced over 70 percent of the output with the balance distributed about equally between the small mines and COMIBOL. Despite higher prices for tungsten, the Bolivian mining industry remained hesitant to expand output of tungsten owing to its unstable price history.

Zinc.—Exports in 1965 increased 40 percent over those of 1964. The major increases took place in the private, medium-size and small mines. The number of zinc mines increased, and recovery of zinc as an accessory mineral increased. The Matilde mine near Lake Titicaca, owned by COMIBOL, has the greatest long-range potential. It contains 3 million tons of fully developed ore that averages 17.5 percent zinc and 2 percent lead. During 1965, negotiations and competition continued among West German, Japanese, and U.S. groups with the Government of Bolivia for the concession to develop the Matilde deposit. At yearend no decision had been reached.

NONMETALS

Asbestos.—During 1965, Bolivia's principal asbestos mine, the property of A. A. Wormald Asbestos Mining Company in the Chapare region of the Cochabamba Department, substantially increased its output of crocidolite. It was reported that the U.S. concern, Philipp Brothers Corp., has contracted to market most of the Bolivian asbestos in the United States.

MINERAL FUELS

Natural Gas.—The total output of natural gas for direct fuel use in Bolivia and for export in 1965 was reported at 3,454 million cubic feet. Over 80 percent came from the Government petroleum concern YPFB and the balance from the Madrejones field (shared equally by YPFB and the Bolivian Oil Co. (BOC)) at Yacuiba near the Argentine border. Exports of natural gas were 630 million cubic feet, all of which came from the Madrejones field and was sent to Argentina. A major portion of the total natural gas produced by YPFB is consumed in the oilfields for secondary recovery methods (gas lift).

The amount of natural gas processed by YPFB for use as a fuel and in gas lift operations in 1965 was 2,824 million cubic feet, compared with 3,006 million cubic feet

in 1964. Some 2,294 million cubic feet of natural gas also were treated to recover 54,605 barrels of natural gasoline.

Petroleum.—During 1965 there were three oil companies active in Bolivia. The Government-owned YPFB accounted for almost 99 percent of total production as it increased output 6 percent over that of 1964. The balance of the 1965 output was provided by the BOC which produced from the Madrejones field. Output of crude oil at this field declined about 44 percent in 1965.

The third oil company operating in the country was the Bolivian Gulf Oil Co. (BOGOC) which has had underway a large development program for the past 10 years. As of the end of 1965 BOGOC had invested almost $92 million, and since 1958 has drilled 138 wells; 31 wells were completed in 1965. Discoveries in the Santa Cruz area (Caranda, Colpa, Rio Grande, Palmar and Santa Cruz) have been developed to the point where 30,000 barrels per day could be produced. Output from the Colpa and Caranda fields will be shipped via a 10- to 12-inch pipeline that was built during 1965 from Santa Cruz to Sica Sica, north of Oruro, at an estimated cost of $25 million. From Sica Sica the oil will be piped to the port of Arica in Chile via a YPFB pipeline. At yearend no oil had been shipped, but it was expected that by mid-1966 about 15,000 barrels a day would be exported from the BOGOC operations.

During 1965 BOGOC and its contractors employed slightly over 400 persons. Exploration work by the firm in 1965 discovered a new oil and gas field, called La Peñas, about 32 kilometers southeast of Santa Cruz. The initial well produced from 11,300 feet and was estimated to be capable of producing 260 barrels of condensate and 8 million cubic feet of gas per day.

Comprehensive exploration activities (surface geology, gravimetric studies, seismic work, aeromagnetometry, and aerial photographic work) were conducted by both BOGOC and YPFB throughout the year. Total reserves in Bolivia have been estimated at 400 million barrels.

During 1965 YPFB reported no new oil or gas discoveries although their drilling activity increased 15 percent to 122,600 feet for the year with 11 drill rigs in use, 4 rigs less than were used in 1964. Out of 28 drill holes finished in 1965 (18 exploitation and 10 exploration), 10 were productive, 13 were abandoned, and 5 were being tested further. There were 130 wells producing in mid-1965.

YPFB operates one large refinery at Cochabamba that accounts for over two-thirds of total Bolivian refinery output, as well as five smaller refineries at Sucre, Santa Cruz, Camiri, Sanandita, and Bermejo. Total Bolivian crude throughput in 1965 was 3.2 million barrels, while estimated total refinery capacity was 12,200 barrels per day. Output from these refineries provided about 97 percent of the domestic consumption which increased about 9 percent over that of 1964. The balance of domestic consumption was provided by imports which consisted mainly of aviation gasoline from Chile and lubricating oils and greases from the United States.

In 1965 exports of crude oil, all of which went to Argentina, were 12 percent lower than those in 1964. YPFB provided about 96 percent of these exports and the balance came from the BOC.

The Mineral Industry of Brazil

By Garn A. Rynearson [1] and F. William Wessel [1]

The relative position of the mineral industry in the Brazilian economy is not easily determined, largely because of incomplete and inexact statistical records. However, it is only fair to say that more persons in positions of official authority and representatives of industry appeared to be recognizing the problem and were actively seeking to improve the situation.

In 1964 mineral production accounted for 1.73 percent of the gross national product of which petroleum alone was 0.56 percent. Insufficient data were available to calculate similar comparative figures for 1965, but it is doubtful if any appreciable trend up or down will be noted when final figures are released.[2]

Sharp increases in iron and manganese ore exports and continued export of substantial portions of the world supply of quartz crystal and mica were the most significant aspects of Brazil's mineral industry performance in 1965. In addition, the columbium operation at Araxá became an important source of exports of both pyrochlore concentrate and ferrocolumbium. Plans to expand aluminum production were announced.

The official government attitude toward mineral development continued favorable during the year. Private interest in mineral enterprise accordingly increased somewhat but gains in this area were modest probably because of caution of foreign investors and the lack of risk capital of Brazilian origin; the latter was partially due to some economic recession during the year.

Decree 55,837, signed March 12, approved a plan to survey and evaluate the nation's mineral resources over a 10-year period. The plan is to be implemented by the Departamento Nacional de Produção Mineral (DNPM).

Resolution 3/65, released on May 13 by the Comissão Nacional de Energia Nucleár, raised to 0.08 percent the permissible thoria content of ilmenite concentrates for export. This is an attainable level and makes possible the exploitation of Brazil's monazite-ilmenite beach sands.

Responsibility for mineral production statistics, under Law 4904, Article 32, Title VII, has been shifted from the Ministério da Agricultura to the Ministério da Minas e Energia; DNPM henceforth will be the operating agency.

The principal sources of data presented in this chapter are the various official documents and reports released by Brazilian Government agencies, unclassified despatches prepared by officers of the U.S. Embassy at Rio de Janeiro and U.S. Consulates elsewhere in Brazil, annual reports of companies operating in Brazil, and such periodicals as Boletim do Instituto Brasileiro de Siderurgia, Revista do Sindicato Nacional da Indústria do Cemento, Conjuntura Econômica, and Engenharia Mineração Metalurgia.

PRODUCTION

The mineral industry in 1965 regained much of the ground lost in 1964, and in many cases exceeded 1963 production figures. Significant output gains were recorded in copper, gold, iron ore, lead ore, tantalite, and pyrochlore among the metals and ores. Tin and nickel maintained their position, and aluminum showed marked improvement over 1964.

Among nonmetals, barite, magnesite, and nitrogenous fertilizers showed major increases; production of mica and quartz crystal also improved. Production of cement

[1] Physical scientist, Division of International Activities.

[2] U.S. Embassy, Rio de Janeiro. Department of State Airgram A-198, Aug. 26, 1966, encl. 1, p. 1.

and phosphatic fertilizers showed little change from 1964; salt production regained its 1963 level, but dolomite production continued to decline, and lime output was somewhat less than in 1964. Data for gypsum in 1965, while showing a decline, are thought to be incomplete as reported production is less than the quantity required by the cement producers.

Petroleum production showed a modest increase, although refinery throughput was off slightly. Coal output was up slightly, and natural gas withdrawals showed a major gain.

e Estimate. p Preliminary. r Revised. NA Not available.

[1] Includes export data on some commodities for which production data are not available and on commodities for which export data are more representative than incomplete data on production.

[2] In addition to commodities tabulated, Brazil produces antimony, bentonite, china and refractory clays, glass sand, kyanite, limestone, pyrite, ocher, thorium compounds, tungsten metal, uranium oxide, and vermiculite, as well as clay, sand, gravel, and stone for construction purposes, but data on quantities are not available.

[3] Preliminary figure for State of Bahia only.

[4] Production of columbite and tantalite is not separately reported; total production for 1961–1963 allocated on basis of export ratio for year.

[5] Exports.

[6] Reported official production for Minas Gerais and Paraná for 1961-64. Data for 1965 includes unofficially reported output for Minas Gerais, Bahia, and Goiás only. Perhaps as much as 60 percent of total gold recovered in Brazil is not reported statistically.

[7] Data from Instituto Brasileiro de Siderurgia.

[8] Data from Instituto Latinoamericano del Fierro y el Acero. Excludes ferrocolumbium, which is listed under columbium.

[9] Includes production of Comissão Nacional de Energia Nuclear (CNEN) for all years, but CNEN was the only producer during 1964-65.

[10] Data on actual production not available except that for 1964–65, when it was reported as 13 tons for each year.

[11] Average tin content of concentrates estimated as 60 percent for 1961–63 and 65 percent for 1964–65.

[12] Production of Comissão Nacional de Energia Nuclear only.

[13] Includes anthophyllite, chrysotile, and tremolite fiber. Data shown for 1961–62 are estimates, as ore rather than fiber is reported as production for some mines.

[14] Data from Sindicato Nacional de Indústria do Cimento (SNIC).

[15] Production of marketable apatite and phosphate rock is not reported separately; however, relative quantities produced are indicated by concentrates sold under government subsidy as follows: Apatite, 1961—95,002 tons; 1962—100,286 tons; 1963—63,422 tons; phosphate rock, 1961—116,753 tons; 1962—90,839 tons; 1963—76,835 tons.

[16] Includes rough and cut (but unset) stones except diamonds and rough agate.

[17] Data provided by Instituto Nacional do Sal.

[18] Data from Plano do Carvão Nacional. Merchantable (cleaned) coal produced was 1,798,000 tons in 1963, 1,782,000 tons in 1964, and 1,985,000 tons in 1965.

[19] Converted from cubic meters at rate of 1 cubic meter=37.32 cubic feet.

TRADE

Brazil's favorable overall trade balance of 1964 tripled during 1965. Exports of mineral commodities, up 49 percent (in U.S. dollars) over 1964, accounted for 12 percent of all exports; mineral commodities imported, off 4 percent from 1964, accounted for 33½ percent of all imports. The unfavorable balance for all mineral commodities was cut from US$296.4 million in 1964 to US$217.2 million in 1965—a 27-percent reduction. For nonfuel mineral commodities, a favorable balance of $11.7 million was recorded in 1965, compared with an unfavorable balance of $38.2 million in 1964.

Major factors in this improvement in trade position were the increased export of metals and ores and the decreased import of mineral fuels. Significant increases over 1964 exports were attained in iron ore (28 percent), iron and steel (160 percent), and manganese ore (42 percent). Significant decreases from 1964 imports developed in coal and coke (24 percent), crude petroleum (8 percent), and refined petroleum products (20 percent).

Exports of columbium and tantalum concentrates increased sharply in 1965 and may become an important export item. Exports of beryl and barite declined, but other export commodities maintained or improved their contribution to trade. Imports of aluminum and zinc increased moderately, and imports of copper increased 24 percent in value from 1964. In the nonmetals, the principal item of increased import was the fertilizer group, up 29 percent to US$31.2 million in 1965.

Table 2.—Brazil: Value of trade in metals and minerals

(Thousand U.S. dollars)

Petroleum:				
Crude—thousands tons	360	----	----	
Refinery products:				
Distillate fuel oil	----	122	----	West Germany 78; Argentina 44.
Residual fuel oil—do	32	1	----	All to Uruguay.
Other	9	8	14	Uruguay 4; Paraguay 3.
Pitch coke	----	----	3	

[1] Less than ½ unit. NA Not available.

[2] Brazil includes pyrochlore under trade classification 2.37.79—Minérios metálicos, n.e. (metalliferrous ores not specified). Starting in 1963 most, if not all, material exported under this category was pyrochlore concentrate. The quantity shown for 1963 was pyrochlore, but those shown for 1964 and 1965 have not been completely verified and might include small amounts of other commodities.

[3] Other sources indicate most, if not all, of quantity shown was ferronickel.

[4] Includes material not identified by commodity in source and commodities not listed separately in table.

[5] Includes emery, artificial corundum, and diamond and other gem stone dust. Excludes grindstones and industrial diamond.

[6] Excludes diamonds and rough agate.

[7] Probably represents rejected material suitable for tumbling and mineral suites.

COMMODITY REVIEW

METALS

Aluminum.—The Montecatini Co., of Italy, in midyear announced a technical assistance agreement with the Companhia Brasileira de Alumínio to expand that company's operations. A construction program already underway at Sorocaba, São Paulo State, will by 1970 increase annual capacity to 100,000 tons of alumina and 50,000 tons of ingot from present levels of 30,000 tons and 14,000 tons, respectively. Cost of the expansion is estimated at US$60 million.

Expanded facilities also are being constructed at Saramenha, near Ouro Prêto, Minas Gerais, for the Alumínio Minas Gerais, S.A. (ALUMINAS), an affiliate of Alcan Aluminium Ltd. of Canada. Existing annual capacity totaled about 32,000 tons of alumina and 15,500 tons of ingot. It is proposed to increase the ingot potential to 22,000 tons by 1968, and ultimately to 44,000 tons thereafter. The company also produces ferroalloys.

A new aluminum company was formed during the year, Companhia Mineira de Alumínio (ALCOMINAS), a joint venture of Brazilian capital, Aluminum Company of America, and Hanna Mining Co. The plant is to be located at Poços de Caldas, and is to draw its bauxite from a reported 16-million-ton reserve in the vicinity.

Columbium.—The pyrochlore mining operation at Araxá, Minas Gerais State, operated throughout 1965, producing 1,197 tons of 57 to 58 percent columbium pentoxide (Cb_2O_5) concentrate. Technologic improvements instituted during 1964 resulted in this improved product; the grade formerly was 54 percent. A better product and a yearend price of US$0.85 per pound, part of a general price increase due to the tight world supply situation, enabled Brazil to double its share of the United States' market.

Production of ferrocolumbium, started in 1964, was actively continued; 277 tons of alloy was produced by a batch thermit-type process. The alloy may be exported without special export licensing since it contains no uranium or thorium.

The management plans to attain monthly production rates of 454 tons of concentrate and 11 tons of ferroalloy.

The Wah Chang Corp. early in 1965 sold its 25 percent interest in the Distribuidora e Exportadora de Minérios e Adubos, S.A. (DEMA), the Araxá operating company, to Molybdenum Corp. and Pato Consolidated Gold Dredging, Ltd., at a reported price of US$1.8 million. The new acquisitions, added to shares already owned by the two purchasers, will be held by the Niobium Corp., a New York company owned two-thirds by Molybdenum Corp. and one-third by Pato, and represent the 50 percent of DEMA held by non-Brazilians.

The Brazilian Government set a maximum export quota of 2,500 tons of concentrate for 1965, but allowed additional export of 1 ton of concentrate for every ton of ferrocolumbium exported.

Ore reserves at Araxá are reported to be at least 185 million tons of 3 percent Cb_2O_5 content.

Copper.—The major source of copper in Brazil continued to be the Mina de Camaquã in the State of Rio Grande do Sul. Concentrates were shipped to the company's smelter

at Itapeva in São Paulo State, and the resultant primary copper was refined at Utinga, also in São Paulo. Production from this mine and the Caraiba deposit in Bahia, both owned by the Cia. Brasileira de Cobre, represented not over 10 percent of domestic demand; consequently, copper remained a major import item.

The company during 1965 contracted with Mitsubishi Metal Mining Co. for technical assistance in the further development of these two mines and a third mine owned by the company but not in production. Additional reserves were developed during the year.

To alleviate the chronic short supply, the DNPM has completed a geochemical exploration project in Bahia, conducted jointly with the U.S. Geological Survey. Two large mineralized areas were outlined. As a result of this and similar continued effort, it is hoped that Brazil will supply half its demand with domestically produced metal by 1972.

Gold.—Production of gold in Brazil in 1965 increased 20 percent over the 1964 level. Of the official total of 171,011 troy ounces, lode mines in Minas Gerais, Bahia, and Goiás produced 93 percent and placer operations in Minas Gerais the remainder. The major producer continued to be the four mines of the Morro Velho group in Minas Gerais, which accounted for 87 percent of the national total.

A new mine began production in May, the lode operation of Mineração Norte Central, Ltda., near Dianópolis, Goiás State. A 135-foot shaft was sunk on the property, followed by crosscuts on the veins. A small (1 ton per hour) amalgamation mill was built and was reportedly producing at the rate of 16 troy ounces per shift.

Much—perhaps more than half—of Brazil's gold production is never reported. Production by the many prospectors in Brazil may have been as much as 240,000 troy ounces in 1965. An informed estimate spoke of about 10,000 troy ounces per month being produced in the Alto Tapajós region of the State of Pará in 1965. It was reported in February that the influx of miners and prospectors into the region had reached the proportions of a gold rush. Other areas of Brazil may yield placer gold equal in amount to that mined in Tapajós.

Iron Ore.—Brazil's output of iron ore in 1965 reached 18,159,922 tons, a 7-percent increase over 1964, and exports totaled a recordbreaking 12.7 million tons.

The Companhia Vale do Rio Doce (CVRD), a government-controlled company, produced 11.5 million tons of which 4.05 million tons were fines. The company exported just over 10 million tons—8.9 million for its own account and 1.12 million for S.A. Mineração da Trindade (SAMITRI) and FERTECO S.A. Administração e Fomento Industrial under the contracts concluded in 1964. These exports were loaded in the port of Vitória, Espirito Santo. Reportedly 16 percent was fines.

Companhia Siderúrgica Nacional (CSN) produced 2.40 million tons from its Casa da Pedra mine during 1965. The blast furnaces at Volta Redonda received 1.27 million tons; the remainder was fine ore, most of which was stockpiled.

While SAMITRI and FERTECO shipped their export ore over the CVRD railroad to the port of Vitória, the St. John del Rey Mining Co. and Companhia Auxiliar de Emprêsas de Mineração (CAEMI) shipped over the Government railroad, Estrada de Ferro Central do Brasil, to the port of Rio de Janeiro. These companies in 1965 accounted for about 1.1 million of the port's 2.6-million-ton iron ore capacity; other mines in the Paraopeba Valley provided the balance.

CVRD continued construction of its new, modern port facilities for iron ore and coal at Ponta do Tubarão, near Vitória and planned to be able to load 6,000 tons per hour by April 1, 1966. Expansion of the port of Rio de Janeiro to 3 million tons capacity was underway.

It was announced in December that the St. John del Rey Mining Co., a Hanna Mining Co. subsidiary, and the Cia. Auxiliar de Emprêsas de Mineração, the Augusto Antunes group, merged to form a new company, Mineraçoes Brasileiras Reunidas (MBR). Iron ore will be mined and steel produced at the new company's holdings in Minas Gerais. A 2-million-ton pelletizing plant will be included, and a 10-million-ton deepwater port is planned for Sepetiba Bay, near Rio de Janeiro.

During the year, discovery of a ferriferous district in the Rio Jatapu area of northeastern Amazonas was announced.[3] The iron ore occurs in sediments probably equivalent to the Minas series. The mineralization is a mixture of hematite and magnetite. A composite sample from outcrops and test pits contained 56.9 percent iron, 3.6 percent silica, and 1.0 percent phosphorus. Preliminary estimates indicate that reserves could exceed 200 million tons.

[3] Da Costa, Heitor Façanha. Novo Distrito Ferrifero No Brasil: Rio Jatapu, Amazonas. Engenharia Mineração Metalurgia. September 1965, pp. 113–119 and November 1965, pp. 209–212, Rio de Janeiro, Brazil.

Iron and Steel.—Decreased demand for ferrous metals in 1965 brought about production declines of 10.4 percent for pig, 1.5 percent for ingot, and 2.7 percent for shapes.

Ten integrated steel plants operated during the year. The dominant producer was Companhia Siderúrgica Nacional (CSN), a government corporation, which produced more than one-third of the nation's pig iron, more than two-fifths of its ingots, and about half its rolled shapes. Following a rising trend, iron smelted with coke accounted for 62 percent of the total pig, while iron smelted with charcoal accordingly declined to 33 percent. Under existing law, iron producers using coke were required to blend domestic and imported coals at a minimum ratio of 3:2 but because of the relatively inferior quality of the domestic coal, this regulation was eased somewhat in order to reduce the cost of pig iron.

Production by States in 1965 is shown in the following table:

State	Thousand tons	
	Pig iron	Steel ingots
Minas Gerais	1,315	1,143
Rio de Janeiro	985	1,399
Bahia, Matto Grosso, Paraná, Pernambuco, Rio Grande do Sul, São Paulo	55	354
Total [1]	2,355	2,896

[1] Data differs slightly from that given in table 1 because of difference in sources.

Source: Anuário Estatístico do Brasil, 1966, p. 152.

Imports of iron and steel in 1965—largely stainless steel and the more complex shapes—showed no increase over 1964. Exports, largely to Japan and Argentina and other Latin American Free Trade Association (LAFTA) members, continued to increase.

Zinc.—In 1965 zinc metal was produced commercially in Brazil for the first time. The Companhia Mercantil e Industrial INGÁ began production late in the year from a plant of 7,200 tons annual capacity located at Ilha de Madeira in Sepetiba Bay, Rio de Janeiro State. Zinc was extracted from calamine (zinc silicate) ore, mined at Vazante, Minas Gerais, and containing about 30 percent zinc. Indústrias Votorantim, S.A., was building a plant of 18,000 tons annual capacity at Três Marias, Minas Gerais, designed to operate on similar ore; this facility was not yet in production.

NONMETALS

Cement.—Twenty-nine cement plants, many in São Paulo State, operated at 83 percent of industry capacity in 1965. Several additional plants were under construction or planned.

Diamond.—Mineração Tejucana, S.A., was preparing to dredge diamonds from the Jequitinhonha River in Minas Gerais State.

Potash.—Oil-well drilling at Carmópolis, Sergipe State, penetrated a thick stratum of rock salt at a relatively shallow depth. The bottom 30 meters of the salt bed, about 500 meters below the surface, contained potash in the form of carnallite and sylvite. In view of 1965 imports of 155,356 tons of potassium chloride, a 41-percent increase over 1964 imports, the Carmópolis discovery may prove significant.

Quartz Crystal.—Early in the year, some quartz crystal of commercial grade was discovered near Cristalina, Goiás State.

MINERAL FUELS

The market pattern of mineral fuels in Brazil in 1965 featured increased production of both mine-run coal and crude petroleum, 3.5 and 3.3 percent, respectively. Imports of these commodities declined by 22.4 and 5.1 percent.

Coal.—Brazil's coal industry improved performance in several respects during 1965. Compared with 1964, production of mine-run and cleaned coal gained 4.2 and 11.4 percent, respectively. Again about two-thirds of the production came from the State of Santa Catarina. Coal cleaning ratios are shown in the following table comparing the producing States:

State	Ratio of cleaned coal to mine-run coal		
	1963	1964	1965
Paraná	0.828	0.785	0.843
Santa Catarina	.659	.471	.467
Rio Grande do Sul	.750	.676	.819
National average	.699	.549	.587

Source: Comissão do Plano do Carvão Nacional.

The iron and steel industry and powerplants remained the dominant coal consumers, as shown in the following table:

Industry	1965 coal consumption (thousand metric tons)		
	Domestic	Imported	Total
Iron and steel	578	830	1,408
Electric power	1,000	--------	1,000
Manufactured gas	58	295	353
Railroads	102	--------	102
Steamships	10	--------	10
Total	1,748	1,125	2,873

Source: Instituto Brasileiro do Geografia e Estatística. Anuário Estatístico do Brasil, v. 27, 1966, p. 298.

The first of two 50,000 kilowatt units planned for the thermal powerplant at Tubarão, Santa Catarina State, began operating in April. This plant is expected to be an important consumer of steam coal (heretofore stockpiled), but markets for much of the power remained to be developed.

Petroleum.—President Castello Branco, on July 9, 1965, revoked the decree of March 13, 1964, that expropriated the six privately owned oil refineries. The refineries had been operated by their owners under permission of the court during the 16-month period.

Resolutions enacted by the Conselho Nacional de Petróleo (CNP) in May opened petrochemical production and oil shale resource development to private industry; the Council reserved the right to approve such proposed projects and maintained other controls.

Prices of petroleum products, increased by CNP on December 11, 1964, were raised again, effective March 1, 1965.

Sixteen drill rigs of various types were ordered from Rumania, for first quarter 1965 delivery, by Petróleo Brasileiro, S.A. (PETROBRÁS), the Government petroleum corporation. Of these drills, three were reportedly capable of drilling to 14,100 feet (4,500 meters), and five others to 4,700 feet (1,500 meters). The first five of these drills were delivered in February.

The first shipment of crude oil from the Carmópolis field was reported in March 1965. Production was expected to reach 15,000 barrels per day by June, but inadequate transportation facilities deterred a more rapid output increase. Near yearend, PETROBRÁS contracted with Servipetrol and Brantley Drilling to drill 240 development wells in the Carmópolis field over a 2-year period.

PETROBRÁS drilled 225 wells during 1965, including 97 for exploration and 128 for development. Total footage increased 11.7 percent over 1964 to a total of 964,477. The discovery of oil in the Miranga field, in the Recôncavo Basin, Bahia State, was considered the most important find of the year. At yearend, the Miranga field was producing 4,400 barrels per day. A showing of oil also was found at 4,500-foot depth in the São João field of the Barreirinhas Basin, along the Maranhão coast.

During 1965 the PETROBRÁS budget included US$38.5 million for exploration, $15 million for production, $24 million for refining, $16.5 million for terminals and pipelines, $8.5 million for marine transport, $14.5 million for petrochemicals, and $5.5 million for oil shale research.

PETROBRÁS planned to explore the Continental Shelf from Maranhão to Espírito Santo. The first target area is off the Alagoas coast, to be drilled during the last half of 1967. Producing wells in 1965 included about 200 offshore wells in All Saints Bay, Bahia State.

The daily rate of oil production increased to 94,000 barrels, 3.3 percent greater than in 1964. The various fields in Bahia State accounted for 99.4 percent of total production; the States of Alagoas and Sergipe, the remainder. Natural gas production averaged 66.0 million cubic feet per day, 28.2 percent over the 1964 rate.

The rate of crude petroleum consumption was estimated at 305,200 barrels per day, 1.7 percent less than in 1964. Refinery throughput included 91.1 million barrels by PETROBRÁS and 20.3 million by privately owned refineries. Imported crude oil amounted to 73 percent of the total supply in 1965, and was obtained from the following sources:

Source	Quantity (million 42-gallon barrels)	Percent of total
Venezuela	29.78	39.3
U.S.S.R.	16.53	21.8
Iraq	13.91	18.4
Kuwait	8.00	10.6
Saudi Arabia	5.41	7.2
Peru	.70	.9
Netherlands Antilles	.52	.7
Nigeria	.45	.6
Colombia	.36	.5
Total	75.66	100.0

The Mineral Industry of British Guiana[1]

By Garn A. Rynearson [2]

The most significant developments in the mineral industry of British Guiana during 1965 again were contributed by the bauxite industry which continued to dominate all other elements of the mining and quarrying sector. Mine output of crude bauxite attained a record high of nearly 3 million tons, and the production of calcined bauxite (abrisive and refractory grades), dried chemical-grade bauxite, and alumina for the export market also reached record levels. In addition, the industry invested more than $9 million [3] in expansion projects during 1965 and announced plans for even larger investments during 1966–68.

Other developments of potential importance to the mineral industry included granting of oil exploration concessions for onshore and offshore areas to four oil companies and recognition of some mineralized areas of potential commercial significance as the result of geophysical, geochemical, and drilling investigations carried out jointly by the Geological Survey and the United Nations Development Programme (Special Fund).

The newly elected coalition Government initiated a number of programs and policies that could have significant effect on developments in the mineral industry. During the year it attained a measure of political and economic stability and undertook programs to improve transportation and communications. To prepare for independence in 1966, the Government enlisted the services of an international team to draw up a seven year development program (1966–72). The plan anticipates the expenditure of approximately $177 million on development projects during 1966–72, and it was estimated that about $201 million would have to be raised during the period to finance the plan and to support consequential current expenditures and debt charges.

To assure a substantial increase in national income, the development program places first priority on diversification of domestic output and points out that the most likely prospects for new industries are (a) import substitution (mainly foodstuffs, textiles, footwear); (b) raising of beef for export; (c) growing bananas for export; (d) production of aluminum metal, which will require extensive feasibility surveys and the eventual expenditure of large sums of capital for the development of hydroelectric facilities to provide adequate sources of cheap electric power; and (e) expansion of the bauxite industry as well as discovery and exploitation of other possible mineral resources such as oil, gas, gold, molybdenum, iron ore, columbite-tantalite, and possibly copper.

The diversification-of-output aspect of the plan was pursued vigorously during 1965 by the Industrial Development Corp.,

[1] Although British Guiana did not become the independent nation of Guyana until May 26, 1966, the new name and corresponding adjective (Guyanese) came into general and at least partly official use during 1965. For example, in preparation for independence, a new Central Bank of Guyana was established, the Government established the Guyana Development Corp., and the Guyana dollar was issued to replace the British West Indies dollar, at par value, as the new monetary unit. Therefore, for standardization, Guyana has been used throughout this chapter wherever use of British Guiana was not required for technical reasons.

[2] Physical scientist, Division of International Activities.

[3] Where necessary, values have been converted from British West Indies dollars (BWI$) or Guyana dollars (G$) to U.S. dollars at the rate of BWI$1.00 and G$1.00 both equal US$0.58.

a government agency created late in 1963 to promote the establishment of new industries. In 1965, the responsibility and authority of this agency expanded to include commercial agriculture, fisheries, forestry, and mining in addition to promotion of manufacturing and tourism, and its name was changed to Guyana Development Corp. The corporation will be the sole agency authorized to promote industrial development, will coordinate all Government activities to encourage and assist enterprises, and will supervise all investments in which the Government has an equity interest. The corporation approved several projects involving minerals during 1965, and will exert considerable influence on future mineral industry development. It can offer incentives to attract new investments, including a 5-year tax holiday on new industries, tariff concessions to protect new industries, accelerated writeoffs of building and equipment costs, duty-free imports of capital investment goods, and a variety of services.

The 7-year development plan also made provisions for, and placed a high priority on, a series of government basic resource surveys, with the expectation that some technical and financial assistance would be forthcoming from the United Nations as well as foreign governments. Several of these surveys will be of prime importance to the future mineral industry development. For example, aerial mapping surveys and hydrologic investigations will be made of areas that offer the best possibilities for developing the hydroelectric power required to establish an aluminum industry as well as other potential projects involving minerals and other commodities. United Nations' participation in these power development surveys has been approved.

Systematic geological investigations during recent years have been geared largely to an aerial geophysical survey project conducted jointly by the United Nations Development Programme (Special Fund) and the Guyana Geological Survey Department. Begun in mid-1962, the project was completed late in 1965 at a total cost of $1.3 million; the United Nations provided approximately $600,000 for airborne contracts, equipment, and specialist services while Guyana contributed nearly $700,000, mainly for ground followup operations (geochemical prospecting, ground geophysics, and drilling in areas of known gold or geochemically indicated base metal mineralization) and local services.

The Geological Survey and the United Nations team were optimistic over the preliminary results of the project, which located areas that appeared to have prospects for copper-gold, copper-zinc, gold, nickel, and molybdenum. The Geological Survey assembled a brochure [4] summarizing preliminary results of the project and including a list of Geological Survey publications and maps issued as of 1965, as well as many of the most recent geological and geophysical maps available.

Because of insufficient technical and financial capabilities to make a reasonably early assessment of more than a few of some 200 target areas indicated by the first Special Fund project, Guyana submitted a request for a 3-year followup project in December. This project was programed for the expenditure of approximately $1.04 million by the United Nations and $1.08 million by Guyana; early approval of the project was expected.

During 1965, Guyana also received assurance that at least 12 man-months of specialist services by the U.S. Geological Survey would be provided under the auspices of the U.S. Agency for International Development (AID). The first project, a geochemical assessment of a promising molybdenum-bearing area at Eagle Mountain in the central part of the country was begun in October.

To further induce private enterprise to engage in exploration and development of the country's mineral resources, the Government began extensive revision of the existing regulations governing mining, exploitation of other natural resources, and investment in industrial enterprises utilizing raw materials of domestic origin.

During the latter part of 1964 and early 1965, a study directed toward revising the mining laws was undertaken under the auspices of the United Nations Technical Assistance Board. Although it was indicated that numerous changes in the laws pertaining to concessions, rents, royalties, and taxes were recommended, any such revisions that may have been legalized in 1965 were not made public as of yearend.

[4] Martin-Kaye, P. H. A. British Guiana: Developments in Mineral Exploration. Geological Survey of British Guiana, February 1966, 27 pp.

After several years of negotiations, new long-term agreements were made by the Government with the two long-established bauxite companies, and special exploration concessions were granted to several oil companies during 1965. All details of these agreements were not made public, but there were indications that some terms concerning the granting of mining and mineral processing concessions may be subject to negotiation.

Preliminary results of a manpower and labor force survey carried out early in 1965 estimated a total labor force of 174,605 of which 36,444 were unemployed as of March. The bauxite industry employed 5,122 persons or about 3.7 percent of the employed labor force. Bauxite companies paid the highest minimum wages in the country, for example, G$9.20 ($4.37) a day for unskilled labor compared with the minimum of G$4.00 ($2.32) paid by the Government for unskilled workers. Worker income from wages and salaries in the bauxite (including alumina) and manganese mining industries rose from $6.9 million in 1961 to an estimated $10.1 million in 1965, following an almost straight-line curve except for 1963, when a crippling general strike decreased workers' total income to $7.25 million compared with a total of $7.71 million in 1962, or about $1 million less than the income that might have accrued if the strike had not occurred.

PRODUCTION

The mineral industry in general increased output of mineral raw materials as well as its relative importance in the overall economy of the country. Increases in production of bauxite (16.3 percent), manganese ore (42 percent), and quarried stone (estimated as roughly 20 percent) accounted for most of the overall gain by the industry during the year. Gold recovery continued at a low level, slightly less than that of the previous year and appreciably less than pre-1959 high. Diamond output rose only a little less than 3 percent, but the quantity recovered was greater than that for any year since 1929.

Official statistics are not available for the actual production of dried bauxite, calcined bauxite, and alumina. Data shown in table 1 for these items are shipments for export and were obtained from various sources. These data indicate that both production and export of dried and calcined bauxite increased, and that of alumina declined. However, it is probable that output of alumina in reality also increased.

Recent economic surveys published by the Government [5] contained data on overall value of mineral production and relative

Stone, rough or crushed	57,664	35,507	11,892	NA	94,688

r Revised. NA Not available.
[1] In addition to commodities tabulated, Guyana produces clay, sand, gravel, additional quantities of stone, and several types of macadam materials, but data on quantity are not available.
[2] Production on which royalties were collected by the Government. Data apparently not corrected for free moisture content.
[3] Data for actual output not available; therefore, shipments for export are the best available measure of output. Data shown for 1961–62 are official export figures. Data for 1963–65 are company shipments reported by Reynolds Metals Co. and Barclays Bank D.C.O. of Georgetown. For details by source, see text on Aluminum.
[4] Approximately 55 to 60 percent of production is estimated to be of gem quality.

contribution of mining and quarrying to the gross domestic product (GDP). The contribution of the mining and quarrying sector (including the processing of bauxite to dried and calcined forms and to alumina) to the GDP during 1961–65 was reported as follows, in mililons of dollars unless otherwise indicated:

	1961	1962	1963	1964	[1] 1965
GDP at current factor cost:					
Total value	$168.1	$178.2	$160.8	$175.0	$189.6
Mining and quarrying:					
Total value	21.7	29.0	20.4	30.8	36.1
Percent of GDP	12.9	16.3	12.7	17.6	19.1

[1] Provisional.

Mining and quarrying has been the fastest growing sector of the economy since 1960, partly because of the start of manganese mining that year, but mainly because of the increasing output of alumina since 1961 when production of this commodity was initiated. As a result of this growth, this sector's contribution to the GDP has rapidly approached that of the nearly stagnant agricultural sector including livestock, which contributed 21.4 percent of the GDP in 1964 compared with 17.6 percent for mining and 21.0 percent in 1965 compared with 19.1 percent for mining. Expansion planned for the next few years may well result in the mining industry becoming the dominant productive sector of the economy.

TRADE

Complete official statistics on foreign trade, have not been published for years subsequent to 1962. No official statistics on 1963 trade have been published but some data on total trade and a few principal commodities were obtained for 1963 through Barclays Bank D.C.O. and the U.S. Consulate General in Georgetown. Partial accounts have been published for 1964 and 1965 trade by the Statistical Bureau of the Ministry of Economic Affairs.

From available trade data, some of which have been revised from previously reported figures, the total value of exports of domestic goods increased from $93.0 million in 1964 to $95.5 million in 1965, a gain over the 1962 total of $93.4 million but still considerably below the record high of $100.2 million recorded for 1963. Reexports, never very significant, varied little during the 4-year period. The value of exports during 1965 was lower than anticipated, owing to low prices paid for Guyana's sugar and rice; however, increased mineral exports more than compensated for these shortfalls. In fact, exports of the bauxite industry (dried and calcined bauxite, alumina), which first exceeded the value of sugar exports in 1964, surpassed the combined value of sugar and rice exports in 1965. In 1965, exports of the major mineral commodities (bauxite, alumina, manganese, and diamond) accounted for 47.3 percent of the total value of exports compared with 40.9 percent in 1964.

Comparative values of trade in selected metals and minerals for 1962–65 were as follows:

	Value (thousand dollars)			
	1962	1963	1964	1965
Exports: [1]				
Metals [2]	35,105	32,733	35,343	41,949
Nonmetals [3]	2,150	2,051	2,614	3,235
Total	37,255	34,784	37,957	45,184
Imports:				
Metals: [4]				
Iron and steel	1,824	NA	2,303	3,105
Nonferrous	290	NA	398	NA
Total metals	2,114	1,614	2,701	NA
Nonmetals [5]	4,294	NA	5,186	4,813
Mineral fuels	7,586	6,983	8,402	9,300
Total	13,994	NA	16,289	NA

NA Not available.
[1] Excludes reexports.
[2] Dried and calcined bauxite, alumina, and manganese ores and concentrates.
[3] Diamonds, uncut and cut but unset.
[4] Excludes gold, all scrap and all metallic ores.
[5] Includes asbestos building materials, cement, agricultural lime and limestone, manufactured fertilizers, and sodium hydroxide.

[1] Official statistics on imports by commodities have not been published for 1963. The latest complete statistics published are those for 1962, whereas official data published for 1964 and 1965 do not include detail for numerous classifications. For some commodities, supplementary data from other sources are shown for 1964 and 1965.

Sources: The Customs and Excise Department, British Guiana: Annual account relating to external trade for the year 1962; The Statistical Bureau, Ministry of Economic Affairs, British Guiana: Monthly account relating to external trade, December (cumulative) 1964 and 1965; Overseas Geological Surveys, Mineral Resources Division, London: Statistical Summary of the Mineral Industry, world production, exports, and imports, 1959–64.

Increased economic activity was reflected to a greater extent by a 19.4 percent increase in the total value of imports, which attained a record high of $103.7 million in 1965 compared with the previous high of $86.9 million in 1964. Although imports were greater in every general trade section, the major increases occurred in machinery and transport equipment, manufactured goods in general (especially metals and metal manufactures), and petroleum products. A considerable part of these imports were destined for use in the large expansion projects underway in the bauxite industry and the road-building and other construction projects that were begun or about to be started in the public sector.

With one exception, the relative ranking and volume of trade between Guyana and its principal trading partners, United Kingdom, United States, Canada, and Trinidad and Tobago, remained virtually the same as for 1964; the United Kingdom (24.8 percent) replaced Canada (23.1 percent) as Guyana's principal customer for its domestic goods, with the United States (18.5 percent) and Trinidad and Tobago (9.0 percent) remaining in third and fourth place, respectively. Among these countries, however, Canada was the only one with which Guyana enjoyed a favorable balance of trade, purchasing only 8.1 percent of its imports from Canada compared with 31.0 percent from the United Kingdom, 24.3 percent from the United States, and 10.9 percent from Trinidad and Tobago.

On December 15, 1965, the Governments of Antigua, Barbados, and Guyana signed an agreement establishing the Caribbean Free Trade Area (CARIFTA) with the intent to reduce and eventually eliminate trade barriers between the three countries. The agreement was scheduled to become effective by September 1966.

COMMODITY REVIEW

METALS

Aluminum.—The country's two bauxite-producing companies, Reynolds Metals Co. and Demerara Bauxite Co. Ltd. (DEMBA), both signed long-term agreements with the Government and announced major expansion programs for 1965. These companies invested between $10 million and $15 million in new facilities during 1965, and announced that contemplated investments during 1966 and 1967 may amount to several times those of 1965.

In February, Reynolds signed a 25-year agreement with the Government (effective as of January 1, 1965) which assured increased government revenues through minimum income tax schedules based mainly on anticipated increases in production. The Government in turn pledged that it would not increase the mutually agreed upon income tax rate, and established fixed royalties and export duties. As a result of this agreement, Reynolds undertook a $4.5 million expansion program to include additional equipment for overburden stripping, mining, river transport, a third bauxite drying kiln (which began operating in September), a dry ore storage building and unloading and loading facilities at Everton.

At yearend, Reynolds announced plans to install a calcining kiln and ancillary facilities at Everton and additional mining and crushing equipment at Kwakwani. The kiln will produce 400 tons of refractory and abrasive bauxite daily beginning in late 1966 or early 1967.

Further expansion plans by Reynolds hinge primarily on the dredging of a deep-water channel through the bar at the mouth of the Berbice River, so that large ocean-going vessels may enter the river mouth to take on full loads of bauxite or other cargo. As of 1965, the maximum depth of the channel was about 17 feet and Reynolds had to transport its bauxite products on 6,500-ton barges to Puerto de Hierro, Venezuela, for transfer to larger vessels; the extra cost of this transfer operation has been estimated at $3 to $4 per ton of bauxite (at a 750,000-ton-per-year shipping rate) whereas the cost of dredging an adequate channel has been estimated at about $3.15 million and maintenance at $700,000 in addition per year.

Although Reynolds 1965 total output was above that of the previous 2 years it fell far short of the record 1962 output. Company shipments, reported as follows, reflect increased crude ore output and success of efforts to capture a larger share of the chemical-grade bauxite market:

Year	Shipments [1] (thousand metric tons)		
	Crude ore from Kwakwani to Everton	Processed ore from Everton	
		Metal-grade	Chemical-grade
1963	272	270	31
1964	315	228	85
1965	381	247	36

[1] All reported in terms of dry bauxite equivalent, calculated to eliminate all free moisture. In actual practice, metallurgical-grade bauxite normally is dried to contain about 5 percent and chemcial-grade to about 3 percent free moisture.

DEMBA, a wholly-owned subsidiary of Alcan Aluminium, Ltd., still is by far the largest bauxite producer, and the only alumina producer, in Guyana. In 1965, the company shipped 895,384 tons of dried bauxite (apparently all of metal grade), 493,753 tons of calcined bauxite, and 279,070 tons of alumina, compared with 553,000 tons of dried bauxite, 466,000 tons of calcined bauxite, and 292,000 tons of alumina in 1964.

DEMBA also implemented major expansion of its facilities during the year with the investment of about $8 million, and at yearend announced plans to invest more than $21 million in additional plant facilities. This latter decision undoubtedly was influenced by the long-term agreements reached between DEMBA and the Government in October.

During 1965, DEMBA commissioned its new 300,000-ton tailings recovery plant to rework old washing plant rejects for additional bauxite. It also completed a new 50,000-ton synthetic mullite plant, although only small quantities of this high quality refractory material were produced on an experimental basis. By midyear, the company's third bucketwheel excavator—a 150-liter machine—was installed to assist in overburden removal. A new evaporator unit was installed at the alumina plant to improve the removal of impurities in the process liquor. The company also experimented successfully with seismic methods for exploration work, and decided to in-

corporate the technique in its regular program. In October, the Guyana Assembly passed a bill permitting DEMBA to start construction of a 770-foot-long bridge across the Demerara River, between Mackenzie and Wismar, and a 4.5-mile-long railway which will provide better access to bauxite mining areas near Christianburg on the west side of the river; the bridge is scheduled for completion by early 1967.

The large investments earmarked for 1966–67 are intended to maintain and expand the company's production levels. Contemplated major projects included: 1. Acquisition of a large walking dragline ($1.2 million), 2. Acquisition of one 300-liter and one 600-liter bucketwheel excavators ($2.3 and $5.5 million, respectively), 3. Installation of an oil-fired boiler and a 12,500-kilowatt turbine to provide additional electric power ($2.6 million), 4. Installation of a 150-ton-per-day calcining kiln (DEMBA's seventh) and ancilliary facilities to increase total calcining capacity to about 700,000 tons per year ($3.2 million), and 5. Construction of the bridge and railway across the river ($1.75 million).

The high production levels attained by the bauxite industry in 1965 were partly abetted by the relative peaceful labor situation that prevailed during most of the year. Reynolds signed an agreement with the Mine Workers' Union in July, increasing wages for some 250 workers. Nonetheless mine operations at Kwakwani were halted for a short time in September when more than 400 workers staged a wildcat strike. The DEMBA operations at Mackenzie were forced to a brief standstill in mid-March by a wildcat strike of 3,000 workers while the company and the union were negotiating the apportionment of a 19.4-percent package wage and fringe benefit increase. Agreement was reached on April 8. Another wildcat strike forced closure of the DEMBA alumina plant in December and subsequently all bauxite operations were suspended as 4,500 workers joined the strike. A back-to-work agreement was reached on January 15, 1966.

Gold.—Gold returns for 1965 showed a slight decrease in total output compared with that of the previous year, but returns by district for 10 months (October and November not reported) indicate that Northwest District output decreased considerably from the 1964 level of 955 troy ounces (which was about average for recent years) but the district again became the major gold-producing area as gold recovery in the Mazaruni District continued to decline to perhaps less than half the abnormally high output of 1,111 ounces recorded for 1963. These decreases were offset by increases to more normal levels in the Cuyuni and Potaro Districts and by the highest output in recent years in the Rupununi District, probably resulting from increased diamond recovery operations during 1965.

Gold output recorded during 1965 was won by individuals or small groups of prospectors working alluvial deposits, mostly by hand washing or a combination of suction dredging and manual recovery of gold and diamond values. Increased mechanization might raise alluvial gold output.

The Geological Survey carried out geochemical and drilling programs in several well known lode gold districts, using panned gold values as one of the controlling factors limiting the areas investigated. The most promising of the areas investigated included the old Peter's Mine and the Jubilee, Million Mount, and other old gold prospects along the Puruni River about midway between the Mazaruni and Cuyuni Rivers. The Peter's Mine operated from 1905 to 1909 and reopened briefly in 1915 and 1916, producing a total of nearly 41,000 ounces of gold. The mine was worked to a maximum depth of 300 feet with gold values still in evidence, but was abandoned because of unfavorable economic factors, including very difficult accessibility and poor recovery (79 percent from 1-ounce-per-ton ore) due to inadequate equipment.

In 1964, the Geological Survey outlined the gold-rich near-surface area at the Peter's Mine by numerous drillholes, and early in 1965, seven diamond-drill holes, totaling 5,316 feet, were drilled. Three of the four holes drilled to intersect the lodes below the lowest mined level yielded cores containing visible gold. Two holes drilled several hundred feet to the north across the strike encountered mineralized lodes but no visible gold. The last hole was drilled to test a nearby magnetic anomaly which proved to be a belt of relatively unmineralized andesite. Although analyses and evaluation of all the data collected had not

been completed by yearend, the Geological Survey was optimistic that the area held possibilities for profitable lode-gold mining.

Manganese Ore.—The production of manganese ore and concentrates by Manganese Mines Management, Ltd., a subsidiary of Union Carbide Corp., at the Matthews Ridge mine in northwest Guyana, increased substantially over annual output of the previous 2 years but was still below that of either 1961 or 1962. During the latter part of 1965, cumulative production from the deposits surpassed the million-ton mark, and cumulative exports of ore by yearend nearly attained that same level. Although the ore reserve reportedly is at least several times that already mined, the product exported has been relatively low-grade, containing only 40 to 42 percent manganese with rather high silica and aluminum content. The low ore grade, coupled with high transport costs, probably will preclude any marked increase in production levels in the near future.

The company began a program of more thorough investigation of its exploration concession to similar, but smaller, manganese deposits at Pipiani on the south side of the Barama River about 25 miles east-southeast of Matthews Ridge.

NONMETALS

Construction Materials.—Increased activity in both the public and the private sectors of the construction industry was an important factor in the economic recovery achieved during 1965. Many new public buildings were built and many others rehabilitated or extended. Construction continued on the new Bank of Guyana, residential construction increased markedly, and private industrial building was about double that of 1964. In addition, some 30 miles of coastal roadway were constructed during the year. Although much of the material required was imported (for example, all the cement, lime, reinforcing rods, structural shapes, sheet, and pipe), output of domestic mineral raw materials such as sand, gravel, stone, as well as various roadbuilding materials apparently was sufficient to satisfy demand. In fact, the Dalli Quarry northeast of Bartica was reactivated to augment the supply of stone necessary for road projects and repair of sea walls. Statistics on output of these construction materials are either incomplete or not available; however, quarrying firms indicated their output was about 20 percent greater than in 1964, and iron and steel and cement imports for 1964 and 1965 were considerably greater than those during the previous 2 years.

The Guyana Development Corp. approved several concessions to establish new industries to produce construction materials, such as clay brick, concrete blocks, and tile. A West German interest was granted a concession to establish a $1.1 million glass plant in the Georgetown area. This plant will utilize white sand of the Berbice Formation which is readily available in the nearby Atkinson area. Guyana has practically inexhaustible resources of this white sand suitable for clear bottle and window glass manufacture. By means of electrostatic separation, a product containing between 0.007 and 0.008 percent Fe_2O_3 can be obtained, and even the strictest grain-size specifications would require rejection of only 30 percent of the crude sand. The projected plant probably will absorb part of the market of about 9 million bottles now imported annually and perhaps produce bottles for export to Guyana's new trading partners, Antigua and Barbados. This or some future plant might also enter into the manufacture of window glass, 826,000 square feet of which was imported by Guyana in 1964, as well as plate glass and other glassware now imported.

The Minister of Trade and Development announced that a British cement firm, The Rugby Portland Cement Co., Ltd., is prepared to install bulk loading, storage, and packing facilities in Guyana upon completion of negotiations for a suitable riverside plant site. Rugby apparently hopes that bulk imports and local bagging will help secure a firmer hold on the major part of the Guyana cement market for its Trinidad subsidiary plant, Trinidad Cement, Ltd., which must compete with suppliers from Venezuela, Jamaica, and possibly Barbados. Guyana does not have readily available raw materials to produce cement locally.

Diamond.—Diamond returns for 1965 registered an increase of slightly more than 8 percent in the number of stones recovered to 112,874 but an increase of only 3 percent in total carats, because the average size of stones found in two of the principal

producing districts was somewhat smaller. Although returns showing data by district for October and November were not available, extrapolation of data indicates that output of all producing districts increased except that of the Potaro District. The marked decrease in its output had been predicted on the basis of the relatively small quantity of diamondiferous alluvial material available along the Potaro River and its tributaries.

The Mazaruni District continued to supply nearly 70 percent of total output and accounted for most of the apparent increase. On the other hand, the Cuyuni District more than doubled its output to the order of about 12,000 carats, and the relatively minor Rupununi District approached an output level of nearly 5,000 carats for the first time since 1958; these two districts thereby roughly compensated for the loss in output of the Potaro District.

Government sources have indicated two basic factors that have influenced the higher level of diamond output which started in 1958. One has been increased accessibility to the remote interior areas via new airstrips and landing pools; construction of 30 new interior landing strips is provided for in the development program for 1966–72. The other has been increased utilization of various types of suction dredges in addition to and in place of the traditional water-dogging (diving) and other essentially manual techniques. Perhaps as many as 200 such dredges were employed in diamond recovery operations during the course of the year. Most of these units were small, and the possible introduction of larger and more efficient equipment, including more refined gravity recovery systems, may lead to increased production of diamond as well as the possible recovery of more gold and other valuable minerals from the alluvial materials processed.

Virtually all of Guyana's diamond output of gem as well as industrial qualities has been exported. Government efforts to promote a cutting industry in the country resulted in the granting of an initial concession to cut and polish diamonds to a West German firm, T. Steiman and Co. Ltd.

MINERAL FUELS AND ENERGY

Petroleum.—Active exploration for commercial deposits of oil and gas in the continental shelf area off the Guyana coastline was renewed as exploration concessions were granted to several firms. Guyana Shell Ltd., a subsidiary of the Royal Dutch/Shell Group, was granted a concession on the shelf area from the Surinam border approximately to the mouth of the Demerara River near Georgetown. Continental Overseas Oil Co. Ltd. obtained a contiguous concession extending northwest roughly to the Waini River; and Globe Petroleum Ltd. received a concession to the smaller area betwen the Continental concession and the Venezuela border. Shell and Globe also reportedly applied for onshore concessions adjacent to their offshore holdings. Guyana Shell Ltd. commenced reconnaissance seismic work in August when two ships under contract to Western Geophysical Co. began surveying the offshore areas. Both Shell and Continental hoped to complete their preliminary seismic surveys by early 1966 and anticipated the start of stratigraphic drilling later in the same year.

Further work in the Takatu basin of the Rupununi District was undertaken during 1965, and the Geological Survey drilled several shallow stratigraphic holes. Geophysical indications of a sequence of several thousand feet of sedimentary rocks in the basin, suggested the possible existence of petroleum and perhaps some evaporite deposits. The Phoenix Canada Oil Co. Ltd. applied for an oil exploration license covering an area of 2,600 square miles of the basin area, but the expected approval still was pending at yearend.

In 1965, the Geological Survey published a history of oil explorations in Guyana prior to 1962.[6] The study, under the auspices of the United Nations, includes a historical and technical review of all material available in 1962 pertaining to the search for oil in the coastal and offshore areas of the country. The published report includes seven maps and charts and recommendations for the type and location of future exploratory work.

Guyana continued efforts to promote a local oil refinery, and to this end a U.S. AID expert advised the Government and the Guyana Development Corp. on this

[6] Simakov, S. N., and V. V. Fedynsky. United Nations Technical Asistance Board. Report on the Prospecting for Oil in British Guiana. Geological Survey of British Guiana, Bull. No. 36, 1965. 48 pp.

matter. In December the Minister of Trade and Development announced that he had discussions with representatives of a large and reputable oil company during a trip to the United Kingdom and the United States, and that the firm made a proposal to complete the erection of a refinery within 2 years should Government approval be granted and a local company formed.

Electric Energy.—The Government has emphasized the urgency for expansion of Guyana's capacity to generate electric energy as a requisite to more rapid industrial development and to a general rise in the standard of living of both urban and rural inhabitants. All electricity generated has been from thermal plants fueled largely by imported fuel oils; however, the country possesses a large, but virtually unappraised, hydroelectric potential. Development of a significant part of this potential as a source of low-cost power conceivably would permit establishment of aluminum smelters, a caustic soda plant (for the alumina industry), and other industries that require relatively large amounts of cheap power.

Government, United Nations, and private experts have made superficial studies of the hydroelectric potential, and two sites for initial feasibility surveys have been suggested: (1) Tiboku Falls on the Mazaruni River, with an estimated potential of 100 to 250 megawatts, and (2) a site at Tiger Hill on the Demerara River, with an estimated potential of 36 to 144 megawatts. A United Nations Special Fund project was approved for a major power survey starting in 1966. This survey will include studies of water power and also the need for development of additional thermal power capacity.

The largest supplier of electricity during 1965 was the Guyana Electricity Corp., a public corporation with plants at Georgetown, Kingston, Ruimveldt, and Anna Regina, which has generated roughly half the electricity consumed in recent years. The municipality of New Amsterdam produces electric power for local use, and the Bookers Sugar Estates owns and operates a small plant at Bartica producing power mainly for residential use. In addition, a number of industrial enterprises, such as the bauxite and manganese companies and sugar and rice mills, generate electricity for their internal use. The following table shows available data on generation and consumption of electricity by sector for the period 1960–65, including that produced at Bartica but excluding the relatively small unreported output of plants at 11 sugar estates and 3 rice mills:

Year	Million kilowatt-hours			
	Total generated	Consumption		
		Residential	Commercial and industrial	Other
1960	88.0	23.2	53.3	2.4
1961	95.8	24.4	57.9	2.9
1962	105.5	27.4	66.1	2.6
1963	101.4	27.9	60.8	3.1
1964	170.6	24.5	130.2	4.5
1965 [1]	194.0	30.0	148.4	4.4

[1] Estimates based on data for first 3 quarters of the year.

The notable increases in production and consumption for the years 1964 and 1965 were largely attributable to corresponding increases in output of calcined bauxite and alumina. A government source estimated that the bauxite industry consumes approximately 40 million kilowatt-hours of electricity per year, roughly one-fifth of total consumption during 1965.

The Mineral Industry of Chile

By Lester R. Brown, Jr.[1]

Chile, one of the more economically developed countries of Latin America, increased its gross national product (GNP) in real terms by 5.8 percent in 1965 over that of the previous year. At current prices, however, the GNP increased 37 percent reaching 20,435 million escudos as compared with 14,882 million escudos in 1964. Although actual value data are not available by sectors of the economy, it has been reported[2] that the mining industry was a significant contributor to the overall economic growth, as the value of its contribution to the GNP during 1965 rose by 24 percent over the 1964 level. Other sectors of the economy recorded individual percentage increases in value contributed to the GNP as follows: Utilities—18, agriculture—7, transportation—4, and industry—3.

Chile continued to be a major supplier of certain mineral commodities in 1965. Although mine and smelter production of copper, Chile's most important product, was lower in 1965 than in 1964, the nation maintained its position as the third largest producer in the free world; Chile also ranked third in the output of molybdenite and remained the world's only producer of nitrates from mineral sources and the largest producer of iodine. Output of iron ores and beneficiated products registered a sizable gain over the previous year. The importance of Chile's major mineral commodities relative to total South American and world production in 1965 is shown in the accompanying table.

In 1965, the value of exports of mineral commodities was about $637 million, or approximately 93 percent of the total Chilean export value of $688 million, while imports of commodities in this group were of minor significance.[3]

Commodity	Chile's share of total (percent)	
	South American production	World production
Copper:		
Mine production	76	12
Smelter production	78	10
Nitrogen compounds:		
Natural nitrates	100	100
All types, including natural nitrates	88	1
Iodine	100	47
Iron ores and beneficiated products	21	2
Molybdenum	85	7

Wildcat strikes during the year in the copper industry were largely responsible for the 8-percent decrease in copper production. A strike was likewise reported in the cement producing industry.

Provisional data released by the Central Bank indicated that the international reserve and payment position at the end of 1965 was the strongest since that of 1959. Factors influencing the 1965 economic advancement included the expansion of trade as a result of the increased world demand for copper, substantial foreign economic assistance, continued political stability, and increased private and public investments in facilities for production of copper, iron ore, and industrial machinery.

The Government was successful in reducing the rate of inflation on the basis of cost of living data. Consumer prices in-

creased only 25.9 percent in 1965 compared with 38 percent in 1964 and 45 percent in 1963. The Chilean escudo depreciated in terms of the U.S. dollar during the year as the average buying rates of the Central Bank, on the Bankers Market Spot Rate and Futures Rate, respectively, increased from Esc2.372 and Esc2.741 per US$1 in 1964 to Esc3.128 and Esc3.130 in 1965. Exchange rates in December 1965 were Esc3.450 and Esc3.544 on the Bankers Market Spot Rate and Futures Rate, respectively.[4]

In January 1965, a measure to establish new norms for the production, manufacture, and sales of copper was introduced in the Chilean Congress. This bill was designed to implement agreements with the large U.S.-owned companies active in Chile and was a vital part of the Administration's program to increase export earnings from copper and gain a greater share of control of the industry for Chile.

Support for the measure was not forthcoming, and it was held up in Congress until the March elections, when the Partido Demócrata Cristiano, (PDC) (Christian Democratic Party), the party of the Administration, obtained a large majority in the Chamber of Deputies and increased representation in the Senate, and the bill was reintroduced to debate. Opposition developed not only from the Left but also from the more Central of the Frente de Acción Popular (FRAP) parties, the Right was only lukewarm in support, and a split on the issue was reported in the PDC itself. At yearend the measure remained unpassed.

Empresa Nacional de Minería, (ENAMI), the State Mining Enterprise, made public a plan to increase production from the smaller and medium-sized properties, by a program of loans, technical assistance, and joint investment with private capital and capital from other agencies such as Corporación de Fomento de la Producción (CORFO) the Government agency for stimulating production. During 1965, loans were made in the amount of $285 million.

The United Nations Special Fund Mineral Survey Project, scheduled to finish its activities in Chile in early 1966, completed the mineral survey of Coquimbo Province in 1965. Five areas of interest relating to copper were studied: Arqueros, Combarbalá, Tilama, Varillar, and Cerro Loica. At Cerro Loica, 70 kilometers southwest of Ovalle, detailed geologic mapping, geochemical, and geophysical studies delineated interesting areas that were later drilled. At yearend, results indicated some sections containing commercial thickness of ore, but the overall extent and importance of the mineralized body was not yet known. The ore appeared to be chalcopyrite finely dispersed in granodiorite.

At other locations in the Province, studies were made with varying degree of success. An airborne magnetic survey from south of Ovalle to the northern limits of Aconcagua Province found some interesting anomalies that were mapped and surveyed on the ground. Indications showed several small iron ore deposits. Sedimentary phosphate beds in the Tongoy Bay area, northwest of Ovalle, were drilled with negative results. Geophysical and geochemical surveys at the Los Mantos de Punitaque mine, south of Ovalle, pointed out favorable areas for new exploitation.

In 1965, Instituto de Investigaciones Geologicas (IIG), (the Government Institute of Geologic Investigations) continued regional geologic mapping and studies of the factors controlling the characteristics and distribution of the country's mineral resources. These studies, concentrated in the north and central regions of the country, placed increased emphasis on economic geology, thus coordinating the work to the immediate development plans of Chile.[5]

PRODUCTION

The production of iron ore and beneficiated products increased 16 percent in 1965 over that of 1964. Both molybdenum and zinc-in-concentrates showed increases, but in lesser amounts. In the nonmetals category, borates, barite, guano, and iodine registered tonnage increases.

The 1965 copper production tonnage equaled only 92 percent of the previous year's total. Most of the decrease was in the Gran Minería sector of the industry, which reported only 91 percent of the pre-

[4] U.S. Embassy, Santiago, Chile. Department of State Airgram A-677, Jan. 22, 1966, 21 pp.

[5] U.S. Embassy, Santiago, Chile. Department of State Airgram A-970 and annex, June 8, 1966, 46 pp.

vious year's tonnage, while the Medium and Small Mines sectors came within 98 percent of their 1964 totals. Gold production in ores, concentrates, and placer output, manganese in ore, and silver in ores and concentrates also decreased in 1965. Cement production, nitrates, and contained sulfur also were below 1964 levels. Crude petroleum production also declined.

Production results for 1965 were obtained from various preliminary sources and will be subject to certain revisions on publication of the 1965 "Anuario" of the State Mine Service of Chile.

e Estimate. p Preliminary. r Revised. NA Not available.

[1] Although data are considered preliminary, figures in some cases supersede those given in commodity chapters of Volume I, 1965.

[2] Includes clay (other), iron oxide pigment, and silica sand.

[3] Includes iron oxide pigments and silica sand.

[4] Includes iron oxide pigments, marble, silica sand, and mica.

[5] Calculated at 35.13 cubic feet per cubic meter.

[6] White gasoline and naphtha.

[7] Includes mineral turpentine, asphalt, and miscellaneous petroleum products.

[8] Includes estimate on Manantiales topping plant production.

TRADE

The value of mineral commodity exports in 1964, the latest year for which complete comparative figures are available, amounted to approximately $556 million. This represented approximately 89 percent of the total export value of $626 million. Imports of mineral commodities in 1964 amounted to $60 million, or about 10 percent of the total import value of $609 million.

The value of the copper exports in 1964, approximately $419 million, amounted to 67 percent of the total Chilean export figure.

In 1965, copper retained its dominant position in Chilean exports, although tonnages were lower than in 1964. Exports of copper in refined forms by the Gran Minería sector of the industry, as indicated by the Monthly Bulletin of the Chilean Central Bank, amounted to approximately 416,000 tons valued at $323 million in 1965, compared with 534,000 tons valued at $371 million in 1964. However, exports of blister copper by the Medium and Small Mines sector increased from approximately 30,400 tons in 1964 to 76,800 tons in 1965, valued at $15.2 million and $84.9 million, respectively.[6]

The export of molybdenum concentrate was lower in 1965 than in 1964 because for the first time a Chilean processing firm, Compañía Carburo y Metalurgia S.A., took a significant part of the country's molybdenum output. In terms of contained molybdenum, 3,072 tons was exported in 1965, compared with 3,984 tons in 1964.

Chilean exports of manganese rose sharply in 1965, 12,168 tons was exported, compared with 3,522 tons in 1964. The increase was credited to improved foreign exchange returns.

Iron ore exports were increased in 1965 over the previous year. Iron ores and beneficiated products exported in 1965 amounted to 10,724,533 tons, compared with 9,113,557 tons in 1964, Japan again was the largest recipient.

Nitrate exports in 1965 amounted to 922,229 tons, compared with 908,427 tons for 1964. There were no significant changes in the market pattern except that mainland China moved into the sixth position in rank of customers.

Iodine export was somewhat smaller in 1965 than in 1964, apparently the result of further Japanese entry into world markets.

Largely owing to import controls, total Chilean imports for 1965 amounted to approximately $604 million, down from $609 million for 1964.

COMMODITY REVIEW

METALS

Copper.—Chilean copper production in 1965 was 8 percent below the previous year's output. Contributing to the reduced production were legal and illegal work stoppages affecting the large, medium, and small mining groups, severe weather, and damages resulting from an earthquake in March. Increased production of electrolytic copper in the large mines group reflected the increased output of the Andes Copper Mining Co. Potrerilles refinery, while the increase in blister copper production by the medium and small mines group resulted from production by the new Chilean Government processing plant at Las Ventanas.

[3] Exports.

The Chuquicamata mine, operated by the Chile Exploration Co., a subsidiary of The Anaconda Company of the United States, reported a copper production of 252,720 tons in 1965, compared with 288,044 tons in 1964. The mine handled a total of 24,028,213 tons of ore materials and 20,280,552 tons of waste, giving an ore to waste ratio of 1.18:1.00.

As this property is located in Chile's northern desert region, it was significant that a fifth 300-foot-diameter tailings thickener to conserve more water for concentrator operation was completed at yearend. This additional water will enable the plant to operate at its rated capacity of 55,000 tons per day. A project has been undertaken to test the feasibility of re-treating leach-ore residue, which might then become an important source of low-cost copper.

The El Salvador mine of the Andes Copper Mining Co., another subsidiary of The Anaconda Company, reported a total copper production of 74,139 tons in 1965, compared with 76,454 tons in 1964. The com-

pany processed 6,945,572 tons of ore with an average grade of 1.465 percent copper. The initial development work was completed on the underground ore-handling system to reduce haulage and increase plant feed.

Despite the 37-day work stoppage, the mine-mill production of the Braden Copper Co., a subsidiary of the Kennecott Copper Corp. of the United States, reached the highest annual rate in the company's history. Smelter production of fine copper was adversely affected by the strike and by a slightly lower grade of mill concentrates. Salient figures for comparison of 1964 and 1965 follow:

	1964	1965
Operating days	344	325
Ore processed ---dry metric tons--	10,510,484	10,933,595
Ore milled ---metric tons--	10,442,949	10,896,557
Copper in heads ---percent--	1.882	1.796
Copper in concentrates ---do---	32.33	32.27
Blister produced ---metric tons--	84,623	75,372
Refined copper produced ---do---	78,994	77,496

The enlargement and concreting of shaft B advanced approximately 350 feet, and was scheduled to enter into operation in mid-1967. Elevator cages will then be able to transport 250 passengers or a fully loaded 25-ton-capacity railroad car.

Empresa Nacional de Minería (ENAMI) owns and operates the Paipote smelter near Copiapo in Atacama Province and the Las Ventanas smelter and refinery on Quintero Bay, just north of Valparaiso. ENAMI also has flotation plants at Aguirre Cerda, Cabildo, Osvaldo Martinez, Illapel, and Cerro Negro and leaching installations at Taltal, Elisa de Bordos, and El Saldo. Through yearend, feed was drawn from medium and small mines of Tarapacá and Antofagasta Provinces in the north to Aisén and Magallanes in the south. Copper concentrates purchased in 1965 amounted to 363,289 tons compared with 232,000 tons in 1964, and tonnages purchased for copper leaching increased to 50,405 tons in 1965 from 19,212 tons in 1964.[7]

Cía. Minera Disputada de las Condes, S.A., a subsidiary of Société Minière et Metallurgique de Penarroya, a French corporation, continued to operate its Disputada and El Soldado mines. The Disputada, northeast of Santiago, reported 1965 production of 1,107,000 tons of ore averaging 1.43 percent copper, while El Soldado recorded a 1965 output of 573,000 tons of ore averaging 2.14 percent copper. The company processed 52,770 tons of resultant concentrate at its Chagres smelter producing 15,712 tons of blister copper. The remaining 23,430 tons of concentrate was exported.

Empresa Minera de Mantos Blancos, S.A. (Mauricio Hochschild y Cía. S.A.I.C.) followed the same pattern as that found in the Gran Minería sector, achieving record production rates, but total output was lower due to strikes. Comparative tonnages for 1964 and 1965 follow:

Product	Quantity (metric tons)	
	1964	1965
Total refined copper products	r 21,309	20,389
Cement copper	3,150	3,127
Refinery slags	181	140
Total	24,640	23,656

Anticipating that from 1968 onward, the grade of the ore will have been reduced to 1.6 percent copper, the company was studying plans to increase monthly plant capacity to 175,000 tons to maintain production at 1965 levels.

The Santiago Mining Company, a subsidiary of The Anaconda Company of the United States, produced 283,926 tons of ore from its La Africana mine near Santiago, and processed this to obtain 27,850 tons of concentrate with a grade of 25.38 percent copper which was shipped to the Government smelter at Las Ventanas.

Production from the mines and plants of Cía. Minera y Comercial Sali Hochschild was approximately 600 tons of copper per month in cement copper and concentrate. Previous to 1965, the company had spent

approximately $4.5 million in developing a new copper property in the coastal range in the Michilla area of Antofagasta Province with reserves reportedly approaching 2.0 million tons of 2.5 to 3.0 percent copper. The mill for the property will be constructed at Michilla Bay. The mine to mill road has been completed, and the mill is expected to be finished in 1968.

Iron Ore.—The Chilean iron ore industry in 1965 recorded the best year-to-year gain in tonnage produced since 1960 in spite of strikes, severe weather, and damage from the March earthquake. Exports of iron ore and beneficiated products also increased during the year to 10,724,533 tons, approximately two-thirds of which was shipped to Japan.

Compañía de Acero del Pacífico S.A., (CAP), the largest producer of iron and steel in Chile and the owner and operator of the Algarrobo iron mine near Huasco in northern Chile, reported the following results of mining activities for 1964 and 1965:

Ore type	Quantity (metric tons)	
	1964	1965
Lump	1,392,471	1,322,977
Blast furnace	1,352,937	2,035,683
Premium fines	85,081	143,170
Total	2,830,489	3,501,830

Through 1965, the following ore processing scheme was used: The ore is sent to a primary crusher and then screened. The coarse ore is classified as open-hearth feed, and the fines are rescreened at a smaller size. Products of this screening are magnetically concentrated; the oversize concentrate is used for blast furnace feed while the finer concentrate is sold for agglomeration. Nonmagnetic rejects are stored for future treatment.

Compañía Minera Santa Fe S.A. recorded a 6.6-percent increase in production of iron ore in 1965, reaching 3,846,184 tons. Producing properties were the Carmen, El Dorado, Cerro Negro Norte, and Desvio Norte mines, all in the Chañaral, Copiapó, and Coquimbo areas.

The ore-processing plants are of a simple construction, generally portable and readily dismantled and reinstalled with a minimum of concrete work. The process generally consists of classification as a preconcentrating step followed by magnetic beneficiation where necessary. Equipment purchased during the year to increase production and transportation capacities included two Reich drills, seven Harnischfeger, P&H 955A shovels, 35-ton pit-trucks, and 32-ton haul trucks.

Santa Fe also owned El Laco, an iron ore deposit 400 kilometers east of Antofagasta in the high Andes mountains that reportedly contains reserves of 300 million tons.

Bethlehem-Chile Iron Mines Co., a subsidiary of the Bethlehem Steel Corp. of the United States, owned and operated the Romeral and the El Tofo mines in Coquimbo Province near La Serena. The Romeral mine produced 2,587,274 tons of beneficiated ore averaging 63.98 percent iron. Romeral ore shipments totaled 2,494,418 tons. Waste and stripping material removed during the year totaled 5,896,782 tons. The El Tofo mine produced 122,330 tons of beneficiated furnace ore averaging 65.24 percent iron and an additional 153,566 tons of lump ore averaging 67.31 percent iron. A wet magnetic beneficiation plant was put in operation at El Tofo during 1965. The company shipped 684,788 tons of its production to the Huachipato steel complex of the Cía. Acero del Pacífico S.A., and exported the remainder.

The Chilean State Mining Service published the following list of iron ore reserves with the qualifications that they assayed 60 percent iron or higher and were of magmatic origin. The reported tonnages were felt to be conservative estimates but should not be considered to be proven ores: [8]

Company	Deposit	Mineral resources (thousand metric tons)	
		Reserves	Mineral potential
Cía. de Acero del Pacífico, S.A.	Algarrobo	70,000	-----
Bethlehem-Chile Iron Mines Co.	El Romeral	16,000	-----
Cía. Minera Santa Fe, S.A.	Various	40,000	520,000
Do.	El Laco	-----	-----
Cía. Minera Santa Bárbara	Various	9,000	-----
Cía. Minera de Atacama Ltda.	Las Adrianitas	10,000	-----
Soc. Minera Cerro Imán	Cerro Imán	4,000	-----
Soc. Minera San Javier	Various	1,000	-----
Soc. Minera Cerro Colorado	Los Colorados	2,000	-----
Cía. Minera de Exportación	Various	500	-----
Cía. Minera Confar	----do	1,500	-----
Various	----do	5,000	5,000
Total		159,000	525,000

Production of the Huachipato plant of Compañía de Acero del Pacifico S.A. (CAP), Chile's major steelmaker, was as follows for the past 3 fiscal years: [9]

Product	Quantity (metric tons)		
	1962–63	1963–64	1964–65
Hot metal	404,922	429,643	406,138
Steel ingots	496,462	502,406	541,095
Semifinished products	414,246	434,659	462,751
Finished products (rolled)	351,803	382,075	363,249
Pipe	7,740	10,245	12,018

The company indicated that, owing to the growth in the domestic consumption of iron and steel products plus the potential export market, acceleration of the expansion programs of the Huachipato plant was warranted. These programs to increase steel production capacity with the consequent lowering of costs will have favorable effects on the rather tight financial results currently derived from Huachipato operations. A plan was devised to raise steel ingot production, starting about 1969 and reaching 1 million tons per year in 1971. This would include increased production of hot metal and crude and semifinished steel with ensuing increases in rolling and finishing mill capacities. In 1965 company profits from the Algarrobo mine considera-

[8] U.S. Embassy, Santiago, Chile. Department of State Airgram A–3, July 1, 1966, p. 1.
[9] Compañía de Acero del Pacífico S.A. (Santiago, Chile). Memoria Anual, 1964/1965.

bly exceeded those obtained from the Huachipato plant complex.

Lead and Zinc.—Empresa Minera Aisén, a subsidiary of Corporación de Fomento de la Produccion (CORFO), remained Chile's sole important lead producer and only known zinc producer in 1965. The Puerto Cristal mines in the Department of Aisén shipped 1,127 dry tons of lead concentrate averaging 56.48 percent lead and 2,174 tons of 51 percent zinc concentrate for processing. This represented a considerable decrease in lead production from the previous year, but an increase in zinc production.

Manganese.—Compañía Manganesos Atacama, S.A. in the Province of Coquimbo, was Chile's sole producer of manganese in 1965, recording an output of 16,588 tons averaging 46.77 percent manganese. Exports for the year totaled 12,168 tons, of which 8,886 tons went to the United States and the remainder to West Germany. Cía Carburo y Metalurgia, S.A. (CARBOMET) reported that it manufactured 4,285 tons of ferromanganese and 3,713 tons of silicomanganese during 1965. CARBOMET exported 2,853 tons of ferromanganese to Colombia, the United States, and Peru and 1,640 tons of silicomanganese to the United States in 1965.

Mercury.—Los Mantos de Punitaqui mine, south of Ovalle in the Province of Coquimbo, remained Chile's only mercury producer in 1965. The company was assisted in the location of additional deposits of mercury by technicians from CORFO, and the United Nations Mineral Survey Team operating in Chile during the year.

Molybdenum.—The 1965 production of molybdenum sulfide, based on preliminary data, exceeded the 1964 figure by a slight amount.

The first Chilean molybdenum mine, the Rosario property, northeast of Rengo in O'Higgins Province, started operations in October and sent a trial shipment of concentrates to Germany.

A Chilean processing firm took a significant part of the country's molybdenum output for the first time; domestic deliveries of contained molybdenum totaled 616 tons. The Compañía y Carburo Metalurgia, S.A., started production of molybdenum oxide and ferromolybdenum, and outputs totaled 1,253 and 100 tons, respectively. Chilean molybdenum shipments to overseas destinations for 1964 and 1965 follow:

Destination	Contained molybdenum (metric tons)	
	1964	1965
West Germany	1,788	1,144
United Kingdom	814	898
Netherlands	528	460
Sweden	532	325
France	185	160
Japan	137	85
Total	3,984	3,072

NONMETALS

Cement.—Chilean cement production in 1965 was 5.6 percent below the 1964 figure. Much of this reduction was credited to work stoppages during the year, but a part was also charged to reduced demand.

Empresas Industriales El Melón S.A. reported a 1965 production of 474,161 tons of cement, charging a loss of some 130,000 tons of output to a strike in November and December. The company continued with its expansion program which included the installation of a primary crusher, a battery of silos for cement storage, and a packaging plant for railroad shipments.

Cemento Cerro Blanco de Polpaico, S.A., reported 483,291 tons of cement produced in 1965, a small decrease from the previous year's output. Production from its mining properties totaled 791,045 tons of limestone, 15,509 tons of kaolin, 7,434 tons of iron oxide, and 141,606 tons of pozzolan.

Cemento Bio-Bio, in Concepción, produced 148,235 tons of cement in 1965, a considerable drop from the previous year's 167,200 tons.

Fertilizer Materials.—*Nitrogenous.*—Production of Chilean nitrate, which had been projected to increase in 1965, actually decreased slightly from that of 1964, because of work stoppages in April and May.

The Anglo-Lautaro Nitrate Company accounted for approximately 88 percent of the total Chilean nitrate output in 1965. The company continued to invest approximately $2 million annually in modernization. In process of completion were the new granulation facilities at the Maria Elena plant, which will have a capacity of 1,000 metric tons daily. Production of boric acid from the new installation at the Coya Sur plant was about 2,400 tons annually.

The Empresa Salitrera Victoria, operating under the Governmental mining enterprise ENAMI, produced an additional 8 percent of the year's total, while the remainder was accounted for principally by Oficina Alemania of the Cía. Salitrera Iquique and Oficina Flor de Chile of the Cía. Salitrera Pedro Perfetti.

Chilean exports of nitrate by destination in 1965 follow:

Destination:	*1965 nitrate export (metric tons)*
United States	398,956
Spain	119,185
Netherlands	67,036
Brazil	57,727
France	47,314
Mainland China	37,366
Others	194,645
Total	922,229

Phosphatic.—The Compañía Salitrera de Tarapacá y Antofagasta, Chile's sole producer of apatite rock, continued in liquidation and limited its 1965 activities to operating its mine and phosphate plant in Coquimbo. Production reached 13,686 tons of "phosphato pelicano" containing 20 percent soluble phosphorus pentoxide (P_2O_5). The process required 11,430 tons of apatite with a grade of 26 percent P_2O_5.[10]

The Sociedad Chilena de Fertilizantes, Ltda., a Government-operated company established by the Empresa de Comercio Agricola and CORFO, continued to be Chile's sole guano producer, operating two mixing plants at Iquique and Mejillones. Both are modern and fully mechanized. Red or fossil guano production in 1965 amounted to 17,958 tons, while the white or recent type came to 3,848 tons.[11]

Iodine.—Chilean iodine production in 1965 amounted to 2,280 tons, of which 2,122 tons came from Cía. Minera Anglo-Lautaro. The ENAMI operation, Empresa Salitrera Victoria, produced an additional 126 tons, while the remainder came from Oficina Alemania and Oficina Flor de Chile operations.

Exports in 1965 totaled 1,751 metric tons, valued at approximately $2.78 million, and were distributed as follows: United States, 681 tons; United Kingdom, 481 tons; France, 225 tons; the Netherlands, 170 tons; West Germany 115 tons; and others, 79 tons.

Lapis Lazuli.—Cía. Minera Carén, Chile's sole producer of lapis lazuli, was able to operate its mine only 5 months during 1965, owing to severe weather conditions. It was reportedly becoming more difficult to recruit labor for this remote and uncomfortable site in the high Andes east of Ovalle. During the year, 19,665 kilograms of material were mined, and since markets

[10] Work cited in footnote 5.
[11] Work cited in footnote 5.

were found for only about half of this amount it was considered doubtful if mining activities would be resumed in 1966.[12]

Limestone.—Chilean limestone production declined slightly from that of 1964. Cemento Cerro Blanco de Polpaico, S.A., reported a production of 791,045 tons during 1965, and Empresas Industriales El Melón, S.A., reported 611,663 tons, for use in their respective cement manufacturing plants. Most of the remainder came from the Guarello Island properties of Cía. de Acero del Pacífico S.A. for the company's iron and steel complex at Huachipato.[13]

Salt.—Chilean salt production reportedly increased 6 percent over the previous year's total. Cía. Sal-Chile, a new company that has acquired the properties of Salinas Punta de Lobos, was planning to expand production from its deposits in the Salar Grande area south of Iquique, in the Province of Tarapacá. Chilean salt needs are estimated at 80,000 tons per year. About half were supplied by Sal-Chile, while the remainder came from Leandro Antonijevic Ltda. and Fistonic, Kinast y Cía., operating in the same area.[14]

Sodium Sulfate.—Chilean sodium sulfate production for 1965 increased 84 percent over the 1964 figure. Most of the production came from the properties of Sociedad Minera Canchones Ltda. near Iquique, with the bulk of the remainder supplied by Sr. Hector Rojas A., who reported a 1965 production of 1,300 tons of 87 percent sodium sulfate and 3,300 tons of 84 percent.[15]

Sulfur.—Chilean sulfur production declined about 23 percent from that of 1964. The country's largest producer, Sociedad Azufrera Aucanquilcha S.A., reduced production from 33,350 tons in 1964 to 28,034 tons in 1965. It was reported that Mauricio Hochschild y Cía. S.A.I.C. and associated companies had purchased additional shares in the Aucanquilcha Corporation during the year. This was to assure an adequate amount of sulfuric acid for the copper treating facilities of Cía. Minera Mantos Blancos.[16]

In addition to Chile's mined sulfur, the Chile Exploration Co. and the Braden Copper Co. each recovered approximately half of an estimated 10,635 tons of sulfur (sulfur content of acid) from smelter gases and pyrite roasting.

MINERAL FUELS

Coal and Coke.—Gross Chilean coal production was slightly lower than that of 1964. Carbonifera Lota-Schwager S.A., in producing 1,293,661 tons, retained its traditional share of total Chilean output. Production for 1965 by mines follows:[17]

Mine	1965 production (metric tons)		Coal type
	Run-of-mine	Marketable	
Lota-Schwager	1,293,661	1,210,873	Bituminous
Colico Sur [1]	132,250	127,305	Do.
Pilpilco [1]	74,405	70,215	Do.
Victoria de Lebu [1]	93,190	92,553	Do.
Plegarias	25,071	22,603	Do.
Nueva Aurora	20,536	20,494	Do.
Pupunahue	11,072	10,493	Lignitic
Catamutun	19,589	19,589	Do.
Pecket Harbor	31,554	30,095	Do.
Others	25,676	24,335	Do.
Total	1,727,004	1,628,555	XX

XX Not applicable.
[1] Operated by CORFO.

An estimate of coal consumption by major consumer groups for 1965 follows:

Consumer group	*Consumption thousand metric tons*
Industry and mining	416
Railroads	322
Coke plants	313
Public utility powerplants	165
Domestic consumption and other	162
Cement plants	160
Gasworks	141
Total	1,679

The Lota-Schwager operation continued to show losses in spite of an intensive modernization program. High mining costs were attributed to the depth of the coal seams, their distance from the mine shafts, and the costs of wages, salaries, and benefits. The company indicated that personnel has been reduced approximately 40 percent in the past 10 years, from 15,600 persons in 1955 to 9,300 in 1965.

[12] Work cited in footnote 5.
[13] Work cited in footnote 5.
[14] Work cited in footnote 5.
[15] Work cited in footnote 5.
[16] Work cited in footnote 5.
[17] Work cited in footnote 5.

Chilean metallurgical coke production, reported at approximately 212,600 tons for 1965, was the result of blending imported U.S. medium-volatile bituminous and locally produced high-volatile bituminous coals. The blend ratio remained about the same as in previous years, with 125,000 tons imported for mixing with 188,000 tons of Chilean coal. Gashouse coke production was estimated at 81,000 tons in 1965, a slight reduction from that of 1964.

Natural Gas.—Chilean natural gas production declined about 1 percent from 1964 output. Of total 1965 production, 72 percent, or 157,582 million cubic feet, was reinjected for repressuring or storage. The remainder was flared or was used for heating or power generation at the Empresa Nacional del Petróleo (ENAP) facilities for operation of a small generating plant at Punta Arenas.

Petroleum.—Chilean petroleum production in 1965 decreased 7.2 percent from that of 1964 after registering a 3.6-percent gain in 1964 over that of 1963. Some of this reduction was charged to an 8-day strike in April at ENAP facilities, and part was credited to a lack of new wells being brought into production. The nation's 1965 output probably ranked Chile sixth among South American producers, following Venezuela, Argentina, Colombia, Brazil, and Peru. The Daniel oilfield (on the Chilean mainland) remained the largest producer in 1965, though its percentage of total production decreased from 37 to about 35 percent. Approximately 49 percent of total production came from mainland fields in 1965, compared with 52 percent in 1964.

According to ENAP's annual report, exploratory wells drilled in 1965 were generally unproductive though some gas accumulations were found. In the Magallanes Zone, 4 seismic crews operated during the year, and some 40 exploration and extension wells were recommended for the Terciaria and Springhill districts. Magallanes Zone drilling during 1965 was reported as follows:

Type of well	Number of completions			
	Petroleum	Gas	Dry	Total
Exploration	—	—	4	4
Extension	3	3	12	18
Development	12	4	5	21
Total	15	7	21	43

In the Central-South Zone, two seismic crews which had been operating during 1965 finished work in November. Four exploratory wells had been put down with generally negative results. A program for future exploration calls for drilling in the Provinces of Llanquihue, Cautín, Ñuble, and Arauco.

Part of Chile's output of crude oil and gas was processed by the topping plant in the Manantiales area and the gas plant at the Cullen field on the Island of Tierra del Fuego. The major Chilean refinery at Concón, was only lightly affected by the March earthquake and processed 16,857,200 barrels of crude oil during 1965. Feed to the plant was 70 percent Chilean crude oil and 30 percent imported. The combined output of these plants enabled the country to be self-sufficient in motor and aviation gasolines, kerosine, and liquid petroleum gas. About 85 percent of the demand for diesel and 50 percent of that for fuel oil were also met by the domestic refineries.

Construction work on the new refinery at Concepción, which will have a daily throughput capacity of 35,850 barrels, progressed on schedule, and at yearend the marine terminal at San Vicente, associated with the refinery, was equipped.

Prior to 1965, the Concón-Maipu pipeline[18] had been completed to San Fernando, and studies had been approved for the construction of a pipeline from Concepción to San Fernando, where it would join with the Concón-Maipu line. Thus, the refinery at Concón and the new plant under construction in Concepción would be connected and able to supply the demands of the Central Valley of Chile. At yearend, these studies had been completed, and construction was projected to start in early 1966.

During 1965, development of plans continued for the projected Chilean petrochemical industry, which will be under the direction of CORFO and ENAP.[19]

The Mineral Industry of Colombia

By Frank E. Noe [1]

The 16-percent rise in Colombia's output of crude petroleum in 1965 resulted in a growth rate of 13.0 percent in the crude mineral-producing sector, the highest ever registered, and increased that sector's share in the gross domestic product to 3.8 percent (at constant 1958 prices). According to preliminary figures, production of metals and nonmetals generally declined in volume, but the value of mineral production, excluding petroleum, increased 23.6 percent to Col$1,042 million.[2] The value of crude oil, natural gas, and petroleum refinery production was not available, but crude oil production has regularly accounted for an estimated 80 percent of all crude mineral output.

Although Colombia remained the leading producer of gem emeralds and the fifth ranked producer of platinum in the world, Colombia's mineral production was important only to the country's rapidly expanding industrial sector.

Through most of 1965, continued uncertainty regarding the interpretation of 1961 modifications of the Petroleum Code caused a decline in most oil company exploration activities. Production and exports of crude oil increased during the year, but new development and growth of the Colombian petroleum industry was generally sluggish, because the controversy between the Government and the private companies continued regarding the interpretation of Law 10 and its regulatory Decree 1348 of 1961 and regarding the applicability of Decree 2140 of 1955, which provided special depletion allowances and other incentives. The issue arose in 1963 when the Government unilaterally interpreted the tax provisions of the law and the validity of contracts established under previous legislation. This problem developed into a public debate which extended to the question of fairness and adequacy of the Government's share in the income and profits of the private operators. The question quickly assumed a political character, a factor which kept it alive and without resolution through 1965. In September, new Ministers of Finance and of Mines and Petroleum took office as the result of a cabinet change. The new Ministers placed a high priority on the resolution of the oil question, and as a result, Decrees 2526 of September 24 and 2760 of October 21 were issued. These instruments interpreted the applicability of Decree 2140 allowances and incentives incorporated in existing contracts and provided for uniformity in the use of the petroleum exchange rate for all transactions including payment of taxes. The legislation also called for the use of one crude oil price (either posted price or the realized price) for calculation of both depletion allowance and income tax. The two decrees in general were favorably accepted by the private companies. With the correction and clarification of the private companies' legal tax position, Government-industry relations appeared to be on a firmer basis than they had been for a long time.

The National Mineral Inventory, financed in part by a $2 million loan by the Agency for International Development, continued at an accelerated pace in all zones covered by the survey. The Government signed a contract in August with Geophoto Services, Inc., and Geophysical Service, Inc., for photointerpretation of three areas totaling 36,900 square kilometers, based on material supplied by Colombia. The National Mineral Inventory will

---

[2] Throughout this chapter values are given in currencies as reported because of differing conversion rates. Free rate of exchange in 1965 averaged Col$16.99 (pesos) per US$1; in 1964 it was Col$10.54 per US$1.

cover four zones containing approximately 70,000 square kilometers which will be systematically studied and mapped geologically. Mineral deposits will be investigated and evaluated as to possible economic development. The four zones consist of (1) Sierra Nevada de Santa Marta (15,500 square kilometers); (2) the central and eastern part of the Departamento de Antioquia, the northern and eastern part of the Departamento de Caldas, and a small portion of the northern part of the Departamento del Tolima (38,385 square kilometers); (3) Departamentos Santander and Norte de Santander (16,625 square kilometers); and (4) Departamento de Cundinamarca (5,330 square kilometers).

In Zone 1, geologic mapping of 7,525 square kilometers was completed. Mineral prospects which warranted further study included limestone, phosphates, talc, kaolin, iron ore, granites, and marble.

In Zone 2, 3,500 square kilometers were mapped, and various mineral deposits investigated. Superficial surveys were made of andalusite (chiastolite), kaolin, mercury, and talc occurrences. Detailed studies were made in areas containing deposits of wollastonite, talc, iron-nickel laterites, and asbestos, and of an altered andesite area containing copper-lead-zinc-silver mineralization.

Activities in Zone 3 were hampered by lack of personnel, and it was not until the middle of November that the program in this area got under way.

In Zone 4, the work was oriented towards the detailed mapping and study of the geologic condition of the salt deposits of the Sabana of Bogotá for the determination of their origin, age, location within the different geologic structures, extension, and the location of new salt deposits to increase reserves which have been very dangerously decreased. At the same time, a study was made of the possibilities of using industrially the residues from the salt-concentrating plants at Zipaquirá and at Nemocón. The search for phosphates was intensified. Superficial studies in the area of Alto del Trigo indicated that the occurrence, concentration, location, and potentiality of the deposit justified more advanced studies, and six holes were drilled at the Quebrada Santibañez. Drill cores were being studied and prepared for chemical analyses. In drill hole 3, the core presented a positive phosphate reaction in greater or lesser degree over almost its entirety, but between 270 and 280 feet a rich phosphatic section was encountered which contained visible grains of collophanite. In hole 6, a 35-foot-thick section beginning at 110 feet also contained visible grains of collophanite. Other phosphate-bearing areas were investigated in the region of Utica-Guaduero, in the area Zipaquirá-Pacho, and in the region of Pandi.

In August the West German Government sent two geologists to inspect coal deposits and certain mineral areas, which were not included in the zones under study by the Mineral Inventory program. After visiting a large part of the country, a program of collaboration was informally proposed which would consist of a Colombian-West German commission made up of six Colombian geologists and four West German advisers, all working under the direction of the Mineral Inventory. At yearend a formal proposal had not been received from the West German Government.

In November three members of Technical Cooperation of France visited the Director of the Mineral Inventory with the suggestion that the Government of France collaborate with the Government of Colombia in a geologic-mining study of an area not covered by other Colombian projects. A 3-year program for the geologic mapping of a 16,000-square-kilometer area in the Department of Boyacá was suggested along with the economic evaluation of such prospects as appeared to have possibilities. The approximate cost of the program was to be Col$10 million of which France would supply 75 percent and Colombia the remainder. The technical team would be made up of six Colombian geologists and two French advisers. The proposal was submitted to the French Government for study, and at yearend the Colombian Government was awaiting a reply.

At yearend the Technical Advisory Committee of the Mineral Inventory was negotiating also with the Government of Canada for technical assistance in connection with the study of the most promising areas of the central Cordillera.

Statistical data for this chapter were derived from official publications of the Ministerio de Minas y Petróleos, Banco de la República, the Departamento Administrativo Nacional de Estadística (DANE),

the Centro de Información de la Industria Petrolera, and the Statistical Office of the United Nations. Further information was obtained from U.S. Embassy, Bogotá, dispatches and from articles and notes appearing in such trade magazines as Petroleum Press Service, World Petroleum Report, World Oil, Petróleo Interamericano, World Mining, and the annual reports of Pato Consolidated Gold Dredging Ltd., International Mining Corp., and Acerías Paz del Rio.

PRODUCTION

Except for a slight increase in the output of mercury and steel ingots, production of all metals and metallic minerals declined during 1965. Production by Acerías Paz del Rio, S.A., and Empresa Siderúrgica, S.A., continued on about the same level as in 1964 while both companies were actively engaged in expansion programs.

The production of nonmetallic mineral commodities and products continued to dominate the nonfuel mineral field; cement production reached a new high and was by far the most valuable industrial mineral commodity. Sulfur production increased approximately 50 percent, also a new high. Salt output declined slightly in volume but increased 27 percent in value reflecting an increase in the local sales price.

[2] Includes 35,000 tons of coke breeze.

TRADE

Although complete, detailed official trade returns have not been published by the Colombian Government for years subsequent to 1963, it is evident from available sources that petroleum, petroleum products, and cement remained Colombia's principal mineral exports in 1965. The value of Colombia's 1965 petroleum exports, as reported by the Petroleum Industry Information Center, was US$96.8 million, of which US$88.2 million was from the sale of crude oil and US$8.6 million from refined products. Petroleum accounted for about 17.9 percent of Colombia's total export value of US$539.1 million. In addition cement exports were valued at US$2.2 million and platinum at US$890,000.

Colombia continued to import a large percentage of its iron and steel requirements mainly in the form of steel mill products. In recent years, Colombia's steel imports have fluctuated around 175,000 tons per year. The chief import items in terms of tonnage have been sheets, pipes, and tinplate although there has been a wide variety of finished steel imports, many of which were imported in comparatively minor volumes.

The United States continued to be Colombia's principal trading partner in 1965 with regard to total trade, supplying approximately 47.8 percent of Colombia's imports by value and receiving about 48 percent of Colombia's exports on the same basis. The Colombian exports to the United States in 1965 were chiefly crude oil and petroleum products. The United States ranked first among recipients of these commodities, accounting for 37 percent. Trinidad ranked second as a destination for all petroleum commodities, taking 29 percent, and the United Kingdom, which did not import Colombian crude oil in 1964, took about 18 percent of the total crude oil exports.

Trinidad was the leading market for total Colombian mineral exports in 1964, receiving 35.7 percent by value compared with 35.2 percent purchased by the United States. Trinidad received only crude oil; the United States purchased a variety of mineral commodities, of which crude oil and petroleum products accounted for approximately 90 percent by value.

Japan ranked second to the United States in supplying Colombia's mineral imports, accounting for 14.2 percent by value of 1964 imports, principally in iron and steel products. The U.S. share of the minerals imported was 36.7 percent, principally in iron and steel, chemical fertilizers, and petroleum products. The following tabulation shows the role of mineral commodities in overall foreign trade of Colombia:

	Value (thousand dollars)		Mineral commodities share of total commodity trade (percent)
	Mineral commodities	Total commodity trade

COMMODITY REVIEW

METALS

Gold.—Gold production decreased 12.6 percent in 1965, marking the lowest country production in more than 40 years. However, the value of production reportedly increased Col$22 million above that for 1964. The International Mining Corp. through subsidiaries and affiliated companies continued to be the principal gold producer. Production from the wholly owned mining companies of the corporation was 109,686 ounces, of which 80,750 ounces came from the underground operations of the Compañía Frontino Gold Mines Ltd., and 28,936 ounces came from dredging operations. The decreased production reportedly was due to the lower grade of gravels worked, as well as to lengthy moves by the dredges to new areas. In addition to output noted above, Pato

Consolidated Gold Dredging Ltd., an affiliate of International Mining Corp. and the largest gold dredging operation in Colombia, operated a fleet of seven dredges which dug approximately 30.5 million cubic yards, a company record, and produced a gold-silver product described as equivalent to 115,367 ounces of gold. The company's presently developed reserves all require digging depths in excess of 80 feet and are sufficient for approximately 15 years for the five large dredges.

The bonus of Col$15 per ounce of gold that had been instituted by the Government in August of 1964 was abolished in mid-1965. However, the Banco de la República continued to purchase gold on the basis of US$35 per ounce, payable 25 percent in U.S. dollars and 75 percent in pesos at the average free exchange rate of the previous week. The bonus was effective for the first half of the year, but as a result of the cancellation of the bonus, gold sales averaged approximately US$35.83 an ounce compared with US$36.28 in 1964.

Iron and Steel.—During 1965, consumption growth continued to outpace expansion of local steelmaking capacity although Acerías Paz del Rio and Empresa Siderúrgica, S.A., were actively engaged in plant expansions. Consumption of finished steel for the year was estimated to be 400,000 tons with an annual growth rate projected at 6.5 percent. Colombia produces roughly half of the country's consumption requirements, while the other half is imported at an annual cost of about US$40 million. Sheets, tubes, and tinplate are the chief import items.

Acerías Paz del Rio, S.A., continued to be the dominant steel producer in Colombia, with an output of 193,000 tons of finished products, 12,000 tons above the 1964 level. The total production was composed of 18,100 tons of flat products,

143,400 tons of nonflat products, and 31,500 tons of wire products.

During the year, the first expansion stage was initiated with the distribution to various Colombian firms of the contracts for the preparation of the grounds, excavations, foundations, and other complementary civil engineering steps. The first expansion stage, which is to be completed in 1968, will permit improved efficiency and increase the capacity of production to some 220,000 tons of finished products per year. Machinery to be installed in this stage include a 42- by 108-inch blooming and slabbing mill, a 56-inch reversing hot-strip finishing mill, a 1,200-ton-per-day sinter plant, a crushing and mixing plant to supply raw materials used in the sintering operation and for charging the blast furnace, a turboblower, soaking pits, and a 25-ton-per-day oxygen plant.

The second largest manufacturer of iron and steel products was the Empresa Siderúrgica, S.A., of Medellin. In 1965 it pro-

duced a total of slightly over 51,000 tons of products, both finished and steel ingot. Ingot production from locally available and imported scrap was 22,518 tons. The firm fabricates reinforcing rods, galvanized water pipes and accessories, electrical conduit, castings for machinery, railroad wheels, and light products from its own ingots. At the end of 1964, an installation was completed for the production of forged grinding balls. At yearend the plant was equipped with six electric furnaces with a capacity for handling a total of 120 tons of steel scrap per day as well as one small cast iron cupola that is run once a week. Two small rolling mills which can produce rods up to four inches in diameter provided stock for the ball plant and for sale. The grinding ball plant consisted of one Hill-Acma ball machine for production of balls from ¾ inch to 2 inches in diameter, and one Chamberburg forge hammer to produce balls from 2½ to 4 inches in diameter. In 1965, 5,554 tons of galvanized pipe and 1,576 tons of electrical conduit were produced on two Yoder tube mills. The pipe and conduit was made from skelp imported from Japan.

In 1965, the company obtained a US$3.95 million loan from the Export-Import Bank for the purchase of U.S. equipment to expand and modernize the Medellin plant. New equipment that will permit an increase in production of steel ingots from 25,000 to 60,000 tons per year include a 25- to 30-ton Lectromelt electric furnace, an electrolytic tinning line, a Concast-type continuous casting machine, and two high-frequency resistance pipe welders. Engineering services and financial and technical advice will be provided by the Forel Equipment Corp. of New York. The expansion is expected to be completed by 1967.

Mercury.—The Southern Union Production Co. of Dallas began exploration for mercury in northern Caldas with reportedly encouraging results.

Nickel.—The Hanna Mining Co. (United States) continued its study of nickel-bearing laterites in northern Colombia while awaiting resolution of legal problems caused by overdenouncement of Hanna's concession by Colombian nationals who filed claims for the exploitation of metals other than nickel.

Platinum.—The Compañía Minera Chocó Pacífico, a subsidiary of the International Mining Corp., accounted for approximately 73 percent of total Colombian platinum production, although output dropped to 8,097 ounces, a decrease of approximately 14 percent from 1964 production. The downward trend in platinum production reflects the lower metal content of ores processed.

Silver.—The Frontino mine of the International Mining Corp., Colombia's largest producer of silver, reported production of 138,336 troy ounces in 1965. However, total country production was reported by the Ministry of Mines and Petroleum as only 113,451 ounces, a decrease of 16,902 ounces. At the same time, the value of 1965 silver production was reported as Col$498,000 above the 1964 value.

NONMETALS

Fertilizer Materials.—The fertilizer plant of Indústria Colombiana de Fertilizantes, owned 65 percent by Colombian Government agencies, ceased operation in September having reportedly lost approximately US$20 million during the firm's 3 years of operation.

Petroquímica del Atlántico proposed an ammonia and urea complex to be built at Barranquilla. Total investment, including plant and equipment and pipelines, was set at US$55 million. A 12-inch pipeline from the Antex Oil & Gas Co. El Difícil oilfield was under construction. Production was scheduled to begin in late 1968 and was projected at 900 tons per day of ammonia and 400 tons per day of urea, with storage facilities for 60,000 tons. As an interim operation to utilize gas from the Antex field, Petroquímica del Atlántico was considering the acquisition of a package ammonia plant on skids. This plant would be installed at Plato, Magdalena, and a 6-inch pipeline would be constructed to connect the plant with the Antex oilfield. The plant would cost US$3 million and would be moved for incorporation into the Barranquilla plant after the latter began production.

Amoniaco del Caribe (AMOCAR), owned by International Petroleum (Colombia) Ltd. (INTERCOL), exported 36,000 tons of ammonia, the only ammonia exports from Colombia, during the first 11 months of 1965.

263-927 O-67—15

Colombia also became an exporter of complete fertilizers with the exportation of a total of 13,500 tons to South Viet-Nam, India, Mexico, Peru, and Argentina by Abonos Colombianos.

MINERAL FUELS

Carbon Black.—Cabot Colombiana, a subsidiary of Cabot Corp., Boston, began production of four grades of carbon black in its Mamonal plant on September 19, 1965. The plant receives natural gas from the San Andrés Development Company and INTERCOL pipeline and aromatic tars from the Cartagena petroleum refinery. The present operating capacity of 5,700 tons per year will be increased by 1,150 tons by the spring of 1967.

Coal.—Acerías Paz del Rio produced 498,000 tons of run-of-mine coal from which 288,000 tons of washed coal was obtained. The company's coal reserves at the end of the year were 22.974 million tons proven, and 36 million tons probable.

Coke.—Acerías Paz del Rio consumed 265,200 tons of coke during the year, 218,200 tons of which were produced in their own installations and the remainder purchased from nearby beehive producers. To augment its byproduct coke oven production, the company constructed 60 beehive ovens at Samacá. Company production of beehive coke was 4,400 tons.

Natural Gas.—Gross production of natural gas in 1965 was 8.3 percent higher than in 1964. The country's second gasline began operations in April when the San Andres Development Co., a John W. Mecom subsidiary, together with INTERCOL, completed a 10-inch, 200-kilometer gasline from Jobo-Tablon field to the industrial complex at Mamonal on Cartagena Bay. This gas, 99.5 percent methane, is transported without the aid of compressors since the pressure at which it is produced is sufficient. Although the ultimate capacity of the pipeline is 50 million cubic feet per day, only 10 million cubic feet per day was run during 1965. At yearend Colombia-Cities Service Petroleum Corp. had finished a gas-processing plant in the Payoa field, and deliveries of gasoline, butane, and propane from this plant were scheduled to begin early in 1966 through the company's new products pipeline to the Barrancabermeja terminal.

[1] Production began in April 1965.

Petroleum.—Crude petroleum production in 1965 was the highest in Colombia's history, approximately 16 percent above the previous record set in 1964. Exports of crude petroleum increased approximately 30 percent to 40.7 million barrels. The increased production of crude oil was due in part to the first full year of operation of the Rio Zulia field, discovered in 1962 by The Sociedad Richmond Petroleum Co. which averaged 30,000 barrels per day during 1965, and also in part to the recovery of production by some companies whose 1964 production was abnormally low due to strikes and to difficulties in the river transport of the crude oil.

There was a moderate overall decrease in exploration activity both in total surface exploration party months and in wildcats drilled. Development drilling also declined during the year. For the first time in Colombia, INTERCOL initiated offshore seismic exploration on the Pacific coast.

In May, Colombia-Cities Service completed the building of a 4½-inch products pipeline from Payoa field to Barrancabermeja. This line has a capacity of 2,500 barrels per day of liquefied petroleum gas (LPG). In addition, the same company has added three 30,000-gallon tanks for storage of LPG at the pipeline terminal. Oleoducto del Zulia, a subsidiary of Richmond Petroleum Co., completed an 8-inch, 200-kilometer branch oil line, with an ultimate capacity of 16,000 barrels per day, from the village of Ayacucho on Richmond's main Rio Zulia-Santa Marta pipeline to Barrancabermeja. At yearend, this line was delivering 6,000 barrels per day of waxy Rio Zulia crude oil to the Empresa Colombiana de Petróleos (ECOPETROL) refinery. ECOPETROL, together with the Department of Caldas, signed a contract with three Mexican firms for the construction of a pipeline to be known as Oleoducto de Caldas. The first 50 kilometers from Salgar to Mariquita will be 8 inches in diameter with a capacity of 12,000 barrels per day. From Mariquita to Armenia, the pipeline will have a diameter of 6 inches and a daily capacity of 6,000 barrels. The line will cross the 12,000-foot-high Andes and will have four pumping stations. Total length of the line will be about 240 kilometers and will cost approximately US$8 million, of which US$7 million has been lent by a Mexican financial group. A consortium composed of Texaco Petroleum Co. and Colombian Gulf Oil Co. announced near yearend that the combined oil venture planned to invest US$70 million over the next 17 years in facilities at Putumayo and in the construction of an oil pipeline across the Andes by way of Cali to the Pacific Ocean at Tumaco or Buenaventura. Sixteen wells have been drilled in the Putumayo field since its discovery in 1964. This major oil strike, centered in the area between Puerto Asis and the San Miguel River, is the first to be found in the Amazon River basin. Because the region is isolated all materials and provisions for the 700 employees on the exploration project must be taken in by heli-

copter. Production potential by 1970 may be 50,000 barrels per day.

Marathon Petroleum Co. Ltd., signed an exploration agreement with ECOPETROL, the State oil company, for a 6-year exploration concession covering 76,000 hectares in middle Magdalena Valley. If a commercial discovery is made, Marathon will be granted a development concession for 25 years after which the property and installations will revert to ECOPETROL. Marathon will bear all exploration costs, but any commercial production will be shared on a 50-50 basis with ECOPETROL, who will also meet half of the development costs. These terms and those relating to royalty payments are similar to those contained in the agreement reached last year between ECOPETROL and Tennessee Colombia, S.A.

ECOPETROL pushed ahead with its ambitious 5-year program, launched at the end of 1964, aiming at a big increase in the company's exploration and development activities, the construction of more pipelines, and expansion in refining capacity and the building of new petrochemical plants and improvement in export terminal facilities. The total cost is estimated at US$140 million of which less than half will be financed from ECOPETROL's own resources and the rest from foreign investors.

[1] Includes natural gasoline and other liquid products from COLPET and Antex. Net crude production was 72,669,591 barrels.

Source: 1963–1964—Memorias del Ministro de Minas y Pertoléos 1964 and 1965; 1965 data from Centro de Información de la Industria Petrolera.

In midyear, work was begun on the doubling of the Barrancabermeja refinery's capacity to 75,000 barrels per day. A US$4 million steam recovery unit being built there will enable the production of 20,000 tons of ethylene and 10,000 tons of propylene annually beginning in 1967. Up to September 1965, expenditure on this part of the program had reached US$12.5 million and Col$33.6 million. The expansion is due for completion in March of 1967. Expansion of the alkylation plant begun in 1964 should also be completed by 1967, doubling its capacity to 3,000 barrels per day. As a result of these two expansion projects, Colombia's aviation gasoline needs will be met from local supplies. Preliminary technical-economic studies connected with the construction of a small refinery at Neiva to process crude oil from Dina were completed, but the decision as to whether the capacity of this plant would be 2,500 or 5,000 barrels per day had not been made by yearend.

The Mineral Industry of Peru

By Bryan R. Frisbie [1] and Lester R. Brown, Jr.[2]

The Peruvian mineral industry continued to grow and prosper in 1965 as the value of mineral production, excluding iron and steel but including refined petroleum, increased from $459 million [3] in 1964 to approximately $469 million in 1965. Total trade registered a net negative balance of $60 million for the year, but mineral and metal exports exceeded similar imports by approximately $188 million.

In spite of a deficit in the overall trade balance, Peru ended the year with a favorable net foreign balance because of a heavy inflow of investment capital both public and private. Although a major portion of this inflow went into manufacturing industries, investment in the mining sector was also of importance as United States, Japanese, and Peruvian companies increased their investments in facilities for production of copper, lead, zinc, iron ore, cement, and petroleum products. Indicators of the general economic progress of Peru follow:

		1963	1964	1965

Mineral production as percentage of GNP		r 12.2	r 12.9	e 11.0

e Estimate. r Revised.

Peru continued to maintain a prominent position among the world's mineral producers during 1965, as shown in the following tabulation of some principal products which includes the percentage of each provided by Peru, and that country's rank among world producers.

Commodity	Approximate percent of total world output	Rank
Bismuth	18	1
Silver	14	3
Copper:		
Mine	3	7
Smelter	3	9
Lead:		
Mine	5	6
Smelter	3	13
Zinc:		
Mine	6	5
Smelter	2	14

The value of mineral industry output was equivalent to about 11 percent of the gross national product (GNP) in 1965, a decline from that of 1964 probably due to increased contributions to the GNP by the manufacturing sector. Distribution of principal values within the mineral industries follows:

A number of laws affecting the mineral industry were promulgated during 1965. Law 15584, passed by the Peruvian Congress on June 11, 1965, modified certain articles in Peru's Mining Code. It provides for increased ground rentals for all

e Estimate.

exploitation concessions as well as penalties in the form of annually increasing ground rentals for exploitation concession holders that do not adequately develop or exploit holdings within 5 years.

The law also authorizes the Mining Bank of Peru to participate up to 30 percent of its capital with small- and medium-size mining producers in exploration and exploitation work under regulations set for this participation, including a provision restricting Mining Bank participation in any individual venture to 50 percent of net expenses.

Supreme Decree No. 34–F of June 19, 1965, authorized the formation of a subsidiary company of the Mining Bank of Peru, to be known as Centro Metalúrgico del Peru, S.A., and empowered this company to proceed with the construction of an industrial complex for electrolytic refining of zinc and production of associated byproducts and fertilizers. The law gave legal authority to the Mining Bank to organize, finance, administer, and operate the industrial complex.

PRODUCTION

Although in general there were no large increases in the tonnages of the various minerals and metals produced, improved prices of some metals and increased output of iron ore in more valuable forms (concentrates and pellets) resulted in a higher value for 1965 mineral production. Production of nonmetals remained fairly constant although bentonite and cement output were exceptions registering significant tonnage increases. In fuel production, bituminous coal production showed a small gain but anthracite tonnage decreased, while crude petroleum production in 1965 held about equal to that of the previous year.

Production statistics have been obtained mainly from the Instituto Nacional de Investigación y Fomentas Mineras, and data furnished are qualified with the statement that there will possibly be a revision of some of these statistics when the Anuario de la Industria Minera del Peru—1965 is published.

Statistics on metals essentially represent the recoverable content in all forms. In calculating recoverable metal, the Peruvian

[2] Includes small Morococha production.
[3] Exports.

Department of Mines reportedly deducts from the assay metal content of ores and concentrates 5 percent in the cases of copper and lead, 10 percent for zinc, iron, manganese, molybdenum, and tungsten; and 35 percent for arsenic, bismuth, cadmium, and tin; these deductions are based on average recoverability experience.

TRADE

The value of mineral exports in 1965 exceeded that of 1964 by 8.76 percent or $24 million and also increased the share of mineral exports in total exports by 3.4 percent.

Preliminary data on the value of 1965 exports [4] are as follows:

Commodity	Value (million dollars)	Percentage of total export
Selected minerals:		
Copper	$121.2	18.1
Iron	47.0	7.0
Silver	39.1	5.8
Lead	37.9	5.7
Zinc	35.8	5.3
Total	281.0	41.9
All other commodities	388.6	58.1
Total	$669.6	100.0

[4] U.S. Embassy, Lima, Peru. State Department Airgram A-507, Mar. 9, 1966, 1 p.

In 1965, the United States was the source of approximately 40 percent by value of Peru's total imports and was a market for about 34 percent by value of Peruvian exports.

The role of mineral trade in Peru's total foreign trade for recent years is illustrated by the following tabulation:

	Value (million dollars)		Mineral commodities share of total trade
	Mineral commodities	Total trade	
Exports:			
1963	202	542	37.3
1964	274	667	41.1
1965	p 298	p 670	44.5
Imports:			
1963	e 50	557	9.0
1964	71	579	12.3
1965	p 110	p 730	15.1
Net trade balance:			
1963	+152	−15	XX
1964	+203	+88	XX
1965	+188	−60	XX

e Estimate. p Preliminary. XX Not applicable.

Table 2.—Peru: Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1963	1964	Principal destinations, 1964
Metals:			
Antimony, gross weight:			
Ore	1,145	1,109	West Germany 326; Belgium 280; Japan 163.
Refined bars	263	426	All to United States.
Antimony, content of:			
Ore	r 634	594	West Germany 172; Belgium 137; Japan 89.
Refined bars	250	400	All to United States.
Bismuth, content of:			
Mixed bars [1]	57	74	West Germany 63; Argentina 11.
Refined bars	447	668	United States 415; United Kingdom 96; France 70.
Cadmium, refined bars	149	212	United States 76; Netherlands 44; Sweden 29.
Copper:			
Gross weight:			
Ore and concentrate	52,070	77,514	Japan 29,948; United States 18,759; West Germany 7,755.
Cement	1,682	1,392	United States 964; Japan 428.
Matte	5,280	1,280	All to Japan.
Blister	114,645	117,027	United States 69,962; Belgium 21,449; West Germany 15,648.
Content of:			
Ore and concentrate	r 15,899	22,375	(2).
Cement	1,074	929	(2).
Matte	2,191	560	All to Japan.
Blister	113,990	115,659	(2).
Mixed bars	165	--------	
Refined bars	5,374	9,395	United States 7,108; Brazil 1,011; Argentina 838.
Electrolytic sheet	24,676	30,776	United States 17,727; Netherlands 7,817; West Germany 2,885.
Total copper content	r 163,369	179,694	
Gold, content of:			
Ores, various ---troy ounces	3,600	2,064	(2).
Concentrates, various ---do	36,597	34,783	(2).
Mixed bars [1] ---do	2,353	1,111	(2).
Blister bars ---do	1,305	1,376	(2).
Total ---do	43,855	39,334	
Iron and steel:			
Iron ore	5,748,663	5,205,190	Japan 2,773,947; Netherlands 734,040; West Germany 550,711.
Bars, plates, and sheets	36	1	All to Ecuador.
Lead:			
Gross weight:			
Ore	6,370	6,453	United States 4,215; Canada 956; West Germany 620.
Concentrate	122,348	115,807	United States 54,050; West Germany 20,982; Canada 15,138.
Content of:			
Ore	r 3,103	2,937	(2).
Concentrate	62,428	61,689	(2).
Mixed bars	38	49	(2).
Refined bars	54,971	102,063	United States 27,268; Japan 18,144; Italy 8,402.
Total lead content	120,540	166,738	
Manganese ore	705	844	All to United States.
Mercury ---76-pound flasks	2,607	3,866	United States 3,716; Argentina 150.
Molybdenum:			
Sulfide, ore and concentrate	951	901	France 386; United Kingdom 278; Belgium 185.
Sulfide (MoS_2) content of concentrate	848	785	France 336; United Kingdom 242; Belgium 161.
Molybdenum (Mo) content of concentrate.	508	471	France 202; United Kingdom 145; Belgium 96.
Selenium:			
Crude metal ---kilograms	9,054	11,177	United Kingdom 3,372; Netherlands 3,293; United States 2,357.
Selenium content ---do	8,965	11,103	United Kingdom 3,349; Netherlands 3,269; United States 2,339.

Lubricants, including greases	17,394	16,533	Mainly from United States.
Asphalt	358	2,738	Trinidad and Tobago 2,371; United States 342.
Vaseline, paraffin, waxes	10,241	10,776	India 6,174; United States 3,765; Indonesia 479.
Other	r 955	764	Mainly from United States.
Total refinery products	r 105,694	159,107	

r Revised.

COMMODITY REVIEW

METALS

Bismuth. — The Julcani operation of Cía. de Minas Buenaventura, S.A., produced 96 tons of bismuth in ores and concentrates compared with 103 tons in 1964. The Julcani operation consists of the Tentodora, Lucrecia, Mimosa, and Herminia mines in the Department of Huancavelica. The Pablo G. Vidalon tunnel, 150 meters below the 420-meter level of the Herminia mine in Julcani was completed to make possible exploitation at greater depth.

Cerro de Pasco Corporation (Cerro-Peru), a Cerro Corp. subsidiary operating in Peru, remained the world's leading bis-

muth metal producer. Its 1965 output of 743.9 tons was exported chiefly to the United States to supply increased demand by traditional bismuth users and manufacturers of a catalyst for production of acrylonitrile used by makers of acrylic textile fibers.

Cadmium —The Cercapuquio mine, of Minas de Cercapuquio, S.A., in the Department of Junín in central Peru produced 33 tons of cadmium in zinc concentrates which were exported. Cerro-Peru increased its production of refined cadmium metal to a total of 215 tons in the form of bars.

Recoverable cadmium content of zinc concentrates for export totaled an estimated 618 tons,[5] which when added to refined cadmium production in Peru gives a total recoverable cadmium output for 1965 of 832 tons, 11.1 percent more than in 1964.

Copper. — Peruvian recoverable copper production increased 0.5 percent over that of the previous year. Improved copper prices during the year caused a 17.2 percent increase in value to approximately $134 million. The Southern Peru Copper Corporation (SPCC) had nearly normal operations in 1965 and increased blister copper production about 3 percent over that of 1964. The Toquepala property in the Department of Tacna, the largest open pit mine in Peru, operated 15 shovels (12 P & H 1,800 electric and 3 P & H diesel) and 120 off-the-highway trucks; 118 KW-Dart trucks, 25- to 100-ton capacity, and 2 Unit Rig Electra Haul trucks, 85-ton capacity. Approximately 180,000 tons of mine material is moved per 24-hour period, using a combination of truck and rail haulage. At yearend, the mine bottom was at an elevation of 3,175 meters; final programed bottom elevation is 3,000 meters, but under existing plans, excavation will not reach below 3,100 meters for 15 years.

Operations of SPCC at Toquepala in recent years have been as follows:

	1963	1964	1965
Ore and waste mined—metric tons	53,802,000	51,130,000	51,790,000
Ore mined—do	10,084,939	10,079,677	10,166,766
Ore-to-waste ratio	1:4.3	1:4.1	1:4.1
Copper content of—			
Milled ore—percent	1.37	1.34	1.29
Blister copper recovered at Ilo smelter—metric tons	119,443	115,665	119,100

Southern Peru Copper Corp. reportedly completed feasibility studies for bringing into production the nearby Cuajones deposit, with an estimated 530-million-ton reserve of 1 percent copper ore. Electrical generating capacity at the company powerplant at Ilo has been increased to 110,000 kilovolt amperes, sufficient for the Cuajones operation when it is brought into production.

Cerro-Peru established a new record for refined copper production, 40,459 tons, 7 percent more than in 1964. The Yauricocha mine, a Cerro-Peru property in the Department of Lima, but near the town of Huancayo in the Department of Junín, was being converted from a producer of relatively high-grade direct-smelting copper ore to a producer of a copper-zinc-lead-silver ore. A 750-ton-per-day concentrator will be placed in operation at the mine in early 1966. Plans also have been completed for bringing into production a mine and concentrator at the Cobriza copper deposit, about 185 kilometers southeast of La Oroya.

The Northern Peru Mining Co., a subsidiary of the American Smelting and Refining Company, (ASARCO), was the third largest copper producer in Peru. In 1965, the Quiruvilca mine, 160 kilometers east of Trujillo, Peru, in the Department of La Libertad, exported 19,668 tons of concentrates and 837 tons of cement copper. In 1965, ASARCO continued evaluation of the Michiquillay copper deposit east of Cajamarca. In August, ASARCO optioned claims from Lampa Mining Co. Ltd., covering the Barenguela copper deposit near Santa Lucia, about 55 kilometers west of Juliaca, and hired the Boyles Bros. Co. to test drill these holdings.

The Anaconda Company, through its

[5] Estimated on the basis of reported output of zinc concentrate for export multiplied by an average cadmium content of 0.24 percent and a recovery factor of 65 percent.

subsidiary, the Andes Exploration Co. of Maine, proceeded with an extensive drilling program at the Cerro Verde copper deposits near Arequipa, in southern Peru. It was anticipated that a decision regarding bringing the property into production would be made in 1966.

Japanese interests were active in Peru during 1965. The Chapi mine, about 64 kilometers from Arequipa, was taken over by a group consisting of Overseas Mineral Resources Development Co., Mitsui Mining & Smelting Co. Ltd., Nippon Mining Co. Ltd., and Toho Zinc Co. Ltd.

Gold and Silver.—Peruvian gold production increased almost 5 percent in 1965; of total output, 39 percent or 37,399 troy ounces was from the Oroya refinery of Cerro-Peru. The Natomas Company of Peru, a subsidiary of the Natomas Company of California, produced 14,773 ounces from 2,328,950 cubic yards of dredged material. The balance was supplied by Andaray Gold Mines Co., Southern Peru Copper Corp., and Cía. Minera San Juan de Lucanas, and as well as by small and medium mines whose gold output was contained in lead and copper concentrates.

Peru's 1965 silver output maintained the country's position as the third largest silver producer in the world behind Mexico and the United States.

Cerro-Peru accounted for almost 58 percent of the total recoverable silver with 20,272,000 troy ounces reported in Cerro's 1965 Annual Report. The company's metallurgists reportedly were making studies for the recovery of silver contained in reserves of oxidized silver-lead ores located on and near the surface at the Cerro de Pasco mine.

Iron Ore.—The Marcona Mining Co. mined iron ore and operated two processing plants on the Peruvian coast about 335 kilometers south of Lima, in the Department of Ica.

The orebodies, covered by a thin mantle of beach deposits, are distributed in a band roughly 5 kilometers wide by 21 kilometers long. The ore of the upper zone is composed largely of hematite, while the underlying primary ore is massive magnetite.

A multimillion dollar expansion program completed in 1963 included a pellet plant with initial annual capacity of over 1 million tons. During 1965, Marcona continued the construction of a second pelletizing plant at San Nicolas with an annual capacity of 2 million tons.

The company sold 5,588,275 tons of iron ore products in 1964 and increased this to 6,807,535 tons in 1965. The 1965 total included 4,917,682 tons of beneficiated products of which 955,087 tons were in the form of pellets. This reflects an increase from 4,805,917 tons of beneficiated products in 1964. Two ports, San Nicolas and San Juan, were used for shipment of Marcona products. The dock at San Nicolas Bay can accommodate ships of up to 100,000 deadweight tons. Ships of up to 50,000-ton size can be loaded at San Juan Bay.

Panamerican Commodities, S.A., Peru's other iron ore producer, operated the Acarí Mine, 56 kilometers from the port of San Juan in the Department of Arequipa, and produced 800,104 tons of ore in 1965.

Iron and Steel.—The Chimbote plant of Sociedad Siderúrgica de Chimbote, S.A., Peru's only integrated steel plant, recorded advances in 1965 over the previous year. Output of steel billets from this facility in the Department of Ancash, 520 kilometers northwest of Lima, increased 6,000 tons to 81,400 tons from which 73,700 tons of rolled steel products were produced.

Expansion of facilities continued during the year. Construction work advanced well while the installation of electrical and mechanical equipment proceeded at a somewhat slower pace. The steel structure for the blast furnace was completed as were the coke bins. A Linz-Donawitz steel plant, a continuous casting plant, and an oxygen plant were in final phases of construction at yearend. Ten water wells to supply industrial water have been completed in the Santa Valley. The belt-conveyor system which will move iron ore from the new pier to the storage area was partially completed.

Lead and Zinc.—Production of recoverable lead in 1965 was approximately 2 percent lower than the 1964 total, while total zinc output registered a 9.6 percent increase over that of 1964, as Cerro-Peru's production of zinc concentrates for export was increased noticeably.

Cerro-Peru's smelting and refining complex at La Oroya, the country's only producer of refined metal, recorded output of

86,559 tons of lead and 61,317 tons of zinc in 1965.[6] In addition 71,051 tons of zinc in concentrates was reportedly produced for export by company mines and mills, some 8,856 tons more than in 1964. As in 1964, Cerro's operations were free from work stoppages. The Graton Tunnel project, a twin-bore, 11.2-kilometer drainage and ventilation tunnel at the Casapalca mine, in the Department of Lima, was slowed by a continuous flow of hot water with temperatures as high as 140° being recorded.

Compañía Minerales Santander, Inc., wholly owned subsidiary of the St. Joseph Lead Co. of New York, reported increased production for 1965 with 10,827 tons of lead concentrate and 54,717 tons of zinc concentrate. The company's mine, Santander, about 185 kilometers northeast of Lima, in the Department of Lima, has been operating as an open pit mine, but preparations were underway for a gradual transfer to underground operations.

Mercury.—The Santa Barbara mine, in the Department of Huancavelica of Sociedad Minera El Brocal, S.A., continued to be the only producer of mercury in Peru.

Molybdenum.—The Southern Peru Copper Corp. produced molybdenite concentrate as a byproduct at its copper flotation mill. Preliminary statistics show that 1,316 tons of concentrate containing 85.19 percent MoS_2 was produced.

Tin.—The Lampa Mining Co. Ltd. of Liverpool, Peru's only tin producer, reported that significant exploration was underway at its San Rafael mine in the Department of Puno. Ore from the five working levels at San Rafael yielded 15 to 17 tons of copper concentrate and 0.2 long tons of tin concentrate daily. The 1965 production was reported at 36.336 long tons of recoverable tin.

Tungsten.—The Pasto Bueno mine of F. Málaga Santolalla e Hijos in the Department of Ancash, continued as Peru's foremost tungsten producer. A small additional amount was obtained by treating mill tailings of Cerro-Peru's Morococha unit.

Other.—Antimony, selenium, tellurium, copper sulfate, and zinc sulfate were produced as byproducts at Cerro de Pasco's smelter and refinery plant at La Oroya.

NONMETALS

Barite.—Exports, totaling 108,000 tons in 1965, exceeded production by about 5,000 tons; domestic requirements and the difference between exports and production presumably was obtained from indigenous stocks.

Bentonite.—Production which averaged only 378 tons per year during 1960–64 increased to over 5,000 tons in 1965. Much of the increase reportedly was consumed by the Marcona Mining Co. in its iron ore concentrate pelletizing plant.

Cement.—Peruvian cement production increased almost 26 percent over the 1964 figure, extending the trend of increasing output that dates from 1961. The new cement plant under construction at Yura, near Arequipa in southern Peru, was expected to begin production about mid-year 1966 at a rate of 500 to 800 tons per day.

Salt.—Estanco de la Sal remained Peru's principal salt producer; Alkalis Peruanos, S.A., (a subsidiary of W. R. Grace & Co.), and Quimica del Pacifico, S.A., produced relatively minor amounts for consumption in their own chemical plants. Most of the salt was produced by solar evaporation of salt brine, much of which was pumped from underground sources.

Fertilizer Materials.—On June 14, an agreement for exploitation of the phosphate and potash deposits in the Sechura Desert of northern Peru, Department of Piura, was signed by Minera Bayovar, S.A. and the Peruvian Government. Bayovar, S.A. is a United States corporation owned jointly by Texada Mines Ltd., a Canadian corporation and Minerales Industriales del Peru, S.A. (much of which is owned by Midepsa Industries, Ltd., a Canadian corporation). The concession comprises some 850 claims within the coastal area of the Sechura Desert. The area was explored for petroleum in the 1920's, and drilling at that time indicated phosphates to a depth of 700 feet; in some places, there are 30 meters of overburden. Reportedly, the deposit contains ore varying from 1.5 to 23 percent phosphorus pentoxide (P_2O_5); drilled reserves contain the equivalent of 561 million tons of 31 percent P_2O_5 phosphate rock and probable reserves are equivalent to 861 million tons of phosphate

[6] Data from corporation annual report for 1965; these figures differ slightly from official Peruvian statistics on lead and zinc metal output.

rock containing 31 percent P_2O_5. In the second half of 1965, Bayovar completed a 200-ton-per-day phosphate pilot plant consisting of a scrubbing unit, classifiers, and flotation equipment.

In the Sechura Desert just northeast of the phosphate deposit is an extensive flat shallow basin forming a brine reservoir filled with permeable and porous sediments saturated with brines containing potassium chloride and magnesium chloride. Within this basin there are three areas under consideration for brine production. Reserves have been calculated as follows:

Area	Million metric tons		
	Brine	Potassium chloride	Magnesium chloride
Zapayal	1,542	6.31	52
Ramon	815	8.15	70
Namuc	684	2.87	25
Total	3,041	17.33	147

Experimental ponds covering 160,000 square meters for recovery by solar evaporation have been built. As projected, output of potassium products will eventually reach approximately 250,000 tons annually which will require 16 square kilometers of evaporation ponds.

MINERAL FUELS

Coal and Coke.—The Northern Peru Mining Co. produced 5,500 tons of anthracite coal for heat and fuel in its camps. Bituminous coal production amounted to 120,086 tons, most of which came from Cerro-Peru's mine at Goyllarizquizga. The run-of-mine material was washed and utilized by the company. From a portion of this coal, the company produced 27,401 tons of metallurgical coke for use at the La Oroya smelter.

The Mining Bank of Peru did considerable exploration work in the anthracite fields in the Santa River region and brought a French Coal Mission to Peru late in 1965 to make a study on the feasibility of increasing anthracite production.

Petroleum.—Total crude petroleum production decreased slightly in 1965 as compared with that of 1964; the increased production from the Continental Shelf Zone was not sufficient to offset the decrease in the Coastal Zone. The percentage of total production from the La Brea y Pariñas fields continued to decline.

Table 4.—Distribution of crude petroleum production by zone and company

(42-gallon barrels)

Zone and company	Production		
	1963	1964	1965
Continental Shelf:			
Belco Petroleum Corp	386,740	555,624	1,063,863
Cabeen Exploration Co	[1] 74,152	[1] 50,022	72,133
Total	460,892	605,646	1,135,996
Coastal:			
Belco Petroleum Corp	181,952	180,181	122,372
Empresa Petrolera Fiscal	2,048,192	2,654,771	2,629,616
International Petroleum Co.,[2]	8,893,016	10,292,890	10,557,893
La Brea y Pariñas	8,603,843	8,114,793	7,357,637
Petrolera Amotape	20,215	16,337	12,578
Total	19,747,218	21,258,972	20,680,096
Eastern:			
Cía. Peruana "El Oriente", S.A	505,337	534,163	583,211
Cía. Petrolera Ganso Azul	754,553	720,271	668,686
Total	1,259,890	1,254,434	1,251,897
Grand total	21,468,000	23,119,052	23,067,989

[1] Formerly Peruvian Pacific Petroleum Co.
[2] Concessions jointly held with Cía. Petrolera Lobitos (Burmah Oil Co.), but operated by International Petroleum Co.

Details of petroleum trade for 1965 are as follows:

Commodity	Thousand U.S. 42-gallon barrels	
	Import	Export
Crude oil	810	2,438
Residual fuel oil	3,018	---
Aviation gasoline	402	---
Diesel fuel oil	6	535
Naphtha (for further refining or blending)	1,739	---
Other	523	27
Total	6,498	3,000

Exploration drilling totaled 32 wells in 1965 as compared with 8 in 1964. Of the 1965 total, 22 were in the Coastal Zone. Development wells totaled 125 for 1965. The Belco Petroleum Corp. erected the first offshore drilling platform in Peruvian waters and completed four wells therefrom by yearend.

Peru's petroleum product consumption pattern changed in 1965 as the fishmeal industry, Peru's largest consumer of residual fuel oil, operated below capacity, and the Lima Light & Power Co. brought its Huinco hydroelectric plant into more complete operation. As a result, consumption of residual fuel oil and diesel fuel oil decreased 7.4 and 5 percent, respectively; however, consumption of motor gasoline, aviation gasoline, turbine fuel, kerosine, and others increased at an annual rate of about 8 percent.

The bulk of Peru's refinery product output was produced by International Petroleum Co.'s Talara plant. The crude oil for this refinery was produced from the La Brea-Pariñas and the InterLob concessions. Rated capacity of this plant at yearend was 55,000 barrels of crude oil per day, but certain modifications should bring it to 57,000 barrels per day during 1966. The 8,500 barrel-per-day capacity of the Conchan Refinery, (Refineria Conchan California, S.A.), south of Lima was not fully utilized because the company's markets were not large enough to absorb rated capacity output.

In the Eastern Zone, Cía. Petrolera Ganso Azul operated a topping plant at Pucallpa, at a rate of 15 percent above that of 1964, processing 225,571 barrels Empresa Petrolera Fiscal at Iquitos increased production 16.5 percent over that of 1964 to 324,814 barrels.

Mobil Oil Co. and its West German associates completed a feasibility study on bringing natural gas to the Lima area from their indicated gas structures at Aguaytía, Pisqui, and Tahuaya, about 50 kilometers northwest of Pucallpa.

Late in 1965, the Government of Peru's Empresa Petrolera Fiscal signed an agreement with Japanese interests for construction of a new 20,000-barrel-per-day refinery at La Pampilla, near Callao, estimated to cost $14,515,000.

At yearend, the longstanding dispute between the International Petroleum Co. and the Gorvernment of Peru over the La Brea property was still unresolved, but it was hoped that a settlement would be reached in 1966.

The Mineral Industry of Surinam

By Garn A. Rynearson [1]

The bauxite-dominated mineral industry of Surinam in 1965 not only surpassed all previous records for output of dried and calcined bauxite products for the export trade, but also inaugurated an important new refinery and smelter complex in which a part of the country's bauxite resources will be processed to higher unit value alumina and some to ingot aluminum as well. Initial production and export of these two commodities late in 1965 brought to fruition the principal goals of the Brokopondo Agreement, signed by the Surinam Government and the Suriname Aluminum Co. (Suralco) in 1958, whereby Suralco agreed to finance, construct, and operate Surinam's first major hydroelectric facility and to expand its bauxite operations to include alumina and aluminum plants. Although the overall project by yearend still was considerably short of capability to operate at or near planned capacities, both Government and industry could take pride in the results of their cooperative efforts.

A United States-French consortium obtained formal approval for joint operations in an offshore petroleum exploration concession and continued geophysical surveys preparatory to resumption of wildcat drilling activity during 1966. In the meantime, the possibility of developing a petroleum industry based on domestic crude oil was stimulated by the accidental discovery of at least a small quantity of recoverable crude oil while drilling a water well in an onshore coastal area. At yearend, however, the existence of commercial deposits of either crude oil or natural gas had not been definitely established.

Planning and feasibility surveys for several new development projects involving utilization of potential but untapped mineral and hydroelectric resources progressed well during 1965. However, much time and effort will be necessary before these projects can have a substantial effect on Surinam's economy. The country's first 10 year plan, which had provided most of the funds to initiate these projects, ended in 1964, but committed funds still were available during 1965, and an interim loan from the Netherlands Government will permit continuation of development programs until yearend 1966. Meanwhile, a new National Development Plan has been drawn up by the Surinam Planning Bureau and submitted to Netherlands experts for study.

The high-level bauxite deposits discovered by the Geological and Mining Service in the Adampada-Kabalebo area of the Bakhuis Mountains in the western part of Surinam are the focal point for the most ambitious of the Government's development programs. It is hoped that these virgin bauxite deposits, with estimated reserves in excess of 400 million tons, will provide the basic incentive for integrating a large and virtually uninhabited part of Surinam into the money economy of the country. The Government has clearly indicated its intent to maintain firm control over the exploitation of bauxite and other resources in the region to assure the concomitant creation of an infrastructure that will permit the country to derive maximum benefit from the existing potential.

Pronouncements by various Government officials emphasized that concessions to exploit Bakhuis bauxite will be granted only on the condition that a portion of the ore be processed to metal in Surinam. To this end, much attention was given to studies and plans to develop the hydroelectric potential of western Surinam to provide

[1] Physical scientist, Division of International Activities.

power for smelters and other industrial and domestic purposes. The Bureau of Waterpower as well as the West German firm of Salzgitter Baugesellshaft m.b.H., the Netherlands Engineering Consultants, and several Government consultants and commissions were engaged in various activities concerning the development of power and transportation facilities in the region. As the result of preliminary studies, the Government apparently envisions one or more hydroelectric dams along the lower Kabalebo River, the main damsite to be at Avanavero, with a total generating capacity of 1.5 million kilowatts. At one time, it was planned to divert water from the Corantijn River into the Kabalebo basin to provide the additional water needed, but this procedure would involve prior settlement of disputed border problems with Guyana; Surinam claims all water rights of the Corantijn River which constitutes the common boundary of the two countries. Later, a less controversial plan was announced which would involve diversion of water to the Kabalebo River from rivers located within the physical boundaries of Surinam.

The development of an adequate transportation network will be a formidable and lengthy process, inasmuch as the western part of Surinam south of the narrow lowland coastal strip is virtually inaccessible except by air to several jungle airstrips or by difficult boat travel along some rivers. Little progress in this sector was accomplished by yearend except at the planning level. The village of Apoera, on the Corantijn River about 50 kilometers north of Avanavero, was mentioned as a possible site to develop a loading port for alumina and other export products that might be produced in the region if and when the Kabalebo project becomes a reality.

Although representatives of the Government and the several interested aluminum companies discussed various proposals and possibilities for exploitation of Bakhuis bauxite either by individual companies or by a consortium, no definite agreements were reached during the year. Nevertheless, in October a consortium comprising Suriname Aluminum Co. (Alcoa subsidiary), N.V. Billiton Maatschappij, Surinam Minerals Corp. (Ormet Corp. subsidiary), and Alcan Aluminium, Ltd., was issued an orientation permit for 1 year (valid until October 1966) to allow the members to evaluate the deposits and make preliminary appraisals of the feasibility of exploitation projects. Although the Kaiser Aluminum Co. was not included in this consortium, this company, and perhaps others as well, reportedly has indicated a definite interest in a smelter operation connected with the Kabalebo development project. In the meantime, the Geological and Mining Service continued its mapping and other investigations in the area.

The Government's development plans also include two other dam projects of lesser importance but which might well be of more immediate significance to the economy, inasmuch as they would provide some relief to an aggravated unemployment problem arising partly out of completion of the Brokopondo construction projects. The Stondansie Dam project on the Nickerie River is essentially an irrigation venture but may also involve a small hydroelectric power facility. The Torarica Dam project, on the Suriname River between Paranam and the Afobaka Dam, will be a multipurpose project. Damming the river at this point will make possible (1) the generation of additional electric power for use in the expanding Paranam-Paramaribo consumer market; (2) the irrigation and leaching (of salt-water contaminated soils) of potential agricultural areas east and west of the river; (3) a bridge connection between roads on each bank; and (4) a lock system at the damsite which will make the river navigable from Paramaribo to Afobaka and greatly facilitate the transport of mineral construction materials (for example, stone from Phedra), as well as forestry and agricultural products from the interior to the coastal area. The lake to be formed in the sandy terrain above the dam would also provide the basis for the formation of an important recreation area. Cost of the Torarica project has been estimated at roughly $10 million,[2] and it would provide employment for approximately 700 workers.

A substantial increase in funds was allocated to the mining sector for 1966, and the Geological and Mining Service expected to increase the tempo of its program of evalu-

[2] Where necessary, values in this chapter have been converted from Surinam guilders or florins (Sur. f) at the rate of Sur. f1.00 equals US$0.535.

ating the mineral resource potential of the country. Systematic geologic mapping of the drainage areas of the Kabalebo, Lucie, Coeroenie, and the upper Saramacca and Tapanahony rivers was to continue, and new areas were to be added to the geophysical exploration and diamond-drilling program being conducted under a United Nations Special Fund project. In addition, the Service planned to introduce geochemical techniques to augment its exploration and research capabilities.

The Central Air Mapping Service, which already has made available aerial photogrammetric maps of a large part of the country, planned to undertake large-scale mapping in the southeastern corner of Surinam during 1966, as well as the preparation of special maps needed for the surveys of mineral and waterpower potentials that are in progress or planned for the near future.

Information concerning the mining and processing operations of the bauxite companies was summarized from company reports, consular dispatches, and consultations with company officials. Other information presented in this chapter is based on various government and industry sources in their original versions or as reviewed by consular dispatches. Reports of the Central Bank van Suriname and the Stichting Planbureau Suriname as well as materials prepared by the Consulate General of The Netherlands at New York were especially useful. Information on petroleum exploration was based in part on material published in the August 1966 issue of the Journal of the American Association of Petroleum Geologists.

PRODUCTION

Dried and calcined bauxite produced and exported from Surinam during 1965 was valued at $43.1 million, compared with $38.9 million in 1964. The initial output of alumina and aluminum for the export market was valued at $3.3 million and $0.5 million, respectively. Royalties on bauxite paid to the Government amounted to $1.82 million during the year. In addition, the bauxite companies paid a large share of the total income tax collected. The bauxite-aluminum industry not only overshadowed all other aspects of the mineral industry, but continued to be one of the largest, if not the largest, contributors to total government income and again accounted for the largest share of any sector in the gross national product of the country. Although the amount of bauxite produced for export probably will not increase, and might even decrease slightly, full operation of the alumina refinery and aluminum smelter at Paranam within the 1966–67 period should result in continued dominance by this industry in Surinam's economy.

The value of gold output in 1965 decreased nearly $70,000 to $220,127. Although the value of reported output of sand, gravel and crushed stone increased markedly from about $64,000 in 1964 to nearly $400,000 in 1965, data for these and other construction materials remained incomplete. Moreover, no value data are available for the manufactured gas produced nor for the electric energy which is generated at Afobaka and several diesel-electric plants located in Paramaribo, Paranam, Moengo, and perhaps a few other scattered localities. Official statistics for electrical energy produced show a gradual increase from 94.8 million kilowatt-hours in 1961 to 128 million in 1964, then a sharp increase to 243.7 million in 1965, which presumably reflects at least a part of the initial below-capacity output of the Afobaka powerplant in the latter part of the year.

Production statistics were derived mainly from data compiled by the General Bureau of Statistics for Surinam, from data gathered by the U.S. Consulate General at Paramaribo, and from data supplied by the bauxite companies. In some instances data given by these and other sources do not agree, especially data pertaining to bauxite and its subproducts. In such cases, company-supplied data were given precedence. Company-reported shipments or official trade data were used to reflect output of some commodities for which actual production figures were considered confidential or simply were not available.

r Revised. NA Not available.

[1] Data are not available for crude bauxite produced for processing into dried and calcined products.

[2] Calculated on the basis of known average moisture content of dried bauxite shipped by Suriname Aluminum Co., an approximate moisture content of 3 percent for dried bauxite shipped by N.V. Billiton Maatschappij, and an estimated average of 30 percent for the chemically combined water content of bauxite that was calcined. Figures do not include dry equivalent of crude bauxite delivered to alumina refinery or used as road metal or other similar uses.

[3] Additional quantities may have been produced and stocked or converted to stocked metal at yearend.

[4] Imports from Surinam by the Netherlands. The Netherlands also imported 11 tons of unspecified metallic ores from Surinam in 1963, most or all of which was cassiterite or columbite-tantalite or both.

[5] U.S. imports for consumption from Surinam.

[6] Original data reported in thousand cubic meters. Converted at rate of 1 cubic meter equal to 35.315 cubic feet.

TRADE

The sharp upward trend in Surinam's foreign trade continued in 1965 as the total value of exports of all commodities of domestic origin increased by $10.5 million to a new high of $58 million, and value of all commodity imports increased by $14.8 million to a record high of $96.1 million; reexports of foreign goods also increased but did not quite reach a total value of $1 million. The major part of the 22-percent increase in exports was attributed to greater exports of bauxite and the addition of small, but significant, initial output of alumina and aluminum to the list of export goods; however, a strong recovery in exports of agricultural products also was a notable factor in the overall increase. Although the rise in imports was not as remarkable as that registered during 1964, the 18-percent increase again reflected mainly the import of goods essential to expansion of the bauxite industry.

Surinam's chronic deficit trade balance, which increased abruptly from $5 million in 1960 to a level of $12 million annually for 1961–63 and to $33.1 million in 1964, amounted to $37.2 million in 1965. For the most part, the relatively large trade deficits

Source: Algemeen Bureau voor de Statistiek, Suriname: Maandstatistiek van de in-en uitvoer per goederensoort en per land, December (cumulative), 1963–65.

of recent years reflected the inflow of capital for expenditures on the Brokopondo project. This trend should reverse markedly during 1966 as these investments begin to pay off in large-scale output and export of alumina and ingot aluminum as well as supplemental capacity to produce bauxite for export, and it may even be possible for Surinam to realize a trade surplus in 1966 or 1967.

Comparative values of trade in metals and minerals for 1963–65 were as follows:

	Value (thousand dollars)		
	1963	1964	1965
Exports:			
Domestic goods:			
Metals	35,373	38,883	46,938
Nonmetals	52	5	63
Total	35,425	38,888	47,001
Reexports:			
Metals	37	54	95
Nonmetals	4	(1)	(1)
Mineral fuels	18	8	19
Total	59	62	114
Imports:			
Metals	2,982	5,638	6,684
Nonmetals	1,623	1,917	3,558
Mineral fuels	5,281	5,741	6,613
Total	9,886	13,296	16,855

[1] Less than $500.

The products of the bauxite companies—dried and calcined bauxite, alumina, and aluminum ingot—represented 99.9 percent of the value of all domestic metal and mineral exports and 80.9 percent of all exports of domestic goods. These percentages were virtually the same as those for 1964, but the relative importance of dried and calcined bauxite products decreased from 82 to 74 percent of total export value, and will continue a downward trend until the Paranam refinery-smelter complex attains optimum utilization of its installed or planned production capacities for high-unit value alumina and aluminum metal.

The total value of metal and mineral imports was 26.8 percent greater than that of 1964 and represented 17.5 percent of all imports. These figures are minimal in that they exclude the value of some raw materials, imported for use in the alumina and aluminum plants (for example: Caustic soda, cryolite, various forms of carbon), that cannot be separately identified in Surinam trade statistics. One such entry, listed as "other inorganic compounds" increased in value by $2.1 million and probably represented raw materials that were an essential element of the mineral industry. Imports of machinery and transport equipment, much of which was destined for use in some phase of the mineral industry, increased in value by $2.3 million. Thus, imports of materials for or closely related to the mineral industry, that is, metals and minerals, certain chemical compounds, and some machinery and transport equipment, accounted for about $7.9 million of the total increase of $14.8 million in imports during 1965.

Official export statistics do not indicate all countries that receive Surinam bauxite products; part of that credited to the United States is eventually consumed by customers in Canada as well as 10 or more unidentified countries on other continents. The United States and Canada, however, consume the bulk (97 percent) of the bauxite exported from Surinam. The consumption patterns for the alumina and aluminum now produced in Surinam are ex-

Table 4.—Bauxite shipments from Surinam
(Metric tons)

Company and destination	1964	1965
Suriname Aluminum Co.:

Total	1,459,491	1,624,370
Grand total	3,984,238	4,368,918

pected to be somewhat different. The alumina produced in 1965 and most of the output for 1966 will be consumed mainly by United States and Netherlands customers or affiliates of Suralco and Billiton in both countries, and most of the aluminum produced by Suralco during the same period probably will be sold to Alcoa customers in Europe because of the advantages accruing from Surinam's associate status in the European Economic Community.

COMMODITY REVIEW

METALS

Aluminum.—The industrial highlight of the year in Surinam was the dedication on October 9 of the new 60,000-metric-ton aluminum smelter of Suriname Aluminum Co. (Suralco), one of the most important foreign subsidiaries of Aluminum Company of America. Her Majesty, Queen Juliana of the Netherlands, officiated at the ceremonial pouring of Surinam's first aluminum in the presence of guest dignitaries from Surinam, the Netherlands, and the United States. Alumina for the smelter was supplied by Suralco's new refinery at Paranam, whose first 200,000-metric-ton unit began shakedown operations with little fanfare in July. The company's integrated Paranam complex was widely publicized as the world's first aluminum operation incorporating mining, refining, and smelting at a single site.[3] The year was studded with numerous other milestones of achievement by the company, culminating with the first export shipment of Surinam aluminum ingots on the last day of December.

In March and August, respectively, Suralco announced it had been authorized to add a third and a fourth unit to the alumina refinery, thus expanding total planned capacity to 800,000 metric tons. The second 200,000-ton unit was completed and started operating late in September, and shipments of alumina from the first two units began early in October. The third unit was scheduled for completion by mid-1966, and the fourth was expected to be operational early in 1967.

Although the gates of Suralco's dam on the Suriname River at Afobaka were closed early in 1964, an extended drought period continued to affect that part of Surinam, and the accumulation of water behind the dam was much slower than had been hoped. One of five 30,000-kilowatt turbine-generator units on line was put into operation in June, but at yearend powerplant operations still were limited to less than one-third of capacity owing to the low water level. Nonetheless, sufficient power was available to start smelting operations on schedule; however, only about two-thirds of one of the two installed potlines was actually in operation at yearend, and it was anticipated that the smelter would have to operate well below capacity during much of 1966, or at least until the drought is broken and the water level rises substantially at Afobaka. The company reportedly has seriously considered installation of standby steam-generating facilities at Paranam to offset the further possibility of drought-caused shortfalls in hydroelectric power.

The Suralco bauxite mines and processing plants in the Moengo and Paranam areas attained record levels of production, resulting in total export shipments of 2,744,548 metric tons of dried and calcined products —representing the equivalent of 2,770,606 metric tons of bone-dry bauxite ore—as well as deliveries of 277,032 tons (calculated to bone-dry basis) of bauxite to the Paranam alumina refinery. In terms of dry bauxite equivalent, total effective bauxite production was 3,047,368 tons which was 18.2 percent higher than that of 1964.

---

[3] This claim might well be disputed by Alumínio Minas Gerais S.A. (Aluminas), an affiliate of the Brazilian subsidiary of Alcan Aluminium Ltd., which has produced alumina and aluminum since 1951 at its plant at Saramenha, Minas Gerais from baxuite mined at deposits only a few kilometers distant from the reduction plant and with power generated mostly at its own hydroelectric plants; the original operator of the Saramenha plant, Electra-Química S.A. (Elquisa) produced about 800 tons of aluminum in 1945, the only year this company operated.

Table 5.—Surinam: Suralco export shipments of bauxite by grade and plant [1]
(Metric tons)

Grade	1964		1965

Total	1,796,345	728,402	1,984,533	760,015

[1] Gross weight as shipped.

Suralco's new Adjoema mine in the Moengo area was in full operation during the year while the nearly depleted Ricanau Hill mine was worked only on a small-scale, cleanup basis. Plans were finalized at year-end to utilize the high-iron portions of the Adjoema deposit in the circuit at the Paranam refinery rather than consider export or other disposal possibilities; the company plans to move this ore to Paranam, utilizing a new push-boat tug and barges, and has adapted equipment previously used to unload Rorac ore to handle that from Adjoema. A previously announced decision to discontinue production of chemical-grade bauxite at Moengo was reaffirmed by company officials; however, output of abrasive-grade bauxite was to be expanded by adding another calcining kiln, the completion of which is scheduled for April 1967.

Mining operations by the company in the Paranam area were largely focused on the Onoribo II and Onoribo IV mines, both of which were in full operation during the year, whereas the ore deposits at Rorac were virtually depleted, and the company expected to close down this mine early in 1966. Preliminary measures in connection with development of a new mine to open the Lelydorp deposit were begun, including land acquisition activities, some detailed drilling, surveying, and road studies. The Lelydorp deposit, like the original Onoribo II deposit, is near the surface and is reflected by a slight topographic elevation. Although appreciable overburden will have to be removed to expose the ore, the deposit will be relatively simple to develop for mining compared with the 10-year effort involved in gaining access to the Onoribo IV deposit, which was not only deeply buried but also adversely located with respect to local fluvial features and therefore presented some rather challenging engineering problems for Suralco to overcome.

N.V. Billiton Maatschappij also produced and shipped record amounts of bauxite in 1965 as gross shipments totaled 1,624,370 metric tons, representing an estimated dry bauxite equivalent of 1,575,640 tons, which are increases of 11.3 percent over the corresponding figures for 1964. The company reported making considerable new investments for improvements in the capacity and efficiency of its production facilities and in the application of more selective mining practices. One of the two bucket-wheel excavators employed to strip overburden was seriously damaged by a landslide in the latter half of the year, but stripping operations were well advanced by that time, and the accident did not disrupt or delay ore mining schedules.

Billiton reportedly has secured long-term contracts covering the marketing of its entire remaining reserve of ore, either in the form of graded bauxite or as alumina to be made on a toll basis at the Suralco refinery from Billiton bauxite. The alumina contracts commit Billiton to begin shipments to Phelps Dodge Corp. in the United States and to Aluminum Delfzijl N.V. in the Netherlands early in 1966; Billiton has a one-sixth interest in the new Delfzijl aluminum smelter.

Both bauxite companies concluded mutually satisfactory agreements with the bauxite workers unions (including Moengo Mijnwerkers Bond and Paranam Werknemers Bond) under which significant wage increases and additional fringe benefits were granted to most employees, including construction workers but excluding staff members and clerical and secretarial help. According to Centrale Bank van Suriname, the bauxite companies employed 2,916 workers in mining and processing operations and 2,557 workers on the Brokopondo projects at the end of 1964. By the end of 1965, however, many phases of the Brokopondo works were finished or nearing com-

pletion, necessitating the layoff of many construction workers; Suralco reported that its construction work force comprised only 1,781 at the end of 1965. On the other hand, the Bank reported that yearend employment in production activities increased appreciably to a record high total of 4,034 workers.

Gold.—The districts along the Marowijne River and its upper tributaries in eastern Surinam continued to be the principal sources of the gold produced. Output in 1965 decreased in all districts except Tapanahony, where output has nearly tripled since 1960. The sharp decline in total production was largely attributed to lower output by the principal producer, Lawa Goudvelden Maatschappij (formerly Northshore Goldfields, Ltd.); operational time of its dredge was limited due to the unusually long dry season and, in addition, the area dredged had been previously worked by other methods. The company planned to dredge more promising ground during 1966 and hoped to increase output considerably, providing weather conditions are such that ample water will be available.

The relatively small amounts of placer gold recovered in districts other than Lawa was won mostly by individual prospectors using hand methods. Preliminary reports indicate that one or more new mechanized gold recovery operations may be undertaken in eastern Surinam in the near future. Late in 1965, Gulf States Lands and Industries, Inc., parent company of Colmar Surinam Oil Co., established the Marowijne Mining Co. (Mijnbouw Maatschappij Marowijne N.V.) and obtained a gold mining concession on which sampling and other exploratory work was planned for 1966.

MINERAL FUELS

Petroleum.—Exploration activities in connection with the possible existence of commercial deposits of petroleum or gas in Surinam territory, both offshore and onshore, generated considerable interest in the country during 1965. On March 1, the original 14-million-acre offshore exploration concession held by Colmar Surinam Oil Co., in which Gulf States Land and Industries, Inc. held a 90-percent interest, was formally revised to permit a consortium of French interests, led by Petropar, to participate as an equal partner with Colmar under a new concession agreement. Colmar in turn acquired a 50-percent interest in the 8.6-million-acre offshore concession the French group held in French Guiana. The new Surinam concession reportedly was granted for a 50-year period and included a provision requiring the drilling of at least three test wells during 1966 and a provision that a portion (at least 500,000 tons) of any crude oil found in the offshore area must be refined in Surinam.

The French interests involved formed an operating company called Suriname Petroleum Maatschappij (Petrosur), based in Paramaribo. Active exploration was resumed in mid-1965 with a conventional marine seismic survey, resulting in a total of 4,358 kilometers of profile which covered most of the Surinam shelf on a reconnaissance pattern and included additional detail over indicated closures. The survey was conducted by Western Geophysical Co. under the joint supervision of Petrosur and Colmar. Joint operations by the Colmar and French groups also were conducted in adjoining French Guiana offshore areas during the year.

A flurry of excitement was caused by the accidental discovery on October 14 of an onshore oil-bearing horizon at the village of Calcutta in Saramacca District, about 60 kilometers west of Paramaribo. The find was made at a depth of about 150 meters by a government crew while drilling for

Table 6.—Surinam: Production of native gold by river district
(Troy ounces)

River district	1961	1962	1963	1964	1965

Total	4,011	2,598	3,548	8,258	6,269

potable water in a school enclave. Two other holes drilled nearby also encountered petroliferous strata; all three wells registered a slight flow of a few barrels per day after strainer pipes had been installed. An analysis of a sample of the oil indicated a gravity of 17° (API) and a high-paraffin base of 25.3 percent.

Although neither the lateral nor the vertical extent of the petroliferous area at Calcutta had been adequately explored by yearend, and the quantity of oil then in evidence was not commercially significant, the actual discovery of recoverable petroleum bolstered hopes of eventually finding commercial deposits somewhere in the coastal or continental shelf areas of Surinam. Ironically, the Calcutta area was included in an onshore concession previously held by Colmar, but the company had permitted its concession rights to expire only a few weeks prior to the discovery.

The Mineral Industry of Venezuela

By Benjamin H. Lim [1]

Performance of the various sectors of Venezuela's mineral industry in 1965 was mixed. Production of petroleum and iron ore, the country's major minerals, increased slightly, but output of gold and diamonds decreased significantly. Crude petroleum output in 1965 amounted to 1,268 million barrels, officially valued at $1,558 million,[2] compared with the 1964 output of 1,242 million barrels valued at $1,537 million. In terms of value the crude petroleum industry contributed 20.3 percent to Venezuela's 1965 gross national product (GNP) of $7,692 million and 21.3 percent[3] of 1964's GNP. The country retained third place among world crude oil producers behind the United States and the U.S.S.R. and remained the leading world petroleum export country, accounting for approximately one-fifth of the world's total. Exports of crude oil and products provided more than 90 percent of the country's total export earnings for the same years.

Iron ore output increased to 17.65 million in 1965, but the industry's contribution to the GNP remained less than 1 percent.

During the latter part of 1965, several proposals were made to amend Venezuela's Law of Eminent Domain. Two of the proposed provisions caused considerable concern. The first of these called for amendment of article 1 of the law to read as follows:

> Article 1: Necessary expropriation will be carried out according to the present law, except for that decreed in Special Laws.
>
> First Paragraph: The State concessionaires that have the right to expropriate through special legislation, due to the public utility of their activities, must conserve to turnover to the nation, without compensation, the lands and permanent works, including accessory installations and equipment which form an integral part of them, which they have acquired through any title, should the concessions be abolished for any reason.

The second proposal of concern was to amend article 51 of the existing law to read, in part, as follows:

> Article 51: When the project is one of those excepted from the formality of a prior designation as a public utility because its condition as such is self-evident, in accordance with the specifications contained in this law, and the agency charged with its execution considers it a matter of urgency, the Court which has jurisdiction in the expropriation proceedings may, within three days after the appropriate petition is filed, and at the request of the expropriating agency, agree to the prior occupation of the property to be expropriated, provided that the petitioner deposits, in money or securities, in a bank or branch or agency of a bank within the district of the Court, the amount at which the petitioner values the property.
>
> If the owner is in agreement with the amount put in escrow and there is no justified opposition, the case will be considered closed.[4]

At yearend, these proposals and others had not been passed by the legislature, but still were being considered.

In October 1965, Venezuela published a National Plan for the period 1965–68. Some of the mineral industry projects included

[1] Physical scientist, Division of International Activities.

[2] Where necessary, values have been converted from bolívares (Bs) to U.S. dollars at the rate of Bs4.50=US$1.

[3] Revised from 26.0 percent as reported in the 1964 Minerals Yearbook, Volume IV.

[4] U.S. Embassy, Caracas, Venezuela. Department of State Airgram A-561, Jan. 21, 1966.

263-927 O-67—17

in the National Plan for the period 1965–66 were as follows: Development of the San Isidro hill iron ore deposit, in Bolívar State; erection of a 15,000-ton-per-year plant to process nickeliferous laterite ore from the deposits of Loma de Hierro in Aragua and Miranda States; and continuation of projects to modernize gold mining facilities of the Government-owned Minas de Oro de El Callao, C.A. (MOCCA), including extensive geological studies to evaluate gold-bearing ores.

The National Plan (1965–68) included a significant section devoted to the crude petroleum producing sector; goals set for this sector were as follows:

	1964	1965	1968
Value of production:			
By sector:			
Private—million bolívares at 1960 prices	8,092	8,415	9,339

Source: Ministerio de Minas e Hidrocarburos, Venezuela. Carta Semanal (English transl.), V. 9, No. 3, Jan. 15, 1966, p. 17.

At yearend the Minister of Mines and Hydrocarbons commented that the deterioration of oil prices during the last several years had slowed in 1965. He attributed this slackening of price erosion to the various measures taken by the Government's Coordinating Commission on Conservation and Marketing of Hydrocarbons. The Minister also commented that the country's oil revenues had not risen in proportion to the increased rate of production. He attributed this to the fact that the country exported more of the lower priced heavy crude and residual oils and less of the higher priced light crude and production oils.

PRODUCTION

The value of Venezuela's total mineral output in 1965 increased as petroleum output was some 25 million barrels above that of the preceding year, and iron ore production increased by 2 million tons.

Gold output declined 29 percent, presumably as a result of lower ore grades. Diamond production was 21 percent below that of 1964 despite the small gain made in the case of bort.

The decline in coal production was largely attributed to the unsuitability of the coal for blast furnace use.

Production of steel ingots and castings in 1965 was 2.5 times that of 1964, indicating completion of new steelmaking installations.

TRADE

The dominant role of mineral exports in Venezuela's overall foreign trade picture is revealed by the following tabulation, covering the most recent years for which data are available:

	Value (million dollars)		Mineral commodities share of total (percent)
	Mineral commodities	All commodities	
Exports:			
1963	1,907.2	1,957.1	97.5
1964	2,011.9	2,053.6	97.9
Imports:			
1963	85.2	822.9	10.4
1964	106.7	1,101.8	9.7
Trade balance:			
1963	+1,822.0	+1,134.2	XX
1964	+1,905.2	+951.8	XX

XX Not applicable.

The distribution of exports by major commodities and commodity groups for 1963 and 1964 was as follows:

Commodity group and commodity	Value (million dollars) [1]	
	1963	1964
Metals:		
Iron ore	73	119
Iron and steel semimanufactures	16	7
Other	2	(2)
Total	91	126
Nonmetals:		
Cement	2	3
Diamond	2	3
Other	(2)	(2)
Total	4	6
Mineral fuels: Petroleum and petroleum refinery products	1,812	1,880
Grand total	1,907	2,012

[1] Data for 1963 differ from that published in Volume IV of Minerals Yearbook for 1964 because a different conversion rate was used in converting Bolívares to U.S. dollars.

The distribution of import expenditures was as follows, by commodity groups:

Commodity group	Value (million dollars)	
	1963	1964
Metals:		
Iron and steel	61	77
Other	11	14
Nonmetals:		
Fertilizer materials	3	2
Construction materials	2	4
Other	2	1
Mineral fuels:		
Solid	2	3
Petroleum and products	4	6
Total	85	107

COMMODITY REVIEW

METALS

Aluminum.—Construction of Venezuela's first integrated aluminum plant moved a step closer to realization when the Export-Import Bank in July 1965 authorized a $12.5 million loan, under the Alliance for Progress, to Aluminio de Caroní, S.A. (ALCASA). The loan made up approximately one-half of the investment required to complete the project and was to be used to finance the purchase in the United States of machinery, equipment, supplies, and services for construction of the initial phases of the proposed plant. ALCASA, a recently organized firm, is jointly owned by Corporación Venezolana de Guayana (CVG), an agency of the Venezuelan Government, and by Reynolds International, Inc.

Ground breaking for the complex was expected in February 1966. Completion date of the initial phases of the plant has been scheduled for late 1967 or early 1968. These phases include the construction of a reduction plant in the Ciudad Guayana industrial complex near the confluence of the Orinoco and Caroní rivers. The reduction plant will use the Bayer-Hall process rather than the direct reduction process, as announced during early months of planning. Alumina for the plant will be supplied from the United States. Capacity of the plant will be approximately 10,000 tons of ingots and billets per year. Tentative plans for doubling this capacity have been drawn and the cost for the additional installations was estimated at $7 million.

In addition to the projected new reduction plant, other installations in the initial phases of construction include hot- and cold-rolling mills, sheet finishing facilities, and facilities for manufacturing electrical

cables.[5] The related semifabricating facilities will have annual capacities of 27,200 tons of hot-rolled sheets, 13,600 tons of cold-rolled sheets, and 11,340 tons of rods. Production of the plant will substitute for some of the aluminum imports, which in total have cost Venezuela about $2.3 million annually in foreign exchange.

At yearend 1965, four significant companies were engaged in aluminum semifabrication: Alcan de Venezuela, an affiliate of Aluminium Ltd., Canada, in La Victoria; Aluminio Nacional S.A. (ALNASA), an affiliate of Kaiser Aluminum and Chemical Corp., in Guacara; Corporación Venezolana de Aluminio (COVENAL), an affiliate of Società Montecatini, Milan, Italy, and of Aluminum Company of America (Alcoa), in Mariara; and Reynolds Aluminum Extrusions Co., an affiliate of Reynolds Metals Co., in Maracaibo. None of these above companies use aluminum slabs as starting material in the production of semimanufactures which consisted mainly of thin sheets and foil. The basic raw materials for these products were hot- and cold-rolled coil sheets imported mainly from the United States, Belgium, the Netherlands, and the United Kingdom. Combined annual output of the four companies was approximately 15,000 tons of various aluminum semimanufactures.

Gold.—Venezuela's entire gold production in 1965 was from the El Callao region of the State of Bolívar. During the latter part of 1965, the Venezuelan Minister of Mines announced that a new state company, in which private capital would be allowed to participate, was to be formed to replace the Government-owned gold mining company, Minas de Oro de Callao, C.A.

(MOCCA). Before formation of a new company, however, officials decided to make further studies and to complete various projects concerning government-operated gold mining facilities. These projects included exploration for new reserves. Liquidation of MOCCA, which started operations in 1953, began at yearend. Chief reason for liquidation was that it had been showing losses every year for some time. Gold output by various producers in Venezuela during 1964 and 1965 was as follows:

Producer	Troy ounces	
	1964	1965
MOCCA	32,275	22,777
Open operations	1,045	593
Other	216	290
Total	33,536	23,660

Source: Ministerio de Minas e Hidrocarburos, Venezuela. Carta Semanal (English transl.), V. 9, No. 9, Feb. 26, 1966, 15 pp.

Iron Ore.—Venezuela's iron ore industry in 1965 continued the upward production trend of the previous year. The industry's gross income in 1965, based on a preliminary production figure [6] of 17.4 million tons, aggregated $134.3 million compared with $115.1 [7] million in 1964. Of this total, $126.3 million ($107.6 million in 1964) was attributed to sales, $6.0 million ($5.6 million in 1964) to Boca Grande Canal tolls; and $2.0 million to services. Net profits of the industry in 1965 also based on preliminary data amounted to $42.4 million compared with $34.0 million in 1964. Costs and operating expenses of the industry in 1965 amounted to $48.2 million ($49.0 million in 1964) while tax revenue totaled $42.3 million ($33.5 million in 1964). The increases in gross income and in net profits were reportedly attributed to increase in sales of 2.3 million tons in 1965 over the 1964 level and to a $0.38 per ton reduction in production costs. Specific taxes levied on the industry in 1964 and 1965 are given as reported in the source in the following tabulation:

Tax item	Thousand dollars	
	1964	1965
Law of mines	622.7	755.1
Consular	494.4	468.3
Municipal and other	314.4	381.3
Total	1,431.5	1,604.7
Income tax reserves	32,072.4	40,666.7
Grand total	33,503.9	42,271.4

Source: Ministerio de Minas e Hidrocarburos, Venezuela. Venezuelan Iron Ore Industry Operations in 1965. Carta Semala (English transl.), V. 9, No. 12, Mar. 19, 1966, p. 9.

Domestic sales of iron ore in 1965 totaled 632,000 tons compared with 574,223 tons in the previous year. Of the 1965 total, 627,022 tons was purchased by Siderúrgica del Orinoco (Matanzas steel plant). The remainder was bought by C.A. Venezolana de Cementos and Siderúrgica Venezolana, S.A. (SIVENSA). Foreign sales of iron ore in 1965 totaled 17.1 million tons, an increase of 15 percent over the previous year. The United States, West Germany, and the United Kingdom imported 73, 11, and 10 percent, respectively, of the total iron ore exported by Venezuela during 1965. The remaining 6 percent was shared by Japan, Italy, Netherlands, and Canada. Thus, of the total sales in 1965, 96 percent was exported and 4 percent was sold in the domestic market. Statistical details on production, domestic sales, and trade for years 1963–65 were as follows:

[6] Financial data relating to revised official production figure of 17.65 million tons are not available.

[7] Revised from figure given in the 1964 Minerals Yearbook, volume IV, on the basis of new data.

[1] Preliminary data; differs with total given in table 1. (Detail by producer for total production figure in table 1 not available.)

Source: Ministerio de Minas e Hindrocarburos, Venezuela. Carta Semanal (English transl.), V. 9, No. 6, Feb. 5, 1966, 15 pp; No. 7, Feb. 12, 1966, 13 pp; No. 8, Feb. 19, 1966, 16 pp; No. 12, Mar. 19, 1966, 15 pp.

Stocks of iron ore on hand as of December 31, 1965, as reported by the mining companies, were as follows: Orinoco Mining Co., 1,001,431 tons; Iron Mines Co. of Venezuela, 586,441 tons.

At yearend 1965, Venezuela's iron ore concessions in force totaled about 29,000 hectares. During 1965 no iron ore concession areas were either relinquished or granted, but the concession held by Oswaldo de Sala was credited to C.A. Barlovento Minera in 1965 reports. Of the existing concessions, the only areas worked during 1965 were held by Orinoco Mining Co. and Iron Mines Co. of Venezuela. Of the total iron ore mining concession area held in 1965, only 4,300 hectares or about 15 percent of the total was under exploitation. The remaining concessions were not sufficiently developed.

Venezuela's most important iron ore reserves are in the so-called Bolívar Iron Bearing Quadrangle and in Cerro Bolívar and El Pao. Orinoco Mining Co. had the Quadrangle concession while Iron Mines Co. of Venezuela has concessions in the latter two areas. Approximately 93 percent of the known iron ore deposits in Venezuela are in these areas. The remaining 7 percent of the deposits are in the States of Miranda and Monagas. At yearend 1965, proved iron ore reserves under concession totaled some 940 million tons, representing an increase of 15 percent above the 1964 level. Total proven reserves including those owned by the Venezuelan Government were 1,616 million tons.[8]

According to the Ministry of Mines and Hydrocarbons, the Venezuelan Government was considering plans for the installation of two iron ore reduction plants to be jointly operated by CVG and foreign-private firms. One project, a part of a larger proposal advanced early in 1964 by Orinoco Mining Co., will include facilities to raise the iron content of the salable product from 60 to 85 percent. The facilities are to be located at Puerto Ordaz and the cost of the project was estimated originally at about $40 million. The other project involves a process developed by Standard Oil Co. of New Jersey. As both processes will use substantial quantities of natural gas, construction of a network of pipelines from the eastern oilfields to the Guayana area has also been planned. The network will supply other natural gas consumers in the area as well as the previously mentioned facilities.

Iron and Steel.—Venezuela's iron and steel industry in 1965 completed some projects begun in earlier years and started others. New projects included rolling mills and reduction facilities.

Siderúrgica Venezolana, S.A. (SIVENSA), and the Government-owned Siderúrgica del Orinoco, S.A. (SIDOR), a part of the Corporación Venezolana de Guayana (CVG), continued as the only significant iron and steel producers. Data for SIVENSA production, as published in the firm's 1965 annual report, indicated output for the period November 1, 1964, to October 31, 1965. During this period, SIVENSA produced 88,928 tons of ingots and 88,567 tons of rolled products.

Unofficial 1965 production data for the SIDOR facilities were as follows:

Product	*Metric tons*
Pig iron	318,604
Ingots	537,437
Blooms	460,506
Semimanufactures:	
Structural shapes	36,251
Wire rod	12,435
Drawn wire	22,083
Seamless pipe	132,387
Bars and rods	55,006

In late 1965, SIVENSA was constructing a new plant near the existing complex at Carretera de Antimano near Caracas. The new plant will have two Lectromet arc furnaces and two Concast S-1, two-strand continuous casting machines with a total annual capacity of 120,000 tons. The machines will be built by Compagnie des Ateliers et Forges de la Loire (CAFL) of France and are scheduled for full production in early 1966.

On July 2, 1965 SIDOR's cumulative ingot steel output reached 1 million tons. This total included 68,563 tons of steel produced in 1962, 287,891 tons in 1963, 359,882 tons in 1964, and 283,664 tons produced in the first 6 omnths of 1965. The principal installations of the plant included

[8] Ministerio de Minas e Hidrocarburos, Caracas, Venezuela. Monthly Bulletin. V. 1, No. 1, July 1, 1966, 28 pp.

mixing plants, electric furnaces, thermoelectric generators, and sheet, tube, and wire mills. The complex has an annual designed capacity of 750,000 tons of steel ingots and 600,000 tons of various semifinished products. Individual product capacities of the plant's components at yearend 1965 were as follows:

Product	*Annual capacity (Metric tons)*
Iron:	
Cast pipe	30,000
Ingot molds and bases	20,000
Total	50,000
Steel:	
Bars and rods	86,150
Structural shapes	70,000
Sheets and plates	10,350
Wire	27,000
Seamless pipe	295,000
Rails and accessories	61,500
Total	550,000
Grand total	600,000

Source: República de Venezuela. Corporación Venezolana de Guayana (CVG). Informe Anual, 1965, p. III–8.

Much of the plant's pipe production is used in the country's petroleum industry. No new facilities were brought into operation at SIDOR during 1965, and the operation of the Strategy-Udy system was finally abandoned because the process was unsuitable to raw materials used.

Apparent consumption of iron and steel products in Venezuela is shown in the following tabulation:

Commodity	Thousand metric tons	
	1964	1965
Pig iron	e 316	317
Ingot steel	440	625
Bars, rods, and other nonflat products except pipe	355	355
Flat products	227	262
Pipes and tubes:		
Seamless	NA	139
Cast iron	NA	42
Galvanized and seamed	NA	77
Other	NA	7
Total	203	265
Grand total	785	882

e Estimate. NA Not available.

NONMETALS

Clay.—In 1965, the clay industry consisted of 23 ceramic plants and over 100 producers of brick and similar construction materials. The three largest ceramic firms were Ceramicas Carabobo S.A., Sanitarios Maracay S.A., and Venezolana de Ceramica C.A. These firms, all located in the Valencia-Maracay industrial complex, have a total capitalization of over $10 million and employ about 1,500 workers. Ceramicas Carabobo S.A. produces mainly bathroom tiles while the other two manufacture chiefly porcelain bathroom fixtures. Other ceramic factories small in comparison, produce mainly bathroom fixtures and other products.

The Venezuelan Institute for Technical Investigations (INVESTI) has studied the possibilities of using lightweight clay aggregates for the construction of low-cost housing and also the use of local clays for ceramic manufacturing.[9]

Fertilizer Materials.—Instituto Venezolano de Petroquímica (IVP), the large Government-owned petrochemical complex at Morón, announced in early 1965 that it planned to increase chemical fertilizer output to more than 107,000 tons during the year. This complex, capable of producing all of Venezuela's basic fertilizer requirements, except potash, was expected to supply 80 percent of the domestic demand in 1965, and all of it in 1966. Production in 1964 and the estimated output in 1965, by product, was reported as follows:

Product	Metric tons	
	1964	1965 e
Ammonium nitrate	11,000	21,600
Ammonium sulfate	46,000	50,000
Ordinary superphosphate	12,000	4,800
Triple superphosphate	15,600	19,200
Urea	12,700	12,000

e Estimate.

Production of the country's other three fertilizer mixing companies was as follows:

Company and plant location	*Daily output (metric tons)*
Pennsalt-Comanil C.A.:	
Maracay	200
Commercial Agropecuario:	
Maracay	150
Casa Agricola: Valencia and Barquisimeto	25

[9] U.S. Embassy, Caracas, Venezuela. Department of State Airgram A–596, Mar. 12, 1965.

Installed capacity of the five fertilizer mixing plants in Venezuela at yearend 1964 was reported to be adequate to supply domestic demand for nitrogenous and phosphatic fertilizers. However, the industry reportedly has been operating at only 80 percent of capacity.

To anticipate future needs and to diversify exports, the Government announced in late 1964 a 5-year petrochemical program with a projected cost of about $2,600 million. The program includes the construction of several petrochemical complexes to be located in Zulia, Falcón, Carabobo, and Anzoátegui States. The installations will consume many domestic raw materials that have been either left unused or exported unprocessed. Projects envisaged under the program include expansion of ammonia and sulfuric acid facilities and expansion of national fertilizer production capacity from the present 150,000 tons per year to 500,000 tons per year.

At yearend 1964, IVP had in its fertilizer component approximately 20 plants producing ammonia, ammonium sulfate, and nitrate, nitric and sulfuric acids, and triple superphosphates. In 1965 the Institute broke ground for a fertilizer plant in Táchira State to process locally available phosphorite minerals for consumption in the local area and for export to neighboring Colombia. It also made tentative plans to build an ammonia plant in the Guayana region with a daily capacity of 1,000 tons. The entire production of this plant is planned for export.[10]

In mid-1965, Krebs & Cie., a French firm, and Wellman-Lord Inc., a U.S. firm, submitted lowest bids to IVP to construct two sulfuric acid plants at Morón. The bids were $4.94 million and $4.96 million, respectively. Construction time was estimated at 15 months. Annual capacity of the plants will total approximately 400,000 tons of sulfuric acid with each plant capable of producing 600 tons per day. It was indicated that the output of these plants will be exported.

In addition to the Government-owned plants, Quimica Tapa-Tapa C.A. near Maracay produced sulfuric acid at a daily rate of 50 tons.[11]

MINERAL FUELS

Coal.—Venezuela's coal production continued to decline. Peak recorded production was achieved in 1963. Output was mostly volatile bituminous coal and all but a small amount came from the State of Táchira. C.A. Minas de Carbón de Lobatera, accounted for over 80 percent of total output in the past few years. Other coal producers in the country included C.A. Minas de Carbón de Naricual, C.A. Cementos Táchira, Ponciano Ruiz, G. Omaña, and Cabonera Taguay.

Petroleum and Natural Gas.—Venezuela's average daily crude oil output in 1965 reached 3.5 million barrels and total annual production was about 26 million barrels more than in 1964. The five largest producers in the country in 1965, Creole Petroleum Corp., Cía. Shell de Venezuela Ltd., Mene Grande Oil Co., Venezuelan Sun Oil Co., and Mobil Oil Co. of Venezuela, together produced 87 percent of total crude output, with Creole alone accounting for 37 percent of the total.

During 1965, 673 wells were completed, 16 percent more than in 1964, and as a result of these completions together with recalculations of reserves elsewhere, the total national proven reserve at yearend 1965 was reported as 17,400 million barrels, 200 million barrels more than at yearend 1964.

Creole, Cía Shell de Venezuela, and Mene Grande continued their dominance over the Nation's petroleum refining industry, together accounting for 86 percent of total refining capacity as shown in the following tabulation:

---

[10] U.S. Embassy, Caracas, Venezuela. Department of State Airgram A-711, Mar. 17, 1966.

[11] Sulphur. No. 59, August 1965, p. 6.

Company	1964		1965	
	Capacity (Thousand 42-gallon barrels daily)	Percent of total capacity	Capacity (Thousand 42-gallon barrels daily)	Percent of total capacity
Creole Petroleum Corp	507	42.9	509	42.4
Cía. Shell de Venezuela Ltd	342	28.9	352	29.3
Mene Grande Oil Co	159	13.5	159	13.3
Mobil Oil Co. of Venezuela	75	6.3	81	6.8
Chevron Oil Co. of Venezuela	46	3.9	46	3.8
Others	53	4.5	53	4.4
Total	1,182	100.0	1,200	100.0

Source: Oficina Técnica de Hidrocarburos, Ministerio de Minas e Hidrocarburos, Venezuela. Informe Sobre las Actividades, 1965. Caracas, Venezuela, 1966, p. 36.

Actual refinery throughput was at almost 98 percent of rated capacity, and for the year totaled 429 million barrels of which Creole processed nearly 170 million barrels.

At midyear, the managing director of the Venezuelan Petroleum Corp. (CVP) announced the award of a contract to Japan Gasoline Co. for enlargement of the CVP refinery at Morón. Facilities to be installed include a 14,000-barrel-per-day crude oil distillation unit, a catalytic refining unit, and three fractionating units. The expansion was slated for completion by September 1966, and the cost reportedly was to total $3.1 million of which a part was to be paid to the Japanese firm in the form of CVP crude oil.[12]

As indicated previously under fertilizer materials, IVP announced plans for expansion of Venezuela's petrochemical industry at yearend 1965. Aside from fertilizer commodities summarized previously, announced product capacities for projected facilities were as follows:

Commodity	*Annual capacity (metric tons)*
Ethylene	150,000
Propylene	90,000
Polyvinyl chloride	50,000
Synthetic rubber	50,000
Polyethylene	40,000

The IVP announcement indicated that the following foreign firms were discussing petrochemical possibilities in the country: Allied Chemical Corp., Union Carbide Corp., B.F. Goodrich Co., American Cyanamid Co., W.R. Grace and Co., Dow Chemical Co., Phillips Petroleum Co., International Minerals and Chemical Corp., Imperial Chemical Industries, Ltd., and Shell Oil Co.

The Mineral Industry of Other South American Areas

By Burton E. Ashley [1]

Contents

ECUADOR

Ecuador remained an unimportant source and a modest consumer of minerals and mineral products in 1965. Output of the few categories of base and precious metals that were produced in 1965 continued to decline. Actual value of production is not determinable from available sources; however, the Central Bank of Ecuador recorded that in 1965 exploitation of mines and quarries accounted for about 2 percent of the gross domestic product. Domestic requirements for minerals again were largely met by imports, and exports were confined to modest quantities of nonferrous metal ores and concentrates, ferrous scrap, and crude petroleum.

Mineral prospecting was carried out during 1965 by both foreign and local interests. U.S. firms were interested in placer gold and were reported to have applied for concessions. Existing placer gold operations were also being studied for possible extension.

The Government of Ecuador joined with the United Nations Special Fund in a $1.4 million program to explore seven major zones of potential mineralization. Part of the program was aimed at training local technicians in geological prospecting. The need for technicians was also recognized by the agreement made between the National Geological and Mines Service and the Central University of Quito to cooperate in the development of engineers and technical personnel.

Pessimism was expressed regarding the near future of base metal mining, and it was indicated that base metal ore at Portovelo was becoming exhausted. The company that works these mines called on the Government for assistance in keeping the mines open and/or finding alternative employment for the miners.

U.S. and British companies prospected actively for oil using modern geophysical methods. Some expansion of refining capability was also announced, chiefly for the production of liquefied gas and asphalt. In addition, two lubricating oil mixing plants were planned to cater to the domestic market.

Recently published figures show that, of 1,477,851 persons employed in 1962, 3,547 worked in the mining and quarrying industry. However, this is not likely a true reflection of the entire mining and minerals industry, since workers in petroleum and metals presumably are excluded from the category listed.

At yearend 1965, an industrial development law was promulgated to encourage certain industries in Ecuador. Various industrial activities are categorized into "Special," 'A," or "B" divisions which receive certain incentive benefits. Briefly, the benefits extend certain tax exemptions and

[1] Physical scientist, Division of International Activities.

freedom from paying duties on necessary materials which must be imported to maintain operations. At yearend 1965, the Special category included production of iron and steel, caustic soda, chemical fertilizers, and sulfuric acid, and salt refining and iodizing. The law does not apply to mining activities in the extraction phase.

A decree concerning petroleum regulations was also published. (See section on "Commodity Review.")

PRODUCTION

Metallic mineral production fell drastically in 1965. Declines of 42 percent and 38 percent were recorded for cadmium (contained in zinc concentrates) and zinc in concentrates, respectively. The general downward trend in output that has been evident for a number of years presumably will continue.

Cement output continued to rise and gained 13 percent over the 1964 figure, and crude petroleum showed a very slight production gain. Rises were also registered in refinery output. Statistics on nonmetallic minerals, particularly those used in the building industry, are ordinarily unavailable.

TRADE

Comparison of total commodity trade and trade in mineral commodities in terms of value for 1963 and 1964 is shown in the following tabulation (data for mineral trade in 1965 are not yet available):

	Value (thousand dollars) [1]		Mineral commodities share of total (percent)
	Mineral commodities	All commodities	
Exports:			
1963	1,244	128,437	1.0

Imports were largely made up of iron and steel semimanufactures and petroleum. The United States, with sales of $68.6 million and purchases of $65.6 million, was Ecuador's chief trading partner in terms of total value. Imports of metals largely came from Belgium, West Germany, France, or the United Kingdom; nonmetallic minerals and petroleum products were generally supplied by the United States.

Table 2.—Ecuador: Exports of metals and minerals

COMMODITY REVIEW

Metals.—*Aluminum.*—Two firms announced in late 1965 that they would install facilities for the manufacture of aluminum doors and window frames. Aluminio Manufacturas Industrias Cía. Ltda. will be located in Quito, and Aluminio Architectónico S.A. in Guayaquil.

Iron and Steel.—The Atlantic Community Development Group for Latin America (ADELA) announced that it had allocated $400,000 to Acerias Nacionales del Ecuador, S.A., for the construction of structural steel fabrication facilities at Guayaquil.

Silver.—It was reported in trade journals that over $1.5 million in silver had been recovered from silver-copper coins for the Ecuadorian Government. Refining was reportedly done by Spiral Metal Co., Inc., of South Amboy, N. J.

Nonmetals.—*Cement.*—The cement plant at Guapán began operations after installation of diesel generating equipment. Empresa Industrias Guapán, S.A., which owns the cement plant, is owned in turn by various government bodies as follows: Caja del Seguro Social, Caja de Pensiones, Instituto de Recuperación Económica, Banco Nacional de Fomento, Consejo Municipal de Cuenca, Consejo Cantonal de Biblián, and Consejo Cantonal de Azogues. Construction of the cement plant started in 1961 and proceeded without undue delay; however, a source of power was not available for the programed startup, and it was only in mid-1965 that actual operations began. Cost of the plant was reported at $4 million plus the cost of a 2,500-kilowatt diesel generating plant. Planned capacity was 200 tons of portland cement daily, a quantity sufficient to supply about 15 percent of the country's requirements.

Fertilizer Materials.—ADELA approved investment of $650,000 in Fertilizantes Ecuatorianos, S.A., for production of sulfu-

ric acid, ammonium sulfate, and various manufactured fertilizers.

Salt.—Industria Salinera Inversionista Dariegas continued its salt production enterprise on San Salvador Island, but at yearend no reports of progress were available. Investment was reported as about $500,000.

Salinera Ecuatoriana, S.A., is progressing with the establishment of its solar salt works northeast of Salinas on the Santa Elena Peninsula. Cost of the project was reportedly around $300,000.

It was reported in early 1965 that the Morton Salt Co., with domestic financial investors, was negotiating for a solar salt site in the vicinity of Salinas. Estimated cost of the plant was $1.5 million. Production was expected to begin in 1967 with a planned annual capacity of 40,000 to 45,000 metric tons. It was indicated that manufacture of caustic soda may also be considered.

Mineral Fuels.—*Petroleum.*—The Minister of Industry and Commerce distributed an open letter to "all oil companies in the world" inviting interest in oil exploration in Ecuador. All available geologic and petroleum data in the Ministry were offered for use of interested parties. Inquiries were to be directed to the Dirección de Minas e Hidrocarburos, Ministerio de Industrias y Comercio, Avenida 10 de Agosto 666, Quito, Ecuador, S.A.

The French Institute of Petroleum agreed with the Ecuador National Geologic Service to conduct a survey of the petroleum potential of Ecuador. Cost of the program was reported at $285,000, of which $217,000 will be furnished by the French and the remainder by Ecuador.

In mid-1965 Supreme Decree 1464, in reference to the petroleum industry, was issued, setting minimum investment standards, limiting the size of concessions to 500,000 hectares, requiring government approval of annual work plans, and levying special taxes on petroleum.

Incentive for petroleum exploration in Ecuador doubtless has been prompted by estimates that known reserves will be exhausted by 1973 at the projected consumption rate.

Production from Ecuador fields averaged 7,998 barrels per day in 1965, a slight increase over 1964 production of 7,876 barrels daily. There were 49 wells completed during 1965, of which 21 were exploration wells and 28 were field wells; successful completions numbered 10 and 27, respectively.

A discovery, not yet fully evaluated, was made on the Carmela claim, north of the Ancón field. Cautivo, Empresa Petrolera Ecuatoriana C.A. had drilled seven successful wells by yearend and had two rigs following a systematic stepout drilling program.

Active prospecting was being carried out by a number of companies in various parts of Ecuador. Added interest in northeast Ecuador was spurred by discoveries over the border in Colombia.

FRENCH GUIANA

With the possible exception of building materials, the mineral potential of French Guiana showed little progress toward the production stage in 1965.

Bauxite output had not started by yearend, and the status of then-existing agreements was in doubt. Gold production lapsed completely in 1965, although it was reported that one prospect was being readied for production in 1966.

An offshore seismic program was carried out in a search for petroleum possibilities.

The Bureau de Recherches Géologiques et Minières (BRGM) continued its geologic mapping program and also carried on ground water investigation for domestic and agricultural uses. Quarry sites were examined as a source of building material; sources of laterite, used in roadbuilding, were also appraised.

Much of the need for construction material was prompted by the choice of Kourou as the site for the space center to be established by the French. It was reported that by 1970 the community would number at least 6,000 people. The space center will doubtlessly have considerable impact on the country, considering all the interrelated amenities that will be required.

PRODUCTION AND TRADE

The only mineral production reported in 1965 was 850 kilograms of columbite-tantalite concentrates. Some nonmetallic building materials were also produced during the year, but quantitative data on this output, if collected, were not reported through official channels.

Trade in mineral commodities remained of little significance, and the value of mineral commodity exports was much smaller than that of mineral commodity imports. Except for columbite-tantalite exports, outgoing mineral products are largely limited to reexports of petroleum and steel items.

In 1964 the United States imported 1,923 kilograms of columbite-tantalite concentrates valued at $7,780; in 1965 the figures had fallen to 406 kilograms valued at $1,452.

Mineral and metal imports in 1965 were valued at $1.7 million; petroleum products made up the largest single category. Other imports were common base and ferrous metals, fertilizers, chemicals, and some construction materials. One necessity which does not appear separately in any of the statistics is salt.

Gold, valued at $23,000, was imported from France in 1965.

In 1965, France supplied 75 percent of French Guiana's imports of all commodities, followed by the United States with 11 percent. Over 71 percent of total exports were directed to the United States, with 23 percent going to France.

The following tabulation shows the relation between trade in all commodities and mineral trade:

	Value (thousand dollars) [1]		Mineral commodities share of total (percent)
	Mineral commodities	All commodities	
Exports:			
1964	[2] 8	683	1.2

COMMODITY REVIEW

Metals.—*Bauxite.*—No bauxite production had been initiated by yearend 1965, and no reports were available as to the plans of Kaiser Aluminum and Chemical Corp. (See Minerals Yearbook, Volume IV, 1964, for details.)

Gold.—BRGM investigated anomalies on the eastern edge of the Ininí quadrangle, finding irregularly occurring quartz veinlets carrying low gold values.

Gold production was supposed to have been resumed at Paul Isnard, 90 kilometers

south of Saint Laurent-du-Maroni, but by yearend no reports of activity had been received.

Nonmetals.—*Construction Materials.*—Of an estimated 12,000 persons employed in 1965, nearly 14 percent were categorized in "construction and public works." Thus, output of construction materials may be of some significance to the local economy, even if such output is not statistically recorded. It is known that laterite is used for road surfacing. Construction material to the value of over $600,000 was reported to have been extracted from one quarry in the vicinity of Kourou.

Mineral Fuels.—Two and one-half crew months of marine seismic work was reportedly done in 1965 by Compagnie Générale de Géophysique and Gulf States Land and Industries of New York. A reconnaissance pattern totaling 3,200 kilometers of line was completed. No specific results were announced.

PARAGUAY

Paraguay's mineral industry output continued to be confined to nonmetallic minerals through yearend 1965, and output was almost entirely for domestic use with only very small tonnages being traded.

At yearend the petroleum refinery was still under construction, but nearing completion.

There was some interest in petroleum exploration, but no definite programs were begun during the year.

While exports of minerals were of negligible value, imports made up nearly 20 percent of Paraguay's total import trade. Purchases of petroleum products, which constituted the bulk of such trade, should show a significant decline in 1966 because of the contribution which may be expected from domestic refinery operations. The refinery, however, will require imports of crude oil as feedstock.

Paraguay's foreign trade has been hampered for some time by limited port facilities at Asunción. With expected increase in exports, improvements in port facilities are urgently required. It was announced at yearend that the World Bank had approved a loan equivalent to $2.8 million

for doubling the capacity of the present port and speeding up port operations in general. The project is expected to take 4 years to complete and will cost nearly $4 million. Funds required in excess of those loaned by the World Bank will be met through port charges and Government of Paraguay contributions.

The port project is related to planned improvement of penetration and access roads.

PRODUCTION

Output of construction materials showed rises in most cases. The most significant increases were in the cases of cement and sand for construction uses, up 28 percent and 24 percent, respectively. A measure of Paraguay's modernization may be detected in the leveling off, or decrease, in the use of forest products for fuel, and the increased reliance on petroleum products as indicated by rising trade figures.

Value of production as published in official government sources lists only lime and cement, totaling $1.6 million. However, more complete data supplied by the U.S. Embassy in Asunción show a mineral production value of $5.2 million for 1965. This is a slight rise over the total reported in 1964.

TRADE

The role of mineral commodity trade in total trade in recent years appears in the following tabulation:

	Value (thousand dollars)		Mineral commodities share of total (percent)
	Mineral commodities	All commodities	
Exports:			
1964	277	49,771	0.6
1965	351	57,267	.6
Imports:			
1964	7,590	39,821	19.0
1965	9,274	51,669	17.9

1964	−7,313	+9,950	XX
1965	−8,923	+5,598	XX

XX Not applicable.

Source: Banco Central del Paraguay, Departamento de Estudios Economicas. Boletin Estadistico Mensual. No. 99, Agosto 1966.

Paraguay's most important trading partners in terms of value of total trade, in 1964 and 1965, were Argentina and the United States. Out of total exports of $57.3 million in 1965, $14.8 million went to Argentina and $14.5 million to the United States; the remaining 49 percent of total value was accounted for largely by Uruguay and by the United Kingdom, Spain, Italy, and other European countries.

r Revised. NA Not available.
[1] Based on industry or government estimates.

Sources: Banco Central del Paraguay, Departamento de Estudios Economicas. Boletin Estadístico Mensual. No. 99, Agosto 1966. U.S. Embassy, Asunción.

Total import value in 1965 was $51.7 million, of which the United States supplied $10.0 million and Argentina $9.0 million. Imports from Germany were higher in 1965 than usual, with a value of $9.0 million. About $2.6 million in value came from the Netherlands Antilles and presumably represented petroleum products.

Petroleum products remained the most important category of mineral imports in Paraguay, and in 1964 and 1965 accounted for over one-half the value of such trade. The next ranking category of import importance in 1965 was iron and steel semimanufactures, followed by nonferrous metals.

During 1964 and 1965, Paraguay's mineral and metal exports and reexports were limited to cement, lime, ocher, aluminum ingots, and scrap iron.

COMMODITY REVIEW

Nonmetals.—*Cement.*—The cement plant of Vallemí, S.A., closed for about 2 months for general renovation. While some shortage of cement was reported during that period, annual production increased. Imports of cement, however, were necessary to satisfy domestic demand.

There were rumors of plans for a competing cement plant. Such rumors may be well founded in view of the progress being made on the Acaray hydroelectric project.

Source: Banco Central del Paraguay. Departamento de Estudios Economicos. Boletin Estadístico Mensual. No. 99, Agosto 1966.

Mineral Fuels.—Petroleum.—Paraguay's only petroleum refinery, Refinería Paraguaya, S.A., had not gone on stream by yearend. However, construction had progressed to the point where production was certain in 1966. A firm source of crude oil was not announced, nor were domestic marketing arrangements settled.

It was reported that U.S. interests were negotiating for oil exploration concessions in northwestern Paraguay. Government interest was reportedly evident.

URUGUAY

The mineral industry of Uruguay continued its uneven pace in 1965, showing mixed gains and losses in output and trade. No discoveries of consequence were announced, nor was any sector of the operating industry greatly expanded. Two announcements concerning heavy mineral beach sands and uranium prospects might lead to future interest and development.

Construction activity in Montevideo eased, but was compensated by greater activity in the interior of the country.

The economy in general grew little, and inflation was evident. After fluctuating considerably and reaching a low of 77 Uruguayan pesos (Ur$) to the U.S. dollar (from around UR$25 to the U.S. dollar), Uruguayan currency was officially stabilized at Ur$58.90 buying and Ur$59.90 selling, per U.S. dollar.

It was reported that the mineral industry afforded employment to about 4,000 persons, of whom about one-half were engaged in the extraction of marble and granite.

The Uruguayan mineral industry has little impact upon world trade, but the local economy benefited from domestically produced cement and other primary construction material. Marble, granite, dolomite, and talc appear to have greater export market potential which remains to be developed.

PRODUCTION

The mineral and metal industry of Uruguay is limited to output of nonmetallic construction material, petroleum refinery products, and some secondary production of aluminum and ferrous metals. Volume of production has generally been on the rise over the last few years, with sporadic interruption in various commodities.

There are no official figures or estimates on the value of production; informal estimates place such value at less than 1 percent of the gross national product, which in 1963 was approximately $1.3 billion.

TRADE

In overall exports, the United States replaced Great Britain as Uruguay's principal customer with 1965 purchases amounting to $32 million. In terms of mineral trade there was little change in direction, with exports going largely to neighboring countries.

The following tabulation shows the relation of mineral trade to overall trade for 1964 and 1965:

	Value (thousand dollars)		Mineral commodities share of total (percent)
	Mineral commodities	All commodities	
Exports:			
1964	r 1,500	178,940	0.8

1964	−33,500	−19,352	XX
1965	−34,063	+40,511	XX

r Revised. XX Not applicable.

COMMODITY REVIEW

Metals.—*Heavy Mineral Beach Sands.*—Beach sands in the Department of Rocha have been studied for some time. An ore reserve of 3 million tons has been reported containing ilmenite, rutile, and monazite. The monazite reserve is expected to contain 6,000 tons of thorium dioxide (ThO_2) and 350 tons of uranium trioxide (U_3O_8). Other areas along the coast may contain as much as 20 million tons of "black sands" which could be the basis of a $500 million industry. Ilmenite concentrates carrying 50.5 percent titanium dioxide (TiO_2) have been obtained on an experimental basis. Evaluation of the deposits was being encouraged by Administración Nacional de Combustibles, Alcohol y Portland (ANCAP), a government company.

e Estimate. NA Not available.
[1] As reported by Revista Latinoamericana de Siderurgia (ILAFA), No. 76, August 1966.
[2] Variously reported as common clay or clay for cement; data probably do not represent total production of either category.
[3] As reported.
[4] Mostly agate, but probably includes some amethyst.
[5] As reported. Probably represents guano-phosphatized volcanic or other igneous rock.
[6] Data are derived from quarterly refinery reports and may not agree exactly with data adjusted on an annual basis.

Iron and Steel.—Some renewed interest has been shown in iron ore deposits in Rivera. It was reported that Cia. de Acero del Pacifico of Chile was to establish a rolling mill in Uruguay; capacity was not announced.

Uranium.—In late 1965 the Uruguayan Atomic Energy Commission announced that uranium had been found by a French prospecting team. The uranium occurs in a clay along the Rio Negro in central Uruguay. Samples testing 0.08 percent uranium gave hope for finding higher values.

Nonmetals.—Cement.—In mid-1965, the Uruguayan Government ended price controls on cement.

Construction Materials.—Toward year-end 1965 a report was issued called a "Study on the Marble, Granite, Dolomite and Talc Situation in Uruguay." The study was sponsored by the U.S. Agency for International Development.

[1] Minor recorded quantity omitted because of value discrepancy.

NOTE.—Quantity figures may be incomplete in some cases because source sometimes shows small additional import value only.

Source: Banco de la República Oriental del Uruguay, Departamento de Investigaciones Economicas. Importaciones Cumplidas 1964 and 1965, Cuadro 27.

The paper dealt with the important aspects of extraction, treatment, marketing, and shipping of dimension stone and talc. Problems peculiar to the Uruguayan industry were discussed, and detailed suggestions including proposed expenditures were made for more efficient, high-output extraction and marketing.

The study should be of great interest to the Uruguayan industry.

Sand.—The glass container manufacturing industry uses locally produced sand. Sand for high-quality glass has been obtained from the Rio Uruguay in the Departments of Paysander and Salto. Sand for lower quality glass comes from the Rio de la Plata. Soda ash must be imported. The four glass container manufacturers, all located in Montevideo, have supplied essentially all of Uruguayan demand. Imports are negligible and enter the country under a high tariff levy.

Mineral Fuels. — *Petroleum.* — Refinery throughput by ANCAP was 11.2 million barrels in 1965. Arrangement for future crude oil supplies was made between ANCAP and British Petroleum (BP) whereby BP will supply 18.9 million barrels of Nigerian and Middle Eastern crude oil over a period of 3 years; ANCAP has the option of taking another 6.3 million barrels during the fourth year. The contract was said to be worth $38 million. Part of the arrangement included a BP loan to ANCAP of $5 million at 6 percent interest.[2]

Contract price of the oil was reported elsewhere as $1.975 per barrel from Kuwait and $2.15 from Nigeria.

In late 1965, it was reported in trade journals that ANCAP purchased 120,000 barrels of Soviet crude oil at $1.68 per barrel, f.o.b., and a similar amount of Algerian crude at $1.85 per barrel, f.o.b. These shipments were considered to be of an experimental nature for refinery suitability tests.

ANCAP was reported to have spudded a wildcat test in Cerro Largo, northeastern Uruguay, in October 1965. Results of this test had not been released at yearend; some doubt was expressed in trade journals about the suitability of the geological environment for success.

Regional Mineral Industry Review of Europe[1]

By L. Nahai [2] and Roman V. Sondermayer [3]

Overall mineral industry productive activity in Europe increased in 1965, following general upward trends in gross national product and total industrial production [4] recorded. The gross national product of non-Communist Europe in market prices in 1965 was estimated at $572 billion and that of Communist Europe at $409 billion. However, the extractive sectors of the mineral industries generally did not fare as well as the processing sectors. In fact, a number of countries recorded lower production levels in this sector in 1965 than in 1964 and most countries had a lower growth rate in extractive industry output than in overall industrial output.

Among the non-Communist nations of Europe, a general decline in coal production and lower levels of iron ore output in France, West Germany, and Luxembourg contributed significantly to the smaller growth rates or declines in extractive indexes. Where higher indexes were registered, this generally resulted from the performance of the petroleum and natural gas industry; exceptions were Greece, Norway, and Sweden. The decline recorded for Czechoslovakia was attributable entirely to poorer performance by that nation's coal industry.

Detailed indexes of production activity by the mineral processing sectors, including metallurgical plants, cement kilns, petroleum refineries, and coal byproduct plants, are not recorded for all countries in Europe; however, these industries constitute a significant part of the overall manufacturing sector, and for this reason, the general manufacturing production indexes together with the overall industrial production indexes have been included for comparative purposes in table 1. Manufacturing production indexes increased in all countries except Luxembourg.

In terms of volume of output, Communist Europe's production of a number of ores exceeded that of non-Communist Europe principally because of the contributions of the U.S.S.R. These included ores of iron, manganese, aluminum, copper, lead, zinc, tin, beryllium, molybdenum, nickel, and tungsten. The situation with regard to metals was mixed, with the Communist nations exceeding in the production of aluminum, antimony, cadmium, copper, gold, platinum, and silver but lagging in production of bismuth, pig iron, steel, magnesium, mercury, tin, and zinc; smelter lead production was about equal. A similar situation prevailed in the nonmetals with non-Communist Europe leading in the production of barite, cement, diatomite, feldspar, fluorspar, gypsum, potash, pyrite, salt, byproduct sulfur, and talc, and with Communist Europe leading in output of asbestos, corundum, gem and industrial diamond, magnesite, mica, phosphate rock, and elemental sulfur. Although solid fuel output of Communist Europe was considerably higher than that of non-Com-

[1] For purposes of this chapter, non-Communist Europe comprises Austria, Belgium, Denmark, Finland, France, the Federal Republic of Germany, Greece, Ireland, Italy, Luxembourg, the Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, and the United Kingdom. Communist Europe comprises Albania, Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, Rumania, the U.S.S.R. (including the U.S.S.R. in Asia) and Yugoslavia.

[2] Chief specialist, West Europe area, Division of International Activities.

[3] Foreign minerals specialist, Division of International Activities.

[4] Luxembourg recorded no gain; data on Albania are not available, therefore, the level of industrial activity in this country in 1965 cannot be compared with that of previous years.

r Revised.
NA Not available.
[1] Data on Albania and Denmark not available. The categories "Extractive industries" and "Manufacturing industries" as used in this table are defined as in Divisions 1, 2, and 3, respectively, of the International Standard Industrial Classification (I.S.I.C.). Major deviations from "Extractive industries" definition are indicated by footnotes to the country entries; footnotes covering similar deviations from "Manufacturing and from the category: All industries" (given as reported in source) are generally omitted.
[2] Includes activities of petroleum refineries and magnesite product producers.
[3] Includes activities of stones, clay, and sand quarries.
[4] Metal mining excluded.
[5] Magnesite roasting included.
[6] This tabulation follows the practice of United Nations practice of including Yugoslavia with the countries listed.
[7] Includes coal and lignite only.
[8] Crude petroleum, natural gas, ferrous and nonferrous ore mining included under manufacturing.
[9] Coking and coal briquetting included under mining; stone quarrying and sand pits included under manufacturing.
[10] Coal briquet plants included under mining, sand pits, clay pits, and stone quarries included under manufacturing.

Source: United Nations. Monthly Bulletin of Statistics. New York, August 1966, pp. 18–27.

munist Europe, a substantial part of it was brown coal or lignite. Quality considerations apply in a reverse manner to iron ore; Communist Europe's output is reported on the basis of material containing 55 percent iron, which is higher than the average of iron ore produced in non-Communist Europe.

While primary smelter copper output is larger in Communist Europe, refined copper production in this area is about 140,000 tons less annually than in non-Communist Europe.[5] Similarly, for refined lead, non-Communist European output was 320,000 tons more than that of Communist Europe. Cement production in non-Communist Europe totaled about 135 million tons and production capacity at the end of 1965 totaled about 160 million tons. The corresponding production figure for Communist Europe was 109 million tons; complete data on capacity was not available.

While non-Communist Europe's crude oil production was only 1.3 percent of world total, compared with 17.1 percent provided by Communist Europe, refinery crude throughput in the West exceeded 347 million tons compared with an estimated 260 million tons for the Communist nations.

[1] Based on production data reported in commodity chapters of volumes I and II Minerals Yearbook, which may differ slightly from that given in country chapters of volume IV as a result of inclusion of revised figures in the latter.
[2] Less than 0.05 percent.

Mineral and mineral product trade continued to account for a significant part of total trade in both major areas of Europe, but the volume of total trade was much greater for non-Communist Europe than for Communist Europe. The former had imports (c.i.f.) totaling $90.4 billion and exports (f.o.b.) of $79.8 billion; corresponding figures for Communist Europe were $20.6 billion [6] and $20.0 billion, respectively. Non-Communist Europe's mineral imports were dominated by crude petroleum, iron ore, and nonferrous ore and metals for refining. The U.S.S.R. and other countries of Communist Europe supplied some of these commodities in exchange for machinery and industrial equipment.

As in 1964, crude oil exports from the U.S.S.R. and refinery product exports from Rumania were the most important items of Communist Europe's mineral trade. The U.S.S.R. exported nearly 13.4 million tons of crude oil to non-Communist Europe, mainly to Italy and West Germany. Chromite, manganese, and pig iron were also exported from the U.S.S.R. and coal from Poland.

[6] Imports of U.S.S.R., Albania, Bulgaria, East Germany, and Poland are f.o.b.; those of Czechoslovakia, Hungary, and Rumania are c.i.f.

NON-COMMUNIST EUROPE [7]

The productive performance of the mineral industry by sectors for non-Communist Europe during 1965 relative to that in past years and to the performance of all industry in the area is summarized in table 3 on the basis of production index numbers. For comparative purposes, similar index numbers for the European Economic Community (EEC)[8] as a group have been included.

In 1965 the gross domestic product of non-Communist European countries increased at rates varying from 1.4 percent for Luxembourg to 11.3 percent for Portugal and about 12 percent for Spain. Denmark, Finland, West Germany, the Netherlands, and Norway recorded gross domestic product growths of 4.5 to 5.5 percent; Switzerland recorded a 4.1-percent increase; Austria, Belgium, France, Ireland, Italy, and Sweden each showed a gross domestic product growth of 2.5 to 3.5 percent, while that of the United Kingdom increased by 2.1 percent.[9] Restrictive measures directed against inflation in France and Italy kept the growth rate down in the first half of the year and the construction industry in Italy continued depressed, adversely influencing the cement industry. In both countries, however, growth of the economy resumed in the second half of the year. Similar but less marked deceleration of economic growth was noted in some of the smaller countries. Restrictive measures were taken or left in force in Belgium, Denmark, West Germany, the Netherlands, and the United Kingdom.

The overall increase in the general European price level may have averaged about 4 percent. Price rises slowed however, particularly in countries such as Belgium, Italy, and France where production increased relatively little.[10]

Price increases were brought about by increased exports and rising overall domestic demand; the latter was more significant in West Germany and the Netherlands than in other EEC countries. Credit restrictions and reduction in planned increases in Government spending were resorted to in Germany; the bank rate was also increased from 3.5 to 4 percent.

MINERAL EXPLORATION AND INDUSTRY DEVELOPMENT

As in 1964, the North Sea, particularly off the coast of the United Kingdom and West Germany, was the area of greatest activity in search of oil and gas in non-Communist Europe. Exploration was carried out in the offshore areas of West Germany, the Netherlands, and the United Kingdom and in the latter area a gas discovery was made late in the year. The Continental Shelf boundaries between the United Kingdom and Norway, the United Kingdom and the Netherlands, Denmark and the Netherlands, and Denmark and Norway were fixed and accepted by the respective Governments. The boundary between the Netherlands and West Germany was agreed upon only as far north as latitude 54° N and only a small section of the Danish-West German boundary was settled.[11] During the year 13 wells were completed in the offshore areas of the United Kingdom and West Germany; in the latter area no success was reported. Norway issued petroleum regulations and awarded hydrocarbon exploration rights to nine companies.

The United Kingdom granted additional offshore areas as follows: 37 licenses comprising 127 blocks, with an area totaling 25,900 square kilometers (10,000 square miles), were awarded to 18 companies, bringing the total of concession areas granted to about 107,000 square kilometers (45,000 square miles). Drilling in the Dutch waters was held back pending issuance of implementing regulations of the Continental Shelf Mining Act. And onshore exploration in the Netherlands stopped after December 15 pending the revision of the Mining Law of 1810. The area surrendered by the North German Consortium was divided into six blocks that were granted to 15 companies operating in various combinations.

Petroleum refining capacity increased in practically all non-Communist countries. Annual refining capacity at yearend totaled about 415 million tons, with Italy having the largest capacity (98 million tons), followed by West Germany (about 80 million tons), the United Kingdom and France (each about 70 million tons), and the Netherlands (30 million tons). With the completion of the Calvo Sotelo refinery, Spain's capacity reached 16 million tons and was expected to increase by 7 million tons more by yearend 1967.

In addition to the major oil and gas search in northern West Europe, notable exploration projects included mineral programs in Ireland (mainly for lead and zinc in County Longford), Norway (copper and pyrite in northern Norway, jointly by the three principal Norwegian pyrite producers), Sweden (iron ore, copper, and other nonferrous metals in northern and central Sweden), and Finland (copper, nickel, iron, pyrite, apatite, and other minerals). In the latter country it was planned to mine the Kemi chromite deposit on a commercial scale.

In Spain, efforts continued to achieve goals set forth for the mineral sector of the economy in the nation's economic and social development plan for 1964–67. These goals included modernization and expansion of productive facilities for the country's principal mineral products—pyrite, lead, zinc, iron ore, iron and steel, potash, and cement. The principal feature of the mineral economy was a large increase in imports and decrease in exports to meet the normal requirements of Spain's expanding economy plus the added requirements of the expansion program itself.

In view of the rapid increase of nuclear power capacity, uranium availability to meet the requirements has become a matter of concern. At the Second Foratom Congress, held in Frankfort in September, the cumulative uranium requirements of non-Communist Europe were estimated at 650,000 tons by the year 2000[12] compared with reserves (excluding Sweden) of 48,000 tons measured and 38,000 tons probable. For the six countries of the EEC, the European Atomic Energy Community (Euratom) has estimated natural uranium requirements at 54,000 tons for 1970–80 and 332,000 tons for 1970–2000.[13] In 1965 uranium ore was produced only in France, Spain and Sweden.

These large uranium requirements focused attention increasingly on the fast breeder reactor. Euratom and the French Atomic Energy Commission were jointly

making studies on fast neutron reactor and were building the Rapsodie and Masurca reactors. Rapsodie, a plutonium reactor with liquid sodium coolant, is scheduled to go critical in 1966. This unit will irradiate fuel elements for the Masurca critical assembly.

Reprocessing of initial fuel charge will be carried out in the Eurochemie plant at Mol, Belgium, which became partially operative in 1965. This plant, which received several tons of irradiated fuel for reprocessing in 1965, is owned by the European Company for the Chemical Processing of Irradiated Fuels in which 13 member countries of the Organization for Economic Cooperation and Development (OECD)[14] participate. The "Dragon" High-Temperature Gas Cooled Reactor Experiment built at Winfrith Heath, England, and completed in 1964 is another joint undertaking of the OECD and has been operating since then.

Non-Communist Europe's steel industry underwent a recession in the year mainly as a result of overcapacity. In the European Coal and Steel Community (ECSC),[15] the excess capacity is expected to persist through 1969. There were a number of moves to improve the competitive position of the area's steel industry. In West Germany, following the merger of Thyssenhütte and Phoenix Rheinrohr in 1964, Hoesch AG and Dortmund Hörder Hüttenunion prepared for a merger slated to actually take place in 1966. The two companies will also collaborate in production with Koninklijke Nederlandsche Hoogovens en Staalfabrieken (Royal Netherlands Blast Furnaces and Steelworks). Steel semimanufactures will be made in the coastal plants of the Dutch firm and fabricated goods will be made in the plants of the West German firm.

In France the largest producers are to merge into two groups with an eventual annual production capacity of 14.6 million tons of crude steel out of France's total steel capacity of 22.5 million tons. Usinor and Lorraine Escaut will combine in one unit (6.3 million tons annual capacity) and De Wendel and Sidelor in another (with 5.6 million tons current capacity and 8.3 million tons upon completion of the Gandrange plant being built by Sacilor, a company owned wholly by De Wendel and Sidelor).

In Luxembourg, Aciéries Réunies de Burbach-Eich Dudelange (Arbed) bought the French company Pont à Moussin's interest in Luxembourg's other major steel producer Hauts Fournaux et Aciéries de Differdange Ingbert-Rumelange (Hadir). To take advantage of availability of foreign ores, a consortium of West German and Belgian producers was planning a 15-million-ton-per-year iron ore processing plant at Rotterdam from which enriched and pelletized ore will be shipped inland. A proposal has been made by the West German steel industry to the High Authority of the European Coal and Steel Community that four selling agencies would handle all West German steel orders, scheduling them between plants according to types.[16]

PRODUCTION

Total industrial production in non-Communist Europe increased by about 4.8 percent in 1965,[17] while the productive performance of the various sectors of the mineral industry was mixed. The extractive sector in total showed no change from that of 1964; however, this was as a result of increases in metal mining and crude oil and natural gas output (6.3 percent and 5.6 percent, respectively) that compensated for declining coal output (4.3 percent lower than in 1964 on the basis of the production index). Mineral processing sectors of industry all recorded gains: 7.9 percent for petroleum and coal products (together with other chemicals), 6.3 percent for the basic metals, and 2.5 percent for the nonmetals. Performance of the individual countries' extractive industries, manufacturing industries, and total industries is given in table 1.

Pig iron and steel production in non-Communist Europe increased by 3.9 and 4.5 percent, respectively, during 1965. The increase in pig iron output was mainly attributable to Italy, with Spain, the Netherlands, and Finland contributing smaller amounts. Similarly, Italy's increased steel output accounted for 51.6 percent of the total increase for West Europe. The Nether-

[14] The OECD comprises all of non-Communist Europe except Finland, and the following nonregional countries: Turkey, Canada, the United States, and Japan.

[17] Growth calculated on the basis of United Nations industrial production index numbers, which include data for Yugoslavia.

lands, Spain, Belgium, and Sweden also had notable steel output increases. It is estimated that non-Communist West European consumption may have increased by 4.3 percent. A number of factors influenced steel consumption. Investment in capital goods in West Germany, Sweden, and the United Kingdom showed an upward trend while Government stabilization programs in France and Italy held back capital goods investment in these countries. Production of passenger cars increased in West Germany by 3 percent while in the United Kingdom the industry operated at the same level as in 1964; in France and Italy the increase was about 10 percent. The low level of construction activity in Italy and increases in France (5 percent), the Netherlands (3.4 percent), West Germany, and the United Kingdom also affected steel consumption.

Total 1965 production of and approximate effective annual capacity for pig iron and crude steel at yearend in non-Communist Europe were as follows:

	Million metric tons	
	Production	Capacity
Pig iron	90.86	106.96
Crude steel	127.37	149.10

Effective annual capacity for production of certain categories of rolled products (sections, wire rod in coils, sheet, and plates, and hot rolled hoop, strip, and skelp) increased to about 106 million tons.

The downward trend in investment in the iron and steel industry continued. In 1965 investment totaled about $1.3 billion compared with $1.7 billion in 1964. Production capacities were already high in relation to demand; it is estimated that 85 percent of the steel capacity was utilized in 1965. In most countries rolling mills accounted for the largest share of expenditures. Non-Communist European steel companies were giving attention mainly to rationalization of their investment schemes and to intercompany agreements and mergers in order to improve their competitive position.

Generally, raw materials for the iron and steel industry were in plentiful supply. Trade in iron ore between European countries decreased slightly, while imports from outside increased by nearly one-fifth. Of 97.2 million tons of iron ore imports into non-Communist European countries in 1965, about 45 percent was from countries outside the OECD compared with 40 percent in 1964. In European OECD countries use of sinter per ton of pig iron produced increased to 1,130 kilograms from 1,085 kilograms in 1964, but expansion of sintering capacity was leveling off.

Production of aluminum (primary and secondary), refined copper, lead, zinc, tin, and nickel in non-Communist Europe increased. Although production of primary smelter copper in the area remained a modest percentage of world total, refined copper output was close to 19 percent of world output. Total production of copper and copper alloy semimanufactures increased 2.2 percent in the main producing countries concerned (Austria, Belgium, France, West Germany, United Kingdom, Italy, Scandinavia, and Switzerland) to 2,806,000 tons.[18] This was the highest annual level reached, although the increase was considerably less than the 11 percent registered in 1964.

Non-Communist Europe's share of world refined lead production was also larger than smelter production—about 26.4 percent. Principal producers of refined lead in the area and their share of world output in 1965 were West Germany 7.2; United Kingdom 5.5; France 4.1; Belgium 3.2; Sweden and Spain 1.7 percent each. Corresponding figures for zinc slab were Belgium 5.9; France 4.8; West Germany 4.5; United Kingdom 2.7; and Italy 2.0.[19]

Potash production increased in all the four principal producing countries of non-Communist Europe. The 4.8 million tons of K_2O equivalent produced in West Europe was 11 percent more than in 1964. Similarly, in 1965 all countries with the exception of Switzerland increased nitrogenous fertilizer production; total output increased 11 percent to about 6 million tons. Phosphatic fertilizer output in the area (comprising simple superphosphate, Thomas slag, and other phosphatic fertilizers) totaled 4.5 million tons of P_2O_5 equivalent, 8.5 percent more than in 1964.

Production of cement in non-Communist Europe increased to about 137 million tons (132.5 million tons in 1964). West Germany was the largest producer, followed

[18] The British Non-Ferrous Metals Federation. Annual Report, 1966. Birmingham, England, 1966, p. 9.

[19] The British Bureau of Non-Ferrous Metal Statistics. World Non-Ferrous Metal Statistics. Birmingham, England, June 1966, pp. 27, 33.

by France, Italy, and the United Kingdom which together accounted for 68 percent of the area's output.

Sulfur consumption in non-Communist Europe in all forms is estimated at 5.34 million tons compared with a production of 5.86 million tons. However, consumption of native sulfur (1,939,000 tons) exceeded production of this form of sulfur by about 58,000 tons.

In the field of energy, both crude oil and natural gas output increased in non-Communist Europe. Supply of refined products (refinery output plus imports) in the European countries of the OECD totaled about 425 million tons[20] of which EEC countries accounted for 270 million tons and European Free Trade Association (EFTA) countries together with Finland for 134 million tons. Petroleum product deliveries for inland consumption totaled 191 million tons in EEC countries, 111 million tons in EFTA countries (including Finland), and 319 million tons in all of the European countries of the OECD.

The coal industry had a difficult year in non-Communist Europe and bituminous coal output fell in all countries except Spain; the decline in the Netherlands, however, was small. Employment in the industry also decreased while coal stocks in major producing countries increased.

A number of governments took measures to assist the industry. In the United Kingdom, the National Coal Board (NCB) was relieved temporarily of the obligation to contribute $28 million per year towards the difference between depreciation at the historic rate and replacement cost. The Coal Industry Act of 1965 canceled 415 million pounds sterling ($1,162 million) of NCB's $2,688 million capital debt to the treasury at end of March 1965. Use of coal in public buildings was to be promoted and the Government was to consider capital reconstruction of the industry.[21] The NCB announced in 1965 an accelerated mine closure program—150 mines were to be closed in the next 2 or 3 years.

The EEC approved members' financial assistance to the coal industry estimated in 1965 to have amounted to $4.20 per ton in West Germany, $4.70 in France, $5.40 in Belgium, and $0.80 in Netherlands for extra social costs (retired miners, etc.) borne by the coal mining industry. In addition subsidy payments for rationalization were made as follows: 40 cents per ton in West Germany and 80 cents per ton in Belgium and France. In West Germany reduction of production targets was accepted by industry and measures were under consideration for giving premiums for mine closing. In Belgium four anthracite mines in the southern basin were closed. Financial assistance to the industry amounted to about $20 million. Reduction of coal output in France followed closely the development plan.

In Spain, the "Fondo de Fomento de la Mineria de Hulla" was established to make available a subsidy totaling $26,500,000 over a 4-year period through 1968. The subsidy will take the form of a specified amount per ton of coal which will vary from year to year and will be paid only to firms which have accepted the converted action plan for coal.

Concurrent with the decline in the coal industry, nuclear capacity in production in non-Communist Europe increased by about 1,200 MW(e)[22] to approximately 4,430 MW(e) distributed as follows: United Kingdom 3,400; Italy 610; France 330; West Germany 71; Belgium 10; Sweden 9. In addition, plants with an estimated total capacity of nearly 4,340 MW(e) under construction as follows by country: United Kingdom 1,875; France 1,060; West Germany 810; Belgium 265; Spain and Sweden each 140; Netherlands 50; and Switzerland 7.[23] In the latter country, a utility company ordered a 350 MW(e) pressurized water reactor during the year and the project for a second 300 MW(e) plant progressed. The utilities forecast 1,500 MW(e) installed capacity by 1975. The United Kingdom fuel policy, published in October 1965, called for a nuclear power program of 8,000 MW(e) in a 6-year period. The 1,200 MW(e) Dungeness B plant of the Central Electricity Generating Board is the first power station under the new program. The Advanced Gas-cooled Reactor design was chosen. The French Fifth Plan of National Development envisages new facilities with 2,500 to 4,000

MW(e) capacities. In pursuit of this program at 500 MW(e) plant (EDF 5) has been decided upon.

TRADE

In the general area of trade policies, there was little progress in the Kennedy Round of tariff negotiations because the EEC could not participate in the negotiations after June when France announced its decision not to take part in Council meetings following disagreement on how to finance EEC's common agricultural policy. Tariff disparities and the exceptions list [24] remained the main issue in negotiation for industrial products. The EEC also objects to calculating tariffs on chemical products on the basis of the American Selling Price valuation. Steel tariffs have also presented problems because these tariffs vary between countries and types of steel.

Mineral commodities continued to constitute more than 17 percent of the total exports and 25 percent of the corresponding imports of the countries of the area in 1965. Both total exports (f.o.b. basis) and imports (c.i.f. basis) reached new highs, $77,748 million and $88,041 million respectively, and mineral commodities in general followed these trends as shown in table 4.

Although EEC, the European Free Trade Association (EFTA), and other area nations have shown increases in both aggregate exports and imports of mineral commodities in both 1964 and 1965, the growth rates have not been uniform. The relative positions of the different trading groups are indicated in table 4. The rank of the various commodity groups is shown in table 5, which indicates the primary position of iron and steel followed by nonferrous metals and petroleum among exports and of petroleum and nonferrous metals among imports. The area had an adverse balance of trade for all but iron and steel and manufactured fertilizers.

Intra-ECSC trade in steel as a whole did not show its customary increase; higher West German imports of semifinished products were balanced by marked drop in those of Italy. ECSC exports to other West European countries rose as a whole. Outside the ECSC, Spain's steel imports increased by about 135 percent. The United Kingdom's exports increased slightly—an appreciable increase in exports to the United States partly offset decreases in export to other countries.

Of mineral commodity exports by non-Communist European countries in 1965, 70.5 percent on a value basis were exports to other non-Communist European countries (intraregional trade), the corresponding figure for imports was 44.4 percent (table 6).

Although the total value of exports to other world areas increased in both 1964 and 1965, the share of exports to these areas has fluctuated from 29.0 percent in 1963 down to 27.4 percent in 1964 and back up to the 1965 figure of 29.5 percent. On the other hand, imports from other areas have shown a steady increase from 55.2 percent in 1963 to 55.6 percent in 1965.

The Near East continued its position as the largest supplier of mineral commodities in view of the dominance of crude oil imports. However, Africa's share was growing at the expense of the Near East. Canada and the United States ranked first among the destinations of West European mineral exports, primarily as a result of large iron and steel exports to the United States.

REGIONAL ECONOMIC ORGANIZATIONS

The European Economic Community (EEC).—France's absence from the Council of Ministers after June 30 slowed Community activities in the second half of the year. There was an additional 10-percent cut in internal tariffs taking effect on January 1. Thus, duties for industrial goods were lowered to 30 percent of their 1957 level. It is expected that the customs union will be complete on July 1, 1968. On April 8 the six countries concluded a "Treaty Establishing a Single Council and Single Commission of the European Communities." [25] However, at yearend the instruments

[24] List submitted in November 1964 by major countries enumerating the industrial products they wanted excepted from the 50-percent linear tariff cut.

[25] The ECSC, Euratom, and the EEC. Each of these has now a separate executive body.

national boundaries was slow and problems of competition policy remained in the forefront.

In 1965 the gross national product of the EEC increased by about 4 percent in constant prices (1958=100) and 7.4 percent in current prices.

Total imports in 1965 were $48,991 million and total exports were $47,904 million (in current prices), 10.9 percent and 12.5 percent higher, respectively, than in 1964. Intracommunity trade accounted for 41.6 percent of all imports and 43.4 percent of all exports. In value intracommunity trade grew by 12 percent against 14.5 percent in the preceding year. The shares of EFTA and the United States in the Community's total imports were 14 percent and 12 percent, respectively; corresponding figure for exports to these destinations were 20 percent and 7 percent, respectively. The Community had a $2.71 billion favorable balance of trade with EFTA but exported $2.26 billion less to the United States than it imported.

Figures in table 4 reflect the role of minerals in total EEC trade on a value basis; tables 7 and 8 give geographic and commodity group distribution of Community trade in mineral commodities. The Community's coal imports from the United States (19.43 million tons) accounted for 70.5 percent of its total coal imports. Although over 93 percent of the coal imports from the United States was coking coal, only 7.29 million tons was used in the steel industry.

Investment expenditures in the coal and steel industry of the Community during 1964 totaled $1,617 million compared with $1,842 million in 1963. The 1964 total was distributed as follows, in percent: Iron and steel industry, 79.8; coal industry, 18.7; and iron mines, 1.5. There was a further reduction in investment envisaged as of January 1, 1965, for the year to a total of $1,377 million with 72 percent for the iron and steel industry, 25.7 percent for coal, and 2.3 percent for iron mines. Of the investment envisaged for the iron and steel industry, 50.1 percent was assigned to rolling mills.[26]

In EEC countries, 699,700 were employed in coal mines (734,800 in 1964), 587,300 in iron and steel plants (591,000 in 1964), and 31,500 in iron mines (34,700 in 1964), for a total of 1,318,500. The reduction of 42,000 in total employment in these industries was more than 3 times the previous yearly drop of 12,000 and is attributed mainly to lower coal industry employment.

[26] European Coal and Steel Community, The High Authority. 14th General Report on the Activities of the Community. (February 1, 1965–January 31, 1966). Luxembourg, March 1966, pp. 219–232.

Energy.—Main features of the EEC's energy economy were the same as in 1964: an increase in petroleum consumption, a decline in coal consumption, and the important role of electricity as an energy form, accounting for about a quarter of energy consumption. Nuclear energy's share remained less than 1 percent.

There were no important developments in implementing the Council of Ministers resolution on adopting a common energy policy. The report of the Consultative Committee on the Fusion of the European Communities suggested that energy, like transportation, be treated as a single sector and its provisions listed in a special chapter in the treaty which would merge the Communities. The report urged that the rules of competition, applied to coal under the ECSC Treaty, be extended to other forms of energy.

Gross internal or apparent energy consumption by the Community in 1965 increased by 10.4 percent to 626 million tons of standard coal equivalent (SCE) from 1964 consumption of 600 million tons. This consumption was distributed by commodity as follows in millions of tons of SCE: Coal, 227; lignite, 33; natural gas, 21; crude petroleum, 304; and primary electricity, 41.[27] About 605 million tons of SCE was converted as follows, in million tons: Powerplants, 108; briqueting plants, 22; coke and gas ovens, 107; blast furnaces, 20; and refineries, 348.

While gross internal energy consumption of the Community increased by 4 percent, petroleum consumption for the Community as a whole increased by 11.3 percent. Coal consumed for electricity production decreased from about 57.0 million tons of SCE to 53.9 million tons, although total primary fuel transformed into electricity remained the same at about 108 million tons of SCE. Favorable hydraulic conditions caused only a small (1.2-percent) increase in thermal electricity production although total electricity output increased by about 6.3 percent. Coal consumption in industry, other than iron and steel, and for domestic use also declined.

Net fuel imports of the Community (including allowance for bunker exports) from non-Community sources increased by about 33 million tons, almost the same as the increase in net imports of petroleum and petroleum products (35 million tons of SCE). Net energy imports were equivalent to 49.9 percent of gross internal energy consumption.

Intra-Community trade in solid fuels consisted of 16.3 million tons of coal, 1.2 million tons of coal briquets, and 9.8 million tons of coke. Intra-Community trade in petroleum products totaled 17.6 million tons. Total yearend pithead stocks of coal stood at 23,169,000 tons, an increase of 8,670,000 tons during the year.

As a result of the rationalization effort, the number of producing coal mines of the Community at yearend showed a further decline to 240. Coal produced from fully mechanized mines (both mining and loading mechanized) accounted for 70.5 percent of total output. In some coal basins the figure was as high as 90 percent. Improvement has been achieved through mining at longface and self-advancing supports. Output of coal per underground man-shift increased by 2.7 percent to 2,461 kilograms; this rate of increase was almost the same as that in 1964, which was the lowest since 1961. Production cost, including interest and amortization, increased 5.5 percent mainly as a result of increased wage scales in 1965; wage increases compared with 1964 levels varied from 6.3 to 9.7 percent. For 1964, manpower cost accounted for 57 percent of production cost of net output in Belgium and West Germany; the corresponding figure for France was 65 percent.[28]

The petroleum refineries of the Community processed 244 million tons of crude oil, 16 percent more than in 1964, and produced 226 million tons of petroleum products, of which 207 million tons was energy products.[29] Crude distillation capacity in member countries increased from 269 million tons at yearend 1964 to 299 million tons at yearend 1965.

Additional export contracts for delivery of Netherlands gas to France and Germany were being negotiated or concluded during

[27] Office Statistique des Communautés Européennes. Statistiques de l'Energie, Brussels, Belgium, 1966. No. 4, 1966, pp. 13, 21.

the year. Starting in 1967, Gas de France will receive 5 billion cubic meters of gas annually. An agreement between Ruhrgas and Nederlandsche Aardolie Maatschappij (NAM) Gas Export of the Netherlands, signed in November, is to run 25 years. Deliveries are scheduled to begin in late 1966 increasing to 3 billion cubic meters by 1975. Negotiations between NAM Gas Export and Gas-Union G.m.b.H. of Frankfurt and Gasversorgung Sued-Deutschland G.m.b.H. of Stuttgart, West Germany, envisage gas delivery within 3 years which would increase 5 to 6 billion cubic meters by 1975. These long-term contracts bring the total of projected exports to 22 to 23 billion cubic meters per year. By 1975 natural gas is expected to supply 8 percent of all the energy requirements of the EEC, with nearly 60 percent of the gas supplied from the Netherlands.

Iron Ore.—Iron ore production in the EEC declined by 3.3 percent to 74.7 million tons of marketable ore (78.75 million tons of mine run ore) but the decline rate was higher in Luxembourg and West Germany, about 8 percent. Of the marketable tonnage 7,307,000 tons was obtained from beneficiation plants. The entire production of iron ore in West Germany was captive and French iron ore fell to 10 percent of total world output. Yearend stocks of ore were 11.8 million tons at mines. Intra-Community trade in iron ore, 20.9 million tons, was about the same as in 1964.

Imports from third countries increased 12.8 percent to 53.7 million tons, mainly because of the greater requirements of Italy and the Netherlands. On the basis of iron content non-EEC ore production was 57 percent of total iron consumption. Of iron ore imports from third countries, West Germany took 55.0 percent followed by Luxembourg 16.7 percent; Italy 14.7 percent; France 7.0 percent; and the Netherlands 6.6 percent. Important supplying countries in 1965 and quantities imported into EEC from these sources were as follows, in thousand tons: Sweden 16,819; Liberia 10,440; Brazil 6,092; Mauretania 4,375; Venezuela 2,811; Peru 2,105; and Canada 2,045.

Share of iron ore of all types used as sinter in the steel industry increased to 55.4 percent (51 percent in 1964). Of 125,534,000 tons of iron ore consumed, 69,519,000 tons was sintered and 54,551,000 tons fed directly to the blast furnace, and the remainder was used in steel plants. Sinter consumption per ton of pig iron increased to 1,086 kilograms (1,031 kilograms in 1964); 68,996,000 tons of sinter was produced.

Average price of imported ore (c.i.f. Community ports) was US17.7 cents per unit of iron (US18.0 cents in 1964). Lorraine ore price ex-mine was US9.68 cents per unit of iron, but this lower price was not sufficient to compensate for the low grade compared with imported ores.

Iron and Steel.—Capacity of steel production exceeded 100 million tons, 8 million tons having been added during 1965; it is expected to reach 118 million tons by 1969. Production capacity was utilized at an average rate of 86 percent. Increase in steel production in 1965 was almost entirely due to increased output in Italy and the Netherlands; output in other countries remained practically unchanged, except for a small increase in Belgium. The share of steel produced by basic oxygen process increased to 19.1 percent (12.6 percent in 1964) at the expense of Thomas and open-hearth processes. Special high-grade and alloy steel showed a further 7.4-percent increase to 6.4 million tons, 7.5 percent of all steel output. Almost half of these steels are produced in Germany.

In 1965 for the first time since the establishment of the Community, cold-rolled sheet less than 3 millimeters thick accounted for about one-fifth the total output of rolled products (excluding pipes). A steady increase in the relative importance of hot-rolled medium sheet and plate and finished coil has been noted since 1963 in contrast with a reduction in the percentage of hot-rolled sheet less than 3 millimeters thick.

Real consumption in terms of crude steel increased 3.9 percent to 71 million tons, but demand did not equal this figure because of drawdown on stocks. Rate of increase in steel consumption continued to trail the industrial production increase. Demand for export was strong.

Community trade in iron ore, scrap, pig iron and ferroalloys, ingots, blooms and billets, and semifinished steel accounted for 6.5 percent of all the imports and 9.2 percent of all exports of the EEC by value in 1965. Intra-Community trade in these commodities accounted for 64 percent of the import and 46 percent of the export of the

r Revised.
[1] Detail do not add to total because of rounding.
[2] Includes small tonnages used in steel plants.
[3] Total scrap consumption including in steel foundries 1963—33,096; 1964—36,336; 1965—36,884.
[4] Includes also non-Treaty items (forged and drawn items, cold drawn wire, steel pipes, and steel pipes accessories) but excludes cast iron pipes and old rails.

Community of these commodities. Compared with 1964, the Community increased its iron and steel exports 11.4 percent by value, with exports to the United States having increased 70 percent on a similar basis. Intra-Community trade in rolled steel items covered by the ECSC treaty totaled 11.8 million tons (12.3 million in 1964),[30] but exports to third countries, totaling 14.3 million tons, exceeded that of 1964 by 3.8 million tons. Decline in the Community's steel imports from third countries is attributable mainly to decline in Italian imports; this country became a net steel exporter instead of a net importer in 1965.

As a result of smaller unit consumption of scrap for pig iron and steel production and larger scrap generation within the Community, scrap imports from third countries were reduced to 1,473,000 million tons from 2,118,000 million tons in 1964. Intra-Community scrap totaled 4,945,000 tons (3,580,000 tons in 1964). Except for small quantities, the ban on export of scrap from the Community remained in force.

Steel prices were lower particularly in the export market. The following lowest listed prices for a number of rolled products indicate the trend:

Type	Price, dollars per ton	
	1964	1965 (December)
Reinforcing rods [1]	94	80
Merchant sheets [1]	96	90
Sections	[2] 97.75	[1] 90
Wire bars [1]	90	89
Plates	[3] 106.3	[1] 89
Thin sheets (hot rolled)	130	108

[1] Belgium.
[2] France.
[3] Netherlands.

The above, mainly Belgian producers' list prices, whose flexibility permits them to follow changes in the market closely, were much lower in part than that of producers in other Community countries which had to aline increasingly with Belgian producer prices. Prices of steel in November 1965 f.o.b. Antwerp were as follows, in dollars per ton: reinforcing bars 70–80; merchant bars 79–81; beams 72–77; wire rods 79–83; steel strip 80–85; plates 79–85; thick sheets 79–85; thin sheets, hot-rolled 101–102, and cold-rolled 100–103. Sales by alinement of Community prices of rolled steel with quoted prices of similar products from third countries averaged 47,400 tons per month.

Action taken by the High Authority in February 1964, increasing steel tariffs of the five member states of the Community to the high level of the Italian customs duties and establishing quotas for import of pig iron and rolled steel from countries with state-controlled trading regimes, were extended to the end of 1965.

The High Authority organized a second conference on steel for October 26–28 with the theme of progress in steel utilization. The conference dealt with five topics: Steel and industrial esthetics, steel surface protection, cold forming of steel, modern methods of assembling steel, and problems of steel utilization in developing countries The High Authority plans to organize a third steel conference in Luxembourg October 26–28, 1966, with the theme of steel in agriculture.

The European Free Trade Association (EFTA).[31]—The problem of establishing close cooperation between EFTA and EEC and avoiding the consequences of a continued separate evolution of the two regional organizations were of concern to the EFTA ministerial meetings in Vienna during May and in Copenhagen during October, respectively. It was felt that a meeting at ministerial level between the two organizations would be desirable to consider means to facilitate the removal of trade barriers and promote economic cooperation in Europe. On the specific issue of tariffs, however, it was hoped that the removal of tariff discrimination between the two trading groups could be achieved within the Kennedy Round negotiations. The EEC crisis made an EFTA initiative for a ministerial meeting with EEC members not feasible.

The Economic Committee of EFTA which was established in December 1964 held meetings in July 1965 and December

[30] Office Statistiques des Communautés Européennes. Sidérurgie (Luxembourg). No. 4, 1966, pp. 100–101.

[31] Austria, Denmark, Norway, Portugal, Sweden, Switzerland, and the United Kingdom are full members; Finland since 1961 has been an associate member. In statistical presentations in this chapter, Finland generally has been excluded, following the practice of the Statistical Office of the United Nations. Where Finland has been included, it has been appropriately noted.

1965, the later at the request of Finland. The purpose of this committee is to examine the economic and financial situation of member states and review their economic and financial policies, the implementation of these policies, and their impact on member states' economies. During the year the Economic Committee studied problems, drawbacks, and benefits of long term planning. The Committee also examined detailed papers on long-run structural problems in some member states.

The 15-percent import surcharge which the British Government imposed in October 1964 was reduced to 10 percent in April 1965. This surcharge applied to imports of most manufactured and semimanufactured goods from any source including EFTA countries. A further 10-percent cut in tariffs on industrial goods traded among the eight EFTA countries was scheduled to go into effect on December 31, 1965; this will bring the tariffs to 20 percent of their 1960 level. The final 20 percent will be eliminated on December 31, 1966. Protective quotas will also be eliminated at the same time as tariffs reach zero. Finland, having become associated with EFTA 1 year after the Stockholm convention came into force, will reduce its tariffs to zero by the end of 1967.[82] During 1965 work continued on the abolition of nontariff trade barriers within EFTA.

Intra-EFTA export of all commodities increased 10.9 percent to $5,825 million in 1965. The EFTA's exports to third countries increased 11.1 percent over those of 1964. Intra-EFTA imports of all commodities increased by 11.0 percent and from third countries by 6.3 percent. With the exception of the United Kingdom and Switzerland, all EFTA countries in 1965 increased their imports in total commodity trade from their partners by 10 to 20 percent. The United Kingdom's surcharge caused the country to import only 7 percent more from other EFTA countries than in 1964; Switzerland increased its imports with other EFTA countries by only 2.5 percent.

Despite increases in intra-EFTA trade, the bulk of the total commodity trade of

To other	17,601	18,668	20,688
Total	22,146	23,979	26,513

EFTA's trade deficit with the EEC for all commodity trade totaled about $2,933 million, 13 percent more than in 1964. While imports from the EEC increased by 9.3 percent in 1965, EFTA's export to this destination increased by only 7.9 percent.

With regard to trade in minerals, EFTA exports of minerals and metals to the EEC shown in table 7, totaled $1.2 billion in value or almost 12 percent of total exports to that area and 32.5 percent of all mineral exports. Among mineral commodity exports, pig iron, ferroalloys and steel were the most important group, followed by nonferrous metals, refined petroleum, and iron ore. The EFTA's mineral commodity imports from the EEC totaled $2,012 million or 32 percent of imports from all sources. On a commodity basis, refined petroleum was the most important category followed by iron and steel, nonferrous metals, nonferrous metal ores, and coal.

COMMUNIST EUROPE [33]

Exacting appraisals of the mineral industries and mineral economies of the Communist countries of Europe, as well as detailed comparison of their performance with that of other countries is hampered by the paucity of certain types of information. Notably, there are virtually no quantitative statistics on capacity to produce or production of nonferrous base metals and precious metals, while trade of these commodities and others are only partly reported for a number of these countries. Reserve data reported are often incomplete with regard to grade and content of deleterious materials. Moreover, mine output of many commodities is reported in terms of gross weight of run-of-mine ore without data on grade, and in general, there is insufficient data on efficiency of recovery of metals and other usable products from crude mine output as well as on efficiency of utilization of these products in manufacturing.

Published official information on the mineral industries of Communist countries in Europe (including the U.S.S.R. in Asia) showed an upward trend for output of most commodities, but the growth was moderate. The stress continued to be on production of basic materials for heavy industry and consumption of minerals for consumer goods remained considerably lower than in the countries of non-Communist Europe. The growth of mineral output value in 1965 was 4 to 6 percent with respect to that of 1964, compared with annual growth rates of 10 to 14 percent during the late 1950's. The lower growth rate in recent years was attributed chiefly to the larger bases to which successive increases must be added, indicating that the minerals economy of the region as a whole has matured considerably.

The U.S.S.R. remained the principal mineral producing country of the area, accounting for 85 to 90 percent of the total output value in 1965. As members of CEMA (Council for Mutual Assistance, or in Russian, Soviet Ekonomicheskoy Vzaimopomoshchi—SEV), the U.S.S.R., Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, and Rumania continued to cooperate in economic and industrial developments under the leadership of the Soviet Union. Albania, although a member of CEMA, was not participating in the organization's work. Yugoslavia remained independent of CEMA, but cooperated with CEMA and its members bilaterally. Yugoslavia also maintained stronger relations with non-Communist countries than did the members of CEMA, and although investments of foreign capital in the classical sense were not possible in Yugoslavia, a number of financial arrangements were made for development of mineral resources during 1965 that involved foreign loans to be repaid with mineral products.

Of the Communist European production totals, the U.S.S.R. accounted for more than 90 percent of the iron ore and crude oil, more than 80 percent of the aluminum and copper, more than 70 percent of pig iron and steel, more than 60 percent of cement, and more than 50 percent of lead and zinc. In output of most other mineral commodities, the U.S.S.R. also remained dominant. Thus shortages and surpluses in the U.S.S.R. dominated the regional supply picture. Communist European mineral trade with the outside world was smaller than might be expected considering the magnitude of territory, mineral resources, and industries. Nonetheless, mineral industry products accounted for a sizable part of the region's total trade in 1965. The total value of Communist Europe mineral trade in 1964, the last year for which complete data are available, was about $1,000 million, with exports accounting for more than $800 million of the total. Communist Europe was a source of raw material for highly industrialized non-Communist Europe, but supplies from this area in most cases could not be considered vital. Significant exports included crude petroleum, manganese, chromite, crude fertilizer materials, and precious metals, and to a lesser extent, pig iron, steel ingots, and high-rank coals.

Generally, earnings from exports to non-Communist countries have been used to obtain machinery and equipment not available in sufficient quantities with in the Communist sector. Because of the apparent shortage of suitable foreign exchange, mineral imports from non-Communist countries were restricted to a few commodities.

[33] Prepared by Roman V. Sondermayer.

Mineral commodity imports were valued at about $200 million and consisted chiefly of nonferrous metal semimanufactures, tin, tungsten, and certain rolled steel shapes.

In the case of mineral trade between Communist countries, that of the U.S.S.R. was dominant and was characterized by large exports of mineral fuels and raw minerals from the U.S.S.R. and imports of semimanufactured products by the U.S.S.R. The U.S.S.R. was a vital supplier of mineral industry commodities to European Communist countries.

Practically all Communist countries were searching for new methods to increase productivity. The profit concept was introduced in some cases as a way of measuring the efficiency of operations. Some of these nations, such as Yugoslavia, considered that profitability was the only justification for operation of a mine or plant, while others, such as the U.S.S.R. remained very cautious in introducing this factor in their mineral industries. Nevertheless, the search for and testing of new methods to increase productivity was underway in 1965.

In the case of Yugoslavia, early reports on the results of the introduction of this concept reflected increased unemployment, higher prices for products and declines in output of some commodities. The decline in employment apparently resulted from layoff of at least some unessential workers, while price increases may be attributed to improved product quality and increased demand. The lower output levels evidently reflected elimination of some inefficient production units. However, the long-term effects on the economy could not be evaluated. Similarly, the effects of economic reforms introduced in East Germany could not be appraised.

Major changes in physical facilities and significant planning changes during 1965 in the mineral industries of the Communist countries are presented on a country-by-country basis as follows:

In the U.S.S.R. development of ferrous and nonferrous metallurgical facilities and the new 7-year plan were among the most notable. Aluminum was in the center of Soviet metal industry activities. The second stage of the Krasnoyarsk aluminum plant, the largest in the country, went on stream in April 1965. The two stages of the plant in operation at yearend produced at 80 percent of capacity. Construction of the Bratsk aluminum plant in Siberia, which reportedly will have an annual output capacity of 800,000 tons of aluminum, was underway. Reports indicated that production would begin in 1966.

In the iron and steel sector of the Soviet mineral economy, the commissioning of the Sokolovsko-Sarbay mining and concentrating combine in Kazakhstan was reported. The combine, with an annual capacity of 26.5 million tons of ore, was reportedly the largest mining and beneficiation combine in the country.

In the area of nonmetals, the first stage of Dzhetygara asbestos plant in Kazakhstan with an annual capacity of 200,000 tons was commissioned at yearend, and new cement plants at Ust'-Kamenogorsk and Achinsk increased Soviet cement capacity by about 1.2 million tons.

Tartar and Bashkir A.S.S.R. were the largest producers of crude oil in the U.S.S.R. but most of the exploratory activities were conducted in western Siberian fields in Tyumen Oblast and on the Mangyshlak Peninsula in Kazakhstan. First shipments of oil were reported in 1965 from these two areas. It is expected that these two areas eventually will become largest producers of oil in the country.

The Albanian mineral industry generally remained an insignificant contributor to the world mineral economy during 1965. Chromite remained its only product of international note. Relatively small developments in its nonferrous metals industry did not change the nation's role in the overall world or the Communist European mineral picture.

Bulgaria continued to develop its mineral resources at a fast pace. The iron and steel plant at Kremikovtsi started operation of a second blast furnace and its first electric furnace for steel production. The completion of a plant for anthracite beneficiation near the Tompson railroad station in the Balkan Mountains was the highlight of Bulgaria's mineral fuels industry.

The mineral industry of Czechoslovakia had a year of moderate expansion, accomplished mostly by improving existing facilities rather than by completing new ones. Construction of the East Slovakian ironworks was the principal project of the mineral industry.

263-927 O-67—20

The Hungarian mineral industry, modest by world standards, continued to develop facilities for bauxite and alumina production. Completion of the first stage of Almafuzito alumina plant, and expansion and completion of the cold-rolling mill at the Dunajvaros ironworks were highlights for 1965.

East Germany continued to expand facilities for production of mineral fuels, petrochemicals, and iron and steel. The construction of Schwartze Pumpe coal combine near Cotobus, commissioning of a second stage in the Schwedt refinery raising capacity to 4 million tons of crude oil per year, commissioning of a new steel rolling mill at Eisenhuettenstadt and opening of a new cadmium plant complete the list of important mineral industry facilities installed during 1965.

Reports indicated that the Polish mineral economy in general lagged behind overall industrial economic growth through 1965. Leading developments in the mineral industry included the beginning of operation of a converter facility and two coking batteries at the Lenin Iron and Steel Plant at Nowa Huta, the start of production in the second processing plant at the Tarnobrzeg sulfur deposits and expansion of facilities at the Plock petroleum refinery.

Although Rumanian output of crude oil ranked second in Europe to that of the U.S.S.R., the industry still accounted for only a minor part of total world crude oil output. In an effort toward diversification, the Rumanian Government was developing other mineral industry facilities. The country's first aluminum plant was commissioned in the summer of 1965 near Saltina. The facility has an annual capacity of 25,000 tons of aluminum which reportedly will be increased to 50,000 tons in the near future. In addition to the Slatina aluminum plant, mineral industry highlights in 1965 included new copper mining and beneficiation facilities at Moldava Nova, the lead-zinc complex at Copsa Mica, and two plants for production of liquefied natural gas, one in Moreni and the second at Olteni.

Yugoslavia remained one of the leading nonferrous metal producers in Europe. Shortages of liquid fuels and high-rank coals that have proved troublesome in the past continued during 1965. The most important mineral developments included the decision to build a new lead-zinc smelter in Titov Veles in Macedonia, the discovery of reportedly significant uranium deposits near Zletovo in Macedonia, and the completion of a new oil refinery in Urje near Rijeka.

The Mineral Industry of Albania

By Roman V. Sondermayer [1]

During 1965 Albania remained a small producer of minerals and mineral products in terms of total world production. The mineral extraction and processing industry had virtually no world significance except in the case of chromite, of which the country produced about 7 percent of the world output in 1965. The industry, however, remained of substantial importance to the country's economy, contributing about 17.5 percent of the nation's social product.[2] In addition to chromite, Albania produced copper ore and blister copper, iron-nickel ores, crude petroleum, asphalt, and small quantities of cement and brown coal. Information on performance of the mineral industry was scarce. Official Albanian sources indicated fulfillment of plans in the mineral industry in 1965 only. Most of the mineral industry products were exported as the local economy did not provide a sufficient market for minerals produced in the country. As a result, minerals accounted for more than 50 percent of the total export of the country. Mainland China and Czechoslovakia were the principal buyers of Albanian mineral products.

The major developments in the mineral industry of Albania in 1965 were completion of some sections of the copper plant at Kukesh Rreth, construction of the cement plant at Elbasan, and construction of the superphosphate plant in Kruje Rreth at Lac. Since the political break with the Soviet Union, Albania's political leadership has stressed the necessity to develop its own technical and natural resources without the aid of the Soviets, but relying on Chinese experience.

PRODUCTION

Statistics on 1965 mineral production of Albania were not available. Albanian sources indicate that plans were fulfilled in all branches of the mineral industry. According to sectors, fulfillment was as follows: Fuel industry 100 percent; copper industry 104 percent; iron-nickel ore industry 100 percent. No information was made public on chromite production. Efforts in production of minerals were concentrated in expansion of existing facilities and exploration.

TRADE

Mineral commodities accounted for an important part of total Albanian foreign trade; however, the small volume of this trade made it chiefly of significance to the domestic economy, rather than to world mineral supplies.

Chromite, crude oil, asphalt, copper ore, blister copper, and iron-nickel ore were the principal export items. Coke, iron and steel semimanufactured products, cement, and sulfuric acid were the principal imports.

Mainland China remained the most significant trade partner in 1965. Czechoslovakia followed China in the volume of mineral commodity trade. More than 80 percent of toal trade was with Communist countries.

Among non-Communist countries, Italy remained Albania's principal trade partner; the trade exchange amounted to about $13 million in 1964. France and Finland also imported Albanian mineral products.

[1] Foreign minerals specialist, Division of International Activities.

[2] Data on gross national product (GNP) for Albania are not available; the social product is the closest reported equivalent but does not correspond directly to the GNP.

COMMODITY REVIEW

METALS

Chromite.—Albania again ranked second to the U.S.S.R. among Communist nations as a producer of chromite. The center of activities was the large mine of Bulqiza. To improve the existing reserve situation and to permit rational expansion of output, exploration was intensive, but results were not announced.

Most of the chromite produced was exported to Czechoslovakia, mainland China, and Yugoslavia.

Copper.—The small copper production of Albania was significant to Communist countries as a group because of the shortage of copper and copper semimanufactures in that part of the world.

The Rubik copper plant in the Mirdit region was the center of copper activities. Construction continued at this facility, which started production in 1964. New equipment was added in several sections and annexes. In the refinery, electrolytic cells were completed, and a new boiler was installed. Apparently the construction continued throughout 1965.

The electric wire plant at Shkoder underwent expansion during 1965. A new section reportedly was under construction, but no information was available on capacity of the plant, either before or after expansion. The plant was built under supervision of technicians from mainland China.

NONMETALS

Cement.—Basic construction work on the 100,000 ton per year cement plant at Elbasan reportedly was near completion at yearend. The installation of equipment should start in 1966.

Fertilizers.—Construction of the superphosphate factory at Lac continued. The plant was built by technicians from the Italian firm, Montecatini, Soc. Generale per l'Industria Mineraria e Chimica and mainland China financed the project. The builders completed the section for production of sulfuric acid and a workshop. No date was reported for the beginning of production.

MINERAL FUELS

Coal.—Lignite and low-rank bituminous coals produced were consumed in the country. A new coal mine of unreported capacity started production near Tepene.

Petroleum.—Production of crude petroleum was of the same order of magnitude as in 1964. Information on activities of the petroleum industry was meager.

A new petroleum institute for research and training personnel was organized in Stalin Town. The institute was staffed by personnel transferred from oilfields and from the former Central Research Laboratory in the same town.

Without disclosing the exact location of a new gasfield Albanian sources reported a strong blowout of natural gas which was successfully brought under control.

The Mineral Industry of Austria

By Justin B. Gowen [1]

Austria's output of marketable ores and minerals derived from domestic resources during 1965 had an estimated value of nearly $250 million, representing an increase of about 4.5 percent over that of 1964. It was equivalent to 2.7 percent of the gross national product estimated at $9,189 million at current prices. However, the importance of the Austrian mineral industry continued to be its capability to process crude minerals into sophisticated semimanufactures and finished materials.

Notable among these products were iron and steel (including high-grade and special steels and their products); aluminum; special alloys and products of molybdenum and tungsten; and high- grade refractories based principally on magnesite.

With an output of salable products valued at more than $500 million, iron and steel lead all other industrial sectors of the Austrian economy. Next among the mineral based industries was petroleum (with an estimated $90 million worth of refinery products) followed by magnesite with more than 1 million tons of salable products valued at about $80 million.

The value in millions of dollars of mine and quarry production for the years 1961–65 follows:

	1961	1962	1963	1964	1965 [1]
Petroleum and natural gas [1]	71.9	74.2	80.3	83.4	89.4
Stone and industrial minerals	66.2	60.0	56.4	69.1	74.8
Coal	40.3	42.3	45.6	44.4	43.0
Metallic ores	33.5	34.3	34.8	35.2	34.9
Salt and brine	6.5	6.7	7.2	7.0	7.2
Total	218.4	217.5	224.3	239.1	249.3

[e] Estimate.
[1] Includes oil shale.

The average of industrial employment increased 3 percent to 624,000, or 26.2 percent of the country's total employment, which increased 0.75 percent to 2,381,500 during 1965. Employment in the minerals and metals industries accounted for about 20 percent of the total of industrial employment.

Important developments affecting minerals industries included initiation of work on the Austrian section of the Transalpine oil pipeline and the passage of an amendment to Austria's foreign trade law. The latter was designed to remove export and/or import restrictions on many commodities including a large number of mineral based products. The new regulations were to become effective on January 1, 1966.

PRODUCTION

Declines were again registered in coal and iron ore production; increases were shown in industrial minerals, some construction materials, and petroleum. Production of crude steel increased only 1 percent and the output of nonferrous metals from all sources declined about 4 percent from that of 1964.

[1] Linz-Donawitz oxygen process.
[2] Crude graphite consumed mainly in blast furnaces.
[3] Calculated at 15° C and 760 millimeters of mercury.

TRADE

The importance of Austria's mineral commodities to overall trade is reflected in the following table:

	Value (million dollars)		Mineral commodities' share of total (percent)
	Mineral commodities trade	Total trade	
Exports:			
1963	r 356.5	1,325.2	26.9
1964	420.8	1,444.4	29.1
1965 p	459.4	1,600.3	28.7
Imports:			
1963	r 394.0	1,675.5	23.5
1964	r 451.1	1,863.4	24.2
1965 p	479.7	2,100.6	22.8
Trade balance:			
1963	−37.5	−350.3	XX
1964	r −30.3	−419.0	XX
1965 p	−20.3	−500.3	XX

r Revised. p Preliminary. XX Not applicable.

Iron and steel continued to be the country's principal foreign exchange earner followed by the nonmineral classes including wood and cork, paper, clothing, and then nonmetals.

The European Economic Community (EEC) continued to be Austria's most important customer, both in gross trade and in the exchange of mineral products. The Federal Republic of Germany was the leading supplier as well as the leading individual customer.

r Revised.

[1] Groups listed are those of the Standard International Trade Classification-Revised (SITC-R) as specified in the United Nations publication, Standard International Trade Classification Revised. Statistical Papers, Series M, No. 34. New York 1961, 135 pp.

[2] Europe has been subdivided as follows: EEC—Belgium, France, West Germany, Italy, Luxembourg, and the Netherlands; EFTA—Denmark, Norway, Portugal, Sweden, Switzerland, and the United Kingdom; East Europe—Albania, Bulgaria, Czechoslovakia, East Germany, Hungary, Poland, Rumania, and the U.S.S.R; Other—Finland, Greece, Ireland, Spain, Turkey, Yugoslavia.

[3] Excludes nitrogenous fertilizers.

[4] Includes some commodities not usually covered in the "Minerals Yearbook."

[5] Grouping as reported is not readily divisible between "Metals" and "Nonmetals."

[6] Excludes mineral tar and crude chemicals produced from petroleum.

[7] Includes peat, natural and manufactured gas, mineral tar, and crude chemicals produced from coal, petroleum, natural gas and electric power.

Nonferrous ashes and residues not elsewhere specified.	6,400	9,982	West Germany 4,150; Italy 3,181; Yugoslavia 2,261.
Other ashes and slag including kelp	3,907	4,239	Italy 3,351; West Germany 815.
Salts and compounds of unspecified rare-earth elements.	158	151	NA.
Other base metals not elsewhere specified, all forms.	24	27	Switzerland 10; United States 9.
Nonmetals:			
Abrasives, pumice and other natural	11	9	Ireland 5; Yugoslavia 3.
Asbestos:			
Crude	r 160	16	All to West Germany.
Cement and cement products	11,383	10,688	West Germany 9,834.
Other asbestos products, excluding friction materials.	1,596	1,924	Italy 391; Poland 208; West Germany 153; Sweden 138; France 132.
Barite and witherite	20	6	All to Lebanon.
Cement, hydraulic	35,962	60,813	Switzerland 37,049; West Germany 23,753.
Chalk	5,028	4,137	West Germany 2,545; Italy 686; Czechoslovakia 614.
Clays and refractories (except magnesite):			
Bentonite	36	53	West Germany 38.
China clay	39,156	34,953	Italy 17,467; West Germany 8,201; Switzerland 5,728.
Fire and dinas clays, crude	1,100	4,008	Hungary 3,409; Italy 557.
Other refractory clays	151	1,468	Italy 1,232.
Cryolite and chiolite, natural	100	50	Mainly to Italy.
Diatomite and other siliceous earths	164	135	Bulgaria 56; Yugoslavia 43.
Diamond and other gem stones, except pearls:			
Uncut—thousand carats	950	30	All to Switzerland.
Other—do	55	55	Mainly to Netherlands.
Dolomite:			
Crude	7,539	13,124	West Germany 13,104.
Sintered, including mortar	10,634	19,904	United Kingdom 6,964; West Germany 6,933; Denmark 1,140; Argentina 1,003.
Other	680	746	France 156; Hungary 125; United Kingdom 120.
Feldspar	562	655	Switzerland 380; Italy 164.
Graphite, natural	19,520	19,153	West Germany 9,450; Italy 6,915; Yugoslavia 728.
Gypsum:			
Crude and sintered	49,686	57,992	West Germany 49,042; Switzerland 8,804.
Gypsum products	25	575	West Germany 570.
Lime, hydraulic and slaked	182	221	West Germany 106; Turkey 60; Switzerland 53.
Limestone, industrial	41	12,894	All to West Germany.

See footnotes at end of table.

Table 3.—Austria: Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodities	1963	1964	Principal destinations, 1964
Nonmetals—Continued			
Magnesite:			
Crude	420	766	West Germany 416; Netherlands 200; Switzerland 105.
Sintered	164,293	236,966	West Germany 103,717; United States 43,556; United Kingdom 30,832.
Caustic calcined	94,574	101,467	West Germany 84,599; Italy 4,058; Switzerland 3,562.
Bricks	107,097	123,328	West Germany 23,782; France 21,388; United Kingdom 13,760; Sweden 10,732.
Other products, not burnt, including chrome-magnesite products.	90,564	119,130	West Germany 40,513; France 21,139; Rumania 9,852; Italy 7,059.
Mica and mica products	38	16	Yugoslavia 7; West Germany 5.
Pigments, earth	2,250	2,572	West Germany 1,235; United Kingdom 522; Netherlands 260.
Quartz and quartzite	181	340	West Germany 241; Netherlands 58; Czechoslovakia 40.
Refractories not elsewhere specified:	498	440	Czechoslovakia 190; West Germany 111.
Heat insulating bricks, etc.			
Fireclay bricks and tiles	1,033	2,542	Czechoslovakia 675; West Germany 636; Denmark 236; Yugoslavia 203.
Other	15	26	U.S.S.R. 20.
Salt brine	1,264	3	Mainly to West Germany.
Sand:			
Quartz	716	314	West Germany 240.
Other	22,248	80,283	West Germany 69,318.
Slate	15	11	All to West Germany.
Stone:			
Marble and other calcareous stone, sawn or crude cut.	50,445	70,662	West Germany 70,161.
Granite and other igneous rock, broken, sawn, or crude cut.	78,933	57,420	West Germany 55,637.
Crushed stone, gravel, macadam	324,259	387,466	West Germany 361,415; Switzerland 24,909.
Talc and soapstone	51,619	55,796	West Germany 27,896; Italy 7,128; Belgium-Luxembourg 5,150.
Vermiculite and mineral wool	86,664	75,994	West Germany 74,122.
Other nonmetals not elsewhere specified:			
Ceramic scrap	393	672	West Germany 652.
Other	326	1,045	West Germany 849.
Mineral fuels:			
Lignite—thousand tons	20	17	All to West Germany.
Coal tar and other mineral tar	413	406	All to West Germany.
High-temperature coal tar distillation products.	3,036	4,435	West Germany 2,662; Italy 1,771.
Pitch and pitch coke	2,426	406	Italy 187; West Germany 119; Hungary 100.
Petroleum refinery products:			
Gasoline	53	60	Czechoslovakia 40; Yugoslavia 15.
Distillate fuel oil	205,927	130,991	West Germany 130,832.
Lubricants	15,176	77,082	East Germany 22,324; Czechoslovakia 20,626; Hungary 9,918; Poland 9,579.
Other mineral oils	r 831	1,182	East Germany 529; Switzerland 155; Poland 113.
Mineral jelly, wax, bitumen, and asphalt.	633	575	West Germany 300; Yugoslavia 124; Switzerland 76.
Electric energy—million kilowatt hours	2,505	3,570	West Germany 2,944.

r Revised. NA Not available.
1 As reported in source; further details on origin (Southern Rhodesia, Zambia, and Malawi) not available.
2 Includes spiegeleisen, shot, powder, and sponge.

COMMODITY REVIEW

METALS

Iron and Steel.—Austria's 1965 output of 3.5 million tons of iron came from two mines in Styria and one mine in Carinthia, all owned and operated by the nationalized Oesterreichisch-Alpine Montangesellschaft. Most important of the three in international economic significance was the Steirischen Erzberg (Styrian Ore Mountain) mine at Eisenerz, Styria, which accounted for nearly 90 percent of Austria's total output of marketable iron ore.

The deposit is the largest of several more or less similar spathic iron ore deposits in the area, which lies between the Northern Limestone Alps and the Central Alps and extends from the vicinity of Semmering into Tyrol. Reserves at Eisenerz are estimated at about 300 million tons of minable ore of all classes. The deposit attains a thickness of 200 meters and forms the major part of an isolated mountain which rises 840 meters above the valley floor.

The mine comprises about 60 opencast

benches covering three sides of the mountain, and an underground mining section for the recovery of ore from below the valley floor. During the 5-year period, 1960–64, the mine produced a daily average of 11,515 tons of marketable iron ore of which about 76 percent came from the opencast workings and 26 percent from underground mining. From the opencast section , 4:0 tons of waste was removed for each ton of marketable ore produced. Underground the ratio was 0.8 ton of waste for 1 ton of ore.

The ore varies from place to place and may be predominantly limonite, siderite, ankerite or ferruginous dolomite, or mixtures of these. Processing consists of heavy media separation and flotation which produce an end product averaging 31 to 32 percent iron and 1.80 to 1.85 percent manganese. Roasting or sintering raises the grade to about 46 percent iron. A roasting plant at Eisenerz treats 300,000 to 400,000 tons annually to meet the requirements of the Donawitz blast furnace works. The remainder is further processed at the Linz-Donau works of Vereinigte Oesterreische Eisen - und Stahlwerke A.G. (VOEST). Current research is designed to develop a process for the recovery of a satisfactory product from the lower grade ore not now included as minable reserve. A successful process would add to the reserves about 60 million tons averaging 20 percent iron.

The replacement of one old blast furnace and the installation of a sinter plant were included in a modernization program being carried out at yearend by Alpine at the Donwitz works. At the beginning of 1965 the blast furnace works consisted of four furnaces, three of which were constructed prior to World War II. Production during the first 6 months of 1965 was at the rate of 746,000 tons of pig iron annually.

In early 1965 a new investment program was approved for VOEST's Linz-Donau works which includes an additional 50 ton Linz-Donawitz (L-D) steel converter in the No. 2 plant, and a continuous steel-casting plant with a capacity of 300,000 tons annually. Although the L-D converter is intended to replace one of two existing 200-ton open hearth furnaces, it would increase the L-D steelmaking capacity by about 600,000 tons while about 150,000 tons of basic open hearth capacity would be liquidated.

Nonferrous Metals.—It was announced that exploration at the Bleiberg-Kreuth lead-zinc mine has disclosed adequate reserves to maintain the operations of the nationalized Bleiberger Bergwerks Union Klagenfurt for 25 to 30 years in the future.

Austrian consumption of nonferrous metals has been reported as follows:

	Thousand metric tons				
	1961	1962	1963	1964	1965 p

NONMETALS

Magnesite. — Nine mines owned and operated by four companies produced 1,815,607 tons of crude magnesite in 1965 establishing a new record high output for this mineral. The previous high was 1,798,681 tons produced in 1961. The Oesterreichisch-Amerikanische Magnesit-Aktiengesellschaft Radenthein was again the principal producer, accounting for about 55 percent of the total output. Veitscher Magnesitewerke Aktiengesellschaft accounted for about 39 percent.

Exports of magnesite and magnesite products (including chrome-magnesite) in 1965 amounted to about 625,000 tons, valued at nearly $57 million, an increase of about 7.5 percent in quantity and 12.8 percent in value.

MINERAL FUELS

Coal (bituminous and lignite) remained Austria's most important source of energy, in terms of heat content and in its effect on the regional economy, through yearend 1964. However, preliminary data for 1965 indicated that its share of the total energy consumed continued to decline as it has each year since 1960 except for 1963, and that during 1965 the energy supplied by petroleum and its derivities had closely approached, or possiblv surpassed that derived from coal and lignite. During 1964 the percentage distribution of total energy consumption by energy sources was as follows: bituminous coal 20.25; lignite 14.66; total coal 34.91; petroleum 30.93; natural gas 10.31; hydropower 20.17; fuelwood 3.76; peat 0.01.

Coal.—The Gruenbach mine, Austria's only bituminous coal mine, was closed down in October because of high costs.

Petroleum.—In December 1965, the Felbertauern tunnel, highest of three tunnels in Austria designed to carry the Trans Alpine pipeline across Alpine ridges, penetrated the crest of the Hohentauern range at an elevation of 5,084 feet. The Ploecken tunnel, crossing the Italian-Austrian border at about 3,050 feet, and the Hahnenkamm tunnel near Kitzbuehel at about 3,300 feet, were expected to be completed early in 1966.

Projected for early construction was the Adriatic-Vienna pipeline, to connect with the Trans Alpine Line at Wuermlach, near the Austrian end of the Ploecken tunnel, and to extend via Arnoldstein-Ferlach, Soboth and Wechsel to the Oesterreichische Mineraloelverwaltung (OMV), refinery at Schwechat, near Vienna. OMV a state-owned organization, will have a 51 percent controlling interest in the pipeline, while the remaining 49 percent will be divided among Socony Mobil Oil Company (Mobil), Bataafse Petroleum Maatschappij N.V. (Shell), British Petroleum Company (BP), Standard Oil Co. of New Jersey (Esso), Cie. Française des Pétroles (CEP) and Ente Nazionale Idrocarburi (ENI).

Refinery capacity remained essentially unchanged at 91,500 barrels per day during 1965, distributed as follows: Mobiloil Austria A.G.-Kagran 3,400 barrels; OMV-Schwechat 84,000 barrels; Shell Austria-Floridsdorf 4,500 barrels.

Oil and gas reserves at the beginning of 1965 were as follows:

The Mineral Industry of Belgium

By Stephen C. Brown [1]

The continued expansion of Belgium's mineral industries was largely responsible for the country's 3-percent growth of gross national product in real terms during 1965. Though the general index of industrial production (1958=100) only rose from 145 in 1964 to 147 in 1965, the production index for the steel industry rose from 147 to 152, for the nonferrous metals industry from 162 to 175, for the petroleum refining industry from 206 to 241, and for the metal-fabricating industries from 160 to 165. Production in the extractive industries (mining and quarrying) and in the nonmetallic mineral industries declined, the index dropping from 92 to 85 for the former, and from 151 to 147 for the latter.[2]

The 3-percent growth for the gross national product (GNP) was a sharp decline from the 5.2-percent growth in 1964, reflecting both a weakening of internal consumer demand and an actual decline, in real terms, of gross domestic fixed investment. High external demand for the products of Belgium's metal industries, caused by threats of a steel strike in the United States and by continuing worldwide scarcities of the major nonferrous metals, provided the principal stimulus both for the mineral industries and for the economy as a whole.[3] Construction lagged, however, and this as well as the growing difficulties of the coal industry was reflected in the declining index for the extractive industries.

Data showing the share of the mineral industries in total gross domestic product (GDP) in 1965 were not available, but 1964 figures indicate that the extractive, iron and steel, and nonferrous metals industries accounted for 4.7 percent of GDP (or 4.6 percent of GNP) in that year. Adding the contributions of the building materials industry (cement, lime, etc.), the fertilizer industry, and the petroleum refining industry would raise this share substantially. The extractive industries alone accounted for 2.5 percent of GNP in 1964, the same share as in 1963.[4]

Employment in the mineral industries in 1965 declined compared with that of 1964. Total employment in these industries at yearend [5] is estimated at about 223,000, compared with 232,000 in 1964. The decline was more than accounted for by a reduction of nearly 10,000 in coal mining.

PRODUCTION

Production of crude steel rose 5 percent in 1965, of pig iron and ferroalloys 3.9 percent, and of iron and steel semimanufactures 7.3 percent. Nonferrous metal output expanded more sharply, refined copper production rising 8.1 percent, smelter lead 32.9 percent, and smelter zinc 7.8 percent. Tin output declined 23.2 percent, reportedly because of a shortage of ores from the Democratic Republic of the Congo (Léopoldville). Output of copper semimanufactures rose 9.5 percent, but production of semimanufactures of most other nonferrous metals was relatively unchanged.

Coal output declined about 1.5 million

e Estimate. r Revised. p Preliminary. NA Not available.
[1] 80 to 90 percent silver.
[2] Includes antimony, cadmium, cobalt, nickel, and other unspecified metals.
[3] Not including annual production of artificial hydraulic lime (5,000 to 6,000 tons per year in 1960–63 and 8,582 tons in 1964).
[4] Including chalk, marl, and travertine.
[5] Converted from production data in thousand square meters of 20-millimeter slabs.
[6] About 98 percent crude coal tar.
[7] At 0° C., 760 millimeters of mercury, and 8,500 kilocalories per cubic meter.
[8] Coke oven and gas plant gas; gross output including gas for own consumption; includes gas produced from hydrocarbons.
[9] Including commercialized refinery gas.

tons, or 7.1 percent, while production of refined petroleum products increased nearly 18 percent. Production of cement and lime was relatively unchanged, while stone and sand and gravel output declined, affected by the decline in construction.

TRADE

The foreign trade of Belgium is not reported separately, being incorporated with that of Luxembourg in the official trade returns of the Belgium-Luxembourg Economic Union (BLEU). Hence the following discussion refers to the trade of both countries rather than to that of Belgium alone.

Increases were recorded in value of mineral trade, both exports and imports, for the BLEU in 1965, but the gains were not as great as were those for total commodity trade, and as a result, the share of total trade accounted for by minerals declined from 1964 to 1965. The Union continued to have a positive trade balance with respect to mineral commodities, and in fact showed a greater net export in 1965 than in 1964, as exports increased $238 million (10.6 percent) while imports increased only $105 million (5.8 percent). The important role of mineral commodities in the overall trade of the Economic Union is shown in the following tabulation:

	Value (million dollars)		Mineral commodities share of total percent
	Mineral commodities [1]	Total commodity trade	
Exports:			
1963	1,943	4,839	40.2
1964	2,238	5,590	40.0
1965	2,476	6,382	38.8
Imports:			
1963	1,573	5,112	30.8
1964	1,808	5,923	30.5
1965	1,913	6,374	30.0
Trade balance:			
1963	+370	−273	XX
1964	+430	−333	XX
1965	+563	+8	XX

XX Not applicable.
[1] Data include values for all commodities listed in tables 2 and 3 of this chapter except gold.

Source: Statistical Office of the United Nations.

Of the total 1965 mineral exports of the Union, principal commodity groups were iron and steel, $1,144 million; copper, $296 million; diamond and other precious stones (including industrial), $292 million; petroleum refinery products, $162 million; and manufactured fertilizers, $139 million.

Principal destinations for 1965 mineral exports and the value of exports to these countries were West Germany, $482 million; France, $385 million; the Netherlands, $335 million; and the United States, $230 million. The European Economic Community (EEC) as a whole took somewhat over half of total mineral exports of the Economic Union.

Of total 1965 mineral imports, major commodity groups were crude oil and petroleum products, $360 million; metal ores and scrap, $303 million (including iron ores and concentrates, $139 million); diamond and other precious stones (including industrial), $281 million; coal, coke, and briquets, $216 million; unwrought copper, $214 million; and iron and steel, $198 million.

Principal sources of imports on a value basis were West Germany, $279 million; France, $249 million; Democratic Republic of the Congo (Léopoldville), $194 million; the Netherlands, $157 million; Iran, $99 million; and the United States, $81 million.

Trade, both imports and exports, in most commodity groups followed the overall upward trend, with coal, coke, and briquets being the only notable exception.

Copper:				
Scrap	9,895	12,699	16,302	West Germany 6,020; Netherlands 2,780; France 2,217.
Refined	248,301	249,818	263,159	France 90,800; West Germany 76,770; Netherlands 19,312.
Semimanufactures	60,373	82,378	90,169	Netherlands 33,626; West Germany 19,927.
Germanium:				
Oxide kilograms	11,700	24,100	17,000	Japan 11,700; Netherlands 6,800.
Metal do	3,800	6,100	6,300	West Germany 3,000; United Kingdom 1,500.
Gold, including semimanufactures. thousand troy ounces	55	55	55	Switzerland 16; United States 13; United Kingdom 13.
Iron and steel:				
Iron ore thousand tons	275	226	67	France 207.
Pyrite cinder do	214	188	199	West Germany 180.
Blast furnace slag and waste. do	1,763	2,126	1,879	West Germany 1,173; Netherlands 718.
Scrap do	521	617	720	West Germany 303; France 262.
Pig iron, including cast iron, sponge, powder. do	140	66	80	France 39; West Germany 22.
Ferro-alloys, including spiegeleisen. thousand tons	37	43	47	United States 18; West Germany 9; France 8.
Ingots and other primary forms. thousand tons	733	1,114	1,201	France 529; West Germany 320.
Semimanufactures:				
Shapes (bars, rods, angles, shapes, sections). thousand tons	3,647	4,020	4,377	United States 927; West Germany 755; Netherlands 574.
Universals, plate, sheet. thousand tons	1,989	2,304	2,679	West Germany 687; France 547.
Hoop and strip. thousand tons	620	748	739	West Germany 198; France 173.
Railway material. do	117	68	116	Netherlands 13; Greece 10; Italy 9; France 7.
Wire do	280	303	318	United States 99; Netherlands 37; West Germany 32.
Tubes, pipes, fittings. do	195	218	246	West Germany 49; Netherlands 44; United States 30.
Castings do	17	18	24	West Germany 7; Netherlands 4.
Lead:				
Ore and concentrate	-------	600	263	All to France.
Ashes and residues containing lead.	1,482	2,845	2,103	Netherlands 1,369; West Germany 701; Sweden 460.
Scrap	2,122	3,351	2,239	West Germany 2,578. France 532.
Pig	70,557	49,614	71,810	West Germany 16,445; Netherlands 12,334; France 12,312.
Semimanufactures	6,453	6,309	7,863	Netherlands 2,441; West Germany 918; Sweden 898.
Oxides	4,454	3,735	3,663	Netherlands 3,153.
Magnesium [2]	272	440	451	United Kingdom 269; United States 131.
Manganese ore	2,477	2,019	7,516	United Kingdom 1,143; France 522; Netherlands 354.
Mercury 76-pound flasks	377	290	319	Netherlands 165; France 52.
Molybdenum:				
Metal [2] kilograms	400	15,800	4,900	West Germany 11,700.
Nickel:				
Unwrought [2]	621	533	470	Netherlands 245; West Germany 115.
Semimanufactures [3]	128	118	166	Netherlands 69.
Platinum and platinum-group metals all forms. value, thousands	$663	$368	$1,025	France $125; West Germany $81; United Kingdom $38; Netherlands $42.
Selenium kilograms	24,500	39,500	42,200	United Kingdom 11,800; United States 8,000; France 7,100.

See footnotes at end of table.

Table 2.—Belgium-Luxembourg: Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal destinations, 1964
Metals—Continued				
Silicon	-------	400	700	United Kingdom 200; Netherlands 200.
Silver:				
Unwrought, partly worked. thousand troy ounces	10,529	10,870	8,131	West Germany 6,771; France 1,897.
Tantalum [2] value, thousands	$15	$35	$157	NA.
Tellurium and arsenic. kilograms	NA	1,000	4,800	NA.
Tin:				
Ore and concentrate. long tons	-------	24	48	All to Spain.
Scrap do	342	317	223	West Germany 106; Netherlands 78; Spain 76.
Ingot do	6,379	4,574	4,110	France 2,239; Netherlands 1,250; West Germany 749.
Semimanufactures do	359	209	179	Spain 79; Switzerland 20.
Oxides do	207	245	198	West Germany 185; Netherlands 41.
Titanium dioxide	6,327	1,588	3,275	France 531; Netherlands 528; Greece 200.
Titanium, vanadium, molybdenum, tantalum, and zirconium ores.	79	8	59	NA.
Tungsten:				
Ore	1	6	25	Mainly to Netherlands.
Metal [2]	7	1	3	Do.
Oxide and hydroxide	11	NA	NA	
Uranium and thorium:				
Ore kilograms	-------	13,100	-------	All to India.
Metal [2] do	900	100	-------	NA.
Other radioactive materials. do	10,900	1,200	3,100	NA.
Zinc:				
Ore	51,113	21,036	12,247	France 8,564; West Germany 6,593; Japan 4,015.
Ashes and residues containing zinc.	20,164	14,095	19,987	West Germany 10,741; Japan 1,531; France 675.
Scrap	5,835	8,575	7,474	France 7,193; West Germany 680.
Slab	122,814	126,742	129,656	West Germany 55,954; France 11,331; United Kingdom 9,613; Italy 7,654.
Dust (blue powder)	15,667	16,136	16,436	France 3,937; West Germany 3,313; United States 2,963.
Semimanufactures	15,600	16,392	17,223	Netherlands 4,357; West Germany 4,248; France 1,866.
Other nonferrous ores	2	1	9	NA.
Other nonferrous waste and scrap	70,239	110,127	170,151	Netherlands 53,255; France 49,246.
Other base metals	7,102	7,985	10,305	United States 3,483; Japan 1,450.
Waste and scrap of precious metals. kilograms	NA	800	NA	Netherlands 300; United Kingdom 200; France 200.
Nonmetals:				
Asbestos	396	130	-------	NA.
Barite	21	194	212	NA.
Building stone:				
Marble and other calcareous stones. thousand tons	837	1,021	915	Netherlands 983.
Other, including worked. thousand tons	154	263	265	Netherlands 253.
Cement thousand tons	1,196	1,435	1,726	Netherlands 1,005; Ivory Coast 93.
Chalk	58,605	76,646	77,866	Netherlands 35,259; France 15,182; West Germany 12,447.
Clays, crude:				
Kaolin	328	72	406	NA.
Nonrefractory	8 275	18,348	25,208	Netherlands 11,420.
Refractory	14,026	9,492	12,616	France 5,747; Netherlands 3,136.
Clay construction materials:				
Nonrefractory	194,726	236,109	212,406	Netherlands 135,734; West Germany 45,024; France 35,306.
Refractory	38,274	41,073	45,068	France 20,451; Netherlands 9,739; Italy 2,760.
Diamond:				
Industrial, including worked. thousand carats	r 8,534	7,834	8,139	United Kingdom 2,367; United States 2,239; Netherlands 777.
Gem:				
Rough do	r 484	1,109	1,235	India 326; Israel 255; United States 218; United Kingdom 153.
Polished do	1,347	1,521	1,561	United States 590; Hong Kong 206; United Kingdom 166.
Diatomite	810	966	941	France 557; Netherlands 197; West Germany 155.

See footnotes at end of table.

Table 2.—Belgium-Luxembourg: Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal destinations, 1964
Nonmetals—Continued				
Dolomite	448,763	496,803	551,458	Netherlands 265,625; France 167,485.
Feldspar, leucite, etc	226	86	42	NA.
Fertilizer materials:				
Nitrogenous:				
Sodium nitrate, natural	250	-------	-------	
Manu- thousand tons factured.	660	549	763	France 140; West Germany 107.
Phosphatic:				
Phosphate rock	25,458	29,088	31,203	Netherlands 13,962; Switzerland 2,957.
Thomas thou. tons slag.	1,745	1,797	1,873	France 589; West Germany 416; Netherlands 190.
Manufactured do	215	282	220	France 158; mainland China 20.
Potassic:				
Potassium salts	5,603	12,843	322	Netherlands 9,912; United States 2,631.
Manu- thousand tons factured.	1,072	967	923	United Kingdom 184; United States 178; Japan 111.
Fluorspar	7	-------	13	
Graphite	13	45	8	NA.
Gypsum and plasters	14,493	15,849	16,464	Netherlands 14,704.
Lime	300,564	341,502	357,640	Netherlands 266,113; France 73,901.
Limestone	716,600	836,060	913,566	Netherlands 636,578; France 189,714.
Lithium minerals	28	-------	26	
Mica	9	23	14	NA.
Precious and semi- kilograms precious stones (except diamond).	8,257	5,161	6,073	United States 2,020; Hong Kong 1,750; Italy 801.
Quartz and quartzite	2,218	40,638	63,667	Netherlands 14,182; West Germany 6,150; Italy 4,706; France 4,516.
Salt	534	1,775	3,448	France 1,615.
Sand, gravel, crushed stone:				
Sand thousand tons	2,804	3,064	3,224	France 1,013; Netherlands 770; West Germany 301.
Gravel and crushed do stone.	3,622	5,575	5,792	Netherlands 3,274; France 1,881.
Slate, including worked	3,667	4,265	5,104	Netherlands 1,804; West Germany 1,482.
Sulfur	8,097	7,809	8,084	Portugal 1,281; India 990; Pakistan 954.
Other mineral substances	58,157	93,861	86,547	Netherlands 74,518; France 4,648.
Mineral fuels:				
Asphalt and bitumen (natural)	196	260	249	NA.
Coal, including thousand tons briquets.	2,659	2,575	1,978	France 1,381; Netherlands 603; West Germany 325.
Coke (from coal) do	485	404	511	France 192; Sweden 103; Denmark 43.
Pitch and pitch coke [4]	26,609	15,411	6,473	France 12,620; Netherlands 2,679.
Gas, petroleum and natural	49,215	47,509	50,404	Netherlands 23,446; France 21,033.
Peat, including briquets	280	337	195	NA.
Petroleum:				
Crude	1	29	-------	NA.
Refinery products (including bunkers):				
Gasoline thou. tons	846	624	862	West Germany 188; Netherlands 145; United Kingdom 114.
Kerosine, in- do cluding white spirit.	209	403	442	Netherlands 245; United Kingdom 53.
Distillate thou. tons fuel oils.	1,314	1,436	1,528	Switzerland 451; Netherlands 411; West Germany 180; France 146.
Residual fuel do oils.	2,258	2,178	2,148	Bunkers 1,436; Netherlands 444; France 158.
Lubricants do	153	143	165	Netherlands 48; Switzerland 29; West Germany 18.
Petrolatum and wax	1,483	940	473	Nigeria 450; Israel 62.
Petroleum coke	27,991	41,058	25,633	France 19,955; United Kingdom 16,318.
Liquefied thou. tons petroleum gas and other gaseous hydrocarbons.	49	48	50	Netherlands 23; France 21.
Bitumen thou. tons and other.[5]	299	276	207	West Germany 137; Netherlands 82.
Carbon black	3,490	3,660	4,414	NA.

r Revised. NA Not available.
[1] Generally, includes alloys.
[2] Including scrap.
[3] Does not include anodes, which are unreported.
[4] From coal and other mineral tars.
[5] Including bituminous mixtures.

Table 3.—Belgium-Luxembourg: Imports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal sources, 1964
Metals: [1]				
Aluminum and aluminum alloys:				
Bauxite	3,251	5,152	7,244	British Guiana 4,272.
Aluminum oxide and hydroxide.	10,388	12,225	11,117	West Germany 6,705; France 5,028.
Scrap	2,352	2,678	3,772	Netherlands 945; France 434; West Germany 346; Austria 326.
Unwrought	89,055	112,633	117,020	France 81,274; United States 9,721; U.S.S.R. 4,821.
Semimanufactures	16,616	18,237	18,668	West Germany 7,607; Netherlands 3,536; France 3,452.
Antimony:				
Oxides	216	291	90	U.S.S.R. 201; United Kingdom 62.
Metal	242	165	113	U.S.S.R. 71; mainland China 35; Netherlands 33; France 20.
Arsenic:				
Oxides and acids	14	75	46	NA.
Beryllium, all forms..kilograms..	400	600	100	All from Netherlands.
Bismuth [2]	120	72	38	South Korea 41; United Kingdom 18.
Cadmium	488	226	332	Republic of the Congo (Léopoldville) 164; Netherlands 19.
Chromium:				
Ore and concentrate	1,031	1,435	987	Philippines 1,008.
Oxide and hydroxide	329	420	353	West Germany 266; France 117.
Metal	72	29	NA	United Kingdom 15; West Germany 11.
Cobalt:				
Oxides and hydroxides. kilograms..	1,100	200	500	NA.
Copper and copper alloys:				
Ore and concetrate	4,024	2,175	2,227	Morocco 1,269; Peru 350; Ecuador 324.
Scrap	36,503	48,945	67,674	West Germany 14,855; France 11,805; Netherlands 11,071.
Ingot, including alloys	280,384	321,929	317,383	Republic of the Congo (Léopoldville) 220,642; Republic of South Africa 22,202.
Semimanufactures	7,047	8,433	9,024	Netherlands 3,407; West Germany 2,613; France 1,365.
Germanium [2]	17	36	26	Netherlands 35.
Gold and gold alloys:				
Unwrought....troy ounces..	318,000	417,960	1,321,395	United Kingdom 212,195; Republic of the Congo (Léopoldville) 192,905.
Semimanufactures....do....	NA	35,366	16,075	United States 28,936.
Iron and steel:				
Iron ore and concentrate. thousand tons..	19,720	22,897	23,745	France 14,453; Sweden 5,742; Liberia 783; Brazil 466.
Pyrite cinder	44,180	115,013	153,811	France 64,673; Spain 38,471.
Blast furnace slag and waste	232,693	233,817	235,359	France 126,426; West Germany 47,202; Netherlands 43,087.
Scrap	87,345	156,684	145,069	Netherlands 67,044; France 51,182; United Kingdom 16,125.
Pig iron, including cast iron, sponge, powder, etc.	476,513	289,433	234,977	West Germany 139,182; France 92,027; East Germany 45,631.
Ferroalloys, including spiegeleisen.	104,860	126,288	119,426	France 56,608; Norway 32,087; West Germany 9,628.
Ingots and other primary forms. thousand tons..	392	592	433	France 199; Netherlands 174; West Germany 78.
Semimanufactures:				
Shapes (bars, rods, angles, shapes, sections). thou. tons..	271	323	353	France 134; West Germany 118; Netherlands 38.
Universals, plate, sheet. do....	210	256	261	West Germany 118; France 98.
Hoop and strip...do....	22	26	28	France 10; West Germany 9; Netherlands 5.

COMMODITY REVIEW

METALS

Aluminum. — Production of secondary aluminum decreased 7.7 percent in 1965, but output of semimanufactures rose nearly 10 percent to more than 135,000 tons. Imports and exports of both ingots and semimanufactures likewise increased. A report in mid-1965 indicated that a feasibility study for a large aluminum ingot plant in Belgium had been undertaken on behalf of unnamed principals, believed to be a consortium of Belgian and U.S. firms. Details were lacking, but it was reported that the project, if realized, would not be completed until 1970. The raw materials reportedly will be imported from North America. If the project goes through, this would be the first primary aluminum plant in Belgium.

Copper.—Belgium's refined copper production in 1965 rose to a new high of 309,356 tons, 8.1 percent above the level of 1964. Output of semimanufactures increased by about 9.5 percent. Exports of refined copper rose 6 percent, with the EEC taking three-fourths of the total. France and West Germany remained the principal markets.

The electrolytic refinery of Societé Général Métallurgie de Hoboken, S.A. at Olen worked at full capacity throughout the year. The semicontinuous slab-casting unit and the continuous casting unit for billets were completed. When completed, the overall rationalization and expansion program in progress at yearend at the Olen plant is expected to increase total casting capacity for copper in merchant shapes by 25 percent to about 350,000 tons per year.

Iron and Steel.—Despite a decline in domestic sales, Belgian steel production rose by 5 percent in 1965 in response to an increase in export demand. Pig iron production increased by only 3.9 percent.

The trend to declining utilization of Lorraine ores continued, while consumption of non-EEC ores of higher grade (chiefly Swedish ore) continued to increase steadily. Two ore carriers, one of 32,000 tons and the other of 54,000 tons were commissioned in 1965, and a third was under construction at yearend. Similarly, the trend towards increased consumption of agglomerated ores and declining utilization of crude ores continued. Scrap consumption per ton of steel increased slightly, while consumption of coke per ton of pig iron continued to decline.

Perhaps the most significant development of the year was the sharp increase in output of oxygen steel by various processes; the production of Linz-Donawitz (LD) steel more than doubled in 1965. Production of LD steel accounted for 16

percent of the total in 1965, compared with 7 percent in 1964.

Despite the high levels of output and exports, the Belgian steel industry continued to be in difficulties as prices weakened on both domestic and export markets and labor costs continued to rise. Exports rose 9.6 percent in quantity, while imports declined 8.9 percent. Apparent domestic consumption declined to 2.9 million tons, of which about 60 percent was supplied by the Belgian steel industry.

A number of investment programs in progress during recent years were concluded in 1965. A new LD steel plant of S.A. Cockerill-Ougrée at Seraing, with two 180-ton oxygen converters, was opened in July, and an oxygen steel plant of S.A. Forges de la Providence at Marchienne-au-Pont was completed in March. A second hot-rolling mill at the new steel plant of S.A. Métallurgique d'Espérance-Longdoz at Chertal went into operation at the beginning of 1965, and cutting facilities for coils and heavy sheets were being expanded during the year.

Société Métallurgique Hainaut-Sambre S.A. planned the construction of two 150-ton LD convertors for the modernization of its mill near Charleroi, but no date was announced for the beginning of construction.

The recipient of the bulk of steel industry investment in Belgium, however, continued to be the entirely new plant being erected at Zelzate near Ghent by Sidérurgie Maritime, for which equipment orders valued at about $70 million were placed during the year. Construction of the new plant was on schedule; the cold-rolling mill went into operation in January 1966, and the plant's first blast furnace was scheduled to begin operations in March 1967, with the second to follow in early 1968. The steelworks and hot-rolling mills were also expected to go into operation by the end of the first quarter of 1967.

Lead and Zinc.—Sharp increases in imports of lead and zinc ores and concentrates in 1965 kept Belgian smelters busy and resulted in a 33-percent increase in output of smelter lead and a 7.8-percent rise in output of zinc. Substantial rises in deliveries of ores and concentrates from Canada, the Republic of South Africa, and Finland accounted for the increased imports of lead ores, while a nearly 100,000-ton increase in imports from Canada more than accounted for the rise in imports of zinc ores and concentrates.

As in the case of copper, strong worldwide demand for lead and zinc kept prices strong and enabled the Belgian refining companies to show good financial results. Société Métallurgie de Hoboken S.A. planned to build a new, larger lead refinery as part of its modernization program, while Société des Mines et Fonderies de Zinc de la Vieille-Montagne (Belgium's largest zinc refinery) renovated its roasting and sulfuric acid division at Balen, and extended the direct fabrication of zinc powder at its Liége works. Compagnies des Métaux d'Overpelt-Lommel et de Corphalic (the second largest zinc producer) invested about $1.8 million in new buildings and equipment.

Exports of refined lead (including alloys) recovered from 1964 levels and rose sharply, with West Germany and the Netherlands providing the principal markets. Exports of refined zinc (including alloys) rose more modestly. Trade in semimanufactures was relatively unchanged.

Tin.—Belgian tin production declined 23.2 percent in 1965, with falling deliveries of ores and concentrates from both the Democratic Republic of the Congo (Léopoldville) and Rwanda-Burundi, Belgium's chief suppliers. Imports and exports of both refined tin and semimanufactures likewise decreased.

Uranium.—In September 1965, Eurochemie (Société Europeene pour le Traitement Chimique des Combustibles Irradiées) inaugurated a plant at Mol for the chemical reprocessing of irridated fuels, reportedly representing an investment of $28 million. Contracts were signed with French and Belgian authorities for the treatment of 23 tons of uranium.

Information on trade and consumption of uranium and other radioactive materials is not available. With inauguration of the nuclear powerplant at Chooz, uranium consumption should increase.

Other Nonferrous Metals.—Cobalt prices increased in 1965, and the expanding market for this metal, especially for special cobalt products, was expected to lead to an increase in the capacity of Métallurgie Hoboken's plant at Olen, where consideration was being given to new treatment procedures. In the case of germanium and

silicon, demand was increasingly concentrated on the more highly processed products.

NONMETALS

Cement and Construction Materials.—Cement output increased 1 percent in 1965, and lime output was practically unchanged from 1964 levels, but production of all other construction materials (stone and sand and gravel) was down sharply from the 1964 levels. Production of glass sand, on the other hand, rose 10 percent. Imports of building materials (except lime) declined sharply, while exports rose substantially, cement leading the way with an increase of 20 percent.

Diamond.—Imports of industrial diamond declined 6.5 percent in 1965, while imports of gem stones rose by 13 percent, total diamond imports remaining at the level of about 15 million carats. Exports rose 16 percent to 12,160,713 carats, with exports of industrial stones showing a rise of 19.5 percent.

Exports of rough gem stones totaled 1,090,001 carats in 1964 and 1,235,136 carats in 1965, having thus reached a level of from three to four times the quantity exported in 1963, before elimination of export controls on unfinished stones. Imports of rough gem stones by 1965 had risen, however, 1.3 million carats, thus more than equaling the rise in exports since 1963. The Belgian industry's supply position in rough stones thus appears not to have been seriously affected.

The diamond trade continued to be an important exchange earner for Belgium, with imports in 1965 valued at about $275 million and exports at about $288 million.[6]

Fertilizers.—Output of Thomas slag rose 3.1 percent, while production of manufactured nitrogenous and phosphatic fertilizers continued to grow. The potassic content of mixed fertilizer output declined by 6 percent. Belgium-Luxembourg imports of nitrogenous and potassic fertilizers rose by 33 percent and 2 percent, respectively, while exports of Thomas slag and manufactured nitrogenous fertilizers rose sharply.

Sulfur.—Imports of elemental sulfur increased by 9 percent, and production of sulfuric acid increased by 10 percent. Exports of sulfur increased by 3.5 percent, but both imports and exports of sulfuric acid declined sharply, indicating a substantial increase in consumption.

MINERAL FUELS

Coal continued to lose ground during 1965 to petroleum in the Belgian energy markets, accounting for 53 percent (as against 59 percent in 1964) of total consumption of primary energy. The share of petroleum and its products in the market rose to 42.8 percent from 40.6 percent in 1964. Total consumption of primary energy in 1965 was estimated at 43.0 million tons of standard coal equivalent, an increase of about 3.6 percent.

Domestic output of coal, natural gas, and electric energy accounted for 43 percent of this total, compared with 47 percent in 1964. Thus, as in most other European countries, the energy revolution in Belgium (though slower than elsewhere) involves both a shift from coal to petroleum-based energy and a shift from domestic sources to imported sources.

Coal.—The continuing decline of the Belgian coal industry is illustrated by comparative 1964 and 1965 figures for production, number of workers, and active mines. In 1965 total production was 19,786,000 tons, the total number of workers (at yearend) 75,073, and total number of active mines 54. Comparison with 1964 figures shows a reduction of 1.5 million tons of output, 9,918 workers, and 4 in active mines. Notwithstanding the clos-

[6] Where necessary, values have been converted from Belgian francs (BF) to U.S. dollars at the rate of BF50=US$1.

ing of four mines and the reduction of output, pithead stocks grew by over 900,000 tons. Despite a resulting recovery in productivity (output per man-shift), practically the whole Belgian coal industry remained financially dependent on government subsidies, whose amount was constantly growing.

Production in the Campine field (at 9.7 million tons) declined only 4.3 percent from 1964 levels and increased in share of total output from 47.6 percent in 1964 to 49.1 percent in 1965. Output of the southern fields (at 10 million tons) showed a decline of 10 percent. The four mines closed during 1965 were in the southern fields (two at Charleroi and two at Liége).

Imports declined in 1965 about 37,000 tons, and exports declined 483,000 tons; apparent total Belgian consumption was down 540,000 tons (2.2 percent) to 24.5 million tons. Belgian coal provided 17.2 million tons (70 percent) of this total, a decline of 871,000 tons from 1964. Imports of anthracite from non-EEC countries were restricted by quota after April, while quotas on industrial coal from these countries remained in force; total non-EEC imports thus showed a decrease for the year of 460,000 tons (14.4 percent); this, however, was almost completelv offset by an increase of 423,000 tons (10 percent) in imports from the European Coal and Steel Community.

Coke ovens (35.8 percent), thermal powerplants (22.8 percent) and domestic uses (18.5 percent) remained the principal markets for Belgian coal, but both the coke ovens, and domestic markets decreased their takings of Belgian coal and increased their consumption of imported coal. Coke oven imports of coal from the United States for custom coking rose from 522,000 tons in 1964 to 680,000 tons in 1965. Only the thermal power market, which increased its consumption of Belgian coal and used less imported coal, seemed to remain firmly in the hands of the domestic industry.

The Belgian Government, pressed by the financial burden of subsidies, both imposed new quotas on imports and by withdrawing subsidies from two enterprises, brought about the closure of the four mines mentioned previously. In April it suspended the recruiting of foreign miners, and at yearend it announced a new subsidy program for the coal mines involving an expenditure of about $32 million in 1966, an increase of $12 million over that of 1965. The program requires the closing of six mines during 1966, eliminating a total capacity of 2.4 million tons or 12 percent of total production. Five of these mines (Gosson, Esperance, Boubier, Ans-Rocour, and Tertre) are in the southern fields, and one (Zwartberg) is in the Campine field. The net effect of these closures, to be phased over the year, is expected to be a reduction of 1.1 million tons in 1966 output, while reduction in employment is estimated at about 9,800. Funds are to be made available for retraining workers, and special efforts (including fiscal and other incentives) are to be made to foster new investment in the affected regions to absorb the displaced workers and offset the economic effect of the mine closures. According to one report, discussions between the Government and the industry for establishment of a

single mining company in the Campine field, with Government participation, were underway in the last quarter.[7]

A large portion of mine labor, however, consists of foreign workers recruited from other countries; at yearend, 65 percent of underground workers and 53 percent of the total labor force consisted of foreigners.

The rapid decline of the Belgian coal industry is due not only to competition from other fuels and rising wage costs but also to the fact that deposits and mining conditions are less favorable than elsewhere, even within the Coal and Steel Community. Coal seams are said to be deeper and less adapted to mechanization. Productivity per man-shift, in physical terms, in recent years has been the lowest in the Community, while per-ton costs and prices have been the highest. At the same time, the shift from coal to other energy sources has proceeded less rapidly in Belgium than in other Community countries, so that restrictions on imports of third-country coal (common throughout the Community) are offset by imports of cheaper coal from neighboring Community countries. At the same time, growing pressures from steel and other industries for cheaper fuel, plus the prospects of early imports of large quantities of Dutch natural gas, are expected to further decrease domestic demand for Belgian coal.[8]

Natural Gas and Manufactured Gas.—Production of methane (firedamp) recovered from coal mines increased by about 19 percent in 1965, and a larger proportion was sold to gas companies. Manufactured gas output rose by 2.7 percent. Total gas production reached 83 million cubic meters.

Towards yearend final agreement was reached with NAM Gas Export of the Netherlands for deliveries of Dutch natural gas to Belgium, to begin at the end of 1966. The Belgian Government had objected to the terms of an earlier (1964) agreement between NAM Gas Export and Distrigaz, a Belgian distributing company, providing that Esso and Shell (partners in NAM) would each take a 25-percent participation in Distrigaz. Objections were also raised, according to reports, to the proposed prices for Dutch gas, and the Belgian Government is reported to have lodged a complaint with the EEC Commission on this score, which however was not pressed and was withdrawn when final agreement was reached.

Under the agreement, Distrigaz is to be reorganized with the Belgian Government participating for one-third, Belgian investors for one third, and Esso and Shell for one-sixth each. Distrigaz is to take over Savgaz, the other Belgian gas distribution company. By the mid-1970's, deliveries of Dutch gas to the public distribution network are expected to reach 3 billion cubic meters per year, with additional quantities going to industries. According to reports, the principle of parity between wholesale prices in Belgium and the Netherlands has been established, and the EEC Commission may be requested to settle any disagreements between the parties on prices or other terms of the contract.[9]

Petroleum.—Crude petroleum throughput in Belgian refineries increased 16.8 percent to 15.6 million tons, while output of finished products rose slightly more (17.7 percent) to 14.8 million tons. Domestic consumption rose 13 percent, to 11.6 million tons. The share of petroleum in energy consumption rose by 5.4 percent, to nearly 43 percent of the total. Petroleum and its products continued to rank first in terms of value among mineral imports, while petroleum products ranked fourth in value among exports. The trade deficit on petroleum account rose only slightly and remained approximately $200 million.

Electric Power. — The Franco-Belgian nuclear power station at Chooz, on which work proceeded on schedule in 1965, is scheduled to go into operation in 1966. Its capacity is rated at 266 megawatts of electricity output. Plans were announced during the year by Belgian utilities for two additional nuclear power stations, each of 600 megawatts. The first is to be built on the left bank of the Scheldt below Antwerp and the second on the Meuse near Hug. Plans call for the Antwerp station to go into operation by 1971.[10]

Power demand in Belgium increased by 6.4 percent in 1965, but the increase in northern Belgium (Antwerp, Ghent, and Bruges) was reported to be substantially higher.[11] Thermal power stations accounted for 98.7 percent of power output in 1965; of this total, coal-fired plants accounted for 64.1 percent and oil and gas-fired plants for 34.6 percent.

The Mineral Industry of Bulgaria

By Roman V. Sondermayer [1]

Nonferrous metals, low-rank coals, and construction materials remained the principal mineral products of Bulgaria in 1965. Lead output comprising about 3.4 percent of the world total and zinc production constituting about 2 percent of the world total were the most prominent minerals. The country also supplied between 1 percent and 0.1 percent of the world's total production of barite, cement, coal (all grades in total), chromite, copper, diatomite, fluorspar, gypsum, iron ore, manganese ore, pig iron, pyrite, salt, steel ingots, and sulfur.

During 1965 the mineral industry contributed approximately 10 percent to the social product [2] of Bulgaria, and the industry and its related facilities employed about 182,000 persons, or roughly 9 percent of the total Bulgarian labor force.

Bulgaria's mineral commodity trade was significant for the economy of the country. Mineral industry exports, predominantly ores, concentrates and ingot lead, zinc, copper, and bismuth, continued to be an important source of foreign exchange. Imports, mostly of mineral fuels, iron ore, apatite, and semimanufactured metal products, were vital for the domestic industry. Although the U.S.S.R. and other Communist countries were the predominant trading partners of Bulgaria, both in export and import, some trade was registered with France, Japan, West Germany, and Austria.

The most important developments in 1965 concerned iron and steel and nonferrous metals. The Kremikovtsi iron and steel plant started operation of a second blast furnace and its first electric furnace for production of steel. The Medet copper combine near Pirodop remained the focal point of the Bulgarian copper industry. The discovery of lead and zinc deposits near Kyustendil and expansion of the Dimitur Blagoev zinc plant near Plovdiv were the high points in lead and zinc activities.

The field of mineral fuels was highlighted by discovery of new brown coal deposits in the central part of Rodopi Mountain, and by completion of the first plant for anthracite beneficiation near the Thompson railroad station in the Balkan Mountains.

Soviet assistance in developing the mineral resources of Bulgaria continued, but participation of other Communist countries increased during 1965. East Germany and Czechoslovakia assisted in development of the Medet project and supplied equipment for open pit mines. The slow pace of construction, shortages of materials, lack of worker's incentives, and political interference in management slowed developments.

[1] Foreign mineral specialist, Division of International Activities.

[2] As in other Communist countries of East Europe, Bulgaria does not report on its gross national product (value of all final goods and services produced) but rather publishes a figure for the social product, which generally excludes items such as banking fees, rent, education, defense, public administration, and health services.

PRODUCTION

Output of most metals and minerals increased in 1965. The share of total output obtained from low-grade ores was higher than in past mineral production of Bulgaria. Mass production methods began to be introduced in surface and underground mining. The operation of beneficiation plants for nonferrous metals was under scrutiny of Soviet and Bulgarian specialists. As a result of the study, the rate

[1] In addition to reported commodities Bulgaria is known to produce gold, silver, asbestos, barite, clays, and salt.

[2] For gross weight of ore, see lead entry.

Sources: Statisticheski Godishnik na Narodna Republika Bulgaria—1965 (Statistical Yearbook of the Peoples Republic of Bulgaria for 1965). Sofia, 1965, 559 pp. Rabotnichesko Delo (Sofia). Jan 29, 1966.

of feed to Soviet-built flotation machines has been increased, and reportedly recovery of metals was higher than in the past.

In the petroleum industry the Bulgarians used conventional rotary drilling and turbodrill. Shutdown time, transportation, and production testing time of an average Bulgarian drilling rig averages about 70 percent of total available rig time. Bulgarians used conventional methods for production of crude oil. Reservoir pressure maintenance projects were not reported.

TRADE

With small exceptions, data on foreign trade in minerals were not made public in Bulgaria during 1965. Partial information from Bulgarian, Soviet Union, and United Nations sources were compiled to produce tables 2 and 3. Most of the figures are incomplete and do not represent the total Bulgarian mineral trade.

The imports of minerals and related products accounted for roughly one-fifth of total imports in 1964. Fuels and metal semimanufactures were principal import items. Exports of minerals contributed one-tenth of total Bulgarian export value in 1964. Nonferrous metals were the principal export items.

COMMODITY REVIEW

METALS

During 1965 Bulgaria had a significant production of nonferrous metals by European standards. The ferrous branch of mineral industry was modest, although much effort and money were put into development of its facilities.

Copper.—Intensive exploration and development of facilities for copper production were characteristic for Bulgaria during 1965. Medet remained the focal point for copper production. The Balkan Mountains area was the primary target of exploration crews.

As a result of intensive exploration, a new copper ore deposit has been discovered near the town of Etropole in the Balkan Mountains. Preliminary results indicated a large copper deposit by Bulgarian standards. The metal content of the ore is reportedly low, but content of gold, selenium, and other rare metals make the economic aspects of production more attractive. According to reports a new open

pit mine and a beneficiation plant were planned. By 1970 the mine and plant should be capable of processing 8 to 10 million tons of ore annually.

Although commissioned at yearend 1964, the Medet combine was not in full operation by the end of 1965. Difficulties with new plant equipment bottlenecks in technology hampered the operations of the combine. Ore production came from the open pit mine and reached a level of over 2 million tons. Output of copper concentrate was around 100,000 tons. According to Bulgarian reports the annual production of the Medet project was planned as follows: Copper ore, 3 to 4 million tons; copper concentrate—150,000 tons, molybdenum concentrate, 500 tons, pyrite concentrate—55,000 tons; and feldspar concentrate, 50,000 tons. The Medet project was a result of joint efforts by mining experts and machine building industries from Czechoslovakia, U.S.S.R., and East Germany in the framework of the SEV [3] economic cooperation. The expansion of the Georgy Damyanov copper combine at Pirodop continued during 1965. When work is completed, the combine will have a capacity of 55,000 tons of electrolytic copper, and sulfuric acid will be produced at the rate of 80,000 tons per year. Most of the Medet concentrates will be smelted and refined here.

Iron and Steel. — The construction of Kremikovtsi iron and steel integrated combine continued in 1965. The project remained the central point in the development of the Bulgarian iron and steel industry. About nine-tenths of the total capital investments in ferrous metallurgy went into the Kremikovtsi metallurgical combine. The work on the open pit mine continued. Reserves were estimated to be around 247 million tons of ore with metal content that varies from 30 to 46 percent iron and variable amounts of barites, silver, and manganese. When completed, the mine is scheduled to produce 5 million tons per year.

Lead and Zinc.—The production of lead, zinc and associated metals was higher by 10 percent than in 1964.

Most of these increases were achieved by better utilization of existing facilities, especially flotation plants. However, activities were not limited to production only. Extensive exploration for lead and zinc was conducted.

Near Kyustendill in the Ossegovo foothills new lead and zinc deposits were disclosed. Reserves and ore quality were not reported, but apparently the deposits must be of fair size with good ore because a mine and beneficiation plant will be built in the near future. Capacity of the new development will be 1.2 million tons of ore per year. The Dimitur Blagoev zinc plant near Plovdiv which employed about 3,000 workers has been expanded. A plant for production of zineb (zinc-ethylene-*bis*-dithiocarbamate) was under construction. The new facility will have an annual capacity of 12,000 tons of zineb. The output will cover the needs of all Communist countries for this important fungicide.

Manganese.—Large deposits of manganese have been discovered near Oboriste village in the Tolbukhin Okrug. Reserves and quality of ore were not reported. According to Bulgarian sources an ore processing plant will be constructed sometime in the future.

NONMETALS

Cement.—Endowed with large quantities of raw materials for production of cement, Bulgaria continued to modernize existing cement plants and build new facilities during 1965. With an annual production of 2.6 million tons and a modest domestic consumption, approximately one-fifth of the output was exported. Targets for 1970 call for an output of 5.5 million tons. The new facilities were built primarily to support more aggressive export of cement.

In the vicinity of Pleven a new cement plant was under construction. It is expected that the first stage of construction will be completed in 1966 with a capacity of 500,000 tons per year. After completion of the second stage, the plant will turn out 1 million tons of cement annually. The plant will be mechanized and its completion was planned for the end of 1968.

Fertilizers.—Having problems with agriculture, the Bulgarian authorities forced development of facilities for production of fertilizers. Plants at Dimitrov Grad and Stara Zagora remained the principal pro-

[3] SEV: Council of Mutual Aid. It includes Albania, Bulgaria, Czechoslovakia, East Germany, Hungary, Mongolia, Poland, Rumania, and the U.S.S.R.

ducers of nitrogenous fertilizers. The construction of Vratsa chemical combine continued. According to the Bulgarian news agency, Bulgarian Telegraph Agency (BTA), the Vratsa plant should start production in the fourth quarter of 1966, and production targets for 1966 were set at 12,000 tons of nitrogen fertilizers.

Fluorspar.—The first Bulgarian fluorspar concentrating plant was under construction in southwestern part of the Rodopi Mountains during 1965; the exact location of the plant was not disclosed. It is expected that production will start early in 1966. When in full operation, the plant will cover all domestic needs and provide 10,000 to 12,000 tons of fluorspar for export. The plant was designed by (Niproruda) Industrial Ores Scientific Research Designing Institute. The plant is supposedly highly mechanized and equipped with machinery produced in Bulgaria.

Gypsum.—The new gypsum mine near Vidin went into production at the beginning of 1965. At yearend the production totaled about 50,000 tons of gypsum.

Salt.—Exploratory drilling led to discovery of salt deposits near Mirovo. Reportedly the total thickness of the salt beds runs about 1,400 meters. At yearend exploration was not concluded, but calculated reserves indicated a large deposit.

MINERAL FUELS

Coal.—With token production of oil and gas, coal remained Bulgaria's principal source of energy during 1965. However, importing of high-rank coals was necessary because the country's production of solid mineral fuels consisted mostly of brown coal and lignite.

Bulgarians were active in exploration and development of new production facilities. Exploration crews discovered a new brown coal deposit in the central part of the Rodopi Mountains. Coal from the new deposit has a calorific value of 5,500 calories per kilogram and an average ash content of about 35 percent; reportedly sulfur content is low. No information on reserves were disclosed. The Georgi Dimitrov coal trust started work on a new open pit mine near Buchino village. In 1970 when the mine is scheduled to be in full operation, production will reach 1.5 million tons of coal per year. The decision for mine development was based on reserves of about 19 million tons of coal.

To equip this and other open pit operations, long term arrangements were made with East Germany for delivery of excavators and conveyors belts. The capacity of each excavator will be about 5,000 cubic meters per hour.

At the beginning of 1965 the first plant for beneficiation on anthracite mined in the Svoge anthracite basin was commissioned in the Iskur gorge of the Balkan Mountains, near the Thompson railroad station. The name of the plant is Tsentralno Obogatitelnaya Fabrika Thompson (Ts. O. F. Thompson) (Thompson Central Beneficiation Factory). The French firm Preparation Industrielle des Combustibles (PIC) designed the plant. In a wet plant with crushing facilities, two beneficiation methods are used, gravitation and flotation. The plant's design capacity was about 300,000 tons of raw anthracite per year.

Petroleum and Natural Gas.—Although efforts were made to expand both crude production and refining, the Bulgarian oil industry remained insignificant by world standards during 1965.

Imports of crude oil and refined petroleum products covered most of the domestic needs. The majority of liquid fuel imports came from the U.S.S.R.

During 1965 Dolni Dubnik area, near Pleven, and Tyulenovo, at the Black Sea shore, remained centers of oil industry activities. Development of the Dolni Dubnik oilfield continued. Several new producing oil wells were drilled, and new facilities for storage of oil have been added in the area. Preparation for exploratory offshore drilling in the Black Sea near Shabla village, in the general area of Tyulenovo, was underway in the fall of 1965. The location of the first group of wells is approximately 1,300 meters from the shore line. Plans were made to build an artificial island from which several directional wells can be drilled. The development of the Chiren gas field continued. A new gas horizon was discovered at 1,930 meters during 1965. Based on this deposit of natural gas, a pipeline 19 kilometers long will be built to connect the field with industry at Vratsa.

The refinery part of the Bulgarian petroleum industry was the better part of the oil operation. The new refinery at

Burgas which operates on Soviet crude oil was expanded during 1965. Atmospheric distillation capacity was increased by 500,000 tons per year. Equipment for the new plant was imported from the U.S.S.R. Plans were made to increase the refinery capacity from 2 million to 5 million tons per year in the near future.

On the basis of expected development drilling in the Dolni Dubnik field, Bulgarian authorities were planning industrial development of the whole area. A new refinery was planned at Dolni Dubnik. The plant will have a capacity of 1 million tons of crude oil per year. The second stage of construction will include a petrochemical plant. No date was fixed for the beginning of operations.

The Mineral Industry of Czechoslovakia

By Roman V. Sondermayer [1]

The general economic recovery of Czechoslovakia was partially reflected in higher output of the country's principal mineral industries and related facilities during 1965.

Mineral resources remained relatively limited, except for coal, kaolin, and magnesite. Substantial imports of mineral raw materials, primarily from other Communist countries, were necessary to cover the needs of its extensive metallurgical and fabrication facilities.

The 1965 mineral output value was about 3 percent larger than that of 1964. New incentive awards and more liberal governmental rules in managing the economy contributed to better performance of the mineral industry. The output of more prominent mineral and metal products expressed in approximate percentages of the total world production were as follows: Magnesite 5.8; coke 3.8; pig iron 1.8 and steel 1.9; antimony 3.2.

Few important mineral developments occurred, chiefly because emphasis was given to improvement of existing facilities and to imports of raw material. The construction of East Slovakian Iron Works continued, and modernization of coal and magnesite mines and related facilities was underway.

PRODUCTION

According to official reports, the mineral industry fulfilled its plans for 1965. Compared with the 1964 increase, a production increase was noted in Czechoslovakia's principal mineral commodities, such as coal and products of the iron and steel industry. Coal was the largest mine product by volume. Because brown coal and lignite together comprised the bulk of the country's coal production, approximately 70 percent of all coal produced was obtained by open-pit mining.

TRADE

Mineral trade was of great importance to the Czechoslovakian economy during 1965. Mineral exports, limited to metal semimanufactures, coal, coke, kaolin, and magnesite, constituted about a quarter of total exports by value.

The country's mineral imports consisted mainly of raw materials. Value of mineral imports were approximately $0.8 billion[2] in 1964. Most of the country's requirements for nonferrous metals, iron ore, crude petroleum, and bituminous coal were met by imports.

Published materials on the foreign trade of Czechoslovakia are incomplete and do not include information on destination of export or the origin of imports. Tables on exchange with the U.S.S.R. show the importance of the U.S.S.R. as a trading partner. Moreover, Soviet statistics show the export of certain commodities to Czechoslovakia that are not recorded in Czechoslovakian import publications.

COMMODITY REVIEW

METALS

Aluminum.—Czechoslovakia's only plant for production of aluminum, near Ziar nad Hronom in central Slovakia, received

[1] In addition to the commodities listed, Czechoslovakia is believed to produce arsenic, silver, uranium, barite, feldspar, and graphite.

bauxite from Yugoslavia, Hungary, and British Guiana. Production was 2,000 tons more than in 1964.

Copper.—A new copper mine and a flotation plant of unreported capacity went into production at Zlaté Hory, north Moravia, in the fall of 1965. The mine was producing ore from a depth of 286 meters.

To achieve more economical operations, the management closed two shafts and slowed down production from a third in polymetallic mines in Banská Štiavnica. Although only two shafts are now in production, output in this area reportedly was increased, and production costs went down.

Gallium.[3]—The first pure gallium (about 2.7 kilograms) was produced by the Julius Fucik Plant of the Spolana Chemical Enterprise in Kaznějob; production of larger quantities of gallium reportedly will start in coming years.

Iron and Steel.—Iron ore production, although higher than that recorded for 1964, remained below the record high recorded in 1963. Economic factors influenced authorities to turn toward importing iron ore and abandoning the production of low-grade domestic ores. Nevertheless, discovery of iron ore deposits in the vicinity of the village of Vyhne was announced, and plans were set to start production in

1967. Iron ore reserves and capacity of the new mine were not disclosed. To make import of iron ore more independent from foreign shipping companies, the Government of Czechoslovakia ordered a 35,000-deadweight-ton bulk carrier in the United Kingdom. The value of the contract was around $2 million.

The steel industry was modernized, and new equipment for continuous casting was purchased from Sweden. Construction of the East Slovakian Iron Works continued. Equipment was tested in the wide-sheet hot rolling mill of the plant. The line will have a capacity of 400,000 tons of sheet per year. The overall construction was behind planned targets. This delay may offset the advantage gained by completion of a wide-gage railway line from the Soviet border to the plant to eliminate the need for reloading imported ore at the border. The 88-kilometer railroad line was ready for testing in fall of 1965.

NONMETALS

Traditionally self-sufficient in major nonmetals, Czechoslovakia continued efforts to improve quality and increase quantity of its production with an aim to expand export.

Diamond.—Exploration for diamonds was

conducted in northwest Czechoslovakia. Through yearend results were not announced, but reports hinted at the possibility of large discoveries, because the geological structures of this area and those in Yakutia, U.S.S.R., are similar.

Fertilizer Materials.—The expansion of facilities for mineral fertilizer production continued during 1965. Construction of a new plant was started at Lovosice, northern Bohemia. The plant will be completed in 1968, and its annual capacity will be 250,000 tons of combined fertilizer. The factory will be part of the North Bohemia Chemical Enterprise.

A nitrogen plant of unreported capacity was under construction at Strážce in east Slovakia. The new nitrogen factory is part of the East Slovak Chemical Combinat. The basic raw material, natural gas, will be supplied by the U.S.S.R. through the new gas line connecting Soviet fields with Czechoslovakia.

Graphite. — Czechoslovakian authorities announced the beginning of production of pure graphite in a new plant at Tyn nad Vltavou, but capacity was not disclosed. The plant products were for use as lubricants, in atomic energy reactors, and in unspecified aerospace applications.

Iodine.—A plant for iodine extraction was under construction at the Doubrava coal mine in Orlova. The technology for iodine production was developed by the Institute at Kutná Hora. The raw material is water from the mines in the Ostravsko-

Karvinská Pánev (Ostrava Kravina Basin). Average content of iodine is 10 to 25 milligrams per liter of mine water. The plant was scheduled to start partial production in late 1966.

Limestone.—The new limestone quarry at Včelary southwest of Košice was under development during 1965. The completed quarry will have a capacity of 5 million tons of crushed limestone per year and will be a highly automated operation. The East Slovakian Iron and Steel Works will be the primary consumer of the quarry's output.

Magnesite.—During 1965 facilities for production of magnesite were modernized, and output was increased.

Perlite.—Facilities for production of expanded perlite underwent modernization. Plans called for a production of expanded perlite eight times higher than the present undisclosed level by 1970.

Geologists from the town of Nová Baňa presented the Košice Ceramics Enterprise with verification of deposits of over 2 million cubic meters of perlite. These deposits initially reported in 1963 are located in the vicinity of Lehôtka pod Brehy in Okres Ziar nad Hronom.

Silica.—Deposits of high-grade silica have been discovered near Švedlar, eastern Slovakia. The discovery was significant because silica deposits near Lučenec in central Slovakia were exhausted. The quarry will be operated by the ceramic plant at Košice.

MINERAL FUELS

Although completion of crude oil pipeline to Czechoslovakia from the U.S.S.R. pushed up the participation of crude oil in the country's overall energy balance, coal remained the principal source of energy during 1965.

Coal.—Bituminous and brown coals accounted for about 80 percent of the energy supply in 1965. The chronic shortage of mine laborers continued and prompted efforts for increased use of mining machinery bought in West Germany, Belgium, Sweden, and Switzerland. Difficulties persisted in the field of coal preparation, and the quality of coal was below the Czechoslovak standards. Weather conditions and lack of storage facilities caused decomposition of coal. Large quantities of coal dust were available in all mines at the end of 1965.

New economic reform and the new system of bonuses forced management to make serious examination of the economic aspects of mine operations. As a result, the Czechoslovak Army Coal Mine in Rynholec, and the Týnec Coal Mine near Plzen were closed. Miners were transferred to operations in the Kladenská Panev (Kladno Basin).

While closing inefficient mines, the Government was also developing new mines and washing facilities in the Northern Mining District near Bílina. A new open-pit mine in this district will have an annual capacity of 15 million tons of coal when completed in 1969.

Czechoslovak authorities announced discovery of coal seams 10 meters thick between Frenštát pod Radhoštem and Trojanovice in the Beskids Mountains of north Moravia.

Petroleum and Natural Gas.—During 1965, crude oil production remained unimportant. Refined petroleum output, while much larger, was still a minor part of the energy supply. The Druzhba pipeline brought most of the crude oil from the U.S.S.R. Drilling activities were concentrated in the eastern part of the country. While drilling on a location near the village of Stretava in the Okres Michalovce, a gas blowout occurred and a fire started. The blowout created a crater, and the rig was lost. After a month of firefighting, when the pressure of the reservoir dropped, the fire died. According to reports, the blowout was caused by a local accumulation of high-pressure gas at the depth of 300 meters.

The Mineral Industry of Denmark [1]

By F. L. Klinger [2]

Denmark's small but active mineral industry continued to expand in 1965. Since the exploited mineral resources of the country were limited to nonmetallic construction materials, lignite, and a little bog iron ore, mining and quarrying accounted for only a fraction of 1 percent of the gross domestic product, estimated at $10.8 billion in 1965 (at market prices).[3]

Expansionary developments in the mineral industry were largely concerned with processing imported materials. Plants were completed or under construction in 1965 in the iron and steel, petroleum refining, fertilizer, and cement industries. The volume of sales of major mineral industry commodities was greater than in 1964 with the exception of structural clay products and solid fuels. In Jutland, development of subsurface salt deposits was well underway and exploration drilling for oil and gas was about to begin. Offshore (North Sea) boundary agreements were also successfully negotiated by Denmark with Norway, Netherlands, and the United Kingdom in 1965, and a limited agreement was reached with West Germany.

The mineral industry employed an estimated 18,000 persons in 1965, including about 3,500 in mining and quarrying.

PRODUCTION

The gross value of crude minerals produced by Denmark in 1965 was estimated at $24 million. Of this value, nonmetals (mainly stone, sand and gravel, and diatomaceous earth) [4] constituted 70 percent; fuels (lignite and peat), 29 percent; and metals (bog iron ore), 1 percent.

In mineral and metal processing, the principal increase in production occurred in petroleum products, output of which rose by more than 20 percent, compared with 1964. In the basic metal industry (iron, steel, and nonferrous metals), turnover increased nearly 15 percent to $75 million, while the volume of output rose 9 percent. In the large nonmetallic mineral processing industry (stone, clay, and glass products), turnover increased 6 percent to $215 million, and the volume of output rose 3 percent. Output of structural clay products was less than in 1964, while production of phosphatic fertilizer was again valued at $30 million.

In 1963, the gross value of production of the mineral industry [5] was estimated at $313 million, equivalent to 8 percent of total industrial output and 3.6 percent of gross national product.

[1] Excluding Greenland, covered under North America section.

[2] Physical scientist, Division of International Activities.

[3] Det Statistiske Departement (Copenhagen). Statistiske Efterretninger. V. 58, No. 15, March 29, 1966. Values in Danish kroner converted to U.S. dollars, using DKr6.907 equals US$1.00.

[4] Not including materials for manufacture of ordinary brick.

[5] Including manufactures of the peat and lignite, primary metals, petroleum and coal, fertilizer, and the stone and clay industries from domestic and imported raw materials. Does not include glass, porcelain, or manufactures of precious metals or stones.

e Estimate. r Revised. NA Not available.

[1] Quantities of merchantable iron ore, as given by United Nations and Organization for Economic Cooperation and Development (OECD) publications, are 20,000 to 29,000 tons less than the figures shown for 1961 through 1964.

[2] Made from imported strip.

[3] Manganese obtained from domestic bog iron ore.

TRADE

Liquid fuels and rolled steel continued to be the principal items in Denmark's mineral commodity trade in 1965. These materials jointly accounted for 47 percent of the value of exports and 62 percent of the value of imports.

Metals accounted for 44 percent of the value of mineral commodity exports, followed by nonmetals and fuels with 28 percent each. Iron and steel, copper, construction materials, and petroleum products were the principal items. Of the value of imports, fuels accounted for 49 percent and metals for 40 percent; the ranking commodities, in order of importance, were rolled steel, petroleum products, fertilizer materials, copper, and aluminum.

	Million dollars		Mineral commodities' share (percent)
	Mineral commodities	Total trade	
Export:			
1964	74.8	2,085	3.6
1965	78.7	2,276	3.4
Import:			
1964	608.7	2,612	23.3

The relative importance of metal and and mineral commodities to total Danish trade is shown by the following tabulation:

Sweden was the principal market for Danish exports [6] of mineral commodities, followed by West Germany and Norway. Exports to Sweden were valued at $27.7 million in 1965, of which petroleum products accounted for 58 percent.

West Germany was the principal supplier of Danish imports,[7] with mineral commodities valued at $118 million, followed by the United Kingdom and Norway. Of the value of British and Norwegian shipments, fuels and fertilizers, respectively, made up more than 60 percent.

Danish exports to Iceland, valued at $258,000, consisted mostly of metal semimanufactures. Imports from Iceland (mostly metal scrap) were valued at $10,000.

The countries of the European Common Market (Belgium, France, West Germany, Italy, Luxembourg, and the Netherlands) accounted for over one fourth of all Danish mineral commidity exports and provided almost two fifths of all imports of these commodities.

[6] Not including nonmetallic mineral manufactures or precious and semiprecious stones S.I.T.C. (Standard International Trade Classification (Revised), Division 66). Exports of these commodities were valued at $24 million, and imports were valued at $47 million, in 1965.

Table 2.—Denmark: Exports of metals and minerals [1]—Continued

(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal destinations, 1964
Sand:				
Foundry and glass sand	3,165	25,727	166,097	Sweden 20,533; West Germany 1,534.
Other	121,173	95,963		West Germany 76,196; Sweden 15,931.
Mineral substances, not elsewhere specified.	2,496	2,438	2,503	West Germany 1,746; United Kingdom 225.
Slag and ash, not elsewhere specified	54,160	78,486	104,696	All to West Germany.
Mineral fuels:				
Asphalt, natural, including manufactures.	729	2,525	773	Japan 1,261; Finland 914; Sweden 153.
Coal derivatives	23,364	17,953	33,135	Netherlands 8,186; West Germany 4,752.
Coke	53,145	44,531	51,046	Sweden 16,537; Norway 15,358.
Lignite, including briquets	51,536	44,266	15,021	West Germany 44,247.
Peat, including briquets and litter	6,543	6,064		West Germany 6,006.
Petroleum refinery products:				
Gasoline	87,272	r 176,837	264,137	Sweden 159,203; United Kingdom 15,634.
Kerosine, including white spirit	r 18,799	r 7,436	4,660	Norway 4,419; Sweden 1,534.
Distillate fuel oil	42,714	111,438	213,624	Sweden 109,622.
Residual fuel oil	218,986	313,698	196,169	Sweden 258,306; Norway 32,105.
Lubricants, including grease	r 5,841	r 6,446	12,822	Norway 5,596; Sweden 2,326.
Liquefied petroleum gases	r 1,079	2,714	2,972	West Germany 1,091; Sweden 918.
Bitumen and other	3,169	4,068	2,050	Sweden 1,457; West Germany 803.
International bunkers:				
Distillate fuel oil	179,000	186,000	168,000	
Residual fuel oil	259,000	352,000	333,000	

r Revised. NA Not available.
[1] Including synthetic corundum.
[2] Including alloys.
[3] Including spiegeleisen and grit, sponge, or powder of iron or steel.
[4] Estimated from quantities reported in units of 100 kilograms.
[5] Including those of magnesite, diatomite, and other refractory materials.
[6] Less than ½ unit.

Table 3.—Denmark: Imports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal sources, 1964
Metals:				
Aluminum:				
Bauxite, oxide and hydroxide [1]	760	759	3,246	British Guiana 406; United States 173.
Scrap [2]	1,234	936	1,273	Sweden 742; United States 159.
Unwrought [2]	5,802	7,237	9,310	Norway 4,670; Canada 1,172.

Total do	6,451	6,984	7,464	

r Revised figure. • Estimate. NA Not available.
[1] Not including synthetic corundum.
[2] Including alloys.
[3] Including spiegeleisen, grit, sponge, and powder of iron or steel.
[4] Including wire rod.
[5] Estimated from quantities reported in units of 100 kilograms.
[6] Calculated from quantities reported in kilograms.

COMMODITY REVIEW

METALS

Iron and Steel.—*Iron Ore.*—Production and exports of bog iron ore from south Jutland were sharply reduced in 1965, compared with previous years. Depletion of reserves may have been responsible for the decline in output. Previous reports had indicated that the deposits would be largely mined out by 1969. Mined on a commercial scale since 1951, the ore has been used chiefly for gas purification in Denmark, Sweden, and the United Kingdom. A small proportion of annual output, containing 10 percent or more of manganese, was used to produce manganese sulfate for the fertilizer industry.

Pig Iron.—Cement-Jern Konsortiet, a subsidiary of the F. L. Smidth Co., continued to account for all Danish production of pig iron. Capacity of the company's rotary furnaces at Aalborg was reported to be 80,000 tons annually in 1965. Using scrap, pyrite cinder, chalk, gashouse coke fines, and fuel oil, the company produces hematite pig iron and an estimated 25,000 to 30,000 tons of cement clinker annually.

Imports of pig iron and ferroalloys in 1965 were 8 percent less than in 1964, while the level of stocks remained at about 60,000 tons throughout the year.

Scrap.—Domestic iron and steel scrap continued to provide the principal raw material for the Danish iron and steel industry. Stocks of scrap increased during 1965 to 193,000 tons at yearend, despite rising metal production and an increase in net exports.

In 1964, scrap consumption for steelmaking was 290,000 tons, of which 91 percent was used in open hearth furnaces and the remainder in electric furnaces. An additional 72,000 tons was used for making pig iron.

Steel.—Danish production, imports, and apparent consumption of steel continued to rise in 1965.

The distribution of production remained the same as in 1964. The principal Danish producer, Det Danske Staalvalsevaerk (DDS), continued to account for all reported output of ingots, bars, sections, and plates. The company accounted for an estimated 90 percent of total domestic output from its open-hearth furnaces and rolling mills at Frederiksvaerk in North Zealand. The remaining 10 percent consisted of castings, mostly produced by the Copenhagen firm of Burmeister & Wain Maskin-og Skibsbyggeri A/S and by Varde Staalvaerke A/S on the west coast of Jutland. The latter two firms also account for most of Denmark's steel production from electric furnaces, which amounted to 22,000 tons in 1964. Total Danish productive capacity for crude steel in 1965 was estimated at 410,000 tons annually.

Imports of steel increased by 9 percent in 1965. The quantity of ingots and other crude forms was doubled, and imports of plates and sections rose by 70,000 tons. Total imports included 42,000 tons of carbon and alloy steel semimanufactures. The total value of all steel imports in 1965 was $183 million ($167 million in 1964), while exports were valued at $17 million ($19 million in 1964).

Apparent domestic consumption of steel, reportedly 1,454,000 tons in 1964, was estimated to have increased by 5 percent in 1965. Consumption in 1964 had been 23 percent higher than that in 1963.

A 22-stand section and wire rod mill was completed in 1965 at the Frederiksvaerk plant of DDS. Also under construction was a hot blast cupola furnace scheduled to begin production in 1966. Total employees at Frederiksvaerk in 1965 numbered 1,608, approximately three-fourths of total employees in Danish iron and steel works.

Nonferrous Metals.—Imports of nonferrous metals,[8] including alloys, in 1965 increased to 100,000 tons, as compared with 93,000 tons in 1964. Semimanufactures made up slightly more than half of this quantity. Copper and aluminum continued to account for the bulk of imported semimanufactures, and lead and zinc accounted for most of the imports of unwrought metal. Net imports of unwrought and scrap metal in 1965 included 15,000 tons of lead, 9,500 tons of zinc, and 7,000 tons of aluminum. At the end of the year,

[8] Unwrought, scrap, and semimanufactures.

metal stocks totaled 46,543 tons, about half of which consisted of copper.

Metal consumption for remelting in Danish nonferrous works in 1963 (latest year for which statistics were available) was 80,000 tons (82,000 tons in 1962), including 34,000 tons of scrap and 23,000 tons of copper and copper alloys. In November of 1963, the nonferrous works employed 1,400 persons.

NONMETALS

Cement and Other Construction Materials.—Building activity, including industrial construction, was reportedly at a record level during the first 9 months of 1965. As compared with 1964, imports of most construction materials increased, while exports of cement, gravel, and structural clay products declined. Estimates by the Organization for Economic Cooperation and Development (OECD) indicated that a 350,000-ton increase in annual productive capacity for cement was expected during 1965, raising the total annual capacity to 2,175,000 tons by yearend. Domestic consumption of cement in 1964 was estimated at 1,784,000 tons, of which 61 percent was delivered in bags and 39 percent in bulk. Ready-mixed concrete accounted for nearly 20 percent of total deliveries.

Nearly all Danish cement continued to be produced in the Aalborg area of north Jutland, by A/S Aalborg Portland Cement-Fabrik, and Dansk Andels Cement-Fabrik. The former company, which accounts for about 85 percent of domestic production, also operated a plant near Copenhagen. The industry employed an estimated 1,900 persons in 1965.

Fertilizer Materials. — Early in 1965, Dansk Svovlsyre-og Superphosphatfabrik A/S, Danish producer of sulfuric acid and fertilizers, announced plans to build a nitric acid plant at Fredericia, Jutland. Upon completion of the plant in early 1967, the company plans to produce nitrogenous - phosphatic - potassic fertilizers. The company is also part owner of Dansk-Norsk Kvaelstoffabrik A/S, a Danish-Norwegian fertilizer firm which completed a plant at Grenaa, Jutland, in late 1964. Annual production capacity of the latter plant was rated at 75,000 tons of ammonium nitrate and 10,000 tons of anhydrous ammonia. In the fertilizer year 1964–65, Danish consumption of fertilizers was equivalent to 168,800 tons of nitrogen; 150,200 tons of potassium; and 54,100 tons of phosphorus.

Salt.—Production of salt at the rate of 150,000 tons per year was expected to begin near Mariager, east Jutland, in late 1966. Dansk Salt I/S, a company formed by the Øresund Cryolite Co. and a Dutch firm, will extract the salt by a solution process from subsurface deposits. Completion of the plant was scheduled for mid-1966.

MINERAL FUELS

Solid Fuels.—Production of lignite and peat, the only natural mineral fuels produced in Denmark, has been gradually declining for several years and this trend apparently continued in 1965, although statistical data on 1965 output was not yet available. Thermal powerplants remained the major lignite consumers. In 1964, consumption in powerplants was 100,000 tons less than in 1963.

Total imports of solid fuels by Denmark in 1965 declined 12 percent in volume and 15 percent in value, compared with 1964. Imports of coal from Poland remained at the 1964 level while deliveries from the United Kingdom and the Soviet Union decreased by 220,000 tons and 90,000 tons, respectively. Imports of coke from British sources were less than half the volume of 1964, although West Germany remained the principal supplier, and shipments from the U.S.S.R. increased.

Petroleum. — *Exploration.*—The Dansk Undergrunds Consortium planned to spud in its first exploration well in November 1965, in east Jutland. The well was identified as Ronde 1, near Folle. The drilling contract was awarded in July to the U.S. firm of Reading and Bates Offishore Drilling Co. of Houston, Tex.

The consortium was joined by two more companies (Standard Oil Co. of California, and Texaco Inc.) in 1965, bringing the number of participating firms to five. The consortium previously consisted of Danish (A. P. Møller) interests (40 percent), Gulf Oil Co. of Denmark (30 percent),

and Shell Denmark Ltd. (30 percent). The concession to explore for hydrocarbon resources in Denmark was granted in 1961 by the Danish Government to the A. P. Møller interests for a period of 50 years.

During 1965, Denmark negotiated agreements with the governments of Norway, Netherlands, and the United Kingdom concerning offshore international boundaries in the North Sea. The agreements were based on the median line principle. A limited agreement was also reached with West Germany in March, extending the Danish-West German land boundary westward about 30 miles to a point equidistant from Blåvandshuk, Denmark, and the West German island of Sylt. Beyond that point, no agreement had been reached by yearend.

Crude Oil Trade.—Imports of crude petroleum were 12 percent more than in 1964. Kuwait continued to be the principal supplying country.

Petroleum Products.—Dansk Esso A/S continued to be the leading producer of petroleum products in 1965 and accounted for 56 percent of Danish production. Output of the company's Kalundborg refinery was 14 percent more than in 1964, with fuel oils accounting for most of the increase. The refinery had a capacity of 25,000 barrels per day.

Gulf Oil Refinery A/S increased its share of production to 37.5 percent in 1965 (33.8 percent in 1964). The company's 30,000-barrel-per-day refinery at Stigsnaes increased production by 33 percent in 1965. Output of distillate fuel oil was 1.2 million barrels more than that of 1964.

At Fredericia in western Jutland, the 40,000 barrel-per-day refinery of Dansk Shell A/S was nearly completed by yearend. The plant was expected to come on stream in early 1966.

The remainder of Danish production, consisting mainly of naphtha, petrochemical feedstocks, liquefied petroleum gases, lubricants, and asphalt was produced by the Maersk refinery (A. P. Møller, associated with Gulf Oil Co.), and several smaller plants. A 5,300-ton tanker was commissioned in February by the Møller-Gulf interests, and a second tanker was being fitted out at yearend.

Imports of petroleum products increased by 10 percent in 1965 and were valued at $177 million. Inland consumption of petroleum products in 1964 was 5,065,000 metric tons, of which distillate and residual oils made up 70 percent and motor gasoline comprised 22 percent. It was estimated that liquid fuels provided 70 percent of Danish energy requirements in 1965. Principal sources for imports of refined products in 1965 were again the United Kingdom and the Netherlands.

Electric Power.—Consumption of electric power in 1965 was 8.8 billion kilowatthours, of which 80 percent was produced by Danish thermal plants, and the remainder was imported mainly from Sweden. In 1965, a 183-kilometer power transmission line (direct current 250 kilovolts, single phase) was completed between Aalborg in Jutland and Goteborg in Sweden. This line, (known as the Konti-Skan connection), connects the Scandinavian power grid with the continental net through West Germany's Nordwestdeutsche Kraftwerke system.

Installed production capacity of Danish powerplants at the end of 1964 was 2,370 megawatts, with an additional 295 megawatts scheduled to be provided by new plants in 1965. Thermal powerplants comprised more than 99.5 percent of the total capacity.

The Mineral Industry of Finland

By F. L. Klinger [1]

The year 1965 was one of continuing growth for the Finnish mineral industry. The volume of production of the mining industry increased 4 percent over that of 1964, and the gross output of the country's 11 metal mines increased by 16 percent. Output of the basic metals industry increased 14 percent as production of pig iron reached the million-ton level. The reduced output of nonferrous metals was partly offset by more favorable prices. The chemical and building materials industries increased production by 7 and 9 percent, respectively. These developments contributed to 5-percent increases in Finland's industrial production and gross national product (GNP) in 1965.

A full year's production was realized at the Raajärvi, Korsnäs, and Metsämonttu mines, all of which were opened in late 1964. Mine development was continued at the Luikonlahti copper deposit; additional ore reserves were announced at the Kotalahti mine (nickel) and at Outokumpu (copper). Modifications intended to increase productive capacity were underway at the Otanmäki and Vihanti mines. In 1965 exploratory work on deposits of copper, nickel, iron, sulfur (pyrite), apatite, graphite, and talc was reported by several companies.

A significant development in 1965 was the announcement by Outokumpu Oy. that the chromite deposits near Kemi would be mined on a commercial scale, and that a ferrochromium plant would be built at Tornio. The Finnish deposits are the most significant resource of chromium known in West Europe.

New plants, completed in 1965, included a new blast furnace at Turku, a phosphoric acid and fertilizer plant at Uusikaupunki, and a sulfuric acid plant at Harjavalta. Construction was continued on the Raahe steelworks and on the petroleum refinery near Porvoo. A large feldspar processing plant neared completion at Kimito. A cobalt recovery plant was also being built at the Kokkola pyrite works.

Employment in the industry was slightly higher than in 1964. Wages increased 3.8 percent at the beginning of 1965 and were expected to rise another 5 percent during 1966. Labor agreements, reached during 1965, were expected to establish a 40-hour workweek throughout Finnish industry by 1970.

A new law, governing offshore explorations, was passed in March. Details were not available.

PRODUCTION

The value of Finnish mine and quarry production in 1965 was estimated at $63.4 million. Metals, principally copper, zinc, iron, and vanadium, constituted 78 percent of this value, followed by nonmetals (principally limestone) with approximately 22 percent, and fuels (peat) less than 1 percent.

The gross value of metals and mineral products,[2] made from indigenous and imported raw materials, was estimated at $228 million in 1965. Metals,[3] (principally iron, steel, and copper) accounted for 54 percent of this value, followed by mineral fuels (petroleum products and coke) with 32 percent, and nonmetals (mostly cement), accounted for 14 percent.

TRADE

The relative importance of mineral commodities to total Finnish trade is reflected in the following tabulation:

	Trade value (million dollars)		Share of total (percent)
	Mineral commodities	All commodities	
Exports:			
1964	74	1,291	5.7
1965	98	1,427	6.8
Imports:			
1964	335	1,505	22.2
1965	394	1,646	23.9
Net trade balance:			
1964	−261	−214	XX
1965	−296	−219	XX

XX Not applicable.
Sources: Statistical Bureau, Board of Customs (Helsinki). Foreign Trade (Ulkomaankauppa). December 1964 and 1965, pp. 56. United Nations. Commodity Trade Statistics, 1964. Series D, v. 14, New York, 1965, pp. 3823–3858.

The increased deficit in 1965 was principally due to the larger imports of liquid fuels, fertilizer materials, and steel semimanufactures.

Metals (principally iron and steel, copper, and zinc) continued to account for more than 95 percent of total mineral commodity exports, followed by nonmetals (3.7 percent) and mineral fuels (0.7 percent). Of the total value of mineral commodity imports, metals (principally iron and steel, aluminum, and copper), accounted for 45 percent, closely followed by mineral fuels, with 42.3 percent. Nonmetal imports were valued at $49 million in 1965, of which approximately $28 million was for fertilizer materials.

Sweden, the principal buyer of Finland's exports of minerals and metals, accounted for more than twice the value of any other country in this category. The Soviet Union, while importing only about $5.6 million worth of Finnish metals and minerals, retained its preeminent position as the major supplier. Principally because of crude oil and coal imports, Finnish purchases from the U.S.S.R. were valued at more than $137 million, almost four times as much as from any other country. For commodities other than fuels, Finland's imports from the Soviet Union were approximately equal in value to those from Sweden, West Germany, and the United Kingdom.

COMMODITY REVIEW

METALS

Aluminum.—Apparent consumption of aluminum in all forms increased in 1965. Imports of unwrought aluminum for the metal industry and of hydroxide for the chemical industry again increased by approximately 2,000 tons, while exports of wire manufactures (mostly cable) were 40 percent less than in 1964. Total value of imports (excluding metal manufactures) rose to about $16 million. Kuusakoski Oy., a producer of aluminum ingots from scrap, was increasing the capacity of its plant at Kauklahti, near Helsinki.

Chromite.—The Elijärvi chromite deposits were being prepared for commercial production by Outokumpu Oy. In the spring of 1966 the company will begin construction of a plant at Tornio, to produce ferrochromium for domestic consumption and export. The plant is scheduled for completion in late 1967, at which time mining at Elijärvi will be at the rate of 100,000 to 150,000 tons of ore per year. The entire mine output will be processed at Tornio.

Outokumpu's decision came after several years of geological and metallurgical research. The Elijärvi deposits are the only known source of chromite in northwest Europe, and reportedly contain about 20 million tons of ore averaging between 20 and 25 percent chromic oxide. The low chromium to iron ratio in the chromite has presented the main obstacle to exploitation of the deposits.

Cobalt.—In 1965 a plant for recovery of cobalt was under construction at the Kokkola works of Outokumpu Oy. The metal will be recovered from pyrite concentrates which have been exported, mainly to West Germany, for many years. The recovery process to be used at Kokkola was developed by Sherritt Gordon Mines Ltd., of Canada. The principal source of cobaltiferous pyrite will probably be the Outokumpu mine, but the mineral also occurs in ore at Kotalahti, Otanmäki, Nivala, and elsewhere in Finland. During 1965, some cobalt was recovered as hydroxide in the nickel refinery at Harjavalta.

Copper.—The 7-percent decrease in copper output by Finnish mines in 1965 was mainly due to ore production cutbacks at the Outokumpu mine, where output was reduced for the fourth successive year. All the principal mines, except the Pyhäsalmi mine, produced less copper in 1965. Metallurgical results at Pyhäsalmi in 1965 were markedly better than in previous years; the copper content of concentrate increased to 22.5 percent, as compared with 15 to 18 percent in previous years. This resulted in a 7-percent increase in mine copper production at Pyhäsalmi despite a 25-percent reduction in the tonnage of concentrate.

Reduced mine output was accompanied by unusually heavy imports of refined cop-

per—double the quantity imported in 1964—and domestic consumption increased by 30 percent to about 29,000 tons. This situation arose from the increased utilization of copper by Outokumpu Oy. for the company's semifinished and finished product lines, with consequent importations of copper by the Finnish Cable Works (Suomen Kaapelitehdas Oy.). Finland maintained a trade surplus in copper in 1965, but it was reduced to less than $2 million as compared with $9 million in 1964.

In October, Outokumpu Oy. began installing facilities at its Harjavalta smelting works to recover copper from slag. This was expected to increase copper recovery to nearly 100 percent as compared with the present level of 97 to 98 percent.

In 1965 development of the Luikonlahti copper deposit was continued by the private firm, Malmikaivos Oy. Mining of the deposit, reportedly containing 8 million tons of ore with 1.5 percent copper, 1 percent zinc, and smaller amounts of nickel and cobalt, was scheduled to begin in 1968. The ore also contains 50 to 55 percent of pyrrhotite and 5 percent of pyrite. The deposite is about 40 kilometers northwest of Outokumpu.

The Virtasalmi copper deposit, discovered in 1964 southwest of Varkaus, was estimated to contain 1 million tons of ore that has an average copper content of 1.25 percent. Discovery of a new copper deposit, 5 kilometers east of the Outokumpu mine, was announced by Outokumpu Oy. The deposit was reported to consist of a narrow but deep orebody similar in grade to the ore mined at Outokumpu. Mining is expected to start by 1969.

At yearend the Ylöjärvi mine was nearing exhaustion and was scheduled to be shut down in the summer of 1966. At the Pori copper works, brass production increased 20 percent to 16,000 tons, and output of the tube mill increased 50 percent.

Iron and Steel.—*Iron ore.*—Increased production of iron ore in 1965 was due mainly to a full year's operation of the Raajärvi mine of Otanmäki Oy. in north Finland. The opencast mine, which started production in September 1964, produced almost 250,000 tons of concentrate in 1965 from 476,000 tons of crude ore. Preparations for underground mining continued and shaft sinking reached a depth of 356 meters. Small increases in production were also realized at the Kärväsvaara mine and at the Kokkola plant of Outokumpu Oy. At the Otanmäki mine there was a slight drop in production in 1965 as expansion of production facilities was begun. The mine and concentrator are scheduled to increase productive capacity 20 percent by 1967.

The Otanmäki company continued investigations of iron deposits at Kolari and of manganiferous iron ore in the Porkkonen-Pahtavaara region. The company was also granted rights to drill for iron ore in the Gulf of Bothnia, 16 kilometers from Raahe. A strong magnetic anomaly was found in this area.

The Jussarö mine of Oy. Vuoksenniska Ab. produced 112,670 tons of magnetite concentrate in 1965 from 286,000 tons of crude ore.

Imports of iron ore in 1965 were 455,000 tons greater than those of 1964. Exports of magnetite concentrate were virtually eliminated, reducing total exports by one-half. The increased domestic consumption was due to the first full year's operation of the new blast furnace at Raahe and to operation of a new blast furnace completed at Turku in September by Oy. Vuoksenniska Ab.

Pig Iron and Ferroalloys.—Production and exports of pig iron in 1965 increased 65 percent over those of 1964. Production averaged about 80,000 tons per month, with a record 95,000 tons produced in November. Completion of the Vuoksenniska company's blast furnace at Turku in September brought the total Finnish capacity to more than 1 million tons annually. Exports totaled 797,000 tons and consisted primarily of Martin cast iron (510,000 tons) and hematite pig iron (240,000 tons).

Imports of ferroalloys reached a record total of 11,000 tons in 1965, mainly due to increased shipments of ferrosilicon, ferrosilicomanganese, and ferrochromium. Utilization of domestic chromite is expected to eliminate imports of ferrochromium by 1968.

Steel.—Production of crude steel and rolled products again showed a modest increase when compared with those of 1964. Imports of scrap, the principal raw material used in Finnish steelworks, were slightly less than in 1964. In the spring, a new casting unit with an annual capacity of 100,000 tons of steel bar was placed in

operation at the Imatra works of Oy. Vuoksenniska Ab.

Construction of the new steelworks at Raahe was continued, with test operations scheduled to begin in 1967. A $1.4 million contract for a 200-ton-per-day oxygen plant was awarded to Air Products Ltd. of the United Kingdom by Rautaruukki Oy. The plant is scheduled to be completed by the end of 1966.

Imports of steel were increased in 1965. The principal items were ingots (up to 24,000 tons) and a 62,000-ton increase in total receipts of bars and sections, sheets and plate, and tubes. Net imports of all semimanufactures increased only 14,000 tons because of a 50,000-ton reduction in rails. Imports of high-carbon and alloy steel increased 37 percent to 22,000 tons, including 12,000 tons of stainless steel sheets and plates. There were no exports of stainless steel.

Lead and Zinc.—Output of mine lead was more than tripled in 1965, as a full year's production was obtained from the Korsnäs and Metsämonttu mines, both of which were reopened in late 1964. The Korsnäs mine produced 6,671 tons of lead concentrate, and the Vihanti mine produced 2.925 tons. A rare-earth metal concentrate was also produced at the Korsnäs mine.

Malminetsijä Oy., a prospecting company, reported discovery of lead deposits near Ilomantsi in a relatively remote area.

A record quantity of mine zinc was produced in 1965. The major share of production continued to come from the Vihanti mine, although output was about 10 percent less than in 1964 because of a drop in ore grade. The increase in overall production was due largely to the improved recovery of zinc from the Pyhäsalmi mine (85 percent as compared with less than 65 percent in 1964). The improved recovery at Pyhäsalmi resulted in a 40-percent increase in output of mine zinc with only a 2-percent rise in the total metal content of ore mined. The Metsämonttu mine produced 7,300 tons of concentrate in 1965, and another 3,300 tons of concentrate was obtained from the Outokumpu mine. Zinc flotation at Outokumpu was started in February, 1964; the ore contains approximately 0.75 percent zinc, 40 to 50 percent of which is recovered in concentrate. At the Metsämonttu mine, development was in progress on the 380-meter level.

Exports of zinc concentrates in 1965 were valued at nearly $12 million and continued to rank second to copper among Finnish nonferrous metal exports.

Nickel.—A drop of 167 tons in refined nickel production in 1965 was exceeded by a 400-ton reduction in exports. Imports, mostly of nickel alloy scrap, increased approximately 400 tons.

As of mid-1965, ore reserves at the Kotalahti mine were reportedly sufficient to last 15 years at the current rate of production. The mine shaft was deepened to 680 meters. At Hitura in the Nivala area, an exploration shaft was completed at a depth of 200 meters and drifting was begun.

Titanium.—Output of ilmenite concentrate at the Otanmäki mine decreased slightly in 1965, but exports increased to 84,000 tons. Apparently drawing on ore stocks, the Mäntyluoto plant of Vuorikemia Oy. increased production of titania; exports were approximately 25 percent more than in 1964 and were valued at about $8 million.

Vanadium.—Production and exports of vanadium pentoxide decreased slightly in 1965, although the value of exports was $500,000 more than in 1964. Expansion of Otanmäki production facilities, started in 1965, will increase the production capacity for vanadium pentoxide 20 percent by 1967.

NONMETALS

Cement and Other Construction Materials.—Activity in the construction industry increased considerably in 1965 and the gross value of production was estimated to be 10 percent greater than that of 1964. By the end of the third quarter, completion of industrial, commercial, and public buildings was running 9 percent ahead of the 1964 level and the number of building starts was 21 percent higher. At yearend, partly because of a severe winter and because of rationalization efforts, unemployment was greater than in the corresponding period of 1964.

An ambitious highway construction program was also underway in 1965. Assisted by a $28.5 million loan from the World Bank in 1964, road construction was greatly increased in 1965, and $117 million was budgeted by the Government for new high-

263-927 O-67—25

way construction in 1966. An additional loan was being sought from the World Bank. According to the Finnish Board of Public Roads and Waterways, 10,000 kilometers of surfaced highway will be needed by 1974 to meet the expected volume of traffic.

The 200,000-ton increase in cement production in 1965 was accompanied by a threefold increase in exports. Imports of all mineral construction materials were valued at $10.6 million in 1965 as compared with $9.6 million in 1964.

Paraisten Kalkkivuori Oy. announced plans to build a 200,000-ton-per-year cement plant at Kolari in north Finland near the Swedish border. If the present railroad is extended from Kauliranta to Kolari, production will begin in mid-1968.

Feldspar.—By yearend a feldspar processing plant being constructed at Kimito (Kemiö) by Lohjan Kalkkitehdas Oy. was nearing completion. The plant will reportedly produce about 50,000 tons of feldspar and 20,000 tons of quartz annually, mostly for export.

Fertilizer Materials.—Typpi Oy., the state-owned nitrogen and fertilizer company, increased nitrogen production by 19 percent in 1965 to a record 72,472 tons. The company was also conducting investigations of apatite deposits in the Siilinjarvi area of east-central Finland where it has an 18-month option on deposits owned by Lohjan Kalkkitehdas Oy.

The phosphoric acid plant of Rikkihappo Oy. at Uusikaupunki was completed, and production began in December. Annual production capacities of the plant include 33,000 tons of phosphoric acid, 100,000 tons of sulfuric acid, and 100,000 tons of complex fertilizers. In 1966, fertilizer production capacity will be increased and a nitric acid plant will be installed.

Pyrite and Sulfur.—Pyrite production at the Pyhäsalmi mine increased for the fourth successive year, rising to 382,500 tons in 1965. The increased output from Pyhäsalmi compensated for declining production at Outokumpu. Pyrite concentrate will be produced at the Vihanti mine in 1967, reportedly at the rate of 240,000 tons per year. Investigation of pyrite deposits in the Eno, Tuupovaara, and Kiihtelysvaara areas will be undertaken by the Outokumpu company during the next 2 years. Exports in 1965 included 62,500 tons of pyrite and 107,500 tons of roastings.

Production of sulfur and sulfur dioxide at the Kokkola smelter increased in 1965, with a total sulfur output of 146,000 tons. Sulfur production was 86 percent of rated plant capacity compared with 80 percent in 1964. Production at Kokkola is expected to increase approximately 50 percent when the cobalt recovery works is completed.

Imports of elemental sulfur increased to 72,400 tons in 1965, and apparent consumption rose to 143,000 tons. Increasing consumption of sulfur in all forms was reflected by the rising production of cellulose, fertilizer. titania, and other products of the chemical industry. A new sulfuric acid plant was placed in operation at Harjavalta by Rikkihappo Oy.

The flash smelting process, developed for pyrite by the Outokumpu company, will be used by Brunswick Mining and Smelting Corp. Ltd. of Canada in a $63 million plant at Belledune, New Brunswick. Licensing arrangements were made through the Lummus Company of New York. The process also has been licensed in Japan.

Talc and Soapstone.—In 1965, Lohjan Kalkkitehdas Oy., Suomen Malmi Oy. (the State ore company) and a group of paper firms were investigating the feasibility of substituting Finnish talc for imported kaolin in the paper industry. If talc can be substituted for one-third of the kaolin, Lohjan Kalkkitehdas intends to produce talc from deposits near Sotkamo.

Soapstone production was discontinued in 1965 when the Nunnanlahti mine of Suomen Vuolukivi Oy. was closed early in the year.

MINERAL FUELS

Coal.—Consumption of coal continued to decline in 1965, although imports rose by 100,000 tons and consumption of anthracite increased as compared with 1964. Total consumption was 1.9 million tons. The overall 6-percent decline was due mostly to the increasing use of liquid fuels for space heating and diesel locomotives.

Coke.—Consumption of coke increased by approximately 15 percent in 1965, exceeding 1 million tons for the first time. The increase was due mainly to the requirements of the new blast furnace at

Raahe. Total coke consumption for metals reduction in 1965 increased 30 percent (to 756,000 tons), while consumption for space heating dropped 15 percent as compared with 1964. Imports of coke totaled 832,000 tons in 1965.

Petroleum.—Imports of crude oil increased 7 percent in 1965. The Soviet Union and Iran remained the principal suppliers. Deliveries from Iran increased by approximately 60 percent.

Consumption of liquid fuels increased 18 percent in 1965. The Naantali refinery of Neste Oy. was able to supply most of the demand for gasoline but only part of the demand for fuel oils. Imports of fuel oils were 30 percent greater than in 1964. A 90,000-ton increase in bitumen imports in 1965 was due to the increased activity in road construction. Total imports of refinery products increased by 31 percent as compared with 1964.

Neste Oy.'s second refinery, under construction at Sköldvik, began test runs in September. The refinery was expected to begin production on a limited scale in February, 1966. When completed, the plant is expected to process 2.2 to 2.5 million tons of crude oil per year. Estimated cost of the project is $56 million.

Oy. Esso Ab., a Finnish subsidiary of the Standard Oil Co. of New Jersey, planned to invest $2 million for expansion of its marketing facilities.

Electric Energy.—Consumption of electric power increased approximately 8 percent in 1965 to 14.6 billion kilowatt hours. Hydroelectric power again accounted for about two-thirds of production. At the end of 1964 the total installed capacity of Finnish powerplants was 3,876 megawatts, with thermal plants accounting for 52 percent and hydroelectric plants for 48 percent. Of additional capacity scheduled for installation during 1965 (390 megawatts), two-thirds was to be installed in thermal plants.

According to Imatran Voima Oy., the State-owned power company, Finland's first atomic powerplant will be located in Loviisa, about 50 miles east of Helsinki. A second site, on the Landskatan peninsula 20 miles north of Pori, was also being considered. Plants for nuclear powerplants of 300- to 350-megawatt capacity reportedly were being developed by Imatran Voima Oy. as well as by a private firm, Ydin Oy.

The TRIGA Mark II research reactor at Otaniemi continued to be operated in 1965, using enriched uranium fuel.

The Mineral Industry of France

By L. Nahai[1]

The mineral industry of France in 1965 generally proved more active than other sectors of the nation's industrial economy. Most sectors of the mineral and energy-producing industry recorded gains in production indexes that for the year as a whole exceeded that of the overall industrial production index. However, solid fuels and metal ore mining recorded declines with respect to 1964 index figures.

During the year, the Government's basic economic policy was a continuation of the stabilization program started in 1963. The nation's economy was generally lethargic in the first half of the year but began to pick up after June. For the year as a whole, the volume of French gross domestic output increased 2.5 percent from the 1964 level. Price increases were limited — wholesale prices increased by 1.2 percent and retail prices by 2.8 percent.

The value of crude mineral output in 1964, the last year for which complete data are available, was about $1,768 million.[2] Distribution of this total by commodity groups was as follows: Energy products (including uranium), $919 million; quarry products, $481 million; metallic minerals, $212 million; and nonmetallic minerals other than quarry products, $156 million. Among major commodities, solid fuels ranked first in value ($741 million), followed by iron ore ($186 million) and sand and gravel ($162 million). As in 1963, the value of crude mineral output was equivalent to 2.2 percent of the gross domestic product (production intérieure brut),[3] which totaled $79 billion in 1964 prices.

The position of France as a consumer of nonferrous metals remained essentially unchanged from that of 1964, as did the degree to which domestic smelter production met French requirements for principal nonferrous metals. Aluminum smelter production exceeded consumption by about 142,000 tons. Domestically refined copper production was equal to about 21 percent of consumption (excluding direct-use scrap), but zinc smelter output was close to consumption and that of lead was equal to about 68 percent of consumption.

As of December 31, 1964, personnel registered in the extractive industry, other than quarrying and slate production, totaled 238,486 (245,846 on December 31, 1963), distributed as follows: Coal and lignite 191,822; iron mining 21,777; other metal mining 5,275; potash 11,906; crude oil, natural gas, asphaltic limestone, and bituminous schist operations 5,648; and other, 2,058. Employment dropped in all categories of mining except in metal mines other than iron ore. About 97,000[4] were engaged in quarrying. Cement and lime plants employed 15,350. Petroleum exploration, production, and refining accounted for 26,769.[5] Among metallurgical plants, the iron and steel industry (exclusive of foundries) employed an average of 130,806 production workers and 42,176[6] salaried employees; ferroalloy plants employed 3,900 and nonferrous metal plants 9,000. The total of personnel listed above, 563,486, was about 3 percent of total French labor force as of January 1, 1965.[7]

[1] Chief specialist, West Europe Area, Division of International Activities.

[2] Where necessary, values have been converted from francs (Fr) to U.S. dollars at the rate of Fr.1 = U.S.$0.20.

[3] Exclusive of value added by financial intermediaries, civil servants, domestic servants, and nonprofit organizations.

[4] This figure includes also workers engaged in making products made of concrete and asbestos cement.

[5] There is some duplication between this figure and the 5,648 employed in the production of crude petroleum, natural gas, asphaltic limestone, and bituminous schist. In addition about 90,000 were employed in petroleum distribution.

[6] Includes salaried employees of activities associated with the iron and steel industry.

PRODUCTION

The index of overall industrial production stood at 142 in 1965 compared with 138 in 1964; indexes for various sectors of the mineral industry, other than petroleum with a 13.2-percent increase, showed only small changes. Solid fuels and metal mining were lower than in 1964 while other sectors were higher.

The steel industry almost maintained its record output of the previous year, and smelter production of many nonferrous metals increased. The highest increase recorded was for magnesium, which almost tripled, followed by aluminum (up 10.8 percent) and lead and zinc (each about 10.6 percent greater than in 1964). Secondary producers again contributed important tonnages of copper, lead, and zinc to total metals supply. Except for iron ore, output of metallic minerals also increased. The index of building and public works also increased but not to the same extent as in 1964; 594,200 permits for construction of dwellings were issued, compared with 575,100 in 1964, and activity in this field favorably influenced output of construction materials and cement. The latter rose 3.3 percent. Among the energy industries, the increase in output of petroleum and refined products was less than that achieved in 1964, while solid fuels output showed a small decline. Production of electricity increased by 8 percent, from 91,344 million kilowatt-hours in 1964 to 98,712 million kilowatt-hours in 1965. Because rainfall conditions were favorable to hydropower generation, thermal plants accounted for only 54 percent of the total in 1965 compared with 63 percent in 1964.

Table 1.—France: Indexes of industrial production

(1959 = 100)

	1964 [1]	1965 [1]	Variation 1964–65 (percent)

XX Not applicable.
[1] Includes commodities listed in tables 4 and 5 of this chapter except gold and cut, but unset gems.

Iron and steel (including scrap), petroleum products, and nonferrous metals (including semimanufactures) were the most important export items in the mineral field accounting for about 10.2, 2.8, and 2.3 percent, respectively, of all French exports. Mineral fuels remained dominant among imports in both tonnage and value, accounting for 52 percent of the value of the tabulated mineral and metal imports and 15 percent of the value of all imports.

In 1965, the value of imports of all nonferrous metals and semimanufactures, ore, and scrap showed a further increase compared with that of 1964. Larger imports of chromium ore and metal, manganese ore and metal, scrap and refined copper, mercury, nickel matte, platinum, tungsten ore, and radioactive materials were contributory factors.

Imports of copper and copper alloy ingots and semimanufactures in 1965 were valued at $250 million; corresponding figures for other principal nonferrous metals were, in million dollars, aluminum 50.4, silver and platinum 46.1, tin 39.2, nickel 21.5, lead 9.6, and zinc 6.2.

There was little change in France's trade pattern as far as destinations were concerned. The other countries of the European Economic Community (EEC) [8]

[8] The EEC includes Belgium, France, Italy, Luxembourg, the Netherlands, and West Germany.

Table 3.—France: Summary of mineral commodity trade in 1965

Commodity	Imports		Exports	
	Quantity (thousand metric tons)	Value (thousand dollars)	Quantity (thousand metric tons)	Value (thousand dollars)
Metals:				
Iron and steel:				
Iron ore, including pyrite cinder	3,985	44,735	20,990	72,097

Source: Statistical office of the United Nations.

and the countries of the European Free Trade Association (EFTA) [9] remained France's most important trading partners. In 1965, 40.9 percent of all exports of France were to other EEC countries and 15.6 percent were to EFTA countries. The corresponding import figures were 38.9 percent from EEC countries and 11.0 percent from the EFTA countries. For the minerals and metals tabulated, France's exports to other EEC nations were 49 percent of the total; those to the EFTA countries were 18 percent. For the same commodities, imports from the EEC countries were 36 percent of the total; those from the EFTA countries were 5 percent.

The principal mineral and metal exports of France in 1964 to other EEC countries were substantially the same as in 1963. French steel exports to this market were equivalent to 42 percent of France's steel exports to all destinations in value. The United States was an important market for aluminum semimanufactures, arsenic anhydride, chromium metal, iron and steel semimanufactures, industrial and gem diamonds, and coal chemicals; for the commodities tabulated France's exports to

[9] The EFTA includes Austria, Denmark, Norway, Portugal, Sweden, Switzerland, and the United Kingdom.

United States totaled about $143 million. EFTA countries (principally United Kingdom) were the largest market for French sulfur and accounted for 51.3 percent of the exports; these countries also received 17 percent of primary steel and semimanufactures and 27 percent of chemical potassic fertilizers. Switzerland took nearly 17 percent of France's exports of coal and coal briquets, 7 percent of steel (including primary forms), and 25 percent of petroleum products. For the latter, Switzerland was France's largest single customer but only by a small margin compared with West Germany.

Iron and steel, solid fuels, copper, lead, and zinc were France's principal imports from its EEC partners. Belgium supplied the bulk of France's imports of cadmium, cobalt, lime, manufactured fertilizers, and dolomite and was an important source of refined copper and semimanufactures, pig lead, slab zinc, and diamonds. Imports from United States included nickel, lead and steel scraps, magnesium, manganese oxide, molybdenum ore, selenium, silver, tantalum, titanium metal, uranium metal and other radioactive materials, zirconium oxide, borates, sulfur, talc, and coal; value of these and other commodities totaled $140 million. Algeria remained the largest source of crude petroleum which, valued at $332 million, was equivalent to 54 percent of France's total imports from the country. Morocco supplied France with phosphates and metallic ores valued at about $53 million, equivalent to 23 percent of all imports to France from Morocco.

Nonmetals—Continued					
Fertilizer materials—Continued					
Manufactured:					
Nitrogenous thousand tons	747	489	645	55	Greece 89; Spain 63; Algeria 53; Belgium-Luxembourg 47.
Phosphatic:					
Basic slag do	303	343	337	NA	Austria 189; Switzerland 127.
Other do	44	55	47	9	Denmark 13; Bulgaria 12; Netherlands 7.
Potassic do	1,239	1,403	1,187	458	Belgium-Luxembourg 260; United Kingdom 191.
Flint (pebbles)	59,877	75,699	80,792	31,765	United Kingdom 20,300; West Germany 15,453; United States 14,456.
Fluorspar	46,572	58,625	86,332	41,770	West Germany 32,101; Sweden 6,283; Belgium-Luxembourg 5,311.
Graphite	1,767	2,284	1,900	1,057	United Kingdom 824; Italy 439; West Germany 289.
Gypsum and anhydrite, including plaster.	648,147	766,524	786,572	480,689	Belgium-Luxembourg 399,734; Sweden 143,749; United Kingdom 57,543.
Lime	115,747	173,545	194,110	157,044	West Germany 93,262; Belgium-Luxembourg 63,752.
Limestone, for flux, cement, etc.	170,378	182,695	179,593	115,038	Belgium-Luxembourg 85,883; Switzerland 46,657.
Lithium and strontium minerals.	NA	238	NA	238	All to West Germany.
Magnesite, including calcine	442	219	534	197	Italy 174.
Mica	99	353	577	136	Libya 116.
Precious and semiprecious stones. [8] value, thousands	$4,810	$6,152	$8,660	$1,073	Switzerland $2,812; West Germany $590; United Kingdom $570.
Pumice	31	53	33	----	NA.
Pyrite	----	2,176	30	2,176	NA
Quartz and quartzite	2,242	1,430	1,874	1,016	NA.
Salt	r 137,266	137,257	94,071	130,133	Belgium-Luxembourg 84,508; West Germany 41,204.
Slate, rough and finished	14,648	18,885	17,089	16,000	Netherlands 7,590; Belgium-Luxembourg 6,008; United Kingdom 2,256.
Stone, sand and gravel: [9]					
Building stone:					
Unfinished	127,809	125,476	120,494	107,415	Belgium-Luxembourg 77,441; West Germany 21,855; Switzerland 10,281.
Finished	7,761	6,448	6,014	4,530	West Germany 2,857; Netherlands 925.
Gravel and other crushed stone. thousand tons	2,959	3,688	5,758	2,831	West Germany 2,490; Switzerland 842; Netherlands 181.
Sand do	1,034	1,360	1,451	1,006	West Germany 629; Switzerland 344; Belgium-Luxembourg 221.
Sulfur, elemental do	r 1,020	1,047	925	245	United Kingdom 379; West Germany 127; Netherlands 94.
Talc and steatite	49,624	51,278	51,182	19,699	West Germany 12,119; United Kingdom 9,060; Switzerland 17,281.
Other mineral substances	145,888	141,614	146,413	25,575	Switzerland 113,439; West Germany 16,644.

See footnotes at end of table.

Table 4.—France: Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	Total export			1964 destinations	
	1963	1964	1965	EEC [1]	Principal destinations
Mineral fuels:					
Asphalt and bitumen, natural	20,506	20,429	19,230	---	United Kingdom 20,290.
Asphalt, worked	3,294	4,498	5,660	2,594	West Germany 1,782; United Kingdom 610.
Coal	1,003,077	915,016	842,581	767,845	West Germany 437,496; Belgium-Luxembourg 225,102; Switzerland 137,312.
Coal briquets	14,105	29,718	40,868	23,760	Italy 19,430; Switzerland 5,811.
Coke	51,145	36,386	57,152	6,964	Switzerland 15,775; Spain 5,395; Turkey 5,082.
Gas:					
Natural, including liquid petroleum gas (propane, butane, and other liquid petroleum gases).	221,804	287,824	392,147	87,009	Spain 72,739; Belgium-Luxembourg 61,366; Portugal 57,589; United Kingdom 36,220.
Manufactured	198,110	37,674	196	37,674	All to Belgium-Luxembourg.
Lignite, including briquets	628	21,570	61,174	---	Spain 21,302.
Peat, including briquets	316	343	488	342	NA.
Petroleum refinery products:					
Gasoline--thousand tons	1,396	1,491	1,889	404	Switzerland 538; United Kingdom 349; West Germany 307;
Kerosine---------do	860	921	490	188	Switzerland 136; international bunkers 237; West Germany 88; United Kingdom 66.
Distillate fuel oil--do	2,606	2,869	3,472	1,304	West Germany 852; Netherlands 310; United Kingdom 162.
Residual fuel oil---do	2,326	2,760	3,137	1,199	West Germany 847; international bunkers 512; Switzerland 416; United Kingdom 284.
Lubricants--------do	225	262	244	72	United Kingdom 41; Algeria 33; West Germany 24.
Other----------do	324	315	349	138	West Germany 85; Switzerland 66; Algeria 51.
Total refined products. do	7,737	8,618	9,581	3,305	Switzerland 2,206; West Germany 2,202; United Kingdom 903; international bunkers 847.
Chemical derivatives of coal, petroleum, or gas.	75,780	77,043	76,886	31,175	Belgium-Luxembourg 14,831; United States 12,399; United Kingdom 11,696.

NA Not available. r Revised.
[1] Belgium, West Germany, Italy, Luxembourg, and the Netherlands.
[2] Excludes artificial corundum.
[3] Including indium and thallium.
[4] Calculated from quantities reported in kilograms.
[5] Including cast iron and shot, grit, powder, and sponge of iron or steel.
[6] Including wire rod.
[7] Alkali, alkaline earth, and rare earth metals except sodium.
[8] Including synthetic and reconstituted stone but not including diamond.
[9] Not including slate, flint, or industrial limestone.

Table 5.—France: Imports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	Total import			1964 sources	
	1963	1964	1965	EEC [1]	Principal sources
Metals:					
Aluminum:					
Bauxite	142,499	145,844	116,508	----------	Greece 68,191; British Guiana 37,198; Surinam 19,889; Ghana 19,235.
Oxide and hydroxide [2]	126,794	67,068	19,700	575	Guinea 56,100; United States 10,369.
Metallurgical residues	1,278	2,897	11,615	2,278	West Germany 1,713; Italy 565; Spain 415.
Metal including alloys:					
Scrap	2,295	2,685	2,165	1,995	Belgium Luxembourg 1,833; United States 386; Canada 118.
Ingots	55,870	72,438	71,694	382	Cameroon 40,713; United States 18,296; Norway 7,408.
Semimanufactures	12,417	16,259	19,425	12,384	West Germany 6,372; Belgium-Luxembourg 4,490; Switzerland 1,060.
Antimony:					
Ore and concentrates	867	2,691	1,678	----------	Republic of South Africa 1,176; Morocco 407; mainland China 301.
Metal, all forms	2,787	2,670	1,737	415	Mainland China 1,780; U.S.S.R. 422; Belgium-Luxembourg 305.
Arsenic, including anhydride	67	114	144	34	Arsenic only: Poland 17; Sweden 12.
Beryllium:					
Ore	122	381	NA	----------	All from Malagasy Republic.
Metal, all forms, value, thousands	$104	$69	$180	$4	United States $60.
Bismuth	665	785	700	90	United Kingdom 564; Peru 60; South Korea 42.
Cadmium	807	578	408	337	Belgium-Luxembourg 319; Republic of the Congo (Léopoldville) 77.
Cobalt:					
Ore	10,522	10,392	11,672	----------	All from Morocco.
Oxide and hydroxide	81	89	131	59	Belgium-Luxembourg 55; United Kingdom 28.
Metal, all forms	270	231	313	189	Belgium-Luxembourg 183; United States 15.
Chromium:					
Ore	153,662	193,395	224,287	----------	U.S.S.R. 78,305; Turkey 46,134; Iran 28,671.
Oxide and hydroxide	1,671	1,502	1,870	1,125	West Germany 1,122; United Kingdom 376.
Metal	11	1	14	1	NA.
Columbium:					
Ore (including tantalum ore)	72	150	138	----------	Canada 130; Nigeria 20.
Metal, all forms, value, thousands	$109	$106	$128	$21	United States $63.
Copper:					
Metallurgical residues	39	851	112	131	Morocco 250.
Matte	50	203	297	46	United States 60; Canada 51.
Metal including alloys:					
Scrap	8,507	7,145	11,855	2,935	Belgium-Luxembourg 2,084; United States 812; Algeria 789.
Blister and other unrefined	8,170	10,808	6,290	220	Republic of the Congo (Léopoldville) 9,334.
Refined	212,430	249,826	262,019	100,305	Belgium-Luxembourg 93,406; Rhodesia-Nyasaland 46,455; United States 33,413; Republic of the Congo (Léopoldville) 21,524; Chile 20,105.

See footnotes at end of table.

Table 5.—France: Imports of metals and minerals—Continued

[9] Including synthetic and reconstituted stone but not including diamond.
[10] Excludes slate, flint, or industrial limestone.

COMMODITY REVIEW

METALS

During the year the Commission of Nonferrous Mines and Metals presented its report for the Fifth Economic Development Plan (1965–70). In preparing its report the Commission was guided by three objectives: To assure the nonferrous metal industry of metropolitan France permanent and independent access to necessary raw materials, to improve as far as possible the unfavorable balance of payment position characterizing French trade in minerals, and to maintain the international competitive position of the industry.

While France has been a net exporter of bauxite, alumina, aluminum, and nickel (produced from nickel matte of New Caledonia), the Commission felt that France may become a net importer with regard to the aluminum industry. The Commission postulated production and consumption of principal nonferrous metals in 1970 as follows:

Commodity	Production (tons)	Consumption (tons)
Ores:		
Bauxite	2,745,000	3,060,000
Alumina (calcined)	941,000	[1]
Chromium		263,000–278,000
Cobalt		14,000
Lead	36,000–42,000	175,000
Manganese		840,000
Molybdenum		6,700–7,000
Tungsten		2,600
Tin	250	[1]
Zinc	31,500–35,500	336,000–358,000
Metals:		
Aluminum:		
Primary	365,000	458,000
Secondary	75,000	
Copper	42,000	360,000
Cobalt	1,000	900
Lead:		
Primary	140,000–145,000	238,500
Secondary	28,500	
Nickel	11,000–15,500	26,000
Tin		12,000
Zinc:		
Primary	230,000–245,000	278,000
Secondary	38,000	

[1] Not indicated.

Bauxite and Aluminum.—All bauxite mining companies were active in exploration and improvement of mining facilities. Bauxite exploration was carried out in the Herault, and important reserves were discovered. The Baume-Sud deposit in the Var was put in production by Compagnie des Produits Chimiques et Électrométallurgiques Péchiney (Péchiney); the company produced 1,394,000 tons of bauxite in 1965, a 9-percent increase from 1964 production. Société des Bauxites de France completed the layout of the Touvres and Derobade mines. Comptair d'Extractions et de Vente des Bauxites, which recorded an output of 112,541 tons in 1964, was concentrating production activities in its new Brignoles area, and Société des Bauxites et Alumines de Provence, which produced 391,000 tons of bauxite in 1964, made improvements in its opencast mine at Cabasse.

The expansion of the Gardanne plant from a daily alumina capacity of 1,100 tons to 1,400 tons was completed, raising the country's annual alumina capacity to an estimated 870,000 tons by yearend.

France remained the world's fourth largest aluminum producer, accounting for 5 percent of world output and 26.6 percent of West European production in 1965. Production in this year was 7.8 percent more than in 1964; Péchiney and Société d'Électro-Chimie, d'Électro-Métallurgie et des Acièries d'Électriques de Ugine (Ugine) produced 272,385 and 68,143 tons, respectively. In addition, 44,878 tons of aluminum ingot from the Edea plant in Cameroon was available to the French aluminum market. Shipment (production) of

semifinished products other than castings remained almost the same as in 1964, totaling 189,300 tons distributed as follows: plate, sheet, and foil 129,900; extrusion and tube products 33,500; wire 22,700; forgings 3,200. In addition 102,700 tons of castings, 9,900 tons of aluminum for the steel industry, and 8,400 tons of aluminum paste were shipped.

As a result of expansion at the Rioupéroux and Noguères plants of Péchiney and the Venthon plant of Ugine, total annual ingot capacity increased to 357,000 tons, with Péchiney having about 280,000 tons [10] and Ugine 77,000 tons. Continued installation of modern rectifiers and improved power consumption were reported by Péchiney.

Shipments by L'Aluminum Français reached 400,100 tons of aluminum content. The share of aluminum alloys in sales continued to increase and reached 27 percent.

Domestic demand did not grow in 1965, and aluminum consumption was 248,598 tons (249,275 tons in 1964), despite the fact that the Renault and Peugeot automobile producers for the first time started making cars with aluminum engine blocks. The domestic price of aluminum ingots was increased in April from $506 to $531 per ton, and the basis was changed from ex-works to delivery-point.

While domestic consumption did not rise significantly, exports increased 34 percent. The EEC and the United States were the two largest markets, receiving 60 and 20 percent, respectively. Of total aluminum exports, four-fifths were ingots.

The rolling mill of Société Rhénalus [11] at Neubreisach on the Rhine, with 100,000 tons' annual capacity was scheduled to start production at the end of 1966. It was hoped that this plan would secure part of the West German market.

Work was underway to increase the daily capacity of the Gardanne alumina plant from 1,100 to 1,420 tons (518,000 tons per year).

On November 15 an agreement was announced which increased integration among the producers of aluminum semifinished products. Péchiney and Ugine, together with their affiliate, L'Aluminium Français, agreed to the following measures:

1. L'Aluminium Français will conclude a long-term agreement with Tréfimétaux (a company formed by the merger of la Compagnie Française des Métaux and Tréfileries et Laminoirs du Havre), the largest French manufacturer of nonferrous sheets, shapes, and other semifinished products, to supply the aluminum need of the Tréfimétaux to the extent that they would not be satisfied from a plant on the island of Curaçao, in the Netherlands Antilles. (Subsequently it was decided not to build the Curaçao plant.)
2. Tréfimétaux and the Compagnie Générale du Duralumin et du Cuivre Cégédur) in which Péchiney and Ugine together are majority holders will reinforce their cooperation with the aim of rationalizing the production and development of aluminum and aluminum alloy semifinished products. Cégédur is the largest French producer of aluminum semifinished products.
3. Tréfimétaux and Coquillard, a subsidiary of Péchiney which specializes in aluminum foil, will develop their activities in aluminum foil together and may eventually create a new, jointly held company in this field.

Copper.—Consumption of primary refined copper was 287,000 tons, a 1.6-percent decline from 1964; it is estimated that 10,000 tons of secondary refined copper was also used. Direct use of scrap in 1964 amounted to 112,900 tons of copper content;[12] in view of large imports of copper in 1965, scrap use was probably greater.

Compared with 1964 figures, 1965 copper imports increased 5 percent for refined unwrought metal, over 4 percent for semimanufactures, and 66 percent for scrap, but declined 42 percent for blister and other unrefined ingots. Unrefined ingot trade of France, however, remained

---

[10] Péchiney capacity by plants was as follows, in metric tons: Noguères 103,000, St. Jean de Naurienne (Savoie) 72,500, Sabart (Ariège) 21,000, Rioupéroux (Isère) 21,000, Auzat (Ariège) 20,500, L'Argentière (Hautes Alpes) 19,000, La Saussaz (Savoie) 11,500, Chedde (Haute Savoie) 8,000, La Praz (Savoie) 3,800.

[11] Formed by Compagnie Général du Duralumin et de Cuivre, or Cégédur (75 percent), and Tréfimétaux du Havre.

[12] Metallgesellschaft A.G. (Metal Statistics 1955–64), Frankfurt, West Germany, 1965, p. 131.

relatively small, while overall copper and copper alloy imports were nearly 5 percent greater.

Production of semifinished copper and copper alloys, in terms of metal content, totaled 386,090 tons, 5 percent less than in 1964. The 1965 output consisted of 179,320 tons of copper wire, 15,000 tons of copper sheets, 39,080 tons of copper tubes, and 152,690 tons of brass products; the latter included 43,550 tons of sheets (including bronze), 102,170 tons of bars and sections, and 6,970 tons of tubes.

Iron Ore.[13]—Domestic iron ore production was 2.3 percent less than in 1964, and shipments to all destinations were 3 percent lower than in 1964, contributing to increases in stocks, which rose to 7.55 million tons at the Lorraine mines and to 8.24 million tons for all of France. Employees on the payroll as of December 31, 1965 totaled 19,955,[14] a decline of 7 percent in one year, but wages increased by 4.2 percent in Lorraine and 3 percent in Western and Pyrénées mines. Many mines had shorter working hours. Only 10 percent of the Lorraine mines were on the full 40-hour week basis during the whole year. Investment in iron mines was at almost the same level as in 1964—almost $18 million in the Lorraine and $2 million in the ore fields of l'Ouest (West) basin. In Lorraine, 17.51 tons was produced per man-shift for surface and underground workers, and in the West 8.60 tons; corresponding figures for 1964 were 16.34 and 7.94 tons, respectively.

[1] Belgium, West Germany, Italy, Luxembourg, and the Netherlands.
[2] Belgium 6,956,304; Luxembourg 7,784,306; Germany (mainly Saar) 5,930,869; Netherlands 170.

In contrast to the situation in domestic output, France increased its imports of high-grade iron ores in 1965. Total receipts of foreign ores were 8.5 percent greater than in 1964, imports from Mauritania, Liberia, Brazil, and Sweden were all larger than in 1964, and as a result, the steel plant at Dunkirk, built to operate primarily on imported ore, showed a significant increase in output.

Total exports declined 6.1 percent and represented 35.2 percent of all shipments of French mines (36.3 percent in 1964). Shipments of French iron ore to Belgium and the Saar declined by 14 and 6.2 percent, respectively, but deliveries to Luxembourg increased by 4.5 percent, apparently because of temporary and exceptional circumstances. Total exports from the iron mines in the west diminished by 25.4 percent; those from the United Kingdom and the Ruhr declined 61 and 84 percent, respectively. According to industry spokesmen, the competitive position of these ores was adversely affected by high transportation charges. The French railroad increased its freight rate 5.1 percent, but negotiations were in progress in West Germany to lower freight rates.

[13] Chambre Syndicale des Mines de Fer de France. Rapport d'Activité pour l'Année 1965. Paris, France, Apr. 22, 1966, 32 pp.
[14] Including workers, engineers, and apprentices.

Construction of a secondary crushing and screening plant in Moyeuvre mine of DeWendel Cie. S.A. was underway. This project will increase production capacity of the mine from 1.8 million tons to about 2.5 million tons per year. Status of the project for equipping the Mairy mine of Union Sidérurgique Lorraine with shafts and surface facilities was not reported. This will increase annual production capacity of the mine from 1.2 million to 3.6 million tons of ore.

The Technical Services of Chambre Syndicale des Mines de Fer de France carried out research on improved mining methods, roof support, use of fuel oil-nitrate explosives, development and use of drilling equipment (jumbos), ore transport within and outside the mine, continuous miners, etc. Health and safety research by the same organization included the study of fuel oil-nitrate explosives and accidents due to fall of rock.

Roof bolting with resins, introduced in 1964, was applied on an industrial scale in 1965. A pilot plant for magnetic roasting was being built at Bazaille and should start operation in 1966. Several mines used this experimental station to carry out tests on crushing, classification, and higher intensity magnetic separation of iron ore.

Iron and Steel.—*Production.*—France did not maintain its record 1964 production levels for pig iron and crude steel in 1965; there were drops of 0.6 and 0.9 per cent in output of pig iron and crude steel, respectively. France's share of world steel output was about 4.3 percent, and the country ranked sixth among world producers and second to West Germany in the EEC.

r Revised. NA Not available.
[1] Includes special pig iron in metric tons as follows: 1961, 72,189; 1962, 31,006; 1963, 6,137; 1964, 42,994; 1965, 3,749.
[2] Detail does not add to total because of rounding.
[3] Excludes scrap used by rolling mills in tons as follows: 1961, 72,323; 1962, 73,075; 1963, 77,866; 1964, 85,858; 1965, 98,284.

The 94,000-ton drop in pig iron production was mainly in that used for steel production; foundry pig iron output fell by only 9,000 tons. The share of hematite-pig iron, obtained from high-grade imported ore, increased again to 10.7 percent (8.2 percent in 1964), although Thomas pig iron remained dominant in total output. Average output of slag per ton of pig iron showed a further decline because of the increased share of high-grade ore smelted. Fuel oil consumption of the industry as a whole, 1,234,440 tons, was practically the same as in 1964.

For the first time, production of pig iron in the North steel area showed a decline compared with that of previous years. Otherwise, there was no significant change in the geographical pattern of production. Of the 94 blast furnaces in operation at yearend, 71 were in the East, 15 in the North, 3 in the Southwest, 1 in the Southeast, and 4 in the West steel area of France.

Thomas steel and open hearth steel constituted 53.0 and 24.4 percent, respectively, of total 1965 crude steel output. Oxygen steel constituted 13.1 percent of the total, but the rate of increase (15 percent) was not as high as in 1964.

Production of special and alloy steel increased to 1,703,000 tons, or 8.7 percent of total crude steel output, distributed as follows, in percent: structural high-grade carbon steel 37, structural alloy steel 38, ball-bearing steel 6, tool steel 5, and stainless steel 14. There was a further increase in stainless steel production to 246,000 tons from 234,000 tons in 1964.

The share of flat products in rolled steel output remained practically unchanged. There were small increases in production of rails, heavy structurals, wire rods, bars, and pipe skelp, but the tonnages of hot- and cold-rolled sheets declined. Galvanized steel and tinplate production went down partly because of a drop in exports.

Consumption and Trade.—There was a slight reduction in French internal demand during the year as a result of stagnation in private investment and lower consumer expenditures. Activity was high in public works, the building industry, engineering, the tube industry, and the manufacture of motor vehicles and agricultural tractors. But steel requirements of shipyards, boiler makers, forging plants, and the equipment industry declined.

In terms of crude steel, apparent consumption fell from 17,808,000 tons to 16,691,000 tons and from 368 kilograms to 341 kilograms per capita. Steel shipments totaled 15.5 million tons of which 5.3 million was for the export market. Actual internal steel consumption may have been more than the 10.2-million-ton domestic shipment reported because steel stocks were depleted considerably during the year. Domestic shipments were distributed as follows, in thousand tons: for conversion 2,554; to steel merchants 2,681; to manufacturing industries 2,751; to railroads, extractive industries, and building industry 1,298; others 189; and special steels 744.

French steel exports (ingots and primary forms and semimanufactures) exceeded its 1964 record by about 500,000 tons and were valued at $908 million. Other EEC

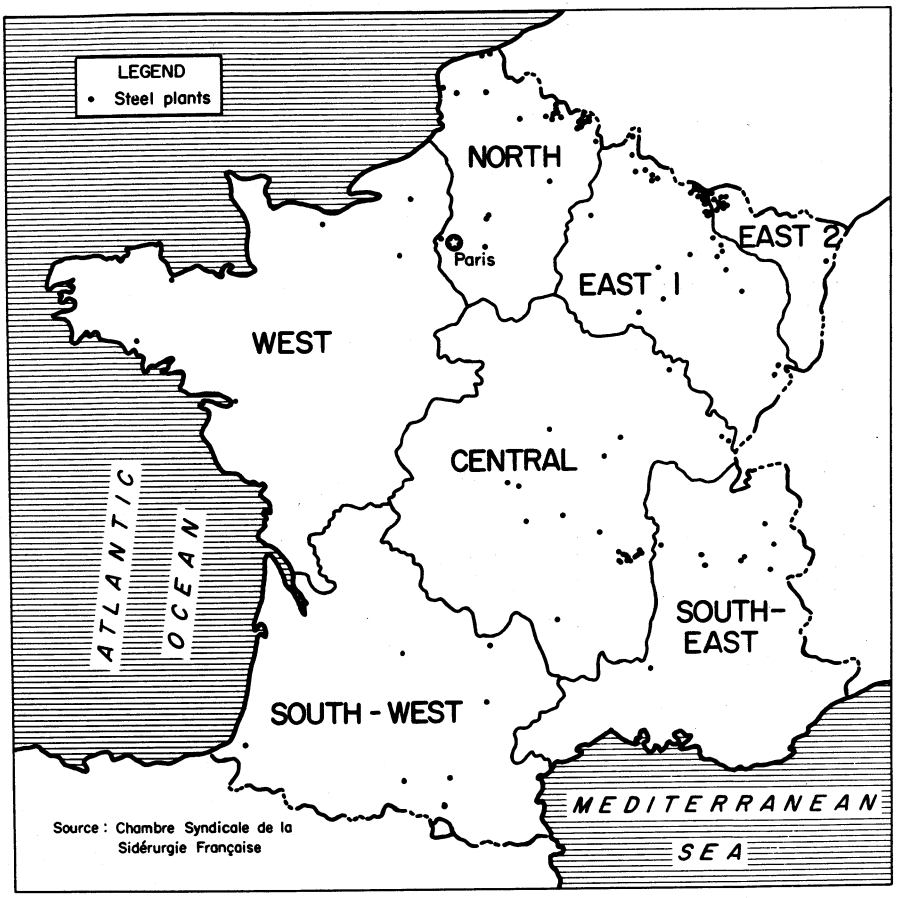

Figure 1.—France: Iron and steel districts and steel plant locations.

countries remained the largest market, receiving 2,774,000 tons. Although imports from EEC countries (3,717,300 tons) still exceeded exports to these destinations, the imbalance was reduced from that of the previous year when French net imports from other EEC countries totaled about 1.17 million tons. Exports outside the EEC increased largely as a result of higher sales in the U.S. market; these reached about 816,000 tons or almost double the 1964 level.

Total imports of primary forms and semimanufactured steel declined by 328,000 tons and $45 million in value. Net contribution of the industry to trade balance increased to $385 million. About one-fifth of French steel needs were met from imports, essentially from other EEC countries which were the source for 96 percent of all steel imports of France.

Facilities and Investments.—In 1965 there were 80 steel companies and 113 plants. Of these plants, 58 produced steel, 9 specialized in pig-iron production, 45 produced rolled steel while one plant produced pig iron and rolled products. In 1965 one-third of these plants had annual capacities of 300,000 to 2,300,000 tons, 17 percent had 100,000 to 300,000-ton annual capacities, and 50 had capacities of 100,000 tons or less

per year.[15] Ten companies produced 86 percent of the 1965 output; the largest, Dunkirk, produced more than 4 million tons. The smaller plants generally made fine and special steel.

The following tabulation gives a distribution by size of the majority of total blast furnaces and various types of steel furnaces available for use in France in 1964:[16]

Facility type and size	Number
Blast furnaces:[1]	
Under 3 meters in diameter	3
3 to 4 meters in diameter	17
4 to 5 meters in diameter	31
5 to 6 meters in diameter	40
6 to 7 meters in diameter	26
7 to 8 meters in diameter	6
Over 8 meters in diameter	5
Total	128
Open hearth furnaces:	
25- to 39-ton capacity	9
40- to 69-ton capacity	34
70- to 89-ton capacity	16
90- to 150-ton capacity	26
Total	85

12- to 18-ton capacity	31
20- to 27-ton capacity	35
28- to 39-ton capacity	24
Over-40-ton capacity	10
Total	100

[1] Data as of January 1, 1965.
[2] Oxygen Lance Poudré; a process that employs powdered lime with a stream of oxygen.

The industry's investment totaled $170.56 million, distributed as follows, in millions of dollars: coking plants 0.76, charge preparation 19.93, blast furnaces 12.46, steel works 16.59, rolling mills 79.18, miscellaneous 41.64. The investment in steelworks was mainly in electric ($7.59 million) and oxygen furnaces ($5.06 million); basic bessemer investment was $2.64 million, and open hearth investment was $1.3 million.

The industry developed a rationalization and modernization plan to improve its competitive position and to increase production capacity to 24 million tons by 1970. The plan reportedly calls for an investment of about $2.3 billion. In 1965, the industry was already carrying a heavy debt load, reportedly about 70 percent of annual sale, with servicing charges running at about 8 percent of annual sales. In view of this the Government made a $60.9 million (300-million-franc) loan to the industry under favorable terms with no interest payment or payment on the capital in the first 5 years. It is believed this was to be the first of a series of loans for the long-term development program.

During the year programs for a number of regroupings and mergers were prepared to create larger units comparable to the large steel companies in West Germany and Italy.

Actual merger occurred in the regrouping of the activities of Forges et Acièries de Nord et Lorraine and Hauts Fourneaux et Forges de Saulnes et Gorcy in iron ore, sinter, and pig iron production, into a joint subsidiary, Hauts Fourneaux Reunis de Saulnes et Uckange. The new concern has annual capacities of 3.5 million tons of iron ore, 800,000 tons of pig iron, and 30,000 tons of calcium carbide. In addition a number of agreements on the joint use of facilities were reached: Usinor's rolling mill at Dunkirk will also be used by Lorraine-Escaut, the wire mill of Saulnes et Gorcy at Saulnes will be shared with Lorraine-Escaut and Acièries et Tréfileries de Neuves-Maisons-Chatillons, and the wire mill of Chiers at Anzin will be used by Usinor. An important company development was that Port-à-Mousson sold its share of the Hauts Forneaux et Acièries de Differdange-St. Ingbert-Rumelange S.A. (HADIR) steelworks in Luxembourg to Acièries Réunies de Burbach-Eich-Dudelange S.A. (ARBED). Port-à-Mousson company is diversifying in other fields but still disposes of 3.5 million tons of steel capacity.

[15] Economic Commission for Europe (Geneva, Switzerland). Steel Committee. Working Paper 317. Aug. 2, 1966, p. 18.
[16] Totals given here are less than those from official sources shown in table 7, but represent the majority of total furnaces.

The Sacilor plant at Gandranges [17] was under construction, as was the ore concentration and sintering plant of Société [18] SAEM at Longwy/St. Martin, due to be completed in 1968. Completion date of the steel plant was advanced to 1967–68.

Ferroalloys.—Of the 432,000 tons of spiegeleisen and high-carbon ferromanganese produced in blast furnaces, 108,000 tons were spiegeleisen and the remainder ferromanganese. Ferroalloys produced in electric furnaces and their monthly average output in 1965 were ferrosilicon (calculated on the basis of 50 percent silicon) 9,919 tons; silicospiegel and ferro-silicomanganese 1,058 tons; ferrochromium 5,957; ferrotitanium, ferrotungsten, ferrovanadium and ferromolybdenum 576 tons (metal content); and others 3,101 tons (metal content). Total monthly average was 20,611 tons.

Iron and Steel Scrap.—France consumed 7,362,000 tons of scrap exclusive of consumption by independent foundries and sintering plants in 1965, compared with 7,701,000 tons in 1964. The 1965 consumption was distributed as follows: 478,000 tons in blast furnaces, 6,884,000 tons in steel mills, and 98,284 tons in rolling mills. In addition, estimated consumption by independent foundries and sintering plants was 260,000 tons and 4,000 tons, respectively. It is estimated that the steel industry bought 2,915,000 tons of scrap for its use: 2,455,000 tons of French origin, 360,000 tons from other European Coal and Steel Community countries, and about 100,000 tons from third countries. The remainder was home scrap. France was a net scrap exporter in 1965 by 1,338,000 tons.

Lead and Zinc.—Results of exploration at Malines and Peyrebrune, carried out by Société Minière et Métallurgique de Peñarroya (Peñarroya), were reportedly encouraging, and the reserve condition in these two concessions has improved. Joint exploration by Bureau de Recherches Géologiques et Minières (BRGM) and the Société des Mines et Fonderies de Zinc de la Vieille Montagne has delineated 120,000 tons of ore with 3 percent lead and 8.4 percent zinc at Vézis with an additional 100,000 to 150,000 tons of probable reserves. Exploration by BRGM and Peñarroya in 1964 indicated a probable 3 million tons of ore at Caboire (Ariège) with 0.8 percent lead and 6 percent zinc. Two deposits in Corsica, Plélauff and Ghisoni-la-Finosa, have reserves of 300,000 tons of ore with 6 percent lead and 7 percent zinc and 600,000 tons with 2.8 percent lead and 2 percent zinc, respectively.

Output of both lead and zinc concentrates increased, resulting mainly from the operation of the Argentière mine in Ardèche. Peñarroya produced 22,850 tons of lead concentrates and 27,763 tons of zinc concentrate in France. Its smelter at Noyelles-Godault produced from domestic and imported concentrates 100,796 tons of lead and 45,089 tons of zinc, or 79 and 23 percent of total French domestic production of refined lead and smelter zinc, respectively. Smelter capacity of this plant was to be increased to 70,000 tons of zinc and 115,000 tons of lead by 1967. Orders were also placed for building a zinc distillation column. The company concluded a long-term contract for purchase of zinc concentrates from the Silvermines property in Ireland operated by Mogol of Ireland, Ltd. starting in 1968.

Compagnie Royale Asturienne des Mines added two new vertical retorts (Creuset) to its Auby smelter in May 1965. This plant has an annual capacity of 60,000 tons of zinc. The new retorts will compensate loss of productive capacity resulting from closure of the Montagne plant in 1963. At this plant construction of a fluidized-bed roaster and extension of sulfuric acid facilities was started. The capacity of the electrolytic zinc plant at Viviez of Vieille Montagne remains at 65,000 to 70,000 tons per year but is expected to increase to 80,000 tons when the hydropower plant on the Selve River starts operating. Secondary zinc was produced from distillation of scrap at Creil, Lunéville, and Honnecky plants, which have a combined capacity of 10,000 to 12,000 tons.

Consumption of both lead and zinc in 1965 diminished from the 1964 level by 16 and 19 percent, respectively. Lead consumption, including lead content of antimonial lead, totaled 144,600 tons; zinc consumption was 186,700 tons, excluding 7,300 tons of zinc dust.

Lead prices generally followed conditions of the international markets, but zinc

[17] A company created by Société de Wendel and Union Sidérurgique Lorraine (Sidélor).
[18] Formed by Société Anonyme de Lorraine-Escaut, Hauts Fourneaux et Forges de Saulnes et Gorcy, and Société des Laminoirs, Hauts Fourneaux, Forges, Fonderies et Usines de la Providence.

prices remained practically unchanged. Average lead price was $323 per ton ($284 in 1964); during the year the price ranged from $271 to $384; it was $307 at year-end.[19] The average zinc price in 1965, $316.70 per ton, was only 90 cents less than the 1964 figure.

Nickel.—The Havre nickel refinery, treating imported nickel matte, produced 6,400 tons of contained nickel—5,900 tons as refined metal and 500 tons as oxide. Nickel consumption of France is estimated as 26,500 tons per year.

Uranium.[20]—Aside from prospecting and exploration for uranium in the three mining divisions of La Crouzille, Forez, and Vendée, work was carried out in Auvergne and continued in l'Hérault where prospecting started in 1964. Private industry activities were limited, but a promising deposit was discovered in Haute-Vienne. Negotiations for long-term supply of uranium from Canada fell through in May because the French Government was not prepared to accept inspection by the International Atomic Energy Agency. In December there were unconfirmed press reports of the possibility of a contract between South Africa and France. Uranium reserves of France increased as follows:[21]

Area	Reserves (tons of contained uranium)		
	1963	1964	1965
Mines and deposits of Commissariat à l'Énergie Atomique (CEA):			
Forez-Morvan	5,470	5,190	4,960
La Crouzille	5,520	6,430	8,880
Vendée	3,670	3,870	3,870
Vosges	2,030	2,030	2,030
Hérault	4,310	5,880	5,680
Total	21,000	23,400	25,420
Private companies in Brittany	1,110	1,130	1,120
Private companies in Massif Central	5,580	5,230	7,290
Grant total	27,690	29,760	33,830

In addition to the 1,072 tons of contained metal from domestic production, France obtained 1,967 tons of preconcentrates from Gabon and Madagascar with 544 tons of uranium content. From these raw materials, concentrates with 1,516 tons of uranium were produced in French beneficiating plants. Three mills (Bessines, l'Écarpière, and Bois-Noirs) treated 746,150 tons of ore; the preconcentrates were treated in the Gueugnon plant and Le Bouchet, the latter handling the uranothorianite from the Malagasy Republic. Estimated annual French uranium requirements for 1980 have been estimated at 3,500 to 5,000 tons.

All the uranium needed by the reactors of CEA and Électricité de France were produced at Malvési and Le Bouchet. The magnesium-thermal reduction process of producing uranium metal, started in Le Bouchet in 1964, will also be utilized in Malvési. For refining uranium, tests on denitration in a fluidized bed, carried out with collaboration of Ugine, led to installation of a pilot plant. Recovery of uranium by ignescent electrolysis of uranium-dioxide (UO_2) is also indicated as a possibility.

The Pierrelatte gas-diffusion plant was inaugurated in January and produced enriched uranium during the year. Production of 8 percent enriched uranium started about midyear. Preparations were underway to start the units for producing higher grade enriched uranium. Enriched uranium was leased or purchased in the United States for CEA's research reactors. Pending completion of the Eurochemie plant at Mol, Beligum, CEA signed two contracts for processing of irradiated uranium with the United States Atomic Energy Commission and the United Kingdom Atomic Energy Authority. The Dounreay reactor will process spent nuclear fuel from the Pegase reactor at Cadarache.

Other Nonferrous Metals.—Ore produced by Société des Mines et Produits Chimques de Salsigne from its mines at Fontaine de Santé and des Ramèles contains gold, silver, copper, bismuth, and arsenic. The company produced 148,195 tons of ore, 26,131 tons of flotation concentrates, and 6,926 tons of matte which contained 1,603 kilograms of gold, 4,777 kilograms of silver, and 410 tons of copper; 52 tons of bismuth and 7,735 tons of arsenic anhydride also were recovered from furnace flue gases. During the year the

[21] Page 184 of work cited in footnote [20].

company added to its flotation circuit, installed jigs, and improved its grinding circuit with the expectation of obtaining better metal recovery.

Tin concentrates were produced by one firm, the Société Comiren à Saint-Renan. Annual consumption of the metal is estimated at 10,000 tons.

NONMETALS

In 1965 production of crude potash and potassium chloride increased, but domestic shipment, comprising 1,037,000 tons of K_2O equivalent was almost the same as in 1964, and exports decreased. As a result stocks at yearend increased to 215,600 tons of K_2O content, compared with 104,500 tons in 1964. Sufficient and comparable data are not available on the 1965 output of the important construction material and quarry industry for detailed analysis of its performance relative to that of 1964 but preliminary information indicates that production of alluvial sand and gravel and plaster increased while output of most other categories declined. In the case of sulfur materials a decline was noted in pyrite production and imports while elemental sulfur output remained substantially the same. These shifts, coupled with smaller sulfur exports, indicated that more sulfur was used domestically.

The value of 1964 nonmetals production exclusive of building raw materials and quarry products totaled about $156 million.[22] Potash, sulfur, and salt were the most important commodities, accounting for 62, 18, and 16 percent, respectively of the total value. Building raw material and quarry products were valued at $481 million, of which about $51 million was accounted for by material used in industry, (including minefill) about $4 million by material used in agriculture, and $426 million by material used in the building industry. The latter figure comprised sand and gravel ($164 million), other building materials such as stone, slate, clays, limestone, and gypsum, but excluding lime and cement ($141 million), and material for road building and similar uses ($121 million).

Value of nonmetal imports and exports including cement and lime in 1965 totaled $201 million and $173 million, respectively. Among imports, phosphate rock ($44 million), clay and other refractory materials ($18 million), stone, and sand and gravel ($18 million), asbestos ($16 million), Thomas slag ($8 million), sulfur ($8 million), and pyrite ($4 million) were the most important. Potash in chemically treated form, sulfur, and cement exports were valued at $40 million, $23 million, and $13 million, respectively.

Cement and Lime.—Cement production in France continued the pattern of uninterrupted increase that has prevailed for the last 20 years,[23] and France became the world's fifth largest producer. The 3.3-percent increase in 1965 was more than the rate for industrial production but considerably less than the 18.8-percent increase in cement production recorded in 1964. The decline in growth rate may be due to the consolidation of increased capacity achieved in 1964 and 1965. Industry spokesmen felt that in the immediate future market outlets for cement would be favorable because of the expected level of housing construction and increased allocation of funds for public works. Furthermore, the Fifth Plan envisages a 35-percent increase in construction and public works between 1966 and 1970 and an annual expenditure of about $600 million for roads compared with $240 million in the Fourth Plan. The Fifth Plan calls for a production of 30 million tons of cement by 1970.

Production of cement in recent years was as follows:

Type	Thousand metric tons				
	1960	1961	1962	1963	1964
Portland	9,281	9,607	11,757	12,647	16,227
Slag (blast furnace)	2,381	2,837	2,203	2,485	2,333
Special	1,130	1,860	1,475	749	983

Type	Thousand metric tons				
	1960	1961	1962	1963	1964
Other slag	865	404	626	1,448	1,144
Total	13,657	14,708	16,061	17,329	20,687
Natural	121	177	397	275	255
Mortar	381	496	424	530	595
Total	14,159	15,381	16,882	18,134	21,537

At the beginning of the year there were 61 plants in operation of which 15 had individual annual capacities exceeding 500,000 tons, 24 had capacities between 300,000 and 500,000 tons, 20 had capacities of 100,000 to 300,000 tons, and 2 had capacities of less than 100,000 tons.

In 1965 the industry used 2,135,000 tons of coal, 875,000 tons of fuel oil, 195 million cubic meters of gas, and 1,860 million kilowatt-hours of electricity. Additives consisted of 3,395,000 tons of blast furnace slag and 885,000 tons of fly ash. French cement consumption increased 5 percent to 21.6 million tons; on a per capita basis, this was 442 kilograms, compared with 551 kilograms in West Germany and 325 kilograms in the United States. The Paris region accounted for 19 percent of the consumption, followed by 16 percent for the Mediterranean area and 14 percent for the southwest. Of total shipments, 43.7 percent was in bulk and the remainder in bags.

During the year about $71 million was invested in the industry. By installing two new kilns in existing plants, and one kiln in a new blast furnace cement plant and improving existing plants, 1.7 million tons of capacity was added. At yearend the annual capacity was 20.3 million tons of clinker and 26.3 million tons of finished products. For 1966 and 1967 it was planned to add 3.11 million tons of capacity: 1,250,000 tons from 4 new plants and 1,860,000 tons from 10 kilns (8 dry, 1 wet, and 1 vertical) in existing plants.

French cement imports, though slightly greater than in 1964, were not important. Exports decreased by 14 percent; non-Communist Europe was the largest regional market, accounting for 53 percent of exports; West Germany was the largest single market, receiving 32 percent of exports.

Employment remained at much the same level for the fourth consecutive year in spite of increased production. Productivity improved 4.5 percent to an estimated 1,590 tons per year per worker, compared with 1,522 tons in 1964. Of the 14,000 employed, 10,400 were workers and the remainder were technical, clerical, and administrative employees. The cement price stayed stable.

In 1964 2,920,000 tons of high purity or fat lime was produced as follows: For use in iron and steel plants 2,042,000 tons, for use in calcium carbide and other chemicals 605,000 tons, for agricultural use including vine culture 273,000 tons. The 300,000 tons of increased output was mainly consumed by the steel industry and agriculture.

There were no significant changes in the number of hydraulic lime-producing plants, except that plants with annual capacities exceeding 50,000 tons increased from 9 to 12 and those with capacities between 30,000 and 50,000 tons dropped from 23 to 20. There were 75 plants in operation at yearend.

At the beginning of 1965, 108 plants producing fat lime were in operation (117 at the beginning of 1964). The drop was caused by a reduction of 16 in the number of small plants (5,000 to 25,000 tons' annual capacity), but this was partly compensated by an increase of 5 in plants with 25,000 to 50,000 tons' annual capacity.

Construction Material and Quarry Products.—In 1964, the latest year for which detailed information is available, there were substantial increases in the production of all categories of quarry products other than those for agricultural use. Output consisted of about 54 million tons of construction materials; 110 million tons of sand and gravel; 58 million tons of road and foundation building materials; 30 million tons of materials for industry such as kaolin and refractory clays, limestone, glass and foundry sands, chalk, and barite; and 1.1 million tons of materials for soil improvement and other agricultural uses, including limestone, gypsum, marl, phosphate, and phosphatic lime. Preliminary monthly average production data for some

items in 1965 indicate that there were declines in the majority of the items listed but a further substantial increase in sand and gravel:

Commodity	Quantity (thousand tons)	
	1964	1965
Calcareous building stone	130	129
Furnace limestone [1]	289	259
Slate	10	10
Plaster	207	217
Alluvial sand and gravel	7,964	9,230
Industrial sand	248	243
Road building material	4,268	4,195
Pozzolana	48	41

[1] For use in blast furnaces, foundries, and sugar mills.

In 1964 the industry employed 97,300 (91,900 in 1963) of whom 82,800 received hourly wages and the remainder salaries. These figures do not include workers in those limestone and clay quarries that were captive operations of the cement plants. The turnover of the industry in 1964 was $982 million.[24]

In 1964 there were 2,783 quarries and sand and gravel pits in operation, distributed as follows, by size of labor force:

Quarry type	Persons employed				
	Less than 20	21 to 50	51 to 100	101 to 200	201 and more
Sand and gravel for construction	1,316	98	23	3	3
Industrial sand	136	12	1	1	—
Road building materials	1,063	100	22	5	—
Total	2,515	210	46	9	3

Potash.—French potash consumption in the last 5 years has increased at an average annual rate of 7 percent. Consumption in 1964 was estimated at 1,050,000 tons of K_2O equivalent and in 1965 at about 1,100,000 tons. Consumption is expected to increase 4.3 percent annually in the next 5 years to 1,350,000 tons K_2O in 1970. Increase in production is limited by the size of existing deposits; another factor is limitation on the pollution of the Rhine River resulting from discharge of saline effluents.

In 1965, France's rank as a world potash producer fell to fifth as output in The Soviet Union increased noticeably. French output constituted about 14 percent of total world output in 1965. The increase in the share of long wall method in total production, noted in 1963, continued in 1964. Beneficiation plants treated 11,114,031 tons of crushed salt: 7,588,221 in hot leach plants, 3,189,425 in flotation plants, and 336,385 in levigation plants in 1964. Of the potassium chloride (KCl) produced in this year, 1,276,138 tons in terms of K_2O equivalent was recovered from hot leach, 594,005 from flotation, and 52,506 from levigation. Recovery percentages of the three methods were 90.12, 93.33, and 85.82 percent, respectively.

Investment in 1964 was directed primarily toward improving existing facilities rather than toward expansion. Investment totaled $7,600,000, of which 60 percent was for maintenance of production facilities. Shipments of crude and processed potash to the internal market in 1965 totaled 1,036,800 tons K_2O equivalent, and exports totaled 764,000 tons K_2O equivalent.[25]

France exported 92,151 tons of crude potash, mainly to other EEC countries. Major destinations for the 1,187,130 tons of chemically treated potassic fertilizer follow: EEC 406,245 tons (Belgium-Luxembourg 217,009, Netherlands 74,221, Italy 66,124, and West Germany 48,890), United Kingdom 223,315, United States 101,957, and Switzerland 69,194.

Salt.—Of the total salt produced in France in 1964, 3,241,577 tons was obtained from rock salt mines and salt springs in the following forms: 2,394,602 in solution, 679,777 as refined salt, and 167,198 as rock

[24] Employment and turnover figures include workers in plants making concrete products, plaster, asbestos cement, mineral wool, and bricks.

Total	799,339	2,458,780	363,404	212,104	105,705

[1] Included in industry.
[2] Includes agriculture and fisheries.
[3] Includes fisheries.

As previously, the major share of the salt in solution was used for making sodium carbonate.

Sulfur and Pyrite.—Sulfur production from all domestic sources in 1964 was 1,609,400 tons; 1,519,600 tons recovered sulfur from the Lacq field and other sources, 78,300 tons in pyrite, 7,200 tons contained in lead and zinc sulfides, and 4,300 tons from spent oxides.[27] About 90,000 tons additional sulfur must have been obtained from metallurgical plants.

The 1965 sulfur production in all forms from all domestic sources was about 1.6 million tons. The decline in production of pyrite was compensated by the increased output of sulfur at Lacq and by the increased quantity of sulfur in lead-zinc ores. Total consumption was about 1,170,000 tons.

France produced 2,841,000 tons of sulfuric acid (exclusive of 75,600 tons of residual acid); sulfuric acid accounted for about 84 percent of the sulfur used in the

[26] Bureau de Documentation Minière. Statistique de l'Industrie Minérale 1964. Paris, France, 1966, p. 61.
[27] Organization for Economic Co-Operation and Development. The Chemical Industry 1964–65. Paris, France, 1966, p. 125.

country. In 1964 phosphatic fertilizer producers used about one third of the sulfuric acid and nitrogen fertilizer producers, one tenth.

Pyrite is now mined only in the Saint-Bel mines operated by St. Gobain. A sulfur recovery unit of 20 tons per day was put in operation by the Compagnie Française des Pétroles in 1964, and a unit of similar capacity is planned for the Union Générale des Pétroles-Union Industrielle des Pétroles UGP-UIP refinery at Ouzouoi-le-Repos which was scheduled to start in 1966.[28] The sulfur will be used in making sulfuric acid.

MINERAL FUELS

For the first time consumption of petroleum products in terms of standard coal equivalent (SCE) exceeded that of coal. The 12-percent increase in petroleum consumption was more than three times the 3.7-percent increase in total energy consumption. Favorable hydraulic conditions increased the contribution of hydroelectric power to total energy consumption.

Table 9.—France: Energy consumption by sources

Type of fuel	1961	1962	1963	1964	1965 p
Quantity:

Coal.—*Production.*—Production of coal (anthracite and bituminous) declined 3.2 percent below the level of the previous year, in keeping with the planned reduction of coal output to 48 million tons by 1970. Although all fields except Dauphiné showed a decline, loss of production in Nord/Pas-de-Calais, the largest producing area, accounted for 64 percent of total decline as follows:

	Thousand metric tons	
	1964	1965
Nord/Pas-de-Calais	26,567	25,489
Lorraine	15,628	15,547
Blanzy	2,468	2,295
Loire	2,223	2,201
Auvergne	941	909
Cévennes	2,307	2,216
Aquitaine	2,117	1,836
Dauphiné	730	752
Other mines or undistributed	49	100
Total	53,030	51,345

The Lorraine field increased its share of national output from 29.5 percent in 1964 to 30.3 percent; Nord/Pas-de-Calais accounted for 49.6 percent of production (50.1 percent in 1964). Lorraine fields remained France's most efficient fields with productivity exceeding that in all other areas. No ploughs or coal picks are used in these mines. Coal cutters and multiple attack faces account for 85 percent of the production.

In 1965, it is estimated that 53 percent of France's total coal output was obtained from seams 1 to 2 meters thick and an additional 17 percent was obtained from seams 2 to 3 meters thick. Weighted average of seam thickness in all faces in 1964 was 1.51 meters. Of all coal produced, about 53 percent was obtained from seams with dips of zero to 20 degrees. Coal production by extraction method in 1965 (corresponding 1960 figures in parentheses) follows, in percent: pickhammer only 23.6 (34.5), pickhammer and explosives 10.2 (12.5), coal cutter 15.3 (10.2), mechanical

[28] Mines et Métallurgie (Paris, France). May 1966, p. 213-214.

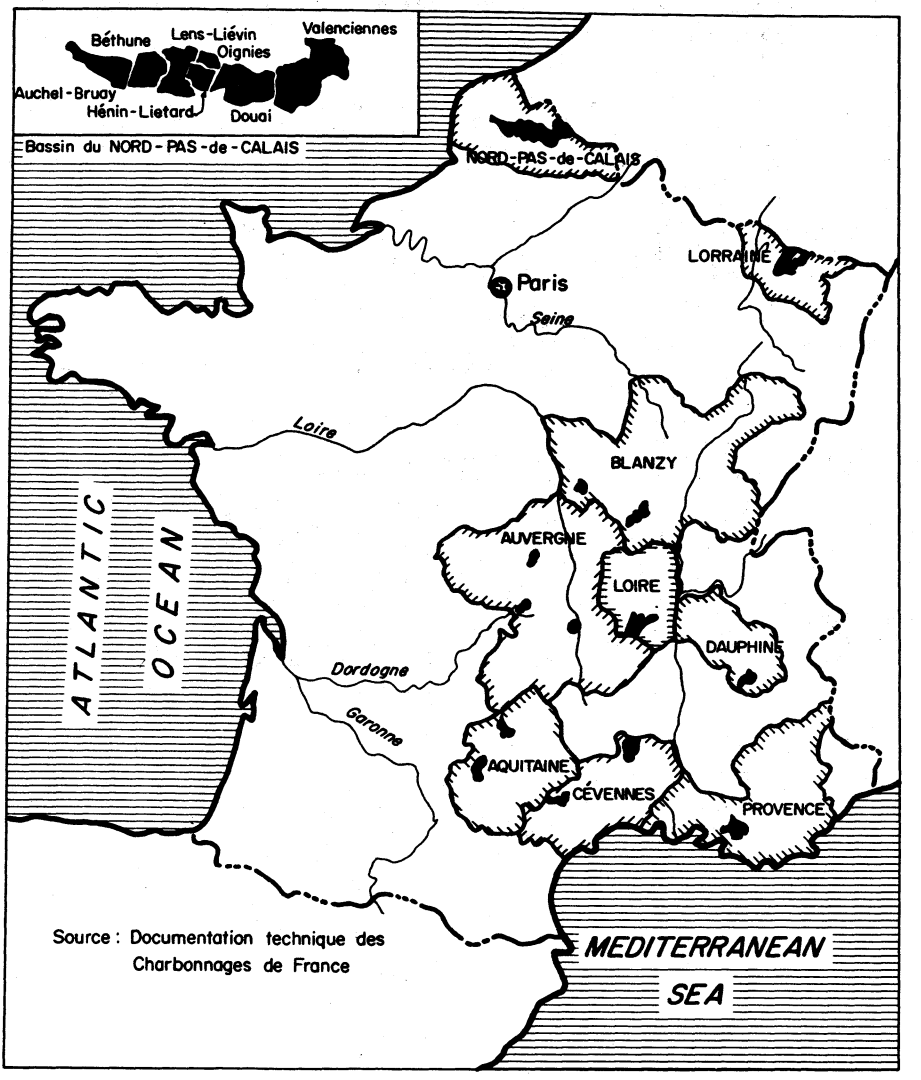

Figure 2.—France: Coal basins.

cutter and explosives 5.6 (7.7), explosives alone 24.1 (19.0), blasting by compressed air 3.4 (3.9), ploughs 17.7 (11.9), and other 0.1 (0.3). Particularly noteworthy during the 1960–65 period was the increase in the number of drum coal cutters (from 95 to 144) and the decline in coal cutters with arm (from 196 to 150). The number of coal ploughs increased from 118 to 178, allowing increased mechanization in thin seams. In 1964, longwall workings provided 68.3 percent of the coal.

Mechanized mines (those in which breaking and loading are mechanized) produced 61.4 percent of net coal mined underground in October 1965, while semimechanized mines (those in which either loading or breaking is mechanized) contributed

[1] Largely 14 to 18 percent volatile matter; a small tonnage has a higher volatile content.
[2] 16 to 28 percent volatile matter.
[3] 25 to 41 percent volatile matter.
[4] 40 to 42 percent volatile matter for the bulk of production in this category.
[5] Detail does not add to total (official data) because of differences in source.

21.6 percent. Average daily production per face in October 1965 was 226 tons (215 tons in October 1964). With increased mechanization, consumption of electricity per ton of coal, excluding that for ventilation, was 5.9 kilowatt-hours for work performed underground; 19.2 kilowatt-hours per ton was required for compressed air. Transformers installed underground had 356,591-kilovolt-ampere capacity. For underground transport, shaking conveyors are practically disappearing (only 13 kilometers in opera-

tion in 1965), and use of belt conveyors (307 kilometers), scraper conveyors (219 kilometers), and locomotive haulage (1,382 kilometers) has increased. At the face, nearly 75 percent of the output is transported by scraper conveyors and 10 percent by gravity conveyors.

In 1965 little progress was reported in the automation of mining operations,[29] but more advances occurred in the remote control of machines such as shearers. Interest in driving coal ploughs by hydrostatic means also increased.

Of the 77 mines operating in 1964, 2 had average daily production of 8,000 tons and over, 10 had average daily production of 4,000 to 8,000 tons, 49 each produced 1,000 to 4,000 tons daily, and the remainder provided less than 1,000 tons apiece per day.

Simultaneously, average length of faces has shown continued increase; in 1964, it averaged 116 meters for all faces, 139 meters for mechanized faces, and 93 meters for nonmechanized faces. Average daily rates of advance for the three classes of faces were 1.28, 1.42, and 1.10 meters, respectively. Three faces produced 1,000 tons and over per day, 5 faces 750 to 1,000 tons, and 34 faces 500 to 750 tons.

Coal production cost increased 5.4 percent to $17.33 per ton in 1965, compared with $16.44[30] in 1964. Higher labor cost resulting from increasing wages was the principal factor contributing to increased production costs. The 1965 cost per ton was composed of labor $11.14; supply $4.02; overhead, taxes, and financial charges $0.96; and amortization $1.21. Sale price of coal, $13.47, was 1.9 percent less than in 1964. Gross deficit on coal exploitation, including amortization, was $206 million, $56 million more than in 1964. The 1965 deficit was partially compensated by profit of $18 million in conversion of coal into electricity, coke, chemicals, and other products. Without amortization, the deficit for the industry as a whole was $73 million ($5.27 million in 1964). Budgetary aid to the coal industry amounted to $124 million. Final deficit, taking into account profit and loss and the Government's participation in the rationalization of the coal mines, was $65 million.[31]

To improve its financial situation, Charbonnage de France is pursuing a policy of diversification into other fields and seeking new applications of coal and byproducts. In cooperation with Électricité de France, cinder ash is recovered at coal-powered stations for use in the building industry. In 1965, 2.1 million tons of coal ash was sold in France: 956,000 tons to cement plants, 726,000 tons for road use, 103,000 tons for cinder blocks, and 339,000 tons for other uses. Of the total sale, the coal mines accounted for 1,146,000 tons. Utilization of shale for brick making is another area of work entrusted to Nord/Pas-de-Calais.

Consumption and Trade.—Apparent consumption of coal and lignite in 1965 declined by about 8 percent to 69 million tons of standard coal equivalent; this included about 66 million tons of coal and 3 million tons of lignite. Real consumption is estimated to have been 200,000 tons less. Domestic coal and lignite accounted for 78 percent of the apparent consumption.

Total sales of solid fuels from all sources declined further to 57.3 million tons (60.5 million tons in 1964). As in 1964, the decline in sales was borne mainly by imported coal (including coal from the Saar). Sales of these coals amounted to 15.9 million tons, 2.2 million tons less than in 1964. Sales to principal customers were as follows, in thousand metric tons: Iron and steel industry 16,746, domestic users and small industry 14,516, other industry 11,359, Électricité de France 9,597, railroads 1,888, Gas de France 891, briquetting plants 1,158, and exports 1,159. Sale to all principal consumers declined, with the sole exception of Électricité de France which bought 1,945,000 tons more.

Although production of thermal electricity by Électricité de France in 1965, 55,000 million kilowatt-hours, was less than in 1964 (59,064 million kilowatt-hours), solid fuel consumption by this organization increased 3.4 percent to compensate the smaller use of fuel oil, natural gas, and blast furnace gas. Total electricity production increased 6.5 percent to 102,200 mil-

[29] United Nations, Economic Commission for Europe, Coal Committee, Sub-Committee on Mining Problems. Report of the Sub-Committee on Mining Problems. Coal/178, Aug. 8, 1966.
[30] Revised to include coal used by coal mines and coal delivered to miners, which were not included previously in arriving at unit cost of production.
[31] Charbonnage de France. Rapport de Gestion 1965. Paris, France, pp. 94–107.

lion kilowatt-hours (96,007 million kilowatt-hours in 1964). Solid fuels accounted for 65 percent of all fuels used in thermal power production; the shares of other fuels in this market, in percent, were fuel oils 20, natural gas 5.5, blast furnace gas 8, and nuclear 1.5.

In the steel industry consumption of coke in blast furnaces, of coal for carbonization, and of coal for gas production declined by 4.1, 1.5, and 18.6 percent, respectively. The decline in blast furnace coke consumption was mainly because of lower consumption per ton of pig iron produced rather than reduced pig iron output. Owing to increased sintering of iron ore, coal consumption for miscellaneous purposes increased 5.7 percent to 2,928,000 tons, from 2,769,000 tons in 1964.

During 1965 another coke oven gas plant in the Paris area was closed so that only five such plants remained in operation. Relative share of primary fuels in the gas supply (output of Gas de France and purchase gas) were as follows, in percent: gas obtained from coal 25.8, natural gas 49.7, and gas from liquid fuels 24.5.

The share of total fuel needs of industry (other than iron and steel and small industry) supplied by solid fuels decreased further to 34.3 percent (39.7 percent in 1964), whereas that supplied by fuel oil increased from 50.3 percent in 1964 to 55.3 percent in 1965. The share of natural gas was 10.4 percent, slightly more than in 1964 (10.0 percent). Total delivery of all fuels to this sector increased to 33.8 million tons of coal equivalent, from 32 million tons in 1964.

Coal prices were substantially the same except for a 5-percent increase in transportation costs starting May 31.

Imports from all principal sources decreased. Purchases of U.S. coal fines for coking increased to 1.3 million tons.

[2] Including 7 tons from Italy.

Source: Bureau de Documentation Minière. Combustibles Minéraux Solides, Statistique Annuelle Définitive. Paris, France, pt. 2, 1965, 6 pp.

Preparation.—There were 64 washing plants in operation in 1964 with an average hourly capacity of 400 tons of raw coal; newer plants have hourly capacities of 1,000 to 1,400 tons. Total capacity was about 24,700 tons, of which 21,500 tons was in new or modernized plants.[32]

In 1965, 87.2 percent of run of mine production was washed, including 43.7 percent delivered marketable coal, 34.5 percent rejects, 6.5 percent middling, and 2.5 percent slime. Of the total coal washed, 50.7 percent was treated in heavy media, 39.2 percent in piston jigs, 8.3 percent in flotation cells, 1.6 percent on pneumatic tables, and 0.2 percent by miscellaneous facilities. Flotation installations in operation totaled 31 in 1964 with hourly capacity of 1,300 tons. Practically all the fine coal (5 to 10 millimeters) is obtained from heavy-media cells. Dried slimes produced by flotation accounted for 9 percent of net annual output. Heavy media cyclone separation, introduced in 1964 at Messeix (Auvergne), was introduced during 1965 at Brassac (also Auvergne) and at Barrois and Bruay in Nord/Pas-de-Calais.

[32] Provisional figures.

Manpower.—The reduction of coal-mining workers, both underground and surface, continued. During the year 6,312 workers left the industry, including 4,277 underground and 2,035 surface workers. Employment on December 31, 1965, in the mines of Charbonnage de France (including lignite) was distributed as follows by area:

Area	Employment		
	Surface	Underground	Total
Nord/Pas-de-Calais	23,418	67,486	90,904
Lorraine	9,167	19,500	28,667
Centre-Midi	10,780	21,449	32,229
Total	43,365	108,435	151,800
Reduction from 1964 figures (percent)	4.5	3.8	4.0

In addition, 8,893 persons were employed in associated plants of the mines of Charbonnage de France.

Average salaries for an 8-hour, 15-minute day, including all premiums but excluding payments for vacation and rest days were as follows:

Year	Average daily salary (dollars)		
	Underground	Surface	Surface and underground
1963 r	7.19	5.61	6.69
1964 r	7.88	6.18	7.34
1965	8.34	6.57	7.79

r Revised.

Fringe benefits and social security payments were equivalent to 84.84 percent of wages. Because of increases in basic wage rates on April 1 and September 1, personnel costs increased by about $20 million for the year as a whole.

Investment.—There was a small increase in total investment in the coal industry because of the increase in investment in conversion facilities; investment in mining and housing continued to decline. Of total investment of $90,340,000 in 1965 (exclusive of recoverable taxes), $49,220,000 was for extraction, $33,620,000 for conversion industries, and $7,490,000 for housing (753 houses completed during the year).

Important projects started under the fourth phase of the modernization program during the year included a washery for coal fines at Barrois in the Nord/Pas-de-Calais area, opening of a new field (Falck) in the La Houve mine group, and deepening the Merlebach mine to 1,036 meters and the Simon mine to 580 meters, both in the Lorraine basin.

Of the sum invested in the conversion facilities, $14,580,000 was spent for powerplants (including $11,600,000 for the Gardanne powerplant); $2,430,000 was spent in coke oven plants to complete work previously undertaken, and for coal preparation, maintenance of gas networks and mechanization of coke pushers. The chemical section had the largest share of investment for conversion facilities, $16,640,000. A fourth nitric acid plant at Mazingarbe and a methanol plant at Harnes were being completed; a 600-ton-per-day ammonia plant was also under construction at Mazingarbe.

Research.—Research was concentrated in the chemical aspects of the industry (about $3.5 million) and in exploring new uses for coal. The work was carried out by Centre d'Études et Recherches de Charbonage (Cherchar) and by the coal mines of Nord/Pas-de-Calais and Lorraine. Research on coal, coke, chemial products, and high polymers was undertaken by Cherchar. Research on fertilizers and heavy water mainly concerned researchers in Nord/Pas-de-Calais, while those in Lorraine, utilizing their specialties, devoted attention to applying the results of Cherchar research to coal chemistry.

Coke and Coke Chemicals.—Coke ovens of the mines of Charbonnage de France accounted for 63 percent of total coke output. Their daily output averaged 23,675 tons, and production capacity remained practically the same as in 1964—25,600 tons per day. A new battery of coke ovens, number 4 in Nord/Pas-de-Calais, was put in operation in December, but this addition to capacity was balanced by closing two other batteries—one at Carbolux and one at Carmaux de Distirex. Of the coal used in coke production, Charbonnage de France carbonized 11,400,000 tons, 89.7 percent of total French-origin coal.

The iron and steel industry remained France's dominant coke consumer, accounting for 81 percent of the tonnage distributed. Of the 8,543,000 tons of coke, semicoke, and agglomerates produced at the coal mines, 5,222,000 tons was shipped to the iron and steel industry, 1.5 million tons was shipped to other industries, and the remainder went to household and export markets or was used for mine consumption.

There was a reduction in crude coal tar production—625,000 tons was produced, compared with 664,000 tons in 1964 and 625,000 tons in 1963. Of these totals, coal mines produced 377,000 tons in 1965, 395,000 tons in 1964, and 355,000 tons in 1963. The increase in production of benzoic hydrocarbons to 397,000 tons in 1965 (362,000 tons in 1964 and 327,000 tons in 1963) resulted mainly from treatment of petroleum; coal mines produced 137,000 tons of these products in 1965. Nitrogen products accounted for more than half of the turnover of coal chemicals produced by the coal mines and their subsidiaries. In 1965, with production of 572,900 tons of ammonia and 430,700 tons of ammonium fertilizers, the coal mines and their subsidiaries accounted for 46 and 39 percent of national output, respectively.

Source: Bureau de Documentation Miniere. Combustibles Minéraux Solides. Statistique Annuelle Définitive. Paris, France, pt. 2, 1961–65.

Patent Fuels.—Coal mines of Charbonnage de France produced 4.48 million tons, and private mines and patent fuel producers other than mines provided 1.33 million tons. Of the total output, 4.4 million tons was classified as boulet (egg-shaped agglomerates used for domestic heating), 1.21 million tons was smokeless agglomerates, and 192,000 tons was briquets. Smokeless agglomerates maintained their popularity with consumers. Four furnaces for producing "anthracene" at Rousseau plant in Valencienne, Nord/Pas-de-Calais, were completed. A new plant was also being built at Blanzy.

Lignite.—Much of the increase in lignite production was obtained from mines in the Landes region, which produced 972,000 tons. Mines of Charbonnage de France in Provence produced 1,697,000 tons (1,606,000 tons in 1964); 19,000 tons was produced by other mines. Lignite shipment to users other than miners' own use and briquetting plants totaled 1,784,000 tons: 962,000 tons to powerplants, 735,000 tons to industry, and 87,000 tons to domestic users and small industry.

Petroleum and Natural Gas.[33]—Domestic production of crude petroleum in 1965, although 5 percent greater than in 1964,

[33] Comité Professionnel du Pétrole. Éléments Statistiques. Activité de l'Industrie Pétrolière, V. 1, Paris, France, 1963–1965.

was only 4.9 percent of total national refinery throughput (5.6 percent in 1964). Consumption of petroleum products increased about 5 million tons from the 1964 record, but the rate of increase was just about half that of 1963 to 1964. The net cost of imports of petroleum and petroleum products to the French economy increased again, from $803 million in 1964 to $926 million in 1965.

In 1965, $475 million was invested in the oil industry with refining, storage, and distribution as the largest areas of expenditure. Taxes on petroleum products contributed $2.1 billion to the general budgets. Tax represented between 74 and 77 percent of the retail price of motor gasoline and 70 percent of that of gas oil.[34]

Government Actions.—A decree with regard to distribution of petroleum products was issued on February 26, 1965, fixing the maximum quantities of gasoline and lubricants that the marketing companies may sell in the French market each year. The decree, which will be valid September 1, 1965, to August 31, 1968, in effect renewed the distribution authorization of April 15, 1953, which was to expire in 1965.

The new quotas include gasoline produced from Algerian and Gabonese as well as other foreign crudes, while previously only gasoline from other foreign crude was considered. As a result, total authorized imports will be 10,250,000 tons, compared with 4,874,374 tons under the previous quota. The share of French marketing companies in the total was increased to 52.82 percent from the previous figure of 51.75 percent. The new quotas leave marketeers room for expansion, but the scope given to the mainly French groups is greater than that given to the international companies. The new decree removes the misgivings of the international oil companies as to their situation should Algerian crude become "foreign crude."

A decree of December 17 merged the Regie Autonome des Pétroles (RAP) and Bureau de Recherches de Pétrole (BRP) into a single entity, Enterprise de Recherches et d'Activités Pétrolières (ERAP) effective January 1, 1966. BRP, which was a holding company for participation in petroleum production and exploration, brings into the new company the following shares of other companies: 27.92 percent of Compagnie Algérienne de Recher-

che et d'Exploitation Pétrolières, 51.5 percent of Compagnie d'Exploration Pétrolière (CEP), 80.91 percent of Compagnie des Pétrolas France-Afrique, 4.5 percent of Compagnie Algérienne de Recherche et d'Exploitation du Pétrole au Sahara (CREPS), 86.66 percent of Société de Participations Pétrolières (PETROPAR), 67.5 percent of Société Anonyme Française de Recherches et d'Exploitation de Pétrole (SAFREP), 51.02 percent of Société Nationale des Pétroles d'Aquitaine (SNPA), 40.51 percent of Société Nationale de Recherche et d'Exploitation des Pétroles en Algérie, and 80.91 percent of Société de Recherches et d'Exploitation Pétrolières (SOREX). RAP, which is directly involved in oil production, will bring a majority interest in Société Auxiliare de la RAP (AUXIRAP) and Société de Gestion des Participations de la RAP, 25.5-percent interest in CREPS, and 33⅓ percent in Union Générale des Pétroles (UGP).[35] ERAP will have available to it annually about 20 million tons of crude (about 54 percent of Franc zone production), of which 17 million tons will be from the Sahara. UGP, controlled by ERAP, at year-end 1965 had 6.2 million tons of annual refinery capacity, including 4 million tons in the Feyzin refinery (Rhone-Alpes), 1.8 million tons in the Ambès refinery, and a 0.4-million-ton share in the Compagnie Rhenane de Raffinage refinery at Reichstett. UGP's plans envisage a 10-million-ton refining capacity, and its market share will be increased, through government measures, to 15 percent. ERAP, through a subsidiary, will also take over the 50-percent share in the Cooperative Association envisaged by the Franco-Algerian agreement detailed in the next paragraph.

The Franco-Algerian oil agreement was signed on July 29, 1965. So far as existing undertakings are concerned, it affects only French companies, as defined in the agreement, and the status of oil-producing companies operating in Algeria in 1965 will remain as specified in the Sahara Petroleum Code and the Evian Accords except for tax arrangements established by the new treaty. However, some of the terms designed originally to encourage exploration in the Sahara have been changed with the objective of increasing government revenue. Thus depletion allowance is canceled and amortization is made similar to the practice in the Near East. The agreement also includes the award of nine concessions (six for oil and three for gas) which will come under the same terms as above.[36]

With regard to taxes, Algeria obtained a guarantee against the effect of lower prices, because for tax purposes, profit will be calculated on a fixed price of $2.08 per barrel for crude f.o.b. Bougie (slightly different for other ports). The 50–50 split in profit is abandoned, and profits tax will be increased in steps to 55 percent in 1969 and will be at this rate after 1969.

The agreement increased the holdings of Société Nationale de Recherche et d'Exploitation des Pétroles en Algerie (S.N. REPAL Algeria) to its initial holdings of 50 percent. Algeria will pay for these shares at a price equivalent to that which it received when it sold its holdings in 1958.

Natural gas concessionnaires are required to deliver to Algeria the amount of gas it wishes to have for the domestic market and for any export contract it may negotiate, the price of the gas to be fixed so as to cover production cost, taxes, and a 12-percent return on capital. Future gas sales to France will be undertaken by a Franco-Algerian company which will share profits on a 50–50 basis.

An important feature of the agreement is the formation of a cooperative association between France and Algeria, which will undertake exploration and production, if oil is found, in an area of 180,000 square kilometers and in any additional areas from exploration permits that are turned over to it.

A declaration of intent was signed in December 1965 between the Électricité de France (EdF) and UGP, the Government's instrument for refining and marketing Saharan crude. Up to now, the EdF has been buying its fuel without long-term contracts from the Refiner's Group, an association of all French oil companies including foreign subsidiaries. The declaration of intent provides for a whole series of contracts to be concluded shortly between the two companies, providing for the supply of several EdF thermal powerplants with fuel from UGP refineries.

[36] Petroleum Press Service. Vol. 32, No. 9, September 1965, p. 324.

Exploration.[37]—Exploration was centered in the Aquitaine and Paris basins in 1965. Of the 59 exploratory wells drilled, 34 were in the Aquitaine basin and 25 in the Paris basin, where the principal objectives were sandstones and carbonates of the Early Cretaceous and Middle and Lower Jurassic.

At yearend 99,740[38] square kilometers of France including offshore areas was covered by exclusive exploration permits. Geophysical and drilling activities continued to decline, geophysical by 11 and drilling by 4 percent. Compared with 117.1 geophysical team-months in 1964, 104.6 team-months were completed in 1965: 95.5 by seismic, 1.5 by gravimetric, and 7.6 by other methods, smaller footage of wells drilled by light rigs accounted for practically all of the decline in total drilling. Of the latter 47 percent were exploratory, 51 percent were reservoir extensions and development, and 2 percent were injection wells. Six wells struck oil (Grandville No. 102, Marolles-en-Hurepoix, and Saint Hilaire No. 1 in the Paris basin, and Cabeil, Bourrache, and La Jaougue No. 1 in the Aquitaine basin) and three wells struck gas (St. Martin de Bossenay in the Paris basin, Meillon No. 1 in Aquitaine, and Fouye West in the Polignac basin.) The producing horizon in the three oil wells of Aquitaine, all discovered by Société Esso de Recherches et de Exploitations Pétrolières (Esso Rep), is Neocomian (Early Cretaceous). Upper Jurassic dolomite is the producing horizon at the Meillon gas discovery.

Table 15.—France: Summary of drilling activities [1]

	Oil wells	Gas wells	Dry wells	Total	Length drilled, meters
Exploration:					
1961	4	1	102	107	166,325
1962	11	----------	88	99	163,788

1965			1	1	(2)

[1] In addition dry wildcat wells were driven as follows: 1961, 30; 1962, 31; 1963, 27; 1964, 6; 1965, 1.
[2] Total drilled 181,700 meters; distribution by type of activity not available.
[3] Excludes shallow depth core drills.

France expanded its interest in oil exploration abroad. Total Oil Marine, Ltd., an affiliate of the Compagnie Français des Pétroles, was operating in the United Kingdom section of the North Sea. Companies in which ERAP has a majority holding have search permits in many European countries. RAP and SNPA in association with private interests and the Spanish state enterprise, Instituto Nacional de Industria, participated in exploration carried out by Empresa Nacional de Petroles de Aragon and Empresa Nacional de Petroles de Navarra.

In Switzerland, SNPA owns 75 percent of the Vaud permit in the region of Lake Léman. In Italy, PETROPAR has formed a subsidiary, Petropar Italia, which in association with Montecatini was interested in petroleum exploration, particularly on the Adriatic offshore areas and in Sicily. Petropar Italia with Petrobelge-AMI- has been drilling at San Chirico on the Tolver permit where gas was discovered. Petroland, a Dutch affiliate of RAP, has made significant gas discoveries in the vicinity of Herbayum in the Frisian Islands. Coparex also formed a Netherlands subsidiary,

[37] King, Robert E. Petroleum Exploration and Production in Europe in 1965. Bull. Am. Assoc. Petrol. Geol., v. 50, No. 8, August 1966, pp. 1634–1642.
[38] This figure does not include 51,700 square kilometer area for which exploration permits had been sought.

Coparex Nederland, for participating in offshore drilling.

An agreement between Saudi Arabia and the Société Auxiliare de la Régie Autonome des Pétroles, wholly owned by the French Government, ratified on April 4, 1965, gave RAP a role in the exploration of the offshore areas of the Red Sea. The area of the exploration license remained to be determined. Under the agreement, upon the discovery of commercial oil, a joint company will be formed; the French share will be 60 percent.

SNPA, BRP, and RAP have a 20 percent share in a concession from Iran in the Persian Gulf. PETROPAR started working in Turkey in 1963 and now has several exploration permits in areas north of Syria and Iraq where in 1965 drilling was carried out to study the Cretaceous.

In Africa, outside the Franc zone, French interest has spread to Nigeria and Libya. SAFREP (Nigeria) Ltd. holds permits for four offshore blocks in the delta of the Niger River and six blocks in the Cretaceous basin and has struck oil in both areas. CEP is already involved in producing crude in Libya. This company and Deutsche Erdoel made bids for additional areas. An SNPA subsidiary has a 20-percent interest in a concession in Libya's Fezzan region. SNPA will participate with AUXIRAP (14 percent), Hispanoil (42 percent), and Murphy Oil (16 percent) to explore areas in Tripolitania and Cyrenaica. In Australia and Canada, French companies have entered into partnership with lease holders, have taken farmouts from other companies, and have taken permits directly.[39]

Australian Aquitaine Petroleum Ltd., the Australian subsidiary of SNPA, with ARCO Ltd., subsidiary of Atlantic Refining Company, have obtained an offshore permit in the Continental Shelf in the Timor Sea. With another group it will explore the regions of Mayneside in southeast Australia. SNPA is not the only French company in Australia. Compagnie Française des Pétroles (CFP) through its subsidiary, the French Petroleum Company (Australia) Ltd., is exploring for its own account in southwestern Queensland and has concluded agreements for exploration in the east-central region of the country. CFP and SNPA work together in the northwestern part of the Perth Basin, and CFP struck gas 230 kilometers north of Perth.

SNPA's oil activities in Canada are carried out under a general agreement with Banff which has numerous permits. In 1964 Aquitaine purchased about 41 percent of Banff's share capital. SNPA, acting as an operator for a group including itself, discovered oil at Rainbow Lake in Alberta on Mobil Oil permits.[40] In November SNPA was negotiating on a 50–50 farmout with Mobil.

Apart from SNPA, Petropar of Canada Ltd. is associated with various independents and is undertaking drilling in the Arctic Island of Canada.

Interest has also been shown in shale and tar sands of North America. Aquitaine of Canada has acquired acreage in Athabasca and Manitoba. Auxirap Corp. of America and Aquitaine Oil Corporation, subsidiaries of ERAP and SNPA, respectively, each have a 5-percent interest in the Oil Shale Corporation of Colorado.

In the North Sea, the French group consists of ERAP 30 percent, CFP 30 percent, and the REX group 10 percent.

In natural gas, Petroland, an RAP subsidiary, has discovered natural gas in the Netherlands. Petropar is a partner in natural gas discovery at Porto Canone, near Pescara in Italy. French participation in petroleum refining includes RAP's share in the Chittagong refinery in East Pakistan, a minority interest of BRP and UGP in a refinery to be built in Cambodia, and participation by French organizations in building a refinery in the Saar.

Crude Oil Production.—During 1965, 33 fields were in production in France including 11 in the Aquitaine basin that together produced 2,442,300 tons, or 82 percent of total national output. The Aquitaine basin increased output over that of 1964 by 8 percent, while output in the Paris basin declined by 6 percent to 521,300 tons and that of the Alsace basin by 20 percent to 24,200 tons. Parentis, Cazaux, and Lavergue were the three largest fields. Esso Rep continued as the largest producing company, accounting for 79 percent of national output (all from Aquitaine); CEP ranked second with 13 percent of the total,

[39] World Petroleum, April 1966, p. 48.
[40] Work cited in footnote [39].

and six other firms accounted for the remaining 8 percent.

Trade.—Almost the entire 9.28-million-ton increase in crude imports came from non-Franc-zone producers: 4.16 million tons from the Near East, 3.57 million tons from Libya and 740,000 tons from the U.S.S.R. Imports from Algeria (17.4 million tons) were at almost the same level as in 1964, but imports from Gabon increased by 238,000 tons. Near East suppliers did not quite maintain their share of the French market; it declined to 51.5 percent, compared with 53 percent in 1964. Libya had the largest increase; 1965 imports from this source were 2.5 times those of 1964. Although the trade agreement between France and the U.S.S.R. called for crude oil import starting at an annual rate of 1.55 million tons in 1965, actual crude import from this source was half the stipulated quantity. Product imports declined by 8 percent in 1965. Distillate and residual fuel oils contributed 72 percent of all product imports. U.S.S.R. and Rumania supplied 1,535,100 tons, and other non-Communist European (mainly EEC) countries supplied 1,067,000 tons. Imports of products from the U.S.S.R. (917,541 tons) declined from those of 1964 (1,126,811 tons).

Partly compensating for the increase in crude oil imports, France increased exports of petroleum products by about 1 million tons, with a value increase of $9 million. All the exports except 602,000 tons were shipped to Western Europe; 4.76 million tons went to other EEC countries, 2.58 million tons to Switzerland, and 1.08 million tons to the United Kingdom. The Netherlands, Switzerland, and West Germany were the principal markets for distillate fuels; these countries, Belgium-Luxembourg, and the United Kingdom were also the principal markets for residual fuel oils. Gasoline shipments were principally to Switzerland, the United Kingdom, and West Germany; together they accounted for 83 percent of gasoline exports.

French affiliates of Esso, Shell, British Petroleum, and Cie. des Produits Chimiques et Raffineries de Berre withdrew from their appeal to the Conseil d'État their objection on points relevant to the decrees issued in February 1963, leaving only those considered to be contrary to the Treaty of Rome.

Consumption.[41]—The internal market for petroleum products exceeded 46 million tons, a 12-percent increase compared with 1964, consumption. However, the rate of increase was lower than in 1964, when it was 17 percent. The decline resulted from general performance of the economy, unfavorable weather in the summer, which presumably reduced summer travel, and smaller sales to Électricité de France. Light and heavy fuel oil accounted for 60 percent; their share of the total market for a number of years follows:

Commodity	Percent of total			
	1962	1963	1964	1965
Gasoline	21.2	19.5	18.5	18.0
Motor gas oil	7.0	6.6	6.4	6.2
Fuel oils	55.5	58.1	59.6	60.0
Other products	16.3	15.8	15.5	15.8
Total	100.0	100.0	100.0	100.0

Domestic heating oil was the largest factor in domestic consumption, increasing by 25 percent. Of the 13.79 million tons shipped to the French market, heating of homes took 6.71 million tons, industrial space heating 5.11 million tons, and agriculture 1.3 million tons. Industry and space heating of dwellings also took almost the entire tonnage of light fuels, 1,843,000 and 942,100 tons, respectively. Principal consumers of heavy fuel oil and their consumption in thousand tons follow: industry 7,680, Électricité de France 2,450, French railroads 735, and domestic space heating 466.

[41] Equivalent to sales to civilian users. The figures do not take into account refineries' own consumption, refinery storage, and transportation losses, or change in the stocks of consumers and retailers.

For the first time sale of high-octane gasoline exceeded that of ordinary gasoline. With 50.7 percent of the total, premium gasoline increased its share of the market by 18.7 percent. The number of private cars and commercial vehicles increased to an estimated 8,775,000; the total number of motor vehicles was 10,843,300. The rate of increase of gasoline consumption was only 8.9 percent, compared with 10.7 percent in 1964. Direct sale of propane and butane to consumers increased 8.4 percent to 1,362,900 tons. Gasworks took 146,000 tons (127,000 tons in 1964), of which 129,500 tons was propane.

The Paris basin was the largest market for petroleum products with 21.7 percent of the market, followed by Nord/Pas-de-Calais with 7.69 percent and Haute Normandie with 5.47 percent. The Paris basin, although the largest market, had a smaller share of the total than in 1964, when it was 23 percent.

Transportation and Distribution.— In 1965, 83 percent of crude oil delivered to metropolitan French ports for French consumption (excluding processing for exports) was carried by French vessels.[42] On December 31, 1965, the French tanker fleet included 93 vessels totaling 3,418,000 deadweight tons. During the year, four new tankers totaling 318,670 deadweight tons were added, one vessel was enlarged from 32,600 to 59,940 tons, and eight other ships totaling 158,542 tons were withdrawn from service. As a result, distribution of vessels by size categories in 1965 was 75,000 tons or more, 5; 50,000 to 74,499 tons, 17; 40,000 to 49,999 tons, 6; 30,000 to 39,999 tons, 32; 15,000 to 29,999 tons, 31; and 10,000 to 14,499 tons, 1. For internal transportation there were 786 barges in service with a total capacity of 465,410 tons; 17,903,469 tons of oil and products were carried by river transportation.

In 1965 the South European Pipeline transported 27.7 million tons of crude (supplying 10 refineries), the Trapil line (the pipeline from Le Havre to Paris) moved 4,753,000 tons of products, and the Parentis-Ambes line transported 2,341,601 tons of crude. At yearend, the South European Pipeline, with 15 pumping stations,

[42] République Française, Ministère de l'Industrie, Direction des Carburants. Activities of the French Oil Industry in the Year 1965. Paris, France, 1966, p. 3.

had 30 million tons' annual capacity; this capacity will be further increased to 35 million tons by mid-1966. Trapil can now transmit 6 million to 6.5 million tons of products annually. The gas pipeline from Le Havre to Paris started operation in March. A spur pipeline from the South European Pipeline (near Besançon) to Cressier in Switzerland was under construction. Proposed was a crude pipeline from the South European Pipeline at Strasbourg to the stite of the refinery in Lorraine that is slated for completion in 1970. A product pipeline from the Marseille area to Lyon with branches to St. Étienne, Dijon, and Geneva was also proposed. A new company, Société du Pipeline Mediterranée Rhon, has been set up to operate the pipeline.[43] UGP and UIP received permission to build and operate a 250-kilometer-crude pipeline, with a 2.5-million-ton initial and 7-million-ton ultimate annual capacity, from Le Havre to the UGP refinery to be built at Grandpuits near Paris.[44]

Refining.—At yearend 1965 France had an annual refining capacity of 70.3 million tons, including about 8 million tons added in 1965. Of this addition, 4.2 million tons was accounted for by the new refineries at Fos-sur-Mer and Vern-sur-Seiche, and the remainder by expansion of existing refineries at Gravenchon, Herrlisheim, Bordeaux, Gonfreville, and Donges. Of the total, 23.7 million tons was located in the Seine basin, 21.5 million tons on the Mediterranean, 10 million tons on the Atlantic, 7.6 million tons in Alsace, 5.5 million tons in the North, and another 2 million tons in the Lyon region.

Fos-sur-Mer, connected by three pipelines to Lavéra, was in full operation in October. This refinery has a middle distillate desulfurization unit with 700,000 tons' annual capacity. Storage capacity totaled 560,000 cubic meters of which 190,000 cubic meters was for crude.[45] The Vern-sur-Seiche refinery came on stream in June. Imported crude was supplied from Donges by a 93-kilometer pipeline. The refinery under construction at Grandpuits will be operated by Compagnie de la Raffinage de l'Isle de France, established jointly by UGP and UIP.

Plans for a new 2.8-million-ton-per-year refinery at Melun, to be built by UGP, have been announced. The refinery capacity of Feyzin is to be doubled to 4 million tons per year. A stream cracker, due to be operative by 1967, with an annual capacity of 150,000 tons of ethylene, 150,000 tons of propylene, and 40,000 of butadiene, will constitute the first stage of construction of a major petrochemical complex.[46] Three other stream crackers are also due to come into operation: a 200,000-ton unit at Esso's Port Jerôme refinery, a 125,000-ton unit at Berre refinery, and a 100,000-ton unit at Lavéra, the latter owned by Naphthachimie.[47]

Refinery output as a whole was 14 percent greater than in 1964. All fuel oils increased 19 percent, heavy fuel oil 15 percent, and domestic heating oil 26 percent. The increase in gasoline output (11 percent) was less than that for all refinery products. In 1965, residual fuel oils accounted for 33 percent, and domestic fuel oil for 23 percent, of gross production. Other products, in percent, were as follows: Gasoline 16; distillate fuel oil 10; bitumen 4; and liquefied petroleum gases 3.

Natural and Manufactured Gas.—Natural gas was discovered at Meillon and Gas de France, and Nederlandsche Aardolie Maatschappij (NAM) reached an agreement to import Dutch gas into France starting in 1967. Natural gas sales were at about the same level as in 1964—5 billion cubic meters.

The Meillon discovery was at a depth of about 4,950 meters in well Meillon I. A daily production of 1.7 million cubic meters from this well was reported in July. Meillon II was being drilled at yearend. The gas at Meillon has 6.5 percent H_2S (15.5 percent at Lacq) and a correspondingly higher methane content.

At yearend a preliminary agreement was made with NAM for delivery of up to 5,000 million cubic meters of gas per year for 20 years. Initial delivery at 1,000 million to 1,500 million cubic meters is scheduled for 1967. The gas will be delivered at

a point to be determined on the Netherland-Belgium frontier. Gas de France will negotiate with Belgium's Distrigas on the price and terms of transit of gas through Belgium.

Under the terms of the oil agreement with Algeria, France is to receive 1,500 million cubic meters of gas per year from Algeria by 1968 in addition to gas now being shipped from this source in liquid form to Le Havre.

According to Gas de France, the last plant reproducing gas from coal will have gone out of production by 1970; at year-end 1965, seven such plants were still in operation. After 1970, all gas requirements are to be met by natural gas and gas produced by cracking light oils.[48] France also has the beginning of underground gas storage in sand at Beynes near Versailles; storage capacity here is 300 million cubic meters.

Production of natural gas declined slightly. Of the 7,910 million cubic meters of natural gas produced, 7,678 million cubic meters was obtained from the Lacq field.

In 1965, 5,016 million cubic meters of natural gas were delivered to consumers[49] distributed as follows in million cubic meters: public distribution and municipalities 1,787; chemical and petrochemical industries 1,572; thermal power plants 688; iron and steel industry 221; glass, lime, plaster, and cement industries 236; paper industry 158; ceramic and construction materials 146 and others 208. Sales to the chemical industry continued to increase as in 1964, but sales to thermal plants were only 70 percent of the 1964 level. Industrial use accounted for 63.53 percent of total sales, and city consumption for 35.56 percent, the remainder being condensate. Geographical distribution of sales varied a little from that of the previous year, with the following percentage distribution being recorded: Aquitaine 29.04; Paris region 17.33; Midi-Pyrénées 18.39; and Rhône-Alpes 13.08. The drop in sales in the Paris

[48] The Economist. Jan. 29, 1966, p. 435.
[49] To be distinguished from sales which would exclude increase or decrease in stock.

region from 22 percent of the total in 1964 was accompanied by increase in the share of Midi-Pyrénées and Rhone-Alpes.

The drop in sale in the Paris area may have resulted from availability of Algerian gas. The methane carrier *Jules Verne* delivered its first cargo of refrigerated gas from Algeria at Le Havre on March 28, 1965. This gas is transported by pipeline to St. Illiers in the Paris region where it is stored.

The Mineral Industry of East Germany

By Roman V. Sondermayer [1]

East Germany continued to produce a variety of mineral commodities in 1965 but output of most commodities was the result of processing imported raw materials, and its mineral industry was of limited significance to the world economy. The Government continued to devlop mineral production facilities, but these expansions had little effect on the level of raw material imports. Principal mineral products with output expressed in approximate percentages of 1965 world totals were fuel briquets 53, brown coal coke 23, potash 14, coal 8, and salt 2.

East German trade in minerals and mineral products was conducted mainly with other Communist countries and was of minor significance to the western world. The trade in mineral commodities with the United States was insignificant. The output value of mining industry was over 2 billion East German marks,[2] and the industry employed over 200,000 persons.

The major efforts in the mineral industry concerned production of mineral fuels and expansion of petrochemical and iron and steel facilities. The Schwartze Pumpe Combine near Cottbus was the center of activities in lignite production, but at yearend 1965, the plant remained incomplete. The expansion of the petroleum refinery at Schwedt was finished; annual capacity of the facility was raised to 4 million tons of crude oil. A steel rolling mill at Eisenhuettenstadt and a cadmium plant as Freiberg complete the list of important mineral industry facilities installed during 1965.

As in the case of many other Communist countries, East Germany introduced an economic reform. The new measures were introduced slowly, and production of some minerals may be cut back, but overall effect of the reform on mineral industry could not be evaluated due to the short time since their inception and conflicting reports on results.

PRODUCTION

The mineral industry production efforts were assisted by the Soviet Union, and in most cases assistance given was geared to cover the needs of the U.S.S.R. Information on nonferrous metal output was not published except for that on aluminum and copper ore. However, it is known that lead, zinc, cadmium, tin, nickel, and uranium were produced.

Open-pit mining prevailed in East Germany because of the nature of the lignite deposits, its largest mineral resource.

[1] Foreign minerals specialist, Division of International Activities.

[2] In ths chapter, values have not been converted from reported East German marks because of the wide variation in official and actual exchange rates.

e Estimate. r Revised.
[1] In addition to reported commodities, East Germany was a known producer of the following (figures represent approximate order of magnitude): Copper 35,000; lead 26,000; nickel 100; tin 600; zinc 4,000 fluorspar 75,000; salt 2,000,000; and peat 500,000.
[2] All types including industrial.
[3] Includes gas coke.
[4] Includes high-temperature coke.

Source: Statistisches Jahrbuch der Deutschen Demokratischen Republik 1966 (Statistical Yearbook of the German Democratic Republic for 1966), Berlin 1966, 580 pp.

TRADE

The basic geographic pattern of East German mineral commodity trade was not reported in official East German trade statistics, but reports from other countries showed that the largest share of trade in minerals, approximately 80 percent of the total, has been with other Communist countries. Imports of iron ore, high ranked coals, and crude oil were essential for the economy and accounted for a large segment of foreign exchange expenditures.

COMMODITY REVIEW

METALS

Aluminum. — East German aluminum production, which is completely based on bauxite from Yugoslavia and Hungary, remained at the same level as that of 1964.

With Soviet technical assistance, reconstruction of the Bitterfeld alumina and aluminum plants was completed at yearend 1965. The alumina section of the plant has been reconstructed and adapted to the Soviet method used in the Kirov aluminum plant in Zaporozhlye, U.S.S.R. Reportedly, the plant will produce 10 percent more alumina and aluminum in 1966 than in 1965, but output for that year was not disclosed. Construction of additional facilities for production of aluminum at Lauta in the Cottbus area was also announced, but capacity of these facilities was not reported.

Cadmium.—At a cost of 5 million East German marks, a plant of unreported capacity for cadmium production was completed at Freiberg Bergbau and Huettenkombinat, and the first electrolytic cadmium was produced in the spring of 1965. Reports state that the cadmium output is 99.95 percent pure. The Freiberg facility is one of 20 enterprises which employ a total of 20,000 persons comprising the East German nonferrous industry.

Copper.—East Germany moved to increase production of copper in the Halle region. In the near future the main output of this region will come from the vicinity of Sangerhausen. More than 1,000 workers will have to be moved from Mansfeld, heretofore the country's largest copper producing area.

Iron and Steel.—Iron and steel production continued to depend heavily on imported iron ore and coke; the U.S.S.R. was the principal source of the iron ore, and Poland provided the largest part of the coke. Despite the country's lack of adequate indigenous resources of iron ore and coking coal, the development of iron and steel production facilities continued. The U.S.S.R. provided both the principal technical advisors and most of the equipment for these expansions.

Assembly work was started on a new cold rolling mill in the East Metallurgical Combine in Eisenhuettenstadt, and production is expected to start at the end of 1968. The planned capacity of the new facility was reported to be 500,000 tons of cold rolled products.

At the beginning of 1965, the largest and most modern hot-dip galvanizing plant in East Germany was commissioned at the Hostaglas Enterprise in Dresden. Plant capacity was reportedly 10,000 tons of galvanized products per year.

The No. 3 plant in Riesa-Zeithain started production of pipes in 1965. In full operation, which is expected to begin in 1972, the plant will produce 80,000 tons of seamless pipes per year.

Other Metals.—Systematic, detailed, and complete reporting on metal mining, beneficiation, and smelting operations was not available during 1965. Partial information indicated a 25-percent decline in nickel ore production because of production costs.

It was announced that tin concentrate production will be increased, but no data were published on the existing level of production nor on the extent of this expansion.

The Dresden Academy Institute for Metallophysics and Very Pure Metals reportedly achieved appreciable results in the production of high-temperature metals such as tungsten, molybdenum, tantalum, and columbium and their alloys.

NONMETALS

Cement.—The construction of the Ruedersdorf No. 4 cement plant was underway during 1965. The project required the biggest investment to date in the building material industry of the country. When completed the plant will have a capacity of 900,000 tons of cement per year.

Fertilizer Materials.—In accordance with governmental efforts to eliminate the shortcomings in the agricultural sector of the economy, development of mines and other facilities for production of mineral fertilizers continued. Construction of a large fertilizer complex at the Schwedt petroleum refinery near the Polish border continued through 1965. The British firm Humphreys and Glasgow and the French group Schneider-Creuzot are involved in construction. East German authorities expect the plant to be operational at yearend 1966. The plant reportedly will have a

nitric acid and lime ammonium capacity adequate to permit production of 520,000 tons of fertilizers and 170,000 tons of ammonia per year. A new plant of unreported capacity for production of superphosphate was under construction in Salzwedel. Target completion date was not reported.

Lime. — A modern lime work started production near Pirna in the Dresden area in 1965. The plant was designed for an annual output of 125,000 tons of lime. Building enterprises in Dresden, Cottbus, and Potsdam will be the principal buyers of the lime.

MINERAL FUELS

Coal and Lignite.—The lignite industry remained the most important element of the East German mineral industry. During 1965 lignite accounted for approximately 80 percent of primary energy of the country. Because East German lignite was of low calorific value most of the output was turned into briquets for use in gasworks, powerplants, cokeries, and low-temperature carbonizing plants. During 1965 imports of high-rank coals remained a necessity for the domestic economy.

The Cottbus area, accounting for about 40 percent of the total lignite output, remained the center of the industry. Construction and development continued on the Schwarze Pumpe Combine which is in the same area. At yearend 1965, the Schwarze Pumpe Combine reportedly had 50 percent of its capacity developed. In addition to open pit mines two briquet factories, two power stations, and part of the plant for manufacturing gas were completed at Schwarze Pumpe.

In 1965 a new set of gas generators was added to existing facilities; when all installations for gas production become operational, Schwarze Pumpe will be able to produce 168 billion cubic feet of gas per year. Construction of coking plants continued. Annual coke output upon completion of facilities is expected to be 1.8 million tons. The completion date for the Combine was set for 1972, 2 years later than the previously scheduled completion date. In the Cottbus lignite basin, development of the opencast mine at Welzow-Zued was underway. The mine is supposed to be highly mechanized and without rails. All transportation of lignite and overburden will be done by conveyor belts. Plans call for a yearly output of 28 million tons of lignite when the mine is completed in 1966.

The underground lignite mine at Goezan in the Halle area was closed because production costs were higher than those of open pit mines. Authorities also closed the subsidiary plant for paraffin, wax, benzol, fuel oil, and coke from lignite. Workers from these facilities have been employed in other mines and chemical plants in the country.

Petroleum and Natural Gas.—No new information was available on results of drilling in Rostock near Stralsund. Deep drilling for oil, over 5,000 meters, was underway during 1965 on the Baltic coast. In this drilling operation Soviet personnel assisted in operating Soviet equipment.

Expansion of the Schwedt refinery at the western terminal of the Druzhba pipeline was completed at yearend 1965. Reports indicated that new annual throughput capacity of the plant will be 4 million tons of crude oil.

Most of the plants for oil production from coal were being converted in 1965 to use crude oil as a raw material; all such facilities are scheduled to be converted by 1970. Crude oil from the Soviet Union will replace coal. This work was underway in plants at Zeitz, Lutzkendorf, Leuna, and Schwarzheide.

The SEV countries [3] decided to develop a pipeline system 330 kilometers long connecting Schwedt refinery with the chemical industry in East Germany. A pipeline from the refinery at Schwedt to the Leuna chemical plant, a part of this overall project, was completed by Polish construction crews.

Manufactured Gas.—To alleviate winter gas shortages and to make possible uniform production levels throughout the year, construction of a unified gas pipeline and underground storage system continued during 1965. The regional gas supply system in the Eberswalde-Angermünde-Finow area in the northern part of Frankfurt/Oder Bezirk was connected with the overall East German pipeline grid. Development of underground gas storage in a 300 meter deep sandstone layer in the Magdeburg district continued.

The Mineral Industry of the Federal Republic of Germany

By L. Nahai [1]

The value of crude mineral production in West Germany in 1965 totaled about $2,390 million.[2] In this year the gross national product (GNP) totaled $112,150 million in current prices, which was 8.4 percent higher than that of 1964. In real terms, however, the GNP increase between 1964 and 1965 was only 4.4 percent, compared with 6.6 percent between 1963 and 1964. Economic expansion slowed in the last half of 1965, primarily because of limitations imposed by resources, particularly labor. The shift in economic expansion from production to services continued to such an extent that the real rate of growth of the producing industries did not equal that of the economy as a whole. Real output for nonfuel mining, decreased 2.1 percent but that for energy increased 5.4 percent in comparison with 1964 levels.

In 1964, the latest year for which data are available, West Germany's mineral industry, excluding petroleum refining and processing, contributed about $9,213 million to the GNP, 8.9 percent of the total. This sum was distributed as follows: Mining $2,400 million; ferrous and nonferrous metal industries $4,270 million; and industries based on stone, earth, fine ceramics, and glass $2,543 million. This contribution includes output of some industrial sectors that are properly classified as manufacturing. Data on petroleum refining and processing are not included because, as reported, they are inseparable from data for the Nation's sizable chemical industry, which as a whole contributed $5,178 million to the GNP.

Total turnover of the mineral industry in 1965 for the various operations shown in table 1 was about 11 percent of the $93,700 million recorded turnover for all industry. Industrial employment in December 1964 averaged 8.4 million, of which the mineral industries accounted for 12 percent.

Government action in the mineral industry in 1965 stressed measures to assist the coal industry. The Federal Government agreed in December to finance the stockpiling of 4 million tons of coal in areas far removed from the coal mining districts. The Government also paid for four nonproducing shifts which reduced annual coal output 1.5 million tons. The Law for the Promotion of Use of Hard Coal in Powerplants of August 12, 1965, gives tax relief for powerplants using coal produced in West Germany or other European Economic Community (EEC) countries (Belgium, France, Italy, Luxembourg and the Netherlands). Measures in force at the start of 1965 to help the industry were continued. These included a $5 per ton import duty on coal from non-EEC countries (in force since February 1959) except for a duty-free quota of 6 million tons per year, a $2.50 per ton duty on light fuel oil and $6.25 on heavy fuel oil (in force since May 1960), favorable rates for transport of coal by rail and inland waterways, and Federal and State Government guarantees for investment in the industry to carry out a rationalization program. Besides the foregoing measures, the Bundestag passed an amendment to the industrial accident insurance law applicable to coal mining on July 1. Under the amendment, the Federal Government will pay two-thirds of the contributions to the industrial accident insurance fund, estimated

[1] Chief West Europe specialist, Division International Activities.

[2] Where necessary, values have been converted from West German marks (DM) to U.S. dollars at the rate of DM4 = US$1. The $2,390 million excludes petroleum and natural gas for which values are not reported.

Grand total	1,067	11,826	1,992	12,172	2,253

[1] Inclusive of forge and hammer works but exclusive of foundries and cold-rolling and cold-drawing mills. Foundries employed 137,000 and had $1,009 million domestic and $89 million foreign sales. Cold-drawing and cold-rolling mills employed 71,000 and had $952 million domestic and $154 million foreign sales.

[2] Exclusive of foundries which employed 28,000 and had $249 million domestic and $10 million foreign sales.

at $25 million. Prior to the amendment, the fund was financed by the employers only. Under the same amendment, the Government ceased making contributions, estimated at $10 million annually, to the miners' retirement funds.

Several measures pertaining to oil had the objective of assisting the coal industry. Voluntary restriction in sale of heavy fuel and heating oils was extended for another year, and for 1966 the industry and Government agreed to an increase of 8 percent over 1965 sales. Effective December 10, 1964, the import of crude oil, diesel oil, and fuel oil into West Germany became subject to licensing. The Government indicated, however, that licenses for import from non-Communist countries would be automatically granted. Nonetheless, the ordinance enables the Government to adjust future rates of increase of oil imports to an extent that will insure the development of a sound energy policy and give a measure of protection to the coal industry. Import licenses were valid for 9 months when the ordinance was issued, but this was subsequently reduced to 6 months.

Similarly, registration of refineries and pipelines became mandatory; petroleum refiners and pipeline operators were required to register the capacities of their facilities with the Bundesamt fuer gewerbliche Wirtschaft (Federal Office for Industrial Economy). This law, which came into effect on June 16, 1965, requires that enterprises that wish to build, substantially modify, or expand such facilities must submit their plans 12 months prior to starting the construction. The rapid expansion of refining capacity, considerably in excess of industry estimates compiled by the Ministry of Economics in 1962, was a factor in the Government's decision to ask for this law.

Regulations stating precisely which re-

fineries and pipelines would have to be registered and which would be exempt from registration were issued by the Federal Minister of Economics and published in the Federal Law Gazette of July 31.

Unrelated to coal industry problems, a law establishing minimum oil stocks was to become effective January 1, 1966.

Exploration of the West German Continental Shelf was being carried out under the provisions of a law which came into force on July 30, 1964. Pending final legislation concerning rights over the shelf, the law established a temporary competent authority for administering exploration and exploitation and provided for exemptions from the general prohibition to explore and exploit the seabed beyond the 3-mile zone. The Oberbergamt in Clausthal-Zellerfeld was appointed as the licensing authority.

The agreement signed December 1, 1964, between the Federal Republic of Germany and the Kingdom of the Netherlands on the Continental Shelf boundary went into effect on September 1, 1965.

On June 9, 1965, the Danish and West German Foreign Ministers signed a protocol establishing the Continental Shelf boundary between the two countries at a point approximately 48 kilometers from shore in the North Sea; boundary agreement beyond this point was not reached. The treaty was ratified by the Bundesrat on November 26. Agreement was also obtained regarding the Continental Shelf boundary on the Baltic Sea, which was to be determined by the median line of the two opposite coasts.

PRODUCTION

West Germany's rank as a world producer of minerals and metals remained about the same as in 1964: first in production of pumice; second in barite, feldspar, potash, and fuel briquets; third in cement, lime, and coke; and fourth in pig iron and crude steel.

While the production index for industry as a whole increased from 150.2 in 1964 to 158.9 in 1965 (1958=100), performance of the various sectors of the mineral industry was mixed as shown below:

Industry sector	Index of production (1958=100) 1964	1965
Coal mining	100.0	95.2
Metal ore mining:		
Iron ore	66.3	61.7
Other	94.7	93.9
Potash and salt	130.1	143.4
Crude oil and gas	186.2	202.3
Stone and earth	193.2	156.5
Nonferrous metals	148.5	152.1
Iron and steel	143.6	136.0

Only nonferrous metals, potash and salt, and oil and gas showed increases; the rate of increase for the latter was the highest.

[e] Estimate. [r] Revised. NA Not available.
[1] Including West Berlin
[2] Includes copper content of pyrites.
[3] Excludes West Berlin 1961–63; includes West Berlin 1964–65.
[4] Exclusive of slate recovered from mine dumps.
[5] Includes briquets produced by independent plants as follows in thousand tons: 1961, 268; 1962, 276; 1963, 261; 1964, 96; 1965, 26.
[6] Associated and unassociated.

TRADE

Imports and exports of mineral commodities in 1965 constituted 25.3 and 17.5 percent, respectively, of all imports and exports of West Germany by value as shown in the following tabulation:

	Value (million dollars)		Mineral commodities share of total trade (percent)
	Mineral commodities	All commodities	
Exports:			
1963	[1] 2,680	[1] 14,616	18.3
1964	[1] 2,818	[1] 16,215	17.4
1965	3,128	17,908	17.5
Imports:			
1963	[1] 3,190	[1] 13,019	24.5
1964	[1] 3,941	[1] 14,613	27.0
1965	4,447	17,591	25.3
Trade balance:			
1963	[1] −510	[1] +1,597	XX
1964	[1] −1,123	[1] +1,602	XX
1965	−1,319	+317	XX

XX Not applicable.
[1] Excludes value of gold.

Among major groups of mineral commodity exports, iron and steel products ranked first in value, accounting for 45 percent of the 1965 total for mineral commodities; solid fuels ranked second accounting for about 17 percent of total value. Among mineral commodity import groups, petroleum and its products ranked first, accounting for 28 percent of total mineral and metal imports and for about 7 percent of all commodity imports. Details on total tonnage and value of 1965 mineral trade by major groups appear in table 3.

In 1965, 35 percent of all exports from West Germany went to the other five countries of the EEC and 27 percent went to the countries of the European Free Trade Association (EFTA).[3] Imports were 38 percent from EEC and 17 percent from EFTA. Imports from EEC countries increased about $1,571 million in 1965, over those of 1964. For the minerals and metals tabulated, West Germany's exports to EEC in 1964 (approximately $1,368 million) were 52 percent of the $2,627 million exports to all countries; for the same commodities, imports were valued at approximately $3,866 million of which 30 percent was from EEC.

[3] Austria, Denmark, Norway, Portugal, Sweden, Switzerland, and United Kingdom.

Table 3.—Federal Republic of Germany: Mineral and metal trade by major commodity groups in 1965

Mineral fuels:				
Solid	24,845	524	9,089	125
Liquid and gaseous, including asphalt	7,452	204	74,809	1,239
Coal—and petroleum—derived crude chemicals including carbon black	192	14	287	17
Total	67,884	3,128	157,565	4,447

[1] Excludes materials that are primarily precious metal ores and waste.
[2] Includes metalloids such as arsenic, tellurium, selenium, phosphorus, and silicon as well as mercury, alkali metals, and rare earth metals.
[3] Includes ores, concentrates, waste and scrap of precious metals, which account for most of the tonnage but for a relatively small part of the value.
[4] Less than ½ unit.
[5] Includes non-metal-bearing metallurgical wastes except Thomas slag.

Dolomite, crude and calcined	73,896	90,596	66,446	Netherlands 50,690; Belgium-Luxembourg 8,252.
Feldspar	12,118	11,762	11,450	Italy 3,306; Belgium-Luxembourg 3,087.
Fertilizer materials:				
Crude, natural:				
Phosphatic	43,238	34,624	---	Austria 41,660.
Potassic	94,400	86,999	74,462	Netherlands 40,257; Belgium-Luxembourg 34,205; United Kingdom 19,613.
Organic, including guano	3,878	---	3,836	Netherlands 3,793.
Manufactured:				
Nitrogenous—thousand tons	1,577	1,359	104	Spain 221; United Kingdom 172; Yugoslavia 101.
Phosphatic:				
Basic slag—do	354	286	283	France 233; Netherlands 50; Austria 30.
Other—do	20	26	3	Denmark 6; Pakistan 3.
Potassic—do	1,473	1,916	338	United Kingdom 177; Denmark 165; Netherlands 151.
Mixed—do	429	453	122	France 110; Malaysia 36; Czechoslovakia 27.
Ammonia, anhydrous—do	80	76	12	Norway 53; Netherlands 9; Switzerland 5.
Fluorspar	12,314	10,598	2,608	Austria 6,640; Netherlands 2,182.
Graphite, natural, crude or ground	6,694	7,758	1,608	United States 1,780; Italy 1,178.
Gypsum and limestone:				
Gypsum and plasters—thousand tons	267	250	211	Netherlands 165; Belgium-Luxembourg 29.
Limestone, excluding dimension stone—do	47	42	46	Netherlands 43.
Lime, hydraulic or slaked—do	359	378	332	Netherlands 298; Switzerland 23.
Magnesite, crude and calcined	8,262	5,631	7,656	France 4,873; Netherlands 2,476.

Table 4.—Federal Republic of Germany: Exports of metals and minerals—Continued
(Metric tons unless otherwise specified)

Commodity	1964	1965	1964 destinations	
			EEC[1]	Principal destinations
Nonmetals—Continued				
Mica:				
Crude, powder and splittings	553	483	54	Switzerland 292; Austria 92.
Worked, including agglomerated splittings	126	NA	33	Denmark 24; Italy 13.
Pigments:				
Earth colors, natural	3,492	3,389	1,773	Belgium-Luxembourg 975; Denmark 738.
Iron oxides and hydroxides, thousand tons	85	98	38	France 22; United Kingdom 10.
Salt, do	871	961	442	Belgium-Luxembourg 415; Sweden 158.
Sodium and potassium compounds, n.e.s.:				
Caustic soda, thousand tons	138	120	60	Netherlands 50; Brazil 14; Yugoslavia 14.
Caustic potash and peroxides of sodium potassium	12,302	12,369	2,496	U.S.S.R. 3,780; Netherlands 1,720; Switzerland 1,715.
Stone, sand and gravel, n.e.s.:				
Dimension stone:				
Unworked and partly worked:				
Marble and other calcareous, thousand tons	4	7	3	Netherlands 1; Belgium-Luxembourg 1.
Slate, do	70	157	63	Netherlands 60; Sweden 6.
Granite, porphyry, other, do	229	398	219	Netherlands 207.
Worked, all types including paving blocks, do	42	32	35	Netherlands 25; Belgium-Luxembourg 10.
Gravel and crushed rock, including macadam, do	6,658	7,484	5,465	Netherlands 4,121; Belgium-Luxembourg 1,323; Switzerland 1,102.
Grinding stones and wheels	7,317	7,585	2,818	Italy 856; Netherlands 823; Switzerland 715.
Quartz and quartzite, crude and partly worked, thousand tons	45	54	23	Austria 12; Italy 9; Belgium-Luxembourg 7.
Sand, excluding metal-bearing, do	1,516	2,316	1,150	Netherlands 1,006; Switzerland 266.
Sulfur and pyrite:				
Pyrite	33	82	---	NA.
Elemental, excluding colloidal and precipitated	24,902	25,883	1,348	United Arab Republic (Egypt) 5,926; Austria 4,969; Pakistan 1,987.
Other elemental	1,210	1,219	291	Netherlands 130; Sweden 110.
Sulfur dioxide	2,762	2,198	358	Sweden 1,465; Austria 659.
Sulfuric acid	75,298	50,893	37,283	Netherlands 33,621; Austria 21,812; United Kingdom 6,293.
Talc, soapstone, steatite	1,215	1,220	359	Switzerland 274; Belgium-Luxembourg 172.
Vermiculite and mineral wool	12,542	14,202	4,129	Switzerland 2,251; Belgium-Luxembourg 1,604; Netherlands 1,144.
Other nonmetallic materials:				
Bromine, fluorine, iodine in pure form	117	427	52	Switzerland 37; Belgium-Luxembourg 26.
Meerschaum, amber, jet	3	1	---	Denmark 1.
Slag and other nonmetalliferous waste from metallurgical operations:				
Derived from iron and steel manufacture, thousand tons	1,108	1,171	1,102	Netherlands 755; France 298.
Other, do	286	362	278	Netherlands 233; France 45.
Mineral substances, n.e.s., do	340	323	181	Netherlands 138; United States 47; Austria 28.
Mineral fuels:				
Asphalt and bitumen, natural	2,088	1,653	1,098	Belgium-Luxembourg 1,098; Austria 891.
Coal, coke, briquets:				
Anthracite and bituminous coal, thousand tons	13,738	13,300	12,214	France 5,747; Netherlands 3,071; Belgium-Luxembourg 2,919.
Bituminous coal briquets, do	386	277	360	Italy 119; France 110; Netherlands 84.
Lignite and lignite briquets, do	1,681	1,342	1,294	France 529; Netherlands 341; Belgium-Luxembourg 222.
Peat and peat briquets, do	164	167	95	Netherlands 71; United States 30.
Coke and semicoke from coal, peat and lignite, do	10,929	9,759	7,745	France 3,732; Belgium-Luxembourg 3,513; Sweden 866.
Carbon black	31,822	29,329	16,136	France 6,829; Netherlands 4,177; Austria 3,546.
Gas, fuel, natural and manufactured, thousand tons	316	300	257	France 110; Belgium-Luxembourg 79; Netherlands 66.
Hydrogen and rate gases	83	112	13	Switzerland 22; United Arab Republic (Egypt) 14.
Petroleum:				
Crude and partly refined oil, thousand tons	---	22	---	
Refinery products:				
Gasoline, do	1,355	1,197	102	United Kingdom 430; Switzerland 334; Denmark 160.

COMMODITY REVIEW

METALS

Although the iron and steel industry generally maintained 1964 production levels during the first part of 1965, a decline in output was apparent toward the end of the year and profits reportedly declined because of the widening gap between costs and receipts.[4]

In contrast, the situation of the nonferrous metal industry improved during the year; the production index increased 10 percent compared with that of 1964. Production of all principal nonferrous metals (including secondary metal) increased: refined copper 6.3 percent, tin 10.2 percent, zinc 7.3 percent, and aluminum (primary only) 6.2 percent. Similarly, production of alloys of aluminum, copper, lead, zinc, and tin increased at rates ranging from 2 to 22 percent.

[4] The Economist. Jan. 29, 1966, pp. 432–433.

The price of copper increased significantly; the $1,580 per ton market price for copper wire bar at yearend was the highest price ever offered. At that time the difference between producers' and market price of copper wire bar was about $740 per ton. The average market price of copper wire bar for the year was $1,290 per ton, or $320 more than in 1964. Producers' price increased from about $720 per ton at the beginning of the year to about $840 per ton at yearend. It is estimated that only 30 to 40 percent of the requirement could be met at producers' price.[5]

Lead and zinc prices increased only in the beginning of the year. Lead prices increased from $365 per ton in January to $422 per ton in February before falling to the lowest level of $275 per ton in July; the yearend price was $322 per ton. Zinc prices did not show a wide range; the yearend price was $305 per ton, compared with $315 per ton in January. Aluminum prices remained stable.

Aluminum.—Aluminum output surpassed the previous record high achieved in 1942. Production of semimanufactures did not change much. Apparently competition in this sector of the industry was very intense, and due to reduced delivery time, there was little purchase for inventory. Castings showed substantial increase because of the favorable situation in the automobile industry, which generally absorbs almost 50 percent of the output.[6]

It is believed that the consumption increase (3 to 4 percent) did not match increases of the previous years. The supply position for primary and secondary aluminum was as follows:

	Thousand metric tons
Production	437
Imports	170
Exports	10
Total available	597
Custom smelting and use of primary metal for production of secondary metal	[1]—44
Direct use of scrap	[1]+22
Change in inventory	[e]—20
Consumption	555

[e] Estimate.
[1] NE-Metalle Düsseldorf, Germany. Feb. 2, 1966, p. 2.

Per capita consumption of aluminum in 1964 by important sectors in kilograms were transportation 2.2, electrical engineering 1.3, building and construction 0.7, and packaging 0.7. Transportation (predominantly road transportation) accounts for 25 percent of total domestic consumption.

Countervailing the large imports of aluminum, exports of semimanufactures (59,642 tons) exceeded imports by almost 27,000 tons. Non-EEC countries were the major sources of aluminum imports in 1965; EEC countries supplied only 27,850 tons of the 138,856 tons of aluminum imported and only 7,873 tons of the 30,663 tons of alloys imported. But these countries supplied nearly 80 percent of the semimanufactures.

In 1965 the Government allowed an 80,000-ton quota for imports at a preferential rate of 5 percent and a 3,000-ton duty-free quota from EEC countries.[7] The entire duty-free quota and an estimated 70,000 tons of the preferential quota were utilized. For 1966, the Government applied to the EEC Commission for a 100,000-ton quota to be imported at a preferential tariff from non-EEC countries.

Iron Ore.—Domestic ore accounted for only 11.5 percent of the iron content of iron ore smelted for production of pig iron. Production of iron ore in West Germany continued to decline in 1965 and four mines were closed. Employment in the industry was only 43 percent of the 1961 level. In 1965 Salzgitter accounted for 62 percent of total output. Ilseder for 30 percent, and Osnabrück for 8 percent. Mines in these areas are linked to iron and steel mills and presumably can maintain their production. Erzbergbau Salzgitter A.G. was developing an iron ore deposit at Salzgitter with a 1.2-million-ton annual capacity to be completed in 1967. Eisenwerkgesellschaft Maximilianhütte m.b.H. has also been developing sections of a deposit at Sulzbach-Rosenberg and building facilities to crush, screen, and stock ore at Auerbach. Ilseder Hütte Eisenerzbergbau had a modernization program of underground equipment which reportedly was scheduled to be completed in 1965. Apparently some work (shaft and drifts) was being carried out by Barbara Erzbergbau Mining Company at Staffhorst to determine

the economic feasibility of mining the deep Upper Jurassic ore.

Iron and Steel.—*Raw material consumption.*—The iron and steel industry as a whole consumed 25.97 million tons of iron (of which 20.50 million tons was contained in iron ore), 15.6 million tons of scrap, 22.35 million tons of solid fuel, 2.09 million tons of liquid fuels, and 890 million cubic meters of oxygen. While solid fuel consumption showed a 4.4-percent decline compared with that of 1964, liquid fuel use increased 9.4 percent. Coke consumption per ton of pig iron averaged 668 kilograms (691 kilograms in 1964) while in many blast furnaces actual consumption was lower than the average.

The small decline in pig iron production is reflected in raw material consumption which for all materials was 2.4 percent less than in 1964. But scrap consumption was nearly 14 percent and blast furnace dust 15 percent less than in the previous year. There was a further increase in use of sinter; iron ore sintered represented 65 percent of all iron ore consumed in pig iron production (60 percent in 1964).

Although scrap consumption per ton of steel averaged 405 kilograms, unit consumption for individual processes varied: 648 kilograms for open hearth, 167 kilograms for oxygen steel, and 69 kilograms for Thomas steel. A substantial share of the scrap requirements of both the steel mills and the foundries continued to be supplied by the plants themselves.

The steel industry (excluding foundries) at yearend employed about 399,000 persons, 3,000 less than at the beginning of the year.

Production.—In 1965 West Germany had an effective capacity to produce 33.1 million tons of pig iron, 44.6 million tons of crude steel, and 33 million tons of finished products. Crude steel production capacity was distributed between types of furnaces as follows, in percent: Open hearth 42.9, basic bessemer 29.5, Linz-Donawitz (LD) and similar oxygen furnaces 19.1, electric 8.5. About 33,000 tons of acid bessemer capacity also existed. Pig iron and steel output represented, respectively, 81.5 and 82.5 of maximum possible output.

In 1965 the country almost maintained the record 1964 output, registering declines

of 0.7 percent in pig iron, 1.4 percent in crude steel, and 0.5 percent in finished steel production. In March monthly production attained a new record peak. However, toward yearend, because of declining domestic orders, the number of hours worked per week was reduced in a number of plants. Outstanding orders at the beginning of December stood at 3,262,700 tons compared with an average of 4,293,200 tons for the first 8 months of the year. Foreign orders, however, were about those of the previous year, the monthly average being 523,300 tons compared with 461,300 tons in 1964. Profitability of the industry has been adversely influenced by trends in labor costs and steel prices. During 1956 to 1965, share of wages and salaries in total costs increased from 13.6 to 19 percent.[8] Since 1960 average receipts per ton of steel had decreased from $135 to $120 per ton. Producers felt that they were handicapped by the German turnover tax and the duty on coal imports, which compelled them to use the more expensive Ruhr coal.

The decline in the share of total pig iron accounted for by Thomas pig iron that had prevailed for some years continued in 1965. Thomas pig iron accounted for 55.2 percent of total pig iron and blast furnace ferroalloys, compared with 57.1 percent in 1964. North Rhine-Westphalia, where the Rhur area is located, produced 68.7 percent of total West German pig iron output, followed by the Saar area with 13.5 percent.

Oxygen and electric furnace steels registered further increases in both tonnage and percentage of total. Flat products, including hoop and strip, maintained their dominant position, accounting for 48.3 percent of total output. Bars and rods other than wire rods were next in importance, with 22.3 percent.

[8] Work cited in footnote 4.

Steel castings	300	341	

Consumption and Trade.—Apparent consumption of steel in West Germany during the first half of the year was at an annual rate of about 34 million tons, on the basis of ingot steel, or an average of 587 kilograms per person. (In arriving at this figure only ECSC treaty items have been included in the trade.) Delivery of steel products in 1965 totaled 23.6 million tons, presumably including delivery for exports. Of this total, flat products accounted for 10.4 million tons (excluding 505,700 tons of tinplate and 333,300 tons of galvanized and other coated plates), and bars and rods accounted for 5.7 million tons; wire rods were the next most important item with 2.8 million tons.

Both imports and exports increased, but exports increased at a higher rate. Exports of ingots, blooms and billets, and rolled steel including pipes and tubes in 1965 (9.57 million tons) were 14.6 percent higher than in 1964 (8.35 million tons). Imports in 1965 (5.59 million tons) were 2.5 percent higher than in 1964 (4.45 million tons).

Lead and Zinc.—In 1965, West Germany produced 1.8 percent of the world's lead and 2.7 percent of zinc in ore. Seven mines were in operation as in 1964; each producing company had its own beneficiation and smelting facilities. Owing to improvement in prices of lead and zinc, the economic condition of the mines was satisfactory. Domestic smelters also showed an increased interest in purchasing West German ore because of widespread shortage.

During the year the Government announced a plan to bring financial stability to the industry. Under the plan a reserve fund may be accumulated by a producing company from the profits of a given fiscal year by multiplying the difference between the "average production cost" of lead and zinc plus a reasonable profit and the annual average price of the metals in the London Metal Exchange plus the import duty, by weight of the metal content of the concentrates. The mining company can put 50 percent of the computed difference into a reserve fund which remains temporarily tax-free. Sixty percent of this reserve fund must be deposited in a blocked account to be used as compensation for losses should any occur within 5 years. The remaining 40 percent may be used for current operations but must be included in the company's total accountability. The fund can be established only in a year when the company shows a profit.

In 1965, domestic ores constituted 47 percent of lead ore and 79 percent of zinc ore smelted in West Germany. In 1965, mines of the Harz area (Goslar) accounted for 60 percent of the lead ore and 39.5 percent of the zinc ore. The Eiffel area accounted for 23 percent of the lead ore and Sauerland, where the Meggen mine is located, accounted for 47.3 percent of zinc ore.[9]

While production of smelter lead remained practically the same as in 1964, smelter zinc output was 8 percent higher. Increasingly, the lead and zinc smelter requirements have been met by raw materials other than ore. While nearly 70 percent of lead produced in German smelters in 1961 was obtained from ores, the figure decreased to 45.8 percent (21.3 percent domestic and 24.5 percent foreign) in 1965; corresponding figures for zinc were 70 percent and 54.8 percent (44.9 percent domestic and 9.9 percent foreign), respectively. Productivity, measured in kilograms of lead and zinc brought to the surface per man-shift, increased from 50.15 kilograms in 1950 to 202.3 kilograms in 1965—an average annual increase of 9.4 percent for this period.

Consumption of both metals increased in 1965 to 275,000 tons of lead and 325,000 tons of zinc—an increase of 6 percent and 1.4 percent, respectively. The approximate percentage distribution of total lead consumption by use in 1963 was as follows: Cables 31, batteries 29, semi-manufactures 16, alloys 7, paint 12, and miscellaneous 5.[10] For the same year zinc consumption was distributed as follows, in percent: Brass 31, galvanizing 26, semimanufactures 20, die castings 16, and zinc oxide 7.

A significant development in plant construction was completion of an Imperial Smelting Process lead-zinc blast furnace in the works of "Berzelius" Metallhuetten-G.m.b.H. (a subsidiary of Metallgesellschaft A.G. of Frankfurt) in Duisburg. The furnace had been under construction since 1963. With the starting of the plant in October 1965, eight of the muffle furnaces (built in 1905 and in operation since 1907)

[9] Fachvereinigung Metallerzbergbau e.V. Jahresbericht und Statistik 1965, p. 6.

[10] Nachrichtendienst der NE-Metalle (Düsseldorf, Germany). June 1965, p. 1.

were abandoned.[11] The plant is highly automated and has many facilities to reduce air and water pollution.

Annual production capacity of the plant will be about 110,000 tons per year: 50,000 tons of zinc, 25,000 to 30,000 tons of lead bullion (Werkblei) from the new furnace, and 15,000 tons of zinc from the remaining muffle furnaces; the rest of the tonnage consists of tin alloys. The lead bullion will be shipped to the Metallgesellschaft's plant, Blei und Silberhuette Braubach, to be refined to soft lead.

The Meggen pyrite-zinc mine output comprised 670,046 metric tons of mine-run material, which included 561,635 tons of ore; 420,122 tons was treated by flotation, with a recovery of 141,513 tons of zinc-bearing pyrite and 257,235 tons of pyrite low in zinc content. The Bayerland mine was the only other pyrite mine in the country.

NONMETALS

The value of nonmetals produced in 1965, exclusive of building raw materials, totaled about $221 million. Building raw materials (stone, sand and gravel, lime, gypsum, slate, lava, and pumice that were used essentially as building material) were vauled at $694 million. Stone and sand and gravel accounted for 44 and 27 percent of this total, respectively. Cement and clinker added another $499 million to the value of building material. However, some of the cement was produced from slags rather than from quarry products.

In 1965, West Germany was a net exporter of barite, cement, refractory clays, gypsum, lime, pumice, quartz, quartzite, and slate. Among imports of nonmetals, the most important items and their values were phosphate rock $37.3 million, asbestos $24.5 million, pyrite $24.4 million, magnesite (including calcined and sintered) $17.2 million, marble and other stones $16.3 million, sulfur $15.1 million, and crushed rock and sand and gravel $13.1 million. Among minerals with exportable surplus, crude and chemically treated potash, cement, refractory clays, and salts were the most important in value with export values of $65.8 million, $18.9 million, $9.7 million, and $7.4 million, respectively.

Expansion of the building industry slowed down during the year. In current prices, value of all construction was 5.0 percent higher than in 1964, compared with an average yearly increase of 13.3 percent for the previous 4 years.[12] In real terms (1954 prices) the 1965 increase was 2.1 percent compared with 12.1 percent in 1964 and an average yearly increase of 7 percent from 1961 to 1964.

Cement.—In 1965 portland cement constituted 74.5 percent of total cement output (including that of West Berlin), about the same ratio as in 1964. The remainder was classified as iron portland cement (30 to 70 percent slag), blast furnace cement (70 to 85 percent slag), and miscellaneous cement and mortar. In 1964, the country had an annual installed capacity of 34.2 million tons. Despite a persistent labor shortage, capacity was to be increased by 4.5 million tons per year by mid-1966 by adding about 14 new furnaces in existing plants. Plant capacity at yearend 1965 was 37.2 million tons.

In 1965, West Germany exported 1.4 million tons of cement and clinker and imported 460,164 tons so that apparent consumption was 33.2 million tons (550 kilograms per person) of which 55 percent was delivered in bulk to internal and external markets. It was anticipated that bulk deliveries might increase to 58 percent of total deliveries by the end of 1966.

Price of portland bulk cement in 10-ton lots, f.o.b. receiving plant, averaged $16.40 per ton in 1964 and remained substantially the same in 1965. The price index was 99.9 (1958=100), compared with 99.7 in 1964. Sales of ready-mixed concrete accounted for about 12 percent of total sales.

Employment in the industry in 1965 totaled 23,000 and annual production per worker was 1,457 tons, a 3-percent increase from the previous year (1,417 tons).

Potash.—There were about 16 potash works in operation, 11 in Lower Saxony, 4 in Hesse, and 1 in Baden-Württemberg. Thirteen plants process crude potash, and three ship the crude potash to other plants for further processing. In addition four plants produced both salt and potash and one produced salt only. The majority of these plants are located near inland water-

ways. The country also has two plants for producing potassium sulfate, two for mixed fertilizers, one for magnesium chloride, and four to make bromine.

Breakdown of production in 1965 by States is not available. In 1964, Lower Saxony produced 51 percent of the crude potash and 58 percent of the marketable potash; the bulk of the remainder was produced in Hesse. At the beginning of 1964 about 15,900 persons were employed in the potash industry of Lower Saxony. In 1964, 138 tons of potassium monoxide was produced per man-year (88 tons in 1956). The increase in productivity resulted from mechanization and rationalization in the industry.

Domestic shipment of potassium fertilizers from July 1, 1964, to June 30, 1965, totaled 1,184,020 tons compared with 1,125,277 tons during the previous 12-month period. This was equivalent to 83.8 kilograms per hectare of arable land, compared with 79.4 kilograms per hectare during the previous 12 months.

Sulfur.—Domestic production of contained sulfur in 1965 was estimated at 527,000 tons; 77,000 tons recovered elemental sulfur, 190,000 tons sulfur in pyrite, and 260,000 tons sulfur from other sources, mainly smelter gases from domestic and imported ores. Requirements were about 1.8 million tons; the difference between output and requirements was met by imports, including 1.5 million tons of pyrite and 485,700 tons of elemental sulfur. In spite of increased imports of crude oil, sulfur recovered from this source did not increase significantly because of growing imports of low-sulfur crude from North Africa. Also an increasing number of refineries manufactured small quantities of sulfuric acid directly from hydrogen sulfide for their own use. In 1965, 70 percent of sulfurous material was used for sulfuric acid, the output of which (including West Berlin) increased to 3.1 million tons, compared with 2.9 million tons in 1964.

West Germany remained the principal market for pyrite in West Europe because sulfuric acid production still was based largely on pyrite. Nonetheless, elemental sulfur imports in 1965 showed a 20-percent increase.

MINERAL FUELS

Energy consumption of West Germany (including West Berlin) in 1965 increased 3.0 percent compared with 1964 figures to a new high of 271 million tons of standard coal equivalent (SCE). Petroleum, hydroelectric power, and natural gas accounted for all of the increase. In addition, these sources of energy made further inroads into

markets heretofore occupied by solid fuels, as shown in the following tabulation:[13]

Energy source	Million tons SCE		Percent of total primary energy consumption	
	1964	1965	1964	1965
Coal:				
Anthracite and bituminous	122.1	114.7	46.4	42.4
Lignite and pitch coal	35.1	32.1	13.3	11.8
Gas, natural	2.5	3.5	1.0	1.3
Hydroelectric power	4.9	7.4	1.9	2.7
Petroleum	96.3	111.3	36.6	41.1
Other	2.1	1.9	.8	.7
Total	263.0	270.9	100.0	100.0

The state of the coal industry was a concern to the Federal Government as well as to the State government of North Rhine-Westphalia and to the industry and the unions. The industry in 1965 marketed an estimated 129 million tons of coal[14] (139 million tons in 1964), a figure which may decline to 105 million tons by 1970.

The coal producing companies agreed to reduce the annual production target from the 140-million-ton annual level that has long been maintained to a new level of 125 million tons, which corresponds to expected sales in 1966. An industry spokesman proposed that the Federal and the State Governments and industry establish a liquidation company that would acquire and subsequently close uneconomic mines. Also under consideration were closure premiums based on the tonnage of annual capacity closed, and a subsidy to assure that 50 percent of total output of electricity would be produced from domestic coal.

[1] Excludes small mines and leases.
[2] Details do not add because of rounding.

Coal.—For the first time since 1952, German coal production fell below 140 million tons; 1965 output was 5 percent less than that of 1964. Even with this decline (partly a result of 4 nonproduction days during the year), stocks of coal at mines at yearend 1965 stood at 14.6 million tons, compared with 8.6 million tons at the end of 1964. Of the total output 86.1 percent was medium- to high-volatile coking coals (Flammkohle and Fettkohle), 5.3 percent was bituminous to semianthracite (Esskohle and Magerkohle), and 8.6 percent was semianthracite to anthracite.

Despite a decline in production, the manpower cost of the industry (excluding premium and separation money for miners and allowances for miners to travel home) was $813.9 million ($784.6 million in 1964). Wages (including house allowance benefits) were increased 10 percent, effective January 1, 1965. Average daily wages for underground workers, surface workers, and all workers combined were $10.19, $7.82, and $9.49, respectively. Corresponding 1964 figures were $9.20, $6.94, and $8.53, respectively. In 1964, provisional production cost per ton of net output, exclusive of opencast working, was $14.85, distributed as follows: Manpower $8.37, materials $5.07, overhead $0.66, and depreciation $0.75. In 1965, manpower cost was 61.9 percent of the $2.13 billion total gross value of production from mines and auxiliary facilities.

Shipments, Consumption, and Trade.—During 1965, 145 million tons of coal was available, about 7 million tons less than in 1964, and this was almost entirely a result

[1] Includes 938,000 tons to emergency stocks.
[2] Includes small quantities used in coke and briquet plants as follows, in thousand tons: 1963, 196; 1964, 73; 1965, 36.
[3] Includes exports to East Germany as follows, in thousand tons: 1963, 129; 1964, 113; 1965, 36.

of reduced domestic production. Shipments to a majority of the consuming sectors declined, particularly to powerplants, gasworks, and railroads. The public utility market remained subject to competition from fuel oil.

As a result of rationalization, the number of operating mines decreased to 107, compared with 115 in 1964 and 173 in 1957. Of the 1965 total, 90 mines were in the Ruhr, 9 in the Saar, 6 in Aachen and 2 in Lower Saxony.

The share of coal produced by fully mechanized mines was 79.5 percent compared with 74.4 percent in 1964 and 39.5 percent in 1960. Output per man-shift increased about 4 percent in 1965.

Production of coal by mine size in 1964 and 1965 was distributed as follows:

Mine size (tons per day)	Percent of total	
	1964	1965
10,000 and more	10.1	4.4
9,000–9,999	3.6	13.2
8,000–8,999	8.0	6.5
7,000–7,999	9.8	7.3
6,000–6,999	11.9	14.1
5,000–5,999	22.4	21.8
3,000–4,999	24.7	23.4
2,999 or less	9.5	9.3

Of the mines in operation 74 had a daily production capacity of 3,000 to 7,000 tons per day. At the end of the year there were 1,350 working faces, each producing about 500 tons of coal daily; average daily advance was 163 centimeters. Six mines were closed during the year with total normal annual production capacity of about 4 million tons.

Of the 1965 coal output, 88.4 million tons was shipped for conversion to secondary forms, including 57.6 million tons to coke, 4.4 million tons to coal briquets, and 26.4 million tons to electricity. Coal-producing companies themselves converted 68.87 million tons of the total (51 percent of total output) as follows, in million tons: Coke plants 50.38, briquets 4.45, and steam and electricity 14.04, of which 5.95 was delivered to other consumers.

Consumption declined in various degrees in all coal consumer groups because of structural changes connected with the continuing competition from fuel oil and because of the high output of hydroelectric power. Consumption by principal sectors was as follows, in thousand tons:

Sector	1963	1964	1965
Transportation	6,783	6,059	4,783
Public utility:			
Powerplants	17,473	18,038	17,422
Gasworks	7,438	6,649	5,641
Waterworks	140	126	108
Total	25,051	24,811	23,171
Coal industry:			
Mines' own consumption	4,576	4,209	4,303
Mine powerplants	10,376	10,508	9,691
Mine coking and briquetting plants	11,502	12,213	12,384
Other	6	4	1
Total	26,460	26,934	26,379
Iron and steel coke ovens [1]	2,176	1,952	1,778
Iron and steel industry	1,709	1,439	1,426
Other industry	16,616	15,549	14,721
Household and small industrial consumers [2]	12,113	8,812	7,574
Delivered to miners [3]	2,351	2,080	1,980
Military services	1,507	1,897	1,907
Total	94,766	89,535	83,719

[1] The difference between the weight of (1) coal input into coke ovens and briquetting plants and (2) coke and briquets produced.
[2] Shipments.
[3] As part of fringe benefits.

For water transportation, coal has become an insignificant source of energy, displaced by petroleum products. Gasworks consumption of coal has declined at an increasing rate both because natural gas has replaced manufactured gas in the energy marketplace and because of increasing use of natural gas, petroleum refinery gas, and liquefied petroleum gas in the gasworks. At yearend 1964, there were only 61 gasworks operating exclusively on coal compared with 132 at the end of 1961. In contrast, 92 gasworks were

using liquid or gaseous hydrocarbons exclusively at yearend 1964, compared with only 40 at the end of 1961. In the same period, 53 gasworks stopped producing gas and joined 337 others that were linked to gas networks at yearend 1961.

Coal consumption by the iron and steel industry was influenced by the reduction in that industry's output as well as by a decrease in blast furnace consumption of coke per ton of iron produced. Fuel oil not only covered increases in consumption of industries other than iron and steel but also displaced some coal from this market. Comparatively mild weather at the beginning of 1965 and competition of light fuel oils adversely influenced delivery to households and small industry. Coal consumption by colliery powerplants, which showed a continuous increase between 1958 and 1964 for a total of 53 percent, declined in 1965 because of an increase in hydropower output. Colliery powerplants produced 25.2 billion kilowatt-hours, or 14.6 percent of all electricity produced; corresponding 1964 figures were 26.4 billion kilowatt-hours, or 16.1 percent. Of the electricity produced, 16.8 billion kilowatt-hours were sold to other consumers (18 billion kilowatt hours in 1964). The central heating plants located at collieries were a new but small factor in consumption.

Exports of coal including coal briquets in 1965 totaled almost 13.6 million tons but were 3.9 percent below the 1964 level. Of the 1965 total, 88.7 percent went to other EEC countries. Principal recipients were France with 5,486,900 tons, Belgium-Luxembourg with 3,187,600 tons, Netherlands with 2,844,800 tons, and Italy with 519,000 tons. West Germany also exported 9,728,500 tons of coke, including 7,026,600 tons to EEC countries such as France (3,293,600 tons) and Belgium-Luxembourg (3,283,700). Other significant destinations were Sweden (682,700 tons), Denmark (410,900 tons), and Austria (403,700 tons). Imports of coal, including coal briquets (7,471,600 tons), were about the same as in 1964. The United States accounted for 5,032,600 tons of the imports, EEC countries for 1,288,200 tons, the United Kingdom for 534,800 tons, and Poland for 408,200 tons. Coke imports, 534,700 tons,[15] almost doubled from the previous year, with 481,000 tons from other EEC countries.

Marketing and Prices.—The High Authority of the European Coal and Steel Community (ECSC) by two decisions of December 15, 1965, prolonged the existence of the Ruhr coal sales agencies, Geitling and Präsident, until March 31, 1968.

Coal prices were increased 25 cents to $1.50 per ton depending on grade and quality (an average of 4 percent). For high-volatile bituminous coal, price per ton was $18.37 in 1965 ($17.62 to $17.87 in 1964).

Coke.—Coke production remained about the same as in 1964, the slight increase in output by coal-mining companies being compensated by a decline in coke produced in steel mills, in thousand tons:

Coke production	1961	1962	1963	1964	1965
Coal-mining companies	37,044	36,054	35,213	37,394	37,903
Steel mills	7,490	7,144	6,682	5,956	5,391
Total	44,534	43,198	41,895	43,350	43,294

Total coke shipments were 9.5 percent less than in 1964, the decline resulting mainly from decreases in both export sales (1,055,000 tons) and domestic iron and steel industry sales (893,000 tons).

Lignite (Braunkohle).—Reduction in lignite briquet production accounted for a large part of the nearly 9-million-ton decrease in lignite output. Powerplants remained the principal market for the lignite, which was not briquetted or otherwise converted, however, sales for this market decreased about 1.1 million tons.

Coal Byproducts and Coke Oven Gas.—There were no significant changes in the production of coke oven gas and other byproducts in the coke ovens of the coal mines.

Total manufactured gas production in 1965 is not available; the 1964 output totaled 42,451 million cubic meters distributed as follows, in million cubic meters: Coal gas 22,607, generator and water gas

[15] Excludes coke from nonbituminous coal.

Table 15.—Federal Republic of Germany: Production of coal byproducts in coke ovens of coal mines

(Thousand metric tons unless otherwise specified)

	1963	1964	1965
Crude tar	1,703	1,752	1,723
Crude benzol	512	526	518

Sales	13,528	13,907	14,134
Loss	260	249	255

[1] All gas converted to 4,300 kilocalories per cubic meter at 760 millimeters of mercury and 0° C.

Source: Verlag Glueckauf GmbH. (Essen), Zahlen zur Kohlenwirtschaft. February 1966, p. 43.

4,309, blast furnace gas 14,840, and other 695.[16] The total was equivalent to 63 percent of the 58,182 million cubic meters of all gas produced in the country in 1964; the remainder comprised natural gas, liquefied petroleum gas, and refinery gas.

Disposal of all gases totaled 58,495[17] million cubic meters, of which 75 percent went to end users, 20 percent went to the gas-producing installations themselves, and 5 percent was accounted for by losses. Corresponding figures for natural and refinery gases were 14,349, 1,129, and 566[18] million cubic meters, respectively. Of the 43,751 million cubic meters, iron and steel industry used 44.2 percent chemical industry 18.7, other industry 19.6, households 9.3, and other consumers 8.2.

Petroleum.—The turnover of the West German petroleum industry, including natural gas producers, totaled $3,265 million, 3.4 percent of the turnover of all industry. Preliminary figures show that the Government revenue from excise tax on petroleum products, amounting to $1.86 billion, was 22.4 percent more than in 1964. It represented 12.8 percent of the Government revenue. Included in this revenue is $153 million obtained from fuel oil tax. Taxes on motor vehicles supplied the States with $655 million revenue. The monthly average employment by the industry was 11,303, including exploration (geology and geophysics), drilling, production, administration, and transport, but not including refining.

Exploration and Drilling.—In 1965, 32 teams were engaged in geophysical work—30 seismic, 1 aeromagnetic, and 1 geoelectric—and 327 team-months were spent with a total expenditure of about $12 million. During the year, 125 wells were completed on land with a total depth of 309,325 meters, compared with 150 wells and 390,797 meters in 1964.[19] In 1965, exploration wells accounted for 117,384 meters, development wells for 93,926 meters, production wells for 96,840 meters, and auxiliary wells for 1,175 meters. Of the 125 wells, 31 were exploration wells of which 4 struck oil, 33 were development wells, and 61 were production wells. Twenty development and 57 production wells were successful, making a total of 81 successful wells. Two natural gas deposits, Dötlingen and Groothusen, were discovered between Weser and Ems, and gas was struck in a well (Fehndorf) west of Ems. A new oil deposit was discovered at Fronhofen in Bavaria, where the Lias has been determined to be oil bearing betwen 1,872 and 1,876 meters.

Drilling in the offshore area of West Germany in the North Sea was carried out

[16] Plesser, N., and R. Pohl. Die Entwicklung der Gaswirtschaft im der Bundesrepublik Deutschland im Jahre 1964 (The Development of the Gas Economy in the Federal Republic of Germany in the Year 1964). Das Gas und Wasserfach, 1965, 20 pp.

[17] The total of consumption, 58,495 million cubic meters, is 313 million cubic meters in excess of production of 58,182, this difference comprises refinery and liquefied petroleum gas input in gas-cracking installations.

[18] The total, 16,044 million cubic meters, is 313 million cubic meters above production. See footnote 17 above.

[19] Erdöl und Kohle. February 1966, pp. 88–90.

by a consortium of 11 firms.[20] Most wells were north and west of Borkum Island and did not result in significant discoveries. The principal wells in 1965 were the following:

Designation	Location	Results
A 1	21 kilometers north of Borkum.	Drilled to 4,000 meters without finding economic gas.
B 2	53 kilometers north of Juist and 60 kilometers west of Heligoland.	Some gas with 60 percent nitrogen. Drilling stopped at 4,600 meters.
C 1	83 kilometers northwest of Borkum.	Uneconomic gas at a depth of more than 4,000 meters.
D 1	35 kilometers northnorthwest of Borkum.	Undetermined quantity of combustible gas.
E 1	43 kilometers north of Borkum.	Completed December 1965.
M 1	15 kilometers northwest of Borkum.	Drilling at yearend 1965.
N 1	110 kilometers northwest of Borkum.	Drilling probably not started at yearend.

Deutsche Erdöl A.G., Deutsche Schachtbau- und Tiefbohrgesellschaft m.b.H., Saarbergwerke A.G., and Wintershall A.G. formed a consortium to drill a deep test well (6,000 meters) at Spieser Höhe near Neunkirchen in the Saar.

The first oil exploration concession for the Continental Shelf of the Baltic Sea was granted by the Federal Mine Inspectorate, Oberbergamt Clausthal-Zellerfeld, to three companies which already held concessions extending to the 3-mile limit off the coast of Schleswig-Holsten. The companies were Deutsche Erdöl A.G., Wintershall A.G., and Gewerkschaft Brigitta (a wholly owned subsidiary of Esso and Shell).

West German firms also participated in oil exploration in North Africa (Algeria, Libya, Morocco, and Ethiopia), the Near East (Iran and Dubai), West Europe (Italy, Spain, and Switzerland) and Canada and Peru; 51,337 meters were drilled abroad.

Reserves and Production.—At the end of 1965 reserve-production ratio stood at 13.5:1, with petroleum reserves totaling 106.4 million tons, compared with 111.1 million tons at the beginning of the year. The 106.4-million-ton total reserve consisted of 81.3 million tons proven and 25.1 million tons probable and was distributed by area as follows in thousand tons: North of Elbe 11,695; between Elbe and Weser 21,523; between Weser and Ems 26,329; west of Ems 41,405; Upper Rhine valley 2,441; and Alpine Foreland 3,000.[21]

Crude production at 7,883,893 tons was 211,275 tons more than in 1964. Rate of increase in production fell further to 3 percent. Nearly four-fifths of the production was from the Elbe to west of Ems.[22]

Table 16.—Federal Republic of Germany: Petroleum and natural gas production by areas, 1963–65

Area	1963	1964	1965
PETROLEUM (tons unless otherwise specified)			
North German basin:			
North of Elbe (Schleswig-Holstein)	800,024	835,575	853,217
Between Elbe and Weser (Hannover)	2,378,738	2,291,221	2,412,178
Between Weser and Ems	1,709,720	1,920,782	1,955,611
West of Ems (Emsland)	1,982,505	2,074,758	2,088,949
Upper Rhine Valley	250,246	243,307	233,992
Alpine Foreland (Bavaria)	261,467	306,975	339,946
Total	7,382,700	7,672,618	7,883,893
Rate of increase, percent	9	4	3
NATURAL GAS (thousand cubic meters unless otherwise specified)			
Between Elbe and Weser (Hannover)	33,622	49,062	49,548
Between Weser and Ems	338,558	690,860	1,172,056
West of Ems (Emsland)	262,132	411,820	664,057
Upper Rhine Valley	65,684	65,077	62,252
Alpine Foreland (Bavaria)	214,998	239,996	272,814
Total	914,994	1,456,815	2,220,727
Total million cubic feet [1]	32,482	51,717	78,836

[1] Converted at the rate of 1 cubic meter = 35.5 cubic feet.

The number of fields exploited declined to 76 (103 in 1963); Ruehlermoor in Emsland remained the largest producing field with a total of 802,776 tons. The distribution of crude oil production by principal producing companies from 1963 to 1965, in percent, was as follows:

Company	1963	1964	1965
Gewerkschaft Elwerath	23.0	23.3	23.9
Deutsche Erdöl A.G.	20.5	19.9	20.1
Wintershall A.G.	15.3	14.5	13.4
Mobil Oil A.G. in Deutschland	10.7	11.0	10.8
Preussag A.G.	10.8	10.5	10.3
Deutsche Schachtbau-und Tiefbohrgesellschaft	6.3	7.0	7.5
Gewerkschaft Brigitta	5.4	5.4	5.0

Crude production by West German firms outside of West Germany amounted to 1.33 million tons, mainly from Libya, where Gelsenberg Benzin A.G., shares a concession with Mobil Oil A.G.

Consumption and Trade.—Total petroleum product requirements, including refinery consumption, bunkers, other deliveries, and exports totaled 83.1 million tons, an increase of 13.0 percent over 1964 requirements. This figure is expected to increase to 90 million tons by 1966. While total requirements (including bunkers) increased by about the same percentage as in 1964, fuel oils increased by 18 percent.

Refining.—Refinery output was equivalent to about 79 percent of requirements, thus necessitating about 15 million tons of products imports. Total crude throughput was 14.3 percent more than the previous year; of this 11.3 percent was indigenous petroleum (13.1 percent in 1964). With the exceptions of kerosine and petroleum coke, output of all products increased. Heating oils (light, medium, and heavy) constituted 57 percent of total output in 1965 (55 percent in 1964).

At yearend 1964 annual refinery throughput capacity totaled 72 million tons, 16 million tons more than at yearend 1963. The corresponding figure for yearend 1965 was about 81 million tons and this was expected to increase to 85 million tons per year by the end of 1966.

Thirteen plants with annual throughput capacity of 3 million tons or more each accounted for 68.8 percent of 1964 capacity. Percentage distribution of total 1964 throughput capacity by company was Esso

Table 17.—Federal Republic of Germany: Shipments of petroleum products
(Metric tons)

Commodity	1963	1964	1965
Domestic sale:			
Gasoline, all kinds	9,272,770	10,840,051	12,103,432

A.G. 20.2; Deutsche Shell A.G. 13.2, Gelsenberg 7.2, and BP Benzin-und Petroleum, A.G. (BP) 9.3. The Rhine-Ruhr area had 45 percent of the capacity, followed by Bavaria with 14 percent, Hamburg and Lower Saxony-Bremen each with roughly 12 percent, southwest Germany with 11.3 percent, and Schleswig-Holstein with about 5 percent.[23] Since yearend 1963 Bavaria's share of total capacity had increased by 5 percent and that of Rhine-Ruhr had increased by 0.4 percent; other areas mentioned above showed declines varying from about 0.5 percent to 1.5 percent.

During the year two new refineries came on stream, the Speyer refinery in the Saar and the refinery of Ente Nazionale Idrocarburi (ENI) in Ingolstadt. The Speyer refinery, completed in January 1965, and owned by Union Générale des Pétroles, was operated by its West German affiliate, Union Treibstoff G.m.b.H. A significant feature of this plant is that it produces 900

Scholven-Chemie A.G.: Gelsenkirchen-Buer	4,000
Union Rheinische Braunkohle-Kraftstoff A.G. (Rhine Brown Coal): Wesseling	3,000
Wintershall A.G.: Salzbergen	220
Total	72,670

million cubic meters of town gas annually from the light distillates, black oils constituting the other principal product. Two processes are used—the Imperial Chemical Industries' catalytic cracking in stream of gasoline to produce lean gas and the British Gas Council's method for making rich gas by hydrogenation of a fraction of the distillates. The two gases are blended and enriched by the addition of liquefied petroleum gas to make a normal town gas of 4,650 kilocalories per cubic meter.

Crude oil is obtained from the South European Pipeline System. A 24-inch-diameter line is led off at Worms to storage tanks at Jockgrim. A 16-inch-diameter, 35-kilometer line from Jockgrim conveys the oil to the refinery.[24] The refinery will use principally Algerian crude.

The ENI refinery, although completed in late 1964, did not come on stream until March 1965 because of delay in the completion of the Central European Pipeline from Genoa. Under an agreement with Esso, the latter supplied ENI's refinery with Libyan crude, some of which is also conveyed to Esso's own refinery by the South European Pipeline. Until completion in December of a 20-inch-diameter and 5-kilometer-long pipeline connecting the ENI refinery to the Rhine-Danube pipeline, the crude was truck-transported to ENI's refinery. The refinery can process Middle East as well as Algerian crude. Capacities of the various units are as follows in tons per year: Unifining-platforming unit 450,000; hydrodesulfurizer for gas oils 300,000; Merox sweetening plant for straight-run gasoline and liquefied petroleum gas 170,000; liquefied petroleum gas fractionation 110,000; sulfur recovery 450,000.

Additional capacity was also created by expansion of the Deutsche Shell refineries at Hamburg and Ingolstadt, at the Esso refinery at Ingolstadt, and at the BP refineries at Hamburg and Dinslaken. At the end of December 1965, the BP Hamburg refinery started operation of a 2.2-million-ton-per-year combination atmospheric and vacuum distillation. Two older distillation units will be operated at lower throughput so that actual capacity increase of the refinery will be 1.4 million to 3.7 million tons per year.[25]

Two refineries were under construction, one at Berghausen in southeast Bavaria with a 2-million-ton annual capacity and one at Vohburg, east of Ingolstadt, with a 4.4-million-ton annual capacity. The first one is being built by Marathon Chemische Werke, a subsidiary of Deutsche Marathon Petroleum A.G. and the second by BP Benzin-und Petroleum, A.G. Three other refineries are planned.

In addition to new refineries under construction and planned, the DEA-Schloven refinery in Karlsruhe is slated for expansion to 5.5-million-ton capacity by 1966. New units will include a crude distillation column with an annual throughput capacity of 3.35 million tons.

Transportation and Distribution.—Crude oil from overseas destined for West German refineries was received at the following ports: Wilhelmshaven-Emden (31.92 percent), Marseilles (30.17 percent), Rotterdam (18.43 percent), Hamburg-Brunsbuettelkoog (17.94 percent), and Bremen (1.54 percent). About 77 percent of the crude oil imported in 1965 was delivered to refineries by pipelines (73 percent in 1964). The remainder was either off-loaded directly from ocean carrier to refinery or delivered by barge or tank cars.

Crude oil deliveries to West German refineries by long distance pipelines for 1963–65 were as follows:

Pipeline	Million metric tons		
	1963	1964	1965
Northwest (Wilhelmshaven-Cologne)	15.5	15.7	17.6
Rotterdam-Rhine	7.9	9.6	10.2
South European	4.8	[1] 12.8	18.2
Total	28.2	38.1	46.0

[1] Of this, 5.4 million tons was transported through the Rhine-Danube line to Ingolstadt.

Capacity of the Northwest line is to be increased to 22 million tons per year by additional pumping capacity. Work on the Trans-Alpine Pipeline (TAL) from Trieste to Ingolstadt continued during the year. This line, which was to be completed in 1967, will have an initial annual capacity of 25 million tons.

The Rhine-Main pipeline, the first West German long-distance pipeline for finished petroleum products, was being built by Shell between its refinery at Godorf, near Cologne, and Frankfurt and Ludwigshaven. BP acquired a 35-percent interest in this line. Under this arrangement a 110-kilo-

World Petroleum, July 1965, p. 31–33.
[25] Erdöl und Kohle. January 1966, p. 65.

meter spur will be laid from the BP refinery at Dinslaken to Godorf to supply naphtha to the Bayer-BP petrochemical plant at Dormagen. When completed, the Rhine-Main pipeline will carry about 4 million tons of products—3 million tons for Shell and 1 million tons for BP.

At the end of 1965, West Germany's tanker fleet consisted of 43 units of more than 6,000 dead weight tons, with a total of 1,395,928 dead weight tons. It ranked 10th among the world's national fleets.[26] This fleet is capable of handling perhaps one-fourth of the country's petroleum transportation requirements.

Natural Gas.[27]—*Reserves.*—Official estimates put natural gas reserves as of January 1, 1965, at 192,700 million cubic meters of which 139,100 million cubic meters were proven.[28] Industry sources give the natural gas reserves as 250,000 million cubic meters. The area betwen Weser and Ems accounted for 93,900 million cubic meters, followed by the West German part of the river Ems area with 70,000 million cubic meters.

Official reserves increased by 42.1 percent from the 135.6-billion-cubic-meter figure reported as of January 1, 1964, as a result of discovery of new fields and finding new gas-bearing horizons in known fields. The gasfield north of the city of Wasserberg in Bavaria was discovered by Mobil Oil A.G. during the year; this has turned out to be a locally significant field with reserves of at least 5 billion cubic meters. A consortium of Wintershall (90 percent) and Mobil Oil A.G. (10 percent) found Upper Carboniferous natural gas in drill hole Emlichheim T_1 at a depth of 3,208 to 3,212 meters at Fehndorf west of Ems. At Dötlingen, between Weser and Ems, gas was found in middle Bundsandstein. Gewerkschaft Brigitta found gas in Rotliegender, the same gas-bearing formation as at Groningen, in well Groothusen Z3 about 13 kilometers northwest of Emden.[29]

Production.—Production of nonassociated gas from gas wells and associated gas from oil wells from 1961 to 1965 was as follows, in millions of cubic meters:

	1961	1962	1963	1964	1965
Nonassociated	481	616	915	1,457	2,221
Associated	225	310	380	510	557
Total	[1] 707	[1] 927	1,295	1,967	2,778

[1] Totals do not add because of rounding.

While associated gas output almost doubled during the 5-year period, nonassociated gas increased almost five times—an increase of 52.4 percent over 1964 output. The area between the Weser and the Ems Rivers, with a 52.7 percent of total output of nonassociated gas, was the largest producing area of nonassociated gas and showed the largest increase in production—52.8 percent above 1964 production. The Barrien field, now connected with the Rehden field by a 50-kilometer pipeline, began production. The area west of the Ems contributed 29.9 percent to total output. Increase in production of these fields resulted mainly from the construction of a second gas pipeline to Dorsten. The Dollart-Ems fields should be important producers, supplying gas through the 205-kilometer Brigitta pipeline to Hamburg. In Bavaria, a substantial increase in production was expected from the Bierwang field (east of Munich), which was to start supplying Munich late in 1966.

Principal producing companies and their share of output of nonassociated gas were:

Company	Percent		
	1963	1964	1965
Wintershall A.G.	35.8	38.1	38.5
Gewerkschaft Elwerath	20.1	19.2	17.8
Mobil Oil A.G. in Deutschland	5.1	8.4	10.2
Gewerkschaft Brigitta	8.5	5.6	7.9

Bayerische Mineral-Industrie (Mobil Oil), Gewerkschaft Elwerath, Mobile Oil A.G. in Deutschland, and Deutsche Erdöl A.G. were the largest associated gas producers with 1965 output of 115,742,000, 115,345,000, 71,199,000, and 57,946,000 cubic meters, respectively.

Production of natural gas from gasfields and associated gas, refinery gas, liquefied

[26] Data supplied by Esso Tankschiff Reederei G.m.b.H.
[27] For details on consumption, see section on Coal Byproducts and Coke Oven Gas.
[28] Petroleum Press Service. June 1965, p. 223.
[29] Erdöl und Kohle. June 1965, p. 499.

petroleum gas, and gas from oil and light benzene totaled 15,731 million cubic meters[30] in 1964 (including West Berlin). In addition 313 million cubic meters of refinery and liquid petroleum gas were added during cracking. These gases constituted 27 percent of total gas production, compared with 11.9 percent in 1960. Of the 16,044 million cubic meters in 1964, 4,200 million cubic meters was natural gas (including associated), 6,260 million cubic meters was refinery gas, 4,513 million cubic meters was liquefied petroleum gas, 632 million cubic meters was gas from liquid hydrocarbons, and 439 million cubic meters was refined cracked gas. Similar details are not yet available for 1965.

Trade.—In 1965, 37,012,980 cubic meters of natural gas was imported from the Netherlands[31] (4,153,396 cubic meters in 1964). Existing contracts between Nederlandse Aardolie Maatschappij Export (NAM-Export) and natural gas marketing organizations in West Germany should increase imports to about 12 billion cubic meters of Netherlands gas. Thyssensche Gas-und Wasserwerke G.m.b.H. (Thyssengas, now 50 percent owned by Esso) and Ruhrgas have an agreement with NAM-Export calling for Thyssengas A.G. to receive 4 billion and Ruhrgas A.G. 2 to 3 billion cubic meters annually. Another agreement betwen the Netherland organization and Gas-Union G.m.b.H. (GU) of Frankfurt and Gasversoergung Süd-Deutschland G.m.b.H. (GSV) of Stuttgart is planning gas deliveries for use in Hesse and Baden-Wuerttemberg within 3 years, the quantity delivered to 5 to 6 billion cubic meters annually by 1975.

Transmission.—Permission has been granted to build pipelines to transport the Netherland gas. The Government of North Rhine-Westphalia has given permission to Thyssengas to build a 36-inch pipeline from the Netherland border at Zevenaar with branches to Cologne, Düsseldorf, Wuppertal, and Düren. The pipeline will be utilized by Thyssengas and Ruhrgas on a 50-50 basis. The same authority approved application of the Deutsche Gesellschaft für Gas-Transport G.m.b.H. to build a trunkline from the Rehden and Bentheim fields to Limburg ander Lahn with a tie-in to Netherland gas. Another company, the Süddeutsche Gas-Transport G.m.b.H., will extend this pipeline from Limburg to Mannheim and Ulm to serve the markets of GU and GSV. These companies will have two-thirds participation in the pipeline company, and Esso and Shell will have each one-sixth. The pipeline, with annual capacity of 8 million cubic meters, will have branches going to Switzerland and Austria.

In October, GSV and Gasverband Mittelland A.G. of Basel reached agreement on delivery of gas from Germany to Switzerland, starting in 1967. Cost of the initial phase of this project was to be about $100 million and the entire line was to cost $250 million.[32] Investment for public gas supply in 1964 totaled $155 million of which $110 million was for gas transport.

A significant company development was that on January 1, 1966, Gewerkschaft Brigitta of Hanover was to acquire a 25-percent interest in Ruhrgas A.G., the largest gas-distributing company in West Germany, which is owned by 32 Ruhr coal companies. The share capital will be increased from $25 million to $37.5 million. Another 25 percent of the shares of Ruhrgas A.G. is offered to Erdgas-Verkauf-Gesellschaft of Munster. The latter is owned by six suppliers of natural gas, which together control about one-third of the West German gas deposits. The six suppliers are Mobil Oil A.G., Gewerkschaft Elwerath (which in turn is partly owned by Esso and Shell), C. Deilmann Bergbau G.m.b.H., Preussag, Wintershall A.G., and Deutsche Schachtbau-und Tiefbohrgesellschaft m.b.H.

[30] Adjusted to calorific content of 4,300 kilocalories per normal cubic meter.

The Mineral Industry of Greece

By Stephen C. Brown [1] and L. Nahai [2]

The Greek economy made further gains in 1965, gross national product at constant prices rising by 7.3 percent, but at the cost of a sharp increase in the country's balance of payments deficit. Most of the major sectors of the mineral industry participated in the general economic growth, but declines were recorded in the output of several important commodities. The index of mine output, heavily weighted by coal, rose by 13 percent. Progress was made with the establishment of an aluminum industry, the construction of the steelworks in the Thessaloniki area, and the reactivation of the nickel project at Larymna. Plans were made for the expansion of fertilizer and cement output. Minerals and mineral products continued to play an important role in foreign trade. Mineral imports accounted for nearly one-fifth by value of total imports, and mineral exports accounted for slightly less than one-tenth by value of all exports.

The Hellenic Industrial Development Bank (ETVA), the Government's development institution, is one of the principal implementing agencies of the Government's 4-year mining development program; other chief implementing agencies are the Directorate General of Mines of the Ministry of Industry and the Institute of Geology and Subsurface Research (IGSR). Progress in fulfilling the Government's 4-year mineral development program was reported to be slow in 1965; both ETVA and the Directorate General engaged in research, in arranging feasibility studies, and the Directorate General also engaged in exploration for oil. IGSR conducted studies of peat deposits at Philippi.

ETVA established a wholly owned subsidiary under the name "General Mineral Prospecting and Mining Company" to engage in mineral research, the development of mining properties, and the sale of processed and unprocessed minerals. The company has a capital of Dr 5 million ($167,000).[3] The 1966 program of the new ETVA subsidiary includes mineral prospecting at 40 sites, reactivation of lead and zinc mines at Kirki, trial operation of an antimony mine at Lahana, development of kaolin and bentonite deposits on Milos Island, development of clay deposits at Laurium, and investigation of asbestos deposits at Kozani.

Other aspects of government policy affecting minerals include a decree raising by 10 percent (retroactively to January 1, 1965) minimum wages paid to miners, the introduction into Parliament of a draft law requiring mining companies to hire graduate mining and metallurgical engineers for their operations, and the conclusion of an agreement between the Government and the official French Bureau de Recherches Geologiques et Minierès for carrying out a hydrogeological survey of Crete over a period of 2 years. Meanwhile, the Center for Planning and Economic Research (KEPE), at the initiative of the Government, completed a draft Five Year Plan for Economic Development and submitted it to the Minister of Coordination. Not made public until early 1966, it calls for a total investment in mining of $167 million over the 5 years 1966–70 as compared with only $39 million in the preceding 5 years. Of this total, $87 million would be for lignite, $63 million for other minerals, and $17 million for research.

---

[3] Where necessary, values have been converted from drachmas (Dr) to U.S. dollars at the rate of Dr30 equals US$1.

PRODUCTION

Output of lignite, Greece's only type of coal, rose sharply by 26 percent. Bauxite output, limited by the export restrictions required by the Government's agreement with Aluminium de Grèce, declined slightly to about 1.1 million tons. Production of zinc concentrate declined, as did output of lead concentrate, but production of smelter lead nearly doubled. Output of manganese concentrate more than doubled.

Production of nonmetallic minerals as a group rose by 15 percent, with cement leading the way with a 20-percent rise. Magnesite output rose sharply, as did production of kaolin. Fertilizer and pyrites production showed more modest increases. Output of petroleum products from Greece's only refinery was practically unchanged. Production of pig iron and steel showed a significant rise.

[p] Preliminary. [e] Estimate. [r] Revised. NA Not available.

[1] In addition to commodities listed, Greece produced a variety of simple construction materials.

[2] Includes refractory and metallurgical ores.

TRADE

Both imports and exports of mineral commodities by Greece in 1965 increased appreciably over those of 1964, as shown in the following tabulation, which also shows the role of these commodities in total trade:

	Value (million dollars)		Mineral commodities share of total (percent)
	Mineral commodities [1]	All commodities	
Exports:			
1963	20.6	290.1	7.1
1964	23.2	308.6	7.5
1965	32.2	327.8	9.8
Imports:			
1963	169.2	804.3	21.0
1964	168.0	885.1	19.0
1965	223.9	1,133.7	19.7
Trade balance:			
1963	−148.6	−514.2	XX
1964	−144.8	−576.5	XX
1965	−191.7	−805.9	XX

XX Not applicable.
[1] Value of commodities listed in tables 2 and 3.

Of total listed mineral exports in 1965, 47 percent by value were shipped to the European Economic Community (EEC) and 13 percent by value were destined for other countries of West Europe. Mineral exports to the United States were valued at $2.4 million and those to the U.S.S.R. were about the same. Bauxite valued at $6.7 million, and magnesite valued at $6.4 million were the principal mineral export commodities; other significant mineral exports were iron and steel, ores and concentrates of lead, zinc and manganese, cement and chromite. Iron and steel exports, valued at nearly $3 million were over 11 times those of 1964 on a value basis.

By value, 51 percent of Greece's mineral imports come from West Europe, including 44 percent from the EEC countries. Individual significant source countries of mineral imports, and the value of their contribution in millions of dollars were: West Germany—30; Italy—22; Belgium-Luxembourg—21; France—21; the U.S.S.R.—20; Saudi Arabia—19; and Iran—17. Imports from the United States were valued at $6.3 million.

Petroleum and petroleum products (valued at $84.4 million) and iron and steel (valued at $63.6 million) continued to be the chief mineral commodity imports, accounting for two-thirds of the 1965 total. Manufactured fertilizers (at $21.6 million) and nonferrous metals (at $17.4 million) were next in order of importance. Approximately $7 million of the value of nonferrous metal imports was for aluminum. Coal, coke, and briquets ($10.9 million) were also significant import items.

Imports of all these items, except manufactured fertilizers, showed significant increases in value as compared with 1964, imports of petroleum and petroleum products rose 56 percent, iron and steel rose 15.5 percent, nonferrous metals rose 21 percent, and coal, coke, and briquets rose 46 percent. Fertilizer imports were practically unchanged in value.

Table 2.—Greece: Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal destinations, 1964
Metals:				
Aluminum:				
Bauxite—thousand tons	1,118	1,063	1,150	U.S.S.R. 436; West Germany 357; France 107; United Kingdom 46; United States 29; Norway 22.

COMMODITY REVIEW

METALS

Aluminum.—Construction of the primary aluminum plant of Aluminion Ellados, otherwise known as Aluminium de Grèce, or Aluminum Company of Greece, was completed in September 1965, but lack of power supply and disagreement over the power rates to be charged prevented the plant from commencing operations during 1965. Negotiations with the Government on revision of the company agreement continued during the second half of the year, and it was expected that production would begin early in 1966. Meanwhile Reynolds Aluminum Co., the U.S. firm holding a 17-percent interest in the company, indicated its intention to withdraw. A new corporation under the name of Greek Aluminum Industry Viohalco-Aluminium S.A. was established by the Greek firm Viohalco, ETVA, and Belgian banking interests to produce drawn and extruded aluminum semimanufactures, steel-reinforced conductors, and aluminum foil. The controlling interest in the firm is held by Viohalco.

Copper.—The Canadian firm, Placer Development Corporation, completed drilling of copper deposits near Skounes, Chalkidiki, and undertook metallurgical tests to determine whether a flotation plant should be established at the mine site. The Skouries project had been abandoned by the Japanese firm, Nippon Mining Company, Ltd., because of difficulties over foreign exchange.

Iron and Steel.—Production of pig iron by Halyvourgiki, S.A., rose 37 percent, crude steel rose 25 percent, and semifinished steel rose 16 percent. The firm announced export orders for $4 million worth of billets and reinforcing bars. Construction of the Esso-Pappas steel mill at Thessaloniki began, and the cold-rolling mill for flat products was expected to go into operation in the second half of 1966. Republic Steel (United States) agreed to participate by furnishing capital and technical assistance, and by training workers. It was reported that the nickel plant at Larco Co., S.A., would include capacity for production of 80,000 tons of steel, per year. At yearend the Government introduced a bill into Parliament to raise import duties on a number of steel products, intended to give protection to the new Esso-Pappas steel plant. A report on the Greek steel industry, requested by the Government, was completed by the British firm, L. M. Manderstam and Partners.

Nickel.—The nickel plant of Larco Co., S.A., was completed in 1965 and was expected to commence operation in early 1966. In addition to an annual output of 4,000 tons of nickel, it is to produce 80,000 tons of steel per year.

NONMETALS

Cement.—Greece had an annual production capacity of 3.7 million tons of cement at the end of 1965. During the year about 500,000 tons of capacity was added. This was accomplished by the addition of one rotary kiln in an existing plant. Apparent consumption was estimated at 3 million tons, or about 360 kilograms per capita. Prices declined slightly during the year. The industry employed about 3,000 persons.

Production of cement rose to a new high in 1965, and plans were made for significant increases in capacity. Titan cement obtained a loan of $1.5 million from the European Investment Bank for expansion of its facilities at Eleusis and signed an agreement with American Cement (United States) to establish a $10 million plant at Patras. Chalkis Cement Company increased its annual capacity to 600,000 tons with startup of a new rotary kiln in May, while Halyps Cement Company obtained Government approval for expansion through the addition of a 500-ton-per-day rotary kiln. The Greek firm, General Cement Company, S.A., planned a $5.5 million expansion and modernization program, to raise its capacity to 2.2 million tons per year, and a group of Greek investors applied for permission to establish a 200,000-ton-per-year plant on Crete.

Fertilizers.—Production of chemical fertilizers also rose to a new high, and a number of new plants came into operation while others were planned. The Ptolemais nitrogenous fertilizer plant of ETVA resumed operations at the end of 1964, and the Nea Carvali sulfophosphate fertilizer plant of the Phosphate Fertilizer Industry, S.A. was inaugurated in May, with completion of the latter installation expected by

yearend. Construction of the $16 million ammonium sulfophosphate and mixed superphosphate plant of Chemical Industries of northern Greece proceeded satisfactorily, and trial runs began at the Thessaloniki plant about the end of the year. Construction of the 100,000-ton Esso-Pappas ammonia plant in Thessaloniki was on schedule, and the plant was expected to go into operation in the first half of 1966. Towards the end of the year the Pappas and Nevros interests agreed on a project for construction of a $35 million compound fertilizer plant at Lamia, supplementing the Esso-Pappas complex at Thessaloniki. With completion envisaged for 1969, it is to have an annual capacity of 500,000 tons of compound fertilizers and include a daily capacity of 900 tons of sulfuric acid, 500 tons of sulfonitrates, and 500 tons of nitric acid. Plans were also made to expand the Chemical Industries of northern Greece plant at Thessaloniki, and the Hellenic Chemical Products and Fertilizer Co. plant at Drapetsona.

The rise of the fertilizer industry in Greece has apparently resulted in a sharp decline of pyrite exports, which dropped from about 57,500 tons in 1964 to less than 8,000 tons in 1965, despite a rise in production. The phosphate rock for manufacture of phosphatic fertilizers is imported mainly from Africa. Imports in 1965 increased nearly sixfold over those of 1964, yet failed to reach the 1963 quantity.

MINERAL FUELS

Lignite and Peat.—Production of lignite rose sharply in 1965. A study prepared by the British firm, Manderstam and Partners indicated that by 1975 Greek thermal powerplants would probably consume about 16 million tons of lignite annually, more than three times the 1965 output; all of this would be expected to come from domestic mines.

However, the report of the IGSR on the large peat deposits near Philippi, said to contain some 2.5 billion tons reserve, suggested that peat might provide an alternative fuel for the thermal plants. Preliminary findings indicated that in spite of high moisture content, the peat has a higher calorific value than the lignite. The final report of the IGSR was turned over to the Public Power Corporation to evaluate the feasibility of using peat as a fuel.

Petroleum.—Output of the Government-owned Aspropyrgos refinery declined only marginally (by 1 percent) from 1964 levels. The 2.5-million-ton-per-year Esso-Pappas refinery was completed and began test runs in November; regular operation was to begin early in 1966. Mobil Oil Company, Inc., The Royal Dutch Shell Group, and The British Petroleum Company Limited submitted to the Government a joint proposal for modernization and expansion of the Aspropyrgos refinery at a cost of $5 million and for the establishment of a third refinery, to cost $45 million. The Aspropyrgos refinery has been operated under lease from the Government by Mobil Oil Company, Inc., and its Greek affiliate, Hydrocarbon. This lease terminates in August 1967.

Exploration for petroleum continued in 1965 without success, the French firm Société Anonyme de Forages (Safor), drilling on the island of Rhodes, and the Italian firm, Società Nazionale Metanodotti (Snam), in the Filiates district of western Epirus, both for the benefit of the Greek Government. Snam abandoned drilling at a depth of 3,827 meters because of damage to its drill rig and the lack of favorable indications; Safor drilled two dry holes on Rhodes.

Esso-Pappas was granted a concession covering a 490-square-kilometer area extending into the sea near Thessaloniki, and an exploration and development agreement was reported to be under negotiation with the Government.

The Mineral Industry of Hungary

By Roman V. Sondermayer [1]

Hungary was a modest producer of a limited number of mineral commodities during 1965, and only bauxite and alumina were of world significance. Hungarian bauxite production was about 4.5 percent of the world total. Output of other more important products—aluminum, cement, coal, pig iron, managanese ore, and steel ingots—ranged betwen 0.5 and 1.8 percent of world totals.

Overall mineral commodity consumption was much larger than the production, requiring substantial imports. Mineral imports, chiefly nonfuel raw materials, high-rank coals, and crude petroleum, remained vital to the country's industry. Exports of bauxite, alumina, and semimanufactured products were significant sources of foreign exchange. Most of the Hungarian trade was with Communist countries, and the U.S.S.R. was the largest trading partner.

The mineral industry provided about 6 percent of the Hungarian social product,[2] the same as in 1964. Roughly one-eighth of the total labor force, or approximately 160,000, persons were employed by the mineral industry in 1965.

During 1965 major devlopments in the metals branch of the Hungarian mineral industry included discovery of a bauxite deposit in the eastern part of Hungary, commissioning of a new bauxite mine with an annual capacity of 200,000 tons at Kosloed Oereghegy, completion of the first stage of Almafuzito Alumina plant expansion, and completion of the cold-rolling mill at Dunajvaros.

The field of mineral fuel production was also active during 1965. Expansion of coal beneficiation in Pecsuj and preparation for exploratory oil drilling to depths exceeding 5,000 meters were the most important events.

Completion of the new lime kiln at Helyoesaba was the only significant event in the nonmetallic mineral industry.

PRODUCTION

Although the technology of overall mineral production in Hungary still cannot be considered advanced, several new developments, mostly small ones, can be regarded as modern and up to date. Underground methods prevailed in production of minerals. Because of inadequate mechanization and lack of incentive in the ranks of workers, productivity remained low in comparison with that in Western Europe.

In oil production, pumping prevailed. Hungarians were using production stimulation methods, fracturing and acidizing, on a wide basis, but secondary recovery operations remained minimal. The Soviet-designed turbodrill was used on about 70 percent of operating oil and gas drilling rigs.

Many plants and facilities of the country's mining and metallurgical industry were designed by Soviet experts and equipped with Soviet equipment. Results were less than expected, and a tendency toward purchasing equipment in the West was noted.

---

[1] Foreign mineral specialist, Division of International Activities.

[2] As in other Communist countries of East Europe, Hungary does not report on its gross national product (value of all final goods and services produced) but rather publishes a figure for the social product, which generally excludes items such as banking fees, rent, education, defense, public administration, and health services.

[1] In addition to reported commodities, Hungary is known to produce arsenic, copper, gold, uranium, zinc, china clay, diatomite, and peat.

Sources: Kozponti Statisztikai Hivatal (Office of Statistical Council). Statisztikai Evkonyv 1964 (Statistical Yearbook for 1964) Budapest 1965, 439 pp. for years 1961 through 1964. Figures for 1965 were taken from U.S. Foreign Service dispatches from the U.S. Legation Budapest and Bureau of Mines files.

TRADE

During 1965 the pattern of Hungarian mineral commodity foreign trade remained the same as in 1964. The country imported most of its raw materials as nonferrous base metals, iron ore, high-rank coals and crude petroleum. Exports consisted of bauxite, manganese ore, (not definitively reported in official statistics) and various semimanufactured products. Hungary's most important trading partner was the U.S.S.R., which provided most of the imported fuels and metallic ores and metals in exchange for semimanufactures and finished products. Foreign trade with Communist countries accounted for up to 80 percent of the total trade of Hungary.

COMMODITY REVIEW

METALS

Bauxite and Aluminum.—Hungarian bauxite output remained among the largest in Europe during 1965, but aluminum production was only modest by world standards as a result of shortages of electric power and funds for building new power plants. Development plans call for larger output of bauxite by opening 12 new bauxite mines during the next 10 years and expanding existing mines in the Halimba, Nyirad, and Darvasto, and Iszkassento-Gyoergy areas. Plans also call for increased alumina output by completion of the second stage of modernization and expansion of the

Almafuzito plant. A large increase in aluminum production was not planned because of an aluminum agreement with the U.S.S.R. by which the Soviets will refine up to 300,000 tons of aluminum per year.

Exploration for bauxite continued during 1965. Hungarian authorities announced the discovery of a significant bauxite deposit in the eastern part of Hungary in the vicinity of Fenyofo and Bakonyszentlaszlo villages. Total reserves were not disclosed, but reports indicated seams 60 meters thick.

The Kisloed Oereghegy bauxite mine was opened in the fall of 1965. The mine capacity was reported to be about 200,000 tons of bauxite per year. The development of Halimba mine continued. When the mine is completed, capacity will be 600,000 tons per year. The first stage of expansion of the Alumafuzito alumina plant was completed in the fall of 1965. The new capacity of the plant was not reported, but when all stages of modernization are completed in 1970, the plant will produce 280,000 tons of alumina.

Germanium.—The first Hungarian germanium oxide plant began test production at the Doroz site of the Coal Chemical Industry Enterprise (Szenfelsolgozo Veguipari Vallalat). The plant will extract germanium oxide from brown coal tar. Equipment for the plant was purchased in East Germany and Czechoslovakia, and Soviet experts helped in the technologic aspects of design.

Iron and Steel.—To cover the annual domestic consumption of about 3 million tons of iron ore, Hungary imported roughly two-thirds of its requirements during 1965. To improve the iron ore supply position, Hungarian authorities continued to develop domestic iron ore resources.

According to reports, Hungarian geologists discovered a new iron ore deposit near the iron ore mine at Rudabanya. The deposit is on the outskirts of the village of Alsotelekes. Part of the deposit consists of limonite, reportedly of good quality.

Production started at the Vilmos mine in the Rudabanya area during the winter of 1965. Total reserves were reported to be around 4 million tons of iron ore. Development of this mine started in 1962 and since then 4.4 million cubic yards of overburden has been removed.

The final stage of the Danubian Iron Works (Dunai Vasnu), namely the highly automated cold-rolling mill, was nearing completion at yearend. The new mill will increase its production gradually and will not be producing at full capacity for another 3 or 4 years. Output for 1965 was planned to be about 20,000 tons of fine sheet, or about one-tenth of projected capacity. In the meantime, a plant with a nitrogen protective atmosphere was completed. The nitrogen will be generated in the iron works coking plant.

In the Diosgyoer Lenin Metallurgical plant a large gas pipe broke and gas ignited, resulting in a 1 day shutdown of the plant and injury of 12 people; the cause of the accident was not disclosed.

NONMETALS

The Hungarian nonmetals industry was small and insignificant by world standards. However, during 1965 output was adequate to cover domestic needs for cement, lime, clays, and other construction materials. Other industrially significant nonmetallic minerals had to be imported because of lack of natural resources.

Cement and Lime.—The planning authorities decided to build a new 1-million-ton-capacity cement plant in Berement near the old plant which has been in operation for nearly 50 years. The new plant is scheduled to begin production in 1970, and full capacity is expected to be reached by 1972.[3]

The new Danubian Cement Works plant at Lablatan has been rated as one of the most efficient cement factories in the country. Only 1,000 kilocalories was consumed per kilogram of clinker produced; energy consumption thus was 50 percent lower than the average of the country. Most of the success of this plant reportedly has been credited to efficient maintenance and adequate supply of spare parts. The Hungarian average of shutdown time for repairs and maintenance is 30 to 40 percent of the available plant time, whereas the Danubian Cement Works consumed only 10 percent.[4]

A gas-fired, almost fully automated lime kiln was completed at Helyocsaba. The annual capacity of the plant was reported to be 110,000 tons of calcinated lime.

Fertilizer Materials.—Consumption of chemical fertilizers reached about 1.7 mil-

[3] Magyar Nemzet, Dec. 12, 1965, p. 6.
[4] Muxzakielet, Sept. 23, 1965, p. 3.

lion tons in 1965. Production of phosphatic and potassic fertilizers was based on imported raw materials; nitrogenous fertilizer output was based on large domestic natural gas reserves and limestone.

The new nitrogenous fertilizer plant at Tiszepalkonya, which started test production and stocks at the mines were high at yearend 1965. Planned annual capacity of this plant was reported to be about 345,000 tons of nitrogenous fertilizer with an average nitrogen content of 34 percent.

MINERAL FUELS

According to Hungarian governmental sources, the mineral supply situation was not completely satisfactory during 1965. Production of coal, as well as production of crude oil, remained at the same level as in 1964. Coal contained 10 to 15 percent ash, and stocks at the mines were high at yearend. Because 90 percent of the coal was low grade, the country imported fairly large quantities of high-rank coals during 1965. Although other fuels were used on a broader base than in the past, coal remained Hungary's principal source of energy.

Coal.—Output of coal totaled 31.4 million tons, virtually the same as in 1964. Out of the total production, 70 percent was brown coal, 14 percent was bituminous, and 16 percent was lignite.

The development of coal mining was slowed by the flooding of Tatabanya, Balnika, and other mines, as well as by a fire in mine No. 3 at Komlo. Chronic shortage of miners persisted, and the overall result of these and other shortcomings was that coal output was only about equal to that of 1964.

Prospecting for coal was at the same level as in the past year, but the results announced indicated discoveries of substantial coal reserves by Hungarian standards. In the general area of Mecsek Mountain new reserves of about 500 million tons of low-grade coal were confirmed. First results of exploration in the Buekk Mountain indicated large reserves of lignite; some estimates set them at about 300 million tons. As the results were only preliminary, it was not possible to draw any conclusion concerning the impact of the discovery on the nation's energy resource picture.

The Governmental effort to improve the energy supply position of the country resulted in the commissioning of new mines. A new open pit mine was commissioned in the Tatabanya Coal Basin. The mine's capacity was reported to be about 500 tons of coal per day. Coal was used by the thermal power plant near Oroszlany. Total reserves of the new open pit mine were estimated to be about 2 million tons. Work was started on a new open pit mine north of Salgotarjan. The coal deposit was discovered by the geologists of the Nograd Coal Mining Trust. Planned mine capacity and extent of reserves of the deposit were not reported. Development of the Torez mine at Visonta continued through 1965. No date was fixed for the beginning of production, but the power generating plant, also named Torez, will be commissioned in 1968. This plant will be the principal consumer of coal mined in the Torez mine.

While developing new facilities for coal production, the Hungarians were also working on constructing facilities for upgrading the quality of the coal that reaches the consumer.

During 1965, the modernization and expansion of the coal benefication plant at the Pecsuj coal combine was completed. New installations will lower the ash content of the coal from 18 to 12 percent.

As Hungary's operating briquet factory has a capacity of only 1,230 tons of briquet per day, authorities decided to start construction of a new facility near the village of Mohra with a planned daily output of 2,000 tons. Balnika mines will provide the coal for this briquet works.

The modest success of the coal industry was overshadowed by explosion, fire, and flooding at several mines. At the mine No. 3 (Zobak pit) of the Komlo coal mine, work was suspended because of underground fire at the depth of 600 meters. At yearend, equipment was moved from the mine and steps had been taken to localize the fire. A gas explosion killed three men in a new section of the Tatabanya mine. Production has been abandoned in the southern (Altaro) section of the Tokado mine after fighting water for more than 1 year. Miners were reemployed in other mines in the area.

Petroleum and Natural Gas.—The petroleum industry, including natural gas production, was characterized by high levels of

activities in all its endeavors, but importation of 2.026 million tons of crude oil was needed to cover the domestic demand. Drilling for exploration and for development of known fields continued. Most of the production comes from Lovasy and Nagyenguel, and expansion of refineries was underway.

In exploration, drilling was concentrated on deeper structures of the Pannonian Basin; a depth of 4,000 meters was reached. Preparation were underway for deep drilling to depths of over 5,000 meters. A symposium held in Budapest with participation of drilling experts from Communist countries and France, as well as imports from the U.S.S.R. and Rumania of equipment capable of drilling over 6,000 meters, indicated deep drilling will be a reality in the near future. According to the Hungarian press, the Transdanubian Petroleum Drilling Enterprise (Dunantuli Koolajfuro Uzem) planned to drill about 100 exploratory wells in the Somogy, Kisalfold, and Nagykanizsa sectors of the country.[5]

During 1965 the most important event in the realm of exploration was the discovery of the Belezna oilfield in Zala County. Associated gas from the field will be supplied to the Nagykanisze gas pipeline network. A second well drilled on the structure at Alogyoe near Szeged was oil bearing. Reserves of these two fields were not disclosed.

A blowout of oil was reported from a formation 2,000 meters deep during drilling operations for thermal waters near Tape village near Szegal. Estimates set the rate of flow at about 27,000 barrels per day. No information was available to indicate when the well was brought under control. In addition to new discoveries, development of the area of Great Plains continued during 1965. A total of 38 producing wells were completed there. In the vicinity of Pusztafoldvar producers were drilled, and the rest were in the vicinity of Eger, Ulles, and Mezohegyes.[6]

Although the development activity was moved to the Great Plains during 1965, Lovasy and Nagyenguel remained Hungary's principal oilfields. Production stimulation methods were widely used and some recourse was made to secondary recovery in an effort to keep production on the 1964 level.

Natural gas development started to change Hungary's energy balance structure in 1965. New gas pipelines and liquefied petroleum gas facilities contributed to significantly larger use of gas by industry. Construction of the natural gas pipeline from Kardoskut to Dunajvaros started in the second half of 1965. The pipeline touches Oroshaza, Szentes, Kiskunfelegyhaza, Kecskemet, Kunszentmiklos, Doemsoed Andony, and Racalamas. The pipeline is expected to be completed in 1966 (a later date than predicted in 1964), and the main consumers will be the iron and steelworks at Dunajvaros and several power plants.

The construction of the Szazhalombatra oil refinery continued. The first crude oil arrived through the Druzba pipeline from the U.S.S.R. and was stored in four 10,000-cubic-meter (about 63,000 barrel) storage tanks. The Szony refinery started production of higher octane gasoline at yearend. Capacity of the refinery was reported to be 150,000 tons of oil per year.

The Mineral Industry of Ireland

By Edgar L. McGinnis [1]

Available statistical data indicate that the mineral industries of Ireland in 1965 maintained their relative position in the economy, due principally to the further expansion of the mineral processing sector. Chief contributors to the growth in this sector were the cement, fertilizer, and petroleum refining industries. In the extractive sector, barite production increased substantially and the revival of lead-zinc mining in 1965 held promise of future progress.

In 1965 the Irish economy grew at the rate of a little less than 3 percent, somewhat below the level of 4 to 4.5 percent registered in 1964. The average growth attained over the 5-year period 1961–65 amounted to 4 percent.

The mineral industry of Ireland remained small in relation to total national output as well as to world supply and demand. According to census data for 1963 (the latest available) the mining and quarrying industries accounted for about 1.9 percent of the total value of industrial production. The inclusion of mineral processing for which detailed figures are not available, would probably raise the proportion modestly. Both imports and exports of mineral commodities increased, the latter substantially since 1963.

Production of lead and zinc concentrates at Tynagh began near yearend and plans continued to bring another lead-zinc-silver deposit at Silvermines to the production stage. Development of a copper-silver mine near Tipperary continued. The expansion of Ireland's petroleum refining capacity by over 30 percent was expected to be completed early in 1966.

No significant change in government policies in regard to minerals was reported during 1965. Ireland, already a member of the Organization for Economic Cooperation and Development (OECD) and the Council of Europe, has predicated its economic development program to a certain extent on membership in the European Economic Community (EEC) which it hopes to achieve by 1970. Also pending was an Irish application for membership in the General Agreement on Tariffs and Trade (GATT).

The program for economic expansion covering 1965–70 was initiated. By 1970 this program hopes to achieve a 50-percent real growth over the 1960 level. The encouragement of direct foreign investment, which has brought new capital into the mining industry, is a part of this program. A free trade agreement was being negotiated with the United Kingdom.

PRODUCTION

Estimates for 1965 output showed declines for most nonmetals, though barite production more than doubled and gains were registered in cement as well as in mineral fuels including coke, milled peat, and petroleum refinery products. Output of the latter showed substantial overall gains as compared with 1964 production. For the first time since 1961 zinc concentrates were produced.

e Estimate. r Revised. NA Not available.

[1] Figures do not include large quantities of granite, stone, sand and gravel, and other materials used by government agencies except for 1964.

[2] Excludes milled peat used in briquets except for 1965.

TRADE

Irish mineral commodity exports continued to increase in 1965, exceeding those of 1964 by 42 percent and accounting for 5.4 percent of total exports. Mineral commodity imports, about 5.4 times larger than exports in 1965 also increased, rising by 5.9 percent from those of 1964, but these commodities again accounted for a slightly smaller share of total imports as shown in the following tabulation:

	Value (million dollars)		Mineral commodities share of total (percent)
	Mineral commodities	All commodities	
Exports:			
1963	$17.8	$535.7	3.3
1964	23.3	608.8	3.8
1965	33.1	610.5	5.4
Imports:			
1963	150.7	857.9	17.6
1964	169.8	973.9	17.4
1965	179.9	1,040.6	17.3
Trade balance:			
1963	−132.9	−322.2	XX
1964	−146.5	−365.1	XX
1965	−146.8	−430.1	XX

XX Not applicable.

On the export side the major items were refined petroleum products ($7 million), nonferrous metals and alloys ($4.9 million), metalliferrous ores and metal scrap ($4.5 million), iron and steel ($4.2 million), and clay and refractory construction materials ($2.4 million). Most of the increase in exports was contributed by refined petroleum products, clay and refractory construction materials, iron and steel, cement and metalliferrous ores, and scrap.

On the import side the chief items were crude and refined petroleum ($64 million), iron and steel ($34.8 million), crude and manufactured fertilizers ($28.8 million), coal ($22.8 million), and nonferrous metals and alloys ($18.9 million). Crude and refined petroleum and iron and steel accounted for the great bulk of the $10.1 million increase in imports.

The United Kingdom remained Ireland's principal trading partner in mineral commodities as well as in total trade, receiving almost 67 percent of total mineral exports and supplying over 38 percent of Irish mineral imports in terms of value. Spain ranked second as a recipient of Ireland's mineral exports, receiving almost 9 percent of the total, followed by West Germany with about 6 percent. Other notable sources of mineral imports and their shares of the total value were Iran—12 percent, West Germany—8 percent, Iraq—7 percent, and Belgium-Luxembourg—7 percent.

COMMODITY REVIEW

METALS

Copper.—Gortdrum Mines, Ltd., a Canadian company, was developing an open pit mine and planned to build a 1,500-ton- per-day copper-silver flotation mill a few kilometers north of the town of Tipperary. Target date for initial production was mid-1967, and the project will include a ship loading facility at the port of Limerick, about 55 kilometers from the mine site.

Diamond drilling has indicated about 4.2 million tons of ore assaying 1.19 percent copper and 0.75 ounce of silver per ton.

Lead, Zinc, and Silver.—Irish Base Metals Ltd., (a subsidiary of the Canadian firm, Northgate Exploration Ltd.), started operations in December at its 2,000-ton-per-day concentrator at the company's lead-zinc-silver mine at Tynagh. Full operation is expected in mid-1966.

The Tynagh mine, described by Irish Base Metals, Ltd., as the first major discovery in Ireland in the last 100 years, was officially opened in October. The project was constructed by the Bechtel Overseas Corporation and represented an investment of $10.8 million.

Financing arrangements were reportedly completed by Mogul of Ireland, Ltd., to bring into production a lead-zinc-silver mine at Silvermines containing ore reserves of over 11 million tons. The company will use the funds to complete mine development and construct a milling plant to treat 3,000 tons of ore per day. Production is scheduled to begin in January 1968.

NONMETALS

Fertilizers.—The nitrogen fertilizer plant of Irish Nitrogen Ltd., (Nitrigin Eireann Teoranta) started production in December. The plant is designed to produce annually 85,000 tons of ammonium sulfate and 65,000 tons of calcium ammonium nitrate.

MINERAL FUELS

Petroleum Refinery Products.—During 1965 the Irish Refining Company Ltd., proceeded with plans to increase the capacity of its Whitegate refinery at Cork Harbour from 1.9 million tons to 2.5 million tons annually, or by a little over 30 percent. The project, which is scheduled to be completed by early 1966, will cost about $8.4 million.

Gasoline taxes were raised by about 3 cents per imperial gallon to a little over 45 cents per imperial gallon.

The Mineral Industry of Italy

By F. L. Klinger [1]

The principal developments in the Italian mineral industry in 1965 were a 30-percent increase in steel production, mainly from new oxygen steelworks, and a continuing high growth rate in the petroleum refining industry. Steel output was brought up to the level of domestic consumption, and Italy became a net exporter of steel for the first time. The industry accounted for most of the increase in steel output of the European Economic Community (EEC) in 1965 and ranked eighth in world production. In the petroleum industry, refinery product output increased by more than 15 percent for the seventh straight year. In refining capacity as well as in output, Italy ranked first among West European countries.

The severe slump in building construction continued to have a depressing effect on metal and mineral consumption. In the cement industry, the slackened demand came at a time when the industry was in the last stages of a major expansion program, and output in 1965 ranged between 60 and 70 percent of rated capacity.

In the mining industry, gross output was slightly below the 1964 level. Four iron mines and the country's only anthracite mine (La Thuile) were closed in 1965. Output from new zinc mines in north Italy and Sardinia and increased production of potash and other nonmetallic minerals helped to compensate, in terms of value of overall output, for reductions in iron ore and crude oil production. The mineral industry continued to be plagued by rapidly rising production costs (particularly the cost of labor, which has doubled in the past 4 years), while overall production has been relatively static and only moderate increases in productivity have been achieved. In the face of added problems of increased foreign competition and impending removal of protective tariffs on lead, zinc, and sulfur, extensive rationalization programs in these industries were continued. Progress of the lead-zinc industry program in Sardinia was particularly impressive.

In related industrial developments, a merger of the Montecatini and Edison companies was almost completed in 1965. The new company, named "Montecatini-Edison," will control all present Italian production of potash and bauxite, 75 percent of the primary aluminum, 60 percent of lead and zinc, most of the chemical fertilizer, and a large proportion of the petrochemical industry, as well as substantial interests in other sectors of the mineral industry such as pyrite, sulfuric acid, and hydrocarbons. Combined sales of the two companies in 1965 amounted to $1,313 million. Montecatini Co. also entered into an agreement with the Soviet Union for construction of six chemical plants valued at about $112 million over the next 5 years.

In other international agreements, the Fiat Co., Italy's largest commercial firm, completed negotiations for construction of a large automotive plant in the Soviet Union valued at about $800 million and expected to involve large purchases of machinery from the United States. The World Bank approved a loan of $100 million for assistance in the industrial development of south Italy, including Sicily and Sardinia, and the Italian National Research Council signed an agreement with the Office of Saline Water of the U.S. Department of the Interior for cooperation in the field of water desalinization.

A draft law to govern offshore exploration and development of oil and gas de-

[1] Physical scientist, Division of International Activities.

posits in Italy's continental-shelf areas had been prepared by yearend, and it was hoped that final legislative action would be taken during 1966. The absence of legislation covering offshore deposits has prevented exploration of these areas except for a coastal strip 15 kilometers wide which is part of the Po Valley Concession reserved to the State hydrocarbons agency, Ente Nazionale Idrocarburi (ENI).

The gross output (value added) of the Italian mineral industry in 1965 was estimated at approximately $2,000 million, of which more than 80 percent was accounted for by manufacturing industries. This was equivalent to about 15 percent of gross industrial output and 3.6 percent of the gross national product, which was estimated at $56,700 million (current prices).

Some employment statistics of the mineral industry and related industries are shown in the tabulation below.

Industry group	Total employment [1]	Average hourly earnings [2]	
		Lire	U.S. dollars
Mining and quarrying	54,195	442	$0.707
Metallurgy	161,382	482	.771
Nonmetallic mineral products	213,590	359	.574
Petroleum and coal products	20,329	579	.926
Other:			
Chemicals and drugs	173,847	417	.667
Construction	468,612	414	.662
All industries	3,377,071	400	.640

PRODUCTION

The gross product of the mining industry in 1965 was valued at $362 million, approximately 4 percent less than in 1964. The decrease was mainly due to reduced output of crude oil, although continuing declines in production of solid fuels, iron ore, and sulfur, and reduced demand for construction materials were also contributing factors. Overall output of metallic and nonmetallic minerals increased over 1964 levels. Substantial gains were recorded for mercury ore, potash ore, barite, fluorspar, and other nonmetals while production of aluminum, lead, and zinc increased modestly. Increased output of natural gas and condensate did not compensate for the loss in crude oil. Production indices for various sectors of the extractive industry are shown in the following tabulation:

Sector	(Base: 1953 = 100)		
	1963	1964	1965
Metallic minerals	101.7	103.3	105.9
Iron ore	101.5	92.2	79.2
Nonferrous ore	101.8	106.2	112.8
Nonmetallic minerals	143.1	139.8	140.1
Sulfur	50.3	36.4	35.6
Block marble	212.9	206.2	198.5
Other	150.5	154.9	161.7
Solid fuels	91.1	77.5	65.1
Liquid and gaseous fuels	399.3	460.2	442.1
Total extractive industry	190.0	202.5	197.2
All industry	241.3	243.9	254.1

Source: Central Statistical Institute (ISTAT; Rome). Bollettino Mensile di Statistica, v. 41, No. 3, March 1966, pp. 27–30.

In contrast to the relatively static production of the domestic mining industry, there were large gains in production of the metallurgical, petroleum refining, and coke-manufacturing industries which are based largely on imported mineral commodities. There was also increased production of chemicals and electric power, which are partly based on domestic mineral resources, but output of cement and other non-

metallic mineral manufactures, which is not only based largely on domestic mineral resources but depends to a great extent on activity in the construction industry, decreased in 1965. Production indices for these industries are shown in the following tabulation:

Industry sector	(Base: 1953 = 100)		
	1963	1964	1965
Metallurgical	275.0	269.1	349.8
Primary iron and steel	303.0	292.1	387.2
Primary nonferrous metals	138.5	156.6	167.2
Nonmetallic mineral manufactures	283.5	300.9	277.5
Cement	282.0	291.6	258.4
Glass	248.8	309.3	294.9
Chemicals	364.4	413.4	434.6
Petroleum refining	379.0	452.8	543.0
Coking plants	196.4	199.2	243.1
Electric power	218.8	232.5	253.3
All manufacturing	246.3	248.0	258.2
All industry	241.3	243.9	254.1

[1] Net exports plus consumption in agglomerating plants and blast furnaces in iron and steel industry.

[2] Includes rerolled scrap.

[3] Includes alloys except solder.

[4] Includes gas oil, and fuel oils less than 5° E ("fluidissimo" and "fluido").

[5] Includes fuel oils greater than 5° E ("semi-fluido" and "denso").

TRADE

Italy's overall trade balance was greatly improved in 1965. The net deficit for the year amounted to only $159 million, less than 13 percent of the 1964 figure and only 6 percent of the $2.5 billion deficit sustained in 1963. Mineral commodity trade increased, and accounted for approximately 8 percent of the $1.1 billion reduction in deficit that was realized in 1965 as shown in the following tabulation:

	Value, million dollars		Mineral commodities share of total trade (percent)
	Mineral commodities	All commodities	
Export:			
1963	665	5,047	13.1
1964	851	5,946	14.2
1965	1,150	7,188	15.9
Import:			
1963	2,123	7,539	28.1
1964	2,043	7,231	28.2
1965	2,256	7,347	30.7
Trade balance:			
1963	—1,458	—2,492	XX
1964	—1,192	—1,275	XX
1965	—1,106	—159	XX

XX Not applicable.

Source: Statistical Office of the United Nations (1966).

The gain in mineral commodity export value was principally due to iron and steel, with assistance from aluminum and building stone. Substantial increases in exports of petroleum products and copper were overshadowed by even larger increases in imports of crude oil and copper scrap. Along with coal, iron ore, and fertilizers, these items continued to dominate Italy's mineral commodity trade, as is shown in the accompanying table:

Commodity	Value, million dollars		Share of mineral commodity trade (percent)	
	1964	1965	1964	1965

Other	53.2	56.2	2.6	2.5
Mineral fuels:				
Coal, including briquets	157.0	151.5	7.7	6.7
Petroleum, crude [7]	787.0	930.5	38.5	41.3
Petroleum products	58.4	62.2	2.9	2.8
Other [4]	20.0	14.8	1.0	.7
Chemical elements, metallic oxides, and inorganic compounds [5]	25.5	28.1	1.2	1.2
Total	2,043.3	2,255.6	100.0	100.0

[1] Including scrap.
[2] Including manufactured fertilizer.
[3] Including other nonmetallic mineral manufactures listed under Groups 661, 662, and 663 (S.I.T.C., revised).
[4] Including crude chemicals derived from coal.
[5] Excluding mercury and including only those elements, metallic oxides and inorganic compounds under Item 513.1(3) and Subgroups 513.2, 513.3, 513.5, and 513.6 (S.I.T.C. revised).
[6] Includes refractory contruction materials.
[7] Including partly refined petroleum.

Source: Statistical Office of United Nations (1966).

Metals continued to account for most of the value of mineral commodity exports in 1965, with 44 percent of the total, followed by fuels (34.1 percent), nonmetals (18.3 percent), and chemical products (3.6 percent). West Germany remained the principal destination with consignments valued at $135 million, followed by France, ($89 million), the United States, ($65 million), and the United Kingdom ($61 million).

Imports of mineral fuels, valued at a record $1.16 billion in 1965, again accounted for slightly more than half (51.5 percent) of the total value of mineral commodity imports, followed by metals (42 percent), nonmetals (5.3 percent), and chemical products (1.2 percent). Because of the dominance of petroleum, Kuwait continued to lead all other countries among sources of Italy's mineral commodity imports. Imports from Kuwait in 1965 were valued at $361 million, followed by those from the United States ($270 million) and West Germany ($228 million).

Zinc:				
Ore and concentrate	39,675	[4] 49,279	30,424	Belgium-Luxembourg 13,392; Austria 12,800; France 7,102.
Oxides	692	565	389	France 254; West Germany 110; Switzerland 65.
Metal and alloys:				
Unwrought	302	1,580	1,423	United States 581; Belgium-Luxembourg 499; mainland China 338; Switzerland 140.
Semimanufactures	304	443	150	Switzerland 221; France 121.
Miscellaneous, n.e.s.:				
Nonferrous ores, including ashes and residues	11,171	20,936	12,866	West Germany 9,024; Belgium-Luxembourg 4,265.
Base metals	1	3	10	NA.
Pyrophoric alloys	2	3	---	NA.
Metallic oxides and hydroxides, n.e.s.	284	24	75	NA.
Metalloids, n.e.s.	323	241	176	NA.
Oxides, hydroxides of barium, strontium, magnesium	306	381	9,341	Belgium-Luxembourg 115; Sweden 37.
Nonmetals:				
Abrasives, n.e.s.:				
Dust, powder of precious and semi-precious stones—kilograms	---	473	---	NA.
Grinding stones	1,257	1,615	2,239	France 355; West Germany 195; United Kingdom 93.
Pumice	343,825	321,734	148,695	Netherlands 131,316; West Germany 90,677; United States 37,443.
Corundum, garnet, tripoli and other	562	402	1,556	
Asbestos	6,412	9,017	25,699	West Germany 3,446; France 3,031.
Asbestos- and fiber-cement products	32,484	50,608	43,591	France 9,443; Tunisia 6,887; Aden 3,164.
Barite, including witherite	22,409	11,186	32,993	West Germany 5,659; Rumania 2,400.
Cement	r 149,796	174,639	567,224	Switzerland 69,184; Libya 25,927; Spain 22,383.
Chalk	225	509	455	Mostly to Switzerland.
Clays and clay construction materials:				
Bentonite	30,061	22,460	21,316	France 7,067; Libya 3,966; Switzerland 3,479; United Kingdom 3,459.
Kaolin	272	350	549	
Other, including andalusite, etc	1,441	1,519	3,023	
Construction materials:				
Refractory	12,629	12,311	17,724	Austria 2,051; West Germany 1,803; Switzerland 1,206.
Nonrefractory	206,938	255,412	337,762	Switzerland 88,231; Libya 49,637; France 44,953.
Cryolite	1	---	36	
Diamond:				
Gem—value, thousands	$234	$192	$50	United Kingdom $154.
Industrial—thousand carats	35	320	---	West Germany 65; Switzerland 45; United States 35.
Diatomite	1,332	801	634	France 604.
Dolomite, including calcined	11,526	10,541	13,992	Switzerland 6,372; Austria 1,892.
Feldspar	19,433	21,763	23,194	West Germany 13,669.
Fertilizer materials:				
Crude:				
Potassium salts	---	4,454	13,444	All to Yugoslavia.
Sodium nitrate	---	25	---	All to Common Market countries.
Manufactured:				
Nitrogenous—thousand tons	1,463	1,012	1,161	United Arab Republic (Egypt) 231; Yugoslavia 154; Greece 146; Spain 129.
Phosphatic—do	48	32	2	Greece 17; Albania 8; Bulgaria 6.
Potassic—do	77	114	135	Poland 17; United States 17; Yugoslavia 13.
Mixed—do	283	512	313	Yugoslavia 187; Czechoslovakia 57.
Ammonia, anhydrous	12,156	13,240	13,664	Greece 5,829; Switzerland 3,046.

See footnotes at end of table.

Table 2.—Italy: Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal destinations, 1964
Nonmetals—Continued				
Fluorspar	38,268	46,658	52,464	United States 34,651.
Graphite	1,516	1,292	1,680	France 889.
Gypsum and plasters	9,367	13,368	18,368	Switzerland 7,288; West Germany 2,852.
Lime	18,646	27,863	37,038	Libya 22,549.
Limestone (industrial)	702	646	869	NA.
Magnesite	109	78	92	NA.
Mica:				
Crude	48	135	166	France 25.
Worked	24	40	32	Yugoslavia 19; France 7.
Pigments, mineral, including iron oxide and hydroxide	1,103	1,811	1,142	United States 538; Sudan 165.
Precious and semiprecious stones (including synthetic), except diamond value, thousands	$142	$241	$326	Switzerland $122; United States $52.
Pyrite, unroasted	101,854	47,555	52,569	Switzerland 31,824; Netherlands 10,100; Austria 5,288.
Quartz and quartzite	5,226	16,678	20,743	Switzerland 9,069; France 6,055.
Salt	75,459	54,833	56,787	Norway 30,369; France 8,804.
Other sodium and potassium compounds:				
Caustic soda	101,995	119,616	218,127	U.S.S.R. 50,016; United Arab Republic (Egypt) 16,544.
Caustic potash	4,246	2,677	2,016	Hungary 670; Rumania 446; Switzerland 404.
Stone, sand and gravel:				
Dimension stone:				
Unworked:				
Granite, porphyry, etc	29,582	32,951	33,836	Switzerland 21,762; West Germany 4,272; Austria 3,719.
Marble and other calcareous	252,837	261,015	269,789	West Germany 67,767; France 33,608; United States 30,712.
Slate	3,429	4,102	5,117	West Germany 1,621; Switzerland 1,172; France 567.
Worked:				
Slate	13,964	17,580	21,869	West Germany 9,515; United States 5,218.
Other	84,414	130,879	195,421	France 38,233; West Germany 37,734; United States 32,294.
Gravel and crushed stone	339,860	443,417	390,177	Switzerland 117,839; West Germany 70,287; Belgium-Luxembourg 51,082.
Sand	178,623	229,029	157,768	Switzerland 227,605.
Strontium minerals	89	134	100	NA.
Sulfur, including purified sulfur	8,121	4,753	2,473	Yugoslavia 2,886; Thailand 592.
Talc and steatite	47,173	43,673	43,013	United States 13,451; United Kingdom 6,698; West Germany 5,763; France 4,646.
Miscellaneous:				
Mineral substances, n.e.s	47,364	67,996	80,372	United Kingdom 62,167.
Inorganic chemicals:				
Hydrogen and rare gases	217	73	93	NA.
Halogens, excluding chlorine	---	123	123	France 73; West Germany 45.
Inorganic acids, oxygen compounds of nonmetals or metalloids	83,697	118,841	111,690	Greece 45,130; Spain 29,355; Turkey 21,638.
Slag, scale and other nonmetal-bearing waste of iron and steel industry	4,948	19,590	26,084	France 16,939.
Other nonmetal-bearing ash and slag	---	359	1,436	All to Common Market countries.
Other, including artificial corundum	761	663	2,274	NA.
Mineral fuels:				
Asphalt and bitumen, natural	9,151	6,969	6,968	United Kingdom 6,324.
Coal, including briquets	23,931	4,218	1,412	Ships' bunkers 2,231; Zanzibar 313; India 192.
Coke	148,769	99,844	120,158	Austria 29,612; Switzerland 20,406; Greece 15,610.
Gas, natural and manufactured, including LPG thousand tons	47	56	145	Lebanon 15; France 10; Spain 8; Brazil 6.
Petroleum:				
Crude	179,311	337	---	NA.
Refinery products:				
Gasoline [5] thousand tons	1,814	1,865	2,503	United Kingdom 369; Switzerland 329; Austria 290.
Kerosine, white spirit, etc.[5] do	485	407	764	India 67; Switzerland 50; Greece 41; Nigeria 33.
Distillate fuel oil [5] do	4,139	5,022	6,383	France 1,002; Switzerland 989; Netherlands 733; United Kingdom 459; West Germany 307; Belgium-Luxembourg 297.
Residual fuel oil [5] do	2,618	2,725	6,376	United Kingdom 970; Austria 257; Greece 247; France 224; Switzerland 184.
Lubricants [5] do	40	88	272	Switzerland 19; United States 12; India 7; France 7.
Petroleum coke do	14	9	14	Switzerland 7; Austria 2.

See footnotes at end of table.

r Revised. NA Not available.

[1] In a number of cases, figures given differ slightly from those appearing in Minerals Yearbook, Volume IV for 1964, in some cases because of revisions in published sources and in other cases because a different source was used.

[2] Excluding artificial corundum.

[3] Includes only material designated for abrasive use.

[4] Mostly produced in petroleum refineries.

[5] Excluding liquefied petroleum gases.

COMMODITY REVIEW

METALS

Aluminum.—Of the bauxite produced in 1965, the Montecatini Co. produced 166,000 tons from the San Giovanni Rotondo mine while the remainder was produced mostly by Società Alluminio Veneto Anonima (SAVA) from mines in Puglia. Montecatini was unable to locate additional bauxite reserves in the Rotondo mine area, but the results of exploration and ore dressing tests on deposits at Boca della Selva in Campania were encouraging and the company applied for mining concessions.

Consumption of bauxite in 1965 for production of alumina was 384,900 tons by the Montecatini Co. and 297,400 tons by SAVA. Other industries consumed 20,000 tons and 19,300 tons were added to stocks. Imports of bauxite increased by 26 percent. The principal source continued to be Yugoslavia, while imports from Guinea and Greece were substantially increased. The value of imports rose to $5.1 million in 1965.

Almost all of the increase in primary aluminum output came from Montecatini plants. The company's output in 1965 increased by 13 percent, to 72,437 tons; SAVA produced 47,978 tons; and 3,690 tons were produced by Alcan Alluminio Italiano. Superpure aluminum was produced almost exclusively by SAVA.

Aluminum consumption in 1965 included 128,000 tons of primary and 66,000 tons of secondary metal including that for export. Approximately 58 percent was used for semimanufactures, 38 percent for castings, and 4 percent for other products. Net domestic consumption was 171,500 tons, compared with 160,000 tons in 1964. Exports of unwrought aluminum and semimanufactures increased by a total of 19,000 tons and were valued at $35 million.

The new rolling mill of Lavorazione Leghe Leggere S.p.A. at Fusina was almost completed by yearend. Initial annual production capacity of the plant will be 47,000 tons. The company was the principal Italian producer of aluminum semimanufactures, with output of 28,400 tons in 1965. At Milan, Società Trafilerie e Laminatoi di Metalli (TLM) completed a new rolling mill with an annual capacity of 25,000 tons. Società Angeletti e Ciucani expected to finish construction of a plant for the production of aluminum sheet coated with synthetic resin. The plant, in which Alcan Aluminium Ltd. has a 26-percent interest, will be the largest of its type in West Europe. Also at Milan, Montecatini installed a four-high, reversible, 1,600-millimeter rolling mill at the Feltre plant. The latter, formerly owned by Metallurgica Feltrina S.p.A., produced 10,000 tons of semimanufactures in 1964.

Copper.—Production, imports, and total consumption of copper increased slightly in 1965 but remained below the levels of 1963. Exports of unwrought copper and semimanufactures continued to increase and were valued at $62 million.

Refined copper consumption in 1965 was 192,000 tons and total copper consumption was 300,000 tons. Of the latter, 140,000 tons were used for wire and cable; 123,300 tons for other semimanufactures; 28,400 tons for castings; and 8,300 tons for chemicals and other products. The principal semifabricators of copper were as follows:

Company	Plant location	Annual production capacity (metric tons)	Affiliated companies
Pirelli S.p.A	Turin, Milan, Naples	100,000	Trefimetaux.
Soc. Metallurgica Italiana S.p.A. (SMI)	Campo Tizzoro (Pistoia), Limestre Pistoiese, Fornaci di Borga (Lucca)	60,000	
Trafilerie e Laminatoi di Metalli S.p.A. (TLM)	Genoa, Milan, Brescia	40,000	Trefimetaux and Fiat.
Delta Metallurgica Ligure S.p.A	Genoa-Cornigliano, Serravalle Scrivia (Alessandria)	25,000	Istituto Recostruzione Italiano and Finmeccanica (Italian Government).
Fiat S.p.A	Turin	15,000

Iron and Steel.—After years of heavy investments and new plant construction, the Italian iron and steel industry in 1965 completed facilities necessary to close the gap between steel production and domestic demand. Completion of the second blast furnace at Taranto, and of a blast furnace and three oxygen converters at Bagnoli, were largely responsible for the 57-percent increase in pig iron output and 30-percent increase in steel production. Italy accounted for 15 percent of EEC steel production.

The nation also became a net exporter of steel for the first time in 1965. While imports of steel were reduced by nearly 800,000 tons, increased domestic output coupled with lagging domestic consumption provided more than 1 million tons in excess of domestic needs. The industry was able to export most of the surplus in the form of rolled steel, although world market conditions were unfavorable and the exports were described as unprofitable. Nevertheless, the industry operated at 87 percent of rated capacity, and the trade surplus in steel was valued at more than $100 million in contrast to the deficits in previous years.

The low level of domestic steel demand in 1965 was attributed to a continuing slump in the construction industry and to a lag in new industrial investment. Steel consumption by various industrial sectors in Italy during the past 3 years, as estimated by the Italsider Co., is shown in the following tabulation:

Industry sector	(Thousand metric tons)		
	1963	1964	1965
Secondary manufactures [1]	3,130	2,660	2,820
Transport	1,960	1,750	1,750
Building	2,140	1,680	1,220
Metal construction [2]	1,915	1,420	1,530
Mechanical	1,190	1,022	930
Public works	780	700	860
Home appliances	420	450	470
Packaging	390	310	390
Casting and forging	570	530	557
Other	1,087	970	970
Total	13,582	11,492	11,547

New capital investment in the iron and steel industry in 1965 was estimated at $373 million. Most of the total investment was concentrated in plants of the Government-controlled Finsider Group.

Expenditure item	Million dollars	
	1964	e 1965
Coke plants	40.5	17.6
Charge preparation	67.6	37.6
Blast furnaces	47.2	26.3
Steel plants	105.7	37.3
Rolling mills	309.6	158.1
General services	256.2	96.3
Total	[1] 826.8	373.2

e Estimate.
[1] Reported as $430 million in volume IV of the Minerals Yearbook 1964.

Iron Ore.—Output of iron ore from Italian mines continued to decline in 1965. Società Mineraria Siderurgica S.p.A. (Ferromin), one of the principal producers, abandoned the Canaglia mine in Sardinia and the Manina mine in Bergamo; it also was preparing to close the Alfredo mine in Brescia. Competition from imports of high grade iron ore caused the company to withdraw from its operations on Elba and at the Gambatesa manganiferous iron ore mine on the mainland, and in April all assets of the company were taken over by the Italsider Co. Up to the time of its dissolution, Ferromin reported production of 102,000 tons of iron ore from Elba in 1965 and 20,000 tons of ore from the Gambatesa mine. The Fiat Co. closed the Antas mine at Cagliari in 1965.

Foreign companies owned by or associated with Ferromin included Sesa Goa Ltd. and Sociedade Mineira Goesa Ltd. (MINGOA) of India (Goa) and Minas del Hierro del Conjuro S.A. of Spain. Of 951,000 tons of ore produced by the Indian

properties in 1965, 304,000 tons were shipped to Italy; 545,000 tons to Japan; and 96,000 tons to destinations in north Europe. Of 258,000 tons produced by the company's Spanish affiliate, 62,500 tons were shipped to the Italsider Co.

In other developments, production of magnetite ore at the mine of Nazionale Cogne S.p.A. in Aosta increased to 312,000 tons (300,000 tons in 1964). The company reported installation of new beneficiation facilities and an 8-percent increase in output of pelletized concentrate. In Tuscany, output of pelletized iron oxide from pyrite by Montecatini's Follonica plant was probably about 300,000 tons in 1965. The plant was scheduled to produce 1,100 tons of pellets daily beginning early in 1965.

New ore preparation plants began operating at the Bagnoli and Cornigliano (Sinigaglia) steelworks of the Italsider Co. New facilities at Bagnoli included two sintering machines. Ore loading facilities were also completed at the company's Servola ironworks at Trieste.

Iron ore imports increased by 57 percent in 1965 and were valued at $76 million. Imports from Liberia increased by 1.2 million tons, and from Algeria by 400 thousand tons. Shipments of ore from Liberia, Mauretania, and Canada, where the Finsider Group has financial interests, increased by 1.75 million tons. The Fiat Co. also had a 3.5 percent share in Société des Mines de Fer du Mekambo, in Gabon.

Scrap.—Iron and steel scrap imports in 1965 increased by 46 percent and were valued at $185 million. Most of the increase was obtained from West Germany and France. Imports from West Germany increased by 745,000 tons as Italy took 90 percent of West German exports.

Scrap purchased by the Finsider Group totaled 1,370,000 tons in 1965, of which 44 percent was obtained from the home market, 32 percent from the United States, and 24 percent from EEC countries. The scrap of U.S. origin was mostly delivered to Bagnoli and Taranto.

The scrap resource in 1965 amounted to 8,893,000 tons, including 3,240,000 tons originating within the industry. Scrap consumption in oxygen steelworks increased from 69,000 tons in 1964 to 822,000 tons in 1965. In electric steelmaking, scrap consumption increased by 504,000 tons while 90,000 tons less was used for open-hearth steel.

Pig Iron.—Blast furnaces completed in 1965 increased the industry's productive capacity for pig iron by 6,100 tons per day. In January, 3,000 tons of daily capacity was added at Taranto; in May, 600 tons of daily capacity was added at Trieste; and in September daily capacity at Bagnoli was raised by 2,500 tons. The Cogne Co. also increased daily output at Aosta by 80 tons daily. These developments increased the industry's monthly output to 400,000 tons by March and 500,000 tons by October.

The Italsider Co. continued to account for approximately 94 percent of national output. An additional 179,000 tons was produced by A.F.L. Falck and 110,000 tons was produced by Nazionale Cogne. Output of the Servola works at Trieste was scheduled to increase to 380,000 tons annually in 1966, and at Bagnoli work was begun to increase the capacity of No. 4 furnace.

Imports of pig iron (including cast iron) increased in 1965 and were valued at $32 million. The principal increases were 95,000 tons from Finland and 30,000 tons from East Germany.

Ingot Steel.—The State-controlled Finsider Group of steel companies produced 7,450,000 tons of crude steel in 1965, approximately 59 percent of the national output. Of this total, Italsider plants produced 6,307,000 tons, including 1,500,000 tons from Taranto. Compared with 1964, Finsider output increased by 48 percent while production from privately owned companies rose by 11 percent. Among the private companies, the A. F. L. Falck Co. increased production to 913,000 tons in 1965, compared with 802,000 tons in 1964 and 712,000 tons in 1963; the increased output was due to operation of the company's new Concordia electric steelworks at Sesto San Giovanni. Production of steel was also increased by Nazionale Cogne to 195,000 tons (150,000 tons in 1964). Many other companies were reported to have increased production in 1965. The national monthly output reached the million-ton level in March and production during the last quarter was equivalent to 14 million tons annually.

The tenfold increase in production of steel by the Linz-Donawitz (L–D) process was due to the completion of three 125- to 150-ton converters at the Bagnoli works and to increased availability of hot metal

at Taranto. Annual output capacities of the L–D plants were rated at 2 million tons for Bagnoli and 2.3 million tons for Taranto. Nazionale Cogne was reportedly planning to install two 35-ton L–D vessels at Aosta for production in 1968.

In electric steelmaking, Società Fabbrica Italiana Tubi completed a new plant for production of steel ingots at Riva Trigoso. The plant has a steelmaking capacity of 70,000 tons annually and will supply ingots to the company's tube mills at Sestri Levante. At Udine, the Bertoli Co. increased its electric furnace capacity to 52,000 tons annually. The Cogne Co. installed a tap-degassing plant at its works in Aosta.

Special Steels.—Production of all types of special steels increased in 1965, as shown in the following tabulation.

	Metric tons		
	1963	1964	1965

At the Terni steelworks, a contract was awarded to a French firm (Sidexport) for installation of plants for continuous casting and hot-rolling of stainless and silicon steel. The French firm is licensed under a Soviet patent in the field of continuous casting. At the Costa Volpino works of the Dalmine Co., an extrusion press and cold-drawing plant for producing tubular products from either stainless or ordinary steel were nearly completed in 1965. The plants have annual capacities of 36,000 tons of extrusions and 42,000 tons of cold-drawn tube.

Rolled Steel.—As in the output of crude steel, the Finsider Group accounted for 60 percent of Italian production of hot-rolled products. Italsider plants produced 4,765,000 tons of hot-rolled steel; 1,241,000 tons of cold-rolled steel (mostly at Novi Ligure); and 343,000 tons of tinplate, galvanized, and other coated products. The Dalmine Co. produced 578,000 tons of seamless and other tubular products (538,000 tons in 1964), of which 200,000 tons were exported.

In the private sector, the Falck Co. produced 774,000 tons of rolled steel, and the Fiat Co. processed 1.7 million tons of ingots. The Fiat Co. produced 1,014,000 motor vehicles and 44,000 tractors in 1965. In addition to the technical cooperation agreement signed with the Soviet Union, the company reportedly signed a trade agreement with mainland China involving the export of trucks and marine motors valued at $3.5 million.

In new plant developments, the welded-pipe mill at Piombino began full production in 1965, and a continuous rolling mill with annual capacity of 400,000 tons of light to medium sections was almost completed. A new continuous strip mill at the Sesto San Giovanni works accounted for the increased production of rolled steel by the Falck Co. Output capacity for sheet, strip, and skelp at Taranto was reported to be 1.5 million tons annually, plus 200,000 tons of welded pipe. At Rome, Società Feram was installing an automatic rolling mill for reinforcing bars with an annual capacity of 56,000 tons.

Steel Trade.—Net foreign trade earnings of $116 million were realized by Italy from crude steel and semimanufactures trade in 1965, compared with a loss of $115 million in 1964. Exports of rolled products were mainly responsible for this development, having increased by nearly 1 million tons and $123 million in value over 1964 levels. Increased exports of bars, rods, sections, and flat products were mainly destined for the United States, EEC countries, and the Republic of South Africa while exports of pipe to Libya and the Soviet Union increased by 65,000 tons and 33,000 tons, respectively. Imports of coils for rerolling were reduced by 150,000 tons each from Japan and the United Kingdom, while imports of sheets and plates from the EEC were reduced by 186,000 tons.

Lead and Zinc.—Improved mine and plant facilities of the Monteponi-Montevecchio and Pertusola companies were principally responsible for the increased lead and zinc production in 1965. In Sardinia, a full year's production from the Sos Enattos mine near Nuoro contributed

substantially to increased zinc and cadmium output by the Monteponi-Montevecchio Co. The company's big concentrator at Campo Pisano also began limited production in October, processing ore from mines of the Monteponi group. A 24-percent increase in output of mine zinc by the Pertusola Co. was mainly due to increased production at the Salafossa mine in north Italy where a new concentrator was completed in 1964. These mines helped to compensate for lower-grade ore encountered in 1965 at San Giovanni and Raibl.

Ore and metal produced by the principal mining companies in 1964–65, is shown in the following tabulation:

Metal	Metric tons unless otherwise specified					
	Società di Pertusola [1]		Monteponi-Montevecchio [1]		Azienda Minerali Metallici Italiana (AMMI) [1]

Source (principal): L'Industria Mineraria (Rome). V. 17, Nos. 6, 7, and 11, 1966, pp. 268, 329, and 516, respectively.

Smelter production of lead and zinc was increased by the Pertusola Co. at La Spezia and Crotone as the company completed the initial phase of its program to expand capacity. Of the electrolytic zinc produced by the Monteponi-Montevecchio Co., 30,276 tons was produced at Porto Marghera and the remainder was produced at Monteponi. The company also produced germanium and oxides of lead and zinc. In other developments, the decreased recovery of secondary zinc in Italy was due to the closing of an electrolytic plant at Piedimulera in 1964, reportedly because of increased costs of labor and electric power.

Apparent consumption of lead and zinc increased in 1965. Net imports of lead in concentrates, scrap, and unwrought metal increased by approximately 35,000 tons, and exports of zinc decreased. Lead imports in 1965 were valued at $23 million, compared with $12.8 million in 1964. Most of the increase in imports came from Canada (ore) and West Germany (scrap). Consumption data for 1964 were reported as follows: lead, 89,000 tons of refined metal with total consumption of 117,000 tons and zinc, 114,000 tons of refined metal with total consumption of 161,000 tons.

The surge of mine and plant developments in the lead and zinc industry, stimulated by impending EEC tariff cuts and the necessity to rationalize production, continued strong in 1965. On the mainland, plans by the major companies to increase the capacity of reduction plants at Porto Marghera, Ponte Nossa, La Spezia, and Crotone apparently remained firm and at the Salafossa mine a heavy-media plant was built to increase the productive potential of the new 1,000-ton-per-day concentrator. In Sardinia, the large "Sartori" and "Faina" projects of the Monteponi-Montevecchio Co. were reported to be 70 percent completed. At least 13 kilometers of new underground workings had been excavated since the projects were started late in 1962, in addition to more than 20,000 feet of drilling. During the course of this work, the proved and probable ore reserves of the company in Sardinia were increased to 25 million tons, containing 1,350,000 tons of zinc and 400,000 tons of lead. This was a total in-

crease of 550,000 tons of contained metal as compared with 1962 figures.

At the "Sartori" project, designed to coordinate production from seven mines of the Monteponi group near Iglesias, the Monteponi and Campo Pisano mines were connected in April and ore began moving to the concentrator in September. The first section of the concentrator was started in October and a second section on December 2. The new concentrator, which will replace five smaller plants, is designed to handle 6,000 tons of ore daily upon completion and will be one of the largest in Europe. At Monteponi, the company began construction of a Waelz furnace to treat 400 tons per day of oxidized zinc ore and was expanding capacity of the electrolytic plant to 22,000 tons annually; both plants were scheduled for completion by early 1967. At the San Gavino lead smelter, capacity of the shot works was being expanded to 12,000 tons annually.

On the "Faina" project at Montevecchio, sinking of the Faina and Fais shafts was continued and the Estella-Rolandi level was extended almost to the Ingurtosu mine. In September the company acquired the Ingurtosu and four other mines from the Pertusola Co.

The tariff protection accorded to the industry by the EEC since 1960 was scheduled to end in March 1966, but in view of the investments committed and the importance of the industry to the EEC as well as to Italy it was likely that protection would be continued. Italian duties on lead and zinc imports from EEC countries were reduced by 15 to 20 percent in 1964.

Mercury.—Output of mercury was practically unchanged from the 1964 level although ore production increased by nearly 17 percent. Several companies reported a drop in average grade. Stabilimento Minerario del Siele, the country's second largest producer, processed 24 percent more ore than in 1964 but increased output of mercury by only 7 percent.

An experimental open-cast mine was opened in low-grade (0.1 percent mercury) deposits of the Siele Co. After 3 months, the operation was stopped because of strong protests from local labor unions although the company insisted that it had a right to test any method which promised to reduce the costs of production.

Exports of mercury decreased 40 percent, with shipments reduced mainly to Japan, the United Kingdom, and West Germany. Because of elevated prices, however, the total value increased to $19 million. In contrast to the previous 2 years, exports were less than production during 1965 and above-ground stocks of mercury increased from 9,595 flasks at midyear to 15,355 flasks at yearend.[2] Domestic consumption of mercury was reported to be between 10,000 and 15,000 flasks annually.

Four new furnaces were being installed in 1965, two by the Siele Co. and one each by Società Mercurifera Italiana and Società Mineraria Rimbotti. The latter two companies are subsidiaries of the Edison and Montecatini companies, respectively. In Siena, Società Mineraria Monte Amiata planned to open a new mine in 1966 at San Filippo d'Orcia.

Titanium.—The Montecatini Co. announced that plans for a new titanium dioxide plant at Scarlino were well advanced. Planned output capacity was 50,000 tons annually for the domestic market and export. Exports of titania in 1965 were valued at $6.7 million, with about one-third destined for East Europe. Imports were valued at $7 million.

NONMETALS

Asbestos.—Production continued to increase. The value of exports tripled to $1.75 million; most of the increase in volume went to West European countries but included 2,000 tons to Poland. Growing competition from Soviet asbestos was noted by Italian producers. The strong European demand for asbestos was attributed to increasing demand for asbestos cement products. Output of asbestos cement products in Italy decreased, mainly because of the slump in construction activity. Imports declined, and the value of exports dropped by $500,000. Slackened demand came at a time when Italian producers were about to begin programs of plant expansion and modernization. Output of asbestos cement products was 610,000 tons in 1963 and 550,000 tons in 1964.

Barite.—Output of barite increased 67 percent in 1965, ranking Italy second to West Germany among West European producers. The increase was partially due to opening of the Su Benatzu and Santa Lucia

[2] Official figures released by Ministry of Industry and Commerce (Rome).

mines in Sardinia. Exports nearly tripled in volume, as 24,000 tons were shipped to the Netherlands, but their value increased only 55 percent. Substantial quantities continued to be imported from Spain.

Cement and Other Construction Materials.—The slump in the construction industry continued throughout 1965 and was reflected in reduced output of cement, lime, bituminous rock, and many other quarry products and nonmetallic mineral manufactures. Employment in the industry decreased about 30 percent during the year and the industry's output, valued at $6.15 billion in 1964, was estimated to have declined by 20 percent. In residential construction, which accounts for about 50 percent of the industry's output, housing starts in the first quarter of 1965 were 51 percent less than in the comparable period of 1964.

Lime production was only two-thirds of total capacity; output of calcined gypsum fell to 500,000 tons, a 28-percent decrease from 1963–64 levels; brick and tile production decreased 20 percent; and cement production was more than 2 million tons less than in 1964.

The cement industry was hit by reduced demand at a time when expansion of productive capacity was reaching a peak. Total annual capacity increased by 3.2 million tons in 1965 and was 29.5 million tons at yearend. Average utilization of capacity in 1965 was about 70 percent although in north Italy, where most of the plants are located, it was only 60 percent. The low level of plant utilization was expected to continue in 1966 because additional increases in overall capacity would probably exceed or keep pace with the anticipated increase in production. Aggregate capacity was scheduled to reach more than 31 million tons annually by the end of 1966.

Cement consumption in 1965 was 20.5 million tons. Exports increased substantially (principally to Spain) but were inadequate to offset the decline in domestic demand, and yearend stocks were 9 percent more than a year earlier. Basic prices for ordinary portland cement were unchanged from the 1961 level of $11.25 per ton. Of cement delivered to the home market, 30 percent was in bulk and the rest was in bags.

In the past 2 years, eight new plants (with nine rotary kilns) have been built, and additions to existing plants included eight rotary kilns and five vertical kilns. Most of the increase in capacity in 1965 was due to completion of a large plant at Palermo by the Italcementi Co.

In highway construction, the 7.4-mile Mont Blanc tunnel was dedicated on July 16. The $64 million structure is reported to be the longest vehicular tunnel in the world. Elsewhere, the superhighway network was scheduled to increase by 400 kilometers in 1966 by opening of the Bologna-Rimini, Bologna-Ferrara, Napoli-Baiano, and Trieste-Palmanova highways.

Feldspar.—A feldspar grinding plant was completed at Livorno by the R. Ginori Co. Other Ginori plants include a tile factory at Gaeta and ceramic plants at Sesto Fiorentino, Milan Lambrate, Pisa, and Mondovi.

Fertilizer Materials.—Potash production in Sicily continued to increase. The Montecatini Co. accounted for 62 percent of the total output, producing 1,067,000 tons of crude salts. All production from the San Cataldo and Palo mines was processed at the Campofranco sulfate plant. The company was also engaged in development work at the Racalmuto mine. Minable ore reserves in the San Cataldo and Palo properties were reported to be 46 million tons (1961), but no figure was available for the Racalmuto deposits.

Subsidiaries of the Edison Co. of Milan presumably accounted for the remainder of potash production. The Santa Caterina mine, operated by Società Industriale Catanese (SINCAT), produced an estimated 150,000 tons of ore that was sent to the company's Priolo plant for processing. Elsewhere, Società Sali Potassici Trinacria produced ore from the Pasquasia mine and was preparing the Corvillo mine for production in 1966. Production facilities reportedly available at the Pasquasia mine include two shafts with a combined haulage capacity of 4,000 tons per day and a 2,000-ton-per-day beneficiation plant. A new section being added to the plant will increase the processing capacity to 3,000 tons daily.

In 1965 the Trinacria Co. entered into an agreement with the Sicilian Mining Agency (EMS) and E.N.I. to jointly exploit the potash reserves of the Pasquasia and Corvillo concessions, which contain a minimum

of 115 million tons of minable ore and 15 million tons of potash (1961 estimate). Participation in the new venture was to include the Edison Co. (49 percent), E.N.I. (40 percent), and EMS (11 percent). Investments planned by the group were reported to total more than $20 million and would include construction of a potassium chloride plant (100,000 tons annually) and a potassium sulfate plant (200,000 tons annually). A second company (EMS 48 percent and ENI and Edison 26 percent each) would invest $16 million in a phosphoric acid plant (120,000 tons annually) to be built at Gela.

Raw phosphate imports in 1965 were valued at $23.4 million. As in 1964, about 50 percent was supplied by the United States and the remainder came mostly from Morocco and Tunisia. A decline of 150,000 tons in shipments from Tunisia appeared to be largely compensated by increased deliveries from the United States and Jordan and by a 67,000-ton increase in imports of basic slag from Belgium-Luxembourg.

Both consumption and exports of fertilizers increased in 1965. Consumption of potash and phosphoric acid in the first 7 months of 1965 was reported to have increased by 56 percent and 26 percent, respectively, over the comparable period of 1964. The value of exports of nitrogenous fertilizers increased by $14 million.

Fluorspar.—Higher world prices for fluorspar appeared to be mainly responsible for the rise in Italian output in 1965. Exports increased and were principally destined for the United States, Netherlands, and West Germany, while imports of fluorspar were sharply reduced and none was purchased from Spain.

In Sardinia, concentration plants at the Santa Lucia mine began production in October. Combined output capacity (fluorspar plus barite) was reported to be 40,000 to 60,000 tons annually. The new facilities were built by Sarrabus Mineraria S.p.A. (SARRAMIN), a subsidiary of the Edison Co. Elsewhere, the Su Benatzu mine and plant, a joint project of Miniere Riunite Varesine (MIRIVA) and Baroid International, may have started production earlier in the year. The Pertusola Co., which operates the Su Zurfuru mine near Cagliari, produced 7,479 tons.

In north Italy, 1965 operations of Società Mineraria Prealpina were described as "normal" by the Edison Co. The Prealpina Co. operates the Torgola mine, Italy's largest fluorspar producer. The Montecatini Co. also reported that temporary difficulties reduced output from its Prestavel mine to 17,600 tons in 1965.

Graphite.—Plans for construction of an artificial graphite plant in Campania were announced by Elettrografite di Forno Allione (a subsidiary of the Union Carbide Co.) and an Italian financial group. The plant will be completed in 1967 and will have a production capacity of 10,500 tons annually.

Magnesium Compounds.—In Sardinia, production of magnesium oxide from seawater and limestone was begun in January by the Sardamag Co. Production capacity of the plant was 50,000 tons annually. Consumption of limestone from local quarries by the plant was expected to reach 200,000 tons per year.

Marble.—In spite of reduced domestic demand and reportedly lower total production, exports of unfinished marble increased in 1965 and were valued at $28 million. Shipments from Carrara rose to 390,000 tons and deliveries to both domestic and foreign markets were increased; producers admitted, however, that price reductions had been necessary to maintain the volume of sales.

Faced with rapidly rising labor costs, which have increased 55 percent since 1962, and increasing foreign competition, the industry continued to increase mechanization in quarries and efficiency of transportation systems. A new processing plant was under construction by the Montecatini Co. at Viareggio.

In November, representatives of the marble and building stone industries of Italy, France, West Germany, and Belgium met in Milan. The principal problems discussed were the need for harmonization of taxes imposed on building stone by individual EEC countries and the growing competition from prefabricated building materials.

Pumice.—Exports of pumice in 1965 decreased to less than half of the 1964 level. Shipments to the Netherlands were reduced by 130,000 tons and to West Germany by 50,000 tons.

Pyrite.—The Montecatini Co. continued to account for most pyrite production, with output of 1,372,000 tons, mainly from its three mines in Tuscany. The product was

used to produce sulfuric acid and pelletized iron concentrate at the company's Scarlino (Follonica) plant. The Monteponi and Montevecchio Co. reported production of 6,500 tons of pyrite in 1965 (9,500 tons in 1964).

Imports of pyrite continued to increase and were valued at $10.8 million. Shipments from Cyprus, Yugoslavia, and Greece were sharply reduced while imports from the Soviet Union were increased by more than 200,000 tons.

Salt.—Production of rock salt in Sicily continued to increase. Output during the first 6 months of 1965 was 362,000 tons, 16 percent more than during the same period in 1964 and 28 percent more than during the corresponding months of 1963. Expansion of coastal loading facilities, mainly to handle output from mines of the Cattolica Eraclea group, was continued. Rock salt was also produced from the Cammarata and Racalmuto districts, the latter in conjunction with potash deposits being developed by the Montecatini Co. Ex-mine prices of salt in 1964 ranged from US$0.72 per ton at Cattolica Eraclea to $1.00 per ton at Cammarata. About 10 percent of Sicilian production has been consumed in Sicily and most of the remainder has been consumed by the chemical industry on the mainland.

In Sardinia, a Government-owned evaporation facility was being built at San Antioco. Anticipated production capacity was 500,000 tons annually.

Sulfur.—Consumption of sulfur in 1965 was reported to be 1.3 million tons, of which 60 percent was supplied from domestic mines, mostly as pyrite. Production of elemental sulfur, now almost entirely confined to Sicily, continued to decline. Yearend stocks of crude fused sulfur held by the Italian Sulfur Agency (E.Z.I.) had dwindled from 4,200 to 600 tons during the first 10 months and foreign deliveries by the Agency ceased. In Sicily, crude ore produced for direct processing by sulfuric acid plants increased to 373,000 tons, as compared with approximately 173,000 tons in 1964. Many of the Sicilian mines came under the management of the Sicilian Mining Board (EMS) or were being developed under EMS programs in 1965.

There was increased production of sulfuric acid. Output of the Montecatini Co. increased to 1,570,000 tons (100-percent basis) in 1965 and the Edison Co. produced an estimated 600,000 tons. The third and fourth sections of Montecatini's acid plant at Scarlino were brought on stream by yearend and production from this plant (350,000 tons in 1965) was expected to double in 1966. Output of sulfuric acid by other mining companies in 1965 included Monteponi and Montevecchio (49,000 tons); Società di Pertusola (38,000 tons); and AMMI (17,000 tons).

Imports of sulfur increased in 1965 as the gap widened between domestic production and industrial demand. The United States replaced Canada as the principal supplier. All imports were strictly controlled to insure that all Italian production was utilized and that gradual rationalization of the sulfur industry could proceed without undue disruption. Authorized import quotas were 95,000 tons for 1965 and 65,000 tons for the first half of 1966. The price to final consumers for both Italian and foreign sulfur was to be approximately $76 per ton c.i.f. Genoa; the difference between this price and the world market price was to be deposited in a special account for aid to the domestic industry. Government protection of the Italian sulfur market was expected to continue until 1968.

Talc.—Higher operating costs and increasing foreign competition contributed to the decline in Italian production in 1965. Exports decreased, particularly to the United States, but the total value remained at about $2.8 million.

Società Talco e Grafite Val Chisone, operator of the Pinerolo mine and Italy's principal producer, had improved its plant facilities but was finding it increasingly difficult to remain competitive because of rising labor costs. The company stated that the cost of wages, salaries, and fringe benefits in 1965 amounted to 77 percent of the costs of production. Of the company's output in 1965, 35 percent was absorbed by the Italian market, 19 percent by the United States, and 46 percent by other countries.

MINERAL FUELS

Coal.—An expected increase in coal output from Sardinian (Sulcis) mines to fuel the new Porto Vesme thermal power station did not materialize in 1965 and production continued to decline at approxi-

mately the same rate as in 1964. Rationalization of the mines, which has been aided by a $15 million development loan from the EEC, was still underway at yearend: mechanization of the Seruci mine, where mining reached the 400-meter level, was nearly completed but the Nuraxi Figus mine was still being developed and had a daily productive capacity of about 600 tons. Although average daily coal output in Italy was 19 percent below the 1964 level and employment was reduced by 10 percent during the year, average underground productivity increased by 14.7 percent to 2.9 tons per man-shift, one of the highest rates in the EEC. By yearend, anthracite production ceased as the La Thuile mine was closed by Nazionale Cogne S.p.A.

A second 240-megawatt generating plant was completed at the Porto Vesme facility during 1965. The powerplants are equipped to use either coal or oil. Because of prevailing high cost of production and relatively low heating value of the coal (4,200 to 4,500 kilocalories per kilogram), it was expected that oil would continue to have a competitive advantage in 1966.

Coal continued to rank high on the list of Italian imports of mineral commodities. Receipts during 1965 were valued at $148 million. The United States remained the principal supplier, increasing its share to nearly 80 percent of the total, including 94 percent of the metallurgical coal, 82 percent of the gas coal, and 34 percent of the steam coal. The U.S.S.R. remained the major supplier of anthracite.

The principal change in inland deliveries of coal in 1965 was the sharp increase in consumption by coking plants as shown in the accompanying tabulation; this change resulted from increased requirements of the iron and steel industry.

Consumer of coal	Thousand tons	
	1964	1965
Coke works	5,962	7,632
Domestic and commercial heating, etc.	1,192	1,030
Thermoelectric plants	669	[1] 631
Gasworks	719	553
Railways	624	553
Glass, ceramic, and building materials	480	250
Chemical industry	209	287
Iron and steelworks	69	40
Briquetting plants	67	66
Mines' consumption [2]	9	10
Other industry	201	143
Total	10,201	11,195

[1] Includes 62,000 tons consumed in pithead power stations.
[2] Including miners' coal.

Source: Statistical Office of the European Communities (Luxembourg). Energy Statistics. No. 4, 1966, pp. 58–61.

Coke.—The 22-percent rise in metallurgical coke output in 1965 was due to increased requirements for pig iron production. The new coke ovens at the Taranto steelworks had their first full year of operation in 1965 and probably accounted for most of the increase. The Montecatini group of coke-producing companies (Cokapuania, Cokitalia, and Vetrocoke) produced 1,630,000 tons, about 8.5 percent less than in 1964. Nationwide investment in coking plants was estimated at $17.6 million in 1965, compared with $40.5 million during 1964. At Vado Ligure, Fornicoke S.p.A. completed enlargement of a coke plant capable of handling 2 million tons of coking fines annually. The project was completed with financial assistance from the EEC.

Most of the coke continued to be made from imported coal. Net imports of coke were further reduced in 1965; the net quantity and value was 150,000 tons and $3.5 million, respectively, compared with 526,000 tons and $12.3 million in 1963. West Germany remained the principal foreign coke supplier and imports from the United Kingdom were almost eliminated.

Inland deliveries of coke are shown in the following tabulation:

Consumer	Thousand tons	
	1964	1965
Iron and steel industry	2,587	4,140
Households, commerce, and handicrafts	1,259	1,352
Chemical industry	305	316
Independent foundries	192	192
Glass, ceramic, and building materials	184	141
Other	34	3
Total inland availability	4,561	6,144
Stocks at yearend	420	282

Electric Energy. — Electricity production continued to increase in 1965, with hydroelectric plants supplying slightly more than half of total output. Although output from all sources increased, the share of conventional thermal plants declined. Output from nuclear plants increased 46 percent as all three stations were operated throughout the year. Production by type of plant is shown in the following tabulation.

	Million kilowatt hours		Share of total output (percent)	
	1964	1965	1964	1965
Hydroelectric	39,328	43,181	51.2	52.3
Thermal (conventional)	32,482	33,333	42.4	40.4
Nuclear	2,401	3,510	3.1	4.2
Geothermal	2,527	2,576	3.3	3.1
Total	76,738	82,600	100.0	100.0

Source: Statistical Office of the European Community (Luxembourg). Energy Statistics, No. 4, 1966.

In thermal powerplants, consumption of liquid fuels continued to increase although not so sharply as in 1964. There was also a substantial increase in consumption of blast-furnace and coke-oven gas because of increased production in the iron and steel industry, while the share of natural gas decreased from 76 percent in 1964 to about 56 percent in 1965. Natural gas was increasingly diverted to the chemicals and synthetic fiber industries. The trends in fuel consumption by thermoelectric plants are shown by the following tabulation, in thousand metric tons:

Fuel	1962	1963	1964	1965
Fuel oil	3,728	4,057	6,097	6,254
Coal	1,167	661	737	710
Lignite	1,729	1,332	1,180	1,003
Gas—SCE [1]	1,227	1,258	1,366	1,538

[1] Standard coal equivalent, at 7,000 kilocalories per kilogram.

Source: Statistical Office of the European Communities (Luxembourg). Energy Statistics, No. 4, 1965 and 1966.

During 1964 and 1965, 11 new thermal power units, with a total nominal capacity of 2,253 megawatts, were scheduled to enter service. Five were new plants and the others were additions to existing stations. Of the total, six were designed to be fueled by oil, four by fuel oil or coal, and one by coal.

Consumption of electric energy by selected divisions of the mineral industry is tabulated below.

Consuming sector	Million kilowatt-hours	
	1964	1965
Chemicals and synthetic fibers	11,787	12,390
Iron and steel	7,294	8,309
Metal manufactures	5,228	5,385
Nonmetallic mineral manufactures	4,756	4,940
Nonferrous metals	2,877	2,960
Petroleum production and refining	720	791
Mining (including coal and lignite)	819	898
Total	33,481	35,673

Source: Statistical Office of the European Communities (Luxembourg). Energy Statistics, No. 4, 1966, p. 128.

Nuclear Energy.—The powerplant at Trino Vercellese, Italy's newest and most powerful nuclear station, completed its first full year of operation in 1965. The reactor went critical in June 1964. In February, the State power authority took over control of the Garigliano powerplant, near Naples, from Società Elettronucleare Nazionale (SENN). Later in the year, the second 5-year plan of the Italian Atomic Energy Commission (CNEN) was approved by the cabinet and sent to the Senate for consideration. The plan proposed expenditures totaling $240 million, including $36.8 million for 1965 and $33.6 million for 1966.

In other developments, the capacity of the SORIN (Società Ricerche Impianti Nucleari) research reactor at Saluggia, near Turin, was increased from 2 to 10 megawatts. In April, an agreement was reached between the United Kingdom Atomic Energy Authority and SNAM to form a company for production and sale of uranium and uranium oxide fuels. The proposal, which was subject to approval by the Italian and British Governments, included construction of a plant at Talmona, 120 kilometers from Milan.

By March 1965, three contracts for the supply of special fuel materials for the

power reactors had been concluded by the European Atomic Energy Community (EURATOM) Supply Agency with the United States Atomic Energy Commission. The contracts involved approximately 20,000 kilograms of U-235 and a value of $178 million.

Some details on Italy's three nuclear powerplants are shown in the following tabulation:

Plant	Capacity (megawatts of electricity)	Reactor type	Date commissioned	Installed cost [1] per kilowatt-hour	Cost [1] of electricity per kilowatt-hour [2]
Latina	200	Gas-graphite	1963	$518	$0.01246
Garigliano	157	Boiling water	1963	446	.01154
Trino Vercellese	257	Pressurized water	1964	279	.00863

[1] Source figures are in European Monetary Authority (EMA) units of account, equivalent to U.S. dollars.
[2] Figures not directly comparable because of differing bases for calculation.

Petroleum.—*Exploration.*—There were no commercial discoveries of oil or gas in Italy in 1965. As compared with 1964, exploration drilling was reduced by 40 percent while development drilling (mostly in the Ravenna, Foggia, and Caltanissetta districts) was nearly doubled. Total footage drilled was 10 percent less. Italian hydrocarbon reserves were estimated at 40 million tons of petroleum and 4,620 billion cubic feet of natural gas.

In November, the draft of a law regulating offshore exploration and exploitation of oil and gas reserves was submitted to the Ministry of Industry and Commerce. The proposed law would reserve all prospecting rights and 25 percent of continental shelf areas to ENI; later, concessions may be granted to private firms, or to joint ventures of private firms and ENI. Exploration permits are presently issued under the basic hydrocarbons law of 1957 and under the special mining law of the semi-autonomous Government of Sicily. Under a 1953 law, ENI concessions already include an Adriatic Sea area between Rimini and Monfalcone extending 15 kilometers offshore. Provisions of the proposed law reportedly meet the requirements of the Geneva Convention regarding international boundaries in continental shelf areas although Italy was not yet a signatory to this convention.

In Sicily, an agreement was signed in July between ENI and the Sicilian Mining Agency (EMS), concerning exploration and development of hydrocarbon resources. The Azienda Generale Petroli Italiani (AGIP) division of ENI will undertake the entire cost or exploration, estimated at $17 million, on two permit areas; if hydrocarbons are found, shares in exploitation of the venture are to be 66.5 percent owned by AGIP and 33.5 percent by Società Azionaria Ricerche Coltivazione Idrocarburi Siciliani (SARCIS). The latter company is owned 90 percent by EMS and 10 percent by AGIP. Permits granted to SARCIS at year-end covered 517,000 hectares.

In exploration abroad, estimated reserves at ENI's oil discovery near El Borma in Tunisia were increased to 35 or 40 million tons, and the company obtained additional exploration permits. Encouraging oil shows were found in Libya (Concession 82), and explorations were continued in the Gulf of Suez area of the United Arab Republic (Egypt), Iran, Morocco, Nigeria, and in several areas of the North Sea where AGIP is associated with the Phillips and Petrofina companies. Exploration permits were relinquished in the Sudan and in the Mekran area of Iran.

Crude Oil Production.—The reduced output of crude oil in 1965 resulted from cutbacks by ENI in production schedules at both the Gela and Ragusa fields in Sicily. Output from the Gela and Ragusa fields was reduced by 20 percent and 16 percent, respectively, and the combined monthly output fell from approximately 250,000 tons in January to 150,000 tons in June. Reduced output was partly due to water infiltration in the Gela field. The Sicilian fields continued to account for 95 percent of domestic crude oil production, and 99.5 percent of all domestic output was produced by ENI. On the mainland, output from the small fields in central and southern Italy exceeded Po Valley production

Table 5.—Italy: Production of crude oil, natural gasoline, and natural gas, by area

Region and Province	Crude petroleum (thousand metric tons)			Natural gasoline (metric tons)			Natural gas (billion cubic feet) [1]		
	1963	1964	1965	1963	1964	1965	1963	1964	1965

[1] Volume obtained after removal of condensable fractions. Figures converted from quantities reported in cubic meters, using 35.314 cubic feet = 1 cubic meter.
[2] Less than ½ unit.

Source: Ministry of Industry and Commerce (Rome). Bollettino Ufficiale degli Idrocarburi, v. 8, 9, 10, No. 7, July 1964, 1965, and 1966 (appendix).

for the first time. Total domestic crude oil reserves were estimated at 40 million tons.

Abroad, ENI produced 6 million tons of crude oil, of which 80 percent was from operations in the United Arab Republic (Egypt) and the remainder from Persian Gulf fields. Investments during the year by the ENI Group for petroleum exploration and development included $32 million in Italy and $37 million abroad.

Pipelines.—The Central European Pipeline carried 4.1 million tons of crude oil in 1965, mostly to the Sannazzaro de' Burgondi and Collombey refineries. The Ferrera-Spluga section of the pipeline was completed during the year, and necessary construction permits for extension of the line to Ingolstadt were granted by West German authorities but opposition from local authorities continued to delay its completion. In the meantime, the Ingolstadt refinery was using only part of its capacity and was being supplied with crude from the South Europe and Rhine-Danube pipelines.

Construction of the Trans-Alpine Pipeline began with work on the Monte Timau tunnel at the Austrian border. Construction of the Italian section of the line, handled by the Bechtel Corp. for Società Italiana per l'Oleodotto Transalpina (SIOT), will cost an estimated $96 million. ENI has a 10-percent interest in SIOT.

In Sicily, the 65-kilometer pipeline from Ragusa to Augusta carried 629,000 tons of crude.

Crude Oil Imports.—Imports of crude oil increased by 22 percent and more than made up for the reduction in domestic production as well as the increased demands of refineries. The principal sources continued to be Kuwait, Saudi Arabia, Iraq, the Soviet Union, Libya, and Iran, in that order. The largest increases (in million tons) came from Kuwait—5.4, Saudi Arabia—2.2, and Iran—1.9.

Refining.—Both processing capacity and output of Italian refineries continued to grow at rates of nearly 20 percent. The 69.37 million tons of crude oil processed in 1965 included 2.24 million tons of domestic crude and represented about 75 percent of total refinery capacity available at the beginning of the year and 62 percent of capacity available at yearend.[3] In refinery output as well as capacity, Italy led all other West European countries in 1965.

New refineries came on stream in 1965 near Milan, (Sannazzaro de' Burgondi; owned by ENI);[4] at Cagliari, Sardinia (Sarroch; owned by S.p.A. Raffinerie Sarde); and at Rome (Raffineria di Roma, S.p.A.). Major additions to existing plants were completed by Esso Standard Italiana and its affiliates at the Augusta (Sicily) and

[3] Actual capacity, including 30 percent legal reserve, was approximately 110 million tons annually as of December 31, 1965, and included 12.8 million tons assigned to petrochemical plants.

[4] Previously reported as having been completed in 1964.

Trecate (near Milan) refineries; other expansions were completed by ENI at Livorno and Gela and by the Mediterranea Co. at Ravenna. By yearend, Shell-Condor S.p.A. had nearly completed an $11 million, 80,000-ton-per-year lubricant plant at Rho (near Milan) and Shell Italiana S.p.A. began construction of a refinery at Taranto. The Taranto refinery, to be completed in 1967, will have a capacity of 4 million tons annually and was expected to cost $46 million. Abroad, ENI's new refinery at Ingolstadt (West Germany) came on stream in March; refineries being built by ENI in the Republic of the Congo (Léopoldville), Tanzania (Dar es Salaam), and Yugoslavia (Fiume) were nearing completion; and the company was scheduled to begin construction of plants in Norway and Ceylon. In 1965, refineries partly or wholly owned by ENI processed 17.5 million tons of crude oil, of which 81 percent was refined in Italy and 19 percent was refined in other countries.

In the transport of petroleum products, a 35-kilometer, 5-strand pipeline was completed in October between the San Quirico refinery (Genoa) of Edouardo Garrone S.p.A. and storage facilities at Arquata Scrivia. Another 80-kilometer pipeline was completed by ENI between Ferrera and Chivasso.

Fuel oils and motor gasoline continued to account for about 75 percent and 13 percent, respectively, of total refinery output. Domestic consumption of petroleum products (excluding international bunkers) is shown in the following tabulation:

Commodity	Thousand metric tons		
	1963	1964	1965
Gasoline	4,600	5,350	5,900
Jet fuel [1]	271	337	340
Kerosine [2]	280	376	486
Gas oil	3,765	3,957	4,107
Other fuel oils [3]	19,600	23,200	25,400
Lubricants	328	330	335
Liquefied petroleum gases	965	1,050	1,135
Petrochemical feedstocks	800	1,100	1,450
Bitumen	950	1,120	1,130
Petroleum coke	180	250	210
Other	646	683	578
Total	32,385	37,753	41,071

[1] Including aviation gasoline.
[2] Including white spirit and solvents.
[3] Neither Italian nor EEC statistics for consumption subdivide "fuel oil" by viscosity or other characteristics. The quantities given thus include "distillate" as well as "residual" fuel oil.

Source: Ministry of Industry and Commerce (Rome). Bollettino Petrolifero, No. 12, December 1963, 1964, 1965.

There were no tax increases on gasoline in 1965. Prices remained at $0.68 per U.S. gallon for regular gasoline and $0.73 for premium gasoline. AGIP reduced gasoline prices about 2.5 cents per gallon in 1965. In gasoline sales, AGIP accounts for about 25 percent of the market, Esso 20 percent, and Shell 18 percent. In 1965 the ENI subsidiary, AGIP U.K., sold its distribution network in the United Kingdom to Esso.

Net exports of petroleum products increased by 46 percent in volume and 36 percent in value. Fuel oils (nonbunker) accounted for 84 percent of the increase, while exports of lubricants nearly tripled. The increased volume went principally to Belgium and the Netherlands, followed by the United Kingdom, Pakistan, Switzerland, the United States, and Spain.

Natural Gas.—The increase in production of natural gas in 1965 was due mainly to a 6-fold increase in output from the Chieti and Matera provinces of southeastern Italy. Production from these areas accounted for about 10 percent of the national output compared with 2 percent in 1964, while fields in the Po Valley provided 86 percent of the total (95 percent in 1964) and the remainder was mostly produced from the Gagliano field in Sicily. ENI continued to account for 98 percent of the national output.

Offshore, in the ENI concession area of the Adriatic, regular production began from the Ravenna Mare gasfield. Eight kilometers east of Ravenna Mare, extension drilling in the Porto Corsini field indicated a gas reserve of about 350 billion cubic feet and the field had six gas wells by yearend. During the Porto Corsini operations, the drilling platform "Paguro" was

destroyed by a blowout from Hole No. 7.

In onshore explorations, small gas pools were found in San Marino and in the suburbs of Milan, and one hole found noncommercial gas (nitrogen) in the Arno river valley. In southeastern Italy, the Portocannone gasfield was further developed by Ausonia Mineraria. Gas reserves at Portocannone were reported to be 210 billion cubic feet.

In the Foggia area, gas reserves in the concession area of the Montecatini and Snia Viscosa companies were reported to be 700 billion cubic feet. At yearend, ENI gas reserves were 3,745 billion cubic feet, of which 1,995 billion were in the Po Valley, 1,050 billion in central and southen Italy, and 700 billion in Sicily. The Montecatini Co. reportedly discovered a new gasfield in Sicily but no details were available.

ENI invested $22 million in gas transport and distribution facilities in 1965. The company's pipeline-network was increased by 129 kilometers and included completion of the Bronte-Catania line (58 kilometers) in Sicily, the Fusignano-Bologna section (39 kilometers) of the Bologna-Ravenna pipeline, and a 22-kilometer branch of the Vasto-Rieti-Terni pipeline. Five other pipelines totaling 305 kilometers were under construction at yearend, including 180 kilometers in Sicily.

Consumption of natural gas for chemical conversion and nonindustrial uses continued to be encouraged by ENI. Deliveries of gas for these purposes increased 13 percent, while declines of 15 and 5 percent, respectively, were registered for thermoelectric plants and industrial fuel. Studies by ENI indicated increasing needs for imported natural gas, and the State agency was developing a program to assure domestic availability of up to 350 billion cubic feet of natural gas annually by 1975.

Consumption of natural gas in Italy in 1965 is shown by the following tabulation:

Consumer:	*Billion cubic feet*[1]
Extractive industry	497
Manufacturing industries:	
Metallurgical	32,215
Nonmetallic mineral manufactures	25,788
Chemical (thermal use)	31,275
Other manufacturing	39,917
For chemical synthesis	61,806
Thermoelectric plants	15,361
Domestic and other uses	61,486
Other	4,562
Total	272,907

The Mineral Industry of Luxembourg

By Stephen C. Brown [1]

The growth of the Luxembourg economy, which had expanded at the rate of 6.5 percent in real terms in 1964, came almost to a halt in 1965; estimates indicate an output increase of approximately 1.5 percent in real terms during the year. Iron and steel industry production, accounting for approximately 70 percent of total output, was practically unchanged from that of 1964. A 365,000-ton decrease in iron ore output was offset by a smaller increase in output of crude steel and semimanufactures. Total output of the steel industry is estimated to have risen by approximately 0.7 percent, while the index of total industrial production rose by only 0.5 percent. Output of most nonmetals declined or was relatively unchanged, though there were increases in production of fertilizer, basic slag, and manufactured phosphatic fertilizer.

Trade in mineral commodities is believed to have increased slightly with imports of iron ore and petroleum products showing substantial increases. A substantial decrease in iron ore exports was offset by small increases in steel and basic slag exports.

No recent data exist to show the proportion of total gross national output (GNP) accounted for by the mineral extractive and processing industries, but there is some reason to believe this proportion may be declining slowly as Luxembourg iron ore output declines. Continuing efforts are being made to diversify the economy through the establishment of other manufacturing industries (for example, chemicals and rubber). Official national account figures show a steady decline of the share of total output attributed to the extractive sector alone (mining, stone and earth) from 3.1 percent in 1955 to 2.3 percent in 1963, the latest year for which these data are available.[2]

PRODUCTION AND FOREIGN TRADE

Production trends in Luxembourg's mineral industries during 1965 were as usual dominated by the fortunes of the iron and steel industry. The most significant change during 1965 was the sharp decline of domestic iron ore output, offset by the steel industry's increased imports of French ores. Output of pig iron declined slightly, while production of crude steel rose by 26,000 tons and production of semimanufactures rose by 13,000 tons. Cement output rose by approximately 10 percent, and basic slag production rose by 2.3 percent.

The official foreign trade statistics of Luxembourg are incorporated with those of Belgium in the trade returns of the Belgian-Luxembourg Economic Union. The data shown in the accompanying tables have been collected from various sources; including the official Annuaire Statistique 1965, L'Economie Luxembourgoise en 1964 and Bulletin du Statec, all published by Service Central de la Statistique et des Etudes Economiques. Other sources used (especially for iron, steel and energy products) were Iron and Steel, and Energy, both published by the Statistical Office of the European Communities. It should be noted that the figures for imports and exports of steel products were derived by analysis of data appearing in tables 60 to 62 of Iron and Steel, 1966, No. 2.

COMMODITY REVIEW

METALS

Iron Ore. — The declining output of Luxembourg iron ore is said to be due to the growing competition of richer ores from other sources and increasing domestic mine wage costs owing to inflationary pressures. The 365,000-ton decline in output in 1965 reflected a 276,000-ton drop in exports and a 100,000-ton decrease in consumption of domestic ores by the Luxembourg industry. Employment in the mines declined to 1,652 in 1965, compared with 1,872 persons employed in 1963. The declining trend of output is expected to continue, with some of the less efficient mines probably being closed.

The 1965 reduction in output was more than accounted for by a 424,000-ton decrease in production of siliceous ores, though output of the lower grade ferruginous limestone also declined. Output of calcareous ores rose slightly. Increased imports from France more than offset the reduction in domestic ore output.

Iron and Steel.—The Luxembourg plants of Aciéres Réunies de Burbach-Eich-Dudelange S.A. (ARBED) produced a total of 2,686,525 tons of steel (down 0.3 percent from 1964), while the Differdange plant of Hauts Fourneaux et Aciéres de Differdange-St. Ingbert-Rumelange S.A. (HADIR) produced 1,423,725 tons, slightly above its 1964 output. The third Luxembourg company, Rodange, produced the balance of approximately 475,000 tons. The operating rate of the Luxembourg industry, at 93.8 percent of capacity, continued to be the highest in the European Coal and Steel Community (ESCS).

At yearend ARBED announced the acquisition of a majority shareholding in HADIR (subject to approval by those with authority in the ECSC in a major move towards rationalization and integration of the Luxembourg industry. The two firms own plants in both Luxembourg and in the Saar, and as ARBED points out in its 1965 Annual Report, not only are the plants near each other but their production is largely complementary.[3]

The acquisition reportedly will result in creating one of the giants of the European

XII, No. 1, 1966 (Supplement to STATEC Bulletin, V. XII, No. 1, 1966).

steel industry, giving ARBED (which also owns or has major interests in plants elsewhere) a capacity of over 5 million tons.

Steel industry fixed investments in 1965 were mainly concentrated on projects for rationalization and modernization. ARBED completed the new 8-meter-hearth-diameter blast furnace at Esch-Belval in June 1965. Construction of its new oxygen steel plant at the same location continued on schedule; it is expected to be completed before the end of 1966. It will be equipped with two 110-ton LD/AC converters (modified version of the Linz-Donawitz converter), a mixer of 1,800 tons capacity, and a new casting hall.

The capacity of the company's oxygen plant at Terre Rouge was also increased. Work on the plant is to be completed by January 1966. The company's casting capacity at its Dudelange works was expected to be increased during 1966, and modernization of its hot rolling mill at the same plant was scheduled for completion by the beginning of 1967.

Other company projects underway included the following: Expansion of oxygen plant capacity at Terre Rouge (to be completed by January 1966); expansion of casting capacity at the Dudelange plant (to be completed during 1966); and modernization of the hot rolling mill at Dudelange, scheduled for completion by the beginning of 1967.

During 1965 HADIR continued construction of a new wide-flange I-beam rolling mill at Differdange; completion was expected by the beginning of 1966.

Three LDAC converters were in use in Luxembourg during 1965. Two more will be added when the new plant of ARBED at Esch-Belval is completed sometime during 1966.

At its small plants in Dommeldange and Eich (near the city of Luxembourg), ARBED produces special forged and cast

The Mineral Industry of the Netherlands

By Stephen C. Brown [1]

The minerals industry of the Netherlands continued to show a record of expansion in 1965, with the natural gas and steel industries leading the way, but there were indications that the rate of growth was somewhat slower than in 1964. The gross national product of the country increased by some 5 percent (in real terms) in 1965, as compared with an 8.2 percent growth rate in 1964; the mineral industry probably maintained its relative position in the economy as a whole.

The rapid expansion of natural gas as a factor in the Dutch energy market accentuated in 1965 the already existing difficulties of the coal industry, and at yearend the Government announced a drastic reorganization plan calling for immediate closure of one State-owned mine, the phasing out of another over a period from 1970 to 1972, the phasing out of two privately owned mines over a period ending in 1970, and provision for subsidies to remaining mines kept in operation.

Rapid progress was made in expanding the domestic natural gas pipeline network and by yearend seven agreements, tentative or firm, had been signed for export deliveries to Belgium, West Germany, and France. One million domestic gas connections were added during 1965.

Crude petroleum output rose and intensive explorations continued for oil and natural gas, with a number of significant gas strikes resulting. No exploration occurred in the Netherlands sector of the North Sea Continental shelf, pending the issuance of implementing regulations by the Government, although authorizing legislation for licensing was enacted during the year.

Plans were announced for a significant expansion of the steel industry, and the new primary aluminum plant at Delfzijl was nearing completion and expected to go into operation in the first half of 1966.

PRODUCTION

Natural gas output more than doubled, crude steel production rose again by 14 percent, and output of primary tin increased 14 percent in 1965. An 8 percent rise in output of primary zinc was offset by an 11 percent decline in lead output. Salt and cement production rose 7 percent and 3.5 percent respectively, while output of nitrogenous fertilizers increased 4.7 percent. Coal production was unchanged but increasing difficulties in marketing, accentuated by the rapid growth of natural gas in the domestic household and industrial markets, led to a 400,000 ton increase in pit-head stocks. Output of both crude petroleum and refinery products increased, the former by 5 percent and the latter by 11 percent.

TRADE

Exports of mineral commodities from the Netherlands were 11 percent higher than in 1964 on a value basis, compared with a 10 percent increase in the value of total commodity exports. In contrast, mineral commodity imports increased only 2 to 3 per-

[2] Including breeze.
[3] Deliveries for sale. Converted from Nm^3 (cubic meters at 15° C and 760 mm mercury) at rate of 35.314 cubic feet per cubic meter.

cent, while total commodity imports were 6 percent greater than those of 1964 on a value basis. As a result, mineral exports played a slightly more important role in total trade in 1965 than in the previous year, while mineral imports accounted for a slightly smaller share of total imports as shown in the following table:

	Value (million dollars)		Mineral commodities share of total (percent)
	Mineral commodities [1]	Total commodities	
Exports:			
1963	908	4,961	18.3
1964	1,041	5,808	17.9
1965	1,155	6,393	18.1
Imports:			
1963	1,360	5,967	22.8
1964	1,661	7,057	23.5
1965	1,698	7,462	22.8
Trade balance:			
1963	−452	−1,006	XX
1964	−620	−1,249	XX
1965	−543	−1,069	XX

XX Not applicable.
[1] Includes value of all commodities listed in Tables 2 and 3 of this chapter except for gold and such diamonds and other precious stones as were classified in sources as being of gem quality.

Source: Statistical Office of the United Nations.

Exports of petroleum and products rose in value by 5 percent to $427 million, of iron and steel by 11 percent to $243 million, and of nonferrous metals (including silver and platinum group metals) by 24 percent to $129 million. Even exports of coal, coke and briquets rose slightly, by 1 percent, to $115 million, while exports of manufactured fertilizers rose by 36 percent to $74 million.

Principal destinations for exports of mineral commodities in 1965 were West Germany, the Belgium-Luxembourg Economic Union, the United Kingdom, and France, with 25.5, 13.8, 13.4 and 8.9 percent of total commidity export value, respectively.

Petroleum and refinery products, iron and steel, nonferrous metals, metal ores and scrap, and coal, coke and briquets (in that order) remained the most important categories of mineral imports by value. Imports of petroleum and products increased 2 percent to $620 million, of nonferrous metals (including silver and platinum metals) 23 percent to $196 million, and of metal ores and scrap 8 percent to $136 million. Imports of iron and steel declined 4 percent, from $392 million in 1964 to $376 million in 1965; imports of coal, coke and briquets fell sharply by 18 percent, from $165 million in 1964 to $136 million in 1965.

Principal sources of mineral imports were West Germany, the Belgium-Luxembourg Economic Union, Kuwait, Indonesia, the United Kingdom, the United States, and Iran, with 22.7, 17.9, 5.1, 4.7, 4.5, 4.5, and 4.3 percent, respectively, of total mineral commodity import values.

The entrepôt trade in crude petroleum and refined products continued at a high level, with entries in bond of 24.9 million tons of crude and withdrawals of 24.7 million tons. Entries of products totaled 16.9 million tons and withdrawals 16 million tons. The net increase of crude in bond was 516,203 tons, and of products, 855,400 tons.

The transit trade in mineral commodities rose by nearly 7 percent, with metal ores (21.3 million tons), coal, coke, and briquets (7.5 million tons), fertilizers and fertilizer materials (5.1 million tons), petroleum and products (5 million tons) and sand, gravel, and crushed stone (4.8 million tons) accounting for the bulk.

COMMODITY REVIEW

METALS

Aluminum.—Work continued on the primary aluminum plant in Delfzijl. The plant, jointly owned by Swiss Aluminium Ltd. (Alusuisse), Koninklijke Nederlandsche Hoogovens en Staalfabrieken N.V. (Hoogovens) and N.V. Billiton Mattaschappij (Billiton) and with an initial annual capacity of about 32,000 tons was expected to start production in the first half of 1966. Production at Alusuisse's anode plant at Botlet began in early 1965. N.V. Lips, of Drunen at yearend announced plans for erection of two new aluminum rolling mills to begin production in mid-1967; one, a hot rolling mill, will have an annual capacity of 30,000 tons, while the second, a cold mill, will have a capacity of 20,000 tons. The firm in 1965 put into operation

r Revised. p Preliminary. NA Not available.
[1] Including alloys.
[2] Excluding gold coin and gold and alloys shipped by post.
[3] Including sponge iron, shot, grit, pellets and powder; spiegeleisen and ferromanganese.
[4] Including other precious metals.
[5] In 1964, not more than 99.7 percent pure; in 1965 at least 99.99 percent pure.
[6] Including articles of piezo-electric quartz.
[7] Includes bunkers for Netherlands ships and aircraft; excludes deliveries to bonded storage.

a new extrusion press with a capacity of 2,500 tons per year. At yearend plans for a second aluminum smelter, to be located in the province of Limburg, were reported to be well advanced, but no details were reported.

Iron and Steel.—Output of crude steel increased 14 percent in 1965, while production of rolled steel rose 10 percent. Exports of pig iron, crude steel, and steel products rose 14 percent, imports declined 13 percent, and apparent consumption of steel declined 5 percent to 3,792,000 tons. The industry operated at 86.7 percent of its estimated capacity at the beginning of the year. Nearly 70 percent of the total output was produced by the oxygen process.

Koninklijke Nederlandsche Hoogovens en Staalfabrieken N.V. and its affiliate, Breedband N.V. (which it took over and liquidated as a separate enterprise in 1965) increased both pig iron and crude steel output 21 percent, while their production of semimanufactures rose only 5 percent. Output of crude steel by Koninklijke Demka Staalfabrieken N.V. (also a Hoogovens subsidiary) increased 6 percent to 126,000 tons, while its production of castings, forgings, rolled and other products rose from 93,820 tons to 117,830 tons.

Production data for N.V. Nederlandsche Kabelfabrieken (NKF), the other major producer, are not available but the company has had in hand an expansion program which includes a new rolling mill of 800,000 tons per year capacity, scheduled for completion in 1966. NKF's plans also include a blast furnace, a new steel plant, and a sintering plant, all scheduled for completion by 1969. When the expansion program is completed NKF is expected to have a crude steel capacity of about 600,000 tons per year.

Two important developments, both announced towards yearend, were Hoogovens' $268 million 5-year plan for expansion of crude steel output from 2.8 million tons to 4 million tons per year, and Hoogoven's participation in the merger of two West German steel firms, Dortmund Hoerder-Huetten Union (DHHU) and Hoesch A.G.,

in the former of which Hoogovens holds 42.8 percent of the shares.

Hoogovens' expansion program includes a second ore quay, a second coke plant, a second oxygen-steel plant equipped with two 225-ton converters (annual capacity 2.5 million tons), a third slabbing mill, of 1 million tons annual capacity, and a second hot-rolling mill with an initial capacity of 2 million tons per year. In 1966, the company reportedly planned to begin construction of a pipe-casting plant capable of producing pipe of 400 millimeters diameter. According to its annual report, plans for the second oxygen-steel plant take account of the eventual possibility of continuous casting of a part of the output.

The merger plans of DHHU and Hoesch include plans for cooperation with Hoogovens and reorganization and rationalization of the three firms' output. Briefly, it provides for the concentration of pig iron and crude steel production at Hoogovens' Ijmuiden plant on the coast, with DHHU's and Hoecsh's plants concentrating on production of semimanufactures for the West German inland market at their plants in the Dortmund region. In this way the operations of the three firms will benefit from the cost advantages of easy access to richer overseas ores for crude steel production, and of a central market location for semimanufactures. Hoogovens is to exchange its holdings in DHHU for an estimated 14 to 16 percent interest in Hoesch, which will acquire DHHU's share capital. Approval of the merger by the ECSC High Authority was requested at the end of the year.

Tin.—Production of primary tin rose 14 percent while ore imports declined 17 percent. Indonesia continued to supply the bulk of ores (17,898 long tons) with smaller quantities coming from Thailand, Republic of South Africa, and the Republic of the Congo (Léopoldville).

NONMETALS

Building Materials.—Cement output increased 100,000 tons (3.4 percent), no doubt reflecting the continuing high level of construction activity in the country. Imports rose 171,000 tons, while exports increased slightly by some 3,200 tons.

Fertilizer Materials.—Production of nitrogenous fertilizers increased 4.7 percent while output of phosphatic and potassic fertilizers was unchanged. Both imports and exports of fertilizers increased; in the case of exports, only nitrogenous fertilizers (export of which rose from 455,000 to 584,000 tons) were important.

Output of sulfuric acid on the other hand rose by 12 percent to over 1 million tons (100 percent H_2SO_4).

MINERAL FUELS

The rapid structural shift in the Dutch energy market accelerated during 1965. In that year coal supplied 29 percent of total energy requirements, compared with 35.3 percent in 1964, while the share of petroleum rose to 66 percent compared with 61.7 percent in 1964, and that of natural gas more than doubled from 2.1 percent in 1964 to 4.5 percent in 1965. In the market for domestic heating, coal supplied only 39.4 percent in 1965 compared with 49.4 percent in 1964, and even in the public utilities market, hitherto a mainstay, coal's energy consumption dropped to 56.9 percent from 60.8 percent in 1964. The expanding steel industry still provided a steady market for coal but the reduction in coke consumption per ton of output as technology improves tends to restrict the possibilities of growth. The rapid growth of natural gas foreshadows a continuing decline in the role of coal.

Coal.—Production of Netherlands mines in 1965 at 11.4 million tons was practically the same as in 1964, but consumption continued to decline and pit-head stocks rose by nearly 400,000 tons to 1,282,600 tons at the yearend, representing over 10 percent of annual production. Public utilities, under government pressure, increased their takings from 4.4 million to 5.1 million tons, but deliveries to the residential, gas plants, industrial (other than iron and steel), and coke oven markets declined sharply. Total employment declined slightly, while productivity (output per man-shift) rose about 2.5 percent.

A new government policy, announced to Parliament in December, officially recognized this situation. It was announced that Staatsmijnen's Maurits mine would be closed beginning in April 1966; that the closure of Staatsmijnen's Wilhelmina mine would begin in 1970 and be completed by 1972; that the privately-owned Willem-Sophia and Domaniale mines would be phased out over a period ending 1970; and that Staatsmijnen's Emma-Hendrick mine would continue in operation after the closure of the Maurits, while the privately-owned Oranje-Nassau and Laura Veresniging mines would be kept open as long as the employment situation in South Limburg required. Provision is to be made for subsidies to the mines, as permitted by the ECSC High Authority decision of 1964, and plans are to be made for alternative economic development in the Province; the first of these, a DAF auto plant, has already been granted State financial assistance for its establishment.

At the same time it was announced that an agreement had been reached with the power stations under which they will take 1.5-1.8 million tons of Netherlands coal annually for the next 10 years, and that Hoogovens (the steel firm) has agreed to take an additional 500,000 tons annually.

A major cause of the sharp decline in coal consumption was the rapid shift to natural gas for home and industrial use. The market for thermal power use was held chiefly because government policies of restricting imports of third country coal to 1964 levels and requiring that power stations bargain separately with Gas Unie, the natural gas distributor, for gas supplies rather than permitting them to benefit from the general industrial rates announced in 1964.

The Netherlands coal industry was clearly in a stage of rapid decline, highlighted at the end of the year by Staatsmijnen's announcement that beginning in 1966 it would shift to the use of natural gas for its chemical feedstock instead of the coal derivative formerly used. The chemical side of staatsmijnen's enterprises has been the expanding and, most profitable of its business for some years.

Petroleum and Natural Gas.—The major event of 1965 in the petroleum and natural

gas industries was the enactment in September of the Continental Shelf Mining Law. Changes were made in the original draft both by the new government which came into power in the spring, and by the Parliament in the process of enacting it. The law covers not only petroleum and natural gas, but also all other mineral deposits of the Continental Shelf and prohibits prospecting, drilling or mining without licenses issued by the Minister of Economic Affairs. Two classes of exploration permits are provided for, the first an exploration (Verkenningsonderzock) or reconnaissance search permit not authorizing drilling, and the second a prospecting (Opsporingsonderzock) permit authorizing exploration by drilling. The exploitation license authorizes development and extraction of the minerals. A key provision authorizes the state to participate up to 50 percent in the development of any oil and gas mineral discoveries. Detailed implementing regulations are to be drafted and promulgated by the Minister of Economics, subject to the right of Parliament to review and approve them within 30 days of presentation by the Minister, upon the demand of one-fifth of the members of either chamber. These implementing regulations had not yet been presented to Parliament by yearend, and consequently exploration in the Dutch sector of the Continental Shelf was deferred.

In November 1965, a bill amending the 1810 Mining Law, intended to provide for regulation of on-shore exploration, was introduced into the second Chamber. To be retroactive to December 15, 1965, if enacted, it would provide for a system of prospecting and exploitation permits similar to those for Continental Shelf mineral activities. Further prospecting after December 15, 1965, was reported to be effectively discouraged pending consideration of the bill.

During 1965, two agreements were signed with the British Government delineating the boundary between the Netherlands and British Continental Shelf areas. The text of a similar treaty with Denmark was agreed on, but was still to be approved. The agreement with the United Kingdom was said to provide for the exploitation of single geological structures extending over the line of demarcation. A less extensive agreement with West Germany, signed at the end of 1964, had extended the border between the two countries for these purposes some 25 nautical miles seward to the 54th parallel.

Petroleum.—NAM's crude petroleum output expanded by 5 percent in 1964 to 2.4 million metric tons, said to represent about 12 percent of the country's total requirements for petroleum products.

The refining industry continued to grow, with total reported throughput rising to 31.2 million tons. Expansion of the capacity of Shell's Pernis (Rotterdam) refinery to 16.5 million tons per year was completed; this is said now to be the biggest refinery in Europe and one of the six largest in the world. Similarly, expansion of Esso's Botlek (Rotterdam) refinery to 8 million metric tons per year was completed, as was the Gulf refinery at Rotterdam, with capacity doubled to 3 million tons per year. Caltex planned to increase capacity of its Pernis refinery from 4.4 million tons per year to 4.8 million tons per year by May 1966.

Meanwhile, Mobil's application for a refinery at Amsterdam was approved in February 1965 by the central and local authorities; it is to be supplied with crude by a 28-inch pipeline from Rotterdam's Europoort. The initial annual capacity is to be 4 million tons, to be raised to 8 million tons by 1973.

British Petroleum (BP) reorganized its interests in the Netherlands, establishing a new company at Amsterdam to act as a holding company (British Petroleum Maatschappij Nederland N.V.), with two subsidiaries, B.P. Raffinaderij Nederland N.V. (to operate BP's new refinery under construction at Rotterdam), and Benzine en Petroleum Handel Maatschappij N.V. (to market products in the Netherlands).

The growth of the petrochemical industry continued. The Dow Chemical Co. planned an 87 kilometer pipeline from Pernis to its chemical plant at Terneuzen, to be supplied with ethylene by Royal Dutch-Shell; and work was to start in late 1965 and a pipeline from Esso's Botlek refinery to Staatsmijnen in Limburg, for shipping light naphtha to Limburg for cracking, with the ethlyene to be retained by Staatsmijnen and the cracked fuel being returned to Botlek. This line, of 20 centimenter diameter and a capacity of 500,000 tons annually, was scheduled for completion by October 1966.

Natural Gas.—The 1.1 trillion cubic meter estimate of proven reserves in the Slochteren field of Groninger was confirmed by the Netherland Geological Survey, and proven reserves in the area of Friesland, Drente, and North Holland not under concession were estimated at 55 billion cubic meters, giving the Netherlands as a whole proven reserves of about 1,161 billion cubic meters. Additional probable reserves were estimated at about 470 billion cubic meters, raising total estimated reserves to 1,631 billion cubic meters. These estimates do not include the recent finds of Petroland and NAM in Friesland, nor the old concession areas of NAM in Drente, Overijssel, and South Holland.

The 1965 deliveries of NAM Gas Unie totaled 1,569 million cubic meters compared with 746 million cubic meters in 1964. Industrial consumers took 31.6 percent of all sales in 1965, compared with 25.7 percent in 1964. Meanwhile, an additional 1 million domestic gas connections (as compared with 500,000 in 1964) were scheduled for completion in 1965, and the total was expected to rise to about 2.5 million by 1968, sufficient to meet the country's expected demand. Deliveries of natural gas were expected to rise to about 3.5 billion cubic meters in 1966.

A total of 280 kilometers of pipeline was added to Gas Unie's network in 1965, the main sections being Hilvarebeek-Sluiskill (100 kilometers), Jutphaas-Voorschoten (55 kilometers), and Ommen-Enschede (50 kilometers). A secondary line was run from Leiden to Botlek (Rotterdam) to supply gas to chemical and petrochemical companies in that area. Gas Unie planned to lay an additional 800 kilometers of pipe in 1966, including feeder lines, regional extensions, and export lines.

Petroland, a consortium of French companies, made several gas strikes in Friesland, and Mobil's discovery in territorial waters off Ameland Island (made in 1964) was reported by the company to be of considerable size. Amoco and Dijas N.V. (a subsidiary of NAM) made new strikes in North Holland. Seven companies or groups have now filed for concessions in this Province: Dyas N.V., Mobil, BP, Gulf, Petroland, Philips Petroleum, and Superior Oil.

Natural gas exports from the Netherland to Belgium came appreciably nearer as the Belgian Government finally approved Gas Export's contract with the Belgian distributing company, Distrigaz, after substantial changes in the contract required by the Government to reduce holdings of Esso and Shell in Distrigaz and to assure that a one-third interest in the firm will be controlled by the Belgian Government. Agreement on the delivery price of gas was finally reached at the end of year. A contract was also signed with Savgaz of Liege for deliveries to eastern Belgium. Construction of a pipeline along the right bank of the Rhine from Zevenaar/Emmerich to Cologne/Bergisch-Gladbach, with branches to Duisberg, Düsseldorf/Werppertal and Dürer-Aacher, was to start in mid-1965, and deliveries to West Germany under the Thyssengas contract were to begin in 1966. Deliveries under the contract signed with Ruhrgas in 1965 were expected to begin in mid-1966. Meanwhile, negotiations began between Gas Export and two other German utilities, Gas Union GmbH (Frankfurt-am-Main) and Gasversorgung Süddentschland GmbH (Stuttgart) for supply of Dutch gas to areas as far south as Württemburg; a pipeline company would be formed to build the line, with which NAM would negotiate. Conclusion of the contract was expected by the end of the year.

Negotiations continued with the British and French utilities for exports of Dutch gas to those two countries. The (British) National Gas Council and NAM awarded a contract for tests of the soil structure, etc. of the North Sea bed and English Channel in order to determine possible routes for subsea pipelines to the United Kingdom, but as exploration intensified in the British sector of the Continental Shelf British interest appeared to lag and the National Gas Council sought to delay a decision until the results of British explorations were better known. Negotiations proceeded, however, with Gaz de France, and at the end of the year a preliminary agreement was announced, subject to approval at Cabinet levels, calling for deliveries beginning in 1967, eventually to reach a total of 5 billion cubic meters annually. By the end of the year therefore, Gas Export had a total of seven agreements, firm or tentative, for export deliveries of gas to Belgium, West Germany and France.

At one point in the protracted negotiations between NAM Gas Export and the Belgian firm Distrigaz, the Belgian Government lodged a complaint with the EEC Commission concerning Gas Export's sales policy, on grounds of violating Community regulations concerning the use of monopoly power. After some investigation, the complaint (which apparently centered mainly on price policies) was withdrawn by the Belgian Government after NAM Gas Export had accepted the contract modifications desired by the Government and an agreement on prices had been reached. The issue in the EEC Commission thus was not pressed to a conclusion.

One unsettled question related to the export marketing of gas discovered by companies other than NAM, especially any that may be discovered on the Continental Shelf. Gas Unie, according to official policy, is to distribute any Continental Shalf gas sold domestically, and Gas Unie's effective monopoly of the domestic market was strengthened when Hoogovens (the Dutch steel firm) abandoned plans to distribute its own gas and signed an agreement with Gas Unie. As for potential Continental Shelf gas, it is expected that it will be marketed primarily outside the Netherlands but no indication has yet been given as to how this will be effected.

Evidence continued to accumulate of a rapid and significant shift to natural gas by industrial consumers within the Netherlands itself. Aside from the rapidly growing petrochemical industry, there were reports that Staatsmijnen (the Government-controlled coal mining firm, itself a shareholder in NAM) is converting entirely to the use of natural gas as a chemical raw material, and that Philip of Eindhoven, the largest privately-owned manufacturing firm in the Netherland, is converting also to natural gas. According to reports, Staatsmijnen is expected to become the largest single consumer of natural gas in 1966, with an eventual annual consumption estimated at 500 million cubic meters.

The Mineral Industry of Norway

By F. L. Klinger [1]

The mining and processing sectors of the Norwegian mineral industry operated at near-capacity levels in 1965, and output of the industry contributed substantially to a growth of nearly 6 percent in gross national Product (GNP) to $6.7 billion [2] (at 1961 prices). Norway remained the leading West European producer of ferroalloys, refined nickel, magnesium, and ilmenite while ranking second in production of primary aluminum and nitrogen. Low cost hydroelectric power continued to stimulate growth of the electrometallurgical and electrochemical industries; rising ferroalloy production and aluminum industry expansion being especially evident. Investment in the mining and primary metals industries was slightly less than in 1964 but was still 30 to 50 percent higher than in 1963.

Details on the value of output and employment of the Norwegian mineral industry by sectors for 1963, the last year for which such details are available, were as follows:

	Million dollars		Number of persons employed (not including owners)
	Gross value of production	Value added, at f.o.b. establishment prices [1]	
Mining industry:			
Coal mines	3.86	3.51	670

Source: Statistisk Sentralbyra (Oslo). Industristatistikk 1963; Statistisk Arbok 1965; and Statistisk Manedshefte, No. 4, 1966. (Central Statistical Bureau (Oslo)). Industrial Statistics 1963; Statistical Yearbook 1965; and Monthly Statistics, No. 4, 1966.

In 1963, the GNP in current prices was $6,320 million.

Offshore boundary agreements negotiated with the United Kingdom and Denmark, and timely legislative action by the Government, led to increased activity in the search for oil and gas in Norwegian areas of the North Sea. The Government conducted geophysical surveys in middle and north Norway, and aeromagnetic maps covering parts of these regions were published. Three of the larger private com-

panies were coordinating prospecting activities and there appeared to be increasing public demand for exploration of the country's mineral resources. Meanwhile, new mines and plants were completed or under construction in several branches of the mineral industry, and the prospects for continued growth appeared to be good.

PRODUCTION

Output of the mining industry in 1965 was 7.4 percent greater than in 1964. Production of metal mines and stone, sand and gravel quarries rose more than 10 percent while mineral quarrying (quartz, feldspar, mica, etc.) increased approximately 2 percent, and output of coal showed a slight decline.

Led by 20-percent increases in production of pig iron, ferroalloys, magnesium, and copper, output of the primary metals industry was 11 percent greater than in 1964. Output of iron and steel, ferroalloys, aluminum, zinc, magnesium, and cobalt was at record levels, and production of nickel and copper was the highest in several years. The index of production for nonmetallic mineral manufacturing increased by 5 percent. In the chemical industry, output of nitrogen and sulfuric acid increased by 7 and 9 percent, respectively, and production of fertilizer and titanium pigment increased. In the energy sector, electric power production rose by 11 percent, but petroleum refining was slightly below the level of 1964.

TRADE

Norwegian trade in mineral commodities increased in 1965, with the overall pattern remaining the same as in 1964. The aggregate value rose to $1,015 million compared with $945 million in 1964. Relationships between mineral commodity trade and total Norwegian trade are shown in the following tabulation:

	Value (million dollars)		Mineral commodities' share of all trade (percent)
	Mineral commodities [1]	All trade [2]	
Exports:			
1963	374.9	1,073.1	34.9
1964	466.5	1,290.3	36.1
1965	488.6	1,442.6	33.8
Imports:			
1963	414.3	1,821.0	22.7
1964	478.3	1,982.3	24.1
1965	526.6	2,205.7	23.8
Net trade balance:			
1963	−39.4	−747.9	XX
1964	−11.8	−692.0	XX
1965	−38.0	−763.1	XX

XX Not applicable.
[1] Excluding gold and precious stones. In 1964, value of gold (unwrought and semimanufactures) was as follows: Exports, $36,000; imports, $1,292,000. Imports of precious stones in 1964 were valued at $389,000.
[2] Excluding gold.

The increased deficit in mineral commodities shown for 1965 was principally due to increased imports of nickel matte and zinc concentrate, coupled with reduced exports of nickel and aluminum. The effect of unusually large imports of chemical fertilizer in 1965 was countered by a $12 million increase in exports. The following table shows the relative importance of the principal mineral commodities in 1964 and 1965.

	Value (million dollars)		Mineral commodity share of trade (percent)	
	1964	1965	1964	1965
Export:				
Nonferrous metals:				
Aluminum [1]	123.8	119.7	26.5	24.4
Nickel [1]	58.6	53.3	12.5	10.9
Other [1]	47.2	56.1	10.1	11.4
Iron and steel:				
Ferroalloys	53.9	61.6	11.5	12.6
Other [1]	48.1	50.2	10.3	10.2
Fertilizers	53.0	65.2	11.3	13.3
Petroleum products	29.1	23.8	6.2	4.8
Import:				
Mineral fuels:				
Solid	22.4	21.8	4.6	4.1
Petroleum products	145.3	140.7	30.3	26.7
Iron and steel [1]	118.6	129.6	24.7	24.6
Alumina	34.7	36.9	7.2	7.0
Nickel-copper matte	47.7	58.7	9.9	11.1
Nonferrous metals [1]	49.5	54.7	10.3	10.3
Fertilizers (manufactured)	5.1	15.0	1.0	2.8
Zinc concentrates	7.1	10.8	1.4	2.0

[1] Including scrap.

The principal trading partners continued to be the United Kingdom, West Germany, Sweden, and the United States. The United Kingdom was the largest supplier and West Germany the largest buyer. Increased exchanges of metals and metallic ores led to a 20-percent increase in the volume of trade with Sweden. Trade with the United States increased in coal, petroleum products, and nickel but declined in aluminum. Canada continued to rank second in the total volume of imports because of large shipments of nickel matte.

[7] Including manufactured articles (380 tons in 1963 and 438 tons in 1964).

COMMODITY REVIEW

METALS

Aluminum.—Norway's productive capacity and output of primary aluminum continued to increase in 1965. The rise in production was partly due to a 14,000-ton expansion in smelter capacity completed early in the year by A/S Norsk Aluminium Co. (NACO) at Høyanger. NACO's installation of a second potline increased total capacity to 28,000 tons annually. Through its subsidiary, A/S Nordisk Aluminiumindustri at Holmestrand, NACO also expanded production capacity for semimanufactures to the same level. The NACO expansion entailed an investment of approximately $14 million.

A/S Ardal og Sunndal Verk continued to account for the major share of Norwe-

gian production in 1965. The State-owned firm reportedly produced 160,700 tons of primary aluminum (152,200 tons in 1964) and 7,600 tons of alloys (12,400 tons in 1964), while deliveries dropped to 144,000 tons (165,900 tons in 1964).[3] Early in the year, the company announced plans to increase capacity of the Sunndalsøra smelter by 45,000 tons annually, by the fall of 1968. Plans include two new potlines and increased hydroelectric facilities, for an investment estimated at $41 million.

New production and sales records were reported in 1965 for primary aluminum made by Møsjoen Aluminum A/S. The Aluminum Company of America and Elektrokemisk A/S, joint owners of the Møsjoen company, announced plans to build an aluminum smelter at Lista, south of Stavanger. Initial production at Lista is expected to be 20,000 to 30,000 tons annually, starting in 1970 or 1971. Earlier in 1965, the firms announced plans to increase capacity of the Møsjoen smelter 23,000 tons by 1967–68.

Sør-Norge Aluminium A/S continued construction of a smelter at Husnes on Hardanger Fjord. Completion of the first of two potlines was expected before year-end, and completion of the second was expected by April 1966.

Another new smelter with a planned annual capacity of approximately 80,000 tons was under construction at Karmøy (northwest of Stavanger) by Alnor A/S, 51 percent of which is owned by Norsk Hydro-Elektrisk Kvaelstof A/S (Norsk Hydro) and the remaining 49 percent is owned by Harvey Aluminum, Inc. An integrated operation to produce aluminum semimanufactures as well as ingots is planned. Investment in the project reportedly totaled $84 million.

Developments in Norwegian primary aluminum capacity are summarized in the following table.

Production of high-purity (99.99 percent) aluminum was continued by A/S Vigeland Brug near Kristiansand.

The value of Norwegian exports of aluminum in 1965 was $4 million less than in 1964, despite increased domestic production. Reduced deliveries of ingot to West Germany, the United Kingdom, and the United States were partially offset by increased shipments to Sweden, Italy, and Switzerland. Imports of alumina from Jamaica increased to 223,000 tons, while shipments from the United States and Guinea were reduced. Total imports of alumina were valued at $36 million.

Columbium.—The Søve columbium mine in Telemark, operated by A/S Norsk Bergverk, was closed on September 1, 1965. In operation since 1953, the mine produced approximately 3,300 tons of pyrochlore concentrate containing 50-percent columbium oxide and a relatively low proportion of tantalum. Part of the concentrate was used in manufacturing ferrocolumbium, and the rest was exported. The mine was the only producer of columbium in West Europe.

Copper.—The 20-percent rise in output of refined copper in 1965 was apparently due to the increased volume of copper-nickel matte processed by Falconbridge Nikkelverk A/S at its Kristiansand refinery.

There was no appreciable change in output of copper from Norwegian mines in 1965, although two small producers had ceased operations during 1964. A/S Sulitjelma Gruber, the leading domestic producer, was increasing productive capacity by a $14 million expansion and modernization program. Norwegian exports of unrefined copper, probably representing Sulitjelma's smelter output, were slightly less than 5,000 tons in 1965 and were mostly sold to West Germany.

Folldal Verk A/S continued development of cupriferous pyrite deposits at Hjerkinn, 125 kilometers south of Trondheim in the Døvre mountains. Production at the Folldal mine, 20 kilometers east of Hjerkinn, was gradually being phased out. The Hjerkinn deposit, 2 kilometers from the Trondheim-Oslo railway, reportedly contains 0.7 to 2 percent copper.

Norwegian exports of copper in 1965 were valued at $7 million over that of 1964, because of an increase of nearly 4,000 tons of refined copper which went primarily to West Germany and Sweden. The value of imports also increased by $5 million, due primarily to a 1,500-ton increase in copper bars and wire.

Iron and Steel.—*Iron Ore.*—The 1965 increase in iron ore production was due mainly to the first full year of operations of the State-owned Rana mine and con-

[3] Metal Bulletin, No. 5104, June 10, 1966, p. 24.

Table 4.—Norway: Primary aluminum producers and plants

Company	Ownership or affiliation (percent)	Location	Production capacity, metric tons per year		
			Installed 1965	Under construction (UC) or planned (p) [1]	Approximate date of completion
A/S Ardal og Sunndal Verk	Norwegian Government	Ardal	110,000

	Harvey Aluminum, Inc. (49)	----do			
Total			278,000	228,000 to 238,000	

[1] Not including possible eventual expansions at Husnes (to 180,000 tons), Karmøy (to 120,000 tons), Møsjoen (to 105,000 tons), or Lista (to 100,000 tons).

centrator in northern Norway. An estimated 260,000 tons of concentrate was produced by Rana Gruber A/S in 1965. Production followed several years of research and testing of the complex magnetite-hematite ore, which contains 33 percent iron. The concentrate was delivered to the nearby steelworks of Norsk Jernverk A/S at Mo-i-Rana.

Because of the shipments from Rana, deliveries of concentrate by A/S Sydvaranger to Norsk Jernverk in 1965 were reduced from 400,000 tons to 145,000 tons. Production of concentrate at Sydvaranger, Norway's largest iron mining operation, was 1.51 million tons. The company was encountering strong competition in West European markets from African iron ores, and total sales in 1965 were 3 percent less than in 1964. In order to meet competition, Sydvaranger has decided to pelletize its entire output of concentrate. Production of pellets at the rate of 1.2 million tons annually is expected to begin in 1968. Under a $10 million expansion plan, the company expects to increase production of concentrate to 2.4 million tons annually by 1970. To achieve this level of production, overburden stripping at the rate of 7 million tons annually will be required. Open pit mining was expected to continue for another 25 years. In Finnmark, the company continued geophysical studies and diamond drilling.

Two other companies decided to build pelletizing plants in 1965—Fosdalens Bergverks A/S, a State-owned company that produces about 260,000 tons of concentrate annually, and Orkla-Grube A/B which recovers a small tonnage of iron concentrate from pyrite mining operations. The only pelletizing plant operating in Norway in 1965 had an annual capacity of 520,000 tons per year and was operated by Norsk Jernverk at Mo-i-Rana.

Development work was continued by Fosdalens Bergverks on new ore bodies at Malm. The company was sinking a circular, 6-meter-diameter shaft which was expected to reach a planned depth of 1,175 meters in 1966. Production from the East ore body was expected by 1970. Minimum cost of the development program was estimated at $7.5 million.

A/S Rødsand Gruber, a subsidiary of Christiania Spigerverk A/S, produced 136,000 tons of concentrate in 1965 from its underground operations at Sunndalsfjord in west Norway. A new shaft was being sunk to the 650-meter level.

Expansion of ore-handling and shipping facilities at the port of Narvik was continued, and the first 50,000-ton vessel was loaded in early 1965. Loading capacity at the port is being increased from 6,000 to 8,000 tons per hour and ships of 65,000-ton capacity were expected to be accommodated by yearend. Total shipping capacity of the port will be increased to 20 million tons annually. The Swedish company, Luossavaara-Kirunavaara A/B (LKAB), which accounts for practically all ore shipments from Narvik, has invested about $5.6 million in the development project.

Exports of Norwegian iron ore in 1965 were valued at $1.5 million less than in 1964. Shipments to West Germany and the United Kingdom were reduced by 230,000 tons and 75,000 tons, respectively, while deliveries to Finland totaled 125,000 tons.

Ferroalloys.—Production of ferroalloys sharply increased for the second consecutive year. Ferrosilicon and ferromanganese accounted for most of the increase. Imports of manganese ore increased in value by $5.8 million, with deliveries from Ghana increasing by nearly 100,000 tons, while the value of chromite imports dropped by $1 million, compared with 1964. The value of ferroalloy exports was more than $61 million, an increase of about $8 million over the 1964 level. Exports of ferromanganese increased by 28,000 tons, exports of ferrosilicon by 21,000 tons, and exports of ferrosilicochrome increased by 11,500 tons. Exports of ferrochrome were reduced by 7,500 tons.

Elektrokemisk A/S continued construction of the Salten Verk ferrosilicon plant at Fauske in northern Norway. The $5 million facility will employ about 100 persons when production begins in the spring of 1967. A 24,000-kilovolt-ampere ferrochrome furnace was also under construction at the Alvik works of A/S Bjølvefossen.

Pig Iron.—The 20-percent increase in pig iron production was almost entirely due to expanded operations at Mo-i-Rana by Norsk Jernverk A/S. The State-owned company reportedly produced 450,000 tons in 1965 (355,000 tons in 1964), and the remainder was produced mostly by Christiania Spigerverk A/S. Production capac-

ity at Mo-i-Rana was increased by 360,000 tons annually in 1964 by completion of two 60,000-kilovolt-ampere furnaces. Norwegian productive capacity in 1965 was about 710,000 tons annually and was expected to increase about 10 percent in 1966.

Steel.—Crude steel output continued to rise in 1965 and appeared to be close to capacity production. Two-thirds of total output was produced at Mo-i-Rana by Norsk Jernverk A/S. Most of the remainder was produced by Christiania Spigerverk. An estimated 25,000 tons of special steel was produced at Jorpeland by Stavanger Elektro-Staalverk A/S. Sixty percent of total output was again produced in electric furnaces, with the remainder produced in two 40-ton Linz-Donawitz converters at Mo-i-Rana. An estimated 385,000 tons of scrap was consumed in steel manufacture, compared with 356,000 tons in 1964. Rolled steel output by Norsk Jernverk in 1965 amounted to 366,000 tons.

Trade in steel was about the same as in 1964, although total semimanufacture imports increased by 40,000 tons and rose $4 million in value. The change was mainly due to increased imports of heavy plate. In crude forms, the principal import continued to be coils for re-rolling, and the main export items were slabs and sheet bars.

The report of the Backe Committee, which was formed in 1964 to determine the causes of financial losses resulting from State operations in the iron and steel industry (Norsk Jernverk A/S and Norsk Koksverk A/S), was completed in 1965. It recommended that Norsk Jernverk take over operations of Norsk Koksverk, that it be exempted from interest payments on its loan capital, and that its capitalization be reduced from $48 million to $35 million. Refinancing of the enterprise was to be provided by the Government, Elektrokemisk, and Christiania Spigerverk, with the latter firm requested to reorganize the company and to supervise its operations.

In other developments, technicians from Christiania Spigerverk were sent to Tunisia to assist in establishment of operations at a new rolling mill being built at Elfouadh, and Tunisian engineers and workers were being trained at the company's plant in Oslo.

Lead and Zinc.—Lead concentrate production in 1965 remained at the 1964 level, but metal content increased by 14 percent. A/S Bleikvassli Gruber operations at Korgen continued to account for almost all production. Concentrate exports to the United Kingdom were only half the quantity shipped in 1964, while deliveries to Belgium increased. Metal imports from South Africa and Peru were sharply reduced in 1965.

Zinc concentrate output was little changed from the levels of the previous 3 years, the Bleikvassli mine being the principal producer. Increased concentrate output by the Sulitjelma and Folldal companies was expected to result from expansion and development projects underway in 1965. The pyrite ore body being developed by Folldal Verk at Hjerkinn was reported to contain 1.2 percent zinc. At Eitrheim, electrolytic zinc production by Det Norske Zinkkompani was an alltime record, and the refinery's capacity was being increased.

Zinc concentrate exports to West Germany in 1965 increased by nearly 4,000 tons, while concentrate imports from Sweden were doubled as compared with those of 1964. However, metal exports decreased owing to reduced shipments to West Germany. Unwrought metal imports from the Soviet Union increased 150 percent to more than 5,000 tons in 1965. These developments brought the value of zinc imports close to the level of exports as compared with a trade surplus of almost $6 million in 1964.

Magnesium.—Production and exports of magnesium continued to increase in 1965. Exports were valued at $14.3 million and included nearly 20,000 tons shipped to West Germany.

Norway was concerned over a proposal by the European Economic Community (EEC) Executive Commission to levy a 1.5-percent duty on magnesium now imported under duty-free quotas from countries outside the EEC. Norwegian exports filled about half of the EEC duty-free quota of 37,000 tons for 1965. The principal buyer of Norwegian magnesium is the Volkswagenwerke A.G. in West Germany.

Norsk Hydro, sole magnesium producer, was converting a chemicals plant at Rjukan in Telemark for the production of magnesium extrusions and castings. The company's subsidiary, A/S Rjukanmaskiner,

was scheduled to start production in 1967. The project involves an investment of $1.5 million.

Molybdenum.—A major increase in production was reportedly planned at the molybdenum mine of A/S Knaben Molybdaengruber, at Fjotland in southwest Norway. At a cost of $1.4 million, annual production is to be increased to an estimated 450,000 tons of crude ore and 800 tons of concentrate.

Nickel.—Nickel production in 1965 at the Kristiansand refinery of Falconbridge Nikkelverk A/S was the second highest on record. As a result, Norwegian production of refined copper and cobalt sharply increased, and output of sulfur dioxide, selenium, and precious metals was probably increased as well. The raw material processed by the refinery is copper-nickel matte from Canada, with typical metal content as follows, in percent: Nickel—48, copper—27, sulfur—22, cobalt—0.8, iron—0.9, arsenic—0.13, lead—0.6, and selenium—0.04. Gold, silver, and metals of the platinum group are also recovered.

The refinery's nickel production capacity will be increased to 40,000 tons annually. More than $1.5 million was spent by the company in 1964–65 for process improvements and quality control.

Despite the high refinery output, exports of nickel were less than in 1964 and declined in value by $5 million. Exports to the Common Market decreased by 3,000 tons. At the same time, matte imports increased by 10,000 tons and increased by $12 million in value, compared with 1964.

Titanium.—Norway's production capacity for ilmenite and titanium pigment continued to increase in 1965. Approximately 280,000 tons of ilmenite concentrate and 85,000 tons of magnetite concentrate were produced by A/S Titania at Sokndal. Ore production was mostly from the company's open pit mine at Tellnes. The Størgangen underground mine was reported to have been closed. With development of the Tellnes mine, the ore-slurry pipeline, and the concentrator and shipping facilities at Sokndal, the company's productive capacity was increased to 400,000 tons of concentrate annually. The development program, started in 1957, has cost a minimum of $10 million. Ore reserves of the company were reported to be 350 million tons.

At Fredrikstad, Titan Company A/S was increasing capacity for production of titanium dioxide from 7,500 to 15,000 tons annually. Plant expansion will be completed in 1966. Both A/S Titania and Titan Co. A/S are subsidiaries of the National Lead Co.

Increased export demand for Norwegian ilmenite in 1965 was met by withdrawals from stocks. Shipments to West Germany and Italy were increased by 26,000 tons and 20,000 tons, respectively, compared with 1964. Total ilmenite exports were valued at $3.8 million, while titanium oxide imports were valued at $2.8 million in 1965.

NONMETALS

Abrasives. — Norton Norge A/S, subsidiary of the Norton Co. of Massachusetts, began production of silicon carbide in August at its new plant in Lillesand. Productive capacity of the plant is 8,000 tons annually, raising total Norwegian capacity to 38,000 tons. Other silicon carbide producers are Arendal Smeltverk A/S, at Eydehavn, with annual capacity of 24,000 tons, and the Løkken Verk plant of Orkla Exolon A/S and Company which has a capacity of 6,000 tons. The Arendal firm is a subsidiary of The Carborundum Co. of Niagara Falls, N.Y., and the other firm is a subsidiary of the Exolon Co. of Tonawanda, N.Y.

Cement.—Production and exports of cement remained very close to 1964 levels although annual productive capacity was increased by an estimated 180,000 tons in 1965. Total productive capacity by the end of the year was estimated at 1.66 million tons and was expected to increase to 2.1 million tons by the end of 1966.[4]

The expansion program of A/S Dalen Portland-Cementfabrik was nearing completion at yearend, and annual capacity of the Brevik works was expected to reach 1.2 million tons in 1966. This program, carried out over the past 6 years, has required an estimated investment of $31 million. Two horizontal kilns were installed in 1964 and the 23-foot-diameter Aerofall mill scheduled for delivery in 1965 was reportedly the first of its type to be used outside of the United Kingdom. The company was considering using the

[4] Organization for Economic Cooperation and Development (OECD) (Paris). The Cement Industry. Statistics 1964 and Trends in 1965. September 1965, 88 pp.

present crushing plant to produce crushed stone aggregate for export when the new mill is installed.

In Oslo a new rotary kiln was ordered by A/S Christiania Portland Cementfabrik. The kiln will increase productive capacity of the company by 500,000 tons annually in 1967.

Exports of cement in 1965 were slightly less than in 1964 but increased 14 percent in value to nearly $3.5 million. The United States continued to be the principal market, followed by West Africa. Under a 10-year agreement reached in 1960, production and sales of the three Norwegian producers (including Nordland Portland Cementfabrik) are coordinated through the Norwegian Cement Association in Oslo.

Fertilizers.—Fertilizers, mostly manufactured from nitrogen and nitrogenous products made in Norway, continue to rank with ferroalloys and nickel as one of the principal mineral export commodities. Exports in 1965 were valued at $65 million and accounted for 72 percent of the total value of nonmetal exports. The trade surplus increased to $46.8 million despite unusually large imports required to meet domestic commitments.

Accounting for almost the entire domestic output of nitrogenous products, Norsk Hydro increased production in 1965, and sales ($82.6 million) were 11 percent higher than in 1964. Output included 1,353,000 tons of calcium and ammonium nitrates; 366,000 tons of compound fertilizers ("nitrophoska"); 148,000 tons of urea; 19,700 tons of nitric acid; and 17,000 tons of liquid ammonia. The company also accounts for most of the limestone consumed by the basic chemicals industry (including fertilizers), estimated at approximately 1 million tons in 1965.

At Herøya, a fuel oil gasification plant for production of 100,000 tons of ammonia per year was completed by Norsk Hydro in October. Cost of the plant was estimated at $14 million. The company also decided to build another plant at Herøya in 1967. The plant will increase ammonia production by an additional 275,000 tons. Both plants will use the steam reforming process, with naphtha as raw material.

Domestic consumption of fertilizer materials in Norway in 1964–65 was estimated at 58,000 tons nitrogen, 55,000 tons of potash, and 45,000 tons of phosphorus pentoxide.

The Soviet Union and Spain, respectively, continued to supply most of Norway's import requirements for phosphate and potash in 1965. Extra import requirements were mainly supplied by the Netherlands.

Pyrite.—Pyrite production remained at the level of the previous 2 years. Cupriferous pyrite accounted for an estimated 60 percent of total output and was produced mostly by Orkla-Grube A/B at Meldal and by Elektrokemisk A/S at Namsskogan. Orkla produced 231,300 tons in 1965. The principal producers of noncupriferous pyrite continued to be A/S Sulitjelma and A/S Stordø Kisgruber, with the latter company producing 69,000 tons in 1965. At least seven other companies produced pyrite, along with byproduct concentrates of copper, zinc, lead, and other metals.

Elektrokemisk acquired control of the Sulitjelma company in 1965. The resulting combination of production capacity for pyrite was estimated at 260,000 tons annually. Explorations of prospective ore bodies in the Fauske region were continued. A joint organization was formed by Elektrokemisk, Orkla, and Sulitjelma in 1965 to coordinate prospecting activities.

Additional drilling of the pyrite deposits at Hjerkinn by Folldal Verk A/S in 1965 reportedly increased known ore reserves. Previous reports indicated proven reserves of 8 to 10 million tons containing approximately 30-percent sulfur. Mining at the rate of 300,000 tons annually was expected to begin in 1966 or 1967 with a yield of 160,000 tons of pyrite, and the company hopes to eventually double this output. Folldal Verk is a subsidiary of A/S Borregaard, a Norwegian pulp and paper company. A large sulfuric acid plant was being built for Borregaard at Sarpsborg (south of Oslo) by Dorr-Oliver, Inc. Scheduled for completion by the end of 1966, the plant will have an annual capacity of 200,000 tons of acid. Pyrite will be shipped by rail from Hjerkinn. Total investment in the mine and plant facilities was reported to be $15 million.

In other developments, Orkla-Grube A/B was using a new subshaft between the 380- and 930-meter levels at Løkken for exploration and development work in the

western part of the ore body. In Finnmark, cupriferous pyrite deposits near Kautokeino in the Bidjovagge region were estimated at 3.6 million tons by the Norwegian Geological Survey.

An 8-percent drop in pyrite exports in 1965 was attributed to a 48,000-ton reduction in shipments to Czechoslovakia. Shipments to Sweden increased by 30,000 tons and compensated for reduced deliveries to West Germany and Denmark.

Stone, Sand and Gravel.—The building stone industry continued to export approximately 40,000 tons each of syenite and slate, mostly to Common Market countries. Total exports were valued at $5.7 million, with syenite ("labrador" or "larvikite") accounting for the largest share. At Skjervøy in Finnmark, A/S Norsk Nefelin continued to increase production of nepheline syenite for the domestic glass and ceramics industries as well as for export. Olivine production was also increased at the State-owned mine and plant south of Ålesund, and exports of sand and gravel increased in value to $1.2 million in 1965.

Other Nonmetals. — Increased graphite output by the Skalands and Jennestad companies north of Narvik led to an increased value of exports (to $800,000), with the United States purchasing 3,700 tons. Quartz production included 9,600 tons of high-grade crystal. Exports of talc and feldspar declined slightly in 1965, to a combined value of $3.4 million, with total shipments to the United Kingdom reduced by 17,000 tons. A decrease in mica production was accompanied by imports of more than 6,000 tons from India.

MINERAL FUELS

Coal and Coke.—Although coal output from the Spitzbergen mines was only slightly less than in 1964, continued production on this scale appeared to depend largely on West German purchases as well as on successful operation of the State-owned cokeworks (Norsk Koksverk A/S) at Mo-i-Rana. Increasing mine costs and the relatively low quality of coal led the sole producing company, Store Norske Spitzbergen Kulkompani, to predict an operat- loss of NKr12 to 14 per ton for the 1966 season. Deliveries by the company in 1965 included 175,000 tons to Norsk Koksverk and 138,000 tons to West Germany, with the remainder of production mostly shipped to private customers in north Norway and to the Norwegian State Railways.

Increased coke requirements of the iron and steel industry and the poor coking qualities of Spitzbergen coal appeared to be responsible for appreciable changes in Norwegian coal and coke trade in 1965. Increased coal exports to West Germany were accompanied by an increase of 115,000 tons of imports (mostly coking coal) from the United States. Coke imports from the United Kingdom declined by 110,000 tons, while there were unusually large exports of low-priced coke, mainly to Rumania, Denmark, and Venezuela.

Norsk Koksverk's coke output appeared to be close to rated capacity in 1965, although much of the product was low grade. It was later reported that acceptable coke could be produced by mixing equal proportions of West Virginia coking coal with the Spitzbergen product. The plant was also unable to fulfill scheduled deliveries of ammonia to the Glomsfjord works of Norsk Hydro. These difficulties were partly responsible for a $5 million loss sustained by Norsk Koksverk in 1965.

Coal consumption in Norway in 1964 was reported to be 521,000 tons, of which cokeworks accounted for 26 percent; the iron and steel industry, 21 percent; other industry 20 percent; railroads and gasworks approximately 7 percent each; and the remainder by other consumers. Total coke consumption in the same year was 415,000 tons, of which the iron and steel industry accounted for 82 percent.

Petroleum.—*Exploration.*—Although not a signatory of the 1958 Geneva Convention on Law of the Sea, Norway negotiated offshore boundary agreements based on the median line principle with the United Kingdom and Denmark in 1965. By September, the Government had granted 21 petroleum-exploitation licenses to eight companies or groups of companies, covering a 40,000-square-kilometer area of the North Sea southwest of Stavanger. The concession holders include Esso Exploration Norway, Inc.; A/S Petronord, 20 percent of which is owned by Norsk Hydro and 80 percent is owned by a group of seven French companies; Caltex (California Asiatic Oil Co. and Texaco Overseas Petroleum Co.); A/S Norske Shell; Norwegian Gulf Oil Production Co.; the Phillips group (Phillips Petroleum Co.,

with subsidiaries of Petrofina S/A of Belgium and Ente Nazionale Idrocarburi of Italy); Syracuse Oils Norge A/S; and the Amoco-Noco group (Amoco-Norway Oil Co., Amerada Petroleum Corp. of Norway, and Norwegian Oil Consortium A/S). Esso and Amoco were expected to begin drilling in 1966. Shell, Petronord, and Phillips planned to begin drilling in 1967. Most of the companies have been conducting explorations in the area since 1963.

Under a royal decree issued by midyear, the Government's share of income from oil production is expected to be 56.25 percent, including a 10-percent royalty. One-fourth of the exploitation concessions must be relinquished after 6 years, and an additional one-fourth must be relinquished after the next 9 years.

Five exploration licenses, covering areas outside of the exploitation concessions, were also granted in 1965. The recipients included A/S Petronord, Esso, Phillips, Amoco, and Norske Murphy Oil Co.

Three companies were formed to provide servicing for offshore operations: International Offshore Services; Norwegian Oil Repairs & Supply Co. Ltd. (NORSCO A/S); and North Sea Exploration Service A/S. The companies were formed by Norwegian shipping interests, with the participation of British, French, Dutch, and Canadian firms.

On Spitzbergen, Caltex began drilling at Blåhuken, 70 kilometers south of the coal mines at Longyearbyen, after 5 years of prospecting and geophysical work. The 24-inch-exploration hole was expected to reach a depth of 3,000 meters by mid-December but was still being drilled at yearend. Caltex had a 2,010-square-kilometer exploration concession and was applying for 260 square kilometers of adjacent area. Investigations on Spitzbergen were also being conducted by the Soviet group, Arktikugol, and Norsk Polar Navigasjon A/S.

Refining.—In early 1965, A/S Norske Esso announced completion of a lubricant refinery at Valløy. The new plant, built by Lurgi A.G. of West Germany, has an annual capacity of 31,000 tons of lubricants and was reported to be one of the most advanced of its type in Europe. The company was also expanding capacity of the Slagen refinery to 19 million barrels of crude oil per year. By yearend, total investment of the company in its two plants, located 75 kilometers south of Oslo near Tønsberg, was estimated at $42 million.

At Risvika, near Stavanger, A/S Norske Shell was building a 2-million-ton refinery, scheduled to go on stream in 1967. Prime contractor for the $40 million project was a subsidiary of the Italian firm, Ente Nazionale Idrocarburi. Underground storage space for 220,000 tons of crude oil was being blasted from solid rock, and port facilities will accommodate tankers of up to 85,000 tons deadweight.

Petroleum Trade and Consumption.—While crude oil imports from Saudi Arabia, Iraq, and Libya were substantially reduced in 1965, those from Venezuela were increased by 900,000 tons. Total value of crude oil imports in 1965 was $47.5 million.

Trade in petroleum products was below the levels of 1964, with imports valued at $93 million and exports valued at $23 million. Imports from The Netherlands Antilles declined by 119,000 tons (principally fuel oils), while exports of petroleum products to Denmark and The Netherlands decreased by 164,000 tons and 130,000 tons, respectively, as compared with 1964. Trade in lubricants showed no appreciable change from 1964 and output of the Valløy refinery appeared to be absorbed by domestic consumption.

Petroleum product consumption (for fuel) in 1964 was estimated at approximately 3.9 million tons, of which fuel oils comprised 78 percent and motor gasoline comprised 15 percent. Increased petroleum coke consumption was reflected by imports, which rose to 177,000 tons in 1965, compared with 115,000 tons in 1963.

Electric Energy.—Electric power production increased to 48.8 billion kilowatt-hours in 1965. Principal consumers continued to be the primary metal, chemical, and paper industries. Total installed capacity of Norwegian powerplants at the end of 1965 was estimated at 9,640 megawatts, of which hydroelectric plants accounted for nearly 99 percent. An additional 680 megawatts of hydroelectric capacity was scheduled for service in 1966. In 1964, thermal powerplants accounted for only 0.2 percent of total electricity production and were fueled exclusively by petroleum products.

In the atomic energy field, the Institutt for Atomenergi (IFA) and Norsk Hydro A/S agreed to cooperate in plans for construction of a land-based nuclear powerplant. The proposed plant would be a 400,000-kilowatt heavy-water reactor located at Herøya. Project cost was estimated at $84 million, and construction was scheduled to begin in 1970. The only nuclear reactors now operating in Norway include a 20,000-kilowatt reactor at the Halden research center near Fredrikstad and several smaller experimental units. In other developments, the IFA director stated that joint Norwegian-Swedish research had reached a point where a decision was needed by 1966 on whether to build a prototype nuclear merchant vessel with a 67,000-ton capacity or to phase out the research program.

The Mineral Industry of Poland

By Bernadette Michalski [1]

High rank coal, sulfur, and zinc were Poland's principal mineral products in 1965. Although sizable aluminum, iron and steel, and petroleum refining industries have been recently developed, these industries are dependent upon raw materials imported principally from the Soviet Union and Hungary.

According to Polish sources, the value of total industrial output in 1965 increased 9 percent over that of 1964, approximately the same increase as was recorded in 1964 with respect to that of 1963. On the basis of a 1963 reported industrial product of Zl448,400 million,[2] a 1965 industrial production value of about Zl530,000 million is indicated.

The extractive industry lagged behind the overall industrial growth through 1964, with an increase of only 5 or 6 percent [3] with respect to output of 1963. The mineral industry's most significant contributions to the increased industrial output were the marked increase in the production of petroleum refinery products and elemental sulfur.

Leading developments in the mineral industry included the beginning of operation of an oxygen converter facility, and two coking coal batteries at the Lenin Iron and Steel Plant at Nowa Huta, the commissioning of a second processing plant at the Tarnobrzeg sulfur deposit, the opening of the Kazimierz brown coal mine, and the construction of additional facilities at the Plock refinery.

PRODUCTION

While aluminum production declined slightly from that in 1964, output of the petroleum and sulfur industries was greatly increased. The production of most other mineral industry products increased moderately, but in many cases failed to achieve planned goals. Commodities for which output fell short of planned goals were as follows: Natural gas 18 percent, brown coal 8 percent, electric power 2 percent, coke 2 percent, and lime 1 percent.

[1] Commodity research specialist, Division of International Activities.

[2] Throughout this chapter, the official currency unit of Poland, the zloty (Zl), has been used rather than the U.S. dollar because actual exchange rates differ considerably from the official Zl 1=US$0.25. In most cases, the zloty is overvalued.

[3] As indicated by United Nation's industrial production indices.

TRADE

The value of Poland's mineral trade in 1964 (the latest year for which full detailed data are available) increased exports rising by 7.6 percent and imports by 24.7 percent. Reported value of mineral trade and total trade and the share of total trade accounted for by mineral commodities are given in the following tabulation:

	Value (thousand zloty)		Share of total mineral commodities (percent)
	Mineral commodities	Total	
Exports:			
1963	r 1,960	7,080	27.7
1964	2,110	8,386	25.1
Imports:			
1963	r 1,797	7,916	22.7
1964	2,241	8,289	27.0
Trade balance:			
1963	+ 163	− 836	XX
1964	− 131	+ 97	XX

r Revised. XX Not applicable.

The U.S.S.R. which accounted for a third of Poland's total trade, remained the country's foremost trading partner. Continued dependence on the U.S.S.R. was evident; Poland's three largest investment projects, the Plock refinery, the Pulawy nitrogen plant, and the Lenin Iron and steel Works are principally, if not totally, dependent upon crude petroleum, natural gas, and iron ore imported from the U.S.S.R.

Reports on trade agreements revealed that about 87 percent of Polish machinery and equipment exports and about 60 percent of the Polish fuel and raw material exports will be directed to the Soviet Ekonomicheskoy Vzayimopomshchi (SEV) countries.[4]

[4] Council of Mutual Aid set up under an intercountry agreement that includes Albania, Bulgaria, Czechoslovakia, East Germany, Hungary, Mongolia, Poland, Rumania, and the U.S.S.R.

COMMODITY REVIEW

METALS

Aluminum.—The construction industry reported serious shortages of aluminum sheet and profiles. These shortages warranted the establishment of a commission to restrict the use of aluminum in construction.[5] The shortage was in part attributed to repeated delays in opening of the Konin Aluminum Plant. The first stage of the plant was most recently scheduled to come on stream in late 1966 with an annual capacity of 50,000 tons of aluminum.

Copper.—The H. Walecki Copper Metallurgical Plant at Legnica was undergoing expansion. By 1968, plant capacity is anticipated to be 60,000 tons of electrolytic copper annually. The Legnica plant was undergoing expansion to accommodate ores from the Lubin and Polkowice I mines now under development.[6]

Iron and Steel.—Production of pig iron, crude steel, and rolled products other than pipe attained planned 1965 output levels. Expansion of pipe manufacturing facilities was slated for the coming 5-year plan (1966–70) by the installation of a Stiefel pipe rolling mill at the Zawiercie metallurgical plant and the installation of seamed pipe manufacturing facilities at the Lenin metallurgical plant in Nowa Huta. Near the close of 1965, an oxygen converter went into operation at Nowa Huta; however, the fifth blast furnace was rescheduled for completion in 1967. This furnace is to have a capacity of 2,000 cubic meters and an annual production capacity of 1 million tons of pig iron. When completed, the fifth blast furnace at Nowa Huta will exceed by 300 cubic meters all others in use in Poland. By yearend, 2 coking batteries, capacity 750,000 tons annually, were installed raising the total number of coking batteries at Nowa Huta to 10.

In January 1965, Poland, Hungary, and Czechoslovakia formed an organization known as Intermetal to coordinate actions in iron and steel manufacturing. In July, Bulgaria, the U.S.S.R., and East Germany joined the organization. Announced goals of the group included utilization of their unused production capacities, expansion of product variety range, and coordination of basic investment plans.[7]

NONMETALS

Cement.—By yearend, full production was finally achieved at the Rudnik cement plant. The plant, representing an investment of 1.1 billion zloty, will produce nearly 1.2 million tons of cement in 1966. Daily output of 4,000 tons clinker, 2,500 tons of fine cinder, and about 100 tons of gypsum for cement production is anticipated at Rudnik in 1966.

About half of all cement produced in

[5] Fundamenty (Warsaw, Poland). No. 38, Sept. 19, 1965, p. 2.
[6] Trybuna Ludu (Warsaw, Poland). Aug. 3, 1965, p. 4.
[7] Polish Economic Survey (Warsaw, Poland). No. 3, 1965, 28 pp.

1965 was 250 grade. The 450-grade light-construction cement contributed only 1 percent to the total cement output. By 1970 the Poles anticipate the 450-grade cement to account for 20 percent of the total cement production.

Fertilizer Materials.—Although production of mineral fertilizers increased by 5 percent over that of 1964, Poland was required to continue imports of these commodities. Construction of the Pulawy I nitrogen plant continued through 1965. Equipment imported from Czechoslovakia as well as that manufactured in Poland was reported late in delivery resulting in disruption of construction schedules. The plant will have an annual capacity of 500,000 tons of ammonia annually when completed. Initial production was to begin in 1966. The Pulawy II nitrogen plant equipped by Danish, British and Austrian firms was under construction in 1965 with completion scheduled for 1968 and with an expected daily production of 1,500 tons of ammonia, 2,700 tons of nitric acid, and 3, 600 tons of ammonium nitrate. Annual production of ammonium nitrate will be 1.1 billion tons or 380,000 tons of nitrogen content.

The Association for Chemical Plant Construction is considering the activation of a third nitrogen fertilizer factory at Pulawy by 1970.

Salt.—Rock salt mining operations were terminated at the Wieliczka deposit in 1965. Brine-pumping installations operating at Wieliczka yielded enough brine to produce 205,000 tons of table salt in 1965. Similar brine-pumping installations to replace rock salt mining at the Bochnia deposit are anticipated in 1966.[8]

Polish salt exports in 1965 increased to nearly 300,000 tons; Czechoslovakia and Hungary were the principal recipients.

Sulfur.—Poland's principal sulfur mine, the Piaseczno, yielded 3.2 million tons of sulfur ore in 1965. Production at this rate was slated to continue until 1970. Development of the Machow mine continued through 1965 with completion anticipated in 1970.

Marked increase in elemental sulfur production was attributed to the commissioning of a second processing plant at Tarnobrzeg.

MINERAL FUELS

Coal.—Poland's increased bituminous coal output was largely the result of greater mine mechanization. In 1965, 47 percent of bituminous coal production was mechanically mined as compared with 43 percent in 1964. The share of mechanically loaded bituminous coal was 51 percent compared with 46 percent in 1964.

Calculated on the basis of heat content per ton, open-pit brown coal is cheaper than hard coal because of (1) relatively higher productivity in open pit mines and, (2) the lower transportation cost for brown coal because deposits are centrally located. About 60 percent of the 1965 brown coal output was consumed by the electric power industry. Efforts in further expansion and modernization in the brown coal industry were underway at yearend. In November a new mine, Kazimierz came on stream in the Konin-Turek basin. In 1966 the mine should yield 500,000 tons of brown coal, and by 1969 it is slated to expand annual production to 4.5 million tons. Other brown coal mines—Jozwin and Wladyslaw—were also being developed and were to be in operation by 1968. Polish Government officials reportedly anticipate that brown coal production will reach 38 million tons in 1970.

Petroleum and Natural Gas.—Poland remained almost totally dependent upon imported crude oil to supply the six refineries. Extensive petroleum exploration activities continued with assistance from the U.S.S.R.; however, no significant increase in petroleum reserves has been reported. In July a well drilled near Puszcza Niepolomicka in Bochnia reportedly struck oil and was described as a gusher, but no further information has been released.

Marked increases in refinery output were credited to the distillation column and reforming unit which came on stream at the Plock refinery in late 1964. A cracking unit with a processing capacity of 750,000 tons of raw material annually which was planned to be operational in late 1965 also may have contributed to increased output. All crude oil processed at Plock (2 million tons in 1965) arrived from the U.S.S.R. via the Druzba pipeline.

While natural gas production failed to

[8] Kurier Polski (Polish Courier). Aug. 2, 1965. Warsaw, Poland, p. 1.

attain the 1965 goal by 18 percent, significant achievements were made in gas main and gas storage unit construction. The gas main from Blachownica to Kedzierzyn was completed in March. A subsurface storage facility was developed for natural gas being supplied to Warsaw, Lodz, and Slask.

The Mineral Industry of Portugal

By Justin B. Gowen [1]

Preliminary data for 1965 showed a continued but small decline in Portugal's mine and quarry production in the face of a strong rise in the country's general economy as a whole. The gross national product (GNP) at factor cost was estimated at $3,863 million compared with $3,384 [2] million in 1964, a rise of about 14 percent at current prices or 11 percent when adjusted to constant prices. Although the index number for mine production (1958=100) declined 5 points from 87 to 82 in 1965, there was a substantial increase in the value of mine and quarry products. However, available data do not permit an estimate of the mining industry's share in the GNP for 1965.

The Interim Development Plan for 1965–67 (Plano Intercalar de Fomento) was inaugurated early in 1965, based in part on an agreement in December 1964 for a $20 million loan in the United States, and supplemented by a domestic issue of 600 million escudos ($20.9 million) to help finance projects under this plan. The Interim Development Plan was designed to help industry bridge the gap between the 2d development plan, which terminated in 1964, and the 3d development plan, which was still in the planning stage.

The main objectives of the plan—speeding the rate of economic growth and bringing about a more equitable distribution of the national income—were subject to coordination with defense efforts, maintaining domestic financial stability and solvency of national currency abroad, and maintaining equilibrium in the labor market.

There will be quite extensive dependence on foreign capital to finance the private sectors under the plan. To clarify the official policy toward foreign investment, the Government promulgated Decree-Law 46–312 with its new regulations with regard to the importation of foreign capital. According to Portuguese sources Decree-Law 46–312 makes official what has long been considered a matter of general policy. However, it has the significant advantage of placing before foreign investors a statement of the Government's attitude toward foreign capital, which is one of encouragement toward investment in industrial sectors approved by the Government. The investment areas affected are not yet known; however, if an application to invest is approved the entrepreneur is now assured of his right to repatriate capital and remit profits.

An important factor in the decline of the mining industry was the continued and increasing shortage of labor. To alleviate this condition the Government, late in 1965 created the National Employment Service (Servico Nacional de Emperego (S.N.E.)) whose principal functions are to provide vocational guidance and free employment placement, coordinate emigration policy with the Overseas Ministry and Emigration Council, and conduct labor market research.

The creation of the S.N.E. was a result of the Government's increasing concern about the illegal movement of labor from Portugal. Studies reported in the press estimated that 84,000 Portuguese emigrated from Metropolitan Portugal in 1965, with 11,000 going to the Portuguese overseas provinces and 73,000 (including 19,000 in violation to legal restrictions) going to foreign countries. The net result was an estimated loss of 44,000 during the preceeding 2 years. It appears that a large

[1] West Europe specialist, Division of International Activities.

[2] Where necessary, values have been converted from escudos (Fsc) to U.S. dollars at the rate of Esc28.75=US$1.00.

percentage of these emigrants were leaving the most dynamic part of the Portuguese economy, the industrial sector, and there was a fear that the shortage of skilled labor beginning to develop there would grow and slow down the growth of this important sector.

In November a new industrial "conditioning" law was announced. The "conditioning" was designed to offer local infant industries initial protection from foreign competition. Although conditioning has been a factor in the Portuguese economy for many years, the new law was designed to provide for more efficient coordination of the views of conflicting interests prior to granting protection to an industry.

PRODUCTION

The decline in the index for crude mineral production in Portugal was reflected in lower output levels for almost all metalliferous ores and concentrates and for most of those crude nonmetallic mineral and fuel commodities for which 1965 output data were available. However, among crude mine products the output of zinc ore and concentrate, manganese ore, and pyrite increased. Despite the general decline in crude material production, iron and steel output and fertilizer production increased somewhat as did the country's modest output of aluminum, aluminum alloys, and refined copper.

TRADE

Portugal's overall commodity foreign trade in 1965 followed the general trend of the economy and showed substantial increases in both exports and imports over those of 1964. However, while total commodity exports increased by nearly 12 percent to $576.4 million, mineral commodity exports declined 5 percent to $48.3 million. Total commodity imports rose by 19 percent to $938.5 million, and mineral commodity imports rose 16 percent to $182.4 million.

The deficit in balance of trade between the exports and imports of mineral commodities amounted to $134.1 million compared with $106.2 million in 1964.

Nonmetallic minerals and manufactures provided more than 56 percent of the mineral exports, while iron and steel, and petroleum products accounted for more than 65 percent of the mineral imports. For mineral commodities, the nations of the European Economic Community (EEC) were Portugal's most important group of customers, as well as Portugal's principal source of supply, accounting for about 36 percent of the exports and 40 percent of the imports. The European Free Trade Area (EFTA), of which Portugal is a member, accounted for 11 percent of the mineral exports and 15 percent of the mineral imports, followed by the United States with 7 percent of the exports and 5 percent of the imports.

Metal, all forms	329	1,188	1,102	Italy 436; Netherlands 404; United Kingdom 165.
Gold bullion and troy ounces	-------	32	170	All to United States.
semimanufactures.				
Iron and steel:				
Iron ore and concentrate, including roasted pyrites.	89,865	23,190	6,825	All to West Germany.
Ashes and residues containing iron.	-------	104	-------	All to Spain.
Scrap	18,380	57,728	30,877	Sweden 21,000; Spain 18,099; Italy 13,500.
Pig iron and ferroalloys	19,920	23,709	4,438	West Germany 9,660; Italy 5,255; Belgium-Luxembourg 2,386.
Semimanufactures:				
Primary forms	11,136	39,805	13,799	Spain 15,636; France 7,855; Turkey 6,929.
Shapes	603	1,944	817	South Viet Nam 1,000; Angola 436.
Plates and sheets	506	727	1,558	Angola 395; Belgium-Luxembourg 121.
Hoop and strip	99	107	125	Angola 62.
Railway track material	60	75	33	Mozambique 28; Angola 22.
Wire	144	318	826	Angola 171; Mozambique 63; United States 63.
Tubes, pipes, and fittings.	7,186	7,791	7,545	Angola 2,531; Mozambique 1,947.
Rough castings and forgings.	260	165	140	Sweden 93; Angola 28.
Lead:				
Ore and concentrate	-------	-------	229	
Oxides	83	118	67	Spain 60; Angola 25.
Metal, all forms	49	66	135	Angola 27; Mozambique 21.
Manganese ore and concentrate	6,145	8,460	2,885	Spain 6,310; Norway 1,000.
Nickel, all forms	2	5	4	United Kingdom 4.
Platinum group troy ounces	542	1,132	1,788	France 857; United Kingdom 275.
metals and alloys.				
Silver and alloys ---do---	96	2,325	3,542	Mozambique 1,190; Angola 876.
Tantalum ore and concentrate	31	26	21	All to United States.
Tin:				
Ore and concentrate. long tons	116	122	35	United Kingdom 102.
Metal, all forms ---do---	246	375	238	United States 333.
Tungsten ore and concentrate	1,219	1,468	1,357	United Kingdom 378; United States 275; Poland 254; Netherlands 223.
Zinc:				
Ore and concentrate	391	729	8,433	France 365; Italy 363.
Metal, all forms	51	103	226	Belgium-Luxembourg 92.
Molybdenum, titanium, vanadium, and zirconium ores.	2,363	2,680	51	Spain 2,578.
Ashes and residues, n.e.s. containing nonferrous metals.	839	2,839	743	United Kingdom 2,068; Belgium-Luxembourg 377.
Nonferrous base metals, n.e.s.	2	4	3	Republic of South Africa 1; Mozambique 1; United Kingdom 1.
Nonmetals:				
Abrasives:				
Natural (diatomite, pumice, and other).	292	553	524	United Kingdom 420; Netherlands 60.
Manufactured, (grindstones, paper, cloth, and powder).	224	353	597	Angola 79; West Germany 77; South Viet Nam 55.
Asbestos:				
Crude	45	2	42	Angola 1.
Asbestos cement and cement products.	657	518	627	Cape Verde Islands 214; Guinea 209.
Barite and witherite, natural	4	109	20	Belgium-Luxembourg 64; United Kingdom 31.
Cement	176,572	391,732	234,353	Spain 368,509; Gibraltar 8,763.
Chalk	60	221	232	Angola 183; Mozambique 33.
Clays, clay products, and refractory products, n.e.s:				
Crude:				
Kaolin	13,005	10,965	10,587	Italy 10,750.
Other clays	164	345	2,941	Angola 112; Spain 100; Mozambique 62.

COMMODITY REVIEW

METALS AND NONMETALS

Copper and Pyrites.—After more than a century of more or less continuous mining, the ore extraction operations at the San Domingos cupriferous pyrites mine of Mason and Barry Ltd., in the Mertola District, Province of Beja was scheduled for closing at the end of 1965. In the meantime, however, the underground stope fillings, remaining ore pillars, and low-grade ore areas were being prepared for leaching of their copper content and its precipitation as cement copper, starting early in 1966. Introduction of the bacteria *Thiobaccillus Thiooxidans* and *Thiobacillus ferrooxidans* is expected to accelerate the leaching process. Revised estimates indicate that the operation will provide about 4,000 tons of metallic copper during the 6 years following its inauguration, and that about 75 percent of the total will be recovered during the first 3 years of the leaching operation.

MINERAL FUELS

Petroleum.—In mid–1965 it was announced that final approval to establish a new refinery at Oporto had been granted to Sociedade Anonima Concessionairi de Refinacao de Petroleos em Portúgal (SACOR), which is 33-percent government owned.

The proposed refinery will have an output capacity of 1.5 million tons, including 80,000 tons of lubricants. Storage capacity will total 3.1 million barrels (500,000 cubic meters).

The Mineral Industry of Rumania

By Roman V. Sondermayer [1]

Petroleum production continued to be Rumania's most important contribution to world mineral supplies; the country accounted for about 1 percent of total crude oil output in 1965. Output of other mineral commodities and related products was significant primarily to the domestic economy; although the country also accounted for about 1 percent of world production of manganese ore, cement, pyrite, and salt. In 1965 Rumanian crude oil output again ranked second in Europe to that of the U.S.S.R. Production of more than 12 million tons was equivalent to approximately 5 percent of the Soviet output. Large scale efforts to develop other mineral resources were in progress. The manufacturing base was expanded, and exploration was carried out on a large scale. In spite of exploration, the domestic raw material position was not significantly improved and many mineral commodity needs were covered wholly or in part by imports.

The estimated share of mineral industry in the 1965 social product was roughly 18 percent. Approximately one-seventh of the total labor force, or 230,000 persons, was employed in the mineral industry Overall foreign trade of Rumania in minerals was modest by world standards except for petroleum exports. Export of refined petroleum products was over 6 million tons; approximately 50 percent went to non-Communist countries of the world and as such they were a significant source of hard foreign currency. Imports covered most of the country's demand in metals semimanufactures.

During 1965 the most significant developments in the mineral industry were the completion of the Slatina aluminum plant (the country's first such facility), the commissioning of copper mine and beneficiation facilities at Moldavia Nouva and Bahan, and the continuation of construction of a steel plant at Galati and lead zinc complex at Copsa Mica. The emphasis on developing metal mines, smelters, and refineries in 1965 reflected the favored status of this sector of industry.

No announcements were made about new significant oil and gas discoveries; apparently, intensive exploratory drilling to over 4.000 meters in depth was without striking results. All activities in production were limited to extension of existing fields. Reports also indicated the first use of steam and underground combustion in production of crude oil in Rumania.

Two new plants for production of liquefied natural gas, one in Moreni and the other at Olteni went into production during 1965.

Development of industry in general and the mineral industry in particular were and are the primary targets of the Rumanian regime with a final aim to gain more independence within the Communist world.

PRODUCTION

Production of most minerals and metals increased in 1965. Petroleum output showed a relatively modest increase when compared with other minerals.

Although authorities continued to try to improve mechanization of mines in Rumania, results were inadequate. At yearend underground mines could not be considered well mechanized. Drilling and crude oil production were the most mod-

[1] Foreign mineral specialist, Division of International Activities.

ern operations of the mineral industry. For drilling operations Rumanians used domestic rigs and Soviet-made turbodrills.

Partial automation of production was introduced in certain oilfields, and the majority of wells were on pumps or were naturally flowing, although artificial lift methods were being used in some fields. Gas repressuring and water flooding were used for maintaining formation pressure.

[p] Preliminary. [r] Revised. [e] Estimate. NA Not available.

[1] In addition to listed commodities, Rumania produces antimony, chromite, copper, gold, molybdenum, zinc, asbestos, feldspar, gypsum, and mica, but quantitative data on production are not available.

[2] Converted from cubic meters; 35 cubic feet equals 1 cubic meter.

TRADE

Lack of published statistics on Rumanian foreign trade of minerals persisted in 1965. Only general information was available, but no breakdown on destination or origin was reported. Most of the available information on trade distribution was from trade books of other countries, particularly the U.S.S.R. Foreign trade in minerals continued to be a State monopoly, planned by the Government as a part of overall economic programing.

During 1965 most of the trade in minerals was with other European Communist countries and East Germany. But Rumania made efforts to increase trade with the non-Communist world.

Approximately two-thirds of the value of Rumanian mineral exports was provided by refined petroleum products. The rest of the mineral trade was modest by world standards. Mineral trade with the United States remained insignificant.

COMMODITY REVIEW

METALS

Aluminum.—On July 30 the first stage of the aluminum plant at Slatina went on stream with an annual capacity of 25,000 tons of aluminum. Plans were made to expand production to 50,000 tons of aluminum in the near future. The highly automated plant was designed by the French firm, Péchiney, Compagnie de Produits Chimiques et Electrometalurgiques, S.A.

The plant used alumina from the Ordea plant. Electric power was supplied by the Craiova thermal powerplant. When the hydropower system is completed at the Iron Gates on the Danube River, Slatina plant's location will be favorable for further expansion of aluminum production.

Bauxite supply for the plant was assured through development of mines in the Crisana Region and the beneficiation complex at Dobresti. Because domestic bauxite contains clay, upgrading is necessary. Capacity of installation is 250,000 tons of bauxite per year.

Copper.—On July 1 the Moldava Nouva copper mining project was completed. The venture is based on cupriferous ore deposits in the southern part of Banat. The mine and the ore dressing facilities were commissioned. They reportedly have a capacity of 660,000 tons of ore per year, yielding a concentrate containing 16 to 20 percent copper as well as pyrite values. At Baia Mare the pyrite is recovered as a concentrate, and the copper concentrate is smelted. Although partially in production, the Baia Mare Chemical and Metallurgical complex was not completed in 1965.

In addition to facilities in Moldova Nouva and Baia Mare, the Rumanians commissioned another mining complex at Lesul Ursului with mine and concentrator. No information on capacity was available.

The well-established Balan Mining Enterprise at Balan was expanded. A third copper ore flotation plant with a daily capacity of 500 tons of ore was commissioned.

Iron and Steel.—During 1965 the known domestic raw material resources for ambitious steel plans remained inadequate, but the development of iron and steel facilities continued in an effort to achieve more independence from U.S.S.R. The iron and steel industry was the key sector in the entire development planning of Rumania.

In 1965 the construction of the Teliuc iron ore beneficiation plant was completed and the expansion of iron ore mines in this region was in full swing. Nevertheless, no information on the capacities of these new developments was available.

Development of a new iron ore mine also was underway in the Poiana Rusca Mountain, the major iron ore area in Rumania. It is expected that when this mine begins full operation, all demands of the plant at Hunedoara will be fulfilled.

The construction of the iron and steel plant at Galati, now called the Geogiu Dej Metallurgical Plant, continued, but plans were changed and the annual steel capacity of the plant proposed for 1970 was lowered from 4 million tons to 2 million tons. It is expected that partial production of the plant will start in 1966. At the Resitsa Iron and Steel Plant a new steel furnace, with a reported annual capacity of about 225,000 tons, started production. The Resitsa combine's ore concentration plant was commissioned. The new line is mechanized and partially automated. With this line in production the plant capacity will be doubled.

The Hunedoara iron and steel plant was modernized and expanded during 1965. Development of a new dolomite quarry, modernization of the rolling mill, and the beginning of production of high-quality steel were the most important developments and events at Hunedoara, the largest iron and steel plant in Rumania.

Lead and Zinc.—Construction of the Copsa Mica plant with the British Imperial Smelting process continued. Capacity of the plant was set at 50,000 tons of lead and 100,000 tons of sulfuric acid. It is reported that the first tests of equipment were underway at yearend.

Mercury.—Without disclosing any details on the quantity of reserves, Rumania announced discovery of new cinnabar deposits on the southern slopes of the Harghita Mountains.

NONMETALS

Cement.—The cement industry remained one of the most advanced sectors of the Rumanian nonmetals industry; rivaled only by the mineral fertilizer producing and processing sector. During 1965 production of cement was adequate for domestic needs and provided a surplus for export.

Construction of the cement plant and the complex for production of construction materials at Biresti near Tirgu-Jiu continued and certain elements of the cement factory were commissioned. When completed, the plant will have an annual capacity of 2 million tons of cement.

Diatomite.—A new line for diatomite beneficiation was reportedly installed in the Odhorei plant, but no information was

available on plant capacity before or after expansion.

Fertilizer Materials.—In the past several years, extensive development of the petrochemical and chemical industries have made possible increased output of fertilizers. These developments have made this industry one of the most modern sectors of the nation's nonmetal industry. The raw material base for production of mineral fertilizers remained Rumanian natural gas and Soviet apatite.

During 1965 the principal activity of nitrogenous fertilizer producers was the elimination of shortcomings in normal operation in plants commissioned since 1960, such as those at Pietra Neamt, Turnu Margurel, and Tirgu Mures.

Reportedly potash deposits were discovered in the country's salt producing areas. Experiments indicated ore unsuitable for beneficiation by standard methods, but Rumanian researchers developed a method for concentrating the crude potash. The resulting product's composition was such that it was rated as having a 50 percent K_2O equivalent content. Based on test results, the Rumanians reportedly planned to develop domestic production of potassic fertilizers in the near future.

Lime.—New lime kilns were put into production at the Bicaz cement plant. Annual output of the plant reportedly will be increased by 70,000 tons.

Other.—To improve the overall situation in production of nonmetals, plans were announced for modernization and expansion of production of certain facilities. Output in 1965 and production targets set for 1970 are as follows:

Commodity	Metric tons	
	1965 production	1970 target
Barite	45,000	105,000
Bentonite	90,000	143,000
Kaolin	35,000	75,000
Talc	115,000	140,000

MINERAL FUELS

With a production of over 12 million tons of crude oil during 1965 Rumania ranked second to the U.S.S.R. in Europe. Domestic production of low-grade solid mineral fuels (over 5 million tons) and large quantities of natural gas together with a small part of total Rumanian oil production satisfied much of the basic energy demand of the country, however, coking coals and coke had to be imported.

Coal.—Lignite was the backbone of the coal output in 1965; about 60 percent of the total coal production was lignite. The principal activities in coal production were concentrated in the Jiu Valley in Oltenia. In Livezem in the Jiu Valley preparations for development of a new mine were started. According to reports, the mine, with a planned annual capacity of about 1.2 million tons, will be the most modern in the area. A new mine started production at Ticani in the Rovinari coal basin in Jiu Valley. The annual capacity of the mine was planned to be about 1.3 million tons. The Rovinary region of the Jiu Valley will become more promising for future coal production when a new dam on the Jiu River is completed. The dam will prevent flooding of the lowlands of the Jiu River. New mines in this area will have a total annual capacity of 7.5 million tons of lignite.

At the Capeni Mining Enterprise a new briquet plant was commissioned. The plant's annual capacity is approximately 100,000 tons of lignite briquets. The plant is fully automated, and the equipment was produced by Rumanian factories. Coal industry progress was overshadowed by a serious coal mine accident. On February 23, 1965, a gas explosion killed 41 and injured 16 miners at the Uricani mine in the Jiu Valley.

Petroleum and Natural Gas.—During 1965 the activities in the Rumanian petroleum industry were characterized by intensive deep drilling without announcement of significant discoveries, introducing steam and underground combustion as production methods on experimental basis, completing gas plants and refineries, and designing modern equipment for drilling and refining.

During 1965 Rumanian drilling activities reached a new record depth of 13,715 feet (4,180 meters) in a well drilled for gas (with unreported results) in Transylvania. At yearend, five other deep wells were drilling with target depths of 15,000 to 16,400 feet (4,550 to 5,000 meters). While drilling to these depths, Rumanians were studying problems of drilling up to 23,000 feet (7,000 meters), apparently

because shallower formations in known oil areas were fully explored and exploitation had reached maximum practical levels. Without disclosing technical or geographical details, the Rumanians announced the beginning of steam injection into reservoirs for oil production. The staff of the Petroleum Research Institute at Cimpiha also developed a version of the underground combustion method to achieve crude oil production from tight formations containing viscous oil, and according to reports, the method was successfully applied in one field. During 1965 oil recovered by secondary production methods and various well production stimulation methods accounted for approximately 10 to 11 percent of the country's total output.

A new plant for thermo-absorption has started production in the Moreni oilfield in the Prahova Valley. The plant has a daily capacity of about 7 million cubic feet (200,000 cubic meters) of gas. Another plant with a daily capacity of about 31.5 million cubic feet (900,000 cubic meters) of gas began to produce liquefied natural gas products in the Oltenia oilfields. This plant was fully automated and is the most modern one in the country.

The catalytic cracking plant of unreported capacity was commissioned in the refinery at Gheorghiu-Dej.

Petroleum equipment production was stepped up and after several years of testing protoype rigs the Rumanians reported the start of production of a standard rig, capable of drilling to 16,400 feet (5,000 meters). A larger rig, designed to drill up to 23,000 feet (7,000 meters) passed tests successfully, and preparations were underway to start production of this rig.

The Mineral Industry of Spain

By Justin B. Gowen [1]

During 1965 Spain's mineral industries continued to expand along with the rest of its national economy under the country's Economic and Social Development Plan for 1964–67. The country maintained its position as the world's leading mercury producer, ranked third in the output of pyrites, fourth in fluorspar, sixth in gypsum, ninth in china clay, tenth in cement and eleventh in magnesite, and was an important producer of lead, salt, talc, tin, titanium, tungsten, and zinc.

The value of output of the extractive mineral industry rose 20 percent from $250 million [2] in 1964 to $301 million in 1965, representing 4.4 percent of the country's industrial product which is estimated at $6,900 million. The value of crude mineral output was equivalent to 1.4 percent of the gross national product (GNP), the same share as in 1964, although the GNP rose from $17,700 million in 1964 to $21,700 million in 1965.

Part of the increase in value was due to the increase in unit prices of mineral products, which rose an average 4.7 percent during the year, although prices of some commodities rose much higher.

Employment in the extractive industries (including quarrying) decreased about 4 percent from 146,200 in 1964 to 140,400 in 1965. This represented slightly more than 1.1 percent of Spain's active labor force of 12,204,500 as reported at yearend. Continued increase in productivity was largely responsible for the decrease in labor.

Major industrial developments that affected the mineral industries during 1965 included the proving of a commercially productive oilfield at Ayoluengo in the Provinces of Burgos and Santander, the proving of a second possible field at nearby Tozo, and the putting on stream of Empresa Nacional "Calvo Sotelo" de Combustibles Liquidos y Lubricantes, S.A.'s new petroleum refinery (Spain's fourth) at Puertollano, raising Spain's total refinery capacity to nearly 16 million tons annually. Other developments were the commissioning of the Empresa Nacional Siderurgica (ENSIDESA) 300,000-ton-per-year cold-rolling mill at Aviles; inauguration of oxygen injection in the ENSIDESA open hearth plant at Aviles; and the granting to the Government-controlled company, Instituto Nacional de Industria (INI), of the exclusive right to exploit the Spanish Sahara phosphate deposits.

On the negative side, one of the costs of expanding the mineral economy was a serious increase in the balance of payments deficit. The value of mineral commodity imports increased 36 percent, from $643.2 million in 1964 to $875.3 million in 1965, while the value of mineral commodity exports increased only 5 percent, from $143.7 million to $151.6 million, leaving a net deficit $723.6 million in mineral trade, a figure 45 percent greater than in 1964. One factor contributing to this deficit was the temporary closing of Spain's most important zinc-lead mine due to collapse and flooding of mine workings in January 1965, but a more significant factor was the increase in mineral imports required by the country's expanding economy, a need that could not be met by Spain's existing capacity to produce these commodities.

Evaluation of the Spanish Economic and Social Development Plan 1964–67 at its midpoint showed mixed results. In general the expansion of the national economy,

[1] West Europe specialist, Division of International Activities.

[2] Where necessary, values have been converted from pesetas (Pts) to US dollars at the rate of Pts 1=US$.0166667.

including most of the important mineral commodities except nonferrous ores, followed the trends foreseen in the plan. However, the possibility that imbalances accompanying the rapid surge in the economy might endanger the future progress of the plan caused concern to some of the country's economists.

The plan called for investment of about $2,484 million in the mineral sector during the 4-year period. Of this total, fuels and energy materials, including powerplants, would require about $1,367 million; iron, lead and zinc ores, pyrites, and potash $132 million; basic iron and steel $282 million; nonferrous metals $63 million; cement and construction materials $304 million; and fertilizers and basic chemicals $336 million.

Results of the third round of applications for investment in the seven growth centers set up under the development plan, announced during the third quarter of 1965, showed that of 342 applications received, 199 applications totaling $234 million were approved. Total investments approved to midyear 1965 were valued at $858.7 million and were expected to create 85,000 jobs. A breakdown of the approved applications on a value basis by industrial sectors showed steel metallurgy ranking first, with 34 percent of the approved investment, followed by chemicals with 21 percent. Most of the investment, by value, was destined for the Huelva area, where heavy chemical industries are located, but substantial interest was also shown in the Seville area.

To lend impetus to the Concerted Action Plan for the coal industry, the Fund for the Support of Coal Mines (Fondo de Fomento de la Mineria de Hulla) was created to provide subsidies during the development period. The subsidies amount to 50 pesetas ($0.83) per ton produced for the 1964–65 period; 37 pesetas ($0.62) per ton for the 1965–66 period; 35 pesetas ($0.58) for the 1966–67 period and 15 pesetas ($0.25) for the 1967–68 period. As a special incentive, the subsidy for the Asturias region, Spain's most important coal region, was increased to 95 pesetas ($1.58) per ton for the 1965–66 period. Only firms which have accepted and signed the Concerted Action Plan are eligible for these benefits.

PRODUCTION

In 1965 substantial gains over 1964 outputs were shown by iron ore (11 percent), fluorspar (42 percent), potash (23 percent), cement (18 percent), fertilizers (20 percent), crude steel (12 percent), steel products (40 percent), petroleum products (15 percent), and electric energy (13 percent). With a production increase of 5.8 percent during 1965, the coal industry recovered from the loss due to strikes during 1964, but this only slightly exceeded the 1963 output.

e Estimate. p Preliminary. r Revised. NA Not available.

[1] Includes copper ores, copper uranium ores, and cupriferous pyrites.

[2] Including production from imported ores and concentrates.

[3] Includes basalt, diabase, fonolite, granite, ophite, porphyry and trachyte.

TRADE

Spain's exports of all commodities during 1965 were valued at $966.5 million; mineral commodities exported totaled $151.6 million. Total imports were valued at $3,003.3 million, of which $875.3 million comprised mineral commodities. The European Economic Community (EEC) and the European Free Trade Area (EFTA) continued to be the major European destinations for Spanish exports. However, among individual destinations for Spain's exports, the United States followed West Germany and the United Kingdom, respectively. These three accounted for a total of $115.5 million, of which $16.5 million were in mineral commodities. As a source of imports by Spain, the United States led all other nations, accounting for imports valued at $527 million, of which nearly $76 million was in minerals.

Roasted pyrites do	696	803	712	West Germany 543; United Kingdom 141.
Oxides	16,832	19,365	18,426	United Kingdom 4,839; United States 2,474; Australia 2,208.
Scrap thousand tons	4	4	---	United States 3.
Pig iron and cast iron do	151	148	110	Japan 74; Italy 24; West Germany 21.
Ferroalloys:				
Ferromanganese do	10	10	7	United States 7; United Kingdom 1.
Other do	10	8	3	West Germany 3; United Kingdom 3.
Steel:				
Primary forms do	51	51	---	Italy 21; Japan 9; Philippines 9.
Semimanufactures:				
Shapes do	2	6	5	West Germany 4.
Plates and sheets do	48	32	3	Italy 23; Colombia 7.
Other do	2	5	9	France 2; Switzerland 1.
Lead and alloys:				
Ashes and residues containing lead	---	1,211	---	All to the United Kingdom.
Lead oxide	20	8	---	Israel 5; Portugal 3.
Unwrought	11,628	1,908	317	United States 500; Portugal 450; Switzerland 400.
Semimanufactures	43	32	26	Andorra 24; Morocco 6.
Magnesium, scrap	5	9	15	All to United Kingdom.
Manganese ore	---	20	2	All to France.
Mercury:				
Metal 76-pound flasks	49,126	70,747	64,781	United States 24,085; Japan 18,750; United Kingdom 8,957; West Germany 6,670.
Oxides	144	135	112	Netherlands 82; Sweden 20.
Molybdenum scrap kilograms	2,645	---	---	
Nickel scrap	4	17	15	Netherlands 9; France 5.
Selenium kilograms	NA	543	295	West Germany 278; France 265.
Silicon	---	440	1,046	United Kingdom 240; West Germany 150.
Tin:				
Ore and concentrate long tons	---	15	1	All to United Kingdom.
Scrap do	8	5	113	All to West Germany.
Unwrought and semimanufactures do	1	494	260	Netherlands 225; United States 150; United Kingdom 89.
Titanium:				
Ore and concentrate (ilmenite)	20,760	26,722	19,108	Italy 13,561; Belgium-Luxembourg 6,700; France 6,450.
Oxide	1,222	1,675	1,795	Belgium-Luxembourg 637; Argentina 443.
Tungsten:				
Ore and concentrate	73	156	246	United Kingdom 115; West Germany 41.
Metal, all forms kilograms	350	---	---	
Uranium ores do	5,200	100	25	All to Austria.
Uranium and thorium salts do	10,500	529	---	All to Egypt.
Zinc and alloys:				
Ore and concentrate	32,694	24,308	6,583	France 9,590; Netherlands 8,338; West Germany 3,007.

See footnote at end of table.

[2] Value $699,000.

COMMODITY REVIEW

METALS

Aluminum.—Revised figures for 1964 showed an increase of 9.1 percent in the output of primary aluminum over that of 1963, while preliminary figures for 1965 showed an increase of 3.5 percent over 1964 output. The 1965 level was somewhat short of the development plan target of 55,000 tons. In contrast, Spanish consumption of aluminum and alloys increased to 64,000 tons, far more than development plan estimates, thereby making necessary a revision of the time schedule for completion of modernization and expansion projects.

Increased imports and decreased exports to supply the additional domestic requirements resulted in trade deficits—which increased from $2.8 million in 1963 to $5.4 million in 1964 and to $15.0 million in 1965—a condition diametrically opposed to the goals of the development plan, to emphasize production for increased exports and eliminate imports as far as possible.

During 1965 the modernization and expansion of capacity continued at the Valladolid works of the Government-owned Empresa Nacional de Aluminio (ENDASA) from about 12,000 tons to a target of 24,000 tons. The development plan also calls for expansion of the Aviles works from 17,500 tons to 37,500 tons in 1967 and to 47,500 tons by the end of 1970, giving Spain a capacity of about 77,000 tons of primary aluminum in 1967 and 97,000 tons by the end of 1970.

Copper.—Prior to 1964 only about 9 percent of Spain's output of copper metal was derived from indigenous ores. A part of this primary copper of domestic origin was recovered as cement copper. This included a small amount from the leaching of oxide ores in the province of Zaragoza, but it mainly came from the leaching of pyrite and roasted pyrite stockpiles and old waste and slag dumps in the province of Huelva. The remainder of the domestic primary production was recovered in concentrates from the treatment of porphyry copper ores mined adjacent to the massive pyrite deposits at Rio Tinto and, starting in 1964, from copper uranium ores in the province of Jaen.

Although copper ores mined in the past from the enriched portions of cupriferous pyrite orebodies once placed Spain high among world copper producers, remaining large cupriferous pyrite reserves with their low copper content do not provide an alternate source to meet domestic requirements.

The four existing copper smelters and five electrolytic refineries in Spain at year-end 1964 had an annual capacity of about 33,000 tons of fire-refined copper and 48,000 tons of electrolytic copper, somewhat more than Spanish requirements. However, most of these plants were old and too small for efficient operation.

Likewise Spain's annual capacity of about 146,000 tons of copper semimanufactures was somewhat more than estimated

requirements for the near future. This capacity was shared among 115 companies, with the five major producers accounting for 90 percent of the total. Smelters and electrolytic refineries in operation at yearend were as follows:

Company	Location	Annual capacity (metric tons)	
		Fire refined	Electrolytic
Sociedad Espanola de Construccion Electro-Mecanicas (SECEM)	Cordoba	---	30,000
Compañia Española de Minas de Rio Tinto	Rio Tinto	13,000	---
Industrias Reunidas Minero-Metalurgicas (Indumetal)	Asua (Vizcaya)	10,000	7,000
Electrolisis del Cobre, S.A.	Palencia	7,000	5,000
Sociedad Industrial Asturiana Santa Barbara	Oviedo	---	4,500
Rafinerias e Industrias Metalurgicas (CARIM)	Barcelona	3,000	---
Cobre Electrolitico y Metales S.A. (CEYMSA)	Gijon	---	2,000
Total		33,000	48,500

Principal copper semimanufacture producers were SECEM (Cordoba), Sociedad Industrial Asturiana Santa Barbara, S.A. (Oviedo), Eduardo K.L. Earle (Vizcaya), Pradera Hermanos (Vizcaya), and Metales y Plateria Ribera (Barcelona).

An investment of about $24 million was foreseen in the Economic and Social Development Plan to modernize, centralize, and expand copper metal producing and processing facilities. This anticipates an annual consumption of 76,600 tons of refined copper and export of 2,500 to 3,000 tons of semi-manufactures by yearend 1967. The most important project under the plan was Rio Tinto's 40,000-ton-per-year smelter at Huelva.

Iron and Steel.—*Iron Ore.*—With iron ore reserves estimated at about 1,000 million tons, and a 1965 annual productive capacity of more than 7.5 million tons, the Spanish iron mining industry anticipated no particular difficulty in meeting expanded requirements for iron ore, originally set at 7.4 million tons, under the Economic and Social Development Plan for the iron and steel industry. However, an investment of $1.7 million was foreseen to centralize and rationalize some operations and to make the industry better able to compete with foreign ores. The 1965 output, 11 percent higher than that of 1964, was obtained from fewer producing units and with a smaller labor force than in 1964. Basic data compiled before the inauguration of the development plan showed 222 iron ore mining enterprises producing from deposits situated in 22 of the 47 Provinces of continental Spain. Of these enterprises, 4 had an annual production of more than 500,000 tons, 4 more each produced from 200,000 to 500,000 tons annually, and 14 produced

from 50,000 to 200,000 tons apiece annually. The remaining 200 each produced less than 50,000 tons annually. The number of producing mines or mine groups, employment, production and consumption of iron ore for 1963 through 1965 are shown as follows.[3]

	1962	1963	1964	1965
Number of producing mines or groups	279	261	202	NA
Total employment in iron ore mining at yearend	14,178	12,094	9,400	9,258

Consumption of iron ore in ironmaking and steelmaking—do	4,485	4,287	4,139	NA

NA Not available. e Estimate.

Spanish domestic iron ore resources by metallogenic provinces at yearend 1963 were as follows:

Metallogenic province [1]	*Reserve (million tons)*
Asturias-Leon-Palencia-Galicia	592.1
Teruel-Guadalajara	115.1
Murcia-Valencia	107.0
Almeria-Granada	62.6
Vizcaya-Santander	60.0
Cordoba-Sevilla-Huelva	27.6
Soria-Zaragoza-Logroño-Burgos	25.4
Extremadura	10.0
Total	999.8

[1] In addition to those listed, Quipuzcoa-Navarra has a reserve of less than 50,000 tons.

Spain's principal domestic iron mining companies as of 1964 and most recent available details on their operations and facilities included the following:

Company	Mines and location	Remarks
Orconera Iron-Ore-Ltd.	Concha, Concha I, Eziquiela and Florencia in Vizcaya Province	Subsidiary of Altos Hornos de Vizcaya; supplies ore (mainly carbonate) to Altos Hornos' works at Sestao and Baracaldo.
Sociedad Franco-Belga de Minas de Somorrostro S.A.	Concha II and San Luis in Vizcaya Province	In 1965 had a capacity of 500,000 tons per year of carbonate ore.
Minero Siderurgica de Ponferrada S.A.	Coto Wagner (Wagnergroup)	In 1961 produced 582,000 tons of carbonate ore from about 30 individual mines of the group on a 14-kilometer-long ore zone; supplies ore to works at Aviles.
Coto Minero "Vivaldi" y Anexas, S.A.	Vivaldi group in Leon Province	In 1961 produced 339,000 tons of carbonate ore from the same zone that the Wagner group mines operate in.
Compañia Andaluza de Minas, S.A.	Marquesada in Granada Province	In 1961 produced 531,000 tons of hematite ore for works at Aviles and for export.
Minas de Hierro del Conjuro, S.A.	Conjuro in Granada Province	In 1961 produced 239,000 tons of ore.
Compañia Minera de Sierra Menera	Sierra Menera in Provinces of Guadalajara and Teruel	In 1965 produced approximately 650,000 tons of limonite ore.

Pig Iron and Steel.—The record output of 3.52 million tons of crude steel was very near the estimated requirement (3.58 million tons) for 1965 under the Economic and Social Development Plan. However, imports of crude steel increased by 178 percent over those of 1964 to 1.4 million tons, and finished steel imports rose by 88.6 percent to 864,000 tons to meet the surges in consumption and stock building. Exports dropped to 17,000 tons of crude steel and less than 500 tons of finished steel.

New estimates of future consumption based on more and better data indicated that minimum national requirements for 1972 would reach 12.31 million tons of crude steel, and that objectives under the development plan and its Concerted Action Plan for the iron and steel industry would be further revised upward.

The status of principal expansion projects of the major iron and steel producers at the end of 1965 is shown below by companies.

Empresa Nacional Siderurgica, S.A., (ENSIDESA): The Aviles works were projected for an annual production of 2.8 million tons of crude steel to be achieved

[3] This compilation does not include iron ore recovered from lead-zinc and tin ores.

in three stages. The first stage was essentially complete when the Economic and Social Development Plan was inaugurated in 1964, at which time the Aviles works consisted of the following plants (with theoretical annual capacities): two blast furnaces (1,140,000 tons pig iron), five acid open hearth furnaces including three of 300 tons each and two of 225 tons each (820,000 tons of crude steel), a blooming mill (1 million tons of blooms and billets), a structural mill (310,000 tons rails), a heavy plate mill (600,000 tons) and a hot strip mill (550,000 tons).

Phase two includes works completed during 1965; or scheduled for completion during 1966 or 1967 as follows: Development and diversion of a part of the Narcea River to insure an adequate water supply for expanded projects at Aviles and Gijon (1965); installation[4] of oxygen injection equipment on the two 225-ton open hearth furnaces, thereby increasing open hearth steel capacity by 80,000 to 100,000 tons annually (1965); installation and inauguration of the first unit of a tonnage oxygen plant with a capacity of 6,000 cubic meters of oxygen and 5,600 cubic meters of nitrogen per hour[5] (1965); installation and inauguration of a tandem 4-stand cold reduction mill with an initial capacity of 300,000 tons of cold rolled strip annually (completed 1965—to be expanded to its maximum capacity of 800,000 tons annually by the end of 1972); two 680,000 ton per year blast furnaces (Nos. 3 and 4), one for completion in 1966 and one in 1967; a new oxygen steelworks with two 65 ton L–D (Linz-Donawitz) converters and one 1,200 ton mixer (1966); and a new slabbing mill (1967).

Phase three includes projects authorized but not yet started in 1965, but scheduled for completion by the end of 1972 as follows: A second Linz-Donawitz type oxygen steelworks with an annual capacity of 1 million tons, including an integrated continuous casting plant; and a semicontinuous hot strip mill with 1.5 million tons annual capacity.

A reestimate of the capacity of the completed Ensidesa works as a unit indicates a possible output of 3.36 million to 4.00 million tons of crude steel and the equivalent in finished steel.

Altos Hornos de Vizcaya, S.A.: In March 1965, Altos Hornos de Vizcaya, S.A., with the participation of the United States Steel Corporation, joined the Concerted Action Plan for the iron and steel industry and officially became a participant in the Economic and Social Development Plan. With credits of $7.5 million from U.S. Steel, and $72 million from the Spanish Government effective during the period 1964–1967, Altos Hornos agreed to continue its expansion and modernization program, started in 1960. New basic objectives were set at 2.1 million tons of crude steel output by the end of 1967 and 2.7 million tons by the end of 1972.

Steel output expansion would be accomplished by increasing production of the 2 year old Sestao L–D steelworks, consisting of two 35-ton converters. To these would be added two 60-ton converters, and a third 60-ton converter would be added later to replace the two smaller ones. This would increase the L–D steel capacity to about 1 million tons annually. The first of the larger converters, reported by the manufacturer to be 70 tons in capacity, was under construction at yearend and scheduled for completion during the latter part of 1966. Additional installations will include two continuous casting lines.

Completed at yearend, and put into operation early in 1966 at Ansio, near Baracaldo, was a new 66-inch, 5-stand semicontinuous hot strip mill with an initial annual capacity of 1.25 million tons, and the possibility for an increase to 2.2 million tons.

UNINSA (Union Siderurgicas Asturianas, S.A.): During 1965 plans were announced, and in March 1966 an agreement was signed under the Concerted Action Plan for the iron and steel industry, whereby UNINSA would be recapitalized to form Spain's third major integrated iron- and steel-producing company. UNINSA was formed in 1961 by the three small Austurian iron and steel companies, Sociedad Metalurgica Duro-Felguera, Sociedad Industrial Asturiana Santa Barbara, and Fabrica Mieres, with small integrated works at Duro-Felguera, Gijon, and Mieres, respectively, to construct and operate at Veriña near Gijon in Asturias province a 200,000-ton-per-year merchant mill.

---

[4] Erroneously reported as a new Siemans plant put into operation during 1964. Bureau of Mines Minerals Yearbook 1964, v. 4, 1966.
[5] At 0°C and 760 mm Hg pressure.

The 1965 plans and 1966 agreement involved a more or less complete merger of the three companies into UNINSA with a capital of $83.3 million, of which the founding companies will contribute 60 percent, the Spanish Government through INI 10 percent, Friedrich Krupp of West Germany 10 percent, and the remainder is to be subscribed by employees. Capital projects will involve an investment of about $285 million and include a new integrated L–D steelworks at Veriña, which will have an initial annual capacity of about 1.6 million tons of steel. Those existing works of the three companies that can be integrated into the operations of the new complex or operated independently as economic units will be retained. The others will be abandoned. However, the announced plans include additional heavy plate, structural, and bar mills.

Sociedad Anonima Basconia: In 1965, Sociedad Anonima Basconia announced plans to invest about $17 million in a new plant for the production of stainless steel cold-rolled strip at Besauri in Vizcaya province. In addition to its own steelworks at Basauri, S.A. Basconia operates jointly with Altos Hornos de Vizcaya at Echevarri in Vizcaya Province a cold sheet mill and tin plate installations.

Echevarria, S.A.: Echevarria, S.A., with small integrated iron and steelworks at Recalde and Santa Agueda in Vizcaya Province, announced a new expansion project which will include a steelworks at Besauri to produce 270,000 tons of special steel ingots and 30,000 tons of special steel forgings annually. Still in the planning stage was a project for an integrated L–D steelworks and rolling mills.

J.M. Astrain, S.A.: In September 1965 J.M. Astrain, S.A., commissioned an 80-ton electric furnace (Spain's largest) with an annual capacity of 150,000 tons of crude steel in Guipuzcoa Province. Also, it was reported that the firm would build a new works to produce 130,000 tons (Spain's normal requirements) of grain-oriented and nonoriented electric sheets annually, under a license agreement with the Armco Steel Corporation.

Union Cerrajera S.A.: Union Cerrajera S.A. put into service at its works in Mondragon in Guipuzcoa province two new 25-ton electric furnaces integrated with a two strand continuous-casting installation that can be expanded to three strands.

Lead and Zinc.—While the 1965 mine lead output changed little compared with that of 1964, zinc concentrate output dropped nearly 60 percent as the result of the loss of production from the Reocin mine due to flooding. By yearend this property had regained only partial production. Exports of lead, an important source of foreign exchange prior to 1964, dropped in 1965 to 343 tons; lead imports, insignificant or nil prior to 1964 jumped to 24,255 tons in 1965.

Exports of zinc, in concentrates and as metal, dropped by 89 percent and 44 percent, respectively, while imports rose to 53,334 tons of concentrates and 1,014 tons of metal in response to expansion requirements and lower domestic output.

Spain's production of lead and zinc ores came from a large number of deposits situated in 21 Provinces, of which Badajoz, Ciudad-Real, Cordoba, Jaen, Murcia and Santander contain major deposits with substantial production records. When the Economic and Social Plan was inaugurated, there were some 200 individual enterprises, each with its own organization, mines, and installations producing lead and/or zinc ores. However, despite total positive reserves estimated to contain at least 700,000 tons of recoverable lead, 750,000 tons of recoverable zinc, and possible reserves of double these amounts, there were only a few enterprises so physically or economically situated that they could survive international competition without some form of assistance. Some assistance has been made available through the Lead Syndicate Service Fund (Fondo del Servicio Syndicale del Plomo), which was designed to stabilize internal prices and at the same time, preserve a balance between production, foreign trade, and consumption.

Although smelting capacity of the 10 existing lead smelters (163,000 tons) was substantially in excess of the annual requirement of 111,000 tons of primary lead estimated under the development plan for 1967, many of these plants and much of the equipment was obsolete. Zinc smelter capacity, rated at about 60,000 tons of electrolytic zinc and 14,000 tons of fire-refined zinc, also considerably exceeded the projected 1967 domestic requirements of 56,000 tons.

Objectives of the development plan with regard to lead and zinc included the following:

1. Formulation of a national program for a more thorough investigation and delineation of ore deposits so that they can be rationally mined to exhaustion of the deposits.

2. Centralization, rationalization, and modernization of mining operations.

3. Reduction of the number of primary lead smelters and refineries to four plants, with minimum capacities of 20,000 to 30,000 tons of lead each, preferably distributed geographically with one in the Cartagena district, one in the Linares district, one on the north coast and one in the south.

4. Development of adequate zinc capacity to treat all domestically produced concentrates, thereby providing for exportation of all zinc as metal or products rather than any in the form of concentrates.

Mercury.—Preliminary data for 1965 show a total mercury output of 74,667 flasks, 5 percent below the record high of 1964. Since the output of mercury-bearing ores increased substantially, the decrease in metal output was due to the processing of lower grade ores.

Development and modernization of the Almaden mine in the Province of Ciudad Real continued toward the goal of 90,000 flasks annual capacity by the end of 1967. Other sources of mercury in Spain included mines in the provinces of Leon and Oviedo.

In Leon the Empresa Minas de Tarna, S.A., continued exploration and development at the Carmina mine in the Maraña zone at 1,750 meters (about 5,750 feet) above sea level. Production was started in 1963 and in 1964 amounted to 7,338 tons with an average mercury content of about 1.4 percent in the form of cinnabar. The ore was treated in a plant near Riaño, comprising three muffel furnaces of 50-kilograms capacity each. Continuous-mining operations were not possible owing to climatic conditions at the high elevation.

In Oviedo the Minas de la Soterrana continued recovery of mercury from the arseno pyrite-mercury mines at Lena and Mieres.

NONMETALS

Cement.—Portland cement output during 1965 increased 1.5 million tons. This reflected production from new installations that were completed under an expansion program calling for addition of 4.2 million tons to the country's portland cement capacity during 1965, and an additional 3.9 million tons during 1966. This would give Spain a total cement capacity of 17.3 million tons by the beginning of 1967. These projects involve the installations of 29 companies and include 8 new plants and 27 additions or other expansion projects.

Other important developments in the cement industry include the organization in 1964 of Asland Asociada to take over the Cordoba plants of La Compania General de Asfaltos y Portland Asland and to build at Cordoba a new plant with an annual capacity of 315,000 tons scheduled for completion early in 1966. During 1965 La Compania General de Asfaltos y Portland Asland transferred to Asland Asociada its

plants in Badajoz and Barcelona that are scheduled for modernization. Participating in the ownership of Asland Asociada are La Compania General de Asfaltos y Portland Asland (40 percent), The Associated Portland Cement Manufacturers, Ltd., (40 percent), and the Banco de Desarrollo Economico (20 percent). Upon completion of current projects the company will become Spain's largest cement producer, with a capacity of about 1,850,000 tons of cement annually.

Fertilizer Materials.—During 1965 Abonos Sevilla S.A., a subsidiary of Union Espanolas Explosivos, inaugurated regular production from its new ammonium nitrate and mixed fertilizer plant at Sevilla. Initial annual capacity was reported at 96,000 tons of ammonium nitrate and 78,000 tons of complex fertilizers.

It was announced early in 1966 that INI would have the sole authority for the issuance of mining concessions in the Spanish Sahara phosphate field.

Pyrites.—Production of pyrites in 1965 remained essentially unchanged from that of 1964, although an annual increase of about 7 percent over the 1958–63 average of about 2,150,000 tons was foreseen during the 4-year development period. Existing capacities are considered adequate to meet the requirements envisaged under the development plan.

Sources of production by area and type for 1964 are shown below:

Table 7.—Spain: Production of pyrites, 1964, by area and type

(Metric tons)

	Huelva	Murcia	Santander	Sevilla	Source not shown	Total	Sulfur content

Sulfur content [1]	1,021,189	18,372	28,692	42,682	24,350	1,135,285	---

[1] Does not include 240,909 tons of cupriferous pyrites produced at Rio Tinto and classified as porphyry copper ore, which was treated by the Orkla process to produce copper matte, elemental sulfur, and sulfuric acid. (See section on copper in text.)

At the end of 1962 pyrite reserves were estimated at 241.85 million tons, distributed as follows:

	Thousand metric tons
Huelva:	
Tharsis group (Compañia de Azufrey Cobre de Tharsis, S.A.)	128.95
Rio Tinto group (Compañia Española de Minas de Rio Tinto, S.A.)	82.00
Others	18.80
Total	229.75
Sevilla	11.10
All others	.50
Total	241.35

These reserves include cupriferous pyrites, which contain an estimated 530,000 tons of recoverable copper.

MINERAL FUELS

Coal.—Coal production resumed its normal rate following loss of production due to strikes in 1964. It was far short, however, of the demand level forecast for 1967 in the Economic and Social Development Plan—22.3 million tons.

Early in 1965 the Government released the Concerted Action Plan for the coal industry, which was designed to make Spain more self-sufficient in coal production.

The Spanish coal industry, like other extractive industries in Spain, through 1965 continued to be characterized by a large number of small producers, many poorly equipped and short of labor. There were 194 anthracite-producing companies of which 3 accounted for 30 percent of the

national production; 109 lignite producing companies, of which 6 accounted for 55 percent of the national production; 167 bituminous coal companies of which 23 accounted for 86 percent of the national production; and 103 companies producing coke and briquets. Forty percent of the fixed equipment in the mines was over 20 years old, and another 30 percent was between 10 and 20 years old.

The Concerted Action Plan outlines means of meeting the production levels forecast in the Development Plan and provides certain benefits for the firms agreeing to meet stipulated conditions. For example, to obtain benefits, a firm, or preferably, a group of firms acting in concord must increase production of salable coal by 20 percent within an agreed upon time, must achieve a certain fixed production per mine, clean the produced coal to meet ash content specifications, concentrate mining operations, and achieve a minimum annual production of 400,000 tons from new mines.

In return for accepting the stipulated conditions the companies may receive modcrate tax rebates for a 4-year period, credit up to 70 percent of the value of new equipment and 5 years amortization for such equipment, tariff duty reductions for imported new equipment not produced in Spain, state subvention of up to 50 percent of the cost of outside technical advice and assistance, and a special subsidy for nonamortized small workings abandoned as a result of adherence to the plan.

Coal companies were given 3 months from the date of publication of the order in which to indicate their interest in adhering to the Concerted Action Plan.

Early in 1966 it was announced that four Spanish companies having extensive coal-mining concessions in northern Spain had agreed to merge their holdings and undertake an ambitious program to modernize their coal production operations. When completed, the merger will represent the largest bituminous coal-mining complex in Spain.

The new firm will be known as Hulla y Energia del Noroeste, S.A. (HUNOSA). Under an 8-year development plan the association expects to reach a production of 5.3 million tons of washed coal per year. The firm also plans to construct two thermal powerplants of 310,000 kilowatts each to use coal not suitable for coking. Estimated investment for the entire project is $66.4 million. If the HUNOSA proposal is approved under the Concerted Action Plan, about 70 percent of the proposed investment could be financed through official credits.

The firms involved in the merger are Sociedad Hullera Española, S.A.; Sociedad Metalurgica Duro-Felguera; Fabrica de Mieres; and Sociedad Industrial Asturiana Santa Barbara. The latter three companies recently merged their iron and steel operations to form UNINSA. (See section on iron and steel).

Petroleum.—During 1965 Spain's imports of crude petroleum and refinery products increased by 7 percent to about 14 million tons, while consumption rose to nearly 12 million tons. At yearend, annual crude throughput capacity stood at about 16 million tons.

In the country's energy balance, petroleum surpassed coal for the first time, supplying 39.4 percent of the energy consumed compared with 36.5 percent for coal and 26.6 percent for hydroelectric power.[6]

During 1965, 30 exploratory wells were drilled in continental Spain, of which 18 were drilled by the American Overseas Petroleum Company (AMOSEAS)—Compania Arrendetaria del Monopolio de Petroles, S.A. (CAMPSA) partnership in the recently discovered Ayoluengo field. Of the total, 12 were producers, all in the Ayoluengo field, giving that field a potential production of more than 3,500 barrels per day. By mid-1966 the potential was estimated at 10,000 barrels per day.

With inauguration of the Puertellano refinery, Spain had the following plants on stream or under construction at the end of 1965:

[6] Petroleum Press Service. April 1966, p. 138.

Plant	Ownership	Location	Annual crude capacity thousand metric tons
On stream:			
Compañia Española de Petroleos, S.A. (CEPSA)	CEPSA 100 percent	Tenerife (Canary Islands)	6,000
Compañia Iberica Rafinadora de Petroleos S.A. (PETROLIBER)	Ministry of Finance 52 percent; Marathon Oil Company 24 percent; Spanish private interests 24 percent.	La Coruna	2,000
Rafineria de Petroleos de Escombreros S.A. (REPESA)	Institut Nacional Industria (INI) 52 percent; CEPSA 24 percent; Caltex Oil Company 24 percent.	Cartagena	6,000
Empresa Nacional "Calvo Sotelo" de Combustibles Liquidos y Lubricantes, S.A.	"Calvo Sotelo" 100 percent	Puertollano	2,000
Total on stream			16,000
Under construction or authorized:

The Mineral Industry of Sweden

By F. L. Klinger [1]

The Swedish mineral industry maintained a high level of activity in 1965. Foreign and domestic demand for the industry's products remained strong. Swedish producers continued to invest in new plants and equipment, in improvement of existing facilities, and in exploration and development of mineral resources. Technologic developments during the year included automation of underground haulage facilities at the country's largest iron mine, installation of new oxygen steelmaking plants, and a new process for direct reduction of iron ore. Additional ore reserves of iron and nonferrous metals were announced.

The main developments in the Swedish nonferrous metals industry in 1965 were decisions to mine the low-grade Aitik copper deposit near Gällivare, to expand existing plant capacities for aluminum smelting at Kubikenborg, and to expand existing capacity for metal semimanufactures at Finspång. Total ore output of the country's nonferrous mines was about 3 percent more than in 1964, but the metal content apparently declined.

In the fuels sector, extraction of petroleum from oil shale was being discontinued at Kvarntorp, but uranium extraction from this type of shale was started at Ranstad. Swedish petroleum refinery capacity was being doubled, and construction of a third nuclear powerplant was begun. Legislation concerning offshore exploration for oil and gas was expected in early 1966.

The Swedish economy appeared to be operating at near capacity. Unemployment was down to 0.5 percent; there was a shortage of both semiskilled and skilled labor, and the mining industry was recruiting men from Finland and other countries. There was a substantial growth of the electrical, mechanical, automotive, shipbuilding, and other metal-consuming industries in 1965.

Other developments affecting the mineral industry included increased wages and higher interest rates. Industrial wages increased 8 percent in 1965, and a similar increase was expected in 1966. The discount rate of the Riksbank (Bank of Sweden) was raised to 5.5 percent, the highest in 33 years, and interest rates of commercial and savings banks rose to 7 percent and higher.

Despite inflationary trends in the economy, the outlook for the mineral industry appeared to be good, although the rates of growth in production and investment were expected to decline.

PRODUCTION

The principal gains in production of the Swedish mineral industry in 1965 were registered in iron ore, iron and steel, nonmetallic construction materials, and petroleum products. Gross output of nonferrous metals was not much different from 1964, although individual metals showed appreciable gains. The production indices indicate the gain in volume as shown in the accompanying table.

[1] Physical scientist, Division of International Activities.

Industry sector	Production indices [1] (1959 = 100)			1965 indices, percent change	
	1963	1964	1965	1964	1963

Total mining and manufacturing	133	145	156	+7.5	+17.2

[1] Source: Statistiska Centralbyrån (Stockholm). Allmän Månadsstatistikk. No. 7, 1966, pp. 464–465.

The value of crude mineral production from Swedish mines and quarries in 1963, the last year for which relatively complete data were available, was estimated at $226 million. Metallic ores and concentrates accounted for 85 percent of the total value, nonmetals accounted for 13 percent and the remainder was made up by mineral fuels.

The principal products are indicated as follows:

Commodity	Value of 1963 output (million dollars) [1]
Metals:	
Iron ore and concentrate	160.4
Copper concentrate	12.2
Lead concentrate	10.5
Zinc concentrate	7.3
Tungsten concentrate	.8
Other ores and concentrates	.4
Total	191.6
Nonmetals:

e Estimate. r Revised. NA Not available.
[1] Including alloys.
[2] Less than ½ unit.
[3] Not including scrap from cold working operations.
[4] Including wire rod.
[5] Byproduct of iron ore concentration at Vitåfors.
[6] For sale.
[7] Not including bituminous shale.
[8] Not including tarmacadam.
[9] Including production from shale oil.

TRADE

Sweden's total trade in mineral commodities was valued at $1,824 million in 1965, an increase of 12 percent as compared with that of 1964. In value, exports increased 10.7 percent while imports rose 13.5 percent. The trade deficit for mineral commodities increased by $66 million in 1965, mainly because of increased imports of copper in all forms and of semimanufactures of iron and steel. However there were also increased imports of other nonferrous metals and nonmetallic commodities including fertilizer materials, sulfur, and refractory clay products. Imports of fuels continued to be the largest item in Swedish mineral commodity trade although their share of the total decreased in 1965. The general role of minerals in overall trade and the relative importance of major commodity groups are shown in the following tabulations in terms of value:

	Value (million dollars)		Mineral commodities share of all commodity trade (percent)
	Mineral commodities [1]	All commodities [2]	
Exports:			
1963	523.2	3,202	16.3
1964	630.9	3,672	17.2
1965	698.9	3,971	17.6
Imports:			
1963	869.9	3,389	25.7
1964	991.7	3,853	25.7
1965	1,125.6	4,376	25.7
Net balance:			
1963	−346.7	−187	XX
1964	−360.8	−181	XX
1965	−426.7	−405	XX

XX Not applicable.
[1] Excluding gold (unwrought and semimanufactures) and precious stones. In 1964, exports of gold were valued at $2.34 million and imports at $6.89 million; exports of precious stones were valued at $526,000 (diamond only) and imports at $2.66 million.
[2] Excluding gold.

[1] Not including castings or forgings, tubes of bearing steel, or pipe blanks of stainless steel.
[2] Including scrap.
[3] Including alumina.
[4] Includes manufactured fertilizers, cement, brick, and other commodities under Sections 27 and 56, and Subgroups 661 and 662, Standard Industrial Trade Classification (S.I.T.C.) (Revised).

West Germany and the United Kingdom continued to be Sweden's principal trading partners for mineral commodities. Exports to West Germany were valued at $171 million and those to the United Kingdom were valued at $108 million. Iron ore accounted for about two thirds of each total, and iron and steel made up most of the remainder. Of the total value of exports, the European Economic Community (EEC) received 42.6 percent; the European Free Trade Association (EFTA), 33 percent; Belgium-Luxembourg 8.7 percent; United States 6.8 percent; and East Europe received 5 percent. Exports to Scandinavian countries amounted to 19.3 percent of the total.

Mineral commodity imports from the United Kingdom in 1965 were valued at $167 million and mainly consisted of petroleum products, iron and steel, nickel, copper, and clays. Imports from West Germany, valued at $131 million, mainly consisted of iron and steel, coke, copper, and other nonferrous metals. Imports from the EEC accounted for 31.7 percent of the total value, followed by the EFTA (27.5 percent), East Europe (9 percent); the Netherlands (8.1 percent), and the United States (5 percent). Imports from Scandinavian countries accounted for 12.8 percent.

Table 2.—Sweden: Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal destinations, 1964

Fertilizer materials:				
Ammonia, anhydrous	102	105	NA	West Germany 104.
Phosphate rock	638	---	NA	
Manufactured fertilizers:				
Nitrogenous	10,751	18,599	24,859	Finland 7,465; United Kingdom 5,786; East Germany 4,970.
Thomas slag	6,820	22,522	20,352	Finland 11,381; East Germany 5,255; West Germany 5,218.
Other	78	126	121	Denmark 105.
Fluorspar	150	59	e 55	Finland 49.
Graphite	36	8	24	NA.
Gypsum and anhydrite, including calcine	235	8	13	NA.
Lime	5,722	6,340	NA	Norway 6,199.
Limestone, for flux, cement, etc	395,260	563,130	549,380	West Germany 292,494; Finland 221,927.
Magnesite, including calcine	193	159	205	Denmark 139.
Mica	6	9	26	NA.
Pyrite	14,055	21,242	13,218	All to United Kingdom.
Quartz and quartzite	73,031	85,745	80,968	Denmark 41,208; West Germany 28,142; United Kingdom 9,598.
Salt	1,245	33	1,378	NA.
Sodium and potassium compounds, n.e.s.:				
Caustic soda	2,734	6,430	NA	NA.
Caustic potash	2,502	2,815	NA	Norway 975; Denmark 450.
Stone, sand and gravel:				
Dimension stone:				
Granite, gneiss	120,915	140,185	143,511	West Germany 90,529; Denmark 17,140; Netherlands 7,614.
Marble, bluestone, other calcareous stone	10,994	10,409	9,611	Denmark 8,925.
Slate	210	321	596	Denmark 108; United Kingdom 70.
Worked, all types	11,892	5,810	NA	West Germany 3,290; Denmark 859.
Gravel and other crushed stone	473,361	544,984	588,876	West Germany 429,770; Denmark 111,430.
Sand	31,549	28,392	39,342	Norway 11,875; Denmark 8,117; Finland 4,318.
Sulfur:				
Crude	139	152	201	Denmark 90.
Purified	51	40	NA	Netherlands 31.

See footnotes at end of table.

Table 2.—Sweden: Exports of metals and minerals—Continued
(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal destinations, 1964
Nonmetals—Continued				
Sulfur—Continued				
Sulfuric acid, including sulfur dioxide	7,963	11,134	NA	Finland 9,315; Norway 1,016.
Talc and steatite	1,458	4,197	5,080	United Kingdom 2,460; Denmark 778.
Miscellaneous materials, n.e.s.:				
Chemical elements	4,926	1,277	[7] 11,104	Norway 649; Switzerland 442.
Hydrogen and rare gases value, thousands	$24	$38	$39	Venezuela $21.
Inorganic acids and oxygen compounds of nonmetals or metalloids	10,986	11,999	[8] 57,523	NA.
Inorganic bases	---	---	[9] 7,161	
Other mineral materials	646	1,655	1,204	Denmark 1,088; West Germany 312; Finland 207.
Slag and ash, including kelp	1,822	3,544	2,375	Denmark 1,832; West Germany 1,712.
Mineral fuels:				
Asphalt and bitumen, natural	43	26	NA	NA.
Carbon black	21	79	NA	Norway 44; Netherlands 20.
Coal	22,919	6,959	2,810	Denmark 6,254.
Coal derivatives	17,461	11,994	17,015	Netherlands 10,483.
Coke, including briquets	7,262	12,175	9,436	West Germany 10,041; Norway 1,292.
Peat, including briquets	6,778	8,662	8,310	Denmark 7,193; United States 1,350.
Petroleum refinery products:				
Gasoline	65,123	129,585	131,071	Denmark 69,223; Norway 55,137.
Kerosine	7,570	6,556	7,901	Norway 4,217.
Distillate fuel oil	65,973	60,156	69,065	Norway 43,126; Denmark 17,030.
Residual fuel oil	38,567	74,051	70,462	Denmark 62,548; Norway 10,448.
Lubricants, including grease	42,059	45,249	45,208	Finland 18,529; Norway 10,651; Denmark 6,033.
Other, including gases	[r] 36,945	47,416	50,568	Denmark 29,881; Norway 8,020; Finland 5,856.
Total	256,237	363,013	374,275	Denmark 184,715; Norway 131,930; Finland 29,451.
International bunkers:				
Distillate fuel oil thousand tons	244	226	248	
Residual fuel oil ---do---	520	587	602	

[e] Estimate. [r] Revised. NA Not available.
[1] Not including synthetic corundum.
[2] Including alloys.
[3] Less than ½ unit.
[4] Estimated from quantities reported in metric tons.
[5] Includes cast iron, and shot, grit, sponge, etc. of iron steel.
[6] Includes oxides of lead, zinc, and other metallic oxides comprising Subgroup 513.5, S.I.T.C. (Revised).
[7] Includes silicon, arsenic, selenium, mercury, chlorine, and other elements comprising Subgroup 513.2, S.I.T.C. (Revised).
[8] Includes arsenic trioxide and sulfuric acid.
[9] Includes oxides and hydroxides of aluminum, copper, vanadium, tungsten, and other metals under Subgroup 513.6, S.I.T.C. (Revised).

Table 3.—Sweden: Imports of metals and minerals
(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal sources, 1964
Metals:				
Aluminum:				
Bauxite	13,790	31,351	22,988	Greece 25,086; British Guiana 3,107.
Oxide and hydroxide [1]	39,115	68,282	70,954	Jamaica 60,863; West Germany 6,988.
Scrap [2]	323	114	NA	U.S.S.R. 92; Denmark 20.
Ingot [2]	36,696	25,273	27,252	Norway 7,822; Canada 5,643; Switzerland 2,431.
Semimanufactures [2]	14,857	20,148	19,015	Belgium-Luxembourg 4,609; United Kingdom 2,812; West Germany 2,507.
Antimony	446	426	NA	Mainland China 225; U.S.S.R. 80; Czechoslovakia 51.

See footnotes at end of table.

Table 3.—Sweden: Imports of metals and minerals—Continued
(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal sources, 1964
Metals—Continued				
Cadmium	188	142	NA	Norway 67; Belgium-Luxembourg 25; Peru 24.
Chromium:				
Ore	115,155	152,055	141,471	U.S.S.R. 70,284; Turkey 33,158; Yugoslavia 21,515.
Oxide	1,016	1,303	1,594	West Germany 1,023; United Kingdom 139.
Metal	107	165	NA	United Kingdom 143.
Cobalt:				
Oxide and hydroxide	8	4	6	Belgium-Luxembourg 3.
Metal	132	237	NA	Belgium-Luxembourg 216.
Copper:				
Ore	78,800	66,966	76,909	Chile 22,583; Canada 19,449; Finland 11,049.
Matte	7,347	10,824	8,431	France 9,443; Belgium-Luxembourg 1,381.
Cuprous oxide	91	105	NA	West Germany 71; Norway 27.
Scrap	3,225	4,691	10,400	United States 1,672; France 910; Norway 738; Denmark 643.
Unwrought [2]	r 68,798	62,342	69,577	Chile 21,883; N. Rhodesia 14,020; Belgium - Luxembourg 10,129; United States 5,231.
Semimanufactures [2]	12,554	18,050	35,294	Finland 4,781; West Germany 3,439; Belgium - Luxembourg 2,223; Austria 2,194.
Gold:				
Ore	2,167	646	NA	All from Bulgaria.
Scrap, residues, etc. value, thousand dollars	$64	$68	NA	All from Denmark.
Unwrought and partly worked [2] troy ounces [3]	225,000	418,000	NA	Mostly from United Kingdom.
Iron and steel:				
Iron ore	2,038	72,120	172,116	Liberia 57,515; Denmark 14,548.
Pyrite cinder	15,371	9,617	19,603	Norway 6,899; Morocco 2,218.
Slag, dross, scale from manufacture of iron or steel	13,028	25,157	17,551	France 13,985; United Kingdom 11,172.
Iron oxide and hydroxide	4,624	5,524	5,928	West Germany 4,634; Spain 520.
Scrap	123,001	239,461	248,268	United States 119,638; United Kingdom 73,722; Portugal 19,443.
Pig iron [4]	192,474	233,760	341,602	U.S.S.R. 89,663; Finland 89,591; West Germany 25,103.
Ferroalloys	r 36,065	39,651	69,432	Norway 23,195; U.S.S.R. 5,612; France 3,136.
Ingots and other primary forms [2]	6,972	5,864	24,001	Finland 2,075; Norway 1,943; West Germany 1,289.
Semimanufactures: [2]				
Bars, rods, sections	224,232	323,737	358,760	Belgium-Luxembourg 91,275; West Germany 79,718; France 58,052; Norway 20,826; Czechoslovakia 18,566.
Universals, plates, sheets	568,229	663,491	734,318	United Kingdom 149,462; West Germany 114,458; Belgium-Luxembourg 106,694; France 67,063; Netherlands 56,373; Denmark 49,221.
Hoop and strip	45,616	52,515	65,552	Belgium-Luxembourg 16,618; West Germany 10,174; United Kingdom 8,702.
Rails and accessories	r 5,179	4,102	5,025	West Germany 2,743; United Kingdom 674.
Wire	9,930	14,316	17,067	United Kingdom 6,779; Belgium-Luxembourg 3,028; West Germany 2,222.
Tube, pipe and fittings	142,546	175,973	204,408	West Germany 67,873; France 34,625; United Kingdom 23,869.
Castings and forgings, unworked	2,556	3,388	5,566	Poland 2,682.
Total semimanufactures	998,288	1,237,522	1,390,696	
Lead: [2]				
Oxide	1,296	1,503	2,232	United Kingdom 639; Poland 460; West Germany 196.
Scrap	593	416	666	All from Norway.
Unwrought	8,213	7,175	7,668	Peru 3,253; Mexico 1,905; Belgium-Luxembourg 814; Denmark 523.

See footnotes at end of table.

Table 3.—Sweden: Imports of metals and minerals—Continued
(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal sources, 1964
Metals—Continued				
Lead—Continued				
Semimanufactures	2,071	2,195	2,005	Belgium-Luxembourg 969; West Germany 648; Norway 354.
Magnesium: [2]				
Unwrought, including scrap	498	591	478	Norway 470; United Kingdom 81; Canada 29.
Semimanufactures	76	40	63	West Germany 18; United States 12.
Manganese:				
Ore	77,373	56,985	95,975	U.S.S.R. 31,233; India 21,602.
Oxide	332	243	494	Japan 200; Netherlands 30.
Metal	1,133	1,138	NA	Republic of South Africa 787; U.S.S.R. 117; Norway 114.
Mercury—76-pound flasks	4,061	1,827	2,118	Italy 841; Spain 638; United Kingdom 174.
Molybdenum:				
Ore and concentrate	2,332	3,071	e 3,000	United States 1,732; Chile 892; Norway 427.
Oxide	---	22	NA	All from Canada.
Metal, wrought and unwrought	23	71	45	United States 33; mainland China 20; West Germany 9.
Nickel:				
Matte	345	381	584	All from Canada.
Scrap	270	630	838	United States 415; Canada 67; United Kingdom 42.
Unwrought [2]	8,587	11,784	13,184	Norway 5,669; Canada 2,937; United Kingdom 2,739.
Semimanufactures [2]	983	828	795	United Kingdom 504; West Germany 105; Norway 92.
Selenium	1	10	NA	Norway 5; Italy 4.
Silicon	18	8	NA	West Germany 7.
Silver and platinum-group metals:				
Ore and concentrate	---	---	2,242	
Residues and other waste	36	103	267	United States 65; France 24.
Silver:				
Unwrought and semimanufactures thousand troy ounces [2]	2,560	2,797	4,244	West Germany 1,286; United Kingdom 1,029; Switzerland 354.
Rolled, or other metal value, thousands	$210	$360	$583	West Germany $250; United Kingdom $110.
Platinum-group metals do	$892	$1,389	$1,533	United Kingdom $472; United States $428; West Germany $423.
Tin:				
Oxide—long tons	67	71	67	United Kingdom 55; West Germany 16.
Unwrought, including scrap [2] do	781	792	1,291	United Kingdom 295; mainland China 230; Malaysia 215.
Semimanufactures [2]—do	115	107	104	United Kingdom 73.
Titanium:				
Ore	3,670	3,474	e 3,500	Australia 3,147.
Dioxide	12,688	13,358	9,803	West Germany 4,773; United Kingdom 2,294; Finland 2,059; Japan 1,918.
Metal	61	90	NA	United Kingdom 67; United States 17.
Tungsten:				
Ore	1,297	1,306	1,881	Canada 828; South Korea 161; U.S.S.R. 120; mainland China 113.
Oxide	72	44	NA	West Germany 38; United Kingdom 5.
Metal	69	95	133	West Germany 65; France 18; South Korea 9.
Uranium and thorium [2] value, thousands	$345	$1,282	$47	All from United States.
Other radioactive materials	12	20	NA	United Kingdom 8; Norway 3.
Vanadium pentoxide	545	527	NA	Finland 425; Republic of South Africa 71; West Germany 30.
Zinc:				
Ore	---	---	496	
Oxide	3,598	3,409	3,509	West Germany 1,312; Netherlands 873; Poland 604.
Scrap [2]	56	62	73	Norway 42; Denmark 19.
Dust (blue powder)	168	120	135	United Kingdom 63; Norway 43.

See footnotes at end of table.
