e Estimate. r Revised. NA Not available.
[1] Excluding artificial corundum.
[2] Including alloys.
[3] Calculated from quantities reported in metric tons.
[4] Includes cast iron, spiegeleisen, and sponge, powder, and shot of iron or steel.
[5] Includes ores of vanadium and tantalum.
[6] Mostly compounds of vanadium, copper, and hydrazine under Subgroup 513.6, S.I.T.C. (revised).
[7] Mostly chlorine under Subgroup 513.2, S.I.T.C. (revised).
[8] Mostly nitric acid under Subgroup 513.3, S.I.T.C. (revised).
[9] Includes partly refined crude as follows: 72,000 tons in 1963, 61,000 tons in 1964, and 99,000 tons in 1965.

COMMODITY REVIEW

METALS

Metal production in Sweden continued to be dominated by a few large firms. Luossavaara-Kiirunavaara AB (LKAB) and Trafik AB Grängesberg-Oxelösund (TGO) accounted for approximately 90 percent of the nation's production of iron ore, while Bolidens Gruvaktiebolag (BGAB) accounted for an equally large proportion of the mine and smelter output of metals other than iron and aluminum. More than half of the nation's output of iron and steel was produced by TGO, Stora Kopparbergs Bergslags AB, and Norrbottens Järnverk AB, although AB Svenska Kullagerfabriken (SKF) and the Uddeholm, Avesta, Fagersta, and Sandviken companies were major producers of special steels. AB Svenska Metallverken (SM) continued to be the largest fabricator of nonferrous metals and the only producer of primary aluminum. The Swedish Government participated in the industry mainly through its 95.7-percent ownership of LKAB and 100-percent ownership of Norrbottens Järnverk AB.

Available information indicated that the sales volume of LKAB, TGO, and SM was approximately $200 million each in 1965,

while that of BGAB was $110 million. Partly because of many foreign subsidiaries, sales of the SKF Group in 1965 were $653 million, more than that of any other Swedish company.

Consumption of some important raw materials in the metal industry is shown in the following tabulation. A more detailed breakdown for the iron and steel industry is given on a subsequent page.

Commodity	Thousand metric tons			
	Iron and steel		Other metals	
	1963	1964	1963	1964
Alumina, including bauxite	(1)	(1)	36	62

Swedish domestic consumption of individual metals, as reported by the Organization for Economic Cooperation and Development (OECD) for the past 3 years, is as follows:

Metal	Thousand metric tons (unless otherwise specified)		
	1963	1964	1965
Steel, crude [1]	4,040.0	4,640.0	5,150.0
Other metals:			
Aluminum, primary	50.7	51.2	44.2
Copper, refined	96.0	96.6	95.3
Lead, refined [2]	51.2	54.9	52.5
Zinc	27.8	28.4	34.0
Nickel, refined	8.4	11.6	13.1
Tin, refined long tons	.6	.7	.8

[1] Apparent home consumption.
[2] Including lead content of antimonial lead.
Source: OECD (Paris). The Iron and Steel Industry in 1965 and Trends in 1966. 1966, Table 27, Statistical Annex. Also: The NonFerrous Metals Industry. 1966, pp. 11–16.

Aluminum.—Aluminum production in Sweden continued to be based entirely on imported raw materials. AB Svenska Metallverken was planning to expand the capacity of the Kristineborg smelter and of the Finspång rolling mill in 1965. Capacity of the smelter will be increased to 53,000 tons annually by 1968 at a cost of $12 million. This is the second 20,000-ton expansion program initiated by the company since 1962. The plant's 1965 capacity of 33,000 tons annually was reached in 1964. The smelter is operated by AB Svenska Aluminum-Kompaniet (SAKO), a subsidiary of SM.

Capacity of the Finspång mill was being doubled, to 70,000 tons annually. The company also decided to install a continuous casting plant, with an annual capacity of 10,000 tons. Other facilities recently built or expanded by SM include a plant for remelting alloys near Avesta, and a foil plant at Skultuna that had an annual capacity of 1,500 tons when it began operation in 1963. Aluminum accounted for more than half of SM sales in 1965.

Swedish imports of aluminum oxide and metal were valued at $36 million, about the same as in 1964. Jamaica and Norway continued to supply most of the alumina

and unwrought metal, while the main sources of semimanufactures were EEC countries and the United Kingdom.

The value of aluminum semimanufacture exports was $7.8 million less than in 1964. The decrease was mostly due to the reduced deliveries of bars and wire to Denmark and Norway and of flat products to Finland.

Copper.[2]—Rising copper prices were an important factor in the sharp rise in value of imports of that metal, as well as in the sales of the nation's principal producers; they also drew attention to a decline in mine output and stimulated reopening of old mines.

The increased output of refined copper in 1965 was derived mostly from imported concentrates. Domestic mine output declined despite higher metal prices and Swedish ores accounted for less than 25 percent of the metal produced. Concentrates produced by BGAB amounted to 66,000 tons as compared with 68,600 tons in 1964. Output of copper ore at Adak, mined by BGAB under a Government lease, was unchanged from the 1964 level.

Reymersholms Gamla Industri AB, recently acquired by BGAB, continued to recover copper from cupriferous pyrite at Oskarshamn. In central Sweden, Stora Kopparbergs Bergslags AB began opencast mining of copper ore at the old Tomtebo mine. The ore was processed at the company's Falun concentrator near Domnarvet.

In Norrbotten province, BGAB was preparing to develop the Aitik copper deposit. 65 kilimeters south of Gällivare. Opencast mining was scheduled to begin in 1968 at the rate of 2 million tons annually. The ore will be processed at the mine to about 32,000 tons of concentrate containing 28 percent copper. The Aitik deposit is estimated to contain 150 million tons of 0.5 percent copper ore, of which 30 million tons can be mined by opencast methods. Cost of the development was estimated at $15 million.

AB Svenska Metallverken was doubling the tube-making capacity of its Västeras plant to 20,000 tons annually, at a cost of $4 million. The company has also invested about $10 million over the last 10 years for production of thin strip at Finspång.

Imports of copper ore and metal, and exports of refined copper were increased substantially in 1965. Imports from Canada and Chile accounted for most of the increase in concentrates and metal, respectively, while shipments of refined copper to the United Kingdom increased by 8,800 tons. Domestic copper consumption in 1965 was distributed as follows: Wire and wire products (65 percent); tubular products (20 percent); flat products (10 percent); and rods (5 percent).[3]

Complex Nonferrous Ores.[4]—Most Swedish metal mines (other than iron ore mines) produce complex ores—ores containing sulfides or other minerals of two or more metals, as shown in the accompanying table. The only mines reported to produce single metals are at Adak (copper) and Laisvall (lead), although the Vassbo deposit is primarily lead ore, and the Aitik deposit is scheduled to produce only copper. Because Swedish sources usually do not report output of individual metals by mine, concentrator, or district, or the metal contents of "complex ore" reserves, these ores are described here as a separate group.

In 1965 BGAB continued to develop the Näsliden copper-lead-zinc deposit and to expand the Långdal mine. Production at Långdal, which is scheduled to replace that from the nearly exhausted Boliden mine, was expected to begin in 1967. Under a contract with the Swedish Board of Trade, the company also continued investigation of the Stekenjokk copper-zinc prospect near Vilhelmina in Norrbotten province. Exploratory drifting was underway from the 275-meter shaft completed in 1964. The Stekenjokk deposit was reported to contain 1.6 percent copper, 3.5 percent zinc, as well as silver and pyrite. The company decided to open new mines (or reopen old ones) at Rävliden, Rakkejaur (near Kristineberg), and Kankberg (near Boliden), but these developments wil take place gradually over the next 2 or 3 years. Deep-level investigations, which recently proved new reserves at the Renström, Kristineberg, and Saxberget mines, were also underway at Garpenberg. Total complex-ore reserves announced by the company in 1965 were 34 million tons; this estimate includes reserves of the Boliden and Långdal mines, but not those of the Rudtjebäck or Rakkejaur mines which are partly Government owned.

[2] For further information on ores containing copper, see Complex Nonferrous Ores.

Vassbo	190,457	194,828	Lead and zinc.
Svärdsjö	70,866	62,177	Lead, zinc, copper, silver.
Kalvbäck	128	---	Lead, zinc, copper, silver.
Total ore	3,611,630	3,553,702	

[1] Other than pyrite. Concentrates contain small quantities of other metals recovered at the respective mines.

Sources: Statistiska Centralbyrån (Stockholm). Bergshantering-Berättelse för År 1963 and År 1964, 1965 and 1966, pp. 57–65. Bolidens Gruvaktiebolag (Stockholm). Annual Reports for 1961 through 1965.

Most of the complex ores continued to be processed by BGAB in concentrators at Boliden, Kristineberg, Garpenberg, and Saxberget. The company also operated concentrators at Adak, Laisvall, and Vassbo.

Iron and Steel.—The productive capacity of the Swedish iron and steel industry continued to increase in 1965. Output and capacity were substantially increased in iron ore mining, processing, and shipping, as well as in metal reduction and processing plants. Output of high-carbon and alloy steel, traditionally a Swedish specialty, continued to rise and accounted for 26 percent of all steel produced.

Exports of iron ore and steel lagged behind production increases not only because of rising domestic demand but because of trade restrictions and increasing competition in foreign markets. The value of exports, however, was substantially higher than in 1964, reflecting increasing production of high-quality or specialized items. The latter trend was also indicated by planned investments which show increasing concentration on cold-rolling plants. Total investments in steelworks for 1964–65 amounted to $95 million, a 21-percent increase compared with that of 1963–64. A further increase of 10 percent was expected in 1966.

Swedish steel prices were generally below foreign steel prices, and in some cases were reportedly less than the cost of production. The industry regarded prices for ordinary steel and for cold-rolled stainless steel as particularly unfavorable during 1965, and at least moderate increases were expected for most items in 1966.

Oxygen steelmaking continued to increase, and output from Kaldo and Linz-Donawitz (L–D) converters was 42 percent greater than that of 1964. There was a drop of 22 percent in production of Thomas steel as four converters were dismantled at Domnarvet.

Total effective production capacity for iron and steel increased about 7 percent in

1965. Domestic consumption of finished steel increased 9 percent, to slightly more than 3.5 million tons.

Total employment (including salaried personnel) in the industry in 1964 was approximately 69,700, including 10,200 in iron mining operations. Mine employment decreased slightly in 1965, but there was an increase of about 800 employees in metal processing plants.

Iron Ore.—Iron ore output continued to increase in 1965 at an annual rate of more than 10 percent. The 2.8-million-ton gain was due largely to expanded operations by LKAB. The company's new Svappavaara opencast mine, 40 kilometers southeast of Kiruna, produced more than 1 million tons of ore in 1965 while increases of 750,000 tons and 450,000 tons were registered at Malmberget and Kiruna, respectively. Total output by LKAB was 22 million tons, including 5.24 million tons from Malmberget and about 500,000 tons from Luossavaara.

Production by the Grängesberg Co. totaled 2.89 million tons, of which 560,000 tons came from the Stråssa mine and the remainder from Grängesberg. Stråssa production included 26,000 tons of manganese ore which was mostly exported to Finland.

The remaining 12 percent of ore output was distributed among more than a dozen other companies, most of which reported production gains in 1965. The following table shows the distribution of iron ore production in 1963, by company and by grade of ore.

Table 5.—Sweden: Principal producers of iron ore, 1963

(Quantities in thousand metric tons)

Company Province Mine or plant:	Ore for direct use[1]		Ore for concentration		Concentrate produced		Total ore and concentrate

[1] Includes sorted, washed, and magnetically cleaned ore, not classified as concentrates.
[2] Not including 4,000 tons containing 22 percent iron and 2 percent phosphorus.
[3] Processed at Vitåfors. Concentrates shown do not include 1,168 tons of apatite concentrates.
[4] Not including 9,000 tons containing 44 to 50 percent iron and 2.4 to 3.6 percent phosphorus.
[5] Containing 4.3 percent manganese and 10.2 percent calcium silicate.
[6] Containing 0.32 percent zinc and 0.23 percent lead.
[7] Containing 4.5 percent manganese.

Source: Statistiska Centralbyrån (Stockholm). Bergshantering-Berättelse för År 1963. 1965, pp. 48–61.

Of total 1965 output, 24.5 million tons was exported, 3.8 million tons was sold on the domestic market, and 1.1 million tons was stockpiled. Total stocks on December 31 were about 4.3 million tons.

The high phosphorus content of most Swedish ores continued to have a depressing effect on export prices. Swedish producers were attempting to overcome this disadvantage by improving product quality and by installing the most modern equipment and methods to reduce unit costs. These efforts were increasingly evident in 1965, as several new concentrating and pelletizing plants were completed or under construction, and improved methods of mining and transportation were being installed.

The Svappavaara mine concentrator, completed in 1965, will furnish 1.5 million tons of concentrate annually to the Kiruna pelletizing plant which was also completed during the year. This raised LKAB's pelletizing capacity to 2 million tons annually. Total annual pelletizing capacity will increase to 3 million tons in 1967 as the output from Svappavaara reaches the scheduled level and a fourth shaft furnace is added to the Malmberget plant. At Stråssa, a second pelletizing unit, scheduled for completion in early 1966, will increase annual capacity to 500,000 tons. These and other projects should increase Sweden's output of iron ore agglomerates by at least 2 million tons by 1966. Consumption of raw materials by agglomerating plants and their output in 1964 were as follows:

Plant name or location	Raw material consumption (thousand metric tons)				
	Iron concentrates	Crushed lump ore	Mill scale	Slag, lime, and other	Product [1]
Domnarvet	850	1	34	178	1,006

Automation of underground transport at Kiruna was continued by LKAB. The centralized traffic control (CTC) system on the 420-meter level was integrated with an IBM–1710 computer. The annual haulage capacity on this level increased to 11 million tons in 1965 and was expected to reach 20 million tons by 1970. In 1965, CTC networks included 19 kilometers of underground track at Kiruna and 40 kilometers at Malmberget, as well as the surface railways between Gällivare and Narvik and Grängesberg-Oxelösund. LKAB also planned to spend $34 million by 1969 in modernizing mining and transportation at Malmberget. Sublevel caving will be used, and rail transport on the 600-meter level will be replaced by trucks.

At Luleå, the Baltic seaport for Kiruna ore, the 13-kilometer deepwater channel was completed. The $42 million port can now accommodate fully loaded ships of up to 37,000 tons.

Scrap.—Consumption of iron and steel scrap in 1965 totaled 2.73 million tons, including 65,000 tons consumed in blast furnaces. Of the scrap used in steelmaking, nearly 60 percent was charged in electric furnaces, 35 percent in open hearth furnaces, and the remainder in oxygen converters.

Pig Iron, Ferroalloys and Steel.—Raw materials consumption and the basic production facilities of the Swedish iron and steel industry are shown in tables 6 and 7.

Table 6.—Sweden: Consumption of raw materials by sectors of the steel industry in 1964

(Thousand metric tons unless otherwise specified)

[1] At yearend.
[2] Under "Steel", individual outputs do not include production for duplex process.
[3] Synthetic pig iron, not otherwise defined. Presumably made mostly from scrap.
[4] Total effective capacity.

Sources: Järnverksföreningen (Stockholm). Svensk Järnstatistik. No. 1, 1966. Statistiska Centralbyrån (Stockholm). Bergshantering-Berättelse för År 1963. 1965, p. 33.

TGO produced 677,000 tons of pig iron in 1965. The Oxelösund works accounted for 637,000 tons and the remainder was produced at Guldsmedshyttan. In addition, 34,000 tons of sponge iron was also produced at Oxelösund. At the Guldsmedshyttan works, the blast furnace was shut down for three months while alterations were made to increase productive capacity. The plant produced 56,000 tons of pig iron in 1964, mostly from Stråssa ore pellets. A new casting shop, with a capacity of 15,000 tons of ingot molds annually, was also completed.

At the Domnarvet works of Stora Kopparbergs Bergslags AB (SKB), a new pig iron plant was completed in 1965. The plant has an output capacity of 40,000 tons annually and is the first commercial-size unit to employ the recently developed Stora-Dored direct reduction process, which produces low-phosphorus pig iron from high-phosphorus iron ore. Although fairly large quantities of oxygen are required, the process permits ore fines (about 100 mesh) to be used without prior agglomeration, and coke consumption is approximately 20 percent less than in blast furnaces.

Production of ferroalloys and the main producing companies in Sweden are shown in tables 8 and 9.

Table 8.—Sweden: Production of ferroalloys

(Metric tons)

	1962	1963	1964
Ferrosilicon	25,971	23,519	27,293

Table 9.—Sweden: Principal companies producing ferroalloys

Company Plant or location	Principal products	Remarks
AB Ferrolegeringar Trollhätan	Full range of ferroalloys	Largest Swedish producer. Ferrochromium capacity about 30,000 tons annually. Also produces silicon, cobalt, silico-zircon, other metals and alloys.
Wargöns AB Vargön Trollhätan	High- and low-carbon ferrochromium (total capacity 15,000–20,000 tons annually); ferromanganese; ferrosilicon.	Annual capacities: Vargön works 50,000 tons; Trollhätan works 15,000 tons.
Avesta Jernverks AB Avesta	Low-carbon ferrochromium (annual capacity 11,000–14,000 tons); ferromolybdenum; ferrotitanium; others.	
Uddeholms AB Hagfors	Low-carbon ferrochromium (annual capacity 4,000 tons); ferromolybdenum; ferrotitanium.	Also produces titanium and other metals.
Gullspångs Elektrokemiska AB Gullspång	Ferrosilicon; ferrotungsten; ferromolybdenum.	Also produces silicon.
Stockholms Superfosfat Fabriks AB Stockholm	do	Do.
Söderfors Bruk Söderfors	Ferrovanadium	Division of Stora Kopparbergs Bergslags AB.
Wikmanshytte Bruks AB Vikmanshyttan	Ferrotungsten	Also produces tungsten carbide and drill steel.

Two 80-ton oxygen (Kaldo) converters were added to the Domnarvet works in 1965. The new vessels replaced four 28-ton Thomas converters. By yearend, SKB's productive capacity for crude steel was approximately 1 million tons annually. The company was also installing a continuous casting machine at Domnarvet, for production of slabs up to 63 inches wide. The single-strand machine was scheduled for completion in 1966.

The Oxelösund works produced 658,000 tons of steel ingots in 1965 (590,000 tons in 1964). Three fourths of the output was produced by two 100-ton Kaldo converters. A third oxygen converter (Linz-Donawitz, 120-ton) was scheduled for installation by 1968. A continuous casting machine (single-strand, output capacity 350,000 tons of slabs annually) was ordered in 1965 for installation by late 1967.

Norrbottens Järnverk AB, a Government-owned company and Sweden's third largest producer of steel, reportedly sustained a financial loss in 1965 despite increased sales. The loss was attributed to higher operating costs, in part due to mechanical difficulties in the hot-strip mill at Luleå. Output capacity for crude steel at the Luleå works in 1965 was approximately 700,000 tons annually. A 60-ton Kaldo converter was added to the plant during 1964.

Production of special steels continued to increase in 1965, as shown by table 10.

Table 10.—Sweden: Production of special steels
(Thousand metric tons)

Type of steel	1963	1964	1965
Unalloyed, high carbon	176.0	198.2	223.8
Stainless	188.0	251.0	275.3
Heat-treatable, case-hardening, including spring steel	161.0	211.1	252.5
Tool steel	55.2	77.6	88.4
High-speed	6.6	10.5	15.8
Free-machining	9.6	9.4	9.4
Other alloy steel, including bearing steel	271.1	347.5	363.0
Total	867.5	1,105.3	1,228.2

Source: Järnverksföreningen (Stockholm). Svensk Järnstatistik. No. 1, 1966.

Columbium-steel plate continued to be TGO's main specialty product at Oxelösund. Although production figures were not available, an increasing quantity of this steel was being processed by the company's plate mill. The total output of heavy plate in 1965 was 388,000 tons.

Avesta Jernverks AB was the leading producer of stainless steel, with output of 90,000 tons. Nyby Bruks AB, which became a division of TGO in 1964, produced 53,000 tons of stainless steel and 26,000 tons of other steel ingots. A new hot rolling mill and an automatic argon-arc welding machine for stainless steel pipe were installed at Nyby in 1965, and a new continuous casting machine (annual capacity 25,000 tons) will be installed in 1966.

At Hellefors, AB Svenska Kullagerfabriken (SKF) began operating a 30-ton ladle furnace for vacuum degassing of steel. The degassing process, which will be used mainly for case-hardening steel, is a new one developed by SKF and Allmänna Svenska Elektriska Aktiebolaget (ASEA), a large Swedish manufacturer of electrical equipment. SKF continued to operate plants at Hofors, Göteborg, Katrineholm, and Bängbro, and expanded its foreign operations by opening a new plant in India and acquiring control of an Italian bearing-steel firm. The SKF Group included at least 12 manufacturing subsidiaries and 30 factories abroad, and total sales in 1965 amounted to $653 million.

In Swedish exports of special steel semimanufactures, bars and wire rod continued to be the largest volume items, while hoop and strip accounted for the largest value ($33 million). In finished products, exports of ball and roller bearings were valued at $44 million in 1965.

Lead and Zinc.[5]—Mine output of both metals was little changed from 1964 levels, with BGAB continuing to account for about 90 percent of the lead and for 60 percent of the zinc. The remaining production was distributed between Bolaget Vieille Montagne, Stora Kopparbergs Bergslags AB, and AB Statsgruvor. The latter firm, owned by the Government, increased its ore-processing capacity at Stollberg by

[5] For further information on ores of these metals, see Complex Nonferrous Ores.

60 percent in 1965, to 170,000 tons annually. BGAB also increased its production of lead dust and zinc clinker.

Mine output of both metals exceeded domestic consumption of crude metal. Most of the output of mine zinc continued to be exported for smelting, so that Sweden remained dependent upon imports to meet zinc metal needs.

The Laisvall mine continued to be the country's principal source of lead. Development of the Kautsky ore body, west of the mine, was nearly completed, and production was scheduled to begin early in 1966. This ore body, developed at a cost of about $2 million, will produce most of the ore mined at Laisvall after 1966.

Lead ore reserves in 1965 were reported by BGAB to total about 33 million tons. Most of this ore is at Laisvall and contains about 4 percent lead. The reserves also include ore at Vassbo in western Sweden and about 1 million tons of ore at Bellviksberg in Västerbotten. The company expected to begin opencast mining at Bellviksberg in 1969.

Expansion of the Långdal mine was continued in 1965, and production was expected to begin in 1967. The Långdal ore contains lead, zinc, pyrite and some silver.

NONMETALS

Cement and Other Construction Materials.—Production and apparent consumption of cement increased in 1965 as the construction industry maintained a high level of activity. The number of residential housing completions was 11 percent more than in 1964, but new housing starts were 4 percent less as the Government took several steps to reduce the volume of building activity. A 10-percent cut in Government construction was ordered in April; applications for $51 million worth of building starts in the Stockholm area were turned down; and other public and private construction projects were ordered postponed. Late in the year, the Government also announced plans to purchase Svenska Durox AB, a company which produces concrete construction materials and indirectly controls about 15 percent of the country's output of porous concrete products and 45 percent of the mineral wool insulation. The plan was regarded as an attempt to control rising prices of construction materials.

Apparent consumption of cement was 3,787,000 tons in 1965, an increase of 3.7 percent over that of 1964. Bulk deliveries comprised an estimated 78 percent of the total (75 percent in 1964) while the remainder was delivered in bags. The total productive capacity for cement apparently remained at 4.15 million tons annually, as no further increases were reported during 1965.

Quarry production of rough cut and crushed stone, including quartz and feldspar for 1964 is shown in the following tabulation:

County	Thousand metric tons				
	Granite and gneiss [1]	Sandstone, quartzite, and flint	Feldspar	Quartz	Limestone, dolomite, and marble
Stockholm [2]	904	---	14	---	528
Uppsala	333	---	---	---	---
Östergötland	445	15	1	4	12

Total	8,261	902	22	168	8,029

[1] Includes 610,000 tons of black and green granites and unspecified quantities of waste rock from mining operations.
[2] Including Stockholm city.
[3] Less than ½ unit.

Source: Statistiska Centralbyrån (Stockholm). Bergshantering-Berättelse för År 1964. May 1966; p. 68.

Pyrite and Sulfur.—Pyrite production remained close to the level of 1964, with BGAB continuing to produce 90 percent of the total output from its Kristineborg and Boliden concentrators. Additional sources of pyrite to be mined in the near future, included the Kankberg and Rakkejaur deposits. Exploration of the Udden (Kedträsk) deposit was to be resumed in 1966.

Two new sulfuric acid plants, each having an annual capacity of 175,000 tons, were completed at Rönnskar and Halsingborg in 1965.

Production of elemental sulfur from oil shale operations at Kvarntorp was not expected to continue through 1966, and an increase in imports seemed likely. Sweden's sulfur consumption was estimated to exceed 400,000 tons annually.

MINERAL FUELS

Coal and Coke.—Coal production reached a new low in 1965. The decline was expected to continue, because the country's only producer (Höganäs-Billesholms AB) planned to close the Nyvång mine in 1966. Most of the coal produced was probably of B grade, since the proportion of A and C grades[6] had fallen off sharply since 1963. The company used part of the output for its own operations and sold the remainder to local consumers. The total output amounted to less than 3 percent of Sweden's apparent domestic consumption and was insignificant in the total energy supply.

Coke production capacity was increased in 1965 by the addition of 28 coke ovens to the Oxelösund steelworks. The new facilities raised the plant capacity to about 475,000 tons annually. Production of coke-oven coke at Oxelösund in 1964 was about 95 percent of the national output.

Imports of coal in 1965, valued at $23 million, were 15 percent less than those in 1964. Purchases from the United States, the principal supplier, were reduced by 17 percent, and deliveries from the United Kingdom and West Germany were down 30 percent. The total quantity received from East Europe declined only slightly; purchases from the Soviet Union were increased by 163,000 tons, largely at the expense of Poland.

Imports of coke, valued at $34 million, also dropped about 15 percent in 1965. Imports from West Germany declined by 203,000 tons and those from the United Kingdom by about 60,000 tons. The total quantity purchased from East European countries rose slightly, but the total value was less than that in 1964, owing to 62,000 tons of low-priced coke received from Poland.

Consumption statistics for coal and coke, through 1964, are as follows:

[6] These grades are based on the following properties: Calorific value, in kilocalories per kilogram: A 4,800–5,600; B 3,900–4,600; C 2,700. Ash content, in percent: A up to 13; B 14–35; C 36–55.

e Estimate.
[1] Annual figures include an estimated 50,000 tons consumed by the iron and steel industry, exclusive of cokeworks.
[2] Other than iron and steel.
[3] Including quantities transformed into blast furnace gas.
Source: O.E.C.D. (Paris). Basic Statistics of Energy 1950–64. 1966, pp. 267–269.

The reductions in imports may have been matched by decreased total consumption in 1965, although increasing consumption in the iron and steel industry and lack of information on stocks made this somewhat uncertain.

Petroleum.—Oil shale continued to be Sweden's only natural hydrocarbon resource. Production at the Kvarntorp plant of Svenska Skifferolje AB declined by 30 percent in 1965 and was expected to cease by 1967. Most of the state-owned facilities were sold to private interests in October and will be converted for cement manufacture. While the Kvarntorp operations produced considerable quantities of elemental sulfur as well as fuel oil, gasoline, liquefiable gases, and ammonia, extraction was expensive and continual government subsidy was necessary to maintain operations. The works provided employment for about 600 persons.

Oil and Gas Exploration.—Geophysical work by the Swedish Geological Survey reportedly indicated that the province of Skåne (southwest Sweden) and adjacent sea areas offer the best prospects for oil and gas exploration in Sweden. Other possibly favorable areas were indicated in the Baltic Sea, south of Gotland and between Sweden's east coast and the Åland Islands. Previously, both the Oljekonsumenterna (OK) cooperative and Axel Johnson and Co. had reportedly drilled unsuccessfully for oil on Gotland and off the east coast of the mainland.

Although Sweden has agreed in principle to the Geneva convention on claims to offshore resources, the Government wished to study the matter further before signing the convention. In 1965, proposed legislation on offshore resources was being circulated and was expected to be acted upon by the Riksdag in the spring of 1966. Discussions were also in progress concerning the formation of an all-Swedish exploration consortium composed of the OK, LKAB, and Johnson companies.

Crude Oil Imports.—Imports of crude and partly refined petroleum in 1965 increased by 7.5 percent and were valued at $61 million. Venezuela remained the principal supplying country, followed by Saudi Arabia and Iraq. Shipments from Iraq increased by 148,000 tons, which was approximately equal to the decline in deliveries from Iran. Imports of Nigerian crude oil (57,000 tons) were reported for the first time.

Refining.—Sweden's refineries were operated at near-maximum levels in 1965 as total throughput increased 7.5 percent to 4.1 million tons. New plants under construction at Gothenburg were expected to double the country's capacity by 1967; AB Svenska Shell was expanding capacity of the Koppartrans refinery to 4 million tons annually (an increase of 1.7 million tons) at an estimated cost of $23 million. The British Petroleum Co. (Svenska BP) was building a large refinery at Syrhaala at an estimated cost of $60 million. The Svenska BP refinery will have an initial capacity of 4 million tons annually. The Gothenburg projects require enlargement of harbor facilities to accommodate 100,000-ton tankers, and the city has already appropriated more than $5 million for the necessary improvements.

AB Nynäs-Petroleum continued to operate refineries at Nynäshamn (south of Stockholm), Malmö, and Gothenburg. The refineries have annual capacities of 1.5, 0.15, and 0.25 million tons, respectively.

Petroleum products continued to be the most important commodity group in Sweden's mineral trade. Net imports increased by 850,000 tons in 1965 and were valued at $337 million. Fuel oils accounted for about 75 percent of the increase in volume and gasoline accounted for the remainder. The increased shipments mainly originated from Trinidad-Tobago and the United Kingdom. The principal supplying countries continued to be the United Kingdom, the Soviet Union, and the Netherlands.

Consumption of petroleum products rose by 11 percent in 1965, with fuel oils registering the largest gains. Inland consumption statistics are as follows:

Product	Thousand metric tons		
	1963	1964	1965
Gasoline	1,905	2,119	2,332
Kerosine	266	259	272
Distillate fuel oil	5,406	5,779	6,505
Residual fuel oil	6,311	6,730	7,625
Other products	1,017	1,093	1,032
Total	14,905	15,980	17,766

Source: O.E.C.D. (Paris). Provisional Oil Statistics by Quarters—1st Quarter 1966. August, 1966; pp. 16–21.

Other products, not specified in the preceding tabulation, included (in 1964) 550,000 tons of aviation fuels; 50,000 tons of liquefied petroleum gases; and 377,000 tons of non-energy products.

Gasoline consumption increased at the same rate as in 1964, although taxes were increased by 5 öre per liter on July 1. The tax increase was countered to some extent by the principal marketing firms which reduced gasoline prices by 2 to 3 öre per liter; all firms, however, announced that they would stop granting discounts and cash rebates. Prior to the tax increase, the retail markup on gasoline was reportedly the highest in Europe.

Uranium and Atomic Energy.—The uranium mine and concentrator at Ranstad (near Skövde) was completed by AB Atomenergi in August and began producing concentrate in November. The plant is designed to produce 170 tons of 70-percent uranium concentrate annually from about 850,000 tons of shale. The shale contains about 0.03 percent uranium and is similar to that mined at Kvarntorp, where the company operated a pilot concentrator until 1962. Final processing of the Ranstad concentrate will be done at Stockholm, where the company produces uranium oxide fuel elements and other radioactive materials.

The Ågesta powerplant supplied 5 million kilowatt-hours of electricity during 1965 and the equivalent of 100 million kilowatt-hours in the form of district heating to the Stockholm suburb of Farsta. The State Power Board assumed responsibility for the Ågesta operation on September 1.

Construction of the Marviken boiling-water reactor was continued. The Marviken plant, 48 kilometers east of Norrköping, is scheduled for completion in 1968; it will have an initial capacity of 140 megawatts of electricity, which will increase to 200 megawatts when a superheat system is installed.

A third atomic power project was announced in mid-1965. Oskarshamnverkets Kraftgrupp AB, a group of public and private utility companies, has contracted for construction of a large powerplant at Simpevarp based on a boiling light-water reactor. The plant will have an output capacity of 400 megawatts of electricity and is scheduled for completion in 1970.

Electric Energy.—Production of electricity increased about 9 percent in 1965, to 49 billion kilowatt-hours. Hydroelectric plants accounted for about 95 percent of the total output although thermoelectric capacity was increasing. The total installed capacity of new plants scheduled for service in 1965 and 1966 was 984 megawatts, of which 60 percent was assigned to thermal plants. Hydroelectric capacity was expected to reach nearly 50 percent of the country's estimated potential by 1968.

Consumption of electric energy in 1965 amounted to 42 billion kilowatt-hours, of which mining and manufacturing accounted for 58 percent. Some statistics on production and industrial consumption of electric power are as follows:

	1962	1963	1964
Number of power stations	1,371	1,380	1,370
Installed generator capacity (megawatts):			
Hydroelectric	9,432	10,007	10,212
Thermal	2,744	3,014	3,097
Total	12,176	13,021	13,309
Production (million kilowatt-hours):			
Hydroelectric	39,099	37,908	43,093

The Mineral Industry of Switzerland

By Stephen C. Brown [1]

Swiss efforts to combat inflationary pressures through a combination of a tight money policy, restrictions on new industrial construction, and limitations on the importation of foreign workers proved effective in 1965. The rate of economic growth (in real terms) was cut back from 5 percent in 1964 to 4.3 percent in 1965, and the mineral industries with few exceptions showed significant declines in output.

The aluminum industry increased primary production by 4.5 percent, but the small steel industry only maintained its 1964 rate of output and the construction material industries (cement, lime, and slate) showed sharp declines in production. The independent Swiss petroleum refinery at Aigle (Raffineries du Rhône) continued to be in difficulties and at the end of the year it was reported that a group of international oil companies had made an offer to take it over. Trade in minerals expanded; imports rose in value by about 5.5 percent, and exports rose in value by 27 percent. These increases were accounted for chiefly by sharp increases in the value of exports of the nonferrous and precious metals and of precious stones and gem stones. However, the great imbalance between values of mineral imports and mineral exports remained, and imports were valued at more than three times mineral exports.

PRODUCTION

The 4.5-percent increase in primary aluminum output and a 24-percent rise in salt production were the only significant increases in mineral output recorded in 1965. Iron ore production increased slightly from the low level of 1964, but steel output remained at the same level. Building materials showed sharp declines, output of cement falling by 7 percent, and output of lime decreased 12 percent. A sharp decline in production of gas plant coke probably reflects declining demand for manufactured gas, for which output data are not available. Unofficial data for 1964 output of petroleum products show a total of 766,017 tons; 1965 data are not available.

[p] Preliminary. [e] Estimate. [r] Revised.

[1] In addition to commodities listed, unreported quantities of several metals, including copper, magnesium, nickel, and zinc were produced from scrap. Building stone, limestone for cement, crushed rock, gypsum, coal briquets, and peat were also produced but output is not reported.

[2] The refinery of Raffineries du Rhône at Aigle, Switzerland's first oil refinery, went on stream in September 1963, but its output has not been officially reported. 1963 and 1965 are from Organization for Economic Cooperation and Development (OECD); data for 1964 are as reported by Petroleum Times, July 9, 1965, from the company's annual report. OECD also list other products as follows: 1963—15,000 tons, 1964—42,000 tons, 1965—none.

TRADE

In terms of value, both imports and exports of mineral commodities rose, the former by 5.5 percent and the latter by 27 percent. They also increased slightly their proportion of total trade, mineral imports rising to 19.8 percent of total imports in 1965 as compared with 19 percent in 1964, while mineral exports rose to 7.1 percent of total exports in 1965 as compared with 6.2 percent in 1964. Mineral imports valued at $726 million and mineral exports at $208.7 million left a deficit on mineral trade of $517.3 million as compared with a deficit on mineral account of $523.8 million in 1964, but as a proportion of the total trade deficit the mineral deficit rose to about 75 percent as compared with about 55 percent in 1964.

On the import side iron and steel ($224 million), petroleum and petroleum products ($193 million), and the nonferrous metals ($109.7 million) remained the chief items, with coal, coke, and briquets following ($37.9 million). Imports of precious metals and precious stones, including industrial diamonds and dust, rose by more than 10 percent to $81.4 million.

On the export side the chief items were aluminum and alloys ($34.9 million), metalliferous ores and scrap ($21.5 million), iron and steel ($20.7 million), and copper and alloys ($13.5 million). Exports of precious metals and precious gem stones, including industrial diamonds and dust, rose sharply from $68.2 million in 1964 to $92.5 million in 1965.

1 Less than ½ of unit.
2 Including rolled gold or silver.
3 Including cast iron, sponge iron, spiegeleisen, powder, shot, grit, and pellets.

COMMODITY REVIEW

METALS

Aluminum.[2]—Despite the 4.5-percent increase in output of primary aluminum in 1965, trade reports indicated a decline of 3 to 4 percent in domestic sales of metal and semimanufactures. Domestic consumption of secondary aluminum was estimated at 6,500 tons as compared with 7,400 tons in 1964. Imports of aluminum and semimanufactures rose by some 5,000 tons but this was more than offset by an increase of 5,154 tons in exports; the import increase was said to consist chiefly of intrafirm transactions in the first half of the year.

Final consumption of aluminum in Switzerland was broken down as follows in 1965, according to a recent estimate (1964 percentages in parentheses): Transport 8.1 percent (7.8 percent); mechanical construction 20.4 percent (19.6 percent); electrical uses 10.8 percent (10.8 percent); construction 24.5 percent (25.1 percent); chemical, food and agricultural equipment 1.3 percent (1.3 percent); packaging 18.3 percent (18.3 percent); household and

[2] Aluminium. V. 42, No. 1, January 1966.

office installations 5.3 percent (5.7 percent); iron and steel industry 1.3 percent (0.8 percent); other metal working industries 2.8 percent (2.8 percent); and various other industries 7.2 percent (7.8 percent).

Prices of ingot aluminum were unchanged during the year.

NONMETALS

Cement.—Production of cement declined by nearly 300,000 tons in 1965, reflecting the cutback in industrial building; imports fell by 70,000 tons and exports rose by nearly 100,000 tons. The Government's antiinflationary policy thus was felt keenly by the industry, but its trade association (Verein Schweiz., Zement-, Kalk-, und Gips-Fabrikanten), writing in its 1964 Annual Report (published in 1965) expressed greater concern at the effects of coming shifts in Switzerland's energy policies. It pointed out that in the past hydropower dams have provided a large market for cement and that this market will disappear as Switzerland shifts to thermal and nuclear power for required additional energy supplies. The national roadbuilding program will not provide a sufficient demand for cement to offset loss of this market according to the association and it predicted a rate of market growth in the future nearer to the rate of population growth than in the past.[3]

MINERAL FUELS

Petroleum.—Data are unavailable for 1965 output of the refinery at Aigle owned by Raffineries du Rhône but trade returns show imports of 1,209,000 tons of crude oil, indicating a throughput in the vicinity of that figure, which represents only about 60 percent of its 2-million-ton capacity. This unsatisfactory situation, said to be due basically to the refinery's lack of marketing and distribution facilities, led to an offer by the Standard Oil Co. of New Jersey and an associated group of international oil companies to take over the refiinery from Raffineries du Rhône. The bid was still pending at yearend. A complicated problem involved in the takeover was reported to be a Raffineries du Rhône contract for the importation of Soviet crude oil, signed in 1965.

Meanwhile construction continued on Shell's new refinery of Cie. de Raffinage Shell (Suisse) at Cressier, near Lake Neuchatel, and it was nearly completed by November. The proposed Mittelland refinery at Ettiswil near Lucerne, was still stymied at yearend by failure to obtain a license for the building of a spur line from the South European pipeline to supply crude oil. (Shell had obtained a permit for a similar line to feed its Cressier refinery.) Similarly, no progress was made in obtaining the necessary permission for another refinery at Sennwald in eastern Switzerland, sponsored by Swiss, Italian and U.S. interests.

Reports indicated that negotiations were going on between Swiss interests and Gasversorgung Suddeutschland (GVS) for purchase of Netherlands natural gas when the proposed pipeline from the Groningen fields to Munich reaches southern West Germany. The gas would be supplied by a spur line to Switzerland from that pipeline.

Swiss consumption of petroleum products has been rising rapidly, showing rates of growth ranging from 15 to 26 percent during 1960–63, followed by increases of 6.6 percent in 1964 and an estimated 14 percent in 1965. Total consumption in 1965 is estimated at 7,984,000 tons. The two refineries at Aigle and Cressier will have, according to estimates, a combined capacity of 4.5 million tons, a little over half the current demand.[4]

Swiss policy towards refinery construction is said to be influenced by the following considerations: (1) A desire to keep a variety of oil transport routes for imports open (including rail and Rhine barges) in order to avoid complete dependence on one or two pipelines; (2) a desire to maintain minimum stocks of certain products in the country; and (3) concern for possible effects of air and water pollution.[5]

of petroleum in Switzerland depend primarily on the authority to license pipelines.[6]

The Mineral Industry of the U.S.S.R.[1]

By V. V. Strishkov[2]

The Soviet Union's share of world industrial production continued to rise and in 1965, constituted for nearly one-fifth of the total world industrial output. The mineral industry contributed 38 billion rubles or about 9 percent of the gross national product (GNP) of the U.S.S.R. and was an important earner of foreign currency.

The apparent self-sufficiency position of the Soviet Union for selected mineral commodities, together with its approximate share of world output of these commodities and rank among world producers are shown in table 1.

In 1965, the output of electric power increased by 48 billion kilowatt-hours over that of 1964, production of petroleum increased 19 million tons, output of gas increased 17 billion cubic meters, and that of coal 24 million tons. There were 2 million workers in ferrous and nonferrous industries and 1.7 million workers in the coal industry of the U.S.S.R. in 1965.

Shipments of practically all of the Soviet mineral commodities that are exported were at increased levels in 1965. The export of fuel from the U.S.S.R. increased and was the largest and fastest growing single commodity group in the Soviet export trade to the West. The Soviets probably will be able to maintain and even increase the rate of growth of their oil exports, in spite of rising home demand and technical difficulties of production and transport.

During 1965, the last year of the 7-year plan (1959–65), many new mineral industry facilities became operational. In the ferrous metals sector, additional mining and concentrating facilities as well as new blast furnaces, smelters, and rolling mills resulted in some significant increases in total capacity.

Although not all of the planned 1959–65 goals were attained, growth of ferrous industry during the period was as follows: Pig iron, 67 percent; steel, 66; rolled metal, 65; pipe, 95; and iron ore, 72 percent. Its share in the fixed assets of all industry amounted to 10.7 percent in 1965. Production of ferrous metals accounted for nearly one-seventh of all fuel and almost a ninth of all electric power consumed in the U.S.S.R.

In the nonferrous industry, output of many base and precious metals particularly nickel, aluminum, cobalt, and platinum increased in comparison with that of 1964. The discovery of rich deposits in the Norilsk area, and the completion of nickel facilities on the Kola Peninsula advanced the U.S.S.R. to one of the leading world producers of nickel and platinum.

Total refining capacity of aluminum plants almost doubled during the years 1962–65, and the country is expected to become a significant exporter of this metal in the future. In 1964, the U.S.S.R. for the first time became a net exporter of copper.

Several new nonferrous enterprises came into operation during 1959–65, and a number of diamond mines were opened in Yakutia.

Capacity of Soviet power stations exceeded 110 million kilowatts in 1965. Several new facilities were put into operation during the year including: The Kiev hydroelectric plant, and the Burshtynskaya (Ivan-Franko Oblast') and Krivoy Rog No. 2 thermal powerplants. Some 800,000–1,200,000 kilowatts were added to existing thermal power plants in the Ukraine, and a fourth turbine to the Lithuanian hydroelectric powerplant.

The production of electric power, coal, and gas were below both industry requirements and 7-year plan targets. New goals were planned for 1965.

[1] Based almost entirely on published Soviet material.

[1] Self-sufficiency is expressed as a ratio of mine production to consumption of primary material. Except as noted, production has been estimated.

[2] Production as reported in Soviet sources.

Chemical production (including fertilizers) increased over the 7 years, 1959–65, with an annual growth rate averaging 13.6 percent compared with 9 percent for industry as a whole. Among the enterprises started up during the period were: Nevinnomyssk, Grodno, Novo-Lipetsk, Navoy, Kuybyshev, and Fergana nitrogen plants; Shchekino chemical combine; Chardzhou, Sumgait, Volkhov, and Kedayaynay superphosphate plants; Rozdol sulfur combine; "Fosforit" combine in Kingisep; and Seligorsk potash combine.

The goals of the 7-year plan were not fulfilled in many areas of chemical production. Mineral fertilizer output totaled 31.3 million tons in 1965, while the planned goal was 35 million tons.

For many years Soviet industrialization was directed toward expansion of heavy industry, with emphasis largely on increases in gross production rather than on efficiency and product quality.

The U.S.S.R. experienced considerable difficulty in the construction of mineral industry projects. Efforts were dispersed over a large number of projects, with the work taking one and one-half to two times as long as specified by the U.S.S.R. State Construction Committee. This resulted in a disparity between capacities of mines, concentration plants, and metallurgical plants.

Many mines and plants were put into operation in spite of numerous inperfections and insufficient equipment. As a result, labor productivity was below planned levels, and a large number of personnel was occupied in repair and auxiliary operations.

At polymetal mines in Kazakhstan the proportion of mechanized labor did not exceed 35 percent, with the majority of auxiliary operations performed manually. In underground coal mining over 50 percent of the workers were nonmechanized.

Decisions of the September Plenum of the Central Committee of the Communist Party of the Soviet Union (C.P.S.U.), with regard to the 5-year plan for 1966–70 will have important significance to the development of Soviet industry, including the mineral producing and processing sector. The draft plan, as approved by the 23d Congress of the C.P.S.U., foresees annual average increases in gross industrial production of about 8.2 percent, or slightly less than that of the 1959–65 7-year plan. The annual rises for capital goods are fixed at around 8.5 percent, and for industrial consumer goods at 7.9 percent. Labor productivity in industry is to be raised by 33 to 35 percent, with the average yearly rates per worker amounting to 6 percent as compared with 4.6 percent for 1961-65.

The plan envisages a 20- to 25-percent reduction in consumption of rolled ferrous metals by machine building and metal processing and not less than 8 to 10 percent in the fuel consumption by industry.

Basic tasks of the new 5-year plan include the more intensive use of equipment, raw material, and supplies; improvement of product quality, reliability, and service life; increase of machine productivity and increase of profitability.

In order to carry out this plan, enormous resources will be required. Capital investment in the U.S.S.R. for the next 5 years has been set at a level of 310 billion rubles as compared with 210 billion rubles for 1961–65. Heavy industry will continue to be transferred to the Eastern Region of the country. The generation of power and production of iron and steel, especially in the Eastern Region, are to be developed to high degree.

The level of Soviet industrial production in 1965 and as planned for 1970 is as follows:

(Million metric tons unless otherwise specified)

Commodity	Production		Planned production		
	1955	1960	1965	1966	1970
Iron ore	71.9	107	153	NA	NA
Pig iron	33.3	46.8	66.2	70.5	94–97
Steel	45.3	65.3	91.0	96.7	124–129
Rolled metal	35.3	50.9	70.9	75.6	95–99
Steel pipes	3.5	5.8	9.0	9.8	14–15
Cement	22.5	45.5	72.4	78	100–105
Mineral fertilizers	9.7	13.9	31.3	35.3	62–65
Coal (bituminous, anthracite, and lignite)	391.3	513	578	598	665–675
Natural gas—billion cubic meters	10.4	47	129	148	225–240
Peat	50.8	53.6	50	NA	92
Petroleum, crude	70.8	148	243	264	345–355
Oil shale	10.8	14.1	21.3	NA	28
Power electric—billion kilowatt-hours	170.2	292.3	507	NA	830–850

NA Not available.

To achieve the planned goals, capacity for usable iron ore is to be increased by 100 million tons, pig iron by 17.8 million tons, ingot steel by 23.2 million tons, and steel pipe by 4.7 million tons.

Technologic changes to be emphasized include increasing use of open-pit iron mining, erection of additional large size (2,700 cubic meters) blast furnaces, and increased smelting of pig iron using oxygen and natural gas. Also, additional and larger (up to 500-ton capacity) oxygen converters are to be installed, electric steel output is to be increased approximately 1.5 times, and continuous casting of steel will be practiced on a large scale. In pipe production, it is planned to increase the share of electrically welded and seamless cold formed pipes, to produce 1.5 times more large-diameter pipe, and to attain an even larger increase in deliveries of high-capacity gas and oil pipes.

In nonferrous metals, directives call for a significant increase in production by completing projects now underway, increasing capacities of existing facilities and developing new installations. Production of aluminum is slated to be raised by 1.9 to 2.1 times, and of copper and zinc by 1.6 to 1.7 times. There will be increases in the production of lead, magnesium, tin, nickel, titanium, tungsten, molybdenum, and precious metals.

The amount of ore mined by openpit methods is to be increased 1.5 times and that from underground mines fivefold. By 1970, 75 percent of the copper output and 80 percent of the nickel output will come from open pit mines. New investments in nonferrous metallurgy is set at over 6 billion rubles, one and a half times more than in the previous 5 years.

Accelerated development is also planned for mineral fuel commodities. From 1950 through 1965 gross output of the fuel industry increased 3.3 times, while the volume of industrial production on the whole increased 4.6 times.

In the forthcoming 5-year period the share of the fuel industry in gross output of all industrial production is to be stabilized. That is, it will be developed at approximately the same rate as for industry as a whole in an effort to better provide the economy with fuel raw materials. Significant shifts will occur in the relative proportion of total energy output accounted for by each major fuel. It is planned to increase natural gas output more than 1.7 times, and oil production almost 1.5 times, while increasing coal by less than 1.2 times. As a result, the share of oil and gas in the fuel production balance of the country will increase from 51.7 percent in 1965 to 60 percent in 1970.

In the coal industry, it is planned to accomplish the production increase with the same number of workers. By 1970, openpit mining should account for up to 28 percent of the total coal output (compared with 24 percent in 1965). An additional 80 mines and pits with 65 million tons of output capacity are scheduled to be brought into production, and 80 existing enterprises are to be renovated. Special attention will be paid to the development of coal preparation, with a number of new plants scheduled for construction.

In mining thin and medium coal seams, overall mechanization, including hydraulic mobile supporting, narrow excavation by means of narrow-web continuous miners, and with integral mobile conveyers is to be stressed.

The growth rate of Soviet oil industry is to be slowed; the new 5-year plan calls for an average annual rate of between 7.3 and 7.9 percent, compared with the 11.5 percent annual average achieved during the past 7-year plan.

Recent production increases have been primarily due to the development of the rich Ural-Volga region ("Second Baku") oilfields. This area will continue to account for about three quarters of the Soviet total production over the next 5 years. The new plan specified that production by 1970 will reach 23.5 million tons in Azerbaydzhan, about 16 million tons in the Ukraine, and 15 million tons in Turkmenistan.

The output of the newly discovered Tyumen' Oblast' ("Third Baku") fields will reach 20 to 25 million tons by 1970 and the plan for the Mangyshlak Peninsula in Kazakhstan ("Fourth Baku") is 15 million tons. East Siberia ("Fifth Baku") is not mentioned in the plan as a prospective oil production area.

Exploration drilling is to total 25.6 million meters during 1966–70, and most of this effort is to be concentrated on the promising new areas. Secondary recovery methods are to be used to an increasing extent; the daily volume of water injection in 1970 is to be 1.6 million cubic meters. The new 5-year plan provides for the laying of 12,000 kilometers of additional oil pipelines.

Oil refinery production by 1970 is expected to be 40 to 50 percent higher than in 1965, but there were no indications of impending changes in overall refinery yield patterns.

Usable natural gas production is slated to increase more rapidly under the 1966–70 plan than it did during 1961–65, and in order to deliver this gas to consumers, 25,000 kilometers of gas pipelines will be built. The Soviet Union has also concluded agreements with governments of Iran and Afghanistan to import gas from these countries, and is undertaking to provide the resources for construction of pipelines from these areas to be completed before 1970.

The growth of the electric power supply industry will be achieved by putting into service new capacities amounting to 64 to 66 million kilowatts, mainly through the construction of large condenser thermal power stations with a capacity of over 2.4 million kilowatts, using 300,000-kilowatt generating units.

PRODUCTION

Mineral production statistics were not officially reported for a number of commodities. Therefore, many of the data in production tables were estimated, and represent, at best, an order of magnitude. The increase in Soviet mineral production in 1965 was not the result of productivity gains, but rather the addition of new capacity.

Some of the sectors did not achieve planned goals for 1965. There was a deficit (as compared to reported established capacity) of 11 million tons of coal, 13 million tons of iron ore, 3 million tons of pig iron, and 2.5 million tons of rolled steel.

Kazakhstan was the nation's leading producer of chromite, copper, lead, zinc, and rare metals, however, the metallurgical enterprises in the Altay region of Kazakhstan experienced raw material shortages in 1965 because of lags in mine expansions.

[1] Estimated except where noted.
[2] In addition to commodities listed, the U.S.S.R. is known to produce gold, but no estimate of output is included.
[3] Excludes production from scrap.
[4] Includes production from scrap.
[5] Reported in Soviet sources.
[6] Data for 1961–64, United Nations Quarterly Bulletin of Steel Statistics for Europe. V. XVI, No. 1, 1965, p. A–23.
[7] Items listed under this heading are produced from semimanufactures listed above and possibly also from imported material. Therefore, these data are not additive to the total of semimanufactures listed.
[8] The average ash content of the coal shipped from the mines was 19.4 percent and average calorific value—a little more than 5,000 kilocalories per kilogram.

[1] Includes finished rolled products, tubes and forgings made of castings, and ingots and billets supplied to other plants for rerolling.

[2] Less than ½ unit.

[3] Detail does not add to total because of rounding.

[4] Reported total; detail does not add to this figure because of omission of data for some republics.

Ferrous metal production volume in the U.S.S.R. during the years 1959–65 increased 1.5 times, with crude steel output reaching about 91 million tons in 1965. Nonetheless, the economy continued to experience shortages of ferrous metals. Soviet statistical data established that millions of tons of iron and steel were not reaching end users in the form of new products because of: (1) excessively high crude metal consumption per unit of finished useable product; (2) low levels of product durability, requiring extensive replacement and repair; and (3) inefficient repair practices. According to Soviet sources, the utilization factor of metal in the metal-working and machine building industries in 1965 was, on the average, 0.6; and that there was a potential for improving metal utilization in these industries by 20 to 25 percent. Some improvement reportedly could be achieved if manufacturers produced smaller forged billets to meet consumer requirements rather than simply striving to meet planned quotas on a tonnage and unit basis.

Approximately half of the new profiles produced reportedly do not meet consumer specifications, but nevertheless were used. Similarly, use of incorrect types and sizes of pipe in the gas industry resulted in the use of 16 percent more metal than was necessary.

TRADE

Tables 4 and 5 are derived from official statistics of the Ministry of Foreign Trade for 1964. Official figures for 1965 are not yet available, but much the same general pattern can be expected.

The value of total Soviet trade expanded from 12.9 billion rubles in 1963 to 13.9 billion rubles in 1964. Exports increased about 5.5 percent and imports were almost 9.5 percent higher in 1964, than in 1963.

Mineral industry products accounted for 40.9 percent of the value of all exports in 1964 compared with 38.4 percent in 1963, an increase of 6.5 percent. The Soviet Union remained a significant exporter of mineral fuels, manganese, iron, and chromite ores, steel ingots, aluminum, precious metals and apatite concentrate.

In 1964, the U.S.S.R. exported 56.6 million tons of petroleum and petroleum products valued at 849 million rubles, a 10.1 percent increase in volume and 3.6 percent in value compared with that of 1963. The big increase was in crude petroleum, which rose 21 percent; more than offsetting a 6 percent drop in refined product exports.

Compared with performance in previous years, Soviet iron and steel was sold to a larger number of countries in 1964. Sales of steel products to African nations have been steadily increasing. Efforts to increase ferroally exports were concentrated on improving quality.

In 1964, the U.S.S.R. became a net exporter of copper. Imports were cut to 10,000 tons, but exports mostly to East Europe totaled about 90,000 tons.

Exports of apatite concentrate rose by about one-third in 1964 to about 3 million tons; much of this increase can be attributed to the heavier requirements of European Communist countries.

In the U.S.S.R., reported production costs, are not the major factor in determining the selling price of a commodity in the country, or to the free world. The Soviet system permits the establishment of selling prices at any level believed desirable to meet political and economic requirements. The workings of this pricing mechanism can be seen by comparing the prices paid for Soviet coal by Communist and non-Communist countries. The Communist countries paid the highest prices for Soviet coal—15.10 rubles per ton f.o.b. border in 1964, compared with 6.70 to 10.00 rubles per ton f.o.b. for sales to the West. The average cost of standard coal including transportation for Soviet consumers in the European U.S.S.R. was 16.30 rubles in 1964. The average f.o.b. border price for crude oil paid by the Communist countries was 16.54 rubles per ton compared with an average of 9.41 by the rest of the world.

Among Soviet imports of minerals and metals; ferrous and nonferrous semimanufactures, steel pipes, bauxite, tin, tungsten concentrate, barite, fluorspar, talc, and mica were the most important items in 1964.

Soviet sources do not record trade in precious metals. Gold sales in world markets in 1965 were estimated at $310 million compared with about $500 million in 1964.

In the case of platinum-group metals, the following 1964 receipts were recorded in United Nations import statistics:

Country	Quantity (thousand troy ounces)	Value (thousand dollars)
France	64	$3,807
West Germany	NA	7,673
Italy	7	736
Japan	NA	978
Netherlands	28	3,384
Switzerland	25	1,140
United Kingdom	6	270
Yugoslavia	167	9,537

NA Not available.

U.S. platinum group imports from the Soviet Union in 1965 comprised 40,345 troy ounces of platinum and 443,555 ounces of palladium; while 1964 U.S. imports included 3,744 troy ounces of unrefined primary and scrap undifferentiated platinum-group metals, 6,351 ounces of platinum, and 126,719 ounces of palladium.

United Nations trade data do not indicate any appreciable exports of silver from the U.S.S.R. to major non-Communist countries.

COMMODITY REVIEW

METALS

With regard to metal production the U.S.S.R. was conducting a quantitative drive, and product quality seemed to be of secondary importance; nevertheless metal output fell short of demand. To meet requirements it will be necessary to increase efficiency of processes at existing mines and plants as well as to provide new capacity.

Nonferrous ore beneficiation facilities continued to experience poor recoveries of metal, particularly from oxide and mixed ores. Lead concentrates produced from mixed ores at the Zyryanovsk and Leninogorsk polymetallic deposits contained only about 60 percent of the lead present in the ore, and zinc concentrates carried only 30 to 50 percent of the zinc present in these ore.

Considerable effort has been put into the development and application of mining machinery. For many years in the nonferrous industry, efforts were directed primarily to the development of machines only for basic operations, and the potential for overall mechanization was underestimated. Methods of ore loading and conveying, which used old equipment and conveyance by scrapers, greatly impeded increases in labor productivity. The quality of drilling rigs and self-propelled equipment lagged.

Presently produced self-propelled equipment does not satisfy the miners. Idle time due to breakdown of individual units and component parts (taking into account repair) is 1.2 to 1.5 times greater than operating time. Existing drilling equipment does not achieve the aims of improvement of ore-mining technology.[3]

Aluminum.—During 1965, there were 12 aluminum plants in operation and this sector was one of the most successful in the nonferrous industry. At the Irkutsk aluminum plant the output of four potlines (each with 84 cells) was about two-thirds of design capacity. In 1966 output of marketable products reportedly will be increased about 25 percent over that of 1965. An experimental aluminum rolling mill was installed at Irkutsk during the year.

The second stage of the Krasnoyarsk aluminum plant, largest in the country, went into production in April. The plant's two units operated at about 80 percent of capacity.

Construction continued on the 800,000 ton per year aluminum plant near Bratsk. It will contain 24 potlines, each over 500 meters long, the first of which is planned to be operational in 1966.

A large aluminum plant (capacity unreported) also was under construction in the Gissar valley in Tadzhikistan, with a target completion date for the first stage set for 1968. It will be supplied with electricity from the Nurek G.E.S. (Nurek hydroelectric power station) and with natural gas from Afghanistan. Work on laying the pipeline from Afghanistan to Dushanbe was begun in 1965.

An experimental potline was commissioned at the Volgograd aluminum plant in October. The large capacity cells, the experimental plant for pumping alumina, and a plant for cleansing waste gases were assembled.

The Turgay bauxite open pits, the main supplier of raw material for the Pavlodar alumina plant, doubled ore production over that of 1964. Mine No. 15/15a in the north Urals bauxite field became operational in January, and will account for 25 percent of all ore extracted in that field. Four more mines being developed are expected to produce almost as much bauxite as was produced by the existing mines prior to completion of No. 15/15a.

A few deposits of bauxite were found on the eastern slopes of the Timanskiy Kryazh Range, and outcrops were found in the center of the Kzylkum desert in Uzbekistan.

Output of the Pavlodar alumina plant in 1965 reached only 80 percent of planned first stage capacity. Nevertheless, this facility, the main supplier of alumina for the Krasnoyarsk aluminum plant, became one of the leading plants of its kind in the U.S.S.R. For 1966, a production increase of 1.8 times over that of 1965 is programed on the basis of putting the second stage into operation.

The development of the technology for producing alumina from the nepheline mines of Kiya-Schal-Tyrsk was given priority in

[3] Narodnoe Khozyaystvo Kazakhstana (The National Economy of Kazakhstan), No. 1, 1966, pp. 1–3.

the Soviet aluminum industry. The process was first put into operation at the Volkhov aluminum combine. The Kirovabad alumina plant began producing alumina for the Sumgait aluminum refinery from raw alunite at the end of December 1965.

The country continued to import substantial quantities of bauxite from Greece.

Antimony.—Production of antimony trioxide increased considerably after the commissioning of a plant at the South Kirgiz mining and metallurgical combine.

Arsenic.—Arsenic production began at the Arachinskiy metallurgical combine in Georgia.

Bismuth.—As in prior years, bismuth was produced in 1965 from tungsten-molybdenum-bismuth and other complex ores. The Lenin Ust' Kamenogorsk lead and zinc combine succeeded in extracting metallic bismuth for the first time. This was the 18th chemical element extracted from Altay polymetallic concentrates.

Cadmium.—As in 1964, cadmium was produced in 1965 almost entirely from the zinc sulfide mineral, sphalerite. The Leninogorsk zinc plant organized the production of electrolytic cadmium for the first time in the Soviet Union.

Chromite.—The U.S.S.R. remained the largest world chromite ore producer. Kazakhstan took first place in production, and output was increasing as the result of the recent discovery of large deposits. The Millionnyy open pit in Aktyubinsk Oblast' operated at full capacity in 1965 and another pit was being prepared. The second crushing and grinding mill was completed at Khrom-Tau at the end of this year. As a result of these projects, shipments of chromite ore from Kazakhstan to ferroalloy plants in the U.S.S.R. and to foreign countries are slated to be doubled. The Donskie chromite open pits in Aktyubinsk Oblast' almost tripled ore extraction between 1959 and 1965. The new 5-year plan envisaged an increase of 1.3 times in chromite extraction by 1970 compared with 1965.

Copper.—The planned 90 percent increase in total Soviet refined copper production during the last 7-year period was almost achieved by yearend 1965. As a result of progress toward the planned goal, the nation reportedly achieved self-sufficiency for the first time in 1964. Of the total 1965 production, copper from the Urals and Kazakhstan accounted for about 80 percent. The Ural mountain area was one of the leading regions for copper deposits.

Copper content of concentrates ranged from 13 to 35 percent.

At the Dzhezkazgan combine mines, productivity in 1965 was at 1958 levels and at the largest and best mechanized copper open pit in the country, the Kounradskiy operation, productivity dropped 8 percent in comparison with 1958 levels. Reports indicated that the idle time of excavators at the Tishinskiy open pit was 34 percent of total calendar time, at the Kounradskiy pit, 21 percent, and at the Dzhezkazgan mine, 20 percent.

In 1965 copper metallurgical enterprises in Kazakhstan experienced raw material shortages because of the lag in development of mines as they had in 1963 and 1964.

Development of the Nikolaevskiy open pit in eastern Kazakhstan was progressing rapidly, and the Orlovskiy mining and concentrating combine was being built in northern Kazakhstan. Construction of Mine No. 55 at the Dzhezkazgan combine was completed. This copper mine, one of the biggest in the U.S.S.R., introduced in the country the extraction of ore with self-propelled equipment.

Copper deposits were discovered some 200 kilometers from Lake Balkhash in the Ayaksk area. The first 50 kilometers of a railway to link the town of Balkhash with the Ayaksk deposits were under construction. A copper deposit amenable to openpit mining was found in the Kuramir mountains, in the vicinity of Almalyk.

A Soviet State commission confirmed the existence of a large copper deposit in the Udokan mountains northeast of Lake Baykal and some 700 kilometers from Chita. The Government has proposed to Japanese copper mining and smelting companies a joint venture to develop the deposits.

A copper ore dressing mill was put into operation at the Uryupin mining combine in Stavropol' Kray. The Kofan copper combine was being renovated and enlarged; plans were made to double the capacity of the Kadzharan copper-molybdenum operation in Armenia, and a plant for producing granulated copper concentrate was installed at the Balkhash mine.

Smelting of copper concentrate by fluidized bed was carried out for the first time in the U.S.S.R. at the Alaverdy copper and

chemical combine. Production of refined copper was started in the Uzbek S.S.R.

Iron and Steel.—*Iron Ore.*—The Soviet iron ore industry in 1965, operated 65 underground mines and 68 open pits with a total capacity of 160 million tons of usable ore (direct smelting ore plus concentrates). In 1965, 73 percent of the usable iron ore production was from open pits. Sixty-two percent of the open pits and 53 percent of all underground mines had annual productive capacities of less than 1 million tons of crude ore. About 17 percent of the open pits had capacities exceeding 5 million tons and only 4 percent of the underground mines exceeded 4 million tons of crude ore a year. The Gigant mine in Krivoy Rog with an annual crude ore capacity of 6 million tons was the largest underground iron mine in the U.S.S.R.

Compared with 1964, production of usable ore in 1965 increased 7.6 million tons or 5 percent. The average grade of all crude ore mined was about 41 percent. Direct shipping ore averaged 54 to 55 percent iron while ore for beneficiation averaged 35 percent. Concentrates produced from the latter averaged 58 percent iron. Production of agglomerate reached 113 million tons in 1965 with an iron content of 57 percent.

Capacities put into operation for production of usable iron ore during the 1959–65 period totaled 112.6 million tons. The increase was obtained chiefly by construction of new plants rather than by expansion at existing plants.

A delay in developing additional mining and concentrating capacities with respect to the goal of 124.6 million tons set under the 7-year plan resulted in difficulties in obtaining needed raw materials at metallurgical operations. Thus, a 4-year delay in the development of pellet production at the Sokolovsko-Sarbaiskiy ore concentration combine had a marked influence on the output of blast furnaces at the Magnitogorsk metallurgical combine. Similarly, a 5-year delay in development of the Teyskiy open pit and in expansion of the Abagur concentration plant required the use of 3 million tons of low quality ore from the Urals and Kazakhstan by the West Siberian metallurgical combine.

The current and fixed assets of the Soviet iron ore industry totaled 2.75 billion rubles at the end of 1965; however the return on capital continued to fall; between 1960 and 1964 the output of usable ore per ruble of assets declined 32 percent.

Many of the machines in the iron ore industry were unreliable or lacked durability. As a result, about half of all the mine workers were engaged in equipment repair in 1965.[4]

The Krivoy Rog Basin in the Ukraine produced about 50 percent of the nation's total 1965 output. Both underground mines and open pits as well as five concentrating plants with a total production of 32 million tons of concentrate were operating in the region. The average iron content of Krivoy Rog usable ore was 54 to 55 percent and that of concentrate was 62 percent. It is planned to increase content of concentrate to 63.8 percent in 1966, and to 65 percent in 1967. By 1970 concentrate production of 50 to 55 million tons is planned.

Five underground mines were being developed in Krivoy Rog in 1965. Two, the Zorya mine and the second stage of the Gvardeyskaya mine, were put into operation. The latter, with an annual capacity of 3.5 million tons of crude ore, is one of the largest in the basin. The third stage of the Southern mining and concentration combine open pit became operational in September, increasing its capacity to 24 million tons of taconite annually. Construction also started on the third stage of this combine's concentrator. The unit scheduled for completion in 1967 will have four sections, and a total annual concentrate capacity of 4.4 million tons containing 65 percent iron.

The first stage of the Severnyy ore-dressing combine in Krivoy Rog, with a yearly concentrate output of 6.5 million tons, was completed in December. Construction was started on a second stage, scheduled for completion by 1970, that will double the capacity of the installation. The first stage of the Ingulets combine, to be the largest in the U.S.S.R. when completed, was commissioned in June, and additional sections became operational in December. At yearend the combine's annual capacity was 4.5 million tons of concentrate.

Concentration facilities of the Novokrivorozhskiy combine in Krivoy Rog were completely reconditioned.

Ore dressing installations were being constructed also in Poltava and Zaporozhye

[4] Ekonomicheskaya Gazeta (Economic Newspaper). Moscow, 1965, No. 39, p. 16.

oblasts in the Ukraine, and five mines were being developed in the Beloozerskiy iron ore deposit in Zaporozhye.

The second center of Soviet iron-ore activity was the Urals, where direct-shipping ore output reached 28 million tons in 1965. In addition, agglomerate production was increased from 18.3 million tons in 1959 to 29 million tons in 1965. A new ore dressing plant was being built for the Magnitogorsk iron and steel combine, to concentrate low-grade, high sulfur ore.

Kazakhstan, with an output of 14.1 million tons in 1965 compared with 13.9 million tons in 1964 ranked third among iron ore producing areas in the country. Iron ore was produced in two oblasts of the republic: In Karaganda at the Atasu mine group and in Kustanay at the Sokolovsko-Sorbay combine. Production costs in Kazakhstan were the lowest in the U.S.S.R.

The Sokolovsko-Sorbay mining and concentrating combine began full scale operation in December. It has an annual throughput of 26.5 million tons of ore, making it one of the largest mining and beneficiation enterprises in the U.S.S.R. The magnetic separation and pelletizing facilities have an annual capacity of 8.4 million tons of concentrate containing 65 percent iron. The combine is the main supplier of iron ore to metallurgical plants in the Urals and Kazakhstan.

Several iron ore projects were developed in Siberia. The first stage of the Korshunovo iron mining and concentrating combine in Irkutsk Oblast' was commissioned in March and deliveries to the West Siberian Steelworks began in April. Initial annual capacity was 6 million tons of crude ore, and 2.5 million tons of dry concentrate containing 60 percent iron. When the second stage is completed, capacity will be doubled.

In November the first stage of the Teyskoe iron ore pit in Khakas Autonomus Oblast', Siberia, with an annual capacity of 2 million tons of ore, was put into operation. A concentrator with an annual output of 1.75 million tons was built at Tashtagol in Kemerovo Oblast'.

In Kursk Oblast', central European U.S.S.R., the second stage of the Mikhaylovka iron combine was commissioned in April. This addition increased annual capacity to 4.5 million tons of ore. Expansion at the Olenogorsk ore dressing combine in Murmansk Oblast' on the Kola Peninsula increased annual capacity to 5.8 million tons of concentrate.

The Chernomorsk No. 2 open pit of the Kamysh-Burun iron ore combine in Crimea was commissioned in January. Reportedly yearly capacity was to be 3 million tons of ore.

Iron ore deposits amenable to open pit mining were discovered near Zhdanov on the coast of the Azov Sea during 1965. The magnetic anomaly contains an estimated 500 million tons of taconite with an iron content of 35 percent. In the Bakal area of the south Urals an iron deposit containing up to 50 percent iron was explored.

An iron deposit found in Aktubinsk Oblast' in Kazakhstan, containing an estimated 100 million to 120 million tons of ore, may provide a possible solution to the raw material supply problem at the Orsk-Khalilovo metallurgical combine.

About 150 million tons of magnetite ore was prospected in the Karamazar mountains in north Tadzhikistan. It was planned to develop a steel industry on the basis of this deposit.

Reportedly the first large iron ore deposit in the Soviet Far East the Galamsk was discovered in the Uda River region about 130 kilometers from the Sea of Okhotsk. Reserves were estimated at up to 250 million tons, half of which are of direct shipping grade.

The U.S.S.R's total mineable iron ore reserves were 46 billion tons, averaging 39.8 percent iron. The estimated measured reserves of iron ore were about 10 billion tons in 1965.

Pig Iron and Steel.—During 1959–65 significant new iron and steel capacities were commissioned: 18 blast furnaces with annual capacity of 18.8 million tons, 51 open-hearth furnaces with a design output totaling 19.1 million tons (most were of 500 to 600-ton nominal capacity, but 6 were of 900-ton capacity), six 100-ton oxygen converters, seven 100-ton electric steel smelting furnaces, and 33 rolling mills with overall capacity of 19.7 million tons.

The number of "industrial production personnel" at enterprises of the Ministry of Ferrous Metallurgy totaled about 1.2 million, 2.4 percent more than in 1964.

Thirty-six enterprises produced 66.2 million tons of pig iron in 1965, 6 percent more than in 1964. Of the total, about 52.5 million tons was produced in furnaces using natural gas for at least a part of the fuel; this was 7.8 million tons more than in 1964. At yearend, 86 furnaces used natural gas. In 1965, 12 furnaces were converted to oxygen enriched blasting. Coke consumption per ton of pig iron produced was reduced from 613 to 589 kilograms.

At plants which do not have natural gas, residual fuel oil was used. Last year its introduction was continued at a number of Ural enterprises and at the Karaganda plant. In all, liquid fuel was used in 25 blast furnaces.

While in 1959 only 53 blast furnaces had a volume of over 1,000 cubic meters, in 1965 there were 77. The volume of the average Soviet blast furnace in 1965 was 22 percent greater than in 1959, around 1,030 cubic meters; however, 25 blast furnaces with individual volumes of less than 300 cubic meters, were still in operation.

In 1965, steel production increased by 7 percent reaching 91 million tons. Of this amount, 80.5 million tons were produced in plants of the Ministry of Ferrous Metallurgy. Distribution of production by process was as follows:

Process	Percentage distribution	
	1964	1965
Open hearth	88.5	88.1
Oxygen converter	4.3	4.8
Electric furnaces	5.0	5.0
Unspecified	2.2	2.1

Furnaces which used natural gas for at least part of its fuel requirements produced 62 percent of the total output in 1965.

Oxygen converter steel was produced mainly by three plants: The Krivoy Rog, the Il'ich and the Petrovskiy. Electric steel production came principally from the Dneprospetsstal' and Chelyabinsk metallurgical plants.

The daily output of steel per square meter of furnace floor at Ministry plants, averaged 8.95 tons in comparison with 8.65 tons in 1964. On the average, the consumption of standard fuel per ton of steel was 165 kilograms in 1965.

Soviet 1965 rolled steel output totaled 70.9 million tons (including finished rolled metal, pipes, forged ingots and rerolling blanks). Of this, 66.3 million tons was from Ministry plants, 6 percent more than in 1964. The greatest production growth took place at: Krivoy Rog, Il'ich, Cherepovets, and Chelyabinsk. Despite increased total output, the production of structural shapes remained inadequate. As a result, according to a Soviet source, steel consumption was 20 percent greater than necessary because of the substitution of less efficient although heavier shapes.

Of the total rolled steel produced, 30 to 35 percent came from some 25 rolling mills installed in the last century.

Reportedly the Soviet Union was first among world producers of steel pipe. In 1965, a total of 9 million tons was manufactured, 11 percent more than in 1964. However, the industry did not satisfy the demands of all sectors of the Soviet economy, and there were a number of serious shortcomings in the industry. For example, despite the substantial growth, planned goals for pipe casing and drill pipe for the petroleum industry remained unfulfilled. Moreover not all pipes were equal to world standards of quality and preciseness of dimensions (for example, boiler pipe and petroleum pipe). More than half of the defects detected involved low quality of pipe metal. Plans for renovating pipe shops and modernizing equipment were being implemented slowly. Finishing equipment in many of the existing shops was not capable of manufacturing high-quality pipes; automation and mechanization were insufficient in finishing and quality control sections, as well as in warehouses of ready products.[5]

In the Soviet ferrous industry production was increasing at a slower rate than the growth of capital investment. In 1965, return on capital decreased 3 percent in comparison with 1964. Incomplete utilization of existing capacities, prolongation of construction projects, and unsatisfactory work of many units and shops were the principal reasons. Unsatisfactory introduction of planned capacities of new units also had pronounced negative effects on the level of returned capital. New units were slow in attaining capacities mainly because actual conditions of their operation did not

[5] Stal' (Steel), Moscow, No. 9, September 1965, pp. 777–780.

correspond with their designed and planned utilization.[6]

Among the main causes leading to failure of the ferrous industry to meet planned production costs were overly large consumption of raw materials, supplies, and energy. These excessive uses stemmed to a considerable degree from high losses due to defective quality of production.[7]

The Ukraine with Krivoy Rog, Zaporozhye, and the Donbas as the main centers, produced 49.2 percent of total Soviet pig iron, 40.7 percent of total ingot steel, and 53.2 percent of total rolled steel. The second center was the vast area of the R.S.F.S.R. including the Urals, Center, and Siberia regions. Kazakhstan ranked third in Soviet ferrous metal production.

In 1965, additional production capacity for 2.0 million tons of pig iron, 1.8 million tons of steel and 1.4 million tons of rolled metal was installed. 1.6 billion rubles of capital investment were available for the Soviet ferrous industry (including mining and concentration). However, at a number of plants installation of equipment had fallen behind schedule. As a result, blast furnace No. 10 at the Magnitogorsk metallurgical combine, rolling mills at the Kommunar and Krivoy Rog plants, the converter shop at the Novo-Lipetsk plant, and the sinter shop at the Il'ich plant in Zhdanov were not commissioned in 1965.

The largest blast furnace in the world, with useful volume of 2,300 cubic meters, was under construction at Il'ich but was not completed by yearend.

A second oxygen converter at the Krivorozhstal' steel plant, the U.S.S.R.'s 13th and largest converter, was slated for completion in October but was not ready for operation at yearend.

Open hearth furnaces at the Orsk-Khalilovo combine and at the Amurstal' plant were put into operation. A new thermic furnace was commissioned at the Zhdanov Il'ich plant in June. A complex for radial method of steel casting was completed at the Rustavi metallurgical plant.

The second 1,300 millimeter automated blooming mill in the Soviet Union was installed at the Chelyabinsk plant. The first mill of this type began operating in 1964 at the Krivoy Rog plant. A new rolling mill at the West Siberian metallurgical plant in Novokuznetsk, with a capacity of 800,000 tons of rolled metal a year, began production in September.

The world's largest electric pipe-welding shop for the production of 159—529 millimeter diameter pipe was completed at the Novomoskovsk steelworks in Dnepropetrovsk Oblast'. A 150 ton capacity pipe drawing mill was commissioned at the Dnepropetrovsk Karl Libknecht in March. The country's first experimental spiral pipe welding mill at the Novomoskovsk metallurgical plant reached its planned capacity in December.

Ferroalloys.—Part of the Soviet effort to improve steel quality was devoted to ferroalloy plants. The first stage of a new smelting shop was commissioned at Zaporozhye. This fully mechanized and automated shop was the largest in the U.S.S.R. An enclosed furnace for melting ferroalloys was commissioned at the Chelyabinsk electrometallurgical works, and the construction of the first electric melting section began at the Yermak plant in Kazakhstan. A ferroalloys plant was under construction in Nikopol', and the Zestafoni ferroalloy plant in the Georgian S.S.R. installed five closed-type electric furnaces.

Lead and Zinc.—In the Altay region of Kazakhstan, construction continued on the Tishinsk mine complex near Leninogorsk. A new ore-dressing installation was commissioned in December, and a zinc works was under construction. Ores from this mine, regarded as one of the richest in the Altay region, contain lead, zinc, gold silver, and other metals. Also in Kazakhstan, work began on a new mine at the Tekely lead and zinc combine, and the Kentau concentration mill for the production of lead and barite was commissioned. The Zyryanovsk concentrating mill, for the first time in the U.S.S.R., obtained zinc concentrate from oxidized lead-zinc ores.

In the Georgian S.S.R., the Morneuli mining and concentrating combine was under development to exploit extensive copper-lead resources found in the area around Bolnisi. This will be the Georgian S.S.R.'s first nonferrous industry enterprise.

Soviet lead-zinc concentration mills used on the average 4 kilograms of flotation reagent and 35 kilowatt hours of energy per ton of ore processed in 1965.

[6] Ekonomicheskaya Gazeta (Economic Newspaper), Moscow, April 1966, No. 14, pp. 24–25.
[7] Work cited in footnote 6.

Magnesium.—In 1965, the Soviet Union produced about 21 percent and consumed over 18 percent of the world production of primary magnesium.

Experimental production of metallic magnesium began at the Ust'-Kamenogorsk titanium-magnesium combine in Kazakhstan, which was under construction in 1965. The new plant is believed to be a major producer of magnesium metal in the country.

Manganese.—The Soviet manganese industry remained the largest in the world. In 1965, 992,000 tons of manganese ore, about 13 percent of total production, was exported.

The Chiatura manganese basin in Georgia, the richest in the U.S.S.R., produced a total of 1.5 million to 2 million tons of concentrates of various grades. There were 15 mines in Chiatura at the beginning of 1965, and two more (with an annual capacity of some 100,000 tons each) were commissioned at yearend. Approximately 80 percent of the ore was extracted by underground methods.

Reportedly the Darkvety carbonate ore concentrating mill in Chiatura, built in 1961 at a cost of 5 million rubles, has been idle since 1962 because metallurgical plants are not using carbonate concentrate.

The nation's second principal manganese basin, the Nikopol' in the Ukraine, has several times greater reserves than Chiatura, but the ore bed is only a little more than 2 meters thick and lies under as much as 80 meters of overburden. More than 70 percent of ore mined was obtained by open pit methods.

Two mines, the No. 1–BIS, with an annual capacity of 200,000 tons of manganese ore and the first stage of the Grushovskaya Mine No. 7, were commissioned in December. The latter, the largest in the Nikopol' basin, will supply annually 500,000 tons of ore, more than twice as much as any other single mine.

The first and second stages at the Chkalov combine, having an annual capacity of almost 1.1 million tons of concentrate, also were commissioned.

The Dzhezdy manganese ore-dressing plant in Karaganda Oblast' was put into operation in May to process low-grade ore for the Yermak ferroalloys plant. In January construction of a manganese reagents plant was started in Rustavi, Georgian S.S.R.

Manganese ore deposits were discovered in the Idzhevan mountains of northern Armenia and in the Zangezur mountains of southern Armenia. A near surface deposit was discovered in Irkutsk Oblast', 40 kilometers from Nizhneudinsk.

Mercury.—The Soviet Union was estimated to have produced about 14 percent of the world total, and was apparently self-sufficient in mercury in 1965.

The Ulugtau mercury mine with metal recovery works was completed in the Kirgiz S.S.R. Extraction of metal was begun on the Chukotsk Peninsula near the Bering Strait. Two mercury deposits close to surface were found in Magadan Oblast'.

Molybdenum.—Output of molybdenum concentrate was estimated at 6,200 tons or 12 percent of the world total in 1965. About 50 percent of the production was from copper-molybdenum ores, about 30 percent from molybdenite ore, and the remainder from tungsten-molybdenum ores.

Armenia occupied first place in the production of molybdenum concentrate from Kadzharan copper-molybdenum ores, but the concentrate was shipped out of the Republic for further processing.

The Chorukh-Dayron mining enterprise started extracting molybdenum ore from a deposit in the Kuraminskiy mountain range in Tadzhikistan. The molybdenum plant of the Balkhash mining and concentrating combine and the Dzhidinskiy tungsten and molybdenum combine in Buryat A.S.S.R. increased output of molybdenum concentrate in 1965.

Nickel.—The U.S.S.R. apparently contributed about 20 percent and consumed less than 19 percent of the nickel produced in the world in 1965.

The Monchegorsk area of the Kola Peninsula and Norilsk area in northern part of western Siberia were the country's foremost nickel producers. The first stage of the ore concentration mill of the Severonickel combine in Monchegorsk with an annual capacity of 2 million tons of copper-nickel ore was commissioned. A new ore-dressing installation was completed at the Norilsk ore-dressing combine and was expected to be operating at full capacity in 1966. In the Talnakh River Valley on the Taymyr Peninsula a mining complex was being established for the openpit mining of polymetallic ores. The complex will include

two open pits, the Mayak and the Komsomol'skiy.

In the southern Urals, the Oktyabr'skiy mine was commissioned and the Novo-Buranovskiy mine was being prepared for exploitation. These open pits will ship ore to the Yuzhno-Ural'skiy nickel combine. An electric furnace was put into operation at the Buruktal nickel combine in Orenburg Oblast'.

Gold.—Since the early 1930's few data on Soviet activities in precious metals exploration, production, trade and stockpiles have been published officially. Available information however indicates that in 1965, the U.S.S.R. was probably second among world producers. Reportedly, about 75 percent of Soviet gold production came from the sub-Arctic Asian area, and most of the remainder from polymetallic ores mined in Kazakhstan and the Urals.

The major areas of gold production reportedly fulfilled or overfulfilled their prescribed 1965 goals. Soviet sources claim gold reserves are sufficient for 16 to 17 years of operation at present rates of extraction, and an intensive exploration effort has been mounted. This effort has resulted in the discovery of a number of rich deposits. In 1965, more than 30 gold placer deposits were surveyed in the Yano-Kolymskiy gold-bearing belt in Magadan Oblast'. This belt is 1,000 kilometers in length and up to 200 kilometers wide. Many gold deposits within its limits have been mined for more than 30 years, but new discoveries have virtually paced the extraction rate, thus known reserves are practically as great as they were at the outset of mining.

Eleven placer deposits, were discovered in the Khabarovsk region, and reserves of placer gold were increased at existing mines in the Udokhan, Vacha, and Yandara River basins. New placer deposits were discovered in the valleys of the Bodaybo, Udokhan and Vinyam Rivers.

Prospecting, completed in the Serebryannaya River Valley in the middle Urals, reportedly revealed one of the largest gold deposits to be discovered in the U.S.S.R.

Discovery of a gold deposit near the upper reaches of the Irtysh River in Kazakhstan resulted in the start of construction on a large mining and processing complex.

Two new mining administrations—Nizhne-Yanskoe and East Chukotskoe—were formed in Magadan Oblast' in 1965. Under the new 5-year plan, output of gold in this area is to be 32 percent higher than under the past 7-year plan.

Enterprises of the Transbaykal gold trust were reconstructing small dredges to exploit gold deposits in Chita Oblast' that can be processed only by such dredges.

A new mine became operational in the Aldan area of Yakut A.S.S.R., and a new ore-dressing combine was being built in this area. The Kamenistyy placer mine in Kamchatka Oblast' was commissioned in 1965.

Platinum.—The U.S.S.R. remained the largest world platinum-group metal producer. Production was believed to be obtained mainly from copper-nickel mines of Severonickel (Kola Peninsula) and Norilsk combines and from placer deposits of the Urals.

Rare Metals.—A new rare metal recovery unit was put into operation at the Ust'-Kamenogorsk combine. Rhenium was recovered from molybdenum and copper concentrates in Armenia.

An installation to extract selenium from sulfur residues was completed at the Chardzhou chemical plant in Turkmen S.S.R. The Leninogorsk zinc plant introduced a new filtration method of extracting selenium.

Tin.—Production of tin continued to be inadequate to meet internal demand, and more than 25 percent of requirements had to be imported in 1965.

New tin concentrate capacity was put into operation at the Solnechnyy ore-dressing combine in Khabarovsk Kray, and development of the open pit continued.

New sources of tin were discovered during the year as the result of an intensive geological exploration program carried out by Ministry of Geology. In the Sikhote-Alin mountains of Maritime Kray, work was started on designing the Ternistoe mine, to exploit one of the recently discovered deposits.

Titanium.—Development of the titanium industry continued in the U.S.S.R., the world's second largest producer. Additional capacities commissioned in 1965 included the electrolysis plant at the Ust'-Kamenogorsk titano-mangnesium combine, under construction since the late 1950's, and new facilities at the Berezniki titanium and magnesium combine, in Perm Oblast'.

Ilmenite was discovered in placer deposits along two right-bank tributaries of the

Dnieper River in the Ukraine. One ilmenite concentrating mill was completed, and construction of another started at the Irshansk mining and concentrating combine in Zhitomir Oblast'. With completion of the latter, this combine will become the country's largest supplier of ilmenite concentrate.

Tungsten.—Production of tungsten was insufficient to satisfy growing domestic needs, and about 20 percent of concentrate requirements had to be imported.

In 1965, the Dzhidinskiy combine in Buryat A.S.S.R. increased output of tungsten concentrate by 2.5 percent as compared with 1964.

Vanadium.—Indigenous requirements for vanadium were satisfied from certain vanadifferous iron ores and small vanadate deposits. The principal sources of vanadium in 1965 continued to be the titaniferrous magnetites of the Kachkanar open pits in the Urals, and the iron ore of Lisakovska deposit in Kazakhstan.

NONMETALS

The Soviet Union produced a wide variety of nonmetals. However, the resource position varies from adequacy or abundance for many nonmetals to apparent shortages of other such as barite, feldspar, fluorspar, mica, and talc.

Amber.—The Kaliningrad amber combine increased its yearly output to 420 tons and in 1965 exported 1.2 million rubles worth of amber and amber jewelry to 30 countries.

Asbestos.—Asbestos industry development was concentrated in the Urals, Kazakhstan, and the Buryat A.S.S.R. The first 200,000 ton-per-year stage of the Dzhetygara asbestos combine in Kazakhstan was commissioned in October, and produced 40,000 tons of asbestos by year end. Construction of the second stage was started and reportedly it will be commissioned in 1967. By that time the combine's capacity is slated to reach 600,000 tons, and it will be one of the largest asbestos producers.

Deposits of two types of asbestos were discovered in Kazakhstan: Anthophyllite in the Mugodzhary hills, and chrysotile in Dzhambul Oblast'. In Buryat A.S.S.R. detailed prospecting of the Molqdezhnoe asbestos deposit was nearly completed and a road to the site was under construction.

Barite.—Barite was mined by both open-pit and underground methods and at some operations crude output was concentrated by flotation. About two-thirds of the country's barite consumption in 1965 was produced domestically, the balance being filled by imports of high-grade barite.

The increase in output in 1965 was attributed largely to the commissioning of new capacities. The second and third stages of the Kentau concentrator were put into operation. Equipped with machinery built in Czechoslovakia from Soviet Union plans, the mill became the largest barite concentrator in the country.

Bentonite.—Armenia, Tadzhikistan, and Kazakhstan remained the three principal centers of bentonite production. The Isfara plant in Tadzhikistan, which supplies ground clay for oil well drilling, was reconstructed and output is expected to increase more than twofold.

New bentonite deposits were found in the Idzhevan mountains in Armenia and construction of a clay works was started at Barsa-Gelmez in Turkmenistan.

Cement.—Cement output was 72.4 million tons, or 11 percent higher than in 1964. Plans called for the construction of 6.6 million tons of new capacity in 1965 but only 4.6 million tons of the total was completed. Small cement plants were put into operation in Magadan and Odessa, and the first stages of plants were completed in Ust'-Kamenogorsk (annual capacity 200,000 tons) and in Achinsk (annual capacity 1 million tons). New capacities were added at the following cement plants: Amvrosievsk, Balakliysk, Bukhtarma, Dneprodzerzhinsk, Kant, Lipetsk, Nikolaev, Volzhsk, Rybnitsa, Punane-Kunda, Semipalatinsk, Alekseevsk, and Ul'yanovsk.

Annual capacity of the Balakliysk cement plant in Khar'kov Oblast', according to official sources the largest in Europe, was almost 3.5 million tons. In 1965 four 185-meter rotary kilns were in operation, and output totaled nearly 2.5 million tons. A fifth kiln will be installed in 1966.

The national average fuel consumption in 1965 was 250 kilograms of standard fuel equivalent per ton of clinker.

Diamond.—The Soviet Union continued to make rapid progress in the expansion or diamond mining. A substantial but unknown quantity of synthetic diamond was also produced in 1965 by plants, in Kiev, Moscow, and Yerevan.

The use of diamond by Soviet industry in past years was severely limited by inadequate supply; however this situation changed radically after discovery of the large Yakut diamond deposits, and the advent of synthetic diamond production. All Soviet demand for diamond tools can now be met by home industry. Reportedly, the demand for diamonds in the Russian union republics totaled 2.6 million carats of stones and 0.6 million carats of powder in 1964.

In 1965, the Mirnyy mine, the largest of the Yakut diamond trust, increased extraction and processing of kimberlite by over 50 percent compared to 1964 levels. Aykhal, the location of the new diamond mining center in Yakutsk A.S.S.R., will be the first town in the country with an artificial climate.

Diamonds were found in the upper reaches of the Anabar River in the arctic area of Yakut A.S.S.R. Important concentrations of diamond were also discovered near the 70th parallel, where Olenek River flows into the Arctic Ocean. Preparations started for commercial exploitation of these deposits.

Several diamond deposits were discovered on the Vishera River north of Perm'Oblast', and two were being exploited commercially, using dredging. The Urals diamond mining administration transferred its base to this locality.

A large diamond-processing works was opened in Smolensk. Operators were trained by experts from other Soviet and foreign jewelry enterprises.

The production of synthetic diamonds and instruments utilizing them was started in Yerevan. In 1964 only one type of synthetic diamond was in production. In 1965, the experimental shop of the Kiev super hard materials institute manufactured three new kinds for industry.

Fertilizer Materials.—Fertilizer production totaled 7.4 million tons in 100 percent nutrient content or 31.3 million in bulk fertilizer content[8] in 1965, but was well behind the target of 35 million tons bulk content set by C.P.S.U. in December 1963. Nevertheless, compared with 1964 output, mineral fertilizer production in 1965 increased over 22 percent. This increase was attained largely through the commissioning of new capacities.

The following enterprises and facilities were completed in 1965: The Novo-Lipetsk, Dorogobuzh, and Kuybyshev nitrogenous fertilizer plants, and Gomel' superphosphate plant in Belorussia; the Angarsk mineral fertilizer plant, the Dzhambul superphosphate plant and mineral fertilizer production facilities at the Lisichansk and Dneprodzerzhinsk chemical combines. The first stage of the Navoi fertilizer combine was commissioned, and the second ammonium producing line at the Novokemerovsk chemical combine started production in December. The Novomoskovsk chemical plant was reequipped to produce a nitrogenous-phosphatic-potassic fertilizer.

A mineral fertilizer plant was under construction in Rustavi, Georgia, and superphosphate facilities were built at the central Urals copper smelting works. Construction of a new phosphoric acid production complex started at the Kedainiai chemical combine in Lithuania and superphosphate plants were being built in southern Kazakhstan.

An increase of about 12 percent in mineral fertilizer output was expected in 1966. Under the plan the following projects were to be put into operation in 1966: The Gorlovka and Dneprodzerzhinsk nitrogenous fertilizer plants, the Odessa superphosphate plant, and Novostebnikovsk potassium combine. Construction will be accelerated at the the Rovno nitrogenous fertilizers plant, and the Yavorov mining and chemical combine.

Phosphate.—The bulk of the increased output of phosphate fertilizers in 1965 may be credited to the greater capacity of the "Apatit" combine on the Kola Peninsula and the commencement of production at Karatau in Kazakhstan.

Geological reserves of phosphate were estimated in 1965 at 2.7 billion tons of phosphorite (overall average grade, 13.8 percent P_2O_5) and 1.6 billion tons of apatite (average grade, 18.5 percent P_2O_5).

The 40 commercial deposits in the Karatau mountains contain over 1.5 billion tons phosphorite. More than half of the reserves

[8] The active ingredients (nitrogen, phosphorous and potash) are expressed in terms of Soviet standard units which are not the same as those used in the United States. Nitrogen is expressed as ammonium sulfate, phosphate is expressed as 18.7 percent P_2O_5, potash is expressed as 41.6 percent K_2O, and ground rock phosphate (phosphatic flour) is expressed as 19 percent P_2O_5.

of the basin will be extracted by underground mining. The second and final stage of the Aksay open pit was commissioned in August, increasing annual capacity to 2 million tons of phosphorite ore. There were 19 rotary drill rigs and 130 25-ton dump trucks at the pit in 1965. Production was started at Molodezhnaya underground mine in the same region.

In 1965, phosphate fertilizer production at the Karatau mining and chemical combine was raised to 1.5 million tons, 300,000 tons more than in 1964. It was planned to increase ore deliveries to the plant five times by 1970.

The second stage of the Kingisepp "Phosphorit" combine in Leningrad Oblast' was put into operation in July. Extraction of phosphorite ore began at the Dzhantas open pit in Dzhambul Oblast'.

Additional phosphorite deposits were found in the Dzhezkazgan area of Kazakhstan, and phosphate rock deposits were discovered near the confluence of the Kama and Vyatka Rvers, in Krasnoyarsk Kray, and in south Uzbekistan.

A deposit of apatite was found 40 kilometers from Kokchetav in Kazakhstan.

There were three underground mines (Kirov, Yukspor, and Rasvumchor) and the Tsentral'nyy open pit (2.5 million ton capacity) in operation at the "Apatit" combine in 1965. At the Kirov mine construction of necessary facilities was started to increase apatite ore output by 1 million tons to 5 million tons.

Reportedly, the "Apatit" combine failed regularly to supply needed raw material to the Konstantinovka chemical plant and other enterprises.

The fourth section of the ore-dressing plant at the Kirovsk apatite combine was commissioned in December, and its annual capacity reached 5 million tons of apatite concentrate (38.5 to 39.4 percent P_2O_5).

Construction started on a second section of the ore and concentrate shipping facilities in Murmansk port, aimed at doubling the loading rate.

Potassium.—Increased potassium fertilizer output in 1965 was attained entirely through the commissioning of new capacities. The more important enterprises and facilities put into operation in 1965 include the first stage of the second Soligorsk potassium combine in Belorussia, the Novostebnikovsk potassium combine in L'vov Oblast', and a new potassium fertilizer production installation at the Ust'-Kamenogorsk magnesium-titanium combine.

Three chemical combines for processing local potassium into fertilizer were under construction in Soligorsk, south Belorussia. According to the plan, the yearly potassium output of these facilities will amount to 3 million tons. It was decided to erect a fourth combine at the Starobin deposit. Construction of another potassium combine started in the north of Perm' Oblast', in the Berezniki area. This is the fourth enterprise in that vast potassium salt basin.

A new potash deposit was discovered at Karlyuk in southern Turkmenistan.

Fluorspar.—Domestic fluorspar output remained significantly inadequate to meet the demand of the industry, and high-grade fluorspar imports continued; these totaled 132,500 tons in 1964.

Fluorspar was mined in Buryat A.S.S.R., in the Soviet Far East and in Central Asia. Reports indicate construction of the Yaroslavsk ore-mining and concentrating combine in the Far East, and of a fluorite concentrating plant, with an annual capacity of 200,000 tons of ore, in Buryat, A.S.S.R. The Yaroslavsk combine will be a major supplier of fluorspar concentrates for the aluminum, electrode manufacturing, and cement industries.

Graphite.—Increased domestic output of natural graphite in 1965 was supplemented by material recovered from metallurgical wastes of the iron and steel enterprises.

Additional capacity planned for 1965 included the Soviet Union's first installation for the production of fettled graphite (a raw material for artificial diamond) at the Zavalovskiy graphite combine in Kirovgrad Oblast', the Ukraine.

Gypsum.—The overall goal of the 7-year plan for gypsum output was not fulfilled as output in 1965 remained at about the 1964 level. At the Rustavi construction materials combine in Georgia a gypsum plant was commissioned in January.

Iodine.—New iodine production capacities were placed in operation in Turkmen S.S.R. A State commission accepted the 16 industrial and auxiliary units of the first stage of the Baku iodine plant in January; construction of the second stage continued. An experimental iodine plant was put into operation near Slavyansk in the Kuban' re-

gion. The iodine was extracted from water discovered during drilling for oil wells.

Kaolin.—Kaolin was mined from open pits in the Ukraine and the Urals. Construction of a kaolin mining combine was started at a large deposit in the vicinity of the Chalgan railway station in Amur Oblast'.

A large kaolin deposit was discovered in the Kokchetav steppes, east of the Urals.

Lime.—The original Soviet 1965 production target for lime, 17 million tons, was fulfilled. The Dzhivil-Aryksk lime plant in Kirgizia, and the Ussuriysk lime combine, the largest in the Far East became operational in 1965. Annual capacity of the latter was 500,000 tons.

Magnesite and Magnesium Compounds.—In the Kara-Bogaz area of Turkmenistan a new chemical plant began manufacturing magnesium dichloride for farms in the central Asian republics. At Satka in Chelyabinsk Oblast', a new rotary furnace, for producing magnesite powder for the metallurgical industry, was put into operation.

The Savina magnesite deposit, in the eastern Sayan Mountains, Irkutsk Oblast' was explored. The reserves, the largest in the country, were of high grade and it was decided to plan a magnesite-calcining and ore-concentrating combine to process ore from this deposit.

Mica.—Irkutsk Oblast' was the main Soviet supplier of muscovite mica; 75 percent of all muscovite deposits in the country were in Mamsko-Chuyskiy Rayon of Irkutsk Oblast'. The Bol'shoy Severnyy mine was the largest mine of the Mama mica trust, and the Irkutsk mica factory was one of the largest enterprises in the country engaged in mica processing.

In 1965, the State allocated 11 million rubles for muscovite mica prospecting. More than 150 teams of geologists, geophysicists, and topographers were assigned to the Mama area in Irkutsk Oblast'.

Strategic-grade mica continued to be imported from India to meet special industrial demands.

Perlite.—Perlite was mined in Armenia and Buryat A.S.S.R. A new unit with annual capacity of 25,000 cubic meters of perlite was under construction at the Arakadzh plant in Armenia. The second stage of a perlite quarry, with an annual capacity of 50,000 cubic meters, was commissioned in Mukhor-Tala, Buryat A.S.S.R., in November.

Refractories.—As in prior years, production of refractories paced rising industrial output, but consumers were not satisfied with product quality. The refractory industry however, continued to direct its major efforts toward quantity in 1965 rather than quality of refractories.

A large refractory materials deposit was discovered near Shorza, northeast of Sevan in Armenia and it was planned to construct a combine at these new pits in 1966.

Refractory clays were mined from the Turgay bauxite open pit operations for shipment to the Chelyabinsk metallurgical plant.

A new deposit of fire clay was surveyed at Barzas in the Kuznetsk coal basin that will be able to meet all requirements of the Kuznetsk metallurgical combine and the West Siberian metallurgical works.

Salt.—The Volodarsk salt mine in Artemovsk, Donetsk Oblast', was renovated. This property has a planned capacity of 5,000 tons of table salt daily, an increase of nearly 50 percent over the capacity before renovation.

The largest salt mine of the U.S.S.R., with a capacity of 2 million tons a year, was being developed in Salarinsk Rayon, Irkutsk Oblast'. In order to operate the mine at full capacity, some 4,000 workers will be needed.

Sulfur.—The Soviet Union is one of the leading countries in sulfur ore reserves but sulfur content is low and production costs high. In 1965, the commercial deposits of sulfur ore were: Rozdol (West Ukraine), Gaurdak and Shorsu (Central Asia), and Vodinsk and Alekseevsk (Volga group).

The Rozdol chemical and ore combine was the largest producer of sulfur and the largest operating sulfur combine in Europe. The Gaurdak deposit in Turkmenia was one of four exploited deposits in Central Asia which, together with the Rozdol deposit near L'vov, provided the bulk of the country's sulfur requirements.

An important factor undoubtedly contributing to the recent increase in elemental sulfur output was initiation of production from mirabilite obtained from the Caspian Sea and treated at the recently opened Kara-Bogas combine.

Other sources of sulfur were receiving attention, including recovery in the form

of sulfuric acid from nonferrous smelter gases and from oil processing.

Construction of the largest facility in Europe for the production of sulfur started at the Yavorov mining and chemical combine in the vicinity of large sulfur deposits in L'vov Oblast'.

The most important new facilities for sulfuric acid production commissioned in 1965 were at the following plants: Krivoy Rog Lenin works, Sumy chemical combine, Balkhash mining and metallurgical combine (first stage), and at the Leninogorsk zinc plant (second stage). New productive capacities were put into operation for the production of natural sulfur in Turkmen S.S.R.

Vermiculite.—The vermiculite deposits of Kola Peninsula were the largest in the U.S.S.R The extensive Urals deposits were the second producing center. A large deposit of vermiculite was found in Kokchetav Oblast', Kazakhstan.

MINERAL FUELS

Among the many goals set for the various branches of the economy, the planned structural change in the Soviet Union's fuels balance was of considerable significance to the mineral industry, as a producer, consumer, and exporter. In 1965, crude oil and natural gas provided 51.6 percent of total fuel production, whereas in 1966 the share of the total to be accounted for by these fuels was slated to increase to 53.5 percent. If planned goals are met, oil production will reach 264 million tons (about 1,924 million barrels); gas, 148,000 million cubic meters (about 5,180,000 million cubic feet); coal (including anthracite and lignite) 598 million tons; and fuel peat 75 million tons.

Production of coal in the U.S.S.R. in 1965 was equivalent to about 420 million tons of standard fuel,[9] while crude oil production was equivalent to less than 347 million tons. It is evident that in development of power sources in the Soviet economy, coal is likely to play a larger role than petroleum.

In spite of the development of the Soviet coal industry, output during recent years has not kept up with the demands of the Soviet economy. Moreover coal exports have intensified this problem.

[9] A metric ton of standard fuel equivalent has a calorific value of 7,000,000 kilocalories (7,000 kilocalories per kilogram) or the equivalent of 27,780,000 British thermal units (or 13,100 B.t.u. per pound).

Although coal's share in the country's fuel production balance has gradually declined, there has been no relaxation in coal industry development plans, as is evidenced by the output target of 665 to 675 million tons of useable coal planned for 1970.

Development of electric power facilities has had one of the highest priorities in the Soviet economy since 1920. During the 1959–65 7-year-plan alone, the annual production of electric power in the U.S.S.R. was increased by more than 270 billion kilowatt-hours, with an average annual rate of growth of 11.6 percent.

Installed capacity of electric stations of the U.S.S.R. at yearend totaled 114 million kilowatts including 22.2 million kilowatts capacity of hydroelectric power. Production is expected to reach 840 to 850 billion kilowatt-hours in 1970.

Coal.—Daily coal output increased from 1.5 million tons in 1958 to 1.7 million tons in 1965. The total tonnage included about 410 million tons for heating and power purposes, 40 percent supplied to electric power stations, 27 percent for communal-domestic requirements, about 11 percent for transport purposes, and 22 percent for other uses.

The requirements for coking coal by the the metallurgical industry were met almost in full.

In 1966, plans call for the coal mining industry to increase its capacity by 20 million tons. The production goal was set at 598 million tons, or nearly a 3.5 percent increase over the 1965 output.

In 1965 there were 877 underground coal mines and 62 open pits which employed 1.7 million workers. The average annual capacity of underground mines was 0.5 million tons and mine timber consumption amounted to 1,380 cubic feet per thousand tons of coal produced. Underground production of coal in 1958–65 increased by 11 percent. Recovery of coal at eight main underground coal combines in the Soviet Union has decreased from 82.6 percent in 1954 to about 70 percent in 1965.

The average ash content of all useable coal was 19.4 percent in 1965, however, home heating fuel ranged up to 45 percent. The calorific value of coal shipped averaged a little more than 5,000 kilocalories. The throughput of coal preparation plants was 172.5 million tons, only 30 percent of the total coal output.

In 1965, 139 million tons or 24 percent of the total coal production came from open pits. The average yearly output per pit was 2.2 million tons. It was planned to mine by 1970 about 195 million tons of coal from 69 open pits each with an average annual capacity of 2.8 million tons. Openpit mining was used in 12 regions of the Soviet Union, with the Urals basin the largest single producer of coal by this method. Next in importance were the deposits of East Siberia, followed in order by those of the Ukrainian brown coal basin, the Far East, Kazakhstan, the Kuznetsk basin, and Central Asia. The lack of large capacity dump cars was the reason for the comparatively low figure of 10.6 percent for this kind of transport in Soviet open pits in 1965.

The average working thickness of the coal seams, according to 1965 data, was 1.32 meters. Figures by basin were: 0.95 meters in the Donets, 2.23 meters in the Kuznetsk, 2.27 meters in Moscow, 1.99 meters in Karaganda and 1.70 meters in the Pechora. The relative share of coal production from gently sloping seams was about 70 percent, that from inclined seams was 14 percent, and that from steep seams was 16 percent. The maximum depth at which underground coal production was carried out reached 1,000 meters in 1965, while the average depth was about 320 meters. Average depths by basin were: 385 meters in the Donets, 205 meters in the Kuznetsk, 300 meters in the Karaganda, 57 meters in the Moscow, and about 400 meters in the Pechora.

Distribution of coal production by mining method was as follows: Longall, 84 percent; slicing, 8 percent; shield, 3.2 percent; room and pillar 2.8 percent; and others, 2 percent.

Coal Preparation.—Preparation of coal for the market did not play a great role in the industry and was normally restricted to coking coals. The shortage of coal and beneficiation facilities forced Soviet planners to direct all efforts to the improvements in quantity rather than quality. Multistage manual preparation in the longwall, and hand sorting on the conveyor from underground mine cars and elsewhere was widespread. Altogether, about 40,000 men and women were employed in hand sorting rock from coal.

In 1965, 142 preparation plants were working in the Soviet Union. The wet method was the principal method used in the mechanical preparation of coal (65 percent), and pneumatic preparation was used to clean about one-third. The use of heavy media was only being introduced in the Soviet Union with the help of the French firm, Préparation Industrielle des Combustibles (P.I.C.), which provided coal treatment plants for the U.S.S.R.

The ash content of washed noncoking coal in 1965, was over 15 percent, and that of coking coal was 8 percent. The large proportions of fines shipped to preparation plants, 50 to 70 percent, complicated operations at preparation plants.

New Capacities.—According to the 1965 plan, the annual capacity of coal mines was to be increased by 24.7 million tons, but this plan was not fulfilled. The Nazarovsk and Irsha-Borodin pits and others were not completed. The more important enterprises put into operation in 1965 included the No. 15 coal mine at the Intaugol' combine, the Biryulinsk No. 1 mine, Safronovsk and Chermgov open pits and Sholokhovsk and Safronovsk preparation plants in the Russian union republic, the Kara-Su open pit in Kirgizia and the Irtyshsk open pit No. 3 in Kazakhstan.

Mechanization.—In the coal industry, mechanization was introduced in mines and to a small degree at preparation plants and open pits, however there were serious shortcomings. A great number of mines which had been accepted as fully mechanized and automated do not conform with the technical level of existing Soviet "Basic Codes and Requirements for Overall Mechanization and Automation", mainly in stopes and development faces. There were no high efficiency continuous miners for hard and viscous coal, while the utilization of cutter-leaders on steep seams did not increase labor productivity significantly. The available machinery did not exclude manual labor at the longwall.[10]

New Soviet machines, together with mechanized hydraulic props, were tested for the first time in the Donets and Karaganda coal basins in 1965. The introduction of a prop-free-front system in longwall coal min-

[10] Mekhanizatsiya i Avtomatizatsiya Proizvodstva (Mechanization and Automation of Production). Moscow, No. 3, 1966, pp. 33–37.

ing followed 12 years after its initiation in Great Britain and West Germany. Until now, the Soviet coal mines have been unable to change over to this system because they have not had a dependable narrow-web extracting machine. It is planned to replace wide-web continuous coal miners by more efficient narrow-web continuous miners.

Coal ploughs were tested for the first time in the Kazakhstan Basin during the year and some 14 ploughs were introduced at the anthracite mines at the Rostov combine (Donets Basin). Introduction of coal ploughs in the Donets Basin, which took place in 1963 to 1965, followed by 12 to 14 years their use in West Germany.

Hydraulic Mining.—Hydraulic mining yielded in 1965 about 3.5 million tons of coal, but completion of additional hydromines has been at much slower rate than was planned. In actual practice hydraulic mining in the U.S.S.R. involves primarily hydraulic transport from the face to the mine surface. Actual cutting of coal is by a combination of conventional and hydraulic methods. Labor productivity was 50 percent below that planned, costs proved to be double, and operational losses of coal were 2.3 times those planned. Consumption of electric power at hydraulic mines in Kuzbas was over 50 kilowatt hours per ton of coal, and consumption of water was 7.7 to 27 cubic meters per ton.

Production Centers. The 10 major and many minor coalfields in the U.S.S.R. produced 428 million tons of hard coal (bituminous and anthracite) and about 150 million tons of lignite in 1965.

The Ukraine, with the Donets and L'vov-Volyn coal basins as the main centers, produced 194 million tons in 1965 and was the foremost coal producing region of the Soviet Union.

The Donets took the first place in the coal industry of the U.S.S.R. Thirteen mines with a total output of 15.5 million tons a year were under development in 1965. A preparation plant went into service at the Gorlovsk-Glubokaya coal mine in December. Its designed capacity was 5,000 tons of coal concentrated in 24 hours. After reconditioning, the Krivorozhsk and Bryansk coal preparation factories in Lugansk Oblast', were commissioned in January.

There were three mines with the total output of 2.7 million tons of coal a year in Dnepropetrovsk Oblast' of the western Donets Basin. Nine new mines were under construction. One of them was to have an annual capacity of 2.4 million tons of coal. The western Donets Basin produced over 7 million tons of coal in 1965.

There were 18 coal mines in the L'vov-Volyn Basin. Development of the Velikomostrovsk Mine, which with a capacity of 1.5 million tons of coal per year will be the largest mine in the basin, started in April. In addition, development of two more coal mining enterprises was in progress.

The Kuznetsk Basin in Siberia was the second major producer of coal and one of the largest centers of fuel supply for Siberia, the Urals, Central Asia, and partially the Center and Volya regions of the European U.S.S.R. This basin produced over 90 million tons of coal in 1965. The first section of the Chernigorsk coal mine in Kuzbas was completed in December. Initial output will be 600,000 tons a year.

Kazakhstan was third in coal production, producing 45.7 million tons. Some 100,000 tons were mined daily at the 37 mines of the Karaganda Coal Basin in 1965. The basin's washeries handle 7 million tons a year and the commissioning of three more washeries in the near future will increase this figure by 14 million tons.

Continuously, since 1961, the production cost of coal in Kazakhstan increased, and planned output was not achieved. Thus, the Churubay-Nurinsk mine No. 1, put into operation in 1959, attained only 42.3 percent of planned capacity in 1965. The Churubay-Nurinsk mine No. 2, which was completed in 1960, produced 71.8 percent of its planned capacity.

The delayed attainment of capacities, low indexes of mining equipment utilization and large coal losses reduced the return on capital at Karaganda coal enterprises from 81 kopecks in 1959 to 58 kopecks in 1965.

Mine No. 35–B in the Karaganda basin was nearing completion. The new 500-meter mine will be the deepest in Kazakhstan. The Churubay-Nurinsk mine No. 14 in the basin was commissioned in 1965, and a coal preparation plant was under construction.

The coal deposits at Ekibastuz in Kazakhstan were estimated at 10 billion tons, all of which can be mined by openpit methods. The three operating pits at the coalfield produced about 14 million tons in 1965. It was planned to renovate these pits and equip them with rotary excavators.

The Moscow Basin, which produced lignite with an ash content of about 45 percent, was the fourth major coal producer in the U.S.S.R. Plans provided for the opening of about 50 mechanized mines with yearly outputs ranging from 0.9 million tons to 1.5 million tons of raw lignite. Four preparation plants are also projected.

The Donets, Kuznetsk, Karaganda, and Pechora coal basins produced over four-fifths of the total coal output in calorific value and 97 percent of the coking coal in the U.S.S.R.

The Chelyabinsk Basin held first place in the total coal production in the Urals area. Construction began on the Vostochnaya-Batyrinsk mine with a yearly capacity of 0.4 million tons. The Raychikhinsk Basin shipped over 12 million tons in 1965. In the Kansk-Achinsk (lignite) and Minusinsk (anthracite) coal basins in Krasnoyarsk Kray it was decided to build 9 open pits and renovate existing ones. In 1965, these basins produced about 8 million tons.

Primorsk Kray produced about 7 million tons of coal in 1965, and construction of a large lignite pit started in the region of Pavlovka village. Openpit mining began at a new coal deposit near Lipovtsy station in the Far East. At the Rettikhovka open pit construction was started on a coal preparation plant which will use the pneumatic process for lignite cleaning.

The Safronovsk open pit in Cheremkhovo Basin, with annual capacity of 6.5 million tons of coal, was put into production in December. The second stage of the Tom'-Usinsk-78 pit with daily output of 16,000 tons was commissioned in January; 70 percent of coal was of coking quality. Eleven mines at the Sakhalin coal combine produced about 4.5 million tons of coal in 1965. The largest coal-preparation plant on Sakhalin Island and the Lermontov open pit No. 2 were being developed at Vakhrushevo, near Yuzhno-Sakhalinsk. Chita Oblast' produced 4.1 million tons of coal.

There were 11 coal mines in operation in Georgia. The first mine on the Shaori deposits, the Komsomol'sk, was under development. Extraction of anthracite started at a mine in Karachaevo-Cherkessk Autonomous Oblast'. The erection of the Soviet Far East's first large washing plant to handle 1.5 million tons of coking coal a year started at the Verkhne-Vilyuysk coalfield.

In 1965, a new coal combine, Kirgizugol' Combine, was created. Two open pits were working in the republic, and one more, the Abshir open pit, with a yearly output of 200,000 tons, was opened in November. In 1965, Kirgizia supplied 1.6 million tons of coal.

Labor Productivity.—Coal cutting and hauling operations were nearly 100 percent mechanized in underground mines, but manual labor was used almost exclusively in conveyer transfer, roof support, and surface operations. Consequently, overall productivity was low and utilization of machines and equipment was unsatisfactory. At the Primorskiy coal basin in 1965 continuous coal miners produced at a monthly average of 4,000 to 4,500 tons, however this amounted to only 32 tons of coal a month per worker. The average output of coal at Donets Basin longwalls was 155 to 210 tons of run-of-mine coal per day, and productivity of a longwall worker was 2.9 to 3.7 tons per shift. In the Budennovugal' Trust of the Donets Basin, with a daily average output of about 12,600 tons of run-of-mine coal, the labor force comprised 19,970 workers and junior servicing personnel, and 2,450 engineers, technicians and white collar workers.

Natural Gas.—Usable Soviet gas extraction in 1965 was 129.2 billion cubic meters, an increase of 17 percent compared with that of 1964, but below the original 7-year plan target of 150 billion cubic meters. Of this quantity 98.6 percent consisted of natural gas and oil associated gasses, and 1.4 percent was gas from gasification of coal and oil shale. In 1965, gas accounted for 15.6 percent of the U.S.S.R. fuel production.

There were over 200 proven fields of natural gas in the Soviet Union; 2,400 wells were operational however 15 to 20 percent of them were idle. Total measured and indicated gas reserves were estimated at 2.5 trillion cubic meters. Trunk gas pipelines totaled about 40,000 kilometers at yearend. Of all the gas produced in the Soviet Union for consumption, about 85 percent was used by industry and most of the remainder for domestic heating. In 1965, natural gas was supplied to about 7 million apartments, serving 40 million people. During the 7-year plan period, Soviet gas production increased over 300 percent.

According to Japanese trading circles, the Soviet Government presented to Japanese industrial and trading interests two projects to develop natural gas resources in northern Sakhalin and Primorskiy Kray with Japanese cooperation.

Gasfields.—The largest fields of natural gas in 1965 were the following: Shebelinka, North Caucasus, and Gazli. Major new gas-producing centers are to be established in Turkmenia, Uzbekistan, Kazakhstan, West and East Siberia.

In 1965 the Ukraine extracted 39.4 billion cubic meters of gas or nearly one-third of the national total. The republic supplied its gas to the Russian union republic, Belorussia, the Baltic S.S.R's, and Poland and will in 1966 supply it also to Moldavia and Czechoslovakia. New deposits will begin to yield in L'vov and Poltava Oblast's, the Crimea, and elsewhere.

Two-thirds of gas extracted in the Ukraine in 1965, 26 billion cubic meters, was supplied by Shebelinka. Another string of the Shebelinka-Belgorod-Kursk-Bryansk gas pipeline, with a throughput of nearly 3 million cubic meters a day, was put into operation. Work began in Moldavia on a 200-kilometer-long main gas pipeline from Shebelinka to Kishinev.

The second largest center of gas production was Krasnodarsk Kray, which produced 23 billion cubic meters of gas or 18 percent of total national output. A new 83-kilometer section of the gas pipeline linking Krasnodarsk Kray with Moscow was put into operation in Lugansk Oblast' on August 11.

The third center of gas production was Uzbek, S.S.R., which produced 16.5 billion cubic meters of gas. The system of gas pipelines linking Bukhara and the Urals stretches more than 4,500 kilometers. Gas from Bukhara fields was already being extensively used by industrial plants in the Urals. The gas industry ministry counted on delivery of 20 billion cubic meters to the Urals in 1966. Construction of the second string of the Bukhara-Urals gas pipeline, 1,500 kilometers long and extending from Gazli in Uzbekistan to the border of Orenburg Oblast', was completed. The first string was extended northward to Nizhniy Tagil. Throughput of the Bukhara-Urals gas pipeline in 1965 was over 11 billion cubic meters. The third string of this gas pipeline will be completed in 1966. Eighty-two kilometers were commissioned in 1965.

Stavropol' Kray produced over 15 million cubic meters of gas in 1965. Production costs for natural gas of this region were the country's lowest. A second gas pipeline was being built from Stavropol' to Tbilisi. The total consumption of gas in the Donets Basin was over 10 billion cubic meters in 1965; all this gas came from Russian union republic gasfields.

The other significant gas producers in 1965 with output in billion cubic meters were: Volgograd Oblast' 7.1, Saratov Oblast' 6.3, Azerbaydzhan 6.2, Bashkir A.S.S.R. 3.0, Tatar A.S.S.R. 2.8, and Kuybyshev Oblast' 2.

The Khabarovsk refinery put into operation an installation for production of liquefied gas with a capacity of 12,000 to 15,000 tons of gas per year. It was estimated that the Sakhalin Oblast' had four deposits of natural gas.

At Markovo on the Lena River, 300 kilometers from Irkutsk, a large natural gas deposit was found. Preparations for laying a 500-kilometer gas pipeline to supply Norilsk were underway. Gas was discovered in the Ararat Valley in 1965, and it was estimated that the deposits were sufficient to supply Armenia from its own gasfields. Construction started on a 62-kilometer gas pipeline from Yerevan to Oktemberyan.

Transportation.—The distant location of the principal consuming centers from the gasfields has made it inevitable that the bulk of natural gas must be transmitted by large pipelines. Over 80 percent of the natural gas produced in 1965 was carried by pipelines and only about 20 percent was consumed at the place of production. In 1965, large-diameter pipelines comprised over half the total length of trunk gas pipelines in the country.

Underground gas reservoirs existed at Moscow, Leningrad, and Kiev. Last year Moscow was supplied with over 4 million cubic meters a day from this source. It was planned to establish others in Uzbekistan and near Yerevan. Later, more will be added near Sverdlovsk, Magnitogorsk, and elsewhere. Construction of the underground storage for natural gas near Tashkent, with a capacity of 1 billion cubic meters, was completed in August. An under-

ground gas storage reservoir was completed at a depth of 800 to 1,000 meters in Georgia. It held a 2-week supply of natural gas for Tbilisi and Rustavi.

Construction of the gas pipeline from the Dashava (Rechka) gasfield in L'vov Oblast' to the Pulawy chemical combine. Lublin Province in Poland, was completed. It was planned to extend this pipeline to Warsaw and to Wroclawek in Bydgoszch Province. The length of the pipeline will be more than 500 kilometers.

The following gas pipelines were commissioned in 1965: The Mali-Su-Iv-Dzhalal-Abad-Osh (Kirgisia), Kotur-Tepe (Turkmenistan) to the Cheleken Peninsula (43 kilometers), Poltava-Kremenchug (120 kilometers), Pereshchepino-Dnepropetrovsk (60 kilometers), and the first stage of the Zyrya-Karagag in Azerbaydzhan (50 kilometers). Construction of the 230-kilometer Minnibaevo-Nizhnekamsk gas pipeline was completed in December.

The construction of the 200 kilometer Afghanistan-U.S.S.R. gas pipeline started in 1965. The pipeline will start at Shibargham in Afghanistan and will join the Central Asian gas pipeline system. Work on laying a gas pipeline from the Volga to the Mari A.S.S.R. started in the Tatar A.S.S.R.

A plan for the construction of a new U.S.S.R.-Czechoslovakia gas pipeline was approved. It will start at Dolina (Dashava) in the Ukraine and run to Bratislava. This 534 kilometer line scheduled for operation in 1967 will supply Ukrainian gas to a chemical combine now under construction in Czechoslovakia. The design of the 7,000-kilometer Central Asia-Moscow gas pipeline was completed and work began.

For the first time in the Soviet Union gas and oil were transported a distance of 100 kilometers through a single pipeline from Prova to Karatau in Kazakhstan.

Exploration.—Deep drilling plans were not fulfilled in 1965 in several regions including Orenburg and Kuybyshev Oblast's. Among the fields that were prospected in 1965 and which have a particularly favorable outlook were those of Novyy Port area of the Yamal Peninsula, Yefremovka in the Ukraine (15 billion cubic meters of reserves), in the neighborhood of Uchkyz in the Kyzyl-Kum (22 billion cubic meters), and the third gas region in the Bashkir, A.S.S.R. Eight new gas deposits were put into operation in Ukraine in 1965. Three gas deposits were discovered in Crimean Oblast'.

New deposits, Yuzhnoe and Tsentral'noe, were discovered on the Ust'-Yurt Plateau in Aktubinsk Oblast'. The advantage of these new Kazakh deposits is their proximity to the route of the Bukhara-Urals gas pipeline, to which they will be connected. A new gas deposit was discovered in the Kara-Kum in eastern Turkmenistan. The deposit is in the area of the Gazli-Urals gas pipeline.

New deposits of natural gas were also discovered in the foothills of the Caucasus, Kalmyk and Chechen-Ingush A.S.S.R.'s, near Dushanbe in Kirgiziya, Saratov and Sverdlovsk Oblast's and other areas of the U.S.S.R.

Petroleum.—Crude oil output increased 9 percent over that of 1964 and totaled 243 million tons (about 1,771 million barrels).

Turbodrilling was rapidly developed and has replaced rotary drilling almost completely. In 1965, about 80 percent of the total footage drilled was by turbodrilling. The maximum depth of drilling obtained in the U.S.S.R. was 16,531 feet, while the average depth of exploration wells was about 7,200 feet and that of producing wells was over 5,200 feet. Planned 1965 drilling targets were about 19.7 million feet of development and about 16.4 million feet of exploratory drilling, but less than 90 percent of the 1965 exploration target was met.

For the first time in the U.S.S.R the Gronzy Oil Research Institute suggested pumping gas into the well instead of water for reservoir pressure control.

The rate of increase in drilling speeds and depth of wells was impeded by obsolescence of drilling rigs, and shortages of specialized transport facilities, durable casing and drill pipes, and good-quality drilling bits. The machine building industry was not able to supply enough special equipment for reservoir surveying, high-pressure pumps for water injection, or submersible electric pumps and devices for deep testing.[11]

In 1965, over 60 oil and gas deposits were discovered in the U.S.S.R., including 9 deposits in the middle reaches of the Ob' River.

The main Soviet oil province, between the Volga and the Urals, was expanded by

[11] Pravda, Dec. 2, 1965.

1 thousand square kilometers. The U.S.S.R. Ministry of Oil Extraction Industry approved a project for the development of new deposits between Kama and Belaya Rivers. Commercial oil production was already underway on a small scale at the Arlansk deposit.

Exploration and Crude Oil Production.—The largest increase in crude oil production occurred in the Tatar and Bashkir autonomous republics and Kuybyshev Oblast'. The Volga-Ural region, which includes these areas, accounted for approximately 80 percent of the total Soviet oil output in 1965. The oilfields of this region, were producing 468,000 tons of oil daily by yearend. Commercial output of oil started at 14 new deposits last year.

In 1965, output of the Tatar A.S.S.R. exceeded that of any other individual area in the country, totaling 76.4 million tons compared with 28.6 million tons in 1958. There were 130 oil deposits being exploited in the republic and new fields were put into operation at the Romashkino deposit. In 1965, 60 new wells were commissioned at fields managed by the Alkeyev oil administration; data on drilling performance by other oil administrations in this republic were not available.

The second producer of crude oil in 1965 was the Bashkir A.S.S.R. Exploitation of five new oil deposits began in the central part of Bashkiria.

The oil industry of Kuybyshev Oblast' was third, and produced about 36 million tons of oil in 1965. Fourteen new deposits were tapped and four deposits were discovered, bringing the total number of known deposits in the region to 350 with reserves sufficient for 20 years' production.

Outside of the Volga-Urals region, Azerbaydzhan produced 21.5 million tons of oil, while about 10 million tons of oil were extracted in Turkmenistan in 1965. Over 50 wells were in operation in Kyzyl-Kum in the latter area. Oil extraction began at the new Komsomolsk deposit in west Turkmenistan, next to the Kotur-Tepe oilfield.

In 1965, the Ukraine supplied about 8 million tons of oil. New deposits, the Novogrigor'evsk in Poltava Oblast' and the Rybalsk in Sumy Oblast' were put into operation. More than 80 new wells were commissioned at the Ukrainian fields last year.

In 1965, a number of new oil regions, in particular the West Siberian fields in Tyumen Oblast' and those of Mangyshlak on the eastern shore of the Caspian Sea in Kazakhstan, started production. In total Kazakhstan produced about 2 million tons of oil in 1965.

In the Mangyshlak Peninsula of Kazakhstan, the first field, Uzen, produced 0.5 million tons of oil in 1965. It was delivered to the refinery at Guryev on the northern shore of the Caspian Sea in western Kazakhstan. The Uzen deposit occupied third place in the U.S.S.R. in the size of reserves, which were more than 1.5 times larger than the total reserves of oil of all the Central Asia republics. Mangyshlak Peninsula oil experts plan to extract 1.8 million tons of crude oil in 1966. Zhetybay oilfield, 70 kilometer from Uzen with a yearly capacity of several million tons, was opened.

In 1965, 74 wells were commissioned on the Mangyshlak Peninsula, which is expected to become a major oil producer in the next few years. According to the latest geological data, the exploitation of all deposits in southern Mangyshlak will make it possible to produce up to 100 million tons of oil annually. The Mangyshlak oil, highly viscous and paraffinic, presents difficult refining problems.

The oil fields on Sakhalin Island produced 2.4 million tons of oil in 1965. Fourteen new oil and gas deposits have been found on the island during the past 4 years and in 1965, prospectors were engaged in large-scale operations to locate oil in the southern part of the island.

Production from offshore fields, particularly in the Caspian, has been rising. In 1965 more than 11.2 million tons, over 50 percent of Azerbaydzhan's total output, was obtained from offshore. More than 1 million tons was extracted on the eastern shore of the Caspian Sea in Turkmenia and a further 0.5 to 0.6 million tons in Dagestan. By 1970 it was proposed to raise oil output in Turkmenia to 15 million tons, of which a large proportion will come from beneath the Caspian waters. In Azerbaydzhan, where production has fallen sharply, measures are now being taken to find new offshore oil deposits.

More than 70 percent of total offshore oil was recovered by artificial stimulation methods. The 1965 footage of offshore drilling was more than 328,000 feet.

Oil was being obtained from offshore platforms in waters about 90 feet deep and drilling was being conducted from platforms in about 130 feet of water. Plans called for erection of platforms in waters nearly 200 feet deep in 1966. In addition, it has been reported that floating drill rigs have been used successfully to drill wells 4,250 feet deep in waters 50 feet deep and that equipment to drill to 9,800 feet in 70 feet of water was nearing completion.

West Siberia contained 25 percent of the oil resources and 10 percent of the natural gas resources of the U.S.S.R. in 1965. The most promising areas were at Surgut and in the north of west Siberia.

In east Siberia the pace of prospecting the Markovo deposit has been accelerated, and about 164,000 feet were drilled in the area. The oil is of a very light type, almost like gasoline. At a new oilfield, 600 kilometers north of Tomsk, the first well began to yield from a depth of about 5,600 feet in November.

In the Urals the 40th oil deposit was discovered in Perm' Oblast', and in Orenburg Oblast', over 20 deposits have so far been discovered. New oil deposits also were found in Krasnodar Kray, near Abinskaya, and in north Dagestan.

Refineries.—In 1965, annual primary oil-refining capacity in the Soviet Union was increased by 15 million tons, and refinery output reportedly increased by 11 percent over that of 1964.

Exports of crude oil increased 21 percent in 1964 over those of 1963, and product exports decreased 6 percent. This in part reflects the shortage of refinery capacity in the Soviet Union itself and the slowness with which new refineries have been brought into operation. Each new refinery needs from 9 to 12 years to pass from the planning stage to full operation.

Oil refining operations in the Ural-Volga and eastern regions have been complicated by increased corrosion of equipment resulting from processing highly sulfurous oil over the past few years.

The new oil industry facilities commissioned in 1965 include an oil refinery near the Karabash reservoir in the Tatar A.S.S.R., the first section of a refinery in Kremechug on the Dnieper River in the Ukraine, a new catalytic reforming plant at the Novyy Yaroslav' refinery, a gasoline-separating unit at the Sumgait oil and chemical combine, and a new production unit for liquefied gas at the Krasnovodsk oil refinery.

One of the largest oil refineries in the U.S.S.R. was being built in Angarsk, and other oil processing enterprises at Fergana, Kherson, Omsk, and Ryazan.

A large oil refinery is to be built in Jurbakas, Lithuania, which will process more oil than all the Baku refineries combined. It will receive oil through a branch of the "Friendship" pipeline. It was decided to modernize and double the capacity of the Guryev oil refinery in Western Kazakhstan on the Caspian Sea.

The Polotsk refinery began to receive oil from the Belorussian fields, thereby reducing its dependence on supplies from the eastern regions of the country. The oil refinery at Kirish, Leningrad Oblast', received the first trainloads of crude oil in December. A pipeline eventually will connect the refinery with the Tatar oilfields.

In 1965, capital investment in the petroleum refining industry of the Azerbaydzhan S.S.R. increased by 8 percent over that of 1964. The 22d C.P.S.U. Congress oil refinery in Azerbaydzhan employed in 1965 over 3,000 workers, half of which were women.

Transportation.—About 70 percent of the total tonnage of crude oil and refinery products moved in the Soviet Union in 1965 was shipped by rail. The mileage of trunk pipelines has been increased considerably in recent years and totaled more than 27,500 kilometers in 1965, including 22,500 kilometers of crude oil lines and 5,000 kilometers of oil products lines. The average distance of oil delivery by pipeline in 1965 was about 450 kilometers.

The Druzba or "Friendship" pipeline, which links the oil fields of Kuybyshev Oblast' with other East European nations, extends more than 4,200 kilometers, including 3,015 kilometers over the territory of the Soviet Union. Oil deliveries through this line to Czechoslovakia, Hungary, Poland, and East Germany were doubled over those of 1964; this was made possible in part by six pumping stations put into operation. An oil refinery near L'vov and another near Syzran' as well as the new Belorussian oilfields were connected to the "Friendship" pipeline.

Construction was underway on a 284-kilometer-long pipeline through Chernigov, Sumy, and Poltava Oblast' to connect several oilfields to a new refinery; on a 780-kilometer line from Markovo on the Lena River to Angarsk and Irkutsk; and on the 1,026 kilometer Ust'-Balyk to Omsk crude oil pipeline.

A second 620-kilometer pipeline from Okha-on-Sakhalin to Komsomol'sk-on-Amur was under construction in 1965. It will carry Sakhalin oil to the Komsomol'sk-on-Amur refinery which supplies products to the Soviet Far East, and Siberia as well as providing exports to Japan, Mongolia and other countries. This refinery has been receiving Sakhalin oil through a World War II-pipeline which is no longer able to meet the demand. The first 145-kilometer section was accepted by a State commission in 1965, and it was planned to put the entire line into operation by 1967.

In Western Siberia, the 410-kilometer Shaim-Tyumen' pipeline was under consrtuction. By 1967 the 1,000-kilometer Ust'-Balyk-Omsk pipeline will make it possible to reduce the Omsk refinery's throughput of oil from the fields in Bashkiria and the Tatar A.S.S.R.

It was reported that the Moscow State Institute of Planning and Designing of Pipelines prepared plans for a new 824 kilometers pipeline from Baku on the Caspian Sea to Batumi on the Black Sea.

Oil Shale.—The Soviet Union produced 21.3 million tons of oil shale in 1965. The main center of production, as in prior years, was the Estonian S.S.R., where output totaled 15.8 million tons.

All the shale mines in Estonia were being switched to the new mechanized room-and-pillar system. For the first time all underground processes were completely mechanized at mine No. 10. The largest existing shale mine produced 1.5 million tons a year.

The new concentration plant at mine No. 7 of the Estonslanets trust was commissioned in August. The shale will be concentrated using the heavy media method. The projected capacity of the plant was 1.8 million tons of marketable shale a year.

In 1965, the shale processing combine in Estonia produced about 500 million cubic meters of butane gas from shale.

New deposits of oil shale were discovered in the Stolen area of Belorussia and in the south of the Ukraine.

The Mineral Industry of the United Kingdom

By Justin B. Gowen [1]

The output of mineral raw materials in the United Kingdom during 1965 was valued at $2,033 million [2] at factor cost at current prices, compared with $2,050 million in 1964, and represented a contribution of about 2.4 percent to the gross national product (GNP) which rose to an estimated value of $86,531 million at factor cost. Compared with the 1964 GNP the increase was 6.3 percent, or 2.7 percent when adjusted to constant prices.

In world production the United Kingdom ranked first in the output of strontium minerals, second in china clay, third in salt, fourth in coal and gypsum, fifth in tin metal and crude steel, and seventh in fluorspar and cement.

Although total industrial employment in the United Kingdom increased by about 215,000, to 23,920,000, and employment in the manufacturing industries increased by 101,000, employment in mining and quarrying decreased by 33,000. Nearly all of the reduction was in coal mining. Revised employment figures for mining, manufacturing, and construction industries during the month of June are shown, in thousands:

	1963	1964	1965
Mining:			
Coal	625	597	565
Other	71	71	70
Total	696	668	635
Manufacturing:			
Chemicals	521	517	523
Metal manufacture	603	629	637
Metal goods not elsewhere specified	560	577	596
Nonmetal manufacture	348	360	362
Other	6,881	6,926	6,991
Total	8,913	9,009	9,109
Construction	1,658	1,711	1,746

Probably the year's most important development affecting the mineral industries was the Government's White Paper, published in May 1965, containing proposals to be embodied in a bill to renationalize the steel industry. It listed 13 major steel companies that would be subject to nationalization in addition to the one (Richard Thomas & Baldwins) that was still under Government ownership from the previous nationalization. On the basis of this White Paper with some revisions, the Iron and Steel Bill was prepared and presented to the House of Commons in July 1966. The purpose of the bill is outlined in the first four paragraphs of the Explanatory and Financial Memorandum prefacing the bill as follows:

> The main purpose of this bill is to bring into public ownership the principal companies concerned with the production of steel in Great Britain. The Bill also provides for the continued control of the development by other companies of substantial production facilities in the basic fields of iron and steelmaking and for the dissolution of the Iron and Steel Board.
>
> A National Steel Corporation is to be established consisting of a chairman and from ten to sixteen other members appointed by the Minister of Power.
>
> The Corporation will hold the securities of the Nationalized companies. They will themselves have power to carry on iron and steel activities, the

[1] West Europe specialist, Division of International Activities.

[2] Where necessary, values have been converted from pounds (£) to U.S. dollars at the rate of £1=US$2.80.

sale of iron and steel products and, with the Minister's consent, any other activities which any publicly-owned company is, or has been, authorized to carry on under its memorandum of association. The Corporation may acquire interests in, or form companies which are wholly or mainly engaged in iron and steel activities or the sale of iron and steel products, and, with Minister's consent, any other companies.

The general duties of the Corporation are to promote the efficient and economical supply of iron and steel products; to avoid undue preference or unfair discrimination between consumers; to promote exports of iron and steel products and other products of the nationalized steel industry; and to promote research and development.

The bill proposes to pay compensation up to about £ 580 million in Government stock according to a formula based on average stock exchange quotations over specified periods of time. It is expected that the changeover will be completed during 1967.

In September 1965 the Government published its National Plan which laid down the guidelines for the national economy during the period 1964–70. It is a detailed statement of expected growth in all sectors of the economy and the Government's policy intentions. The objective of the plan is to achieve an increase of 25 percent (£ 8,000 million) in the GNP by 1970 (which is the equivalent of 3.8 percent annually) mainly by means of increased productivity. The effect of the plan on the mineral industries was not yet apparent at yearend.

PRODUCTION

Moderate gains in the output of nonmetals, especially fluorspar and salt, and the construction materials were more than offset by decreases in output of coal which was 3.2 percent less than in 1964, and iron ore production, which was 5.6 percent less than in 1964. Moderate increases were shown in the output of crude steel which rose by 4.6 percent over the 1964 output,[3] and of nonferrous metals which increased by about 1 percent over the 1964 output.

[3] Revised from 53 weeks' output as reported in 1964 Minerals Yearbook, volume IV, to basis of 52 weeks for comparability.

[3] Data are as reported in source for Divisions 51 and 59 of the Standard International Trade Classification—Revised (SITC–R) and as such includes commodities listed in detailed trade tables of this chapter under metals, nonmetals and mineral fuels as well as a few nonmineral items. Total listed here is not readily divisable into these categories.

Source: Statistical Office of the United Nations.

TRADE

In October 1964 a temporary import surcharge of 15 percent was imposed on imports of certain classes of manufactured and semimanufactured goods to alleviate the rapidly growing negative trade balance and the consequent unfavorable effect on the balance of payments. In April 1965 the import surcharge was reduced to 10 percent, and it remained at that level through yearend.

Although mineral commodities accounted for only 13 percent in value of exports of United Kingdom produce, and 24 percent in value of all of the United Kingdom's imports for consumption, this trade in minerals accounted for nearly 84 percent of the unfavorable balance in the United Kingdom's foreign trade in commodities during 1965.

Exports of United Kingdom produce increased by 11 percent in 1965 to $13,226.8 million of which $1,728.1 million was in mineral products. Predominating among the latter were exports of iron and steel, nonferrous metals, and petroleum products. The European Economic Community (EEC) continued to be the most important area of consignment both in total and in mineral products. The United States continued to be the United Kingdom's foremost individual trading partner with regard to both exports and imports.

The United Kingdom's imports for consumption were valued at $15,654.3 million of which $3,756.9 million was in mineral products. The leading mineral supplying areas were the Near East, West Europe, Africa, and North America. The leading individual suppliers of mineral products were Canada, $434.6 million; Kuwait, $252.6 million; and the United States, $224.6 million.

Tin plate and tinned sheets do----	465	395	397	Republic of South Africa 81; Argentina 47; Sweden 29; Spain 26.
Other---do----	156	183	217	Finland 24; China (mainland) 16; New Zealand 15; Norway 13.
Hoop and strip-------do----	r 161	105	96	India 15; Turkey 13; United States 11; Finland 9; Sweden 6.
Railway track material do----	96	182	306	Republic of South Africa 34; Nigeria 24; France 21; West Germany 18; Peru 14.
Wire----------do----	117	123	126	United States 22; Canada 15; New Zealand 13; India 9.
Tubes, pipes and fittings do----	r 513	550	550	United States 46; Netherlands 42; Algeria 33; Canada 30; Trinidad 26.
Rough castings and forgings do----	15	23	42	Belgium-Luxembourg 7; Netherlands 4; Sweden 4.
Lead:				
Lead oxides----------	r 4,136	4,344	4,774	Ireland 992; West Germany 344; Australia 229; Pakistan 203.
Metal and alloys:				
Unwrought----------	r 42,927	40,119	42,822	West Germany 2,279.
Semimanufactures----------	r 1,983	1,986	1,902	Norway 153; Hong Kong 114; India 101; Malaysia 96; Pakistan 78.
Magnesium and alloys, unwrought and semimanufactures----------	r 1,894	1,659	1,769	West Germany 905; France 213.
Nickel:				
Matte and speiss----------	NA	278	NA	Sweden 96.
Oxides----------	488	151	39	NA.
Metal and alloys:				
Unwrought----------	r 23,971	27,319	28,228	West Germany 8,116; Sweden 3,789; France 4,150; Italy 3,250.
Semimanufactures----------	6,447	7,617	6,829	United States 786; Australia 768; France 754; Sweden 643.
Platinum group metals thousand troy ounces--	866	781	906	Canada 248; United States 185; Japan 107.
Silver and alloys, unwrought and semimanufactured----------do----	r 21,362	21,139	28,676	Italy 5,412; Belgium-Luxembourg 3,549; France 1,599; West Germany 1,569.
Tin:				
Ores and concentrates, long tons--	---	73	---	All to United States.
Oxides----------do----	r 460	405	411	Spain 69; Sweden 56; Mexico 38; Brazil 36.
Metal and alloys:				
Unwrought----------do----	r 11,161	9,409	9,275	United States 1,788; U.S.S.R. 1,091; France 987; West Germany 715; Netherlands 650.
Semimanufactures----do----	335	520	975	Norway 209; West Germany 99.

See footnotes at end of table.

Table 3.—United Kingdom: Exports[1] of metals and Minerals—Continued
(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal destinations, 1964
Metals:—Continued				
Tungsten ores and concentrates	---	1,326	---	West Germany 519; United States 398; Poland 171; France 91.
Zinc:				
Zinc oxides	r 7,140	5,698	3,688	Australia 945; West Germany 617; Ireland 472; Nigeria 372; Malaysia 335.
Metal and alloys:				
Unwrought	8,941	6,023	1,254	Belgium-Luxembourg 2,096; Japan 755; Thailand 711.
Semimanufactures	r 4,402	5,622	6,289	Netherlands 1,008; France 421; Australia 347; Chile 342; Ireland 306.
Nonferrous base metals, not elsewhere specified:				
Ores and concentrates	13,677	15,864	16,612	West Germany 3,655; Belgium-Luxembourg 3,157; Spain 1,947; Republic of South Africa 1,319; France 1,129.
Scrap	34,399	33,162	50,162	Belgium-Luxembourg 8,749; West Germany 5,250; Netherlands 3,284; Spain 1,880; Sweden 1,524.
Nonmetals:				
Abrasives, natural, n.e.s.	4,066	4,701	3,175	Ireland 1,556; Australia 406; India 260.
Asbestos:				
Crude or simply processed	r 8,248	5,773	6,040	West Germany 1,131; United States 1,047; Italy 732.
Asbestos cement products	r 45,848	58,868	38,353	Sudan 13,905; Nigeria 11,846; Ghana 2,810; Ireland 2,652.
Fabricated asbestos products, excluding friction materials	26,478	29,193	---	NA.
Cement, hydraulic---thousand tons	r 313	293	281	Ghana 63; Australia 25; Mauritius 21; Sierra Leone 14.
Clays and refractories:				
Crude:				
China clay---thousand tons	1,271	1,383	1,506	NA.
All other---do	320	368	382	NA.
Total---do	1,591	1,751	1,888	West Germany 285; Italy 260; France 194; Sweden 169; Finland 159.
Clay construction materials:				
Brick and other nonrefractory---do	63	68	71	Australia 14; United States 8; Canada 6; Malaysia 3.
Refractory---do	142	141	157	Netherlands 16; Sweden 13; Australia 12; Ireland 10; Belgium-Luxembourg 10; Canada 9; India 6.
Construction materials	12,248	8,769	7,750	Ireland 3,467; Norway 1,604; France 1,076.
Corundum artificial	NA	1,304	809	NA.
Fertilizer materials, manufactured:				
Nitrogenous---thousand tons	394	384	439	Ceylon 106; Malaysia 86; Spain 46.
Other---do	r 16	20	55	Spain 4; Netherlands 3; Cuba 3.
Gypsum	6,831	7,724	NA	NA.
Iodine---kilograms	16,353	24,591	NA	NA.
Lime	25,195	30,338	38,165	Norway 6,056; Nigeria 4,835; Ghana 2,355.
Pigments, mineral	5,464	6,504	3,661	NA.
Quartz, mica and feldspar	r 9,532	17,585	24,463	Australia 2,372; Norway 1,152; Finland 876.
Salt---thousand tons	368	363	405	Sweden 101; Nigeria 66; New Zealand 33.
Stone, sand and gravel---do	r 163	189	212	West Germany 78; Ireland 49; Sweden 20.
Cut stone	r 2,005	2,099	3,829	Ireland 850; Canada 477; West Germany 98.
Strontium minerals (celestite)	9,588	15,479	NA	NA.
Crude minerals, n.e.s.---thousand tons	170	173	252	Norway 95; Sweden 25; United States 8; West Germany 6.
Slag, scalings, dross, etc---do	361	386	327	West Germany 346; Denmark 15; Sweden 11.

See footnotes at end of table.

Table 3.—United Kingdom: Exports [1] of metals and Minerals—Continued
(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal destinations, 1964
Mineral fuels:				
Carbon black	38,278	38,416	38,466	NA.
Coal, anthracite and bituminous thousand tons	8,002	5,965	3,856	Netherlands 1,521; France 980; Denmark 675; West Germany 642; Belgium-Luxembourg 630; Ireland 523.
Coal briquets do	138	51	33	France 23; Ireland 15; Norway 7.
Coke from coal and lignite do	r 2,052	1,489	1,009	Norway 535; Sweden 234; Portugal 205.
Petroleum:				
Crude and partly refined thousand barrels	r 10,522	2,507	1,997	Netherlands 2,486.
Refinery products:				
Gasoline do	r 12,138	11,017	13,513	Sweden 3,999; Denmark 2,322; France 1,367.
Kerosine do	r 7,028	5,921	6,249	Ireland 1,452; Sweden 1,265; Denmark 1,096.
Distillate fuels do	r 26,104	24,757	29,112	Denmark 5,318; West Germany 5,043; Norway 1,792; Netherlands 1,698.
Residual fuel oil do	r 20,843	21,378	25,792	Sweden 6,859; Denmark 4,666; Norway 3,951; West Germany 2,590.
Lubricants:				
Oils do	r 3,653	3,696	3,643	Belgium 284; Netherlands 277; India 276; West Germany 268; Australia 196; Norway 185; Republic of South Africa 180; Ireland 175.
Greases and impregnating compounds thousand tons	34	35	76	NA.
Mineral jelly and waxes do	r 8	6	5	West Germany 2; Ireland 1; Republic of South Africa 1.
Nonchemical coal and petroleum wastes	---	261	246	Norway 42; Spain 30; Netherlands 15; Sweden 8.
Electric energy megawatt-hours	120,658	305,963	103,069	All to France.

r Revised. NA Not available.
[1] Excluding reexports.

Table 4.—United Kingdom: Reexports of metals and minerals
(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal destinations, 1964
Metals:				
Aluminum and alloys, unwrought	66	480	183	United States 205; West Germany 153; Ireland 57.
Copper and alloys, unwrought	12,064	638	3,321	United States 331; Italy 254.
Lead and lead alloys, unwrought	803	2,617	5,429	Japan 1,726; Poland 560; West Germany 152.
Mercury 76-pound flasks	3,829	11,400	13,025	Japan 2,176; Rumania 986; West Germany 986; India 841; Poland 754.
Nickel and alloys:				
Unwrought	4,757	10,482	9,895	Italy 2,466; West Germany 2,422; Sweden 2,392; France 1,893.
Semimanufactures	---	741	799	Sweden 135; Spain 123; Republic of South Africa 123; West Germany 109.
Tin and alloys, unwrought long tons	219	252	180	U.S.S.R. 140; United States 75; Uruguay 19.
Zinc and alloys, unwrought	728	3,375	8,270	United States 848; Netherlands 640; Denmark 341.
Nonmetals:				
Asbestos, crude or simply processed	120	227	152	France 36.
Fertilizer materials, manufactured	3,409	2,297	2,030	NA.
Graphite natural	98	61	67	NA.
Mica, including splittings and waste	240	246	2,493	NA.
Quartz, mica, and feldspar	1,405	236	2,533	West Germany 55; Spain 37; Italy 30; France 26.
Salt	---	915	---	Poland 913.
Stone, sand and gravel	---	59,512	---	Netherlands 59,337.
Talc, natural steatite	7,038	7,369	323	Republic of South Africa 3,494; Ireland 2,540.

Table 4.—United Kingdom: Reexports of metals and minerals—Continued
(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal destinations, 1964
Mineral fuels:				
Coal, coke and briquets	93	9	29	NA.
Petroleum:				
Crude—thousand barrels	---	422	---	Ireland 422.
Refinery products:				
Gasoline—do	18	87	55	Ireland 86.
Kerosine—do	53	107	30	Spain 50; Ireland 47; Netherlands 5.
Distillate fuels—do	761	275	31	Netherlands 269; West Germany 4.
Residual fuel oil—do	1,179	---	8	
Lubricating oils, greases	---	---	11	
Lubricants (high petroleum contents)	---	---	11	
Mineral jelly, wax—thousand tons	10	---	---	

NA Not available.

Table 5.—United Kingdom: Imports of metals and minerals
(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal sources, 1964
Metals:				
Aluminum:				
Bauxite—thousand tons	337	381	474	Ghana 213; Greece 63; France 58.
Metal and alloys:				
Scrap	r 9,368	12,255	23,772	United States 6,512; U.S.S.R. 2,810.
Unwrought	270,631	331,618	324,074	Canada 177,017; Norway 77,698; United States 36,944.
Semimanufactures	25,649	26,733	24,312	Belgium-Luxembourg 9,086; Ireland 3,883; Austria 2,541.
Antimony ore and concentrates	r 11,995	(1)	(1)	NA.
Arsenic trioxide	8,951	9,773	11,089	NA.
Bismuth:				
Metal	428	619	394	NA.
Alloys	282	385	297	NA.
Cadmium	r 1,424	1,596	1,454	Canada 534; United States 431; U.S.S.R. 116.
Chromite	r 162,595	225,558	205,004	Philippines 106,557; Republic of South Africa 89,848.
Cobalt:				
Oxides	NA	1,006	873	NA.
Metal	387	1,553	1,833	NA.
Columbium-tantalum ores	821	1,555	1,780	NA.
Copper and alloys:				
Ores and concentrates	117	1,373	811	Peru 1,311.
Metal and alloys:				
Scrap	r 2,204	3,630	5,758	Ireland 706; United States 344; Netherlands 323; France 308.
Unwrought:				
Blister	r 101,113	100,656	74,210	Federation of Rhodesia and Nyasaland 50,303; Chile 42,014.
Electrolytic	r 358,692	383,067	445,994	Zambia 188,116; Canada 99,464; United States 44,775.
Fire refined	r 41,110	42,068	42,289	Chile 31,805; Republic of South Africa 7,823.
Alloys, including master alloys	618	313	127	NA.
Semimanufactures	r 4,330	9,956	7,350	Canada 3,622; Federation of Rhodesia and Nyasaland 1,832; West Germany 1,002.
Gold:				
Ores, concentrates, jewelers sweeping, etc. estimated gold content—thousand troy ounces	r 1	65	NA	NA.
Bullion:				
Unrefined—do	1,676	1,550	1,527	NA.
Refined—do	32,623	39,299	37,885	NA.
Other—do	3	5	9	NA.
Gold coin—do	419	359	605	NA.

See footnotes at end of table.

Table 5.—United Kingdom: Imports of metals and minerals—Continued
(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal sources, 1964
Metals:—Continued				
Iron and steel:				
Iron ore and concentrates:				
Iron ore excluding pyrites thousand tons	14,551	18,309	18,609	Sweden 5,507; Canada 3,324; Venezuela 1,714; Liberia 1,623; Mauritania 1,410.
Roasted pyrites do	---	609	567	Sweden 173; Spain 168; Italy 140.
Scrap do	5	14	74	Canada 9; United States 1.
Pig iron, including shot and sponge iron do	201	353	333	Canada 79; Finland 79; Norway 59; East Germany 56.
Ferroalloys:				
Ferromanganese do	55	63	82	Republic of South Africa 39; Norway 10.
Ferrochromium do	35	48	62	Sweden 10; Norway 8; Republic of South Africa 6.
Ferrosilicochromium do	4	5	124	Federation of Rhodesia and Nyasaland 2; Norway 2.
Ferrosilicon do	89	110		Norway 57; Canada 29; U.S.S.R. 11.
Silicomanganese do	28	36	33	Norway 31; U.S.S.R. 2.
Other do	3	5	7	Norway 2; U.S.S.R. 1.
Steel ingots and other primary forms do	r 262	465	30	West Germany 153; Canada 88; United States 67.
Coils for rerolling do	246	176	---	United States 100; U.S.S.R. 48.
Semimanufactures:				
Wire rod do	80	86	34	Belgium-Luxembourg 35; Sweden 20; Norway 14.
Other bars and rods do	174	187	104	Belgium-Luxembourg 72; France 36; Sweden 35.
Angles, shapes, and sections do	28	39	9	Belgium-Luxembourg 13; West Germany 8; Norway 7.
Plates and sheets:				
Heavy and medium plate do	70	60	31	Sweden 21; Austria 10; Australia 8.
Thin plates and sheets:				
Uncoated do	295	426	236	Netherlands 194; Austria 65; West Germany 47.
Coated:				
Tinplate and tinned sheets thousand tons	2	19	---	United States 6; Canada 5; Belgium-Luxembourg 4.
Other do	17	43	NA	Canada 20; Belgium-Luxembourg 8; United States 5.
Hoop and strip do	13	42	37	Belgium-Luxembourg 23; United States 6; West Germany 3; Sweden 3.
Tubes, pipes, and fittings do	16	26	68	Sweden 12; United States 4; West Germany 4.
Wire, single strand do	6	5	5	Sweden 2; Belgium-Luxembourg 1.
Rough castings and forgings do	r 2	1	2	Mainly from Norway.
Lead:				
Ores and concentrates	r 34,893	r 31,508	22,027	Australia 12,910; Canada 12,466; Norway 5,208.
Metal and alloys:				
Scrap	r 1,681	4,235	2,713	Canada 980; Australia 575; New Zealand 498.
Bullion	58,936	61,558	219,039	All from Australia.
Refined lead	124,378	133,725		Australia 76,215; Canada 39,942; Zambia 3,913.
Magnesium and alloys:				
Scrap	502	683	350	Belgium-Luxembourg 229; West Germany 151; Netherlands 90.
Unwrought and semimanufactures	4,133	3,209	4,584	NA.
Manganese ore and concentrates thousand tons	r 314	534	503	U.S.S.R. 155; Republic of South Africa 126; Brazil 92.
Mercury 76-pound flasks	r 24,570	33,620	30,487	Italy 21,872; Spain 9,341.
Molybdenum ore and concentrates	r 5,873	6,541	8,177	NA.
Nickel:				
Ores and concentrates	5	---	---	
Matte and speiss	62,620	57,363	65,076	Canada 55,820.

See footnotes at end of table.

Table 5.—United Kingdom: Imports of metals and minerals—Continued
(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal sources, 1964
Metals:—Continued				
Nickel:—Continued				
Metal and alloys:				
Scrap	2,533	3,798	3,263	United States 1,363; Netherlands 1,062; France 523.
Unwrought	r 13,337	29,794	26,861	Canada 22,605; Norway 5,484.
Semimanufactures	r 3,145	5,105	2,847	United States 3,120; Canada 1,412.
Platinum group metals, all forms thousand troy ounces	86	108	148	U.S.S.R. 28; Italy 21; United States 18; Switzerland 10.
Selenium	130	150	178	NA.
Silicon	8,990	10,584	12,000	NA.
Silver:				
Ores and concentrates	135	---	240	NA.
Unwrought and semimanufactures—thousand troy ounces	21,517	62,487	46,825	United States 49,199; Australia 5,081; Mexico 2,152.
Tin:				
Ores and concentrates long tons	r 45,610	44,821	45,370	Bolivia 38,919; Indonesia 1,626; Republic of South Africa 954.
Metal and alloys:				
Scrap—do	698	1,138	1,131	France 220; Netherlands 178; United States 159; Australia 104.
Unwrought—do	r 7,926	8,936	9,265	Nigeria 5,529; Malaysia 1,893.
Semimanufactures—do	r 46	33	NA	NA.
Titanium ores and concentrates:				
Ilmenite	230,490	181,841	270,695	NA.
Other	18,563	35,495	17,508	NA.
Tungsten ore and concentrates	r 5,426	6,381	8,063	U.S.S.R. 1,021; Republic of Korea 1,020; Bolivia 921; Australia 548; China (mainland) 504.
Zinc:				
Ores and concentrates	r 215,101	308,958	233,779	Australia 213,483; Iran 28,455; South Africa 25,640.
Scrap	2,980	3,380	1,966	Netherlands 1,023; West Germany 571; Sweden 488.
Metal and alloys:				
Unwrought:				
High purity	r 79,948	89,029	86,291	Canada 43,349; Australia 12,504; Peru 8,976.
Electrolytic	r 61,329	77,652	87,525	U.S.S.R. 27,180; Canada 25,399; Australia 11,581.
Other	r 21,177	26,888	23,134	Canada 22,177; United States 3,329.
Semimanufactures	r 864	596	NA	NA.
Zirconium ore and concentrates	32,897	50,160	42,920	NA.
Other:				
Nonferrous ores and concentrates, not elsewhere specified	979	1 29,433	1 15,370	NA.
Metalliferous nonferrous waste, not elsewhere specified	36,579	33,677	64,604	NA.
Nonferrous base metals, n.e.s.:				
Tungsten, molybdenum, tantalum	r 94	150	187	Austria 97; United States 13; Canada 11.
Other	6,866	9,507	8,994	United States 2,978; Federation of Rhodesia and Nyasaland 1,447; Japan 1,203.
Nonmetals:				
Asbestos:				
Crude	160,082	186,555	178,958	Canada 91,601; Malawi 45,852; Republic of South Africa 32,608.
Asbestos cement products	24,357	29,783	34,456	Belgium - Luxembourg 18,977; France 5,387; South Africa 3,089.
Barite and witherite	r 28,448	47,328	68,205	Morocco 28,650; Spain 8,765.
Boron:				
Crude natural borates	r 26,300	30,374	42,787	Netherlands 14,806; Turkey 8,174; United States 7,393.
Borax	r 21,732	27,717	22,201	NA.
Cement hydraulic—thousand tons	247	420	1,126	Ireland 253; Denmark 51.
Chalk	3,215	1,694	1,099	France 1,509.
Clays and clay products:				
Crude:				
Andalusite, kyanite, sillimanite, mullite, dinas, and chamotte	19,848	27,798	26,587	NA.

COMMODITY REVIEW

METALS

Home consumption of crude steel estimated at 23.47 million tons in 1965 showed little change from that of 1964, while the consumption of nonferrous metals showed a general increase.

Aluminum.—In January 1965 the R.T.Z. Metals Limited, a wholly owned subsidiary of the Rio Tinto Zinc Corp., put into operation an aluminum extrusion plant at Widnes, Lancashire, that has an annual capacity of 5,000 tons of extrusions. The announced purpose of the plant is to process virgin aluminum from the Bell Bay, Tasmania, Australia, primary reduction works which is jointly owned by the Rio Tinto Zinc Corp. and the Kaiser Aluminum Co. It was planned to add a small zinc extrusion section in the aluminum plant for the production of special zinc products.

Iron and Steel.—For the second successive year production of crude steel exceeded that of any previous year. Capacity at year-end was estimated at 31.36 million tons, an increase of nearly 6 percent over that of 1964. Average utilization of capacity was about 88 percent compared with 89 percent in 1964. Consumption of finished steel increased nearly 5 percent over the 1964 level on a 52-week basis.

In response to measures designed to ease the balance of payments deficit, exports of iron and steel increased from 3.89 million tons in 1964 to 4.13 million tons in 1965, while imports decreased from 2.16 million tons in 1964 to 1.22 million tons in 1965. Stocks increased by only 90,000 tons.

Total requirements for crude steel in 1970 under the national plan were estimated at 32.26 million tons, of which 31.24 million tons would be supplied from domestic production and 0.76 million tons from imports. Export requirements were estimated at 4.32 million tons.

Nationalization.—In addition to the Government-owned Richard Thomas &

Baldwins, Ltd., the following major British steel companies were declared subject to nationalization in the White Paper on Iron and Steel:

Colvilles, Ltd.
Consett Iron Co., Ltd.
Dorman Long (Steel), Ltd.
English Steel Corporation, Ltd.
Lancashire Steel Manufacturing Co., Ltd.
South Durham Steel and Iron Co., Ltd.
The Steel Company of Wales, Ltd.
Stewarts and Lloyds, Ltd.
John Summers & Sons, Ltd.
The United Steel Companies, Ltd.
G.K.N. Steel Co., Ltd.
Tube Investments, Ltd.
The Park Gate Iron and Steel Co., Ltd.
Round Oak Steel Works, Ltd.

Development.—An important result of research by the British Iron and Steel Research Association was the development of the Spray steelmaking process on a pilot plant scale at its Sheffield laboratories. By this process, hot blast furnace metal was directly refined in a receiving ladle to provide "a product suitable as the starting point for a wide range of steels." Plans include a commercial scale plant for one of the steel companies scheduled for nationalization.

[3] Weighted average, based on quantities of each grade received.
[4] Includes burnt spent and black oxides, flue dust, scale, slag, and other materials.
[5] Includes direct castings not shown in table.
[6] Includes cinder, purple ore, scale, and slag.
[7] Included with "Other."
[8] Includes some material for conversion into products also listed in this table.

New development projects costing $280,000 or more each, completed or in progress during 1965, involved a capital expenditure of nearly $100 million during the year. Although several major steelmaking expansion or replacement projects were completed, the general stress was on improvement of product quality and operating efficiency. Major projects completed during 1965 and those in progress or authorized during 1965 are as follows:

Company	Type of project
COMPLETED DURING 1965	
Alloy Steel Rods Ltd.	A new wire-rod mill.
Appleby-Frodingham Steel., branch of The United Steel Companies, Ltd.	Conversion of the fourth open hearth steel furnace to the "Ajax" oxygen injection process (an Appleby-Frodingham research development); installation of two further strands on the rod and bar mill; and two additional sinter strands.
Dorman Long (Steel) Ltd., Lackenby Works	Completion of the installation of a four-high universal plate mill and continued installation of a new rod mill scheduled for completion early in 1966.
Cleveland Works	Installation of an 80-ton electric arc furnace at the North Steel Plant and scrap charging equipment at the South Steel Plant.
G.K.N. Steel Company Ltd., Brymbo Steel Works	Improvements to existing blast furnace.

Company	Type of project
COMPLETED DURING 1965—Continued	
Lancashire Steel Manufacturing Co. Ltd., Warrington Works	Installation of a 22-inch medium section mill.
Park Gate Iron and Steel Co. Ltd	Installation of a heat treatment plant and ancillary equipment.
Round Oak Steel Works Ltd	Installation of a vacuum degassing plant and a fume cleaning plant.
Steel Company of Wales Ltd., Margam, Abbey Works	Increase of blowing capacity for three blast furnaces; installation of fume cleaning equipment for four open hearth furnaces.
Steel Peech & Tozer, branch of The United Steel Companies Ltd	Installation of sixth electric arc furnace, thereby completing the replacement of open hearth steelmaking facilities at Templeborough and Rotherham by six 100-ton electric arc furnaces.
Stewarts & Lloyds Ltd.:	
Billston Works	A vacuum degassing plant and two additional soaking pits.
Corby Works	Two 100-ton basic oxygen LDAC [1] steelmaking vessels, and improvements to the ore preparation, sintering, and strip finishing plants.
Wolsingham Steel Co. Ltd	Installation of a 30-ton electric arc furnace.
IN PROGRESS OR AUTHORIZED IN 1965	
Firth Brown Ltd	Replacement of open hearth furnaces by electric arc furnaces.
Consett Iron Co. Ltd	Conversion of a 100-ton Kaldo steelmaking vessel to a 150-ton LD vessel at the Consett Works.
Richard Thomas & Baldwins Ltd., Panteg Works	Replacement of the open hearth steelmaking plant by a 60-ton electric arc furnace.

[1] A modification of the Linz-Donawitz (LD) process.

Lead and Zinc.—Early in 1966 the Rio Tinto Zinc Corp. announced plans for the installation of a new Imperial Smelting Furnace at Avonmouth. The facility, with a capacity of 90,000 tons of zinc annually, is to replace the existing experimental prototype furnace in which the Imperial smelting process was largely developed. The new works, scheduled for completion in 1972 would give the Avonmouth works together with the Swansea works (comprising the United Kingdom's first standard size Imperial Smelting Furnace) a combined capacity of 180,000 tons of slab zinc and 44,000 tons of lead annually. The new facility is expected to also increase annual cadmium output to 500 tons, raise the annual national sulfuric acid capacity to 440,000 tons, and produce 75,000 tons of phosphoric acid per year. Capital cost was estimated at about $35.6 million.

Tin.—The South Crofty mine at Redruth, the Geevor mine at Pendeen, and the dredging operation of Hydraulic Tin Inc. near Truro, all in Cornwall, again accounted for nearly all of the United Kingdom's output of tin concentrates. At yearend, however, there were some 15 additional domestic or international companies either actively engaged in prospecting and exploration, or preparing to prospect for new tin deposits, and unknown extensions to known deposits, and/or to reexamine known mineralized areas remaining from former mining operations in Cornwall. A thorough investigation of all old dumps or slime and sand accumulations from former mining operations and of possible placer deposits is also being carried out.

A very promising area was being made available for mining and exploration under the sea through the unwatering of the Levant mine of Geevor Tin Mines Ltd., made possible by that company's successful plugging of a breach in the sea floor which led directly into the old mine workings.

NONMETALS

Fluorspar.—Fluorspar output in 1965 was 11 percent above that of 1964 and nearly double that of 1963, placing the United Kingdom among the world's leading producers of fluorspar. This was made possible by the completion by Glebe Mines Ltd. at Eyam, Derbyshire, of the new Cavendish gravity-flotation plant for the treatment of ores from the Ladywash mine and the newly developed Sallet Hole mine, as well as for treatment of customs ores from old dumps and other sources in the district. Glebe Mines Ltd. is a subsidiary of Laporte Industries Ltd., a diversified chemical manufacturing company that has acquired

extensive mineral reserves in the Southern Pennine orefield.

The annual rated capacity of the Cavendish plant, built on the site of the Cupola Mining and Milling Co., is 70,000 tons of acid-grade fluorspar, 30,000 tons of metallurgical-grade fluorspar, 18,000 tons of barite, and 3,850 tons of lead filter cake.

MINERAL FUELS

A further decrease in coal output (3.2 percent in 1965 compared with that of 1964) against an increase in total energy consumption (4 percent in 1965 compared with that of 1964) reflected, among other causes, the continued trend toward the supply of energy growth requirements from petroleum and natural gas, as well as the replacement of coal as a source of energy for certain industries in which the economic advantages of petroleum outweigh the disadvantages, including its effect on the balance of payments. Out of a total increase in energy consumption amounting to the equivalent of 11.7 million tons of average bituminous coal (SCE),[4] all primary forms of energy contributed to the gain except coal which lost 2 million tons. The share of coal in total energy consumption dropped from 65.4 percent in 1964 to 62.2 percent in 1965 while petroleum's share rose from 32.7 percent in 1964 to 34.6 percent in 1965.

[4] One ton of Standard Coal Equivalent (SCE) is the equivalent of 1 ton of average British coal as consumed.

r Revised.

[1] Conversion factors:
1 ton average salable coal=1 ton coal equivalent.
1 ton oil=1.7 tons coal.
300 therms colliery methane=1 long ton coal or 295 therms=1 metric ton coal.
40,000 cubic feet coke oven gas=1 long ton coal or 1,115 cubic meters=1 metric ton coal.
1 ton coke breeze=0.9 ton coal.
Coal equivalent of hard coke and gas coke is the coal used at coke ovens less coke, coke breeze, and coke oven gas supplied to consumers, to stocks or for export. Other solid fuels show coal used for production of briquets, etc.

[2] Adjusted for imports or exports.

Source: Ministry of Power Statistical Digest 1965.

In October 1965 the Government issued a White Paper on Fuel Policy outlining the main problems involved in protecting and maintaining a domestic energy supply in competition with imported fuels. The estimates of supply and demand were based on the National Plan which foresaw a total increase of 13.5 percent in energy requirements by 1970 to 329 million metric tons of SCE representing an average annual increase of about 2.1 percent annually. The White Paper also foresaw a decrease in coal production to a level of 170 to 180 million tons annually by 1970; the use of petroleum and/or natural gas for additional supplies of primary fuels to the manufactured gas industry with an estimated annual growth rate of 7.5 percent, doubling the capacity by 1970; an increase in atomic energy capacity to 8,000 megawatts by 1975 including a gas-cooled reactor of 1,200-megawatt capacity for the Dungeness "B" plant in 1970, and one new reactor each year during the following years to 1975; and an increase in petroleum refinery output to 98.5 million metric tons by 1970, compared with a demand of 94.5 million tons.

Specific measures designed to improve the position of coal included the provision of funds to deal with human problems arising from concentration of production and the closing of uneconomic coal mines, provision for the retraining of displaced miners, provision of housing, and encouragement of new industries in the affected areas. Probably the most important measure from a cost of production standpoint was the writing off of $1,200 million from a total capital debt of $2,688 million carried on the books of the National Coal Board, thereby reducing interest charges by $80 million annually.

Subsquent to the publication of the White Paper extensive natural gas reserves were discovered in the British sector of the North Sea, making necessary the development of a new fuel policy and a revision of certain guidelines in the national plan for energy. Such a revision is expected to be published during 1967.

Coal.—An important factor contributing to the difficulties of the coal mining industry was the shortage of labor, both as to numbers available for employment as well as voluntary absenteeism of those employed, which averaged about 17 percent for 1965. Substantial gains were made in productivity, obtained through closing of additional uneconomic mines, further concentration of operations, and continued mechanization of mining.

Probably the most important technological advance in coal mining in the United Kingdom was the development of the remotely operated longwall face (ROLF) of which 20 were in the planning stage by the end of the fiscal year 1965–66 (March 1966.) A prototype mine—the Bevercotes—was being prepared to start operations early in 1966. The equipment involves both remotely controlled and automatic mining and loading equipment which can operate on a longwall face. The Bevercotes is expected to produce 6,000 tons daily by 1968–69.

r Revised. NA Not available.
[1] For 52 weeks ending March 26, 1965.
[2] For fiscal year ending in March of following year.
[3] Liquefied petroleum gases reported under the heading Gas are also included among petroleum product deliveries under the heading Petroleum. Other gas production listed under the heading Gas is in part obtained from coal, coke and petroleum products listed under consumption and/or deliveries of these materials in appropriate sections of the table.
[4] One therm equals 100,000 British thermal units (Btu).

Natural Gas.—In September 1965 the British Petroleum Co.'s rig Sea Gem discovered natural gas in the British sector of the North Sea continental shelf. Subsequent discoveries were reported at nine other places indicating at least five commercial gasfields in the British sector. In addition the Home Oil Co. drilled a discovery well on the mainland at Lockton, near Scarborough, Yorkshire, which was eventually measured at 510 million cubic feet per day.

While estimates of production potential of the onshore and offshore deposits varied greatly at mid-year 1966, it was evident that the British gas industry was already considering a program for conversion of their system to supply natural gas within their long term planning.

Petroleum.—Although the Fuel Policy of October 1965 forsees an annual refinery output of 98.5 million metric tons, equivalent to a crude distillation capacity of about 104 million tons, by the end of 1970, projects in progress and/or scheduled for completion by the end of 1968 are expected to exceed that capacity. Refinery capacities of 1965 was as follows:

Company and refinery	Location	Crude oil distillation capacity at yearend (Thousand metric tons per year)	
		1964 [1]	1965
British Petroleum Co.:			
Kent	Isle of Grain	10,161	10,161

[2] Plant closed down at end of 1964.

Additional facilities in progress or definitely scheduled include expansion of facilities at the Fawley refinery (a 5-million-ton) increase underway) and at the Coryton refinery (a 700,000-ton increase underway), and the following new refineries: Gulf Oil Co. at Milford Haven (3 million tons); Continental Oil Co. at Immingham (3 million tons); Phillips-Imperial Petroleum, Ltd. at Billingham (11 million tons); Lindsay Oil Refinery, Ltd. at Killingholme, owned by Total Oil Products (GB), Ltd., and Petrofina (GB), Ltd. (7 million tons); and Isle of Man Petroleums Lt. (500,000 tons).

The Mineral Industry of Yugoslavia

By Roman V. Sondermayer [1]

Yugoslavia maintained its position as one of the leading producers of nonferrous metals in Europe during 1965. The more prominent minerals, with production expressed in approximate percentages of the 1965 world totals, were as follows: Mercury, 6.8 percent; antimony, barite, bauxite, lead, and magnesite, 4 to 5 percent; and chromite, copper, feldspar, pyrite, silver, and zinc, 1 to 2 percent. Economic difficulties of the country as well as shortages of electric power and fuel, low productivity, deficiencies in management, and shortage of foreign exchange slowed down mineral industry growth.

The 1965 mineral and metal output value for the country was about $640 million,[2] roughly 7 percent above that of 1964. The mineral industry contributed about 10 percent of the gross national product in 1965 and employed about one-fourth of the total labor force, or 280,000 people.

In July 1965, the country enacted an economic reform. Essentials of the reform could be summarized as a movement toward a market-oriented economy with more freedom given to enterprises and gradual withdrawal of the political factor in economic decision making but without changing fundamental principles of the Communist economy.

This reform gave more control over production and distribution to the various enterprises and began gradual withdrawal of State and party interference in economic decision making. Changes also were made in the distribution of net profit between the State and the enterprises, permitting the enterprises to retain 71 percent of net profits as compared with 51 percent before the reform. However, substantial reduction in State subsidies to producers was included in the measure, which should make the enterprises both cost and market conscious and which should lead to gradual elimination of less efficient operations. In addition, price controls were eliminated on some materials and were retained only for basic necessities.

The dinar (Din) was devaluated from $1.00 equals Din. 750 to $1.00 equals Din. 1,250. Beginning January 1, 1966, a new dinar will be introduced. One hundred old dinars will have the value of 1 new dinar. To lessen the costs of the monetary change, conversion to new currency will be made over a 4-year period. An appraisal of the ultimate influences of the reform on the country's mineral industry was not possible because of the short period of time that this reform has been in effect, but the short-term effects of the reform on the country's economy were adverse. Prices began to soar, unemployment continued to increase and as a solution to the unemployment problem, labor migration to the west was officially blessed by the Communist party and the Government. The salaries of all workers and employees rose but the standard of living declined because improvements in salaries did not cover price increases.

The most important mineral developments during 1965 were in the nonferrous and petroleum industries. Highlights included decisions to build a new lead-zinc smelter in Titov Veles in Macedonia, discovery of a significant uranium deposit near Zletovo in Macedonia, and completion of a new oil refinery in Urje near Rijeka.

The principal activities in the ferrous branch were limited on construction of the Skopje integrated works and modernization of iron and steel plants at Zenica, Smederevo, and Sisak.

---

[1] Foreign mineral specialist, Division of International Activities.

[2] Where necessary and possible, values have been converted from dinars (Din) to U.S. dollars at the rate of Din 1,200=$1.00.

PRODUCTION

Economic difficulties of the country stressed once more the need for improved utilization of existing facilities rather than development of new ones. Switching to opencast mining whenever possible was common. Mass methods in production of ore in both underground and opencast mining were used on a larger scale than in 1964.

Petroleum production and refining, although modest by world standards, was performed by modern and efficient methods. All three methods for production of crude oil (flowing, pumping, and gaslifting) were widely used. Equipment and plants in the petroleum industry were modern and operations were automated. In other branches of mineral industry, the stage of automation was not considered satisfactory.

Table 1.—Yugoslavia: Production of selected metals and minerals

TRADE

Minerals continued to occupy an important position in overall trade, in both exports and imports. During 1964 mineral exports valued at about $43.6 million accounted for 16.4 percent of total export value and mineral imports valued at $77.1 million constituted 17.4 percent of total import values.

Nonferrous metals contributed most significantly to Yugoslavia's mineral export, accounting for $24.8 million or roughly 50 percent of the value of all mineral exports in 1964, a 5-percent decrease from 1963 figures.

The imports of the iron and steel industry products totaled $38.7 million, about 50 percent of the total value of mineral imports.

2 Includes sponge iron, shot powder, grit and similar forms.

COMMODITY REVIEW

METALS

Aluminum.—Exploration for bauxite was intensive and concentrated in Hercegovina although new discoveries were announced in Kosovo and Metohija. Extensive exploratory work was performed in the general area of Posušje and Jablanica in Hercegovina. According to reports, new reserves totaled 800,000 tons of bauxite. Exploration was financed by the bauxite mining enterprise in Mostar, Hercegovina, and by the enterprise which had been established to construct an alumina and aluminum plant in Mostar.

The exploration of a bauxite deposit in Grabovica, Kosovo-Metohija, discovered in 1959, was completed. Confirmed reserves totaled 1.5 million tons. Preparations were underway for production. The U.S.S.R. was reported to be the prospective buyer of this bauxite.

The Yugoslav Investment Bank granted the necessary credit for the construction of the alumina and aluminum plant at Mostar, and a new enterprise was organized with the primary task of constructing the plant. The Yugoslavs reported planned capacity of the plant's first phase to be 200,000 tons of alumina and 20,000 tons of aluminum. However, at yearend, there was evidence that this project might be canceled early in 1966 in favor of a generally similar plant in Montenegro.

Antimony.—Discoveries of antimony mineralization were reported near the Yugoslav antimony center at Zajača in west Serbia. Reserves of the new deposits were not disclosed. Management of the antimony mine and smelter at Zajača was studying the possibility of a complete change of the technological process at the antimony smelter.

Copper.—Management of the Bor smelter accepted a program for the expansion of its facilities. Plans called for a total production of 95,000 tons of electrolytic copper in 1972. Production of ore at Majdanpek will be increased from the present 3.6 million tons per year to 11 million tons per year. A new factory for production of 240,000 tons of sulfuric acid was also included in the development plan.

Meanwhile in the Bor smelter, a new chimney with special filters was put into operation. Expected recovery of copper dust will be around 500 tons annually. The first time in its history the Bor enterprise started to leach copper from waters that were coming from mine and tailing dumps, and construction of a modern, full scale plant began after trial production showed good results.

Germanium.—The Copper Institute at Bor performed successful experiments in obtaining germanium from Bor copper concentrates. It is estimated that at the present rate of copper concentrate output, annual production of 4 tons of germanium would be possible. No report was made regarding the beginning of industrial production of germanium.

Iron and Steel.—The principal event in the iron and steel industry was the continu-

ing construction of the iron and steel plant at Skopje, Macedonia. The first steel was expected to be produced in July 1966. Production of the first phase of the plant will be 300,000 tons of steel annually. In 1963, plans were set to expand output to 600,000 tons of steel in a second stage, and by 1970 the facility is scheduled to be producing 940,000 tons of steel per year. Iron ore will be supplied from mines in Macedonia. Gas and coking coal are supposed to be delivered by the Kosovo combine near Obilić in Kosovo and Metohija.

Efforts to alleviate shortages of ferrous products on the domestic market dominated activities of the entire steel industry in 1965.

Lead and Zinc.—A new smelter will be built in Titov Veles, Macedonia. The Economic Bank of Macedonia granted the necessary funds totaling 28.8 billion dinars. The construction is expected to last 3 years. Annual capacity of the smelter will be 32,000 tons of zinc, 30,500 tons of refined lead, 17.5 tons of bismuth, and about 645,000 troy ounces of silver. In connection with the construction of the smelter at Titov Veles, Zletovo and Sasi mines were being modernized. Capacities of beneficiation plants will be increased to 80,000 tons of lead concentrates and 45,000 tons of zinc concentrates per year.

The largest lead and zinc producer in the country, the Trepča Mining and Metallurgical combine at Zvečan, Serbia, was planning modernization and expansion of its mines and other facilities. According to reports Trepča should double production of lead, zinc, and their byproducts in 1968. Smelter gases will be used for production of 65,000 tons of sulfuric acid.

The lead and zinc mine at Mojkovac, Montenegro, was developed in 1965. Reserves of 7.5 million tons of ore were reported. Ultimate production goals call for an annual output of 29,000 tons of zinc concentrate, 16,000 tons of lead and copper concentrate, and 118,000 tons of pyrite.

Selenium.—A facility for production of pure selenium will be added to the Bor copper electrolysis plant. Equipment was purchased abroad and was already in Yugoslavia at yearend. No information on the capacity of the plant was disclosed.

Uranium.—After 3 years of prospecting, Yugoslav geologists confirmed the presence of uranium mineralization in the Kratovo-Zletovska River area in Macedonia. The reserves of ore were not disclosed but reports indicated that deposits are the largest in the country. At yearend, exploration continued in the regions of Nežilovo and Pogled.

NONMETALS

Feldspar.—The enterprise for production of feldspar located in Toplica, Serbia, expanded its activities in 1965. A new feldspar beneficiation plant was put into operation at yearend. Capacity of the plant will be 20,000 tons per year of feldspar with 10,000 crystals per cubic millimeter. Approximately 290 million dinars has been invested in the new separator. All production for 1966 was sold to the exporting firms.

Fertilizers.—After several years of delay, construction of the nitrogenous fertilizer plant at Kutina in Croatia began in the summer of 1965. Annual production of the new plant will be 800,000 tons of fertilizers. Large reserves of natural gas and limestone in the area will provide adequate supply of raw material for the plant. Some of the plant equipment will be produced in the country and some will be imported from France, Belgium, and Italy. Out of the total of 950 employees, only 16 percent will be employed in production; 40 percent will be engaged in maintenance and the rest will work on research and in administration.

Sand.—The Zajača smelting enterprise opened its foundry sand quarries after purchasing machinery for sand production and building a new sand washery near the village of Gornja Koviljača in Serbia. Reserves of sand were estimated to be of an order of magnitude of 10 million tons. It is expected that production of quartz sand for production of glass will start in the near future.

MINERAL FUELS

During 1965, coal remained the principal source of energy in Yugoslavia; petroleum and natural gas were emerging as significant competitors, but their use was limited by lack of means for distribution and adequate industrial and home appliances. Because of large reserves of low-grade coals, upgrading and conversion of this material to higher forms of energy such as gas and power remained the primary task of the coal industry. Several facilities for drying, gasification, and production of thermal power were under construction or completed. A basic plan for a gas and oil pipeline system was approved and the expansion of oil refining capacity continued.

Coal.—On June 8, 1965, an explosion of methane gas occurred in the Orasi shaft in the brown coal mine at Kakanj, Bosnia. After rescue operations were completed 128 bodies were recovered. The majority of deaths reportedly resulted from gas developed after explosion. The disaster triggered a series of investigations including one by the Federal Parliament. The official report prepared by the Mining Inspectorate did not positively determine the immediate cause of the accident nor did it fix responsibility, but apparently the catastrophy resulted from several factors which in summary reflected inadequate mine safety practice by all concerned, including miners, technical staff, and all authorities of political and administrative levels. As a result, the Secretary of Industry of Bosna i Hercegovina resigned, the party committee of the Kakanj mine was fired, and 10 members of the mine technical staff were arrested and brought to trial. Of the accused, seven were cleared and three were convicted.

Completion of the gasification plant at Valenje scheduled for the end of 1965 was postponed and may have been canceled; no reasons were reported. The plant, when and if completed, will handle 96 million cubic feet of gas per day. The British company Humphreys and Glasgow Ltd., supplied gas purifiers and extended a long term credit totaling $15.4 million. Enterprises from Czechoslovakia supplied compressors for the project.

In the Kosovo Metohija lignite basin in Obilić, a new open pit mine was commissioned with an annual capacity of 2.2 million tons of lignite. The mine was equipped with power shovels and overburden stripping machines imported from East Germany. The new thermal powerplant at Obilić with the annual capacity of 65 megawatts started production late in the spring of 1965. At the same time, construction was under way on a gas plant at Obilić and on a gas pipeline from Obilić to Skopje. All these new facilities are part of the large Kosovo chemical combine production of which is based on 6.5 billion tons of lignite reserves.

The lignite mine in Kreka, Bosnia, started production from its first open pit. The beginning of operation was a turning point in mining in this area. In pursuit of more profitable operation, the mine management was shifting production from underground to open pit operations.

The Soko brown-coal mine near Sokobanja opened new shafts; coal reserves here were set at 70 million tons. The new mine was completely mechanized. A coal beneficiation plant of adequate size for annual coal production of 180,000 tons was constructed. Beneficiated coal was moved to the railroad terminal at Rgosta by an aerial tramway 19.5 kilometers long. In addition to facilities for coal production, the mine administration was building living quarters and other facilities for miners and staff at Sokobanja.

The Kolubara open pit mine, part of the large Kolubara mining enterprise, was closed in the summer of 1965. The mine produced 200,000 tons of lignite annually and employed 300 workers. Production was becoming less profitable as reserves were exhausted.

The overall situation in the coal industry did not change during 1965; despite larger output of coal, traditional difficulties in supply continued. Prices of coal were increased twice during the year and the financial situation of mines improved. Although the salaries of miners were higher than ever, the turnover of workers in coal mines remained high and the shortage of miners persisted.

Petroleum and Natural Gas.—The principal events in the petroleum industry were the continued exploration of the Pannonian basin and the Dinaric Alps; the development of known oilfields and gasfields; expansion of refining capacities; and approval of a basic plan for a countrywide pipeline system.

Main activities in oil and gas exploration were scattered all through the Pannonian basin. No new discoveries were reported during 1965. The exploration of the Dinaric Alps, along the Adriatic coast and inland was restricted by shortage of capital. At yearend, geological institutes and enterprises concerned were evaluating exploration results from the standpoint of regional geology related to possible accumulations of oil and gas.

Development of known fields near Ivanić Grad, Žutica, Ježevo, Pepelana, and Jagnedovac in Croatia and the Serbian fields near Kikinda in Banat and Mokrin in Bačka were given priority status. In the Kikinda oilfield, a faulty wellhead valve assembly permitted unrestricted flow of oil and gas for several days before it was controlled.

Gojlo, the oldest oilfield in Croatia and one of the oldest in the country, was closed during the beginning of 1965. Because of low yield, production had become unprofitable.

The new refinery at Rijeka, the 1.3-million-ton-per year Urinj plant on the bay of Bakar, started production during the fall of 1965. The plant is fully automated and requires only 230 workers to operate it. Equipment was obtained from the Italian company, Sociata Nacionale Metandoti, a subsidiary of Ente Nazionale Idrocarburi (ENI). The same concern extended a credit which the Yugoslavs will repay with the refinery's products over the next 5 years. Total investments in the plant were approximately 17 billion dinars. The expansion of the refinery at Bosanski Brod continued. According to reports, the capacity of the refinery will be 2.5 million tons per year when modernization is completed. While the modernization was underway at the main plant, a new facility for regeneration of motor oils was under construction at Modrica near the refinery. The new development will have a capacity of 10,000 tons of motor oil annually. Construction of the refinery at Pancevo entered its second year. This refinery, which was being built according to United States' designs, will be supplied with equipment produced by British firms. During 1965 most of the refinery buildings as well as roads were completed.

A general plan was approved for a network of pipelines that would cover the country. According to reports, construction of the trunk line from Rijeka refinery on the Adriatic coast to the refinery at Sisak in the Sava river valley in Croatia was ready to start in 1966. Apparently, the new Yugoslav pipeline system can be extended toward the northern oilfields, and from there it can be connected with the existing Hungarian pipelines and the Soviet Druzhba pipeline. Sometime in the future, when the Yugoslav pipelines are connected with the Hungarian pipelines, Soviet oil can be brought to the Adriatic.

Not far from the existing carbon black plant at Kutina, a new facility was under construction during 1965. The annual capacity of the new plant will be 6,000 tons, or more than the country's 1965 production. The engineering design for the new plant is of United States' origin, but most of the equipment will be produced in France. The plant is being built for Metan Kutina, which is part of the INA (Industrija Nafte i plina) combinat at Zagreb.

Regional Mineral Industry Review of Africa

By Thomas C. Denton [1] and Henry E. Stipp [2]

In 1965 Africa maintained its position as a region of the world essential to advanced non-Communist nations for supply of vital metals and minerals. The position stemmed from the fact that Africa produced in large quantity a number of key minerals of which either or both resources and production capacity elsewhere did not approach the needs of the free world. The Republic of South Africa alone contributed more than three quarters of the gold mined in the entire non-Communist world besides an estimated 60 percent of metals of the platinum group and the entire new supply of amosite asbestos, and Africa as a whole was nearly the non-Communist world's only source of gem and industrial diamond. Africa also accounted for 83 percent of non-Communist world cobalt production.

Besides these massive contributions, Africa in 1965 provided 50 percent or more of the new supply from non-Communist countries of the following mineral commodities: Lithium minerals, corundum, manganese ore, and chromite, and over 20 percent of new supply from non-Communist countries of columbium-tantalum concentrates, antimony, beryl, vanadium, phosphate rock, and copper. Africa also accounted for 18 percent of the non-Communist world's output of uranium, 14 percent of its tin, 11 percent of its lead, 9 percent of its zinc, and 8.9 percent of its crude oil output. With respect to chromite, at yearend Africa's reserves of the mineral were far larger than those of all other non-Communist regions combined. This probably also held true for manganese ore. In the case of crude oil, the fact that Africa's share of non-Communist world output was 1.6 percentage points greater than in 1964 was significant, particularly inasmuch as the output rate was continuing to increase at yearend.

The great bulk of these and other commodities continued to be produced for export to countries outside Africa, but continuing industrialization in South Africa had resulted in substantial consumption increases there, particularly of such items as asbestos, iron ore and steel melt additive metals, copper, lead and zinc, and phosphates. South Africa also consumed some 45 million tons of coal, produced in the country itself. It was also significant that capacity for petroleum refining and cement manufacture in Africa as a whole increased substantially.

At yearend it was evident that Africa soon would also be a large source of rutile (titanium) and potash, the former from a deposit in Sierra Leone and the latter from either or both Ethiopia and Republic of the Congo (Brazzaville). With this new output virtually the only mineral commodities vital to industry that Africa does not produce in significant quantity will be primary aluminum, mercury, and molybdenum.

Toward yearend a political development occurred that could adversely affect the availability of mineral supplies from Africa in the immediate future. On November 11 the self-governing British colony of Southern Rhodesia unilaterally declared Rhodesia independent. The British Government promptly declared the action illegal and treasonable and imposed selective economic sanctions against Rhodesia. By yearend Zambia, Rhodesia's neighbor to the north, had become involved in the

Table 1.—Major multilateral and unilateral assistance given African countries in mineral and related areas, in 1965

Country	Contributor	Contribution
Algeria	United Nations	Natural resources and economic development survey. Involves steel production, metal fabrication, and natural gas markets.
Burundi	----do	Geological and mineral studies. Minerals included: Bauxite, diamond, and iron ore.
Cameroon	----do	Partially financed study of granites by Association of African Geological Services.
Do	France: Bureau de Recherches et Géologiques Minières (BRGM).	Was granted right to explore for copper, lead, silver, cadmium, germanium, and gallium. A 4-year project, renewable for two 4-year periods.
Central African Republic	BRGM	Uranium search.
Chad	----do	Hydrologic study and geologic mapping in Fort Lamy area. Also, clays, talc, and diatomite investigated elsewhere.
Congo, Republic of (Brazzaville)	----do	Partner in lead-zinc mining at M'Passa.
Do	International Bank for Reconstruction and Development (IBRD).	Loan agreement providing 60 percent of financing of a potash project.
Do	West Germany	Credit for a cement plant.
Do	U.S.S.R	Credit, including funds for mineral exploration, potash development and hydroelectric power development.
Dahomey	BRGM	Mineral exploration.
Ethiopia	U.S.S.R	Financial and technical assistance in building an oil refinery.
Do	Yugoslavia	Financed and built a cement plant.
Gabon	United Nations	Investigated iron ore developments.
Do	IBRD	Provided a loan toward railroad and harbor construction.
Ghana	----do	Provided credit toward construction of an aluminum smelter.
Do	Rumania	Oil exploration.
Do	U.S.S.R	Furnished technical personnel to Ghana Geological Survey.
Ivory Coast	United Nations	Three-year mineral survey program.
Do	BRGM	Geologic study; aeromagnetic survey; exploratory drilling and mining; investigation of cinnabar deposits; study of a diamond area.
Do	France: Fonds d'Aide et de Cooperation (FAC)	Grant for general geologic and mineral studies.
Kenya	United Nations	Mineral resources survey.

Liberia	United States: Agency for International Development (AID).	Mineral resources survey and regional geological survey.
Do	IBRD	Loan to a company to increase iron ore production.
Malagasy Republic	United Nations	Contributed toward mineral, ground-water, and energy resources studies.
Do	BRGM	Geologic investigations of chromite deposits; prospecting and exploration for various minerals.
Do	FAC	Exploration for diamond, phosphate, lead, platinum, and other minerals.
Do	European Economic Community: European Development Fund (EDF).	Financed chromite development.
Mali	BRGM	Petroleum exploration; diamond investigations; geologic mapping.
Do	U.S.S.R	Provided credit toward cement plant construction.
Mauritania	BRGM	Geologic, hydraulic, and mineral surveys; regional geologic mapping and airborne geologic surveys.
Morocco	IBRD	Provided loan toward expansion of the phosphate industry.
Niger	BRGM	BRGM was granted a 3-year permit to prospect. Investigated gold occurrences.
Do	France: Commissariat d'Energie Atomique (CEA)	Uranium prospecting.
Senegal	United Nations	Geologic, geochemical, and geophysical surveys. Investigations for chromite, gold, and diamond.
Do	BRGM	Geologic mapping and phosphate rock study.
Somali Republic	United Nations	Minerals survey and iron ore investigation.
Sudan	IBRD	Granted a loan to improve and expand railroads and river and harbor facilities.
Tanzania	United Nations	Three-year mineral survey.
Togo	----do	Minerals survey.
Tunisia	----do	Exploratory drilling and geophysical surveys.
Uganda	----do	Ground-water surveys.
Do	Canada	Investigation of anomalies indicated in an earlier airborne geophysical survey.
Do	United Kingdom	Mineral surveys.
United Arab Republic (Egypt)	United Nations	Mineral surveys.
Upper Volta	----do	Provided part of funds for ground-water and mineral surveys.

dispute and it appeared that both Rhodesia's production of chromite and asbestos and Zambia's copper production might be drastically curtailed.

During the year agencies of the United Nations, particularly its Special Fund, were engaged in or became committed to projects in several African countries that directly or indirectly related to the mineral industry. Also involved in such projects, via loans, grants, studies, etc., were governmental agencies of various countries operating unilaterally, agencies of the European Economic Community (EEC), and the International Bank for Reconstruction and Development (IBRD) and its affiliates. In addition, the French Government-owned, incorporated company, Bureau de Récherches Geologique et Miniére, explored on its own behalf and undertook mineral exploration projects for various Francophone countries of Africa.

UNITED STATES CAPITAL INVOLVEMENT IN AFRICAN MINERAL INDUSTRY

United States private capital investment in African mineral and petroleum industry continued to expand. At yearend U.S. companies were interested in varying degree in most mining, metallurgical, and petroleum activities in Africa. The involvement in countries with existing diversified important mineral industry perhaps was smallest in the Democratic Republic of the Congo (Léopoldville), and largest in the Republic of South Africa, including South-West Africa. In Libya U.S. companies dominated the petroleum situation, both with respect to crude production and concession acreage held. In South Africa and Southern Rhodesia U.S. capital controlled the major part of chromite reserves and production. Iron mining in Liberia was largely in the hands of companies with large U.S. equity. In Gabon a U.S. corporation held nearly a half interest in a company that in 1965 was the world's largest producer of manganese ore. U.S. capital was largely involved in companies accounting for over 40 percent of Zambia's large copper production.

PRODUCTION

Strong markets existed in 1965 for most of the minerals and metals that Africa produces in important quantity. Largely as a result of these markets, Africa's output generally improved compared with that of 1964. The major exception was uranium (U_3O_8) production in South Africa which fell by 29 percent, reflecting a decline in contractural commitments to the atomic energy agencies of the Governments of the United States and the United Kingdom. In addition declines occurred in production of beryl, lithium minerals, tin and industrial diamond, ranging from 6 percent for tin and diamond to 22 percent for beryl. The decrease for beryl reflected substantial declines in the output of Mozambique (down 23 percent from that of 1964), and of the Republic of Uganda (down 51 percent). On the other hand, the Republic of Rwanda exported 756 tons in 1965, which compares with 328 tons produced in 1964. The export probably was the alltime record for Rwanda.

METALS

Chromite. — In 1965 the Republic of South Africa was the largest producer of chromite in the non-Communist world, a position the country generally has held for some years. Southern Rhodesia ranked with Turkey for second place. Together, South Africa and Rhodesia produced 1.5 million tons in 1965. South Africa consumed about 20 percent of its output. The Malagasy Republic and Republic of Sudan were the other African producers in 1965. Malagasy's reserves were reported as 6 million tons of proved and probable ore.

Cobalt.—The Democratic Republic of Congo (Léopoldville) and Zambia contributed in the form of metal, respectively, 71 percent and 13 percent of the 11,764 tons of cobalt produced in Africa in 1965. In addition Morocco contributed 1,832 tons contained in complex sulfide concentrates averaging 11 percent cobalt, most of which was exported to France for processing.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] Details may differ from figures in commodity chapters because of later revisions.

[2] Excludes Albania, Bulgaria, China (mainland), Cuba, Czechoslovakia, East Germany, Hungary, North Korea, Mongolia, Poland, Rumania, U.S.S.R., North Viet-Nam, and Yugoslavia.

[3] Includes ferroalloys.

[4] Content of primary platinum raw materials.

Columbium and Tantalum Concentrates.—Nigeria was by a wide margin the free world's largest producer of columbite in 1965. Its output of 2.6 million kilograms accounted for about 84 percent of non-Communist production of the mineral. Much of the Nigerian columbite is relatively rich in tantalum. For this reason certain Nigerian columbites have been important raw materials for tantalum metal producers during periods of high demand for the metal and inadequate availability of tantalite and other tantalum-rich minerals more desirable as a tantalum raw material. Nigeria also produced tantalite (128,000 kilograms) in 1965 and there were six other African producers of tantalum raw materials, particularly Mozambique, from which United States imports were 125,368 kilograms, and the Democratic Republic of the Congo (Léopoldville) which produced 72,405 kilograms.

Copper.—Since 1962 six political divisions of Africa have contributed to its smelter production of copper (either or both blister copper and refined copper). At 1.122 million tons (27.1 percent of free world output) smelter production in 1965 was 5 percent higher than in 1964. The contributors, and the share of each of total African output in percent, were Republic of Zambia 63, Democratic Republic of the Congo (Léopoldville) 26, Republic of South Africa 5, South-West Africa 3, and Southern Rhodesia and Republic of Uganda each 1.5. In addition to blister and refined copper, approximately 18,000 tons of copper were produced in concentrates for export overseas. Producers of these materials included Algeria, Morocco, and South-West Africa.

The output achieved in 1965 was the alltime record for Africa. That such production could be maintained in the immediate future seemed doubtful at yearend.

Gold.—Gold production in Africa in 1965 continued to increase, but at a slower rate than in previous years. The failure to maintain the pace of recent years primarily resulted from a decline in the rate of expansion of output of South Africa, which accounted for 95 percent of African output, with Ghana and Southern Rhodesia, the next largest African producers, contributing respectively 2.4 percent and 1.7 percent of the African total. At yearend it appeared that African gold production had reached a level from which important further increase could not be expected in the forseeable future, barring discovery of a new large goldfield.

Iron Ore.—A feature of the year was continued improvement in iron ore production. At 39.4 million tons, output was 32 percent higher than that in 1964 and three times that of the period 1955–59. There were 12 significant producers, 7 of which contributed 1 million tons or more as follows in million tons: Liberia 15.9, Mauritania 6, South Africa 5.8, Algeria 3.1, Sierra Leone 2.1, Tunisia 1.1, and Swaziland 1. The ore was produced exclusively for export, mostly to West Europe and Japan, except in the case of South Africa where local sales of iron ore totaled 4.7 million tons in 1965.

At yearend further expansion of the industry was indicated, particularly in Liberia where a washing and pelletizing plant with annual capacity of 2 million tons of pellets was under construction at the port of Buchanan.

Manganese Ore.—The 4.4 million tons of manganese ore produced in Africa in 1965 was a new record high for the continent. Five countries accounted for 93 percent of the output as follows: South Africa 35 percent; Republic of Gabon 29 percent; Republic of Ghana 13 percent; and Democratic Republic of the Congo (Léopoldville) and Morocco, each 8 percent. South Africa itself consumed about a third of its production of 1.6 million tons. With that exception the ore was mined for export. Gabon's production of 1.3 million tons was realized by one company, Compagnie Miniére de l'Ogooúe (COMILOG), which with that tonnage became the largest producer of manganese ore in the non-Communist world.

Platinum.—By yearend the Republic of South Africa had firmly established itself as the largest producer of platinum and other metals of that group in the non-Communist world. The U.S. Bureau of Mines estimated the 1965 output of Rustenburg Platinum Mines Ltd., the only significant producer in South Africa, at 750,000 ounces (platinum-group metals as a whole). Although this estimate may have been high, Rustenburg later announced plans to increase output of plati-

num alone to 750,000 ounces by 1970. This increase would mean an output of about 1.2 million ounces of platinum-group metals.

NONMETALS

Diamond, phosphate rock, and asbestos accounted for the great bulk of value of nonmetallic minerals produced in Africa in 1965. At $415.3 million, raw diamond sales by De Beers Consolidated Mines Ltd. were a record for the fifth successive year and exceeded 1964 sales by $41.4 million. Ten political divisions of Africa were significant producers.

The value of phosphate and asbestos output amounted to about $147 million and $44 million respectively. While Morocco accounted for the major part of phosphate output (about 61 percent), seven other countries each produced from 86,000 tons (Algeria) to 3 million tons (Tunisia), and at 16 million tons, total African output was 3 percent higher than in 1964. A significant feature with respect to phosphates was that at yearend South Africa was approaching self-sufficiency.

With respect to asbestos, although there was recorded production in 6 countries or areas, the great bulk of African output continued to be contributed by South Africa (52 percent), Southern Rhodesia (37 percent), and Swaziland (9 percent). Besides being the world's only producer of amosite asbestos, South Africa continued to contribute the great bulk of crocidolite asbestos. For the whole continent asbestos output was 11 percent larger than that of 1964.

MINERALS FUELS

The outstanding development of the year occurred in the petroleum area. Crude oil output at 811.7 million barrels was 30.2 percent larger than that of 1964 and at yearend production capacity was increasing. Major contributors to 1965 African crude oil production were: Libya (55 percent), Algeria (25 percent), Nigeria (12 percent), and Egypt (6 percent). Republic of Gabon, Angola, Morocco, and Republic of the Congo (Brazzaville), in that order, were also producing crude, and besides in the countries named above, exploration was being conducted in Ethiopia, Somalia, Mozambique, Cameroon, Ghana, Senegal, and Spanish Sahara.

Crude oil refining capacity also was increasing. At yearend 21 refineries were operating and 6 refineries were under construction.

The natural gas industry expanded production 116 percent compared with that of 1964, and from Algeria liquefied natural gas was being exported in large quantity to the United Kingdom and France.

CONTRIBUTION TO MINERAL SUPPLIES OF SELECTED COUNTRIES [3]

Several mineral commodities that are exported from Africa in important quantities reach the consuming country in part via third countries outside the continent. For this reason and because trade reports of some countries fail to provide mineral commodity detail, it is difficult to determine the true African contribution to the mineral imports of a given country. This applies particularly to raw diamond and to a lesser extent to cobalt, primary platinum raw materials, and primary germanium raw materials.

UNITED STATES

United States industry continued to rely heavily on Africa for mineral and metal supplies. In 1964 imports direct from Africa included more than 25 items, with a total value of about $230 million. The imports included $59 million of raw and uncut diamond. Total U.S. imports of diamond, some 92 percent of which was mined in Africa, were valued at $259 million, comprising $150 million of gem diamond and $60 million of industrial diamond. While there were no direct imports of platinum-group metals, the value of total platinum imports in 1964 was $50 million, of which perhaps half or even more represented platinum-group metals mined in South Africa.

Imports from Africa of other metals and minerals for which for lack of significant domestic resources the United States is dependent on imports or essentially so, and in percent the share of total imports represented, included the following: amo-

[3] Information presented here on Africa's contribution is for 1964 if not stated otherwise.

site and crocidollte asbestos each 100, chromium ore 55, columbium and tantalum concentrates 53, manganese ore and beryllium ore each 51, cobalt 46, antimony 37, germanium 21, and tin 6.

Significant also was the fact that U.S. imports direct from Africa of crude petroleum became substantial in 1964, amounting to 4 percent of total crude oil imports and valued at $3.2 million.

COUNTRIES OF THE EUROPEAN ECONOMIC COMMUNITY

The European Economic Community (EEC)[4] relies more heavily on imports of mineral, metal, and energy supplies than does the United States, its resources being less abundant and less diversified. Moreover the EEC obtains a much larger share of its mineral imports from Africa because of the close commercial ties that developed during the period of colonial rule, and because the EEC countries are closer to the African ports than the United States.

The value of EEC mineral imports (including petroleum) direct from Africa in 1964 was roughly $1,780 million, eight times the value of these imports into the United States in 1964, and about 21 percent of total EEC mineral imports. Indirect imports, particularly of raw diamond from the United Kingdom, made Africa's true contribution substantially larger than 21 percent.

The imports from Africa included more than 25 commodities. By value crude petroleum was the largest item, amounting to $908 million, or 28 percent of the EEC's total crude oil imports of $3,254 million.

UNITED KINGDOM

In 1965 the United Kingdom maintained the preferred position among importers of African gold, platinum raw materials, and diamond that it has held for many years. During the first 11 months of 1965 imports of unrefined gold bullion from African countries other than South Africa amounted to 1,265,230 ounces. Imports of refined gold bullion from South Africa amounted to 32,471,550 ounces (about $1.14 billion). The 1965 imports from Africa of platinum raw materials were valued at $38 million; this figure includes some silver however. Raw gem diamond from Africa was valued at $301 million, compared with total raw gem diamond imports of $496 million.

In 1964 (most recent year for which complete foreign trade statistics were available) the United Kingdom's mineral imports from Africa included the following eight additional items in quantities ranging from 64 percent to 29 percent of the total imports: Crude phosphates 64 percent, ferromanganese 62, refined and blister copper, chromium ore and concentrates and asbestos each 48, cobalt 47, iron ore 29.

JAPAN

Japan imported in 1964 roughly $2,500 million of raw minerals, crude and refined metals, and crude petroleum. Represented by some 17 commodities, the direct contribution of Africa to the total value was about $142 million or about 6 percent. Items imported from Africa and valued at $2 million or more comprised $62.2 million of copper of which $58.8 million was blister and refined copper, $25.9 million of iron ore, $19.4 million of pig iron, $9.3 million of phosphate rock, $6.1 million of asbestos, and $2.4 million of ferroalloys. Value of imports direct from Africa of raw diamond, manganese ore, chromium ore and concentrate, and crude petroleum in millions of dollars was 1.3, 1.6, 1.2, and 1.2, respectively.

At yearend long-term contracts existed for delivery to Japan of pig iron and iron ore from the Republic of South Africa and of iron ore from Swaziland.

IMPORTS INTO AFRICA

Africa's major energy, metal, and mineral imports continued to be petroleum products, crude petroleum, iron and steel semimanufactures, cement including clinker, and fertilizers. The approximate volume of these imports in 1963 and 1964, the most recent years for which the figures were available, are as follows

	Million metric tons	
	1963	*1964*
Petroleum products	24.9	16.6
Crude petroleum	7.8	12.9
Iron and steel semimanufactures	1.6	2.5
Cement [1]	2.2	2.5
Fertilizers	2.2	2.0

[1] Includes lime and other raw construction materials.

The 33-percent decline in petroleum product imports from 1963 to 1964 was largely accounted for by South Africa and Algeria, where such imports fell from 12.8 to 7.8 million tons and from 1.7 to 0.4 million tons respectively. South Africa increased refinery output from existing facilities during 1964 and in Algeria a new refinery went on stream early in the year. The large increase in imports of crude petroleum from outside Africa was primarily attributed to South Africa, which thus far has failed to find petroleum and obtains crude oil mostly from Near East fields. South Africa more than doubled its imports, from about 2.2 million tons in 1963 to 4.5 million tons in 1964.

The increase of more than 50 percent in imports of iron and steel semimanufactures largely reflected increases in such imports by South Africa (185,000 tons), Ghana (161,000 tons), and Nigeria (121,000 tons). At yearend there were still no important integrated iron and steel facilities in Africa outside South Africa and it appeared that the continent as a whole would continue to depend largely on imports of semimanufactures for some time to come.

That no significant change in cement imports occurred from 1963 to 1964 in part reflects establishment of increased capacity for cement manufacture in several African countries. At yearend this trend was expected to continue.

The largest consumers of manufactured fertilizers and fertilizer raw materials are South Africa, Egypt, and Southern Rhodesia, in that order. Their combined imports in 1963 and 1964 totaled about 1.8 and 1.5 million tons respectively. At yearend South Africa was working toward self-sufficiency in phosphate rock, which in 1963 and 1964 comprised, respectively, 70 percent and 44 percent of total fertilizer imports of 1.2 million and 685,000 tons. In the United Arab Republic (Egypt) superphosphate manufacturing capacity was being expanded, and expansion of phosphate rock production was being considered. In Southern Rhodesia, where nitrogenous fertilizers are mostly required, production capacity for phosphate rock and superphosphate by yearend had become sufficient to meet the country's superphosphate requirements.

The Mineral Industry of Algeria[1]

By Walter C. Woodmansee [2]

As in 1964, the Algerian mineral industry was dominated by the petroleum sector, which continued as the principal source of revenue and the main subject of mineral news from the country. The prolonged French-Algerian oil negotiations were concluded in July, effective at yearend, and inaugurated a new policy influencing French, United States, and other petroleum operations in the country. Because this conference extended through most of the year, little initiative was shown in petroleum exploration, although successful development drilling continued and several oil discoveries were announced.

The trend toward greater Algerian Government control of the country's resources was advanced by the oil agreements with the French. In January, government authorities warned holders of about 75 inactive mining concessions that they might lose property control if mining activity was not commenced within 2 months. These mines were mostly copper-lead-zinc deposits, abandoned by French owners in 1962 when Algeria became independent. In June the Government announced the nationalization of all diatomite mines and quarries and about 60 other, largely inactive mines. Control was turned over to the Bureau Algérien de Recherches et d'Exploitations Minières (BAREM), the State mining agency. Petroleum acreage was relinquished to the Government; requests for petroleum permits were denied as it became increasingly difficult to obtain or renew permits or concessions. As the year ended, further announcements regarding petroleum policy and mine nationalization were expected.

In mid-1965, 39 petroleum companies were operating 112 concessions in the Algerian Sahara, including 15 French, 12 United States, 5 West German, 4 Italian, and 3 British companies. Oil and gas were produced from 550 to 600 wells. Algeria was surpassed during the year by Libya as the continent's largest oil producer. Large oil and gas production capacity remained shut-in because of limited pipeline capacity.

In December, agreement was reached between the United Nations and the Algerian Government on a $1.2 million, 2-year survey of natural resources and economic development possibilities, including steel production, metal fabrication, and foreign markets for natural gas.

PRODUCTION

Except for marketed natural gas, there were no pronounced changes in mineral production during the year. Output of petroleum, by far the most important mineral commodity, was essentially the same as the 1964 output; expansion was not possible without additional pipeline capacity. Marketed dry natural gas increased 117 percent with expansion of foreign markets for liquid methane in France and the United Kingdom. Natural gas output, however, remained small relative to resource potential. Iron mining continued to move forward, following recovery from the low period of 1962–63. Progress was made toward completion of the iron and steel plant at Annaba. Copper, lead, and zinc ore output showed a slight decline, attributed to the labor situation. In the industrial mineral sector, output data on

[1] Considerable mining information in this chapter was derived from mineral reports prepared by R. B. Duncan, Dept. of State, U.S. Embassy, Algiers.

[2] Physical scientist, Division of International Activities.

e Estimate. r Revised. NA Not available.

[1] In addition to commodities listed, Algeria produces other types of construction materials, but data on output are not available.

[2] Estimated recoverable silver content of lead and zinc concentrates.

[3] Undifferentiated metals produced in foundries.

[4] Production of Algiers refinery (Société Raffinerie Algérienne), which commenced operations in February 1964; totals do not include relatively small output of a field topping plant at Hassi Messaoud.

several commodities were not available. Cleanup mining continued at the nearly exhausted Kouif phosphate mine, while development was underway on the new phosphate rock deposit at Djebel Onk.

The overall value of metal and mineral output is not known, but crude oil, condensate, and natural gas sales were probably valued in excess of $500 million.[3] Iron

[3] Where necessary, values have been converted from Algerian dinars (DA) to U.S. dollars at the rate of DA 1=$0.2046.

ore output was valued at $23 million, and the base metal concentrates were valued at about $8.7 million. Algeria's operating and capital budget was $843 million during 1965.

TRADE

For the years of review, complete official trade statistics of Algeria were not available; most data were derived from European Economic Community (EEC) statistics on foreign trade with Algeria, supplemented by Algerian sources. According to International Monetary Fund estimates, total Algerian trade in 1964 was as follows: Exports—$710 million, imports—$739 million. EEC data indicate that Algerian metal and mineral exports to the Community were valued at $440.6 million, including $418.7 million for oil and gas; corresponding Algerian imports of metals and minerals from the Community were valued at $52.3 million, including $28.3 million for iron and steel. A large share of this trade continued with France.

COMMODITY REVIEW

METALS

Antimony.—Early in the year, the Société de la Vieille Montagne reopened the Hamman N'Bails antimony mine in eastern Algeria. This mine produced a small ore tonnage.

Copper.—Despite favorable world market prices, output of copper decreased slightly at the Aïn Barbar mine, Algeria's only producing copper mine, located near Annaba in the northeast coastal area. Difficulties were experienced in recruiting experienced mining personnel for expanded operations.

Starting in March, a Bulgarian mission conducted a drilling program at Kef Oum Teboul, near the Tunisian border.

Iron Ore.—Production increased 14 percent over that of 1964, partly because of a larger market in Italy, which became the leading foreign purchaser during 1965. Preliminary information indicates that in 1965 principal Algerian exports of iron ore, in thousands of metric tons, were as follows: Italy 1,222, United Kingdom 1,010, Bulgaria 170, West Germany 163, and Belgium-Luxembourg 103. The United States imported 53,000 tons from Algeria during the year.

Seven mines were productive at the beginning of the year. Output in recent years, including the latest year for which data are available, was as follows:

Mine	Metric tons		
	1962	1963	1964
Ouenza-Bou Khadra	1,505,544	1,458,313	2,171,934
Khanguet	142,837	157,318	182,938
Beni-Saf	159,119	181,551	174,585
Zaccar	153,960	90,483	138,924
Timezrit	91,046	67,870	46,608
Rouina		7,038	15,776
El Maden	9,377	13,421	15,380
Total	2,061,883	1,975,994	2,746,145

The resurgence of iron mining in Algeria during 1964–65 has been attributed to a greater demand for iron ore in Western Europe; new markets in the U.S.S.R., Czechoslovakia, Poland, and the United States; low ore prices accepted by Algerian producers; and good industrial relations at Algerian mines.[4]

The Ouenza-Bou Khadra ore deposits in eastern Algeria, operated by Société de l'Ouenza, a private firm in which the Algerian Government holds 30 percent of the stock, continued to account for about 80 percent of the ore output in 1965. The other producing mines, which are worker-managed (autogéré) or are operated by BAREM, were hampered by low-grade ore and a lack of qualified mine personnel. Operators of the Zaccar mine, near Algiers, were unable to fulfill an ore contract concluded with the United Kingdom in April 1965. Exports from this mine were suspended in September, when settling of the dock at the Algiers port precluded ore loading.

Although Ouenza-Bou Khadra ore sales were about 200,000 tons higher than in 1964, profits were changed relatively little, because of low prices and increased operating costs. The mines operated by BAREM were more adversely affected by these factors.

Iron ore exploration during 1965 was limited to drilling programs by the U.S.S.R. at the Zaccar mine and by Bulgarian technicians at the Beni Saf mine in western Algeria.

Domestic consumption of iron ore, largely in cement plants, was 12,797 tons in 1965 compared with 14,743 tons in 1964.

Iron and Steel.—The Algerian Government through the Caisse Française d'Equipment pour le Developpement de l'Algérie acquired majority share holdings in the Société Nationale de Sidérurgie (formerly Société Bônoise de Sidérurgie), the Government's new iron and steel plant at Annaba. A total of about $6.1 million, originally planned for construction of furnaces, was used in purchasing installations

[4] Mines et Métallurgie. No. 3599, October 1965, pp. 439–440.

for the first construction stage from French private interests. Plant construction, started in 1959, originally was planned for completion in 1963, but several delays necessitated rescheduling. The French built the pig iron division. Late in 1964, it was reported that the U.S.S.R. had agreed to build the steelmaking plant,[5] but a year later,[6] the French firm, Société Française d'Equipment Sidérurgique (SOFRESID), agreed to engineer the steel plant in cooperation with Soviet technicians. Work on the foundry section was started during 1965. Specifications for iron and steelmaking facilities have been changed during the construction period; in 1965 plans called for a blast furnace (capacity not reported) fitted for fuel injection, two 50-ton oxygen converters (annual capacity 500,000 tons), and a continuous casting machine.

Lead and Zinc.—Favorable market conditions led to a rise of nearly 10 percent in lead-concentrate output. Although data on foreign markets are incomplete for 1965, the major purchasers of Algerian mine lead were Italy, Greece, and Morocco.

Although ore output in 1965 was higher at the El Abed and Oued Zounder mines, near the Moroccan border, zinc content was reduced. This decline was somewhat offset by a marked increase in oxide ore (calamine) at the Ouarsenis mine, which was rehabilitated during 1964–65. Exports of concentrate exceeded production in 1965, resulting in lower stocks at the mines. France and Spain were the main buyers of Algerian zinc concentrate during the year; the United States purchased 4,842 tons.

Exploration for lead-zinc ores and capital improvements at mines and mills continued at a moderate pace during the year. A new ore body discovered at the El Abed mine was developed further, and mining is expected to begin in 1966. New lead ore bodies also were discovered at the Ouarsenis mine. A Yugoslav firm continued drilling and underground work at Kherset Youcef and Djebel Gustat. A Bulgarian mission drilled at Kef Oum Teboul, near the Tunisian border, and at Guerrouma in central Algeria. Results of exploration are not known.

Silver.—In 1964 lead concentrate at the El Abed and Oued Zounder mines reportedly contained 839 grams of silver per ton, and zinc concentrate contained 244 grams of silver.[7]

NONMETALS

Barite.—Output increased sharply during the year, because of greater demand for barite in oil drilling in the Algerian Sahara. Consumption of barite was 28,504 tons, 33 percent greater than in 1964. Exports were only about 1,500 tons, nearly all to Nigeria. In May, BAREM, which exercises a monopoly over the processing and marketing of barite, reopened the Keddara mine, near Algiers, and began exploration in the Grande Kabylie. Early in the year, the Government appointed a commissioner to oversee barite mining operations of two producing companies.

Source. Chambre Syndicale des Mines d'Algérie-Compte, Rendu-de L'Assemblée Générale Annuelle, June 1965.

Fertilizer Materials.—Limited production of phosphate rock continued at the nearly exhausted Kouif deposit. Exports were resumed, 57,000 tons from Kouif stockpiles and mine cleanup work reportedly having been sold, largely to West Germany and France. Development continued on the new deposit at Djebel Onk, where reserves in excess of 500 million tons have been established. Railroad and electric power connections and a new town site have been developed. One hundred 48-ton rail cars for phosphate haulage were fabricated at Annaba, where port loading facilities used for Kouif phosphate will also be used for Djebel Onk phosphate. Société du Djebel Onk, in which the Algerian Government holds a one-third interest, was formed as mine operator. A treatment plant for crushing, cleaning, calcining, washing, and drying was under construction during the year. Crude phosphate rock of 53 to 60-percent bone phosphate of lime (BPL) is to be upgraded to 75-percent BPL. Production at an annual rate of 800,000 tons has been anticipated for 1966.

Algeria continued to import large quantities of nitrogenous and potassic fertilizers from the European Common Market countries, principally France. Superphosphate was produced at plants in Oran, Algiers, and Annaba.

Pyrite. — Labor-management difficulties at the Aïn Ben Merouane mine, Algeria's only operating pyrite mine, resulted in a production decline and led to reorganization of the mine by BAREM. During the year BAREM installed new flotation equipment and began exploratory drilling. Pyrite consumption at fertilizer plants was 23,256 tons, and 35,880 tons were exported to Italy and France.

MINERAL FUELS

Coal.—Reported plans to close the BAREM-managed coal mine of Houilleres du Sud Oranais, following conversion of the thermal-electric powerplant at Colomb-Béchar to diesel fuel, have apparently been postponed. BAREM has introduced measures to reduce costs.

Petroleum.—Crude oil production dropped slightly below the 1964 rate but remained near the maximum for available pipeline capacity during 1964–65 (daily rate of about 550,000 barrels). Construction work continued on the new Haoud el Hamra-Arzew pipeline, which is expected to add about 200,000 barrels per day to pipeline capacity and a further 240,000 barrels daily when additional pumping stations, planned for a later date, are completed. The pipeline construction contract between Société Nationale de Transport et de Commercialization des Hydrocarbures (SONATRACH), an Algerian Government agency, and John Brown Ltd., a British firm, called for completion of the initial project in October 1965. However, construction problems developed, chiefly in transportation of equipment inland from the Oran docks and a shortage of experienced labor. Thus commercial use of the line was delayed until early 1966. During the year, the line was welded out and tested, and the crude-oil tank farm was installed at the Arzew terminal. In October, the first of three vessels for pilotage, customs, and mooring duties was completed in the United Kingdom for John Brown Ltd., which will operate the port under contract with the Algerian Government. In November, 17 companies signed contracts for the delivery of crude oil through the new line.

A second major expansion in the Compagnie de Transport par Pipe-lines au Sahara (TRAPSA) pipeline, connecting the Polignac Basin oilfields to the port at La Skhirra in Tunisia, was completed in April. Capacity was increased from 200,000 to 270,000 barrels daily with the addition of two new pumping stations, very-high frequency control, and new communications equipment.

Potential production at several large oilfields in the Triassic and Polignac basins remained partially or wholly shut-in. The new SONATRACH pipeline will permit increased production at the Rhourde el Baguel, Gassi Touil, and El Gassi-El Agreb fields. A new 16-inch feeder line was under construction from the latter to the Haoud el Hamra gathering center. A new line between the Zarzaitine Northeast and main Zarzaitine fields permitted the flow of natural gas liquids from the large Alrar gasfield. Other feeder lines were under construction or planned.

The pilot gas-injection project in the Hassi Messaoud field, involving seven wells, was completed. Details on success of the project were not available at yearend, but

preliminary reports indicated favorable results.

Compagnie de Recherches et d'Exploitation du Pétrole au Sahara (CREPS), the country's largest crude oil producer, commenced water injection [8] of 9 to 10 million gallons per day in 20 to 30 wells in the large Zarzaitine field, where production fell 19 percent in 1965. Difficulties were encountered in maintaining an adequate water supply and in injecting water to the oil-bearing zones.

Exploration and Development.—Exploratory drilling declined sharply during 1965; most petroleum drilling activity was developmental, testing for extensions of structures and oil deposits in and near producing fields. The following data indicate the change in these activities during 1964–65:

	1964	1965
Exploration:		
Geophysical team-months	119.3	40.7
Footage drilled thousand feet	302	161
Number of wells completed	52	24
Development:		
Footage drilled thousand feet	472	512
Number of wells completed	82	88

The decline in drilling activity was attributed to the lack of sufficient pipeline capacity to deliver additional oil and to uncertainty regarding the future of the industry during the French-Algerian oil negotiations, which terminated in July 1965. The only seismic programs operating late in the year were sponsored by the Algerian Government. Step out drilling by Compagnie des Pétroles France-Afrique (COPEFA) at Gassi Touil and by Sinclair Sahara Petroleum Co. at Rhourde el Baguel increased reserves at these fields. New oil reserves were proved at Rhourde Hamra. Extension drilling also resulted in increased oil reserves at the Tin Fouyé North and East fields and increased gas reserves at Tin Fouyé West, Oued Zenani, and Zarzaitine. Drilling continued at Askarène and Guelta late in the year.

Of the 24 exploratory wells completed, 2 led to commercial discoveries. Compagnie Française des Pétroles (Algérie) (CFPA) discovered commercial oil at Haoud Berkaoui, west of Hassi Messaoud, and Société Nationale de Recherche et d'Exploration des Pétroles en Algérie (SNREPAL) discovered oil at Nezla Nard on its Oued Mya permit, south of Hassi Messaoud. Of the 134 exploratory and development wells drilled in 1964 (the latest year for which details are available), 72 were successful oil wells, 11 were gas wells, and 51 were dry holes.

Oilfields at In Aksmil, Hassi Mazoula, and Temedratine became new producers during the year. The large Alrar gasfield was productive during a lengthy trial run.

Table 5.—Algeria: Crude oil production by field

(Thousand metric tons)

El Adeb Larache	494	486
Other	425	773
Total	23,655	26,226

Natural Gas.—Marketing of dry natural gas more than doubled during 1965, largely because of expansion of export markets for liquefied methane. Production of natural gas liquids (condensate) increased correspondingly. The Hassi R'Mel gasfield remained the predominant source. Reported recoverable reserves of 35.3 million million cubic feet [9] ranked this field as one of the world's largest.

Production remained small relative to potential gas output, but the Algerian Government made plans for moving more natural gas to Mediterranean ports. Another gas pipeline connecting the Rhourde Nouss, Gassi Touil, and Alrar fields to the coast was considered.[10] Existing pipelines were also to be expanded. The Société de Transport du Gaz Naturel d'Hassi R-Mel à Arzew (SOTHRA) line from the Hassi R'Mel gasfield to Arzew has a new dis-

patcher at St. Leu, near Oran, which is provided with telemetry and telecommand equipment for future use with pumping stations. This equipment will carry out routine and alarm inspections of the line and will regulate the pumps.

Delivery of liquefied methane to the United Kingdom, commenced in late 1964, continued at an annual rate of 1-billion cubic-meters gas equivalent (700,000 tons liquid methane). The French tanker vessel, *Jules Verne,* arrived at Arzew in March to load the first shipment of liquefied methane for delivery to Le Havre.

Minor operational difficulties with refrigerator compressors and refrigerant leakage were experienced at the Arzew liquefaction plant of Compagnie Algérienne du Methane Liquids (CAMEL), but the first year of operation was considered successful. The plant and process were described in several sources.[11]

Early in the year, Spain and Algeria signed a trade pact for future Spanish purchases of Algerian gas and oil in exchange for Algerian purchases of industrial goods from Spain. Algerian authorities also negotiated for future markets for Sahara gas in Austria, Yugoslavia, and Czechoslovakia, either by tanker shipment of liquid methane or possibly by sub-Mediterranean pipeline delivery of gas.

Electricité et Gaz Algérienne (EGA), the Algerian public utility company, announced a policy of uniform gas prices and a 30-percent lowering of rates, effective January 1, 1966.

Refinery Products.—The new Algiers refinery of Société de la Raffinerie d'Alger (SRA), on stream in early 1964, completed its first full calendar year of production. Operations were not continual during 1965 because of occasional shortages of crude oil and because of a limited domestic demand for petroleum products. Crude oil throughput was 1,603,000 tons during the year. Imports of refined products were curtailed during 1964 (and apparently also in 1965, although data are not available), because the refinery was able to provide most domestic supplies.

The small Hassi Messaoud refinery continued to provide gasoline, distillate fuel oil, kerosine, and liquefied petroleum gas for the local market; estimated crude oil throughput was 1.5 million barrels, and refined product output was 1.4 million barrels, during the year.

In March, the Algerian Government announced plans for two new 3- to 5-million-ton refineries, possibly at Arzew and Algiers. but there were no further developments on this by yearend. Société Nationale Distribution was announced as a new government agency concerned with distribution and sales of petroleum products to government organizations and the armed forces.

French-Algerian Petroleum Agreements.—Yearend 1965 marked the beginning of a new petroleum policy in Algeria. After 20 months the French-Algerian oil negotiations were terminated in July; the agreements were ratified by the French National Assembly in October; instruments of ratification were exchanged in Paris on November 30; and the new policy became effective 30 days later. The accords were for 15 years' duration, renegotiable at 5-year intervals with agreement of both parties.

The negotiations and accords reached were the subject of considerable interest to the petroleum world during the year.[12] The accords reportedly comprised 53 articles and 12 annexes. France retained a privileged position in oil and gas exploration and development; Algeria was to receive greater financial returns (higher tax rates including new tax-reference prices, stricter tax allowances and regulations on capital remittance, larger share in profits), a more active role in all sectors of the petroleum industry, and long-term French financial and technical aid.

Of particular interest was the "Cooperative Association," created for joint French-Algerian exploration and development of 70,000 square miles of prime oil land. Late in the year it was announced that the Algerian partner would be a subdivision of SONATRACH, and the French partner

V. 63, No. 31, Aug. 2, 1965, pp. 84–86; Petroleum Press Service. V. 32, No. 9, September 1965, pp. 324–327; Arab Oil. August–September 1965, pp. 38–40.

was established under the name Société Pétrolière Française en Algérie.[13]

Following announcement of the French-Algerian oil accords, Algerian authorities spelled out the effect of these accords on non-French, foreign oil companies in the country.[14] Compliance with the higher tax rates and the new amortization-depletion provisions was expected, but the effects of the tax-reference price system and the role of non-French companies in future exploration and development remained unsettled at yearend.

The Mineral Industry of Angola, Mozambique, and Portuguese Guinea

By Henry E. Stipp [1]

The mineral industries of the Portuguese Provinces of Angola and Mozambique had a combined production (excluding petroleum refinery products) valued at approximately $64.0 million [2] in 1965 compared with $63.1 million in 1964. There was no mineral production recorded in Portuguese Guinea.

Exports of diamond and iron ore remained an important source of foreign exchange for Angola. In 1965 this province ranked seventh on a quantity basis among world diamond producers with output valued at $32.5 million. Iron ore production was valued at $6.5 million. Mozambique ranked fourth among world producers of columbite-tantalite and ranked fifth as a world producer of beryl.

The most significant event relating to minerals in Angola was the agreement between Companhia Mineira do Lobito and a European syndicate to develop the Cassinga iron ore deposits. In Mozambique the most important minerals development in 1965 was the drilling of the fourth productive gas well near Inhassoro.

ANGOLA

Mineral production in Angola decreased in quantity from that of 1964, but the value remained relatively the same. Although output of two of the principal minerals of Angola, iron ore and crude petroleum, decreased, the production and unit value of diamond, one of Angola's chief sources of foreign exchange, increased. Angola's mining industries were characterized as offering the brightest prospects for the economy of the Province in the immediate future.[3] Foreign investor interest in this field has been significant. The Government recently has shown considerable interest in attracting foreign investment. A decree was issued authorizing the establishment of firms in nonstrategic fields with 100 percent foreign capital throughout Portuguese territory. The decree also guaranteed full remittance of profits and repatriation of capital for such investments. A law was also issued providing greater protection of local industry from foreign competition.

In 1965, Angola's mining industry employed 30,249 salaried workers compared with total employment by private industry of 357,851 salaried workers.

PRODUCTION

The principal mineral commodities produced in Angola were diamond, crude oil, refinery products, and iron ore. Diamond production increased slightly in 1965 compared with the diamond output in 1964. Crude oil output was reduced sharply because of a revision downward in the estimated reserves of the Tobias field. Total output of refinery products in 1965 increased about 4.6 percent over that of 1964. Iron ore output was reduced reportedly because of rail transportation difficulties to the ports of Mocamedes, Lobito, and Luanda. Production of metals, minerals,

and mineral fuels (excluding petroleum products) was valued at about $56.4 million compared with output valued at about $56 million in 1964. Refined petroleum products were valued at $10.1 million, down from $14.9 million in 1964. Diamond was valued at $32.5 million, an increase over the $28.7 million in 1964.

Table 1.—Angola: Production of metals and minerals
(Metric tons unless otherwise specified)

e Estimate. r Revised. NA Not available.

TRADE

Detailed trade data for Angola were not available for 1964 and 1965, but on the basis of preliminary official returns, it was apparent that mineral exports in 1965 again accounted for about one-fifth of total Angolan exports, while mineral imports accounted for an increasing share of total imports as shown below:

	Value (million dollars)		Minerals commodities share of total (percent)
	Mineral commodities [1]	Total commodities [2]	
Exports:			
1964 [3]	41.2	r 205.3	20.0
1965	42.4	201.6	21.0
Imports:			
1964 [3]	10.1	165.0	6.1
1965	17.7	196.5	9.0
Trade balance:			
1964	+31.1	r +40.3	XX
1965	+24.7	+5.1	XX

r Revised. XX Not applicable.

[1] Values given are for those mineral commodities listed in table 3.

[2] Source: Boletim do Instituto Nacional de Estatistica. XI–Ultramar. No. 3, March 1965, p. 7; No. 4, April 1966, p. 5.

[3] Where necessary, monetary conversions for 1964 have been made at the rate of 28.58 escudo=US$1.00.

Among reported mineral export commodities, diamond, valued at $31.7 million, accounted for about 75 percent of the total value in 1965. Iron ore, valued at approximately $5.1 million, accounted for about 12 percent of the total value. Crude oil and petroleum product exports together were valued at approximately $4.2 million and ranked third among Angolan mineral exports accounting for about 10 perecent of the total value.

The principal metal and mineral import groups of Angola in 1965 were iron and steel products, valued at $13.0 million, and petroleum refinery products, valued at about $3.1 million.

In 1965, metropolitan Portugal remained Angola's principal trading partner on the basis of trade in all commodities, as shown in the following tabulation:

Trading partner	Percent of total Angolan exports received	Percent of total Angolan imports supplied
Portugal	35.2	47.5
United States	23.1	7.9
United Kingdom	1.3	11.2
Netherlands	11.8	1.6
Germany, Federal Republic of	5.5	8.2
Other African countries	4.1	2.6

The delivery of diamond exports to Portugal rather than to the United Kingdom that began in 1964 was intensified in 1965 when the total exports of this commodity were delivered to Portugal. As a result, the United Kingdom, the chief recipient of Angolan mineral exports in 1963, declined as a prominent recipient of total exports.

COMMODITY REVIEW

Metals.—*Beryl.*—Deposits containing about 10 percent beryllium oxide (BeO) were reportedly discovered in the Huila district of southern Angola.[4]

Copper.—There was no production of copper in 1965. Three concessions for prospecting and producing copper were in effect.[5] The Angolan Copper Company, which had operated the exhausted Mavoio deposits, was reportedly negotiating with another firm for joint exploitation of the Tetelo deposits. These deposits in the high Zambeze area were estimated to comprise 10 million tons of minerals containing 3 to 4 percent copper.[6] The Angolan Mining Company, an affiliate of Anglo-American Corporation of South Africa Ltd., claimed to have located possibly exploitable deposits in its concession in the east-central panhandle of Angola. The Lobito Mining Company, which discovered indications of rich copper in the Mocamedes district, was assessing reserves. These deposits are near a major railroad and an excellent port.

Gold.—Although production has been declining since 1962, government officials indicated that potential production could be much larger than that reflected by production statistics, especially in the central plateau of the Province.[7]

[6] Annales Des Mines. Metaux Courants-Cuivre. May 1966, p. 408.
[7] Page 31 of work cited in footnote 3.

Iron Ore.—Production of ore was reduced in the later months of 1965, owing to transportation difficulties.[8] About 250,000 tons of high-grade ore were stockpiled at the Cuima and Cassinga mines of Companhia Mineira do Lobito awaiting transport to the coast.

The Cassinga mining operation of Companhia Mineira do Lobito and its subsidiary, the Lombig Mining Company, continued to be a major economic hope of the Province.[9] The conclusion of a series of agreements was reached with a consortium headed by Krupp interests of West Germany, for development of the Cassinga iron ore deposits.[10] Cia. Mineira do Lobito placed contracts with the Krupp Consortium valued at $52 million for mining and transportation equipment, telecommunications and port-loading facilities. Total iron ore reserves in the Cassinga area were estimated at 30 million tons of high-grade (68 percent iron) ore, 75 millon tons of pebble ore (62 to 64 percent iron) and several hundred million tons of low-grade (42 to 45 percent iron) ore. At yearend Companhia Mineira do Lobito reportedly signed contracts with six Japanese steel companies for delivery of 1 million tons of iron ore annually for the next 6 years.[11] The price of the ore, which will come from the Cassinga deposits, was said to be $8.14 per ton for ore of 64-percent iron content. Companhia Mineira do Lobito reportedly has formulated plans for marketing up to 5 million tons of Cassinga ore annually by 1967.

Manganese Ore.—There has been no production since 1962, but exports from existing stocks continued in 1965. The Angolan Manganese Company made shipments from the production of established mines at Saia. The Bermanite-Quissama Company shipped ore recovered from prospecting operations. However, both companies have had difficulty locating markets because of high silicate and sulfur content of the ore.[12] There has been a large cutback in prospecting, and the Angolan Manganese Co. was concentrating on iron ore production.

Tin.—A tin deposit was reportedly discovered in the Lau region.[13]

Nonmetals. — *Diamond.* — Companhia de Diamantes de Angola (DIAMANG) continued to produce diamonds in northeastern Angola at a rate of more than 1 million carats per year. The company employed 29,000 workers, making it the largest private employer in Angola.[14] In 1964, 76 percent of total output mined was gem quality and 24 percent was industrial quality. Diamond exports since 1963 have been made through a new subsidiary of DIAMANG, the Sociedade Portuguesa de Lapidacao de Diamantes in Lisbon. The Angola Exploration Co. (Pty.), Ltd., which was given a concession in 1964, lost it for failure to put down the necessary funds required by the contract. In November 1964, the Government awarded a concession to Joao Antonio Veiga, a local businessman. The concession area covers most of the Angolan coast from Ambriz south to the Southwest African border. Veiga reportedly began exploration activity in the south, but sales of diamond were not shown by Veiga in 1965. An application for exploration rights was pending for Wynand Johannes du Toit.

Mica.—Production ceased with the beginning of the rebellion because the most important mines were in areas where access was precarious.[15] There was some production of scrap mica in southern Angola, but foreign marketing of this material has been difficult.

Phosphates.—Studies by the Angolan Government reportedly have confirmed 27 million tons of exploitable reserves, about 15 million tons in the Cabinda area and 12 million tons on the northwestern coast, north of Ambrizete.[16] Four companies applied for concessions in these areas. They were as follows: Fosfangol, an affiliate of Cia. Uniao do Fabril; COFRAMET, a

[16] Page 30 of work cited in footnote 3.

French company; and the Lobito Mining Company.

Salt.—Production of salt remained an important local small industry, particularly in towns such as Lobito and Mocamedes, where salt was used chiefly for drying fish.

Mineral Fuels.—*Asphalt, Natural.*—Two major companies produced 22,874 tons in 1965. All output was consumed locally.

Petroleum.—This industry, which includes crude production, refining, and distribution, again ranked as the third most important economic activity in Angola next to the coffee and diamond industries. Total investment at the beginning of 1965 in crude production and refining was calculated at about $75 million. The gross product of the industry in 1965 was valued at about $11 million. An agreement was reached between the Portuguese Government and Companhia de Petroleos de Angola (Petrangol), under which Petrangol's exploration permits in Angola were extended to yearend 1970.[17] The company was to spend $26 million in the Cuanza area of central Angola and in the northern area of Angola. The agreement was renewable for an additional 5 years. The estimate of reserves in Compagnie Financiere de Petroles (Petrofina), the parent concern of Petrangol, Tobias deposit was revised downward to 60 million barrels from the previous estimate of 200 million barrels.[18] This resulted in a sharp reduction in crude production and exports in 1965. Total Angolan reserves of crude oil were estimated at 100 million barrels.

About 83 percent of the 1965 crude production was refined locally in the 650,000-ton capacity Petrofina refinery, the only one in Angola. All the refinery's production was consumed locally except for 1,824 tons of gasoline and 200,296 tons of fuel oil.

Affiliates of two United States firms, Mobil Oil Portuguesa and Texaco Africa, Ltd. were engaged in petroleum distribution in Angola, operating in competition with two foreign companies (Shell Company of West Africa, Ltd. and Petrofina) and one Portuguese company, Sociedade Anonima Concessionaria Da Refinacao De Petroleos Em Portugal.

MOZAMBIQUE

The mineral industry of Mozambique, producing metals and minerals valued at about $7.5 million in 1965, was small compared with world standards. The refining of imported crude oil by the Matola refinery also produced products valued at about $8.4 million. The two principal mining activities in Mozambique were the production of coal near Tete and the recovery of columbite-tantalite and associated minerals from pegmatites of the Alto Ligonha district, southwest of Nampula.[19] The most significant development has been the recent discovery of natural gas in the Pande area near Inhassaro and in the Buzi area near Beira.

Much of Mozambique's income was derived from the shipment of minerals, fuels, and other materials from and to landlocked neighboring countries.

PRODUCTION

Production of metals, minerals, and mineral fuels decreased generally in 1965 compared with that of 1964. Output of columbium and tantalum minerals and concentrates, one of Mozambique's principal earners of foreign exchange, decreased 31 percent from 1964, and bituminous coal, another important export item, dropped slightly in output. Petroleum refinery output decreased 30 percent from that of 1964. The only mineral commodities to show a significant increase in production were montmorillonite, tourmaline, and cement.

TRADE

Detailed data on trade for Mozambique were not available for 1964 and 1965. However, based upon official reports of the value of selected mineral commodities traded, reports of the value of total trade for the entire year of 1964, and reports of the value of the first 11 months of 1965, it could be estimated that trade in mineral and in total commodities for 1965 was approximately the same as that of 1964.

In 1965, exports of petroleum products valued at about $6.6 million accounted for the largest part of mineral exports and constituted about 6.7 percent of total exports. Metalliferous ores and metal scrap shipments from Mozambique were second in value amounting to about $1.5 million, followed by exports of coal, coke, and briquets valued at $0.7 million.

Mineral imports for 1965 were about three times as large as exports, contributing to the adverse balance of trade in mineral commodities as well as in total merchandise trade. Imports of iron and steel products valued at $11.3 million accounted for the

	Value (million dollars) [1]		Mineral commodities share of total (percent)
	Mineral commodities	Total commodities	
Exports:			
1964	9.1	106.5	8.5
1965 [2]	8.7	98.0	8.9
Imports:			
1964	26.4	156.8	16.8
1965 [2]	24.6	154.5	15.9
Trade balance:			
1965	−17.3	−50.3	XX
1965	−15.9	−56.5	XX

XX Not applicable.

[1] Values given were obtained from Boletim do Instituto Nacional de Estatistica. XI-ULTRAMAR (overseas areas). No. 4 and No. 6, April 1965 and June 1966, pp. 7, 17–19 and pp. 6, 18–20.

[2] Values for mineral commodities and total trade in 1965 are for the first 11 months of the year only.

largest part of mineral imports and were about 7.3 percent of total commodity imports. Crude oil imports valued at $7.7 million were second in importance, followed by petroleum products valued at $3.0 million, coal and coke valued at $1.5 million, and fertilizers valued at $1.1 million.

Portugal continued its role as Mozambique's principal trading partner in 1965,[20] based upon trade in all commodities, as shown in the following tabulation:

Country	Percent of total Mozambique exports received	Percent of total imports supplied
Portugal	37.2	35.0
South Africa, Republic of	10.7	10.5
United Kingdom	4.7	10.6
Germany, Federal Republic of	3.7	7.7
India	14.4	.1
United States	4.9	3.8
Other African countries	5.5	1.7

The ports of Beira and Lourenco Marques in Mozambique continued to serve as the principal points of entry and exit for commodities transshipped through Mozambique by the countries of Zambia, Democratic Republic of the Congo (Kinshasa), Malawi, Southern Rhodesia, and Swaziland, and in addition received and shipped some goods for the Republic of South Africa. For calendar year 1965, minerals loaded at Beira totaled 1,023,469 tons compared with 935,633 tons in 1964.[21] Cargo off-loaded in 1965 included 851 tons of cement and 954,863 tons of petroleum products compared with 536 tons of cement and 582,814 tons of petroleum products in 1964. At the port of Lourenco Marques 3,556,697 tons of minerals were loaded in 1965 compared with 2,497,393 tons loaded in 1964. The quantity of fuel loaded in 1965 totaled 391,281 tons compared with 406,766 tons loaded in 1964. Coal exports from the port were 598,158 tons in 1965 compared with 579,236 tons exported in 1964. Cargo off-loaded in the 1965 period contained 1,897,488 tons of fuel compared with 1,824,012 tons in 1964.

COMMODITY REVIEW

Metals.—*Columbite and Tantalite.*—Production of 53 tons of concentrates in 1965 (exclusive of microlite) compared with 47 tons mined in 1964, but output generally has been declining since 1960 because of decreased market prices.[22] The principal producers, Sociedade Mineira de Marropino and Empresa Mineira do Alto Ligonha, located southwest of Nampula, were troubled by technical and transportation difficulties. Several firms reportedly were trying to obtain control of the operating concerns. They would like to re-equip and modernize mines and plants to put their operation on a more profitable basis.

Copper.—A mine near Umtali, Rhodesia, was opened in 1963 by Edmundian Investments (Pty.) Ltd.[23] In 1964, production was 122 tons of chalcopyrite containing 20 percent copper, in 1965, 340 tons of ore. Ore reserves were estimated at 12,000 tons with a 10-percent copper content. The mine was flooded in the lower levels, which as a result could not be worked in 1965. A ball mill and small flotation plant with a capacity of 100 tons per month were located near the mine. Rand Mines, Ltd. of Johannesburg signed an agreement with the operating company to explore the mineralized area near the mine.

Gold.—Deposits were reportedly found in the Lourenco Marques district, near Matola.[24] A group said to be connected with outside interests applied for a concession to explore for gold, silver, and asbestos.

Ilmenite.—Large deposits were located near Port Pebane on the Mozambique channel.[25] Potential exports could approach 30,000 tons per year; however, the deposits were not being worked because of transportation problems.

Iron Ore.—Large reserves of iron ore with a high content of titanium were found in the Tete district.[26] The deposits were not being developed because the long distance to the coast would make ore shipments too expensive for profitable operation. Deposits at Namapa, district of Moçambique were being considered for investigation in order to estimate the area's mineral potential.[27]

Nonmetals. — *Diamond.* — Two residents were granted a concession to prospect for diamonds in the Chicualacuala, Pafurs, and Malvernia regions.[28] A company to exploit any discovery was being formed with a capitalization of about $418,000.

Fertilizers.—A plant for the manufacture of fertilizers and sulfuric acid was to be constructed by Sociedade de Estudos e Investimentos at Lourenco Marques and Société d'Expansion Commerciale et Industrielle of Paris, France.[29] The plant, which will cost over $3.5 million was to start producing in 1967. Annual plant capacity reportedly will be 30,000 tons of superphosphate, 500,000 tons of sulfuric acid, 20,000 tons of ammonia, and 60,000 tons of ammonium sulfate.[30]

Montmorillonite.—Mozambique's only producer of this commodity, Luzinada Umbeluzi Mina, Ltd., located near Lourenco Marques, started mining in 1962.[31] A major share of the company was held by G. & W. Base & Industrial Minerals (Pty.) Ltd. of Johannesburg, Republic of South Africa. The larger part of production was exported in 1965; however, some was consumed locally in oil-well drilling. Markets for the material were said to be uncertain.

Mineral Fuels.—*Petroleum.*—In October a well drilled by the Mozambique Gulf Oil Company in the Pande area, 40 miles from Inhassoro, encountered gas at a depth of 5,316 feet.[32] This was the fourth productive well out of seventeen drilled by the company. All wells have been drilled to depths of from 10,000 to 12,000 feet. The

productive wells, one near Beira and three in the Pande area, have struck gas at depths between 3,000 and 5,000 feet. The Pande area was closer to a potential market, the Johannesburg area; therefore, it has been selected for intensive study. The Beira field will be investigated more thoroughly in the future.

PORTUGUESE GUINEA

Official statistics recorded no exports of metals, minerals and mineral fuels from Portuguese Guinea in 1964 and the first 5 months of 1965. It is unlikely that there was any production of minerals, except minor production of construction materials for local consumption. Total exports in 1964 were 50,110 tons of commodities valued at $5.6 million.[33] During the first 5 months of 1965 total exports were 14,171 tons valued at $1.8 million. In 1964 mineral imports consisted of 6,678 tons of cement valued at $137,785, 10,419 tons of gasoline valued at $930,357; and 10,676 tons of fuel and diesel oil valued at $653,929.[34] During the first 5 months of 1965 mineral imports were cement 4,726 tons valued at $96,964, gasoline 2,965 tons valued at $281,321, kerosine 816 tons valued at $61,893, and fuel and diesel oil 1,835 tons valued at $113,929.[35] In 1964 total imports were 62,249 tons of materials valued at $15.4 million; in the first 5 months of 1965 total imports were 26,084 tons valued at $5.8 million.

Long-term economic development of oil and bauxite deposits was reportedly possible.[36] ESSO Exploration Guiné, a subsidiary of Standard Oil Corp. of New Jersey, was preparing to start oil prospecting in the interior again after 3 years of inactivity. Bauxite deposits of 110,000 tons were reported to occur near the border with Guinea; however, they have not been developed because of transportation and financial difficulties.

The Mineral Industry of Basutoland, Bechuanaland, and Swaziland

By Henry E. Stipp [1]

Metals and mineral production in the British High Commission Territories of Basutoland, Bechuanaland, and Swaziland in 1965 consisted principally of asbestos and iron ore. A number of other commodities were mined in minor quantities. The attainment of full production at Swaziland's Ngwenya iron mine and the increase in coal production at the Mpaka colliery were the most significant events in the mineral industry. Of potential importance to the economy of Bechuanaland was the possibility of exploiting recently discovered copper deposits. The recovery of two large alluvial diamonds in Basutoland was also noteworthy.

The Territories moved closer to a self-governing status in 1965, although Britain retained some responsibility for their economic viability, defense, and foreign relations. Basutoland was scheduled to become independent on October 4, 1966 and will be named the Kingdom of Lesotho. Bechuanaland will become the independent Republic of Botswana on October 1, 1966. Swaziland was to receive internal self-rule in 1966 and was to receive independence at the end of 1969.

BASUTOLAND

The recovery of small quantities of alluvial diamonds by individual Basuto diggers was the only significant productive mineral operation in Basutoland in 1965. A diamond of 103.5 carats was found on September 17 in the Letšeng la Draai diggings, and on October 7 a 527-carat diamond was recovered from these diggings.[2] The number of laborers working at Letšeng la Draai fluctuated between 400 and 600 in 1964. Production of gem diamonds from various diggings in 1965 totaled 2,489 carats valued at $664,785,[3] and industrial stones totaled 3,003 carats valued at $85,160.[4]

The Overseas Geological Survey carried out tests on some kimberlite occurrences and prospected for diamonds in the Orange and Caledon Rivers.[5]

In May the Swaziland Geological Survey, at the request of the Basutoland Government, prospected in the vicinity of Maseru for clay deposits.[6] Preliminary kiln tests indicated that the clay in four fields of the area was suitable for making bricks.

As in previous years Basutoland furnished laborers for work in mines outside the colony, chiefly in the Republic of South Africa. In 1965 the number of Basuto diggers recruited for this work totaled 81,675 compared with 62,985 in 1964.

BECHUANALAND

The mineral industry of Bechuanaland continued to decline in importance to the total economy of the country in 1965. The closing of the only producing asbestos mine and the curtailment of manganese ore mining were blows to the mineral economy. However, a number of other deposits were being explored and their development could be of significance in diversifying the economy of the protectorate, which was chiefly agricultural. Reportedly the system of having mineral rights owned by the tribes in their territories has inhibited mineral development. It was theorized that the control of mineral rights by the Government of Bechuanaland would encourage prospecting by the public and by small companies, thus speeding the discovery of mineral deposits. The number of persons recruited for mining work outside the protectorate averaged about 1,600 persons per month during 1965.

PRODUCTION AND TRADE

Total production of metals and minerals in Bechuanaland decreased again to $251,395 compared with $552,000 in 1964. Asbestos output dropped sharply in 1965, owing to the closing of the Moshaneng mine in November. Production of manganese ore also decreased significantly from that of 1964, because of a reduction in the scale of mining at the Ootse mine. A minor quantity of talc was produced during prospecting in the Moshaneng area. Talc could be of future importance if large scale markets could be developed.

Total exports of metals and minerals were valued at $306,803 in 1965 compared with $399,790 in 1964. This was the lowest value recorded for mineral exports since 1957.[7]

Bechuanaland's import of metals and minerals remained negligible. Chief imports consist of general merchandise, textiles, vehicles and spare parts, maize, and other foodstuffs. In 1964 imports (as measured by domestic sales) of gasoline totaled 1,305,960 U.S. gallons and diesel fuel oil totaled 1,992,240 U.S. gallons.

COMMODITY REVIEW

Metals.—*Copper.*—Roan Selection Trust Ltd. continued to make progress in prospecting by diamond drilling at two occurrences.[8] The company reportedly found limited but encouraging quantities of copper minerals in the Matsitamma area, about 95 kilometers west of Francistown. Geophysical surveying and drilling on a copper-nickel deposit at Sedibe, 95 kilometers southeast of Francistown was started in December 1965.[9]

Iron.—The Overseas Geological Survey prospected a deposit of low-grade iron ore (30 to 35 percent iron) in the Bamangwato Tribal Territory.[10] Reserves were estimated at 85 million tons.

Manganese.—Low-grade ore reserves, believed to be large in size, were found in the Bamangwato Tribal Territory by the Overseas Geological Survey.[11] Plans to mine reserves of battery-grade manganese ore in the Lobatsi Block, reported at yearend 1964, were not carried out, and no other new properties were opened.

Nonmetals.—*Asbestos.*—The Moshaneng mine of Marlime Chrysotile Asbestos Corp. Ltd., was placed on a reduced production basis in June and was closed in November. This relatively small mining company was reportedly susceptible to any increase in production costs and marketing problems.[12]

Table 1.—Bechuanaland: Production of metals and minerals

Commodity		1961	1962	1963	1964	1965
Metals:						
Gold	troy ounces	261	288	142	9	------
Manganese ore	metric tons	28,791	24,002	10,776	24,599	8,815
Silver	troy ounces	39	33	21	1	------
Nonmetals:						
Asbestos, chrysotile	metric tons	1,745	2,155	2,148	1,960	806
Talc	do	------	------	------	------	48

Diamond.—Kimberlite Searches, Ltd., a subsidiary of De Beers Consolidated Mines Ltd., found encouraging indications of diamonds in the northern Bamangwato Tribal Territory, west of Francistown.[13]

Gypsum.—Fairly large deposits of gypsum reportedly have been discovered in the Foley area; however, they are a long distance from the railroad.[14] Because of the low unit cost for gypsum and the lack of a large nearby market, the deposits probably will not be exploited for a long time.

Salt and Soda Ash.—Technical studies were completed on the brines located in the Sua Pan in the Makarikari Pans area, and a detailed technical report was prepared.[15] A market study of the requirement for soda ash and salt in southern Africa was also made; however, no conclusions were reached on the feasibility of the development of these deposits.

Mineral Fuels.—*Coal.*—Although there are extensive deposits of coal (313 million tons) in the Bamangwato Tribal Territory near the railroad line, it was doubtful that they would be exploited in the near future,[16] because of the low quality and high-moisture content of the coal. A market for coal for some industrial purposes might be developed in the Republic of South Africa, but competition from collieries in the Transvaal would make this difficult.

SWAZILAND

The mineral industry of Swaziland continued to increase in importance to the territory's economy, setting new records in production and export of mineral commodities. Employment in the industry totaled 24,199 laborers including 2,438 skilled workers, compared with a total of 20,034 laborers in 1964. Employment of workers for mines outside of Swaziland totaled about 5,800 persons in 1965.

An aerial geophysical survey of Swaziland was scheduled to start in early 1966.[17] The survey will be conducted under a $800,000 grant from a United Nations Special Fund.

PRODUCTION AND TRADE

Total production of metals and minerals were valued at $14.5 million compared with $7.9 million in 1964. Production of asbestos and iron ore accounted for 98.8 percent of total value in 1965. The most significant mineral event of the year in Swaziland was the increased output of iron ore from the Ngwenya mine, which practically reached the planned annual production rate. The increase in the output of coal at the Mpaka colliery was also of interest.

In 1965 Swaziland's exports of crude mineral commodities were valued at $14.4 million compared with $7.9 million in

1964. This was an increase of 82 percent, owing chiefly to larger shipments of iron ore to Japan. Total exports increased 33 percent from 1964 to 1965.[18]

Swaziland's imports come chiefly from or through the Republic of South Africa. Only about 10 percent are imported directly from Mozambique or overseas countries. The principal metals and minerals imported in 1965 were as follows: Gasoline, diesel oil, and lubricating oils and greases valued at $2,633,388; fertilizers valued at $1,663,800; piping for buildings, irrigations, etc. valued at $1,188,630; cement, bricks, and asbestos products valued at $1,292,970; steel reinforcement and corrugated iron valued at $399,000; and plumbing and sanitary fittings valued at $22,780.

COMMODITY REVIEW

Metals.—*Gold.*—The decrease in total output of gold in 1965 was largely the result of the closing of the Waterfall mine, which had been Swaziland's richest producer.[19] Some gold was produced at the mine by reworking the slime dumps. Drilling operations were carried out at the dormant Daisy mine. Two mines in the Forbes Reef area, the She and the Waterfall, were the site of new gold reef discoveries. The reefs were being studied for quantity and grade of ore. The Piggs Peak mine, dormant since 1950, was surveyed thoroughly. The survey indicated a possibility that the mine could be productive again.

Iron Ore.—The Ngwenya open pit mine of Swaziland Iron Ore Development Co. Ltd., reached full production during 1965.[20] A series of holes were drilled to test the attitude and grade of the deposit at depth. A deposit in the Forbes Reef area near the Ngwenya mine was also investigated. Preliminary studies indicated the existence of substantial quantities of siderite ($FeCO_3$) in the area. A deposit of haematite and specularite (Fe_2O_3) at the Iron Hill mine was said to contain 15 million tons of 48.66 percent iron and 22.28 percent silica.[21]

Nonmetals.—*Asbestos.*—The Havelock mine continued to produce on an increasing scale in response to a rise in the price of asbestos fiber. An occurrence of short fiber chrysotile was scheduled to be drilled in early 1966. A quarter of a mile west-southwest of the Havelock mine an asbestos deposit was examined extensively by the Swaziland Mines Department and Mineral Holdings, Ltd.[22] A serpentine structure about 1 mile long and 450 feet in average width, which contained pseudo-asbestos fibers, was discovered in the Umkomazaan Valley near Nottingham Hill. Numerous other small bodies of serpentinites occur in this area.

Barite.—Production recovered after a sharp drop in 1964. New techniques in

shipping the ore to market were said to be responsible for increased sales.

Mica.—Large quantities of mica schist were found in the Mahlangatsha Mountains.[23] It was planned to grind the mica to minus 400-mesh size for use as a filler in paint.

Pyrophyllite.—Production decreased owing to a reduction in mining operations in Swaziland by a producer which also mined pyrophyllite from a deposit in the Transvaal. This latter source had a competitive advantage over the Swaziland deposit, because of lower rail costs to markets.

Mineral Fuels.—*Coal.*—Production increased sharply at the Mpaka colliery of Swaziland Collieries, Ltd. The low-volatile bituminous coal containing 12 to 14 percent ash was extracted from a 7- to 8-foot thick seam dipping 5 degrees east. Reserves were estimated at about 160 million tons. The mine is 95 to 115 kilometers from the port of Lourenço Marques, Mozambique. A 75-ton-per-hour washing plant was constructed and began operating in September. The plant using magnetite as a heavy media eliminates shale and produces a sized, washed product suitable for the export market. In 1965 inadequate rail transportation facilities resulted in decreased sales of coal to consumers in Lourenço Marques and also to the railways. A coal deposit at Maloma owned by the Johannesburg Consolidated Investment Co. Ltd. was being investigated by drilling.

The Mineral Industry of the Democratic Republic of the Congo (Leopoldville) [1]

By Henry E. Stipp [2]

In general the mineral industry of the Democratic Republic of the Congo (Léopoldville) continued to make significant contributions to the economy of the country in 1965; however, some sectors of the industry suffered decreases in production and large financial losses as a result of the disruption of mining, transportation, and communication activities by civil disorder. These disturbances reached their peak in 1964 and early 1965; but by late 1965 they had been brought under control in most areas. Mining companies that had been affected by the disturbances were in the process of replacing lost equipment and personnel, and mining had resumed on a limited scale at the close of 1965.

Total production of metals and minerals increased somewhat over that of 1964, but output of some commodities including gold, tungsten, and diamond, decreased sharply.

Although production of metals and minerals was affected by civil disturbances in 1964 and 1965, mineral exports decreased only moderately, chiefly because of large stocks which had accumulated within the country in previous years.

In 1965, the Governments of the Congo (Léopoldville) and Belgium negotiated an agreement that gave the Congolese Government shareholdings in several mining firms and confirmed the Congo's right to collect taxes from mining companies. Its action of 1964 in dissolving the Comité Special du Katanga, the Compagnie des Chemins de Fer du Congo Supérieur aux Grands Lacs Africains, and the Comité National du Kivu [3] led to the agreement. As a result of the 1965 settlement, the Government of the Congo (Léopoldville) became an important shareholder in Union Minière du Haut-Katanga (UMHK), the largest mining firm in the Congo, with 222,950 of the 1,242,000 shares outstanding.[4]

During 1965 the Government required that all earnings from sales abroad be transferred to the Congo. Later in the year, financial regulations on UMHK were eased in an effort to expand production of copper and cobalt, and thereby improve foreign exchange income. In 1965, UMHK contributed $87.3 million[5] to the state for taxes, export duties, and money derived from the dual rate of exchange.[6] In addition to this direct income, the economy of the country benefited from the numerous UMHK activities in other fields. As the largest non-Government employer in the nation, the company employed 22,366 laborers and 2,247 supervisors in 1965. Of the supervisors, 229 were Africans. Employees and dependents totaled 107,718

[1] Effective July 1, 1966, the name of the capital of the Congo (Léopoldville) was formally changed from Léopoldville to Kinshasa. However, because this change occurred during 1966, too late for inclusion in all yearbook chapters, the old name (Léopoldville) has been used throughout Volume IV of the Minerals Yearbook.

at the end of the year. The company continued to provide vocational and educational training for its employees and their dependents. Attendance at company primary schools totaled 25,972 pupils.

In May four Congolese were named to the UMHK Board of Directors.[7] This was the first time in the company's history that Congolese were given a place on the board. The company also appointed a Congolese as auditor in the Brussels Office.

On August 30, 1965, the President of the Congo (Léopoldville) signed a councilor decrée, which described guarantees accorded private investments in the Congo.[8] Rules applicable to firms engaged in economic activity in the Congo were also defined.

PRODUCTION

Production of most metals and mineral commodities increased somewhat over output in 1964. Commodities produced by firms located in the northern and eastern sections of the Congo, for the most part, decreased in output owing to disturbances caused by the rebellion. The value of metal and mineral production in 1965 was estimated at $278.3 million compared with about $234.3 million in 1964. The rise in output and unit price of copper was chiefly responsible for the 1965 increase.

e Estimated. r Revised.
[1] Does not include data on simple construction materials for which reports are incomplete.
[2] U.S. imports.
[3] Includes production by Union Miniere du Haut-Katanga and Société Metallurgique du Katanga.
[4] Average grade 48 percent.
[5] This represents recorded diamond production; it is estimated that an additional 12 to 14 million carats valued at about $35 million were illegally produced and exported.
[6] For local use only.

TRADE

The Congo (Léopoldville) has had a favorable trade balance for many years, and this continued in 1964, as shown in the following table of trade statistics for 1963 and 1964:

	Value (million dollars) [1]		Mineral commodities share of total (percent)
	Mineral commodities	All commodities	
Exports:			
1963	213.3	307.9	69.3
1964	r 182.3	r 349.7	52.1
Imports:			
1963	48.3	207.7	23.3
1964	39.7	r 288.3	13.8
Trade balance:			
1963	+165.0	+100.2	XX
1964	+142.6	r +61.4	XX

r Revised. XX Not applicable.
[1] Where necessary, monetary conversions have been made at the following rates: Prior to November 1963, CF65 equals US$1.00; since that time, CF150 equals US$1.00 (the official rate). However, the unofficial rate used in actual practice has exceeded the official rate by as much as CF30 per dollar, reaching CF180 equals US$1.00.

Exports of some metals and minerals in 1964 were not as large as those of 1963 owing to disruption of facilities and services, chiefly in the northern and eastern sections of the country; nevertheless export values did not decline as much as did export tonnages because of generally increased world commodity prices. Copper, the most important metal exported, was valued at $85.7 million, followed by cobalt and its alloys valued at $19.0 million, zinc, zinc ore, and concentrate valued at $18.0 million, and tin and tin concentrate with a value of $15.4 million. Diamond was the most valuable nonmetallic mineral export accounting for $28.7 million.

Mineral fuels, chiefly petroleum products, were the highest valued import commodity group, at $19.9 million, followed by iron and steel valued at $14.1 million.

In 1964 Belgium was the principal destination for exports of most commodities from the Congo (Léopoldville), with 50.6 percent of the total value, followed by Italy with 9.6 percent, United Kingdom 9.5 percent, France 6.7 percent, West Germany 5.5 percent, and the United States 5.2 percent. African countries received commodities valued at 3.7 percent of the total value of the country's exports.

Belgium supplied 35.7 percent of the nation's total imports by value while the United States provided 23.8 percent on the same basis. Much of the U.S. exports to the Congo were supplied under United States Agency for International Development and Public Law 480 programs. Other non-Communist European countries shipped 22.9 percent by value of the Congo's total imports, while African countries supplied 10.9 percent.

Table 2.—Democratic Republic of the Congo (Léopoldville): Exports of metals and minerals

Other	--------	6,714	Venezuela 4,734; Canary Islands 1,420.

r Revised. NA Not available.
[1] Includes unwrought, scrap, and semimanufactures.
[2] Crude gold and gold partially worked.
[3] Include with "Other" in 1963.
[4] Includes the following (in tons): Graphite 5, mica 13, carbon black 7, and meerschaum 0.8.
[5] Consists of mineral cinders.

COMMODITY REVIEW

METALS

Cadmium.—The entirety of the country's metallic cadmium output was produced by Société Métallurgique du Katanga (Métalkat), a subsidiary of UMHK. Production included 126 tons of electrolytic cadmium rods,[9] which were produced from cadmium-containing cements prepared by treating 5,493 tons of flue dusts from the Lubumbashi smelter at Elisabethville and by treating 253 tons of dusts from the sulfuric acid plants of Société Générale Industrielle et Chimique du Katanga (Sogechim) at Jadotville.

Cobalt.—Output by UMHK in the year ending January 31, 1965 totaled 8,388 tons compared with 7,676 tons in 1964.[10] Production consisted of 3,474 tons of electrolytic granules, 3,574 tons of commercial-grade cobalt cathodes, 1,315 tons of other types of cobalt cathodes, and 25 tons of other cobalt products. The cobalt electrolysis section of the Shituru plant produced cobalt cathodes, of which some were refined at the plant and some exported. The Shituru refinery also produced cobalt granules, which were sent to the Luilu plant for processing. Principally commercial-grade cathodes were produced by the electrolysis section of the Luilu plant and were refined by the vacuum-degassing section.

Columbium - Tantalum. — Compagnie Géologique et Minière des Ingénieurs et Industriels Belges (GEOMINES) produced 32 tons of columbite-tantalite concentrate

[9] Union Minière Du Haut-Katanga. Rapport Annuel, 1965. May 26, 1966, pp. 5–47.
[10] Page 17 of work cited in footnote 9.

in the fiscal year ended June 30, 1965, compared with 100 tons in fiscal year 1964.[11]

Mining companies in the provinces of North Kivu, Central Kivu, and Maniema reportedly operated at about 70 percent of the 1963 production level, owing to insecurity from rebel activity.[12]

The Société Minière de Lulshe, a company formed by Union Carbide Corp., Compagnie Minière des Grands Lacs Africains (MGL), and Société Kivumines for the development of the columbium (niobium) deposits at Bingo and Lulshe, was constructing a pilot plant at Bingo.[13] The plant was to have a capacity to concentrate from 10 to 20 tons of ore per day and was expected to begin operating in early 1966. The deposits have been surveyed and the Bingo occurrence proved commercially feasible; however, the Lulshe deposit would require a larger investment to exploit and will not be developed until the political situation stabilizes.

Copper.—UMHK, the Republic's only copper mining firm and largest copper metal producer reported output of 287,568 tons in 1965, compared with 275,547 tons in 1964.[14] Electrolytic copper ingots constituted 151,514 tons, cathodes 71,447 tons, blister and other types 64,600 tons, and copper in products amounted to 7 tons of total copper output.

The UMHK subsidiary, Métalkat, produced 1,037 tons of copper in 1965 compared with 1,093 tons in 1964.

The quantity of ore mined by UMHK totaled 8,661,651 tons, which was divided among the various mines as follows:

Mine	Ore production (metric tons)
West group:	
Musonoi	2,458,390
Kamoto	1,496,141
Ruwe	1,523,650
South group:	
Kipushi	1,145,105
Central group:	
Kambove-West	1,103,352
Sesa	271,886
Kakanda	663,127

In addition to the ore extracted, about 17.3 million cubic meters of waste material was removed with the ore. Extraction of ore from the West and Central group mines increased owing to the use of new equipment and improved maintenance of machines. Output from the Kipushi underground mine reached a new high because of increased use of mechanization and better working techniques. Production from the Ruwe open pit mine, which decreased in 1964, rose to its previous rate of output. A river was diverted from the Sesa mine by a tunnel to permit removal of overburden in preparation for open pit operation.

Ore processed by concentrating plants in fiscal 1965 totaled 8,399,419 tons as shown in the following table:

[11] Compagnie Géologique et Minière des Ingénieurs et Industriels Belges (GEOMINES). (Rapports présentés a l'assemblée générale des actionnaires du 14 Décembre 1965) November 1965, p. 2.

NA Not available.
[1] Stocked ores.
[2] Oxide concentrates from retreated materials.

The Lubumbashi smelter of UMHK produced 65,484 tons of blister copper chiefly from Kipushi sulfide concentrates and produced 11,004 tons of crude copper from Kambove and Ruwe oxide ore concentrates. Crude copper was used for preparing soluble anodes at the Shituru electrolytic plant. Flue dusts containing cadmium and germanium recovered for processing at Métalkat's Kolwezi plant totaled 4,103 tons.

The copper electrolysis section of UMHK's Shituru plant at Jadotville produced 114,517 tons of copper cathodes, and the starting-sheet section produced 10,952 tons. Refinery output from two furnaces was 153,374 tons of ingots. Soluble anodes output totaled 28,892 tons. The cobalt-electrolysis section produced 5,379 tons of cathodes, while the refinery prepared 3,546 tons of cobalt granules.

Output of UMHK's Luilu electrolytic plant was 107,481 tons of copper cathodes and 7,982 tons of soluble anodes produced from Kolwezi concentrates.

Gold.—Société Métallurgie Hoboken of Belgium recovered about 835 troy ounces of gold from refining crude copper originating in the Congo (Léopoldville). The gold was returned to UMHK, the producer of the crude copper.[15]

Despite the insurrection that disrupted mining operations, Société Des Mines D'or de Kilo-Moto produced 161,947 troy ounces of gold in 1964 compared with 162,486 troy ounces in 1963.[16] It was reported that an estimated 45,032 troy ounces of the 1964 output was confiscated by the authorities.

Iron and Steel.—The steelworks at Inga, about 50 kilometers north of Matadi, was expected to begin producing in 1972.[17] Annual output was scheduled at 200,000 tons. Iron ore was to be supplied from mines near Kimpako about 125 kilometers northeast of Inga.

Lead. — UMHK's sintering plant and electric furnace at Jadotville produced 1,551 tons of lead in 1965.[18]

Manganese.—In 1965 Société Minière de Kisenge produced 320,000 tons of manganese ore from its Kisenge mine compared with 290,000 tons in 1964.[19] The company's Kasekelesa mine near Lufupa remained inactive. Société Afripile, a subsidiary of Société Minière de Kisenge, was scheduled to begin manufacturing dry cell batteries in a plant at Kisenge, using Congolese material in 1965. Nothing further was reported on this operation at yearend.

Silver. — Société Métallurgie Hoboken returned 1,538,411 troy ounces of silver to UMHK in 1965 which had been recovered from refining crude copper in Belgium.[20]

Tin.—After the liberation of Kalima and Punia from rebel occupation, Syndicat Minière d'Etain (Symétain) moved quickly to resume mining in these areas.[21] Production of cassiterite concentrates containing 75 percent tin totaled 2,762 long tons in 1964 and 3,110 long tons in 1965.

GEOMINES produced 2,372 long tons of cassiterite in fiscal 1965 compared with 2,063 long tons in fiscal 1964.[22]

Production was interrupted for 2 months during the year in the company's Lualaba region holdings. The smelter at Manono produced 1,793 long tons of metallic tin in fiscal 1965.

Zinc.—In 1965, copper-zinc ores from the mine at Kipushi yielded 204,136 tons of concentrates containing 58.37 percent zinc.[23]

Sogechim processed 135,807 tons of concentrates from Kipushi that produced 116,483 tons of sulfuric acid and 112,597 tons of roasted concentrates for UMHK. The latter firm sold 95,155 tons of roasted concentrates to Métalkat and exported 80,898 tons of concentrates. Métalkat remained the Republic's sole metallic zinc producer.

NONMETALS

Cement. — Ciments du Congo (Cico) produced 147,000 tons of cement during the first 11 months of 1965.[24] Monthly production averaged 12,000 tons for the first 6 months but rose to 15,000 tons in July, and this level was maintained through November.

[23] Page 17 of work cited in footnote 9.
[24] Belgo-American Development Corporation. Belgo-American Letter. Ciments du Congo (Cico). January 1966, p. 6.

The company Ciments du Katanga an affiliate of Société d'Etudes et de Gestion de Cimenteries produced 47,756 tons of cement in the fiscal year ending June 1965.[25]

Sales of Société des Ciments Metallurgiques de Jadotville, a subsidiary of UMHK, totaled 18,600 tons in 1965 compared with 12,885 tons in 1964. The plant of Société des Ciments du Kivu was not operative in 1965.[26]

The only cement plant in the Kivu and Maniema area remained closed.[27] This plant near Katana reportedly will resume operations when local consumption increases.

Diamond.—Strengthening of the central Government's mining police was advocated by Société Minière de Bakwanga (MIBA) in order to control illicit diamond production in South Kasai province, especially in reserve zones not being exploited by the company.[28] MIBA recommended that additional personnel and equipment be obtained for the mining police force from donations by other countries.

The United States Government was negotiating to purchase approximately US$20 million of Congolese industrial diamond.[29] Sale of the diamond slated for the U.S. strategic stockpile will aid the Republic's marketing problems and help to stabilize the economy.

A report was published describing the geology of diamond-bearing rocks in the Kundelungu mountain area of Katanga.[30] According to the Congolese Ministry of Mines 28 kimberlite pipes have been located and diamonds of industrial grade were reported to be present in the area. It has not been determined if the deposits are commercially exploitable.

Stone, Sand, and Gravel.—Output of Union Minière's Katonto quarry totaled 128,434 tons after crushing, for ballast and cement manufacture. The company's Kakontwe quarry produced 224,648 tons of limestone in fiscal year 1965 compared with 179,630 tons in fiscal 1964.[31] The Katonto quarry also yielded 29,086 tons of sand.

MINERAL FUELS

Coal. — Charbonnages de la Luena, a subsidiary of UMHK, produced 113,660 tons from the Kaluku coal measures in 1965 compared with 100,190 tons in 1964.[32]

Petroleum.—Machinery and equipment for the refinery to be built by Société Congo Italienne de Reffrinage (SOCIR) at Kinloa near the mouth of the Congo river, was ready for shipment from Italy, however work on the project was at a standstill.[33] A lack of hard currency for procurement of machinery and equipment was the major obstacle in completing the project. Despite the lack of progress on the refinery, SOCIR continued to train Congolese technicians. Most petroleum representatives appeared optimistic about the refinery and future economic prospects of the Congo.

All drilling operations conducted by Société Congolaise de Recherches et d'Exploitation Petrolières (SOCOREP) in the Bas Congo area north of Moanda were stopped.[34] Six persons were employed to maintain disassembled equipment, which was to be shipped to Angola. SOCOREP was preparing to hire a seismological group to carry out further investigations in the area.

The Mineral Industry of Ethiopia [1]

By Walter C. Woodmansee [2]

Total value of Ethiopia's mineral output in 1965 has not been reported but was probably about $6 million. The principal commodities and estimated values were cement, $3.9 million; gold, $855,000; salt, $356,000; and lime, $161,000.[3]

The mineral industry continued to play a minor role in the nation's economy, accounting for less than 1 percent of the gross national product, which was not accurately known but probably was nearly $1 billion during 1965. However, certain events during the year indicated possible new mineral activities. The Ministry of Mines planned increased efforts in mineral exploration, and further efforts were made to attract new industry.

In March Major Assefa Lema was appointed Minister of State for Mines and State Domains, a new post. Late in the year, the Ministry of Mines was under reorganization. The Ministry reportedly had 40 government prospectors and 8 engineers on its staff, and 65 students in training. In December, the Ministry, by letter to the U.S. ambassador, requested the services of five U.S. specialists in mineral development. A draft of a new mining law, which has been in planning for some time, was sent to a U.S. legal firm for review and suggestions. Yugoslav, West German, and U.S.S.R. technicans also were involved in mineral industry development or production.

Ministry of Mines exploration parties were investigating resources of asbestos, iron, nickel, platinum, and tungsten, the latter at Yubdo in Wollega Province. Potash mine development continued at Dallol and could represent the largest private investment in the country's mineral industry if plans are carried out in 1966. Progress was made on a new galvanizing and corrugated sheet plant at Asmara, Eritrea. The new Addis Ababa cement plant was in full production and another plant was completed late in the year.

Petroleum exploration was underway by three companies, of which one drilled unsuccessfully in the Ogaden desert, the second started drilling in the Red Sea off the coast of Eritrea, and the third made plans for drilling in a nearby offshore area.

PRODUCTION

There were few marked changes in mineral production activities. For the first time in several years, data were made available on gold mining in the Kebre Mengist (formerly Adola) goldfields. Manganese mining apparently continued at the Tigre concession at Enkafala, about 20 kilometers southwest of Dallol, although production was not reported. Cement output more than doubled as production at the new Addis Ababa plant reached capacity. Clays, limestone, and brick were produced in the vicinities of major cities for local construction use. Gypsum was used primarily in the cement industry.

---

[1] T. J. Burke, U.S. Embassy, Addis Ababa, provided information helpful in the preparation of this chapter.

[3] Where necessary, values have been converted from Ethiopian dollars to U.S. dollars at the rate of Eth$1=US$0.4032.

Table 1.—Ethiopia: Production of metals and minerals [1]

(Metric tons unless otherwise specified)

Commodity [2]	1961	1962	1963	1964	1965
Metals:					
Gold—troy ounces	47,029	28,015	e 27,300	e 27,300	24,236
Manganese ore, shipments	7,000	6,000	[3] 3,496	[3] 3,248	NA
Platinum, placer—troy ounces	e 180	e 180	e 180	e 180	352
Nonmetals:					
Cement—thousand tons	30	41	34	e 44	96
Feldspar	3,000	432	e 500	e r 1,000	-----
Gypsum	NA	NA	NA	e r 1,000	e 2,500
Kaolin	4,000	1,000	e 500	e 500	e 200
Lime [4]	4,538	5,488	4,408	e 6,000	e 4,000
Salt [4]—thousand tons	151	198	255	263	188

e Estimate. r Revised. NA Not available.

[1] Includes Eritrea.

[2] In addition to commodities listed, Ethiopia has produced small quantities of asbestos, barite, copper ore, lead ore, iron ore, mica, pumice, sulfur and various construction materials, but quantitative data are not available.

[3] U.S. imports.

[4] Data are for years ending September 10.

TRADE

Available trade data for 1964 and 1965 are incomplete, particularly with regard to sources and destinations. The major mineral export during these years was salt, valued at $301,000 in 1964 and $270,000 in 1965 (about 80 percent of total mineral export value), and shipped mainly to Japan.

Available information on imports indicates the following sources of metals and minerals during 1964:

Commodity	Principal sources, 1964 (metric tons)
Iron and steel semimanufactures:	
Bars	Italy 2,335; Belgium-Luxembourg 1,339.
Plate and sheet	Japan 13,712; Belgium-Luxembourg 1,753.
Tubes, pipes, and fittings	Belgium-Luxembourg 974; Italy 499; Japan 284.
Wire	U.S.S.R. 1,130; Italy 755.
Lime, cement, and other construction materials	Israel 8,171; Yugoslavia 4,810.
Petroleum refinery products	Iran 97,031; Saudi Arabia 24,370.

Principal mineral imports during 1965 were petroleum refinery products, $9.4 million ($9.5 million in 1964); iron and steel, $5.5 million ($6.3 million in 1964); and various nonmetals, $1.97 million ($1.9 million in 1964). The relationships between mineral and total trade during these years were as follows:

	Million dollars		Mineral commodities' share of total trade, (percent)
	Mineral commodities [1]	All commodities	
Exports:			
1964	0.4	105.8	0.4
1965	0.4	117.0	0.3
Imports:			
1964	18.0	124.0	14.5
1965	17.5	133.4	13.1
Trade balance:			
1964	−17.6	−18.2	XX
1965	−17.1	−16.4	XX

XX Not applicable.

[1] Values given are for only those commodities listed in table 2 of this chapter.

COMMODITY REVIEW

METALS

Copper.—The Ministry of Mines conducted a drilling project at the Adi Rassi prospect. Four holes, totaling about 2,000 feet, were drilled. Results are not known, but Ministry officials reported that a U.S. firm was interested in development of the property.

Drilling of another prospect, on Mount Saccar, near the Asmara-Massawa road about 50 kilometers from Asmara, Eritrea, was planned, but information on the project was lacking. A Yugoslav firm, Rudis, had been awarded a drilling contract for 2,000 meters in 1964.

Gold.—The Kebre Mengist goldfields accounted for more than 95 percent of reported gold output. The remainder came from a small mine southeast of Lake Margareita in southern Ethiopia. Ministry of Mines officials believe that substantial quantities, produced by prospectors in various parts of the country, remain unreported.

In April a new $1.4-million, 1,500-kilowatt, hydroelectric plant on the Mormora River began providing electric power to the Bore and Shanka placer projects in the Kebre Mengist goldfield. According to the Ministry of Mines, gold reserves there are considered sufficient for 10 years of operation.

Iron and Steel.—Steel Co. of Ethiopia was incorporated to operate a proposed sheet plant at Asmara. The company is privately owned, comprising Ethiopian, United Kingdom, Indian, and Italian shareholders. In July further private subscription and public sale of shares was announced. The plant will produce plain and galvanized sheet, including corrugated sheet, and related steel products.

Nickel.—Discovery of two deposits was reported by the Ministry of Mines, but details on tonnage and grade are incomplete. A garnierite deposit totaling 60,000 to 70,000 tons was found near the Kebre Mengist goldfield. A nickel-bearing serpentine deposit, containing 1 to 4 percent nickel, also was reported but the location was not disclosed.

NONMETALS

Asbestos.—A deposit discovered in large quantities, near Kebre Mengist, in 1964 was under further investigation. Another discovery was reported at Harrar from which asbestos samples were sent to the United States for analysis.

Cement.—The plant at Addis Ababa, which was financed and built by a Yugoslavian firm, went into production in August 1964. Technical difficulties with clay raw materials and the heat-exchange system were overcome and the plant was operating at the planned 70,000–ton–per–year rate. In September construction started on an asbestos cement sheet and pipe plant integrated with the cement plant. The Ethiopian Government will hold the major interest in this new plant.

Operating tests were conducted at the new cement plant at Massawa in late 1965. Full production was expected in 1966. The $4.7-million plant was built by Freidrich Krupp Maschinen und Stahlbau for Eritrea Cement Share Co., in which the Ethiopian Government is the major shareholder. In May, a rail spur was under construction from the plant to the Massawa-Asmara-Agordot rail line. A loading pier at Massawa and road construction were planned. Products are super-, high-, and common-quality cement. The rated annual capacity of 70,000 tons can be doubled when sufficient demand has developed.

Total cement capacity of the Addis Ababa, Massawa, and the older Dire Dawa installations is 180,000 tons per year. Domestic consumption is increasing and was estimated to be 140,000 tons at yearend.

Potash.—Development at the Dallol deposit, Tigre Province, included a 300-foot shaft and about 1,000 feet of drift. Sampling indicated a grade of 30 percent K_2O. A pilot plant for treating 2 to 3 tons of crude potash per day was built late in the year.

The future of the project was uncertain at yearend. The concession contract between the Ethiopian Government and Ralph M. Parsons Co., Los Angeles, Calif., was renegotiated in late 1964, permitting the Parsons Co. to defer exploitation until November 1965. If exploitation ensues, a total investment of $40 to $50 million was planned. Planned mine capacity was 600,000 tons per year. A processing plant for a product of 60 percent K_2O also was scheduled.

MINERAL FUELS

Petroleum.—Exploration was concentrated in the Ogaden desert (Elwerath Oil Co.) and the Red Sea coast of Eritrea (Gulf Oil Co. of Ethiopia and Mobil Petroleum Ethiopia, Inc.). Elwerath, holding a 185,000-square-kilometer concession, completed a 10,044-foot wildcat well (dry), the fourth unsuccessful well on the mainland. Geophysical work continued, but preliminary indications were unfavorable, according to company sources.

Exploration by Gulf included 1 month of airborne magnetometer survey, 3 months of seismic work, 2 months of marine seismic work, and 3 months of geological study on its 28,250-square-kilometer concession along the coast and offshore, opposite and south of Massawa. In December a wildcat well was spudded in offshore, near Massawa, on the Nola III drilling platform.

Mobil concluded 8 months of shallow water seismic, 1 month of land seismic, 6 months of gravity survey, and 1 full year of geologic work on its 10,400-square-kilometer tract, north of Massawa. Study and interpretation of field data were underway. The company planned offshore drilling in 1966 from the same platform employed by Gulf.[4]

Ethiopia's first oil refinery, at Assab, was scheduled for completion in late 1966, several months behind the original planned date. Rated capacity is 10,000 barrels per day, and 2,000 barrels per day for catalytic reforming. The U.S.S.R. provided financial and technical aid during construction of the $13-million plant. The Ethiopian Government expects to save substantial foreign exchange with domestic production of refinery products; imports of these products cost about $9.4 million annually during 1964–65.

The Mineral Industry of Gabon

By Henry E. Stipp [1]

The mineral industry of Gabon made significant contributions to the economy of the country as advances in production of the principal mineral commodities continued. The 1965 value of mineral production at $52.9 million [2] was equal to almost 15 percent of the gross domestic product estimated at $354 million in 1965.

Gabon had a positive trade balance in mineral commodities as well as in total trade in 1965. Exports of mineral commodities valued at $51.3 million were 23 percent larger than those of 1964. Imports of mineral commodities also increased, totaling $8.4 million or about 11 percent greater than imports in 1964.

The Government of Gabon's 5-year development plan for 1966 to 1970 provided for total investments of $385.7 million. The mineral industry was scheduled to receive $109.6 million or 28 percent of total investments. The sum of $102 million will be spent on road maintenance and completion of major road networks. A deep-water port at Owendo will be created under the plan. However, the Owendo-Belinga railroad will only be started under this 5-year plan. Foreign private investment was to provide for 61 percent of total expenditure during the period. Foreign aid and domestic fiscal revenue was to contribute 26 percent and 13 percent, respectively, of financial requirements.

PRODUCTION

Substantial increases in production of Gabon's principal mineral products were recorded in 1965. Output of manganese ore increased 35 percent compared with that of 1964, uranium concentrate increased 24 percent, and crude petroleum increased 19 percent. Gold production decreased 13 percent compared with 1964 production.

NA Not available.

[1] In addition to commodities listed, construction materials such as clays and sand and gravel were also produced, but no quantitative data are available.

[2] Manganese content 50–53 percent.

TRADE

Gabon's minerals trade in 1965 consisted principally of exports of gold, manganese ore, uranium concentrate, and crude petroleum. Shipment of manganese ore increased 30 percent over that of 1964, and crude oil export increased 20 percent; however, uranium concentrate shipments were less than 1 percent greater than those of 1964, and gold export decreased 1 percent. Imports of mineral commodities, far exceeded on a value basis by mineral exports, consisted chiefly of iron and steel products, cement, and petroleum refinery products. Iron and steel imports increased almost 16 percent over those of 1964 while cement imports decreased 1 percent and imports of refinery products increased 0.4 percent over those of 1964. The relationship of trade in mineral commodities to total trade has been summarized in the adjacent table:

	Million dollars		Mineral commodities share of total trade (percent)
	Mineral commodities [1]	All commodities	
Exports:			
1964	41.7	90.1	46.3
1965	51.3	97.0	52.8
Imports:			
1964	7.6	55.7	1.4
1965	8.4	62.5	1.3
Trade balance:			
1964	+34.1	+34.4	XX
1965	+42.9	+34.5	XX

XX Not applicable.

[1] Values given are only for those commodities listed in tables 2 and 3 of this chapter.

France continued to be Gabon's principal trading partner in 1965 receiving 49 percent (by value) of total exports, while supplying 58 percent of Gabon's total imports. The United States was also an important trading partner of Gabon receiving 18 percent (by value) of the latter's total exports and shipping 12 percent of Gabon's imports. Other countries that conducted significant trade with Gabon were West Germany, United Kingdom, and Netherlands.

COMMODITY REVIEW

METALS

Chromite.—Mineral resource studies conducted by the Bureau De Recherches Géologiques Et Minières (BRGM), for the Government of Gabon, indicated the occurrence of chromite in the vicinity of Boone and Makokou, along the route of the proposed railway from the Port of Okanda to Belinga.[3]

Copper.—Detailed investigation of copper indications previously discovered in the Boone-Makokou area showed that the mineralization was not extensive. A general geologic and prospecting survey, conducted by BRGM in an area to the west of the valley of the Ofooué River southeast of Etéké indicated that geologic conditions were favorable for the occurrence of deposits of copper in rocks similar to those of the Republic of the Congo (Léopoldville).

Gold.—Société Gabonaise de Recherches et d'Exploitation, a government-controlled company produced 37,134 troy ounces (1,155 kilograms) of gold from alluvial deposits in the districts of Etéké, Lastourville, Makokou-Belinga, N'Djole, and M'Bigou. A large part of the output came from the deposit N'Dangui near Lastourville, in east-central Gabon. Most of the gold was exported to France. However, a small quantity was used by local artisans for producing jewelry. The BRGM conducted a detailed study of gold deposits in the Etéké region for the Government of Gabon.[4] Results of the study were said to warrant further investigation.

Iron Ore.—Geologic surveys and studies conducted in 1964 by BRGM for Syndicat de Recherches de Fer et de Manganèse dans Nord-Gabon established the existence of a large deposit of high-grade iron ore near Minkebe, 72 kilometers northwest of Belinga.[5] Ore reserves have been estimated to be at least 1 billion tons containing 60 to 65 percent iron. The deposit will be exploited by Société des Mines de Fer de

[3] Bureau De Recherches Géologiques Et Minières (Paris). Rapport Annuel 1965. Dec. 31, 1965 pp. 52–53.

[4] Work cited in footnote 3.

[5] Work cited in footnote 3.

Mekambo (SOMIFER), a consortium of United States and European firms. By 1972 the mines are expected to be producing at a rate of 5 million metric tons annually.[6] Later, extraction will be increased to 10 million tons of ore annually. The ore will be transported by rail about 560 kilometers to the port of Owendo, near Libreville. Sedes, a French engineering bureau, made a study on the economic effects of exploiting the Minkebe iron ore deposits and constructing a railway from Belinga to the port of Owendo.[7] Installation of the mining complex at Belinga and port facilities at Owendo reportedly will cost the SOMIFER consortium about $137 million. The railway will cost about $133 million. It will be integrated with the existing system and operated by the National Railways Administration. The work will be financed by a group consisting of the International Bank for Reconstruction and Development, the United States Agency for International Development, the European Investment Fund, France, and West Germany.

Lead and Zinc.—Research was conducted by BRGM on possible lead-zinc occurences in the Cretaceous marine series in the vicinity of Lake Azinga.[8] Results of the survey were negative; however, an investigation of formations along the coast north of Libreville and Mayanmba indicated areas favorable for concentrations of heavy minerals.

Manganese.—Production of manganese ore in 1965 was valued at about $29 million, almost 56 percent of the total value of Gabonese mineral production. Compagnie Miniere de l'Ogooue (COMILOG) mined all the ore produced in Gabon from its Moana mine in the upper section of the Ogooue River. The deposit, consisting of a 10- to 25-foot-thick bed of ore under a barren capping of about the same thickness, occurs in several plateaus near the village of Moana.[9] Proved ore reserves were estimated at 200 million tons containing 48 to 50 percent manganese. As of 1965, trucks with a capacity of 30 tons hauled ore from the opencast mine to the washing plant where it was crushed at the rate of 450 tons per hour and washed in two countercurrent rotating drums. The product of this operation was a lumpy ore carrying 50 to 53 percent manganese, 5 to 10 percent water, 2 to 4 percent iron, 1 to 3 percent silica, 5 to 7 percent alumina, and 0.09 to 0.13 percent phosphorus. A small quantity of ore was concentrated on vibrating tables yielding a product containing 83 to 85 percent manganese dioxide for use as a depolarizing agent in dry cell batteries.

Uranium.—Compagnie des Mines d'Uranium de Franceville produced uranium ore valued at about $8.7 million from its Maunana mine, about half way between Libreville and Lastourville. Here an entire industrial center and a community for 1,000 workers and their families have been established.[10] The industrial complex, completed in March 1961, includes two separate extracting and processing sections. The open-pit mine has been worked to a depth of 230 feet and also some mining was done in underground shafts sunk in 1964. Ore, hauled to the crusher station and processing plants by a system of trucks and conveyor belts, was pulped, treated with sulfuric acid, and reacted with magnesium to precipitate magnesium uranate, containing about 15 percent uranium metal. The magnesium uranate was filtered, dryed, and stored for shipment to France. Another local facility produced sulfuric acid and energy for plants furnishing electric power to the complex.

NONMETALS

Cement.—The plan to erect a cement plant near the port of Owendo was delayed[11] when a new study indicated that it would be economically more advisable to establish the plant near the calcareous deposit on the island of Coniguet, near Libreville. Moreover, capacity of the plant has not been determined. The originally proposed 100,000-ton annual capacity would far exceed 1965 national consumption, estimated at about 35,000 tons, and markets for the remaining 65,000 tons per year would be difficult to develop because neighboring countries such as Cameroon have plans to erect similar plants. The administrative council of Société des Ciments Portland Gabonais was studying plans to install

a plant with a capacity of 50,000 tons sufficient to cover anticipated national requirements.

Diamond.—BRGM made a study of diamond mineralization in areas near Franceville, Etéké, and Mitzic.[12] Two groups of stones were distinguished, one of dendritic origin and the other group which reportedly originated in kimberlite rock.

Fertilizer Materials.—*Phosphates.*—Studies were conducted by BRGM on indications of phosphate deposits, discovered by Société Pétrolieres in a sedimentary basin north of the Iquela Lagoon, near the coast about 160 kilometers south of Port Gentil.[13]

MINERAL FUELS

Petroleum.—Production of crude oil, the second largest mineral industry activity in Gabon, increased over 19 percent compared with that of 1964. Exports in 1965 were valued at $14.7 million, 15 percent of total export value. Proved petroleum reserves were estimated at 170 million barrels in 1965. Société des Pétroles d'Afrique Equatoriale (SPAFE) held concessionary exploration rights in the area extending from somewhat north of Libreville to somewhat south of Pointe Noire in the Republic of Congo (Brazzaville).[14] Shell Gabon (formerly Compagnie Shell pour Recherches et Exploration au Gabon), the only other producer in Gabon, held exploration rights on a 50-percent basis with SPAFE in three areas, Sette Cama, Sette Cama South, and Sette Cama West. Fields at Cap Lopez, Pointe Clairette, Techengue, M'Bega, and Ozouri, all owned by SPAFE, reportedly were nearing exhaustion. The recently discovered Anguille field, owned by SPAFE and located west of Sette Cama, and the Gamba field, jointly owned by Shell Gabon and SPAFE and located south of Sette Cama were considered to be bright spots for the future. Reserves in the Anguille field were unknown as only four wells have been drilled to a depth of 2,000 meters. Reserves in the Gamba field were estimated at 75 million barrels of 33.5° gravity crude oil.[15] Sixteen of 22 wells drilled here have struck oil in a sandstone of Cretaceous age at 3,000 to 4,000-foot depths.

SPAFE and Shell Gabon collaborated in an extensive survey program. A seismic survey was being completed on the Lambarene area, and seismic survey teams were based at Koumaga and near Diema.

An oil line, 7 kilometers long, was being constructed from the Gamba field to take crude oil out to tankers waiting at sea.

The oil-producing industry employed about 1,600 Africans and 155 Europeans in 1965, and there were 104 Africans and 2 Europeans employed in oil products distribution.

Shell de l'Afrique Equatorial et du Cameroon, a separate company from Shell Gabon operated depots for gasoline distribution at Libreville, Alembe, Lambarene, N'joli, and Mayonomi. It was estimated that Shell had about 30 percent of the market for petroleum products, Mobil Oil de L'Afrique Equatoriale about 25 percent, Société des Pétroles BP d'Afrique Occidentale 24 percent, a subsidiary of Texaco Inc. 9 percent, a subsidiary of Compagnie Francaise des Pétroles 8 percent, and a subsidiary of Petrofina, S.A. had about 4 percent of the market for petroleum products.

The work of constructing the refinery at Port Gentil was awarded to the Société parisienne pour l'Industrie Electrique.[16] Société Foster Wheeler Francaise will be responsible for the engineering on the refinery, which was expected to be completed by the close of 1967.

The Mineral Industry of Ghana

By Roderick G. Murchison [1] and Walter C. Woodmansee [2]

Although Ghana produced only a limited number of mineral commodities in 1965, the country maintained a significant world position as a source of several commodities, including diamond, manganese ore, gold, and bauxite. Gold followed cocoa as Ghana's second largest source of foreign exchange. Preliminary data indicate that the value of mineral output (except refined petroleum) was about $60 million, an estimated 3 percent of a gross national product of $2,035 million (current prices).[3]

In January, a Soviet geological survey group of 40 exploration technicians became an integral part of the Ghana Geological Survey. The Soviet group totaled 84 in 1963 and 65 in 1964.

Throughout the year the minerals industry was hurt by the continuing inflationary trend, increased taxation, shortages of mining supplies and equipment, and stricter regulations on import licenses, including licenses for items essential to mine production. In spite of these problems, Ashanti Goldfields Corp. Ltd., the large, private gold producer, and Consolidated African Selection Trust Ltd. (CAST), continued substantial expansion programs. During the year the Government passed a Minerals and Metals Act, Sales Tax Act, Social Security Act, and Foreign Travel Tax Act, all affecting mineral operators. The Minerals and Metals Act, passed by Parliament in March, created a Ministry of Mines and Mineral Resources, charged with regulating the mineral industry. This marked the first time in Ghana's history that a ministry was created solely for the administration of the country's mines and mineral resources. The new legislation granted the Ministry authority to inspect mines and mineral properties, to require operating companies to provide production data, to set fees for mineral licenses and permits, and to establish mineral policies, including policies regarding conservation.[4] In May a new section, concerned with diamond and gold sales and defining offenses for illegal activities, was added to the Act.

Under the Social Security Act, effective July 1, 1965, companies were required to contribute to the fund a sum equal to 15 percent of total wages paid. The Sales Tax Act placed an 11.5 percent tax on all petroleum products and a gasoline tax of 7 cents per gallon.

The Government assumed control over several sectors of the mineral industry; by yearend the following State-owned agencies had been incorporated: State Brick and Tile Corp., State Diamond Marketing Corp., State Diamond Mining Corp., State Gold Mining Corp., State Marble Works Corp., State Metal Industries Corp., Kwame Nkrumah Steelworks Corp., and Sheet and Metal Works Corp.

Ashanti Goldfields was supplied with hydroelectric power from the new Volta River Dam at Akosombo in 1965, improving the company's financial position. Volta Aluminium Co. Ltd. (VALCO), the new aluminum producer, was connected to this power source in September. Other gold-mining operations also were expected to receive Volta hydroelectric power.

The mineral industry ranked third, after cocoa and timber, as an employer among industries earning foreign exchange. Di-

[1] Regional minerals attache, U.S. Embassy, Accra.

[2] Physical scientist, Division of International Activities.

[3] Department of State, Agency for International Development, AID Economic Data Book. Where necessary, values have been converted from Ghanaian pounds (£G) to U.S. dollars at the rate of £G1 = $2.80. On July 19, 1965, a new decimal currency, the cedi, was introduced; the conversion rate is 1 cedi = $1.17.

[4] U.S. Embassy, Accra, Ghana. State Department Airgram A-368, Mar. 21, 1965, p. 3.

rect employment in the mineral industry was 25,000 to 26,000 Africans and about 500 non-Africans, according to the Ghana Chamber of Mines and the Central Bureau of Statistics. Distribution by operation at yearend was as follows:

Operation:	*Africans*	*Non-Africans*
Gold	18,396	344
Diamond	3,263	75
Manganese	2,300	27
Bauxite	465	15
Salt	420	—
Iron and steel	400	7
Refined petroleum	320	50

In addition, an estimated 8,000 African contract diggers worked government-allotted mining leases for diamonds early in the year, but at yearend the number had substantially decreased. In addition, 258 Africans and 18 non-Africans were engaged in mineral prospecting. The number of expatriates in the mining industry decreased by 102, due to continued Africanization and to difficulty in hiring suitable staff from overseas.

PRODUCTION

As in recent years, gold, diamond, refined petroleum products, manganese ore, and bauxite were the essential mineral commodities produced. Bauxite and manganese mining showed increases in 1965, whereas gold and diamond mining and output of petroleum products were lower. Gold mining was adversely affected by depleted reserves at Government-operated mines. Heavy illegal traffic in diamond continued, and a drop in individual digger production on government leases caused a lower recorded output in the diamond industry. Delays in receipt of foreign crude oil caused occasional refinery output losses.

Ghana's first steel production was reported from the new steelworks, which operated intermittently and produced only 8,000 tons of mill products. The first cement plant went into production in January, and a second was under construction at yearend.

e Estimate. r Revised.

[1] In addition to commodities listed, cement production started in 1965, but output data are not available. Stone was quarried; output was 1.5 million cubic yards in 1964.

TRADE

Metal and mineral trade showed a favorable balance in 1964, the latest year for which complete data are available, but the total trade balance remained in deficit as follows:

	Million dollars		Mineral commodities share of total trade (percent)
	Mineral commodities [1]	Total trade	
Exports:			
1963	54	299	18.1
1964	63	317	19.9
Imports:			
1963	53	365	14.5
1964	59	340	17.4
Trade balance:			
1963	+1	−66	XX
1964	+4	−23	XX

XX Not applicable.
[1] Values given are for only those commodities listed in tables 2 and 3 of this chapter.
Source: Statistical Office of the United Nations. Values for gold exports, not listed in UN statistics, have been included.

Values for the three leading mineral exports, which comprised 92 percent of total mineral exports, were as follows in 1964: Gold $28.9 million, diamond $17.1 million, and manganese ore $12.1 million. The principal recipients of Ghana mineral commodities were United Kingdom, $36.0 million, including all gold shipments; Japan, $11.3 million; Belgium-Luxembourg, $7.1 million; Netherlands, $6.4 million; and United States, $4.4 million. In addition, mineral commodities valued at $146,000 were reexported in 1964.

Principal metal and mineral imports in 1964 were as follows: Iron and steel, $18.5 million, largely from the European Economic Community; crude petroleum, $14.4 million; cement, $11.6 million; nonferrous metals, $4.9 million; and refined petroleum products, $4.7 million. The United Kingdom continued as the main source of these materials, providing goods valued at $11.8 million, followed by West Germany, $11.6 million; Nigeria, $9.4 million; U.S.S.R., $5.6 million; and Libya, $5.2 million.

Data available for most of 1965 indicate a continued overall trade deficit and favorable balance in mineral commodities. Mineral exports for January through November were valued at $60.9 million; corresponding imports were $51.8 million. Gold, diamond, manganese ore, and bauxite continued as chief mineral exports, although gold exports apparently declined by about 7 percent. The United States received 204,000 tons of manganese ore, valued at $5.5 million, during this period.

COMMODITY REVIEW

METALS

Aluminum.—Construction on the Volta Aluminum Co. Ltd. (VALCO), $128 million reduction plant at Tema was about 30 percent completed at yearend. Target date for plant completion was April 1967. The project was partially financed by an Export-Import Bank credit of $98 million. With a total work force of 4,000, VALCO was a major employer during the year. Initial plant capacity was reported in various sources as 100,000 to 130,000 tons of ingot annually. Plans called for the use of imported alumina, at least during the early years of operation, and export of ingot.

Electric power from the Akosombo Dam was delivered to Tema in September. VALCO contracted with the Volta River Authority for up to 300,000 kilowatts annually for 30 years.[5] Dedication ceremonies for the official opening of the dam were announced for January 1966.

Ghana Aluminium Products Ltd., a fabricating company jointly owned by the Gha-

[5] The Financial Times (London). Jan. 24, 1966.

naian Government and Aluminium Ltd. of Canada, continued to operate at only partial capacity because of continuing shortages of raw materials and equipment.

Bauxite.—Mine production at Owaso by British Aluminium Co. Ltd (BAL), of which Reynolds Metals Co. owns 47.7 percent, was stepped up to a record high level, largely due to improved ore haulage from mine to washing plant. Late in the year, BAL was engaged in the development of a second deposit in the area.

The Ghana Geological Survey, in cooperation with Kaiser Engineers, Inc., carried out a series of small drilling projects on bauxite deposits in the Volta region. Results of those investigations were not made public.

Gold.—Mine output of gold declined appreciably in 1965, due mainly to smaller output at State Gold Mining Corp. properties. The only privately owned gold company, Ashanti Goldfields Corp. Ltd., reported mining activities and earnings for the fiscal year ending September 30, 1965, at a level similar to 1964. Ashanti produced 461,336 troy ounces from 528,000 tons of ore at its Ashanti, Ayeinm, and Justice mines during calendar year 1965, 61 percent of the total Ghanaian gold output, 3 percent more than in 1964. During the company's fiscal year, sales were 466,953 ounces from ore with an average grade of slightly over 1 ounce per ton and with a 88.99 percent recovery. Gross value of output was $16,487,000; working profit was $5,887,000 ($5,938,000 in 1964) of which $3,718,000 was paid in taxes to the Ghanaian Government. The company reported ore reserves totaling 3,344,760 tons at 1 ounce per ton, as of September 1965. Total operational cost was $16.14 per ton, $0.35 less than in 1964, a cost reduction attributed to savings in electric power costs and the use of ammonium nitrate for blasting. In September, Ashanti became the first large industrial consumer to obtain power from the Volta River Authority's new Akosombo Dam. The company estimated that this new power supply would save $600,000 to $700,000 annually, although new taxes would absorb more than half of this savings.[6]

The State Gold Mining Corp., a new State-owned holding company which owned and operated six mines at yearend, produced 293,855 troy ounces, a decrease of 21 percent from 1964 production. Shortage of foreign exchange for supplies and equipment and continued attrition of expatriate technicians contributed to the decline in output, but the major factor was the failure to develop new ore as reserves were depleted. The State Gold Mining Corp. replaced the State Mining Corp. in February. Operating gold-mining companies under its control at yearend were Amalgamated Banket Areas (ABA), Ariston-Ghana Main Reef, Bibiani, Bremang Gold Dredging, and Konongo. Two of these Government mines experienced shutdowns varying from 2 weeks to 1 month on several occasions due to shortages of cyanide and other mill reagents.

The Konongo mine and its installations and equipment were purchased by the State Gold Mining Corp. from Konongo Gold Mines Ltd. of Consolidated Goldfields Group, effective April 1, 1965, after lengthy negotiations. The former private operator had worked out the minable ore and had scheduled mine shutdown for March. The new Government management planned new mine exploration by the Geological Survey of Ghana and temporary mill shutdown in July. Employment was reduced at the mine, and attempts were made to transfer workers to other State-operated mines. At yearend the former owner was unable to liquidate its assets in Ghana and distribute funds in London because of a lack of sterling coverage in Ghana.

In late 1964, construction began on the $800,000 Tarkwa gold refinery with proposed U.S.S.R. financial and technical assistance. Planned annual capacity was 1 million ounces of standard 98 percent gold bullion and byproduct silver. At yearend 1965, the building was completed except for connection to electric power and water supply, but U.S.S.R. technical personnel and equipment had not arrived.

Iron and Steel.—The 30,000-ton-per-year Kwame Nkrumah Steelworks at Tema completed its first full year of operation. The plant operated at less than one-third of capacity; output was only 8,000 tons of steel reinforcing bars and angles. Production was handicapped by shortages of domestic scrap, foreign exchange for pur-

[6] Ashanti Goldfields Corp. Ltd. Sixty-ninth Annual Report and Statement of Accounts for the Year Ended 30 September 1965. London, 20 pp.

chase of foreign scrap, equipment, and experienced staff.

Manganese. — Production and foreign sales of manganese ore by African Manganese Co. Ltd., subsidiary of Union Carbide Corp. and the only manganese producer in the country, increased from its Nsuta mine. Demand was greater for low-grade carbonate ores. The operating company conducted research on beneficiation of the carbonate ores and built a vertical kiln for a pilot plant operation.

Exports during January-November 1965 included 43,345 tons of battery-grade ore and 530,517 tons of ore containing 30 percent or more manganese. Total value was about $13.4 million. The United States received 25,269 tons of battery-grade ore, valued at nearly $1 million, and 179,162 tons of plus 30 percent manganese ore, valued at $4.4 million. A total of 196,564 tons of plus 30 percent ore was shipped to Norway.

NONMETALS

Cement.—In January, the country's first domestic cement was made at the $1 million Tema Cement Works, which has capacity of 200,000 tons per year and was part of the Tema Harbor expansion program. The plant was built by Parkinson Howard (Ghana), Ltd.[7]

Clinker grinding started at Tema in May. The plant used imported raw materials, but development of nearby limestone deposits was planned. Construction was by Parkinson Howard and Associated Portland Cement Manufacturers Ltd., both United Kingdom-based firms.

Another cement plant was under construction at Takoradi Harbor late in the year. A Polish state enterprise had an estimated $3.9 million construction contract.

Diamond.—Continuing a decline started in 1961, recorded output was nearly 16 percent below the 1964 total and 30 percent below that of 1962, the last year of a free diamond market in Ghana. Exports in 1964 were valued at $17,137,000.

Production by Consolidated African Selection Trust Ltd. (CAST) has been expanded gradually, but reported output by direct employees at Government mines and by contract diggers (individual African miners) on Government leases has fallen off substantially, at least in part because of false declarations by diggers and Government restrictions on licensing. Output in thousands of carats during 1961–64 was as follows:

Year	Consolidated African Selection Trust Ltd.	Diggers	Total
1961	1,966	1,248	3,214
1962	2,264	944	3,208
1963	2,119	559	2,678
1964	2,289	379	2,668

CAST was in the midst of an $8 million expansion program during which the company expected to raise output to 2.5 million carats in 1966. In June 1965 company production was at an annual rate of 2.1 million carats.[8] A new $3-million No. 12 washing plant with annual capacity of 655,000 cubic yards and theoretical maximum recovery of 1 million carats per year went on stream at Akwatia on the Birim River in June. CAST planned to finance a large part of its expansion program by reinvesting company profits for about 3 years.

In February the Ministry of Trade announced in Parliament that the Diamond Marketing Board was reconstituted as the State Diamond Marketing Corp., which would control diamond processing as well as sales and distribution. The Ministry of Mines and Mineral Resources voided all digging licenses, and the State Diamond Marketing Corp. assumed control of all diamond properties except those of CAST and Akim Concessions Ltd., in an attempt to eliminate illicit traffic in diamonds. In May a new section was added to the Minerals Act to control smuggling. Since 1962 a steadily increasing number of licensed diggers had smuggled their diamonds out of Ghana to the hard currency markets in Nigeria and the Ivory Coast, where higher prices commonly were paid.

Plans for the Government-sponsored project for dredging the Birim River from its confluence with the Pra River easterly to the town of Kade, at an estimated cost of $23.8 million, were completed, and financing was sought in Western Europe.

Limestone.—The Geological Survey con-

[7] U.S. Embassy, Accra, Ghana. State Department Airgram A–272. Jan. 24, 1965, p. 5.

[8] Mining Journal. Review of Consolidated African Selection Trust Ltd. Annual Report. V. 265, No. 6796, Nov. 19, 1965, p. 372.

tinued exploration work on limestone deposits at Nauli on the coast in western Ghana and at Buipe in the northern region. The Nauli deposit, reported at depth of 500 feet, was investigated as a source of raw material for a cement plant under construction at Takoradi.

At Asuboni in the east, 10,000 tons were mined early in the year for use at the Kwame Nkrumah Steelworks. Mining continued but was temporary; the deposit lies within the area to be flooded by the new Volta River Dam at Akosombo.

MINERAL FUELS

Petroleum.—In accord with a $15 million agreement with the U.S.S.R. for 1 million tons of crude oil, Ghana imported 3,473,000 barrels of crude oil from that country during January-November 1965. Early in the year the U.S.S.R. reportedly failed to meet delivery dates, necessitating a brief shutdown of the Tema refinery. Residual fuel oil output, far in excess of domestic needs, was exported from large stocks as follows, in thousand barrels: Italy, 911; United Kingdom, 244; mainland China, 115; other, 111.

Until midyear, the refinery was supplied with crude oil by several marketers in the country in proportion to their shares of the market. When Soviet crude oil started to arrive, the 3-year contract between the Government and domestic marketers was suspended on June 20, and the marketing companies reluctantly agreed to distribute products refined from the Soviet crude oil, taken from the Ghana Purchasing Commission.[9]

The joint Ghana-Rumania oil exploration project continued through the year. Favorable structures were reported located at Atiari and Anloga in the Keta basin on the coast in eastern Ghana. A Rumanian advance drilling team arrived in September. At yearend, two Rumanian drill rigs, each capable of drilling 6,000 feet, were in the littoral area at Keta and planned drilling in early 1966.

In June the Minister of Fuel and Power announced a $670,000 contract with A. Lang Ltd., a Swiss firm, for construction of oil workers' camps for 200 people at Keta.

The Mineral Industry of Guinea

By Henry E. Stipp [1]

Guinea's production of minerals in 1965 generally increased compared with that of 1964. The minerals industry contributed significantly to the country's economy with total output valued at about $41.8 million,[2] a sum equal to 17 percent of the total gross national product estimated at $245 million. Although Guinea was primarily an exporter of agricultural products up to 1960, the export of mineral commodities has grown to such an extent that in 1964 they accounted for 83 percent by value of total exports from Guinea. Mineral imports by Guinea constituted about 11 percent of total imports in the same year.

The potential for future exploitation of minerals in Guinea is great. Large quantities of bauxite occur in deposits near Boké, and these are to be developed in the near future by Compagnie des Bauxites de Guinée, a firm jointly owned by Harvey Aluminum, Inc., and the Government of Guinea. Vast quantities of iron ore are waiting to be developed in the Nimba and Simandou Mountains of Eastern Guinea. New deposits of diamonds have been discovered recently, and these are to be developed by the Guinean Government with the help of Soviet technicians. Under the Government's 7-year plan for economic development (1964–71) $7.4 million was reportedly allotted to the minerals industry for planning and general research. A number of mineral plants also were scheduled for construction under a $60.3 million development fund. These included an aluminum fabricating plant, a petroleum refinery, a cement plant, a granite quarry, a salt plant, a fertilizer plant, and three brick factories.

PRODUCTION

Crude mineral production of Guinea in 1965 was valued at an estimated $41.8 million, compared with $40 million in 1964. Increases in output of bauxite and alumina, the nation's most valuable mineral products, presumably more than made up for the 51,000-ton decline in iron ore production. Diamond and gold production, al-

though not officially reported, were estimated to be about on a par with output levels of 1964. Of the total estimated value of mineral production in 1965, alumina accounted for about $33.7 million.

TRADE

Detailed customs information on Guinea's foreign trade for 1964 and 1965 was not available; statistics on exports were obtained from company reports, while import data was compiled from the data on exports of major developed nations to Guinea as reported by the statistical office of the United Nations.[3] Although these statistics represent the greater part of Guinea's trade, they fail to include some trade with smaller nations, which in some instances could represent significant quantities of material.

Exports of mineral commodities in 1965 were valued at approximately $42.7 million compared with about $35.4 million in 1964. Details on total trade for 1965 were not available; however, in 1964, total exports from Guinea were valued at about $42.6 million. Of this sum mineral exports accounted for over 83 percent of total exports, and agricultural commodities supplied the remaining 17 percent. Mineral exports consisted chiefly of alumina, bauxite, iron ore, and diamonds as shown in table 2.

Norway received the largest quantity of total exports from Guinea in 1964, valued at $7.7 million, followed by the United States, which received $7.1 million and France which received $5.4 million. U.S.S.R. imports were valued at about $2.2 million.

Mineral commodities imported by Guinea in 1964 were valued at about $4.6 million compared with total commodity imports of approximately $41.8 million. The principal mineral imports consisted of petroleum products, cement, and iron and steel products.

The U.S.S.R. supplied large quantities of mineral commodities, chiefly petroleum products, and cement valued at an estimated $9.2 million in total, but exports from this country were not listed in United Nations data. Among exporters listed by the United Nations, France was foremost with total commodity exports valued at $11.5 million, followed by the United States with $10.4 million, and the United Kingdom $4.9 million. The United States exported chiefly agricultural products, machinery, transport equipment, and mineral fuels.

COMMODITY REVIEW

METALS

Aluminum.—Bauxite was mined in 1965 by Bauxites de Kassa, the country's only producer, from its deposit on Kassa Island in the Los group, near Conakry. Reserves at Kassa have been variously estimated from around a quarter of a million tons to over half a million tons.

A loan of $1.7 million was made by the World Bank to the Republic of Guinea for financing field and engineering studies on the construction of a railroad, seaport, and

town.[4] The railroad would extend 137 kilometers from the port and town near Dougofissa to Sangaredi, the site of a bauxite mine being developed by Compagnie des Bauxites de Guinée, a subsidiary of Harvey Aluminum, Inc., and the Government of Guinea. This subsidiary was established in 1963 to develop the Boké bauxite deposits of northwestern Guinea, which are reportedly among the world's largest. The railroad would transport bauxite to the port where it could be loaded at the rate of 2,000 tons per hour. An organization known as l'Office de Aménagement de Boké (OFAB) was created by the Government of Guinea to manage construction activities, administration of installations, and preparation of contracts with Compagnie des Bauxites de Guinée.[5] A trade agreement betwen Guinea and Hungary provided for export of bauxite, alumina, and agricultural commodities by Guinea in exchange for manufactured products including aluminum semimanufactures.[6]

The substantial increase in the output of alumina by Compagnie International pour la Production de l'Alumine (FRIA), a subsidiary of United States and West European firms, was apparently the result of more efficient operation of plant and equipment. The company was reportedly adding a furnace at its Kimbo plant, about 145 kilometers north of Conakry; however, the furnace did not begin production in 1965.

An aluminum fabricating plant was erected near Conakry by Harvey Aluminum, Inc., with the aid of a $200,000 U.S. Government investment guarantee.[7] The plant was constructed under Guinea's 7-year plan 1964–71. The Government of Guinea will become half owner of the plant when Harvey's investment is amortized. Société Guinéenne de Fabrique d'Articles de Ménage et de tôles Ondulees (SOGUIFAB), a Harvey subsidiary, produced utensils, corrugated sheet, and roof gutters from aluminum sheet imported from Cameroon. Output was estimated at several thousand tons of aluminum products per year. Harvey Aluminum, Inc., also planned to construct an alumina plant and an aluminum smelter,[8] which would eventually supply aluminum to the fabricating plant.

Iron Ore.—Production by Société Miniére de Conakry, from its open pit mine near Kaloum about 10 kilometers northeast of Conakry, reportedly decreased because of deteriorating condition of equipment. It was estimated that production could be increased to over 800,000 tons per year with new and repaired equipment. Ore was hauled from the mine to the port at Con-

akry on a 9-kilometer-wide gage track, where it was stockpiled. Boats of up to 9.4-meter draft were loaded by belt conveyors at the rate of 1,000 tons per hour.

The iron ore deposits near Conakry reportedly consist chiefly of a laterite-covered ridge extending 40 kilometers in a northeast direction from the city.[9] From the surface to a depth of 7 to 10 meters, a bed of ore occurs containing 53 percent iron, 9 percent aluminum oxide, 1.5 percent silicon dioxide, 1.9 percent chromium oxide, 0.15 percent nickel oxide, 0.1 percent sulfur, and 0.085 percent phosphorous. Below this is a soft ore bed varying from a few meters to over 100 meters in thickness and containing about 57 percent iron. An igneous rock, dunite, considered the source rock of the iron ore lies below the lower ore bed. Total reserves were given as 3,000 million tons of iron, 58 million tons of chromium, 12.8 million tons of nickel, and 254 million tons of alumina. Research was being conducted on methods of separating chromium, aluminum, and nickel from the iron ore. Technical studies were said to be successful; however, the economic feasibility of the separation process has not been determined.

No progress was reported in negotiations between various consortiums and the Government of Guinea with regard to development of iron ore deposits in the Nimba and Simandou Mountains of eastern Guinea.

NONMETALS

Clay Products.—A brick and tile factory was completed in 1963 with Yugoslav assistance.[10] Initial production totaled 16 million units; 9 million bricks of all sizes and 7 million tiles. However, construction requirements caused production to be increased to 12 million bricks per year. The use of bricks for construction in place of cement saved much foreign exchange for Guinea. The brick factory employed 136 persons including 6 Yugoslav technicians.

Diamond.—Although diamond output in 1965 was unreported the output was believed to be 21,000 carats of gem diamonds and 51,000 carats of industrial stones. In April, diamonds were discovered in the Farecaria region southeast of Conakry by Soviet geologists.[11]

Stone.—At Maneah on the south side of the Conakry peninsula, granite was being quarried for railway and road ballast.[12]

The Mineral Industry of the Ivory Coast

By Henry E. Stipp [1]

In 1965 the mineral industry of the Ivory Coast produced commodities valued at $7.4 million,[2] a sum equal to less than 1 percent of the estimated gross national product of about $830 million. Principal mineral commodities produced and exported in 1965 were manganese ore and diamonds. Imports of metals and minerals consisted chiefly of iron and steel products, cement and other building materials, fertilizers and petroleum, crude and refined products. The Ivory Coast enjoyed a favorable overall balance of trade, but the mineral trade balance was unfavorable.

In December 1964, the French Government granted $1.3 million for a number of projects in the Ivory Coast[3] including $518,367 for geological and mineral studies. Later in 1964, a second phase of the assistance program was approved, which included an additional $338,776 for other projects in the mineral field.

The Bureau de Recherches Géologiques et Minières (BRGM) conducted a general geologic study of the southwest section of the Ivory Coast for the State-owned company, Société pour le Développment Minièr de la Côte d'Ivoire (SODEMI).[4] BRGM also experimented on the use of an aeromagnetic survey to locate sulfide mineralization in the volcanic-sedimentary basin east of Bouake, and conducted drilling and exploratory mining in a mineralized area north of Toulepleu. In addition, two occurrences of cinnabar northeast of Bouake were being prospected thoroughly by BRGM, and the company conducted geologic, photogeologic, and geochemical studies in the diamondiferous area northeast of Korhogo.

SODEMI initiated its second triennial plan for mineral development.[5]

The Ivory Coast Government and the United Nations started a 3-year mineral-prospecting program that was expected to cost about $1.9 million. The purpose of the program was to evaluate the economic potential of mineral resources discovered in the southwestern part of the country.

PRODUCTION

Diamond mining operations with an output valued at about $3.6 million and manganese ore output valued at $3.8 million accounted for the largest part of the Ivory Coast's total recorded mineral production of $7.4 million. Diamond production continued at about the same level as in 1964, while output of manganese ore increased by nearly one-third. Columbium-tantalum output decreased almost 27 percent.

Total	do	549,330	283,911	179,659	200,271	198,293

TRADE

The Ivory Coast had a positive total trade balance in 1965; however, a negative trade balance was recorded for mineral commodities. The comparison of mineral trade to total trade for 1964 and 1965 is shown in the following table.

In 1965, France remained the principal trading partner of the Ivory Coast, supplying 62.4 percent by value of the total Ivory Coast imports and receiving 37.7 percent by value of total exports. France also ranked high in mineral commodity trade, receiving most of the diamonds exported by the African nation and supplying a large part of the iron and steel imports of the Ivory Coast, along with a number of other less valuable commodities. Belgium-Luxembourg, Venezuela, West Germany, United States, and Italy ranked high in total trade and also in trade in mineral commodities as shown in tables 2 and 3.

	Value (million dollars)		Mineral commodities' share of total (percent)
	Mineral commodities [1]	All commodities	
Exports:			
1964	6.5	302.1	2.2
1965	8.8	277.2	3.2
Imports:			
1964	30.7	245.0	12.5
1965	31.1	236.1	13.2
Trade balance:			
1964	−24.2	+57.1	XX
1965	−22.3	+41.1	XX

XX Not applicable.
[1] Value for mineral commodities are for those shown in tables 2 and 3.

COMMODITY REVIEW

METALS

Aluminum.—A bauxite deposit was reported near the site of the proposed Bandama Dam.[6] SODEMI, a government-owned company was said to be investigating the deposit.

Iron and Steel.—During the year, erection of a small plant in the Ivory Coast was considered.[7] The rolling mill would turn out reinforcing rods and small sections from scrap metal obtained locally and from Mauritania and Guinea as well. A study for the plant was completed by Compagnie d'Etudes et de Gestion Industrielle of France.

A general study of iron formations in the western part of the country indicated the existence of iron resources of at least 400 million to 500 million tons.[8] However these deposits were regarded as uneconomic on the basis of their distance from the coast and their grade, which would necessitate beneficiation.

Manganese.—Total production of 179,785 tons consisted of 99,792 tons containing 46 percent manganese, 53,649 tons containing 40 percent manganese, and 26,344 tons fines. Exports in 1965 were reported as 170,524 tons, 63 percent higher than in 1964. Increased sale of low-grade ore to the United States reportedly was the chief reason for the increase in exports.[9] At the 1964 rate of depletion, reserves of the Grand Lahon deposits reportedly would last only 6 to 8 years. However, if world demand increased sufficiently, deposits near Odienne could be developed. These deposits were said to contain 1.2 million tons of proven reserves and 2 million tons of probable reserves.[10]

Tantalite.—Good prospects of tantalite associated with beryl, gold, and lithium were discovered in the Issia region.[11]

NONMETALS

Cement.—There are no known limestone deposits in the Ivory Coast; therefore, plans were formulated to import cement clinker and gypsum. Two clinker grinding plants were slated to be operating by late 1965 to supply Ivory Coast requirements for cement.

Clays.—A deposit of clay suitable for making bricks was discovered near Grand-Bassam. Known reserves were reported as 1.7 million cubic meters, and probable reserves were described as enormous.[12] On the Gounioube plateau in the vicinity of Abidjan, a deposit of white clay was reported containing proved reserves of 3 million cubic meters. This material was said to be suitable for manufacturing crockery, porcelain, and refractories. Reserves of over 2 million cubic meters of clay occur on the plateaus of Banco and Adonkoua.

Diamond.—Of total 1965 diamond output Société Anonyme de Recherches et d'Exploitation Minières de Côte d'Ivoire (SAREMCI) produced 171,940 carats; Société Diamantifère de Côte d'Ivoire (SODIAMCI) produced 25,207 carats and Société Minière des Bandamas (SMB), an affiliate of SAREMCI, produced 1,146 carats. Reserves at the SAREMCI operation were estimated to be sufficient for 5 more years.[13] Expansion of the SODIAMCI plant and equipment was expected to increase production in 1966 despite a decrease in the grade of material processed. The Watson Company, prospecting in an area to the north of Seguela was said to have had excellent results. Proved reserves reportedly exceeded 100,000 carats. The possibility of erecting a treatment plant with a capacity of 30,000 carats per year was being studied. A treatment plant was built by SMB near Tortiya, and monthly production was reported as 1,000 to 1,500 carats. A prospecting program in the Dabakola area was

started by Diamond Corporation Côte d'Ivoire in cooperation with SODEMI.

Fertilizer Materials.—Requirements for fertilizers were expected to reach 47,000 tons in 1965. Imports in 1964 were 21,960 tons. It has been reported that a fertilizer plant with 60,000-ton initial capacity was scheduled to be built by 1966. The plant was designed to use naphtha from the petroleum refinery at Abidjan and to use phosphate rock imported from Togo or Senegal. The cost of the plant was estimated at $8.5 million.

MINERAL FUELS

Petroleum.—The new oil refinery at Abidjan started producing at the close of 1965.[14] The plant was designed to operate annually on 700,000 tons of crude oil from Gabon, Nigeria, or Algeria. The plant is owned by Société Ivoirienne de Raffinage, a joint venture company, among its members are Standard Oil Co. of New Jersey, Mobil Oil Co., Standard Oil Co. of New York, and Texaco Inc.

The Mineral Industry of Kenya, Tanzania, and Uganda

By Thomas C. Denton [1]

The three countries of this chapter continued to comprise the East African Common Market (EACM), which they established shortly after achieving independence, and continued to belong to the East African Common Services Organization (EACS), which administers railways and harbors, collection of customs and excise revenue, postal and telecommunications services, and civil aviation. The countries also continued to use a common currency, the standard unit of which is the East African shilling, controlled by the East African Currency Board which maintains a stable rate of sterling exchange. At yearend 20 East Africa shillings (EAsh) were equivalent to 1 pound sterling.[2]

The common market scheme tended to favor Kenya, in part because Kenya was the only member with a petroleum refinery. In 1964 Kenya's interterritorial transfers totaled $72 million, Tanzania's $14 million, and Uganda's $27 million. The Kenya transfers included $7 million worth of petroleum refinery products, whereas such transfers by Tanzania and Uganda were respectively about $40,000 and $1 million.

Toward yearend the common market was tending to disintegrate, despite the fact that during the past 5 years interregional trade had nearly doubled. In October Tanzania placed restrictions on certain Kenya products. Official Kenya policy was that retaliatory action would not be taken against Tanzanian and Ugandan imports. But in order to protect local industries, the Kenya Government put import controls on certain items from countries outside East Africa, and manufacturers were forced to seek markets elsewhere.

A further movement away from the goal of ultimate achievement of political unity was the decision taken by each of the countries to break away from the East African Currency Board and to establish a central bank which would issue its own currency.

East African railways and harbors continued to be the part of EACS most important to the mineral industry in the three countries. Freight hauled by the railways totaled about 4.4 million tons, about 168,000 tons more than in 1964. Import and export cargo tonnages handled at the ports of Mombasa in Kenya and Dar es Salaam, Tanga, and Mtwara in Tanzania reached 6.9 million tons, 590,000 tons higher than in 1964. Imports through Mombasa included nearly 2 million tons of petroleum.

In April 1965 meetings were held between representatives of Tanzania and adjacent Zambia on behalf of the Governments of the East African countries and the EACS. A purpose of the meetings was to investigate possibilities for improving trade and existing transport links between the EACS countries and Indian Ocean ports in Tanzania. In addition a feasibility study was proposed for an all-rail link between Zambia and the EACS countries and an Indian Ocean port in Tanzania. At yearend a survey of the physical and economic aspects of the proposal was to be undertaken by Canadian and British experts whose Governments would share the cost.

[1] Africa specialist, Division of International Activities.

[2] Where necessary, values have been converted from East Africa shillings (EAsh) and pounds sterling (£) to U.S. dollars at the rates: EAsh 1 equals US$0.14 and £1 equals US$2.80.

KENYA

In 1965 the mineral industry exclusive of petroleum refining produced about 2 percent of Kenya's Gross Domestic Product (GDP), which has increased somewhat each year since 1961. About 13 million barrels of crude oil were processed during the year, and the contribution to GDP of petroleum refining probably exceeded that of other mineral processing and of mining combined.

Salient statistics for the mining industry in 1963 and in 1964 (most recent year for which information was available) were as follows:

	1963	1964
Expenditures:		
Prospecting—thousands	$3,856	$1,420
Mine development—do	6	8
Mining and milling—do	1,540	1,505
Number of persons employed:		
Africans	1,360	1,074
Asians	109	109
Europeans (whites)	94	60
Total basic cash wages paid:		
Africans—thousands	552	355
Asians—do	240	207
Europeans (whites)—do	663	443

In the second half of 1964 United Nations technical personnel reached Kenya, and the U.N.-Kenya Government mineral resources survey in western Kenya, agreed upon early in 1964, was begun. The survey was continued throughout 1965. It required the closing of most of western Kenya to prospecting and mining, excepting areas already covered by valid prospecting and mining titles. The closure will continue in effect until completion of the survey.

PRODUCTION

At $18.2 million the value of Kenya's mineral production, exclusive of petroleum products, in 1965 was $2.6 million higher than in 1964.

Cement and soda ash again were the major items. The breakdown of total value in 1964 and 1965 was as follows:

	Thousand dollars	
	1964	1965
Cement	9,081	10,621
Soda ash	2,486	2,572
Copper concentrate	1,812	2,431
Salt	849	1,478
Gold	471	400
Silver	70	27
Other	799	671
Total	15,569	18,200

[2] Scrap.

TRADE

As shown in the following table, Kenya had an unfavorable balance of foreign trade in 1964, both with respect to mineral commodities and total trade. A deficit also occurred in 1965.

	1964 value (million dollars)		Mineral commodities share of total trade (percent)
	Mineral commodities	Total commodities	
Exports	13	132	9.8
Imports	41	214	19.2
Trade balance	−28	−82	XX

XX Not applicable.

Kenya continued virtually to preclude trade with the Republic of South Africa. The embargo made difficult procurement of coal for Kenya's relatively important cement industry at satisfactory prices. While a small tonnage was imported from South Africa in 1964, the most recent year for which complete information is available, the great bulk of 1964 imports came from "other countries" and from Mozambique. There was also difficulty in disposing of Kenya's important output of soda ash, about half of which the Republic of South Africa had been taking.

Exports.—According to the U.S. Embassy, Nairobi, 1965 exports totaled a record $21.4 million, 4.1 percent more than in 1964. Exports of petroleum products doubled during the year, and at $12.6 million took third place among Kenya's exports.[3]

Imports.—Total 1965 imports from all countries were valued at $282 million, 23.4 percent more than in 1964. Major increases included crude petroleum ($4.8 million) and iron and steel ($3.1 million). The largest supplier was the United Kingdom ($70.6 million). The United States for the first time was the second most important exporter to Kenya.

[2] The 1964 statistics for refinery products recorded here exclude quantities officially reported as "negative quantities," caused by transfer from one territory to another of products imported in a previous year.

COMMODITY REVIEW

Metals.—*Copper and Gold.*—The Macalder copper mine, owned by Macalder-Nyanza Mines Ltd., was expected to be exhausted by May 1966. For many years Macalder has been the major source of Kenya's small output of copper concentrate.

During the year, exploration of the Migori gold vein about 3 kilometers from Macalder was completed. Ore reserves were estimated at about 1,400 short tons, with average gold content of 0.9 ounces per ton.

Platinum.—Johnson Matthey and Company of London were granted an exclusive prospecting license for platinum in the West Pokot District.

Nonmetals.—*Cement.*—Enlargement of the plant at Mombasa of British Portland Cement Company was completed during 1965. The project cost $700,000 and increased the annual cement capacity of the plant to 635,000 tons.

Other Nonmetals.—Toward yearend it appeared that Kenya's exports of soda ash and diatomite would improve. A trade agreement was concluded under which India would increase imports of those commodities.

Nonmetallic minerals being investigated during the year included kyanite at Murka and Coast Province, asbestos in West Province and Teita Hills, and sapphires from Kinziki in the West Province.

Mineral Fuels.—*Petroleum.*—In 1965, the East African Refineries Ltd. plant at Mombasa reportedly produced a total of 1,237,000 metric tons of products compared with 1,471,000 tons in 1964. Crude throughput in 1964 totaled 1,544,000 tons; comparable data for 1965 were not available.

In supplying the figures the management observed that neither aviation gasolines nor lubricating oils were manufactured by this refinery.

In 1965 the refinery increased output by 18.8 percent compared with 1964 results, which was perhaps the most significant development in Kenya mineral industry during the year.

BP-Shell Company was granted an oil-prospecting license for the North Eastern Province of Kenya. BP-Shell Company has been conducting a survey of 310,000 square kilometers and proposed to survey an additional 12,300 square kilometers.

TANZANIA

The mineral industry was a significant contributor to the Gross National Product (GNP) of Tanzania in 1965. Excluding Zanzibar, GNP at current prices was about $750 million, to which mineral industry contributed about 3.5 percent. Diamond accounted for nearly 77 percent of mineral industry contribution and gold for 12 percent. The volume of diamond produced was about 2 percent of non-Communist world output in 1965; by value the contribution was much higher. The share of the gold-mining industry in non-Communist-world gold production was about 0.2 percent, and for Africa as a whole was about 0.3 percent.

For some years Tanzania's mineral industry has been a major contributor to foreign exchange earnings, mostly from diamond exports. In 1965 mineral exports comprised 13 percent of the value of all domestic exports; the contribution in 1963 and 1964 was 11 percent and 12 percent, respectively.

With respect to the labor situation, significant statistics for employment in June 1965 were reported as follows: [4]

Employees by industrial division:	
Mining and quarrying	7,192
Agriculture	139,162
Other	187,401
Total	333,755
Mining and quarrying wage bill:	
Citizens, thousands	$2,251
Noncitizens, do	$2,425
Total, do	$4,676

[4] Central Statistical Bureau. The United Republic of Tanzania. Employment and earnings in Tanzania in 1965. Dar es Salaam, Tanzania, April 1965.

Regarding the whole year, the Mineral Resources Division of the Ministry of Industries, Mineral Resources and Power reported that labor relations within the mining industry were good. Africanization continued at a satisfactory level, and a number of Tanzanians attended courses of instruction. Difficulties were encountered in recruiting suitable professional and technical personnel from overseas, and the prob-

lem was expected to continue.[5]

An agreement was signed during the year by the Minister of Finance and a representative of the United Nations Special Fund (UNSF) for exploration of the Lake Victoria goldfields over the next 3 years. The cost of the project will be $616,000 from the UNSF and an estimated contribution of $47,600 to be made by the Tanzanian Government. Ground investigations will be undertaken of anomalies indicated by aerial geophysical surveys made in 1959-60. Airborne and ground operations also will be undertaken in other promising areas. The UNSF will provide experts and pay for 3,500-line kilometers of aerial geophysical survey and 6,100 meters of diamond drilling. The Tanzanian Government will make available senior professional staff, transportation and laboratory services, field officers' operating costs and labor. Besides the possibility of finding new ore bodies, the project will train Tanzanians in modern exploration techniques and will provide training of geology and mineral industry students returning from abroad.[6]

At yearend the Mines and the Geological Survey Divisions of the Tanzania Ministry of Industries, Mineral Resources and Power were to be reorganized under one division, called the Mineral Resources Division, with headquarters in Dodoma. The headquarters of the Mines Division would be moved from Dar es Salaam to Dodoma, but a mining warden's office will remain open in Dar es Salaam under the new division.

No new mines were opened in 1965. As to the immediate future outlook for the mining industry, it was anticipated that diamond production would be maintained at around the 1965 level. On the other hand, the outlook for gold was discouraging. Production would fall considerably because two important mines would close down in 1966. Rejuvenation of gold mining in Tanzania was heavily dependent on the outcome of the UNSF project mentioned earlier, and associated work by Tanzania's Mineral Resources Division. As to tin, the outlook remained good, although uncertainty existed regarding the size of minable reserves in the principal mine (Kyerwa).

PRODUCTION

As measured by the value of exports and local sales, Tanzania produced about $26.4 million worth of minerals and metals in 1965, about 7.3 percent more than in 1964. The increase largely resulted from improvement in diamond exports, which were $1.3 million higher than in 1964.

e Estimate. r Revised.

[1] Besides commodities listed, unrecorded quantities of construction materials are produced.

[2] Generally includes ruby, sapphire, chrysoprase, corundum, garnet, tourmaline, and zircon.

[3] Scrap.

TRADE

Unlike Kenya, Tanzania enjoyed a favorable foreign trade balance in 1964 both in mineral commodities and total trade, as seen in the following table:

	1964 value (million dollars)		Mineral commodities share of total trade (percent)
	Mineral commodities	Total commodities	
Exports	21	196	10.7
Imports	16	123	13.0
Trade balance	+5	+73	XX

XX Not applicable.

The virtual ban on trade with Portugal and its territories declared in November 1964 was continued in 1965.

Tanzania's 1964 exports to commonwealth countries were 52 percent of total exports and included diamond valued at $19 million to the United Kingdom. For imports the share of the commonwealth was 44 percent and included imports valued at $14 million from the United Kingdom.

COMMODITY REVIEW

Metals.—*Gold.*—Tanzania's three principal gold mines at Geita, Kiabakari, and Buhemba accounted for about 96 percent of 1965 gold output. Their operations were submarginal. Small operators including cooperatives continued to work in the Geita, North Mara, Nzega, and Mpanda areas and in the old Lupa goldfields near Chunya.

The Geita gold mine production was valued at $1,503,000. Work was confined to stoping developed ore including pillars prior to planned closure of the mine early in 1966. Tangold Mining Company Ltd. at Kiabakari produced $1,280,000 of gold. Stoping continued down to the 470-meter level, where ore grade was better, but deeper development was not considered feasible because the ore body was pinching out. The mine was expected to close down in the second half of 1966. Production from the Buhemba mine, a subsidiary of Williamson Diamonds Ltd., amounted to $328,000. The output was realized at a loss; however, projected more efficient ore treatment may reduce costs.

The possibility of establishing a gold subsidy was again considered, but no suitable formula was found.

Tin.—World tin prices were strong and tin miners in Karagwe had a relatively prosperous year, realizing about $2,926 per long ton of concentrates sold. Keyerwa Syndicate Ltd. from its open pit Kaborishoke mine produced 61 percent of the total value of concentrate output. The remainder came from small operators, whose methods for the most part were primitive.

Nonmetals.—*Construction Materials.*—Increased building activity resulted in a high level of output and sales of construction

[1] Less than ½ unit.

materials throughout the year. The cement plant of Tanganyika Portland Cement Company at Wazo Hill near Dar es Salaam was expected to go into production early in 1966. The company was investigating the possibility of obtaining its gypsum requirements from deposits near Mkomazi, Lushoto area, and Itigi, Manejoni area.

Diamond.—Both production and exports of diamond, virtually all by Williamson Diamonds Ltd. and its adjoining subsidiary, New Alamasi Ltd., reached record lev-

els. Contributing to the record were increased throughput at the main Mwadui plant, involving a higher percentage of surface gravel treated, and the occurrence of some rich patches in the gravel. The increased recovery was offset however by a higher proportion of small stone sizes, with a resultant reduction in the average price obtained per carat. Williamson continued to prospect for diamonds. A low-grade discovery at Kahama was being developed for mining in 1966.

A revised diamond sales agreement with the De Beers sales organization was finalized during the year.

Other Gem Stones.—The year saw considerable activity in prospecting for and mining other gem material, mostly by small operators. Several discoveries were made. Export sales were mainly of ruby, sapphire, chrysophase, garnet, tourmaline, and amethyst. Overseas firms were much interested in rose garnet as a semiprecious stone, and zircon also attracted attention. During the year the stones could be exported only under export permits issued to claim holders by the Mineral Resources Division. The Government expected to introduce legislation to establish a central gem-grading and gem-buying office, and to promote local gem-cutting and polishing enterprises.

Mica.—Output improved mainly because of dry weather prevailing in the Uluguru area, which provides about 90 percent of Tanzania's mica output. Small operators belonging to two cooperatives accounted for roughly 40 percent of Uluguru production. Two licensed dealers in Morogoro processed the crude mica. A license was granted a dealer in the Mpanda area.

Salt.—Most of the salt produced in 1965 came from Nyanza Salt Mines (T) Ltd., from a brine spring at Uvinza. Coastal solar evaporation works also produced salt. Powell Duffryn Technical Services Ltd. of the United Kingdom surveyed methods for reducing costs and increasing salt production at Uvinza.

Mineral Fuels.—*Petroleum.*—The $14 million oil refinery under construction at Kigomboni near Dar es Salaam was expected to go on stream by August 1966. Annual capacity for crude oil was expected to be about 600,000 tons. When in full production, the facility will require around 300 workers.

UGANDA

The gross domestic product of Uganda in 1965 at current prices was about $625 million, to which mineral industry contributed about $30 million, or nearly 5 percent. The value of exports including reexports was about $179 million, to which mineral industry contributed nearly 14 percent, mostly represented by exports of blister copper. The industry, excluding quarrying, employed 7,305 persons.

Exploration activity was expanded during the year. The Drilling Division was to have 20 new drilling machines. A British mineral exploration team was formed, mainly to investigate tin deposits in western Uganda. Partly financed by the UNSF, the Karamoja ground water survey was begun. The Canadian Aid Team was mainly active in ground followup work in the areas surveyed earlier during the UNSF airborne survey. By yearend, work in area A (Karamoja) had been largely completed and work had begun in area B (Aswa zone). Except in two small parts where exploratory drilling was proposed, area A was thrown open for general prospecting. Certain carbonatite centers in eastern Uganda were reinvestigated, and geochemical surveys were conducted in Kigezi in western Uganda.

By the end of 1965, 14 industries involving capital investments totaling $14.4 million had been started in Uganda since the country became independent on October 9, 1962. Four of the industries are government enterprises, the remainder being in private hands. Completed projects include a steel rolling mill and a galvanized iron sheeting plant.

Toward yearend the chairman of Government-owned Uganda Development Corporation disclosed that the Corporation planned to spend $51.1 million in new development over the next 5 years.

PRODUCTION

The value of Uganda's mineral production in 1965 was an alltime record $30 mil-

1 Exports.

lion, largely because of higher prices obtained for copper. Production of cement, lime, and apatite increased compared with 1964 output.

TRADE

In 1965 minerals again were Uganda's third most valuable export after cotton and coffee. The provisional value for minerals was $25 million, 12 percent higher than in 1964 and double the 1963 figure. Copper accounted for about 96 percent of total value.

In 1964 Uganda realized a favorable foreign trade balance in mineral commodities and with respect to total trade, as shown in the following table:

	1964 value (million dollars)		Mineral commodities share of total trade (percent)
	Mineral commodities	Total commodities	
Exports	18	180	10

COMMODITY REVIEW

Metals.—*Beryl.*—Low prices for beryl prevailed during the year and production declined sharply. The mineral was mined in the Mengo, Kigezi, and Ankole Districts.

Copper.—Kilembe Mines Ltd., in western Uganda in the foothills of the Mountains of the Moon, continued to be Uganda's only copper producer and most important mining company. The volume of blister copper produced was somewhat less than in 1964, but at $24.2 million the estimated value of output was nearly 30 percent higher. Ore mined totaled 941,000 tons, about 40,000 tons more than in 1964. Reserves of proved and possible ore at year-end were reported at 5.9 million tons averaging 2.0 percent copper. At the smelter at Jinja, equipment was being installed to recover copper being lost in flue dust. Training facilities for local employees were improved and expanded. The company's program for gradual Ugandanization of the operation was continued.

Iron and Steel.—The Steel Corporation of East Africa Ltd. reportedly produced about 17,000 tons of ingots and 13,000 tons of finished products during the year.

Tantalite-Columbite.—Small quantities of these minerals (8 tons) reportedly were mined during the year in Buganda Kingdom and in western Uganda.

Tungsten.—An appreciable output of wolframite was reported from the Kigezi District. The largest producer was Bjordal Mines Ltd., which has an open pit mine and a gravity mill.

Nonmetals. — *Fertilizer Materials.* — The 1964 Kampala Agreement, which apportioned industrial development between Kenya, Tanzania, and Uganda, allotted the fertilizer industry to Uganda. Toward the end of 1965, a consortium of West German companies signed an agreement with the Ugandan Government under which an additional fertilizer plant would be established, using local raw materials to produce annually 100,000 tons of calcium ammonium nitrate. Tororo Industrial Chemicals and Fertilizers Ltd. (T.I.C.A.F.) already was operating a fertilizer plant in Uganda, producing from Sukulu apatite about 25,000 tons of single superphosphate annually. T.I.C.A.F. is a subsidiary of Government-owned Uganda Development Co. Ltd. Imperial Chemical Industries Ltd., through its Kenya subsidiary, Twiga Chemicals Ltd., are managing agents for T.I.C.A.F.

The Mineral Industry of Liberia

By Walter C. Woodmansee [1]

Iron ore was essentially Liberia's only indigenous mineral product. Most diamond bought and sold in Monrovia originated outside the country. Iron ore provided $112.4 million in export earnings and was the principal factor in Liberia's large trade surplus. A fourth mine, Bong Mining Company, joined the iron ore producers and contributed to the output of nearly 16 million tons in 1965. Liberian American-Swedish Minerals Co., Join Venture Operating Co. (LAMCO JV), the principal producer, planned Africa's first iron ore pelletizing plant. Liberia passed the United Kingdom to rank eighth in the free world in iron ore output. The country also was the largest producer in Africa, contributing 40 percent of total output of iron ore on the continent.

The United States Agency for International Development (AID) continued its geological assistance program. A geological map of Liberia at 1:250,000 was in preparation, mineral resources were under investigation, and Liberians were trained in geological work.

PRODUCTION

The iron-mining sector, which dominated the mineral industry, moved forward in production and sales. A fourth major mine was brought into production, and two other deposits were under investigation. Output of gold and construction materials was small and showed no appreciable change from that of 1964. Diamond shipments, largely originating in other West African countries but not recorded as a part of these countries' output, were reduced slightly.

Table 1.—Liberia: Production of metals and minerals

e Estimate. r Revised.
[1] In addition to commodities listed, construction materials also were produced, but output data are not available.
[2] Year ended Aug. 31, 1963.

TRADE

Adequate data on imports of metals and minerals are lacking for 1964 and 1965. Export earnings from iron ore totaled $112,412,000 in 1965 ($86,765,000 in 1964); foreign exchange earnings from diamond were $3,552,000 in 1965 ($3,894,000 in 1964). Because of continued expansion of iron ore sales, the total trade balance, which was

[1] Physical scientist, Division of International Activities.

favorable in 1964 for the first time in many years, apparently improved further in 1965. The relationships between mineral trade and total trade for 1963 and 1964 were estimated as follows:

	Million dollars		Mineral commodities' share of total trade (percent)
	Mineral commodities [1]	All commodities	
Exports:			
1963	49.1	[2] 81.1	60.5
1964	[e] 92.0	[2] 131.8	[e] 69.8
Imports:			
1963	13.6	108.0	12.6
1964	[e] 17.0	111.2	[e] 15.3
Net trade balance:			
1963	+35.5	−26.9	XX
1964	[e] +75.0	+20.6	XX

[e] Estimate. XX Not applicable.
[1] Values given are for only those commodities listed in table 2 of this chapter.
[2] Includes reexports ($5.2 million in 1963, not reported in 1964).

[1] Except for iron ore and concentrate, all commodities listed are re-exports. In addition, small quantities of clay construction materials, certain inorganic chemicals, mineral pigments, and salt are reexported.
[2] Received at Netherlands ports but probably largely in transit to West Germany.
[3] Shipments of trading companies in Liberia.

COMMODITY REVIEW

METALS

Gold.—Recorded output of gold valued at $78,382 was sold to the Bank of Monrovia. However, a large share of actual gold output from hand placer operations remained unrecorded and went to goldsmiths, jewelers, and others.

Iron Ore.—Mining operations and shipments to foreign destinations showed marked expansion during 1965. Total mine output and exports increased 22.8 percent and 28.1 percent, respectively. The 1965 output, by ore type and company, was distributed as follows:

	Metric tons
Liberian American-Swedish Minerals Co., Joint Venture Operating Co. (LAMCO JV)	
Direct shipping ore	8,709,262
National Iron Ore Co. Ltd.	
Direct shipping ore	2,906,237
Liberia Mining Co. Ltd.	
Direct shipping ore	1,399,868
Concentrate	1,206,561
Bong Mining Co.	
Concentrate	1,737,000
Total	15,958,928

Shipments, nearly equal to production, were valued at $112,412,000, making iron ore Liberia's most important export item.

LAMCO Joint Venture Operating Co. (LAMCO JV).—This company, owned by Liberian American-Swedish Minerals Co. (LAMCO) (75 percent) and Bethlehem Steel Corp. (25 percent), continued expansion of all phases of its operation and in November attained a monthly mining rate of 839,495 tons.

In June LAMCO JV announced plans for construction of new washing and pelletizing plants at Buchanan. The latter will be the first in Africa and one of the largest outside North America. Planned annual capacity of the washing plant was 10 million tons of ore. Pelletizing capacity was rated at 2 million tons annually, raising total ore and concentrate output to about 10 million tons per year. Construction work started during the dry season in late 1965; completion was scheduled for late 1967. Grängesberg Co., the Swedish firm which is manager for LAMCO JV, established a project organization in which the International Construction Co. Ltd., London, was engaged as consulting engineers and field supervisors. Bethlehem Steel Corp. was to supervise contractors and procurement of supplies in the United States. Dravo Corp. in Pittsburgh was granted a contract for design and construction of the pelletizing plant. Svenska Entreprenad A.B. Sentab received the contract for site preparation and foundation work. Other contract negotiations continued at yearend.

Estimated cost of this expansion program was $51.4 million, making LAMCO JV's total investment $282 million in Liberia. Expansion was financed by issuing of new shares ($11 million), an Export-Import

Total	---	---	1,567
Grand total	6,285	12,232	15,668

[1] Substantially larger than production; NIOC buys fine ore from LMC. LMC shipments therefore are correspondingly lower than production at that mine.

Bank loan ($23 million), Bethlehem Steel Corp. ($13 million), and the remainder from retained earnings.

LAMCO JV's net earnings were $12,344,000 compared with $4,914,000 in 1964. Distributable profit was $7,408,000 in 1965. Total sales were $42,595,000 ($33,642,000 in 1964). The company employed 3,754 workers and staff, including 3,200 Liberians.[2]

The Attorney General of Liberia granted LAMCO JV rights to a 70-square-kilometer area in the Kitoma mountains, where reserves were estimated at 750 million tons of ore containing 40 to 60 percent iron. These reserves were claimed by both LAMCO JV and Kitoma Mining and Trading Company. Kitoma was to receive compensation for exploration costs.

National Iron Ore Co. Ltd. (NIOC).—A mining rate of about 3 million tons per year was maintained. Improvement of facilities continued during the year.

Liberia Mining Co. Ltd. (LMC).—Production at the Bomi Hills mine continued at the 1964 rate. No new reserves were found, and dwindling reserves of shipping-grade ore were estimated sufficient for only 9 years at the 1965 mining rate.

Joint exploration by LMC and NIOC in the Gbee Mountains, Lofa County, proved large low-grade resources (38 to 40 percent iron), which LMC planned to develop. Ore will be transported by rail 32 kilometers to Bomi for concentration.

Bong Mining Co.—The Bong Range mine, 112 kilometers northeast of Monrovia, became Liberia's fourth major iron producer. The mine went into partial production in March and full production, 3-million-ton-per-year rate, began in April. An increase to a 5-million-ton rate was planned. First ore delivery was made in June. The mine was officially opened on November 12.

The operation represents an investment of $80 to $90 million. Run-of-mine ore averaging 40 percent iron is upgraded by separators to 62 to 65 percent iron. Company officials reported reserves of 300 million tons in one ore body, and 150 million tons in another deposit. One ton of crude ore produced one-half ton of concentrate.

Bong Mining Co. was incorporated in 1961 as operating company for Deutsche-Liberian Mining Co., a consortium of West German Ruhr steel interests (75 percent) and Societa Finanziaria Ria Siderurgica per Azioni (Finsider) (25 percent). According to the Bureau of Natural Resources and Surveys, the mine employed 1,536 unskilled workers, 275 foreign technical personnel and staff, and 47 Liberian technical personnel as of the fiscal year ended August 31, 1965.

Proposed Iron and Steel Plant.—Liberian authorities continued efforts to establish an integrated iron and steel plant in Buchanan to serve West African markets. In 1964 Buchanan was selected as most favorable location after a United Nations Economic Commission for Africa (UNECA) feasibility study of four proposed sites in West Africa, based on estimated costs of production and distribution of steel. From August 2 to 6, a consultative meeting was held in Monrovia, at the invitation of the Liberian Government. The meeting was attended by representatives of UNECA, the Organization for African Unity, and eight other nations. Liberia sought regional agreement and cooperation in establishing a 700,000-ton-per-year plant for crude and finished steel at Buchanan, but no decision was reached. An interim committee was formed to pursue the matter further and report within 6 months to an appropriate intergovernmental body.[3]

In September, A. Romeo Horton, Secretary of the Department of Commerce and Industry and Head of the Liberian Steel Mill Committee, visited the United States and met with World Bank officials concerning the proposed steel mill. Late in the year, Liberian delegates planned a trip to Vienna and London to discuss plant technology.

NONMETALS

Diamond.—Two mining companies, one (name unknown) working near the Mano River and the other (Diamond Mining Co.) not reporting its activities or production, probably produced a few thousand carats of diamond. The bulk of output given in table 1, however, represents stones originating in Sierra Leone, Ghana, Democratic Republic of the Congo, and probably other countries of West Africa, and sold to licensed buyers in Monrovia. These shipments, according to the Bureau of Natural Resources and Surveys, were as follows:

[2] Liberian Iron Ore Ltd. Annual Report 1965, April 1966, 24 pp.

[3] U.S. Embassy, Monrovia, Liberia. State Department Dispatch A–68, Sept. 23, 1965, 14 pp.

Type	Carats	Value (U.S. dollars)
1964:		
Bort and industrial	273,498	307,835
Gem	298,370	3,585,761
Total	571,868	3,893,596
1965:		
Bort and industrial	262,850	403,695
Gem	276,574	3,148,779
Total	539,424	3,552,474

Royalty paid to the Liberian Government was $532,871 in 1965, compared with $584,023 in 1964.

MINERAL FUELS

No further progress was made toward construction of a petroleum refinery, which has been under consideration since 1961. Toward the end of 1965, Liberia Refining Co., a subsidiary of Dynalectric Corp. which held a concession agreement to build the refinery, claimed that location of the plant site was selected near Monrovia.

The Mineral Industry of Libya[1]

By Walter C. Woodmansee[2]

Principal mineral developments in Libya during 1965 concerned the petroleum industry, which continued as the nation's predominant source of revenue and foreign exchange. Revenues from the petroleum industry were estimated at over $300 million in 1965, substantially more than in 1964 (including increases derived from 1965 amendments to the Petroleum Law of 1955).[3] This revision was expected to add $100 to $140 million to annual revenues. The state budget for 1965–66 was established at $464 million, including approximately $230 million for 1965.[4]

At midyear, cumulative oil company investment and expenditures in Libya totaled about $1,500 million.[5] The petroleum industry employed 12,600 people, including 9,500 Libyans. In November, Esso Standard Libya, Inc., opened an industrial training center at Marsa el-Brega to train Libyan nationals in petroleum operations.

PRODUCTION

The petroleum industry was developed further during 1965; daily output of crude oil was 1.2 to 1.3 million barrels through most of the year and attained a rate of 1.4 million barrels by yearend, ranking Libya sixth among petroleum-producing countries.

Five consortia—Esso Standard Libya, Inc., Oasis Oil Co. Libya, Inc., Mobil Libya Petroleum Co./Gelsenberg Benzin A.G., American Overseas Petroleum Co. Ltd. (Amoseas), and Phillips Petroleum Co.—were active oil producers, while two others — British Petroleum Exploration Ltd./Nelson Bunker Hunt and Pan American Petroleum Co. — neared the production stage. At yearend there were 47 oilfields, including 7 discovered in 1965, and more than 800 producing wells. Total daily pipeline capacity, including that connected to the new Sarir line not yet in commercial production, was 1.6 million barrels, and estimates envisioned a future daily capacity of 3 million barrels.

Progress also was made toward marketing associated natural gas, which through 1965 was flared in large quantities. Esso Standard Libya, Inc., a major oil producer, negotiated long-term contracts with Italian and Spanish firms for future delivery of liquefied gas by large-capacity tankers and made plans for natural gas pipelines and a liquefaction plant.

In the metals and nonmetals sectors, significant developments were few. The Geological Society, Ministry of Industry, commenced collecting data on more than 300 active quarry operations, largely in building stone and crushed rock. Projects were planned or were underway on building materials, glass, fertilizers, and asphalt. Libyan Metal Industry Co. reportedly began production of steel bars in May, but further information on the operation was lacking at yearend.

---

[1] Statistics are available only on mining operations conducted by the Ministry of Industry, which include gypsum and salt. Various quarry products, including building stone, clay, marble, mica, sand, and sulfur, have been mined sporadically for local use.
[2] Flared or used as fuel in oilfield operations.

TRADE

Preliminary information indicated that exports of crude oil reached nearly 443 million barrels, valued at nearly $785 million on posted prices, in 1965. The following tabulation illustrates the relationship of mineral industry trade to total trade during 1963–64, the latest years for which these data are available:

	Value (million dollars)		Minerals' share of total (percent)
	Mineral commodities [1]	All commodities	
Exports:			
1963	369	374	98.7
1964	695	701	99.1
Imports:			
1963	45	239	18.8
1964	54	292	18.5
Trade balance:			
1963	+324	+135	XX
1964	+641	+409	XX

XX Not applicable.
[1] Values given are for only those commodities listed in tables 2 and 3 of this chapter.

Crude oil accounted for nearly all mineral exports. Import values, divided by commodity group, during 1964 were as follows: Metals $32.1 million, largely iron and steel pipes and tubes but also including $2.2 million in nonmonetary gold; nonmetals $9.0 million, largely cement, ceramic ware, and fertilizers; and mineral fuels $13.3 million, largely petroleum products.

Crude oil exports continued to be shipped from three terminal ports—Marsa el-Brega 206 million barrels, Ras es-Sidr 184 million barrels, and Ras Lanuf 53 million barrels. A fourth port was under development at Marsa el-Hariga, near Tobruk in eastern Libya, for oil from the new Sarir field, where reserves were estimated at 10 billion barrels.[6]

Petroleum companies operating in Libya imported supplies and equipment valued at $61 million in 1965, compared with $78.8 million in 1964. The 1965 value was the lowest since 1961, indicating the industry has progressed toward production as exploration and oilfield development declined.

Libya also reexported goods valued at $8.2 million in 1964, including $0.9 million involving the mineral industry, largely iron and steel tubes, pipes, and fittings.

COMMODITY REVIEW

NONMETALS

Cement.—During 1965 the Libyan Government took further steps to encourage development of a domestic cement industry. National Cement Co., 70 percent of the shares in which were purchased by the Government, started construction on its 120,000-ton-per-year cement plant near Homs, Tripolitania. A Board of Directors was appointed to consider bids for plant equipment and, late in the year, granted a contract to a West German firm for machinery. Port facilities were under construction at Homs. National Cement Co. was granted a 20-year concession for limestone development in the area. Drilling of limestone and clay deposits was underway near Tripoli.

Another cement plant, also financially backed by the Government, was planned by Libyan Cement Co., near Benghazi. Foreign consultants were engaged to recommend an appropriate plant site.

Salt.—According to the Ministry of Industry, salt was not produced in 1965, because a 1964 surplus provided for domestic demand. A new installation for marine salt recovery, with an annual capacity of 5,000 to 6,000 tons, was under construction near Benghazi.

MINERAL FUELS

Petroleum.—Production and export of crude oil continued upward as new oilfields and pipeline facilities were developed. Production rose 40 percent over that of 1964, and exports totaled 443 million barrels, valued at nearly $785 million. The daily output rate reached 1.4 million barrels late in the year.

The year started with oil flow limited to a rate of 1 million barrels per day because a series of storms in the Gulf of Sirte delayed tanker loadings. The daily rate was 1.2 million barrels in March and continued at 1.2 to 1.3 million barrels through most of the year.

Over 200 productive wells were brought in, including 10 discovery wells. Seven fields became producers: Jebel, Raleh, Maghil, and Ain Jarbi of Esso Standard; Ora of Mobil/Gelsenberg; Kotla of Amoseas; and Umm Farud of Phillips. The Jebel field, 19 kilometers southeast of Esso's Zelten field, was reported capable of 40,000 barrels per day. Phillips' Umm Farud field produced at a rate of 10,000 to 15,000 barrels daily and was considered capable of 25,000 barrels daily. Pan American made an important discovery at Khuff, where production at about 15,000 barrels per day was anticipated. The Mobil/Gelsenberg Amal field also neared the production stage. Phillips discovered its third productive well in western Libya; the well tested at 1,800 barrels per day, but the region was not considered commercial, because productive wells are widely separated.

Operations were affected briefly by two incidents of apparent sabotage. On May 14, four oil wells in the British Petroleum/Nelson Bunker Hunt Sarir field caught fire after explosions and a fifth

Table 4.—Production of crude oil and natural gas, 1965

Phillips Petroleum Co	Umm Farud	1,065	180
Total		445,374	305,271

well ran wild.[7] In July, explosions and fire at Esso's Marsa el-Brega port terminal caused the loss of three 268,000-barrel crude oil storage tanks and damage to a 36-inch water pipeline. Orders for construction of replacement tanks were placed with a Libyan firm. The incidents were investigated by Government authorities. Installations were guarded by the Libyan Army and Police, and more effective security measures were planned. The last fire at the Sarir field was brought under control on June 11. Production was not handicapped because the field had not been connected to pipeline.

A pipeline explosion at Oasis's Samah field on November 3 killed 10 men. This was considered the worst accident involving petroleum operations in the country. Production from four fields was interrupted for about 10 days.

On May 27, the Libyan Government requested bids on new oil concession areas involving 185,000 square miles, including relinquished acreage. This was the first such announcement in several years. The bid deadline was July 29, and bids were publicly opened in Baida on July 31. Representatives of 48 companies, which individually or grouped had bid on 104 land parcels, assembled in the Council of Ministers conference room to witness the opening. The Libyan Government had indicated several factors considered preferential in consideration of granting concessions.[8] Announcement of concession awards was delayed while authorities considered revisions of basic petroleum laws.

On November 20, King Idris signed a Royal Decree, amending certain provisions of Petroleum Law No. 25 of 1955. The OPEC (Organization of Petroleum Exporting Countries) formula for calculating taxes was thereby applied to petroleum companies operating in Libya. The amendments revised the calculation of crude oil discounts and price reductions, which allegedly had caused substantial revenue losses to the Government. Royalties were to be considered as production expenses only and not as advance payment on the 50–50 profit split, as formerly permitted. It was estimated that this would increase revenue by $0.14 per barrel. Also, income was to be based on officially posted prices (about $2.20 per barrel for 40° gravity oil), less a maximum permissible discount of 7.5 percent for 1965 sales, and 6.5 percent for 1966 sales, rather than on realized price (about $1.60 per barrel). Another stipulation limited expenses deductible in connection with marketing, prior to computation of taxable income, to $0.005 per barrel. These adjustments were expected to add $100 million to $140 million to revenues during 1965. The new oil laws were discussed in several sources.[9]

Amendments to the petroleum law were passed unanimously by the Chamber of Deputies and the Senate on December 8 and 9, respectively. The decree included a number of inducements for the 24 concession holders to amend their agreements in accordance with the OPEC formula by December 15. Inducements involved quittance on disputes over prices, rebates, discounts, allowances, and royalties that existed during 1964. At yearend, most operating companies had amended their agreements to conform with the new regulations.

The Royal Decree also set a January 6, 1966, deadline for the 48 companies applying for new concessions to indicate their acceptance of the OPEC formula and to amend their applications. Several companies withdrew; others amended their bids. At yearend, negotiations were in progress, and no new announcements had been made on awarding of new concessions.

Late in 1965, Amerada Petroleum Corp. sold half of its one-third interest in Oasis Oil Co., Inc., to Libya Shell N.V., giving Shell a one-sixth interest in Oasis, effective January 1, 1966, subject to approval of the Libyan Government.[10] Shell agreed to pay about $64 million to Amerada for pre-1966 Amerada expenditures and to purchase a specified quantity of crude oil from Amerada's remaining share. Shell formed a new subsidiary company for this operation.

Exploration and Development. — The downward trend in exploration, started in

Producing, discovery	17	10
Dry	178	155
Total	409	359
Total tested production rate of new wells barrels per day	21,862	7,237

Esso Standard continued stepout drilling at its Jebel field. In the west, Phillips drilled in Concession 90, and Libya Shell N.V. completed 7 wells for a total of 40 unsuccessful wells and terminated exploratory drilling. Compagnie des Pétroles Total carried out a seismic survey in Concession 49. Campagnie Ricerche Idrocarburi (CORI), subsidiary of the Italian firm Ente Nazionale Idrocarburi (ENI), made a significant oil discovery in eastern Libya (Concession 82). It bottomed at 13,600 feet and is believed to be the deepest oil well in the country and a possible extension of the large Sarir field.

As an incentive to petroleum activity, the Government announced in August that foreign-owned companies engaged in exploration, installation of electronic and telecommunication equipment, and pipelime construction are exempt from Libyanization requirements of the Commercial Code.

Pipelines.—In February Mobil/Gelsenberg/Amoseas announced plans for a new 283-kilometer, 30-inch pipeline from the Amal field to the port terminal at Ras Lanuf. Contracts were awarded in June to Arabian Bechtel Corp.; Brown and Root Overseas Ltd.; Libyan Engineering and Contracting Co.; National Development Co./Toyo Kanetsu Ltd.; and Chicago Bridge Ltd. for various construction phases. The first shipments of pipe arrived at Ras Lanuf in July, and the line was completely welded out late in the year. Production was expected in early 1966. A $28-million total cost was reported by the press.

Oasis Oil Co. began a $12.6-million expansion program on its major line to Ras es-Sidr and feeder lines, raising daily throughput capacity from 530,000 to 680,000 barrels. Additions consisted of a 139-kilometer, 30-inch line; a 48-kilometer, 24-inch line; a pump station at Gattar; generating equipment for increased power; and improved power distribution systems. The project was virtually complete at yearend.

Esso Standard completed new gathering and feeder lines from its new fields to the main pipeline and a 4,000-horsepower booster pump station on the main line, which raised capacity from 550,000 to 605,000 barrels daily. The Kotla, Umm Farud, Khuff, and Ora fields were connected by feeder lines to the main pipelines.

At yearend, four operating pipeline systems had total throughput capacity of about 1.5 million barrels per day. Work continued on a fifth major line—the British Petroleum/Hunt 515-kilometer, 34-inch line from the Sarir field to the new oil port of Marsa el-Harega, near Tobruk, in eastern Libya. Jetty construction was underway at the port.

Natural Gas.—Oilfields continued to produce large quantities of associated natural gas, most of which was flared. In March the Libyan Council of Ministers appointed an Energy Committee, headed by the Minister of Petroleum Affairs, to study proposals for gas commercialization and attempt to develop markets. Late in the year, two contracts for the sale of liquefied gas were announced—one with the Italian Societa Nazionale Metanodotti (SNAM), a subsidiary of ENI, involving 235 million cubic feet per day for 20 years; and the other with Catalana de Gaz, Barcelona, Spain, for 110 million cubic feet per day for 15 years.[11] Liquefied natural gas (LNG) output for this contract was considered equivalent to 80,000 barrels per day. Large LNG tankers with capacity of 250,000 barrels were planned. Esso Standard awarded an $8.4-million contract to Air Products and Chemicals Co. (U.S.) for design and engineering of the refrigeration plant at Marsa el-Brega. A new gas pipeline parallel to the Zelten-Marsa el-Brega line was planned.

In August, Libyan Atlantic Refining Co./Phillips, drilling offshore on the ship, *Glomar V,* struck a pocket of high-pressure gas which ran out of control for 11 days

[11] Petroleum Press Service. V. 32, No. 12, December 1965, p. 466.

Table 5.—Libya: Data on main crude oil pipelines

Operating company and year of initial operation	From—	To—	Length (kilometers)	Diameter (inches)
Oasis:				
1962	Dahra	Ras es-Sidr	140	30
1963	Samah	Dahra	201	32
Esso Standard (1961)	Zelten	Marsa el-Brega	171	30
Mobil/Gelsenberg/Amoseas:

1964	Ora/Beda	Asida	135	24
1966	Amal	Ras Lanuf	283	30
British Petroleum/Nelson Bunker Hunt (1966)	Sarir	Marsa el-Harega	515	34

	Capacity (thousand barrels per day)	Ultimate capacity (thousand barrels per day)	Port terminal and installations
Oasis:			
1962	680	750	Ras es-Sidr: 4 tanker berths; storage capacity 4.7 million barrels in 15 tanks.
1963	-------	--------	
Esso Standard (1961)	605	650	Marsa el-Brega: 4 tanker berths; storage capacity 4.3 million barrels in 16 tanks.
Mobil/Gelsenberg/Amoseas:			
1964	185	500	Ras Lanuf: 2 tanker berths; storage capacity 1.5 million barrels in 3 tanks.
1964	-------	--------	
1966	100	500	Ras Lanuf: 1 tanker berth; storage capacity 1.5 million barrels in 3 tanks.
British Petroleum/Nelson Bunker Hunt (1966)	100	600	Marsa el-Harega, near Tobruk; line under construction at end of 1965.
Total	1,670	3,000	

before it was sealed off. The discovery was not considered commercial. The exploration group had a 7-million-acre offshore concession and drilled several wells in water as deep as 525 feet.[12]

Refineries.—The Esso Sirte, Inc., 8,500-barrel-per-day refinery at Marsa el-Brega remained inoperative during the year, owing to a continuing lack of agreement between Esso and the Government on refinery product prices. However, in October King Idris signed a Royal Decree establishing excise taxes on domestic refinery products, thereby removing a major barrier to their production.[13]

Marketing continued to be restricted to three companies: Esso, Shell, and Societá Lidica per il Petrolio S.p.A. (Asseil); 49 percent of Asseil was owned by ENI of Italy and 51 percent by Libyan interests. Effective May 1, the Esso marketing organization, formerly operating independently, became a department of Esso Standard, a major operator in the country. Shell maintained marketing separate from its oilfield subsidiary.

The Mineral Industry of the Malagasy Republic

By Walter C. Woodmansee [1]

As in previous years, the Malagasy Republic's mineral industry was dominated by the mining sector. A large chromite deposit was under development, backed largely by Société d'Électro-Chimie, d'Électro Metallurgie, et des Aciéries Électriques d'Ugine (Ugine) and the Malagasy Government. The Malagasy Republic was the world's chief source of phlogopite mica and ranked fourth in the free world as a graphite producer. The United States received important quantities of both of these commodities. Uranothorianite production provided a significant share of uranium requirements in France.

Several domestic and foreign agencies were actively engaged in projects directly related to mineral development. The Service Géologique continued a geologic mapping program at a scale of 1:100,000 and planned to complete five sheets during the year. This office also conducted field studies on graphite, gold, mica, quartz, clays, and limestone (the latter in conjunction with a new cement plant planned in the Hauts-Plateaux) and geochemical studies on several metals.

The French Bureau de Recherches Géologiques et Minières conducted a diversified program in several regions. Its activities included geologic mapping of 7,000 square kilometers in the Andriamena chromite area, prospecting and geochemical exploration for numerous metallic and nonmetallic minerals, engineering studies on soils, and hydrogeology in 20 localities. Drilling was planned in several areas. Another French organization, Fonds d'Aide et de Coopération (FAC), had exploration programs for diamond, phosphate, copper, lead, zinc, molybdenum, and platinum. Fonds Européen de Developpement (FED), a European Economic Community agency, provided financial assistance for chromite development.

In October several United Nations Special Fund projects were underway or planned. These included assistance in the study of mineral and ground water resources in southern Malagasy, the development of energy resources, and the improvement of the railroad system. United Nations funds made available for all projects totaled $3.5 million,[2] and the Malagasy Government was to contribute $9.8 million.[3]

The 1964–68 development plan called for increases in output of most minerals. Total programed investment in the mineral industry during this period was $23.7 million, of which $20.2 million would be private and the remainder would be public funds.[4]

Aluminum products and cement were included among materials granted preferential treatment under terms of the investment code. Benefits to investors include reduced taxes on imported materials for processing and on profits for stated periods of time; protective tariffs and quotas on imported competing goods were also established.

[4] Industries et Travaux d'Outremer. No. 136, March 1965, p. 194.

PRODUCTION

Mine-head value of total reported mine output in 1965 was $3.3 million. Graphite with a value of $1,169,000, replaced uranothorianite as the most valued product, while the latter dropped to $996,000 (actual export value). Graphite production showed a marked improvement, owing to better marketing conditions, whereas the mining of uranothorianite was handicapped by shortages of shipping-grade ore. Production of phlogopite mica, another important mineral product, was valued at $555,000, almost the same as that of 1964. Semiprecious gem stones were valued at $191,000. Other notable mineral products were quartz crystal, particularly the peizoelectric variety, and monazite, both of which showed higher output during 1965.

Data on cement production, which began in 1964, became available for the first time. Output has been small relative to demand and went to areas near the plant. A second plant was planned in the Hauts-Plateaux region of the interior.

A small plant for galvanized and corrugated sheet, which apparently was used largely for roofing, was completed at Tamatave late in the year.

TRADE

Foreign trade in metals and minerals in 1964, the latest year for which complete data are available, was characterized by exports of graphite and phlogopite mica, which together accounted for two-thirds of total mineral export value, and imports of steel semimanufactures and petroleum refinery products. Steel import value was $6.6 million, and that for petroleum refinery products was $7.1 million. The unfavorable trade balance in mineral and total trade is indicated in the following tabulation:

	Million dollars		Mineral commodities' share of total (percent)
	Mineral commodities [1]	All commodities	
Exports:			
1963	r3.8	82.7	4.6
1964	3.7	92.5	4.0
Imports:			
1963	r18.7	128.5	14.6
1964	17.2	136.5	12.6
Trade balance:			
1963	−14.9	−45.8	XX
1964	−13.5	−44.0	XX

r Revised. XX Not applicable.
[1] Values given are for only those commodities listed in tables 2 and 3 of this chapter.

COMMODITY REVIEW

METALS

Bauxite.—Compagnie de Produits Chimiques et Électrométallurgiques Péchiney, through continued exploration, determined that bauxite resources totaling about 70 million tons in the Manantenina region, north of Fort Dauphin, may be economically exploitable. Government authorities studied possible methods of sea transport.

Chromite.—Ugine discontinued operations at the Ranomena mine, 37 kilometers north of the port of Tamatave, on August 31 after producing 6,500 tons of concentrate during the year. Geologic study and exploration continued in the Andriamena area, 180 kilometers north of Tananarive in the Hauts-Plateaux. Ugine reported reserves of 3 million tons of chromite proved and a similar tonnage probable. The largest deposit, Bemanevika, contains 2 million tons with an average of 42 percent chromic oxide (Cr_2O_3) and average chromium-iron ratio of 2.6:1 at the surface and 3.0:1 at depth. Remaining ore is in numerous relatively small ore bodies ranging from several thousand to 200,000 tons.

Compagnie Minière d'Andriamena was formed to develop and exploit the deposit. Initial capacity would be about 100,000 tons of concentrate per year. The possibility of an electrometallurgical plant for silicochrome also was under consideration. A $7-million, all-weather road from mine to railhead was planned for construction in 1966, financed by Ugine, the Malagasy Government, FED, and FAC.

Participation in the company was reported as follows: Ugine 55 percent, Malagasy Government 20 percent, Pechiney, 10 percent, Compagnie Financière pour l'Out-

[1] Scrap, unwrought, and semimanufactures, including alloys, unless otherwise specified.

remer 10 percent, and Compagnie de Mokta 5 percent.[5]

Iron and Steel.—A plant for galvanized and corrugated sheet was completed at Tamatave in December. Production was expected in early 1966 at an annual rate of 12,000 tons. Sheet will be provided for domestic use and also for the Comoro Islands and Réunion.

Monazite.—Société de Traitement des Sables du Sud de Madagascar produced 810 tons of monazite (696 tons in 1964) from beach sands along the coast near Fort Dauphin.[6] The remainder of total monazite output, 275 tons, presumably was produced by Établissements Tricot at Isandravisany, north of Manantenina, although data on this operation were not available.

Uranothorianite.—Concentrate production declined in 1965 because of mining and milling difficulties. Société des Minerais de la Grande Isle (SMGI) had trouble maintaining adequate ore grade at Ikatefa and at Amboasary-Kelly, where work was suspended temporarily. Also, water for the washing plant was in short supply.

NONMETALS

Cement.—The only cement plant in the country, that of Société des Ciments Vicat at Amboania, provided for about one-third of domestic requirements, the remainder being imported. The Amboania plant supplied the northwest region.

A 150,000-ton-per-year plant was planned near Antsirabe in the Hauts-Plateaux of the central part of the country, where the market is about 70,000 tons annually. The new plant was expected to operate initially at partial capacity to supply cement to the interior of the country; it was believed that cement could not be economically shipped to the coast for export.

The proposal for the Antsirabe plant resulted from a Westinghouse Electric Corp. study made in 1963. Foreign participation was expected to furnish 30 to 70 percent of the capital and also provide technical assistance.

Graphite.—Output included 8,874 tons of fine graphite and 8,141 tons of flake graphite. The total represented a recovery from the 1964 slump, which was attributed to decreased deliveries to U.S. stockpiles. Exports in 1965 were 17,900 tons, chiefly to the United Kingdom and the United States.

Mica.—SMGI and Société des Mines d'Ampandrandava, important phlogopite mica producers, merged in 1965.[7] The former produced 250 tons and the latter 159 tons during the year. The main producing areas were Benato, Ampandrandava, and Sakamasy. All producers cooperated, where possible, to reduce costs. Exploration was fairly widespread in mica areas throughout the southern part of the country.

MINERAL FUELS

Petroleum.—In June a government decree announced exploration agreement between Société des Pétroles de Madagascar (SPM) and Société Française des Pétroles Elwerath

(SOFRAPEL), the French subsidiary of Gewerkschaft Elwerath. SOFRAPEL has a one-half interest in SPM permits totaling nearly 100,000 square kilometers.[8] Permit areas and programs were announced.[9]

A wildcat test hole of a seismic high in the Tuilerie structure, Majunga basin, was terminated at 8,723 feet in July. Gas emulsion and salt water were encountered in Jurassic strata. Seismic work was conducted in the Betsiboka River delta, where drilling was planned in 1966.[10] SPM also investigated bituminous sandstone at Pemolanga.

Construction continued on the country's first petroleum refinery, at Tamatave, where capacity will be 12,000 barrels daily.

The Mineral Industry of Morocco[1]

By Walter C. Woodmansee [2]

The Moroccan minerals industry had a record year in 1965. According to estimates of the Association des Industries Minières, total value of mineral production (including crude oil) was $180 million,[3] compared with $174 million in 1964. Phosphate rock accounted for about 67 percent of the total. Mineral industry output value was equal to 7.8 percent of the gross national product of $2,300 million (1962 prices) and followed agriculture as second most important contributor to the national product.

Morocco maintained free world ranking as an ore producer of cobalt (second), lead (sixth), manganese (sixth), and phosphate rock (second). The country also was the leading world exporter of phosphate rock.

The new government budget, made public in February, included research and development projects on lead-zinc deposits near Midelt and Moulouya, potash deposits near Khemisset, and fluorspar deposits near Meknes. An economic survey mission, organized by the World Bank and started in 1964, formulated a development program for the 1965–70 period. The mission report was not available at yearend, but was concerned mainly with expansion of phosphate mining and the Safi chemical complex.

In June, following the declaration whereby the King assumed full authority for government operations under the constitutional "state of exception," Mohamed Laghzaoui, then the Director-General of the Office Chérifienne des Phosphates (OCP), was named also Minister of Industry, Mines, and Tourism. In July, however, Mr. Laghzaoui resigned, and his positions were divided among a Minister of Industry and Mines, a Minister of Tourism, and a new Director-General of the OCP. The Bureau de Recherches et de Participations Minières (BRPM) and the Bureau d'Etudes et de Participations Industrielles (BEPI), both government agencies concerned with mineral activities, retained their semi-independent status.

At yearend, 30,929 workers were employed in the minerals industry, differing only slightly from the 1964 total. Distribution of this total by main sectors of the industry was as follows: Phosphate 12,864 lead-zinc 4,820, coal 4,229, manganese 2,839, iron 2,727, crude petroleum 680, copper 525, cobalt 474, antimony 423, barite 396, and pyrite-pyrrhotite 302. The lead smelter at Oued-el-Haimer employed 305 workers.

PRODUCTION

The overall improvement in the minerals industry, as reflected in increased value of total output, took place in spite of a decrease in output of phosphate rock, the most important mineral commodity, comprising more than 60 percent of total value. The main Khouribga phosphate mines showed a higher output, which, however, was more than offset by a loss at the Youssoufia mine, where reserves were further depleted. A major development program, involving two new phosphate mines and a washing-drying center in the Khouribga area, was advanced during the year.

[1] Much information for this chapter was provided by Walter A. Hayden, U.S. Embassy, Rabat, Morocco.

[2] Physical scientist, Division of International Activities.

[3] Where necessary, values have been converted from dirhams (DH) at the rate of DH5.06= US$1.

e Estimate r Revised.

[1] In addition to commodities listed, Morocco also produced small quantities of copper matte from lead smelting, phosphatic fertilizer, and various quarry products, but production data are not available.

[2] Partial figure.

[3] Includes refinery fuel and losses, which are not listed separately in detail.

The Safi industrial complex, where phosphatic fertilizers and chemicals will be produced on a large scale, went into partial production. A new pyrrhotite mine was opened near the pyrite deposits at Kettara, providing sulfur for use at Safi and substantial byproduct copper in cinder for the export market.

The nonferrous metal mining sector showed improved output; several mines were reopened and renewed exploration was stimulated by favorable world markets for antimony, copper, lead, and zinc. United States companies expressed interest in copper, lead-zinc, barite, and fluorspar mine development. A new iron mine development program was initiated, including a pelletizing plant. Output of metal-

lurgical manganese was increased markedly.

The search for oil continued, both by government agencies and by foreign private participants, but no successes were announced. The limited oil reserves were further depleted, necessitating imports of large quantities of crude oil. A natural gasfield was discovered and was considered a source of industrial fuel.

TRADE

Morocco's trade balance in metals and minerals was favorable during 1964, the latest year for which complete trade data were available, whereas the total trade balance improved but remained in deficit. A marked increase in imports of iron and steel products was the principal reason for the reduced trade balance in mineral commodities. The relationship between mineral commodities and total trade is indicated below:

	Million dollars		Mineral commodities share of total trade (percent)
	Mineral commodities [1]	Total trade	
Exports:			
1963	137	384	35.7
1964	166	432	38.4
Imports:			
1963	29	443	6.5
1964	70	460	15.2
Trade balance:			
1963	+108	−59	XX
1964	+96	−28	XX

XX Not applicable.
[1] Values given are for only those commodities listed in tables 2 and 3 of this chapter.

Phosphate rock remained Morocco's predominant mineral export, as indicated in the following tabulation of principal mineral trade commodities:

Commodity	Value of 1964 export (million dollars)
Exports:	
Phosphate rock	$114
Lead concentrate	13
Manganese ore	10
Iron ore	8
Zinc concentrate	4
Cobalt concentrate	3
All other mineral commodities	14
Imports:	
Iron and steel	28
Petroleum:	
Crude	17
Refinery products	8
All other mineral commodities	17

France continued as Morocco's leading trading partner in mineral commodities as well as in total trade. According to data from the Statistical Office of the United Nations, mineral exports to France totaled $60.5 million in 1964, largely phosphate rock and nonferrous metal ores and concentrates. Other recipients of major shares of Moroccan minerals were West Germany $20.9 million, United Kingdom $16.4 million, and Belgium-Luxembourg $14.4 million. The United States received mineral commodities valued at $4.7 million.

Moroccan imports from France totaled $37.8 million in 1964, largely iron and steel.

Preliminary information for 1965 indicated a slight increase in mineral export value to about $170 million. Table 4 gives exports of the principal mineral commodities during 1965. Corresponding estimated mineral imports were about $65 million during 1965, a slight decrease, due mainly to lower receipts of coal and iron and steel.

Table 2.—Morocco: Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1963	1964	Principal destinations, 1964
Metals:			
Aluminum:

COMMODITY REVIEW

METALS

Antimony. — Mine output showed a marked increase as several mines were reopened. Omnium de Gerance Industrielle et Minière (OGIM) was the largest producer from several small mines near Djemaa deM'Rirt, northeast of Oued Zem. Although operations expanded during the year, employment in 1964 decreased from 462 to 423 at yearend.

Cobalt.—Compagnie de Tifnout Tiranimine absorbed Société Minière de Bou Azzer et du Graara (SMAG) and assumed control of the new mine at Aghbar, 10 kilometers east of the exhausted Bou Azzer mine. Exploration continued at Aghbar; reserves in the area assured only 3 years' production at an extraction rate of 400,000 tons of ore at 1.5 percent cobalt.[4]

Copper.—Société des Mines de Bou Skour produced 55,000 tons of sulfide and oxide ores, averaging about 3 percent copper, and 3,500 tons of concentrate containing 36 to 37 percent copper, at its Bou Skour mine. Ore reserves at Bou Skour totaled 300,000 tons in early 1965. The balance of Moroccan mine copper output was largely from Djebel Klakh, Azegour, and other small properties in the High-Atlas, south of Marrakech. In addition, substantial quantities of copper were contained in pyrite and pyrrhotite mined at Kettara, where the ore contains 0.6 to 0.8 percent byproduct copper. Because of prevailing high market prices for copper, prospects for new mine development and reopening of old mines were good.

The Moroccan Government has expressed the hope that mine production of copper will increase to a point at which it would be economically feasible to construct a smelter. According to the press, a Yugoslav group agreed to exploit copper deposits in the Anti-Atlas in cooperation with the BRPM and also to assist in con-

[4] Mines et Métallurgie No. 7, July–August 1965, p. 337.

struction of a smelter if such a project should become feasible.

On May 26, 1965, a small washing plant to produce copper concentrate was formally dedicated at Irhem, 150 kilometers southeast of Agadir, where two small copper deposits were under development and where copper prospects were considered good. Copper ore at 2 to 2.5 percent copper was concentrated to 30 to 35 percent copper at a rate of 5 tons of concentrate per day, according to officials of the Direction des Mines. This project was a joint effort of the BRPM and a Czech firm, resulting from a 1961 agreement. The Czechs provided mining equipment and the washing plant at a cost of $4 million, which is to be repaid by supply of the mineral product. The Moroccan Government furnished capital for exploration and development.[5]

Iron and Steel.—The Uixan and Sétolazar iron mines of Société des Mines du Rif (formerly Compagnie Espagnole des Mines du Rif), near Nador on the Mediterranean coast, accounted for the bulk of 1965 iron ore output. The company initiated a new development program, with European assistance, to lower costs and produce a better quality product. Plans called for a new 350-meter central shaft, an annual mining rate of 1.2 million tons, and a 800,000-ton pelletizing plant. Although production was greater in 1965 than that of 1964, ore sales dropped off.

Renewed interest was shown in the long-considered Nador integrated steel mill, using Rif iron raw materials, but at yearend no specific program had been announced.

Lead and Zinc.—There were no major changes in this sector during 1965. Exploration for new deposits and investigations of old lead-zinc workings continued, although no new mines were developed during the year. The BRPM conducted surveys in the High Moulouya, where a development company was planned, and in Bou Madine and the Jebilet.

In 1964, the latest year for which data are available, the principal lead concentrate producers were Bou Beker 19,495 tons, Mibladen 17,624 tons, Aouli 16,980 tons, Touissit 14,500 tons, and Djebel Aouam 12,380 tons. These mines accounted for 78 percent of total output of lead concentrate. About 80 percent of zinc concentrate output originated at two mines—Bou Beker, 37,900 tons, and Touissit, 27,450 tons. Lead output at Djebel Aouam, operated by Compagnie Royale Asturienne des Mines, S.A., reportedly increased 30 percent in 1965. Exploration by Société Minière et Métallurgique de Penarroya at Aouli discovered new ore in certain veins.

The Oued el Haimer lead smelter of Fonderies Penarroya-Zellidja produced 18,839 tons of pig lead from 24,960 tons of concentrate, largely from Bou Beker but including about 2,600 tons from Algeria. The Moroccan Government announced plans for a second lead smelter, at Kenitra, for treating Tafilalet ores.

Manganese.—The Imini mine of Société Anonyme Chérifienne d'Etudes Minières (SACEM), an affiliate of the French Compagnie de Mokta, maintained its position as leading mine manganese producer. Although complete data are not available, Imini apparently produced about 140,000 tons of metallurgical-grade manganese in 1965, well below the mine capacity of 250,000 tons. Output at Imini and at other manganese mines was curtailed by marketing difficulties. Two Birtley tables, ordered in 1964, were installed at Imini for treating fines from stockpile and rejects from the main treatment plant at a rate of 32,000 tons per year.

Output of metallurgical-grade ore, by mine, was as follows during 1964: Imini 134,700 tons, Bou Arfa 81,200 tons, and Tiharatine 11,300 tons; remaining output was derived from retreatment of dumps at Tiouine (about 26,000 tons) and several small mines of the miners' cooperative at Ouarzazate (about 13,000 tons).

In 1965, 106,750 tons of Imini metallurgical manganese ore was agglomerated to 84,800 tons sinter at Sidi Maarouf, compared with 81,000 tons ore sintered to 64,700 tons in 1964.

As of January 1965, stocks were as follows: Metallurgical 48,048 tons and chemical 38,671 tons.[6]

NONMETALS

Phosphate. — Production of phosphate rock at Khouribga, the principal mining area, was greater in 1965, but the mining rate declined at Youssoufia, the other pro-

[5] U.S. Embassy, Rabat, Morocco. State Department Airgram A–433, June 8, 1965, 2 pp.
[6] U.S. Embassy, Rabat, Morocco. State Department Airgram A–372, May 7, 1965, 1 p.

ducing center which is gradually being phased out, resulting in an overall lower output, as shown in the following tabulation:

Year	Thousand tons					
	Khouribga [1]		Youssoufia		Total	
	Wet	Dry	Wet	Dry	Wet	Dry
1964	6,763	7,203	3,050	2,895	9,813	10,098
1965	7,405	7,351	2,767	2,473	10,172	9,824

[1] The 1964 output of dry phosphate rock was reported higher than that in the wet state; this is attributed to a drawing from wet mine stockpiles for the drying plant.

Development continued on three projects in the Khouribga area—the open pit and underground mines at Meraa el Arech, 20 kilometers east of Khouribga; the open pit at Sidi Daoui Sud, 25 kilometers east of Khouribga; and the washing and drying plants at Beni Idir. Construction was underway on a conveyor belt system connecting the mines to processing plants. Meraa el Arech was expected to enter production in early 1966 at an annual rate of 2 million tons. Construction of service buildings and storage facilities were completed at this mine. The first section of the drying plant at Beni Idir, with four ovens, each having capacity of 1 million tons per year, was readied for operation at yearend, and six additional ovens were planned. Completion of the washing plant was planned for 1967. Production from the Sidi Daoui Sud open pit also was expected in 1967. Reserves, as reported by OCP, were 100 million tons at 72–75 percent bone phosphate of lime (BPL) at Meraa el Arech and 245 million tons at 58–75 percent BPL at Sidi Daoui Sud.[7]

In November the Export-Import Bank authorized a credit of $24 million to OCP for the purchase of U.S. mining equipment to be used in the $56.6 million phosphate mining expansion. OCP planned a production of 17 million tons of phosphate rock by 1970–71. The order included a 60-cubic-yard dragline, a 9-cubic-yard dragline, earthmoving equipment, drill rigs and equipment, conveyor belts, and heavy-duty trucks for use at Meraa el Arech and Sidi Daoui Sud.[8]

The chemical complex at Safi, on the Atlantic coast 60 kilometers west of the Youssoufia phosphate mining area, was officially inaugurated by King Hassan II in June. Technical difficulties were encountered during early operations. Annual production capacity was 200,000 tons triple superphosphate, 150,000 tons diammonium phosphate, and 14,000 tons phosphoric acid. In addition to local phosphate rock, raw materials included pyrite and pyrrhotite form Kettara. An agreement was made between OCP and the Algerian Ministry of Economics for temporary supply of ammonia from Arzew, Algeria, until an ammonia plant is built at Safi.

Early in the year, OCP, the Government agency controlling the mining and marketing of phosphate, sought United States and other foreign participation in financing and management of Société Maroc-Chemie, a subsidiary of OCP responsible for the Safi chemical plant. OCP had planned an initial investment of $40 million at Safi. West Germany provided $9.8 million for roads, services, and water canalization.[9]

The long-planned project for participation of Occidental Petroleum Corp. in the Safi project remained in the discussion stage. An accord in principle was signed by OCP and Occidental whereby a joint company was considered with capitalization of $100 million, part of which was for Safi construction.[10] At yearend, negotiations continued for a $37.5 million superphosphoric acid plant, rated at 1,000 tons per day and expandable to 5,000 tons daily by 1970, and an ammonium phosphate plant (capacity unreported).

With demand for crude phosphate increasing, domestic consumption reached 240,000 tons in 1965. The Safi works ab-

[7] Mining Journal. V. 265, No. 6794, Nov. 5, 1965, p. 319.

[9] The Economist. V. 215, No. 6356, June 19-25, 1965, p. 1433.
[10] Mining Journal. V. 264, No. 6766, Apr. 23, 1965, p. 317.

sorbed about 50,000 tons. Consumption of phosphate rock was expected to attain a yearly rate of 500,000 tons with expanded production.

In conjunction with Tunisia and Jordan, OCP authorities formed Office des Producteurs de Phosphates to coordinate phosphate sales, following conferences at Amman, Jordan, and Rabat, Morocco. OCP attempted to conclude long-term agreements for phosphate sales. In June a contract was made with Compagnie Royale Asturienne des Mines for 500,000 tons of phosphate rock over a 5-year period. Marketing of superphosphate from Safi was difficult. In July the first sale, 10,000 tons, was made to South Korea, which in October ordered 50,000 tons valued at $3 million.

Potash.—BRPM and Mines Domaniales de Potasse d'Alsace, the French potash firm, jointly conducted geophysical exploration and deep drilling in the Khemisset basin, 70 kilometers southeast of Rabat. Results of exploration were not announced. Discoveries of potash also were reported in the Doukkola and Zemmour basins.

Pyrite and Pyrrhotite.—Production of pyrite, containing 30 percent sulfur and up to 6 percent copper, continued at a slightly reduced scale at Kettara, 30 kilometers northwest of Marrakech. Société d'Exploitation des Pyrrhotines de Kettara was formed in January to mine extensive pyrrhotite deposits nearby. The first years' production, 128,014 tons, largely went to Safi for use in sulfuric acid.

MINERAL FUELS

Coal.—Anthracite production at Djerada continued at a planned rate of about 400,000 tons per year, which, however, exceeded domestic demand and exports. The mining rate was maintained for mine efficiency and employment purposes. Stocks of anthracite totaled 325,000 tons at the start of the year.

Solid fuel requirements continued to decline. Consumption was 339,600 tons in 1964 and 314,000 tons in 1965, mainly for electric power (97,900 tons in 1965) and cement (53,600 tons in 1965).[11] Difficulty was encountered in marketing anthracite.

Bituminous coal was received from Poland in 1965 pursuant to a new trade agreement signed on February 15, 1965, providing for a quota of 70,000 tons during the year.

Natural Gas. — Early in the year, the Moroccan Government authorized increased imports of butane as an emergency measure because of a growing shortage; the consumption rate for butane had increased 16 percent, whereas output was falling.[12]

Discovery of an important natural gas deposit at Kechoula, near Essaouira, was announced late in the year. Proved reserves were reported at 16 to 18 billion cubic feet. SCP and Office Chérifienne des Phosphates (OCP) considered the feasibility of a 200-kilometer pipeline to deliver this gas as fuel for the Youssoufia phosphate works.[13]

In 1965, the Haricha gasfield produced about 350 million cubic feet, of which about 35 million cubic feet was used by the Sidi Kacem refinery as fuel.

Petroleum. — Production of crude oil from the two active fields—Rharb and Sidi Rhalem—remained at a rate of about 2,000 barrels per day, only about 10 percent of requirements. Imports of crude oil more than doubled in 1964 to supply the two refineries. Production from the Rharb field declined in both 1964 and 1965 as reserves were being depleted. Recoverable reserves of both fields were reported at 1,687,000 tons.[14]

Only 23,772 feet were drilled by two active drill rigs, compared with 45,600 feet in 1964 and 94,800 feet in 1962. A review of exploration activity for the year follows:

Three wells were completed and one minor oil showing was reported—that of Deutsche Schactbau—und Tiefbor G.m.b.H. in the region of Berguent.[15] A number of companies abandoned exploratory work, at least on certain permits. The Doukkala and Essaouira D permits were reduced in size in accordance with the Petroleum Law. A new exploration agreement between Bureau de Recherches et Participations Minières (BRPM) and Petrofina, S.A., the Belgian firm, was for the Sebou (2,800 square kilometers) and Sebou B (5,000 square kilometers) areas on the Rharb plain. At yearend, SCP, a petroleum company shared between BRPM and the French State company Bureau de Recherches des Pétroles (BRP), held eight permit areas totaling 15,565 kilometers.

Geologic investigations were conducted by SCP in two permit areas (Essaouira and Moulouya). Seismic work (weight-dropping method) was conducted on the Moulouya permit. SCP also had seismic crews on another permit area for 1 month and the Essaouira offshore permit (gas exploder method) for 1 month.

Other foreign interests continued exploration in conjunction with BRPM. PREUSSAG worked the Paleozoic sediments of the Doukkala permit, including geologic studies and seismic work, and also made a 2-month geochemical study in the Safi area. Société Anonyme Marocaine-Italienne des Pétroles (SOMIP), subsidiary of AGIP Mineraria, relinquished its permit near Colomb-Béchar after unsuccessful drilling and moved into the Haut Plateaux, south of Oujda, where 7 months of seismic work (weight-dropping method) was completed on the Tendrara anticline. Drilling was planned for 1966. Petrofina conducted geologic, geophysical, and geochemical work on the Sebou permits. Two wells were drilled—one was dry and abandoned, and the other, at Souk-el-Arba, was suspended at 3,750 feet awaiting arrival of another drill rig. CANDEL, operator on the Ksar-es-Souk permits, carried out geologic and seismic work, and planned drilling in 1966.[16]

Crude oil throughput at the Société Marocaine Italienne de Raffinage (SAMIR) refinery at Mohammedia was 699,000 tons in 1964; throughput at SCP's Sidi Kacem refinery was 375,000 tons. The total country crude oil throughput rate was 20,000 to 28,000 barrels per day.

The Mineral Industry of Nigeria

By Walter C. Woodmansee [1]

Nigeria became more prominent as a world producer and exporter of petroleum in 1965. Oil exploration continued at a high level, particularly offshore, where a record success ratio of about 85 percent was attained. Crude oil became the country's leading export, surpassing agricultural products which traditionally has been the chief source of foreign exchange. Fourteen petroleum companies, including 9 U.S. firms, were engaged in petroleum exploration and development, and more than 40 U.S. companies were engaged in all phases of the industry.

Basic conditions for foreign investment remained good. No difficulties were encountered in repatriation of profits. Tax relief was planned for new mining ventures. Capital allowances on machinery and buildings continued to be generous. There were no problems in labor supply.[2]

The Geological Survey Division, Ministry of Mines and Power, announced plans for increased mineral exploration including aeromagnetic surveys, geologic mapping, and mineral investigations under the National Development Plan for 1962–68. Technical assistance was provided by Canada, United Kingdom, and Italy, with efforts concentrated in the Western Region and in tin-mining areas of the Plateau Province, Northern Region.

According to the Federal Office of Statistics, 50,717 laborers were employed in the metallic minerals sector in early 1965, nearly all in connection with tin mining and smelting. The petroleum industry employed 3,135 persons in exploration, including 2,668 Nigerians, and more than 10,000 persons were probably engaged throughout the industry, including service and supply.[3] The Nigerian Coal Corp. employed 3,157 persons, including 2,412 underground miners, at the Enugu Colliery.

PRODUCTION

Nigeria's output of crude oil showed the world's fastest rate of expansion in 1965 and reached 300,000 barrels per day late in the year. New oil wells became productive at a steady rate throughout the year. Increased crude oil production resulted in a corresponding growth in associated and nonassociated natural gas output, which was largely flared. Sales of natural gas increased moderately as new industrial demand for natural gas fuel was developed. Late in the year, Nigeria's first domestic refined petroleum products were delivered to local consumers from the new petroleum refinery near Port Harcourt.

In the metals sector, mine production of cassiterite was the highest for several years, and output of tin ingot also showed a gain. The cement industry showed continued growth.

[1] In addition to commodities listed, lead and zinc concentrates and a few tons of tungsten and molybdenum ores are produced, but exact output data are not available.

[2] U.S. imports.

TRADE

The trade balance in mineral commodities was favorable in 1965, primarily because of increased crude oil exports, whereas the total trade balance improved but remained in deficit, as shown in the following table:

	Million dollars		Mineral commodities share of total (percent)
	Mineral commodities [1]	Total trade	
Exports:			
1963	87	518	16.8
1964	118	576	20.5
1965	230	728	31.6
Imports:			
1963	100	574	17.4
1964	136	711	19.1
1965	134	772	17.4

1963	—13	—56	XX
1964	—18	—135	XX
1965	+96	—44	XX

XX Not applicable.

[1] Values given are for only those commodities listed in table 2 and 3 of this chapter.

Source: Statistical Office of the United Nations.

Crude oil became Nigeria's leading export for the first time. Exports of crude oil were valued at $181.6 million, compared with $76.8 million in 1964.[4] Exports of tin, which followed crude oil in mineral export value, were $41.7 million compared with $35.0 million in 1964. The United Kingdom received mineral commodities valued at $131.8 million from Nigeria in 1965, or 57.3 percent of Nigeria's mineral exports. Minerals sent to the United States were valued at $21.7 million.

Principal mineral imports were iron and steel $53.6 million ($53.0 million in 1964) and petroleum products $48.4 million ($54.1 million in 1964).[5]

Shell-BP Petroleum Development Co. of Nigeria Ltd. exported 87.7 million barrels of crude oil and sold 1.5 million barrels to local markets, according to company re-

[4] Where necessary, values have been converted from Nigerian pounds to U.S. dollars at the rate of £1 = $2.80.

[1] Includes columbium-tantalum and zirconium ores.
[2] In addition, estimated reexports and bunker loadings of refined products were 1.5 million barrels annnually during 1963–64 and 1.1 million barrels in 1965.

Principal source: Statistical Office of the United Nations.

ports. Nigerian Gulf Oil Co. Ltd. joined Shell-BP as an oil exporter and sent 9.3 million barrels to foreign markets. Petrobrás, Brazilian state oil agency, concluded a contract with Nigerian Gulf for 460,000 barrels of crude oil in 1965, valued at $830,000, shipped in Brazilian tankers. Nigerian Gulf began oil exports to the United States in May.

An export tariff of $8.40 per ton of metal scrap was introduced to conserve the domestic supply. In April, import tariffs were reduced on cement, wire rods, galvanized wire, and anthracite. Duty on cement imported by approved manufacturers, formerly $14 per ton or 75 percent ad valorem, became 33⅓ percent ad valorem. Import duty on clinker was reduced from $2.80 per ton to $1.40 per ton. Wire rods and galvanized wire import duties were lowered from 33⅓ percent to 20 percent ad valorem for certain manufacturers. A former 33⅓ percent ad valorem tax on anthracite for tin smelting was rescinded.[6]

COMMODITY REVIEW

METALS

Aluminum.—Nigeria's first aluminum rolling mill was planned at Port Harcourt, and the third plant for aluminum corrugated roofing sheet was planned at Lagos.

Iron and Steel.—In August, an agreement was signed between the Nigerian Government and a western consortium for the development of an $84-million iron and steel industry, the first fully integrated facility

r Revised. NA Not available.
[1] Imports of manufactured gas and minor quantities of petroleum coke and natural gas are reported in terms of value: $409,000 in 1963, $338,000 in 1964, and $491,000 in 1965.

Principal source: Statistical Office of the United Nations.

on the west coast of Africa. Plans called for facilities at two locations; pig iron and crude steel facilities were planned for construction at Lokoja in the Northern Region, near iron ore and limestone deposits, and a steel casting and rolling mill were to be constructed at Onitsha on the Niger River in the Eastern Region. Rolling mill capacity will be in the range of 125,000 to 250,000 tons per year.

The operating company, United Nigerian Iron and Steel Co. (UNISCO), is a consortium of Wellman-Smith-Owens Engineering Corp. (United Kingdom); Demag A.G., Didier-Werke A.G., and Ferrostaal A.G. (West Germany); and Nigerian Steel Associates, Inc. (Westinghouse Electric International, Inc. and Koppers International, Inc., United States).[7]

Lead and Zinc.—Exports of lead and zinc concentrates commenced from the Abakaliki mine, Eastern Nigeria, which was reopened in 1964. Exploratory drilling revealed two tabular ore bodies, which were under development. A new crushing plant was completely installed, and surface plant construction continued.

Molybdenum.—Charter Consolidated Ltd., London, planned an aerial survey, geochemical prospecting, and drilling of an area in Plateau Province.

Tin and Columbite.—The 1965 output of cassiterite, the highest since 1957, was valued at $41.4 million, compared with $35 million in 1964. Columbite output was 65 percent of the free world total in 1965 and was valued at $3.25 million.

Company profits and tin prices were favorable during the year. The tin price was increased to $4,796 per long ton in late 1964, dropped slightly in March 1965, and

[7] Mining Journal. V. 265, No. 6784, Aug. 27, 1965, p. 149.

remained at an average of $3,828 through most of the year.[8] Contract prices for columbium-tantalum concentrate in ratio of 10:1 were about $18 per long ton while $22.40 per ton was often realized in the open market.

Amalgamated Tin Mines of Nigeria Ltd., the principal producer, reported increased profits for 1965, although the company's tin output was lower than that of 1964. The company paid royalty and taxes of nearly $4.2 million to the Nigerian Government during the year. The main deposit at Odegi of United Tin Areas of Nigeria Ltd., a relatively small producer, was under geologic investigation.

Bisichi Tin Co. (Nigeria) Ltd., second in tin output in Nigeria and leading world producer of columbite, announced plans for increased mine production at Bukuru, Plateau Province, Northern Region. Two new pumps have been acquired for providing high water pressure for breaking mineralized ground and also for jig operation.

The Ministry of Mines and Power reported renewed prospecting near Kano and at Riruwai, 210 kilometers southeast of Kano, after a 9-year lapse. The Ministry also signed the Third International Tin Agreement in London on behalf of the Nigerian Government. Cassiterite and columbite reserves, as reported by the Ministry and depleted by 1965 output, were 116,800 long tons and 32,200 metric tons, respectively.

A ground geophysical survey on the Jos Plateau, sponsored by the United Kingdom Ministry of Overseas Development, was completed early in the year. A report, "Geophysical Prospecting for Basalt-Covered Alluvial Cassiterite on the Jos Plateau, Northern Nigeria" was prepared by D. J. M. Smith, Overseas Geological Surveys, Geophysical Division.

NONMETALS

Cement.—Total capacity, according to the Northern Nigeria Ministry of Trade and Industry, was increased to 1.5 million tons annually from four clinker grinding plants and four cement plants, including three under construction in 1965. Domestic demand was on the order of 900,000 tons per year. Producing companies were Nigerian Cement Co. Ltd. (Eastern Region), West African Portland Cement Co. Ltd. (Western Region), and Cement Co. of Northern Nigeria Ltd. (Northern Region).

Cement prices were higher, and a cement shortage prevailed at times. The Government lowered import duty on cement and clinker, but competition to hold prices down was lacking. Distribution and marketing were handicapped by limited railroad transportation facilities.

In March, Northern Nigerian Development Corp. announced plans for a new plant making a wide range of asbestos cement products at Kaduna. A French firm, Société Fives lil Caille, conducted a feasibility survey for a third cement plant in the Northern Region.

Lime.—Cideco Ltd., Lagos, an Israeli-owned firm, announced plans to establish a lime industry. The company estimated an investment of $1.4 million and anticipated purchasing plant machinery in the United States. Annual plant capacity will be 20,000 tons of quicklime and 10,000 tons of hydrated lime. Location of the plant site depends on a survey of limestone deposits near Ewokeri in the Western Region and Gboko in the southeast part of the Northern Region.[9]

MINERAL FUELS

Coal.—Coal production continued to expand in 1965, and exports of briquets to Ghana increased markedly in 1964. According to the Nigerian Coal Corp., the contract for sales to Ghana was increased to 48,000 tons for the fiscal year ending March 31, 1965, and output per man-shift was reported as 34.7 tons for miners and 16.7 tons overall. The Corporation also sought coal markets in West African countries other than Ghana.

The Federal Office of Statistics, Lagos, reported average monthly domestic sales of 55,802 tons in 1964 (the last year for which these data are available), distributed as follows: Nigerian Railway Corp., 20,198 tons; public utilities, 13,604 tons; direct sales from mines, 8,909 tons; and other, including bunkers, 13,091 tons.

Petroleum.—Nigeria showed the world's largest rate of expansion as an oil producer in 1965, moved into 13th place in world ranking, and ranked third in Africa follow-

[8] Tin International. March 1966, p. 65.
[9] U.S. Embassy, Lagos, Nigeria. State Department Airgram A-736, May 29, 1965, 2 pp.

ing Libya and Algeria. Oil also became Nigeria's leading export.

Output of crude oil increased 126 percent over that of 1964. A spectacular drilling success ratio continued, as increased emphasis was placed on offshore operations. Several new fields were under development at yearend; continuing discoveries and further expansion of the industry were indicated for 1966.

Table 4.—Nigeria: Oil and gas production, by field, 1965

Field	Oil (thousand barrels)	Gas (million cubic feet)
Bomu	24,512	18,886
Imo River	18,590	10,737
Umuechem	14,245	17,275
Okan	9,666	6,520
Korokoro	9,362	10,452
Olomoro	5,530	1,257
Obigbo North	5,063	3,275
Uzere West	4,476	2,056
Agbada	1,840	2,068
Ebubu	1,725	1,549
Oloibiri	1,667	605
Uzere East	1,141	704
Afam	890	2,458
Apara	647	1,596
Total	99,354	79,438

The 1965 average daily production rate for crude oil was 272,000 barrels, compared with 120,000 barrels in 1964. In August, the rate passed 300,000 barrels daily and for December was 359,724 barrels, according to Nigerian Ministry of Mines and Power statistics. Shell-BP Petroleum Development Co. of Nigeria, Ltd., continued to dominate the industry, accounting for 90 percent of the 1965 output. In April Nigerian Gulf Oil Co. Ltd. became the country's second largest oil producer, when production began from the offshore Okan field, yielding 9.7 million barrels in 1965.

At yearend 14 petroleum companies were engaged in Nigerian oil operations, including 9 U.S.-based companies. In addition to Shell-BP and Gulf, participants active in exploration and development were American Overseas Petroleum Co. (Amoseas); AGIP Mineraria, an Italian Government oil affiliate; Mobil Exploration Nigeria Inc.; Phillips Petroleum Co.; Société Anonyme Française de Recherches et d'Exploitations Petrolières (Nigeria) Ltd. (SAFRAP), a French firm; and Tennessee Nigeria, Inc. (Tennessee Gas Transmission Co. with its partners Sinclair Nigerian Oil Corp. and Sunray Nigeria, Inc.). Early in the year, Shell-BP had 65 fields or separated discoveries, largely shut-in or "suspended" wells not tied to pipeline.[10] Few fields were fully developed or completely defined. Shell-BP producing fields totaled 13 in the Eastern Region and 5 in the Western Region. Gulf's Okan field had 21 producing wells. All output was from flowing wells. By yearend the other concession holders had made oil strikes, most on their first wells, and were engaged in stepout drilling and field development. Crude oil reserves were increasing as offshore development continued; early in the year they were estimated at 3 billion barrels, largely onshore,[11] and yearend estimates were as high as 10 billion barrels.

Shell-BP had invested $420 million in exploration and development through 1964.[12] Estimated revenues paid to the Nigerian Government by oil companies, based on a 50/50 profit split, were $25 million in 1965.[13]

The Ministry of Mines and Power was in the process of reviewing petroleum laws and preparing new legislation consolidating the various laws under the Division of Petroleum. Oil producing companies contributed to a training fund under which Nigerians study oil technology and other fields abroad or receive on-the-job training.[14]

Other significant developments were the inauguration of Nigeria's first oil refinery, which went on stream in October, and advanced progress in negotiations between United Kingdom and Nigerian authorities on the natural gas liquefaction plant proposed in 1964.

Exploration and Development.—Exploration and development continued at a fast pace as more companies joined in the search for oil. Work onshore in the Eastern and Midwestern Regions of the Niger delta stressed field development; the discovery rate slumped slightly compared with that of 1964. Exploration became more intense offshore. Shell-BP, Gulf, Amoseas, and Mobil were actively engaged in drilling operations offshore. All companies reported discoveries and development programs. The

offshore success ratio was about 85 percent, a record, and the onshore ratio was about 60 percent.[15] Offshore rigs consisted of two jackups, a submersible Delta platform, and two inland barges for use near shore.

Shell-BP drilled more than 900,000 feet and 87 holes in the Eastern and Midwestern Regions and offshore.[16] About 35 holes were land wildcats with a 50-percent success ratio. Offshore, Shell-BP was successful in five of seven wells drilled to midyear.

Shell-BP's Trans-Niger pipeline was officially opened in June, adding 50,000 barrels per day from the Eriemu, Kokori, Ughelli, Uzere, and Olomoro fields in the Western Region to the 200,000 barrels per day flowing from the Eastern Region to the Bonny terminal. Pipeline construction and terminal expansion continued at yearend.

Sixteen seismic parties were in the field at yearend, distributed by company as follows: Shell-BP 6, SAFRAP 6, Tennessee 2, Phillips 1, and AGIP 1. Esso West Africa, Inc., a newcomer to Nigeria, investigated two exploration concessions in the Abakaliki-Ogoja area, Eastern Region. Canadian Aero Services, Ltd., completed an aerial photo survey of an area of 1,000 square miles on the delta. Decca Navigation Co. made a hydrographic study of the Nigerian coast for the Nigerian Government and operating companies.

Refining.—The new $28 million, 45,000-barrel-per-day refinery of Nigerian Petroleum Refining Co. (owned 50 percent by the Nigerian Government, 25 percent by Shell, 25 percent by British Petroleum) at Alesa-Eleme, near Port Harcourt, underwent operational tests during August and September and was on stream commercially in October. According to Ministry of Mines and Power monthly bulletins, refinery throughput from October to December was 1,518,885 barrels, including 110,486 barrels of imported material classified as kerosine. Crude oil was from the Imo River and Umuechen fields. The refinery will supply the domestic market, where demand was estimated at 25,000 barrels per day, and will provide fuel oils for exports. Indigenous refinery production reportedly will save $30 million per year in foreign exchange.[17]

Two ancillary projects were announced—a small liquefied petroleum gas (LPG) plant for 100,000 barrels annually and an experimental plant for byproduct recovery. A new marine loading jetty, accommodating tankers up to 18,000 deadweight-tons, was finished in July. The Nigerian Railway Corp. built a 26-kilometer spur line to the refinery.

Natural Gas.—Domestic gas sales increased during 1965 but remained small relative to gross output of associated and nonassociated gas, most of which was flared. Sales totaled 3,163 million cubic feet according to the Ministry of Mines and Power. Gross output exceeded 200 million cubic feet per day. Crude oil contained an estimated 800 to 900 cubic feet of gas per barrel.

The new petroleum refinery will use about 4 million cubic feet per day as fuel.[18] A powerplant near Port Harcourt used natural gas at a daily rate of 6 million cubic feet, and nearby industry used 1.3 million cubic feet daily. Main sources in the Eastern Region were the Afam, Korokoro, Apara, and Imo River fields. The Imo River field served the nearby Aba textile mill by Shell-BP's 30-kilometer, largely aluminum pipeline, which represents the first industrial use of natural gas in the country.[19] In the Midwestern Region the Ughelli field supplied a local power station. Natural gas markets were reviewed in an article, "Nigeria, the Federal Government's Control of the Oil Industry and the Development of Crude Oil Production in the Niger Delta", by R. K. Dickie.[20]

Further progress was made in negotiations between Conch International Methane, Ltd., and the Nigerian Government for a proposed gas liquefaction plant. Specifications called for a processing capacity of 100 million cubic feet per day, or 700,000 tons liquefied natural gas (LNG) annually. Feasibility and cost studies continued at yearend. Estimated costs included $50 million for the main plant on Bonny Island, $34 million for two LNG tankers,

Table 5.—Nigeria: Salient petroleum exploration and development activities, 1965

Company	Location	Activity
American Overseas Petroleum Ltd. (Amoseas)	Block F, Pennington field, Block G.	Five discoveries in six wells drilled. Discovery well in Pennington field flowed at 1,730 barrels per day of 33.7 API oil, at 5,100 feet. Survey team arrived at Port Harcourt in April for preliminary study of production facilities.
Mobil Exploration Nigeria Ltd.	Blocks L and M	11 wildcat wells, 5 producers. Stepout drilling late in year.
Nigeria AGIP Oil Co. Ltd.	Block 34, Eboka field	First successful well completed in June; two dry holes. Joined with Phillips (see below) near yearend, but remained operating partner.
Nigerian Gulf Oil Co. Ltd.	Offshore: Block D, Okan field.	Construction included well-head equipment, gathering and flow lines, storage tanks. Production rate reached 49,000 barrels daily from 19 wells. Work on loading facilities completed; production and auxiliary equipment for 75,000 barrels per day; 10-kilometer, 26-inch underwater pipeline from field gathering platform to temporary offshore mooring terminal. Storage capacity at terminal increased to 386,000 barrels. Preliminary field and laboratory soil tests made for proposed new onshore tank farm in Midwestern Region.
	Block C	Discovery made in October. Gulf brought "Glomar V" drilling ship and another drill rig into area. Several wildcats productive.
	Onshore: Block 29 e, Robertkin field.	Discovery early in year; 2,300 barrel-per-day flow rate, 38.5° API, perforations at 11,802 feet. Located in delta marshes, 48-kilometers southwest of Port Harcourt.
Phillips Petroleum Co	Blocks 43–47	Formerly Block 30, relinquished by Tennessee and subdivided. Acquired 50 percent of AGIP Block 34.
Société Anonyme Francaise de Recherches et d'Exploitations Petrolières (Nigeria) Ltd. (SAFRAP).	Blocks 35 Band C, Obagi-Uberte fields.	Seven productive wells completed. Contract given for 40-kilometer, 12-inch pipeline connecting field to Trans-Niger pipeline. French seismic party worked delta perimeter and Niger River borders. Obagi production planned in 1966. Reserves 500 million barrels oil equivalent.
Shell–BP Petroleum Development Co. of Nigeria Ltd.	Onshore, Eastern Region	Pumping and flow stations completed or in construction at Imo River, Obigdo North, Bomu, and Agbada; second station started at Imo River. Contract made with Willbros (Overseas), Ltd., for Rumuekpe-Bomu, 78-kilometer, 28-inch pipeline. Booster station under construction at Rumuekpe field. Imo River-Ebubu, 12-inch line, Nkpoku-Ebubu, 8-inch line, Obigdo North-Ebubu, 6-inch line, Korokoro-Afam, 8-inch gas line, Bomu-Ebubu, 8-inch gas line, under construction or completed. Storage tank construction continued at Bonny terminal; tanks 9-10 completed; Phase III, including tanks 11-14, underway; increase throughout capacity to 400,000 barrels per day; dredging for 50,000-ton tankers; storage capacity 1.7 million barrels.
	Onshore, Midwestern Region.	Pumping and metering stations completed or in construction at Olomoro, Kokori, Ughelli, Uzere. Trans-Niger line, 224-kilometers, completed in June, connecting to Eastern Region. Branch lines Uzere-Rumuekpe, 18-inch, Ughelli-Eriemu, 16-inch, Kokori-Eriemu, 10-inch, completed in April. Field development at Meja, Meta, Meren, Delta fields.

Table 5.—Nigeria: Salient petroleum exploration and development activities, 1965—Continued

Company	Location	Activity
Shell-BP Petroleum Development Co. of Nigeria Ltd.	Offshore, Blocks, E, H, J, and K.	Well in Block E, 13 kilometers off mouth of Dodo River, blew out in July after hitting gas pocket. "Triton" platform, owned by Offshore Venezuela, C.A., disabled and drilling suspended until new platform arrived from Netherlands. Drilling successful in Blocks H, J, and K at depths of 2,500-8,500 feet.
Tennessee Nigeria, Inc--	Block 33 c, Brass River field.	Located 96 kilometers southwest of Port Harcourt; two discoveries, 1,736 barrels per day of 41° API oil, and 2,000 barrels of 32° API oil. Plan production 50,000 barrels per day from 27 wells in 1966.
	Block 33 b, Owopele field.	Midwestern Region; more than 1,000 barrels per day of 22° API oil.

and $14 million for pipeline construction. The United Kingdom Gas Council, which received liquefied methane from Algeria, wanted cheaper gas from a Commonwealth source to reduce the need for foreign exchange payment. Although unit price had not been determined, it was estimated that Algerian gas would cost approximately one-third more per therm than Nigerian gas.[21]

"Utilization of Natural Gas in the Nigerian Economy", a report on natural gas market conditions in Nigeria prepared by Canadian Industrial Gas Ltd., Calgary, became available to the public and was reviewed in the press.[22] The survey was made for the Ministry of Mines and Power in 1964 and was financed by the Special Commonwealth Africa Aid Program.

Proved natural gas reserves were reported at 1,700,000 million cubic feet.[23] Fields in the Port Harcourt area produced 50 million cubic feet of associated gas per day in 1965, and gross nonassociated gas output in the area was estimated at more than 100 million cubic feet per day, most of which was flared.[24]

Considerable interest was shown in development of gas-based byproducts for the export market. Signal Oil & Gas Co., California, associated with Canadian Industrial Gas Ltd., negotiated with Ministry of Mines and Power officials for a liquefied petroleum gas (LPG) plant where liquefied natural gas will be processed. Petrochemical and fertilizer industries also were under consideration.

The Mineral Industry of Rhodesia (Southern Rhodesia), Zambia, and Malawi

By Thomas C. Denton [1] and William F. Keyes [2]

On November 11, 1965, Southern Rhodesia, then a self-governing British colony, declared itself independent and sovereign within the British Commonwealth of Nations. The British Government refused to recognize this unilaterial declaration of independence (UDI) and promptly took economic action against Southern Rhodesia. The United States and other members of the United Nations collaborated in this economic action in varying degrees. At yearend the dispute had not been resolved. The status of the other political divisions discussed in this chapter remained unchanged from that at the end of 1964. Both Zambia and Malawi were independent countries within the British Commonwealth of Nations, Zambia (formerly Northern Rhodesia) having achieved that status on October 24, 1964, and Malawi (formerly Nyasaland) on July 6, 1964.

SOUTHERN RHODESIA

With the end of the third quarter of 1965, Southern Rhodesia suspended publishing mineral production statistics and deferred further releases of such figures until the political and economic situation resulting from the UDI had been clarified. Statistics of foreign trade, however, were published for all of 1965.

European employment in mining was 2,692 in June 1965, compared with an average of 2,531 in 1964. African employment rose similarly, to 40,066 compared with 39,026. Gold mining was the only sector of the industry to show a decline in employment, which was consonant with a decline that occurred in production of gold. The origins of the 40,066 Africans employed on June 30 were, in percent, as follows: Rhodesia 39; Zambia 15; Malawi 25; Mozambique 17; other countries 4.

The Ministry of Mines rejected the Development Plan for the Mining Industry that the Mining Promotion Council drew up early in the year. The plan proposed that the Government set up a Minerals Development Corporation to finance new mining ventures, and recommended formation of a Government-Industry Mining Affairs Board to coordinate both Government and private minerals activities. The Ministry of Mines' rejection of the plan was on the grounds that the existing Industrial Development Corporation was fully capable of making loans to mining companies and that the Ministry could not accept placing a private manager of the board in authority over Government minerals agencies. The purpose of the council's recommendations on this latter point was to circumvent limitations on Government salaries, which cannot be greater than $11,200 per year, so as to employ a high-caliber business executive to promote the mining industry.

[1] Africa specialist, Division of International Activities.
[2] Regional minerals officer, U.S. Consulate General, Johannesburg, Republic of South Africa.

PRODUCTION

Mineral production rose almost month by month during the three quarters of 1965 for which statistics were available. Gold was virtually the only mineral to register a decline. Total value for the first three quarters was $66 million, nearly $11 million higher than in the corresponding period of 1964, as shown in the following tabulation:

Commodity	Value—January–September (million dollars)	
	1964	1965
Asbestos	14.3	17.5
Gold	15.0	14.3
Copper	8.7	13.1
Coal (sold)	6.9	8.2
Chromite	4.7	5.3
Other minerals	5.5	7.6
Total	55.1	66.0

Early in 1965 the Minister of Mines expected mineral production for the year to reach $84 million or more, and reports at the end of the third quarter indicated that this goal would be attained; the unilateral declaration of independence, coming as it did on November 11, probably did not alter the trend of rising production. The production recorded for the first three quarters was at the annual rate of $87.9 million.

TRADE

The Central Statistical Office, Salisbury, issued an Annual Statement of External Trade for 1965 in commodity and country detail, similar to the one issued in 1964. Prior to 1964 (beginning in 1953), Southern Rhodesia's external trade accounts were included as a part of trade accounts of Federation of Rhodesia and Nyasaland. These latter accounts did not document interterritorial trade in detail, therefore data for 1963 comparable to that given for 1964 and 1965 could not be compiled.

In 1964 and 1965 Rhodesia had a large favorable balance of external trade with respect to both total trade and trade in mineral commodities. In each case the balance was distinctly more favorable in 1965 than in 1964. The favorable balance in total trade increased from $90.5 million to $125.7 million and for minerals from $54.7 million to $84.1 million, as shown in the following tabulation:

	Thousand dollars		Mineral commodities share of total (percent)
	Mineral commodities [1]	Total commodities	
Exports: [2]			
1964	100,795	351,140	28.7
1965	131,063	417,897	31.4
Reexports:			
1964	4,975	42,412	11.7
1965	6,213	43,235	14.4
Imports:			
1964	51,090	303,064	16.9
1965	53,161	335,409	15.8
Trade balance:			
1964	+54,680	+90,488	XX
1965	+84,115	+125,723	XX

XX Not applicable.
[1] Values include only those mineral commodities listed in tables 2 and 3 of this chapter.
[2] Includes net gold sales of $19,841,000 in 1964 and of $19,023,000 in 1965.

Exports.—Mineral exports in 1965 ($131 million in all) included 13 categories valued at $1 million or more, as follows (figures represent millions of dollars): Asbestos 30; gold 19 (net sales); copper 18; chromite 11; coal and coke 8; pig iron 7; petroleum refinery products 6; iron and steel semimanufactures 5; ferrochrome 5; iron and steel billets, etc. 2; tin ingot 2; iron ore 1; miscellaneous ores and concentrates 3.

Imports.—Principal mineral imports in 1965 in order of value were petroleum products, iron and steel semimanufactures, and fertilizer materials. The values of these imports in 1965 in thousands of dollars were respectively 15,479, 14,365, and 13,178. Reexports, in thousands of dollars, amounted to 719, 2,111, and 3,027, respectively. The official Statement of External Trade of Rhodesia for 1965 did not record imports of crude petroleum, which were probably about 4 million barrels.

Direction of Trade.—In recent years the bulk of Rhodesia's general imports have come from the United Kingdom, the Republic of South Africa, the United States, Japan, West Germany, and Zambia. In 1965 imports totaled $335.4 million; in percent the contributions of these countries to the total figure were, respectively, 30.3, 22.9, 6.8, 5.5, 4.1, and 3.6, or 73.2 percent in all. With respect to domestic exports the pattern in 1965 was somewhat different. The exports totaled $398.9 million and principal recipients were, in percent of the total: Zambia 25.3; the United Kingdom 22.1; West Germany 9.0; the

Republic of South Africa	73,808	15,053	76,891	13,317
West Germany	11,631	2,881	13,622	2,562
Japan	12,284	652	18,497	1,288
Malawi	4,561	53	3,912	42
United States	20,597	902	22,952	1,996

Republic of South Africa 9.0; Malawi 5.4; and Japan 5.2; these countries thus received 76.0 percent of total domestic exports. The United States ranked eighth at $9.8 million. The total export figure does not include $19 million (£6,794) of gold bullion Rhodesia sold in 1965, most of which presumably went to the United Kingdom.

COMMODITY REVIEW

Metals.—*Antimony*—Production of antimony, long a byproduct from the Sebakwe gold mine near Que Que, rose from 44

tons in 1964 to 230 tons in 1965 (9 months), largely on the strength of a few months' operation of the new pilot flotation plant of Rhodesian Antimony (Pvt.), Ltd., also near Que Que.

Chromium.—Output of chromite during the first 9 months of 1965 was equivalent to an annual rate of 567,000 tons, 27 percent higher than the tonnage produced in 1964. Rhodesia Chrome Mines Ltd. (RCM), a subsidiary of Union Carbide Corp., the largest producer in Rhodesia, increased production to about 340,000 tons from under 272,000 tons in 1964. RCM's exports in 1965 were 313,000 tons, of which about 60 percent reportedly went to the United States and about 5 percent went to the United Kingdom.

Development continued on two ore bodies at the mine in the Belingwe district, southwest of Fort Victoria, of Inyala Chrome Co. (Pvt.) Ltd., a subsidiary of Associated Ore and Metals Co. Mining started on the No. 1 ore body, the product being high-grade, hard, lumpy chromite. Fines were being accumulated until the gravity-concentrating plant was in operation in 1966.

Rhodesian Alloys (Pvt.) Ltd. at Gwelo in August announced a $5.6 million expansion that should nearly treble production of low-carbon ferrochrome, from the present rate of 15,400 tons per year to 45,400 tons per year. Three additional 15,000 kilovolt-ampere furnaces will be installed. In addition, an experimental char plant was being erected on a site adjacent to the ferrochrome plant at a cost of $84,000. It will use low-temperature carbonization to produce 650 tons per month of char, which has a higher volatile content than the metallurgical coke from Wankie colliery now used. If this method of production proves as satisfactory as expected, the plant was to be expanded to produce 91,000 tons to supply both Rhodesian Alloys and the domestic market for smokeless fuels.

Windsor Ferroalloys (Pvt.) Ltd., at Que Que, the other ferrochrome producer in Rhodesia, was acquired by Rhodesia Chrome Mines Ltd. in May. Windsor was operating at a loss and owed the Rhodesian Government $3.6 million. At yearend the plant was producing ferrochrome silicon from Selukwe ores, for which the principal market was Japan. Capacity was to be tripled from the existing 11,000 tons per year of product.

Copper.—Average quarterly production of new copper during the first 9 months of 1965 was at the rate of 16,484 tons annually, about 1,200 tons more than was produced in 1964. The output was largely fire-refined copper produced at the Alaska smelter near Sinoia, controlled by a South African company, Messina (Transvaal) Development Co. Ltd. In addition, at Messina's Umkondo mine near the South African border, copper-in-concentrates was produced at the rate of about 1,450 tons annually and then shipped by train to the Messina smelter in South Africa.

Messina's new leach plant at Mangula was officially opened by the Prime Minister on August 30, 1965. In September the stockpile of oxidized ore to be leached totaled 2.85 million tons averaging 1.13 percent copper. At yearend about 900 tons of ore per day was being leached, equivalent to over 2,200 tons of cement copper production per year. This figure was expected to be doubled later.

As of September 30, 1965, Messina reported the following ore reserves for its three mines in Rhodesia:

Mine	Thousand tons	Grade (percent copper)
Mangula	15,164	1.39
Alaska	1,789	1.87
Umkondo	176	3.06

The tonnage reported for Umkondo was more than double that reported for 1964, and copper content was significantly higher, as a result of new discoveries.

Gold.—Production for all of 1965 was indicated to have been 4 or 5 percent under the 575,386 ounces produced in 1964, when by value gold was Rhodesia's leading mineral product. The decline in production came in the face of Government efforts during the past 2 years to stimulate small-scale operations. Many mines had been hit by rising costs and were in danger of closing; others were near closing because of the exhaustion of ore. The Turk mine near Inyati, one of the oldest mines in Rhodesia, announced that it would close in February 1966, primarily because ore reserves would then be exhausted. It has been producing about 1,000 ounces of gold per month.

Larger companies continued to explore abandoned gold districts. At yearend Anglo American Corporation was still examining three old mines, the Renco mine south of Fort Victoria, the Sabi mine near Shabani, and the Felixburg mines at Felixburg north of Fort Victoria. Rio Tinto (Rhodesia) Ltd. was examining its concession areas, stimulated by the prospective closing of its Cam and Motor mine, the largest Rhodesian gold producer. Coronation Syndicate Ltd. was examining several mines. The Syndicate faces exhaustion of its Kanyemba and Arcturus mines.

In a report submitted in February 1966, the Select Committee on the Mining Industry declared that a decline in Rhodesian gold production was inevitable unless increased government subsidies, in the form of development allowances for low-grade ores, were granted to the industry.

Iron and Steel.—Iron ore production in all of 1965 is indicated to have been about 70 percent larger than in 1964, or about 1.4 million tons. Export railings, all to Lourenço Marques, Mozambique, were at the annual rate of about 522,000 tons, compared with 380,307 tons in 1964. Exports in 1964, presumably tallied at the Southern Rhodesia-Mozambique border, were 286,570 tons, all to Japan.

Sales by the Rhodesian Iron and Steel Co. Ltd., (RISCO) in the first half of 1965 were 140,114 tons of pig and foundry iron and 50,933 tons of semifinished steel and steel sections. According to the chairman of RISCO, production of about 317,000 of pig iron in all of 1965 was entirely sold by midyear.

During the year RISCO announced plans for expansion of capacity, which presumably were held in abeyance as a result of retaliatory action taken against Rhodesia after the UDI on November 11. The plans were to spend between $784,000 and $840,000 on new equipment to increase steelmaking capacity, and $19.6 million over 2½ years to increase pig iron capacity. In addition, the United Nations Economic Commission for East and Central Africa in October had recommended establishment of 1 million-ton-per-year iron and steel plant at Que Que, to serve the entire central African market.

Nickel.—At yearend it appeared that Rhodesia would soon become a significant nickel producer. Output of concentrates averaging about 15 percent nickel was 2,679 tons in January-September 1965. This output compares with 783 tons produced in 1964, mostly in the fourth quarter. Trojan Nickel Mining Company (Pvt.) Ltd. was the producer, from claims near Bindura north of Sudbury. The nickel minerals are mostly the arsenides, chloanite and niccolite. In June 1965 Anglo American Corp. of South Africa Ltd., took an option to examine an area of 272 square kilometers that included the claims. The investigation was expected to take about 1 year.

Besides this development, Rio Tinto (Rhodesia) Ltd. decided to put into production by 1967, at a cost of about $11.2 million, the Empress nickel mine situated 48 kilometers west of Gatooma. Over the years Rio Tinto had spent $2.8 million on the Empress mine and had developed a substantial ore tonnage. The nickel mineral here is the iron-nickel sulfide, pentlandite.

Tantalum and Cesium—Tantalum ore production declined. In the January-September period 31 tons was produced, indicating production for the year of about 41 tons, which compares with 64 tons produced in 1964. The Benson mine north of Salisbury appeared to have produced no microlite after June. Other tantalum ore (columbite-tantalite) production was by Kamativi Tin Mines Ltd., as a byproduct of tin mining.

A pollucite (cesium) ore body discovered in the Benson mine in 1964 continued to be mined on a small scale in 1965. Bikita Minerals (Pty.) Ltd., whose reserves of pollucite are substantial, also shipped some of the mineral in 1965.

Tin.—At yearend the outlook was for increased production of tin. The only significant producer of the metal, Kamativi Tin Mines Ltd., east of Wankie and near the Zambia border, had nearly completed its new shaft. Mill capacity was 45,000 tons per month, and most of the ore going to the mill was to be underground ore, which is richer than the open pit ore supplied the mill in recent years. The former contains up to 0.4 percent tin, compared with 0.1 to 0.2 percent for surface ore.

Nonmetals.—*Asbestos.* — Production of chrysotile asbestos in the first 9 months of 1965 was 14,830 tons larger than that in the same period of 1964, and for the whole year probably about 33 percent higher than in all of 1964.

Rhodesian and General Asbestos Corporation (Pvt.), Ltd., awarded a contract to deepen a shaft at the Birthday section of the company's mines at Shaboni. The shaft will be converted from a rectangular to a circular shaft of 7-meter diameter, and will be bottomed at a depth of 666 meters. In 1964 a haulageway was completed that connects the Birthday section with the Nil Desperandum section, allowing all ore mined to be treated at the former. At the latter section dump ore was being treated. At the company's Gaths and King mines a shaft 6 meters in diameter and 445 meters deep was scheduled for completion by mid-1966.

Mineral Fuels.—*Coal.* — Production of coal during the first 9 months was at the annual rate of 3.4 million tons compared with 3 million tons produced in 1964. Peak annual output to the present was 3.8 million tons, realized in 1954.

At yearend Wankie Colliery Co. Ltd., Rhodesia's only coal producer, was considering the possibility of establishing strip workings east of the existing No. 3 colliery workings. The project would represent the first strip mining to be undertaken in Rhodesia. In addition, the company was building the experimental char plant at Gwelo mentioned in the discussion of chormium and was considering building in the near future a new coal preparation plant and new retort coke ovens.

Petroleum.—The Beira-Feruka (Umtali) pipeline operated from January to November 1965 only, pumping 4,186,000 barrels of crude oil to Feruka over this period. Gross earnings of the pipeline company in 1965 amounted to $5.9 million, of which $4.5 million were paid in charges to the Mozambique Administration of Railways. The owner of the pipeline is Companhia do Pipeline Moçambique-Rhodesia, S.A.R.L.[3]

ZAMBIA

Zambian mineral industry prospered in 1965, largely as a result of high copper prices and despite labor unrest that resulted in strikes both by Zambian and European labor. The value of total mineral output increased by 22 percent compared with that of 1964, reaching $508.2 million, copper accounted for $480.1 million. Gross national product (market price) rose to $779.5 million from $586.3 million in 1964.[4] At yearend, however, the immediate outlook was obscure. While the Rhodesia UDI in November had little effect on the economic situation in 1965, it introduced many uncertain factors into future prospects.

On May 7, 1965, the Government announced that, effective October 24, 1964, it intended to retain the formula for assessing copper royalties that the British South Africa Company had applied previously. This means that the amount of royalty is determined not by producers' selling prices but by reference to the average prices for copper on the London Metal Exchange. At the same time the Government announced that it would give special consideration to the position of mines operating at a loss.

Late in the year the Zambian Government decided to establish a specialized Metals and Minerals Development Unit within the Ministry of Mines, to provide the Government with experts who can deal on a professional level with the copper companies and with other countries that produce copper, in matters pertaining to production levels, taxation, and Government mining policy in general. The unit was to be staffed by economists, lawyers, and statisticians.

African employment in mining and quarrying rose in Zambia's first year of independence from 42,700 at the end of September 1964 to 45,540 12 months later. In the same period employment of Europeans fell from 8,150 to 7,490. There was an acute shortage of skilled manpower which was accentuated by substantial net emigration.[5]

PRODUCTION

The value of mineral production was $91.6 million higher than in 1964, and

[3] U.S. Consulate General, Lourenco Marques, Department of State Airgram 188, May 11, 1966.

[4] Republic of Zambia, Ministry of Finance (Lusaka). Economic Report, 1966. P. 30.

[5] Page 14 of work cited in footnote 4.

copper accounted for 94.5 percent of the total value, as indicated in the following tabulation:

Commodity	Value of mineral production (millions)	
	1964	1965
Copper, blister and electrolytic	$392.2	$480.1
Zinc	14.4	13.6
Lead	3.2	6.1
Cobalt	4.4	4.8
Other minerals	2.4	3.6
Total	416.6	508.2

TRADE

At $238 million Zambia's favorable balance of visible trade in 1965 was nearly as large as the $250.6 million favorable balance achieved in 1964, and the total value of merchandise trade increased by 21 percent. Exports and imports were respectively 15 percent and 35 percent higher than in 1964.

During the year the Zambia Government issued the first of a new series of Annual Trade Reports, covering the year 1964.[6]

The 15-percent increase in exports in 1965, to $526.4 million, was almost entirely the result of sharply improved copper price. The volume of copper exports did not increase. Copper accounted for 92 percent of export earnings (91 percent in 1964); zinc, lead, manganese ore, and cobalt contributed 4 percent. Thus the mineral industry provided 96 percent of export earnings in 1965.

COMMODITY REVIEW

Metals.—*Cobalt.*—Rhokana Corp. Ltd., one of the Zambia mining companies administered by Anglo American Corp. of South Africa Ltd. (Anglo), was the only producer of cobalt metal in 1965, inasmuch as Chibuluma Mines Ltd. (administered by Roan Selection Trust Ltd.) stockpiled its cobalt-bearing concentrates following

closure of its cobalt smelter at Ndola in 1964. Rhokana increased its production during 1964 in response to much improved demand, and from late 1964 to June 1965 was producing at an annual rate of 1,500 to 1,600 tons. Sales in the year ending June 30, 1965 were 1,552 tons, the highest ever achieved. Rhokana has introduced a cyanide-regrind circuit in the cobalt plant, which has considerably improved recovery by increasing the selectivity of the cobalt-copper separation in the flotation step.

Copper.—Zambia's 1965 production of blister and electrolytic copper totaled 684,701 tons valued at $480 million, of which 163,526 tons was blister and 521,175 tons was electrolytic copper. These figures represent increases of about 42,000 tons and $88 million over the 1964 results. The volume was about 15 percent of free world copper production in 1965.

The price at which the producers sold copper rose during the year but remained well under the London Metal Exchange price. Early in 1966 the producers' price stood at 42 cents per pound.

The largest companies in Zambia that Anglo controlled and administered during the year continued to be Rhokana Copper Refineries Ltd. and the following producing mining companies: Nchanga Consolidated Copper Mines Ltd. (financial year ends March 31), Rhokana Corp. Ltd. (year ends June 30), and Bancroft Mines Ltd., an Nchanga subsidiary (year ends March 31). The total 1965 copper output of the mining companies was 402,000 tons, about 13 percent higher than in 1964 and about 10 percent of free world mine pro-

[1] The statistics for 1964 are for Zambia alone, whereas those for 1963 are for the former Federation of Rhodesia and Nyasaland (dissolved Dec. 31, 1963), which comprised Southern Rhodesia (Rhodesia), Northern Rhodesia (Zambia), and Nyasaland (Malawi).

[2] Less than ½ unit.

duction of copper in 1965. Ore reserves at financial yearend were reported as follows:

	Thousand tons	Grade (percent copper)
Nchanga	217,841	4.28
Rhokana	108,330	2.95[1]
Bancroft	84,992	3.56
Total	411,163	3.78

[1] Plus about 0.13 percent cobalt.

Nchanga reached its scheduled delivery of 100,000 tons of ore per month to Bancroft's concentrator, and Nchanga's production of electrolytic and blister copper in the year ending March 31, 1966, was expected to be 254,000 tons. Instead of the $14 million to $22.4 million expansion program that would have been needed if the Bancroft concentrator had not been used, a smaller $7 million program was being carried out to enable this production rate to be maintained in the face of a decreasing ore grade. The program included installation of a crushing and washing plant with a monthly capacity of 272,000 tons. This plant was to be fed with ore brought in trucks from the Nchanga open pit mine. The coarser fraction of the product was to go to Bancroft, and the finer to Nchanga's concentrator. The washed ore would be more suitable metallurgically than Chingola high-grade ore, and handling difficulties in the rainy season would be eliminated. This rationalization should improve Bancroft's financial situation, although Bancroft continued to operate at a loss in 1965.

Rhokana's production of finished copper in the year ended June 30, 1965, was 101,600 tons, about 7,000 tons less than in the previous year. The decrease was largely due to rock pressure problems in Rhokana's Mindola mine, which reduced ore deliveries from the mine by 354,000 tons; only part of this decrease was made up by increased deliveries from the Rhokana's Nkona mine.

Prospecting and exploration by companies of the Anglo group continued. Such expenditures were at the annual rate of about $1.7 million.

Late in 1965 the commercial scale (500 tons per day) TORCO (treatment of refractory ores) plant was completed and put in operation by three companies of the Anglo group. Successful operation of the plant could greatly enhance the prospects of several idle properties that have large reserves of oxide-silicate ores, such as Bwana Mikubwa and Kansanshi.

Roan Selection Trust Ltd. (RST) continued to operate its Luanshya Division (formerly Roan Antelope Mine) and to control and administer Ndola Copper refineries and the following producing mining companies: Mufulira Copper Mines Ltd., Chibuluma Mines Ltd., and Chambishi Mines Ltd. The financial years of these companies end June 30. In the year ended June 30, 1965, the mining companies produced 281,441 tons of finished copper, a record for companies of the RST group for the second successive year. Ore reserves of the companies and of the undeveloped property of Boluda Mines Ltd. of the RST group as of June 30, 1965, were reported as follows:

	Thousand tons	Grade (percent copper)
Mufulira	160,368	4.28
Luanshya Division	86,150	2.87
Chibuluma	7,667	4.83[1]
Chambisi	32,000	3.37
Baluba	102,000	2.41[2]
Total	388,185	3.41

[1] Plus 0.18 percent cobalt.
[2] Plus 0.16 percent cobalt.

Mufulira completed extensions to its refinery and at yearend could handle all of its rated output of 165,000 tons of copper annually, plus 18,000 tons contained in Chambishi sulfide concentrates. The cost of the extensions was $4.6 million.

Luanskya Division produced 93,468 tons of copper in the 1964–65 financial year, somewhat less than in the previous year. There were no plans to increase production at this high-cost mine.

Chibuluma copper production fell slightly to 22,981 tons, which is about the capacity of the operation. There were no immediate plans to increase output.

Chambishi produced its first copper in April 1965, from oxide ore. Late in 1965 the surface plant was completed by bringing the sulfide concentrator into production. The concentrator was to produce annually about 18,000 tons of copper contained in high-grade concentrates which

Mufulira will smelt. Additional production by the roast leach plant will bring total copper capacity to 26,400 tons per year, but in the year ending June 30, 1966, only about 15,000 tons will be produced.

RST continued to explore its extensive exclusive prospecting areas, which were extended in 1965 to include additional ground south of RST's concession in the Mwinilunga area. All four of RST's exploration companies—Baluba, Chisangwa, Kadola, and Mwinilunga—were active.

Lead and Zinc.—The only producer of lead and zinc in Zambia, The Zambia Broken Hill Development Co. Ltd. (Anglo group), increased lead production by 62 percent. Zinc production, at about the 1964 level, included 98.5-percent grade zinc and 99.95-percent grade zinc in about equal proportions.

The company had experienced difficulty in 1964 in operating its Imperial Smelting Furnace with a high lead content in the sinter which is fed to it, and lead content had to be lowered. This difficulty was overcome in 1965, but the goal of producing 70,000 tons of combined metals was not achieved; this goal should be reached in 1966.

Three factors make it unlikely that dividends will be maintained in the near future at the 1965 level, according to the chairman: Lower prices for lead and zinc, increasing costs of production, and a substantial expansion program. It is estimated that some $7 million will be spent in the next 5 years on prospecting, mining plant, housing, and the concentrator and smelter; of this sum, $2.8 million will be spent in 1966.

Nonmetals.—*Cement.*—The cement industry continued to expand. The Zambian Government increased its share in the only producer, Chilanga Cement Ltd., to 40 percent by purchase of 1.98 million shares at 8 shillings ($1.12) each, payable over 5 years. The existing factory, south of Lusaka, was to add a third kiln to increase capacity 50 percent over the present 180,000 tons per year by mid-1966, and a second plant was planned for Ndola, with a capacity of 180,000 tons per year. The cost of the total expansion is estimated at $8.4 million. Zambia in 1965 imported cement at an increasing rate to cope with growing construction activity. Cement sales in 1965 totaled 236,000 tons.

Gypsum.—At Lochinvar near Monze, 120 miles southwest of Lusaka, Anglo American Corp. of South Africa Ltd. was opening the country's first gypsum mine, to supply the cement industry. Gypsum previously was imported from Republic of South Africa. A processing plant was being built at a cost of $112,000, with a capacity of 90,000 tons of product per year. Reserves at Lochinvar were roughly estimated 900,000 tons.

Mica.—Small-scale production of mica continued in the Lundazi district on the Malawi border. The activity had been encouraged by the British South Africa Company to provide local employment, and the Zambian Government was continuing to promote it.

Mineral Fuels.—*Coal.* — There was no production of coal in Zambia in 1965, but development of the largest known deposit was commenced late in the year to provide an indigenous source to offset possible loss of imports from Southern Rhodesia.

Two areas have been mapped and investigated for coal deposits: The Zambezi Valley north of Lake Kariba, and the Luano Valley, a downfaulted area 50 miles southeast of Broken Hill. The most promising occurrences are in the mid-Zambezi Valley and of these the largest is at Nkandabwe, 45 miles southeast of Choma. The coal seams occur in the Gwembe coal formation, in a downfaulted block of Lower Karroo sediments, over an 8- by 1½-mile area. The main seam ranges in minable thickness from 6 to 9 feet in the workable area, and dips about 20° southeast; approximately 17 million recoverable tons were estimated here by the Northern Rhodesian Geological Survey (Bulletins No. 1, 1959; No. 3, 1963; No. 4, 1960). The quality of the coal is mediocre; average ash is 24 percent, calorific value is about 10,500 B.t.u. per pound, and volatile matter is about 22 percent.

In October 1965 plans were announced to form a company to develop the Nkandabwe deposit. The Zambian Government has a 50-percent interest in the company, to be called the Nkandabwe Coal Company (Pvt.) Ltd. The remaining interests will be divided between Anglo and RST.

Late in 1965 a contract for site preparation was awarded to the Amalgamated Construction Company, of Kitwe, an Anglo subsidiary, and a contract for transport of the coal to the railroad siding at Batoka, 20 miles northeast of Choma, was given to Zalbro United Transport, of Choma. The announced production goal was an annual output of 720,000 tons, starting by mid-1966. The mine was to be opencast, and a total of 3 million tons of overburden was to be removed. Anglo and RST agreed to buy the first 3 million tons of coal.

MALAWI

Mineral production in Malawi during the year was limited to construction materials. Nyasaland Portland Cement Company at Changalumi west of Zambia produced 31,493 tons of cement clinker, using about 45,000 tons of limestone, 2,700 tons of shale, and 900 tons of laterite. Stone quarried amounted to about 3,770 cubic meters. An unrecorded quantity of clay was mined in rural areas.

With respect to the future, plans still existed ultimately to utilize the bauxite on the Lichenya Plateau, where 54 million tons have been proven.

The strontianite-rich rare-earth occurrence at Kangankunde Hill was optioned to mid-1966 to a local businessman, who reportedly was advised that a fair price for the ore would be $280 (£100) per ton.

The Geological Survey of Malawi was completing a geological survey of the country to a scale of 1:100,000. The work was expected to be completed by the end of 1969, when the functions of the Geological Survey would be oriented toward engineering geology. Some decrease in personnel, all expatriate, was expected.

The first annual publication on Malawi's external trade was issued during the year by the Director of Census and Statistics, National Statistical Office, Zomba. It was for 1964. The compilation of the statistics and the preparation of the volume was undertaken by the Central Statistical Office of Southern Rhodesia at Salisbury. The volume reports total domestic exports of $32.2 million and imports less reexports of $37.3 million, or an unfavorable balance of visible trade of $5.1 million in 1964. Imports in the minerals area comprised iron and steel and nonferrous metal semimanufactures and petroleum products. Scrap metal was the largest mineral export.

The Mineral Industry of Senegal

By Walter C. Woodmansee [1]

The main features of Senegal's mineral industry in 1965 were continued expansion in the mining and marketing of phosphate rock; termination of beach sand mining of ilmenite, rutile, and zircon, output of which had decreased markedly in 1964; and a large increase in imports of crude petroleum as feedstock at the new M'Bao refinery.

Crude phosphate rock and small quantities of processed phosphatic fertilizers accounted for about $11 million of the total mineral production valued at $15 million.[2]

Mineral investigations were conducted by the Bureau de Recherches Géologiques et Minières (BRGM), the French Government mineral exploration company, and by the United Nations. The BRGM completed arrangements for nonferrous mineral prospecting in southeast Senegal for 2 years beginning January 15, 1966. The BRGM also completed the last two of seven geologic maps of eastern Senegal at a scale of 1:200,000 and was preparing a report on the geology of this region. The hydrogeology of the Haut Delta area was under investigation, and a hydrogeologic map of Senegal at a scale of 1:500,000 was in preparation. The BRGM also studied phosphate rock deposits of the Eocene period in the Lac de Guiers region and construction stone on Cape Verde Peninsula.

A United Nations Special Fund project, involving geologic, geophysical, and geochemical work in eastern Senegal, was extended through 1966. Discoveries were made of chromite in the Gabou area, near the eastern border, gold along the Dialé and Makabingui Rivers, and diamond in the drainages of the Faleme River and tributaries. The United Nations also sponsored the training of Senegalese for government geologic and mining work.

PRODUCTION

Mineral industry output in 1965 included crude phosphate rock, petroleum refinery products, processed phosphatic fertilizers, and salt. The phosphate rock mining rate reached 1 million tons annually, and further increases were planned. Data on petroleum refinery output, which exceeded 300,000 tons in 1964, the first full year of operation, were not available for 1965. However, the supply of imported crude oil available for refinery feedstock indicated an increase in output of refinery products. Phosphatic fertilizer output was largely for the export market; refined petroleum production was for both the domestic and export (Mali and Mauritania) markets; salt output provided for domestic demand and small exports.

[1] Physical scientist, Division of International Activities.

[2] Where necessary, values have been converted from the African Financial Community franc (CFAF) to U.S. dollars at the rate of CFAF245 = $1.00.

e Estimate.
[1] Derived from crude aluminum phosphate output.
[2] Includes products marketed under trade names of Baylifos and Phosphal.
[3] Includes production of Mauritania, estimated at 500 to 800 tons per year.

TRADE

As in previous years, Senegal during 1965 was a notable world source of phosphate rock and an importer of iron and steel and energy products. Exports of phosphate rock were valued at $6.8 million in 1963, $9.6 million in 1964, and $10.8 million in 1965, accounting for the bulk of the country's mineral export values. Iron and steel imports totaled $5.4 million in 1964 and $5.6 million in 1965. Imports of petroleum refinery products have been adjusted in relation to production from the new refinery, which went on stream in late 1963 supplied wholly by imported crude oil. Imports of energy products totaled nearly $8.0 million in 1964 and $10.3 million in 1965.[3]

The following tabulation illustrates the relationship between mineral trade and total trade in recent years:

[3] Statistical Office of the European Communities, Overseas Associates: Foreign Trade Statistics; January-December 1963, pp. 35–44 and 97–105; No. 40, 1965, 31 pp.; and No. 7, 1966, pp. 19–45.

	Million dollars		Mineral commodities share of total (percent)

COMMODITY REVIEW

METALS

Ilmenite, Rutile, and Zircon.—Société Minière Gaziello, which is part of the Compagnie de Produits Chimiques et Électrométallurgiques Pechiney organization, terminated beach sand operations at Djifere in February and moved its equipment to a new site in the M'Bao-Joal region, about 70 kilometers south of Dakar.[4] In April, however, the company decided to abandon the new property because of excessive chomium content of the concentrate. No production was reported during 1965 for the first time in many years.

NONMETALS

Diamond. — The BRGM joined with Anglo American Corporation of South Africa Ltd. in a diamond prospecting venture in eastern Senegal. Washing tests, geochemical investigations, and sampling of alluvial concentrations were conducted. Results were not encouraging, and work was discontinued.[5]

Fertilizer Materials.—*Phosphate Rock.*— Mine expansion continued at the Taiba property, 18 kilometers north of Tivaouane, where output of calcium phosphate by Compagnie Sénégalaise des Phosphates de Taiba was expected to reach 1.5 million tons in 1966. In May, new installations raising annual capacity to 1 million tons were dedicated by President Senghor. International Minerals & Chemical Corp. (IMC), of Skokie, Ill., which held a 12-percent interest in the operating company, had an option to purchase additional interests to a total of 51 percent. In December, however, IMC announced that this option would not be exercised.

Proved reserves at Taiba, early in the year, were reported at 38 million tons of crude phosphate rock amenable to upgrading to 82 percent bone phosphate of lime and 60 million tons of probable ore.[6]

The Thiès deposit of aluminum phosphate, 85 kilometers east of Dakar, was worked during the November to April dry season because of limited demand. Société Sénégalaise des Phosphates de Thiès, mine operator and subsidiary of Pechiney, the large French mining and metallurgical company, was granted a prospecting permit of 2,000 square kilometers in an area east of Tivaouane.

Reserves of crude aluminum phosphate at Thiès were 37 million tons at 29.5 percent P_2O_5 and 65 million tons at 28 percent P_2O_5.[7]

Syndicat de Recherches de Phosphates du Lac de Guiers, comprising the Government of Senegal (10 percent), BRGM (35 percent), and Pechiney (55 percent), was granted an exploration permit to a 5,800-square kilometer area in the Lac de Guiers region. Shaft sinking and exploratory drilling were conducted, but results were unfavorable, and the project was abandoned later in the year.

Manufactured fertilizers.—Société Industrielle des Engrais du Sénégal, a French consortium largely held by Société des Potasses d'Alsace, the French potash monopoly, was formed to establish a new fertilizer plant. The company applied to the International Bank for Reconstruction and Development for financing, and representatives of the International Finance Corp. visited Senegal to investigate loan possibilities.[8] No action had been taken by yearend.

Stone.—The BRGM conducted exploration for construction stone on Cape Verde Peninsula and selected five sandstone and basalt deposits for further investigation.

MINERAL FUELS

Petroleum.—The entire offshore coastal area of Senegal was taken up in oil concessions granted to three operators: Esso Exploration Senegal, Inc., 10,448 square kilometers from latitude 14°N northward to the border with Mauritania; Société des Pétroles du Senegal (SPS), 3,320 square kilometers from latitude 14°N south to and including the offshore of Gambia; and Compagnie Pétroles Total (Afrique Ouest) (COPETAO), 10,670 square kilometers south of Gambia to the Portuguese Guinea border.

Esso agreed to spend $2.4 million over a 5-year period on its offshore concession.[9]

[9] U.S. Embassy, Dakar, Senegal. State Department Dispatch A–479, June 22, 1965, 1 pp.

From September to December, an airborne magnetic survey was conducted, and seismic work was planned.

SPS, comprising BP Exploration Co. Ltd. and Société Francaise des Pétroles BP (50 percent), and other French state and private interest (50 percent), completed a 1-month marine seismic survey.

COPETAO, an affiliate of Compagnie Française des Pétroles, completed a seismic survey, started in 1964, and a 4-month gravity survey of a domal structure. Drilling of the structure was planned for 1966 upon arrival of a mobile drilling platform, *Ile de France,* from the Netherlands. The first well site is 25 kilometers off the Casamance coast.[10]

A 42-percent increase in crude oil imports indicated that the refinery of Société Africaine de Raffinage (SAR) at M'Bao probably expanded production; official output data were not available. SAR ownership was described as follows: [11] Société Africaine des Pétroles, 30 percent; British Petroleum Co. Ltd., Compagnie Française des Pétroles Aquitaines, Mobil Oil Co., Shell Oil Co., and Texas Oil Co., each 11.8 percent; Banque Sénégalaise de Developpement, 10 percent; and Esso Oil Co., 1 percent.

The refinery produced two grades of gasoline, kerosine, jet fuel, distillate and residual fuel oil, and liquefied petroleum gas for Senegal, Mali, and Mauritania.

The Mineral Industry of Sierra Leone

By Henry E. Stipp [1]

The minerals industry continued to be one of the principal sectors of the Sierra Leone economy in 1965. Production of diamond continued at about the same rate; however output of iron ore and bauxite increased substantially.

Mineral commodity exports in 1965 presumably accounted for about three-fourths of total exports as they did in 1964, but despite increases apparently failed to produce a favorable overall trade balance. Diamond, the nation's most important single source of foreign exchange, accounted for about 60 percent by value of all mineral exports.

Although the country ranked seventh among world diamond producers in terms of quantity of output in 1965, its high ratio of gem quality stones to industrial stones ranked it fourth in terms of value in 1964 and probably in 1965 as well, behind South-West Africa, Republic of South Africa, and Republic of the Congo (Leopoldville).

An estimated 7,800 persons were employed by mining companies in 1965, and an additional 40,000 individuals were reported [2] to be privately mining alluvial diamonds. Thus employment in the minerals industry constituted a large percentage of the 105,000 reported wage earners [3] in the nation.

The Government of Sierra Leone continued its policy of encouraging prospecting for new deposits of minerals and announced its intention to revive alluvial gold mining in the Northern Province.

A loan of $3.8 million [4] was granted to Sierra Leone by the World Bank for expansion of electric power generating and distribution facilities.

The Sierra Leone Chamber of Mines was formed in 1965 to assume the function of the former Sierra Leone Mining Association, which was dissolved recently. The new organization consisted of the Sierra Leone Development Co. Ltd. (DELCO); Sierra Leone Selection Trust Ltd.; Sierra Leone Ore & Metal Co. Ltd.; and Sherbro Minerals Ltd.

PRODUCTION

Total production of diamonds dropped slightly from that of 1964. While output of Sierra Leone Selection Trust increased slightly, production of individual diggers from alluvial deposits fell sharply. Annual production was expected to remain at current levels for the next few years, but in the long run production is uncertain. A small decrease in the price of diamonds contributed to their decrease in value from $55.8 million in 1964 to $51.7 million in 1965.

Iron ore production increased slightly and is expected to reach 2.7 million tons annually in the near future. Output of bauxite also increased from that of 1964. An expansion project underway at yearend was expected to increase production to 500,000 tons annually. Production of rutile, to begin in late 1966, was scheduled at the rate of 100,000 tons per year.

The total value of minerals produced in 1965 was approximately $68.2 million, a decrease of 3.8 percent from the $70.9 million value of 1964.

TRADE

The role of mineral commodities in the total foreign trade of Sierra Leone is shown in the following tabulation:

	Value (million dollars)		Minerals' share of total (percent)
	Mineral commodities [1]	Total	
Exports:			
1963	37	81	46
1964	71	95	75
Imports:			
1963	13	84	15
1964	15	99	15
Trade balance:			
1963	+24	—3	XX
1964	+56	—4	XX

XX Not applicable.
[1] Values given are for only those commodities listed in tables 2 and 3 of this chapter.

Sierra Leone's export of metals and minerals in 1964 increased substantially over those of 1963. Diamonds valued at $55.8 million, were the most important mineral export commodity; however, iron ore, valued at $14.6 million, and bauxite at $570,000, also contributed to the nation's favorable balance of trade in minerals.

Imports of metals and minerals, which increased slightly over those of 1963, consisted largely of mineral fuels valued at $10.2 million and iron and steel products valued at $2.7 million.

In 1964 Sierra Leone increased its import of commodities from the United States 14 percent over those of 1963. Among these items, valued at $4.9 million, was $400,000 of mining and construction machinery.

COMMODITY REVIEW

METALS

Bauxite.—The Geological Survey of Sierra Leone reported occurrences of bauxite in 1928; however, prospecting for deposits on a large scale was not undertaken until 1953.[5] In 1960 extensive bauxite deposits were discovered in the Mokanji Hills in the Moyamba District. An exclusive prospecting license was granted to Suisse Aluminum Co. of Zurich, Switzerland, for the Mokanji Hills deposit and for an earlier discovery in the Gbonge Hills. Sierra Leone Ore & Metal Co., a subsidiary of Suisse, mined and shipped a small quantity of ore in 1963, and in 1964 exports rose to 129,000 tons.

Chromium.—Sierra Leone's only chromite mine, an underground operation in the Eastern Province, remained closed in 1965, because the deposit was too low in grade to be mined economically. Between

[5] Work cited in footnote 2, p. 128.

1937 and the announced closure date in 1963, over 330,000 tons of chromite was produced and exported. Exports in 1964 were possible as a result of draw down of accumulated production at the mine and as a result of mine cleanup.

Gold.—The mining of gold in Sierra Leone probably began in the 15th century, but production was first recorded in 1929 when 937 ounces were mined.[6] Between 1929 and 1963 about 350,000 ounces were produced, with peak output of 40,000 ounces occurring in 1936. In 1965 small quantities of gold were produced locally and sold to Freetown jewelry makers for domestic consumption; however, no production was recorded by mining firms. In 1964 Sierra Leone Selection Trust recovered 49 ounces of gold as a byproduct of diamond concentration.

DELCO and four other mining companies (one British and three from the United States) were granted exclusive prospecting rights over 880 square miles in the Sula mountains and Kangari Hills area in Koinadugu and Tonkolili Districts.[7] The search was reported to be primarily for gold, lead, and zinc. Large scale exploration was scheduled to start in May 1966 and to extend for 4 years.

Iron Ore.—DELCO, the British owned operator of Sierra Leone's only iron ore mine, has operated the mine, about 88 kilometers northeast of Freetown since 1932. DELCO will be eligible for tax relief of $1.75 million for the 1965–66 fiscal year, owing to capital improvements on its mine. The company loaned the Government of Sierra Leone $2.8 million. Reserves at the company's property, the Marampa mine, were estimated at 90 million tons with an average iron content of 49 percent. Cumulative output through year-end 1965 totaled over 34 million tons.

The Tonkolili deposits, 50 miles east of Marampa, were discovered in 1927. They have not been exploited, owing to the presence of considerable alumina, which complicates ore dressing. Reserves were estimated at more than 100 million tons, with a minimum iron content of 53 percent. Other occurrences of iron ore are known, but their economic value has not been determined.

Titanium.—Reserves of rutile (TiO_2), estimated at more than 30 million tons, have been proved in the Bonthe and Moyamba districts of southwestern Sierra Leone.[8] Sherbro Minerals Ltd., jointly owned by British Titan Products Co. Ltd. and Pittsburgh Plate Glass Co., signed a $2.8 million contract with Taylor Woodrow of Sierra Leone for construction of a rutile mine and port facilities near Gbangbama, south of Freetown.[9]

Sherbro Minerals Ltd., contracted for the purchase of marine equipment to be used in recovering and transporting rutile from the firm's deposits in the Bonthe District.[10] The firm planned to operate a diesel-electric suction dredge on a strip of coastal plain, in an area 40 kilometers inland from the coast. Rutile will be piped from the dredge to floating and lakeshore processing plants through a floating pipeline. Concentrated ore will be trucked 16 miles to the Gbangbaia Creek, loaded into 2,000-ton-capacity cargo barges and pushed by a 600-horsepower towboat to the Sherbro estuary. Here the rutile will be transferred to ocean freighters by derrick, bucket-ladder, and belt-conveyor loader. Production, which is expected to be about 100,000 tons annually, is to begin in late 1966.

NONMETALS

Cement.—A bill was introduced in the Sierra Leone Legislature which would forbid foreigners to manufacture cement blocks for sale or to supply granite and sand. The Government placed a ban on this activity effective April 1, 1965.[11]

Diamond—Sierra Leone Selection Trust produced 677,000 carats in the fiscal year ended June 30, 1965 compared with 663,000 carats in the year ended June 30, 1964.[12] Production in fiscal 1965 reportedly was valued at about $9.3 million. Increased production in fiscal 1965 was the result of a higher grade of gravel milled, while the quantity treated remained the same. Examination of kimberlite deposits in the Koidu and Tonga areas indicated a

small potential reserve in a 0.6-acre pipe at Koidu. Operations on the scale of 100,000 carats per year could result, if economic considerations prove favorable. A report was published that described the Sierra Leone Alluvial Diamond Mining Act and the progress made since its adoption.[13]

The mining of diamonds by Sierra Leoneans has been going on legally since 1956. It was estimated that an average of 40,000 persons were now engaged in alluvial diamond mining.[14]

The Government Diamond Office purchased 809,570 carats of diamonds valued at $31.6 million in 1965, compared with 777,844 carats valued at $32.3 million in 1964.[15] Overall diamond production in 1965, which consisted of 45-percent gem quality and 55-percent industrial, was valued at $51.7 million.

Parliament passed the Diamond Cutting Factory Act of August 7, 1965, ratifying the agreement between the Sierra Leone Government and Leon Tempelsman & Son of New York for establishment of a diamond cutting and polishing factory. Construction of the plant was completed toward the end of 1965, and production began.

Water.—A new water treatment plant was opened near Freetown on December 13.[16] The plant, jointly financed by Sierra Leone and the United Kingdom, is part of the Guma Valley water project, which is to cost about $14 million and be completed in 4 to 6 months.

MINERAL FUELS

Petroleum.—The Minister of Mines was authorized to issue oil exploration or prospecting licenses and oil mining leases by chapter 197 of the laws enacted by the House of Representatives in August 1958.[17] The Governor-General can implement the law detailing operating requirements.

The Haifa Refineries Ltd. of Israel was awarded a contract on March 29 for construction and management of an 8,000 to 10,000 barrel-per-day[18] oil refinery to be located near Freetown.[19] Management of the plant will be for an 8-year term. Products such as gasoline, kerosine, gas oil, diesel oil, and fuel oil will be consumed domestically. Some diesel and fuel oil will be for international marine bunkers.

The operation by foreigners of any petrol or fuel station, with the exception of service stations attached to garages, was banned by the Government of Sierra Leone effective April 1, 1965.[20]

The Mineral Industry of the Republic of South Africa

By Thomas C. Denton [1] and William F. Keyes [2]

In 1965 mineral and mineral-based industry continued to be the backbone of the Republic's economy. This status mostly resulted from high gold production, high employment, large purchases from other home industries including agriculture, and important export earnings.

On the basis of figures published by the South African Reserve Bank, the real gross domestic product (GDP) of the Republic (at 1958 prices) was 5 percent larger in 1965 than in 1964. The increase was realized at least in part as a result of an increase in the value of the output of mineral and mineral-based industry, and occurred against a background of drought-reduced agricultural output, rising prices, import restrictions, and other hindrances.

A further indication of the importance of mining in the economy was that in October 1965, its estimated total number of employees was 618,742, which compares with an estimated total of 1,150,000 employed in all other industries of the Republic.[3] Mine labor statistics for all of 1965 were not available.

Unskilled labor was in sufficient supply during the year, but the shortage of skilled labor continued to be acute, particularly in the gold mining industry. Campaigns to recruit skilled labor in Europe met with some success. Statistics for labor and other facets of South African mining industry in recent years appear in the table that follows:

Source: Republic of South Africa, Department of Mines. Annual Reports, including Reports of the Government Mining Engineer and the Geological Survey for years ended 31st December 1962, 1963, and 1964.

The contribution of the Republic to world mineral supplies improved significantly with respect to platinum and for gold continued the upward trend of recent years, reaching 74 percent of non-Communist world production compared with 72.5 percent in 1964. For eight other minerals the contribution to non-Communist world supply ranged from 34 percent for antimony to 11.4 percent for asbestos, as shown in the table that follows.

Commodity	South Africa's share of world putput (percent)			
	Total world		Non-Communist world	
	1964	1965	1964	1965
Gold	63.1	64.0	r 72.5	74.0
Platinum	r 23.5	25.3	r 57.1	59.5

r Revised. NA Not available.

In December the Department of Planning released its Economic Development Programme (EDP) for the period 1965–70,[4] the second such publication, the earlier one being for 1964–69. The targets aimed at in the program are those to be attained if an average real growth of 5.5 percent in the gross domestic product (GDP) is to be realized during the 7-year period from 1963 to 1970 as a whole. In addition the program incorporates the effects of some technical improvements in quantitative estimates of the EDP in 1965.

In the new program there were the following projections of production with respect to nine major sectors of mineral and mineral-based industry.

Sector	Million dollars	
	1964	1970
Gold mining, including uranium	1,126.0	1,201.0
Coal mining	97.9	133.4
Other mining and quarrying	388.9	522.6
Basic iron and steel products	391.9	624.1
Basic nonferrous metals	116.1	180.5
Petroleum and coal products	211.8	418.0
Basic industrial chemicals	270.6	437.6
Metal products	592.3	865.3
Nonmetallic mineral products	277.2	388.8
Total	3,472.7	4,771.3

It is notable that during the entire 7-year period the value of gold and uranium production increases by only $75 million, or 6.7 percent.

A mining rights bill was introduced into Parliament. It is essentially a consolidating measure, but includes changes aimed at removing defects in previous legislation. The bill amended laws relating to prospecting for and mining precious metals, base minerals, and petroleum, and dealing in unwrought precious metals. Similar legislation for precious stones was passed in 1964.

The Government was studying the possibility of permitting base mineral prospectors to operate in diamond prospecting areas of the northwest Cape Province. Such action was opposed by holders of diamond prospecting rights on the grounds that it would interfere with their operations. The exclusion of other mineral prospectors from diamond areas was a provision of the Cape Government's Mineral Law Amendment Act of 1907.

During the year the annual report for 1963 of the Director, Government Metallurgical Laboratory, was issued.[5] The report is the second to be circulated to the public. It states that during 1963 an effort was made to increase to an appropriate level the amount of fundamental research undertaken by the laboratory. Such research was begun by the ore-dressing section, particularly in the field of flotation, on conversion of manganese in low-grade manganese ores to manganese sulfate, on extracting asbestos by wet methods, and on fundamental aspects of leaching reactions.

[4] Republic of South Africa, Department of Planning, Pretoria. Economic Development Programme for the Republic of South Africa, 1965–70, December 1965, 92 pp.

[5] Government Metallurgical Laboratory, Johannesburg. Annual Report, 1963. 1965, pp. 14.

The Analytical Section undertook fundamental projects in atomic absorption, flame photometry, and spectroscopy.

Much applied research was undertaken, some of it on a long-term basis. Such projects included investigation of the recovery of alumina from nonbauxitic material, examination of refractory gold ores that occur in the Republic, and assistance in the design of a sampling unit and in developing a process for recovering baddeleyite (a zirconium oxide) from apatite flotation tailings. An efficient flotation process was developed for concentrating sulfide nickel ore from the Matooster mine in the Pilanesberg area.

The report lists some 400 nonconfidential project reports that the laboratory issued through 1963.

In 1960 the Geological Survey prepared a report on the exploitation of mineral resources situated in the Bantu homelands. At yearend the report had not yet been released, pending a government decision on the type and extent of development to be permitted in these areas.

PRODUCTION

Although in recent years the percentage contribution of mining to the Republic's gross national product has tended to decline, mine output itself nevertheless has steadily increased. Equally important, the output of mineral-based industry has grown steadily and has tended to include increasingly sophisticated items. Production of ferroalloys more than doubled in the period 1961–65.

Increased local consumption of domestic mineral production reflects the growth of this vital sector of the economy. The volume of local sales of manganese ore and chromium ore in 1965 was respectively 34 percent and 52 percent higher than in 1964.

The index of the physical volume of mining production averaged 162.4 in 1965 compared with 156.9 in 1964 (1957=100). For gold alone the index rose by 5 percent, the smallest annual increase in many years. Increases of 16.2 percent and 20.6 percent were recorded for iron ore and manganese ore, respectively. The indexes for building materials and asbestos rose by 5.8 and 12.6 percent respectively.[6]

The Department of Mines of South Africa issues a quarterly minerals information circular which includes the value of local sales and exports. The report takes into account separately raw minerals, refined gold and silver, blister and refined copper, refined tin, and vanadium oxide. It also includes uranium (U_3O_8), refined nickel, and semiprocessed platinum products. For some years the nickel and platinum have not been reported separately but have been included in the item "other". In 1965 uranium was also put there.

The value of South Africa's mineral pro-

p Preliminary.
[1] Comprises uranium (U_3O_8) and in 1961 relatively small quantities of monazite.
[2] Included in other minerals. Estimated at $46.5 million.

Source: Republic of South Africa, Department of Mines. Minerals Quarterly Information Circular, October to December issues for 1961 through 1965.

duction in 1965 as represented by the value of gold and silver production, diamond sales, and the value of local sales and exports of other minerals, as reported in the circular, was $1,614.1 million. The comparable figure for 1964 was $1,518.7 million, and for 1961, $1,252.2 million. Each year since 1961 or earlier gold has accounted for 60 percent or somewhat more of total value and in 1965 the contribution of gold was 66 percent. The next largest contributor in 1965 probably was platinum, with diamond ranking third. At yearend the outlook was for some further increase in gold production and substantial increases for platinum and diamonds.

[4] A rock containing up to 98.4 percent SiO_2.

[5] Decorative material resulting from oxidation and silicification of crocidolite.

TRADE

The statistical territory for the external trade statistics of the Republic of South Africa includes the Territories of Basutoland, Bechuanaland, and Swaziland, besides the Territory of South-West Africa, and no separate official trade statistics are recorded for the trade between these territories and the Republic. Hence items of external trade involving only the Republic are not always identifiable. For this chapter, however, the problem applies mostly to imports (which for the territories are small) because most export data have been taken from a supplementary source that lists the Republic's mineral exports separately.

The Republic's chronic deficit in merchandise trade declined somewhat toward the end of 1965, mainly owing to a sharp reduction in imports accomplished by government-imposed restrictions.[7] The deficit for the entire year approached $1,000 million[8] and was the highest ever recorded. The comparable figure for the deficit in 1964 was about $700 million. The statistics from which the deficits were computed did not include gold and uranium and probably not platinum. Against these deficits, the value of the Republic's gold production in 1964 and 1965 was respectively $1,018.9 million and $1,069.4 million, and uranium exports were valued at respectively $81.3 million and about $46.5 million.

With respect to the direction of trade, total imports in 1964 were $2,136 million, and the principal suppliers were, in percent: United Kingdom 29; United States 19; West Germany 11; Japan 5. Total exports, with the exclusions noted earlier, amounted to $1,454 million. Major markets were, in percent: United Kingdom 31; United States 9; and Japan 9. Major mineral commodity exports besides gold and uranium were diamond, metals, ferroalloys, metallic ores, and asbestos.[9]

With respect to mineral commodities exclusively, including mineral fuels but excluding gold, South Africa continued to have a favorable trade balance. In 1964 exports exceeded imports by $222 million, as shown in the table that follows. These exports were nearly 39 percent of total merchandise exports. Reexports amounted to $95 million, to which diamond contributed about $85 million.

During the year, a new international marketing organization, Imex (Pty.) Ltd., was formed in South Africa with the object of securing and developing export markets for South African goods. The sponsors and shareholders of the company include the Anglo American Corporation of South Africa Ltd., General Mining and Finance Corporation Ltd., Industrial Development Corporation of South Africa Ltd., The Netherlands Bank of South Africa Ltd., Union Acceptance Ltd., and Walker Brothers (London) Ltd. The company intends to handle the direct exporting and marketing of primary products, semiprocessed commodities, consumer goods, durables, and capital equipment.

	Million dollars		Mineral commodities' share of total (percent)
	Mineral commodities	Total trade	
Exports:[1]			
1963	452	1,282	35.3
1964	564	1,454	38.8
Imports:			
1963	267	1,683	15.9
1964	342	2,136	16.0
Trade balance:			
1963	+185	−401	XX
1964	+222	−682	XX

XX Not applicable.
[1] Excludes gold and uranium and, probably, platinum. Uranium (U_3O_8) exports in 1963 and 1964 were respectively $93.5 million and $81.3 million.

U.S. Mineral Imports From South Africa.—U.S. imports for consumption from South Africa in 1965 included $114.4 million of mineral commodities, excluding iron and steel semimanufactures. Principal items by value of the 1965 imports follow:

Commodity	Value, thousand dollars
Uranium (U_3O_8)	[1] 46,496
Diamond, gem and industrial	31,121
Ferroalloys	10,154
Asbestos	7,218
Manganese ore	3,947
Chromium ore	1,887
Antimony ore	1,864
Total	102,687

Table 3.—Republic of South Africa: Exports of metals and minerals [1]

(Metric tons unless otherwise specified)

Commodity	1963	1964	Principal destinations, 1964
Metals:			
Antimony concentrate	19,474	21,741	United Kingdom 13,323; United States 5,927; France 1,108; Japan 864.
Beryllium ore	270	84	All to United States.
Bismuth concentrate	---	1	NA.
Chromite	587,444	629,384	United States 383,108; West Germany 94,564; United Kingdom 90,602; Japan 31,027.
Copper:			
Contained in concentrate	592	3,340	Japan 3,323.
Blister and fire refined	52,399	53,302	United States 20,455; Belgium 8,484; United Kingdom 7,935; West Germany 6,096; Austria 3,455.
Iron and steel:			
Iron ore—thousand tons	604	1,085	Japan 1,070.
Iron and steel scrap	NA	848	Japan 537.
Pig iron, spiegeleisen, powder, and shot:			
Pig iron	218,821	353,612	Japan 227,241; United States 73,923.
Other	---	8,354	Netherlands 5,296.
Ferroalloys:			
Ferrochromium	NA	28,559	United Kingdom 7,645; United States 5,244; West Germany 3,334; Sweden 3,062; Japan 3,044.
Ferromanganese	106,544	122,240	United Kingdom 41,100; United States 22,003; Australia 18,015; Italy 16,531; West Germany 6,512.
Ferrosilicon	NA	20,740	Australia 6,481; Japan 3,970; United Kingdom 3,436; Netherlands 2,138; Italy 1,280.
Other	38,936	4,575	United States 2,032; Venezuela 1,244.
Total	145,480	176,114	
Steel ingots and other primary forms	2,935	3,549	Mozambique 2,849; Rhodesia 610.
Semimanufactures:			
Bars, rods, angles, shapes, and sections	80,157	29,579	United States 9,068; Rhodesia 8,784; Zambia 4,866; Mozambique 1,165; United Kingdom 698.
Universals, plates, and sheets	145,275	65,545	Rhodesia 31,823; Zambia 10,858; United Kingdom 6,759; United States 5,243; Mozambique 4,751; Italy 3,969.
Hoop and strip	---	1,536	Rhodesia 810; Zambia 378.
Rails and accessories	21,117	18,647	Rhodesia 15,616; Mozambique 1,695; Zambia 1,199.
Iron and steel wire	NA	2,230	Rhodesia 1,404; Mozambique 329; Zambia 180.
Tubes, pipes, and fittings	20,634	20,498	Rhodesia 7,800; Zambia 6,356; Mozambique 5,010.
Castings and forgings, rough	---	364	United Kingdom 197; Rhodesia 144.
Total	267,183	138,399	
Manganese:			
Ore:			
Metallurgical grade	852,540	819,851	France 197,530; United States 179,877; United Kingdom 139,725; West Germany 63,287.
Chemical grade	8,532	9,618	United Kingdom 7,346; Japan 1,360.
Manganiferous iron ore	41,374	128,607	West Germany 116,743; Netherlands 11,864.
Total	902,446	958,076	
Electrolytic metal	4,532	4,826	United Kingdom 859; Sweden 809; United States 772; France 616; Canada 535.
Monazite	3,102	---	
Platinum-group metals	NA	NA	
Silver—thousand troy ounces	1,679	1,700	All to United Kingdom.
Tantalite—kilograms	r 2,086	381	Do.
Tin concentrate—long tons	1,155	878	Do.
Titanium, illmenite	14,691	---	
Tungsten concentrate	5	20	West Germany 14; United Kingdom 5.
Uranium (U_3O_8)	3,756	3,388	NA.
Vanadium:			
Fused oxide	1,731	3,243	NA.
Ammonium vanadate	24	61	NA.
Zirconium concentrate	2,544	73	NA.
Nonferrous metal scrap	941	3,962	Belgium 3,032.

See footnotes at end of table.

Table 3.—Republic of South Africa: Exports of metals and minerals [1]—Continued

(Metric tons unless otherwise specified)

Commodity	1963	1964	Principal destinations, 1964
Nonmetals:			
Andalusite and sillimanite	43,296	53,959	Japan 26,219; United Kingdom 1,596.
Asbestos:			
Amosite	66,133	74,174	United Kingdom 21,539; United States 19,216; Japan 6,585; Australia 6,399; Italy 4,730.
Chrysotile	14,614	25,921	Japan 9,534; West Germany 3,776; Rhodesia 3,758; United Kingdom 2,503; Italy 2,028.
Crocidolite:			
Cape blue	77,596	88,119	United States 18,326; Japan 11,342; Italy 10,342; France 6,973; United Kingdom 6,458.
Transvaal blue	8,445	9,714	United States 4,164; Japan 2,611; Italy 1,391.
Tremolite	8	---	
Total	166,796	197,928	
Barite	---	14	All to Rhodesia.
Cement, including refractory cements	34,932	51,786	Mauritius 20,827; Reunion 17,586; Malagasy Republic 9,479.
Corundum, crystal	72	53	NA.
Diamond, exports and reexports:			
Exports:			
Gem:			
Rough, uncut thousand carats	2,043	1,809	United Kingdom 1,616.
Cut, unmounted	124	111	Belgium 47; Hong Kong 27; United States 21; Netherlands 8.

[1] The statistical territory for the external trade statistics of the Republic of South Africa includes the British High Commission Territories of Basutoland, Swaziland, and Bechuanaland Protectorate besides the Territory of South-West Africa. (No separate statistics for the trade between these territories and the Republic are recorded).

[2] Included in the total.

[3] Probably includes appreciable gem diamond.

COMMODITY REVIEW

METALS

Aluminum.—The Government-owned Industrial Development Corporation (I.D.C.) of South Africa toward yearend decided to underwrite construction of a primary aluminum smelter, which will be the first such facility in the country. The smelter will have an initial annual capacity of 38,000 tons of aluminum and will cost about $49 million. It will be situated in a border area (adjacent to a Bantustan), several of which have been found suitable. Alumina for the plant will be imported at the outset because bauxite has not been found in South Africa; the search for an aluminum raw material was continuing.

Alcan Aluminium Ltd., the country's major aluminum fabricator, opened at Pietermaritzburg (Natal) a $2.8 million 72-inch cold rolling mill. The annual aluminum consumption of the country was expected to rise to 45,000 tons by 1970, which compares with estimated consumption in 1965 of 27,000 tons.[10]

Antimony.—Consolidated Murchison (Transvaal) Goldfields & Development Co., Ltd. (Murchison), the sole antimony producer in South Africa, supplied 26 percent of U.S. general imports of antimony in 1965, compared with 24 percent in 1964 and 23 percent in 1963.

The mine was worked to capacity during the year. Combined production of concentrates and cobbed ore averaging 60.91 percent antimony was 20,548 tons, compared with 21,381 tons at 60.46 percent antimony in 1964. In addition, 3,922 ounces of gold was recovered (5,602 ounces in 1964). Ore milled totaled 188,059 tons, 7,620 tons more than in 1964. At yearend ore reserves taking into account combined antimony and gold content amounted to 435,000 tons, up 30,000 tons from 1964 and the largest reserves reported since 1955 or earlier. Stocks of cobbed ore and concentrate on hand totaled 5,050 tons.

By the end of January the Alpha shaft had been sunk to its final depth of 1,102 meters, and except for minor items, installation of permanent equipment had been completed. By means of an auxilliary winze the extension of the Gravelotte shaft was completed to 20 level where exploratory development was in progress at yearend.

Murchison's operating profit and dividend declarations for 1965 were respectively $4.1 million and $2.47 million, compared with $3.7 million and $2.07 million in 1964. At yearend demand for the ore and concentrate Murchison produces reportedly remained steady, although the London price for antimony metal declined during the year.

Chromium.—Production and exports of chromite increased over 10 percent in 1965

[10] South African Mining and Engineering Journal (Johannesburg). V. 76, pt. 1, No. 3764, Mar. 26, 1965, p. 885.

compared with the 1964 figures, and local sales by 52 percent. The value of 1965 sales and exports was respectively $1.3 million and $8.4 million. In view of the establishment in 1964 of two ferrochromium plants and of the present construction of a stainless steel plant, local sales of chromite were expected to continue to grow.

In 1965 some 12 large or medium sized companies were producing chromite from two areas in the Bushveld Igneous Complex in Transvaal Province. Export railings from the areas in 1965 to Lourenco Marques in Mozambique totaled 691,196 tons. Most of the ore was loaded at seven sidings: Steelpoort (201,488 tons), Northam (131,423), Burgersfort (115,603), Bleskop (100,891); Rustenburg (71,369), Boshoek (46,270), and Marikana (23,604).

Copper.—O'okiep Copper Co. Ltd. in the Nababeep area of Cape Province established several financial records in its financial year ended June 30, 1965. The records were achieved as a result of high copper prices and despite only nominally increased blister copper production, a decrease in average copper content of ore milled, and rising wage and materials costs. Sales of blister copper totaled 43,915 tons compared with 38,025 tons in the previous financial year. Salient financial results in million dollars for these years follow:

	Year ended June 30	
	1964	1965
Metal sales	24.98	41.71
Net operating income	10.87	23.95
Provision for income taxes	2.74	6.99
Net profit	7.37	17.18
Dividends declared	7.86	15.01

O'okiep blister copper averages about 99.4 percent copper, and about 0.14 ounce of gold and 3.4 ounces of silver per short ton. The average price obtained for the 43,915 tons of blister copper that O'okiep sold in the 1965 financial year was 43.08 cents per pound, or 94.97 cents per kilogram. This compares with 29.79 cents per pound, or 65.68 cents per kilogram, obtained for blister copper sold in the previous financial year computed on the same basis as for 1965.[11]

During the year 2.6 million tons of ore, averaging 1.79 percent copper and obtained from seven mines, was treated in three separate mills. The tonnage compares with 2.4 million tons averaging 1.93 percent copper milled in the previous financial year.

The smelter treated 1.33 million tons of concentrates and other new metal-bearing material averaging 31.64 percent copper, producing 41,800 tons of blister copper averaging 99.37 percent copper and per short ton (2,000 pounds) 0.14 ounce of gold and 3.44 ounces of silver. In the previous year 41,688 tons of blister copper was produced.

Ore reserves at yearend totaled 25.14 million tons of sulfide ore averaging 1.81 percent copper and 414,000 tons of oxide ore averaging 1.01 percent copper. No major new ore discoveries were made.

At yearend O'okiep reportedly was employing 919 "Europeans" (whites), 1,535 "Coloureds" (mixed racial origin), and 2,079 "Bantu" (Negroes).

Palabora Mining Co. Ltd. at yearend was approaching production from its open-pit copper mine in North Eastern Transvaal, where over 270 million tons of ore averaging 0.69 percent copper had been developed. Stripping had started in 1964 and by the end of 1965 about 13 million tons of material had been mined, of which 1.5 million tons was sulfide ore. Milling and smelting facilities can process 30,000 tons of ore per day, yielding 73,000 tons of blister copper annually.

The 270-ton-per-day sulfuric acid plant was under construction. It will supply a local phosphate fertilizer plant under a long-term contract. Also under construction was a $5 million plant to produce annually 80,000 tons of magnetite concentrate for Japanese steel companies.

Gold.—In 1965 for the 14th successive year, the Republic's gold production again increased, reaching 30.55 million ounces valued at $1,073 million. The comparable figures for 1964 were 29.11 million ounces and $1,023 million. The 1965 volume of production was about 74 percent of non-Communist-world gold production, which compares with the 72.5 percent contribution by South Africa in 1964.

Of the total 1965 volume, all but 438,000 ounces was produced from mines in the Witwatersrand sedimentary basin and its extension (Rand), which are members of the 76-year-old Transvaal and Orange Free State Chamber of Mines. While production

[11] Republic of South Africa chapter of Bureau of Mines Minerals Yearbook 1964, Volume IV, reported 25.54 cents, but on an "ex-mine" basis.

from the Rand has increased each year since 1955, and further increase is forecast for some years, the annual rate of increase has been declining and probably will continue to do so until the peak of output is reached. Annual rates of increase in recent years have been as follows, in percent: 1960–61, 7.29; 1961–62, 11.12; 1962–63, 7.61; 1963–64, 6.12; 1964–65, 4.95. The Government's second Economic Development Program for the Republic estimates that in the 6-year period from 1964 to 1970, gold production will have expanded 12 percent, or at an average annual rate of 2 percent.

With respect to 1965 results of the operations of Chamber members as a whole, while gold output increased, operating profit declined somewhat. Seven mines sustained losses. Costs continued to rise, largely because of wage increases granted both to white and nonwhite employees, and to higher prices for supplies and services. There was an adequate supply of nonwhite labor, but the shortage of skilled white labor continued to be severe.

At the 75th annual meeting of the Chamber held in Johannesburg in June 1965, C. B. Anderson, retring president, said in part with reference to rising costs:

> . . . . I would again stress that every cent increase in working costs per ton milled transfers a quantity of ore in every mine—be the mine old or new, a low-grade or a high-grade producer—from the payable to the unpayable category. In aggregate, over the industry as a whole, the quantity of ore transferred is considerable. This ore will be left unmined, possibly forever, and so lost to South Africa and to the world. Furthermore, the lives of individual mines are progressively shortened and the day of the decline of the gold mining industry as a whole is brought appreciably nearer. This elimination of payable ore is constantly progressing and should not be overlooked in the popular acclaim of spectacular figures of output revenue and profits.

In March the South African Government stopped the experiment of certain gold mines whereby promising nonwhites were being given jobs requiring increased responsibility and skill. The experiment was undertaken as part of an effort both to combat the developing shortage of white labor and as part of a campaign to improve efficiency, which in fact did improve in 1965. Compared with that of 1960, the tonnage of ore handled by the whole industry increased by 11.4 percent, while the

Table 5.—Salient statistics of gold and uranium production by members of the Transvaal and Orange Free State Chamber of Mines

	1963	1964	1965

Source: Union Corporation Ltd. report and accounts for the year ended Dec. 31, 1965. Statistics published by the Transvaal and Orange Free State Chamber of Mines.

white labor decreased by 11.3 percent and the nonwhite force by 3.2 percent.[12]

Mines controlled by Anglo American Corporation of South Africa Ltd. (Anglo) accounted for 37.7 percent of the total 1965 output of the gold mining industry, compared with 36 percent in 1964, and their aggregate operating profit rose by $16.8 million to $203 million. Union Corporation Ltd. companies accounted for 13.2 percent of total production and realized an aggregate working profit of $63.9 million, $1.9 million less than in 1964.

In the year ended June 30, 1965, 12 producing gold and uranium mines administered by Gold Fields of South Africa Ltd. (wholly owned by Consolidated Gold Fields Ltd.) for the first time produced over 5 million ounces of gold. Aggregate operating profit rose by 10 percent to $88.2 million,[13] a new record.

During the year ended June 30, 1965, West Driefontein Gold Mining Co. Ltd. (administered by Goldfields) produced 2,146,451 ounces of gold ($75 million). This was the first time in the history of mining that a mine had produced more than 2 million ounces of gold in a period of 12 months.

Kloof Gold Mining Co. Ltd. expected to reach production by January 1968, at an estimated total cost of $60.2 million of which $21 million was raised in August 1964 to meet expenditures during the first 2 years. The company's base area is underlain by conglomerate ore estimated at 90.7 million tons containing 40 million ounces of gold ($1,400 million).

An important development of the year was the formation by Johannesburg Consolidated Investment Co. Ltd. of the new Elsburg Gold Mining Co. Ltd. Elsburg will exploit a new mining lease lying to the southwest of Western Area's mine. The project is expected to begin production in the middle of 1969, milling 45,000 tons of ore per month.

Kinross Mines Ltd. in the Evander area made excellent progress during the year in the sinking of its two vertical shafts and the construction of surface facilities.

Cementation Co. (Africa) (Pty.) Ltd. of Johannesburg won the contract to sink the new No. 5 shaft of Hartebeestfontein Gold Mining Co. Ltd. The shaft will reach a final depth of 2,007 meters (6,580 feet) and inside its concrete lining will be 9 meters (29½ feet) in diameter. With this inside diameter the shaft will be one of the largest of its kind in the world. The contract also specifies installation of a concrete partition from collar to bottom, dividing the shaft into upcast and downcast ventilation channels. The downcast channel will have four hoisting compartments. The shaft was started late in 1965 and is expected to be operational by the end of 1968. A total of 29 Europeans (whites) including the administrative staff and 320 Bantu (Negroes) will be employed in sinking it.[14]

Iron and Steel and Ferroalloys.—The iron and steel industry continued to grow in 1965 despite some slowing down of the economy as a whole. The industry, aided by foreign capital and technical assistance, was beginning to include products not previously manufactured locally; for example, stainless steel. The 1965 production of the industry as a whole was 10 percent higher than in 1964. The largest increase (20 percent) occurred in pig iron production; steel production rose 3 percent. Government controlled and operated South African Iron & Steel Industrial Corp. Ltd. (ISCOR) supplied 85 percent of 1965 output. Total employment in the iron and steel industry in 1964 was estimated at 41,000 (18,000 whites, 23,000 nonwhites).

The import levies introduced in 1964 to pay for supplementary steel imports were permanently incorporated into basic domestic steel prices. Effective January 3, 1966, prices for products of ISCOR's Pretoria plant were raised $5.6 per short ton; and effective March 28, 1966, the price of Vanderbijlpart steel plate was raised $6.65 per short tons. These price increases are the first since 1952. Reportedly their effect was to raise producers' selling prices by between 6.7 and 7.4 percent.

ISCOR estimated that from October 1964 to March 31, 1966, about 816,000 tons of steel products will have been imported under the general levy import scheme, mostly from Japan and Italy. During the period from October 1964 to June 30, 1965, about 397,000 tons were imported under the scheme.

Pig iron exports, very largely to Japan, rose nearly 80 percent compared with those

[13] Converted from £ sterling at 1£=$2.80.
[12] South African Mining and Engineering Journal (Johannesburg). V. 77, pt. 1, Apr. 1, 1966, p. 705.
[14] Coal, Gold, and Base Minerals (Johannesburg). V. 13, No. 11, January 1966, p. 14.

in 1964. With this principal exception exports of iron and steel were moderate. This situation was expected to continue until the home industry could more nearly satisfy domestic demand. According to Dr. F. P. Jacobsz, chairman of Union Steel Corp. South Africa, annual steel consumption in the country was estimated at 186 kilograms per capita (one-third of U.S. per capita consumption) and to be increasing at the rate of 8 percent per year (versus 2.9 percent in the United States). At this growth rate South Africa's steel consumption would exceed 4.5 million tons by 1970.

Despite the growing domestic iron and steel demand, the Government's revised Economic Development Programme provides for a substantial increase in exports of basic iron and steel products between 1964 and 1970. The program put the value of such exports in 1964 at about $50.8 million and stated that the figure would increase to $81.5 million by 1970.

ISCOR's $784 million expansion program at its steel plants at Pretoria and Vanderbijlpart was on schedule. For the financial year that began July 1, 1965, additions and improvements were expected to cost $140 million. This scheduled work included at Pretoria modernization of No. 1 sinter plant and the stoves of No. 1 blast furnace and completion of a second oxygen plant with daily capacity of 95 tons. At Vanderbijlpark the work included construction of a sixth open hearth furnace with 360 ton capacity and an electrolytic tinning line. In addition, $9.8 million was being spent on improvements at ISCOR's Sishen and Thabazimbi iron mines.

ISCOR's ultimate production target for its existing plants is 4.1 million tons of steel ingots annually. Earlier the target was expected to be reached by 1973, but ISCOR chairman F. Meyer in his annual report for the 1965 financial year predicted that the target would be reached by 1969. In addition, ISCOR was planning to build a third major steel works, probably on the east coast.

The Southern Cross Steel Co., jointly owned by Rand Mines Ltd. and the U.S. Eastern Stainless Steel Corp., expected to commission South Africa's first stainless steel plant, at Middleburg, Transvaal Province, in October or November 1966. Annual production of the $14.7 million plant by 1970 was estimated at 23,000 tons.

The iron, steel, and vanadium plant to be built at Witbank in Transvaal Province by Highveld Steel & Vanadium Corp. Ltd. was scheduled to begin operating in 1969, not in 1968 as previously reported. The vanadium product of the plant will be vanadium-rich slag, not vanadium pentoxide as previously reported.

In a speech in Johannesburg in September 1965 the Minister of Planning, J. F. W. Haak, cited the country's distinct export potential for ferroalloys. He mentioned the Republic's large reserves of chromite, manganese ore, and silica, and that it has one of the world's largest vanadium plants.

That the potential cited exists is apparent from the performance of the Republic's ferroalloy industry in recent years. Including spiegeleisen, in presumably relatively small quantity, production rose uninterruptedly from 159,000 tons in 1961 to 230,000 tons in 1964 to 332,000 tons in 1965. Exports in 1964 (most recent year for which data are available) totaled 176,076 tons valued at $21.6 million, compared with 145,275 tons valued at $18.1 million in 1963. The exports comprise mostly ferromanganese, ferrochromium, and ferrosilicon, for which export values in 1964 in million of dollars were respectively 13.7, 4.8, and 2.6.

Manganese.—Local sales and exports of manganese ore were valued at $6.3 million and $18.6 million, respectively, 39 percent and 20 percent higher than in 1964. Exports of chemical grade ore declined slightly, while local sales improved.

The Associated Manganese Mines of South Africa, Ltd. (AMM), earned $4.7 million, 43 percent more than in 1964, owing to higher prices and record shipments of iron and manganese ores. Shipments of the ores totaled 840,000 and 616,000 tons respectively. At the plant of AMM's wholly owned Feralloys, Ltd. capital expenditures totaled $283,000 in 1965, and Feralloy's $4.2 million, 3-year expansion plan was completed.

South African Manganese Ltd., the other large South African manganese producer, produced 800,000 tons of manganese ore in the year ending June 30, 1965, at its Hotazel, Lohathla, and Mamatwan mines, 85,000 tons more than in the previous financial year.

Electrolytic Metal Corp. (Pty.) Ltd. produced 5,035 tons of electrolytic manganese in 1965, and plans to expand capacity to 7,600 tons annually. The project was delayed by shortages of labor and contractor facilities.

A paper was prepared for publication which describes two sources of battery-grade manganese in the western Transvaal, the Gopani and Orient mines.[15]

Platinum.—Rustenburg Platinum Mines Ltd. (RPM), continued to be the only significant producer of platinum group metals in the Republic. RPM does not publish production, and there was much speculation in Johannesburg and elsewhere as to that figure for 1965. The Bureau of Mines has estimated RPM's 1965 production at 750,000 ounces, for combined platinum and other metals of the group. The estimate is 150,000 ounces larger than that made for 1964 and again ranks South Africa as by far the largest platinum producer in the free world.

RPM's financial year ends August 31. During the 1965 financial year the mines (Rustenburg and Union) operated at capacity and mine output substantially increased. The flow of refined marketable metal also increased. The expansion program in progress during the year was on schedule and the designed rate of mine output would be reached during March 1966. Toward the end of 1966 all of the refined platinum resulting from the program would be available to the market.

A long-term agreement made in 1964 with a consortium headed by the Central Mining/Rand Mines group became operative. On a royalty basis RPM was mining in the consortium's Brakspruit property adjacent to RPM's Rustenburg mine, and in April 1965 regular deliveries to the consortium of platinum group metals were begun. The deliveries were in the form of converter matte and metallics (blanket table concentrates of platinum minerals).

On January 18, 1965, RPM raised its published price for platinum from the equivalent of $89.60[16] per ounce to the equivalent of $100.10 per ounce, where it remained during 1965. The company also increased its prices for palladium, rhodium, and osmium. With respect to platinum, RPM reported that as at November 17, 1965, the "free market price" of platinum (mostly Soviet platinum) was the equivalent of about $168 per ounce.

	Value, million U.S. dollars	
	1964	1965
Net revenue from sales of metals	23.7	19.1
Taxation and State's share of profits	8.9	5.2
Dividends declared	11.6	11.6

The following financial items appeared in the report of RPM for the year ending August 31, 1964.

According to the report, the decline that occurred in revenue from metal sales resulted from a reduction in the volume of sales of platinum.

The principal ultimate markets for Rustenburg platinum continued to be the United States and the United Kingdom, along with Japan and certain European countries.

Uranium.—On August 5 the Prime Minister inaugurated the Republic's first nuclear reactor, Safari I, at Pelindaba, which cost $330 million to build,[17] and during the year the Atomic Energy Board was asked to thoroughly study nuclear energy as a source of energy for the Republic.

Seven mines produced uranium as a byproduct of gold mining during the year; namely, Buffelsfontein, Harmony, Hartebeestfontein, Vaal Reefs-Western Reefs (a joint production scheme), Virginia, and West Rand Consolidated gold mines. An eighth mine, Zandpan, was preparing for production, using the Hartebeestfontein plant.

Early in the year the South African Government invited uranium producers to stockpile production in excess of current contracts, and it was estimated that the value of domestic stocks of uranium (U_3O_8) would be about $28 million in 1966, and about $70 million by 1970. Stockpiles took some of the 2,673 tons produced in 1965, which was 1,363 tons less than 1964 output and reflected a decline in contractural commitments to the United States Atomic Energy Commission and the United Kingdom Atomic Energy Authority. Total exports during the first 6 months of 1965 (no later data available) were valued at $32.7 million. Final deliveries to the United

[16] Converted from £ sterling at £=$2.80.

[17] Mining Journal (London). V. 265, No. 6784, Aug. 27, 1965, p. 149.

States will be made in 1966 and deliveries to the United Kingdom will begin in 1967.

In August the Minister of Mines announced that the Republic's uranium reserves at the present price of gold were 172,000 tons of recoverable uranium oxide at a price for uranium oxide of $17.64 per kilogram ($8.00 per pound); this was 30,000 tons above the previous estimate. Early in 1966 the Minister added that reserves were 172,000 tons at $22.05 per kilogram ($10.00 per pound), 204,000 tons at $33.07 per kilogram ($15.00 per pound), and 240,000 tons at $44.10 per kilogram ($20.00 per pound).

A pilot plant was operated as a cooperative research program by the Atomic Energy Board and Buffelsfontein Gold Mining Co., Ltd., to investigate the production of nuclear-grade uranium by a combination of sulfuric acid election and solvent extraction. The procedure, known as the Bufflex process, reportedly satisfies economically the most stringent specifications for nuclear-grade uranium, except as regards cobalt, molybdenum, and hafnium contamination.[18]

Vanadium.—Vanadium oxide (V_2O_5) exports in the form of fused oxide fell sharply, from 3,243 tons worth $5.8 million in 1964 to 2,148 tons valued at $4.3 million. Exports in 1964 had included a large quantity of material from stocks.

The sole producer in 1965 was Transvaal Vanadium Co. (Pty.) Ltd., which in November 1965 became a wholly owned subsidiary of Highveld Steel & Vanadium Corp., Ltd. But during the year control of the assets of the Federale Vanadium Company was acquired by Ruighoek Chrome Mines (Pty.) Ltd., a subsidiary of Union Carbide Corp. of the United States, and Federale's plant near Pretoria (operated experimentally in 1963) will be put into commercial production. Vanadiferous magnetite which Federale had used, will be the vanadium raw material. Mining and milling, beginning in mid-1966, will be undertaken by Ucar Minerals Corp., another Carbide subsidiary.

The steel and vanadium complex of Highveld Steel & Vanadium Corp. Ltd. (formerly Highveld Development Co. Ltd.) was expected to be commissioned at Witbank at a cost of about $164 million, including working capital. Vanadiferous magnetite will be mined at the new Mapoch's mine at Roossenekal, eastern Transvaal, at a cost of $9.8 million. Reserves there stood at 18 million tons containing 13 percent titanium, 1.6 percent vanadium (V_2O_5) and 56 percent iron. Ore will be provided initially at a rate of 900,000 tons a year. At the Witbank plant 435,000 tons annually of pig iron containing most of the vanadium will be produced initially. Oxygen will be blown into the molten pig to slag off vanadium at the initial rate of 10.4 million kilograms per year.

NONMETALS

Asbestos.—Total output of the three varieties of asbestos mined in the Republic rose by 11.6 percent compared with the 1964 output. Crocidolite registered the largest increase, 18 percent. The value of local sales more than doubled, but total export value in thousand dollars showed little change, as follows:

	Local sales [1]		Exports [1]	
	1964	1965	1964	1965
Amosite	176	273	10,867	10,557
Chrysotile	584	1,149	2,945	2,571
Crocidolite	351	1,083	19,607	20,544
Total	1,111	2,505	33,419	33,672

[1] Local sales values are free on rail; export values are f.o.b. port of shipment.

The United States generally has ranked second after the United Kingdom in consumption of South African asbestos. United States imports of the material in 1965 were valued at $7.2 million, with amosite and crocidolite accounting for $2.6 million and $4.1 million, respectively.

A new system of fiber extraction was introduced at the crocidolite property of Mercncor Asbestos Mines in the Kuruman district of Cape Province. In this method, known as the impact system, the fiber-bearing rock is thrown against an impact plate; experience has shown that the rock is shattered and the fiber freed more efficiently than through the use of hammer mills. The new plant has a capacity of about 635 tons of fiber per month.

The Barberton chrysotile asbestos property, near Malelane in the Eastern Trans-

[18] Faure, A., and coauthors. The Production of High Purity Uranium at a South African Gold Mine. J. South African Institute of Min. and Met., v. 66, No. 8, March 1966, pp. 339-341.

vaal, was reopened after having been closed for 2 years. About 180 tons per month of fiber will be produced.

South Africa's needs for asbestos more than doubled in the period 1960–65 and this pattern appeared likely to continue. Further increases in mine capacity were foreseen as a result and to meet export demand.[19]

Diamond.—Production of natural diamond increased by 12.9 percent compared with 1964 production. About 92 percent of 1965 output came from underground mines; 383,632 carats were obtained from alluvial workings. The figure for alluvials compares with 585,390 carats recovered from alluvial deposits in 1964.

Sales at 4.8 million carats valued at $69.4 million (R49,601,476) were 8.8 percent in volume and 12.2 percent in value greater than in 1964. The value per carat of 372,417 carats of alluvial stones included in the total was $52.08 (R37.20), whereas the value per carat of 4,472,632 carats of mine stones making up the remainder was $11.17 (R7.98).

At yearend the outlook was for a continuation of the firm market for diamond that existed in 1965.

De Beers Consolidated Mines Ltd.—De Beers accounts for the order of 80 percent of world sales of raw diamond. The following are some salient features of the statement of the chairman supplementing De Beers report for 1965. For the fifth successive year diamond sales by De Beers Central Selling Organization were a record. At $415.3 million, sales exceeded the total for 1964 by $42.4 million. At yearend the market for gem diamond was firm. Sales of industrial diamond were good and increasing. A growing demand existed for the synthetic grit produced in Shannon, Ireland, by Ultra High Pressure Units (Ireland) Ltd., an associated company, and in South Africa new types of grit were being developed by the De Beers company, Ultra High Pressure Units, Ltd.

The Diamond Producers' Association agreement and the related agreements with the selling companies were modified and renewed for another 5 years. Satisfactory new purchase agreements were concluded with Companhia de Diamantes de Angola and the Diamond Corp. Tanzania Ltd.

The increase in diamond sales was largely made possible by increased output from mines of the De Beers group. The output of mines in the Republic operated by the De Beers company increased by 212,113 carats to 1,900,216 carats, which included the first contribution from the new Finsch mine of 95,217 carats. Further increases were expected in 1966 in Namaqualand, where prospecting had established substantial reserves, and at Finsch. Premier mine in Transvaal Province (owned half by De Beers and half by the Government) completed its expansion program and production increased to 2,439,000 carats, from 2,224,012 carats in 1964.

During 1965 Marine Diamond Corp. in South-West Africa Ltd. became a subsidiary of Consolidated Diamond Mines of South West Africa Ltd., and hence of De Beers. Diamond reserves of Marine were stated to be "probably large," making Marine "a potentially important producer." Anglo American Corporation of South Africa Ltd. assumed technical direction of Marine's activities, and the chairman reported that "we are confident that we will eventually succeed in putting the Corporation (Marine) on a profitable basis, although quick results cannot be expected."

De Beers profit before taxes was $161 million, up $9.1 million from that of 1964. After providing for taxation and deducting minority interests, the profit attributable to De Beers increased by $4.5 million to $102 million. Taxation absorbed $45 million, $4.9 million more than in 1964.

Fluorspar.—Production of fluorspar again increased by 9 percent compared with 1964 output.

Buffalo Fluorspar (Pty.) Ltd. expanded rated capacity to 1,600 tons per month and it was expected that output would reach that figure by mid-1966. Proven reserves of ore for open pit mining were about 4.8 million tons, and a further 350,000 tons exist on a nearby farm over which the company obtained mining rights. Besides supplying the major portion of the domestic market for ceramic grade fluorspar, the company exports acid grade spar to Japan and Australia.[20]

Nitrogen.—African Explosives & Chemical Industries (AE & CI) called for tenders for its $22.4 million ammonia plant at Umbogintwini, Natal and Fisons (Pty.) Ltd.

[19] General Mining and Finance Corp., Ltd. Annual Report, 1965.
[20] Rand Daily Mail (Johannesburg). June 3, 1965.

placed a contract for the first stage of a $23.8 million ammonia plant at Milnerton, Cape Province. Fisons' output will be solely for the fertilizer field in the form of nitric acid, ammonium nitrate, and limestone ammonium nitrate, while much of AE & CI's output will go to industry in general, and the explosives industry. Total capacity of AE & CI should reach 254,000 tons per year of ammonia, Fisons about 90,000 tons, and a third plant, completed by the South African Coal, Oil & Gas Corp., Ltd. (SASOL) in 1964, will reach 60,000 tons per year, all by 1967. This total capacity will be larger than that needed locally, and a surplus for export is expected.

Phosphates.—The Phosphate Development Corporation Ltd. (FOSKOR) produced 3.6 million tons of foskorite ore during the fiscal year to June 30, 1965, and produced 446,000 tons of apatite concentrate. Mining of foskorite ore will be discontinued in 1966, and lower grade pyroxenite ore will be mined. Reserves of pyroxenite ore are potentially adequate to provide for the country's requirements for hundreds of years to come. Plant extensions at FOSKOR were completed and officially commissioned in August. Production capacity of the plant is now 540,000 tons of salable concentrates per annum, sufficient to supply the major portion of the Republic's requirements. During the fiscal year FOSKOR's price for phosphates (about 37 percent P_2O_5) was reduced to $12.89 per ton, compared with $14.95 in the previous financial period. With the disappearance of revenue from copper concentrates, which are a byproduct of foskorite mining, it is not expected that any further reductions will be possible. Other byproducts are titaniferous magnetite, for which no market has been found, and baddeleyite (zirconium oxide), for which markets are being sought.

Windmill Fertilizers S.A. (Pty.) Ltd. completed its new factory at Sasolburg, Orange Free State, in July at a cost of $8.4 million, and started manufacture of superphosphate; the factory will produce a wide range of fertilizers with a total output of up to 454,000 tons per year.

Silica.—Delmas Silica (Edms.) Bpk. with quarries about 6 miles from Delmas, began to produce silica in about 1959, but only recently has a modern plant been commissioned to produce pure silica for the glass, ceramic, iron and steel, and ferroalloy industries. The deposits have been drilled to a depth of 183 meters (600 feet) and reserves of very high grade material have been estimated at about 27 million tons. The average analysis of material being quarried from one of the deposits was, in percent: SiO_2, 99.5; Al_2O_3, 0.35; Fe_2O_3, 0.02. At yearend the capacity of the plant was governed by the size of two washers and was 27 tons per hour. Provision for a third washer was made and when installed plant capacity will be 41 tons per hour.[21]

Allied Quartzite (Pty.) Ltd. was developing extensive deposits of slab quartzite at the Lekkersing quarry near Port Nolloth, Namaqualand, Cape Province. The quartzite reportedly is among the hardest known, and the deposits are said to be the largest in the world. Contracts have been obtained for shipments to Europe and the United States.

In December De Beers Consolidated Mines, Ltd., called for tenders for the right to mine quartzite from deposits on the company's Oograbies West and Kwakanab farms in Namaqualand 20 miles from Port Nolloth. De Beers conservatively estimated the deposits to contain over 1 million tons of quartzite.

Soda Ash.—The plans of Salt & Soda Corp. Ltd. to manufacture soda ash were abandoned during the year. Goldfields of South Africa Ltd., was considering the possibility of mining soda ash in South-West Africa and refining it in the converted uranium plant of the Vogelstruisbult mine, which was closed in 1964.

Vermiculite.—The value of local sales of vermiculite increased over 20 percent to $155,506 but export sales declined slightly to $2 million. The only producer, Palabora Mining Co. Ltd., planned a drive to increase exports to the United States. Use of chartered ships and establishment of a stockpile near New York were proposed.

MINERAL FUELS

Coal.—The coal industry continued to expand owing to steady increase in internal demand. While coal exports were somewhat lower than in 1964, production and local sales were, respectively, 7.9 percent and 8.4 percent, greater than in 1964; and compared with 1962 sales those of 1965 were

[21] Coal, Gold and Base Minerals (Johannesburg). V. 13, No. 11, January 1966, p. 32.

16 percent higher. The value of sales per short ton free on rail increased to $2.05 from $1.93 in 1964. These figures probably represent the cheapest coal sales price at mine in the free world today.

In December the Electricity Supply Commission (ESCOM) awarded the coal contract for its new 2-million-kilowatt power station to Anglo-American Corporation of South Africa Ltd., acting on behalf of a consortium of companies. The station, to be called Arnot station, will be one of the world's largest coal-fired power stations. It will begin to operate in 1971 and at full capacity will burn annually about 6.3 million tons of coal. The coal will be supplied by four new collieries to be established in an area between Middleburg and Belfast in eastern Transvaal Province.

The new station is part of ESCOM's expansion program which by 1975 will have doubled the Republic's present capacity of about 6 million kilowatts. Leading authorities estimate that by the year 2000 South Africa's power requirements could have increased to about 10 times the present level. Although nuclear power stations may well be operating in the Republic by the late 1970's, the estimated increase in power needs is such as virtually to preclude abandonment of coal-fired stations in favor of nuclear stations. It appears that both power sources will be needed for many years.[22]

Petroleum.—The search for oil in South Africa was further intensified during the year. Southern Oil Exploration Corp., wholly owned by the Government, in October contracted for the drilling of three holes, in the Richmond, Sutherland, and Fraserburg districts of Cape Province. The holes will be drilled to depths of between 3,000 and 3,700 meters and are expected to require a year to complete.

Anglo Transvaal Consolidated Investment Co. Ltd., jointly with other companies, formed Zululand Oil Exploration Co. (Pty.) Ltd. in August. The new company was assigned rights to prospecting leases over about 14,000 square kilometers in northern Zululand (Natal Province) and the bed of the sea to the limits of South African territorial waters and the continental shelf.

Toward yearend at least seven syndicates were reported active in drilling in areas that had been surveyed geologically or geophysically. Several United States companies sent representatives to South Africa during the year to investigate oil possibilities.[23]

According to the South African Mining and Engineering Journal[24] the 27th oil refinery owned by the Standard Oil Co. of California (Caltex) will be officially opened and go on stream at Killarney, Cape Province, in April 1966.

The $27.4 million project has been described as the most integrated refinery that Caltex has yet undertaken. Capacity for crude will be about 30,000 barrels daily. Storage capacity for crude is 1.2 million barrels. The crude oil will come from the Middle East, with 20 tankers docking at Cape Town each year. The largest tanker will be 65,000 tons deadweight, and capable of discharging 60,000 tons of crude oil over a 3-day period. Effluent from the refinery will be discharged into Table Bay by pipeline about 460 meters long.

A significant event of the year was the completion of the pipeline for petroleum products from Durban to the Witwatersrand. The line will lessen the load on the railroad connecting those areas, which carries the heaviest tonnage in the country and whose capacity cannot be readily increased because it traverses rugged country.

The Mineral Industry of South-West Africa

By William F. Keyes [1] and Charles L. Kimbell [2]

As in previous years, the mineral industry in 1965 was the most important economic activity in the Territory of South-West Africa. The value of minerals exports, including some very minor local sales, was $161.2 million[3], an increase of $30.5 million over the 1964 total. This was more than half the gross domestic product of the Territory, although exact figures on the latter are not available. Output value of diamond, blister copper, and refined lead made up nearly 90 percent of the total value of mineral commodity output, and was significantly greater in 1965 than in 1964. The only major commodity recording a significant decline was zinc-lead ore.

Sales of diamonds, which were slightly less than production, were valued at $98.4 million in 1965, or almost 24 percent of total world gem sales by the Central Selling Organization. Vanadium output, about 15 percent higher than in 1964, contributed a significant part of total free-world output, and the Territory ranked second only to the United States as a mine source of this metal among free-world producers. Zinc concentrate and metallic cadmium also were produced in quantity, but production of germanium on a major scale was not realized because of lack of markets. Small quantities of lithium ores, tin concentrates, tin-tungsten concentrates and salt were also produced for export and iron ore (for use as flux) salt, phosphates and simple construction materials were produced for domestic markets. Reserves of most of these materials, both for export and indigenous use, were sufficient to permit output to continue at the 1965 levels or possibly at an expanded level for some time to come.

Thirteen companies reportedly[4] conducted exploration for diamond, base metals, nonmetallic minerals, and petroleum in South-West Africa in 1965. The two largest mining companies, Consolidated Diamond Mines and Tsumeb Corp. Ltd., were among these. Prospecting for oil was carried on by the subsidiary of a U.S. petroleum company.

The minerals industry of South-West Africa employed about 13,600 persons in 1965, a slight increase over the number of persons employed in 1964. The greatest increases in employment were at the Tsumeb copper-lead mine, which employed about 5,000 persons, at Consolidated Diamond Mines, which employed about 4,800 persons and at the tin-tungsten and lead-zinc-vanadium mines of the South-West Africa Co. Ltd., which employed about 1,100 persons. A shortage of skilled workers was noted.

New developments in mining included the takeover of the marine diamond-dredging operation by De Beers' subsidiary, the Consolidated Diamond Mines of South-West Africa Co. Ltd.; initial production of silver metal at the Tsumeb smelter; the reopening of the only manganese mine; and the start of operations at a new tin mine.

PRODUCTION

Although the total value of mineral production is not reported for the Territory of South-West Africa, the value of total sales may be taken as an approximation of the value of production. These sales consist almost entirely of exports but include modest local sales, chiefly of nonmetallic minerals. Total sales amounted to $161.2 million in 1965, $30.5 million greater than the value of total sales in 1964. The increase was due largely to a higher rate of diamond mining on the major concession along the coast and to increased production by Tsumeb Corp. Ltd.

e Estimate. r Revised.

[1] Compiled from Minerals, the Quarterly Information Circular of the Department of Mines of the Republic of South Africa, from company annual reports, and from Beerman's All Mining Yearbook, 1965. Data on metal content of concentrates containing copper, lead, and zinc have been revised from that reported in the 1964 edition of the Minerals Yearbook, Volume IV, in order to show metal content of total Territorial output on a calendar year basis rather than only the output of Tsumeb Corp. on a fiscal (July 1–June 30) year basis. Data for silver output are from Tsumeb Corp. on a fiscal year basis and considerably exceed officially reported quantities.

[2] In addition, construction materials such as common clay, sand and gravel are presumably produced, but quantitative data are not available.

[3] Data given here as reported in Minerals considerably exceed figures published by the Territory's sole producer, Tsumeb Corp., for years ended June 30. Tsumeb data, reported as recoverable cadmium content of concentrates produced for years ended June 30 of that stated, were as follows in metric tons: 1961–123; 1962–109; 1963–114; 1964–99; 1965–108.

[4] Figures represent only those ores and concentrates produced for export sale in that form; they exclude ores produced and processed within the Territory to concentrates, and concentrates produced and processed within the Territory to metals.

[5] In addition to ores and concentrates listed under this heading, see Polymetal concentrates at the end of the list of metals.

[6] Includes content of all ores and concentrates produced, including those Tsumeb Corp. concentrates smelted in the Territory as well as those exported as ores and concentrates.

[7] The accuracy of the germanium figures is questionable.

[8] Less than ½ unit.

[9] Includes copper-lead-silver, lead-copper-silver, copper-lead, and zinc-cadmium concentrates produced by Tsumeb Corp. for export; does not include concentrates of these types smelted in the Territory.

TRADE

The value of mineral commodity exports from South-West Africa, reported separately from the value of local sales for the first time,[5] reached $160 million, almost $29.7 million more than the revised export value of $130.3 million recorded for 1964. This new high chiefly resulted from increased diamond sales and both larger shipments and higher unit prices for nonferrous metal commodity exports. Increased diamond exports alone accounted for about half of the increase in total exports.

Major categories of mineral exports and the value of exports in these categories were as follows:

Commodity	Value, million dollars		
	1963	1964	1965
Diamond	57.4	84.4	98.4
Blister copper	11.3	19.5	21.0
Refined lead	.1	10.0	20.7
Complex concentrates [1]	14.5	11.0	14.3

[1] Copper-lead-silver and zinc-cadmium concentrates.

Together, these four commodities accounted for 96.5 percent of total export sales; most of the remainder resulted from exports of tin concentrates from the Uis mine, lead-vanadium concentrates from the Berg Aukas mine and tin-tungsten concentrates from the Brandberg West mine.

Mineral commodities continued to be the chief export product group of the Territory although exact comparison to total exports is impossible because data on gen-

[5] Department of Mines, Republic of South Africa. Quarterly Information Circular, Minerals, October to December 1965. Pretoria, South Africa, pp. 46–49.

eral exports have not been published separately from those of the Republic of South Africa. Likewise, total and mineral commodity imports are not reported separately. Fuels, including coal delivered by rail from the Republic of South Africa, and petroleum products, made up most of the tonnage and presumably also accounted for a large share of total value of imports.

In addition to total reliance upon imports to meet fuel requirements, much of the Territory's need for other mineral commodities also was met by imports. Indigenous resources in 1965 supplied about 32,800 tons of iron ore for use as a metallurgical flux, about 480 tons of guano fertilizer, about 26,600 tons of various grades of salt, and 56 tons of slate for domestic use. Local quarries presumably met virtually the entire need of the Territory for stone and sand and gravel. Requirements for cement, iron and steel, nonferrous metals, and other mineral manufactures were filled entirely by imports.

COMMODITY REVIEW

METALS

As in previous years, 3 large companies were producing metalliferous ores in South-West Africa in 1965, and 15 smaller producers were reported.[6] The only smelting operations were carried on by the Tsumeb Corp. Ltd., which produced blister copper, refined lead, commercial silver, cadmium, germanium dioxide, and black arsenic derived from ores from two mines; in addition Tsumeb produced complex copper-lead-silver concentrates and zinc-cadmium concentrates, both for export in that form. The South-West Africa Co. Ltd. was the only other producer of lead and zinc, milling ore from its Berg Aukas mine to produce lead and zinc concentrates as well as all the Territory's vanadium concentrates. In addition, this company produced tin-tungsten concentrates from its Brandberg West mine. The third large metal producer was the Industrial Minerals Exploration (Pty.) Ltd., whose Uis tin mine accounted for more than half the tin output. The remaining producers contributed to the output of ores of beryllium, bismuth, columbium, copper, gold, lithium, tantalum, tin, and tungsten.

Copper, Lead, Vanadium, Zinc, and Associated Metals.—*The Tsumeb Corp. Ltd.*—During the fiscal year ended June 30, 1965, the value of Tsumeb's metal sales increased by 60 percent over that of 1964, to a total of $72.0 million, and net profits more than doubled, to $26.4 million. The increases were due to larger sales and higher metal

[6] Pages 43–53 of work cited in footnote 5.

prices. The figures for metal sales and net profits were the highest in the company's history, materially exceeding the previous record year of 1956. The company's income tax payments also increased two and a half times over those of 1964, to $12.3 million.

Capital expenditure on the expansion program, including the copper smelter, the lead smelter, the cadmium plant, the germanium plant, the townsite, and the Kombat mine, totaled $30.4 million in the 5-year period ending June 30, 1965. Further authorized capital expenditure on new construction subsequent to this period was $5.7 million. This included $1.6 million on the two smelters, $1.4 million for increasing capacity at the Kombat mine to 36,000 metric tons of ore per month, and additional sums on European and African housing and other surface plants. Expenditure on the smelters will improve technical operations and hygienic conditions, and provide facilities necessary to smelt all of the company's concentrate products.

Operations at Tsumeb for the year ended June 30, 1965, are summarized in table 3.

Table 3.—South-West Africa: Operations of Tsumeb Corp. Ltd.

As of June 30, 1965, ore reserves at the company's two mines were estimated as follows:

	Metric tons	Grade, percent		
		Copper	Lead	Zinc
Tsumeb mine:				
Positive ore	8,149,381	4.91	11.02	3.64
Kombat mine:				
Positive ore	1,015,870	2.64	2.37	---
Probable ore	2,333,211	2.29	2.87	---

Source: Tsumeb Corp. Ltd. Annual Report, 1965.

In addition to normal exploration and development at the Tsumeb and Kombat mines, the company performed 1,499 meters of diamond drilling on the Gross Otavi Mining Area which gave encouraging results leading to plans for further drilling. Also, at the Matchless Mine, 42 kilometers southwest of Windhoek, 1,522 meters of diamond drilling was completed in testing copper pyritic mineralization, as a part of a continuing effort to locate areas of higher copper content. On the Tsumeb Exploration, Ltd. Concession Area unsuccessful surface diamond drilling was done at the

Domingo Copper Prospect, and further drilling to determine structures was carried out at the Kombat South Prospect.

During the fiscal year, studies continued on refractory ores being encountered at depth in the Tsumeb mine. Mill operations were put on a 7 day week two and sometimes three weeks each month in order to meet the production schedule. (Normally, mill operations are on a six day week.) At the Kombat mill the feed during the period October to January contained a high proportion of highly oxidized ore, mixed with phyllite, and this adversely affected the copper-lead separation.

Throughout the year the copper smelter operated on copper concentrates from the Tsumeb and Kombat mines, together with soda matte and speiss from the lead smelter. Production approached the annual capacity of 32,600 metric tons. The lead smelter and refinery increased production over that of 1964, the initial year of operation, as difficulties in the blast furnace section were overcome with the addition of continuous slag and base bullion tapping and modfications in the sinter plant.

Initial production from the silver refinery was reported in the first quarter of 1965. The cadmium plant, which has an approximate capacity of 181 metric tons of metal per year, operated as a pilot plant until May 1965, when it was suspended because of the high-aresenic content of the lead blast-furnace dust which constitutes the feed. Test work showed that retorting of the cadmium sponge would permit production of high-grade cadmium, and operations commenced again later in the year. Production of germanium has been at a standstill since 1963 because of market conditions, but shipments continued to be made from stocks. The sulfuric acid plant operated intermittently to supply the cadmium plant. The arsenic oxide plant operated satisfactorily, producing black arsenic assaying 88.10 percent As_2O_3 from lead plant speiss and copper smelter flue dust. Market demand for this product, however, was not great.

The South-West Africa Co. Ltd. (SWAC).—Ore broken at SWAC's Berg Aukas lead-zinc-vanadium mine during 1965 was 174,780 metric tons, and about 108,800 tons was milled. In addition 5,933 tons of massive zinc-lead ore were handpicked for shipment. After completion of the main shaft to 262 meters (the 860-foot level), development was increased, largely on the 660-foot level, for production in 1966. Further drilling will be undertaken to test ore known to exist to at least 610 meters below surface.

The tonnages of flotation concentrates and handpicked ore produced in 1964 and 1965 were as follows:

Commodity	Output (metric tons)	
	1964 r	1965
Concentrates:		
Lead-vanadium	9,920	11,480
Zinc silicate	11,020	12,750
Zinc sulfide	7,180	340
Zinc-lead sulfide and oxide	7,550	5,610
Ore:		
Zinc-lead sulfide and oxide	16,400	5,930
Total	52,070	36,110

r Revised.

Source: South-West Africa Administration, Mines Division. Annual Report, 1965. Windhoek, South-West Africa, 1966, p. 24.

Ore reserves at the Berg Aukas mine were reported at the end of calendar year 1965 to be about 517,000 metric tons of assured ore, carrying 0.8 percent vanadium pentoxide (V_2O_5), 5.0 percent lead, and 32.0 percent zinc; and 254,000 tons analyzing 0.8 percent vanadium pentoxide, 4.0 percent lead, and 38.0 percent zinc. There was a decrease of 45,000 tons in total assured and indicated ore from the total of 1964, and the vanadium pentoxide content of the assured ore was recalculated and was given as 0.8 percent in 1965, rather than 1.56 percent as reported in 1964.

In 1966 the company plans to expand the crushing plant, and to provide additional housing and office accommodations.

Other Operations.—Copper production was reported from two small mines during the year. The Emka Mining and Trading Co. (Pty.), Ltd. produced 307 tons of concentrate assaying 26 percent copper at its Onganya mine, near Windhoek, and the Khan mine of Khan Mine (Pty.) Ltd., near Swakopmund, produced 450 tons of 50 to 55 percent copper concentrate. The Klein Aub mine in the Rehoboth Gebiet, operated by the Klein Aub Kopermaatskappy (Edms.) Bpk., which is controlled by Federale Volksbeleggings, Bpk., will come into production in 1966. Two inclined shafts have been completed to permit development of the ore body.

The South African Iron and Steel Corporation (ISCOR), early in 1966 exercised its option, held through its subsidiary Industrial Minerals Corporation, to mine zinc ore in the Lorelei area bordering the Orange River. Preliminary estimates are that ore reserve is about 5 million tons containing 6 percent zinc and minor amounts of lead and silver.

Iron Ore.—The only production of iron ore in 1964 was from the Kalkfield mine, operated by the Tsumeb Corp. to supply flux for its lead smelter. Production in 1965 was more than double that of 1964, as smelter operation was increased to near capacity.

Manganese.—The Otjosondu manganese mine was leased on tribute by the owner, S. A. Minerals Corp. Ltd., early in the year, and mining of ore commenced in March 1965.[7] Production was increased to 943 metric tons in December. All ore mined, which averaged 43 percent manganese, was stockpiled pending sale. The leasing company, Walvis Bay Mining Company (Pty.) Ltd., a subsidiary of Consolidated African Mines, proposes to build a portable screening and sorting plant to produce four grades of ore, down to 35 percent manganese. An ultimate production of 3,600 tons monthly is envisioned. At the end of 1965 the ore reserve was estimated at 135,000 metric tons.

Tin and Tungsten.—Production of tin concentrate increased 3.7 percent in 1965, following completion of expansion early in the year at the Uis mine of Industrial Minerals Exploration (Pty.) Ltd., a subsidiary of ISCOR. During the year large-scale waste stripping of the pegmatite ore bodies was started, and several thousand feet of diamond drilling was carried out to outline the ore. The reserve was estimated to be 18 million long tons of ore averaging 0.13 percent tin.[8] Early in 1965 ISCOR started operation of a tin smelting plant at its Vanderbijlpark works in South Africa, to smelt all Uis concentrates. It is expected that virtually all ISCOR requirements, presently about 53 long tons of tin per month, will be met by production at Uis.[9]

Production of tin-tungsten concentrates at the Brandberg West mine of the South West Africa Co. declined for the second year, to 598 metric tons in 1965; 345,417 tons of ore were broken, and 85,385 tons were milled. Both production and working costs were adversely affected by the need to change the shape of the quarry.[10] Ore reserves decreased by 272,000 metric tons during the year, and at the end of 1965 stood at 1,360,000 tons containing a total of 0.23 percent tin and WO_3,[11] of which about three-quarters was tin.

Strathmore Tin (Pty.) Ltd. prospected in its concession area northeast of Cape Cross. Tin-bearing pegmatites were exposed by bulldozing and blasting trenches in the overlying layers of gypsum, and depth and continuity were tested through 1,205 meters of drilling. A pilot plant was erected for bulk testing. Results of the test work were to be available in 1966.

NONMETALS

Diamond.—The Consolidated Diamond Mines of South-West Africa Co. Ltd. (CDM) again produced most of the Territory's diamond output, accounting for over 86 percent of the total. Other significant production was by the Marine Diamond Corp. Ltd. (MDC), control of which was acquired by CDM in October 1965. Salient diamond industry statistics are summarized in table 4.

Consolidated Diamond Mines of South-West Africa Co. Ltd.—The company's goal of producing 1.5 million carats of diamond annually was almost attained during 1965; output reached 1,436,766 carats, compared

[1] Volume dredged totaled 1,879,000 cubic meters, including 1,869,000 cubic meters in mining operations and 10,000 cubic meters in prospecting activities.

[2] Property held in 1964 by Westies Minerale (Edms.) Beperk, and ceded to Sarusas Ontwikkelings-Korporasie during 1965.

[3] Less than ½ of unit.

[4] Of total output, origin by company of 182 carats is not reported; this quantity presumably originated from one, some, or all of the companies indicated by this note.

with 1,253,645 carats in 1964, of which 95 percent was gem stones, averaging 0.96 carats per stone. Larger scraper loaders and rear dumpers have been introduced. Two Vacuveyors, a vacuum cleaner-like bedrock cleaning machine, were in operation at yearend as a possible solution to this difficult problem which heretofore has required much hand labor; five additional Vacuveyors were to be installed. Three new field-screening plants were commissioned, bringing the total number to 18, and thus completing the expansion program. Eight of the field-screening plants have been equipped with Yuba jigs, to decrease the volume of material that must be transported to the central plant. At the central-treatment plant some initial difficulties were experienced with the heavy-media circuit that was installed in 1965 and that incorporates Wedag drum separators, but these difficulties have been overcome, and the old section of the plant was closed down in September.

At the end of 1965 the company's reserve of diamondiferous gravel was estimated at 65.6 million cubic meters, containing 19.7 million carats, a 6.6-percent decline in carat content with respect to the yearend 1964 estimate.

Revenue from diamonds was $92.3 million in 1965, compared with $75.6 million in 1964. The increase was due to firm market conditions and the expanded production at the mine.[12]

[12] The Consolidated Diamond Mines of SWAC Ltd. Annual Report, 1965.

Marine Diamond Corporation (MDC).—The MDC recovered the bulk of its diamond output from the bed of the ocean between the mouth of the Orange River and Diaz Point; a small proportion of the company total was recovered from the foreshore area bordering CDM's Diamond Area No. 1. MDC acquired this area from CDM in May 1965 when the latter obtained a 29-percent interest in MDC. Serious loss of production occurred as a result of the grounding of the mining barge Colpontoon for one and a half months early in 1965; the Diamantkus, a former naval vessel converted to mining, was withdrawn from service for overhaul during May. Early in 1966 it was decided to replace the Diamantkus with a new mining barge. In the financial year ending June 30, 1965, a net loss of nearly $2 million was incurred by the company, and a further net loss of $1.88 million was sustained in the period July 1 to December 31, 1965; a large proportion of this loss was attributed to the depreciation of fixed assests and to the writing off of obsolete equipment.[13] In October, control of MDC was acquired by CDM, through its effective control of Orama Holdings, which holds 58 percent of MDC, and of Sea Diamond Corporation, which has 29 percent of MDC.

Salient figures on costs for the recovery of diamond from the seabed and sale values of such output by MDC were as follows:

	1964	1965
Field cost per carat recovered:		
Mining operations	$7.14	$27.73
Prospecting operations	4,390.48	6,060.01
Average	r 8.58	29.53
Sale value, average per carat	29.40	31.46

r Revised.

About 99 percent of the diamonds recovered were gem quality, and the average size was 0.40 carats each.

Other Producers.—Production of diamonds by De Beers Consolidated Mines, Ltd., in three grant areas between the Unjab and Hoanib Rivers again declined because of a lower content of diamond in the material mined. Prospecting continued while plans for the future program were under review.

Westies Minerale (Edms.) Bpk. ceded its 10-mile-wide concession area on the coast between the Hoanib River and 18° south latitude to Sarusas Ontwikkelings-Korporasie. Very little mining for diamonds was carried out.

Tidal Diamonds SWA (Pty.) Ltd., a subsidiary of CDM and the Tidewater Oil Co. carried out prospecting on the seabed and on its land concession in Diamond Area II. Some diamonds were found in the sea at Hottentot Bay, but none of economic value in the Saddle Hill area on land. Further prospecting was contemplated at yearend in the Meob and Oyster Cliff areas, further north. Sand dunes are a major obstacle to prospecting operations.

Prospecting was continued by Desert Diamonds (Pty.) Ltd. in its 5-mile-wide grant area on the coast between the Ugab and Unjab Rivers. A program of plant expansion was completed in December, and the expanded screening facility reportedly will handle 40 tons per hour of gravel. Other equipment installed during the year included a heavy-media separation unit and a jig. A mobile screening plant to facilitate field operations was under construction at yearend.

Oranje-Kunene Diamante Bpk. continued to hold its sea concession areas betwen Diaz Point and Hottentot Bay and between the northern boundary of Diamond Area II and the Kunene River, as far west as the continental shelf. The former area has been charted and contoured. The firm developed a new suction head which enables its prospecting vessel to draw core samples from deposits in water up to 150 feet deep, but during 1965, little valuation work was done, and diamond recovery totaled only 6 carats.

Lithium Minerals and Associated Minerals.—S.W.A. Lithium Mines (Pty.) Ltd. produced 898 metric tons of petalite, 193 tons

[13] Work cited in footnote 12.

of lepidolite, and 28 tons of amblygonite in 1965, which represented over 73 percent of the lithium minerals produced in the Territory; in addition the company produced 4 tons of beryl, 41 tons of beryl fines, and 1 ton each of pollucite and bismuth ore. Reserves at the company's Helikon and Rubicon mines in the Karibib area were reported to be approximately 1,600 metric tons for hand sorting, and about 900,000 tons that could be concentrated by flotation.[14]

Salt and Soda Ash.—Investigations into methods of producing soda ash from the Otjivalunda pans, west of the Etosha pan, have been suspended by the South-West Africa Co. Ltd., pending a decision by the South-West Africa Administration on the question of transport.[15]

The major producer of salt was the South-West Africa Salt Company (Pty.) Ltd., from seawater in pans near Swakopmund. Output totaled 92,576 tons of which 24,770 tons were treated; sales totaled 71,317 tons. R. Gossow was the principal rock salt producer, from operations in the same area. Three other salt producers were reported active during the year.

MINERAL FUELS

No production of petroleum or coal was reported in the Territory during 1965, and virtually all energy material requirements continued to be met by imports from South Africa. Major consumers of coal and coke were the Tsumeb mine, which has lead and copper smelters, coal-fired steam-driven generators, and public power stations. Other mines employed diesel generators to supply power; the railroads also have been largely dieselized.

Etosha Petroleum Company (Pty.) Ltd.'s concession passed to control of the Kewanee Overseas Oil Company, a subsidiary of the Kewanee Oil Company of Pennsylvania, during the year. Surface exploration was continued, but no drilling was undertaken. The Artnell Exploration Company, Ltd. relinquished its concession near Mariental and ceased all operations in the Territory in 1965. A new concession to prospect for oil was granted to Mankor Beleggings Bpk. for an area of 8,950 square miles west of Windhoek.

The Mineral Industry of Sudan

By Henry E. Stipp [1]

The mineral industry of Sudan continued to play a minor part in the nation's economy in 1965. Production of metal and mineral commodities valued at $4.2 million [2] was equal to only 0.3 percent of the gross national product of $1,367 million, and employment by the mineral industry constituted only a very small part of the total labor force estimated at 3.5 million. Despite the small size of Sudan's mineral industry, the nation had a number of prospects for exploiting mineral deposits on a larger scale. Significant developments in 1965 included the offer of a British firm to exploit iron ore deposits at Jebel Abu Tulu, southern Kordofan Province; the possibility that deposits of asbestos recently discovered at Qala en Nahl in Kassala Province would be exploited by a joint Canadian and Sudanese firm; and the discovery of tin and tungsten deposits near the sixth cataract of of the Nile River at Saba Loqa.

A loan of $31 million for assistance in financing improvement and expansion of Sudan's railway system and river and port facilities was granted by the World Bank.[3] The development of an improved and expanded transportation system remained essential to further development of Sudan's mineral resources.

PRODUCTION

Sudan's total output of metal and mineral commodities was estimated to have increased somewhat over that of 1964. Significant increases in production of chromite and iron ore were recorded, while manganese output apparently declined. Gold output continued the steady decline that began in 1963. Production of mineral commodities in 1965 was valued at about $4.2 million compared with output valued at $3.9 million in 1964.

[e] Estimate. NA Not available.

[1] Data reported are not official and may represent mine shipments rather than actual production.

TRADE

Sudan reported a negative trade balance in both mineral commodities and total trade; however, the 1965 trade deficit in both categories was reduced considerably from that of 1964, as shown in the following table:

	Million dollars		Mineral commodities share of total trade (percent)
	Mineral commodities [1]	All commodities	
Exports and reexports:			
1964	1.7	197.0	0.9
1965	2.5	195.0	1.3
Imports:			
1964	41.7	274.0	15.2
1965	26.5	207.5	12.8
Trade balance:			
1964	−40.0	−77.0	XX
1965	−24.0	−12.5	XX

XX Not applicable.

[1] Values given are for only those commodities listed in tables 2 and 3 of this chapter.

Exports and reexports of metal and mineral commodities increased 47 percent over those of 1964 but still accounted for only a very small part of Sudan's total exports. These commodities consisted principally of petroleum products valued at $932,000, nonferrous scrap valued at $604,000 and iron ore valued at $473,000.

Imports of metal and mineral commodities in 1965 decreased substantially from those of 1964. Principal mineral commodity groups imported in 1965 were petroleum refinery products, valued at $9.6 million, iron and steel products, valued at $7.0 million; and cement valued at $1.7 million. Metal and mineral imports were supplied mainly by United Kingdom ($4.9 million), Belgium-Luxembourg ($2.6 million), Japan ($2.2 million), Italy ($1.7 million), West Germany ($1.4 million) and India ($1 million).

Table 2.—Sudan: Exports and reexports of metals and minerals

COMMODITY REVIEW

METALS

Chromite.—The Mining and Trading Company Ltd. of Sudan mined a small quantity of ore from an open-pit mine in the Ingenessa Hills region of Blue Nile Province.[4] Reportedly the ore contained 48 to 52 percent chromium. Chromite ore sold for $22.00 to $24.00 per metric ton. Ore was trucked 127 kilometers from the mine to the railhead at Damasin. The Sudan Railways has been requested by the mining company to extend the railway to Begis to reduce the truck haul. General Mining Enterprises, an associate firm, was developing several properties in the Ingenessa Hills.

Copper.—Deposits near Hofrat el Nahas in southern Darfur Province remained un-

[4] U.S. Embassy, Khartoum, Sudan. State Department Airgram 393, May 29, 1966, 3 pp.

developed in 1965.[5] A team of mining specialists from Japanese and Italian mining firms planned to drill 20 holes to explore the property, but the project was abandoned. Ore would have to be trucked 320 kilometers to a railhead because plans for extending the rail line southward from Nyala also have been abandoned.

Iron Ore.—The Central Desert Mining Co. exploited deposits of the Fodikum group in the northern Red Sea hills area of Kassala Province, 269 kilometers north of Port Sudan.[6] A British firm was interested in developing deposits at Jebel Abu Tulu in southern Kordofan Province. The firm was contemplating an initial investment of $5.7 to $8.6 million. Ore from these deposits was estimated to contain 61.2 percent iron and 7 percent silica. Reserves were said to total 35 million tons.

Manganese.—The Central Desert Mining Company reportedly exported 500 to 600 tons of ore to Yugoslavia.[7] The ore was produced by Sudanese miners from deposits in the Holaib Triangle area and purchased by the company.

Tin and Tungsten.—Deposits were recently reported to occur near the sixth cataract of the Nile at Saba Loqa.[8]

NONMETALS

Asbestos.—Deposits were discovered recently at Qala en Nahl in Kassala Province.[9] Two representatives of a Canadian mining firm were investigating the possibility of establishing a joint mining venture.

MINERAL FUELS

Petroleum.—The Port Sudan oil refinery processed imported oil throughout 1965. In August, a fire damaged part of the plant and stopped gasoline production for a brief period,[10] however, output of other products continued.

Agip Mineraria (Sudan) Ltd. renewed its oil exploration concession with the Sudan Government for 2 more years. The concession covers exploration along the Red Sea coast.

Four distributors continued to operate in Sudan, importing most of their requirements. These were Shell and BP (Sudan) Ltd., Mobil Oil de l'Afrique Occidentale, Nile Import and Trading Oil Co.—Total Afrique Ouist, and AGIP (Sudan) Ltd. Some petroleum products were trucked to the Abeche area of eastern Chad from Nyala, Darfur Province. Transportation costs were reportedly lower to eastern Chad from Port Sudan than from Nigeria.

The Mineral Industry of Tunisia

By Henry E. Stipp [1]

Tunisia's mineral industry recorded increased production of almost all mineral commodities in 1965. Notable gains were made in output of iron ore, 20 percent; phosphate rock, 11 percent; lead concentrate, 18 percent; zinc concentrate, 25 percent; and salt, 66 percent. Production of metals and minerals was valued at $51 million,[2] and was equivalent to almost 6 percent of the gross national product.

The mineral industry was of significant importance to the nation's economy; mineral products accounted for over 30 percent of the total value of exports. Sales of phosphates increased substantially, owing to strong world demand for fertilizer materials. Increased output of the new NPK Engrais plant provided more phosphates for export. The value of lead exports almost doubled as the price of lead on the world market increased. Iron ore exports also showed growth.

Probably the most significant event in the minerals sector was the disclosure that the oil discovery near El Borma by Société Italo-Tunisienne d'Exploitation Pétrolière (SITEP) constituted a major oilfield. Reserves of the field were estimated at about 250 million barrels.

Employment in the principal mines (iron, lead-zinc, and phosphate) in December 1965 totaled 13,582 workers, compared with 11,681 in December 1964. This was almost 0.3 percent of the total population of 4,630,000 persons, or about 0.9 percent of the estimated working force of 1,543,000.

The Government of Tunisia provisionally removed the 15 percent ad valorem export tax on hyperphosphates and superphosphates in a decree issued July 19, 1965.

An exploration project was being conducted in the Foussana Basin near Kasserine under a special fund of the United Nations. The work consisted of geophysical exploration and drilling of about 16,000 meters (52,520 feet) of rock.

PRODUCTION

Production of most metals and minerals increased, compared with the 1964 output, resulting in a value increase for metals and minerals output (exclusive of petroleum refinery products) of 16 percent to $51 million, compared with the 1964 value of $44 million.

TRADE

The role of mineral commodities in the total foreign trade of Tunisia is reflected in the following tabulation:

	Value (million dollars)		Minerals share of total (percent)
	Mineral commodities	Total	
Exports:			
1963	36	126	29
1964	39	130	30
Imports:			
1963	40	222	18
1964	45	248	18
Trade balance:			
1963	−4	−96	XX
1964	−6	−118	XX

XX Not applicable.

e Estimate. r Revised. NA Not available.

Significant increases were posted in exports of phosphates, iron ore, zinc, mercury, and cement. Phosphates were the most valuable commodity exported at $27.6 million,[3] followed by iron ore valued at $5.5 million, lead valued at $2.8 million, and cement valued at $1.3 million.

Rolled-steel products valued at $22.3 million, were the most costly group of mineral commodity imports. Imports of petroleum refinery products decreased noticeably to $6.6 million in 1964 compared with $18 million in 1963. This was owing to production from the new oil refinery, located near Bizerte, which began producing in 1964. Imports of crude oil increased consequently and were valued at $8.7 million in 1964 compared with $1.2 million in 1963.

COMMODITY REVIEW

METALS

Iron Ore.—Production of iron ore from the Djérissa mine increased 5 percent from 716,015 tons in 1964 to 753,119 tons in 1965.[4] Output from the Tamera-Douaria mine increased 63 percent from 223,557 tons in 1964 to 363,557 tons in 1965. There was no production from the Nebeur (iron-lead ore) mine, which was inactive throughout the year. National consumption of iron ore totaled 66,345 tons in 1965. The Djérissa mine exported 772,994 tons compared with 720,803 tons in 1964, while the Tamera-Douaria mine exported 204,353 tons compared with 224,150 tons in 1964.

Iron and Steel.—The integrated iron and steel mill at El Fouladh, near Menzel Bourguiba, began test operations in November.[5] The plant which was expected to produce 40,000 tons of rolled products in 1966, was completely automated, and employed modern steelmaking techniques. It was scheduled to reach full capacity of 70,000 tons in 1967.

Lead and Zinc.—The decrease in ore production from mines such as El Gréfa, Sidi Bou Aouane, Djebel Semène was more

[3] On September 28, 1964, the Tunisian dinar was devalued from a par value of US$2.38 to US$1.905. Value of trade for 1963 converted at old rate. Value of trade for 1964 converted at rate of 1D=US$2.261.

r Revised. NA Not available.

[1] Includes unalloyed and alloyed unwrought and semimanufactured forms.

The Mégrine smelter also produced 33,758 troy ounces of silver in 1965.

Total zinc concentrate output increased 26 percent over that of 1964 as shown below:

Mine	Production (metric tons)	
	1964	1965
El Akhouat (55 percent zinc content)	5,896	6,738
Djebel Semène (35 percent zinc content)	-----	683
Total	5,896	7,421

Mineral mixtures containing zinc also were produced at Sidi Bou Aouane (2,717 tons) and Fedj El Adoum (2,020 tons) in 1965.

Mercury.—The Djebel Arja mine produced 36 flasks of mercury (76-pound flasks) with a working force of 92 employees.[7]

The development of the El Arja mercury mine, about 6 miles from Tabarka in the province of Sank El Arba, was described.[8] The polymetal ore, which was being produced at a rate of 1 million tons per year, was reportedly equally rich in lead and zinc. The construction of a washing plant for separating the ores of the three metals has extended the life of the deposit. The resulting mercury concentrate contains 70 kilograms of mercury per cubic meter in contrast to the run of mine ore grade of 2 kilograms per cubic meter.

NONMETALS

Clay Products.—A new brick factory at Djemmal near Sousse, inaugurated on August 31,[9] was expected to produce 50,000 tons per year of various types of brick. The bulk of output will be exported to Libya.

Fertilizer Materials.—Production of phosphate rock in 1965 increased almost 11 percent over that of 1964,[10] with gains recorded by each producer as follows:

Mine	Production (metric tons)	
	1964	1965
Gafsa	1,858,826	2,100,646
M'Dilla	538,183	542,210
Koloa-Djerda	353,930	396,980
Total	2,750,939	3,039,836

The three phosphate companies operating in Tunisia were placed under control of Osman Bahri, President Director General of the National Office of Mines (Office National des Mines).[11] The Compagnie des Phosphates et du Chemin de Fer Gafsa (GAFSA) (51-percent Government-owned), which produces two-thirds of the nation's phosphate, had a 20-percent interest in the Compagnie Tunisienne des Phosphates du Djebel M'Dilla (CIPHOS) complex and a 100-percent interest in the Société Tunisienne d'Exploitation Phosphatière (STEPHOS) company, the two other producers of phosphates.

In June the Government of Tunisia signed an agreement with Poland for $6 million worth of mining equipment in exchange for phosphate rock.[12] The equipment would go to the Gafsa Company. This firm signed a contract financed by the U.S. Agency for International Development (AID) with the Ralph M. Parsons Co. of Los Angeles for a feasibility study on renewal of equipment and expansion of production capacity.

Production of triple superphosphate increased appreciably during 1965 owing to operation of the new NPK fertilizer plant near Sfax. This plant became an important source of foreign exchange in the first 6 months of 1965, with exports of 57,000 tons of all types of phosphates, and was expected to reach full capacity of 150,000 tons of superphosphates in 1966. Expansion of the Société Industrielle d'Acide Phosphorique et d'Engrais superphosphate plant (40-percent Government-owned) to 170,000 tons per year was planned.[13]

A feasibiilty study was conducted by a U.S. firm to determine if a phosphate rock deposit at Kef el Dour could be used to manufacture superphosphoric acid.[14]

A nitrogenous fertilizer complex will be built at Gabes for Industries Chimiques Maghrebines S.A. by Cia. Tecnica Industria Petroli Spa., an Italian firm.[15] The $30

million complex will consist of a 65,000-ton-per-year anhydrous ammonia plant, a 200,000-ton-per-year ammonium phosphate facility, and an 80,000-ton-per-year ammonium nitrate plant. The bulk of output from this plant will be exported.

A report was published that described production, trade, and utilization of phosphate, nitrate, and potassium fertilizers in Tunisia.[16] Annual consumption of fertilizers, estimated at 65,000 to 70,000 tons for 1965 was expected to increase significantly in 4 or 5 years with further development of the agricultural industry.

Fluorspar.—Three mines, Hammam Zriba, Djebel Ouest, and Djebel Staa, produced 5,000 tons in 1965.[17]

Salt.—From 1955 through 1962 marine salt was recovered from three salinas for local consumption and export.[18] In 1962 the last year for which details were available, output of the Mégrine salina was reported as 16,000 tons, Sousse-Monastir 85,000 tons, and Sfax 69,000 tons. Local consumption in 1962 was 25,000 tons, and 145,000 tons was exported.

MINERAL FUELS

Petroleum.—The El Borma field in southern Tunisia, discovered in May 1964 by Société Italo-Tunisienne d'Exploitation Pétrolière (SITEP), was estimated to have reserves of about 250 million barrels.[19] Twelve producing wells were completed on a 14-kilometer north-west south-east trend. Production, which was scheduled to begin in 1966 at a rate of 20,000 barrels per day, will be moved through a 115-kilometer 14-inch feeder line that will connect with the Compagnie de Transport pai Pipe-lines au Sahara (TRAPSA) pipeline. This pipeline goes from the Edjeleh area of Algeria northwards to La Skhirra on the Tunisian coast.

In addition to the concession at El Borma, SITEP was granted a permit in January for a 16,162-square-kilometer area south of El Borma.[20] In December Ente Nazionale Idrocarburi (ENI), the parent concern of SITEP, was granted a 12,010 square kilometer concession tract in the Bir Aouine section north of El Borma. The total acreage assigned to Italian firms now consists of 29,785 square kilometers. In order to obtain these concessions, AGIP Mineraria, an affiliate company of ENI, offered a bonus of $9 million to the Tunisian Government, and ENI also gave a $12 million loan repayable in 7 years at 6 percent interest. A new company, Société Anonyme d'Exploitation (SAEP), was formed to work the new Bir Aouine concession.

Western Tunisia Co., a subsidiary of Signal Oil & Gas Co., acquired a new concession in the Sahel area near Kairouan and Sousse.[21] Western Tunisia, acting for a group of six companies, carried out operations on two groups of exploration permits. On the Rimrock Tidelands, Inc. permit one well was abandoned at 7,918 feet, and a second well was started in August. At the end of 1965 this well was being drilled below 13,500 feet. Another well was started in December near the city of Sfax. On the Tunisian Husky Oil Corp. permit onshore Western Tunisia drilled a dry hole to 9,782 feet near Bou Thadi. Three dry wells were drilled on the Husky permit offshore. The first, located 24 kilometers northeast of the Kerkennah Islands, was abandoned at 12,962 feet, the second, 19 kilometers southeast of Djerba Island, was abandoned at 4,176 feet, and the third well near the southern Kerkennah Island was abandoned at 10,015 feet.

The Mineral Industry of the United Arab Republic (Egypt)

By Henry E. Stipp [1]

The mineral industry of the United Arab Republic (Egypt) made a significant contribution to that nation's economy in 1965. Total mineral industry output valued at about $462 million [2] accounted for almost 10 percent of the estimated 1965 gross national product of $4,700 million. The petroleum sector's output valued at over $368 million led that of other segments of the mineral industry, followed by phosphate rock valued at $6.1 million, cement $4.1 million, iron ore $3.8 million, salt $3.7 million, and limestone $3.6 million.

Exports of salt, manganese ore, gypsum, and most petroleum refinery products increased; however, exports of crude petroleum and fertilizer materials decreased appreciably from those of 1964.

The extractive industry employed approximately 19,000 persons [3] in 1965 out of a total labor force of 7.3 million workers.

The second 5-year plan for social and economic development (1965–70) included 27 mining projects scheduled for completion. A total of $141.3 million was set aside for these projects. The sum of $28.5 million was desnigated for exploration and development, chiefly of iron ore, dolomite, limestone, coal, and phosphate deposits.

The Governing Council of the United Nations Special Fund appropriated $1.8 million in June 1965 for assessment of the mineral potential of the Aswan region.

PRODUCTION

Metals and minerals production in the United Arab Republic (Egypt) generally showed a decreasing trend; however, output of several commodities increased over that of 1964. From the economic viewpoint, the 4-percent increase in crude oil output, the 38-percent increase in gypsum production were most significant, but from the mineral requirements viewpoint, increases in production of asbestos (85 percent), barite (237 percent), and talc (135 percent) were of interest. The most important mineral commodities that decreased in output from 1964 were manganese ore (44 percent), phosphate rock (3 percent), iron ore (2 percent), and salt (27 percent).

e Estimate. r Revised. NA Not available.

[1] Includes annually about 5,000 tons of MnO_2.

[2] It is estimated that of this amount, 42,600 tons were ore with 13 percent Mn.

[3] Contains refractory clay in 1963 and is believed also to contain clay in 1962.

[4] As reported; subject to revision.

TRADE

The role of mineral commodities in the total foreign trade of the United Arab Republic (Egypt) is reflected in the following tabulation:

	Value (million dollars)		
	Mineral commodities [1]	Total	Minerals' share of total (percent)
Trade balance:			
1963	135	r 493	XX
1964	144	517	XX
Exports:			
1963	r 70	r 651	11
1964	72	673	11
Imports:			
1963	205	1,144	18
1964	217	1,190	18

r Revised. XX Not applicable.
[1] Values given are for only those commodities listed in tables 2 and 3 of this chapter.

Destinations for exports and origins of imports were available only for several of the more important commodities.

Exports of most petroleum products increased, but this was more than offset by decreased crude oil and residual fuel oil shipments. Exports of phosphate materials, and cement decreased significantly; whereas manganese ore, gypsum and salt sales increased substantially. Shipments of manganese ore went principally to Italy (61,400 tons), Belgium (40,640 tons), and West Germany (28,193 tons). Sales of phosphate rock were made chiefly to Yugoslavia (114,123 tons), India (69,393 tons), and Ceylon (49,198 tons). Significant quantities of steatite were exported in 1964 to East Germany and the United Kingdom. Crude oil exports went mainly to East Germany (1,712,000 tons), Spain (1,093,000 tons), and Italy (752,000 tons). Gasoline exports were sent to Netherlands (154,00 tons), United States (132,000 tons), and United Kingdom (82,000 tons). The destination for the total quantity of kerosine (13,000 tons) exported in 1964 was given as Gaza, Palestine.

In the absence of complete data on distribution of mineral commodity trade in 1964, the following particulars on distribution of total trade are included. In 1964, the U.S.S.R. purchased the largest share of United Arab Republic products (17.9 percent of total exports) valued at $120.3 million, followed by Czechoslovakia (9.6 percent) valued at $64.9 million, India (5.7 percent) valued at $38.2 million, and West Germany (5.5 percent) valued at $37 million.[4]

Imports of metals and minerals listed in table 3 for 1964 were valued at $211 million compared with imports of $205 million in 1963; an increase of about 3 percent. Crude petroleum, the largest import commodity increased from $78.4 mil-

[2] Includes unwrought, semimanufactures, and scrap.

lion in 1963 to $87.8 million in 1964; whereas petroleum refinery products decreased by about $8.3 million. Imports of iron bars and rods increased $8.9 million to $13.2 million in 1964. Imports of iron sheets rose by $6 million; but tubes and pipes decreased by about $5.7 million. Coal and coke imports for use principally by the steel mills, increased by $4.3 million. Increased local production of kerosine, was reported to be responsible for a decrease of $5.2 million in imports of liquefied petroleum gas.[5]

As in the case of export data, information on the geographic pattern of imports is not available for 1964, but the following information on distribution of total imports by origin has been provided. In 1964, the United States was reportedly the origin of 29.8 percent of total imports, these imports from the United States were valued at $354.6 million. West Germany ranked second with 11.3 percent or $134.9 million and the U.S.S.R. was the third most important source with 7.7 percent or $92.2 million.

During 1965 the United Arab Republic signed trade protocols or agreements with Algeria, Bulgaria, Czechoslovakia, East Germany, Ethiopia, Ghana, Greece, Hungary, India, Kenya, North Korea, Sierra Leone, Somalia, Spain, and Sudan. Mineral commodities that will be exported to these countries include crude oil, petroleum

[5] Central Bank of Egypt. (Cairo) Econ. Rev. V. 5, No. 2, 1965, p. 149.

refinery products, petrochemicals, manganese ore, phosphate and nitrate fertilizers, and cement. Imports from these countries include iron ore, iron bars, iron and steel pipes, reinforced steel bars, other steel products, bauxite, fertilizers, equipment and parts for copper and steel mills, and excavating, leveling, and extracting machinery.

Trade talks on integrating the economy of Egypt and Iraq were held during the latter half of 1965.

The Phillips Petroleum Co. of the United States received an order for the sale of 157,000 tons of ammonium sulfate to the Misr Foreign Trade Co. of the United Arab Republic Government.[6]

COMMODITY REVIEW

METALS

Aluminum.—No additional information was reported on the proposed aluminum reduction plant to be constructed at Aswan by Centrozap, a Polish trade organization.

Iron and Steel.—Czechoslovakia was scheduled to build an electric furnace steel plant for smelting iron at Aswan, under terms of an agreement with the United Arab Republic signed in June. The integrated iron and steel plant at Helwan, south of Cairo was slated for expansion. Production of pig iron will be increased from the reported 360,000 tons capacity to about 1.2 million tons in 1970. Production costs at the Helwan plant have been increasing in recent years, owing chiefly to the higher price paid for iron ore from the Aswan mines. These mines achieved a record production of 436,000 tons in fiscal year 1965, owing to the practice of mining selectively in order to obtain ore of about 44-percent iron and 19-percent silica content. Several beneficiation processes have been investigated; however, none has been able to increase the iron content above 53.9 percent. Reserves at Aswan were estimated recently at 27 million tons, whereas future demand (supply for Helwan plant until Bahariya ore becomes available about 1968 and to supply proposed Aswan mill for 50 years) could total approximately 134 million tons.[7] Adequate deposits are believed to exist in the Aswan area, but their quantity, quality, and location needs to be determined. Transportation of iron ore from Aswan also presents problems.

One of the principal exploitation projects of the second 5-year plan is the development of the Bahariya iron ore deposits. This project, which has a planned output of 4 million tons of high-grade ore by 1972, was still in the planning stage in 1965. Transportation was also one of the chief problems involved in using iron ore from the Bahariya area. The General Organization for Industrialization, a Government agency, was studying offers by foreign companies for construction of a 330-kilometer railway and highway between Bahariya and the Egyptian Iron & Steel Co. plant in Helwan. Total cost of the project was estimated at $143.6 million.

The ferromanganese plant at Abu Zenima to operate on Sinai manganese ore was nearing completion. This facility, which will have a production capacity of 10,000 tons of ferromanganese and 27,000 tons of cast iron per year, was expected to cost $21,597,440. The plant was designed to use natural gas from the Belayim oilfields. Also, it will provide for the region potable water, distilled by using the hot gases from the gas turbine generators that supply electric power to the smelter.

Titanium.—The Black Sands Co. was seeking foreign aid to exploit the ilmenite and rutile deposits of the Nile Delta. Expansion of the company's facilities was to be completed in 1969, as an industrial project of the second 5-year plan. Under the 5-year plan, a report was published that evaluated reserves of the Black Sands Co. and reviewed plans for development of the deposit.[8] A 4.6-square-mile area contained proved reserves of 37 million tons of economic minerals.

Uranium.—Deposits of pitchblende were discovered in the Eastern Desert near

[6] U.S. Embassy, Cairo, U.A.R. (Egypt). Department of State Airgram A-981, June 23, 1965, p. 2.

[7] Ebasco Services Inc., Cairo U.A.R. Team. Review and Analysis of Exploration, Development, and Operations of Aswan Iron Ore Mines. Cairo, United Arab Republic (Egypt). (Contract AID/Nesa-37) August 1964, 93 pp.

Quseir on the Red Sea, in the Wadi al-Gemal north of Qarum Lake, and between Port Said and Damietta.[9] A preliminary estimate of reserves in the Port Said-Damietta area totaled 80 million tons containing 0.6 percent monazite, 0.03 percent thorium, and 0.0025 percent uranium. A second plant for processing atomic fuel from monazite was completed. Uranium ore, found in the Eastern Desert area, was treated with a recently developed method designed to provide fuel for nuclear reactors. Government officials were considering bids, received from four foreign companies, for construction of a nuclear power and desalinization plant near Alexandria.

NONMETALS

Dolomite and Limestone.—Expansion of dolomite and limestone producing facilities was included as part of the project to construct a rail line and highway from Bahariya to Helwan.

Gypsum.—Capacity of the Abou Ghosen gypsum deposit will be expanded from its 1965 output of 216,000 tons per year to 900,000 tons per year under the second 5-year plan. Exports will be expanded, and more gypsum will be made available for domestic use. Gypsum and anhydrite deposits at Ras Gemsa, Safaga, and Ras Malaab were investigated by a team from EBS Management Consultants Inc. for the General Organization for Industrialization, a Government agency.

Fertilizer Materials.—Phosphate rock production decreased 3 percent compared with that of 1964, and 8 percent below the peak year of 1963 despite Government emphasis on increased agricultural production. Sales of phosphate have been declining, because the low grade rock produced has difficulty competing with the beneficiated phosphate exports of other North African countries. The tricalcium phosphate content of exports from the United Arab Republic averaged from 63.6 to 67.7 percent compared with tricalcium phosphate contents of up to 72 percent for exports from other nations in the area. The country's phosphate industry has been confronted with problems including rising production costs, shortages of transportation, inefficient, costly handling, and lack of spare parts and replacement units for older installations.

Reviews on the manufacture of metaphosphates and the potential development of a phosphorus and phosphate industry in the nation were published.[10]

A new ammonium sulfate plant of a 200,000-ton-per-year capacity was to be constructed at Attaka, near Suez, for Société el Nasr d'Engrais et d'Industries Chimiques. The plant will use naphtha as a source of ammonia, and ammonium sulfate will be produced by double decomposition of gypsum and ammonium carbonate.

Superphosphate producing capacity was scheduled for expansion at Abu Zaabal and a superphosphate plant with a 120,000-ton annual capacity was to be completed at Kafr El Zayat. No progress was reported on the construction of a 200,000-ton-per-year superphosphate plant in Assiut. The triple superphosphate plant to be erected at Aswan was still in the planning stage. This plant is to include a 25-ton-per-day electric furnace for production of elemental phosphorus.[11] The acid produced from the phosphorus will be used to manufacture 25,000 tons per year of triple superphosphate, 8,000 tons per year of tetrasodium pyrophosphate, and 8,000 tons per year of sodium tripolyphosphate. A dicalcium phosphate plant of 12,000-ton-per-year capacity also was scheduled for construction at Aswan.

Current nitrogen production capacity was scheduled to increase to about 450,000 tons per year by 1970, almost double present output. A urea plant of 95,000-ton-per-year capacity was to be erected at the coke and chemical works of El Nasr Coke & Heavy Chemicals Co., S.A.A., at Helwan. Calcium ammonium nitrate also will be produced from byproduct gas of the urea manufacturing process.

Salt.—Annual production from marine salt pans in the Port Said and Alexandria area was to be increased from about 600,000 to 1.1 million tons. The bulk of the increased output would be exported and a

[11] Nitrogen. New Facilities for Egypt's Fertilizer Industry. No. 37, September 1965, p. 20.

small part would be consumed by domestic caustic soda plants.

MINERAL FUELS

Coal.—Production of the El Meghara coal mine on the Sinai Peninsula was reported as 20,000 tons per year, but it was scheduled to increase to about 620,000 tons per year when the deposits are fully developed. The coal will be consumed by the Helwan iron and steel works and will partially replace imported coking coal. Work was progressing on a road from Ismailia to the mine site at Meghara.

Coke.—Coke-oven gas from two 900-ton-per-day batteries and one 1,800-ton-per-day unit of the El Nasr Coke & Heavy Chemical Co. at Helwan will provide basic raw material for manufacturing urea.

Petroleum.—*Exploration.*—The oil strike of Pan American U.A.R. Petroleum Co. in the Gulf of Suez near the village of El Tor was probably the most important event of the year. The discovery well found oil at two different levels; at a depth of about 5,000 feet, a flow of 2,000 barrels per day of 24° to 26° A.P.I. crude oil and at a depth of about 6,000 feet, a flow of 10,820 barrels per day of 25° to 30° A.P.I. crude oil. It has been estimated that Pan American's discovery, named the El Morgan field, indicated preliminary reserves of 630 million barrels, and the field, when fully developed, was expected to produce 100,000 barrels per day.[12] Present production of crude oil in the United Arab Republic (Egypt) is estimated at about 125,000 barrels per day. A second well, drilled about 3 kilometers from Pan American's El Morgan well, also struck oil. The second well was said to be similar to the first in quantity and quality of oil, but the pay zone was not nearly as thick. In the latter part of the year a third well was completed in the El Morgan field with results similar to the first two. A platform was to be located at the site of the first well by mid-1966, from which multiple wells will be directionally drilled. A new company has been formed by Pan American U.A.R. Petroleum Co. and the Egyptian General Petroleum Corp. to develop the El Morgan field. Pan American also started a new well on a recently discovered structure in its Western Desert concession in preparation for starting its first well in November.[13]

Five seismic crews were operating in the Western Desert concession of Phillips Petroleum Co. Phillips' first well was to be started in November about 95 kilometers west of Alexandria and 26 kilometers inland from the Mediterranean Coast.

International Egyptian Oil Co. had two seismic crews surveying its Delta concession. A seismic survey of International's Gulf of Suez concession area at Khalig al-Zait was completed in the latter part of the year. Compagnie Orientale des Petroles d'Egypt (COPE) also made a discovery near Gharah, offshore from the Sinai Peninsula in the Gulf of Suez.[14] The well produced 2,500 barrels per day of 31° A.P.I. crude oil from a depth of 7,218 feet. COPE produced 97,377 barrels per day from its concession on the Sinai Peninsula.

An oil strike was made by Egyptian General Petroleum Corp. (EGPC) 4 miles north of its Ras Bakr pool. Results of flow tests were not announced.

Total reserves of crude oil as of June 1965 were estimated at 2 billion barrels,[15] and gas reserves apparently were about 1.5 million cubic feet.

Refining.—The Suez refinery's coke plant began producing in April. Output of the plant was estimated at 1.7 million tons per year. The plant, which cost about $57.5 million, was built by Compagnie Italiani Petroli for the Suez Oil Processing Co. Other units of the complex were expected to be inaugurated in midyear.[16]

A powerplant, that was designed to consume 360,000 tons per year of coke produced by the Italian built Suez refinery coke plant, also began operating in April. The plant consisting of four 25,000 kilowatt units and space for another unit was constructed by U.S.S.R. technicians.[17]

The second 5-year plan allocated $126.5 million for construction of a petrochemical complex at Alexandria. Ten separate fac-

tories will be built to produce synthetic rubber, plastics, raw pharmaceuticals, synthetic fibers, fertilizers, alcohol, insecticides, and other petrochemicals.

Transportation, Suez Canal.—The Canal Authority increased tolls for all ships 1 percent, effective July 1, 1965. From January through September 1965 oil tankers accounted for about 74 percent of total new tonnage (184,028,905) passing through the canal. Of the 15,207 ships traversing the canal during this period 7,280 were oil tankers; of the 167,554,000 tons of cargo 120,762,000 tons was petroleum. The largest part of the petroleum 115,151,000 tons was northbound with Italy (29,585,000 tons), England (18,954,000 tons), and France (18,912,000 tons) receiving the largest quantity. The chief sources of supply for this petroleum were Kuwait (47,502,000 tons), Iran (28,682,000 tons), and Saudi Arabia (20,006,000 tons). Of the petroleum northward bound 106,037,000 tons was crude oil.

Other minerals that passed through the canal northward during the 9 months included iron ore (2,510,000 tons), manganese ore (854,000 tons), ilmenite and rutile (348,000 tons), lead (340,000 tons), zinc (247,000 tons), chrome (214,000 tons), tin (168,000 long tons), copper (140,000 tons), bauxite (82,000 tons), others (246,000 tons).

Southbound petroleum totaled 5,611,000 tons of which 1,465,000 was crude oil. Sources of the petroleum were U.S.S.R. 3,906,000 tons, Rumania 777,000 tons, and Italy 559,000 tons. Destinations of the southbound petroleum were Japan 2,811,000 tons, India 1,153,000 tons, and Pakistan 361,000 tons.

The Mineral Industry of Other Areas of Africa

By Walter C. Woodmansee [1]

Contents

Of the 16 countries and territories covered in this chapter, all except Gambia and the Spanish Sahara are overseas associates of the European Economic Community (EEC).[2] Except for Burundi, Gambia, Rwanda, Somali Republic, and the Spanish Sahara, all also are members of the Communauté Française Afrique (CFA) for which the franc is the standard monetary unit. Where necessary for the 13 CFA members, CFA francs have been converted to U.S. dollars at the rate of CFAF245 = US$1.00. Monetary conversion rates for each of the 5 nonmembers are indicated in the sections on these countries.

BURUNDI

Reported mineral production in the Kingdom of Burundi during 1965 was limited to cassiterite, bastnaesite, and limestone, although construction materials such as clay, sand, and gravel probably were produced in small quantities for local use. The mineral industry was of little importance to the economy; output of cassiterite and bastnaesite contributed only an estimated $80,000 to $90,000 to the gross national product (GNP) of about $150 million.[3]

Although mining activity was small, mineral prospecting and exploration were advanced during the year. The Département Géologie et Mines, staffed with Belgian and French personnel, some under United Nations auspices, undertook geological and mineral studies. Mineral commodities under investigation included diamond, bauxite, iron ore, and kaolin. Iron ore deposits of relatively high grade are known, but distance from markets precluded development. Discovery of a large gossan in the Crete Congo-Nil was reported, and investigation was proceeding.

[1] Physical scientist, Division of International Activities.

[2] Other African continent associates, covered in other chapters of this volume, are Algeria, Democratic Republic of the Congo (Léopoldville), Gabon, Ivory Coast, Malagasy Republic, and Senegal.

[3] Where necessary, Burundi francs (BF) have been converted to U.S. dollars at the rate of 50BF=$1.00 prior to Feb. 11, 1965, when the Burundi franc was officially devaluated, and 87.5BF=$1 after that date.

PRODUCTION

Cassiterite mining continued by contract workers who supplied the operating company, Syndicat Minier d'Etain (MINETAIN), with a specified quantity and disposed of the remainder in other markets. Bastnaesite production, which began in August, totaled 75 tons during the year. A large increase was planned during 1966.

Table 1.—Burundi: Production of metals and minerals
(Metric tons unless otherwise specified)

Commodity [1]		1961	1962	1963	1964	1965
Metals:						
Columbium-tantalum concentrate		(2)	2	2	NA	NA
Rare earth metal concentrate (bastnaesite)		---	---	---	---	75
Tin:						
Cassiterite concentrate	long tons	(2)	35	25	22	16
Content of concentrate	do	(2)	26	16	NA	NA
Nonmetals: Limestone		NA	NA	360	120	150

NA Not available.
[1] In addition, construction materials such as clay, sand, and gravel are produced, but quantitative data are not available.
[2] Production, if any, included with that of Rwanda.

TRADE

Minerals produced entered the export market. The United States received about 10 tons of bastnaesite concentrate in 1965, and a large part of the remainder reportedly went to West Germany. In addition, some 2.3 million carats of diamond were reported as exports during 1965. Most of these apparently originated in the Democratic Republic of the Congo (Léopoldville) and were sold in Burundi.

Reported mineral imports during 1964 and 1965 were as follows:

	1964		January through September 1965	
	Metric tons	Value (thousands)	Metric tons	Value (thousands)
Cement	8,752	$340	5,363	$211
Salt	6,970	288	6,841	267
Petroleum fuels	16,099	1,368	7,795	595
Lubricants	900	214	355	113

The main sources of these commodities were the Democratic Republic of the Congo (cement), Tanzania (salt and gasoline), Iran (various petroleum refinery products), and the Netherlands (lubricants).

An estimate of the relationship between mineral and total trade during these years is given below (excluding diamond, which originated in other countries):

	Value (thousands)		Mineral commodities share of total trade (percent)
	Mineral commodities (estimate)	All commodities	
Exports:			
1964	$40	$19,600	0.2
1965	90	14,000	.6
Imports:			
1964	2,200	17,200	12.8
1965	1,600	18,600	8.6
Trade balance:			
1964	−2,160	+2,400	XX
1965	−1,510	−4,600	XX

XX Not applicable.

CAMEROON

The mineral industry of the Federal Republic of Cameroon in 1965 essentially remained limited to aluminum production, which contributed 3 to 4 percent to the estimated GNP of $575 million. Although there were few known economically exploitable minerals, the search continued for new mineral deposits. In January President Ahidjo requested Federal Assembly approval of the Office Nationale de la Recherche Scientifique et Technique to replace the Institut de Recherches Scientifiques du Cameroon. In March 20 geologists arrived to study granites in the north. The group was organized by the Association of African Geological Services, financed by the United Nations and the Union of Geological Sciences.

Late in the year, the President signed two decrees granting mineral exploration rights to the French Bureau de Recherches Géologiques et Minières (BRGM) for copper, lead, silver, cadmium, germanium, and gallium in the Ntole, Mamfe, and Kumba regions of the west. Duration of the concession is 4 years, renewable for two 4-year periods.[4]

There was new activity in oil exploration, and prospects for oil discovery were considered good. Offshore drilling was underway by one company, and a second company was granted a concession and planned drilling in 1966.

PRODUCTION

Aluminum ingot from the Edéa reduction plant was Cameroon's only important mineral product. Small quantities of gold from the Bétaré-Oya region and tin concentrate from Mayo-Darlé represented the only other recorded mineral production. Guinea was the principal source of alumina for processing at Edéa.

TRADE

The year 1964 was the first in which trade statistics of East and West Cameroon were combined in national sources since unification in 1961. East Cameroon accounted for a large part of both mineral and total trade.

Union Douanière et Economique de l'Afrique Centrale (UDEAC), a trade union comprising Cameroon, Central African Republic, Chad, Congo (Brazzaville), and Gabon, was organized in 1965 and was in effect as of January 1, 1966. Final negotiations between these countries, regarding fiscal and customs tariffs, were conducted at a conference at Douala in October 1965.

During 1964, the latest year for which complete data are available, the principal mineral imports (with values in parentheses) were petroleum refinery products ($8.5 million), alumina ($7.2 million), and iron and steel ($6.3 million). Aluminum exports were valued at $21.1 million, nearly 98 percent of total mineral exports. The relationship between mineral and total trade during 1963 and 1964 was as follows:

[4] U.S. Embassy, Yaunde. Department of State Airgram A-81, Oct. 26, 1965, p. 1.

	Value (thousand dollars)		Mineral commodities share of total trade (percent)
	Mineral commodities [1]	All commodities

COMMODITY REVIEW

Metals.—*Aluminum.*—Compagnie Camerounaise d'Aluminium Péchiney—Ugine (ALUCAM), producer of ingot at Edéa, celebrated its 10th anniversary of operation in Cameroon. The company is the second largest capitalized enterprise in the country. It employed 57 French and 30 Cameroon technical personnel and 450 Cameroon laborers. A gradual shift to greater operation by Cameroon nationals continued.

Société Camerounaise de Transformation de l'Aluminium (SOCATRAL) was organized as operating company for the proposed rolling mill at Edéa. Companies also were formed for power and the production of finished aluminum products.

Gold.—No details were reported on gold-mining operations, although there was a significant increase in reported output. Early in the year, the Government began negotiations with a West German geological firm for investigations for alluvial gold in Lom and Kadéi Departments.

Mineral Fuels.—*Petroleum.*—The new offshore drilling barge of Société de Recherches et d'Exploitation des Pétroles au Cameroon (CEREPCA) was inaugurated on February 6. The barge was built by Chantiers de France Gironde at a cost of $8.2 million. It has four sliding 164-foot columns and can operate in water 66 to 98 feet deep; sections added to columns can increase operating depth to 180 feet. Drilling started in February on a structure detected by seismic methods in the Sanaga Maritime permit between the Sanaga and Nyong Rivers. The well was abandoned dry at 12,467 feet in June. Further offshore drilling was planned to test the Miocene section.

Early in the year, representatives of Marathon International Oil Co., Mobil Exploration Equatorial Africa, Inc., and Continental Oil Co. arrived in Yaoundé to negotiate for offshore concessions. By Presidential decree of June 16, 1965, Mobil was granted a 3,750-square-kilometer offshore oil and gas concession. Under terms of the concession, an expenditure of $1.5 million was required during the concession period. Mobil conducted 2 months of seismic reconnaissance and planned drilling in 1966.[5]

CENTRAL AFRICAN REPUBLIC

During 1965 the Central African Republic produced 3.7 percent of world output of gem-quality diamond and 0.9 percent of world output of industrial diamond. Essentially the country's only mineral product, diamond output contributed $14,985,000 to the GNP, estimated at $70 million.

The search for minerals continued. Recent discoveries of copper, iron ore, tin, and zinc have been reported, but economic value of these mineral occurrences remained unreported.

PRODUCTION

Diamond output increased to a record high, but output of byproduct alluvial gold, the only other mineral commodity for which output is recorded, decreased substantially.

TRADE

Metal and mineral trade showed an increased surplus in 1965 because of expanded diamond output and export, whereas total trade again showed a small deficit. These data for 1963–65 were as follows:

	Value (thousands)		Mineral commodities share of total trade (percent)
	Mineral commodities [1]	All commodities	
Exports:			
1963	$10,636	$21,996	48.4
1964	12,625	28,921	43.7
1965	14,446	26,359	54.8
Imports:			
1963	2,829	26,340	10.7
1964	r 3,384	29,848	11.3
1965	3,635	27,427	13.3
Trade balance:			
1963	+7,807	−4,344	XX
1964	+9,241	−927	XX
1965	+10,811	−1,068	XX

r Revised. XX Not applicable.
[1] Includes only those commodities listed in table 6 of this chapter.

Export earnings from diamond totaled $14.2 million in 1965, compared with $12.4 million in 1964. Diamond therefore com-

[5] Bulletin of the American Association of Petroleum Geologists. V. 50, No. 8, August 1966, p. 1709.

prised 98 percent of mineral export value and 54 percent of total export value.

The principal mineral imports in 1965 and corresponding values were petroleum refinery products, $1.8 million ($1.3 million in 1964), and iron and steel, $673,000 ($867,000 in 1964).

COMMODITY REVIEW

Metals.—*Uranium.*—The BRGM, in conjunction with Compagnie Française des Minerais d'Uranium, performed preliminary geological exploration near M'Patou in the Bakouma region. Results were favorable, and a detailed study was planned.

Nonmetals.—*Diamond.*—Of the 1965 output, which increased 21 percent over that of 1964, 445,016 carats were mined by private diggers and 91,794 carats by industrial companies, principally Compagnie Centrafricaine de Mines (CENTRAMINES). Although exact data were not available, about half of this output was gem-quality diamond and the other half was industrial diamond. Prospecting and exploration continued in the Berberati area.

By a 1964 decree, the Government had attempted to regulate diamond markets and prices. All foreigners, including Senegalese, Mauritanians, and Malians, who had bought from native diggers and sold to offices of European companies in Bangui

e Estimate.
[1] For details on specific commodities included, see section on source materials.

and Carnot, were barred from diamond-mining areas. In October 1965, several foreign firms engaged in diamond trade were granted licenses for buying offices. Most were undisclosed, but new offices included those of Harry Winston, Inc., New York; Société Diamantaire de France, Paris; and Compagnie Internationale d'Exploitation des Diamants et d'Or, Brussels. The total number of international offices authorized to purchase diamond was eight—3 French, 3 American, 1 Israeli, and 1 Belgian.

CHAD

There were no economically important mineral developments in the Republic of Chad during 1965; natron, mined near Lake Chad, remained the only recorded mineral product. Its export value in 1965 was $256,000 and it therefore contributed only about 0.1 percent to an estimated GNP of $190 million.

A 5-year plan announced by the Government of Chad included study of minerals in the Doba area, evaporites in the Lake Chad region, mineralized veins at Soborom, and reconnaissance geological mapping at Abeche Est. Early in the year, M. Louis Joffret, Director of Mines, reporting to the Comité National de Recherches Hydrologiques et Géologiques, mentioned interest in uranium in the Tibesti Mountains of the north, granite in the Ouaddaï region of the east, and gas in the Lake Chad area. In September the Government announced plans to seek United Nations Special Fund Aid in mineral development.

The BRGM continued hydrogeologic study and mapping in the Fort Lamy area and investigations for clay, kaolin, talc, and diatomite in other parts of the country.

PRODUCTION

Natron production at the Liwa and Kaya works along Lake Chad was estimated to be 7,100 tons in 1965 (r 6,757 tons in 1964 and r 8,654 tons in 1963). In addition, small quantities (1,000 to 2,000 tons annually) of natron and salts are gathered for domestic use in the Borkou-Ennedi-Tibesti northern region,[6] and simple construction materials such as clay, sand, and gravel presumably were extracted for local use, but extent of these activities was not reported.

TRADE

Chad mineral trade remained characterized by exports of natron, reexports of petroleum refinery products, and imports of iron and steel semiproducts and petroleum refinery products. The relation of mineral trade to total trade during 1963–65 was as follows:

	Value (thousands)		Mineral commodities share of total trade (percent)
	Mineral commodities [1]	All commodities	
Exports:			
1963	$335	$22,707	1.5
1964	r 869	26,510	3.3
1965	1,237	27,253	4.5
Imports:			
1963	6,505	29,034	22.4
1964	7,599	34,585	22.0
1965	8,395	31,193	26.9
Trade balance:			
1963	−6,170	−6,327	XX
1964	−6,730	−8,075	XX
1965	−7,158	−3,960	XX

r Revised. XX Not applicable.
[1] Includes only those commodities listed in table 7 of this chapter.

The values for total trade indicated above do not include UDEAC and noncontrolled trade, which are not accurately reported but were considered substantial. Including these markets, total trade values for 1965 were estimated as follows: Exports $37.3 million and imports $47.6 million.[7]

Exports of natron were valued at $256,000 in 1965 ($189,000 in 1964), and reexports of petroleum refinery products were valued at $963,000 ($678,000 in 1964). The main metal and mineral imports and their values were iron and steel, $825,000 ($1.4 million in 1964), and petroleum refinery products, $6.3 million ($4.8 million in 1964). The decline in the latter was attributed to lower demand following withdrawal of French military forces.

COMMODITY REVIEW

[3] For details on specific commodities included, see section on source materials.

activities on the Erdis plateau, Borkou-Ennedi-Tibesti northern region. In August a presidential decree cancelled PETROPAR's 152,000-square-kilometer concession. M. Louis Joffret, Minister of Mines, sought United States participation in exploration. Representatives of Ente Nazionale Idrocarburi (ENI), the Italian Government company, conferred with Chadian officials on oil exploration.[8]

CONGO (BRAZZAVILLE)

As in previous years, mineral activity of the Republic of Congo (Brazzaville) was confined to the production of copper-lead-zinc ores, cassiterite, alluvial gold, and crude petroleum. Based on export value, these materials contributed $2.1 million to a GNP of about $45 million.

The most significant mineral industry news was the continued development of the Holle potash deposit, which will provide considerable needed revenue and foreign exchange earnings. The target date for initiation of production is 1968. The country's first cement plant also was under construction. The Government's 1964–68 economic plan provided funds for exploration for several metals, diamond, and petroleum. Under terms of a technical cooperation agreement late in 1964, the U.S.S.R. provided an $8.9 million credit, including funds for mineral exploration, potash mine development, and hydroelectric power development at the Kouilou Dam.[9]

PRODUCTION

Mine production of copper, lead-zinc, and tin were reported only in terms of concentrate and estimated grade, and contained metal tonnages are therefore only approximate. Output of these metals and gold showed a significant increase during 1965. Crude oil, the only other mineral commodity produced, showed a continued decline as small reserves at the Point Indienne field were being depleted.

e Estimate. r Revised.
[1] In addition, construction materials such as clay, sand, and gravel are probably produced, but quantitative data are not available. Diamond output, credited by some sources to the Congo (Brazzaville), is believed to have originated wholly outside the country.
[2] Metal content of marketable ore or concentrate produced, except gold which is fine metal recovered in mining.

TRADE

Congo (Brazzaville) depends heavily for export earnings on diamond entering the country through illicit channels, chiefly if not entirely from the Democratic Republic of the Congo (Léopoldville); exports of diamond from Congo (Brazzaville) have averaged more than 5 million carats annually in recent years. They were valued at $19,957,000 in 1965 ($19,716,000 in 1964), or 90 precent of the mineral exports from Congo (Brazzaville) and nearly 43 percent of total exports of all goods. The following tabulation indicates how these exports contributed to a large trade surplus in minerals and alleviated substantially the unfavorable overall trade balance:

	Value (thousands)		Mineral commodities share of total trade (percent)
	Mineral commodities [1]	All commodities	
Exports:			
1963	$21,283	$41,631	51.1
1964	21,710	47,407	45.8
1965	22,032	46,804	47.1
Imports:			
1963	8,292	61,755	13.4
1964	8,637	64,839	13.3
1965	8,980	67,709	13.3
Trade balance:			
1963	+12,991	−20,124	XX
1964	+13,073	−17,432	XX
1965	+13,052	−20,905	XX

XX Not applicable.
[1] Includes only those commodities in tables 9 and 10 of this chapter.

These totals do not include small quantities of gold which are officially exported annually. In 1964, the latest year for which data are available, 1,833 troy ounces valued at $51,000 was exported. Principal mineral exports and their value in 1965, other than diamond, were crude oil, $973,000 ($1,042,000 in 1964), and nonferrous concentrates (lead-zinc and cassiterite), $793,000 ($442,000 in 1964).

Congo (Brazzaville) mineral imports in 1965 comprised principally petroleum refinery products valued at $3.6 million ($4.1 million in 1964) and iron and steel valued at $3.3 million ($2.4 million in 1964).

COMMODITY REVIEW

Metals.—*Copper.*—Production of mine copper was renewed in 1965. Output was 168 tons of ore and concentrate of 27 to 40 percent copper. The source was unreported but presumably was the M'Passa lead-zinc deposit, where byproduct copper was produced in 1963.

Gold.—Increased output was reported by diggers in the Kelli, Kouilou, and Dolisie areas.

Lead and Zinc.—The M'Passa mine of Syndicat de M'Passa (SMM), an association of the BRGM and Compagnie Minière de Congo (CMC), produced 19,740 tons of concentrate containing about 15 percent lead and 35 percent zinc; output was 36 percent higher than in 1964.

Tin.—Compagnie Métallurgique et Minière (CMM) produced 60 tons of cassiterite containing about 70 percent tin at Moufoumbi in the northern part of Kouilou prefecture. Prospecting and exploration continued. A concentrating plant was under construction as part of a plan to double production capacity.

Nonmetals.—*Cement.*—Ground was broken for the Cementerie Domaniales $6.3 million, 80,000-ton plant at Loutété, 180 kilometers from Brazzaville. West Germany provided a $2.5 million credit. West Ger-

man firms will build the plant and also provide technical and administrative personnel for a 5-year period.

Potash.—Exploration and development continued at Hollé, 45 kilometers inland from Pointe Noir, where a large, rich potash deposit was discovered in 1960. During shaft-sinking operations, it was necessary to freeze the ground because of a groundwater problem. A 900,000-ton potassium chloride (KCl) plant (500,000 tons K_2O equivalent) was planned for completion in 1968.[10] Development investment was estimated at $70 million, the International Bank for Reconstruction and Development (IBRD) providing 60 percent, with the remainder from participating companies.[11]

Mineral Fuels. — *Petroleum.* — Crude oil output at the small Point Indienne field continued a downward trend because of a gradual depletion of limited reserves. Output was at the rate of about 1,670 barrels per day. At yearend, reserves were estimated at 5 million barrels crude oil and 10 billion cubic feet of natural gas, sufficient only until 1970 at the planned production rate.[12]

An exploration arrangement between Société des Pétroles d'Afrique (SPAFE) and Mobil Oil Co., Inc., was terminated because of unfavorable exploration results in previous years. No wells were drilled during 1965. SPAFE was engaged in interpretation and review of data in Paris.[13]

Shell Co. of Equatorial Africa was granted authorization for a lubricant plant at Pointe Noir. Under terms of the agreement, Shell will have preferential status under terms of the investment code, which includes relief from customs duties and other fiscal advantages for 7 years.[14]

DAHOMEY

As in 1964, the Republic of Dahomey had no recorded crude mineral production, although small quantities of alluvial gold, marine salt, and simple construction materials were produced. In the coastal urban areas, Société Acier et Béton produced steel pipe and cement blocks, and Usines de Préfabrications Dahoméennes made tiles and cement blocks. These mining and processing activities contributed insignificantly to a GNP estimated at $90 million.

Mineral prospecting and exploration continued in several parts of the country. The BRGM was active along rivers and in the mountainous north. The Prakla organization, Hanover, West Germany, conducted an airborne magnetometer-radiometric survey, and Service des Mines geological teams made ground investigations of recorded anomalies from this survey.

Mineral commodities under investigation included beryl, cassiterite, chromite, columbite-tantalite, gold, ilmenite, iron ore,

manganese, monazite, nickel, rutile, scheelite, diamond, lignite, limestone, marble, phosphate rock, and potash. Plans for a proposed cement plant near the large limestone deposit at Yamaigo Onigbolo remained in the negotiating stage as financing was still unarranged. A 5-million-ton marble deposit was discovered near the Ouémé River, a few kilometers from Dadjo village.

TRADE

In 1964, the latest year for which complete data were available, mineral exports were negligible, consisting largely of reexported petroleum refinery products ($14,000). Dahomey's principal mineral import commodity groups in 1964 and their values were petroleum refinery products ($1.8 million) iron and steel ($1.7 million), and cement and other building materials ($1.2 million). Lower imports in the latter was attributed to a decline in construction activity. The following tabulation indicates the role of mineral and metal trade in Dahomey's total trade:

	Value (thousands)		Mineral commodities share of total trade (percent)
	Mineral commodities [1]	All commodities	
Exports:			
1963	$60	$12,779	0.5
1964	30	13,182	.2
Imports:

1964	−5,507	−18,263	XX

r Revised. XX Not applicable.
[1] Includes only those commodities listed in tables 11 and 12 of this chapter.

COMMODITY REVIEW

Metals.—*Aluminum.*—A new firm, Aluminium Alcan du Dahomey (DALCAN), was organized as operator of a plant for roofing sheet at Cotonou. Aluminum Company of Canada (ALCAN) holds a 51-percent interest; the remainder is held by Banque Dāhoméenne de Développement

and private Dahomey investors. Planned capacity was 1,500 tons per year of corrugated and other sheet. Late in the year, an announcement indicated that ALCAN had agreed to provide $80,000 on long-term loan and to extend a credit of $160,000 for importing aluminum sheet. The new company was granted class A status under the investment code, whereby it is tax exempt and pays no import duty on operating supplies for 5 years.

Nonmetals.—*Diamond.*—In August, Diamond Corp. of Ivory Coast Ltd., a subsidiary of DeBeers Consolidated Mines Ltd., was granted the first diamond prospecting permit in Dahomey—a 3-year permit for investigation of kimberlite-type formations in various parts of the country. In November two British geologists representing the Diamond Corp. arrived for a 10-month survey of the Dassa-Zoumé and northern regions.[15]

Fertilizer Raw Materials.—Shell West Africa Ltd. was granted 20 prospecting permits for potash, phosphate, and associated salts in the coastal sedimentary basin. A Shell company geologist also was in Dahomey investigating the phosphate-bearing formation which extends across Dahomey between Togo and Nigeria.

Mineral Fuels.—*Petroleum.*—Union Oil Co. of Dahomey, which late in 1964 was granted a concession covering the entire coastal region of the country, conducted geologic and photogeologic work onshore and seismic work offshore. The latter indicated the presence of a deep sedimentary basin, where further work was planned.

A joint venture involving Cabol Enterprises Ltd. (Canada) and Baho American Oil Co. (United States) was also granted a concession for 1965–66. No information was available on activities of this operation.

FRENCH SOMALILAND

Through 1965 there was no organized mineral industry in French Somaliland and no recorded production or export of mineral commodities. However, small quantities of crude construction materials such as clay, sand, and gravel were presumably extracted for local use. The principal metal and mineral imports and their values were petroleum refinery products, $489,000 ($477,000 in 1964), cement and other construction materials, $284,000 ($240,000 in 1964), and rough castings and forgings of iron and steel, $152,000 ($150,000 in 1964). Value of total mineral imports was $1,009,000, only 4.4 percent of value of all imported goods during 1965.

Table 13.—French Somaliland: Imports of selected metals and minerals

(Metric tons)

Commodity	1964	1965	Principal sources, 1964
Metals: Iron and steel: Castings and forgings, unworked.	512	1,030	Japan 181; France 172; Belgium-Luxembourg 102.
Nonmetals:			
Cement, lime, and other building materials [1].	12,427	15,691	U.S.S.R. 5,454; Poland 2,683; France 1,941; Israel 1,699.
Nonmetallic minerals, crude, unspecified [1].	1,101	466	Italy 514; United Kingdom 261; Poland 250.
Mineral fuels:			
Petroleum:			
Crude and partly refined	1,517	1,694	Aden 67; others unspecified.
Refinery products	14,350	14,453	Kenya 207; United States 113; Netherlands 94; others unspecified.

[1] For details on specific commodities included, see section on source materials.

GAMBIA

Gambia, granted independence on February 18, 1965, had no organized mineral-producing industry through yearend. The only mineral activity was in the petroleum sector. Société des Pétroles du Senegal (SPS), an association of Bureau Recherche des Pétroles and British Petroleum Exploration Co., held an exploration concession for the entire country. A brief marine seismic survey was conducted in January 1965.[16]

[15] Mining Journal. V. 266, No. 6811, Mar. 4, 1966, p. 152.

[16] Page 99 of work cited in footnote 8.

MALI

Mineral production contributed little to the economy of the Republic of Mali in 1965. Reported mineral industry activity was limited to the extraction of salt, gold, and marble, but simple construction materials such as clay, sand, and gravel presumably also were extracted for local use. According to the Director of the Bureau de Documentation Minière (formerly Bureau Minière) about 3,000 tons of salt are regularly produced by solar evaporation annually, but there was no significant production of gold or marble. Gold was panned near Kangaba and Kéniéba by natives in cooperation with the Bureau de Documentation Minière. Marble blocks and chips were quarried near Bafoulabé for use in a small tile plant in Bamako, where equipment for sawing and preparation of blocks was recently installed.

The search for minerals continued by the BRGM and the U.S.S.R. in conjunction with the Bureau de Documentation Minière. The BRGM was involved mainly in petroleum exploration in the Taoudenni basin, diamond investigations in the kimberlite-type deposits of the Faléme basin near Kéniéba, and geologic mapping in the Gourma area. The Bureau de Documentation Minière studied iron ore deposits along the Dakar-Bamako railroad, petroleum possibilities west of Gao, and phosphate deposits near Lahoualou.

Representatives of Selection Trust Exploration Ltd. and Harry Winston, Inc., New York, also were interested in diamond possibilities near Kéniéba.

In January authorities of the Government of Mali signed an agreement with the U.S.S.R. for construction of a $6 million, 50,000-ton cement plant at an unreported location.

TRADE

Malian mineral trade in 1964, the latest year for which complete data are available, was characterized by imports mainly of petroleum refinery products and iron and steel and reexport of petroleum products. Recorded mineral exports and reexports during 1963 and 1964 were as follows, in metric tons:

Commodity	1963	1964
Iron and steel, scrap	42	----
Cement, lime, and other building materials[1]	22	----
Nonmetallic minerals, crude, unspecified [1]	539	270
Petroleum refinery products	65	[2] 5,543

[1] For details on specific commodities, see section on source materials.
[2] Includes gasoline 2,706; kerosine 2,799; and lubricants 38. Principal destinations were Venezuela 3,018; British Guiana 737; United States 501; and France 447.

Value of imported petroleum products was $2.3 million and of iron and steel, $1.3 million. The role of mineral trade in overall trade values was as follows:

	Value (thousands)		Mineral commodities share of total trade (percent)
	Mineral commodities [1]	All commodities [2]	
Exports:			
1963	$ r 79	$r 10,556	0.8
1964	231	16,590	1.4
Imports:			
1963	4,499	34,246	13.1
1964	4,699	36,578	12.8
Trade balance:			
1963	r −4,420	r −23,690	XX
1964	−4,468	−19,988	XX

r Revised. XX Not applicable.
[1] Includes only those commodities listed in table 14 and in the preceding tabulation on mineral exports.
[2] Includes only trade under control of customs service; does not include imports of equipment for various aid projects and substantial uncontrolled trade with neighboring countries.

MAURITANIA

In 1965 iron mining became the most important sector of the economy of the Islamic Republic of Mauritania and the key to the attainment of economic viability. Iron ore exports, valued at $50.7 million, were nearly equal to half of the country's GNP, estimated at $110 million. Mauritania ranked second, after Liberia, among African iron-ore exporting nations. According to estimates made in the Government's operating budget for 1966, royalties from iron ore sales would provide $5,750,000, nearly 30 percent of estimated total government revenue. This income was expected to terminate dependence on French budgetary support.

The iron-mining sector employed 3,419 persons, including 2,700 Mauritanians and 719 foreigners, largely Europeans. The country's total labor force was estimated at 17,200 including 8,200 in the public sector.[17]

The BRGM conducted geologic, hydrogeologic, and mineral investigations in several parts of the country. A geologic map of Mauritania was in preparation in six sheets at a scale of 1:1,000,000. An airborne magnetic-radiometric survey was carried out, and anomalies discovered were investigated on the ground. Systematic exploration, including a drilling program, were planned in the Amsaga area.

PRODUCTION

Expansion of iron ore output continued toward a planned annual rate of 7.5 million tons in 1968. Salt output, probably on the order of several hundred tons per year, fluctuates considerably depending on local demand. The only other mineral products of domestic origin were construction materials, used largely in the building of the iron-mining installations and roads, but data on production or consumption were not available.

TRADE

Iron ore again dominated Mauritania's export picture in 1965; shipments abroad were valued at $50.7 million. Data on total exports of all goods were not available for 1965, but iron ore undoubtedly accounted for a larger share of the total than in 1964,

[17] U.S. Embassy, Nouakchott. Department of State Airgram A-219, June 10, 1966, p. 1.

Table 15.—Mauritania: Production of metals and minerals

Metals: Iron ore—thousand metric tons	300	1,000	r 1,678	r 5,080	6,284
Nonmetals: Salt [e]—metric tons	500	500	600	600	600

[e] Estimate. [r] Revised.
[1] In addition construction materials such as gypsum, clay, sand, and gravel are produced, but quantitative data are not available.

when it accounted for an estimated 94 percent of total export earnings.

Statistical data on Mauritanian trade were incomplete. European Economic Community statistics, which are the basis for most of the trade figures given in this chapter, do not include iron ore exports and have been modified in totals given in the accompanying tabulation. Official Mauritanian statistics include customs trade to and from Mauritanian seaports and airports but may not include goods entering the country from Senegal (Mauritania-Senegal customs union) and goods involved in traditional uncontrolled commercial activity between these countries and Mali.

In1964 the Mauritanian trade balance was favorable for the first time, apparently by a substantial margin, because of the growing shipments of iron ore. Values for mineral and total trade are estimated as follows:

	Value (thousands)		Mineral commodities share of total trade (percent)
	Mineral commodities [1]	All commodities	
Exports:			
1963	$r 10,801	$r 15,853	68.1
1964	42,524	44,944	94.6
Imports:			
1963	r 3,986	30,016	13.3
1964	2,102	15,714	13.4
Trade balance:			
1963	r +6,815	r −14,163	XX
1964	+40,422	+29,230	XX

r Revised. XX Not applicable.
[1] Includes only those commodities listed in tables 16 and 17 of this chapter.

Iron-ore mining operations have accounted for about one-quarter of the value of total imports annually in recent years. Principal mineral imports in 1964 were petroleum refinery products, $1,019,000 ($803,000 in 1963), and iron and steel, $603,000 ($2,645,000 in 1963, apparently mainly for rails for iron-ore haulage). Mineral export trade other than iron ore was essentially reexports of petroleum products.

COMMODITY REVIEW

Metals.—*Copper.*—Société de Cuivre de Mauritanie (SOCUMA), a firm established in June 1964 and representing U.S., Canadian, French, and Mauritanian Government interests, studied methods of mining and milling the copper-gold ore at the Akjoujt deposit. The company held an 18-month option which terminated at the end of 1965. Negotiations for financing development operations continued during the year, although no definite financial arrangements were made. The Mauritanian Government sought financial assistance through the International Bank for Reconstruction and Development (IBRD) and the Fond Européen du Développement. Estimated development cost was $40 million.

Iron Ore.—Production and export of iron ore from the Fort Gourand mine showed continued expansion in 1965. During the year, 5,965,000 tons were shipped from Port Étienne; value, based on a rate of $8.50 per ton, was $50.7 million (4,983,000 tons, $42.3 million in 1964). Société des Mines de Fer de Mauritanie (MIFERMA) paid royalties totaling $5,081,633 to the Mauritanian Government in 1965. Principal export destinations were, in thousand tons: United Kingdom 1,554; West Germany 1,181; France 1,165; Italy 996; Belgium-Luxembourg 576; Netherlands 324; and United States 139.[18]

Three mining sections were in operation in 1965. Their output was as follows in thousand metric tons:

Mining section	Shipping grade ore	Mixed ore
Tazadit	5,412	708
F'Derick	757	---
Rouessa	115	53
Total	6,284	761

The Rouessa section was opened during the year. A 7-kilometer road was built, connecting the mine to the crushing plant at Tazadit. The road can accommodate 65-ton trucks and was built over difficult terrain. MIFERMA invested $8.5 million in the Rouessa operation.

In late 1964 the conveyor belt to the rail loading station at Tazadit was badly damaged by fire, necessitating a shutdown for several weeks. A new belt system of larger capacity was installed. MIFERMA planned production of 6.4 million tons in 1966, 6.8 million tons in 1967, and 7.5 million tons in 1968. Total investment to June 1965 was $180 million. The company planned to invest an additional $34 million, including

[18] Page 762 of work cited in footnote 6.

[2] For details on specific commodities included, see section on source materials.

Rouessa development and general expansion to the projected 1968 mining rate.

Established ore reserves at the three main sites in million metric tons were as follows in 1965: [19]

Mining section	Proven	Probable	Total
Tazadit	87	20	107
F'Derick	23	10	33
Rouessa	15	45	60
Total	125	75	200

Mineral Fuels.—*Petroleum.*—Exploration permits of Société de Participations Pétrolières (PETROPAR), covering an area extending from Nouakchott northward to Port Étienne, and of Société Africaine des Pétroles (SAP) in the Port Étienne area, expired on April 1, 1965, and were not renewed. Société des Pétroles de Valence (SPV) explored the northern region of Mauritania with unfavorable results. The company retained a permit in the northeast, but all work was suspended.[20]

[19] U.S. Embassy, Nouakchott. Department of State Airgram A–219, June 10, 1966, p. 8.
[20] Page 1719 of work cited in footnote 5.

NIGER

Mineral production in the Republic of Niger was limited to cassiterite and quarried construction materials. A cement plant was under development with production expected in 1966. With cassiterite output valued at $190,000, gypsum at $37,000, and construction materials probably at less than $100,000, the mineral industry apparently contributed little to a GNP estimated at $240 million.

The French Commissariat d'Energie Atomique (CEA) continued its search for uranium in northern Niger, apparently with encouraging results. By decree on August 18, 1965, the BRGM was granted a prospecting permit covering 9,500 square kilometers in the northwest corner of Niger. The permit was effective as of October 1, 1965, for 3 years. Minerals to be sought include bismuth, copper, lithium, molybdenum, tin, tungsten, and others. The BRGM, committed to expenditure of $48,000 per year in the permit area, had worked in the area during 1961–63 and apparently located favorable mineral indications.[21]

The Direction des Mines geological mapping program continued in several localities. A geological map of Niger at 1:2,000,000 was in preparation.

PRODUCTION AND TRADE

There were no major changes in Niger's mining industry. Output of cassiterite, the only metallic mineral produced, improved slightly. Construction materials were quarried in greater quantity for use mainly in road building. Gypsum was produced for the first time for use in a new cement plant.

Niger's mineral and metal trade again involved essentially export of cassiterite concentrate and import mainly of petroleum refinery products and iron and steel semimanufactures, particularly construction steel. The country's balance of trade remained in deficit, as indicated below, including the latest available data:

	Value (thousands)		Mineral commodities share of total trade (percent)
	Mineral commodities [1]	All commodities	
Exports:			
1963	^{re} 163	^{re} 19,809	0.8
1964	^{e}198	^{e} 21,453	.9
Imports:			
1963	3,835	22,712	16.9
1964	4,962	33,539	14.8
Trade balance:			
1963	^{re} −3,672	^{re} −2,903	XX
1964	−4,764	−12,086	XX

^{r} Revised. ^{e} Estimate. XX Not applicable.
[1] Imports include only those commodities listed in table 19 of this chapter.

The above statistics are from EEC and Niger Government sources and do not include widespread unrecorded trade principally between Niger and Nigeria. Mineral exports reported by the EEC do not include official Niger estimates for value of cassiterite concentrate, which was $190,000 delivered at Jos, Nigeria ($149,000 in 1963). Imports of petroleum refinery products were valued at $2.7 million, about the same as in 1963. Imports of iron and steel semimanufactures more than doubled, from $448,000 in 1963 to $1,028,000 in 1964.

COMMODITY REVIEW

Metals.—*Gold.*—The BRGM continued reconnaisance and detailed exploration along the Sirba River, a tributary of the Niger River north of Niamey, and in the Tillabery region. Several indications of gold were revealed.

The Niger Government granted a 5-year research permit to a private individual

[21] U.S. Embassy, Niamey. Department of State Airgram A–134, Jan. 17, 1966, 1 p.

[1] Includes unwrought and semimanufactures unless otherwise specified.
[2] For details on specific commodities included, see section on source materials.

who had prospected the Sirba area with a small native crew. The permit covers 2,960 square kilometers.

Molybdenum.—In August the BRGM was granted a prospecting permit in the Liptako region, west of the Niger River. This French State agency planned to start investigations in January 1966.

Tin.—Cassiterite production increased slightly at El-Mecki and Taraouadji in the Aïr region, north of Agaden. Value of the concentrate delivered at Jos, Nigeria, was $2,436 per ton, or $190,000. Société Minière du Niger, the operating company which is owned 75 percent by the Niger Government, continued exploration in the region. The company employed 281 staff personnel and laborers at yearend.

Uranium and Other Radioactive Minerals.—The CEA continued prospecting, geological study, drilling, and airborne surveys in northern Niger and reportedly made a significant uranium discovery, although details were not known. This French agency held permits totaling 348,000 square kilometers and planned to spend $1.6 million per year for exploration in the region. Further drilling in mineralized areas was planned for 1966.

Nonmetals.—*Cement.*—A cement plant of 45,000-tons annual capacity was under construction at Malbaza, a village 460 kilometers east of Niamey. A large limestone deposit was developed nearby.

Gypsum.—Production began on a small scale near Malbaza for use at the new cement plant. The Direction des Mines et de la Géologie planned a detailed ore reserve study in the region.

Other.—At yearend 31 construction material pits, near Niamey, Maradi, and Zinder, were registered with the Direction des Mines. Clay, sand, gravel, and crushed rock were used mainly in roadbuilding.

Salt was produced at Bilma in the east and at several other locations for local consumption, but no output estimates were made.

Mineral fuels.—*Coal.*—The CEA discovered coal at Tchirezine, Agades region, during uranium investigations. The coal reportedly is noncoking but has high calorific value. Government authorities planned eight to ten exploratory bore holes in 1966.

Petroleum.—Exploration was discon-

tinued in 1964, and none took place in 1965. Société de Participations Pétrolières (PETROPAR) allowed its 38,000-square-kilometer Djado permit to lapse on July 1, 1965, and planned interpretation and evaluation of data gathered in exploration.

According to the Direction des Mines, domestic consumption of major petroleum products, supplied wholly by imports, was as follows during 1964 and 1965, in thousand 42-gallon barrels:

Commodity	1964	1965
Aviation gasoline	22	23
Jet fuel	34	30
Motor gasoline	96	96
Kerosine	28	27
Distillate fuel oil	78	90
Total	258	266

RWANDA

Production of cassiterite, the principal mineral commodity of the Republic of Rwanda, showed a slight decrease in 1965, but most other minerals showed increases. Principal minerals produced and their export values during 1965 were as follows:

Commodity:	*Value* [1]
Beryl	$90,997
Cassiterite	2,530,190
Columbite-tantalite	40,998
Tungsten	58,547
Natural gas, methane	40,000
Total	2,760,732

[1] Where necessary, values have been converted from Rwandan francs (RF) to U.S. dollars at the unofficial rate of RF100=$1.

Considering that Rwanda has a fairly well-developed construction materials sector involving quarry operations and brick, tile, and pottery installations, it appears that minerals contributed about 2 percent of the GNP, which was estimated at $140 million in 1965.

Illegal traffic in gold, cassiterite, and the other metallic minerals was heavy and caused a substantial loss in revenue to the Rwandan Government. Regulations required deposit in the Banque Nationale of all foreign exchange earned from mineral sales. These funds were deposited to the seller's account at the official exchange rate (RF50=$1.00), which is about one-half of the free rate. This policy encouraged smuggling to Uganda, where the more favorable exchange rate was available.

Of a total labor force of 51,400, about 7,000 miners were employed in Rwanda at yearend.

PRODUCTION AND TRADE

Mining of beryl, columbite-tantalite, gold, cassiterite, and wolframite continued to be an important source of foreign exchange. Significant quantities of these minerals, including practically all gold, also were involved in illegal traffic across the border into Uganda, where higher prices were obtainable because of a more favorable exchange rate for the seller.

Table 20.—Rwanda: Production of metals and minerals [1]

e Estimate. NA Not available.

[1] Based mainly on exports; few production statistics are available.

[2] Includes small quantity of mixed cassiterite-columbite-tantalite concentrate.

Statistics reported by the Direction de l'Office Général des Statistiques indicate the following relationships between mineral and total trade during 1964 and 1965:

	Value (thousands)		Mineral commodities share of total trade (percent)
	Mineral commodities [1]	All commodities	
Exports:			
1964	$2,115	$5,776	36.6
1965	2,721	6,825	39.9
Imports:			
1964	1,283	6,004	21.4
1965	1,838	10,472	17.6
Trade balance:			
1964	+832	−228	XX
1965	+883	−3,647	XX

XX Not applicable.
[1] Includes only those commodities listed in table 21 of this section.

Cassiterite concentrate provided 93 percent of the foreign exchange earnings from minerals during 1965 and 96 percent in 1964. The main mineral imports and values in 1964 and 1965, respectively, were petroleum refinery products, $458,630 and $691,120; iron and steel, $380,730 and $553,480, and cement, $302,550 and $368,640.

Countries of origin and destination of Rwandan mineral trade were not reported, but most of this trade presumably involved Belgium and other countries of western Europe. Trade patterns developed during colonial times have not changed greatly since independence. Products have been specifically designed in these countries for mining companies in Rwanda and other central African countries.

COMMODITY REVIEW

Metals.—*Columbite - Tantalite.*—Production of concentrate was 49,550 kilograms at 42 percent columbium pentoxide and 28 percent tantalum pentoxide. This output was valued at $40,998 in the export market. Data on mining activity are lacking, but a large part of this output presumably was separated from mixed cassiterite concentrate by MINETAIN (formerly Société des Mines d'Etain du Ruanda-Urundi) at its Katumba plant. The company produced 315 tons of this mixed concentrate in 1964, compared with 235 tons in 1963.

Gold.—Most gold mined in Rwanda leaves the country illegally, although black-market placer gold has occasionally been offered for sale in the country. Output from various sources probably was 100 to 200 ounces annually. MINETAIN reported sales of 26 ounces to the Banque Nationale in 164.

Tin.—Cassiterite mining was approximately at the 1964 level, based on reported output. However, an estimated 20 percent of actual output, or about 30 tons per month, was smuggled across the border into Uganda. Details on mining activities were not available, but it appeared that the following companies were involved: MINETAIN, Compagnie Géologique et Minière du Rwanda (GEORWANDA), Société Minière de Muhinga et de Kigali (SOMUKI, and Compagnie de Recherches et d'Exploitation Minière (COREM).

[1] Sources and destinations were not reported.
[2] Includes small quantity of mixed cassiterite-columbite-tantalite concentrate.
[3] Includes unwrought and semimanufactures unless otherwise specified.

MINETAIN, a subsidiary of Union Minière du Haut Katanga, produced nearly 600 tons of cassiterite concentrate annually from 1963 to 1965 from several mining localities and its concentrator at Katumba. Mine development was underway to double production at Mount Kigali, where an average of 1.5 kilograms of cassiterite was recovered per cubic meter of alluvial material. The Rwandan Government owned 30 percent of MINETAIN.

GEORWANDA, a subsidiary of Géomines, North Katanga, Democratic Republic of the Congo (Léopoldville), operated the Rwinkwavu mine in the southern part of the Parc National. Output averaged about 25 tons of cassiterite concentrate monthly. The mine is the most mechanized in Rwanda, and production was rising. Crude ore is shoveled to a conveyor belt and undergoes washing, crushing, jigging, and shaking at the concentrator. Recovery was about 95 percent. According to the mine manager, reserves were 12,000 tons cassiterite at 800 grams per cubic meter of alluvium. The company employed 5 Europeans and 800 natives.[22]

Data on SOMUKI mining activities during 1965 were not available. The company is a subsidiary of Société Financière des Caoutchoucs, a large holding company with numerous interests, primarily in rubber plantations, and is partially owned (30 percent) by the Rwanda Government. Its Rutongo mine is situated 20 kilometers south of MINETAIN's Kigali mines.

COREM's mines at Nemba and Ntebe were managed by GEORWANDA. The mines were small producers but were considered to have good potential. Nemba produced an average of about 2 tons of cassiterite concentrate monthly from a lateritic zone in schistose rocks. An overhead cable bucket conveyor carries ore from the mine to a washing plant at Lake Rugwero. Dredging operations in the lake and nearby Nyabarongo Swamp were considered. At Ntebe, southeast of Kigali on the north shore of Lake Mugesera, the concentrate was produced by handpanning methods.[23]

About 1 ton per month was sold to the mining company; the remaining output apparently was smuggled to Uganda.

Tungsten.—The average grade of reported wolframite output was 68 percent WO_2, and output was valued at $58,547. MINETAIN produced 38 tons of ore and concentrate in 1964; data on other sources were not available. Activity apparently centered in the northwest, where the Bugarama and Kifurwe mines were reopened by private companies. Much output was stockpiled following the closure of the Cyanika-Kisoro border and the resulting loss of markets in Uganda.

Operators sought United States financing through sale, lease, or partnership at the Gahengere mine, Kigali. A proposal was made for a union of all producers in a cooperative company which would mine tungsten ore and produce tungsten metal and semifinished products.

Nonmetals. — *Construction Materials.* — Clay, sand and gravel, building stone, and lime were produced for building purposes, but no production data were reported. Brick, tile, and pottery plants were in operation. A 1964 United Nations study recommended a cement plant at Shangugu but, insofar as known, no further efforts were made to establish an industry. A quartzite deposit 40 kilometers from Kigali provided building stone for Kigali airport construction. Clay deposits derived from weathered basalt were investigated by the Direction des Mines in the Mibirizi area but appeared of limited extent.

Mineral Fuels.—*Natural Gas.*—Methane, dissolved in deep waters of Lake Kivu, reportedly was produced but details were not available. One source reported sale of 1 million cubic meters 35 million cubic feet) at a price of 4 cents per cubic meter. Authorities reported reserves of 57 billion cubic meters.

SOMALI REPUBLIC

Mineral production did not gain in importance in the Somali Republic during 1965 and remained confined to limestone, meerschaum, and salt. Total value of these products was not reported but probably did not exceed $200,000, so that mineral

[22] U.S. Embassy, Kigali. Department of State Airgram AID A–20, Sept. 27, 1965, 5 pp.
[23] U.S. Embassy, Kigali. Department of State Airgram AID A–22, Oct. 18, 1965, 3 pp.

industry contribution to the GNP of approximately $100 million was inconsequential.[24]

The Somali Government continued to encourage mineral investment in the country. Petroleum exploration concessions included duty free provisions, generous provisions for renewal, and a 50 : 50 split of profits realized between the Government and the concessionaire. A United Nations Special Fund mineral survey, underway for 3 years, made progress toward delineating iron ore deposits in the Baidoa region and continued in other known mineralized areas.

PRODUCTION AND TRADE

In addition to known production activity for salt and meerschaum, the Somali mineral industry probably also produced clay, sand and gravel, limestone, and other construction materials for local use. Quantitative data on output are available only for salt; available recorded production and estimates from 1961 to 1965 have been as follows:

	Metric tons
1961	2,000
1962	e 2,000
1963	2,200
1964	5,581
1965	e 5,000

r Revised.

Most metals and minerals were imported for domestic markets. Principal mineral imports during 1964, the latest year for which complete data were available, were iron and steel, $1.5 million ($1.7 million in 1963); petroleum refinery products, $2.4 million ($1.9 million in 1963); and cement, $930,000 ($534,000 in 1963).

Mineral exports were negligible and included small quantities of iron and steel scrap. Iron and steel semimanufactures, cement, and nonferrous metals were reexported on a small scale.

Trade, as shown in the accompaning table, was differentiated by region in offi-

[24] Where necessary, values have been converted from Somali shillings (SoSh) to U.S. dollars at the rate of 1 SoSh=US$0.14.

cial statistics of the Central Statistical Office. A large part of both mineral and total trade involved the Southern Region.

COMMODITY REVIEW

Metals.—*Iron Ore.*—Deposits in the Bur Dur and Bur Galan hills, near Baidoa, which have been under investigation by a United Nations survey team for 3 years, have not been exploited. Latest reserve estimates indicated the presence if two 100-million-ton deposits with grade of 42 percent iron.

Iron and Steel.—On October 14 President Aden Abdulla Osman inaugurated Fersomala S.R.L., Somali's first steel plant. This plant produces reinforcing rods from scrap. The production rate is 20 tons per day. Twenty Somalians and 8 Italians were employed at the plant.

Other Metals.—Possibly exploitable deposits of several metals occur in the northern mountainous region and in the Baidoa-El Bur area. Occurrences include minerals containing beryllium, bismuth, columbium-tantalum, cobalt, copper, lead-zinc, manganese, molybdenum, nickel, tin, and titanium.

Nonmetals.—*Cement.*—Imports from the U.S.S.R. and Kenya increased substantially. Proceeds from the sale of Soviet cement were loaned to the Somali Government for use in financing Soviet aid projects. Cement provided by Kenya originated at the Mombasa cement works.

The possibility was considered of constructing a cement plant in the Berbera area, where deposits of limestone and clay are known, but no definite project had materialized by yearend.

Gypsum.—A report by a United Nations survey team in 1963 indicated that a high-quality deposit of gypsum and anhydrite, about 30 kilometers from the port of Berbera, has reserves adequate to support a 200,000-ton-per-year mining rate for 50 years. However, further exploration was necessary for an accurate reserve estimate. The Somali Government attempted to arrange financing for this exploration and

for an engineering and feasibility study of the deposit. Foreign markets also were sought, particularly to the east. If markets are found, the Somali Government hoped to obtain international financing for mining and processing facilities.

Meerschaum.—Deposits of good-quality meerschaum, with low density and high porosity, near the town of El Bur, have several potential industrial uses. Interest in Somali meerschaum has increased as supplies from other world sources reportedly were dwindling. Traditional Somali artisans and one manufacturer of crude and semifinished smoking pipes used minor quantities. One official estimate placed annual production at 20 tons to 30 tons. Reserves have not been definitely established but were believed to total several million tons.

A small quantity of meerschaum was exported to the United States for use in the manufacture of pipes and accessories. The Somali Government reported that a British firm may take several thousand tons annually for use in drilling muds.

Salt.—Salt production continued almost entirely for the domestic market with small quantities exported. Output was not reported, but total output of Gezira, Zeila, and numerous other coastal evaporation basins was about 5,000 tons per year.

The Somali Government sought foreign assistance in reactivating the Hafun saltworks where an annual output rate of 200,000 tons ceased in 1941. An Italian firm reportedly expressed interest in performing a detailed feasibility study at this site, but no agreement had been reached at yearend.

Other Nonmetals.—Limestone and sandstone were quarried for construction uses, but production was unrecorded. A small marble deposit was discovered at Bur Acaba, near Mogadiscio, and may be used for construction in the capital area.

Occurrences of feldspar, fluorspar, kaolin, mica, and talc were under investigation by Government agencies.

Mineral Fuels.—*Petroleum.*—Late in 1965, interest in oil exploration appeared to be waning. Somali Gulf Oil Co., following similar action taken by Mobil Petroleum Co. in 1964, discontinued operations and relinquished its concession, effective at yearend. Sinclair Somal Oil Co. also considered withdrawal from Somalia but discovered gas, although not in commercial quantities, at its Afgoi No. 1 well in December and apparently decided to renegotiate its contract with the Somali Government.

U.S. companies spent $30 million in oil exploration to the end of 1964, and British and Italian firms spent $15 million before leaving the country. From 1957 to 1965, 28 unsuccessful wells were drilled by the following companies: Sinclair 15, Mobil 7, Azienda Generale Italiana Petroli (AGIP) Mineraria 4, and Gulf 2.

Sinclair completed two dry wildcat wells at depths of 13,537 feet and 13,349 feet and, at yearend, was drilling its third well at 31,660 feet. The company also completed a 10-month seismic survey. In May, half of the original concession was relinquished.[25]

Somali Gulf, the only other company actively engaged in drilling during the year, plugged and abandoned its first wildcat well, 53 kilometers west of Afmadu, at a depth of 9,405 feet. A second wildcat, started in March, 45 kilometers to the northwest, was abandoned at 10,110 feet.

Based on imports, the domestic market apparently absorbed 350,000 to 400,000 barrels of refinery products yearly during 1963 and 1964, the latest years for which data were available. AGIP Mineraria supplied all products in the south from its Mogadiscio terminal. Shell Oil Co. imported all refined products in the north and supplied retailers from its Berbera depot.

SPANISH SAHARA

Progress apparently was made toward partnerships and development of the large phosphate deposit at Bou-Craa, about 100 kilometers southeast of l Aaiún in the Province of Sahara. However, most details on activities during the year remained of a confidential nature; little information on the deposit and negotiations for its development were made available to the public.

Discovery of the phosphate basin was made by Empresa Nacional Minera del Sahara, S.A. (ENMINSA), the Spanish national company, during geological investigations in May 1963. ENMINSA conducted exploration, including 473 drill holes and 244 pits and trenches, during 1963–64. Data

[25] Page 1735 of work cited in footnote 5.

released indicated ore reserves exceeding 1 billion tons and grade of about 70 percent bone phosphate of lime, amenable to open pit development.

At yearend, negotiations for partners and construction contracts were underway, largely clouded in secrecy. ENMINSA contacted U.S. and other companies of the Western industrialized nations having financial resources and technical skills.

TOGO

The Republic of Togo's mineral industry remained dominated by the mining of phosphate rock. According to the Direction des Mines, output value of this commodity was $10.7 million, making it an important contributor to a GNP of about $150 million. In 1965 Togo produced 1.5 percent of the world supply of phosphate rock. Togo followed Morocco and Tunisia and ranked about on a par with Senegal among African producers. At yearend, the phosphate industry employed 1,050, including 883 miners and laborers.

In October Davison Chemical Corp., a division of W. R. Grace and Co., which holds a substantial interest in the phisphate property, planned a feasibility study for a fertilizer plant in Togo.

The United Nations Special Fund sponsored a mineral exploration program, which will be in effect until mid-1967. As a result of this survey, limestone perhaps suitable as a basis for a cement industry, was discovered near Lomé.

The first 5-year development plan (1966–70), adopted in July by the National Assembly, contained proposals for brick, cement, and fertilizers plants, marine salt production, and a small metal-working establishment. A new investment code improved an already good investment climate. New benefits included exemption from taxes on exports, imports, and profits; accelerated depreciation allowances; and guaranteed availability of foreign exchange.

PRODUCTION AND TRADE

As in previous years, phosphate rock was Togo's only recorded mineral product, although small quantities of simple construction materials such as clay, sand, gravel, and stone were presumably extracted for local use.

Output of salable phosphate rock has been reported as follows:

Year	*Metric tons*
1961	117,897
1962	193,000
1963	587,500
1964	r 752,000
1965	973,635

r Revised.

Togo's mineral trade was characterized by export of phosphate rock and import of iron and steel, cement, and petroleum refinery products. Phosphate rock accounted for essentially all export earnings from minerals. Its significance as an earner of foreign exchange and as a favorable influence on a continued unfavorable trade balance is indicated in the following tabulation:

	Value (thousands)		Mineral commodities share of total trade (percent)
	Mineral commodities [1]	All commodities	
Exports:			
1963	$4,396	$18,265	24.1
1964	7,942	30,173	26.3
1965	8,714	27,056	32.2
Imports:			
1963	4,868	29,031	16.8
1964	4,795	41,664	11.5
1965	4,888	44,963	10.9
Trade balance:			
1963	−472	−10,766	XX
1964	+3,147	−11,491	XX
1965	+3,826	−17,907	XX

XX Not applicable.

[1] Includes only those commodities listed in tables 24 and 25 of this chapter.

These values are from European Economic Community (EEC) sources and are substantially less for phosphate rock than values quoted by the Togolaise Direction des Mines. According to the EEC, value of phosphate rock exports was $7,891,000 in 1964 and $8,690,000 in 1965. Principal mineral imports were iron and steel, $1.5 million ($1.6 million in 1964); cement, $1.2 million ($742,000 in 1964); and petroleum products, $1.5 million ($1.8 million in 1964).

[1] Includes unwrought and semimanufactures unless otherwise specified.

[2] For details on specific commodities included, see section on source materials.

COMMODITY REVIEW

Nonmetals.—*Limestone.*—Discovery of a large limestone deposit near Lomé was reported. This could form the basis for a cement industry in Togo.

Phosphate Rock.—Expansion continued at the Hahotoe mine of Compagnie Togolaise des Mines du Bénin (CTMB). The 1965 output of 973,635 tons of marketable dry phosphate rock at a grade of 80 to 81 percent bone phosphate of lime was derived from 1,963,309 tons of crude rock, according to the Direction des Mines. Annual capacity was expanded to 1.2 million tons of marketable product with addition of a third washing line in August at the Bpeme processing plant, 22 railroad kilometers from the mine. New equipment planned during the year included a wheel excavator, a stacker-loader, and a power shovel. Total investment was estimated at $30 million.

In 1965 phosphate rock was shipped to 12 countries, mainly France (237,858 tons), the Netherlands (231,034 tons), Australia (135,444 tons), Japan (113,011 tons), and Italy (90,585). Other recipients, in order of tonnage received, were Belgium, West Germany, the United States, the United Kingdom, Brazil, Sweden, and Uruguay.

Mineral Fuels.—*Petroleum.*—There was little interest and no activity in oil exploration during 1965.

Storage tank capacity for gasoline, distillate fuel oil, and lubricants was approximately doubled with construction of a second depot, 8 kilometers east of Lomé, by Société Togolaise d'Entreposage (STE). This new company is a consortium of the following five petroleum companies: British Petroleum Ltd., Compagnie Française de Distribution des Pétroles en Afrique, Mobil Oil Co. of West Africa, Shell Oil Corp., and Texaco Africa Ltd. Late in 1964, AGIP Mineraria had opened a storage depot 30 kilometers east of Lomé, using a pipeline from the phosphate-loading pier.

Estimated capacity of these storage facilities by product at yearend was in thousand 42-gallon barrels:

Product	AGIP	STE
Gasoline	20	19
Distillate fuel oil	12	19
Lubricants	9	13

UPPER VOLTA

The mineral industry of the Republic of Upper Volta remained small and was a minor contributor to the overall economy. Value of the limited mineral output was not reported but was on the order of $1.5 million, based on estimates for gold, gold-bearing materials, and construction materials such as clay, sand, gravel, stone, and brick, produced for small local consumption. The GNP was estimated to be $212 million.

United Nations Special Fund and United States Agency for International Development (AID) assistance continued in hydrogeological and mineral investigations. United Nations studies involved a ground water survey south and southeast of Ouagadougou and gold, copper, diamond, and other mineral studies in the Gaoua region. This was a $1.7 million project of which the United Nations provided 58 percent.

The French national company BRGM conducted an airborne geophysical survey and anomaly study in the east, geological work in the east and southwest, and investigations for diamonds along the Volta Noire and Comoe Rivers. Other nations (ECC countries, the United States, Japan, Israel, and Taiwan) also were involved in development projects and technical assistance.

PRODUCTION AND TRADE

Gold mining at Poura, the only active mining operation recording production in Upper Volta, showed little change from prevoius activities. No new reserves were established, and it appeared that closure of the mine was imminent. Although no quantitative data are available, simple construction materials and small numbers of bricks were produced for local use. Output of crude gold, approximately 75 percent

fine, from amalgamation at Poura was as follows in recent years:

	Troy ounces
1961	15,497
1962	39,770
1963	44,786
1964	r 32,665
1965	34,468

r Revised.

Upper Volta's principal mineral exports were crude gold and gold-bearing materials from Poura mining and amalgamation. Iron and steel semimanufactures and petroleum refinery products were reexported.

Main mineral imports during 1964, the latest year for which complete data were available, were iron and steel semimanufactures, $1 million ($1.2 million in 1963); petroleum products, $1.4 million ($1.3 million in 1963); and cement $546,000 ($603,000 in 1963). These materials comprise a significant share of total trade, as indicated in the following:

	Value (thousands)		Mineral commodities share of total trade (percent)
	Mineral commodities [1]	All commodities	
Exports:			
1963	r $314	r $9,317	3.4
1964	244	12,172	2.0
Imports:			
1963	r 3,771	36,997	10.2
1964	3,654	39,674	9.2
Trade balance:			
1963	r −3,457	r −27,680	XX
1964	−3,410	−27,502	XX

r Revised. XX Not applicable.
[1] Includes only those commodities listed in tables 26 and 27 of this chapter.

These totals do not include gold, which traditionally goes to Paris markets. At world prices, this gold presumably was valued at about $1.2 million.

COMMODITY REVIEW

Metals.—*Gold.*—The Poura mine, 175 kilometers southwest of Ouagadougou, continued operations at a rate similar to that of 1964. Established reserves were further depleted, and Société des Mines de Poura, which has operated at a loss in recent years, expected to terminate operations in 1966. Average gold content of ore was 0.5 troy ounces per ton.

Essentially all crude gold, 34,273 ounces in 1965, went to Paris for sale. Metallurgical rejects from Poura were exported mainly to Sweden for processing and reimported as fine gold.

Manganese.—Progress was made toward development of the Tambao deposit, Oudalan Province, 360 kilometers northeast of Ouagadougou. This deposit was discovered in 1960 by the BRGM, which subsequently established a substantial reserve. The deposit comprises two steeply dipping lenticular ore bodies. Workings include two exploratory adits, each intersecting the ore bodies.

Japanese interest, representing five Japanese companies, and African Manganese Co., the British subsidiary of Union Carbide Corp., negotiated for joint development of the deposit. The Japanese sent a 15-man survey mission, which concluded that ore reserves exceed 15 million tons of 48 to 53 percent manganese. Final negotia-

[2] For details on specific commodities included, see section on source materials.

tions were underway at yearend. An investment of $26.5 million was envisioned, including a 216-kilometer railroad extension to the property.

A loan for construction of transportation facilities was sought through the International Bank for Reconstruction and Development. The Government requested United Nations Special Fund assistance in a feasibility study and exploration in 1966.

SOURCE MATERIALS

Principal sources of information on metal and mineral production and on exploration, mining, metallurgical, and petroleum activities were professional journals and dispatches from U.S. embassies and other U.S. Department of State posts located in the countries discussed in this chapter. Of particular use were annual minerals reports from L. M. Rives, Bujumbura, Burundi; J. P. Ferriter, Nouakchott, Mauritania; R. S. Thompson, Niamey, Niger; and A. M. Hardy, Mogadiscio, Somali Republic.

Trade data for the most part were derived from European Economic Community (EEC) volumes on overseas associates in Africa; for Rwanda and the Somali Republic, official trade statistics of the respective governments were used. The EEC sources include several general reporting categories, each of which encompasses a number of mineral commodities. The following table indicates items included within each category:

Descriptive category used in trade tables in this chapter	SITC category number [1]	Full list of items included
Abrasives, natural	275	Industrial diamonds; dust and powder of natural or synthetic precious or semiprecious stones; infusorial earths; pumice stone; emergy; natural corundum and other natural abrasives.
Cement, lime, and other building materials.	661	Cement (all types); lime; worked building and monumental (dimension) stone; asbestos cement and fiber cement building materials including vegetal substances agglomerated with mineral binding substances; asphalt building materials.
Clay construction materials	662	Refractory bricks and other construction materials of infusorial earths, kieselguhr, and siliceous earths, other; refractory bricks; refractory cements and mortars; nonrefractory ceramic bricks, tiles, pipes and similar products including roofing tiles, ceramic piping, unglazed tile and glazed tile.
Stone, sand, and gravel	273	Building and monumental (dimension) stone, not further worked than roughly split, roughly squared or squared by sawing (including sandstone, slate, marble, limestone, granite, porphyry, and others); gypsum plasters; limestone flux; calcareous stone used for manufacture of lime and cement; sand (excluding metal-bearing sand); gravel and crushed stone (including tarred macadam).
Nonmetallic minerals, crude, unspecified.	276	Natural asphalt and bitumen; clays and other refractory minerals including graphite, dolomite and magnesite; salt; asbestos (crude washed or ground, including asbestos waste); mica; feldspar; fluorspar; cryolite; chiolite; natural quartz; quartzite; slag, dross, scalings and similar waste from iron or steel manufacture (except Thomas slag); chalk; earth colors; barite; witherite; meerschaum; amber; jet; steatite; talc; natural arsenic sulfides; crude borate minerals; and others not specified.
Nonmetallic mineral manufactures.	663	Abrasive products such as grinding wheels, grinding stones, abrasive cloths, and abrasive papers; worked mica, mineral insulating materials other than in the crude mined state; articles made of plaster, cement, concrete or artificial stone; refractory products other than refractory construction materials; asbestos manufactures; and ceramic materials, not elsewhere listed, including laboratory and industrial ceramic products.

[1] Standard–International Trade Classification categories, as outlined in Standard Industrial Trade Classification Revised. Statistical Papers Series M, No. 34, Statistical Office of the Department of Economic and Social Affairs, United Nations, New York, 1961, 135 pp.

Although a wide variety of items is included in each group, it is unlikely that many items were actually involved in trade. Category 661 probably involved mainly cement; and category 662, mainly simple brick, tile, and ceramic piping. Trade in other categories may include one or several commodities.

Estimates on dollar value for GNP of each country were derived from Overseas Business Reports, Market Indicators for Africa, and Market Profiles for Africa, published by the Bureau of International Commerce, U.S. Department of Commerce.

Regional Mineral Industry Review of the Near East

By James A. West [1]

Near East region countries continued to supply a large share of the world's energy requirements in 1965. The area accounted for nearly 27 percent of estimated total world crude oil output and for about 60 percent of world exports of this commodity. Also, it was the source of more than 40 percent of the world's petroleum refinery products exports. Although other mineral industry activities remained relatively insignificant in comparison with petroleum, regional production and export of certain metallic and nonmetallic mineral commodities were of world significance. Of these commodities, chief in importance were chromium, copper, mercury, antimony, boron, potash, and phosphate rock.

The Near East region contains the largest and most productive oil resources in the world. Petroleum exploration and development operations during 1965 resulted in crude oil reserve additions of almost 8 billion barrels to increase proved reserves to 219 billion barrels at yearend, an amount equal to nearly 68.5 percent of the world's proved oil reserves. Near East countries' production of crude oil averaged a record 8,337,575 barrels per day in 1965, an increase of nearly 11 percent over that of 1964. On an annual basis, Kuwait continued as the leading oil producer in the Near East; however, Saudi Arabia was a close second and its rate of production in late 1965 exceeded that of Kuwait. The major oil producing nations and their percentage of total area crude oil output was Kuwait, 26.0; Saudi Arabia 24.3; Iran, 22.3; and Iraq 15.9.

In 1965, petroleum remained the dominant industrial activity of the Near East and continued to have a pronounced impact on economic, social, and political developments in the region. Crude oil and refinery products production was valued at an estimated $5,536 million, accounting for almost 22 percent of the combined gross national product (GNP) of all countries in the Near East region. Regional governments received an estimated $2,434 million in revenues from the petroleum industry. Also, it was the principal source of foreign exchange that resulted in a favorable trade balance of an estimated $2,000 million in 1965.

The most significant petroleum industry developments in the Near East in 1965 were the increased offshore exploration activity in the Persian Gulf that resulted in major new oilfield discoveries; the continued development of previously discovered oilfields in the Persian Gulf; the rapid emergence of the Sheikdom of Abu Dhabi as a prolific oil producer; and the completion of the world's largest crude oil shipment terminal at Kharg Island in the offshore area of Iran.

Negotiations between oil concessionaires and the Governments of Iraq and Kuwait continued in 1965. A tentative agreement was reportedly reached between the Government of Iraq and the Iraq Petroleum Companies group on the long-standing dispute concerning the relinquishment of concession areas. However, at yearend the accord had not been submitted to the Iraqi Parliament to obtain the required ratification. The Kuwait National Assembly did not ratify a 1964 agreement with Kuwait Oil Co. providing for expensing of royalty oil payments and changes in tax accounting procedures. The agreement was reached as a result of negotiations between major oil concessionaires and country members of the Organization of Petroleum Exporting Countries (OPEC), a semiofficial organization representing the Near East

[1] Chief specialist, Near East and South Asia, Division of International Activities.

countries of Kuwait, Saudi Arabia, Iran, Iraq, and Qatar. The OPEC agreement was ratified by the Governments of Saudi Arabia, Iran, and Qatar.

Continuing the trend of recent years, Near East Governments increased their share of participation in petroleum industry operations and earnings in 1965. All new oil concessions and most industrial development projects, such as petrochemical and refinery construction, were awarded only on a joint venture basis with Government-owned national companies having majority equity. The concessionaire provides essentially all risk capital, and the Governments are assured a minimum of 75 percent of profits under equity and tax provisions.

Table 1.—Near East: Salient statistics of the petroleum industry in 1965

Country	Production (thousand 42-gallon barrels)		Exports (thousand 42-gallon barrels)		Estimated reserves (million 42-gallon barrels)	Estimated revenue to Government (million dollars)	Estimated value of production (million dollars)	GNP [1] (million dollars)

e Estimate.
[1] In current prices.

Aside from petroleum, Near East countries continued to produce and export important quantities of certain metals and nonmentals during 1965. Turkey and Iran remained large producers of chromite and increased chromite output in 1965 over that of 1964 by 37.5 and 25 percent, respectively. The combined chromite output of Near East countries was nearly 15 percent of world production. Other significant metals produced in the region and percent of 1965 world output were as follows: Antimony, 3.4; copper, 1.2; and mercury, 1.0. Certain nonmetallic minerals produced in regional countries were of world significance. Turkey increased its production of boron minerals by nearly 31 percent and continued to account for about one-sixth of the total world output. Potash production in Israel and phosphate rock produced in both Israel and Jordan accounted for 2.3 and 1.8 percent of the world output of these fertilizer raw materials in 1965. The gross value of polished diamond exports from Israel reached $138 million in 1964, ranking Israel third among world diamond processors.

The Governments of the Near East region implemented and expanded programs for the development of mineral resources other than petroleum. The Governments of Iran and the U.S.S.R. entered into an agreement for the construction of Iran's first integrated iron and steel mill. Soviet technical and financial assistance for the steel mill is to be repaid by Soviet purchase of Iranian natural gas. Iran plans to construct a pipeline system to transport natural gas to major Iranian cities and to the Soviet border. In Saudi Arabia, the Government expanded and initiated new projects to explore and assess mineral resources

in the northeast area of the country where recent surveys indicated potentially significant deposits of iron ore, gold, silver, copper, barite, phosphate, and other minerals. Israel increased the capacity of its Dead Sea works to produce potash. In Jordan, progress was made on projects to develop mines, roads, and port facilities to increase phosphate rock output. All units of Turkey's new Eregli steel plant became fully operational during 1965.

Near East countries continued to make an important contribution to world mineral trade. The area supplied about one-half of total world exports of crude oil and petroleum products in 1964. In general, area countries were dependent on imports for most metallic and nonmetallic minerals needed for their growing economic development. On the basis of official trade statistics available for 1964, supplemented by estimates where necessary, the relative significance of mineral trade to total trade for the whole region is shown in the following tabulation:

Near East: Mineral trade balance in 1964

	Value of mineral trade (million dollars)	Value of total trade (million dollars)	Share of mineral trade to total trade (percent)
Exports	5,226	6,456	81
Imports	1,076	4,424	24
Trade balance	+4,150	+2,032	--

The contributions of each of the major mineral commodity categories to total minerals trade in 1964 was as follows:

	Value of imports (million dollars)	Value of exports (million dollars)
Metals	400	60
Nonmetals	278	172
Fuels	398	4,994
Total	1,076	5,226

The Mineral Industry of Bahrain

By James A. West [1]

Petroleum refining and production continued as the major industrial activity and only significant mineral industry of Bahrain in 1965. A substantial increase in indigenous crude oil production, a new offshore oil concession award, completion of facilities required to place the offshore Abu Safah field in production, and increased exploration activity were the most notable oil industry developments affecting Bahrain this year.

Although crude oil production from the single oilfield on the island increased by 15.5 percent over that of 1964, Bahrain continued to account for less than 1 percent of Middle East oil production in 1965. As in recent years, Bahrain continued as a major oil refining center in the Middle East and accounted for about 7.5 percent of the production and 6 percent of the exports of petroleum refinery products from this area during 1965.

In 1965, the petroleum industry contributed an estimated $34 million to the Bahrain economy. It was the direct source of nearly 80 percent of all government revenue and provided about 90 percent of foreign exchange earnings. The industry employed about 5,000 Bahraini personnel and 1,000 persons of other nationalities.

In September 1965, the Government awarded an oil concession to the Continental Oil Co. (CONOCO) on offshore areas previously relinquished by Bahrain Petroleum Co. (BAPCO), an affiliate of Standard Oil Co. of California and Texaco, Inc., that until then was the sole petroleum concessionaire in Bahrain.

The Governments of Bahrain and Saudi Arabia completed arrangements for placing the offshore Abu Safah field on production at a rate of 30,000 barrels per day, beginning on January 1, 1966. The field is in an offshore area where each Government has agreed to jointly share oil revenues before oil development.

PRODUCTION

For the second consecutive year, a significant gain in crude oil production was realized from the Bahrain field, the only producing field on the island. Output during 1965 was 15.5 percent greater than that of 1964 and 26 percent greater than that of 1963. Output of petroleum products from the BAPCO refinery in 1965 declined 4.7 percent from that of 1964. Although all indigenous production is processed, crude oil imported by pipeline from Saudi Arabia continued to supply more than two-thirds of the feedstock for the refinery.

Residual fuel oil	31,483	34,827	33,362	27,682	27,534
Other	1,150	379	187	740	837
Total	74,257	82,935	79,080	70,939	67,621
Refinery fuel and loss	5,632	5,745	5,608	8,361	6,737

[1] In addition to commodities listed, small quantities of construction materials are produced, but quantitative data on output are not available.

TRADE

Refined petroleum products, having an estimated gross value of $175 million, continued as the only significant mineral export of Bahrain during 1965.

Imports of Saudi Arabian crude oil continued the downward trend of recent years because of reduced refinery runs and increased Bahrain crude oil production.

Bahrain continued in its traditional role as a major trading center in the lower Persian Gulf area. Available statistics for 1964 show that all imports, excluding petroleum, were valued at $78 million and that reexports were valued at $24 million. Limited information suggests that the value of mineral and metal imports was about 5 percent of the total.

COMMODITY REVIEW

MINERAL FUELS

Petroleum and Natural Gas.—The offshore concession awarded to CONOCO consists of two areas comprising approximately 600,000 acres. The largest is north-northwest of Bahrain island and adjoins CONOCO's offshore Qatar concession. The smaller is an irregular area surrounding Huwar Island to the south of Bahrain. Detailed terms of the agreement have not been announced, but they conform generally to those of other recent agreements in the area except that there is no participation by the Government in the operating company.

Oil exploration activity increased markedly during 1965. BAPCO conducted seismic surveys on Bahrain, on Umm Nasan and Sitra Islands, and adjoining marine areas. Also, BAPCO drilled a deep exploration well on the west coast of Bahrain 4.5 miles south of Zallaq. The well was plugged and abandoned because no commercial oil was discovered. CONOCO began marine seismic surveys on its new concession areas and the initial surveys were being evaluated at yearend.

The Arabian American Oil Co. (ARAMCO) completed facilities to place the Abu Safah offshore field on production at 30,000 barrels per day. The Governments of Bahrain and Saudi Arabia will share equally in profits from the field. Six wells were connected to a central production platform and a 31-mile 18-inch-diameter submarine pipeline to transport production from the platform to ARAMCO's Ras Tanura terminal was completed.

All oil production was from the Bahrain field which was discovered in 1932. The field attained a record output in excess of 60,000 barrels per day in the last quarter of 1965. This increase was largely a result of infill drilling and the installation of high-capacity pumping units on several wells.

Proved crude oil reserves were reported [2] as 230 million barrels at yearend.

The BAPCO refinery operated at about 80 percent of capacity, processing crude oil at an average rate of 196,340 barrels per day.

An estimated 20 million cubic feet per day of natural gas was utilized as fuel by the Government-owned powerplant at Manama. Lesser quantities were utilized for reinjection, gas lift, and other field operations.

[2] Oil and Gas Journal. V. 63, No. 52, Dec. 27, 1965, p. 83.

The Mineral Industry of Cyprus

By E. Shekarchi [1]

Minerals remained one of Cyprus' most important resources, accounting for about 34 percent of its total export. Copper concentrates, pyrites, chromite, and some nonmetals, such as asbestos, gypsum, and mineral pigments, continued to be the principal source of foreign exchange. Directly, mining contributed 8 percent to the estimated 1965 gross national product (GNP) of $348 million.[2]

The largest company, the U.S.-owned Cyprus Mines Corp., produced between 60 and 70 percent of the island's mineral output. Of the total labor force, 2 percent, or approximately 5,500 people, were employed in mining and quarrying operations. The total population of Cyprus showed an annual growth of 1 percent at the end of 1964. The GNP based on 1962 prices was estimated at about $348 million in 1965, a drop of about 4.4 percent from the $364 million recorded for 1963.

Both consumption and investment decreased, and unemployment increased in 1964. The island's per capita gross national product, based on 1962 prices, decreased about 4 percent from the highest level in 1963.

Agreements were signed between the Governments of Cyprus and the U.S.S.R. which provided for the exchange of goods manufactured in the participating countries. Under these agreements in 1965, 1,000 long tons of iron and steel rolling-mill products, 25,000 long tons of cement, and 3,000 long tons of superphosphates were to be delivered to Cyprus. It was expected that these figures would be increased to 1,500, 3,000, and 50,000 tons, respectively, by 1967.

After 2½ years of investigation, Parliament, on July 30, 1965, ratified the creation of a refinery, the largest single foreign capital investment since Cyprus became independent. The Cyprus Government and a Consortium composed of subsidiaries of the Royal Dutch/Shell group, British Petroleum Co. Ltd., and Socony Mobil Oil Co. Inc. will participate on a 50–50 basis in a refinery to be located at Larnaca. The initial capacity is to be 500,000 tons per year, but it is hoped that by 1975 it will have been expanded to supply all of the island's needs.

The Cyprus Geological Survey Department reportedly organized a drilling crew in 1964 and commenced drilling in an area southwest of Nicosia with two government-owned rigs. Drilling operations at Kato Moni, Potami, Pera, and Nikitari resulted in completion of six holes with a total footage of 3,350. Four successful holes yielded from 850 to 4,300 barrels of oil per day.

The only mineral exploration drilling in 1965 was in the Ayios Ioannis area; a small rig found disseminated chalcopyrite at a depth of 70 feet. A second hole drilled in Kambia encountered no economically significant mineral zone.

PRODUCTION

The 1965 value of Cyprus' mineral production totaled about $30 million, about 20 percent higher than values of 1962. Since the cessation of political disturbances, mineral production generally seemed to return to the 1962 level. Among the metals, copper and chromite production in 1965 showed increases of 57 percent and 66 percent, respectively, compared with that of 1964. Of nonmetals, noticeable increases shown included those of 35 percent in crude gypsum and 142 percent in lumber production.

[1] Foreign mineral specialist, Division of International Activities.

[2] Where necessary, values have been converted from Cyprus pounds (C£) to U.S. dollars at the rate of C£.357143=US$1.00.

TRADE

The importance of mineral commodity trade in the total trade of Cyprus in 1964 is illustrated in the following tabulation:

Cyprus: Mineral trade balance in 1964

	Mineral trade value (million dollars)	Total trade value (million dollars)	Share of total trade accounted for by mineral trade (percent)
Exports	20.0	58	34
Imports	18.8	109	20
Trade balance	1.2	51	XX

XX Not applicable.

A large portion of the total exports, approximately $13 million, resulted from the sale of metals, while nonmetals brought only $7 million. Among nonmetals, pyrites accounted for the highest share, approximately $4 million. Barter arrangements for Cypriot chromite were concluded with Czechoslovakia and Bulgaria during 1965.

Of the total value of mineral imports, mineral fuels, metals, and nonmetals accounted for $8.8 million, $5.3 million, and $4.7 million, respectively.

Historically, the United Kingdom and West Germany have supplied the iron and steel demands of Cyprus which totaled approximately $4.5 million. However, under a trade agreement signed in 1965, the U.S.S.R. became a main supplier during 1965 and will continue until 1967. The agreement was based on barter arrangement rather than on hard currency payment. Cyprus will receive mineral commodities in exchange for nonmineral commodities.

COMMODITY REVIEW

METALS

Chromite.—Exports of chromite in 1964 more than doubled those of 1963 because world marketing conditions were better, although prices remained relatively low. In a barter agreement signed between the Governments of Cyprus and Czechoslovakia in February 1965, chromite was specifically mentioned as one of the raw material exchange items. A similar agreement was signed between the Governments of Cyprus and Bulgaria on April 19, 1965.

During 1964 Hellenic Mining Co. of Cyprus acquired the Cyprus Chrome Co. holdings which had been idle for several years. It appears that production as well as export of chromite in Cyprus is on an upswing after the very low production level in 1964.

Copper.—Two major copper producing companies, Cyprus Mines Corp. (CMC) and Hellenic Mining Co., were active during 1965.

Since the end of World War II, CMC has both extended the volume of its operations and incorporated a number of improved techniques in its ore treatment processes. Entirely dependent on exports, CMC has shipped its products to seven countries in Western Europe. High-grade nonarsenical flotation pyrites, of which CMC has been Europe's largest supplier,

have been delivered at an annual rate of between 500,000 and 600,000 tons.

Stripping of the Skouriotissa ore body, which began in 1962 in preparation for the foreseen decline in production of the Movrovouni ore body, continued in 1965, and full production was maintained.

As a result of a research program undertaken by Battelle Memorial Institute in the United States and Lurgi G.m.b.H. in West Germany, a technique was perfected by which excellent pyrite pellets can be produced from Cypriot pyrite flotation concentrate. However, no decision was taken to enter into pellet production, because the sulfur price level was uncertain.

The Hellenic Mining Co., which has been mining in Cyprus since 1948, transferred all company interest to the Greek Community of Cyprus in 1964. The production of Hellenic Mining Co. has come from two mines, Kalovassos and Tamassos. Most of the Kalovassos mine output comes from several small underground veins. Tamassos mine is one of the largest open pit operations in Cyprus. It yields noncupreous pyrites which are treated in the nearby Mitsero mill (capacity 3,600 tons per day) and shipped from Karavostassi, one of the most modern ports on the Mediterranean. At the port, 1,000 tons per hour can be loaded, and water depth at pierhead is 10 fathoms, permitting vessels of any size to dock.

NONMETALS

Asbestos.—The island's only asbestos mine, situated in the Greek Cypriot belt of the Troodos Mountain, produced about 14,300 metric tons in 1965 or 2,300 tons more than the 1964 production.

Lime.—Production of lime in 1965 has declined almost threefold from the peak year of 1963 because of the sluggishness of the country's construction industry.

The Mineral Industry of Iran

By E. Shekarchi [1]

Iran's mineral industry, marked by increased production of petroleum, chromium, manganese, and many nonmetallic minerals, set new records in 1965. Among crude petroleum producing nations, Iran, ranked sixth, and in the Middle East, it ranked third, after Kuwait and Saudi Arabia. With the expansion of chromite production, Iran has been recognized as a dependable source of metallurgical-grade ore and as a producer with an even brighter future.

The Iranian Government's income from the Consortium (Iranian Oil Exploration and Producing Co. and Iranian Oil Refining Co.) totaled approximately $514 million [2] in 1965 compared with $480 million in 1964.

The total gross national product (GNP) based on current prices was estimated at $5,638 million in 1965, slightly higher than that of 1964. This also was the case with per capita GNP which was estimated at about $221 in 1965. Approximately 200,000 people were engaged in industrial employment with the petroleum industry providing employment for about 26 percent. Unemployment fluctuated between 5 and 15 percent of the total force owing to seasonal changes. Population was estimated by the United Nations to be about 23.4 million with a 2.5-percent annual growth.[3]

The Iranian Parliament passed a petrochemical industry act in 1965, by which the National Petrochemical Co., a Government corporation, could enter into a joint venture with Iranian or foreign firms provided that 50 percent of shares in such a venture are held by the National Petrochemical Co. A further stipulation requires that any contracts negotiated be approved by the High Petroleum Council, the General Assembly of the National Iranian Oil Co., the Council of Ministers, and the joint Parliamentary Economic and Finance Committee.

In the first half of 1965, the World Bank approved two separate loans to Iran totaling $40.5 million for a road development program. This development program, it is said, will provide important access to six agricultural and two large mineral producing regions in Iran. One loan was for $32 million and the other for $8.5 million. The former loan was to be used for the construction and improvement of 1,050 miles of highway from the Afghanistan border to Bandar Abbas on the Persian Gulf and the latter was to improve feeder roads to the main highway.

Additional development work and reorganization of existing loading and storage facilities of the Iranian petroleum industry continued in 1965. The work involved expanding the depot on Kharg Island into one of the largest crude petroleum terminals, not only in the Persian Gulf, but in the world. The 10-square-mile island had a 2.5-million-barrel-per-day capacity as of January 1966.

On November 20, 1965, a new agreement was signed between the Ministry of Economy and Pomeroy (Pomeroy-Hawaiian Dredging-Morrison-Knudsen), a U.S. firm that was building a new port facility at Bandar Abbas. The contract calls for three additional commercial berths to handle 10,000-ton ships and related facilities, as well as a naval base adjacent to the

[1] Foreign minerals specialist, Division of International Activities.

[2] Where necessary, values have been converted from rials (Rls) to U.S. dollars at the rate of Rls75.75 = $1.00.

[3] The Iranian calendar year begins on March 21; where information given in this chapter is on the basis of the Iranian calendar year, such years have been indicated by hyphenated years (i.e. 1963-64).

port. These additions will double the originally planned facilities and will cost about $7.6 million, all of which will be financed by the Iranian Government. With approximately 30 percent of the previous contract work completed, it was estimated that with newly announced additions, the port will be completed within 5 years.

PRODUCTION

Production of crude petroleum in 1965, with a 10-percent increase over the 1964 level, and an increased production of natural gas (22.7 percent higher than that of 1964) were the most remarkable achievements in the mineral industry of Iran during the year. Among the nonmetals, production of barite and cement apparently leveled off to supply the domestic demand, while with the introduction of the new petrochemical and fertilizer industry, output of sulfur is expected to increase substantially.

Chromite production was up 25 percent and since there has been difficulties with the supply from African sources, Iran has gained more status as a world source of metallurgical-grade ore. Not much change was reported in manganese production, whlie lead ore production showed a 13-percent increase over that of 1964. With the first steel plant of Iran in the planning stage, an intensive search and increased production activities in iron ore occurred in 1965. Iron ore production reached a new high of 59,000 tons. Copper ore production attained a new peak with about 70-percent increase over the 1964 production level.

TRADE

In the Iranian calendar year beginning March 20, 1964, among the leading export items crude petroleum set a peak and as usual led all other commodities, with a total of approximately $1,110 million, which was about $298 million, or 36 percent, higher than in the previous year. Quantitatively, lead ore and concentrates, manganese ore, and zinc ore exports showed increases of about 58 percent, 121 percent, and 195 percent, respectively. Of nonmetals, export of cement was marked by a 48-percent increase, while that of coal and lignite decreased about 120 percent in 1964 compared with that of 1963.

The export of fertilizers was especially noticeable because for the first time the Iranian petrochemical industry, which be-

gan limited operation only a couple of years ago, entered the international market.

Imports of industrial metals and minerals were valued at about $92.4 million, of which about $80.5 million were spent on iron and steel. The total value of nonmetals imports in 1964 was approximately $72 million.

COMMODITY REVIEW

METALS

Chromite. — Chromite production advanced to a new high of about 150,000 metric tons, 25 percent greater than 1964 production. A twofold output increase by 1967 was forecast for both main producing companies, Esfandegeh Mining Co. and Faryab Mining Co. Apparently good quality of the hard lumpy metallurgical-grade ore and a favorable chronium-iron ratio has placed Iranian chromite in great demand in the world market. Among the most interested customers for Iran's chromite, Japan ranked first, followed by France, West Germany, and Australia. By overcoming transport and loading difficulties by 1967, Iran's chromite producers expect to claim an even larger share of the world market.

Copper. — Exploration for copper was continued by the Geological Survey of Iran during 1965, both in producing mines and in the three separate mineralized regions, Azerbaijan, Sistan, and Kerman. No findings of substantial interest were reported; however, exploration was scheduled to continue in 1966.

Iron and Steel.—It was announced in the first part of 1965 that construction of Iran's first rolling mill had begun in Khuzestan, 10 kilometers south of Ahwas. The participants in the project are said to include: A West German firm, Demag A.G., with 9-percent equity which will handle the engineering work; a U.S. firm, Philipp Brothers Corp., with 31-percent interest; the Industrial and Mining Development Bank of Iran with 15 percent; Iranian industrialists, the Rezai brothers, with a 40-percent equity; and other Iranian private shareholders with 5 percent. The mill was slated to be completed in 20 months at a cost of about $8 million. The initial annual capacity reportedly would be 75,000 metric tons with provisions for increase to 100,000 metric tons annually.

After considering proposals submitted by West Germany, Czechoslovakia, the United States, and the U.S.S.R. for development of Iran's steel industry, Government officials found the Soviet proposal advantageous to Iran. A tentative agreement was signed in the latter part of 1965 by which the U.S.S.R. agreed to supply an integrated steel mill, expenses of part of a gas pipeline to the Soviet border, and a machine tool plant. In exchange, Iran was to supply the U.S.S.R. with $911 million worth of natural gas during the next 15 years.

The steel mill will have an initial annual capacity of 500,000 to 600,000 tons of steel which is to be doubled in the second phase and is to go into production in 1968. The machine tool plant is to have an operational capacity of 25,000 metric tons annually. The gas pipeline is to be built from the Iranian gas reservoir in oilfields to Astara, a small port on the Iran-Soviet border on the midwestern shore of the Caspian Sea.

According to press reports, part of the 1963 French credit of $61 million will be used to cover the foreign exchange costs of Shah Abbas dam on the Zayandeh Rud River, 100 kilometers west of Isfahan. The Shah Abbas dam will provide an adequate supply of water for the Isfahan steel mill as well as for irrigation purposes. A contract was signed between the Government and a consortium of three French companies (Enterprises Campenon - Barnard S.A., Etablissements Billiard, and Société Française d' Entreprises de Dragages et de Travaux Publics S.A.) for the construction of the dam at an estimated cost of $33 million.

Lead and Zinc.—Systematic exploration of the lead-zinc district near Yazd in west-central Iran by the Iranian Ministry of Economy and the U.S. Agency for International Development (AID), and private mine developments by the British firm Rio Tinto Co. Ltd., resulted in a conspicuous increase of lead-zinc ore exports from Iran in 1965. As reported in 1964, drilling work had confirmed 35 million metric tons of reserves containing 4.0 percent lead and 11 percent zinc in four deposits which have been systematically explored. A map accompanying an AID publication [4] indicated that at least 48 different lead-zinc deposits have been recognized in Iran, primarily in the west-central and north-central sections of the country. Elimination of transportation problems could make Iran a significant source of lead and zinc for the international market.

[4] Wright, Wilford S. Lead and Zinc in Iran. Agency for International Development. 231 pp.

NONMETALS

Barite.—Iran's barite producers, Sherkat Sahami Magcobar-e-Iran (Magcobar Iran S.A.) and Iran Barite Co. enjoyed another successful year of operations as a result of the country's oil industry drilling activities. Magcobar Iran S.A. was founded in 1959 by Magnet Cove Barium Corp. Ltd. and Iranian private companies, while Iran Barite Co. was formed in 1962.

Most of the barite deposits in Iran are of the replacement type, along fractures and faulted planes. Barite deposits occur either as narrow lenses or pods and veinlets.

Fertilizer Materials. — Construction of Iran's first fertilizer plant, north of Shiraz on the Shiraz-Isfahan highway, began in 1959, and the facility was inaugurated in the latter part of 1964. The plant, wholly owned by the Iranian Government, was the first enterprise in the country outside of the petroleum industry to use natural gas commercially as a feedstock. Gas is brought to the plant by a 260-kilometer pipeline from the Gach Saran oilfield. Daily production of the plant reportedly would be 120 metric tons of urea and 120 metric tons of ammonium nitrate.

National Petrochemical Co. (NPC), a subsidiary of the National Iranian Oil Co., concluded an agreement with Allied Chemical Corp. of the United States, calling for formation of a 50-50 partnership to set up major petrochemical facilities near Bandar Shahpour, a port on the northeastern tip of the Persian Gulf. The initial phase of the petrochemical complex will involve an investment of $100 million to build a plant to produce daily 1,000 tons of ammonia, 1,000 tons of sulfur and mixed fertilizers, and an unspecified quantity of urea. Future expansion envisaged will permit production of melamine, methanol, formaldehyde, and other chemical compounds. Feedstock natural gas for the complex will come from Masjid-e Suleyman oilfield. Construction of the plant is expected to start in early 1966 and completion is scheduled for 1968.

No detailed information on the phosphate deposits found in the Zagros range in 1964 were available. Apparently the Geological Survey team was examining the finds with a hope to prove a substantial reserve. Unconfirmed reports also indicated a new phosphate occurrence in the Gorgan region in northern Iran.

Glass Sand.—The Pan American Corp. of New York and the Industrial Mining and Development Bank of Iran signed an agreement in July of 1965 for the establishment of a sheet glass plant near the city of Kazvin. The plant is expected to produce 10,000 to 13,000 tons of sheet glass annually. Proven reserves of high quality raw material (95 percent SiO_2) near Kazvin reportedly is estimated to be 3 million metric tons.

MINERAL FUELS

Petroleum.—Most of Iran's exports of petroleum were made through the major trading companies that hold shares in the Consortium (Iranian Oil Exploration and Producing Co. and Iranian Oil Refining Co.).

While total export of Iranian crude oil and products has increased more than fivefold over the past 10 years, exports of products alone have increased at only about half that rate; thus the proportion of the products to total exports has accordingly decreased from 40 percent in 1955 to only 19 percent in 1964.

Table 4.—Iran: Summary of petroleum exports (Consortium)
(Thousand 42-gallon barrels)

Year	Crude oil	Products	Total exports	Products as percent of total
1955	61,767	40,517	102,284	40
1956	105,819	76,087	181,906	42
1957	141,830	103,341	245,171	42
1958	178,585	99,279	277,864	36
1959	212,656	101,443	314,099	32
1960	246,285	109,993	356,278	31
1961	305,181	92,409	397,590	23
1962	338,373	109,629	448,002	24
1963	388,404	111,441	499,845	22
1964	460,273	109,936	570,209	19

Consortium.—Aside from setting a record by producing 2 million barrels of oil on 1 day (August 2, 1965), and averaging 1,808,000 barrels per day in 1965, the Consortium's most noticeable achievement during the year was the impressive progress of the scheme known as The Cham Project, whereby Kharg Island and Bandar Mashur port, both in the Persian Gulf, will become Iran's most important ports for oil exports. By the end of the year, construction work at Kharg Island on 11 new tanks, each capable of holding 0.5 million barrels, was well advanced. Progress on extending the jetty from an L-shape to a T-shape continued during the year. The jetty, when completed, will provide 10 berths with sufficient depth of water and loading facilities to handle future supertankers.

Another achievement of the Consortium was the successful completion of 170 kilometers of 42-inch-diameter pipeline from Agha Jari to Ganaweh and of two additional 30-inch-diameter submarine lines from Ganaweh to Kharg Island, a distance of 43 kilometers. Reportedly loading of Agha Jari crude oil through new facilities at Kharg Island began in November 1965.

During 1965, a net total of 662.6 million barrels of crude oil was produced, a 9.2 percent increase over 1964. Agha Jari remained the largest producing field throughout the year, with an average daily output of 833,000 barrels; Gachsaran was second with 509,000 barrels per day, followed by Ahwaz field. Other fields operating throughout 1965 included Masjid-e Suleyman, Lali, Haft Gel, Naft-e Safid, Pazanun, Kharg, Bibi Hakimeh, and Karanj. During the latter part of 1965, the Marun field was placed on production at an initial rate of 20,000 barrels per day.

Extensive development activities in 1965, including completion of 18 development wells, of which 5 were development-delineation and reservoir observation wells at Bibi Hakimeh, 4 at Marun, 3 at Karanj, 1 at Faris, 2 at Rag-e Safid, 1 at Paznun, 1 at Agha Jari, and 1 at Gachsaran. During 1965, the Consortium completed work on 50 drilling and workover wells, of which 36 were producers with an initial production potential of 399,000 barrels per day.

Total drilled footage in 1965 for exploration and development was reported to be 34,601 feet and 157,702 feet, respectively. In Kupal, a significant new field, two exploration wells were drilled with positive results, while the exploration well at Darquain was found to be nonproductive.

The Consortium's Abadan refinery throughput for 1965 totaled 18,561,000 metric tons. Approximately 80 percent of the total refinery products were exported by the trading companies to various countries throughout the world and the remainder were delivered to the National Iranian Oil Company (NIOC) for Iran's domestic consumption.

By developing and expanding programing procedure through increased use of computers, Iranian Oil Refining Company was able in 1965 to offer a wider product-yield choice for a given crude run. By this means, the Abadan refinery will be able to better tailor its product yield to market demands.

The construction and testing of the new 26-inch hot block oil line between Abadan and Bandar Mashur port on the Persian Gulf was completed in 1965, except for the pump units and heaters that are ultimately to be used.

National Iranian Oil Co. (NIOC).—In 1965, the former Iran Oil Company was revived to act as NIOC's export subsidiary. Up to the latter part of 1965, this organization exported about 3 million barrels of Darius crude oil and 7 million barrels of Bahregansar crude oil in Iran's account and, jointly with American International Oil Co., exported an undisclosed amount to joint customers.

An agreement that was signed between NIOC and Afghanistan in 1960 to supply refinery products to Afghanistan was extended in 1965; also, NIOC accepted the managing and fueling of Afghanistan's Kandhar and Kabul airports. NIOC, along with Iran Pan-American Oil Co. (IPAC), has accepted in 1965 to supply petroleum to the Madras refinery in India. Under this acceptance, IPAS will handle both marketing and transportation. Reportedly, the Indian Government agreed to import 40 million tons of IPAC crude oil over the next 20 years. The Madras refinery, a joint venture between IPAC (26 percent) and the Indian Government

(74 percent), has a 50,000-barrel-per-day capacity and is expected to be completed by 1967.

As in the past several years, NIOC, the only agent for domestic distribution and marketing of refinery products in the country, drew two-thirds of its supplies from the Abadan refinery and the remainder from the Consortium's Masjid-i Suleyman topping plant and from its own Naft-e Shah topping plant and Kermanshah refinery.

Construction work on NIOC's new refinery near Tehran, with an 80,000-barrel-per-day capacity, continued in 1965. Crude oil for this refinery will be transported by the Ahwaz-Tehran pipeline. The Tehran refinery reportedly will include an Isomex unit designed to maximize yield of middle distillates which are in great demand in northern provinces of the country.

In 1965, the activities of NIOC included drilling Alborz well No. 14 for development purposes, but operations were abandoned at 1,113 meters. Exploratory drilling was mostly in South Siah Kuh, Tange-Bijar, Pahlavi-Dej, and Eymer areas with a total of approximately 7,846 meters. NIOC's net production from Naft-e Shah was about 2,761,000 barrels which was used as feedstock in Naft-e Shah's topping plant and the Kermanshah refinery. Geologic and seismic crews of NIOC completed about 36 crew-months of investigation and mapping work in Dezful, Behbahan, Gachsaran, Kermanshah, and other parts of the county during 1965.

In the area of joint Iranian Government-private enterprise ventures, five separate agreements were signed between the NIOC and representatives of the successful bidders for offshore oil district No. 1 in the Persian Gulf. All five agreements provided for a 75-25 profit split in favor of NIOC. Under the agreement, the companies have consented to pay taxes on their 50-percent share of the crude oil produced on the basis of the posted rather than realized prices. Also, the companies agreed and paid a total of $185 million as bonus payments. The agreements with companies will run for 15 years and are renewable for three terms of 5 years each. The names of the companies, initial bonus, and approximate coverage of area are given in table 5.

It was agreed also that all exploration costs until discovery of commercial crude oil will be carried by the participating oil company. NIOC was to be liable for half of exploration cost only if the crude oil found is commercial, in which case NIOC will amortize its share by paying in crude petroleum from its one-half share of output over a period of several years.

Some of the activities of newly organized companies were as follows: Dashtestan Offshore Petroleum Co. (DOPCO) drilled one well to a depth of 2,788 meters; Iranian Marine International Oil Co. (IMINOCO) drilled two wells totaling 5,704 meters; Faris Petroleum Co. (F.P.C.) drilled one well to a depth of 2,449 meters; Iranian Offshore Petroleum Co. (IROPCO) drilled one well to a depth of 2,317

Table 5.—Iran: National Iranian Oil Company's partners [1]

Name of joint company	Partners	Initial bonus (million dollars)	Approximate area (square kilometers)
Dashtestan Offshore Petroleum Co. (DOPCO).	Royal Dutch/Shell Oil Co.	$59	6,075

meters; and one well was drilled to a depth of 2,912 meters by Lavan Petroleum Co. (LAPCO), which was the only announced producer among those drilled by the newly organized petroleum companies.

Iran Pan-American Oil Co. (IPAC).—IPAC drilled in Darius, Syrus, and other Persian Gulf concessions in 1965 to a total of approximately 17,019 meters. Of the total drilling, 13,161 meters was for development and the remainder was for exploratory purposes. Crude oil production of IPAC amounted to almost 6.9 million barrels compared with 1.1 million barrels in 1964, most of which was exported.

Société Iran-Italienne Des Pétroles (SIRIP).—SIRIP drilled four wells, primarily for exploratory purposes, in Palinorus, Galal, and Kuh-e Rij for a total of 3,067 meters in 1965. SIRIP's production from Bahregansar was approximately 8.7 million barrels, slightly less than that of 1964, and was mostly exported.

Natural Gas.—Iran reportedly has the largest known natural gas reserves in the Middle East, approximately 70 trillion cubic feet. A conservative estimate made in 1964 put the gases flared every day in three Iranian oilfields at about 700 million cubic feet, equivalent to about 55 million barrels of crude petroleum per year. Coordinated efforts by the NIOC and the Government of Iran to utilize properly the vast economic and industrial energy of natural gas were increased in 1965; talks were initiated on installation of an aluminum plant, petrochemical works, and additional fertilizer manufacturing facilities. Moreover, distribution and marketing of natural gas to small industry and industrial users in Iran was suggested, and a tentative agreement for export of natural gas to the U.S.S.R. was concluded.

In 1965, natural gas was utilized mostly in the Marvdasht fertilizer plant near Shiraz at the same rate as that of 1963 and 1964, approximately 40 billion cubic feet. No detailed information was available on the amount that was used in the cement and sugar factories in Fars Province in 1965.

Table 6 summarizes the natural gas production and consumption from 1961 to 1965, both by the Consortium and NIOC.

Table 6.—Iran: Natural gas production and consumption

(Million cubic feet)

The Mineral Industry of Iraq

By James A. West [1]

The long established petroleum industry continued to maintain Iraq among the world's leading producers of liquid fuels in 1965 despite extremely limited development of oil resources and no exploration activity since 1961. The cement industry increased production and exports during 1965. Small quantities of salt, minor building materials, natural bitumen, gypsum, and clays were the only other mineral products.

In 1965, Iraq's crude oil output, averaging nearly 1.322 million barrels per day, was about 4.3 percent of total world production and 15.2 percent of Near East output. Direct oil payments to the Government amounted to nearly $368 million in 1965, accounting for an estimated 80 percent of all Government revenues and about 22 percent of Iraq's national income. The oil industry employed directly an estimated 14,000 Iraqis, or about 20 percent of the total industrial labor force. Cement plants employed about 2,500 persons.

In June, the Government of Iraq announced that an agreement in principle had been reached with the Iraq Petroleum Companies group (IPC group) on the long-standing dispute over law 80 of December 1961 which required relinquishment of 99.5 percent of the oil concession areas long held by the IPC group. At year-end, the agreement had not been ratified by the Council of Ministers. Law 11 of February 1964, which established the wholly Government-owned Iraqi National Oil Co. (INOC) to develop and exploit oil resources in relinquished areas, was amended to establish INOC as a commercial company subject to law 88 of July 26. This amendment permits INOC greater freedom to operate as a private company while retaining the privileges of a Government entity.

The Government announced a new 5-year development plan for the period April 1, 1965, to March 31, 1970. The plan provides for total expenditures in excess of $2,000 million, of which about $1,500 million is scheduled for public sector projects. Approximately $260 million is earmarked for investment in public sector minerals industry projects. This total includes about $130 million for chemical and petrochemical industries, $75 million for oil and natural gas projects, $35 million for steel projects, and $20 million for construction materials industries.

PRODUCTION

The trend of annual gains in crude oil production each successive year continued with 1965 output exceeding that of 1964 by 4.4 percent. In 1965, cement output increased by nearly 20.0 percent over that of 1964. Total mineral output was valued at an estimated $880 million, with oil accounting for about 98 percent of this total.

TRADE

Petroleum exports in 1964 were valued at almost $789 million and accounted for 95 percent of the value of all exports. The only other significant mineral export was cement which was valued at $5.4 million.

Essentially all metals and most industrial minerals are imported. In 1964, total mineral imports were valued at $30.3 million. Iron and steel, valued at $25.6 million, continued as the most significant mineral commodity imported.

COMMODITY REVIEW

METALS

Iron and Steel.—Feasibility studies for a proposed iron and steel plant were nearing completion. The studies, being performed by Koppers International Co. for the Government, were to determine whether to proceed with construction of the plant. Some scrap iron was exported from Iraq during the year. Scrap iron exports were banned in 1958 in the expectation that an Iraqi steel mill would be constructed and would require all local scrap.

NONMETALS

Cement.—Operating under Government ownership, the six cement plants increased output in 1965 by nearly 20 percent over that of 1964. This increase resulted from rising internal consumption and higher export demand. Consumption during 1965 amounted to 65 percent of the total output of 1,285 million tons. Total 1965 cement production was valued at an estimated $18 million.

On April 1, the Cement Marketing Bureau & Construction Materials Co. was formed by the Government Economic Establishment. The new company is responsible for marketing and exporting all locally produced cement and was authorized to import white cement and other construction materials. The company began

negotiating for imports of these materials with several foreign suppliers.

Ceramic Materials.—On March 3, the Ministry of Industry announced that a contract for engineering design and construction supervision of the ceramics plant at Ramadi was awarded to the Japanese Consulting Institute. An economic feasibility study on the project prepared by this firm was approved by the Government on January 6. The $6 million plant will utilize dolomite and other local raw materials to produce an estimated 34,000 tons of ceramics annually.

On November 15, a contract was awarded to an Iraqi firm for the first stage of construction of the long-delayed glass factory at Ramadi. This project is being built with Soviet economic and technical assistance.

Sulfur.—On January 31, the Government awarded a contract to the U.S. firm Ralph M. Parsons Co. and its British subsidiary, Powergas Co., for construction of a sulfur extraction plant at Kirkuk. The plant will

process about 78 million cubic feet per day of sour natural gas from the Kirkuk oilfield and recover an estimated 100,000 tons of elemental sulfur annually. The estimated cost of the plant is $23 million. Completion of the plant is scheduled for May 1, 1967.

MINERAL FUELS

Petroleum and Natural Gas.—As of January 1, 1966, the proved crude oil reserves of Iraq were reported [2] as 25 billion barrels, or nearly 7 percent of total world reserves.

Except for relatively minor quantities of oil production from the Government-operated Naft Khaneh field in the Khanaqin area along the Iraq-Iran border and heavy oil for the Quayara asphalt plant, all crude oil was produced from seven fields operated by the Iraq Petroleum Companies group (IPC group). The Kirkuk, Bai Hassan, and Jambur fields in the Iraq Petroleum Co. (IPC) area produced at an average rate of 908,925 barrels per day, accounting for nearly 70 percent of total output. The giant Kirkuk field continued to produce at sustained rates in excess of 800,000 barrels per day in response to a highly successful water injection program. Water injection at an average rate of about 1.2 million barrels per day during 1965 permitted record high production while maintaining reservoir pressure. The Rumaila and Zubair fields of Basrah Petroleum Co. (BPC) in southern Iraq together produced nearly 373,000 barrels per day, with Rumaila accounting for 80 percent of the total. Output of the Ain Zalah and Butmah fields of Mosul Petroleum Co. (MPC) remained steady at about 26,000 barrels per day.

Exploration by the IPC group companies remained suspended in 1965. Drilling operations were limited to development drilling with only two rigs active throughout most of the year.

An estimated 900 million cubic feet per day of associated natural gas was produced in Iraq during 1965. About 5 percent of this gas was utilized in field operations or supplied to the Government power-generating stations at Dibbis and Najibiyah.

Government oil agencies took actions to implement a number of major petroleum and natural gas processing and distribution projects. Construction of a 4,000-ton-per-year grease plant at the Daura refinery was nearing completion at yearend. A contract was awarded to Societa Nazionale Metanodotti Progetti (SNAM) of Italy for construction of a 36,000-ton-per-year lubricating oil plant to supplement the existing 25,000-ton-per-year plant at the Daura refinery. The estimated cost of the plant is $11.6 million and completion is scheduled for the latter part of 1967. Techno-export of Czechoslovakia was awarded a contract for construction of a hydrogen desulfurization plant at Daura to process 7,000 to 12,500 barrels per day of kerosine. The U.S. firm, Kellogg International, submitted specifications for expansion of the Daura refinery capacity from 50,000 to 75,000 barrels per day of petroleum products. Construction of a 12- to 16-inch-diameter loop on the existing Kirkuk-Baghdad oil pipeline was begun in October to increase pipeline capacity to meet refinery expansion requirements.

On September 20, bids were opened for construction of two 300-kilometer parallel pipelines (a 16-inch natural gas and an 8-inch liquids line) from Kirkuk to Baghdad, a natural gas distribution system in Baghdad, and a 12,000-barrel-per-day liquefied petroleum gas (LPG) plant at Taji near Baghdad. SNAM submitted a low bid of $16.5 million for the pipelines while Société Parisienne pour l'Industrie Electrique of France was low bidder at $9.8 million on the LPG plant. Other projects under active consideration were an oil products storage depot at Zaafaraniya, refineries at Basra and Mosul, and various petrochemical projects.

The Mineral Industry of Israel

By E. Shekarchi [1]

Although Israel is not richly endowed with mineral resources, its mineral industry continued to receive significant attention in 1965. The mineral industry is a foreign exchange earner in this country where exports are still only about half the imports.

The potash industry of the Dead Sea area, phosphate production in the Oron fields, and the diamond-cutting industry remained the most significant mineral industry contributors to the Israeli economy. Preliminary data on production of other minerals—cement, gypsum, elemental bromine, bromine compounds, and copper—suggest that the total production value increased in 1965. The high level of economic activity was maintained, the total gross national product (GNP) at current prices rose to approximately $3,670 million,[2] and per capita GNP, based on 1962 prices, rose to about $1,165 in 1965.

As immigration fell to less than 2,000 persons per month, the labor force was believed to have grown about 3.2 percent as compared with 4.5 percent growth in 1963 and 1964. The labor force employed in the country was about 856,000. The mineral industry and mining claimed about 25 percent of the labor force in 1965.

In June 1965 a loan agreement amounting to about $4.4 million was signed by U.S. Agency for International Development (AID) and Timna copper mines of Israel.

It was announced in the latter part of 1965 by the Director of the Ministry of Commerce and Industry that an investment of about $7 million in petroleum and chemical enterprises would be made during the next 3 years.

The Geological Survey of Israel extended its research into the mineralized areas rather than concentrating on known mineral deposits. Results of their activity included locating new sand deposits for glass manufacturing, discovery of 3 million metric tons of copper ore in the Timna area, and discovery of phosphate reserves in in the Negev region.

According to Israeli Government, the World Bank and some private U.S. banks agreed in the first part of 1965 to finance three projects at the Dead Sea Works Ltd. in Sedom. These projects consisted of the following: An addition to present potash production facilities bringing annual capacity to 1 million tons; construction of a $4 million plant to produce magnesite, the first of its kind in Israel; and an investment of $1.7 million in a plant which will produce 7,000 metric tons of chlorine annually.

In the latter part of 1965 it was announced that Haifa Refiineries Ltd. was actively seeking cooperation of a U.S. partner to erect a new refinery at Eilat, which is Israel's port on the Red Sea, with an initial annual throughput capacity of 250,000 metric tons.

An agreement was signed between Israel's Ministry of Commerce and Industry and an unidentified U.S. firm to erect a phosphoric acid plant in the Arad region of the northern Negev.

PRODUCTION

New production records were set in 1965. The most noticeable increases were 44 percent in copper, 22 percent in cement, and 29 percent in phosphate rock production. The production of potash almost doubled in 1965 when compared with that of 1964. Total refinery production set a new high in 1965, almost three times the 1961 level.

[1] Metal content of cement copper exports, calculated on basis of 75 percent copper.

TRADE

In 1964, gross export earnings from minerals and metals, excluding petroleum and diamond, were about $16 million in comparison to $12.5 million in 1963, or an increase of 28 percent. The gross value of diamond exports amounted to $137.6 million compared with $116 million in 1963. Among metals and concentrates, copper showed the leading export value, about $10 million, and among nonmetals, fertilizer accounted for approximately $2 million.

Gross imports of minerals and metals in 1964 were at the same rate as those of 1963, except there was a $10 million (or 18 percent) increase in iron and steel imports in 1964. Israel's foreign trade publications do not give the countries of destination and origin for exports and imports; however, from the available information, the United States, United Kingdom, and the European Economic Community apparently remained the principal trading partners.

COMMODITY REVIEW

METALS

Copper.—The Timna copper mine, 25 kilometers north of Eilat, continued its successful operation producing 10,000 tons of copper cement in 1965, an increase of 3,000 tons over the 1964 level. Plans were being studied to raise annual output to 15,000 tons of copper cement in 1966 by improving mining techniques and ore recovery. In this connection a loan agreement between AID and Timna copper mines was signed. The loan, said to be about $4.4 million, is repayable in dollars in 20 years.

NONMETALS

Diamond.—In 1964, the gross value of polished diamond exports reached about $138 million compared with $116 million in 1963, a rise of 19 percent. The annual rate of growth of diamond exports, on the

whole, surpassed that of all other exports together. Rough diamond took first place in imports for industry with regard to import value. In 1964, imports of rough diamond totaled $117 million compared with $100 million in 1963.

[1] Source: State of Israel, Ministry of Commerce and Industry, Foreign Trade, 1964. pp. 162.

The spectacular expansion which characterized Israeli export of polished gem diamond over the past decade has apparently slowed down. It is possible that the saturation point has been reached for the type of stones being worked and that a new diversification in the industry has to be expected.

Phosphate.—Production of phosphate from the Oron fields increased, amounting to 388,000 tons of beneficiated ore.

It was announced in the latter part of 1965 that an agreement had been concluded between the Israeli Ministry of Commerce and Industry and a U.S. firm for building a phosphoric acid plant in the Arad region of the northern Negev. The U.S. interest will provide marketing and technical knowl-

edge and the Israeli Government will furnish basic services such as railways, road construction, and water supply. Detailed information on the capacity of the plant and the investment involved were not available.

Potash.—Preliminary steps for expansion of existing potash installations and for erection of new plants for magnesite and chlorine production were taken by the Dead Sea Works Ltd. in Sedom. The potash project will include an additional plant with a capacity from 0.6 million to 1 million tons. The new projects envisage a magnesite plant with an annual capacity of 30,000 tons and a chlorine production plant with an annual capacity of 7,000 tons to be ready by 1967.

It was reported that construction of new potash evaporation basins in the southern part of the Dead Sea was nearing completion in the latter part of 1965.

MINERAL FUELS

Petroleum.—*Crude Oil and Natural Gas.*—Apparently the amendment to Israel's petroleum law that was aimed at stimulating oil prospecting produced results. Although the country has not showed rich reservoirs, capital backing for both foreign private and domestic exploration has increased rapidly, and such activities continued throughout 1965.

The economy, demanding an annual increase of 15 percent in petroleum and its products, has stimulated oil exploration because Heletz field is providing only about one-tenth of annual demand, and the chance of finding new fields seems highly possible.

One of the most aggressive of the foreign companies was Petrocana Ltd. of Montreal, operating on the basis of encouraging results of a seismic survey completed in the Israeli continental shelf area. Several promising structures in its five blockholdings were discovered. In 1965 Livingston Oil Co. of Oklahoma took a half interest in Petrocana's offshore holdings. A capital investment of about $5 million would be allotted for drilling on these properties with a spudding date set in the early spring of 1966.

Another foreign group known as Arava Corp., composed of United States Smelting, Refining and Mining Co. (50-percent share), Detroit's Max Fisher (25 percent), and the Paz, Oil and Trading Co. Ltd. (25 percent), completed a gravimetric survey on its holdings south of the Dead Sea in 1965 and were preparing background work for a detailed seismic study in 1966. Paz was also seeking exploration rights in the Dead Sea for its own company.

Natural gas from the Negev fields was used primarily as power for the tremendous potash and phosphate plant and for small industries in the Dinona-Oron-Sedom area. A growing domestic demand for petroleum and petrochemical products has stimulated new projects in both fields.

Four Israeli companies were actively searching for petroleum and gas during 1965. Lapidoth Israel Oil Prospectors Corp. Ltd. (LTOP), 56.2-percent Government-owned, has been the most successful domestic company in petroleum production. In 1965 alone, the company completed 7 producing wells out of 18 drilled. In its Heletz field complex, the only producing field in the country, LTOP has completed through yearend 41 producing wells out of 73 operations. Heletz field was found in September 1955 by LTOP. As the field developed, a complex subsurface structure evolved, and it was thought that there were three principal pools—Heletz, Kokhav, and Brur. However, reexamination of the area's structure showed that, for all practical purposes, the three pools are one, and a step-out well was planned in each area. Also in 1965, LTOP spudded a new remote wildcat well on its Ashkelon permit along the Mediterranean coast.

Naphtha Israel Petroleum Corp. Ltd. (NIPC), 62.75-percent Government-owned, has been very successful in finding natural gas. Three promising developed fields are Zohar field with eight wells and an estimated 40-billion-cubic-foot reserve, Hakanaim field with two wells and an estimated 10-billion-cubic-foot reserve, and Kidod field with two wells and an estimated 10-billion-cubic-foot reserve.

Petroleum Services Ltd. (PSL), 100-percent Government-owned, has functioned primarily by handling all Government interests in Israel's small oil area and by providing housekeeping operations.

National Oil Company, also wholly Government-owned, held a major portion of the coastal plain permits through late 1965. After spending $9 million during 5 years of

unsuccessful drilling, the operation was suspended, and all personnel and equipment were transferred to LTOP. Reportedly, the companies' permits will be farmed out to interested groups under PSL direction.

The most important element influencing exploration in Israel was the discovery of oil deep in Jurassic beds. Previously, all production was from Lower Cretaceous sands at an average depth of 4,000 to 6,000 feet, while recent findings were at depths of about 3,000 to 7,000 feet. It should be pointed out that gasfields in the northeastern Negev region of Arad are also in Jurassic beds at depths of 3,000 to 6,000 feet.

Refineries and Pipelines.[3]—Haifa Refineries Ltd. plant underwent a rapid expansion by boosting its daily capacity to 92,000 barrels in 1965. A further expansion to boost daily capacity to 110,000 barrels was planned for 1966. Sonol Refineries Ltd. in the south on the Gulf of Aqaba continued the construction of its new refinery at Eilat. The completion date reportedly is set for the latter part of 1966, and daily plant capacity should be 5,000 barrels.

In 1965, capacity of the 413-kilometer, 16-inch Trans-Israel pipeline from Eilat to Haifa was increased to 74,000 barrels per day. Through installation of new pumping facilities, a target capacity of 100,000 barrels per day was planned and a subsequent increase to 120,000 barrels per day was envisioned.

The Mineral Industry of Jordan

By E. Shekarchi [1]

Phosphate rock remained the most important mineral product of the Hashemite Kingdom of Jordan in 1965. The country's output constituted over 1 percent of the total world production for the year. The importance of phosphate rock production to the domestic economy was evident in that it accounted for about 29 percent of the value of total exports or $6.6 [2] million in 1964. Jordan's gross national product (GNP) was estimated at $415 million in 1965, only slightly above that of 1964, and the value of mineral production was estimated at about $16 million.

Out of a total labor force estimated at 440,000, approximately 25 percent remained unemployed simply because of a lack of jobs. Moreover, persons of Jordanian birth, including semiskilled and skilled workers who have been unable to find jobs in Jordan continued to find employment in neighboring oil-producing Arab States. The mineral industry employed only a small fraction of the total labor force.

The mineral industry, dominated by production of phosphate rock, cement, and petroleum refinery products, in recent years has played a much more significant role in the country's economy than in the past, chiefly as a result of expansion programs completed during the last 5 years. In 1965, the country's only cement plant furnished virtually the entire domestic demand. Phosphate rock output again increased, and with new developments in transportation facilities, including harbor expansion, further increases seem feasible.

On August 10, 1965, Jordan and Saudi Arabia signed an agreement in Amman on the modification and demarcation of the international boundary between these countries. By this agreement, the length of the Jordanian coast on the Gulf of Aqaba was extended to 25 kilometers, an increase of 19 kilometers; however, if petroleum is discovered in this extension area, the countries would share the income equally.

Jordan retained its membership in the General World Association of Raw Phosphate Producers which now has a membership comprised of Jordan, Tunisia, and Morocco. Prices of phosphate were raised in June 1964 by agreement among the members; however, no attempt has yet been made for market allocation among the producing countries.

After Jordan's House of Representatives on April 19, 1965, passed a law creating a regional organization to carry out the Arab plan for exploiting the Jordan River and its tributaries, the Arab Jordan River Board announced in the latter part of 1965 that the site for the Mukheibeh Dam was approved and an order was issued to the contractor to begin work. Details of plans concerning the reservoir, electric potentiality, and irrigation possibilities were not available except that the Othman Contracting Co. of the United Arab Republic (Egypt) was the lowest bidder and was going ahead with work.

To extract potash from the Dead Sea, the Arab Potash Co., owned by the Jordanian Government, contracted with Jacobs Engineering Co. of Pasadena, Calif., to do a feasibility study. In 1965, for the first time an iron and steel company was established in Jordan by the Government.

[1] Foreign mineral specialist, Division of International Activities.

[2] Where necessary, values have been converted from the Jordanian dinar (JD) at the rate of JD1=U.S.$2.80.

PRODUCTION

Phosphate rock extraction reached a new high in 1965, over 36 percent greater than in 1964. Available preliminary information, however, indicated that the high level of production in 1965 was not reflected in export sales because inadequate facilities for handling and storage at Aqaba remained a bottleneck.

Although no major mineral deposits were discovered in 1965, prospecting was continued for new deposits and known deposits of iron, manganese, and copper were test drilled.

[1] In addition to commodities listed, Jordan also produces limestone for cement manufacture.
[2] Estimate, based on reported 10 percent increase in refinery output.

TRADE

Despite increases in production of phosphate rock, Jordan's most important mineral export, the country in 1965 apparently had a negative trade balance in mineral commodities of about the same magnitude as in 1964, when the value of mineral imports exceeded that of mineral exports by about $8.9 million.

In 1964, the total export value of nonmetallic minerals from Jordan amounted to $6.9 million, or about 28 percent of total export and about $2.5 million more than in 1963. Among various export commodities, phosphate rock export practically doubled in 1964 and was again a main exchange earner while cement, marble, and granite rock followed. Yugoslavia assumed first place as a destination for Jordanian phosphate rock exports, followed by India and Turkey.

Imports of metals, nonmetals, and mineral fuels were valued at approximately

$7.4 million, $920,000, and $7.5 million, respectively. Among the metals, iron and steel ranked first with about $7 million, while copper and aluminum semimanufactures imports were valued at about $184,000.

COMMODITY REVIEW

METALS

Iron and Steel.—Jordan Iron Industries Co., the country's first steel company, was established in 1965 with a capital of $1.4 million. The company ordered an Italian-built steel plant which will use scrap and pig iron and will have an annual capacity of 40,000 metric tons of finished iron and steel, including concrete reinforcing rods, wire, and door and window frames.

Manganese.—Following recommendations of West German geologists who completed preliminary studies of the Wadi Dana manganese deposits in 1965, the Jordan Development Board reportedly planned further exploration of the area aimed at finding additional ore bodies and to determine if the property is economically feasible. Initial unconfirmed reports listed an indicated reserve of 65,000 tons of unspecified grade.

NONMETALS

Phosphate Rock.—Available information indicates that phosphate rock exports in 1965 did not increase as significantly as did production, reversing the stock change pattern of 1964 when exports exceeded output by a sizable margin, permitting a reduction of excessive unsold stocks.

The Jordan Phosphate Co. board of directors, which was dismissed by the King in 1963, reconvened and the company was returned to private shareholders in 1964. At that time, the capitalization was expanded and the government's share was increased to slightly more than 50 percent. In August 1965, the cabinet approved a

plan for the consolidation of all phosphate mining operations in Jordan, including Rusaifa and Al Hasa, merging them into one company. The cabinet also approved capitalization for the expanded company at a level of $8.4 million and authorized a board of directors composed of five government and four stockholder representatives.

Several companies from abroad had expressed an interest in participation in exploitation and marketing of Jordanian phosphate; however, by the end of 1965, no agreement was reached.

The consulting firm of Ralph M. Parsons Co. of Los Angeles, Calif., which showed a proven reserve of 30 million tons of commercial grade phosphate (average bone phosphate of lime (BPL) content of 68 percent) in the first stage of its contract, continued with the second stage of the contract and was completing the design of mining facilities at Al Hasa. The new Al Hasa plant reportedly will have a capacity of 500,000 metric tons annually, expandable to 1 million tons.

Potash.—The Arab Potash Co. contracted with Jacobs Engineering Co. of Pasadena, Calif., to do a feasibility study on development of a plant at the southern tip of the Dead Sea for extraction of potash.

Arab Potash Co. is a cooperative enterprise of the Governments of Jordan, Kuwait, Lebanon, and Saudi Arabia, as well as private Jordanian capital. The feasibility study, which includes detailed estimates of the potential output volume and market value, was to be completed by mid-1965; however, through the latter part of 1965, detailed results of the study were not made available to the public.

By yearend the Economic Minister opened talks at the World Bank headquarters, seeking a loan to help finance a potash project in Jordan. Apparently the scheme will cost about $60 million, of which Jordan was asking World Bank to finance $30 million and U.S. Agency for International Development to supply $15 million.

Sulfur.—Preliminary information indicated that the Ministry of National Economy gave concession rights to a newly established firm, Jordan Sulfur Mines Development Co. Ltd., for exploitation of sulfur deposits in the Jordan valley. The deposits are parallel to the Jordan River, extending from 4 to 21 kilometers north of the Dead Sea. Estimated reserves were reported to be approximately 400 million tons with a recoverable sulfur possibility of 35 million tons. By yearend, no sulfur production was reported.

MINERAL FUELS

Petroleum.—John W. Mecom (Mecom Oil Co.), an independent U.S. oil operator who has a 40-year concession agreement for petroleum exploration with drilling obligation of 2,000 feet annually, continued wildcat drilling in 1965. The first and second holes drilled to depths of 12,468 and 4,648 feet, respectively, were abandoned. The third wildcat at Azzum, 30 kilometers northwest of Nablus, had to be abandoned at a depth of only 1,800 feet due to adverse conditions. In the latter part of 1965, the company reportedly was surveying a fourth well site, 14 kilometers southeast of Kacak.

The crude throughput in the petroleum refinery at Zerka during 1964 was 2,648,000 barrels, a 9-percent increase over that of 1963.

The Mineral Industry of Kuwait

By James A. West [1]

Kuwait retained its position as the leading crude oil producing country of the Near East and ranked fourth among world oil-producing nations in 1965. The small sheikdom accounted for about one-fourth of area production and nearly 7 percent of world petroleum supply during 1965.

The petroleum industry remained the mainstay of Kuwait's economy, providing more than 90 percent of all Government revenues and foreign exchange earnings. In 1965, total Government revenues from petroleum operations in Kuwait and in the Kuwait-Saudi Arabia Neutral Zone were an estimated $608 million. This sum does not include additional revenues which may accrue to the Government if it ratifies a 1964 agreement with Kuwait Oil Co. (KOC) providing for the expensing of royalty oil payments and other changes in tax-accounting procedures. The failure of the National Assembly to ratify this agreement, and subsequent lack of a solution, was the most serious problem between oil concessionaires and the Government throughout 1965.

The Government continued to encourage and participate in projects to expand and diversify the industrial development of the economy. In early 1965, the National Industries Law was promulgated by the National Assembly. The law requires licenses for all processing and manufacturing activities and offers Government assistance in low-interest loans, site allocation, and tariff protection.

Substantial progress was made in the construction of new plants and facilities in the Government-sponsored Shuaiba industrial complex. The Kuwait Chemical Fertilizer Co. (owned 60 percent by Kuwait Petrochemical Industries Co. and 20 percent each by British Petroleum Co. and Gulf Oil Corp.) continued construction of four petrochemical fertilizer plants to produce ammonia, urea, ammonium sulfate, and sulfuric acid at rates of 400 to 500 tons per day. Construction of a 95,000-barrel-per-day oil refinery by the Fluor Corp. for Kuwait National Petroleum Co. (KNPC) (60 percent Government-owned) was begun late in 1965. Construction of a cargo pier, powerplant, salt water conversion plant, and other ancillary facilities progressed satisfactorily.

PRODUCTION

Crude oil production at a record rate of 2,169,600 barrels per day in 1965 maintained Kuwait as the leading producer in the Near East. Nevertheless, this rate was only 2.2 percent greater than that of 1964 and Kuwait's share of total area output declined from about 28 percent in 1964 to 26 percent in 1965. Refinery runs averaged 220,037 barrels per day in 1965.

Minor construction materials and building stones are produced but quantitative data are not usually reported. Available data for 1964 show that 12,067 tons of lime and 32.8 million sand lime bricks were produced from local materials. These materials were valued at about $1.9 million.

[1] Chief specialist, Near East-South Asia, Division of International Activities.

TRADE

Kuwait continued to supply more than 10 percent of the world petroleum export demand in 1965. These exports, from Kuwait proper (excluding those from the Kuwait-Saudi Arabia Neutral zone), were valued at about $1,200 million.

Available trade statistics show that total imports declined in value from $324 million in 1963 to $322 million in 1964. Imports of metals and minerals were valued at about $25 million. Iron and steel products accounted for nearly three-fourths this value while cement made up most of the remaining one-fourth. About 10 percent of total imports are reexported.

In July 1965, the Kuwait National Assembly voted against participation by Kuwait in the Arab Economic Unity Agreement and Common Market.

COMMODITY REVIEW

METALS

Iron and Steel—Imports continued to supply all iron and steel required for Kuwait's booming construction industry. The Kuwait Pipe Co. operated throughout the year producing spiral welded pipe utilizing imported steel skelp. The Kuwait National Industries Co. (half Government-owned) considered a joint-venture proposal by Japanese steel companies for construction of a 30,000-ton-per-year welded-pipe plant in Kuwait.

NONMETALS

Construction Materials.—The Kuwait National Industries Co. was formed to service construction material needs and encourage development of light industry. This company, owned 50 percent by the Government and 50 percent by private investors, operates a sand-lime brick plant, a concrete block and pipe plant, and an asbestos-cement works. The company proceeded with plans to construct a 150,000-ton-per-year cement plant in Kuwait to use indigenous limestone resources. Bids for construction of the $3 million plant are being evaluated.

MINERAL FUELS

Petroleum.—With an estimated proved crude oil reserve of 62,500 million barrels [2] as of January 1, 1966, Kuwait ranked first among nations having developed oil resources. The reserve declined by 500 million barrels during the year because exploration and development drilling did not provide additions to reserves sufficient to offset the record producing rate. Nevertheless, the reserve-to-production ratio of about 80:1 was among the largest in the world.

KOC, owned jointly by British Petroleum Co. Ltd., and Gulf Oil Corp., continued as the only oil producer in Kuwait proper in 1965. As in the past, most oil was produced from the Burgan and Magwa-Ahmadi fields where about 415 producing wells are completed in Cretaceous sandstone reservoirs at depths of 3,500 to 5,000 feet. Significant quantities of oil were produced from about 62 deeper wells (8,000 to 10,000 feet) completed in Cretaceous reservoirs of the Raudhatain, Minagish, Sabriya, Umm Gudair, and Bahra fields. The KOC refinery at Mina al-Ahmadi continued to operate at about 90 percent of its rated capacity of 250,000 barrels per day. The liquefied petroleum gas (LPG) processing facilities of the refinery were expanded to meet rising LPG export demands.

In July, KOC effected a 10-percent pay increase for its approximately 5,500 employees, about one-fourth of whom are Kuwait nationals and 35 percent are Arabs from neighboring countries. KOC payments to employees and contractors and local purchases of materials contributed more than $40 million to the local economy.

The Government-controlled Kuwait National Petroleum Co. negotiated an agreement with HISPANOIL (a group of Spanish industrial, banking, and oil interests) to exploit the oil concession areas relinquished by KOC in 1963. Although final terms of the agreement have not been ratified by the Kuwait Government, it is reported that the Spanish Government as-

[2] Oil and Gas Journal. V. 63, No. 52, Dec. 27, 1965, p. 83.

sured the company 25 percent of Spain's crude oil import market for a period of 15 years, beginning in 1970. Exploration costs will be borne by HISPANOIL until commercial oil production is established. Thereafter, KNPC will compensate HISPANOIL for 51 percent of the costs and participate in ownership of the joint company on this basis.

Natural Gas.—More than 1.1 billion standard cubic feet per day of natural gas was produced in association with oil recovery. Nearly 10 percent of this gas was utilized by local powerplants and light industry. Approximately 90 million cubic feet per day was reinjected in the Burgan field for reservoir pressure maintenance. KOC completed the construction of a 50-million-cubic-foot-per-day injection plant in the Raudhatain field and began construction of a 150-million-cubic-foot-per-day plant for injecting Burgan gas into the main reservoir of the Minagish field.

The Mineral Industry of the Kuwait-Saudi Arabia Neutral Zone

By James A. West [1]

Petroleum remained the only mineral industry activity of the Neutral Zone during 1965. The small treaty zone, held jointly by Kuwait and Saudi Arabia, ranked fifth in oil production among Near East producing States, accounting for nearly 4.5 percent of the area's output. The Governments of Kuwait and Saudi Arabia together received about $70 million in oil revenues from Neutral Zone operations in 1965. About 2,400 persons were employed by the operating companies.

The Governments of Kuwait and Saudi Arabia assumed administration of separate areas of the Neutral Zone in accordance with their 1964 agreement. Discussions were continued in efforts to reach agreement on the ownership of offshore islands and fixing of boundaries of the zone.

PRODUCTION

The record crude oil production rate of 362,424 barrels per day in 1965 was divided almost equally between the offshore and onshore areas of the Neutral Zone. This rate was only 0.7 percent greater than that of 1964. Onshore production declined about 2.4 percent while offshore output increased by 4.1 percent. In August, a tanker fire destroyed the offshore oil-loading jetty at Khafji. This accident and reduced export demand limited offshore production throughout most of the year.

About 98,000 barrels per day of onshore crude oil was partially refined to produce fuel oil and naphtha. These products are frequently mixed with crude oil prior to export.

[1] Chief specialist, Near East-South Asia, Division of International Activities.

Table 1.—Kuwait-Saudi Arabia Neutral Zone: Production of petroleum and petroleum products

(Thousand 42-gallon barrels)

	1961	1962	1963	1964	1965

COMMODITY REVIEW

MINERAL FUELS

Petroleum.—No new additions to proved crude oil reserves were reported in 1965 and reserves declined to an estimated 12.4 billion barrels [2] at yearend.

The American Independent Oil Co. (Aminoil) and Getty Oil Co. (Getty) continued to obtain most of their joint onshore production from the multizone Wafra field. The south Fuwaris field, placed on production in mid-1964, was found to have a very limited sustained producing capacity. Although facilities to produce up to 20,000 barrels of oil per day were installed, current production from eight wells is 5,000 barrels per day. Almost two-thirds of the 408 producing wells in the Wafra field are now equipped with pumping units or are shut in. A number of the shallow Eocene wells were deepened and recompleted in the Ratawi zone. An exploratory deep test well was drilled to below 12,000 feet with negative results.

The Japanese-owned Arabian Oil Co. Ltd. (AOC) production was entirely from the Khafji field. Only 44 of the 54 wells completed in the field are connected to production facilities. Most of these wells are completed in the Bahrain sandstone zone at an average depth of 5,500 feet while a few are completed in the Ratawi limestone at an average depth of 7,200 feet. Several of the Bahrain zone wells were deepened for dual completion in the Ratawi zone. AOC used temporary loading facilities, which were installed in a remarkably short time following the tanker fire in August, and began reconstruction of the permanent oil-loading jetty. Completion of permanent facilities is scheduled for August 1966.

The Aminoil refinery in Kuwait and the Getty refinery in the Neutral Zone processed an average of 97,852 barrels per day of crude oil. Fuel oil and naphtha were the only products produced. Construction was nearing completion on modifications to the Getty refinery which will permit this plant to produce a wider range of products. Construction of AOC's 30,000- barrel-per-day Ras al-Khafji refinery was progressing on schedule.

The Mineral Industry of Lebanon

By James A. West [1]

Lebanon has traditionally served as a leading entrepôt for an extensive area of the Near East. Its strategic location, enterprising merchants, and liberal commercial and trade policies have made trade the most important sector of the national economy. About 30 percent of the national income, estimated at $628 million in 1964, was derived from this sector. The domestic mineral industry was a relatively insignificant contributor to the national economy, but Lebanon continued to serve as a transit and export point for Iraqi and Saudi Arabian crude oil. Petroleum refining, cement manufacture, and iron and steel rerolling are the major mineral industries of the country. These industries employed an estimated 20 percent of the industrial labor force of about 60,000 workers and accounted for about 7 percent of the gross national product, estimated at $950 million, in 1964.

PRODUCTION

The general trend of annual increases in the production of metal and mineral products in recent years continued during 1965. Total mineral output in 1965 was valued at an estimated $69 million. Petroleum refinery output accounted for about 48.5 percent of this total, while cement, iron and steel semimanufactures, and salt accounted for about 27, 22, and 2.5 percent of the total, respectively.

e Estimate.

TRADE

Lebanon continued to depend on imports for most of its mineral requirements. The relative importance of mineral commodity trade to total trade during 1964, the latest year for which statistics are available, is shown in the following tabulation:

	Value of mineral trade (million dollars)	Value of total trade (million dollars)	Share of mineral trade to total trade (percent)
Exports	7	68	10
Imports	129	431	30
Trade balance	−122	−363	--

The contributions of each of the major mineral commodity categories to total mineral trade in 1964 were as follows:

	Value of imports (million dollars)	Value of exports (million dollars)
Metals	101	4
Nonmetals	8	2
Fuels	20	1
Total	129	7

Lebanon remained a major world gold marketing center, and gold imports in 1964 were valued at $81 million or 80 percent of all metal imports. Iron and steel imports were valued at about $17 million. Fertilizer minerals, valued at about $2.5 million in 1964, were the major nonmetallic mineral import. Gem stones, cement, and marble imports were valued at about $1 million each.

COMMODITY REVIEW

METALS

Iron Ore.—The occurrence of extensive deposits of ferruginous sediments near the Cedars of Lebanon, a resort area about 25 kilometers southeast of Tripoli, has been known for centuries. Ancient Roman diggings attest to the earliest efforts to exploit these deposits. The deposits outcrop over a wide area, and reserves are probably large. However, sample analyses indicate that most of the deposits are of low grade, having less than 50-percent iron content.

From 1953 to 1962, small quantities of iron ore were mined and processed into pig iron at a nearby plant operated intermittently by the National Iron & Steel Manufacturing Co. The pig iron was produced by a special fuel oil reducing process using a rotary kiln instead of a conventional blast furnace. About 200,000 metric tons of pig iron was exported to West Germany between 1953 and 1958. Exports ceased thereafter because of increased freight rates and a decline in ore quality. The plant was operated sporadically until 1961 and produced 2,000 to 3,000 tons of pig iron annually for local consumption. Production since 1961 has been insignificant.

In recent years, a number of Lebanese firms have acquired exploration permits and conducted limited investigations to determine if the deposits could again be commerically exploited. In 1964, the National Ores Co. initiated an exploration and processing study of the deposits in an area where it holds large exploration permits. Under a consulting contract from this company, a group of Czechoslovakian technicians began preliminary field and laboratory tests. The results of their efforts are unknown.

Iron and Steel.—There were two steel processing mills in Lebanon at yearend. The Consolidated Steel Co. of Lebanon (CSL) plant at Amchit has a rolling capacity of 90,000 tons annually and, has scrap smelting facilities to produce 40,000 tons of ingots annually. The Ghandour Steel Co. plant at Tripoli has similar facilities, but the capacity of this plant is reported to be approximately half that of CSL. During 1965, both plants operated rolling mills only, utilizing imported steel ingots. The scrap smelting facilities were not operated because they proved uneconomic under prevailing marketing conditions.

Both of the plants produce mostly bars and sheets and began marketing these products in 1962. Long established importers of finished steel products provided stiff competition to the local industry. To afford some protection to the Lebanese steel industry, the Government raised the customs tariff on finished steel from 8 to 15 percent ad valorem, effective September 7, 1965.

NONMETALS

Cement.—Lebanon's two cement producers, Societe des Ciments Libanis and Cimenterie Nationale, have a combined annual capacity of approximately 1,150,000 tons. Both plants are at Chekka, about 18 kilometers south of Tripoli on the Mediterranean where there are extensive limestone deposits. In 1965, the plants operated at 86 percent of capacity and supplied essentially all domestic consumption. Cement output in 1965 exceeded that of 1964 by 10 percent. This increase was due largely to a substantial increase in customs duty on cement imports. Early in 1965, the import duty on cement was increased from 8 percent ad valorem to a specific duty of $6.49 per ton, provided this was not less than 40 percent ad valorem.

In late 1964, the Government Council of Ministers approved plans for construction of a new cement plant at Siblin in the Chouf District of south Lebanon.

Salt.—All salt was produced by solar evaporation of sea water. Production was from numerous small saltworks in the northern coastal area which are operated seasonally from May to September.

Other.—Lime was produced for manufacture of cement and as a building material. A hydraulic lime plant at Fatri began operations in 1964. Numerous small mines and

quarries produced building stone, sand, gravel, and other minor construction materials for local consumption, but quantitative data on their output are unavailable.

MINERAL FUELS

Petroleum.—Although Lebanon has no known indigenous petroleum resources, petroleum pipeline, terminal operation, and refining remained the most important of the few basic industries of the country. Lebanon serves as a transit and export point on the Mediterranean for both Saudi Arabian and Iraqi crude oil. Crude oil from Saudi Arabia passes through south Lebanon in a pipeline operated by Trans-Arabian Pipeline Co. (Tapline) to an export terminal at Sidon. Iraq Petroleum Co. (IPC) operates pipelines that transport Iraqi crude oil to an export terminal at Tripoli in northern Lebanon. Crude oil receipts at Tapline and IPC terminals during 1965 averaged 441,544 and 325,628 barrels per day, respectively. Government revenue from transit fees in 1965 was an estimated $8.6 million.

Petroleum refinery product output has increased steadily in recent years in response to increased domestic consumption and export demand. Crude oil runs to the nation's two refineries averaged slightly more than 30,000 barrels per day in 1965 with each refinery processing almost equal amounts of crude oil. The IPC refinery at Tripoli processed Iraqi crude oil supplied from the company's pipeline terminal. Construction of facilities to expand the crude oil processing capacity of the Tripoli refinery from 15,000 to 35,000 barrels daily was nearing completion at yearend. The Mediterranean Refining Co. (MEDRECO) refinery at Sidon processed Saudi Arabian crude oil supplied from the Tapline terminal. In late 1965, the Government and MEDRECO concluded an agreement (subject to ratification by the Parliament) which amends the 1945 refinery construction and operating agreement. The agreement provides for increased royalty payments on processed crude oil, fixes the net profit, settles past tax claims, and requires distribution of 20 percent of refinery production to national distribution companies.

The Mineral Industry of Saudi Arabia

By James A. West [1]

With a greatly accelerated rate of crude oil output in 1965, Saudi Arabia strengthened its position among the leading oil producing and exporting nations of the world. Crude oil production during 1965 exceeded that of 1964 by nearly 18 percent. Producing at an average rate of 2,024,870 barrels per day, Saudi Arabia accounted for nearly 7 percent of the world's total crude oil output in 1965. On an annual basis, Kuwait continued as the leading oil producing nation in the Near East area; however, Saudi Arabia was a close second and its rate of production during December exceeded that of Kuwait.

Petroleum remained the dominant industrial activity and the only significant mineral industry of Saudi Arabia. In 1965, cement, salt, gypsum, and small quantities of minor construction materials were produced for domestic consumption. Gold and silver mines were formerly operated commercially, but production was discontinued in 1954. Recent mineral surveys indicate potentially significant deposits of iron ore, gold, silver, copper, barite, phosphate, and other minerals. Investigations to determine the feasibility of commercial exploitation of these resources are in progress.

Petroleum produced during 1965 was valued at an estimated $1,300 million. In 1965, direct payments to the Government by oil companies operating in Saudi Arabia and in the Kuwait-Saudi Arabia Neutral Zone were an estimated $653 million, accounting for about 90 percent of total Government revenues. In addition, the petroleum industry indirectly contributed about $120 million to the economy in wages and local expenditures for goods and services. The petroleum industry employed approximately 14,250 persons and about 1,000 workers were engaged in other mineral industry activities.

The Government initiated several new projects to explore and assess the mineral resources of Saudi Arabia. The Ministry of Petroleum and Mineral Resources (Petromin) concluded a bilateral agreement with the U.S. Geological Survey (USGS) to provide scientific and technical assistance in mineral exploration and evaluation programs. Under an earlier agreement, the USGS prepared and published a series of geological maps that cover the kingdom on a scale of 1 inch to 500,000 miles. The Bureau de Recherches Geologiques, Geophysiques et Minieres (BRGM), a French Government agency, began mineral exploration in three areas of northwestern Saudi Arabia under the auspices of Petromin. A consortium of three international companies began an aerial survey of the 15,000-square-mile area in an effort to find new mineral resources. Under the direction of BRGM, the survey will utilize the latest airborne magnetometer and scintillation counter equipment.

On March 14, the Government ratified an oil concession agreement with the French Government firm, Régie Autonome des Petroles (RAP). The concession includes three coastal and offshore areas along the Red Sea, comprising 26,500 square kilometers. Negotiations were continued with numerous other oil companies inter-

[1] Chief specialist, Near East–South Asia, Division of International Activities.

ested in acquiring new oil concessions in the central and Red Sea coastal areas.

Occidental Petroleum Corp. concluded an agreement with Petromin for the supervision of construction and for the operation of a 600-ton-per-day anhydrous ammonia plant at Dammam. The Saudi Arabian Fertilizer Co. was formed to manage the plant. The wholly Saudi Arabian-owned company was capitalized at $22 million, and 48 percent of the shares were offered to the public. Negotiations were continued with several international firms for the establishment of various petrochemical, oil processing, and other mineral development projects.

The Government continued efforts to resolve boundary disputes with neighboring countries. Agreements were concluded with Jordan and Qatar, defining their offshore and onshore boundaries. Saudi Arabia and Iran agreed to cooperate in a photographic mapping and Hiran survey of the Persian Gulf. Negotiations to establish agreement on a median line boundary were continued.

A "Regulations for Companies" law was enacted by Royal Decree on July 20. The new law is mainly a codification of existing practice and sets forth comprehensive regulations for the incorporation, operation, and liquidation of virtually all businesses in the country.

PRODUCTION

Saudi Arabia registered an outstanding gain in crude oil and refinery products production in 1965. Crude oil output reached a record high rate of 2,024,870 barrels per day, exceeding 1964 production by 308,765 barrels daily. Refinery throughput averaged 316,606 barrels per day.

TRADE

Except for crude petroleum and refinery product data, no detailed statistics are available for trade in mineral commodities.

Crude oil and petroleum product exports in 1965 were valued at an estimated $1,300 million and accounted for approximately 99 percent of the value of all exports.

Total imports were valued at an estimated $394 million in 1964. Imports of mineral commodities, mainly iron and steel, cement and other construction materials, comprise an estimated 10 percent of this total. Also, petroleum lubricants and aviation gasoline imports accounted for about 10 per cent of the value of all mineral imports. In 1965, petroleum product imports consisted of an estimated 155,000 barrels of aviation gasoline and 20,000 barrels of lubricants.

Table 2.—Saudi Arabia: Exports and reexports of petroleum and petroleum products [1]

[1] Data on geographic distribution on individual items are not available. The continental distribution of total crude oil and refinery products produced by the Arabian American Oil Co. (ARAMCO) (excluding bunkers) in 1965 was as follows, in percent: Europe 43.7; Asia and Australia 37.4; North America 9.7; South America 6.0; and Africa 3.2.

COMMODITY REVIEW

METALS

Iron and Steel.—Construction of a steel rolling mill at Jidda was begun in July. The mill is scheduled for completion in October 1966. Initially, the mill will process imported steel pellets to produce up to 45,000 tons per year of bars, sections, and other steel construction materials. Beneficiation tests of local iron ores were continued in order to determine the technical and economic feasibility of utilizing the large deposits of low-grade iron ores, known to occur in the Red Sea coastal area.

NONMETALS

Construction Materials.—Saudi Arabia's two cement plants (the Arabian Cement Co. plant at Jidda and the Saudi Cement Co. plant at Hofuf) operated at about 90 percent of their combined daily capacity of 750 tons per day during 1964 and 1965. These plants supplied about 30 percent of the estimated domestic demand for cement. The Saudi Cement Co. proceeded with plans to install a second kiln and double its capacity from 300 to 600 tons per day. Small quantities of gypsum, lime, marble, and other minor construction materials continued to be produced for local consumption, but quantitative data on their output are not available.

MINERAL FUELS

Petroleum and Natural Gas.—The Arabian American Oil Co. (Aramco) continued as the only oil operating company in Saudi Arabia proper. In August, the cumulative oil production by Aramco reached 7,000 million barrels. The company announced that estimated petroleum and natural gas reserves at yearend were 63,707 million barrels and 26,438 billion cubic feet, respectively. The petroleum reserve is nearly 20 percent of the total reported world reserve and places Saudi Arabia first among the world's oil producing countries.

Aramco increased its oil-producing capacity by the installation of additional oil-handling facilities and expanded exploration and development well-drilling programs throughout 1965.

The producing capacity of the Safaniya offshore field was increased by 150,000 barrels per day to 600,000 barrels daily and work to increase capacity further was in progress at yearend. Twelve additional wells were connected for production and a fourth submarine pipeline was completed. A 66-mile section of 40/42-inch-diameter pipeline from Khursaniya to Ras Tanura was completed and placed in service. A parallel pipeline was released and will be used to place the offshore Manifa field into production at rates up to 90,000 barrels per day by early 1966. Six additional wells in the Qatif field were connected to new production facilities and raised the capacity of the field by 30,000 barrels daily. A 29-mile, 8-inch-diameter submarine pipeline from the offshore Abu Safah field (shared jointly by Saudi Arabia and Bahrain) was completed. Abu Safah

was placed on test production and was scheduled to produce up to 30,000 barrels per day in early 1966. Work progressed on the construction of production facilities and pipelines to increase capacity of the southern area of the Ghawar field by 190,000 barrels daily.

Drilling was completed on 50 wells and 3 additional wells were abandoned. Total footage drilled in 1965 was 348,474 feet, an increase of 39 percent over that of 1964. Completions included 38 producing wells, 9 water injection wells, and 3 observation wells. An offshore well drilled 16 miles east of the nearest Safaniya well resulted in the discovery of the Zuluf field. An exploratory well at Niban on the northern fringe of the Rub al-Khali desert proved nonproductive and was abandoned. Two stratigraphic wells drilled in the Dibdibah gravel plains area were abandoned. An exploration well at Jaham, 28 miles northwest of the Khurais field, was drilling at yearend.

The record 1965 oil production of nearly 2,025,000 barrels daily was from nine fields having about 300 wells connected to producing facilities. The giant Ghawar field was the leading producer, accounting for 44 percent of total output. Other major producing fields and their percent of total output were: Safaniya, 23.3; Abqaiq, 20.2; and Khursaniya, 6.4. The Abu Hadriya Qatif, Dammam, Fadhili, and Khurais fields combined produced the remaining 6.1 percent.

Reservoir fluid injection programs to assure maximum economic oil recovery were continued and expanded by Aramco. Average daily rates of water injection into the Abqaiq, Ghawar, and Khursaniya fields were 629,035, 202,605, and 14,420 barrels per day, respectively. Gas injection into the Abqaiq field averaged 164 million cubic feet daily. The Ain Dar gas injection plant underwent extensive modification throughout most of the year, but was returned to partial operation on October 5 and injected gas at an average daily rate of 143 million cubic feet to yearend. Also, liquefied petroleum gases, equivalent to about 28 million cubic feet per day, were injected into the Abqaiq and Ghawar fields.

The Mineral Industry of the Syrian Arab Republic

By E. Shekarchi[1]

The Syrian mineral industry remained insignificant as a foreign exchange earner during 1965; however, income from transit royalties of the Trans-Arabian Pipeline Co. (Tapline) and the pipeline of the Iraq Petroleum Co. (IPC) contributed significantly to government revenues, approximately $30 million in 1964. Total export of metals and minerals, including refinery products, amounted to about $583,000[2] in 1964, whereas imports of metals and minerals amounted to about $44 million.

Total gross national product (GNP) in current prices was $850 million in 1964 with a per capita GNP of $155, compared with $148 in 1963. Annual population growth based on 1965 estimation was 3 percent. Of the total population of 5.7 million people, 39 percent constituted the labor force. An estimated 6,600 persons were engaged in mineral-based industry, including mining, quarrying, and cement factories, and petroleum refineries.

The first 5-year development plan, which dated from the union with Egypt, was terminated after 4½ years, at the end of 1964. The Government, rather than present a new plan immediately, elected to make 1965 a year of transition and to prepare a new 5-year plan for 1966–71.

Progress on the project to dam the Euphrates River has been extremely slow. Although a loan of $14 million was arranged at 3¼-percent interest, payable over 20 years, beginning when signed by the Economy Ministers of West Germany and Syrian Arab Republic, only technical studies of the project were conducted in 1965. The project was to study utilization of the land to be irrigated by the proposed dam on a pilot plant scale.

In March 1965, the Government of Syria took possession, under the nationalization act, of the country's nine private oil marketing companies and placed them under the direction of the Ministry of Industry to be operated by the Syrian General Petroleum Authority. Properties nationalized were entirely in marketing and were formerly owned by such major companies as the Royal Dutch/Shell group, Standard Oil Co. of New Jersey, and Socony Mobil Oil Co. Although the owners were said to be compensated, details of the arrangements were not disclosed.

In the latter part of 1965, the Director of Tartous Port Construction stated that the terminus of the Karatchuk oil pipeline would not be placed within the port of Tartous itself, but rather that it would be extended as a sea line to where the depth of the water is sufficient for large tankers. The authorities hoped that the first stage of the port construction would be completed by mid-1966 so that it could be utilized in importing material needed for the construction of the pipeline.

On April 27, the electrical powerplant of the Homs-Hama Electric Co. was inaugurated. The plant, which was constructed by the Czechoslovakian firm, Techno-Export, will produce 30,000 kilowatts per day. Some of this power is to be used at the nearby Homs refinery.

An agreement between the Government of Syria and a British consortium to build an oil pipeline from Karatchuk oilfields to Homs refinery was signed in 1965.

---

[1] Foreign mineral specialist, Division of International Activities.

[2] Where necessary, values have been converted from the Syrian pound (SL) at the rate of SL3.83=U.S.$1.00 although there was a currency fluctuation of 10 to 15 percent during the year.

PRODUCTION

The small mineral production of the Syrian Arab Republic in 1965 only slightly exceeded that of 1964. However, 5-year production records for some commodities showed significant increases. Production of natural asphalt, cement, gypsum, and salt have almost doubled. During the past 5 years, no such outstanding increase has been made in production of petroleum refinery products. Comparison of refinery production figures for 1961 and 1965 shows an increase of only about 30 percent.

TRADE

Syria remained dependent on imports for supplies of all metals, most industrial minerals, and a significant part of commercial fuels. The value of all imports for 1964 was $235 million, nearly the same as in 1963. Imports of metals and minerals accounted for approximately $44 million in 1964. Imports of ingot and scrap copper, ingot lead, and iron and steel decreased because of reduced light construction in the country.

Total export of the country in 1964 was valued at about $176 million, compared with $189 million in 1963. Since Syria is primarily an agricultural country, export of industrial minerals and metals remained insignificant, only about $500,000 worth in 1964.

COMMODITY REVIEW

METALS

No significant discovery of metals of economic value was reported in 1965, although geological investigation continued. Most of the domestic requirement of metals and related industrial minerals continued to be met by imports.

NONMETALS

Cement.—The Société Nationale pour la Fabrication du Ciment et Materiaux du Construction continued its expansion program in 1965 by addition of facilities 5 miles out of Damascus for producing prefabricated cement goods such as telephone poles, and of a plant for the production of asbestos cement.

An agreement was signed between the Ministry of Communication and the Soviet Union for construction of a prestressed concrete factory to produce telegraph poles. The factory is to be built in Aleppo and will have a capacity of three poles per day.

Fertilizer Materials. — *Nitrogenous.* — The nitrogen fertilizer plant at Homs which has been under consideration since 1957, moved a step forward in 1965. At yearend, it appeared that the planned annual capacity of the plant had been increased to 150,000 tons of Cal-Nitro fertilizer of 25 percent nitrogen content, and that it will consist of three major units for the production of ammonia, nitric acid, and Cal-Nitro fertilizer. According to the Ministry of Industry's estimate, the plant will cost $30 million and will begin production in late 1968. The plant will be built by Soviet, Czechoslovakian, and Italian interests.

Phosphatic.—The exploitation of Syrian phosphate at Palmyra, which was the subject of a feasibility study by a U.S. engineering firm, also progressed, with shipment of 500 tons to Poland, East Germany, and Rumania for analysis and beneficiation test purposes. No contracts were signed by the end of 1965.

MINERAL FUELS

Petroleum.—*Refining.*—A contract for the expansion of the Homs oil refinery was signed between the Ministry of Industry and the Czechoslovakian State firm, Techno-Export, in 1965. Under the contract, the capacity of the refinery, owned by the Syrian Government, was to be increased from 1 million tons to 1.7 million tons annually. The General Petroleum Authority was experimenting at Homs refinery with Syrian crude oil extracted from the Suwaidiyah and Karatchuk fields (23° to 24° API and 22° API, respectively, and with high sulfur content) either to use this crude directly or to blend it with IPC and Tapline crude oil. Through yearend, the refinery ran on feedstock crude from IPC and Tapline which have an obligation to supply crude at reduced rates to Homs as part of their agreement.

Pipelines.—An agreement was signed between the Government of Syria and a British consortium, consisting of Coustain & Press (Overseas) Ltd. and Stewarts & Lloyds Ltd., to build a crude oil pipeline through Syria in the latter part of 1965. The pipeline is to be extended from Karatchuk in northwestern Syria to Homs refinery and from Homs to the port of Tartous on the Mediterranean. The distance is about 640 kilometers and construction is expected to take about 2½ years. The project, calling for a loan of $38.5 million, would be financed by five British banks and would be repayable over 10 to 15 years at 5½-percent interest. The initial throughput will be 5 million tons a year, capable of being expanded to 7.5 million tons annually. The planned diameter of the pipeline was 18 to 22 inches with five pumping stations. It was scheduled to go into operation in 1968 with an initial capacity of 100,000 barrels per day.

The Mineral Industry of Turkey

By E. Shekarchi [1]

The mineral industry of Turkey experienced a record high year in 1965, both in volume of mineral production and export value of minerals and primary products. The gross value of minerals and primary metals and nonmetals, excluding petroleum products and iron ore, was estimated to be approximately $391 million, an increase of 30 percent over that of commodities reported for 1964. Total value of mineral commodity exports, including fuels, in 1965 comprised 9.5 percent of the country's total export value and reached approximately $43.6 million, 18 percent and 65 percent higher than export values of 1964 and 1963, respectively. With production of more than 500,000 tons of chromite of all grades, Turkey contributed about 11 percent to the total world production of this commodity and ranked third among the chromite-producing nations.

According to estimates made by the Agency for International Development (AID) in 1965, the population of Turkey has almost doubled during the last 30 years. It was reported to be about 31.1 million with an annual growth rate of 2.5 percent. Labor status reportedly remained the same as in 1964 with 75 percent engaged in agriculture and the remaining 25 percent employed in the industrial sectors of the economy, including mining and mineral processing.

Based on 1962 prices, the total gross national product (GNP) in 1965 was reported to be $7,245 million [2] or an increase of 5.4 percent over that of 1964, while per capita GNP increased 2.6 percent.

Turkey at the end of 1965 completed the third year of its first 5-year plan. The overall rate of growth as originally planned (7 percent) was not reached and international advisors to the State Planning Organization (SPO) were doubtful that the 1966 planned growth rate would be achieved. The work on the second 5-year plan (1968–73) began in 1965; SPO, with the experience of the problems of the first 5-year plan, had a more realistic view and established general guidelines to approach the problem.

The Government in power at the start of the year fell in February 1965. The new government formed following the October election did not have sufficient time to do much more than organize itself and prepare its legislative program; therefore, no legislation of importance relating to the mining industry was acted upon during 1965.

All sectors and units of the Ereğli iron and steel plant, owned by Ereğli Demir ve Çelik Fabrikalari T.A.S. (Erdemir), a private enterprise financed by U.S., German, and Turkish capital, became fully operational in March of 1965. All of the expanded facilities of the State-owned Karabük plant were operating at near capacity at yearend except the structural steel and foundry units which remained incomplete.

A magnesite mining and calcining operation controlled by U.S. interests and known as Continental Magnezit Ltd. secured approval under the foreign investment law No. 6224 to increase its investment in order to double production of caustic magnesite for export.

As an associate member of the European Economic Community and as a full member of the Organization for Economic Cooperation and Development, Turkey received in 1965 considerable assistance, not

[1] Foreign minerals specialist, Division of International Activities.

[2] Where necessary, values have been converted from Turkish lira (TL) to U.S. dollars at the rate of TL1=US$0.11.

only in the form of loans but also in the form of special concessionary import quotas which were granted in an effort to support development of Turkey's natural resources.

A number of protocols involving metal and mineral projects were signed between the Turkish Government and the U.S.S.R. Among these were proposals for a sulfuric acid plant, a petroleum refinery, and an aluminum complex extending from bauxite to the finished product. However, by year-end, no definite commitments were made by either side on these projects.

The Mineral Research and Exploration Institute (MTA), a government agency with a budget increased to $6.5 million annually, continued throughout 1965 a broad mapping and exploration program for phosphate, uranium, lignite, bauxite, and petroleum. The 1:25,000 scale geological mapping program of MTA made good progress in the Zamanti River lead-zinc province, and geochemical surveys for nonferrous metals were conducted in the Zamanti, Kure, Keban, and Balya districts. However, no detailed information on results of these studies was available by the end of 1965.

Even though no new discoveries of mineral deposits were reported in 1965, the mining department of the Ministry of Energy and Natural Resources issued 63 mineral concessions including 27 for lignite, 12 for iron, 12 for chromite, 3 for boron minerals, 2 each for asbestos, lead-zinc, and magnesite, and 1 each for zinc, flourspar, and pyrite. Mining activities and claims on new areas for future development were clearly in high gear.

Turkiye Petrolleri A.O. (TPAO), a State-owned exploration and refining company, awarded contracts for construction of a pipeline from the Batman refinery in southeast Turkey to the Mediterranean Sea port of Iskenderum during 1965.

In the preparation of this chapter, the author has drawn background information from the extensive reporting of the U.S. Foreign Service dispatches and the annual mineral report prepared primarily by Clarence A. Wendel, the minerals attaché with the U.S. Embassy in Ankara, and furnished to the Bureau of Mines. Detailed statistics on the mineral trade of the country were obtained primarily from the Office of Statistics of the United Nations.

PRODUCTION

The gross value of mineral products, including some manufactures such as steel and cement but excluding petroleum products and iron ore, increased by 30 percent in 1965 or from $300 million to about $391 million. Crude minerals alone, excluding fertilizers, cement, coke, pig iron, steel, and ferrochrome, showed a gain of 7 percent in 1965 compared to the 1964 figures. Among the major minerals contributing to this gain were chromite, copper, iron ore, borates, magnesite, and petroleum. Chromite production was up 37 percent in 1965 compared with the 1964 output and registered the highest production level since the peak year, 1958. Output of blister copper showed a 1-percent increase in 1965, while iron ore production increased 5.6 percent to a new record level in an effort to supply both steel plants.

Within the nonmetallic mineral sector of the industry, boron mineral producers continued an expansion program which led to a 33-percent production increase in 1965, while magnesite output was almost doubled. Production of lignite increased by 7.6 percent, as bituminous coal output fell off slightly in 1965 in comparison to the 1964 production level. Reflecting Turkey's determination to be self-sufficient in petroleum, the output of crude petroleum was increased by 64 percent in 1965.

TRADE

The value of all mineral commodity exports from Turkey in 1965 was approximately $44 million, which constituted about 9.5 percent of total commodity export of $459 million. Copper exports, valued at $18.7 million in 1965, remained the leading mineral exchange earner, followed by chromite and ferrochromium, together valued at $10.7 million, and borates with a value of $4.1 million. Quantitatively, copper shipments in 1965, ore and blister combined, increased 32 percent over those

[1] Ore and regulus contain 45 percent and 49 percent antimony, respectively, in 1965.

[2] Includes remelted scrap through 1962.

of 1964; exports of chromite and ferrochrome were up 22 percent in total and those of borate minerals were up 29 percent. Increased export value of copper and chromite was primarily due to premium prices in the international market. Exports of magnesite, crude and calcined, and cupreous pyrite increased by 71 percent and 29 percent, respectively, in 1965 compared with 1964 export while shipments of manganese ore and mercury decreased.

Total merchandise imports in 1965 were valued at $572 million; of this, mineral commodities were valued at about $154 million. Among metallic mineral commodities imported in 1965, iron and steel, in-

cluding (primary) ingots, and semimanufactures, but excluding pig iron, ferroalloys, and scrap, were valued at $47.2 million compared with $39.7 million in 1964. In spite of substantial improvements during 1965, the petroleum industry of Turkey remained dependent on foreign crude oil to the extent of about $48 million. Other notable changes in imports were a 257-percent increase in aluminum ingot, valued at $3 million in 1965, and a 50-percent decrease in cement imports in 1965.

COMMODITY REVIEW

METALS

Aluminum.—The first production of bauxite in Turkey was reported in 1964 when MTA mined and shipped high-silica bauxite ore from the Akseki deposits. Output of bauxite more than doubled in 1965.

SPO reportedly has entrusted Etibank with the responsibility of developing the deposits and producing 50,000 metric tons of aluminum annually. Apparently the proposed aluminum industry in Turkey will be based on two high-grade bauxite deposites discovered near Seydişehir known as Mortas and Dogan Kuzu. A systematic drilling of the Seydişehir deposits was completed in 1965 and reserves of about 30 million tons were established with the following chemical analysis: 60 to 65 percent alumina, 6 to 7 percent silica, and 14 to 16 percent ferric oxide. In the latter part of 1965, the drilling program was shifted to the Saimbeyli area southeast of Kayseri where bauxite beds similar to those at Seydişehir were encountered. Preliminary estimates of reserve in this locality have been determined to be over 10 million tons.

At yearend, no firm decision regarding

the erection of proposed plants for production of alumina and aluminum metal producing facilities were available. However, various foreign participation offers were said to be under consideration.

Antimony.—Özdemir Antimuan Madenleri A/S Sirketi produced about 90 percent of total Turkish antimony ore and concentrate in 1965. The remaining 10 percent came mostly from the newly discovered polymetallic mines of Rasih ve Ihsan Madençilik Sirketi near Nigde. The Mutlu Battery Co. completed a new plant in Kartal in 1965 and regulus production of the company reached a new high of 107 tons, a twofold increase over 1964 output. Most of the company's production was used domestically.

Chromite and Ferrochrome.—In 1965 the Turkish chromite industry experienced the highest production level within the last 5 years. Under the stimulus of higher market prices, run-of-mine production reached about 567,062 tons, of which some 300,000 tons had to be concentrated. Etibank produced from its Güleman property 143,000 tons of metallurgical-grade ore and 13,670 tons of refractory grade ore, and from its Üçköprü mines 14,435 tons of concentrate and 76,205 tons of high-grade metallurgical ore. Among principal private producers, Türk Maadin ranked first with about 110,000 tons of concentrate and 5,000 tons of lump ore from its operation at Kavak and Göçük near Eskişehir, followed by Sitki Koçman with production of about 50,000 tons of high-grade lump ore from the Muğla area, and by Ömer Inönü and associates with production of about 30,000 tons of concentrate from the Harmancik and Tokat areas.

The entire production of 7,473 tons of ferrochromium from Etibank's Antalya plant was sold during the year. In preparation of this ferrochrome, 13,447 tons of concentrates and 7,125 tons of lump ores from domestic production were utilized.

Copper.—The State enterprise, Etibank, remained the sole copper producer of Turkey. Production of blister copper in 1965 from Etibank's Ergani and Murgul smelters was 18,500 and 7,800 tons, respectively. This blister copper was derived from the Ergani and Murgul mines. Production of straight copper ore at Ergani totaled 322,025 tons including 226,980 tons of direct smelting ore averaging 7.32 percent copper, and 95,045 tons of milling grade ore averaging 2.72 percent copper. Output of the Murgul mine consisted entirely of milling grade ore—495,352 tons containing 1.93 percent copper. In addition, 8,100 tons of hand-sorted ore containing 10 percent copper was produced by Etibank's Küre mine for direct shipment to West Germany and this property also produced 132,166 tons of cupriferous pyrite containing 2.69 percent copper for the export market. However, export of blister in 1965 was about double that of 1963 and 55 percent greater than the 1964 export level.

In order to utilize the low-grade ore from Ergani mine, the flotation plant was expanded, and by yearend 800 tons per day was being treated. The Minister of Power and Natural Resources confirmed that Etibank has signed a contract with the Ralph M. Parsons Co. for AID-financed feasibility study of ore discovered in the Murgul region. The new deposit is only 1 kilometer from the present opencast mine area and has an estimated reserve of 20 million tons of ore containing 0.5 percent or more copper and averaging 1.25 percent copper.

Tentative overall plans of the copper industry call for erection of a new 2,500-ton-per-day concentrator at the Murgul mine, a pipeline to transport concentrates to the port of Hopa on the Black Sea coast, and a smelter and sulfuric acid plant at Samsun to produce 40,000 tons of anode copper and 150,000 tons of sulfuric acid annually.

Geologists of MTA reportedly have discovered large high-grade copper deposits near Farkisli not far from Iskenderun in southern Turkey. No detailed information on grade and reserves of this discovery was available at yearend.

Iron and Steel.—Production of iron ore, primarily for domestic consumption, registered an alltime high of 1.53 million tons in 1965. The State-owned and operated Karabük Steel Co.'s Divriği mine lead all ore producers with approximately 897,000 tons, followed by Demir Export (Koç) Co.'s production of about 257,000 tons from two mines. Shipments of salable ore from operating mines and companies from 1963 to 1965 is shown in table. 4.

The private mines supplying iron ore to Ereğli fell short of the scheduled delivery and it seemed probable that if this trend continues and no new discoveries are

[1] New company.

found within the country, Turkey may seek a new source of raw material abroad. Although no new discoveries were reported in 1965, reassessment of Rasih ve Ihsan Mining Co.'s Sakarkaya mine near Milâs indicated the possibility of 12 million tons of magnetite ore containing 1 to 2 percent sulfur.

The Ereğli iron and steel plant of Erdemir was brought into full operation 6 months ahead of the orginal work schedule. Erdemir, a private enterprise engineered and built by a consortium of U.S. companies (Koppers Co., Inc., Blaw-Knox Co., and Westinghouse International), received a loan of $129 million from AID, the largest single industrial loan of its kind ever granted. The remaining cost of $146 million was raised privately and in the form of a loan to the Turkish Government from the West German Government. However, the consortium, as part of their pay for services, equipment, and funds advanced, collectively hold a minority stock interest in Erdemir. Erdemir has already sold nearly $11 million worth of common stock to nearly 2,000 Turkish citizens.

Present plans call for production of about 400,000 tons a year of crude steel, plus 100,000 tons of pig iron. The 400,000 tons of ingot produced annually is then to be processed into about 300,000 tons of steel semimanufactures.

Turkey's other integrated plant, the State-owned Karabük steel works, was operated at near capacity by the end of 1965; however, some of the most recent expanded facilities for structural sheet and foundry section remained incomplete and no completion date was given.

In the private sector of the steel industry, Metaş plant at Izmir increased production of ingot steel from imported scrap to almost 45,000 tons in 1965. Also during the year, the company initiated an active campaign to find an indigenous supply source of iron ore for a sponge iron plant. If successful, this campaign would eliminate the dependence on imported scrap.

Lead and Zinc.—In 1965 mine production of lead and zinc ores in general was about the same as that of 1964. Due to decreasing prices in export markets, particularly for calcined zinc ore, the high production and export expectation of 1964 was not realized in 1965. In addition to decreased prices, a strike at the Simav mine which began in August and was not settled by yearend contributed to the reduced output in 1965.

A new potentially important discovery was reported in the Hekimhan area near Malatya province by Rasih ve Ihsan Madencilik Şirketi. No detailed information regarding grade or reserves was available.

Rasih ve Ihsan remained the principal producer of mixed lead-zinc ore mined from company holdings in Akdağ Madeni, located betwen Yozgat and Sivas, and from various small mines in the Black Sea area. Özdedeoglu Co. which produced zinc carbonate and mixed sulfide ores from four mines, all in the Zamanti River area, ranked second.

Manganese.—Available data indicate that manganese ore production during 1965 was 30 percent less than in 1964 and was about equal to manganese ore export in 1965. In addition, a substantial tonnage of mangani-

ferous iron ore containing 2 to 5 percent manganese reportedly was produced in the country. However, the manganese requirements of both Ereğli and Karabük steel plants apparently were met by indigenous manganese output other than that reported.

Mercury.—Both mercury production and export declined during 1965, although several new mines came into production.

Etibank produced 1,250 flasks from Haliköy property near Izmir, as well as from the new operation that it had acquired the previous year near Konya. Most promising were the new openings in the Ladik concessions in the Konya area where Etibank produced about 54 flasks of mercury during the year. The average mercury content of Haliköy mine ore was given at 0.25 percent while the Ladik property's grade is said to be about 0.5 percent. No detailed information was available on reserves of these properties.

Among the private producers, the most promising mercury operation was that of Rasih ve Ihsan's Eskigümüş mine where recoveries of up to 3 flasks a day were reported. The ore body was described as a stibnite and scheelite-bearing quartz vein with cinnabar pockets containing 2 to 10 percent mercury. In order to have the maximum recovery at present, a very selective mining concentrating mostly on cinnabar pockets was adopted.

NONMETALS

Asbestos.—Production of crude asbestos was slightly higher in 1965 than in 1964, but the increase had no effect on imports of high-quality material. Total asbestos imports in 1965 were 8 percent greater than in 1964 and practically doubled those of 1963.

Barite.—The Turkish Mining Development Fund awarded credits in 1965 to a private mine operator, Hamdi Bozbag, to improve mining conditions at newly acquired properties and to erect a new modern grinding plant at Elazig. The plant will treat 2,000 tons of ore annually. Bozbag reportedly exported a total 14,200 tons of high-grade ore to the United States in 1964 and 1965 but these shipments are not reflected in official trade statistics. Reportedly, Bozbag's newly acquired properties near Maraş have an indicated reserves of 150,000 tons of high-quality ore, suitable for grinding.

Boron Minerals.—Both production and export of boron minerals set a new record in 1965, with totals of 170,977 and 152,564 tons, respectively. Production was up 33 percent and export increased about 28.8 percent from that of 1964.

Etibank remained the main single producer, followed by private producer Türk Boraks Madencilik (Turk Borax), a subsidiary of Borax Consolidated Ltd., and Rasih vs Ihsan and Haşamettin Yakal.

Construction on the borax and boric acid plants, Etibank ventures at Bandirma, continued during the year with a tentative completion date set for yearend 1966 or the early part of 1967. The plant reportedly will process 35,000 tons of ore to produce 20,000 tons of borax and 500 tons of boric acid annually.

Rasih vs Ihsan Maden Ltd., formed a joint venture with Pilkington Brothers of England to supply 25,000 to 50,000 tons of clean crushed colemanite annually for direct use in fiberglass production. Drilling by the British partner and detailed mapping has proven ore reserves of about 3 million tons in Rasih ve Ihsan's property.

Cement.—Continuing a straight-line growth rate, cement output reached a new high in 1965 with about a 10-percent increase over the 1964 production level. This increase resulted from expansion of existing plants at Söke, Gaziantep, Afyon, and Elazig.

Among the various State and private cement producing organizations, Turkiye Çimento Sanayii T.A.S. ranked first, with an output of 1,495,000 tons. Private sector production supplied by several plants totaled 1,569,000 tons including 197,000 tons produced by Sümerbank Çimento Sanayii Muessesesi. The Ankara municipal plant recorded an output of 180,000 tons.

Emery.—In 1965 export of emery, principally to the United States and the Netherlands, expanded by 80 percent over that of 1964. The reported average value of exportable material was slightly over $12 per ton, f.o.b. Turkish port.

Fertilizer Materials.—Most of Turkey's phosphate rock requirement was met by imports from Israel and Jordan; receipts increased 8 percent in 1965 compared with those of 1964.

MTA continued exploration and research in the recently found phosphate deposits of southeast Turkey. The announced reserves of 100 million tons of phosphate

rock reportedly consist of low-grade material averaging 10 to 12 percent phosphorus pentoxide (P_2O_5) in beds about 1 to 1½ meters thick. In an effort to determine whether this low-grade material can be upgraded, Etibank in June 1965 announced that a contract for a second feasibility study had been signed with a West German firm. However, by the end of 1965, no detailed information from this study was available.

Fertilizer output increased 32 percent in 1965 over the 1964 level. Although this was a substantial increase, about doubling 1962 production, SPO placed highest priority on further increases in production of fertilizer materials so as to increase the agricultural output of Turkey. On this basis, SPO has recommended doubling of the production capacity of Azot Sanayii T.A.S. (Turkish Nitrate Corp.) plant at Kütahya during the year. Also a five-man fertilizer team from the U.S. Tennessee Valley Authority operating under an AID loan to Turkey, agreed in principle to cooperate with SPO on the improvement of the fertilizer industry.

The 46-percent increase in superphosphate output from the 1964 level was most remarkable in comparison with the slight increase in ammonium sulfate output and the slight decrease in ammonium nitrate production in the same period. However, 1964 superphosphate output was considerably below the 1963 level.

Magnesite.—Production and export of magnesite in 1965 almost doubled the 1964 figures. Most of the production was from the Bursa-Eskişehir area where the high-grade ore occurs. Magnesite occurs in veins, stockworks, and lenses of considerable size in serpentinized ultrabasic rocks throughout Turkey. The wide distribution of ultrabasic rock in the country enhances the possibilities for even greater development of magnesite than that already assured on the basis of the present limited exploration. Indicated reserves of magnesite in 1965 remained around 15 million tons.

The prospects for commercial production of calcined magnesite for marketing in Europe were so attractive that the Turkish subsidiaries of both Continental Ore Co. and Vietscher Magnesit Werke, A.G. of Austria, Continental Manyezit Ltd. Şirketi and Manyezit Anonim Şirketi, respectively, applied for expansion permits in 1965. The former was importing equipment to expand production of caustic-grade magnesite to 28,000 tons annually with plans for future expansion to 28,000 tons of caustic and 30,000 tons of dead-burned magnesite for export by 1969. The latter until 1965 had purchased crude magnesite from private producers as feed for its calcining plant, but during the year it acquired exploration permits and was in process of developing its own mine. This firm's expansion plans called for an expansion of plant capacity from 10,000 tons to 20,000 tons of dead-burned magnesite annually.

On the basis of MTA's extensive drilling and evaluation, Sümerbank decided to establish a plant with a 26,500-ton annual capacity at Meram near Konya to produce sintered magnesite. Production from this plant is expected to meet most of Turkish metallurgical grade requirements. The contract for the construction of the plant was apparently awarded to a Japanese firm at an approximate cost of $5.5 million.

Marble.—Although marble production remained at the same level in 1965 as in 1964, export increased by about 18 percent. Most of the production came from Marmara, Afyon, Sögüt-Bilecik, and the Gebze region, all located in the northwest section of the country.

Pyrite.—In 1965 output of the Küre pyrite operations, 31 kilometers south of the Black Sea, remained at about the same level as in 1964. Ore produced reportedly contained about 2.69 percent copper. About 8,100 tons of high-grade ore averaging 10 percent copper was hand sorted from various mines in the Küre region and was shipped to West Germany. Systematic diamond drilling

Table 5.—Turkey: Production of chemical fertilizer
(Metric tons)

Commodity	1963	1964	1965
Ammonium nitrate	58,744	85,913	85,000
Ammonium sulfate	88,513	63,487	91,600
Superphosphate	175,000	151,530	221,300
Total	322,257	300,930	397,900

by Etibank continued during the year and new massive ore bodies were delineated, containing an average of 3 to 4 percent copper with estimated reserves of 2 million tons.

Sulfur.—Despite Turkey's pressing need for more fertilizer, estimated refined sulfur output totaled only 23,000 tons, about 4 percent more than in 1964. Possible establishment of new plants in Ergani, Izmir, and elsewhere by Etibank remained under consideration, but no actual construction work was reported by yearend. One of the Etibank proposals most recently advanced was for a sulfuric acid plant to be established at Samsun in connection with the new 40,000-ton-per-year copper smelter.

MINERAL FUELS

Although Turkey has large reserves of lignite scattered throughout the country, the two largest contributors to the total energy supply of Turkey remained fuelwood or charcoal and animal waste. Apparently these materials supplied 48 percent of the total energy requirement in 1965, while petroleum, coal, and hydroelectric power furnished the remainder.

Bituminous Coal.—Production of washed coal for the first time in recent years decreased by 1.3 percent at the Zonguldak-Armaçuk group of mines operated by the Türkiye Kömür Işletmeleri Kurumu (TKI), the Turkish State coal mining enterprise. Apparently wage increases granted in 1964 resulted in an operating loss in 1965, and profits realized in 1963 and 1964 were not repeated. After many years of production experience, TKI's operation suffered 70 fatalities and 8,400 lost-time injuries with a daily working force of 19,000 men.

During the year, a greater percentage of sales of Zonguldak coal was made to the Karabük and Ereğli steel plants for production of metallurgical grade coke.

A small private mine near Diyarbakir produced on a commercial scale about 12,000 tons of bituminous coal; this represented the first private enterprise bituminous coal production since nationalization of foreign and Turkish mining operations at Zonguldak was completed in 1936.

During the year a decrease in use of coal for domestic and industrial consumption was recorded as greater quantities of domestic lignite and fuel oil became available. The reserves of bituminous coal that are known on the Black Sea coast in the Zonguldak coal basin were variously estimated from 1,000 million to 5,000 million metric tons.

Coke.—Production of all types of coke reached a record high of 1.434 million tons in 1965. The record production represented an increase of 29.5 percent over that of 1964. Karbük steel mill was the leading coke producer in 1965 with about 860,000 tons, followed by Ereğli steel plant, 383,000 tons, municipal gas plants about 116,000 tons, and Zonguldak semi-coke plant 75,000 tons.

Lignite.—Turkey has large lignite deposits scattered throughout the country with reserves estimated to total between 150 million and 300 million tons. Although the only extensive recorded lignite production is from the western provinces, there are numerous deposits known in the eastern provinces which produced on a commercial scale for the first time in 1965.

Production of lignite in 1965 from State-owned mines operated by TKI remained almost at the same level as in 1964. However, output of numerous privately operated mines, ranging from 100 metric tons to 308,000 tons annually in individual output, together recorded an increase of about 22.6 percent compared with the 1964 level. Production of some of the principal private mines is shown in table 7. Due to lack of

detailed information on small privately operated mines, they have not been included.

In 1965 Western Lignite Operations of TKI concluded a loan agreement with AID for expansion of the Tunçbilek washing plant to 2 million tons annual capacity and for modernization of the Seyitömer opencast mining operations.

Petroleum.—*Crude Oil.*—According to announcements made by the Ministry of Industry, Turkish crude oil output in 1965 reached a new high, 64 percent greater than in 1964; the increase was shared by all producing companies as shown in table 8.

For the first time, the combined production of the privately owned companies exceeded the production of the Government-owned TPAO. It was expected that until the Batman-Iskenderun pipeline is completed, production will not exceed the 1965 level appreciably.

The discoveries during 1963 and 1964 at fields such as Selma raised hopes that Turkey might soon be self-sufficient in the production of crude oil. However, the extensive exploration activity in 1965 and the drilling of several dry holes at Selma indicated that these hopes will not be realized in the near future if at all, and that Turkey must depend on the foreign market for crude petroleum.

Foreign companies producing petroleum in Turkey reported the following results of exploration activities for all operating firms: TPAO drilled a total of 76 exploratory wells and discovered oil in 5; Mobil drilled 29 exploratory wells, of which 5 were discovery wells; and Shell has drilled 17 exploratory wells, of which 4 were discovery wells.

By yearend, it was reported that the French firm, Société de Participations Pétrolières, made a discovery of good quality 35° API gravity oil in district V at Malahermo Number 1. However, no details on reserves or well-test results were available.

Total	5,986	9,816	64

Detailed geological mapping and geophysical studies by MTA in Erzurum province near the village of Tekman were augmented by a drilling program using a rig capable of reaching a depth of 1,000 meters. The drilling program was to be completed sometime in 1966; detailed information on results in 1965 was not available at yearend.

Refining.—Turkish refinery production totaled about 31 million barrels from three plants, one each in Batman, Izmit, and Mersin. Most of the domestic production of about 9.8 million barrels and nearly 22.6 million barrels of crude oil imported from Saudi Arabia and Iraq constituted the feedstock.

Pipelines.—TPAO awarded a contract for construction of a pipeline from Batman (southeast Turkey) to the Mediterranean seaport of Iskenderun to Enterprise de Recherche et d'Activités Petrolièrs of France and Tekint Co. of Italy. The 18-inch pipeline will be 560 kilometers long and cost about $34 million. The initial capacity of 70,000 barrels daily can be expanded to 100,000 barrels per day with the addition of more pumps. Initial plans call for construction of 14 storage tanks, each with a 150,000-barrel capacity, 2 pumping stations, and 1 port facility. Feasibility studies were carried out by Brown and Root Engineering Co. of the United States, which also has been awarded supervision of the project that is scheduled for completion in early 1967.

The pipeline will be used primarily by TPAO, Royal Dutch/Shell, and Socony Mobil Oil Co. which have developed substantial production and reserves east of the Tigris River in southeast Turkey.

The Mineral Industry of Other Arabian Peninsula Areas

By James A. West [1]

CONTENTS

QATAR

The petroleum industry of Qatar accounted for about 2.6 percent of Near East area crude oil production in 1965. Essentially all oil produced was exported as crude oil. These oil exports, valued at an estimated $155 million in 1965, were the source of essentially all foreign exchange and most Government revenues. Direct payments to the Government by the oil operating companies in 1965 were an estimated $75 million. As the sheikdom's only significant industrial activity, the petroleum industry indirectly supports much of the local commercial and construction activity. Oil operators employ about 2,400 persons, or nearly 14 percent of the estimated total work force.

The Governments of Qatar and Saudi Arabia reached agreement on the definition of their onshore and offshore boundaries. Negotiations were continued with other neighboring States in an effort to resolve boundary disputes.

The Qatar Petroleum Co. (QPC) relinquished to the Government an additional 1,104 square miles of its oil concession area. Originally, QPC held oil rights to the entire peninsula but had relinquished much of the area previously in 1961 and 1963. At the end of 1965 QPC retained only about 20 percent of the original concession, the immediate area of the Dukhan oilfield on the west coast of the peninsula.

PRODUCTION

Crude oil continued as the only significant mineral commodity produced in Qatar. Increased offshore oil production was largely responsible for the 8 percent gain in 1965 output over that of 1964. A trend of rapidly expanding offshore oil production and relatively stable onshore production is indicated.

Small quantities of crude oil were partially refined at the QPC topping plant at Doha to recover about 425 barrels per day of gasoline and other fuels required for domestic consumption.

TRADE

Crude oil exports, valued at an estimated $155 million in 1965, continued as Qatar's only significant mineral commodity export.

Very limited information suggests that the value of all imports into Qatar in recent years averaged about $25 to $30 million annually. Mineral commodity imports, consisting mostly of construction materials, fuels, and lubricants have accounted for about 10 percent of the value of all imports.

[1] Chief specialist, Near East and South Asia, Division of International Activities.

COMMODITY REVIEW

Mineral Fuels.—*Petroleum.*—The long-developed Dukhan field, operated by QPC, continued as the major oil producer and the only onshore field. Its 1965 output averaged 193,682 barrels per day, exceeding that of 1964 by 2.4 percent. QPC drilling activity was limited to well workover operations. Mechanical troubles idled the miscible gas injection plant throughout most of the year; however, a water injection program was begun and about 1.25 million barrels of water was injected into the main producing reservoir. These fluid injection projects are to maintain reservoir pressure and increase ultimate oil recovery.

Shell Oil Co. of Qatar Ltd. (Shell) continued to develop the offshore Idd al Sharqi and Maydam Mazam fields near Halul Island. Several additional producing wells were drilled in these fields. A production platform designed to handle 120,000 barrels per day of crude oil from the Maydam Mazam field was constructed. Construction of a permanent terminal on Halul Island, together with oil-gathering pipelines and tanker loading facilities to handle up to 150,000 barrels per day of output from both fields, was nearing completion at yearend. This facility will replace the existing temporary loading facilities at Idd al Sharqi that have limited oil production to about 30,000 barrels per day. In December, the first tanker was loaded from the new terminal.

Continental Oil Co. (CONOCO) continued seismic exploration activities in offshore and onshore areas of its recently acquired oil concessions in Qatar.

Proved oil reserves in Qatar were reported[2] as 3,000 million barrels at yearend.

TRUCIAL STATES

The Trucial States include the seven coastal area sheikdoms of the southeastern Arabian peninsula that border on the Persian Gulf. They are Abu Dhabi, Dubai, Sharjah, Ajman, Umm al-Qaiwain, Ras al-Khaimah, and Fujairah. The area was the scene of accelerated petroleum exploration and development activity in 1965 although oil production has been established only in Abu Dhabi. Crude oil production from the onshore and offshore areas of Abu Dhabi continued to be expanded rapidly.

[2] Oil and Gas Jour. V. 63, No. 52, Dec. 27, 1965, p. 83.

As the only major industrial activity of the Trucial States, the petroleum industry continued to have a marked impact on the economy of the entire area. The industry employed an estimated 2,500 persons. Also, a large expansion in trade and a minor boom in construction and commercial activities in this largely underdeveloped area has resulted from oil company expenditures and direct oil payments to the States. In September, the Ruler of Abu Dhabi and the Abu Dhabi Petroleum Co., Ltd. (ADPC), agreed to revise their oil concession agreement to provide sharing of profits on a 50-50 basis, effective January 1, 1965. The original agreement, signed in 1939, provided generally a fixed royalty at a much lower rate. Since direct oil payments account for more than 90 percent of all revenues to the Trucial States, these revenues increased sharply from an estimated $20 million in 1964 to $85 million in 1965. As a result of the revised profit-sharing agreement, essentially all of the monetary increase resulting from greater oil output accrued to Abu Dhabi.

On March 1, the Rulers of the Trucial States agreed to jointly plan for development of the area and to seek unconditional aid from any source to finance needed development. The Trucial States Development Office, operating under the Trucial States Council, was established to administer funds and carry out approved development programs. The United Kingdom, Saudi Arabia, Abu Dhabi, Qatar, and Bahrain have agreed to contribute nearly $7 million to a fund to be called the Trucial States Development Fund. The first major project was that of constructing an all-weather road from Dubai to Ras al-Khaimah, thus linking five of the seven sheikdoms.

PRODUCTION AND TRADE

Crude oil was the only significant mineral commodity produced in the Trucial States in 1965; however, small quantities of simple building materials were produced for local use. All crude oil production was from Abu Dhabi where output was expanded throughout 1965. Gains of more than 50 percent in 1965 crude oil production over that of 1964 were registered in both onshore and offshore areas. The increases resulted from new fields' development and completion of additional oil handling facilities.

All oil produced is exported as crude oil. In 1965, these oil exports, valued at an estimated $175 million, accounted for an estimated 97 percent of the value of all exports. Other exports were chiefly reexports from Dubai.

The port of Dubai remained the Trucial States' principal import and transit trade center. Total imports during the first half of 1965 were valued at $24.4 million, an increase of about 20 percent over the corresponding period of 1964. Mineral imports, consisting of construction materials and petroleum refinery products, accounted for 10 percent of the value of all imports.

COMMODITY REVIEW

Mineral Fuels.—*Petroleum.*—Active exploration, development, and exploitation of the oil resources of Abu Dhabi continued throughout 1965. Onshore, ADPC discovered a major new oilfield at Abu Jidu about 80 kilometers southeast of the Murban field. As a result of negative exploratory drilling in other areas, ADPC relinquished four separate areas of its concession to the Government. The original oil concession covered all of Abu Dhabi and adjoining territorial waters. Additional de-

velopment wells, production facilities, and a 35-kilometer, 24-inch-diameter spur pipeline that provides production capacity of up to 150,000 barrels per day from the Bu Hasa field were completed. The field was placed on production in April. These new facilities at Bu Hasa, together with existing Murban field facilities, raised ADPC producing potential to 240,000 barrels per day, the nominal capacity of the 24-inch-diameter pipeline to the loading terminal at Jebel Dhanna. In 1965, these two fields accounted for all onshore production at a record rate averaging almost 192,500 barrels daily.

In the offshore area of Abu Dhabi, Abu Dhabi Marine Areas, Ltd. (ADMA), discovered a new oilfield at El Bunduq, about 18 miles southwest of Das Island. Additional delineation drilling at the Zakum field, about 80 kilometers southeast of Das Island, confirmed this 1963 discovery as a major field. Average production of nearly 91,000 barrels per day was all from the Umm Shaif field. Development at the field was completed late in 1964 when 8 additional wells were connected for production to bring the total number of wells to 26. All production is piped to the Das Island export terminal which has a nominal oil-handling capacity of 90,000 barrels per day.

In Dubai, the Dubai Petroleum Co. continued exploration in the onshore areas of the sheikdom. A deep exploration well drilled at Remah in the southeast corner of Dubai proved nonproductive and was abandoned at an undisclosed depth early in 1965. Previously, one offshore well and another well onshore had been abandoned as dry holes. At yearend, preparations were being made to drill a second well in the offshore area.

In Sharjah, Ajman, and Umm al-Qaiwain, oil exploration was continued by John W. Mecom on a concession held in partnership with Pure Oil Co. A well drilled in northeast Umm al-Qaiwain to a depth of 8,500 feet was abandoned as dry. At yearend, a well was being drilled in Sharjah near the Ajman border.

In Ras al-Khaimah, seismic surveys were conducted by Union Oil Co. of California on concessions held jointly with Southern Natural Gas Co. No drilling operations were initiated during the year.

Negotiations were continued for oil concessions in the sheikdom of Fujairah but no definite agreements were reported.

MUSCAT AND OMAN

Petroleum Development Oman, Ltd. (PDO), began to implement its $75 million program to bring into commercial production the oil resources in its onshore concessions of the Sultanate of Muscat and Oman. The company awarded a contract to Williams Brothers of Tulsa, Okla., for construction of a 250-kilometer 32- to 36-inch-diameter pipeline from the Natih, Fahud, and Yibal fields of western Oman to Saih al-Malih on the Gulf of Oman. Contracts for construction of an oil terminal, offshore tanker loading facilities, oil storage tanks, and related facilities were awarded to several other international construction firms. Two rigs were active throughout the year drilling additional development wells in the Natih and Fahud fields. Construction was in progress at yearend and completion of facilities to export up to 200,000 barrels per day of crude oil by mid–1967 is planned.

In the Dhofar area of the Sultanate, seismic oil exploration surveys were continued but no new well drilling was reported. Continental Oil Co. acquired a one-third interest in the oil concession, covering all of Dhofar and its offshore area, previously held jointly by John W. Mecom and Pure Oil Co.

Negotiations for oil concessions in the offshore area of the Sultanate were reported but no definite agreements were announced.

FEDERATION OF SOUTH ARABIA

The Aden Colony continued as the only political entity among the 14 sheikdoms of the East and West Aden Protectorates comprising the Federation of South Arabia that had significant mineral production and trade in 1965. Although significant quantities of salt were produced by solar evaporation of sea water, refining of im-

ported crude oil, export of petroleum products and bunkering remained Aden's dominant industrial activity. In 1965, petroleum refinery production was valued at an estimated $140 million, including value added of about $42 million. Petroleum refining and port operations (largely bunkering and petroleum trade) contributed an estimated $70 million to Aden's gross national product of about $235 million. The mineral industry employed about one-fourth of the industrial labor force or an estimated 3,100 persons, including about 2,000 in petroleum refining, 1,000 in bunkering, and 80 in salt production.

Petroleum exploration operations were continued in the East Aden Protectorate sheikdoms of Qu'ayti, Kathiri, and Mahrah. Although these States are not members of the Federation of South Arabia, their economies are directly related to it.

The Federation continued to receive development assistance from the United Kingdom. Construction of roads has been emphasized in development plans as essential to the economic development of the area. Considerable progress was made on construction of a 146-kilometer road from Abyan to Mudiyah.

PRODUCTION AND TRADE

The British Petroleum Co. (Aden) Ltd. (BP) refinery operated at full capacity of 136,000 barrels per day. The gross value of refinery output in 1965 was valued at an estimated $140 million while that of salt production was about $200,000.

Trade in petroleum and refinery products continued to account for about 50 percent of the value of total trade. In 1965, exports of refinery products (excluding bunkers) were valued at an estimated $95 million. As a result of political and labor disturbances, bunkers supplied to ships at Aden in 1965 declined by about 18 percent from that of 1964. The estimated value of all bunkers delivered to 5,727 ships in 1965 was $45 million.

Imports of metals and minerals in 1965 were valued at an estimated $125 million. Crude oil and petroleum accounted for about 95 percent of the value of all mineral imports.

COMMODITY REVIEW

Nonmetals.—*Salt.*—The Indo-Aden Salt Co. was the sole producer of salt in Aden. The trend of declining production and export continued. Most sales were for export to the low-priced Japanese market. Increased labor costs and low salt prices combined to limit output by this company.

Mineral Fuels.—*Petroleum.*—Despite labor instability during the first 5 months of 1965 at the BP refinery, production was maintained at a level slightly in excess of the rated nominal capacity (136,000 barrels per day) of the plant. In May, BP granted a 20-percent wage increase to all employees.

The American International Oil Co., a Standard Oil Co. of Indiana affiliate, continued oil exploration operations in its East Aden Protectorate concessions. A well drilled to a depth of 5,750 feet at Tarfayt (about 100 miles northeast of Thamud) was nonproductive. Initial seismic exploration surveys were completed and suspended pending evaluation of results.

YEMEN

The mineral industry continued to play an unimportant role in the economy of Yemen. As an almost totally underdeveloped industrial nation, Yemen's minerals exploration has been limited. Rock salt deposits are Yemen's only known mineral resource of significant commercial value. The exploitation of these salt deposits had been discontinued in 1964 and was not resumed in 1965.

Continuing civil strife and armed conflict in Yemen had a mixed influence on the economy. The negative aspects of political conflict were partially offset by foreign technical and financial assistance to various development programs. The United States Agency for International Development completed construction of the 225-mile Mocha-Taiz-Sanaa road project. Also, Yemen concluded agreements with the Soviet Union and mainland China for additional road projects. Building and other construction continued active in Sanaa, Hodeida, and Taiz. Soviet and Rumanian geological exploration teams were active in Yemen but the results of their efforts are unknown.

PRODUCTION AND TRADE

Except for small quantities of simple construction materials produced for local consumption, the only mining activity of

recent years was production of salt for export to Japan. Under terms of a 5-year contract that expired in February 1964, the following salt production was reported:

Year	Quantity (metric tons)	Year	Quantity (metric tons)
1959	100,000	1963	100,000
1960	100,000	1964	35,000
1961	120,000	1965	-----
1962	150,000		

Trade statistics for 1964 show that total Yemeni exports were valued at approximately $4 million. No minerals or metals exports are indicated. Total imports were valued at approximately $19 million, with minerals and metals accounting for almost 26 percent of this total. Principal mineral imports and estimated values were building materials ($2.7 million); petroleum products ($1.8 million); iron and steel ($0.25 million).

COMMODITY REVIEW

Nonmetals.—*Salt.*—The Salif Salt Co. (jointly owned by the Governments of Yemen and the United Arab Republic (Egypt)) began to repair and rehabilitate the salt mining and loading facilities at Salif. In November, a contract was signed with a Japanese firm under which the company will undertake to export 120,000 to 150,000 tons annually to Japan. The first shipment was scheduled for January 1966.

Mineral Fuels.—*Petroleum.*—No petroleum exploration activity was reported during 1965. The jointly owned Yemen Petroleum Co. (held 51 percent by the Government of Yemen and 49 percent by the United Arab Republic (Egypt)) supplied all petroleum refinery products to Yemen under its monopoly granted by the Government. Estimated domestic consumption of petroleum products in 1965 was gasoline, 59,000 barrels; kerosene, 115,000 barrels; diesel fuel, 52,000 barrels; and small quantities of bottled liquefied petroleum gases.

Regional Mineral Industry Review of South Asia

By James A. West [1]

The South Asian countries of India, Pakistan, Afghanistan, Ceylon, Nepal, Bhutan, and Sikkim are to varying degrees just beginning to achieve significant economic and industrial development. These countries are richly endowed with certain mineral resources, and development of these resources is being accelerated. In 1965, the mineral industry remained a relatively small sector of the region's economy, accounting for only about 1 percent of its estimated gross national product of $62,528 million. Nevertheless, the estimated $630 million total value of minerals produced in South Asia during 1965 represented an increase of nearly 15 percent over that of 1964.

India continued as the dominant mineral producer of the region, accounting for 85 percent of the total value of all minerals produced in 1965. India increased its output of iron ore, manganese, mica, coal, and petroleum. Pakistan accounted for 13 percent of the value of the region's output and recorded increased output of iron ore, chromite, coal, natural gas, and most other minerals. The small mineral industry of Ceylon attained remarkable growth in the production of ilmenite, graphite, and gem stones. The mineral industry of Afghanistan remained relatively insignificant, although development of large known resources of natural gas was continued. Nepal, Bhutan, and Sikkim produced no commercially significant quantities of minerals in 1965.

South Asian production of certain mineral commodities was of world significance. The most important minerals produced in 1965 and South Asia's share, in percent of total world output, were as follows: Mica, 19.1; manganese ore, 9.1; salt, 4.9; talc and soapstone, 4.4; iron ore, 3.9; cement, 2.8; gypsum, 2.8; coal, 2.5; magnesite, 2.5; bauxite, 1.9; and graphite, 1.7.

Trade in mineral commodities continued as an important sector of total trade in South Asia in 1965. On the basis of the most recent statistics available for 1964, the relative significance of mineral trade to total trade for all seven countries combined was as follows:

	Value (million dollars)		Mineral commodities share of total
	Mineral commodities	All commodities	
Exports	221	2,752	8
Imports	951	4,287	22
Trade balance	—730	—1,535	XX

XX Not applicable.

Principal exports were iron ore, manganese ore, mica, and graphite. The region was dependent upon imports for most base metals, crude oil and petroleum products, fertilizers, much iron and steel semimanufactures, and many industrial minerals. The contributions of each of the major mineral commodity categories to total minerals trade in 1964 follow:

Commodity group	Value (million dollars)	
	Imports	Exports
Metals	540	155
Nonmetals	138	37
Fuels	273	29
Total	951	221

[1] Chief specialist, Near East-South Asia, Division of International Activities.

Governments of the region initiated and expanded programs for the development of mineral resources. The planned development and exploitation of mineral resources as scheduled in successive 5-year plans continued as key programs in the Government of India's policy to expand and diversify the industrial base of the national economy. Projects to expand iron and steel, nonferrous metals, petroleum, and other mineral production capacity were assigned high priority in the fourth 5-year plan (1966–71). Under the third 5-year plan (1965–70), the Government of Pakistan embarked on an ambitious program of mineral resource development aimed at greatly expanding the output of natural gas, coal, and petroleum. The Governments of Afghanistan and the U.S.S.R. concluded an agreement for exploitation of the large natural gas reserves of northern Afghanistan. The U.S.S.R. agreed to continue financial and technical assistance in developing natural gas reserves, pipelines, a thermal powerplant, and a fertilizer plant in exchange for large-scale gas exports to the U.S.S.R. In Ceylon, the Government awarded a contract to an Italian firm for construction of the island's first petroleum refinery.

The Mineral Industry of Afghanistan

By James A. West [1]

The economy of Afghanistan has always been predominantly agricultural and pastoral. In 1965, the mineral industry continued as a relatively insignificant sector of the nation's economy, accounting for less than 0.6 percent of the estimated gross national product of $1,200 million.

During 1965 cement, coal, and salt were the only mineral commodities produced commercially for domestic consumption. Small quantities of lapis lazuli were mined seasonally for export. Large natural gas reserves have been discovered and partially developed in the northern area of the country. Other mineral resources of potential importance include a reportedly large deposit of high-grade iron ore and small deposits of chromite, beryl, lead, zinc, mica, talc, and uranium. The remote geographical location of landlocked Afghanistan, inadequately developed internal transportation facilities, lack of domestic markets, and insufficient financial and technological resources have limited exploration for and exploitation of these mineral resources.

The most significant mineral industry development in 1965 was the conclusion of an agreement between the Governments of Afghanistan and the U.S.S.R. for exploitation of natural gas reserves in the Shibarghan area of northern Afghanistan. The U.S.S.R. agreed to finance and assist in the construction of pipelines, a thermal powerplant, and a fertilizer plant. Large-scale exports of natural gas to the U.S.S.R. will be made in repayment of the Soviet loan financing the entire project.

The completion or near completion of major road construction projects during 1965 has substantially improved internal communications and enhanced prospects for mineral industry exploration and development activities. The Salang road and tunnel from Kabul to Pul-i-Khumri, opened in August 1964, was kept open throughout 1965 despite heavy snowfalls. The Kabul-Kandahar road, being built with U.S. assistance, was near completion. The Kandahar-Herat-Torghundi road, built with U.S.S.R. assistance, was completed. Construction was begun in May on a highway to extend the Salang Pass road from Pul-i-Khumri to Mazar-i-Sharif and ultimately to Shibarghan. This road, being built with U.S.S.R. assistance, should greatly aid in the development of natural gas and coal resources in the north-central area of the country.

PRODUCTION

Production of all commercially significant mineral commodities during 1965 increased substantially over that of 1964. The estimated value of listed mineral production increased from $4.6 million in 1964 to $6.98 million in 1965. In addition to those commodities listed, small quantities of minor construction materials, clays, gypsum, talc, and marble were produced and consumed locally, but data are insufficient for quantitative estimates of output.

[1] Chief specialist, Near East and South Asia, Division of International Activities.

TRADE

In 1965, Afghanistan had no significant mineral commodity exports and remained dependent on imports for essentially all its requirements for metals, petroleum products, and most nonmetallic minerals. Based on Central Bank exchange data, total trade during the Afghan calendar year ending March 20, 1965, was valued at $212.1 million. Total imports were valued at $141.4 million, with reported mineral commodities comprising at least 10 percent of this total. Quantitative data are only available for petroleum products imports.

COMMODITY REVIEW

METALS

Beryl.—A U.S.S.R. minerals survey team continued exploration and evaluation activities to assess the importance of recent beryl discoveries in the Kunar area. The Afghan Ministry of Mines and Industries announced in July that deposits discovered at Dari-i-Noor, Dari-i-Paich, and Chapa-Dari contain an estimated 51,000 tons of beryllium and 39,300 tons of lithium oxide.

Iron Ore.—The presence of an extensive iron ore deposit at Hajigak in the Hindu Kush Mountains has been known for many years. As a result of geological investigations, conducted by a Soviet-assisted survey team, the Ministry of Mines and Industries announced that the Hajigak deposit contains an estimated reserve of 2 billion tons of hematite ore having an average iron content of 63 percent. Various plans for exploitation of the deposit are under consideration, including the possible use of natural gas for direct reduction of the ore to pig iron.

NONMETALS

Barite.—The small quantity of barite produced was utilized for oil and gas well-drilling operations in the north-central area of the country. The barite was mined

from deposits in the immediate area for this specific purpose.

Cement.—The Government-owned Ghori and Jabal-i-Seraj cement plants steadily increased output throughout 1965 to near their rated capacities of 400 and 100 tons per day, respectively. These plants continued to supply all the domestic cement requirements in 1965, but demand was expected to exceed plant capacity in the near future. The Government announced plans for construction of a 300-ton-per-day capacity plant at Herat.

Lapis Lazuli.—Deposits in the Badakshan province of northern Afghanistan were reported to contain an estimated 1,300 tons of lapis lazuli. Small mines were operated seasonally, and output, mostly of fair to poor quality, was exported to West Germany to be cut and polished.

Salt.—Most rock salt was produced from opencast mines near Tallequan where salt domes outcrop. In the summer months, salt continued to be obtained from the evaporation of brine from salt lakes near Mukhar and along the Iranian border southeast of Herat. Lack of adequate transportation continued to limit salt output.

MINERAL FUELS

Coal.—Nearly all coal produced in 1965 was from the Government-owned Karkar and Ishpushta mines in north-central Afghanistan. These mines continued to supply the nation's two cement plants and the Kabul area with coal. However, the Karkar and Ishpushta coal reserves are limited and the coal is of poor quality. The U.S. Agency for International Development continued to assist in the development of a coal mine at Darra-i-Suf. Although located some 400 miles from Kabul, the Darra-i-Suf coal reserves, an estimated 60 million tons, are being developed to supply up to 150,000 tons annually to meet Afghanistan's growing coal demand. It was reported that a U.S.S.R. survey team had discovered an estimated 25-million-ton coal reserve at Shaba-shak, approximately 10 miles from Darra-i-Suf.

A portion of the coal produced was made into briquets by hand methods, and by the use of simple machinery. Construction of a modern briqueting plant, purchased in France, was continued. This plant was scheduled to begin operating in 1966.

Petroleum and Natural Gas.—In 1965, the Afghan Petroleum Exploration Department (APED), Ministry of Mines and Industries, continued oil and gas exploration activities but concentrated on the development of known gasfields in the Shibarghan area of north-central Afghanistan. Assisted by the U.S.S.R., APED drilled additional wells to delineate the gas reserves and develop the Khwaja Gogirdak and Yatim-Tagh gasfields for exploitation. At yearend, a total of 11 wells had been drilled to depths ranging from 2,400 to 9,200 feet at Khwaja Gogirdak, and 16 wells had been drilled to depths of 1,300 to 7,400 feet at Yatim-Tagh and the nearby Yalanghach structure. Proved gas reserves in the Cretaceous gas reservoirs of these fields were an estimated 2,400 billion cubic feet. A second well drilled at Khwaja Borhan confirms this 1964 discovery as a commercial gas and condensate field. At Andkhoi (Aska), the deepest well drilled to date in Afghanistan was completed in the Jurassic section at a depth of 11,516 feet and was being tested.

At midyear, the Governments of Afghanistan and the U.S.S.R. signed contracts providing Soviet financial and technical assistance for construction of facilities to exploit and utilize natural gas reserves from the Shibarghan area. Planned facilities include a 98-kilometer, 32-inch-diameter pipeline to export up to 240 billion cubic feet of gas annually to the U.S.S.R. on the border at Kelif; a 24,000-kilowatt-hour thermal powerplant and a chemical fertilizer plant with a capacity to produce 105,000 tons of urea annually at a site near Mazar-i-Sharif; and an 88-kilometer, 12¾-inch-diameter pipeline to supply up to 200 million cubic feet of gas annually to these plants. Initial construction was begun late in 1965, and all facilities were scheduled to be completed in 3½ years. Proceeds from the sale of exported gas are to be used to repay Soviet loans for the project.

A geological survey team from West Germany, conducting mineral investigations in southern Afghanistan, encountered surface indications that there may be hydrocarbons in the province of Paktia. On September 20, 1965, the German mission concluded an agreement with the Afganistan Government to conduct an aerial magnetometer survey of a 150,000-square-kilometer area in an effort to locate oil and gas prospects.

The Mineral Industry of Ceylon

By E. Shekarchi [1]

Ceylon's mineral industry, although small, experienced a remarkable growth in 1965 with production valued at about $6.9 million. Ilmenite and graphite remained the main contributions of Ceylon to world mineral supplies. Exports of minerals, excluding precious and semiprecious stones, were valued at $1.6 million in 1964. Total gross national product (GNP) in 1965, based on 1962 prices, was estimated to be about $1,575 million with a GNP per capita of about $139, slightly lower than in 1964. The estimated population in 1965 was reported to be 11.3 million with an annual growth rate of 3 percent. Of the population, 3 percent or about 339,000, constituted the country's total labor force, and of this, agriculture accounted for about 52 percent, manufacturing (including the minerals industry) 12 percent, trade and commerce 8 percent, service 12 percent, and others 16 percent. Registered unemployment in 1964 was about 157,000 people.

The most significant development in the island's mineral industry was the signing of a contract in October 1965 between Ceylon Petroleum Corp. and Ente Nazionale Idrocarburi (ENI) of Italy to build a refinery in Ceylon that was planned to reduce import expenditures for energy requirements.

On March 16, 1965, the Government of Ceylon issued a statement summarized in the booklet, "Government Policy on Private Foreign Investment," outlining the need for private foreign investment in Ceylon, facilities granted to foreign investors, security of investment, area of investment, and the inducements offered to investors. The whole effort seems to be favorable and logical, especially the announcement that all foreign investments' approval will be under one department, eliminating the previous multiplicity of departments involved.

In early 1965, a resolution sanctioning the investment of $40 million initial capital for a State fertilizer manufacturing corporation was passed. The proposed initial capacity of such an operation was about 250 tons per day. No details on the type of products expected were available.

Utilizing a great deal of geophysical equipment and many methods, the Geological Survey of Ceylon continued mineral exploration in 1965 with emphasis mostly on magnesite graphite, gem pits, and iron ore. The Geological Survey continued its program for geologic mapping of the country.

PRODUCTION

Several commodities showed significant increases in production in 1965. Among them, the 33 percent increase in salt output was most significant, followed by glass sand output, up 77 percent; cement production, up 14 percent; and ilmenite output, up 7 percent with respect to 1964 production levels. Official production figures on graphite were not available, but exports, a fairly reliable gage of output, declined 19 percent in 1965 from the 1964 level.

e Estimated. r Revised. NA Not available.
[1] Ceylon also produces a wide variety of precious and semiprecious gems but no reliable data on output are available. Exports for all types of gem stones in 1965 reportedly totaled 71,254 carats.

TRADE

Total value of recorded mineral exports in 1964, the last year for which complete data are available, was about $3.12 million, almost double that of 1963. Although complete quantitative data on precious and semiprecious gem stone exports were not available, they remained the leading mineral export commodity, followed by graphite and ilmenite.

Requirements for most metals, some nonmetals, and all mineral fuels were met through imports, valued at $17.5 million, $11.6 million, and $21.7 million, respectively. In the metals sector, iron and steel accounted for about $12.4 million, and in the nonmetallic segment, fertilizers were the largest in value at $7.3 million. Quantitatively, imports of petroleum products were 17 percent higher than those of 1963, the U.S.S.R. was the main source of supply.

COMMODITY REVIEW

METALS

Iron and Steel.—Progress was made in the construction of the U.S.S.R.-aided steel plant on 307 acres of land in Oruwela. The first stage of the three-stage project is expected to go into operation in 1967. The annual capacity of this stage, originally set at 35,000 tons with two shifts, has been increased to 90,000 tons in three shifts.

According to a Ceylon Steel Corp. report, some larger iron ore findings by the Geological Survey Department of Ceylon have been evaluated by U.S.S.R. geologists. It is reported that these deposits will satisfy the iron ore requirements of the steel plant. These findings, in the Kottekekanda-Panirendawa area on the west coast, reportedly have a possible reserve of 6 million metric tons of high-grade ore.

Ilmenite.—Heavy storm damage in the Pulmoddai area apparently did not hamper the production of ilmenite; production reached a new high in 1965.

Expansion of the fully mechanized factory at Pulmoddai continued through the year. Titaniferous sand was mined by Priestman excavators and heaped into large dunes on the beach. The collected sand was passed through 60-mesh screens and electromagnetic separation units to separate and concentrate the ilmenite. The resulting concentrate average 99 percent ilmenite with the following chemical analysis:

titanium dioxide (TiO_2)—54.40 percent; ferrous oxide (FeO)—20.07 percent; ferric oxide (Fe_2O_3)—21.66 percent; traces of manganese oxide (MnO), chromic oxide (Cr_2O_3), sulfur and phosphorous.

Reported visible reserves of 4 million tons of pure ilmenite apparently are maintained by fresh deposition resulting from wave action in the lagoon following each period of excavation; such replacement evidently requires only a few months. To date, the operating company had limited its action to an area about 1,000 feet long and 200 feet wide in which the deposit varies from 5 to 10 feet in depth; however, similar deposits extend about 6.4 kilometers along the coast.

NONMETALS

Monazite.—According to reports of the Geological Survey of Ceylon, the pilot plant installed in the Katukurunda area on the west coast of Ceylon operated through 1965, processing black sand and producing about 600 metric tons of monazite-containing sand. No detailed information was available on reserves of the monazite deposits; however, thorianite and baddeleyite reported to be associated with the monazite may have economic value.

Fertilizer Materials.—In 1965, a program of long-term loans was initiated for fertilizer storage facilities. The program called for increasing the storage capacity with an expenditure of $3.2 million. The funds reportedly will be used for putting up buildings as well as purchasing land that will provide small and medium-sized storage areas in many parts of the country.

MINERAL FUELS

Coal.—Coal imports in 1964, according to Ceylon's customs' reports, were almost 30,000 tons more than in 1963. Favorable prices offered by the Republic of South Africa seemed to be the principal factor for Ceylon's choice of supply source. Apparently South Africa can deliver coal at $13 c.i.f. per long ton which is almost $4.00 below Indian coal or approximately $7.00 under Australian coal.

Petroleum.—The Government of Ceylon in 1965, in spite of delaying tactics by the opposition within the Government, finally signed a formal agreement with Shell Co. of Ceylon Ltd., Caltex Ceylon Ltd., and Esso Standard Eastern, Inc. (Ceylon), that concerned the compensation for oil companies' marketing assets which were taken over by Ceylon Petroleum Corp. The total payment is about $11.6 million; of this Shell will receive approximately $6.9 million and within 5 years the other two companies will each get about $2.35 million with 3-percent interest. Also, it was agreed that the companies will maintain for 5 years their bunkering trade of about 400,000 tons per year of aviation refueling rights.

The newly constituted State Ceylon Petroleum Corp. carried on exploration throughout 1965 with the cooperation of the Geological Survey of Ceylon in the northwestern coastal area. Reportedly, a seismic survey by both organizations has been scheduled on land and offshore in this area by early 1966.

In 1965, about 5 million barrels of major refinery products were imported by the Ceylon Petroleum Corp. and consumed in the country; about 80 percent came from U.S.S.R. and the remainder from Rumania and other sources. However, Ceylon Petroleum Corp. hopes to supply this demand by processing imported crude oil in a domestic refinery, thus saving substantially on foreign exchange.

The contract for the long delayed and the much discussed Ceylon refinery finally was signed with ENI of Italy in October 1965. Although it was reported in 1964 that the Czechoslovakian firm, Techno Export, had a turnkey contract, apparently the negotiations did not go through, and ENI, the lowest bidder (about $16 million), will build the refinery. Details on refinery capacity and expected completion date were not available.

The Mineral Industry of India

By James A. West [1]

India has outstanding resources of high-grade iron ore, coal, manganese, mica, bauxite, rare-earth minerals, beryl, gypsum, refractories, and building materials. The nation's most serious mineral deficiencies are a complete lack of or inadequate domestic resources of most nonferrous metals; certain nonmetallic minerals including sulfur, fertilizer raw materials, asbestos, borax, and other industrial minerals; and petroleum and natural gas.

The Indian mineral industry continued as an important segment of the national economy. The value of mineral production (exclusive of minor minerals and prescribed fissionable minerals) in 1965 totaled an estimated $536 million or about 1.1 percent of the gross national product of India. Foreign exchange earnings from the exports of ores and minerals during 1965 totaled an estimated $170 million, accounting for about 10 percent of the value of all Indian exports.

Total mineral industry employment in 1965 was nearly 6.5 percent of the total industrial labor force of an estimated 14 million workers. An estimated 591,000 workers were engaged in mines and quarries; iron and steel plants employed about 215,000 persons, and nonferrous metal processing plants, petroleum operations, and cement plants employed about 100,000 persons.

The Government of India participates to a large extent in the minerals industry of the nation through various agencies and many public sector enterprises. The planned development and exploitation of mineral resources as scheduled in successive 5-year plans continued as key programs in the Government's policy to expand and diversify the industrial base of the national economy. Although considerable progress was made in 1965, most of the projects to expand iron and steel, nonferrous metals, petroleum, and other mineral production capacity by the end of the third 5-year plan (1965–66) were far behind schedule. This has resulted in revised and more realistic targets in the fourth 5-year plan. The investment program for fiscal 1966–67 provides $113 million for mineral development, most of which was allocated to coal, iron ore, copper, and lignite projects. Steel plant development and expansion costs were estimated at $235 million for the same period.

In 1965, India's already serious shortages of foreign exchange became more acute because of the necessity to increase food imports, the excessive costs of the Indo-Pakistan conflict, and the subsequent suspension of financial and technological aid from the United States and other countries. This caused shortages of most nonferrous metals and other mineral raw materials that are normally imported. Also, expansion and development of the minerals industry was seriously impeded because of restrictions placed on the purchase of modern machinery, special equipment, and spare parts from external sources.

In contrast to the short supply position of most minerals, coal remained in a serious oversupply position. As in 1964, coal production greatly exceeded demand and a serious coal supply-demand imbalance existed throughout 1965. Anticipated demand failed to develop because of delays in the completion of planned coal-consuming industrial projects, partial conversion of national railroads from coal to diesel fuel, and other factors.

[1] Chief specialist, Near East-South Asia, Division of International Activities.

PRODUCTION

In general, both the quantity and value of all important minerals produced in India during 1965 was greater than that of 1964. In contrast to the relatively lower output of minerals in 1964, the 1965 increases reestablished the general upward trend evident during the 1961 to 1963 period.

Quantitatively, the overall trend of increased output was reflected by a substantial rise of 10.3 points in the index of mineral output. The 1965 index (base: 1960=100) was 130.5 compared with 120.2 in 1964. Among selected sectors, the 1965 index of coal mining, metal mining, and nonmetallic minerals was 132.5, 119.3, and 137.2, respectively. Domestic production of crude oil and refinery products during 1965 increased 33 percent and 4 percent, respectively, from that of 1964.

Excluding minor minerals and fissionable minerals protected under the Atomic Energy Act of 1948, the value of minerals produced in India (including Goa) during 1965 was an estimated $536 million. Mineral fuels accounted for 75.5 percent of the total value; metallic minerals, 14.0 percent; and nonmetallic minerals, 10.5 percent. Individual commodity valuations of the most important minerals were as follows: Coal and lignite, $368 million; iron ore, $39.5 million; petroleum and natural gas, $36 million; limestone, $25.8 million; manganese, $16.7 million; salt, $15.3 million; gold, $8.8 million; copper ore, $5.2 million; and mica, $4.8 million.

TRADE

Trade in mineral commodities continued to account for a relatively large share of total Indian trade. The latest available statistics (for the financial year ending March 31, 1965) are as shown in the following tabulation:

	Million dollars		Share of mineral trade to total trade (percent)
	Value of mineral trade	Value of total trade	
Exports	206.2	1,754.0	11.7
Imports	599.3	2,652.9	22.6
Trade balance	−393.1	−898.9	----

In terms of value, the contributions of each of the major mineral commodity categories to total mineral trade during the 1964–65 financial year were as follows:

	Million dollars	
	Value of imports	Value of exports
Metals	353.8	152.7
Nonmetals	88.4	28.5
Fuels	157.1	25.0
Total	599.3	206.2

India's principal mineral exports were iron ore, manganese ore, and mica, valued at $81.4 million, $28.2 million, and $20.2 million, respectively for the year ending March 31, 1965. The nation remained dependent on imports to supply most of its requirements for nonferrous metals and continued to import large quantities of iron and steel, certain nonmetallic minerals, and petroleum. In 1964–65, iron and steel imports were valued at $225.5 million; copper, $47.3 million; lead and zinc, $33.5 million; fertilizer minerals, $61.5 million; sulfur, $11.4 million; and petroleum, $157 million.

r Revised.

[1] For financial year ending March 31.

COMMODITY REVIEW

METALS

Antimony.—India produces no antimony ore and all metal continued to be processed from imported concentrates solely by Star Metal Refinery, Ltd., of Bombay. In 1965, the plant operated at about 85 percent of its rated capacity of 1,000 tons annually.

Aluminum and Bauxite.—Bauxite is the only nonferrous metal ore found in abundance in India and aluminum production continued as its major nonferrous metal industry. Extensive exploration in recent years has resulted in the discovery of bauxite deposits throughout the country, having estimated total reserves of about 276 million metric tons. An estimated 74 million tons of this reserve has an alumina content greater than 50 percent.

Demand for aluminum continued to exceed the supply from domestic production and licensed imports even though domestic output has nearly quadrupled in the past 5 years. Acute shortages have developed largely because of the Government's policy requiring the substitution of aluminum for copper in an effort to decrease foreign exchange expenditures. Estimated total demand in 1965 was about 120,000 tons compared with a supply of less than 100,000 tons.

The Government took additional steps to expand domestic aluminum-producing capacity in both the private and public sectors of the industry. The planned target for ingot production capacity to be reached by the end of the fourth 5-year plan (1970–71) is 272,500 tons. The Madras Aluminum Co. integrated aluminum processing plant at Mettur (constructed by Montecatini Co. of Italy in collaboration with private Indian investors) began operation in 1965. This plant, with an ingot capacity of 10,000 tons per year, increased total Indian capacity to almost 70,000 tons.

The Hindustan Aluminum Co. (jointly owned by Kaiser Aluminum Co., Birla Brothers, and the Indian public) continued construction to expand the present capacity of its Renukoot smelter from 20,000 to 60,000 tons per year. Also, the Government issued a letter of intent to the company to further expand the capacity of the Renukoot plant to 120,000 tons annually during the fourth 5-year plan (1966–71).

The privately owned Indian Aluminum Co. continued construction at its Alwaye, Kerala, plant to expand ingot production from present capacity of 10,600 to 15,600 tons annually.

The Government continued negotiations for the establishment of three proposed public sector aluminum plants. An initial project report for a proposed plant at Korba in Madhya Pradesh to produce 120,000 tons of alumina and 30,000 tons of metal annually was completed by Chemokomplex of Hungary. Later, the Soviet Union offered assistance to India for construction of a 100,000-ton-capacity smelter at Korba. As a result, India concluded an agreement with Hungary to prepare a new project study to increase the capacity of the alumina plant to 200,000 tons to form an integrated project with the larger smelter. The proposed Koyna and Mysore projects for new plants with annual capacities of 25,000 and 30,000 tons, respectively, were under consideration but no definite plans were announced.

Chromite.—India has adequate resources of chromite to meet demands of its growing iron and steel industry. The largest deposits are those in the Keonjhar district of Orissa, Singhbhum district of Bihar, and Hassan and Mysore districts of Mysore. Reserves of all grades are estimated at 4.9 million tons. About 20 percent of the reserve is of metallurgical grade (45 percent or more CR_2O_3).

Production of chromite in 1965 was expanded largely in response to increased export demand. Domestic demand of about 25,000 tons was used mostly in the manufacture of refractory bricks for the iron and steel plants.

Copper.—Throughout 1965, demand for copper far exceeded the available supply. Limited domestic production and restricted imports, due to foreign exchange shortages, were sufficient to meet only about 60 percent of the estimated annual demand of 120,000 tons.

The Indian Copper Corp. (ICC) was the sole commercial producer of copper ore and metal. The company produced ore from three mines in the Ghatsila region of the Singhbum district in Bihar and operat-

ed a smelter at Moubhandar to produce fire refined metal. ICC continued construction of facilities to expand output. Its 8,400-ton electrolytic refinery at Ghatsila was nearing completion at yearend despite continued delays. Under a $16.8 million expansion program, ICC plans to replace its existing smelter with a modern flash smelter having an annual capacity of 12,950 tons and install byproduct recovery plants to produce 260 tons per year of nickel sulfate and 100 tons per day of sulfuric acid.

The Bureau of Mines and Geological Survey of India conducted exploration surveys in eight copper mineralization areas in the States of Rajasthan, Bihar, and Andhra Pradesh. Proved reserves of about 33 million tons of 1 percent copper ore at Khetri, Rajasthan are reported by the Indian Bureau of Mines. The agencies reported estimated proved reserves of 70 million metric tons of 0.8 to 2.0 percent ores in the Singhbum copper belt of Bihar.

The Government of India continued to support projects for the development of domestic copper resources and invited proposals by foreign investors for joint ventures in establishing smelters in India to process imported ores.

In June, the Government-owned National Minerals Development Corp. (NMDC) and a consortium of French industrialists signed an interim agreement for development of the Khetri copper deposits. Later, the French Government agreed to extend an $18 million credit to finance equipment purchases required for the planned 21,000-metric-ton-per-year-capacity project. NMDC continued to evaluate the Rakha copper deposit in Bihar and issued a preliminary study indicating a potential production of 31,000 tons per year of copper metal from this deposit. Negotiations for technical and financial assistance in the development of Rakha were conducted but no definite agreements were announced.

Gold.—All gold production was from mines in the State of Mysore. Most production was from mines operated by Kolar Gold Mining Undertakings, a Federal Government entity, in the Kolar goldfields. The State of Mysore operated the Hutti mines in the Raichur district to produce small quantities of gold. Construction proceeded on a new crushing and grinding plant at Hutti to increase mine output from 350 to 1,000 tons daily.

Proved ore reserves in the Kolar goldfields are reported as 3.8 million metric tons and those of Hutti as 500,000 tons. The average extraction grade of gold ore produced during 1964 at Kolar goldfields was 7.42 grams per metric ton.

Iron Ore.—Indian iron ore resources are of world importance and are the nation's most valuable metallic mineral asset. An estimated 22,000 million tons of high-grade ore reserves and about four times this quantity of low-grade ore resources are reported from every State of India. The most important deposits are those in Goa, Bihar, Orissa, Mysore, Madhya Pradesh, Maharashtra, and Andhra Pradesh.

The estimated minehead value of iron ore produced in 1965 was nearly $40 million. Almost one-half of ore produced was exported. These exports, valued at about $83 million f.o.b. for calendar 1965, were the largest earner of foreign exchange among mineral commodities traded. Total 1965 output was from approximately 250 opencast mines; however, six largely mechanized mines accounted for about one-half of total ore produced.

The Government of India continued to give top priority to the development of public sector iron ore projects to expand exports and meet the increased demand of the growing domestic iron and steel industry. Planned annual production targets to be achieved by the end of the fourth 5-year plan (1970–71) are 33 million tons for domestic consumption and 25 million tons for exports. Planned programs to achieve this expansion of capacity by 35 million tons include large-scale mine mechanization, the construction of beneficiation and pelletization plants to upgrade quality and utilize fines, improvement of transportation, and the simultaneous development of ore-handling facilities at six ports.

The Government-owned National Mineral Development Corp. made substantial progress in the development of the Kiriburu and Bailadila iron ore deposits. These deposits are being developed, with Japanese technical and financial assistance, to export 6 million tons of ore annually to Japan under long-term purchase agreements. The Kiriburu project, with facilities to produce 2 million tons per year, was completed but production was limited because of delay in completion of modern mechanical ore-handling facilities at the

port of Visakhapatnam. In August, the mechanical loading plant began operating at limited capacity. Upon completion, the port will have an ore-handling capacity of 8.2 million tons per year.

Development of large high-grade iron ore deposits at Dhalli Pahar in Madhya Pradesh was begun. These mines will supply ore required to expand capacity of the Bhilai steel mill from 1.2 to 3.5 million tons annually.

Iron and Steel.—In 1965, the Indian iron and steel industry achieved a fuller utilization of existing plants, made substantial progress in construction of facilities to expand existing plant capacity, and implemented planned programs for new public sector steel plants.

As in recent years, the industry maintained the trend of marginal increases in the production of crude and finished steel. Both the private and public sectors, which share almost equally the current installed producing capacity of about 6.4 million metric tons of ingot steel annually, operated at near capacity. Production of nearly all categories of finished steel by primary producers, secondary producers, and rerollers during 1965 exceeded that of 1964.

The Government-owned Hindustan Steel Ltd., operator of the Rourkela, Bhilai, and Durgapur public sector plants, reportedly realized a net profit of $4.2 million in 1965 after allowing for interest and depreciation charges of $61.3 million. This profit is the first earned by the company since its inception in 1958. Construction of facilities to expand the capacity of all three plants continued. The expansion program to increase the capacity of the Bhilai plant from 1 to 2.5 million tons of ingots per year was nearly completed at yearend. The U.S.S.R., which provided financial and technical assistance in the construction of Bhilai, agreed to provide further assistance to expand the annual ingot capacity of the plant to 3.5 million tons. Work continued on the expansion of the Durgapur (British assisted) and Rourkela (West German assisted) steel mills to increase their capacities from the existing 1 million tons each to 1.8 and 1.6 million tons, respectively. The Governments of India and the United Kingdom reached an agreement covering a credit of $168 million to a British consortium to supply equipment and machinery for the further expansion of Durgapur to a capacity of 3.4 million tons. Negotiations with the West German Government for a further expansion of the Rourkela plant were in progress.

In January, the Governments of India and the U.S.S.R. signed an agreement for construction of India's fourth public sector iron and steel plant. In December, the U.S.S.R. presented to the Indian Government a detailed project report for the proposed plant. The report provides for the construction of a plant at Bokaro in Bihar State with an initial annual capacity of 1.7 million tons of ingot steel to be expanded to 4 million tons in a second stage and ultimately to 5.5 million tons. The U.S.S.R. has agreed to provide a credit of $211 million to assist in financing the foreign exchange costs of the first stage of the plant. The reported total cost for completion of the first stage of the project was an estimated $1,300 million.

The British-American Steel Works for India Consortium (BASIC) completed a study for the Indian Government concerning the proposed construction of a fifth public sector plant. BASIC has reportedly agreed to finance the foreign exchange costs of the project and provide technical

assistance in the design and construction of the plant. It recommended that a plant with an annual ingot capacity of 1.5 million tons be located at Viskhapatnam, Andhra Pradesh.

The Mysore Iron and Steel Works Ltd. (owned 60 percent by the Government of Mysore State and 40 percent by the Federal Government) completed an expansion program to raise the mild steel capacity of its Bhadravti plant to 145,000 tons per annum. Construction of facilities to produce 77,000 tons of alloy and special steels was continued. One 20-ton electric arc furnace a second 20-ton furnace and an 8-ton furnace was scheduled for April 1966.

In the private sector, the most significant development was the resolution of questions concerning the repayment of government loans granted to Tata Iron and Steel Co. (TISCO) and Indian Iron and Steel Co. (IISCO). Under recent legislation, the Government was empowered to convert outstanding loans of both companies to equity and thus, in effect, give the Government financial and management control of the companies. Under these circumstances, expansion plans were deferred because of the reluctance of the International Bank for Reconstruction and Development to extend financial assistance to the companies. The companies have agreed to repay half of their outstanding loans now and the balance with interest by 1972. TISCO was authorized to expand its annual ingot producing capacity from 2 to 4 million tons. IISCO proceeded with plans to expand its capacity from 1 to 2 million tons.

The iron and steel industry remained India's major consumer of mineral raw materials. In 1965, steel plants consumed the following quantities, in millions of metric tons, of raw materials: Iron ore, 10.9; coking coal, 10.1; noncoking coal, 1.0; limestone, 3.3; dolomite, 0.8; scrap, 1.5; and managanese, 0.3.

Demand for iron and steel continued to exceed supply. Only 5.5 million tons of finished steel was available to meet the officially estimated demand of 6.2 million tons. The quantity of salable pig iron continued to meet less than half the estimated demand of 2.5 million tons. Alloy and special steels, essentially all of which were imported, continued to be in very short supply. The gap between domestic steel production and demand is expected to continue until current investments in expansion result in greatly increased production.

Effective August 31, the Government removed statutory price and distribution controls on pig iron. This action was a continuation of the policy initiated in 1964 to remove such controls on about two-thirds of all domestic steel products.

Lead-Zinc.—Known resources of lead and zinc are extremely limited and all domestic production was solely from mines at Zawar in Rajasthan operated by the Metal Corporation of India Ltd. (MCI). The company operated a smelter at Tundhoo near Udaipur to process lead concentrate but zinc concentrate was shipped to Japan for smelting on a toll basis with recovered metal returned to India.

The major mine development and processing plant expansion program undertaken by MCI suffered severe setbacks during the year. Construction of ore processing and smelting plants to recover 18,000 tons of zinc and 11,000 tons of lead annually was delayed because of serious financial and other problems. In October, the Government of India promulgated an ordinance expropriating the company and assumed management responsibilities. On November 22, the Lok Sabha (Parliament) approved a bill to nationalize MCI. Court cases to settle the legality of the action are in progress. Meanwhile, construction was suspended and production was minimal.

The Cominco Binani Zinc Ltd. made progress on construction of its Alwaye, Kerala smelter. Upon completion in 1966, the plant will process imported concentrate to produce 12,000 tons of zinc annually. Capacity is to be expanded to 20,000 tons ultimately.

The Government of Poland offered financial and technical assistance for construction of a proposed 30,000-ton-per-year zinc smelter at Visakhpatnam, Andhra Pradesh, to process imported concentrates. A preliminary project report was completed and submitted to the Indian Government.

Imports continued to supply about 90 percent of lead and zinc requirements. These metals were in short supply owing to limited foreign exchange funds and these shortages are expected to become even more acute in the next few years.

Manganese.—The manganese ore reserves of India total about 180 million tons, or nearly 10 percent of the known world re-

sources of commercially recoverable ore. The great manganese ore belt of Maharashtra and Madhya Pradesh contains an estimated 80 million tons of 35 percent grade ore. Other large deposits occur in Goa and in various areas of Orissa, Bihar, Gujurat, Andhra Pradesh, and Rajasthan.

India has long been one of the largest producers and suppliers of manganese ore in the world market. Indian production of all grades of manganese ore in 1965 exceeded that of 1964 by nearly 28 percent. This increase was largely in response to increased export demand in 1964; however, in 1965 both the quantity and value of manganese ore exports declined sharply. Exports of 1.15 million tons having a value of $19.7 million in 1965 were about 30 percent below those of 1964. The decline was largely due to the discontinuance of barter sales, effective January 1, 1965.

In July, the Government-owned Minerals and Metals Trading Corp. (MMTC) assumed sole responsibility for the negotiation and coordination of all manganese ore exports, except for ore produced or acquired by Manganese Ore Ltd. in which the Government owns 51 percent equity. This Government of India action was taken in an effort to stimulate exports, provide financial assistance, and accelerate modernization and development of the nation's mines.

Most of the nearly 400 mines are small to medium-sized operations that are inadequately mechanized. Low productivity, combined with rising labor and transportation costs, has lessened India's competitive position in world manganese markets.

Domestic consumption of manganese ore by the iron and steel industry was 324,600 tons in 1965, an increase of 16.6 percent over that of 1964.

Mineral Sands.—The rare-earth minerals contained in beach sand deposits along the coast of Kerala and Madras are of world significance. Reserves have never been fully assessed but the sands are known to contain large quantities of ilmenite, rutile, zircon, sillimanite, and monazite. In 1962, the Indian Bureau of Mines estimated the reserves of ilmenite in the beach sands at 356 million tons. Recoverable monazite in these sands has been estimated as 5 million tons.

India produced and exported more than 75 percent of total world ilmenite output before World War II. Exports reached a peak of about 350,000 tons in 1957 and have since declined to an insignificant 15,000 tons in 1965. Contaminants that adversely affect metal recovery and world competition from highly developed deposits in other countries are the major factors responsible for India's loss of world markets. Domestic consumption of about 15,000 tons in 1965 was processed by Travancore Titanium Products, Ltd. to produce titanium dioxide for paint pigments.

All rutile was produced by F. X. Pereira Minerals Co. from tailings at its mines at Quilon, Kerala. All output was consumed locally.

Data on monazite production is withheld under government laws for prescribed substances. Monazite is processed at the Atomic Energy Establishment plant at Trombay to produce thorium nuclear fuels for the country's electric power generating reactors.

NONMETALS

Cement.—In recent years, demand for cement has exceeded supply even though an increasing trend in production has been maintained. In 1965, the domestic supply was 2.5 million tons short of the estimated demand of 13 million tons. The Indian cement industry, consisting of 34 private and 3 public sector plants located throughout India, operated at about 95 percent of its installed capacity of 11 million tons per year.

The most significant development during 1965 was the lifting of price and distribution controls on the industry by the Indian Government. For over 23 years, the cement industry has operated under various controls set by the Government-owned State Trading Corp. of India (STC). The decision of the Government to relax controls was announced on August 26 but did not become effective until January 1, 1966. Delay in implementation was caused by the Indo-Pakistan emergency. An industry organization was formed to coordinate allocation and distribution functions previously handled by STC. Effective January 1, 1966, the industry raised the uniform free-on-rail-destination price of cement by $3.36 per metric ton. Fifty percent of each company's output was reserved for government purchase at a rebate of $1.26 per ton. Also, the industry agreed to freeze dividends at current levels and utilize extra earnings to expand plant capacity.

The Government-owned Cement Corp. of India was registered as a private limited company on January 18. The company was established to promote expansion of the cement industry in an effort to meet the production target of 23 million tons per year by the end of the fourth 5-year plan (1970–71). It was announced in Parliament that the company would construct eight new cement plants, each with a capacity of 200,000 tons annually.

Mica.—In 1965, India remained the world's leading producer and exporter of block and sheet mica and mica splittings. As in the past, India continued to supply nearly 80 percent of the annual world requirements for these commodities. Mica exports, valued at $23.1 million in 1965, were second only to those of iron ore as India's most valuable export mineral commodity.

Although quantitative data on reserves are unknown, the deposits of muscovite mica in Bihar, Rajasthan, and Andhra Pradesh are considered virtually inexhaustible for the foreseeable future at current producing rates. Bihar was the leading producing State, accounting for nearly one-half of total output. An estimated 23,000 persons were employed in some 700 small mines and mica dressing operations in India.

The regulatory measures imposed on the mica trade by the Indian Government during 1964 appear to have corrected certain malpractices and increased foreign exchange earnings. In 1965, the value of mica exports exceeded that of 1964 by $2.6 million.

Salt.—Nearly all salt was produced by solar evaporation of sea water along the coasts of Gujarat, Madras, Maharashtra, and Andhra Pradesh. Rock salt mines at Mandi in Himachal Pradesh continued to produce about 3,000 tons annually. Despite a small increase in 1965 salt production, the value of total output declined from $18 million in 1964 to $15.4 million in 1965. A sharp fall in salt prices that began in 1964 continued in 1965.

In 1965, exports of salt (mainly to Japan) increased to 267,000 tons, a gain of almost 12 percent over that of 1964. Nearly 95 percent of total output was for domestic consumption, principally for human use.

The fourth 5-year plan target for salt production was set at 8 million tons by 1970–71. Most of the increase was earmarked for export.

Sulfur and Pyrite.—India produces no sulfur and foreign exchange problems limited the available supply from imports to about 80 percent of the estimated demand of 350,000 tons in 1965. As a result, the open market prices of crude, roll, and powder forms of sulfur in Bombay increased from $84 per metric ton at the end of 1964 to $168 per ton.

The Pyrites and Chemical Development Co., Ltd., a government entity established in 1960 to exploit the large Amjhore pyrite deposits in Bihar, continued efforts to establish sulfur and sulfur-based industries to develop these deposits. The company arranged for pilot plant tests for sulfur extraction from pyrites to be conducted in Finland. Also, the Central Fuel Research Institute proceeded with research projects to this end. In January 1965, the Indian Government approved a mining project for the annual production of 240,000 tons of pyrite ore at Amjhore.

MINERAL FUELS

Coal.—Coal remained as India's most valuable mineral resource in 1965, accounting for 73 percent of the value of all mineral production. As in recent years, coal supplied nearly one-half of the total commercial energy consumed in 1965. Indian reserves of bituminous coal are estimated in excess of 115 billion metric tons; however, only about 2.5 million tons of this reserve is of coking grade.

Since 1964, coal production has greatly exceeded demand and a severe coal supply-demand imbalance existed throughout 1965. Government planners initially established a production-consumption goal of 98 million tons to be achieved by the end of the third 5-year plan (1965–66) but this was subsequently revised downward to about 70 million tons. The anticipated increased demand for coal failed to develop because of delays in the expansion and completion of planned coal-consuming industrial projects, declining consumption by the national railroads as a result of partial electrification and dieselization, increased use of fuel oil by certain industrial plants, and related factors. During 1965, total coal mine production reached 67 million tons despite curtailed mining operations. At

yearend, pithead and purchaser stocks were about 8 million tons.

An estimated 800 coal mines were in operation in Indian coalfields during 1965. Most mines are nonmechanized and less than half the total produced more than 25,000 tons monthly. Average daily employment in all mines was about 400,000 persons. Bihar was the leading producing State, accounting for about 45 percent of total output. West Bengal mines accounted for nearly 30 percent and Madhya Pradesh, Andhra Pradesh, Orissa, Maharashtra, and Assam accounted for the remaining production.

Most mines are privately owned but the Government-owned National Coal Development Corp. (NCDC) operated 21 public sector mines and 2 washeries in the major coalfields that accounted for about 20 percent of total production. Planned expansion and development of both the private and public sectors of the coal industry to supply the major share of India's growing commercial energy needs continued as the main energy policy of the Government. Coal production and consumption targets under the fourth 5-year plan are for annual increases of 5 million tons to reach a total of 92 million tons by 1970–71. Most of the increase was scheduled for the development of public sector mines by NCDC with technical and financial assistance from various foreign governments. Polish collaboration in the development of seven underground mines in the Jhari coalfields of Bihar for coking coal production was continued. Work on the first two mines and a washery was in progress. The U.S.S.R. extended assistance for the development of two deep mines, an open-cast mine, and a washery at Korba in Madhya Pradesh. The United States, United Kingdom, and France provided assistance for other NCDC projects.

In an effort to increase coal exports, the Indian Government gave the Government-owned Minerals and Metals Trading Corp. a monopoly on coal exports, effective September 1, 1965. On December 24, the Government authorized an increase of all coal and coke prices of 8 and 11 cents per ton, respectively.

Lignite.—Production of lignite in 1965 increased by 47 percent over that of 1964. Essentially all output was from the open-cast mines in the Neyveli area of Madras operated by the Government-owned Neyveli Lignite Corp. All production was utilized at the corporation's 250,000-kilowatt thermal powerplant and its briqueting and carbonization plants, which began initial operation in July 1965. Lignite production of 3.56 million metric tons annually was planned to meet requirements of the powerplant, a fertilizer plant, and the briqueting plant. Under the fourth 5-year plan, it was proposed to increase mine output to 6.3 million tons to facilitate expansion of the thermal powerplant capacity to 600,000 kilowatts.

Lignite reserves in the Neyveli area are estimated at 2,000 million tons. An estimated 200 million tons are easily workable by opencast methods. The deposit occurs in a single seam at a depth of about 160 feet.

Petroleum.—All phases of the petroleum industry are regulated and largely controlled by the Government of India. Various agencies continued and implemented programs to develop indigenous petroleum resources, expand refining capacity, and increase the public sector role in petroleum products distribution and marketing.

All oil exploration and most petroleum and natural gas producing operations are conducted by the Government-owned Oil and Natural Gas Commission (ONGC) and Oil India, Ltd., owned 50 percent by Burmah Oil Co. and 50 percent by the Indian Government. Oil India operations are limited to concession areas in Assam and in the Northeast Frontier Agency. The ONGC operates throughout India. Aside from these organizations, oil was produced from the long-established Digboi oilfield in Assam by the Assam Oil Co., a wholly owned subsidiary of Burmah Oil Co.

Petroleum and natural gas production was about equally divided between the States of Assam and Gujarat, the only areas in India having proved petroleum resources. The ONGC carried out extensive exploration and development well drilling throughout India, drilling a total of 98 wells. Most wells were drilled to develop the Ankleshwar and Kalol oilfields and the Cambay gasfield of Gujarat and the Lakwa field in Assam. Drilling at Lakwa was reported to have discovered probable oil reserves of 300 to 350 million barrels. New oilfield discoveries were reported at Navagaon in Gujarat and at Rudrasagar in Assam. Also, ONGC drilled exploration wells

in the Cauvery Basin in Madras and in various other States but no commercial oil deposits were found. Oil India operated four rigs to drill additional development wells in the proven Nahorkatiya, Hugrijan and Moran fields of upper Assam. Exploration activities on the concession area near these fields, acquired in 1963, was continued. Five wells drilled in this area since 1963 have proved nonproductive.

As in recent years, ONGC continued to receive substantial technical and financial assistance from foreign governments in its efforts to find and develop additional petroleum resources. The U.S.S.R. has provided about $85 million in foreign credit and much technical aid. ONGC has received about $20 million in foreign credits and assistance from Italy and France and some technical assistance from the United Kingdom, Rumania, Yugoslavia, and Czechoslovakia. During 1965, ONGC concluded contract drilling agreements with an Italian Government oil entity for offshore and onshore operations. French and Yugoslavian oil entities were awarded contracts for other onshore drilling operations. A Soviet seismic ship conducted geophysical surveys off the coast of south India and a French firm continued seismic surveys of the Jaisalmar area of Rajasthan.

During 1965, Indian crude oil refinery capacity was increased by 40,000 barrels per day to reach a total capacity of 240,000 barrels per day. All expansion was in the public sector, since the Government adhered to its policy of prohibiting the private sector from expanding beyond its present capacity of about 165,000 barrels per day. Planned new refinery construction programs are all in the public sector, although private companies may be allowed to participate on a minority equity basis.

On October 11, 1965, the first 20,000-barrel-per-day unit of the Soviet-assisted Koyali refinery near Bombay was commissioned and began processing domestic crude from the Ankleshwar oilfield in Gujarat. Construction of a second 20,000-barrel-per-day unit was nearing completion at yearend. A third and final unit to bring the total capacity to 60,000 barrels per day was scheduled for completion in 1966.

The first 20,000-barrel-per-day unit of the Barauni refinery in Bihar, built and financed with U.S.S.R. assistance, was formally commissioned in January 1965. A second unit of equal capacity was completed late in 1965 and the U.S.S.R. agreed to assist in expanding the capacity further to 60,000 barrels per day. This refinery and the public sector Gauhati refinery in Assam processed domestic crude; however, the high wax content of the crude caused considerable difficulties. Barauni refinery products were not up to specifications and the refinery was operated intermittently to permit modifications of the plant to overcome operational difficulties.

Construction of the 50,000-barrel-per-day Cochin refinery in Kerala progressed but was behind schedule. It was expected to be completed in 1965 but delays required rescheduling of the completion date to March 1966. This refinery is being built with private industry participation by Cochin Refineries, Ltd., a company owned 51 percent by the Government of India, 25 percent by Phillips Petroleum Co., 11 percent by the State of Kerala government, and 13 percent by private Indian investors.

After lengthy negotiations, an agreement for construction of a 50,000-barrel-per-day refinery at Madras was signed on November 18 between the Indian Government and the National Iranian Oil Co. (NIOC) and the American International Oil Co. (AMOCO). The agreement provides for construction of the refinery by a newly formed company owned 74 percent by the Indian Government and 26 percent jointly by NIOC and AMOCO. These companies will finance $30 million of the estimated $50 million cost of the refinery and supply up to 50,000 barrels per day of crude to the refinery under a long-term supply contract.

The Government of India and Esso Standard Eastern, Inc. signed an agreement on September 15, 1965, for the construction of a lubricating oil products plant at Bombay. Each party owns 50 percent equity in a newly formed company that will build and operate a plant with a planned output of 145,000 metric tons annually of automotive and industrial lubricants. Completion of the $15 million plant was scheduled for 1968.

The public sector Indian Oil Corp. (IOC) extended its petroleum products distribution and marketing operations in 1965. In efforts to conserve foreign exchange, the Indian Government concluded additional bilateral trade agreements with the U.S.S.R. for petroleum products imports by IOC. Under previous agreements.

the U.S.S.R. agreed to supply 1.5 million tons of products over the 3-fiscal-year period 1963–66 and an additional 800,000 tons in fiscal 1965–66. Effective April 1, 1965, the Government suspended private sector imports of kerosine and diesel oil during the period April to September and substituted imports of Soviet products by IOC. This substitution strained IOC capabilities and the Government urged the private companies to handle and exchange Soviet product imports. The companies refused but continued normal exchange of domestic products between marketing areas to minimize distribution and marketing problems. Private companies' imports of aviation turbine fuel and fuel oil were also in effect suspended by government actions that increased excise taxes on these products. On November 1, IOC began to supply aviation fuel to civil airlines for the first time.

The Government continued to exert pressure on private companies to reduce the price of crude oil imports to their refineries. In January, private companies reduced the price of crude oil imports by about 2 cents per barrel and further reduced prices on July 1 to a greater extent. The companies priced crude imports at $1.34 to $1.48 per barrel that had previously ranged up to $1.55 per barrel. An Oil Prices Inquiry Committee, otherwise known as the Talukdar Committee, was established by the Government to investigate and recommend crude oil and petroleum products pricing policy.

Total consumption of petroleum products in 1965 was an estimated 81.3 million barrels, an increase of 4.5 percent over that of 1964. Crude oil imports supplied about 70 percent of all oil processed and petroleum products imports accounted for 26.7 percent of total consumption.

The Mineral Industry of Pakistan

By E. Shekarchi [1]

Pakistan's mineral industry, although of little impact in the world mineral supply picture, continued in 1965 to contribute to the overall rapid rate of economic growth of the Nation, a growth pattern that in general has prevailed through the entire second 5-year plan that ended in June 1965. The country's gross national product (GNP) [2] rose by more than 28 percent, and per capita income increased about 13 percent in the 5 years covered by the plan, compared with goals of 24 percent and 11 percent, respectively. The rate of growth of the GNP was estimated to have declined to about 4 percent during 1965, compared with an average of 5.5 percent in the previous 4 years. The lower rate for 1965 was attributed mainly to a decline in agricultural output because of unfavorable weather, while the sharp rising trend of industrial production, particularly in the mineral industry, continued in 1965.

Total population in both sections of Pakistan was estimated at about 113.8 million with an annual growth of 2.6 percent. The labor force comprised 32 percent of the total population or approximately 30 million (13 million in West Pakistan and 17 million in East Pakistan). Only a small fraction of the labor force was employed by the mineral industry. As a result of emergency conditions stemming from the Indian-Pakistani crisis including shortages of some raw materials, a substantial number of workers were idle in 1965.

In 1965, the Government of Pakistan published an outline of its third 5-year plan (1965–70) which is part of a broad 20-year program for economic development in the country. With the beginning of the third 5-year plan, Pakistan embarked on an ambitious program of mineral resource development which envisages annual production targets of 200,000 million cubic feet of natural gas, 3 million metric tons of coal, and 5 million barrels of petroleum by 1970.

To close the gap between successful exploration for minerals and full economic exploitation of these resources, the Pakistan Government established a mineral processing and metallurgical institute in 1965 at Quetta, West Pakistan. The intended purposes of the institute are to identify and analyze mineral samples, recommend sound beneficiation processes for economic exploitation of suitable resources, and report their findings, thus bringing discoveries to the attention of industry.

West Pakistan Water and Power Development Authority (WAPDA), a Government agency, announced as one of its goals for the third 5-year plan an expansion of its electric power-generating capacity to more than 1.6 million kilowatts, as compared with the yearend 1965 capacity of 650,000 kilowatts. The new output will come primarily from Mangla Dam (600 megawatts) and from enlarged thermal generator plants in the north and south operating on natural gas from the Sui gasfields.

During 1965, construction work progressed according to schedule on the major Indus Basin installations, namely construction on the Mangla Dam complex, three replacement link canals, and three barrages.

At the end of 1965, total installed electric capacity in both wings of Pakistan

[1] Foreign minerals specialist, Division of International Activities.

[2] Where necessary, values have been converted from Pakistan rupees (PRs) at the rate of PRs 4.76 = US$1.

was estimated at 1.4 million kilowatts; however, in the third 5-year plan, total capacity is expected to increase to 2.4 million kilowatts. About three-quarters of the present power production is hydroelectric power from West Pakistan.

PRODUCTION

Among the metallic ores and metals produced in Pakistan during 1965, iron ore showed the greatest gain, with nearly a fourfold increase over the 1964 output. Chromite production increased 5 percent, while antimony output showed a 25-percent decrease in comparison to the 1964 level. Manganese production was not reported for 1965, but it was estimated that about 1,000 metric tons of ore was produced and consumed domestically.

Noteworthy among the nonmetallic commodities produced in the country were china clay, fuller's earth, mica, and salt which increased about 33 percent, 69 percent, 59 percent, and 21 percent, respectively. Fertilizer production in 1965 showed a 17-percent decrease compared with the estimated 1964 figure and a 2.5 percent decrease, compared with the reported 1963 figures. Production of cement increased about 14 percent in 1965, while total limestone and marble output slightly decreased.

Despite the large natural gas resources of the country, production of this commodity increased only 13 percent in 1965. With the completion of new refineries and fertilizer plants, it is expected that natural gas output will be doubled in the near future. As a result of extensive exploration and the initiation of a large-scale exploitation program, coal production was slightly above the 1963 and 1964 levels, while petroleum output apparently leveled off, reflecting the fact that extensive petroleum exploration has not had very promising results during the previous 3 years. Governmental opinions on the prospects of significant oil discoveries and development were manifested in efforts to seek a partnership arrangement with oil-producing countries of the Persian Gulf region.

e Estimate. NA Not available. p Preliminary. r Revised.

[1] Except where otherwise noted, output is all from West Pakistan.

[2] Officially reported as iron ore, but consists of test lots obtained during exploration which were not used to recover iron.

[3] Includes East Pakistan as follows: Ingot steel: 1962—139, 1963—2,118.

[4] Includes East Pakistan as follows: 1959—44, 1960—70, 1961—96, 1962—90, 1963—77.

[5] Includes: Urea 117,350; superphosphate 8,128; ammonium sulfate 43,283; and ammonium nitrate 79,251 in 1963.

[6] Revisions made from Central Treaty Organization (CENTO) publications.

[7] Includes East Pakistan.

[8] Includes bitumen only.

TRADE

Although detailed information on the quantity of mineral exports was not available for 1964, data on the value of exports of several commodities indicated substantial increases. Metalliferous ore and scrap export values in 1964 were nearly four times those of 1963, while export values for iron and steel increased threefold, and salt export value nearly doubled. The value of total exports in 1964 was reported at $494 million, of which mineral commodities accounted for 2.5 percent, showing that Pakistan remains primarily an agricultural country, depending heavily on imports of metals and minerals.

The value of all mineral imports was given at $253 million, which constituted about 25 percent of the value of all commodities imported in 1964. Available information on metal imports indicate that total iron and steel receipts increased 45 percent while zinc and tin commodity imports each nearly doubled in 1964 compared with that of 1963. Also the imports of lead metal and its alloys were nearly six times the 1963 level. Crude petroleum imports showed an increase of 19 percent in 1964 over that of 1963, while total refinery products registered an 8-percent decrease, and coal and coke categories decreased about 42 percent.

COMMODITY REVIEW

METALS

Chromite.—The 5-percent increase in chromite output in 1965 was possible primarily because of an agreement to a barter arrangement with communist European countries involving Pakistan chromite exports, and probably was influenced as well by political problems in Southern Rhodesia whose continued contribution to free-world chromite supplies was questionable. It was expected by chromite mine owners that Pakistan might achieve in 1966 an output level near that of the peak year of 1960.

Several articles published by the Geological Survey of Pakistan claimed that low-grade deposits of chromite could be exploited economically, but such exploitation would be profitable only under detailed cost estimates, given in these reports, which included low mining costs and introduction of ore concentration facilities.

Iron and Steel.—Salzgitter Industriebau G.m.b.H. of West Germany was asked by the West Pakistan Industrial Development Corp. (WPIDC) to act as general consulting engineers for the heavy mechanical, electrical, and hydroelectric complexes which will be installed at Kalabagh and which were based upon feasibility reports submitted by this firm. The total cost of the Kalabagh steel mill was given as approximately $100 million.

In the latter part of 1965, the East Pakistan Industrial Development Corp. (EPIDC) announced that work on the iron and steel mill at Chittagong, the first such facility in East Pakistan, was continuing, and it was expected that the mill would go into trial production sometime in 1966. The initial capacity of the mill presumably is 150,000 metric tons of iron and steel products annually, with provision for expansion to 250,000 tons.

By the end of 1965, no confirmed details on the construction of a steel mill in Karachi were available. The mill reportedly will have an initial annual output capacity of 350,000 tons. Both the Karachi and Chittagong plants will use imported pig iron and scrap as raw material, and together they are expected to supply about half of Pakistan's current steel requirement.

A ban on domestic sales of iron and steel products imposed during the Indian-Pakistani conflict was lifted, effective October 1965; written permission from the Government's controller to engage in trade of such products was no longer needed.

NONMETALS

Barite.—Recent geological investigation of the barite deposits of Pakistan by the

Pakistan Geological Survey indicated that all known barite deposits are located in the western provinces of the country. These deposits in Khuzdar and Hazara regions were estimated to contain more than 1.5 million tons. Most of the potentially commercial deposits are reported to be vein and replacement type in Precambrian, Jurassic, and Pleistocene rocks. However, it is concluded in the geologic report that successful commercial exploitation of Pakistan's barite resources would require some improvements in existing transportation facilities as well as development of milling and concentration installations. By yearend 1965, no detailed information was available on the 2,400-ton-per-year crushing and grinding plant previously reported under construction in Quetta. The original target completion date for this facility, financed by West German and local private investments, was mid-1965.

Cement.—Cement production in 1965 increased about 14 percent over that of 1964. Most of the cement plants are located in West Pakistan, and shortage of raw material in East Pakistan has made manufacturing of this commodity economically difficult. Moreover, apparently because of transport costs, shipment of cement from West Pakistan to East Pakistan has not been feasible; therefore, East Pakistan has regularly imported 60 to 70 percent of its annual consumption from neighboring countries, principally mainland China.

Even in West Pakistan, cement shortages continued and, as a part of overall efforts to alleviate this problem, the first of two 600-ton-per-day kilns of the Pakistan Cement Co. factory at Hattar near Rawalpindi was commissioned in December 1965. Both kilns were expected to be in full production in 1966, with a total annual production of 400,000 tons.

In East Pakistan, discovery of suitable limestone deposits at Baklabozar in the northeast district of Sylhet, just inside the East Pakistan border with India, may provide the raw material base for additional output in this section. The Assam Bengal cement plant now can be operated continuously from indigenous limestone. Production capacity of this formerly Indian-owned facility reportedly is around 200,000 tons per year, and the EPIDC, which operated this facility in 1965, reportedly was considering a second plant of the same capacity near the limestone quarry at Baklabozar if the quarry can supply sufficient feedstock for the existing plant and the new facility as well.

Fertilizer Materials.—With the demand for fertilizer surpassing domestic production, the Government of Pakistan has given priority to the construction of 10 new fertilizer plants in the third 5-year plan, which began July 1, 1965. Estimated cost of the new facilities is approximately $253 million with six plants scheduled for East Pakistan and four plants planned for West Pakistan. In addition to the state plants, the Government of Pakistan will allow two fertilizer plants to be set up by private concerns. By the end of the third 5-year plan, it is expected that 1 million tons of urea, and over 500,000 tons of ammonium sulfate and nitrate, and 24,000 tons of triple superphosphate will be produced annually.

The Agriculture Department reported that consumption of fertilizer increased threefold during the past 5 years. To assure a steady growth of consumption, the Government is pushing an agricultural education campaign over the next 5 years providing a more effective distribution of agents to permit explanation of application of balanced fertilizers to more consumers.

To make the fertilizer program a reality, the United Nations will grant during the next 3 years a total of about $1.5 million for feasibility studies of the petrochemical and fertilizer industry in Pakistan with emphasis on planning, including plant location, marketing system, and training of personnel.

In 1965, Esso Standard Eastern Oil Co., Inc., and the Government of Pakistan signed an agreement to build a $26 million ammonia-urea complex. The plant will use natural gas from the Mari field as feedstock and will produce about 173,000 tons of urea and 100,000 tons of ammonia per year. Completion of the plant is expected sometime in 1967.

The Hitachi Shipbuilding & Engineering Co. of Japan, under a Japanese consortium pledge of $30 million to Pakistan, was to provide an ammonium sulfate plant with a 150-metric-ton daily capacity at an estimated cost of $1.7 million. It is reported that the plant will be built at

Dandkhel for the WPIDC with completion scheduled for 1967.

Gypsum.—The gypsum industry, with production 5 percent higher than 1964, remained in the preliminary stages of growth. It is assumed that gypsum production will increase in view of the existence of vast known reserves in economically feasible deposits and the growing domestic demand in the cement and fertilizer industries. Although plans of the Gypsum Board of Pakistan to meet any demand by the fertilizer and cement industries were underway, no details of the plans were available at the end of 1965. Known reserves in two localities, the Salt Range of the Sargodha-Rawalpindi Division and the Kohat Salt Range in Peshawar Division, exceed 100 million tons of pure gypsum.

Marble.—Marble output, 25 percent lower in 1965 than in 1964, was about the same as that of 1963. A recent report issued by the Geological Survey of Pakistan showed proved reserves of green marble (onyx) in the Chagai district about 400 kilometers west-southwest of Quetta and showed proved reserves of other marbles in the Peshawar, Nowshera, and Mardan regions to be about 120 million cubic feet. Also, possible reserves of 13 million cubic feet of marble were mentioned in Azad Kashmir, 48 kilometers from Muzaffarabad. All of the marble deposits are located in West Pakistan.

According to reports by the Investment Advisory Center of Pakistan, if the quarrying technique, quality control, transportation, and packing facilities could be improved, the marble industry of Pakistan could become a main source of foreign exchange earning.

MINERAL FUELS

The search for oil in Pakistan, as undertaken most recently by Pakistan Oil and Gas Development Corp., has discovered no commercially significant oil after almost 5 years of planning, surveying, and drilling; however, during 1965, Pakistan's production of petroleum hydrocarbons (petroleum, natural gas, and condensate) increased 9 percent over that of 1964 and met about 41 percent of the country's total petroleum hydrocarbon requirements. Even though increased use of natural gas for industrial purposes resulted in reduced fuel imports, particularly of petroleum products, the country continued to be dependent on foreign supplies for about 60 percent of total fuel requirements.

Coal.—Pakistan continued efforts to expand and modernize mining facilities but was unable to increase the total output of its coalfields at Makarwal, Sor Range, Degari, and Shariagh significantly over the 1964 total of 1.2 million tons.

Apart from the proved reserves of the previously mentioned coalfields totaling 20 million tons, possible reserves in new findings by the Geological Survey of Pakistan at Bogra (East Pakistan) and Lakhar (West Pakistan) have been estimated at 925 million tons. Reportedly, out of an estimated 750 million tons possible reserve at Bogra, only 200 million tons have been considered possibly economic under existing conditions. Although most of the area is affected by a high-water table for much of the year, an exploration shaft was started by EPIDC in cooperation with Geological Survey of Pakistan at Jamalganj in 1965. Full-scale mining operation is envisioned under the fourth 5-year plan period (1970–75).

Petroleum.—*Crude Oil.*—During 1965, indigenous production of crude oil was 3.62 million barrels, all of which came from the Dhulian oilfield near Rawalpindi. This was processed by the Attock Oil Company's (AOC) refinery at Morgah. The AOC refinery products satisfied less than one-fifth of the country's requirements, and the balance was met from imports.

The Government of Pakistan in 1965 authorized Regie Autonome des Petroles (RAP), a French firm, to conduct a geological survey to determine the oil and gas reserves and possibilities in East Pakistan. The investigation was not expected to begin until after the 1966 monsoon season.

Drilling work of Pakistan Petroleum Ltd. and Burmah Oil Co. in conjunction with Pakistan Oilfields Ltd. (Attock Oil Co. plus Pakistani Government and private capital) continued during 1965 at Kundian, Adhi, and Pezu. No information was available on their findings at yearend.

Refineries.—In the east wing of Pakistan, construction work stopped in 1965 at Chittagong refinery because of the withdrawal of RAP, which supplied the foreign exchange and had a 50-percent share of the crude oil supply rights for 10 years. The

EPIDC stepped in temporarily while foreign investors were being invited to take RAP shares; however, by the end of 1965, no permanent solution had been found.

National Refinery Ltd. continued construction of its 10,000-barrel-per-day refinery near Karachi in 1965. This refinery reportedly will produce lubricants and asphalt from feedstock supplied by Pan American Oil Co. from its Darius offshore field in the Persian Gulf. Completion was scheduled for 1966, and estimated cost is said to be approximately $17 million.

Natural Gas.—Total natural gas production from the gasfield at Sui and Dhulian in West Pakistan and Sylhet and Chhatak in East Pakistan during 1965 rose to a new level of 67,000 million cubic feet, about 13 percent more than the 1964 production level. About 81 percent of total 1965 production came from Sui gasfield, Pakistan's major gasfield, which has an estimated recoverable reserve of 6.3 million million cubic feet. About 9 percent came from the Dhulian field, and the remaining 9 percent was produced by the Sylhet and Chhatak fields.

Approximately 98 percent of the Sui gasfield production was utilized by industrial units, such as electricity generation and cement and fertilizer production, while the entire output of Sylhet and Chhatak went to the Fenchuganj fertilizer factories.

In June 1965, completion of the Multan-Lyallpur pipeline section extended the transmission systems 555 kilometers north from the Sui gasfield, and thus Sui gas was made available to several industrial units in the Lyallpur area. At the end of November 1965, the 144-kilometer Lyallpur-Harawpur section of the pipeline was completed to carry Sui gas to cement plants at Gharibwal and Dandot. Work on the Lyallpur-Lahore branch of the gas pipeline, with an expected completion date in 1966, continued during 1965.

To provide feedstock for Esso-Pakistan's fertilizer plant being built at Daharki, Esso Southeast Asia started drilling in November 1965 on the first development well at the Mari gasfield, 760 kilometers northeast of Karachi.

The Pakistan Oil and Gas Development Corp. which has been drilling for oil with the help of the U.S.S.R. technicians since 1961, announced that it had struck natural gas at Jaldi in East Pakistan in May 1965 and at Sari Sing in West Pakistan in November 1965. No detailed information pertinent to reserves and quality of new findings were available.

Regional Mineral Industry Review of the Far East[1]

By J. M. West[2]

Expanded war in Viet-Nam overshadowed activities in the Far East in 1965, diverting capital and materials from potential regional development projects. Japan withstood a period of business recession that was particularly felt by its coal mining and iron and steel industries. Toward yearend signs of improvement began to show. Despite the recession with attendant credit restrictions and forced cutbacks in areas of overproduction, Japan's overall industrial output rose nearly 5 percent during the year. Foreign trade, liberalized in 1964, was a strong point in the Japanese economy and took the place of lagging domestic demand. Japan maintained its third place in world production of iron and steel ahead of West Germany and in 1965 was the world's foremost exporter of iron and steel in primary and semimanufactured forms.

Economic setbacks in mainland China caused by its "Great Leap" failures and subsequent withdrawal of Soviet technical assistance were difficulties relegated to the past. However, a newly formed "Red Guard" political group, part of a so-called cultural revolution, was due to cause new disruptions in 1966. Nevertheless, significant gains were claimed in Chinese industry, and the country approached self-sufficiency in petroleum in 1965 by virtue of its Tach'ing oilfield. Restoration of friendly relations was achieved between South Korea and Japan accompanied by Japanese offers of industrial aid and increased trade. Indonesia's economy was deteriorating; the country withdrew from regional development organizations and continued its stubborn confrontation policy against Malaysia throughout 1965. Late in the year, after a Communist uprising had been quelled, there was a period of political retrenchment and it was hoped that economic improvements would follow. Petroleum remained a strong area in Indonesia's varied resources, and its production was increasing. Tin output declined, however, because of operating difficulties.

The Philippines, Thailand, and Malaysia all showed significant industrial growth and promising mineral potential. From the standpoint of foreign investment, the Philippines remained a questionable area, although positive legislative actions had been discussed. Proposals for large-scale nickel development were turned down and at least one major copper development was blocked because of uncertainties about the laws. Tin mining in Thailand and Malaya made major gains. In Taiwan, U.S. aid was phased out, although cooperative projects remained in some fields. The country was considered to have reached the economic position whereby new industrial investment was self-generating.

An event of substantial importance to the Far East was the founding of the Asia De-

[1] The area considered in this review is defined as that part of east Asia which lies southeast of the Soviet Union and east of the Indian-Pakistan subcontinent; the Soviet Far East, Australia, and Oceania are not included in the area described. For convenience in discussion the area has been subdivided into the following three geographical regions: Southeast Asia-Burma, Thailand, Laos, Cambodia, South Viet-Nam, Malaysia, Indonesia, and the Philippines; Northeast Asia-Japan, South Korea, Taiwan, and Hong Kong; and mainland East Asia-mainland China, North Korea, Mongolia, and North Viet-Nam.

[2] Far East specialist, Division of International Activities.

North Viet-Nam	18	63	1,500–2,000	3	3

[1] Approximate Gross National Product.
[2] Significance according to roughly estimated production value and value added by processing is ranked in the following order: 1—Over $500 million, 2—$100-500 million, 3—$50-100 million, and 4—Less than $50 million.

velopment Bank (ADB).[3] The bank, in which the majority of the capital was subscribed by Far East countries, will be the nucleus of a wide range of development projects in Asian countries. Capitalized at $1,000 million, the ADB will be located in Manila, Philippines. Another encouraging development was reactivation of the Association of Southeast Asian States (ASA), bringing together the area's developing countries for cooperative efforts. Various other organizations were active, in particular, the United Nations' Economic Commission for Asia and the Far East, (ECAFE) which carried out intensive surveys and planning of mineral and related industrial development possibilities. The great interest of the Far East in petroleum and fuels, was expressed at the ECAFE symposium at Tokyo, Japan, in November 1965.[4]

On the whole, the mineral industry of the region made impressive advances, with Japan the outstanding example of growth and technical improvements in processing. Mainland China was not far behind in size of industry but remained technologically less advanced although trying hard to compensate for isolation from the non-Communist world. Between them, the two countries probably were responsible for at least four-fifths of the Far East's mineral output.

Mainland China, with all its resources and nearly two-thirds of the population of the Far East, had an equivalent or possibly lower level of mineral output value including value added by processing than did Japan. Industries in both countries were diversified. Other major mineral producers included North Korea, noted for nonferrous metals; Indonesia with oil, tin, nickel ore, and bauxite; the Philippines with copper, iron, and chromite ores; Malaysia with tin, bauxite, and iron ore; Thailand with tin; and South Korea with tungsten.

Overall, the Far East in 1965 produced approximately 55 million tons of iron ore, 58 million tons of steel, 56 million tons of hydraulic cement, almost 390 million tons of coal, and 288 million barrels (about 41 million tons) of crude oil. The area remained important in the world production of tin and tungsten.

Japan was by far the area's most important country in mineral trade, requiring exceptionally large imports of crude oil, fertilizer raw materials, iron ore, and base metal ores to supply its active smelting

All coal including anthracite	13.8	Mainland China, Japan, North Korea, South Korea, Taiwan, North Viet-Nam.
Crude oil	2.6	Indonesia, mainland China, Brunei, Japan, Burma.

[1] Mostly amorphous graphite used as fuel.

and manufacturing industries. Japanese mineral products also maintained a strong position in the Far East as well as in world trade. Nearly one-third of its steel exports, most fertilizer exports, two-thirds of the cement exports, and one-tenth of its refined oil exports went to countries within the region. However, as can be concluded from the accompanying trade table, a large part of Japanese trade was conducted with countries outside the region. These countries included the United States, countries of the Middle East and West Europe, the Latin American countries, Australia, Canada, and African countries. Japan's main trading partners with the Far East were, in descending order of mineral trade values, the Philippines, mainland China, Malaya, Taiwan, Thailand, and the Ryukyu Islands. Mineral trade with Far East countries comprised 25 percent of Japan's mineral export value and 18 percent of its mineral import value. The Communist Far East accounted in 1965 for 12.5 percent of Japan's Far East mineral export value and 17.5 percent of its mineral import value, compared with 10.2-and 14.6-percent shares in 1964 and 5.0-and 8.4-percent shares in 1963. Coal and pig iron were among those Japanese imports to rise while Japanese exports to the Communist Far East included increasing quantities of fertilizers and iron and steel products.

Table 3.—Japan's trade in selected mineral commodities with other Far East countries in 1965

Commodity	Total quantity traded throughout the world (thousand metric tons unless otherwise specified)	Percent to or from Far East	Principal destinations or sources within the Far East
Exports:			
Metals:			
Aluminum, unwrought	29	10	Mainland China, Burma, South Korea, Thailand.
Copper, unwrought	3	52	Taiwan.
Iron and steel:			
Ingots, blooms, and billets	458	23	Philippines, Ryukyu Islands, South Korea.
Coils for rerolling	889	3	Philippines and Taiwan.
Semimanufactures	8,343	33	Philippines, Thailand, Taiwan, Hong Kong, mainland China, Malaya, South Korea, Singapore, Indonesia, Burma.
Lead, unwrought	9	42	Taiwan, South Korea, Indonesia, Philippines.
Zinc, unwrought	55	27	South Korea, Philippines, Taiwan, Malaya, Singapore.
Nonmetals:			
Cement	1,601	64	Indonesia, Hong Kong, Singapore, Ryukyu Islands.
Fertilizers, manufactured (including anhydrous ammonia)	1,789	93	Mainland China, South Korea, Taiwan, Philippines.

Refinery products do.	105	12	Singapore, Indonesia.

SOUTHEAST ASIA

Troubles in Southeast Asia deepened with intensified warfare in South Viet-Nam, counteraction in North Viet-Nam, Communist harrassment in many sections, division of Singapore and Malaysia, and Indonesia's economic deterioration. On the brighter side, Malaysia, Thailand, and the Philippines made significant advances in the minerals sector. Thailand became an oil refiner of some significance and placed a tin smelter in operation; Malaysia and Singapore had additional oil refineries and iron and steel facilities under construction; and the Philippines increased metal ore reserves, added cement capacity, expanded oil refining and fertilizer facilities, and began construction on a major integrated iron and steel plant. Tin production within the area increased 6 percent in 1965 to nearly 100,000 tons of tin-in-concentrates on the strength of activities in Thailand and Malaya. The subject of offshore prospecting came to the forefront and worldwide interest focused on the potentials of Thailand, Malaysia, and Indonesia offshore tin and oil reserves. Mineral advances were minor in other countries of the area. No development was reported on a potentially large iron ore discovery in Laos; Burma seemed to have de-emphasized minerals; Cambodia discussed plans with the French to build an oil refinery; and South Viet-Nam was unable to carry out its limited industrial plans.

Indonesia's international debts continued to accumulate in 1965, and foreign assistance in mineral development, although still available, was more difficult to obtain. Production of crude oil, a major source of foreign exchange, increased, and there were increases in nickel and bauxite output for export to Japan. However, production of refined oil, cement, and coal all decreased, which offset other gains. High labor costs, broken equipment, bad transportation, and inadequate planning hampered mining.

Crude oil production reportedly reached 178 million barrels in 1965 but the surplus of refined oil for export declined. More of the oil was consumed domestically partly because of the extremely low prices set by the Government. A new lubricant plant reduced dependence on foreign sources for lubricating oils. Exploration for oil was relatively successful. New fields were under active development by the Japanese in the Medan area of northern Sumatra, and by others in Kalimantan (Borneo) and in central and southern Sumatra. At yearend P. T. Shell Indonesia sold its extensive properties to the Indonesian Government.

Re-equipping of tin mines with European assistance continued slowly, and tin production declined because of domestic unrest. A large new dredge built in the United Kingdom was due to arrive in early 1966 to boost tin output. Completion of the new tin smelter at Muntok was delayed by technical problems, so tin concentrates continued to be exported. Mining of nickel in Sulawesi (Celebes) and bauxite on Bintan Island, near Singapore, expanded; revived interest was shown in a large disseminated copper deposit in West Irian (West New Guinea), and copper deposits were studied in southern Sulawesi. Attempts were made to resume gold mining in southern Sumatra and West Java. Construction of the Tjilegon steel plant in West Java was slowed, and the unfinished Tonassa cement project, near Macassar, was struck by fire. A Dutch company began diamond mining in Kalimantan.

Malaysian tin accounted for about 9 percent of the Nation's GNP in 1965, with production rising to nearly 64,000 long tons of tin-in-concentrates, a postwar record. Gravel pump mines, requiring limited capital, were important contributors to the GNP with an increase of over 200 individual operations during the year. The Government conducted further examinations of Malay reservations for tin and assisted landowners in forming mine organizations. New areas were opened for tin exploration including offshore waters, for which prospecting rights were hotly contested by major companies.

Trade with Malaysia was interrupted when Singapore decided to leave the Federation of Malayasia in August 1965, but minerals were not greatly affected except for tariff changes. Plants for manufacturing chemicals and fertilizers neared completion at Klang, Malaya. Expansions in oil refining were underway in both Singapore and Malaya. The Malayawata Iron and Steel Co., a joint Japanese venture which is to include blast furnaces, was finally under construction at Prai, Malaya, and steel-from-

263-927 O-67—70

scrap facilities were being expanded in Singapore. Several more iron mines operated in Malaya in 1965 and output was higher although ore prices were lower than in 1964. The Rompin-Pasaki iron mines under development in southern Trengannu increased output. Several new bauxite mines operated in Johore State, Malaya, but the Sematan mine, in Sarawak, closed down when reserves ran out.

Prospecting continued in northern Borneo for gold, bauxite, oil, and copper; offshore drilling was successful in Brunei providing good flows of oil and natural gas; geophysical surveys were in progress in Sabah. Copper discoveries were under investigation in the mountains of central Sabah, and the potential for the area appeared promising.

Thailand produced about 10 percent of the world's tin in 1965, increasing output to 19,045 long tons of tin-in-concentrates, 22 percent over the 1964 level. Gravel pump operations in the south, encouraged by high tin prices, were major contributors to the rise. The new tin smelter at Phuket opened shortly after midyear with combined capacity of its two furnaces rated at 20,000 tons of tin-in-concentrates per year. Simultaneously, a ban went into effect on concentrate exports, and tin metal exports began shortly after. Plant operators, having startup problems, found tin ore stockpiles growing faster than anticipated and planned immediate furnace expansions. Surveys of offshore tin deposits were fruitful, and considerable increase in tin production was anticipated from these sources. Efforts were underway to modernize Thai mining laws, to establish offshore regulations, and to encourage mining and prospecting for various minerals in the north.

Fluorspar, manganese, and antimony mining remained active. Reports were issued describing Thai manganese and fluorspar deposits. The new Sriracha oil refinery performed well, and the Government's Bangchak refinery was to be expanded to a more economic level of operation. There were reports of another refinery in planning to produce asphalts. A fertilizer plant was under construction; a cement plant neared completion in the south; a new cement plant was scheduled for construction in the northeast; and cement expansions were scheduled for other locations.

Cement requirements have risen sharply in connection with construction projects for roads, electric power facilities, irrigation, and harbor improvements. Several steel pipe plants were opened, and a steel mill was being built in the Bangkok area. A large new iron mine was in production; iron ore reserves in the Loei area were increased by United Nations surveys; and interest was stronger in a reportedly large zinc deposit in northwestern Thailand.

Affairs of government superseded mineral development in Burma, although future plans called for more attention in this area. There were reports of successful oil exploration, but crude output declined. Refineries drew on imported crude oil for expanded throughputs to meet domestic requirements. A new section of the Syrian oil refinery operated satisfactorily. Production at the famous Bawdwin lead-zinc-silver mines, now under government ownership, was less than in 1964 and, apparently, the mine-run ore was lower grade. Proposals to build a new flotation plant and zinc smelter were revealed, but plans remained vague. In the south, recently found iron deposits remained undeveloped, and tin-tungsten mines operated at reduced levels. The Thayetmyo cement plant was scheduled to expand capacity. Trade was more strictly controlled in 1965, and the country became even more isolated in pursuing its policy of independence and nonalinement.

In Laos, tin mining continued but nothing further was reported on the large iron ore discovery near Xieng Khouang said to be suitable, in part, for open pit mining. Surveys of potential hydropower projects were conducted, and preliminary work was started on the Nam Ngum hydroelectric development north of the capital. Little was done on reported lead, gold, coal, and nonmetallic deposits or on oil investigations. Mineral imports, largely of iron and steel, oil products, and cement, were increasing.

Cambodia produced cement, fertilizer, gem stones, a little salt and gold, and had several hydroelectric projects under construction. Cement, glass, fertilizer, and electric power plants were scheduled for construction with aid from Soviet and mainland China assistance programs; France was to supply power, transportation, and port facilities. A small oil refinery was to be built by a French firm.

Philippine mineral production rose significantly, with notable increases in copper, chromite, and iron ore. Cement and refined oil production also made important gains. An uncertain investment climate continued over the minerals industry, but the removal of a 20-percent retention system on exports led to some improvement of income to mineral producers.

Construction began on a long-waited integrated iron and steel plant at Iligan on Mindanao. Delays occurred later because domestic funds, though committed, were withheld from the project. A second steel complex lacked capital to get started. A third smaller plant was still in planning. Oil exploration was in a depressed condition, and capital for further search seemed exhausted. However, several helpful bills were passed by the Philippines Congress, including one that eliminated exploration taxes and another that extended a moratorium on work obligations of oil leaseholders.

A new fine-ore treatment plant for chromite was in operation; output more than offset a decline in lump ore and plus 10-mesh tonnages, but market demand for the upgraded ore was not up to expectations. Refractory chromite reserves increased by nearly 5 million tons of ore; mine capacity for metallurgical-grade ore was expanded. A new iron ore pelletizing plant began operations but had technical problems; the process was found to require an excessive amount of bentonite as binder and sulfur content of pellets was higher than expected.

Potential for copper in the Philippines appeared even better than previously estimated. One of the newest developments was on Balabac Island, Palawan, where Benguet Consolidated, Inc., acquired rights to mine a 500,000-ton deposit containing 4.5 percent copper ore and considerable pyrite. New or expanded mills were being built at several important mines, and copper leaching was expected to add to production. Marcopper Mining Corp. (formerly Pamex) suspended development work at its large and promising Marinduque Island copper deposit while a determination of rights and assurances were sought.

Native sulfur deposits were discovered in Leyte, and a reportedly large lead-zinc deposit was found in Mindaneao. Extensive nickel laterite deposits remained untapped, the Government having rejected bids for development by foreign investors. The cement industry expanded and output rose sharply. A new fertilizer plant started operation slowly because of malfunctioning equipment. Tinplate and steel-casting facilities were enlarged. Domestic coking coal was blended successfully, and a new source of silica sand was in production. There were large increases in crude oil imports and refining.

NORTHEAST ASIA

Favored by relative political stability, the northeast region of Asia, with Japan the dominant influence, made excellent progress in 1965. Opportunities for investment were considered good throughout the area. Japanese mineral industries, although held back by lower demand in some sectors, responded well to development efforts. Domestic markets were generally depressed, but much of the slack was taken up by larger export sales. Japan continued to exploit its own resources and to process both indigenous and imported raw materials from many parts of the world. Thus, the mineral industries provided more than one-tenth of Japan's 1965 GNP. Taiwan's mineral industry increased nearly one-fourth in extractive output value in 1965 and set impressive goals emphasizing fuels and power. In South Korea, overall mine output value increased only 4 percent in 1965; most of this output was coal. Progress in the mineral processing sector continued, with steel, fertilizer, and cement expansions, and a new oil refinery in full operation. Hong Kong advanced mainly in light industries and because of its trading dominance there were resulting increases in consumption of fuels, metals and minerals.

Japan intensified mineral activities abroad in 1965 through its private mining and trading companies and quasi-Government Overseas Mineral Resources Development Co., Ltd. These activities included exploring, developing, equipping, financing, and supplying technical knowledge. There were few areas of the world that did not feel Japanese influence in the competition for minerals. Involvement generally took the

form of cooperative projects or outright purchases of minerals at tightly negotiated prices. Often, accompanying sales of Japanese equipment and contracts for related transportation, power, or other facilities and services were consumated. Among areas where notable investment was indicated were Canada, Alaska, Australia, South America (Brazil and West Coast), central Africa, India, and the East Indies. Even mainland China and the Soviet Far East were not beyond the realm of Japanese contact, with overtures for cooperative mineral projects reported from those areas.

Japan's own mineral-processing industries, notably iron and steel, oil refining, cement, fertilizers, and nonferrous metal smelting, were still undergoing considerable expansion, although industrialists were less confident about investment than in previous years. Domestic metal mining made little progress and nonmetallic mining actually declined. Coal output was 1.5 million tons lower than in 1964. This decrease was offset in the nation's energy balance by imported petroleum, which was processed domestically by a refining industry which by 1965 had become firmly ranked as third in the world. Crude steel output, despite being held down by industry-wide curtailment, increased through the help of large exports of steel products to the United States where inventories were being accumulated. Vigorous efforts to sell steel aboard were expected to continue in 1966.

Copper production was particularly notable because of the world shortage, and electrolytic output increased 9 percent. Copper ores were more expensive, and increasing ingot prices barely kept up with rising ore and other costs. One result of the copper shortage was that the Government began considering some form of stockpiling to protect the metal-working industries and to provide some stability. Stockpiling could extend similarly to other commodities. Domestic mining companies were granted a special tax privilege related to rising costs of exploration and mining at greater depths.

Supply of iron ore from foreign sources was further diversified by additional contracts with new Australian producers. Steel scrap requirements declined because of increasing use of oxygen converters. Major steel producers made further plant improvements; seven more blast furnaces and nine more oxygen converters were placed in operation. Major additions were made at Kawasaki Steel Corp's. Chiba plant, Sumitomo Metal Industry Ltd's. Wakayama works, and Yawata Iron and Steel Co's. Sakai plant. Nippon Kokan K. K.'s new Fukuyama works, to start with 1.5 million tons of crude steel capacity in 1966, was scheduled by 1970 to become Japan's largest steel center.

In nonferrous metals, a major event was the startup of the 60,000 ton-per-year Onahama copper smelter of the combine, Mitsubishi Metal Mining Co. Ltd., Dowa Mining Co. Ltd., and Furukawa Electric Industry Co. Ltd. Renewed activity in lead-zinc and competitive requirements prompted Dowa Mining and Nippon Mining Co., Ltd., to plan a 60,000-ton-per-year smelter on Japan's west coast using an adaptation of the Imperial Smelting Process to treat Dowa's metallurgically complex "black ores." The smelter would replace an outmoded plant at Kosaka. Construction of mine facilities was underway to exploit such black ores, recently discovered in quantity in northeast Honshu where reserves are said to total over 60 million tons. Ores contained significant values in copper, zinc, lead, gold, and silver. Zinc exports increased by nearly 50,000 tons of metal in 1965; the rise was due to a sharp increase in ore imports from Peru and to the expanding zinc smelter capacity.

Aluminum substitution for copper increased and contributed to an upsurge in demand for the light metal. As a result, imports of aluminum ingot rose, including those from the Soviet Union, and Japan's three aluminum refiners planned to boost total smelting capacity to 340,000 tons per year in 1966–67. Capacity for alumina exceeded consumption and nearly one-fifth of the output was exported in 1965. A further increase in supply of bauxite from Australia was expected, because of recent mine developments.

Coal mining costs were higher and the specter of increasing coal imports, valued at more than $60 million above those of 1964, accelerated the shift to petroleum and natural gas as fuel in Japan. Crude oil imports, largely from the Middle East, rose 16 percent to 73 million tons, and refining capacity expanded to 2 million barrels (about 300,000 tons) per day. Showa Oil Co. was completing a new refinery at Niigata to

replace the one destroyed by an earthquake in 1964, and at least four other refineries were being expanded. Additional capacity of more than 155,000 barrels per day was scheduled for 1966. Imports of liquefied natural gas (methane) where due in sizable quantity by 1968.

Coal production, which is largely used for thermal electric power and is a major factor in South Korea's mineral industry, advanced during the year; output increased by over 0.5 million tons; cement also made a large gain, nearly 30 percent more being produced in 1965. Iron ore output rose, and exports reached a value of $7.5 million, almost one-fourth higher than those in 1964. Fluorspar and talc were among nonmetallics realizing declines in output. Output of tungsten, for which South Korea is noted, slumped greatly, although export earnings rose nearly two-fifths to $6.6 million owing to better world prices. At the rich Government-owned Sangdong tungsten mine, work started belatedly on an expansion program to include shaft deepening and mill improvements. Byproduct bismuth and molybdenum recoveries improved.

A potentially large disseminated molybdenite deposit was found in the Toktong-Choyang area. The new lead refining section at the Changhang nonferrous smelter had furnace problems, and the flotation plant lacked adequate water. Changhang treated a larger tonnage of domestic copper ore but produced less electrolytic copper for export in 1965. The nonferrous outlook was improved by development of significant ore reserves and milling facilities in various parts of the country.

Work began on another cement plant, and plans were reported for a major installation (3 million tons or more), which would be the country's seventh plant. Oil refining at Ulsan's new industrial center was scheduled for expansion to a capacity of 55,000 barrels daily by late 1966. As development of the large Hongchon Chaun iron ore property progressed northeast of Seoul further discussions were held on building an integrated iron and steel plant. Major fertilizer manufacturing additions were underway, and an aluminum refinery may be established. The United States continued to actively assist the Government in conducting mineral resource surveys and provided technical support. Japanese influence in South Korea was expected to rise following a normalization of long-strained relations between the two countries.

On Taiwan, a promising oil and natural gas belt was discovered in the Paoshan area of Hsinchu Province, adding to previously developed gas resources in the Miaoli area. Natural gas output nearly doubled to about 11 million cubic feet. Prospects were so good that industrialists planned an extensive petrochemical industry based on natural gas. As part of oil refining at Kaohsiung, a naptha cracking unit was under construction as a base for petrochemicals, plastics, and synthetic rubber. The Kaohsiung oil refinery was to be doubled in capacity to about 3 million tons annual throughout, and domestic oil exploration was to be stepped up. Government plans called for an oil refinery to be built in northern Taiwan, oil and natural gas plant expansions at Miaoli, and pipeline transport of oil. Coal output was slightly higher in 1965, and was consumed largely in electric power generation. Investigation of potential geothermal power sources centered on the Yangmingshan area where plans were made to start extensive drilling and testing. Taiwan's aluminum industry operated close to capacity, except as limited by power supply in dry months and processed its own alumina from bauxite imported from Malaysia. Further expansions were planned in all phases of the operation. More aluminum fabricating facilities were being built, covering a wide variety of products. Export markets for surplus cement were good; South Viet-Nam remained a large purchaser. A plan was outlined to build an integrated iron and steel plant, possibly at Kaohsiung. A 5-million-ton nickel sulfide deposit containing 0.14 to 0.35 percent nickel was discovered overlapping Ilan and Hualien Provinces. Fertilizer capacity approached the million-ton-per-year mark, with further increases planned on the basis of natural gas developments. A 2-million-ton bentonite deposit was discovered in Ping Tung Province in the south.

Hong Kong continued to produce and export iron ore from its Ma On Shan mine in the New Territories and produced small quantities of other minerals. Land reclamation was an important activity in Hong

Kong's thriving harbor area. Construction was at record levels; cement, fuel oil, and electrical power requirements were rising sharply. Metal fabrication and gem cutting continued to be sizable industries. Ship-breaking for scrap steel declined.

MAINLAND EAST ASIA

Mainland East Asia, with its four contiguously situated Communist countries centered around mainland China, had another year of fair industrial advancement, which was partly due to the war in Viet-Nam. Mineral industries held high priorities in economic development programs. In mainland China during the year great effort was expended on attaining international atomic status, on developing heavy industry, on producing fertilizers and chemicals for agriculture, on increasing coal production, and on reaching virtual independence in crude oil production. Not so large, but locally significant were mineral achievements in North Korea and North Viet-Nam. Mongolia made moderate progress with its Darkhan industrial project and in mineral surveys.

The domestic orientation of mainland China's mineral industry remained little changed in 1965; a few shortages were supplemented by imports. Shipments of some traditional mineral export commodities such as tin and tungsten apparently declined, while imports of chemical fertilizers, fertilizer raw materials, machinery, special steels, copper, and several other mineral products increased. Efforts to import complete manufacturing plants, including oil refining, metallurgical, and fertilizer units were notable. A decline in petroleum imports signified that mainland China was on the verge of self-sufficiency at least in crude oil production. The country's second atomic bomb blast took place on May 14 in the western desert, suggesting that in the field of radioactive raw materials and atomic technology China might be more advanced than previous estimates have indicated. Three uranium mines were reported to have come into production in Kiangsi and Kwangtung Provinces with combined daily output of 2,500 tons of uranium ore.

Productivity in coal mining was said to have improved through wider mechanization, and coal quality was somewhat better but remained generally poor by Western standards. Output of coal reached about 300 million tons, surpassed only by outputs of the Soviet Union and of the United States. Production from the Pingtingshan mines, in Honan Province, where major expansions had been recently completed, was about two-thirds higher than that in 1964. Centrally controlled conveyers and a hydraulic transport system were placed in operation at Fushun. Improved washing and blending of coking coals and conservation of best quality coals for appropriate purposes were widely promoted. Greater quantities of coking and other coals were shipped to Japan.

Oil production improved significantly, particular success was claimed at the Tach'ing field, near Anta, in Manchuria. Moreover, Tach'ing became a symbol of progress to be emulated in other industries; a large local refinery had been completed, but crude output exceeded capacity and the excess was being piped or shipped elsewhere for processing. China's supply of crude oil had improved so much through this and other developments that excess crude oil reportedly was offered for export to Japan. Meanwhile, although domestic manufacture of refinery and oilfield equipment was expanding, large orders for refining plant equipment were placed abroad, chiefly in West Germany and Italy. Improvement in supply of refined oil products was indicated by the drop in such imports from the Soviet Union and by one-fifth decrease in the price of domestic gasoline.

Increased Chinese steel production was related mainly to greater smelting efficiency and more rolling capacity. Introduction of fuel injection for blast furnaces resulted in lower coke ratios; equipment was being installed for vacuum casting of steel to improve ingot quality. Large contracts were negotiated for Austrian, West German, and Japanese steelmaking equipment. A number of projects were completed at Anshan, China's largest steel center, including rebuilding of 4 of its 10 blast furnaces. Wuhan, with two large blast furnaces, operated at full capacity of about 1.5 million ingot tons. Maanshan became better integrated,

with ingot and mill improvements, and China's first top-blown oxygen converter went into operation at Shihchingshan.

News on nonferrous metals was not very conclusive. Copper was imported in various forms, and, while much new copper ore was said to have been found, smelting facilities remained relatively poor. The Chinese reportedly were negotiating with the Japanese for new copper smelting facilities. They also were interested in assistance to expand aluminum production and to obtain titanium ingots and titanium manufacturing equipment. China remained acutely short of chromite and nickel but had surplus manganese and pushed antimony, gallium, and selenium sales on the world market.

Some improvements in the cement industry resulted in slightly higher output. Fertilizer facilities were expanded under a high priority program, and raw materials exploitation received emphasis. Both cement and fertilizer industries were characterized by a multitude of small local operations in addition to those at main centers. Byproduct oil shale was utilized as a raw material in one cement plant; use of pozzolanic materials and slags in concrete increased. Several large phosphate mines were under development in Hupeh and Kweichow Provinces; utilization of low-grade ores containing as little as 18 percent phosphorus pentoxide was deemed practical. It was a good year for evaporation of salt. A rich new asbestos deposit was being developed, and overtures were made for Canadian asbestos milling equipment.

A 12-percent increase in mine output value was claimed for North Korea's well diversified minerals industry, with a large increase in investment devoted to mine development. Official sources also claimed exceptional advances in electric power, coal, and iron ore developments. Tungsten, graphite, and magnesite output were of world prominence, and many other industry sectors including producers of fertilizer, chemicals, steel, and nonferrous metals contributed to the country's standing as a minerals producer. Production of coal, mainly anthracite, increased to approximately 19.2 million tons in 1965; output of iron ore rose almost one-fourth to about 5.9 million tons and production of steel was one-tenth higher. Musan, the large iron mine in the north, expanded production to about 2.4 million tons and increased its ore shipments to Japan. An Austrian-designed oxygen-converter steel plant with a planned capacity of 600-tons-per-year was scheduled for construction. This plant would add about one-third to total steel capacity. Nonferrous metal mines were opened and expanded; pyrite processing increased. In the energy sector, coal and hydroelectric power were emphasized over oil which was dependent on Soviet sources. Nevertheless, in this connection the country's first oil refinery which would operate on imported crude oil, was being seriously considered. Strip mining of coal expanded; ground support in the underground mines was a growing concern.

North Viet-Nam's mineral industry remained active with considerable assistance from its Communits partners. Despite the disruptions of war, anthracite and iron ore outputs appeared undiminished, and phosphate, cement, and nonferrous metal industries either improved or maintained their standings. Coal, salt, cement, chromite, and pig iron were exported; chromite went to mainland China. The Soviet Union supplied most of the refined oil products consumed. At the Thai Nguyen iron and steel complex, a third blast furnace neared completion and hydropower, iron ore sintering, coking, and byproduct facilities were being installed. A rolling mill was under construction with Communist Chinese help. In Quang Nai Province, a large iron deposit suitable for open pit mining was under investigation. Cement expansion was completed at Haiphong, and capacity for nitrogenous fertilizers was increased by a plant at Ha-Bao.

Superphosphates were produced from large resources of domestic apatite rock. Rumanian assistance was given to establishing a 500,000-ton-per-year apatite-processing plant at Laokai, in the northwest.

Mongolia produced fluorspar, its one mineral product of world consequence, at somewhat higher levels than in 1964. Locally, coal was important; output was greater in 1965, although it was far short of planned goals. A little oil was produced and refined at Dzuun Bayan. Construction

of steelmaking facilities progressed at the new Darkhan industrial complex, north of Ulan Bator, where power, coal, iron ore, and other industrial minerals were also under development. More East European and Soviet assistance was provided in mineral exploration, and perlite, rare metals, and gold were said to have been discovered.

The Mineral Industry of Burma

By J. M. West [1]

Burma has an agricultural economy, but has long been considered a potentially mineral rich region, with its oil, gas, lead, zinc, silver, tin, and tungsten resources in 1965 less than fully developed. Mineral output had fallen behind that of neighboring Thailand, whose production in 1964 was of about the same order of value. Production of crude oil, the major item, failed to keep pace and output declined in 1965, and petroleum refinery output, which was partly from imported crude oil, strained to supply domestic demand. At the same time, greater efforts went into increasing crude oil supplies by exploration and secondary recovery experiments. Cement and salt production continued at a steady level, but metallic output appeared to be declining.

In trade, payments for some imports were withheld, which led to temporary constraints by suppliers, even though the Government's Central Deposit financial reserves position appeared quite sound. Following completion of Japanese war reparations in April, Japan initiated a 12-year $140 million [2] economic assistance program. Mainland China assisted Burma with the construction of bridges over the Salween River at Ta-Kaw, at Kunhing, and at Kunlong. The U.S.S.R. offered assistance in mining, was interested in a dam to be built on the Baluchaung River, near Mobye, Kayah State, and helped with the construction of the Kyetmauktaung dam. This assistance moved the anticipated completion date to August 1966. Burma's gross national product was probably even lower in 1965 than the $1.63 billion reported in 1963–64, its mineral industry contributed an estimated 3 percent of the overall product. For this country of about 25 million people, only metallic lead and silver had international significance and the country's output of each of these was less than 1 percent of world demand.

Burma's Minister of Mines in 1965, Commander Thaung Tin, was connected with the military leadership, as were most other members of the Government. The Revolutionary Government, which came to power on March 2, 1962, was committed to socialism and nationalization and in 1965 took another step in that direction when General Ne Win, Chairman of the Union of Burma Revolutionary Council, Rangoon, signed into law on October 18 the 1965 Socialist Economic System Construction Rights Act. This reserved to the Government the right to set up any economic undertaking as a new nationalized enterprise, and to nationalize, take over temporarily, step in and supervise, and/or prescribe rules and regulations for all or part of an economic enterprise. A new Trade Council, which succeeded the People's Stores Corp. in October, exercised increasing control over domestic commerce and took actions to overcome the widespread illegal trading. Mineral products were included in an expanded list of controlled commodities; Burma's chronic problem of purchase and distribution of goods continued to hamper growth of the mineral industry. Moves toward greater centralization left a gap in supervision, and reliable trade and production data became scarce. The National Planning Ministry submitted a draft of a 5-year economic development plan for fiscal years 1965–66 to 1969–70 (Burma's fiscal year runs from October 1 to September 30), in which the emphasis on minerals was expected to be

[1] Far East specialist, Division of International Activities.

[2] Where necessary values have been converted from Kyats (K) to U.S. dollars at the rate of K4.73=US$1.00.

increased. Capital investment due for mining had been raised previously from $7.6 million in 1964–65 to $12.3 million in 1965–66.

PRODUCTION

The level of mineral production declined in 1965, with the industry's contribution to the economy probably $40 to $45 million, and with petroleum and gas accounting for one-half or more of this. About one-fourth of the total was from nonferrous metals and ores produced by the famous Bawdwin mines, now in Government hands, and Mergui-Tavoy area tin-tungsten properties. Metallic production showed little evidence of responding to higher world prices, because of domestic controls. Iron and steel was a single plant industry. Cement production continued at about capacity, and Japanese machinery arrived for an addition at the Thayetmyo cement plant to increase output to 1,000 tons daily. Burma's electric power generation was higher in 1965, reaching 33,158 million kilowatt hours in the first 10 months; in 1964 it totaled 37,730 million kilowatt hours. Industrial users consumed about one-fourth of the total. Installed capacity remained at 191,000 kilowatts.

Table 1.—Burma: Production of metals and minerals
(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	1964	1965 [e]
Metals:					
Antimonial lead (18 to 20 percent antimony) [1]	413	459	578	[e] 500	560
Antimony ore (40 to 50 percent antimony)	151	68	NA	NA	50
Copper matte (40 percent copper) [1]	279	370	NA	[e] 300	340
Gold, refined—troy ounces	194	[e] 200	[e] 200	[e] 200	200
Iron and steel:					
Iron ore	[e] 15,000	9,162	NA	NA	5,000
Steel ingot [e]	11,000	13,000	15,000	15,000	15,000
Rolled steel [e]	8,000	10,000	12,000	12,000	12,000
Lead:					
Concentrate (50 to 60 percent lead) [1]	29,007	33,449	32,936	31,002	30,000

[e] Estimate. [r] Revised. NA Not available.
[1] Output of Burma Corp. (1951), Ltd. as reported in 1961–63; figures tantamount to national production. Other companies sporadically produce small quantities of lead, zinc, and silver.
[2] Crude silver; compares with 2,076,000 ounces produced in 1963.
[3] Burma also produces a variety of semiprecious and precious stones, including amber, jade, ruby, sapphire, and spinel.
[4] For 1962 and 1963, residual fuel is apparently not included and "Other" is comprised mainly of distillate fuel.

TRADE

Publication of detailed trade data was at a standstill but it was known that most metallic ores and concentrates, except tin, continued to go to Japan and silver presumably to the United Kingdom. Japan imported 14,387 tons of zinc concentrate and 71 tons of tungsten ore and concentrate from Burma in 1965. Tin ore continued to go to Malayan smelters for refining. Mineral exports made up less than 5 percent of Burma's total shipments; the balance was chiefly rice. It was necessary to import crude oil to meet expanding refinery demand at Syriam, and paraffin wax remained an exported byproduct. U.S.S.R. was the principal source of such crude oil. Jade was handled by Myanma Export/Import Corp., a Government agency, and, along with other gems, about 70 tons of unpolished jade was being exported annually to Hong Kong. Fertilizers were imported, of which about 34,000 tons, mostly phosphatic, was consumed in the 1964–65 season. Imports of coal and coke in 1964 were valued at $3.1 million and cement at $700,000. Base metal manufacture imports, valued at $26.6 million in 1964, comprised nearly 10 percent of all imports and were second only to machinery and transport equipment, emphasizing the undeveloped state of such domestic industries. It was announced in October that People's Stores Corp. was dissolved, and activities were taken over by the new Trade Council, which proceeded to bring strict controls to sales of mineral products and industrial raw materials, as well as other goods.

COMMODITY REVIEW

METALS

Iron and Steel.—Burma's only steel mill, at Ywama, Insein, continued to use domestic scrap iron, but supplies were about depleted. Its 12-ton electric furnace was capable of producing 20,000 tons of steel ingot annually. Steel mill products in the 1963–64 fiscal year included:

Product	*Quantity (metric tons)*
Bars and rods	6,330
Sheets	6,400
Wire nails	1,320
Barbed wire	560

No progress was reported on iron ore developments following earlier West German surveys in the Pangpet area by Krupp Industries and Japanese studies of deposits in the Mergui, Toungoo, and Thaton areas of southern Burma.

Lead, Zinc, and Silver.—Burma Corp. Ltd., formerly British-owned in part, and nationalized in early 1965, was renamed People's Bawdwin Industry and continued to operate about as before. Compensation to be paid former stockholders was not immediately determined. Details on production were not available, since issuance of regular monthly company reports stopped in mid-1964, but output probably was maintained at about the same or at a slightly lower rate. A proposal to invest about $2 million in a mill to produce 40,000 tons or more of lead-zinc concentrates annually and to build a zinc smelter at Namtu was reported in a Burmese newspaper. Japan was again successful in bidding on zinc ore and concentrate exports and continued to take virtually all of the Bawdwin mine output. Smelted lead was exported as in the past. Depletion has made mining more difficult but large tonnages of low-grade ores remain.

Tin and Tungsten.—Ore buying centers were operated by the Government in the southern tin-tungsten producing area of Burma since mid-1964, but prices were too low to encourage mining, and several step increases appeared to have little inducement. The once large producer, Mawchi mines, in southern Shan States, continued operating; the Yawa tin lode mine and Tenasserim Mining Co. operations had been combined into the Kyaukmedaung Mine Project; and Anglo-Bruma Tin Co. Ltd., was now the Heinda Mine Project. Shipments took place from several ports; Tavoy exports alone were reported ni 1964 to include 195 long tons of tin concentrate, 32 long tons of tin blocks, and 621 tons of tungsten (probably tin and tungsten) concentrates.

MINERAL FUELS

Coal.—Limited work was done on developing the Kalewa coalfield, which sup-

plied coal for local use by a brick plant and railroad. At least seven workable seams are known in northern Burma. Coal and coke were imported at the rate of about 300,000 tons annually.

Petroleum.—Crude oil production continued to decline as outputs dropped at the Chauk and Lanywa oilfields, although intensified exploration was beginning to bring results. Three waterflood projects were in operation at Chauk, and projects for hydraulic fracturing and hot oil injection were planned at both the Chauk and Yenangyaung fields. The latter field reportedly produced at a rate of about 4,600 barrels per day in 1964, supplying 40 to 45 percent of Burma's output.

In addition to contract oil studies by foreign firms, several Burmese field groups were making geophysical surveys, and a total of five exploratory drill units, including two that were Rumanian-equipped, were active in the Myanaung, Prome, Chauk, and Yenangyat areas. A successful 8,500-foot hole was drilled at the northern edge of Yanangyaung's Pin Chaung field, adding to its extent. Pin Chaung has a number of free-flowing wells and during high water from monsoons its old and new sections become isolated. Myanaung reportedly had a 300-barrel-per-day exploratory hole. After oil was discovered in the Henzada district, road construction was started to the Irriwaddy River to move equipment and transport oil. Also promising was an oil discovery in the Kogwe Hills, near Inma, in the Prome district. Rumanian-assisted explorations at Chauk were said in early 1966 to have found additional oil at 6,000 feet, and natural gas was expected at deeper levels.

Burma's refining capacity was estimated at 21,900 barrels per day; 11,900 barrels were from the new section of the Syriam plant. Overall operations were considerably below capacity, but were considered adequate for the country's requirements. Crude oil from U.S.S.R. continued to go to the Syriam refinery in 1965. Construction of liquefied petroleum gas and lubricating oil plants was contemplated.

The Mineral Industry of Mainland China

By K. P. Wang [1]

Mainland China continued to be an important mineral producer by world standards, although not in terms of per capita output. Its estimated 1965 mineral output value (mine output plus added value derived from smelting and processing) of approximately $4 billion ranked the country just within the first 10 top mineral producing nations of the world. Although far behind that of Japan, mainland China's mineral output value exceeded that of the rest of the Far East countries put together. The mining component of the Chinese mineral industry remained much stronger than the metallurgical component. As in previous years, basic industries like coal, steel, cement, oil, and salt constituted the backbone of mineral enterprises. Many well-known export minerals and metals were also produced.

The country was one of the three foremost world producers of bituminous coal, anthracite coal, tin, tungsten, antimony, salt, and magnesite. It also ranked about fifth or better in the output of bismuth, manganese, mercury, molybdenite, asbestos, fluorspar, pyrite, talc, and graphite; about seventh in iron and steel; and about tenth in the major nonferrous metals, cement, barite, phosphate rock, and sulfur. Notable production deficiencies continued in chromite, nickel, copper, and phosphate rock. Mainland China imported sizeable tonnages of special finished steels and chemical fertilizers from Japan and Western Europe.

The most significant mineral developments again concerned petroleum. In 1965 the country had clearly become "mainly self-sufficient" in oil, with the Tach'ing field primarily responsible. A large refinery has also been built at the Tach'ing field. This, however, was not adequate for handling local crude; and the surplus was shipped to other areas in a special pipeline. Chinese offers to sell Tach'ing crude to Japan apparently were serious, although conceived as a temporary measure. Importance of Tach'ing is such that it probably furnished about one-third of mainland China's crude and one-fourth of the refined petroleum. Large increases in refinery production were reported for the Karamai refinery in Sinkiang; this is rather significant in the light of completion of the western railroad connecting Tihua (Urumchi), the provincial capital, with the North China coast. Additional, and more diversified, refining equipment was also installed at Lanchow in Kansu. Shanghai and other industrial centers manufactured many types of oil-drilling and refining equipment.

On May 14, mainland China exploded its second atomic bomb somewhere in the west, almost certainly in Sinkiang Province. It was more sophisticated than the first, and again uranium 235 apparently was used instead of plutonium. Although a plant in Lanchow was believed to have gaseous diffusion capability, most of the U–235 used may mave been made in Czechoslovakia from Chinese ores.

In iron and steel, the effort was to increase production through application of new techniques in existing facilities; to further diversify the variety of products made; to continue construction of partially completed steel centers; to employ more coal blending to conserve coking coal for blast furnace operations; to introduce oxygen converters to complement the open hearths; to relieve the shortage of special rolled products through production and imports; to negotiate purchase of some foreign steel equipment and plants; and to plan for expanded operations in the fu-

[1] Chief specialist, East Europe-Far East, Division of International Activities.

ture. A million-ton increase in steel output over that of 1964 may have been achieved. At yearend, a big steel deal was being negotiated to have an international consortium headed by West German firms (DEMAG Aktiengesellschaft and others) build a large integrated steel plant valued at possibly $150 million and presumably equipped with pelletizing plant, oxygen converters, hot and cold rolling mills, and tube and railing facilities.

The coal industry continued to make progress along conventional lines of development. The shaft sinking program was accelerated for both old and new mines. Mining productivity was raised through greater mechanization, but the best output per man-day was still below 2.5 metric tons of coal. Improvements were specifically mentioned for the Fushun, Fuhsin, Tatung, Huainan, Pingtingshan, Chinghsi, and Yangchuan mines, among others. Much stress was placed on blending weakly-caking coals with good coals for iron smelting. Despite slightly higher production, increased coal demand called for economies in coal consumption.

Continued great emphasis was given to fertilizers. A substantial increase in output was claimed, so that the 1965 figure was at least 5 million tons of chemical fertilizers; imports from Japan and western Europe were also much higher than in the previous year. Local phosphate rock was still inadequate, in view of the 603,571 metric tons exported by Morocco to mainland China during the 12 months of 1965. Cement output increased by perhaps 5 percent, with at least one large new plant in operation. At the foremost asbestos center— Shihmien in Szechuan— an expansion program was nearly completed and new ore reserves were found. A long-term contract was signed with the Japanese to supply them with large tonnages of fluorspar. Salt output reached the highest level in the last 5 years.

By yearend, mainland China was making preparations to start on its third 5-year plan covering 1966–70. This would mean a 3-year lapse since the end of the second 5-year plan. No announcement was made regarding the national targets for the coming years. However, specific industries were urged to devise plans for expanded production. Policies and programs, pursued in recent years in terms of consolidation and maximum utilization of available facilities, have brought about notable improvements in industrial growth and overall economy. In fact, the Chinese claim that industrial output rose by 15 percent in 1964 and that the target of another 11 percent in 1965 was overfulfilled.

Mainland Chinese economic planning still stressed agriculture, light industry, and heavy industry, in that order. However, heavy industry was gaining ground and more basic construction was underway. The Chinese realized that new facilities had to be created in order to make significant further advances in industrialization. In 1965, there was evidence that industries such as machinery and equipment, machine tools, power and electronics, nonferrous metals, and building materials were being built up in anticipation of greater effort in basic construction.

Minerals and certain heavy industries, such as coal mining, petroleum extraction, iron and steel, cement, and chemicals, have long been recognized by the regime as being indispensable to the country's economic development. Accordingly, continued stress was placed on optimum performance from facilities at hand. Production targets were raised only slightly. Rather, the policy was to improve product quality, diversify products, streamline operations, and conserve materials. Improvements were made at many mines and plants, and the more promising of the smaller mines and plants were slated for expansion. Construction of new projects was at a greater pace than last year. Special attention was given to the development of metal fabrication facilities.

Much effort went into assisting agriculture. Production of chemical fertilizers and their raw materials was greatly expanded; imports of fertilizers were doubled; and foreign help in building fertilizer plants was sought. Even steel production was partly geared to agricultural requirements, resulting in the manufacture of more agricultural tools and machinery. Pesticide output was increased by petroleum refineries and chemical processing plants.

Mainland China pursued an independent policy in mineral trade, doing less business with the U.S.S.R. than previously and trading more with other Communist countries as well as non-Communist countries. In carrying out a program of developing a strong self-reliant industrial

system, many mineral and industrial facilities of Chinese design and construction were placed in operation. Withdrawal of Soviet technical aid dictated this policy. To keep up with world developments, a special effort was also made in 1965 to procure additional advanced technical know-how through purchase of foreign plants and materials and permitting foreign technicians and advisers to come in.

The Chinese Communists continued to stress "specialization and cooperation in developing mass production." Numerous national technical conferences were held on specific subjects. The larger and more established industrial units helped the smaller and newer ones. Some factories and cities exchanged workers for the purpose of pushing adult education and improving industrial skills. There was close cooperation between universities and institutes and mines and industries. Such were some of the steps taken in preparation for an "industrial upsurge."

PRODUCTION

Mineral output value rose by possibly 5 percent over that of 1964. The 1965 level was more than in any of the preceding 5 years, except for the exaggerated figures claimed for 1960. The mineral industry, with a strong mining base and an improving metallurgical sector, operated substantially in a conventional manner, having done away with most of the haphazard operations.

Coal and iron and steel each accounted for more than one-third of the mineral output value; petroleum, nonferrous metals, and cement together made up for about one-fourth. Output of many individual metals and nonmetals represented significant shares of world totals.

The Chinese Communists have not reported any mineral output statistics for 5 years, having been traditionally secretive about their "colored" metals (nonferrous metals, etc.). Nevertheless, general trends are clear. Fertilizer, salt, and petroleum production made the most notable gains in 1964, followed by steel, cement, and coal. Nonferrous base metals remained somewhat stationary, whereas output of a few of the famous "export" metals may well have dropped.

It was claimed that the Ministries of Metallurgy, Coal, Power, Petroleum, and Chemical Industry met their 1965 targets in November, and that iron and steel, nonferrous metals, coal, petroleum, chemicals, fertilizers, cement, salt, and many others reportedly achieved remarkable increases in output.

r Revised.
1 Estimated.
2 Mostly diasporic bauxite. Data shown include only the bauxite for aluminum manufacture; in addition 100,000 to 200,000 tons were produced each year for making refractories.
3 Converted to equivalent 50 percent Fe ore.

TRADE

Overall trade volume of mainland China, never much of a trading country, showed a one-sixth increase in 1965 to possibly $3.8 billion. Minerals and metals remained significant in total trade, although occupying lesser positions than in 1963–64. Apparently, oil imports declined, imports of metal products increased, imports of chemical fertilizers rose sharply, exports of traditional surplus minerals and metals dropped somewhat, exports of cement may have declined slightly, and exports of asbestos and salt increased. There were no published trade figures from mainland China, and data from countries trading with China were used. Accordingly, official trade statistics from the U.S.S.R., Japan, and Poland have been presented to show trends. Political differences and completion of debt payment by mainland China brought about reduced Sino-Soviet mineral trade. Conversely, trade with Western Europe and Japan rose by more than 50 percent and trade with Eastern Europe also was higher. On April 29, a new Sino-Soviet trade agreement was

signed that might lead to an improved trade relationship.

Increased trade with the British was brought about mainly through Chinese purchases of $120 million worth of gold, $6 million worth of platinum, copper and copper alloys, steel products, and machinery and chemicals. Trade with the French declined momentarily, whereas trade with the West Germans and Italians soared. While continuing to export seamless steel pipes to China, West German firms were negotiating to furnish various metallurgical plants, a Lurgi oil plant, a naphtha cracking plant, and a glass plant, among others. An important deal involving the Italians was the sale and construction of a catalytic reforming oil refinery in Manchuria. A contract was signed with Swedish companies (Atlas-Copco AB, ASEA or Allmanna Svenska Elektriska AB, and AB Svenska Flaktfabrieken) to develop a copper mine and an iron mine in China. An Austrian firm agreed to provide oxygen converters. The British and Italians each have a contract to build a fertilizer plant. The Japanese were furnishing fertilizers, steel products, and steel fabrication and fertilizer manufacturing facilities to mainland China. Thus, Chinese imports of plants, equipment, and know-how in the mineral-related fields constituted an important part of the overall trade.

COMMODITY REVIEW

METALS

Iron and Steel.—The Chinese Communists claim that 1965 output targets for iron ore, coking coal, pig iron, crude steel, and steel products were fiulfilled a month ahead of schedule.[2] Most likely, Chinese steel production increased to about 15 million tons.

Higher output was mainly achieved through improvements in furnace efficiency and operation of additional rolling mills at existing steel bases, rather than establishment of new steel bases. Smelting processes were intensified, with the introduction of fuel injection in blast furnaces (resulting in reduced coke ratios), greater use of oxygen and magnesia-alumina bricks in open-hearth furnaces, and placing into operation the first locally made top-blown oxygen converter.

The need for employing advanced know-

[2] Ta-kung-pao (Peiping). Dec. 23, 1965, p. 1.

how was shown by efforts to buy foreign equipment and plants. A contract was signed at yearend to obtain a few LD (Linz Donawitz) converters from Oesterreich-Alpine Montangesellschaft of Austria. Negotiations were underway to explore the possibility of purchasing equipment from West Germany. Contracts were concluded in the fall of 1965 to purchase a "medium, light shape mill" and wire-drawing plant from the Kobe Steel Co. Ltd. of Japan, possibly for $8.33 million.[3] Electric furnaces were being bought from the Daido Steel Manufacturing Co. and other Japanese firms.

The Chinese Communists also claim successful trial production of more than 500 new types of steel and rolled steel including many stainless and other alloy steels. Among the new steel products are high pressure nonrust plates for boilers and fertilizer plants, thick cold-rolled steel, durable shaft steel for cars, channel beams for tractors, alloy steel plates for oil cracking, steel tubing for deep oil drilling, and spiral-shape coolers for petroleum refining.[4]

Despite many new products, the need for imports remained serious. Small quantities of pig iron have long been traded with the Soviet Union for finished steel. Western Europe supplied sizable quantities of special steels. Steel imports from Japan, already large, were increasing. The Chinese may import as much as half a million tons of steel products from Japan in 1966. During the Kwangchow Fair alone, held in China late in 1965, the Japanese received bookings (for delivery in April 1966 to March 1967) for 330,000 tons of ordinary steels and 27,500 tons of special steels, about twice the previous annual shipments to China. Exports of pig iron to Japan were down perhaps two-fifths from the previous high of about 1 million metric tons in 1964. Not much Hainan or other Chinese iron ore went to Japan, and coal shipments were only somewhat more than a half million tons.

Anshan, the country's great steel center which may have produced as much as 6 million tons of steel ingot and roughly 170 types of new steel products, overfulfilled its 1965 targets 25 days ahead of schedule while completing a number of basic engineering projects. The Chinese Communists claim that the following projects were brought into operation: A primary crushing plant at the Yench'ien'shan iron mine; replacement of spiral classifiers with hydrotators at various iron ore washing plants resulting in a 9-percent increase in iron recovery to 83 percent; screening and sizing units at the East Anshan sintering plant; an acid-alkaline pickling unit to complement an existing rolling mill; and a large size oxygen plant to provide oxygen for open-hearth furnace operations.[5]

Four of the 10 blast furnaces at Anshan (Nos. 4, 7, 9, and 10) were reconstructed.[6] High-temperature corrosion-resistant "carbon bricks" were substituted for refractory bricks in furnace bottoms. New cooling systems were built around the furnaces. The latest kind of automatic viewers were installed at the base of furnaces to keep continual surveillance of corrosion by molten iron. These innovations resulted in prolonging furnace life between repairs by one-fourth. At the No. 9 furnace, the hot-draft temperature was raised from 1,100° to 1,230° C, coke consumption per metric ton of pig was reduced by about 40 kilograms, and output was raised by 8 percent. Operation of the No. 10 furnace (1,513 cubic meters and Anshan's largest) was improved, bringing pig iron output up to 2,600 tons daily.

The Wuhan steel center, with two large blast furnaces (1,386 and 1,436 cubic meters), five open-hearth furnaces (one 250-ton and four 500-ton), a sintering plant, three byproduct coke plants, a large blooming mill, and various finished steel rolling mills, was operating at full capacity with the equipment available, producing just over 1.5 million tons of steel ingot.

The Paotou steel center had integrated operations oriented around a 1,513-cubic-meter blast furnace, possibly two 600-ton open-hearth furnaces, a large ore concentrator, a byproduct coke plant, and necessary rolling facilities. Steel ingot output probably is on the order of 0.8 million tons. Much work was done on coal blending, with more than half of coal needs satisfied by local weakly caking or non-

[3] Japan Metal Bulletin, (Sangyo Press Ltd.; Tokyo). Aug. 31, 1965, p. 1.
[4] Jen-min Jih-pao (People's daily; Pieping). Dec. 23, 1965, p. 1.
[5] Ta-kung-pao (Pieping). Oct. 26, 1965, p. 1.
[6] Jen-min Jih-pao (People's Daily; Pieping). Sept. 1, 1965, p. 2.

caking coals which greatly reduced the amount of coking coal brought from Hopeh and Shansi.

The Shanghai steel industry increased output somewhat over that of 1964, in line with greater local industrial activity. Steel ingot production was probably 1.5 to 2 million tons. The Shanghai No. 1 and Shanghai No. 3 plants were specifically cited as having improved operations to reach the national advanced level.

The Maanshan steel plant became truly integrated, with a build-up of steel ingot and products capacities since early 1964 to match the pig iron capacity. Maanshan has more than a dozen small blast furnaces of 100 to 250 cubic meters, five converter shops and two open-hearth shops, and presumably two rolling mills. All told, Maanshan is potentially capable of producing more than 1 million tons of steel products annually. This steel center was singled out as having made basic improvements in 1965 that resulted in large increases of output.[7]

The Shihchingshan-Tangshan-Tientsin-Peiping complex, with an annual capacity of more than 1.5 million tons of steel, had a good year. Shihchingshan's pig iron output still came from three blast furnaces (largest is 1,000 cubic meters), but steel output increased as a result of China's first top-blown oxygen converter being placed in operation.[8]

The Taiyuan steel works, located in a new industrial center, was fully integrated and capable of producing more than two-thirds of a million tons of steel yearly. Five blast furnaces were in existence, the largest being 963 cubic meters (also 291 and 146 cubic-meter ones); three 30 to 50 ton open-hearth furnaces plus electric furnaces and converters, and corresponding rolling facilities. A coke byproduct fertilizer plant went through its first full year of operation.

The Chungking steelworks, with a 620-cubic-meter blast furnace (also 134 and 55-cubic-meter ones), four open-hearth furnaces (two 50-ton and two 20-ton), byproduct coke ovens, converters, and rolling mills, is a little smaller than the Taiyuan steelworks. Chungking was thoroughly inspected late in 1965, resulting in technical improvements such as less downtime in open-hearth operations, reduction of raw material consumption, and better heat and energy balances. More than 40 new products were made, and a large size coal grader-mixer was installed. As at most other steelworks, coal blending resulted in greater use of local coals and less consumption of high grade coking coals obtained from elsewhere.

At the Penshi (Penhsihu or Pench'i) steelworks in Manchuria, better known for blast furnaces and byproduct coke ovens, steel producing facilities have been gradually built up in recent years. This center is about the size of Taiyuan and Chungking for pig iron but considerably smaller in terms of steel.

Other Metals.—The Chinese Communists have hardly mentioned their "colored" metals industries in recent years. However, fragmentary information on trade and developments indicated nonferrous base metals had a reasonably good year, whereas the so-called "export metals" apparently did not fare too well. It was claimed that "colored" metals in general achieved significant increases in output and that many mining and metallurgical projects in manganese, magnesite, copper, lead, zinc, aluminum, and tin were under construction.

Manganese ore output, ranking fifth in the world, was more than adequate to meet the demands of the steel industry. Hsiangt'an in Hunan, Mukwei and Leip'ing in Kwangsi, Ch'in Hsien and Fangch'eng in Kwangtung, Tsunyi in Kweichow, and Wafangtzu in Manchuria were among the principal producers. There was a small surplus for export. In 1964, Poland imported 20,100 tons of Chinese manganese ore, Japan 6,265 tons, and West Germany 3,222 tons. Chromite was in short supply, with Albania furnishing 66,000 tons in 1963. Magnesia-alumina brick was widely substituted for refractory chromite. The nickel shortage was also severe, with imports probably coming from the Soviet Union, Cuba, and France (originating in New Caledonia). A contract to purchase 9,300 tons of nickel from Société Le Nickel over a 4-year period was being negotiated in April 1965. The Chinese steel industry consumed only a minor part of large quantities of tungsten and molybdenum produced in the country.

With regard to nonferrous base metals

[7] Ta-kung-pao (Peiping). Dec. 3, 1965, p. 2.
[8] China Reconstructs (Peiping). Sept. 1965, p. 19.

and light metals, copper and aluminum were the items of short supply. A Chinese nonferrous delegation visiting Japan made some interesting observations on their country's copper situation.[9] Copper was being imported; recent imports included 7,500 tons of wires and bars from Chile. Much new ore has been delineated, and copper reserves are believed to be larger than those of Chile. Poor smelting facilities held back mine production. Accordingly, the Chinese delegation was negotiating the purchase of copper smelters from the Japanese. Nonferrous scrap drives have been conducted in China.

According to the Japanese, mainland China was importing about 1,000 tons of aluminum ingot per month, mainly from Canada, Norway, and France.[10] The shortage was not great, however, since aluminum output, primarily from the Fushun plant in Manchuria, was nearly ten times that of imports. The Chinese Communists continued to show interest in getting European and Japanese help in expanding aluminum facilities. Late in the year, they were also interested in acquiring titanium ingots or titanium manufacturing equipment from the Japanese. China had recently been importing about 5,000 tons of rutile annually from Australia. Lead-zinc production apparently was at stabilized levels, and there was little trade.

Little information was available in 1965 on mainland China's famous "export metals"—tin, tungsten, antimony, mercury, molybdenum, and bismuth. However, China ranked fourth or higher among world countries in the production of all these metals. Compared with 1963 and earlier, lesser quantities entered world trade, implying that output may have declined or stocks increased. Tin output possibly held its own, whereas accountable exports declined considerably. Some electrolytic tin of 99.95 percent was offered for sale. Tungsten production probably dropped to the lowest level in a decade; exports were hard to push despite rising prices towards yearend. More Chinese antimony regulus was offered in the world markets during 1965, although there were few takers. Kwangsi became a significant new source of antimoy ore. Mercury production remained at high levels, but exports declined despite the very high quality product offered for sale. There was no news on bismuth. During 1964, Poland and Japan each imported 300 to 400 tons of Chinese molybdenum concentrates and the Soviet Union, unreported additional quantities. Generally speaking, the country was not able to increase export of minerals because potential buyers questioned its capability to maintain steady supplies.

The second atomic blast on May 14 and another one forecasted for 1966 raised the question of Chinese capabilities and resources of radioactive materials. One possible answer to the puzzle was given by a technician who escaped the country late in the year.[11] Three mines were reported to have started production: Maoshan and Chushan in Chuannan County of Kiangsi Province, and Hsiachuang in Weiyuan County of Kwangtung Province. Their combined daily output was said to be 2,500 tons of uranium ore. This was partly processed at the Chuchou plant in Hunan Province and from there sent to Czechoslovakia for further treatment. Mainland China paid no cash but gave the Czechs half of the processed uranium. This might explain why the country has been able to produce uranium 235 cheaply rather than overburden the Lanchow gaseous diffusion plant in Kansu Province.

Mainland China has been producing various kinds of rare earth metals and alloys for use in the optical, metallurgical, and atomic energy industries. Probably the most important producing center was Chinchow in Liaoning Province, Manchuria. The China National Metals and Minerals Import and Export Corporation was offering gallium and selenium of 99.99 percent purity for export.

NONMETALS

Asbestos.—Asbestos production probably increased slightly as compared with the previous year. Most of the 10 new projects at Shihmien, Szechuan—the country's main asbestos center—were presumably completed. A new large and rich deposit was reportedly discovered a few years ago, and the Chinese Communists were intent on developing it. When some Canadian asbestos experts were in Szechuan, the

[9] Japan Metal Bulletin (Sangyo Press Ltd.; Tokyo). Aug. 10, 1965, p. 2.
[10] Japan Metal Bulletin (Sangyo Press Ltd.; Tokyo). July 31, 1965, p. 3.
[11] Far Eastern Economic Review (Hong Kong). Dec. 9, 1965, p. 476.

Chinese were interested in buying beneficiation equipment from them. Shihmien asbestos is good grade, and some was sold in foreign markets. For example, Poland and Japan imported 1,432 and 282 metric tons respectively in 1964. Most of the roughly 130,000 tons of asbestos produced in 1965, however, was consumed domestically.

Cement.—Significant progress was claimed for the cement industry. It appears that output had risen slightly, and product quality and variety improved considerably. The 11-million-ton cement production estimated for 1965 was still several million tons less than the high claimed for 1960. Small plants contributed 15 to 20 percent of the total output. Internal demand for cement increased somewhat, whereas exports apparently declined. Through 1964, the country had been exporting about 1 million tons annually, with Hong Kong the leading purchaser and the Soviet Far East an important second. In 1965, however, Hong Kong imported about 715,000 tons during the year from mainland China, and the U.S.S.R. may have stopped imports altogether.

Nearly half of the approximately 50 large and medium cement plants (100,000-ton to 1-million-ton annual capacity) were mentioned in the Chinese press during 1963–65, and it was claimed that more than 10 modern plants (200,000 to 700,000 tons) and some 80 small plants (less than 100,000-ton size) had been built in the last few years. Some of the larger newly built plants are: Tatung in Shansi, Kunming in Yunnan, Yao Hsien in Shensi, Yungteng in Kansu, Chungking in Szechuan, Kwangchow in Kwangtung, Liuchow in Kwangsi, Kweiyang in Kweichow, and Mutanchiang in Kirin.

Development and expansion of mines and quarries for cement production continued. Sufficient limestone reserves had been developed at the K'ungshan quarry near Nanking to meet the needs of the Chungkuo and Kiangnan cement plants in Kiangsu for 50 years. The Huangchinshan limestone quarry in Hupeh developed for the Huasin cement plant was brought into full-scale production around August; it was said to be highly mechanized and equipped with electric shovels.[12] The Fushun cement plant in Manchuria continued to use byproduct oil shale as a raw material. Increasing quantities of clinker and slag were being used in concrete mixing. Gypsum has never been a problem; indigenous mines provided about 400,000 tons of gypsum consumed in cement manufacture in 1965.

Fertilizer and Chemical Materials.—To cope with the food problem for a growing population, continued emphasis was placed on developing fertilizers and chemical raw materials. Extraction of pyrite and phosphates were given high priority. The apparent substantial increase in overall fertilizer output indicates that pyrite production topped 1.5 million tons. The only two known large pyrite mines in operation were Hsiangshan (near Maanshan) in Anhwei Province and Yingte in Kwangtung Province, which together probably provided half of the national output. Many small pyrite mines were being worked, and one additional large, high-grade deposit was under development. A large quantity of pyrite mined in Szechuan and Shansi Provinces was converted to elemental sulfur. Byproduct sulfur from nonferrous ores was utilized to some extent to supplement pyrite in sulfuric acid manufacture.

Phosphate rock production presumably increased somewhat over that of 1964. The principal mine was Chinghsiang in Hupeh Province; a second important deposit—K'aiyang in Kweichow Province—was under development. Low-grade phosphate ores from Liuyang in Hunan and Nantung in Kiangsu were successfully converted into chemical fertilizers containing 18 percent or more P_2O_5 at local plants.[13] There were many other small producers in Southwest China. However, indigenous output met only about half the demand. Phosphate rock imports from Morocco alone were 778,406 tons in 1964 compared with 603,571 tons in 1965 (Moroccan figures). Some apatite also came from Laokay, North Viet-Nam.

Chemical fertilizer production in mainland China during the first 11 months of 1965 reportedly topped that for all of 1964 by 2.79 million tons.[14] This would imply that the country produced at least 5 million tons of all chemical fertilizers,

[12] Kung-jen Jih-pao (Workers Daily; Peiping). Sept. 1, 1965, p. 3.
[13] Ta-kung-poa (Peiping). Nov. 2, 1965, p. 1.
[14] Ta-kung-pao (Peiping). Dec. 12, 1965, p. 1.

perhaps a little less than half phosphatic and most of the rest nitrogenous. There were about 11 sizeable phosphate plants, headed by Nanking with possibly ½-million-ton annual capacity and including a new plant—Chuchow in Hunan. Nanking, Dairen, Lanchow, Kaifeng, and Wuching (in Shanghai) were among the larger nitrogenous fertilizer plants. Many dozens of small fertilizer plants were also in existence.

The nation can consume far more chemical fertilizers than those produced in that country. Even the Chinese themselves talk about the need for 15 to 20 million tons of phosphatic fertilizers, not to mention other fertilizers. Imports were increased to relieve the shortage—about 1.2 million tons in 1964 and 2.5 million tons in 1965 (two-fifths from Japan and the rest from Western Europe). Imports from Japan are expected to be 50 percent greater in 1966 as compared with those of 1965. A number of European-built fertilizer plants have been contracted for delivery in 1965–66, including a large plant from Humphreys and Glasgow Ltd., of the United Kingdom for Luchow (southwest of Chungking) and another one from the Italian firm, Montecatini, Soc. Generale per l'Industria Mineraria e Chimica.

With pyrite as the main sulfur-bearing raw material used in making sulfuric acid and fertilizer, it was possible to save the elemental sulfur extracted for other vital uses and for export. During 1965, about half of the roughly 250,000 tons of sulfur produced came from pyrite and the other half was derived from 20-percent sulfur ores. In 1964, the Soviet Union imported 25,000 tons of sulfur from China and Poland and Japan 19,000 and 10,500 tons, respectively.

With regard to potassic fertilizer raw material, the progress in exploiting a multibillion-ton carnallite deposit at Charkhan Lake in Tsaidam Basin, Tsinghai, is not known, although extraction was started many years ago.

Fluorspar. — Chinese fluorspar production, which ranks high by world standards, apparently increased somewhat as compared with that of the last few years. Output from Chekiang and North China remained steady, but Kwangsi Province has become a significant new source. Slightly more than half of the fluorspar was exported. During 1964, importing countries gave the following figures, in metric tons: Japan 69,048, U.S.S.R. 30,700, Poland 15,200, and West Germany 3,218. In mid-1965, the Kamisho Company of Tokyo, which specializes in fluorspar, concluded on behalf of the Japanese consumers a long-term contract with the Chinese, whereby China is to supply all that Kamisho needs for an indefinite period beginning in April 1966. Domestically, fluorspar was consumed in the manufacture of steel, aluminum, and ceramics, and in atomic energy.

Magnesite.—Southern Manchurian magnesite found in a belt extending from Tashihch'iao northeast to Lienshankuan continued to be of great world significance. Output of perhaps 1 million tons was on a par with the previous year and the probable peak in 1960. The Anshan Steelworks pioneered the use of magnesia-alumina refractory bricks for iron and steel smelting in China, and the practice has been extended to most other large steel centers. Despite growing domestic demand, small quantities of magnesite and magnesia have been traditionally available for export.

Salt.—Mainland China retained its position as the world's second largest producer of salt, after the United States. The national target was achieved 20 days ahead of schedule and output, substantially more than in 1964, was claimed to be the highest in the last 5 years.[15] Although most salt was consumed for food purposes, industrial demand was rising and it was necessary to stress quality along with increased output. Byproduct recovery made significant headway, in terms of the production of potassium chloride, bromine, boric acid, iodine, and barium chloride, etc.

Operating conditions were particularly good for the four main producing provinces—Kiangsu, Shantung, Hopeh, and Liaoning—which furnished nearly three-fourths of the national output. Last year was an unproductive year for these provinces because of excessive rainfall. In contrast, most salt fields surpassed their production quotas in 1965, including all the fields in Kiangsu, the Chinchow field and the P'itzuwo chemical plant in Liaon-

[15] Jen-min Jih-pao (People's Daily; Peiping). Dec. 25, 1965, p. 1.

ing, the Yangk'o, Shoukuang, and Ts'ai-yangtzu fields in Shantung, and the Hanku, Nanp'u, and Tawop'eng fields in Hopeh.[16]

Many technical changes were made during the year to improve operations, both in the coastal salt fields and in the salt wells and rock salt mines in Southwest China. More dredges, trawlers, cable traction devices, tractors, small cars, and scrapers were used. Strong dikes were built in some salt fields in Liaoning Province where a supply of rocks was easily available. At the Tzuliuching salt wells near the gasfields of Szechuan Province, operations were improved by lengthening the pipe sections, decreasing the pipe diameter, recycling more of the mother liquor, and cutting down on natural gas consumption. In the rock salt mines of Kunming, Yunnan Province, the double-pipe-water-solution method (solution mining) was introduced in place of solid rock mining with great savings in cost.[17]

Increased production of salt stimulated slightly higher exports than in 1964. In 1965, mainland China exported roughly 1 million tons of salt, mainly to Japan. In 1964, Japan imported 697,790 tons of Chinese salt and the Soviet Union 102,000 tons.

Other Nonmetals. — Barite production was maintained at a significant level—about 3 percent of the world total. Despite meeting the growing needs of oil drilling, roughly one-tenth of the barite was exported. Approximately two-fifths of the high-grade steatite talc from Taling, Liaoning, was exported, mainly to the U.S.S.R. and Japan. A surplus of borax continued, although no information was available on the very large boron-bearing lake deposits in the Iksaydam area of Tsaidam, Tsinghai. Erection of a number of new glass plants called for new supplies of high-grade silica. Polished marble slabs became established as a new nonmetal export product.

MINERAL FUELS

Coal.—The Chinese Communists claim that their 1965 coal production target was fulfilled during the first 10 days of December. "Based upon data on the 71 large coal mining enterprises directly under the Ministry of Coal Industry . . . average productivity increased by 14 percent over the previous year, ash content of coals went down significantly, and timber consumption per 10,000 metric tons of coal output decreased by more than 30 cubic meters." [18] By shortening construction time, about 16 "pairs of new coal shafts" were scheduled to be brought into production in 1965;[19] this would mean roughly 10 million tons of additional annual capacity. This information indicates improved performance and slightly higher production.

Of the approximately 300 million tons of coal estimated to have been produced by mainland China in 1965, the bulk was bituminus coal with only about 20 million tons of anthracite. Hydraulic mining may have contributed 20 million to 25 million tons of output. The big seven coal mining centers (Fushun, Fuhsin, Kailan, Huainan, Chihsi, Hokang, and Tatung, roughly in descending order) each produced 10 million to 20 million tons and together some 100 million tons. More than a dozen mines were in the 2- to 9-million-ton range, and many others were in the 1- to 2-million-ton range. The rest of the country's coal output came from numerous small mines with annual capacities from 100,000 to 1 million tons.

The Chinese press gave some general indiction of the production status for certain coal producing areas. Eight large mines of Liaoning Province (includes Fushun and Fuhsin) reportedly achieved their combined 1965 targets 28 days ahead of schedule. The Tatung coal mines in Shansi Province presumably met their quota 25 days ahead of schedule. The Huainan coal mines in Anhwei Province underwent modernization, particularly the Hsieh-chia-chi mine, leading to greater productivity. During the first 11 months of 1965, output of the Pingtingshan mines (supplier of coking coal to the Wuhan Steelworks) in Honan Province was 69 percent higher than during the corresponding period of 1964. The Yangchuan mines in Shansi also topped its 1965 target in early December. Pingtingshan and Yangchuan are 5 to 9 million-ton mines. Many small mines in Szechuan Province were streamlined to raise combined capacity by about 3 million

[16] Jen-min Jih-pao (People's Daily; Peiping). June 15, 1965, p. 1.
[17] Ta-kung-pao (Peiping). June 25, 1965, p. 2; Dec. 11, 1965, p. 1.
[18] Ta-kung-pao (Peiping). Dec. 23, 1965, p. 1.
[19] Jen-min Jih-pao (People's Daily; Peiping). June 16, 1965, p. 1.

tons or about half of existing annual capacity.

Various specific developments were reported. The Fushun mines underwent substantial mechanization in the underground part of its operations, with the installation of centrally controlled belt conveyors and a hydraulic transport system to bring coal up from a 600-meter depth. The Ch'inghomen vertical shafts of the Fuhsin mines, rated at 600,000 tons of coal yearly, were brought into production. The Meiyukou pit of the Tatung mines was further mechanized, with "cutter loader" breaking and loading the coal on to conveyor belts. The 900,000-ton Shuiku coking coal mine of Fenhsiao in Shansi, the 600,000-ton Wanhouyao mine in Huaipei area of Anhwei, and the ½-million-ton plus Hungyuan mine in Szechuan were placed in operation near yearend. The 450,000-ton Peit'outsui vertical shafts of the Yangchuan mines became operative, along with similar capacity vertical shafts at the Tunghua mines, Kirin. The Shihch'echieh mines of Shansi, in attaining a per capita daily output of 2.456 metric tons, was said to have achieved the highest productivity in the country. The Chinshi mines, China's most famous anthracite producer, set a national record of 351 meters per month in tunnelling, and its drilling crews were sent to many other mines for demonstrations. The Shuangyashan mines in Heilungkiang Province have been using concrete supports to a great extent. The Chiaotso anthracite mine in Honan was finally dewatered.

Much was accomplished in improving coal quality and extraction indices. Large coal beneficiation capacities have been developed in recent years and most coal bases, particularly the new shafts and pits, have such facilities. There was considerable emphasis on washing and blending of coking coals to meet the needs of the steel industry; local weakly and noncaking coals near the steel centers were used as much as possible. A great drive was in progress to conserve quality coal for the most appropriate uses and to achieve economies in the consumption of coal. These efforts resulted in improved efficiency rather than overall shortage. The domestic supply of coking coal remained adequate, but in addition the Chinese have been shipping increasing quantities of coking coal and anthracite to Japan. In the first 10 months of 1965, the Japanese received about 450,000 tons of Chinese coal from mines like Chunghsing and Fengfeng. Production figures indicated that the country's coal exports were still negligible.

Petroleum.—The Chinese Communists claimed that mainland China's 1965 crude oil target was achieved 47 days ahead of schedule and that goals for production of kerosine, gasoline, diesel fuel, and lubricants were fulfilled by November 4.[20] A conservative estimate of crude oil output for 1965 would be 10 million tons, possibly 1 million tons more than refinery output.

Additional production altered the overall supply position, as the country truly became virtually self-sufficient in oil. Imports, primarily consisting of refined products from the Soviet Union, were much smaller than a few years ago; the amount brought in from the U.S.S.R. dropped to nominal levels as compared with 504,900 tons in 1964. Rumania and Albania apparently no longer furnishing China with much oil. However, Chinese offers to sell crude oil to Japan appeared to materialize, and there was talk about extending a pipeline from Manchuria to North Korea. More oil was distributed to the civilian economy, and the price of gasoline was cut 18.6 percent.[21]

The main factor which improved the oil supply was the continuing success of the Tach'ing field around Saert'u just northwest of Anta, which in turn is north of the Harbin-Tsitsihar railroad in Manchuria. Much specific information was reported on this field, and Tach'ing was often mentioned in the press as the example to emulate by other industries. Discovered in 1959, Tach'ing started large-scale production in 1963 and steadily expanded output of crude oil to probably more than 3.5 million tons annually. A large oil refinery has been built locally,[22] but its capacity was not large enough to handle crude output. Surplus crude oil was being shipped out in a special pipeline, heated to prevent the high-paraffin crude from solidifying. The Chinchou subfield is said to be in the same district.

Many articles described the technical

[20] Ta-kung-pao (Peiping). Dec. 23, 1965, p. 1.
[21] Petroleum Press Service (London). V. 32, No. 4, Apr. 1965, p. 155.
[22] Ta-kunk-pao (Peiping). Jan. 1, 1966, p. 3.

achievements of Tach'ing.[23] Drilling techniques have attained efficient levels, with good straight holes drilled in record speed, very high recovery of cores, and successful wells to a depth of more than 4,500 meters. Steel casings for deep holes are being partly made by Chinese plants. After 1.7 million analyses and "20,000 kilometers of curves on graphs," the early simultaneous (multiformation) water injection method was adopted, which reportedly had paid off in steady and very high-level production since the beginning of operations. A new and smaller "Christmas tree" assembly was introduced to solve the valve problem. Three separate oil refining units were installed. Tach'ing with about 40,000 workers had become the training base for supply technicians to other fields.

The Karamai complex (oilfield and refinery at Karamai and another refinery at Tushantzu) may have reached a stabilized annual production level of 1.5 million to 2 million tons. More than a dozen projects were completed, including the new Karamai refinery,[24] which was undoubtedly responsible for large increases claimed in the production of petroleum products.

The Yumen oilfield has long been stabilized at the 1.5-million- to 2-million-ton annual level. Surplus crude went to the Lanchow refinery in the same province. Six new installations were placed in operation in 1965, mainly to improve quality and diversification of products; among these installations was one to upgrade lubricants and another to convert or liquefy waste refinery gases into gasoline.[25] Most equipment was made in the machinery plant attached to the Lanchow refinery. Lanchow has produced increasing quantities of ammonium fertilizers (mainly urea).

The Shanghai refinery's thermal cracking plant was producing at higher rates after having been enlarged. Shanghai has become an important center for producing oil-refining and drilling equipment. The Szechuan gasfields and the smaller oilfields were presumably operating at the previous year's levels, with better distribution of products. There was hardly any news of Tsaidam, which was considered a major field a few years ago.

The Fushun shale oil center in Manchuria, with 7,000 workers, produced about 2 million tons of refined oil—roughly the same amount as in 1964. Modernization of the No. 1 Refinery resulted in much more efficient operations. There was no news on the Maoming shale oil center in Kwangtung, reportedly completed a few years ago and probably rated at more than 1 million-ton annual capacity.

Much drilling equipment as well as many rail, truck, and river and coastal tankers were produced, but more significant was the large amount and variety of refinery equipment made. Mainland China was able to make most of the simpler types of equipment needed in the oil industry. But need for imported refinery equipment persisted. The West German firm, Lurgi Gesellschaft, was supposed to have delivered a $12.5 million oil-cracking and olefin separation plant. Orders were also placed with the Italian firm, Sham-Projetti (subsidiary of ENI or Ente Nazionale Idrocarburi), for a $9 million refinery to be installed in 1966; a report late in 1965 states that the equipment had arrived and Italian experts were supervising construction of this 100,000-ton catalytic reforming plant somewhere in Manchuria.[26]

The Mineral Industry of Indonesia

By J. M. West [1]

Crude petroleum, providing four-fifths of Indonesia's mineral income and accounting for about 2 percent of the world production, was a relatively strong factor in the nation's precarious economy in 1965. Production rose during the year and several significant discoveries were made as explorations continued. While P. T. Stanvac Indonesia and Caltex Pacific Oil Co., the two U.S. oil companies with major operations, remained in business, the facilities and property of the British/Dutch-owned P. T. Shell Indonesia were sold to the Government at yearend. Output of tin, also an important foreign exchange earner, declined in tonnage and accounted for approximately 7 percent of the world total in 1965, placing Indonesia behind Thailand and down to sixth in world rank. Muntok's new tin smelter was still idle in December, although test runs had been made a year earlier, and concentrates continued to be sent to the Netherlands for smelting. Besides oil, bauxite and nickel ore appeared to be he only minerals to gain in output, bolstered largely by Japanese demand. Total value of mineral production was somewhat less than that of 1964. Indonesian copper potential was of increasing interest.

Indonesia terminated membership in the United Nations on January 20 and in the Economic Commission for Asia and the Far East (ECAFE) on March 31. Money exchange became more complicated, and following an attempted coup at the end of September, living costs rose steeply. On December 9 the open exchange rate was US$1.00 equals 30,000 rupiahs, and the tourist rate was pegged at US$1.00 equals 5,250 rupiahs. Currency revaluation in December resulted in exchange of 1 new rupiah for each 1,000 old ones at a 10-percent discount.

Despite all of the problems, foreign aid continued to be received in the mineral field, such as tin mining equipment from the Netherlands, West Germany, and United Kingdom; assistance with coal mining, and cement, iron and steel, and fertilizer plants from Communist countries; and with development in oil, bauxite, and nickel by Japan. First deliveries were due on 250 West German trucks, some probably for mine use, and three West German 14,000-kilowatt gas-turbine powerplants were on order at yearend. The Export-Import Bank-financed Surabaya steam powerplant was commissioned, and construction began on a Japanese 150,000-kilowatt thermal powerplant at Tanjoengpriok, near Djakarta. The French-engineered Djatiluhur hydroelectric project, in West Java, was progressing. Five powerplants having a combined potential for 1.2 million kilowatts were included in plans being prepared by Soviet experts for the Asahan River hydroelectric project in North Sumatra. Probably the first of these will be the 320,000-kilowatt Siguragura plant to supply power both for a planned aluminum plant at Mabar and for the city of Medan.

Typifying the Government attitude, at least to the time of the attempted coup, was President Sukarno's August 17 announcement on the occasion of the nation's twentieth anniversary that Indonesia has the full right to nationalize or even to confiscate any foreign capital which is antagonistic to Indonesian policies. This followed the July 13 repeal of the Indonesian law on foreign investment (enacted in 1958) which had offered a degree of protection but never was applied. The Gov-

[1] Far East specialist, Division of International Activities.

ernment had been following a generally unsuccessful production-sharing concept in foreign investment since 1962, whereby a foreign enterprise would advance equipment, technical knowledge, and advisory personnel to an Indonesian partner for a mining, industrial, or other project, with repayment in the form of a specified percentage of production. However, it became evident that regulations were too inflexible, so in January changes were made. These changes included the following:

Credit could be repaid out of other export commodities without waiting for an enterprise to begin production, a foreign firm may exercise its own control for a specified time, duties and taxes will be exempted on commodities imported for project construction, and the Bank of Indonesia will relax somewhat its guarantee conditions.

Compensation for nationalized private property remained a question. The Minister of Mines was busy revamping an 8-year plan that had been found too optimistic; worker's welfare projects were among intended improvements. On March 31 the Department of Basic Industry and Mining was split into three departments, with Chairul Saleh remaining as Minister of Oil and Natural Gas, as Minister and Coordinator for Development, and as Third Deputy Prime Minister. New ministers were named for Basic Industry and for Mining, and the President of the Government's Permina Oil Co., Brigadier General Ibnu Sutowa, was named Minister of Oil and Gas Affairs attached to the Presidium. Government supervisory teams were active in private oil company affairs. Transportation was a weak point in the economy. The Government particularly felt the need to improve deteriorating rail equipment and shipping. The Government boosted prices on gasoline and other oil products to somewhere near production costs after a period of almost giveaway sales.

PRODUCTION

Indonesia's Central Bureau of Statistics suspended publication of statistical reports on September 22; thus most of the production data herein for 1965 have been estimated. Crude oil, the main export product, gained, with output approximately 5 percent higher in 1965. Tin production dropped, after having risen in 1964; the output was estimated at only 14,698 long tons of tin-in-concentrates, but was expected to respond to operations of one or more new dredges and renovations due to be completed in 1966. Bangka Island continued to be the leading source of tin. A small amount of tin was refined, but the new smelter at Muntok apparently was not yet operational. Bauxite and nickel mining were bright spots because of Japanese endeavors. Production of coal and most other commodities was lower.

TRADE

Mineral exports continued to be a major source of foreign exchange, with Japan the chief destination except for tin concentrates. These went to the Netherlands, since access to Penang refineries was cut off by the so-called confrontation with Malaysia, and new domestic refining had not started. Netherlands imports for the first 10 months totaled about 13,500 long tons of tin-in-concentrates, with 2,500 tons in October alone. Shipments in 1964 totaled 19,300 long tons. During 1964 the Netherlands had also imported 1,212,000 metric tons of refined Indonesian oil products, largely residual fuel oil. Exports of metals and equipment to Indonesia from Japan, West Germany, and the Netherlands were generally increasing, while U.S. trade declined. Over $24 million in iron and steel was supplied to Indonesia from all sources in 1964, and sulfur totaling an estimated 7,500 tons was shipped from the United States and Canada. U.S. lubricating oils valued at $2.3 million were shipped to Indonesia in the first 9 months of the year. This compared with lubricants valued at $6.3 million shipped by various countries to Indonesia in 1964, of which over half was from the United States. Trade representatives wanted to purchase cement and sheet glass from South Korea. Complexities of Indonesian trade were dis-

[1] Officially reported Indonesian statistics representing government output; private production by small unorganized producers may be as much as 30,000 troy ounces per year.

[2] Breakdown reported for 1961, in thousand barrels, as follows: Gasoline 18,215, kerosine 14,766, distillate fuel oil 18,883, residual fuel oil 26,168, and other 1,810.

cussed.[2] Although past records of payment were generally good, longer payment terms were wanted; because of increasing financial weakness, foreign suppliers became more cautious.

Provisional data available for 1964 showed $271 million of $744 million in total exports (excluding West Irian) brought in by petroleum, the highest since 1961. Tin, with a gross value of $29 million in 1964, was the third ranking export product after oil and rubber and was just ahead of coffee and palm oil. West Irian exports of all goods totaled $43 million in 1964, 40 percent of which was attributed to petroleum. The lack of data on oil necessitates omission of the export table for crude petroleum and refinery products shown in the 1964 edition of the Minerals Yearbook.

COMMODITY REVIEW

METALS

Aluminum (Bauxite).—Bintan Island bauxite production expanded to a rate of about 60,000 tons monthly, virtually all going to Japan and supplying about one-third of Japanese requirements.

Copper.—Reports indicated that copper mining might be resumed in 1966 in the Sankoropi area of South Sulawesi (Celebes) a a result of Yugoslavian surveys. Interest in a major West Irian copper discovery of a few years ago revived, and a possible

$60 million development was under discussion.

Gold and Silver.—It was announced late in the year that gold and silver mines, including the principal producer of record, the Tjikotok, in West Java, would be nationalized, with operations closely regulated henceforth. One source speculated that five times the officially reported gold may have been produced secretly. The Government joined in investigating a 1964 discovery of gold at Lagos, in the Riau Island group. Rehabilitation of idle mines at Lalos, Tutut, and Leban Tandai in South Sumatra and at Tjikondang in West Java was part of an 8-year Government program initiated in 1963, but no renewed mining was reported in this connection.

Iron and Steel.—Construction on the Soviet-assisted Tjilegon iron and steel project, due for completion in 1967 with 100,000 tons annual capacity, made virtually no advance and remained only about one-fourth complete at yearend. A West German blast furnace unit arrived for installation at Lamping, Sumatra.

Manganese.—Operations were virtually all at one small mine in Java.

Nickel.—Nickel ore output and exports, all to Japan, rose sharply in 1965, because of stimulation by a production-sharing contract with the Japanese Sulawesi Nickel Development Co., signed with Indonesian Nickel Mining Corp., which provided a 7-year credit for mining equipment and expertise. By August the newly expanding Pomalaa mine, in southeast Sulawesi, was producing about 12,000 tons of ore monthly, while the older Mantang Island mine was approaching half that rate. The Japanese developer was reported considering plans to build a $22 million 32,000-ton-per-year ferronickel smelter in Sulawesi, based on extensive Indonesian reserves, which have been estimated at 40 million tons containing 1.5 to 2.3 percent nickel with 0.005 percent cobalt. Ores are lateritic, containing 25 to 48 percent iron and a little chromium. Deposits in the Malili district of Sulawesi were under study.

Tin.—Although reports were incomplete, tin output apparently fell to less than 15,000 long tons of tin-in-concentrates, owing partly to labor problems and to setbacks in rebuilding mine and dredge equipment. Production in the first 11 months totaled 13,573 long tons compared with 14,869 tons in the same period of 1964, with Bangka Island the source of three-fifths of production, Billiton one-fourth, and Singkep supplying the rest. Hopes for doubling production in a few years seemed far from realization, although tin resources were more than adequate. One report estimated 610,000 tons of tin-in-concentrates of good grade remained, without considering potentials of unexplored and offshore areas.

Bangka No. 1, one of the largest tin dredges designed for offshore service and capable of operating to depths of 131 feet with 420,000 cubic yards monthly capacity, was launched in the United Kingdom and was scheduled at yearend to move to Indonesian waters. West German sources were due to supply by April 1966 10 small dredges, including suction-cutter and grab types, having a total capacity of about 2,000 tons of concentrates yearly; Netherlands' firms negotiated a contract to overhaul and modernize a number of tin dredges and to rebuild the central electric power station at Mantung. Work on the first two dredges was to start in 1966. Negotiations also went ahead with Netherlands interests for rehabilitating 70 open

tin mines and with a West German firm to rehabilitate the Kelapa Kampit underground mine on Belitung, once producing 2,000 tons yearly. Eight dredges operated in offshore waters in 1965, and the arrival of Bangka No. 1 will add one more. A French concern was also approached for help in an offshore tin-dredging project. A similar project to have been conducted under the United Nations Special Fund was shelved earlier by Indonesia's withdrawal from the United Nations.

The Muntok tin smelter, designed for production of 25,000 tons of tin metal annually, was reported to have run successful tests in late 1964; however, it was not expected to start up commercially until 1966 because of uncompleted portions. Tin concentrates continued in the interim to go to the Netherlands for smelting.

NONMETALS

Asphalt.—Although badly needed for road construction and repair, supplies of asphalt rock, mined on the remote island of Butung, south of Sulawesi, were lower because of transportation difficulties.

Cement.—Shortages of cement delayed completion of industrial plants and slowed the completion of hydroelectric construction and repairs to deteriorating highways. The partially completed $6.5 million Tonasa cement project, near Macassar, being built with Czechoslovak assistance, was seriously damaged by two successive fires in September, and production, planned to start in 1966 or 1967, was further delayed. Meanwhile, output of the important Gresik cement plant dropped because of poor machinery maintenance and labor troubles. Limited supplies of better quality limestone were being depleted unnecessarily at the Gresik quarry. Production was estimated to have reached only about 220,000 tons in the first 10½ months of 1965 compared with a projected annual production of 325,000 tons. The Indarung cement plant, also Government-owned, continued to operate at Padang. Govemment projects received priority for available outputs, while others relied on an allocation system of cement imports, which came from Japan and mainland China. The latter was reported to have offered to help in building several small cement plants.

Diamond.—The Netherlands firm, Asscher Diamond Company, Ltd., signed an agreement with the Indonesian Government to exploit the Kalimantan diamond fields, where gem quality stone has been produced in the past. Diamond smuggling was expected to be reduced by stricter security measures under the new arrangement. Yearly output in the millions of dollars was predicted.

Fertilizer Materials.—Output of the Government's 100,000-ton urea plant (new in 1963) in Palembang, Sumatra, declined an estimated one-fifth in 1965 as foreign operating personnel were replaced by less-experienced workers, and warehouses were filled because of transportation shortages. Production costs remained relatively low, and officials were considering export possibilities to help with foreign exchange, even though domestic demand for fertilizer was quite strong as indicated by the black market. Nothing was reported on the country's other fertilizer plant, privately owned by M. V. Tjirebon Phosphate and General Industrial Co., at Tjirebon, Java, and operation may have ceased. A Government purchasing agent signed a contract in March to buy 10,000 tons of ammonium sulfate and phosphate mixed fertilizer from Japan at $87.47 per ton, f.o.b. West Germany was another source of sulfate fertilizers. Two major projects were under discussion: Japanese doubling of the Palembang plant's capacity and a new Italian-backed 100,000-ton urea plant that would use bunker oil for methane and be situated near Surabaya.

MINERAL FUELS

Coal.—East German technicians conducted a survey of the Bukit Asam coal mines in South Sumatra, Indonesia's largest, but at midyear had not yet decided on what kind of assistance would be forthcoming. A Hungarian group discussed designs for a carbon electrode plant to be supplied by that country. Coal production continued to decline and could hardly meet two-thirds of the 35,000 tons of coal needed monthly by railroads to maintain schedules. Railways in the latter half of the year expected both coal supply and operating rates to drop to about half of normal.

Petroleum.—Crude oil production and exports continued to rise, but increased do-

mestic consumption of refined products left smaller quantities of such products for export. Crude oil outputs during the first 9 months of 1965 were as follows for private companies, in thousand 42-gallon barrels: Caltex Pacific Oil Co., 88,027; P. T. Stanvac Indonesia, 15,291; and P. T. Shell Indonesia, 18,906. Government companies, Pertamin, Permina, and Permigan, together produced an estimated 10.9 million barrels in the same period. Compared with 1964 production, output by P. T. Shell Indonesia was falling behind, while the others were ahead. P. T. Shell Indonesia operated two refineries, one with a 110,000-barrel-per-day capacity at Pladju, near Palembang, Sumatra, and the other, a 75,000-barrel-per-day unit at Balikpapan, Borneo. The South Sumatra field produced nearly two-thirds of Shell's crude oil and the rest, except for a small quantity from Java, came from Borneo. P. T. Stanvac Indonesia operated its 72,000 barrel-per-day refinery at Sungai Gerong, also near Palembang, and produced crude oil in approximately equal amounts from the South and Central Sumatran fields. About four-fifths of Caltex Pacific Oil Co. crude oil came from Minas, and the remainder came from its Duri fields. Crude oil was produced by Pertamin in South Sumatra and Kalimantan, by Permina in North Sumatra, and by Permigan in Java. In addition, Permina operated a small refinery in North Sumatra and Permigan operated one in Tjepu, Java.

Exports of crude oil continued, chiefly to Japan and Australia. The 1964 domestic consumption of refined products, based on refinery shipments, was estimated at 32.8 million barrels, including the following, in million barrels: Aviation gasoline, 0.2; motor gasoline, 8.97; turbine fuel, 0.4; kerosine, 10.3; automotive diesel, 7.58; industrial diesel, 1.03; and fuel oil 4.32. Lubricants, based on imported stock, were coming into short supply. Several blending plants remained active, and Permina's new lubricating oil plant at Pangkalan Brandau operated at about two-thirds of eventual capacity of 36,000 barrels annually. Sharply higher gasoline and oil prices accompanied a reverse in government policy to sell at a loss on these items.

At least three new oilfields have been outlined by Caltex at Bekasop, Pematang, and Petani, all east of the major field at Duri, Central Sumatra. Minas and Duri crude oil continued to flow from these fields via a 30-inch pipeline to the port at Dumai, and branches were under construction to Bekasop and Pematang. Shell had success with several wildcat drill holes at Warukin, near Tandjung in Kalimantan, and at Belimbing, near Pladju in South Sumatra. The Asamara Oil Co. (Canadian) strike in North Sumatra, in Atjeh, north of Medan, yielded 52-degree gravity oil, and flows from three wells were capped pending completion of a pipeline to the coast. Pan American Oil Co. (United States), on its 10th dry hole, was not so fortunate. Pertamin made its first strike, flowing 500-barrels-per-day, northwest of Palembang. Northern Sumatran Petroleum Development Co. (Japan) purchased the offshore concession of Refining Associates, Inc. (United States) in Sumatra and and planned a $14 million expenditure in the next few years. The Japanese company agreed to take just 40 percent of any output in repayment and profits. In West Irian, Serang Oil Co., under Permina control, continued producing a few hundred tons of crude oil daily for export, while Dutch New Guinea Oil Co. closed down because of depletion. Japan Petroleum Exploration Co. discussed possibilities of exploring for oil on West Irian's offshore islands.

Shell signed a contract on December 30 to sell its Indonesian assets to the Government of Indonesia, including two refineries and its oilfields, for $110 million paid over 5 years, with 90 percent probably to be taken in the form of products. Final agreements were being worked out. U.S.-owned P. T. Stanvac Indonesia and Caltex Pacific Oil Co. maintained operations under the shadow of nationalization.

The Mineral Industry of Japan

By Benjamin H. Lim [1] and J. M. West [2]

Japan's mineral industry retained its approximate sixth place in the world with an estimated mineral and metal output value (mine output value plus added value derived from smelting and processing) on the order of $5,100 million, slightly higher than in 1964. These impressive values were achieved mostly as the result of accelerated expansion of Japan's mineral industry during the last 5 years. While the country's domestic mineral resource base was only of moderate significance in 1965, its metallurgical and petroleum refining industries had become very large and diversified to meet the demands of the Japanese industrial-manufacturing economy.

Japan's mineral industry in 1965, however, did not enjoy the brisk business activity of the last several years, a time of unprecedented economic growth. The tight money policy initiated by the Government near the end of 1963 to stop erosion of the nation's international payment credits was felt by the economy throughout 1965 with serious repercussions on the nation's basic industries.

After a record expansion rate throughout 1964, some 10 percent above the 1963 pace, the 1965 growth rate in the mineral industry, for the most part, became almost static, and there were bankruptcies among small, less efficient, and financially weak mining and mineral fabricating firms. Petroleum and chemical processing, both restrained, nonetheless went counter to the general trend in the mineral industry and maintained high rates of expansion.

The influence of the tight money policy and the attendant economic slump on the nation's mineral-based industries, except for petroleum, was reflected in lowered production indexes:

Industry	Production index (1960=100)			Index change (points)	
	1963	1964	1965	1963–64	1964–65
Mining	107.7	107.9	106.1	+0.2	−1.8
Manufacturing	143.7	169.1	175.7	+25.4	+6.6
Chemical	152.7	178.9	201.9	+26.2	+23.0
Petroleum and coal products	159.8	184.5	209.7	+24.7	+25.2
Ceramics	136.0	155.6	159.6	+19.6	+4.0
Iron and steel	140.4	172.8	177.7	+32.4	+4.9
Nonferrous metals	132.9	161.9	161.2	+29.0	

Source: Japanese Economic Statistics. Economic Planning Agency, Japanese Government, Tokyo, Japan. Bull. 92, May 1966, p. 8.

However, a continued feeling of optimism as to future business conditions was shown by growth indexes of production capacity:

Industry	Capacity index (1960=100)		Index change (points)
	1964	1965	1964–65
Steel	181.2	199.0	+17.8
Nonferrous metals	165.7	182.1	+16.4
Overall mining and manufacturing	168.6	183.8	+15.2

The increased level of nonferrous metal capacity was to a significant extent the result of greater activity on the part of copper smelting firms stemming from the general world copper shortage; an 8 percent increase in smelter copper output to 366,000 tons was recorded, as well as an increase in the copper price to nearly $2,300 per ton by yearend, about 60 percent above the yearend 1964 level. Despite the price increase, Japanese copper

smelters claimed that little profit was earned in 1965.

Japan's steel industry, with a phenomenal expansion rate in the recent past, expanded without abatement in 1965. The industry's rapid growth, however, has been attended by development of economic imbalances such as inadequate internal fund accumulation by many enterprises and by delays in modernization. Structural changes in the expanding steel industry either were not matched with corrective measures or were matched at too late a date, and these imbalances became more apparent as the tight money policy took firmer hold on the economy. Inventories mounted, particularly those of semimanufactures such as hot- and cold-rolled steel, despite a rigidly enforced 10-percent cutback in crude steel output in September 1965. The supply surplus, resulting from both overproduction and greatly diminished domestic demand, weakened the market. Producers then attempted downward price adjustments to bring supply and demand functions to a closer approximation, but the lower prices aggravated already taut financial circumstances of many firms in the industry. As the recession deepened toward the end of 1965, heavy debt burdens coupled with dwindling domestic sales and inaccessibility to more credit forced some less efficient, less affluent, and small-scale steel manufacturers into bankruptcies or mergers.

The strikingly high rate of iron and steel export in 1965 (9.7 million tons, or nearly one-half more than in 1964) may turn out to be only a temporary windfall to the Japanese steel producers. The high 1965 outflow was chiefly due to unusually large purchases by U.S. importers as a hedge against the possibility of a prolonged strike by U.S. steelworkers. It was also a result of aggressive efforts by Japanese exporters to locate overseas markets in the face of diminished domestic demand.

The coal industry's plight worsened in 1965. The industry was caught between expanding consumption of petroleum and its own rising operation costs. It appears the 1964 policy of scrapping inefficient mines and building efficient ones gave a small measure of success; financial returns of some companies showed small profits in 1965 after many years of heavy losses.

To alleviate problems of the country's mining industry, the Japanese Government in 1965 instituted a variety of programs directed toward assisting domestic mining in the form of loans and subsidies, favorable taxation, protective tariffs, special measures for small and marginal mines, technical cooperation, management consulting services, and surveys by the Government's geological branch. For example, from April 1, 1965, Japanese mining companies were allowed a special tax privilege in that the companies were entitled to tax exemption for 15 percent of their ore sales. The tax-exempt portion of the ore sales was to be used by the firms for prospecting and developing new mines.

The Resources Research Institute, under the Ministry of International Trade and Industry (MITI), conducted studies on a number of mineral problems, stressing coal and fuel. Fields of activities included hydraulic mining, underground gasification, large-diameter boring, transport of coal slurry, oil refining, fuel utilization, mine safety, and industrial pollution control.

As for the overall economy, excessive expansion of industry in the past 5 years and business recession in 1965 led the Government to take special measures to aid recovery. In the fiscal 1966 budget, the Government stressed programs of economic recovery and social development, with special attention given to public works, home construction, and disaster relief. Plans featured home construction, reduction of rates charged by financial institutions on loans to medium and small enterprises, expanded funds for highway construction, increased shipbuilding, and government underwriting of local public bonds.

Inflation and rising wages were serious problems in 1965. An Economic Planning Agency report stated that Japan's rate of consumer price increases in the 10 years ending in 1965 was four times that of the United States and twice that of the United Kingdom and West Germany. Rising labor costs induced further investment in plant and machinery despite conditions of overcapacity. To counter the recession, cartel agreements were encouraged by the Government with the object to limit output on an industrywide basis, thus distributing individual company business losses more evenly. The Fair Trade Commission in late January 1965 approved such a cartel by nine special steel manufacturers and an agreement to cut back production followed.

Among industries designated by The Ministry of International Trade and Industry (MITI) early in 1965 as suffering from overcapacity and in need of corrective measures were steel, special steel, cement, and oil refining. These became subject to government approval of financing plans on an industrywide basis rather than on an individual company basis. Although the Government in 1965 approved a number of major investments in Japan by foreign corporations and a rising number of technological assistance contracts, the latter largely in the field of chemicals, there was mounting criticism of restrictive investment policies. The value of foreign investments approved in fiscal 1965 (ending March 1966) dipped to $528.5 million compared with $912.8 million in fiscal 1964. A large proportion of the fiscal 1965 total went into mineral processing industries such as oil.

Rationalization and modernization of metallurgical and refining facilities processing indigenous and imported materials continued. Government efforts to support and modernize the coal industry were only partially successful in limiting further deterioration, and new measures were called for, specifically, increased coal prices, subsidies to deficit-laden companies, and increased compensation for hazardous mining conditions.

A program was underway in 1965 to stimulate foreign investments, including participation in mineral exploitation, particularly in North and South America, Australia, and central Africa. Measures being considered to promote external investments included a system to prevent double taxation and to allow tax deductions on interests and profits, greater investment backing by the Japanese Export-Import Bank, an increase in maximum insurance on investment from 50 to 90 percent, establishment of an Overseas Investment Center within Japan's Asian Economic Research Institute increasing investment services to businessmen, and a new organization for special assistance to medium and small enterprises interested in investing abroad.

Japan's quasi-Government Overseas Mineral Resources Development Co., Ltd., with 50 percent private industry participation by some 13 principal nonferrous metal mining companies, expanded its activities in exploration and development of raw material sources abroad. Surveys and negotiations were in progress in west coast South American countries for copper, lead, and zinc properties, and in Africa on manganese deposits in Upper Volta and various minerals in southern Katanga in the Republic of the Congo (Léopoldville). Iron and steel was the subject of other development in Brazil. Japan continued assistance to Indonesia in development of Sumatran oil resources. Normalization of relations with South Korea brought Japanese assistance in the form of industrial loans and the prospect of greater participation in the South Korean mineral industry. The Japan Resources Survey Council planned in 1965 to send a mission to Australia to conduct studies of iron ore, bauxite, lead, zinc, and copper ores to encourage Japanese investment and trade. Japanese contacts with mainland China and the U.S.S.R. increased along with expanding mineral trade with those countries. In regard to trading with mainland China a government advisory agency recommended that a single export channel be established to handle all agreements on trade and payments. There were overtures from the U.S.S.R. for Japan to assist in developing natural gas in the Soviet Sakhalin area, an oil pipeline across eastern Siberia, and copper mining in the Lake Baikal region. Japan would supply equipment and technical skills in exchange for mineral raw materials.

PRODUCTION

In 1965, Japan retained third position behind the United States and the Soviet Union among world steel producers, having overtaken West Germany by a small margin in 1964. Among Free World producers, Japan ranked fifth in aluminum production, second in titanium, first in pyrite and pyrophyllite, and fourth in cement. In mineral fuels, Japan ranked third among world crude petroleum refiners although the country produced only a very minute amount of crude oil.

Value of Japan's mineral industry output in 1965 of approximately $5,100 million was equivalent to about 6.0 percent of the country's gross national product (GNP) of $83,901 million (in current dollars) in 1965 compared with about 6.5 percent of

the GNP of $76,899 million in 1964. Although the GNP of these 2 years in current dollars indicated an approximate 9-percent expansion, the real growth rate for 1965 was reportedly only about 3 percent after using the appropriate deflater.

While Japan's mineral processing industries, notably its iron and steel and nonferrous metal smelting industries, expanded rapidly in the last few years, the domestic metal mining industry has remained somewhat static. Mine output of most metals in 1965 was on a par with or slightly above 1964 levels. Nonmetallic mine output in 1965 showed a slight overall decline when compared with the 1964 output. Significant decreases were noted for clay (kaolin), dolomite, gypsum, and sulfur. Increases took place in feldspar (aplite), quicklime, and limestone.

The value (at factor costs) of the 1965 indigenous crude mineral output alone was reported at approximately $714 million compared with $653 million in 1964. The value of these crude minerals to the end users was estimated to total $1,400 million in 1965 and $1,200 million in 1964. Two categories of minerals, primary metal ores (other than iron) and coal, accounted for nearly three-fourths of the total value of 1965 output. Value added to crude domestic minerals via transportation and processing amounted to about $800 million in 1965 and about $600 million in 1964. Thus, approximately 55 to 60 percent of the total value of mineral industry output during 1965 was derived from transporting and processing imported raw materials. Of the total derived from imported raw materials, iron and steel accounted for about 40 percent; nonferrous metals, chiefly aluminum, copper, and zinc, for 8 percent; and that from petroleum refining for 10 percent.

A significant event in Japan's mining industry during 1965 was the start of construction of production facilities to exploit major deposits of so-called "black ores" developed in the last few years in northeast Japan. These ores are now known to contain rich amounts of copper, gold, lead, silver, and zinc, economically recoverable by modern smelting processes. During the year, Dowa Mining Co. and at least three other large mining firms have completed development plans for the area. Reserves of black ore reportedly totaled 60 million tons valued at approximately $3,000 million.[3]

Despite the intensity with which Japanese companies have attempted to locate indigenous ores, the domestic mineral resource base is inadequate to support the country's mineral processing and consuming industries. For this reason and the relatively lower costs of imported raw materials, the nation's industry continued to participate in developing foreign mineral deposits despite the slower economic pace and added financial strains during 1965. Japanese ore smelters were extremely active in negotiating long-term contracts to procure foreign mineral supplies; for example, Japan's iron and steel industry had investments totaling more than $5,040 million by yearend 1965 for prospecting and developing foreign iron ore deposits. Similarly, Japanese nonferrous metal smelters at yearend 1965 had investments in overseas mines amounting to more than $8,400 million.

TRADE

The value of total Japanese trade in mineral commodities (except gold) increased by about $742 million in 1965 over that of 1964, reaching a new high of $4,966 million, while total Japanese merchandise trade increased by $2,010 million to $16,622 million. These increases occurred despite the much lower economic growth rate in 1965; that is, 3.9 percent compared with 17.8 percent in 1964. Comparative data on mineral commodity trade and total merchandise trade for recent years follow:

	Value (million dollars)		Mineral commodities share of total (percent)
	Mineral commodities	All commodities

Japan's chief mineral export was iron and steel, chiefly semimanufactures, that accounted for 78 percent of the total mineral exports in 1964 and 77 percent in 1965 (scrap excluded). In this category, the United States was, by far, Japan's best customer. In 1964 and 1965, the United States bought respectively $307 million and $513 million of these commodities. These levels of purchases represented 34 and 40 percent respectively of the total value of iron and steel products exported during 1964 and 1965. In the category of nonferrous metal ores, metals and semimanufactures (except gold), the United States also led all other countries by taking 34 percent ($20 mil-

Table 2.—Japan: Exports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal destinations, 1965
Metals:				
Aluminum:				
Bauxite	400	600	800	Taiwan 400.
Alumina	102,100	104,268	95,038	United States 70,169; Australia 22,734.
Aluminum hydroxide	3,635	NA	7,104	NA.
Metal and alloys:				
Scrap	-------	-------	154	India 102.
Unwrought	r 14,112	r 19,173	29,168	United States 24,257; Argentina 1,864.
Semimanufactures	r 18,227	17,187	25,221	United States 9,160.
Bismuth and alloys, all forms	162	249	197	United Kingdom 146.
Cadmium and alloys, all forms	194	351	716	United Kingdom 432; United States 118; Netherlands 97.
Chromium:				
Ore and concentrate	-------	-------	1,537	North Korea 1,437.
Oxides and hydroxides	-------	-------	532	South Korea 147; Taiwan 142; Australia 58; United States 58.
Cobalt oxides and hydroxides	-------	-------	21	West Germany 20.
Copper:				
Ore concentrate and matte	-------	255	-------	
Metal and alloys:				
Scrap	-------	-------	6,169	Netherlands 1,906; West Germany 885; Italy 745; Sweden 676.
Unwrought	1,481	1,621	2,681	Taiwan 1,571.
Semimanufactures	r 18,315	26,652	50,440	United States 15,112; Hong Kong 7,307.
Iron and steel:				
Ore and concentrate (mainly roasted pyrite).	-------	-------	11,013	All to Taiwan.
Scrap	1,785	4,307	2,801	Ryukyu Islands 1,163; Taiwan 1,118.
Pig, sponge, and cast iron, iron powder, and shot.	654	1,848	6,422	Philippines 3,274; United States 1,000.
Ferroalloys:				
Ferrochrome	7,964	3,861	23,733	United States 12,728; United Kingdom 6,450.
Ferromanganese	14,385	8,864	15,314	United States 10,591; United Kingdom 2,476.
Ferrosilicomanganese	3,760	434	723	United States 417; Singapore 153.
Ferrovanadium	382	327	311	North Korea 305.
Other	r 960	582	1,818	NA.
Primary forms:				
Ingots, thousand tons	1	26	39	Philippines 23; Ryukyu Islands 14.
Blooms, billets, and slabs, do	56	33	419	Argentina 229; Australia 55.
Coils for rerolling, do	272	630	889	United States 637; Spain 101.
Semimanufactures:				
Wire rod, do	479	545	742	United States 620.
Bars and other rods, do	840	r 602	757	United States 177; Taiwan 90; Australia 72.
Large sections, do	170	235	397	United States 171; Australia 62.
Small sections, do	65	168	323	United States 159; Republic of South Africa 43.
Plates and sheets:				
Heavy, including universals, do	464	680	926	United States 336; Republic of South Africa 93.

See footnotes at end of table.

(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal destinations, 1965
Metals—Continued				
Plates and sheets—Continued				
Medium ---do---	129	102	227	United States 126.
Thin, uncoated ---do---	1,054	1,338	1,889	United States 739.
Tinplate ---do---	r 189	296	356	United States 75; Taiwan 34.
Other coated ---do---	420	503	571	United States 266; Burma 29.
Hoop and strip ---do---	81	94	166	United States 22; South Korea 22; Canada 20; Thailand 16.
Rails and accessories ---do---	59	33	170	Australia 62; Mexico 32; Thailand 18; Pakistan 18.
Wire ---do---	269	329	393	United States 208; Thailand 36.
Pipes, tubes, and fittings:				
Cast pipes and tubes	20	7	10	Hong Kong 4; Ryukyu Islands 2; Singapore 2.
Seamless pipes and tubes	230	253	401	U.S.S.R. 112; mainland China 68; United States 43.
Other pipes and tubes	467	667	869	United States 488; Saudi Arabia 67.
Fittings	35	34	145	United States 98; Peru 10.
Castings and forgings	(1)	(1)	1	Mainly to United States.
Lead:				
Oxides	-------	-------	222	U.S.S.R. 200.
Metal and alloys, unwrought and semimanufactures.	3,897	1,301	11,535	United States 4,791; Taiwan 3,157; South Korea 1,404.
Magnesium metal and alloys, all forms	20	22	107	United States 52; Netherlands 50.
Manganese:				
Ore and concentrate	486	-------	362	United Kingdom 173.
Oxides	r 9,102	11,577	18,939	West Germany 2,042; United Kingdom 1,700.
Mercury ---76-pound flasks---	464	-------	2,610	Taiwan 1,595; Netherlands 725.
Molybdenum metal and alloys, all forms	28	125	25	Australia 13; New Zealand 5.
Nickel:				
Ore, concentrate, matte and speiss	-------	657	723	All to West Germany.
Metal and alloys, unwrought and semimanufactures.	133	250	384	Mainland China 186; Thailand 58.
Platinum group metals and alloys, all forms thousand troy ounces	44	5	6	United States 5.
Selenium	48	46	31	United Kingdom 22.
Silver and alloys, unwrought and semimanufactures ---thousand troy ounces---	142	2,913	154	Taiwan 60; United States 50; South Korea 36.
Tantalum, metal and alloys, all forms	51	-------	4	West Germany 3.
Tin:				
Ore and concentrate ---long tons---	-------	-------	18	All to United Kingdom.
Oxides ---do---	-------	-------	87	United States 56; United Kingdom 15.
Metal and alloys, unwrought and semimanufactures ---long tons---	1,049	112	331	Thailand 110; Netherlands 70; United Kingdom 64.
Titanium:				
Oxides:				
Rutile type	13,234	20,812	21,129	Mainland China 4,029; United States 3,271.
Other	10,720	15,166	16,984	United States 9,358; mainland China 2,734.
Metal including alloys, all forms	1,435	1,689	3,536	United States 2,433; United Kingdom 683.
Tungsten:				
Ore and concentrate	-------	-------	20	All to North Korea.
Metal and alloys, all forms	56	15	106	India 80; West Germany 8.
Zinc:				
Oxides	159	173	337	Indonesia 217; Singapore 44.
Dust (blue powder)	-------	-------	440	India 323; Taiwan 60; South Korea 52.
Metal and alloys:				
Unwrought	1,139	5,405	55,404	United States 13,090; Italy 7,748; India 7,703.
Semimanufactures	797	858	1,071	Taiwan 186; Indonesia 167; Hong Kong 118; India 117; Philippines 109.
Other:				
Ores and concentrates, n.e.s.	-------	-------	1,705	Unspecified 1,023; Taiwan 610.
Metalliferous nonferrous waste and scrap	421	135	19	All to United Kingdom.
Arsenic, boron, phosphorus, silicon, and tellurium.	NA	NA	461	United States 182; India 119; Pakistan 48.
Alkali, alkaline earth, and rare-earth metals	-------	-------	49	NA.
Ferrocerium and other pyrophoric alloys	71	111	113	Hong Kong 45; Thailand 18; Singapore 13.
Nonferrous base metals, n.e.s.	7,502	6,157	11,271	United States 3,463; United Kingdom 2,704; U.S.S.R. 1,420; West Germany 1,360.

See footnotes at end of table.

Table 2.—Japan: Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal destinations, 1965
Nonmetals:				
Abrasives, except diamond, n.e.s.	348	463	496	Taiwan 339.
Asbestos, crude	108	54	769	NA.
Cement thousand tons	2,011	r 1,781	1,601	Indonesia 263; Hong Kong 241; Ryukyu Islands 218; Singapore 209.
Chalk	9,753	8,350	8,470	Thailand 1,997; Hong Kong 1,996; Singapore 1,455.
Clays and clay products:				
Crude, clay, n.e.s.	9,897	30,651	46,534	Pakistan 30,486; Philippines 6,310.
Construction materials:				
Refractory	11,273	19,617	39,545	Philippines 8,262; Pakistan 7,895; South Korea 6,074.
Nonrefractory thousand tons	188	NA	NA	Over half to United States on basis of value.
Diamond:				
Industrial thousand carats	70	65	110	United Kingdom 50; South Korea 15.
Gem, not set or strung do	16	2,006	676	Netherlands 557; Australia 75.
Diatomite and other infusorial earths	156	456	443	Malaya 190.
Dolomite, crude and calcined	1,845	2,316	2,277	Philippines 2,080.
Feldspar, fluorspar and nepheline syenite	1,802	1,776	2,619	Taiwan 2,280.
Fertilizer materials:				
Crude:				
Phosphatic	11,477	723	-------	
Other	170	11	-------	
Manufactured, excluding ammonia:				
Nitrogenous thousand tons	1,576	919	1,363	Mainland China 498; South Korea 394; Taiwan 194.
Phosphatic do	85	207	194	Mainland China 153.
Potassic do	9	10	18	Indonesia 9; Ryukyu Islands 7.
Mixed do	77	163	143	Mainland China 55; Philippines 21; Thailand 20; South Korea 18.
Ammonia, anhydrous do	45	58	71	Philippines 47; Australia 22.
Gems, including industrial precious and semi-precious stones, not elsewhere specified:				
Dust and powder, including diamond dust thousand carats	15	NA	25	Sweden 5; United Kingdom 5; United States 5.
Other, excluding diamond and including piezoelectric quartz kilograms	9,810	12,817	10,324	United States 4,505; India 3,203; Hong Kong 1,889.
Graphite, natural	421	351	700	Thailand 459; Burma 153.
Gypsum and plasters	7,502	7,002	7,335	Singapore 6,477.
Iodine	1,128	1,329	1,396	United States 366; France 312; West Germany 256; India 143.
Limestone, excluding dimension stone thousand tons	293	359	423	Hong Kong 216; Australia 200.
Lime	6,716	5,984	6,255	Singapore 1,827; Hong Kong 1,692; Ryukyu Islands 1,773.
Magnesite	3,452	13,605	10,895	United States 8,502; Canada 2,000.
Mica, all forms	529	72	82	Taiwan 38; mainland China 8.
Phosphorus, red	216	316	344	India 116; United States 97; Pakistan 48.
Pigments, mineral, iron oxides and hydroxides	273	403	333	Taiwan 220; West Germany 40.
Sodium and potassium hydroxides and peroxides	30,729	42,655	55,142	U.S.S.R. 19,943; Burma 8,200; India 7,637; Philippines 6,045.
Stone, sand and gravel:				
Dimension stone; n.e.s.:				
Crude, roughly split and roughly squared.	544	443	409	Ryukyu Islands 323.
Worked	950	1,292	1,104	Cambodia 750; Ryukyu Islands 164.
Gravel and crushed stone	3,074	4,965	1,063	Ryukyu Islands 269; United States 204; Singapore 104.
Grinding and polishing wheels and stones	531	801	988	United States 166; Philippines 153.
Quartz and quartzite	-------	-------	371	NA.
Sand, excluding metal-bearing	918	1,462	1,969	Hong Kong 1,337; Philippines 439.
Sulfur:				
Elemental, all forms	135	156	191	NA.
Sulfuric acid	2,669	750	634	Indonesia 239; Ryukyu Islands 145.
Talc, soapstone and steatite	3,029	639	4,836	NA.
Other:				
Slags, dross, scalings, and other non-metal-bearing wastes of metallurgical works.	1,065	6,777	1,888	NA.
Oxides of barium, magnesium, and strontium.	NA	NA	13,260	United States 7,150; Australia 4,670.
Crude nonmetallic substances, n.e.s.	NA	NA	1,723	Taiwan 1,339.

See footnotes at end of table.

Table 2.—Japan: Exports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal destinations, 1965
Mineral fuels:				
Coal, coke, and briquets:				
Coal—thousand tons	92	60	67	Mainly to South Korea.
Coke	16	10	29	South Korea 18; Hong Kong 4; Philippines 3; Thailand 3.
Carbon black	4,789	9,000	9,675	Mainland China 2,222; U.S.S.R. 1,831; Taiwan 1,537; Indonesia 1,140.
Gas, fuel, natural and manufactured	2,181	3,037	1,184,572	France 1,175,289.
Hydrogen and rare gases	30	49	42	Singapore 10; Philippines 4.
Petroleum:				
Partly refined oil thousand 42-gallon barrels	-------	18	46	South Korea 45.
Refinery products:				
Gasoline—do	2,062	r 2,585	3,333	Ryukyu Islands 1,124; United States 1,112; Australia 888.
Kerosine—do	683	1,383	1,407	Hong Kong 467; Ryukyu Islands 371; Australia 165.
Fuel oil:				
Distillate—do	578	1,217	1,327	Ryukyu Islands 443; Australia 309; Thailand 151.
Residual—do	1	r 192	106	South Korea 97.
Lubricating oil—do	2,785	r 647	916	Taiwan 525; South Korea 293.
Greases	4,533	1,488	4,924	Malaya 3,198.
Petroleum jelly and wax thousand tons	8	12	13	Philippines 2; Taiwan 2; Brazil 2; South Korea 1; Peru 1; Dominican Republic 1.
Bitumen—do	176	96	94	Indonesia 42; Pakistan 18; Burma 13.
Other—do	30	37	24	All to South Korea.

r Revised. NA Not available.
[1] Less than ½ unit.

Table 3.—Japan: Imports of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal sources, 1965
Metals:				
Aluminum:				
Bauxite and concentrates of aluminum thousand tons	1,421	1,622	1,675	Indonesia 564; Malaya 457; Australia 419.
Alumina, all forms	r 49,900	r 50,233	54,747	Australia 54,212.
Metal and alloys:				
Scrap	18,526	25,231	9,376	United States 4,328; Canada 1,363; Hong Kong 1,048.
Unwrought	23,239	r 34,395	42,310	Canada 22,933; U.S.S.R. 13,850; United States 4,895.
Semimanufactures	838	1,817	940	United States 704.
Antimony, ore and concentrate	6,196	6,501	4,545	Bolivia 1,606; mainland China 1,144.
Arsenic, oxides and acids	2,676	2,204	2,567	France 1,749; Sweden 760.
Chromium:				
Chromite[1]	226,516	396,427	360,299	Philippines 113,971; Turkey 109,200; Republic of South Africa 52,223.
Oxides	50	52	106	All from West Germany.
Copper:				
Ore, concentrate and matte	600,150	620,381	618,621	Philippines 246,631; Canada 188,998.
Metal and alloys:				
Scrap	82,850	107,907	64,949	United States 42,227.
Ingot	r 56,377	r 122,418	115,038	Zambia 81,251; United States 22,827.
Semimanufactures	1,279	5,978	11,527	Chile 7,394; United Kingdom 2,936.
Iron and steel:				
Iron ore, including roasted pyrite thousand tons	26,268	31,236	39,018	India (including Goa) 7,913; Malaya 6,956; Chile 6,929; Peru 4,532.
Scrap[2]—do	4,368	4,986	3,363	United States 2,315; India 432.
Pig iron and ferroalloys—do	1,565	3,423	2,640	U.S.S.R. 775; South Africa 541; mainland China 528.
Ingots and other primary forms—do	4	7	2	Spain 1.
Semimanufactures—do	49	27	22	Australia 8; United States 7.

See footnotes at end of table.

Table 3.—Japan: Imports of metals and minerals—Continued

(Metric tons unless otherwise specified)

Commodity	1963	1964	1965	Principal sources, 1965
Metals—Continued				
Lead:				
Ore and concentrate	68,649	51,704	67,247	Australia 33,089; Bolivia 11,041; Peru 10,361; South Korea 6,782.
Metal, all forms	25,084	70,417	41,262	Peru 10,659; Australia 9,297; Republic of South Africa 8,827.
Magnesium, unwrought and semimanufactures	495	898	569	United States 394.
Manganese ore and concentrate[3]	367,730	558,951	1,064,839	India 457,080; U.S.S.R. 108,228; Brazil 103,402.
Mercury—76-pound flasks	3,026	5,065	2,747	Italy 1,329; Spain 1,279.
Molybdenum:				
Ore and concentrate	3,100	5,078	5,032	United States 3,010; Canada 1,066.
Metal, all forms	6	112	62	U.S.S.R. 40; United States 12.

NA Not available.
[1] Includes both refractory and metallurgical chromite; originating in the Philippines is refractory grade.
[2] Includes only that scrap classified as for smelting; scrap classified as suitable for remanufacturing comprising 223,549 tons in 1963, 113,439 tons in 1964, 43,479 tons in 1965 is not included.
[3] Includes ferruginous manganese ore, which amounted to 115,430 tons in 1963, 226,424 tons in 1964, and 365,109 tons in 1965.

lion) of the total in 1964 and 36 percent ($47 million) in 1965. All metals as a group together accounted for 83 percent and 85 percent of the total mineral commodity exports in 1964 and 1965 respectively. Exports of nonmetals, chiefly cement and chemical fertilizers, and petroleum refinery products accounted for most of the remainder of the mineral exports. Of these latter commodities, the United States imported less than $1 million while most of the balance was exported to mainland China and other Far Eastern countries.

Approximately 32 percent of Japan's total mineral commodity import expenditure was for crude and partly refined petroleum in 1965. Kuwait, Iran, Saudi Arabia, and the Kuwait-Saudi Arabia Neutral Zone accounted for 79 percent of the crude petroleum shipped to Japan in that year. Petroleum refinery products, mainly for domestic consumption for energy purposes and as feedstocks for the expanding petrochemical industry, accounted for an additional 9 percent of total mineral commodity imports. Ranking behind petroleum and its products among Japanese mineral imports in 1964 and 1965 was iron ore, which came mainly from Malaya, Peru, and Chile, and was valued at $420 million in 1964 and $524 million in 1965, accounting for 14 and 16 percent of the total mineral imports during these 2 years, respectively. Adding the iron and steel scrap and semimanufactured imports to iron ore the combined sum would total over 25 percent of the aggregate mineral commodity imports in 1964 and 1965. In these latter categories, especially the scrap, the United States was the chief supplier. Nonferrous ores and metals (including scrap), mostly from nearby Far Eastern countries, totaled about 18 percent of the mineral imports in both 1964 and 1965. Coal, coke, and briquets, predominantly from the United States and Australia, amounted to $211 million in 1964 and $272 million in 1965 and accounted for 7 and 8 percent, respectively, of total mineral imports during these years.

COMMODITY REVIEW

METALS

Aluminum.—Japan's aluminum industry remained entirely dependent upon foreign sources for its bauxite; Indonesia, Malaysia, and Australia together provided approximately 86 percent of Japan's bauxite imports in 1965. At yearend 1965, Japan's ingot aluminum production capacity was almost 350,000 tons. Approximate capacities of major Japanese aluminum smelters at yearend 1965 were Mitsubishi Chemical Industries Limited, 60,000 tons; Nippon Light Metal Co., Ltd., 125,000 tons; Showa

Denko K.K., 80,000 tons; and Sumitomo Chemical Co., Ltd., 80,000 tons.[4]

Aluminum ingot production in 1965 increased about 11 percent to nearly 294,000 tons while that of semimanufactured aluminum products declined almost 6 percent to 157,000 tons. The decline in output of semimanufactures, including rolling mill and diecast products, resulted from production cutbacks in Japan's electric machinery industry, the country's major consumer of the metal. Decreased demand for aluminum semimanufactures also brought about the slower expansion rate in ingot output (11 percent between 1964 and 1965 compared with 19 percent between 1963 and 1964). In addition to a slackened domestic consumer demand, the smallness of Japan's share of the international market and growing inventories of all types of aluminum products concomitant with increasing capacities all along the production line, aggravated the Japanese aluminum industry in 1965.

Despite these market conditions, several aluminum smelters expanded or made plans to expand their facilities in 1965; an overall expansion of 100,000 tons by 1968 was planned. Capacity of Mitsubishi Chemical's aluminum refinery at Naoetsu, on the west coast of Honshu, was doubled to 60,000 tons per year by completion of new facilities during the latter part of 1965. An official of Nippon Light Metal Co., Ltd., announced in late 1965 that his company completed plans to establish a 50,000-ton-per-year aluminum smelter. Reportedly, the new plant will be either near Shimizu or near Kambata, and construction was planned to begin in 1966 with completion expected during 1968. Also Sumitomo Chemical Co., Ltd., announced completion of plans for a refinery at Niihama in North Shikoku. Construction of the new plant was to be achieved in several stages, with completion of the 30,000-ton-per-year first stage due in October 1967 at an estimated cost of approximately $22 million. Under existing plans, the second and third stages will each add 30,000 tons per year to capacity. Completion dates for these later two stages were scheduled for 1969 and 1971. The fourth and final currently planned stage will add another 15,000 tons to annual capacity to give a total plant capacity of 105,000 tons yearly. Completion date for the fourth stage was scheduled for 1973. These capacities, together with those of the firm's facilities existing in 1965, will give Sumitomo a total annual capacity of 185,000 tons of primary aluminum by 1973.[5]

Because domestic aluminum consumption showed little promise for significant increase in the foreseeable future under existing market conditions, aluminum manufacturers were active during 1965 in promoting wider application of aluminum in existing products and in obtaining a larger share of the existing international market. In developing greater use for aluminum, Nippon Light Metal, Furukawa Electric Co., Showa Denko, and Hitachi Wire and Cable Co. have organized their affiliated firms to specialize in utilizing aluminum in the manufacture of vehicles, construction materials, and household utensils and appliances. In developing foreign markets, Nippon Light Metal Co. signed a contract with mainland China for the export of 600 tons of aluminum ingots. This company also has been seeking other Communist countries as outlets for aluminum, while other companies sought to expand their share in Southeast Asia's market. Japanese aluminum industry officials specifically sought long-term contracts for ingots. Notably, Mitsubishi Chemical in midyear concluded a contract to deliver ingots to a firm in the Philippines, and by yearend had shipped to that firm 2,000 tons on a trial basis.

Copper.—Japan's total ingot copper production increased by nearly 6 percent in 1965 with respect to 1964 output. Slightly over half of total output in both years was derived from imported ores, concentrates, and matte, and about a quarter of the total was produced from scrap; domestic ores provided slightly less than 25 percent of total metal production (primary and secondary).

Total value of copper imports in 1965 was approximately $271.7 million, including $128.2 million for copper ores, concentrates, and matte; $98.4 million for copper and copper alloy ingots and semimanufactures; and $45.1 million for copper scrap. The 1964 total was $253.4 million of which $102.2 million was for ores, concentrates, and matte, $87.0 million was for ingots and

[4] Japan Metal Bulletin. The Sangyo Press, Ltd. (Tokyo). No. 1887, Dec. 18, 1965, p. 3.
[5] Far Eastern Economic Review (Hong Kong). V. 49, No. 1, July 1, 1965, p. 29.

semimanufactures, and $64.2 million for scrap. The severe shortage of copper raw materials in 1965 brought about significant price increases. In 1964, Japanese buyers paid an average price of $154 per ton for copper ore and concentrate and $660 per ton for ingot; whereas, in 1965 the average price for ore and concentrate was $185 per ton and that for ingot was $750. Copper scrap prices went up to $695 per ton in 1965 from $595 in 1964. At these high prices, Japan's importers were extremely aggressive in locating copper raw materials, and this aggressiveness drew a formal protest from West Germany to the Nonferrous Metal Committee of the Organization for Economic Cooperation and Development (OECD).

One effect of the copper ore shortage was to induce some of the Japanese copper smelters to import greater amounts of blister copper. In this regard, Toho Zinc Co., Ltd., contracted for 8,000 tons of such copper from a South African firm to be delivered over a 2-year period beginning in April 1966.

The price increases for copper raw materials were exceeded by gains in world prices for copper products, and the heavy international demand resulted in increased exports of copper products from Japan. Export of unwrought copper and alloys in 1965 amounted to 2,681 tons compared with 1,621 tons in 1964 and copper and copper alloy semimanufacture shipments totaled 50,440 tons compared with 26,652 tons in 1964. Value of 1965 exports totaled $2.5 million for unwrought metal and $50.4 million for semimanufactures. In 1964, value for unwrought metal exports was only $1.2 million and that for semimanufactures $21.8 million. The most notable increase in the export of copper was in the case of materials for electrical purposes, which went from 3,200 tons in 1964 to 10,400 tons in 1965. Largest importers of these particular items during the year were West Germany, Taiwan, Thailand, and Hong Kong. International demand for copper commodities was so heavy in 1965 that Japanese firms acting previously as importers of copper commodities became exporters of copper alloys, scrap, sheets, wire, and other copper semimanufactures to the extent that there was a shortage of such commodities in the domestic market.

Thus, under conditions of heavy exports of copper in all forms and high raw material costs, prices for copper in Japan's domestic market in 1965 soared, with prices for some of the semifinished goods more than doubling by the latter part of 1965. As a consequence, Japan's copper consumers suffered from rising prices and declining domestic material availability. These factors and others depressed domestic consumption of copper more than one-half in comparison with the 1964 level. In an attempt to bring relief to the domestic users, the Ministry of International Trade and Industry issued regulative measures to restrict copper exports. These measures, however, were put into effect too late to have any great effects during 1965.

The general Japanese recession during a greater part of 1965 further aggravated the situation. Had there been no recession or one of much shorter duration, the severity of the Japanese copper consumers' plight might have been much less; but, as it was, Japanese copper producers were confronted with a dilemma by yearend. If they raised domestic prices commensurate to those in the world market, they risked the possibility that local consumers might cease operations thereby reducing the producers' sales, but if the producers did not raise prices, they would suffer losses because of raw material costs and the embargo on copper exports.

Believing that the copper ore shortage would persist at least into the foreseeable future, six Japanese copper smelters jointly accepted a request from the U.S.S.R. to develop a copper mine about 480 kilometers east of Lake Baikal. Participants in the joint venture were Mitsui Mining and Smelting Co., Ltd., Dowa Mining Co., Ltd., Nippon Mining Co., Ltd., Mitsubishi Metal Mining Co., Ltd., Sumitomo Shoji Kaisha, Ltd., and Sumitomo Metal Mining Co., Ltd. These six firms also have been negotiating jointly with the Indian State of Madras to develop a copper mine there with Japanese capital.[6] Dowa Mining Co., Ltd., with the cooperation of the Daiwa Bank, Ltd., laid plans to establish a new copper mining company in Fiji under the name of Fiji Mining Co. The new firm, capitalized at about $835,000, will have Banno Mining Co. carry out its mining operations at the Undu mine on the island

[6] Far Eastern Economic Review (Hong Kong). V. 51, No. 7, Feb. 17, 1966, pp. 331–332.

of Vanua Levu. Development of the mine will start with surface deposits, reserves of which were estimated to total 135,000 tons of ore with an average 5 percent copper content. Initial output has been scheduled for 2,500 tons per month, beginning in early 1967.[7] Furukawa Mining Co. discovered a new copper vein at its Ashio mine with reserves estimated at 500,000 tons with a copper content between 1.8 and 2.0 percent. Officials of the firm believed the new vein can be economically exploited because of the existing equipment at the mine.[8]

This intensive search for copper raw materials is in keeping with the industry's increased smelting capacity. In September 1965 Onahama Smelting and Refining Co. inaugurated its 5,000-ton-per-month copper smelting facilities. Onahama was jointly formed by Mitsubishi Metal Mining Co., Dowa Mining Co., and Furukawa Electric Industry Co. in 1962 for large-scale smelting. Onahama has made plans to double its existing capacity in the immediate future and has invited three other large copper smelting concerns to participate in the second phase of the joint venture. Should these concerns—Mitsui Mining and Smelting Co., Sumitomo Mining Co., and Nippon Mining Co.—accept the invitation, Onahama will become a unique company in which all the six firms currently constituting Japan's copper smelting industry will have a share.

Although electrolytic copper output was 30,000 tons more in 1965 than that produced in 1964, semimanufactured copper products output, chiefly rolled copper, was down to 312,000 tons in 1965 from 392,000 tons in 1964. Moreover, as a result of raw material costs and other economic factors, smelter output was cut by about 10 percent in late 1965.

Monthly rolled copper consumption in Japan in 1965 by various major users were as follows: Industry, 110 tons; chemical industry, 242 tons; metal products, 6,547 tons; electric machines, 3,139 tons; telecommunication, 1,573 tons; rolling stocks, 1,540 tons; shipbuilding, 585 tons; military ordnance, 130 tons; general machinery, 2,367 tons; other manufacturing industry, 4,721 tons; construction, 984 tons; semifinished products, 2,770 tons; exports, 2,568 tons.[9] Total monthly domestic requirement of rolled copper averages approximately 25,000 tons; and with exports added, the requirement would be 28,000 tons per month or about 336,000 tons annually.

Ferroalloys, Ferroalloy Metals, and Their Ores.—Output of ferroalloys in 1965 was 687,566 tons compared with the record high of 692,632 tons achieved in 1964. The 1965 production, however, slightly exceeded the year's target output of 684,002 tons by Japan's 33 ferroalloy producers and was considerably more than the projected demand of 609,400 tons.[10]

The curtailment in ferroalloy output was precipitated by cutbacks in special steel production during the latter half of 1965. Although the decline was small when compared with the 1964 figure, it was sufficient to cause some diseconomies of scale of production which in turn induced some financial strains, especially among the smaller producers and traders. As a result of generally unfavorable events during early 1965 and an expected sluggish market in the immediate future, Japanese ferroalloy producers hastened during the late months of 1965 to restructure their industry via mergers and cartelization. Upon the recommendation of the Ministry of International Trade and Industry (MITI), Tekkosha Co., Lt., Azunia Kako Co., Ltd., and Toshiba Denko Co., Ltd., were studying the feasibility of a merger. In 1964, the combined output of these firms constituted 27.8 percent of total ferromanganese output, 11.6 percent of ferrosilicon output, 32.1 percent of total ferrochrome output, and 25.5 percent of total ferroalloy production. If merged, the resulting company would be the largest ferroalloy producer in Japan.[11] In late November 1965, the Fair Trade Commission approved a 21-firm application for the formation of a ferroalloy cartel during the period October 18, 1965, to March 31, 1966. Primary function of the cartel was to regulate production and sales to maintain prices.[12]

Japan continued to rely very heavily on

imports for its sources of ferroalloy metals. India has been the chief source of manganese, and in 1964 supplied 84.4 percent of Japan's total manganese imports. However, in 1965 India's share fell to 457,000 tons (inclusive of ferruginous manganese ore and concentrates) or 42.9 percent of a total of 1,065,000 tons. The decline in India's share was principally caused by the 1965 confrontation between India and Pakistan. Subsequently, Japan imported higher cost manganese ores and concentrates from Brazil at an average price of about $33 per ton, Australia, $36 per ton, and New Hebrides, $38 per ton, compared with $29 per ton for Indian ore. However, Japan paid the Soviet Union, the second largest supplier of the commodity to Japan in 1965, only $18 per ton in 1964 and 1965. Chromite ores were still principally supplied by the Republic of the Philippines (32 percent) and nickel ores by New Caledonia (89 percent) in 1965. Molybdenum ores and concentrates were principally supplied by the United States (60 percent) and Canada (21 percent) during the same year.

Iron and Steel.—Despite the business recession during the second half of 1965, Japan's steel industry fared well and continued expansion and renovation plans. Overall production of pig iron, crude steel, and steel semimanufactures all attained new highs. Japan thus kept its place as the third largest producer of crude steel in 1965, outpaced only by the United States and the U.S.S.R. It was particularly noteworthy that the 1965 record outputs were attained in spite of a 10-percent production cutback, in force since July 1965, reflecting the significantly higher output rate during the first 6 months.

Production.—Of the total output of pig iron in 1965, blast furnaces accounted for 27.0 million tons. Blast furnaces in actual operation during 1965 numbered 46. Three new giant blast furnaces were put into commission in 1965: The No. 5 blast furnace (capacity, 2,142 cubic meters) at the Chiba Steel plant of Kawasaki Steel Corp. in March; the No. 3 blast furnace (1,650 cubic meters) at the Wakayama Works of Sumitomo Metal Industries in April; and the No. 1 blast furnace (2,047 cubic meters) at the Sakai installation of Yawata Iron and Steel Co., Ltd., in June.[13]

Fuji Steel Co. converted the No. 2 furnace at its Muroran complex (1,042 cubic meters capacity) into a high-pressure furnace (1,239 cubic meters). Total number of high-pressure furnaces at yearend 1965 was 13, 4 more than in 1964. Average blast furnace productivity in 1965 was 1.4 tons per cubic meter per day an average consumption of coke per ton of pig iron was 506 kilograms compared with 508 kilograms in 1964 and 521 kilograms in 1963. Yawata Steel Co. held the record during the year with an average of 486 kilograms for its 11 blast furnaces. The industry continued its research during the year on feasibility of using naphtha, natural gas, and light oils as reducing agents in developing new direct iron ore to steel processes.

The significant increase in output of pig iron in 1965 was ascribed to the rising proportion of crude steel produced by the Linz-Donawitz (LD) process which depends more heavily on pig iron as raw material. With the reduction in steel output during the second half of the year, leading Japanese steel producers continued to raise the operation rate of oxygen converters, resulting in a 10-percent increase in LD output compared with the first 6 months, while the more costly open-hearth output declined by 40 percent. LD steel production in 1965 amounted to 22.6 million tons, 5.0 million tons above the 1964 level, and 55 percent of the total 1965 crude steel output compared with 44 percent in 1964 and 38 percent in 1963. This proportion of oxygen converter steel is extremely high compared with that of the other leading steelmaking countries. The open-hearth method in Japan accounted for 21.6 percent of all the steel produced in 1965, and electric furnaces for 19.9 percent.

The product mix of the 1965 output of hot-rolled ordinary steel semimanufactures differed widely from that of 1964. In 1965, strip mill production was considerably below the 1964 level, while output of steel sections, shapes, and bars was significantly higher. Production of special or alloy steel products during 1965 declined from approximately 2.5 million tons to 2.4 million tons, chiefly because of slackened demand

[13] The Oriental Economist. Iron and Steel Industry Going Strong. V. 34, No. 666, April 1966, pp. 233–237.

for these steels by their prime consumers, the machine manufacturers. Approximate annual capacities and number of production units for various iron and steel products in Japan at yearend 1964 and 1965 were as follows:

Facility	Rated 1964 yearend capacity (thousand metric tons)	Units	Rated 1965 yearend capacity (thousand metric tons)	Units
Pig iron capacity:[1]				
Blast furnaces	22,162	41	25,534	48
Electric furnaces	632	72	523	55
Other furnaces	321	10	334	9
Total	23,115	123	26,391	112
Steelmaking capacity:[1]				
Open-hearth	16,463	118	11,318	82
Converters	16,468	36	24,745	45
Electric furnaces	11,346	763	11,357	722
Total	44,277	917	47,420	849
Heavy shape mills[2]	3,015	14	4,905	16
Medium and light shape mills[2]	16,532	592	18,440	594
Wire rod mills[2]	4,471	24	5,383	28
Heavy plate mills[2]	6,517	38	6,817	39
Hot strip mills[2]	15,900	11	16,974	14
Cold strip mills[2]	8,116	43	e 10,000	48

[2] Japan Metal Bulletin. Sangyo Press, Ltd. (Tokyo). Jan. 30, 1965, p. 3 (1964 data). Feb. 13, 1965, p. 3 (1965 data). May 27, 1965, p. 2 (1965 data). Nov. 11, 1965, pp. 1–2 (1964 data).

Trade.—Japan's lack of sufficient domestic raw materials to supply its steel industry continued to necessitate imports of huge quantities of iron ore, coal, and iron and steel scrap. In 1965, only 1.5 million tons of domestic iron ore (iron sand) was produced, while about 39 million tons was imported. Thus, more than 95 percent of Japan's annual iron ore needs were met by imports. Of the 1965 total import, about 20 percent came from Malaya, 19 percent from India (including Goa), 17 percent from Chile, 11 percent from Peru, 7 percent from the United States, and 5 percent from Canada.

Imports of iron ore in the near future may be even closer to 100 percent of requirements since Yawata Iron and Steel Co., Ltd., decided recently to dissolve its affiliated Ariake Iron Manufacturing Co., which was established in March 1961 to produce steel from iron sand in Ariake Bay, Kyushu. Reasons for the dissolution were that steel production from iron sand was not economical, iron sand resources in Ariake Bay were not accurately surveyed, and iron sand found in deeper areas of the ocean floor was uneconomical to exploit. Officials of Yawata also decided to dismantle Ariake's equipment and transported it to one of Yawata's complexes to produce sponge iron. Ariake's 50-acre site will house some other company in the Yawata group.[14]

Japan's 1965 importation of iron and steel scrap was 1.7 million tons lower than in 1964, chiefly because of increased operations of LD converters, and because of a continuing trend toward greater use of these furnaces and reduced use of open hearths, further decreases in scrap imports are expected. Of the 1965 total scrap iron and steel imports, the United States supplied approximately 68.8 percent; India, 12.8 percent; Australia, 8.6 percent; and U.S.S.R., 2.6 percent.

Exports of iron and steel products in 1965, at 9.91 million tons, were equivalent to 12.71 million tons of crude steel, compared with 6.92 million tons, equivalent to 8.95 million tons of crude steel, in 1964. Ordinary rolled steel products constituted by far the largest part of the total. For example, in 1964 and 1965, respectively, the exports of this commodity were 5.91 million tons (valued at $735 million) and 8.24 million tons (valued at $1,009 million). The United States purchased 2.10 million tons of these products in 1964 and 3.73 million tons in 1965. The other major categories of iron and steel commodities exported during 1964 and 1965 were, respec-

[14] Japan Metal Bulletin. Yawata Dissolves Affiliated Ariake Iron Mfg. The Sangyo Press, Ltd. (Tokyo). No. 1897, Jan. 22, 1966, p. 2.

tively, reprocessed steel products, 707,000 and 808,000 tons; incompletely finished steel products, 59,000 and 459,000 tons; and rolled special steel products, 221,000 and 346,000 tons. The United States was also a major buyer in these categories except in the incompletely finished products in which it bought only very small amounts in both years.

Consumption.—Domestic consumption of iron and steel products was approximately 77.5 percent and 69.2 percent of the 1964 and 1965 crude steel output, respectively. Out of a total of 32.45 million tons of rolled steel products produced in 1965, domestic users consumed 25.30 million tons during the year, an increase of 9.4 percent over the previous year's total. Breakdown of domestic end uses for 1965 was as follows, in thousand metric tons: Construction and civil engineering, 4,049; shipbuilding 2,153; autos, 1,200; billets, semis, and casting steel, 887; industrial machinery, 645; electrical machinery, 463; household and business machines, 148; rolling stock 95; bicycles 40; other machinery and tools, 20; deliveries to dealers, 4,743.[15]

Financial Situation.—Japan's steel industry's rapid growth in very recent years, 26.3 percent in 1964 and 14.4 percent in 1963, was not without growth pains, external economic dislocations, and internal structural imbalances. One of the more serious problems facing the industry in 1965 was its financial structure vulnerability. Reportedly[16] large investments in plant and equipment during recent years have not been compensated sufficiently by increases in production and sales; thus overall net profits were not proportional to physical expansion of the industry. To offset lower net profits, there was some reduction in raw material and other factor costs, but, in general, these reductions were not sufficient to offset investment costs. Aggravating the situation further was the general decrease in the number of governmental policies to hedge business earnings; such as accelerated depreciations, retained profits, and other nonoperating expenses. These and other conditions resulted in an increased rigidity in the industry's income-expense structure with a concomitant rise in Japan's steel industry break-even point, which, for example, went from 77 percent of sales in 1960 to 90 percent of sales in 1963.

The weak financial structure of the industry was emphasized by Sanyo Special Steel Co., Ltd., which went into receivership in early 1964. An article pointed out that the bankruptcy of Sanyo Steel and other large industrial enterprises in recent years revealed weaknesses in the interlocking structure of Japanese business and banking firms.[17]

Capital investment plans of 107 steel companies for the 1966 Japanese fiscal year (April 1, 1966, through March 31, 1967) were recently summed up and released by the Ministry of International Trade and Industry (MITI). These data together with comparable figures for the previous fiscal year were as follows, by categories:

Category	Number of companies	Capital investment (million dollars)	
		1965[1]	1966[1]
Ordinary steel	35	441.7	517.5
Special steel	21	39.6	38.6
Special wires	7	1.7	1.9
Ferroalloys	26	6.7	8.6
Secondary products	18	20.3	15.6
Total	107	510.0	582.2

[1] Fiscal year ended March 31.

Technology.—Japan's steel industry has also increased use of automatic and automated controls. In 1965, more automatic equipment was installed to handle raw materials, especially of ore from carrier to blast furnace, and computers for operation of open-hearth furnaces were initiated at Nippon Kokan Kabushiki Kaisha's Kawasaki plant. The latter operation was said to be the first in the world. More rolling mills were also equipped with automated devices in 1965 with concomitant production increases. As an illustration, output of buttwelded pipes increased from 7.5 tons per hour in 1964 to from 9 to 10 tons per hour after automation.

There also has been a rapid increase in Japanese utilization of continuous casting

[15] Japan Metal Bulletin. How Was the Steel Used in 1965? The Sangyo Press, Ltd. (Tokyo). No. 1919, Feb. 22, 1966, p. 2.

machines in recent years. During 1965, a Rossi type continuous casting machine (180,000 tons per year) was installed at the Kawasaki plant of Nippon Yakin Kogyo Co., Ltd., and Yamote Steel Co. reportedly planned to install a Rossi type continuous slab casting machine also. Yawata Iron and Steel Co., Ltd., and Toshiba Steel Co. planned to install Olsson type machines in the near future. Kobe Steel Works, Ltd., began installing in 1965 continuous casting machines of Soviet design, and Fuji Iron and Steel Co., Ltd., continued pilot operation of a continuous slab casting machine developed by itself.

Japan's exports of steel industry technology in 1965 included the manufacturing techniques for electrical steel sheets by Kawasaki Steel Corp. to Compagnie des Ateliers et Forges de la Loire of France and a special method of treating steel sheets by Toyo Kohan Co., Ltd., to Rasselstein A.G. of West Germany. Major imports of iron and steel technology from the United States in 1965 included these: Electric Furnace Co. to Yawata Iron and Steel Co., Ltd., design and manufacture of heating furnaces for 72-inch continuous galvanizing lines; Armco Steel Corp. to Fuji Iron and Steel Co., Ltd., manufacture of hot- and cold-rolled steel pipes and tubes; Republic Steel Corp. to Kawasaki Steel Corp., manufacture of hot- and cold-rolled steel sheets; Blaw-Knox Co. to Sumitomo Metal Industries, Ltd., seamless pipemaking machines; Wheeling Steel Corp. to Kobe Steel, Lt., continuous galvanizing of steel sheets and coil; General Alloys Co. to Daido Steel Co., Ltd., manufacture of corrosion-and heat-resistant steel casting; Union Carbide Corp. to Tekkosha Co., Ltd., manufacture of low-carbon ferro-alloys by vacuum furnaces.[18]

Lead.—Japan's lead industry in 1965 experienced difficulties stemming from excess stocks and depressed prices. Prior to the 1965 recession normal monthly lead demand had averaged 13,000 to 14,000 tons, but, with the recession, demand from the battery industry, the largest user, decreased to 8,000 tons. As the recession deepened during the closing months of 1965, lead inventories built up rapidly, and prices fell from the approximately $389 per ton level reached at the beginning of the year,[19] to approximately $269 per ton, the lowest Japanese price for lead since the end of World War II. Because world lead prices did not decline as markedly as did the Japanese price, producers acted to expand export sales. As a result of these efforts, total lead and lead alloy exports increased 887 percent to 11,535 tons and at yearend Japan was hoping to continue to export surplus lead ingots while trying to delay additional contracted shipments of lead raw materials into the country.

As a consequence of the economic difficulties, output of lead ingot from both primary and secondary sources declined by 2.4 percent to about 165,250 tons, and lead semimanufactures output in 1965 fell about 7 percent to approximately 42,100 tons.

Despite the fall in Japan's 1965 economy, some major Japanese lead producers went ahead of schedule in expanding their plant facilities. In May 1965, Mitsubishi Cominco Smelting Co. was formally established with an authorized capital of $2.8 million between Mitsubishi Metal Mining Co., Ltd. (55 percent) and Consolidated Mining and Smelting Corp. of Canada (COMINCO) (45 percent). Plans were completed to construct a $2.2 million plant at Mitsubishi's Naoshima Smelting Works with an initial annual capacity of 3,000 tons. Completion date of the plant was scheduled for June 1966. One of the provisions of the joint venture was the supply of 22,500 to 31,500 tons of dried lead ore per year by COMINCO for 10 years. The ore or concentrate with a 75 percent metal content will be supplied by Pine Point Mining Co., a subsidiary of COMINCO.[20]

Sumitomo Metal Mining Co. Ltd.'s $7.5 million lead production facilities in its new plant at Harima were nearing completion at the end of 1965. In January 1966, production of electrolytic lead using the Imperial Smelting Process began with an initial output of 60 tons. Rated capacity of the new plant was 1,500 tons of lead and 3,000 tons of zinc per month. Ore for the Harima plant will be supplied mainly by the Rio Tinto-Zinc Corp., Ltd. Mitsui Mining and Smelting Co., Ltd., announced in

[18] Far East Iron and Steel Trade Reports. Technical Developments in Japan's Steel Industry 1965. No. 133, Feb. 12, 1966, pp. 7–8.
[19] Japan Metal Bulletin. The Sangyo Press, Ltd. (Tokyo). No. 1747, Jan. 19, 1965, p. 1.
[20] Japan Metal Bulletin. The Sangyo Press, Ltd. (Tokyo). No. 1801, May 27, 1965, p. 1

mid-1965 that its Central Research Laboratory's staff developed segregation methods for treatment of Japanese "black ores." Using the new methods in conjunction with the Imperial Smelting Process, greater efficiency can be attained in extracting copper, gold, lead, silver, and zinc from the black ores than by using conventional flotation methods. Mitsui Mining and Smelting applied for patents for its segregation methods.[21]

Magnesium.—Despite the 1965 recession that severely affected many of Japan's metal manufacturers and fabricators, magnesium producers achieved record output levels. Total magnesium output for 1965 was reported as 7,950 tons, but this figure included only 3,785 tons of primary metal, the balance being magnesium recovered from titanium reduction, which after recovery is reused by the titanium producers. Furukawa Magnesium Co. was the sole Japanese primary producer of magnesium in 1965. Ube Industries, Ltd., however, announced plans in July 1965 to produce magnesium from magnesium chloride in conjunction with its affiliated company, Ube Chemical Industries Co., Ltd.[22]

The Magnesium Commission of the Japan Light Metals Society estimated that the country's magnesium industry, including those facilities recovering magnesium from titanium reduction operations, will have an average growth rate of 18 percent per year and will be producing at a rate of 13,090 tons per year by 1968. Estimated 1968 demand divided by the various uses were as follows: Reductants, 8,500 tons; aluminum manufacturing, 1,730 tons; nodular iron, 1,550 tons; forging, 660 tons; alloying, 290 tons; other uses, 360 tons. The projected 1968 amount was criticized as being too conservative and did not take into consideration the probable demand for magnesium by Japan's rapidly expanding automobile and structural industries.

Although magnesium smelting started in Japan in 1929, mainly to supply the metal to Japan's growing aircraft industry, it suspended operation after World War II when the aircraft industry went out of business. Magnesium production was revived in 1957, primarily to supply the metal as a reducing agent to the titanium industry. In 1965, more than 60 percent of the total annual output of magnesium was used to produce titanium.

Titanium.—Osaka Titanium Co. Ltd. and Toho Titanium Co. Ltd. were Japan's only titanium producers in 1965. Output for 1965, generally unaffected by the recession, was about 5,200 tons of sponge, ranking Japan third among world titanium metal producers after the United States and the U.S.S.R. Titanium rolling and forging were undertaken by a few firms with Kobe Steel Works, Ltd., having 80 percent of the market. The remainder was largely divided between Sumitomo Light Metal Co. Ltd. and Nippon Mining Co. Ltd.[23]

In recent years there was a notable growth of Japanese domestic titanium consumption, particularly that by the country's petrochemical industry. The increased domestic demand together with that in the world market, especially from Communist countries, prompted expansion of smelting capacities. Toho Titanium raised its smelting capacity in September 1965 to 28,000 tons per year, 4,000 tons above its 1964 capacity; and Osaka Titanium increased its capacity to 3,000 tons per year in October 1965, 6,000 tons above the company's 1964 level.[24]

Zinc.—Japan's zinc industry in 1965 fared somewhat better than those of copper and lead even though the industry's chief domestic consumers, galvanized steel and rolled copper fabricators, substantially reduced their purchases in 1965 with respect to those of 1964. Fortunately for the country's zinc industry, however, there was a relatively heavy demand in the world market for unwrought zinc during 1965 and Japan was able to export much of its surplus zinc. Spurred by the business in the international zinc market, some of the largest Japanese producers either renovated and expanded their existing facilities or made definite plans to construct new ones. Among those zinc producers who expanded their facilities in 1965 were Mitsui Mining and Smelting Co. Ltd., Toho Zinc Co. Ltd., Mitsubishi Metal Mining Co. Ltd., Dowa Mining Co. Ltd., and Nippon Soda Co. Ltd.

At yearend 1965 Japan's zinc producing capacity was estimated at about 450,000

[21] Japan Metal Bulletin. The Sangyo Press, Ltd. (Tokyo). No. 1805, June 5, 1965, p. 2.
[22] Japan Metal Bulletin. The Sangyo Press, Ltd. (Tokyo). No. 1816, July 1, 1965, p. 1.
[23] Mining Journal (London). V. 265, No. 6799, Dec. 10, 1965, p. 424.
[24] Metal Bulletin (London). No. 4975, Feb. 23, 1965, p. 25.

tons, of which approximately 300,00 tons was electrolytic and the remainder was distilled and other types of refined zinc. Domestic mine zinc production in 1965 was 221,000 tons, 5,000 tons more than the 1964 output, and total smelter output of zinc metal in 1965 was about 342,100 tons compared with 285,800 tons in 1964. Domestic consumption (production less exports) of zinc in 1965 was slightly above the previous year's level, 286,000 tons in 1965 compared with 279,500 tons in 1964. Announced plans for further expansion by the Japanese zinc smelters, if carried out, would add an additional 200,000 tons to existing capacities, and would give the industry an annual total capacity of 650,000 tons. To head off problems that could result from excess capacity, the Ministry of International Trade and Industry (MITI) urged Japanese zinc smelting firms to curtail their expansion plans drastically but the zinc smelters disagreed with MITI's recommendations. While they did not question the projections as drawn up by the Mining Industry Council, they reportedly believed that the international market could absorb any excess zinc Japan might produce, apparently basing their conclusions on the fact that during 1965 Japan exported nearly 57,000 tons of zinc and alloys valued at about $18 million compared with only about 6,000 tons in 1964 valued at about $4 million. Moreover, the Japanese zinc smelters believed they could enhance the industry's world market position, especially with regard to Southeast Asian countries, by negotiating for long-term supply contracts.[25]

NONMETALS

Cement.—Japan ranked almost equal to West Germany in world cement production behind the United States and the Soviet Union and held on to first place as a cement exporter despite lagging markets both at home and abroad. Some decline in domestic demand was not altogether unexpected after the construction spurt brought on by the Olympic Games in 1964, but a dip in private demand resulting from the general business slump and an unduly long rainy season held consumption down even more through most of 1965. Toward yearend, consumption was responding to government business support programs, especially in the sector of private homc construction. With overcapacity and overproduction, fierce sales competition forced profits down and nearly all companies suffered. Average wholesale price of cement, $16.32 per ton in January, rose to $16.65 per ton in December; the market price, however, was reported to have dipped as low as $15.70 per ton in July, but from that point rose sharply as producers resisted price-cutting.

Cement exports decreased 10 percent in tonnage and 16 percent in value, partly the result of increasing self-sufficiency of other Far East countries. Clinker shipments to Hong Kong and Singapore found competition from Taiwan and mainland China suppliers. The tonnage of cement shipped to Indonesia was greater but shipments to other destinations declined. Total value of cement exports was $21 million, or about 1 percent of all mineral exports in 1965.

Japan's cement production capacity increased about 2 million tons during the year to 54.1 million tons in December, with expansions by such companies as Nihon Cement Co., Ltd., Sumitomo Cement Co., Ltd., Chichibu Cement Co., Ltd., and Daiichi Cement Co., Ltd.; Nozawa Cement Co., Ltd.'s, installation of two 2,300-ton-per-day Lepol kilns at its Hikone plant was completed. Overall utilization of capacity was estimated at only 65 percent. The question of economic use of certain idle capacity arose; it was pointed out that probably one-third of the 220 kilns in use were more than 15 years old and generally of substandard operational efficiency. Because of excessive capacity, the Japanese Government announced in June 1965 that for a 3-year period no new plants or expansions would be permitted. Replacement of old equipment, it is assumed, would be encouraged by this move. Based on an anticipated 8-percent annual increase in demand, cement output was predicted by 1970 to reach 50 million tons annually.

Fertilizer and Chemical Materials.—Leading Japanese chemical firms in 1965 included Sumitomo Chemical Co., Ltd., Mitsubishi Chemical Industries, Ltd., Ube Industries, Ltd., and Showa Denko, K.K., with Toyo Koatsu Industries, Inc., singularly outstanding as a fertilizer producer. Japanese fertilizers and chemicals maintained their strong world position in 1965, amply provided with domestic resources in some raw materials but almost completely

[25] Japan Metal Bulletin. The Sangyo Press, Ltd. (Tokyo). No. 1895, Jan. 18, 1966, pp. 2–3.

lacking in others. Phosphate rock, potassium salts, and increasing amounts of sulfur were particularly needed. Outputs of various fertilizers included 2.49 million tons of ammonium sulfate, 1.25 million tons of urea, 340,000 tons of calcium cyanamide, 1.55 million tons of calcium superphosphate, and 3.35 million tons of compound fertilizers. Basic chemicals produced amounted to 2.16 million tons of ammonia, mostly going into fertilizers, 770,000 tons of soda ash, 230,000 tons of liquid chlorine, and 1.34 million tons of caustic soda. Production of pyrites, a major source of sulfur, increased 4 percent in 1965, while refined sulfur output decreased 12 percent. Sulfuric acid production, about one-half for fertilizers, increased 5 percent to 5.65 million tons (100 percent acid) and stimulated elemental sulfur imports, as sulfur from domestic sulfide ores became more expensive to produce.

In efforts to hold down the cost of acid in Japan the Ministry of International Trade and Industry (MITI) urged construction by private industry assisted by government loans of at least two 1,000-ton-per-day sulfuric acid plants operating on imported elemental sulfur, one plant at Osaka and the other in the Choguku area. Sulfide ore producers were expected to oppose the plan because of possible depressing effects on sulfide prices, but it was felt the increased use of imports was necessary. Requirements amounting to about 200,000 tons of sulfur annually would probably come from Canada.

While ammonia continued to be made mostly by nitrogen fixation, a sharp turn was seen toward utilizing naphtha for the necessary hydrogen, leading to the probable replacement of crude oil feedstocks for this purpose. Quantities of naphtha needed for ammonia were estimated about 1.6 million barrels in 1965 rising to nearly 6 million barrels in 1967. Butane was also expected to come into use for hydrogen in Toyo Koatsu's operations, with quantities consumed in fertilizers rising from 200,000 to 1.5 million barrels in the same period. Most sulfur and pyrite consumed were of domestic origin, but shortages were showing up and sulfur imports more than doubled in 1965, nearly one-half of the total coming from mainland China and the rest from Canada. Salt imports of 3.54 million tons in 1965 were slightly lower than in 1964. Salt processing in Japan has reached a relatively high degree of efficiency; however, imported salt continues about half as costly as domestic salt, and has brought the Government to place arbitrary restrictions on quantities produced. About half of the crude fertilizer materials imported in 1965 came from the United States.

At Niigata, Toyo Gas Chemical Industry, Ltd., a subsidiary of Toyo Koatsu, was adding a 36,000-ton-per-year complex fertilizer plant, to include 30-ton-per-day phosphoric acid and 60-ton-per-day ammonium phosphate units. Other companies installing complex fertilizer facilities included Nitto Chemical Industry Co., Ltd., Nisson Chemical Industries, Ltd., and Onoda Chemical Industry Co., Ltd. Capacity of 20 Japanese producers of phosphoric acid more than doubled in 1964–65 to 397,900 tons of acid annually as of April 1, 1965, and further expansions were underway by at least 6 companies. Following trial marketing of a new slow-acting fertilizer called cyclodiurea, Chisso Corp. decided to build a 12,000-ton-per-year plant for its manufacture at the Minamata works. Showa Denko K.K. planned to build a 500-ton-per-day ammonia plant at its Kawasaki works under Imperial Chemical Industries, Ltd., (United Kingdom) license. Japanese companies were active in selling complete fertilizer plants for installation abroad and vied for contracts in the Soviet Union, mainland China, South Korea, the State of Alaska, and elsewhere.

Exports of fertilizers rose sharply in 1965, chiefly the result of increased demands for ammonium sulfate and urea types. Total exports reached 1.79 million tons of fertilizers, of which 39 percent went to mainland China, 23 percent to South Korea, 11 percent to Taiwan, and most of the remainder to Indonesia and the Philippines. Value of these exports totaled $87 million, 53 percent higher than in 1964. About 19 percent of all fertilizer production was exported. In contrast, nearly 52 percent of the ammonium sulfate production was exported compared with 38 percent in 1964. Exports to South Korea and Taiwan were expected to drop because of new fertilizer plants scheduled soon for operation, but according to trade discussions in progress, mainland China's imports from Japan could expand by as much as 70 percent in 1966–1968. Mitsui & Co., Ltd., continued to handle a large share of the fertilizer export business.

Other Nonmetals.—Besides the use of Japan's widely occurring limestone in cement and for construction it found a variety of less important uses for such products as burned lime, flux, calcium carbide, and fillers. Low-grade domestic gypsum from northern Honshu filled most of the requirements for cement; some byproduct gypsum was also utilized. High-quality gypsum was imported from Morocco and the United Arab Republic to supply needs for the purer material. Pyrophyllite was an outstanding product of Japan and together with feldspars, clays, talc, and silica, contributed to a flourishing ceramics industry. Special types of kaolin were imported from the United States and South Korea. Barite output was adequate for moderate demands; fluorspar, locally not abundant, was supplemented by imports, about one-third of which came from mainland China. Asbestos, generally of short fiber length, was mined in the Yamabe district of Hokkaido (chrysotile) and in Kyushu (amphibole), but most industrial demand was met by imports, of which over half came from Canada.

MINERAL FUELS

Coal.—Japan's 1965 coal output amounted to only about 49.5 million tons, continuing its unabated decline extending back to 1961. Distribution of 1965 production by type was as follows: Steam quality, 35 million tons; coking, 12.4 million tons; anthracite, 1.6 million tons; and natural coke, 500,000 tons.

At yearend, coal reserves in Japan were estimated at about 20,200 million tons, but quality was generally low. Moreover, the price of domestic coal remained relatively higher than foreign coal owing to mining conditions such as depth (average depth of working seams is about 1,200 feet, and the maximum depth in most fields are 3,000 feet), inclination and pitch of seams, faulting, and the gassy nature of many mines. Also the extensive underground workings require relatively long travel time for miners. In some instances, this travel time plus the usual downtime in operations reduced actual productive time to 40 percent of the total shift time. An added consideration was the fact that a substantial portion of Japan's coal reserves are undersea and must be worked by special methods, particularly at the important Kyuslm seams. Approximately 20 percent of the output came from about 15 undersea coal mines.[26] As a consequence of such conditions, the productivity of Japanese coal miners was less than 1 ton per man-shift for underground workers compared to almost 14 tons in the United States.

Kyushu and Hokkaido continued to be the principal producing areas, each accounting for about 45 percent of total output. East and West Honshu accounted for most of the remainder. Seventeen major companies produced 70 percent of the output while about 300 smaller and generally inefficient operators provided the remainder.

High operating costs have raised serious financial difficulties in Japan's coal industry. The cumulative losses of the 17 major coal mine operators by March 1965 amounted to $227.8 million while short-term debt was $474.2 million, and by March 1966 operating deficits were estimated to total $277.8 million and short-term debt to reach $555.6 million. Moreover, in face of these financial difficulties, Japanese coal operators have been compelled to reduce coal prices because of competition from petroleum products. In a rationalization program coal prices were reduced by an average of $3.33 per ton and production methods were realined; changes included substantial reduction of labor force, closing of submarginal mines, and introduction of huge quantities of capital equipment.

To alleviate the interest burden on Japan's coal industry, MITI proposed to sell $333.3 million in bonds to the Coal Mining Industry Council. According to the MITI plan, the 10-year bonds would be issued at an annual interest rate of 3.5 percent to creditors of coal mining companies in the next fiscal year to cover debts accumulated through their reorganization programs. In addition, direct subsidies of $0.56 or more per ton would be paid to cover operating losses, and any increase in railway freight rates would be born by public funds.[27]

Despite generally poor conditions in the industry, there was a mark of optimism. It was reported that Mitsubishi Mining Co. has plans to develop a new coal deposit on Hokkaido. Initial development was sched-

[26] O'Brian, C. L. Some Comments on the Japanese Coal Industry. Canadian Min. and Met. Bull. (Montreal, Canada). V. 58, No. 637, May 1965, pp. 539–546.

[27] Takita, K. Unprofitable Coal. Far Eastern Economic Review (Hong Kong). V. 50, No. 11 Dec. 16, 1965, pp. 524–525.

uled for sometime in 1966 and the start of production for 1970. This will be the first development of a major coal mine in Japan in several years.

Virtually all of the domestically produced coking grade of bituminous coal is consumed by the country's iron and steel industry, while the boiler and anthracite varieties are used for steam generation in thermal power stations, locomotives, and space heating boilers.

In 1965, approximately 16.0 million tons of bituminous coal and 1.1 million tons of anthracite coal were imported. Nearly all of the bituminous coal imports in 1965 consisted of coking qualities, amounting to 15.9 million tons or 93.2 percent of total foreign coal receipts, compared with 1964 figures of 12 million tons or 90.6 percent of the total. Total value of 1965 coal imports was $272.0 million including anthracite coal valued at $19.8 million. The previous year's total was $211.2 million including anthracite coal valued at $21.8 million. The United States continued to be Japan's main supplier of coal in 1965 followed by Australia, the U.S.S.R., and Canada.

Petroleum and Natural Gas.—Japan's petroleum industry continued to boom, relying heavily on foreign investment capital and imported crude and fuel oils, with domestic crude oil production accountable for less than 1 percent of requirements. Oil imports, including products, were valued at $1,304 million in 1965 compared with $1,160 million in 1964; the value of crude oil imports alone rose to $1,031 million in 1965 compared with $931 million in 1964. Imported petroleum represented 16 percent of the total value of all Japanese imports in 1965. The quantity of crude oil imported was 73.3 million tons, 16 percent higher than in 1964; an increase of 13 million tons or 17 percent was recorded in fuel oils. Middle East producers supplied about 88 percent of 1965 crude oil imports. Major oil companies supplying foreign crude oil to Japan included the following, in approximate order of importance: California Texas Oil Corp. (Caltex), Esso Standard Eastern, Inc. (Esso), Arabian Oil Co., Koninklijke Nederlandsche Petroleum Maatschappij N.V. (Royal Dutch Shell), Mobil Oil Co., Union Oil Co. of California, Gulf Oil Co., and Tidewater Oil Co. Arabian Oil, with its Khafji offshore field in the Kuwait-Saudi Arabia Neutral Zone, was the only Japanese-owned overseas crude producer with the exception of one company getting started in North Sumatra.

Consumption, as indicated by domestic refined product sales, increased 19 percent in 1965 to about 535 million barrels. A major factor in the rise was increased use of heavy fuel oil in manufacturing at the expense of coal. Jet fuel increases were associated with expanding international air traffic. Burgeoning petrochemicals took more oil, and naphtha, used largely in fertilizer manufacture, showed a significant consumption gain. Natural gas, a domestic resource, was increasingly important in the chemical industry, in home heating, and other uses. In both consumption and refining, Japan maintained third place in the world after the United States and the Soviet Union. Its total rated refinery throughput capacity rose 17.4 percent to 2,017,640 barrels per day at yearend 1965.

The petroleum share of total energy supplies has grown steadily in recent years. Under Japan's Medium-Term Economic Plan (1964–68), total energy demand in fiscal 1968 (April 1968 through March 1969) is to reach 286 million tons in standard terms of 7,000 kilocalories per kilogram of coal, 1.6 times higher than in fiscal 1963. Energy sources are expected as follows: 65 percent from petroleum, 23 percent from coal, 9 percent from hydropower, and 3 percent from other sources including natural gas and atomic power. The Government is charged under the plan to take measures to assure the stable supply of inexpensive petroleum while maintaining the industry's independence, to disperse supply sources, develop domestic oil and natural gas, build large capacity oil tankers, increase storage facilities, and to rationalize distribution systems.

Table 4.—Domestic sales[1] of refined petroleum products in Japan, 1964–65

(Million 42-gallon barrels)

Product	1964	1965	Percent change
Gasoline	60.9	66.5	9
Naphtha	29.9	46.1	54
Jet fuel	2.7	3.3	22
Kerosine	26.9	31.9	19
Gas oil	30.1	33.9	13
Fuel oil	254.6	298.6	17
Lubricating oil	8.7	9.1	4
Asphalt	7.2	8.3	15
Greases	.3	.3	--
Paraffin	.4	.5	25
LP gases[2]	27.8	36.4	31
Total	449.5	534.9	19

[1] Sales by refiners, importers, and dealers to domestic end users.
[2] Includes producers private consumption.

Japanese overseas operations in 1965 provided an estimated 15 percent of imported crude, nearly all high-sulfur oil from Khafji in the Kuwait-Saudi Arabia Neutral Zone. In North Sumatra, the Japanese North Sumatra Oil Development Cooperation Co., Ltd. operated the Rantau, Paluh, and Tabuhan fields under a production sharing agreement with Permina, and Indonesian Government oil corporation. Several prospecting and other development programs were underway in Indonesia, Sabah, Canada, and Alaska. Far East Oil Trading Co., established for the purpose of importing Indonesian oil, was expected to handle about 6 million barrels of crude oil imports in Japan's fiscal 1965 (ending March 31, 1966), increasing to 12 million barrels annually in fiscal 1967 and thereafter. Idemitsu Kosan Co., Ltd., the largest importer of Soviet crude oil and grade C fuel oil, was expected to increase its crude imports from the Soviet Union to about 15 million barrels annually following trade discussions with that country.

In 1965, 20 refining companies with 37 refineries were in operation in Japan. Of the refineries, 28 with 95 percent of the total capacity were located on the east coast, 7 on the west coast, and 2 in Hokkaido. Some major foreign company affiliations with Japanese refiners, with foreign capital shares totaling 50 percent in each case were these: California Texas Oil Corp.-Koa Oil Co., Ltd., and Nippon Petroleum Refining Co., Ltd., Tidewater Oil Co.-Mitsubishi Oil Co., Ltd., Anglo-Saxon Petroleum Co. (United Kingdom)-Showa Oil Co., Ltd., and Esso Standard Eastern, Inc., and Mobil Oil Co.-Toa Nenryo Kogyo K.K. Other affiliations through loans and investments included Union Oil Co. with Maruzen Oil Co., Esso with General Sekiyu Co., Ltd., and Shell with a Showa subsidiary, Showa Yokkaichi Sekiyu Co., Ltd. Most companies maintained close relations with their Japanese partners, providing technical assistance, financing when needed, crude oil supply, marketing, and other services.

There was no letup but some government restraint in the continuing trend of expansion and integration of refining units. Several hydrocracking units for producing liquefied petroleum gases, (LPG) gasoline, and kerosine were completed or under construction in 1965. Hydrotreatment plants for processing lubricant oils were gaining in use. Production of hydrogen from light naphtha was becoming important. Proposed investment in refining set for 1965 was 12 percent higher than in 1964, rising to about $191 million, nearly one-fourth of this for new refinery construction. Scheduled for 1966 were two topping plants, adding 155,000 barrels per day capacity, and two reformer plants, adding 12,100 barrels per day to reforming capacity. Among additions in progress in 1965 were four topping, five catalytic reforming, and two hydrocracking plants.

Showa Oil, whose refinery at Niigata was virtually destroyed in the 1964 earthquake, was completing a new 40,000-barrel-per-day plant there and a merger of Showa with Shell Sekiyu, Royal Dutch Shell's subsidiary, was discussed. Shell had helped finance Showa's rebuilding. Idemitsu Kosan Co., Ltd., planned an 80,000-barrel-per-day refinery at Himeji, near Osaka, and a 30,000-barrel-per-day hydrodesulfurizing plant at either Himeji or Chiba. The latter would be one of Japan's first major plants for desulfurizing heavy grade C fuel oil. Negotiations were in progress with Gulf Oil Corp. for a $40 million loan on the project tied in with a supply agreement with Gulf for Idemitsu to purchase 150 million barrels of Kuwait crude oil over a 15-year period.

Fuji Sekiyu, Ltd., formed by a consortium of Arabian Oil and others, was expected to receive a $20 million loan from Gulf Oil to build a 70,000-barrel-per-day refinery at Chiba tied to a contract with Gulf to supply three-fifths of the crude oil requirements, probably from Iran's Gach Saran field, the rest coming from Khafji. Among companies scheduled to increase capacity in fiscal 1966 were Mitsubishi Oil Co., Ltd., at Mizushima, Maruzen Oil Co., at Chiba, and Asia Oil Co., Ltd., at Yokohama, together adding 155,000 barrels per day by April 1967. Other refiners permitted to expand included Idemitsu, Toa Oil Co., Ltd., and Nichimo Oil Co., Ltd., with plants of 80,000, 60,000 and 30,000 barrels per day capacity, respectively, due for completion by April 1968; new firms, Kyokuto Oil Co., Ltd., and Kansai Oil Co., Ltd., were authorized to build 60,000-barrel-per-day plants at Chiba and Sakai, respectively, for completion in October 1968; Fuji Sekiyu, Ltd., received authority to build a 70,000-barrel-per-day plant at Chiba (see previous Gulf Oil negotiations)

and Seibu Oil Co., Ltd., for a 50,000-barrel-per-day plant in Yamaguchi Prefecture in fiscal 1969. Shell Sekiyu concluded a basic agreement with the last-named Seibu for its financing and product sales. The flood of activity on new refineries brought a recommendation from the Petroleum Council, a government advisory body, that no further applications for construction be accepted until 1973.

Major domestic marketers of oil products were Nippon Oil, with about one-fifth of total sales, followed by Idemitsu with one-sixth. A new joint sales company was formed under government guidance in July by Nippon Mining, Asia Oil, and Toa Oil, the three together accounting for 12 percent of the domestic product market, and a similar arrangement was being considered for Maruzen Oil and Daikyo Oil, having about 9 and 5 percent of the market, respectively, in 1965. A proposed merger of Showa Oil and Shell Sekiyu would give the resulting company about one-eighth of the total market. Japan had about 21,000 service stations operated by 14 companies during 1965 and was building new stations at the rate of 1,500 annually.

Domestic crude oil production on west coast Honshu continued to decline from the high in 1963 and was several percent lower than in 1964. Natural gas output from the same general area declined 4 percent in volume. Teikoku Oil Co. produced about two-fifths of all natural gas and oil in Japan, with quasi-Government Japan Petroleum Exploration Co., Ltd. (Japex), accounting for most of the balance of crude oil and nearly one-fourth of the natural gas output. Natural gas was used increasingly for production of ammonia and methanol, principally in Niigata, Akita, and in Yamagata Prefecture. Import of liquefied natural gas to these areas was in the planning stages. Tokyo Gas Co. was preparing a request for government permission to import 315,000 barrels of liquefied natural gas annually starting in 1968. As plans materialized, it appeared that Alaska would be at least one source, with U.S. and Japanese companies cooperating to probably build a liquefaction plant near the Alaskan coastal town of Nikishka. Over half of the natural gas consumed went to the chemical industry in 1965. The largest gasfield was Kubicki, producing 1.4 million cubic meters of gas daily, and including offshore wellheads. Japex also had offshore operations near Akita where oil was produced from the Tsuchizaki field.

Overseas oil transportation and the trend to large tankers has been an exceptional feature of the Japanese industry in recent years. Japan has become the world's leading shipbuilder and provides tankers not only for itself but for many other countries too. One of the newest superships is a 160,000 deadweight-ton tanker to be delivered to its Norwegian owner in 1967. Idemitsu Oil has announced plans for a 205,000 deadweight-ton tanker to operate in conjunction with its Himeji refinery due for startup in April 1968, and larger ships are on the drawing boards. One of the world's largest LPG tankers was launched in 1965 in Japan. It was designed to carry 46,100 cubic meters of liquefied propane and butane and will operate between Kuwait and Japan.

The Mineral Industry of North Korea

By J. M. West [1]

Minerals and mineral processing contributed more than one-half billion dollars to North Korea's economy in 1965, a sum greater than that produced in any other Far East Asian country except Japan and mainland China, and triple the output value of South Korea's mineral industry. Furthermore, in per capita terms, the nation ranked second only to Japan in the Far East in mineral and metal output value. In world standing, North Korea was among the first five in output of tungsten, graphite, and magnesite. The country was important for lead, zinc, pyrite, and barite production also, besides having a notable production of coal, iron ore, pig iron, cement, gold, copper, bismuth, cadmium, fluorspar, phosphate, salt, and talc.

There seemed little doubt that important advances were made in expanding electric power, coal, and iron ore facilities in 1965. Gross industrial output value was reportedly 14 percent more than that of 1964, and investment in the mining sector was reportedly 72 percent higher. Overall mine output gained approximately 12 percent in value.

Although no conversion rate for the North Korean won is established, an idea of the share of the national budget allotted to minerals can be had by comparing a few published figures. Capital investment in mining, 67 million won in 1963, rose to 82 million won in 1964, and was 80 million won in the first half of 1965. Capital construction in 1964 totaled 680 million won, and total expenditure, according to the 1964 budget, was given as 3,418 won. Hence, mining was allotted about 12 percent of the total capital construction funds and 2.4 percent of the total expenditures in that year. The 1965 budget called for increased spending to 3,722 million won, including 879 million won for heavy industry and 124 million won for light industry.

An intensive drive underway in 1965 to expand coal production showed signs of success. Strip mining in particular was responsive. Greater overall labor efficiency was claimed, as represented by a 12-percent increase in industrial productivity, although such gain was not reflected in wages. The extractive industry was said to have been supplied in the first half of 1965 with 45 new excavators, 500 vehicles, 90 trams, 200 mine cars, 100 air compressors, 200 winches, and 3,600 rock drills. Major advances were made at the Musan iron mine. New blast and open-hearth furnaces were opened at the Hwanghae steel plant. Facilities were renovated and expanded at the Kimchaek steel plant and at the Namp'o and Munpyong nonferrous smelters. Also during 1965 the completion of 35 big pits and 29 medium and small ore mines was reported. Besides varying progress on a number of ore dressing plants, approximately 130 small-to-medium coal mines were said to have opened.

Hydroelectric plants suffered from dry weather and operated below capacity, but new thermal installations more than made up the deficiency. Construction of a new railway linking the east and west coasts, Pokkye to Chihari to Pyongsan, made progress, and the Chongjin railway, extending to the Chinese border, was opened. About one-fifth of North Korea's railways have been electrified. Double tracking of the Musan-Komusan line continued, as did electrification of the Pyongyang-Sinsongchon line.

---

[1] Far East specialist, Division of International Activities.

PRODUCTION

Estimates of production value for the North Korean mineral industry, including value added by primary processing, indicated a possible 18-percent gain in output over that of 1964 to a value of roughly $520 million. Greatest gains were in coal and steel, which contributed slightly less than one-third and one-quarter, respectively, of the total value. Such increases roughly paralleled a reported 14-percent increase in gross industrial output value for 1965, slightly less than the 17-percent increase claimed in 1964, and seemed to substantiate reports of good progress in North Korean economic development. Other outstanding mineral products, in approximate order of value, were iron ore, pig iron, cement, zinc, lead, copper, and magnesite. Despite apparent successes in achieving some mineral production goals the output figures for steel and cement were less than the announced targets.

Table 1.—North Korea: Production of metals and minerals [1]

(Metric tons unless otherwise specified)

Commodity [2]	1961	1962	1963	1964	1965

Clinker, do	100	200	385	400	400
Pyrite, do	300	350	400	420	450
Salt, do	392	421	450	400	500
Talc and soapstone	15,000	20,000	20,000	20,000	20,000
Mineral fuels:					
Coal:					
Anthracite, thousand tons	7,500	9,000	9,700	11,200	14,900
Bituminous [5], do	4,000	4,000	4,000	4,000	4,000
Other, do	290	200	340	300	300
Total, do	11,790	13,200	14,040	15,500	19,200
Coke, do	900	1,100	1,200	1,400	1,600

[1] All figures are estimated, except for iron and steel items (ferroalloy data are estimated), magnesite (1963 only), salt (1961–62 only), and coal. The firm figures are official North Korean data.

[2] Many other mineral commodities are produced, but reasonable output estimates cannot be made. These include antimony, beryl, bismuth, chrome, cobalt, manganese ore, mineral sands (ilmenite, zircon, columbite, rutile, monazite), minor and rare metals (selenium, tellurium, germanium, indium, silicon), molybdenite, alum, arsenopyrite, asbestos, boracite, clays, kaolin, lepidolite, limonite, mica (phlogopite), and silica (including glass sands).

[3] 1961 data apparently represent crude ore, most of which was 30 to 40 percent iron grade. 1962–65 data undoubtedly included some concentrates.

[4] Includes Krupp-Renn granulated iron or luppe.

[5] Low calorific value, much of which might be classified as low-rank coals.

TRADE

Mineral and metal exports were important components of North Korean trade, possibly on the order of 15 percent of the total value of trade in 1965. Of first importance has been trade with the Soviet Union, second with mainland China, and probably third with Japan. Japan's imports, mostly metals and ores from North Korea in 1964, were valued at about $20 million. Minerals also have been traded with the East European countries, metallic lead is an outstanding example, and some trade appeared to be developing with West Europe, notably France. Specific trade information is not available from official North Korean sources nor is mainland China's trade reported. In the absence of official statistics, mineral imports from North Korea by the Soviet Union and Japan and petroleum exports by the Soviet Union to North Korea have been provided to indicate trends.

Available 1964 data show a general decline in the Soviet imports from North Korea compared with the 1964 imports, although rolled steel, zinc metal, and talc tonnages were all higher. A decline was registered in Soviet petroleum product exports to North Korea; the total was 437,500 tons in 1964 compared with 451,300 tons in 1963. Soviet exports to North Korea in 1964 also included 5,400 tons of ferroalloys, 10,182 tons of iron and steel semimanufactures, 1,700 tons of nonferrous metals and alloys of which 633 tons was in rolled products, and 800 tons of asbestos. Japan's purchases were moderately diversified and included a number in the metal and nonmetal categories. Iron concentrates from North Korea's Musan mine and zinc concentrates going to Japan marked significant increases in 1965, but pig iron shipments declined. During 1965 North Korea imported approximately 35,000 tons of iron and steel products, 1,437 tons of chromium ore and concentrate, and ferroalloys, including 840 tons of ferronickel, 305 tons of ferrotungsten, and 375 tons of other ferroalloys from Japan. In 1964 Japan exported 327 tons of ferrovanadium to North Korea. Lead ingot exports to the Soviet Union and East Europe were reportedly rising in the second half of 1965; European shipments

Greases	2,100	1,400
Paraffin	1,500	1,700

[1] The U.S.S.R. is North Korea's main source of petroleum. Data are derived from official export statistics of the Soviet Union.

from North Korea were said to have reached several thousand tons monthly.

Another agreement was signed to supply mainland China in 1965–66 with commodities including magnesia clinker, anthracite, magnetite and other ores, pig iron, rolled steel, cement, and chemical products in exchange for Chinese coking coal, coke, petroleum products, ores, chemical products, rolled steel and metal alloys. A considerable increase in overall trade with China was proposed. An agreement with the Soviet Union called for North Korea to export rolled steel, various special steels, nonferrous metals, magnesia clinker and other nonmetals, building materials, and chemicals in exchange for Soviet machinery, oil products, ferrous and nonferrous rolled stock, and chemicals. Trade was to exceed that of 1965. A French company voiced interest in establishing a long term contract for purchase of North Korean nonferrous metals, iron and steel products, and cement. Japanese officials studied ways by which private Japanese trade associations might transact trade agreements with North Korea without involving the Japanese Government.

COMMODITY REVIEW

METALS

Iron Ore.—Nearly one-fourth increase in iron ore output was claimed in 1965; output during the first half of the year was 520,000 tons greater than in the first half of 1965. The Musan mine, in the northeast, provided 138,000 tons more concentrate than in 1964. Efforts were to be made in 1966 to fulfill output plans in 11 months and produce 200,000 tons of concentrate above the amount planned during the year. This would place Musan production at about 2.4 million tons in 1966. Musan's mill was expanded and magnetite recoveries increased several percent. At the Mandok magnetite-pyrite-copper mine in Hamgyong-Namdo, a large new mill with annual capacity of 560,000 tons of ore was in operation. In the western part of the country, Hasong, the Unyul (Ullyul), and several other iron mines jointly produced about one-tenth more than in 1964.

Iron and Steel.—The biggest news in the iron and steel industry was the negotiation between Vereinigte Oesterreichische Eisen- und Stahlwerke A.G. (VOEST), the important Austrian steel firm, and the North Korean government for construction of a $30 million Linz-Donawitz (L-D) steel plant with an annual capacity of 600,000 tons of steel. Location for the plant was not revealed, but Musan wtih its large iron ore reserves and rail links to mainland China's coking coal producing area was considered the likely choice. Progress on arranging financial backing was not disclosed.

Outputs of ingot and rolled steel during the year increased 9 and 14 percent, respectively. In comparing progress in the first half of 1965 to the corresponding period of 1964, blast furnace utilization of capacity increased 4 percent, and average steel output of open-hearth furnaces, per square meter of furnace area, increased 12 percent. Consumption of electric power per ton of steel declined 3.5 percent. A 50,000-ton blast furnace, No. 5, was completed at Hwanghae, where through the first 9 months of 1965, 80,000 more tons of steel was produced than in the corresponding period of 1964. The plant also placed in operation a new 200 cubic-meter open-hearth furnace, No. 6. Hwanghae was credited at the beginning of 1965 with 400,000 tons of annual steel capacity. At Kimchaek, the No. 2 blast furnace, with renovation and automatic controls, was said to have increased capacity by 80 tons of heat. The No. 1 furnace was also undergoing expansion.

The steel industry produced more than 20 major varieties of rolled products in 1965. Improved balance of products according to types and sizes was achieved, and at the Kangson and Songjin Steel Works, high-

speed steel and single-seam pipe production processes were improved. Songjin's No. 3 electric furnace was modernized. Output of rolled steel and of pig iron and luppe (granulated iron) exceeded plans for the first quarter of 1966 by 4 percent, indicating that continued advances could be expected during 1966. Targets previously set for 1967 included 2.3 million tons of pig iron and granulated iron, 2.3 million tons of steel, and 1.7 million tons of rolled steel products. The Chongjin Steel Works produced mainly luppe and was boosting output. A drive was started to collect and conserve scrap steel, suggesting a shortage in that commodity. It was necessary to import iron and steel products, some ferroalloys, and chromite in 1965 to supplement production.

Nonferrous Metals.—Nonferrous ore output was reported about 8 percent higher in 1965. Output of the Hungnam smelter, a major nonferrous metallurgical plant on the east coast, surpassed planned quotas in 1965. Also the value of production rose 44 percent from that of 1964, largely a result of higher metal prices. At the Namp'o copper-zinc smelter on the west coast, the No. 2 nonferrous rolling mill was completed, and at the Munpyong lead-zinc plant, the second Waelz kiln was installed. Mill expansions were completed at the Komdok lead-zinc mine and at the Nagyon, Kyongsu, and Tanchon mines.

A number of small-to-medium-sized mines were being reopened. Tunnel advance in these mines, during the first half of 1965, was about two-thirds greater than in the first half of 1964. Automatic control devices were installed at a number of mines, including the Songhung, North Korea's largest gold-silver-copper mine, where a pyrite flotation plant has been opened. Recent major mine developments were made at Hochon, the Kyongsu, and Tokyon mines; recently reopened or expanded were the Holtong, Manyon, and Taeyutong mines, the last-named a major gold-copper-scheelite producer. The Yongyang mine, in South Hamgyong Province, and the Manyon mine were said to be making good progress at the turn of the year.

Cement.—Less Soviet demand for North Korean cement apparently was responsible in part for the 1965 production decrease of 8 percent, approximately 210,000 tons. Soviet imports had fallen during 1963–64 by 172,000 tons, but mainland China remained an important market. Some six cement plants are active in North Korea. One of the smaller plants, the Komusan, increased output 70 tons daily through a one-third expansion in grinding capacity. The Haeju cement plant made minor improvement.

Fertilizer Materials.—The 1964 fertilizer production target of 950,000 tons apparently was not reached. Only 640,000 tons was reported delivered to farmers, indicating distribution problems. Output in 1965 was 5 percent lower than in 1964, but was probably higher than the 853,000 tons reported in 1963. Larger quantities reached the market in the first half of the year than in the corresponding period of 1964. Fertilizer facilities were being expanded in 1965. The first phase of a synthetic ammonia plant, based on gasification of coal, was completed at the Hungnam fertilizer plant. Progress was made on an ammonia plant at the Aoji Chemical Factory, on the No. 2 carbide plant at the Pongung Chemical Factory, and on a nitrogenous fertilizer plant at the Chongsu Chemical Factory. The Sunchon nitrogenous fertilizer plant was also expanded.

Large quantities of apatite were mined for making superphosphate, and pyrite was recovered for its sulfur from metallurgical plants to meet requirements. A new pyrite recovery plant, with an output capacity of 20,000 tons of concentrate yearly, operated at the Songhung mine.

Magnesite.—Production estimates have been based largely on reported magnesia clinker output for 1963. Output has grown significantly since 1960. The U.S.S.R. has received considerable tonnages of clinker each year. China and Japan have also been markets. Large reserves of magnesite were reported in 1962, with estimates ranging from 1 to 6.5 billion tons. One of the important areas is in the Machon Mountain Range along the borders of Hamgyong-Namdo, Hamgyong-Pukto, and Yanggang-Do.

Silica.—Silica production at the Yongan so-called "silicate ore" plant in North Hamgyong-Namdo increased and probably contributed to the reported 9-percent rise in plate glass production during 1965.

MINERAL FUELS

Plans were disclosed for construction of North Korea's first oil refinery, although the location was not given. Crude oil, together with technical assistance, is to be supplied by the U.S.S.R.; capacity will be 40,000 barrels per day. Petroleum product imports from the U.S.S.R., which declined 3 percent from 1963 to 1964, apparently were being replaced by increasing imports from China in 1964 and 1965.

Electrical power output increased 7 percent in 1965, even though some hydroelectric plants failed to operate at full capacity, because of a dry season. The Pyongyang thermal electric plant reached two-fifths of its planned 500,000-kilowatt capacity with the installation of its fourth generator. The 260,000-kilowatt Kanggye Youth Power Station (hydroelectric) was in operation, the Songwoncho and No. 3 Chongdan powerplants came on line, and construction continued on the 400,000-kilowatt Unbong powerplant, as well as on many smaller plants including the Kuan and Hasinwon. Power output was said to have increased by 627 million kilowatt-hours during 1964, reaching a total of 12,393 million kilowatt-hours.

Coal.—Coal output during the first half of 1965 exceeded that of the corresponding half of 1964 by 1.62 million tons and for the year increased 25 percent over the total output in 1964. Increases were attributed to a one-third rise in anthracite output. Strip mines, in particular, were active, and about 130 small-to-medium-sized mines, mostly of 10,000 tons or less annual capacity, were opened. Among the larger mines operating were the Anju, Aoji, Hamyon, Kocham, Kogonwon, Onsong, Yongdong, and Yongnon. New shafts were constructed during the year at the Anju, Aoji, Hamyon, and Kogonwon mines. At Anju, output increased by 15,000 tons and good progress was made on the concreting of passageways; Yongdong's output rose 70,000 tons in the first 11 months of 1965 and the need for timbering decreased. More steel roof supports were in use, and most coal was said to be transported by machine in the larger pits. During the first half of 1965 overall mine development work included 144,000 meters of tunneling and 43,000 meters of concreting.

Major strip mines included the Choyang, Hungnyong, and Sinchang; new ones were opened in the Hokyong, Hyongpong, Masin, and Yongtae areas. Equipment installed in new strip mines included 16 large excavators, 10 bulldozers, and 90 heavy-duty trucks. Both the amount of stripping and coal output from open cut mines doubled.

Small-to-medium-sized mines produced approximately 2 million tons more than in 1964 and accounted for one-fifth of the total coal produced. Improvements were made at a plant in Hoeryong where coal mining equipment is being manufactured.

The Mineral Industry of South Korea

By J. M. West [1]

Progress toward industrialization of this basically agricultural country of over 28 million people with only limited mineral resources was outstanding in 1965. The mineral and quarrying sector supported by Agency for International Development (AID) geological and engineering assistance, made impressive gains, showing a growth rate of 14.8 percent and contributing 2.9 percent (on value added basis at 1960 constant prices) to the gross national product (GNP). Extractive industry gains were estimated at 30 percent, based on current prices, reflecting in part the inflationary trend. This compared with a net GNP rise estimated at 8 percent in 1965. In mineral processing, the manufacture of cement, iron and steel, fertilizers, and refining of petroleum accounted for approximately 2 to 3 percent of the GNP.

Coal, tungsten, and iron ore remained the principal crude mineral products. South Korea supplied about 6 percent of the world's tungsten and nearly half of its graphite (largely the amorphous variety). Nonmetallic minerals were becoming more important, and fertilizers, in particular, were due for great expansion with construction starting or about to start on at least three large plants to supplement imports. During 1965 construction began on another cement plant, the Ulsan oil refinery reached capacity and was due for expansion, and coal mine output continued to rise.

Tungsten production failed to respond to stronger markets, apparently because of mine problems. An iron ore development, Hongchon Chaun, northeast of Seoul, appeared promising as the supply base of a much-wanted integrated iron and steel mill. Electric power, given high priority in government planning, contributed greatly to the economy, with a large increase in 1965 and more to come as about 6 new installations were expected on line in 1966–68. Thermal power, mostly from coal, supplied about 72 percent of the electrical output. Mining costs increased as wholesale price indexes went up 15 percent for fuels and power and 18 percent for building materials, chiefly cement.

A proposed Foreign Capital Induction Law under review late in 1965 contained the provision that foreign investors could repatriate dividends without limit. If this provision were to remain in the final act, it would be an important inducement for foreign participation in South Korean industry. New foreign investments were being actively promoted through industrial feasibility studies financed by a $2 million AID loan approved in September. Besides approving some major investments, the Government guaranteed various commercial loans, including the largest to date—$44 million for a Japanese-financed fertilizer plant—and at least one technical assistance contract for Kukdong Oil Corp.

In search of a way to control excess foreign capital inflow from a single source, the Government considered forming an international investment consortium. Normalization of relations with Japan drew nearer, and massive Japanese investments were being arranged in anticipation, including $200 million in government loans and $300 million in private commercial loans.

Government-owned enterprises continued to dominate such major enterprises as electric power, steel, oil refining, coal, railroads, tungsten, base metal refining, and fertilizers. President Pak Chong-Hui announced in his State-of-the-Nation address plans to build thermal powerplants in Seoul and elsewhere, an integrated iron

[1] Far East specialist, Division of International Activities.

and steel mill, an aluminum refinery, another major cement plant, and to establish other industrial centers similar to the one at Ulsan.

The second 5-year Economic Development Plan, being drawn up to go into effect in 1967 and concentrating on industrialization, called for doubling the GNP in 1971. An integrated transportation investment plan was being prepared for 1967–71 with the help of the International Bank for Reconstruction and Development. To expand foreign trade, the Government took steps to liberalize restrictions, particularly emphasizing export development.

In other developments, U.S. scientists examined the feasibility of joining with South Korean scientists in establishing an Institute of Applied Science and Industrial Technology; electrification of the Seoul-Inchon Railway was considered after double tracking the line.

The Government was especially active in electric power. Following multiple-purpose development studies with U.S. Department of the Interior assistance in the Han River Basin, the Government announced a 10-year plan for construction of nine dams, four each on the Han and Naktong Rivers and one on the Kum River, to generate a total of nearly 500,000 kilowatts. The first of these, an 80,000 kilowatt French-financed installation was getting underway at Paltang at yearend. Japanese credits were to be used for hydroplants at Chungju (150,000 kilowatts); Tanyang (86,000 kilowatts); at a site on the Soyang River (90,000 kilowatts); and to add a third 40,000-kilowatt unit to the Chongpyong hydroplant. Thermal powerplants were planned for completion at Seoul by 1968 (125,000 kilowatts) and at Yongnam by 1969 (150,000 to 200,000 kilowatts). Advance planning for the 125,000 kilowatt Yongdong plant, on the east coast, indicated that a site closer to coal mines was desirable. The 50,000-kilowatt second generator at Yongwol went into operation in June.

PRODUCTION

Mineral production including processing value rose an estimated $12 million, about 7 percent over that of 1964, the greatest gains again having been in cement, with nearly a 40-percent increase, and in coal, 6 percent higher than in 1964. Mine production indices, however, declined 4 percent for metals and 10 percent for nonmetals, as export demand lagged for such minerals as amorphous graphite and kaolin. Output of gold and silver fell behind during installation of a cyanide treatment plant at Changhang, and tungsten production was held back by the need for development work at Sangdong, where all but about 5 percent of South Korea's tungsten is mined. Output of fertilizers by two plants was higher than the approximately 130,000 tons produced in 1964. Oil refining at Ulsan reached capacity and was adequate for most domestic needs. Electrical power output rose an impressive 20.4 percent in 1965 to 3,249 million kilowatt hours, much of the increase attributed to new thermal plant capacity, thus calling for more coal.

Table 1.—South Korea: Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	1964	1965
Metals:

[1] Previously reported as quartzite.

[2] Production started in March 1964 at Ulsan refinery; 1964 data as reported by Korea Oil Corp.

TRADE

The following tabulation indicates the relative changes in major components of South Korean mineral trade between 1964 and 1965:

	Value (million dollars)	
	1964	1965
Exports:		
Metalliferous ores (mainly tungsten and iron)	13.2	17.8
Iron and steel	4.5	12.7
Other metals and products	2.9	2.9
Nonmetals and products	1.9	2.8
Anthracite coal (including coke and briquettes)	2.4	1.9
Total	24.9	38.1
Imports:		
Fertilizers	55.9	66.0
Petroleum and products	25.9	28.9
Iron and steel	14.8	24.7
Nonferrous metals and products	4.2	9.0
Bituminous coal	2.5	2.4
Total	103.3	131.0

Crude mineral exports rose in value from $21.8 million in 1964 to an estimated $27.6 million and comprised about 15 percent of overall exports, which were valued about $180 million, nearly half again the previous year's total. Besides crude minerals, $12.7 million worth of iron and steel products was exported in 1965 compared with $4.5 million in 1964. The rise is largely attributed to shipments of galvanized sheets, imported as plain sheets from Japan, coated, and exported to South Viet-Nam. In base metals, new export products were copper scrap and plate; lead metal was to be exported for the first time. Nonmetallic mineral exports rose in value, probably because of initiation of cement exports, including white cement, in late 1965.

Imports of mineral products were higher in 1965, with $10 million increases each in the fertilizer and iron and steel categories. More nonferrous metals and petroleum were imported, the oil largely in crude form since the start of refining operations. Japan's share of trade was increasing, both as a result of normalizing relations with South Korea and gradual cutback of AID-supported trade. In 1965, AID financed only 30 percent of total imports compared with 85 percent in 1957 and 62 percent in 1962. Both Japan and the United States were large suppliers of fertilizer and iron and steel products. A number of simplifications were made in South Korea's trade system [2], and a fluctuating exchange rate was placed in effect, with a lower limit of 255 won to U.S. $1.

[2] U.S. Department of Commerce. Korea Eases Import Restriction, Adopts Fluctuating Exchange Rate. Internat. Commerce, v. 71, No. 18, May 3, 1965, p. 24.

COMMODITY REVIEW

METALS

Iron Ore and Steel.—Development of the country's iron ore resources was making good progress, and iron ore output rose for the year despite heavy midyear rains that hampered mining. The Mulkum mine, northwest of Pusan, and Kyongin mine, west of Seoul, largely responsible for the spurt in 1964 output, were fully operating, and a new mine was scheduled to start production at Ulsan. Ore exports to Japan continued to rise; imports of iron and steel products also increased. Sizable tonnages of iron and scrap from the United States were consumed in the domestic steel industry. Annual steelmaking capacity was estimated at 275,000 tons,[3] with rolling capacity at about 400,-

[3] U.S. Embassy, Seoul, South Korea. Department of State Airgram A-119, Sept. 26, 1965, 2 pp.

000 tons. Seoul, Pusan, and Inchon were the main centers. Inchon Heavy Industry Corp. operated the largest plant, equipped with a 70,000-metric-ton open hearth furnace, a 100,000-ton blooming and medium section mill, a 18,000-ton sheet mill, and a 10,000-ton galvanizer.

A significant discovery of iron ore was made in following up favorable aerial surveys, and the property known as the Hongchon Chaun iron mine near Chaun-ni, about 65 kilometers northeast of Seoul, was under development. Limited core drilling indicated probable ore reserves of 25 million tons, and possibly twice this amount, containing 35 to 40 percent iron. The ore is said to contain several percent manganese; phosphorus in the form of apatite, which tests indicate can be removed; and a carbonate gangue. Proven reserves at the Soyonpyong-do Island titaniferous magnetite iron mine were listed at 2.7 million tons, as outlined by the current drilling program. The Wongdong iron mine, east of Hwanghii, Kangwon-do, was producing 1,000 tons per month of 56 percent ore for Samhwa Iron Manufacturing Co., South Korea's only pig iron producer, whose capacity was being expanded to 36,000 tons annually. Diamond-drilling of geophysical anomalies was proceeding at Kyung In iron mine; ore from the Okchon iron mine was going to a smelter in Pusan; and the Puk Samchok iron mine produced about 1,000 tons monthly.

At least two proposals were being considered for new iron and steel plants. One, with a designed capacity of 300,000 to 400,000 tons of ingots, would be financed by a $22 million Japanese loan and be constructed by Choil Iron Manufacturing Co. (South Korea). The other would be for addition to the Government's Inchon Heavy Industry plant, possibly financed in part by West German companies, providing an added 125,000 tons of ingot capacity plus fabricating facilities. Public sale of shares in the Inchon plant was discussed as a means of financing.

Outlook for iron and steel indicated a rise in demand to 710,000 tons annually by 1975. Current demand for cold-rolled sheet alone has been estimated at 3,000 to 4,000 tons monthly. Japan's Yawata Iron & Steel Co. Ltd., contracted to supply a South Korean firm with a 5,000-ton per month thin-plate and sheet-rolling reversing mill and to furnish necessary feedstock. A procedure by which cold-rolled sheets were imported from Japan on consignment, were galvanized, exported to South Viet-Nam, and were paid for by AID funds was found to contradict AID procurement rules, and such trade was stopped in November. However, later in December restrictions were removed under conditions that all dollar earnings from steel products be used to import U.S. raw material or certain goods of U.S. origin. Kyung Sung Industrial Co., Ltd., of Seoul, in view of pipe demand for urban water supply lines, applied for $430,000 in AID funds to set up large-diameter pipe facilities to produce 8,000 tons annually. A Japanese industrial group studied feasibility of an integrated steel mill, possibly at Pusan.

Tungsten, Bismuth, and Molybdenum.—Despite improved world prices and firm demand, tungsten output declined again as it has every year since 1961, because of the hesitancy in expanding the famous Sangdong mine. The Government-owned Korea Tungsten Mining Co. Ltd., operator of the large mine, was starting on a 3-year expansion program aimed at development of a 15-to 20-year ore reserve, the first phase included a major shaft-sinking project made necessary because of the depth of the workings—over 2,000 feet. In the mill, plans were made to expand daily flotation capacity from 1,200 to 1,800 tons of ore. Mill tests showed that better size distribution and other operating improvements could raise capacity. Tungsten was recovered both as flotation concentrate and from middling and off-grade ores as synthetic scheelite. Average overall recoveries of tungsten were about 76 percent.

Bismuth and molybdenum concentrates from flotation were treated at the Yongdongpo refinery; a low-grade molybdenum byproduct from chemical treatment was sold separately. Doré (gold and silver bullion) was recovered in Seoul from crude bismuth metal. In the area around the Sangdong mine, geophysical and soil surveys showed promising anomalies and more detailed studies were recommended. The Wolak tungsten mine in Chungchong Province continued production at a rate of 50 to 60 tons of wolframite concentrates plus 8 to 10 tons of molybdenite concentrates annually. Bismuth was recovered by onsite roasting. A disseminated molybdenite deposite, thought to be sizable, was discovered

bordering a stock of Pulkuksa granite during geochemical sampling in the Toktong-Choyang area, and a detailed geological study of the area was urged. Exploration at the Dalsung tungsten mine showed favorable gold/silver values, and vein sampling continued. At the Changsu molybdenite mine, a heavy mineral survey of the area was unsuccessful, but mine reserves were increased and a small mill was being built after pilot mill testing.

Copper, Lead, Zinc, and Gold.—Still unresolved were troubles in blending stockpiled ores from many sources at the Changhang smelter to achieve proper plant feed. Complex ores were separated at Changhang in a flotation mill, copper concentrates treated in a copper circuit, lead in the lead plant, zinc concentrates sold, and pyrite tailings cyanided along with other gold-silver ores. In the copper section a pelletizer and second blast furnace and converter went into operation. Monthly output reached about 320 tons of blister copper by yearend. Cupola furnaces melted brass shell casings. The electrolytic copper refinery produced 229 tons of cathodes and 5 tons of copper sulfate during November. At the lead plant, a 3-month shutdown of the reverberatory furnace was necessary for flue repairs, but in November 141 tons of refined lead bar was produced. Roasting of lead ores was troublesome and attempts to recover metals lost in flue dusts continued; successful pilot plant recovery was made of an 82 percent arsenic trioxide product. A brief test was run at the new cyanide plant before going into operation. In May, it was necessary to close the flotation plant for lack of fresh water. From tests it was determined that saline water could be substituted from the Kumi River, and although some smelting loss was expected because of chlorides, operations were resumed using this supply.

Appreciable reserves of 1.5 percent copper ore were developed at the Il Kwang mine, north of Pusan, formerly the country's largest copper producer; exploration continued with plans to rebuild the mill and operate at 200 ore-tons per day in 1966 shipping to Changhang. Pilot plant milling was considered at the Chilgok and Kwimyong lead-zinc-copper mines, and the Yeong Hwa lead-zinc mine was getting a portable crushing plant. Taisung Industrial Co. dedicated a 100-ton-per-day copper-and-zinc flotation mill at its Mooil mine in Kyongsang Province, where 200,000 tons of reserves have been developed. The Renka mines, supplying Toho Zinc Co. Ltd., in Japan, were expanding monthly output to 15,000 ore-tons. This was expected to yield 1,200 tons of zinc and 900 tons of lead concentrates. Suiho Mining Co. (South Korea) was interested in reactivating the long-closed Nichigetsu and other mines in the south. Beach sands near Mosulpo, on the southwest tip of Cheju Island, reportedly were found to have interesting gold and silver values. The Kwang Chon gold dredge of Yang Wang Industrial Co. operated in tidal flats south of the town of Kwang Chon on the west coast, daily handling of 3,000 cubic yards to a depth of 30 feet and recovering about 20 cents worth of gold per cubic yard.

NONMETALS

Barite.—A promising barite mine was being developed near Yong Tap-ni. A U.S. company, International Minerals & Chemicals Corp., expressed interest in finding a sizable source of barite to provide return cargo to the United States on ships carrying phosphate rock to South Korean fertilizer producers. Potential purchases of up to 10,000 tons monthly were envisioned.

Cement.—Following the entry into production of three cement plants in 1964, slack winter demand forced plants to cut back sharply from December 1964 through February 1965. Regular operations resumed in March and output reached a monthly record in July of 186,525 metric tons, with the year's output showing a substantial gain. Sangyong Cement Co. and Mitsubishi Shoji Kaisha Ltd., of Japan, were reportedly negotiating the construction of a single large plant that could double or even triple South Korean cement capacity by 1971, despite the current cement surplus for the internal market. Domestic consumption was estimated at 1.35 million tons in 1965, about 70 percent of capacity.

Looking ahead, the Government nevertheless was starting on construction of a 400,000-ton plant at Kyong-won. In addition to five major cement plants in operation, the small Koryo Cement Co. plant at Changsong produced about 50 tons of cement daily for a local block, pipe, and tile

factory. To make South Korean cement more competitive for foreign export, the industry requested government supports in the form of special power and fuel rates or even direct subsidy. High-quality limestone was generally abundant and efforts were being made to improve mining practices.

Feldspar.—Bo In Industrial Co. Ltd., operated the An Yang pegmatite mine, southwest of Seoul, a long-time source of soda feldspar near exhausion.

Fertilizer Materials. — Promotional efforts by the Government to encourage farmers in adequate and beneficial use of fertilizers, particularly mixed types, intensified, and consumption rates rose. South Korea continued heavy imports of Japanese fertilizers in the second year of a large 3-year purchase agreement ($24 million worth in the first half of 1965); the United States remained a large supplier of phosphatic fertilizers.

Two Government-owned plants producing urea operated near capacity at Chungju and Naju, and plans were readied for construction of three new plants. Two of these, approximately identical and costing about $45 million each with annual capacities of 180,000 metric tons of mixed fertilizers and 84,000 tons of urea, were to be built by Fluor Corp. of the United States, one at Chinhae, west of Pusan, and the other at Ulsan. Both projects were joint ventures of United States companies and the South Korean Government. Gulf Oil Corp. with a $10.5 million equity joined with Chinhae Chemical Fertilizer Co. in the Chinhae project, and a consortium of Swift & Co. and Skelly Oil Co. investing $10 million shared in the Ulsan project with Yongnam Chemical Co. and Chungju Fertilizer Co. AID loans were authorized in June for half of the estimated costs, and risk guarantees were provided to protect U.S. investors. Plants were due for completion in early 1967. The third new plant was to be supplied by the Japanese through Mitsui Bussan in partnership with Hankuk Fertilizer Co., which was, in turn, backed by the Interore Corp. of the United States and South Korean investors. It was expected to be built at Pusan, to cost about $44 million, and to produce 330,000 tons of urea annually, utilizing the Toyo Koatsu Industries, Inc., process.

In addition, the Government granted Korea Fertilizer Industrial Co. Ltd., approval of a $700,000 investment for production of fused magnesium phosphate fertilizer.

Fluorspar.—About one-fifth of South Korea's fluorspar output came from the Kumi mine, near Tanyang, where reserves were estimated to exceed 20,000 tons of plus 50 percent calcium fluoride; most of this property's output in 1965 was of plus 65 percent calcium fluoride grade. The Chunchon-Sinpo mine, in Kangwon-do, produced about 1,000 tons monthly of hand-sorted fluorspar, 70 percent and higher grade, all for export, and operators planned to install a mill.

Graphite.—At the Shiheung graphite mine, improvements were made in ore handling and transportation. New mills operated at Tansan and Pyongtaek with combined annual capacity of 3,500 tons of graphite. A fairly broad distribution of surface showings of graphite was disclosed by mapping in the Kimpo area; mixed anthracite and graphite beds were mapped in the central part of the country.

Kaolin.—A 30,000-ton kaolin plant, finished last year, operated at Masan. An excellent description of the South Korean kaolin industry was published.[4] Eighty-two individual mines operated in 1964, with the main center in the Hadong area, 15 miles west of Chinju. Products consisted primarily of pink and white halloysite clay, of which about one-third was being exported to Japan.

Pyrophyllite.—Tongnae Pyrophyllite Co. operated the Tongnae mine, producing 900 tons per month of pyrophyllite for domestic and export markets, and the company planned to open the Imke deposit, 0.6 mile south of the main workings. About 1,000 tons of pyrophyllite monthly was produced from the Hwangson mine, where there were plans to double output. The Wando mine, located on Nohwa Island, south of Mokpo, operated on about the same scale. In 1965 the Kooam mine, Hyongsang Province, supplied 3,200 tons of pyrophyllite, mostly to domestic buyers.

Quartz.—Hansung Trading Co's. Chonnam silica mine, in Cholla-namdo, produced quartz from a 50-foot-wide vein for export

[4] Heikes, G. C., Hyung Ki Kim, and others. The Kaolins of Korea. Agency for International Development, U.S. Operations Mission to Korea, Seoul, Korea, August 1965, 104 pp.

to Japan. With a probable million-ton reserve, the company considered a plan to develop by adit and expand output.

Talc.—Il Shin Industrial Co., with its Tongyang talc mine in Chungchong Province, produced at a rate of 20,000 tons annually, operated a grinding mill at Chungju, and was developing a new talc orebody. A new 12,000-ton talc grinding plant was operating at Sinbo.

Vermiculite.—Heung Kook Industrial & Housing Co. recognizing the possibilities of substantial quantities of vermiculite in its 10-square-mile landholding in the Sanjon area, operated a pilot exfoliation plant near Seoul and planned to use the product in low-cost housing.

MINERAL FUELS

Coal.—Coal production continued its upward trend, with six main Government-owned mines, operated by Daihan Coal Corp., supplying just under half of the output. At the Changsong mine, source of nearly two-fifths of Daihan's output, preparations were made to purchase a new main hoist. Changsong is the site of a $9.5 million AID development loan project for a deep shaft and modern preparation plant scheduled for completion by 1967. A Pittsburgh firm has been awarded the contract for building the preparation plant. Pierce Management Corp., of the United States, continued its advisory role here and in other coal development projects under Government contract and AID supervision. Lignites in the southeast and mixed anthracite-graphite beds in central Korea were investigated.

Coal prices, already boosted 15 percent in November 1964, were due for a similar increase in May 1965, as rising costs caused Daihan Coal's fiscal balance to narrow. Sizable exports of coal and amorphous graphite-coal mixtures continued to Japan. Bituminous coal was imported chiefly for the iron and steel industry. The Government's current development program for coal envisaged a 14.5 million-ton rate of output by 1971, about three-fourths of the output to come from private mines. Amalgamation of small private mines was being pushed, especially in the northwest, to attain more efficient unit operations.

Petroleum.—Lacking any oil resource, South Korea imported crude oil from Kuwait under a 15-year supply contract with Gulf Oil Corp., a principal in the 35,000-barrel-per-day Ulsan refinery. Opened in 1964, the plant is operated by the Government's Korea Oil Corp. Refining rates reached capacity in May 1965 and plans were announced to expand throughput to 55,000 barrels per day in 1966.[5] During 1964, 5.29 million barrels of crude oil spiked with gas oil and heavy fuel oil was processed, yielding an estimated 4.84 million barrels of products. Imports in the same period included 5.83 million barrels of spiked crude oil plus 0.24 million barrels of cutting oil. Total oil and product imports in 1964 were valued at $25.9 million, including $13.3 million worth of crude oil. Consumption of refined products was estimated to total 7.46 million barrels in 1964, an increase of nearly 2 million barrels since 1961. Demand was expected to rise to 28 million barrels by 1971, assuming a proposed petrochemical industry is established. Improvements were made in transportation and storage facilities, but more tanker ships were needed and negotiations were under way to get them. About one-half of the refined product was being transported by sea; future increases to 70 percent were projected.

Petroleum's contribution to national energy supply was expected to rise from 14 percent in 1965 to 24 percent in 1971. Plans were reported to build a lubricating oil plant to supplement several small existing blending plants, and a tentative plan was under consideration to use forthcoming Japanese Government credits in financing a $40 million petrochemical complex that would crack 400,000 tons of naphtha annually. Raw materials apparently would come from a second South Korean refinery yet to be built.

The Korean Geological Survey investigated the east coast Pohang sedimentary basin for oil. Private company drilling in 1964–65, south of Pohang, detected minor flows of natural gas, chiefly after reaching the Hungnae formation at about the 1,900-foot depth. Drill cores were being studied for indications of oil.

The Mineral Industries of Malaysia and Singapore

(Including Independent Sultanate of Brunei)

By J. M. West [1]

Singapore on August 9 officially separated from the Malaysian Federation of 11 States of Malaya plus the regions of Sarawak and Sabah in north Borneo, after attempts for economic and trade consolidation failed for several years. Malaysia with roughly 9.4 million people and Singapore with its 1.8 million people continued on friendly terms although internal trade was disrupted temporarily. The separation had little effect on extractive mineral industry because this was largely confined to the Malayan States and Sarawak, but it did raise questions about which area might be the more favorable for industrial investment. Both Malaysia and Singapore have benefited from major new industries in recent years, including oil refineries, metal fabrication and smelting facilities, and cement plants; both openly invited foreign investment and offered substantial incentives.

Malaysia, exclusive of Singapore, lists rubber, tin, timber, and iron ore among its leading export products. The first two were credited in 1965 for nearly one-third of the gross national product (GNP) and over one-half of the export earnings; tin alone accounted for nearly 9 percent of the GNP. Malaysia recorded a 6-percent increase in tin output during the year, maintaining first place in world production, well ahead of Bolivia and mainland China, and supplying nearly one-third of the world's total production of tin concentrate as well as a major portion of the refined metal. Other minerals, including iron ore, bauxite, petroleum, and cement, contributed an estimated 3 percent to the GNP.

Singapore's GNP, estimated at $824 million in 1964 or about 30 percent of the Malaysian GNP, was apparently higher in 1965, with the Singapore Government emphasizing both industrialization and traditional entrepôt trade to expand the economy. Petroleum refining and iron and steel manufacturing were recent industrial acquisitions.

The economy of the Sultanate of Brunei continued to be tied to oil, the source of nearly all income, and the outlook for future revenues was improving with offshore discoveries and the possibility for sale to Japan of natural gas in liquefied form.

Among significant developments in the entire area during 1965, the expansion of Malayan tin mining, largely by increase in gravel pump operations, ranked foremost. This required considerable effort in the face of declining ore grades and was spurred by favorable tin prices. Active prospecting for offshore tin deposits was about to get underway. Several major tin dredges were under construction and at least one was commissioned in 1965.

The outlook for iron ore producers improved with the start of construction of an integrated iron and steel plant on the west coast of Malaya. Producers will become less dependent on the export market as a result. Singapore's steel facilities were expanding and the installation of a blast furnace which would utilize Malayan iron ores was under consideration. Copper discoveries in Sabah were hailed as promising, and exploration was accelerated. Two more bauxite mines opened in Malaya, but

[1] Far East specialist, Division of International Activities.

the one mine in Sarawak was closed. In Malaya a cement plant, new in 1964, was in process of doubling capacity and a large fertilizer and chemical complex on the west coast neared completion. Oil prospecting was active in 1965 with emphasis on offshore areas of Sabah, Brunei, and Sarawak. At Singapore, another major oil refinery neared completion, and one more was in the planning stage; expansion of a recently completed refinery at Port Dickson, Malaya, also was being planned.

Malaysia and Singapore continued to have stable and prosperous economies based on free-enterprise with minimum controls, encouraging investment through a variety of Government activities. Singapore, for example, placed no restriction on capital participation and allowed free repatriation of profits and capital; special tax incentives and concessions were negotiated. In a speech by Singapore's Minister of Finance on November 19, 1965, added incentives were disclosed; the Government was preparing to allow fast depreciation for certain industries, particularly those export-oriented, with writeoffs within as short a period as 3 years, and would allow greater tax deductions on sales promotions. Another incentive was Singapore's removal of duty on fuel oil where used in manufacturing. U.S. investors were encouraged by a revision of the U.S.-Malaysia Investment Guaranty Agreement to extend coverage of losses due to war risks to all of Malaysia.

Singapore's 5-year plan (1966–70) was announced under which about two-thirds of planned Government expenditures of $500 million would go for economic development projects. Malaysia also announced its first 5-year plan (1966–70), providing for systematic industrial expansion with equal treatment for both foreign and domestic firms. Under the plan greater efforts were to be made in Sarawak and Sabah to develop natural resources and infrastructure such as roads and power. In estimating available income, Malaysia's plan assumed a 4.6-percent-per-year decline in contribution from the mining sector because of anticipated decline in mineral reserves, particularly tin and iron ore. The plan foresaw a marked decline in output of tin by dredging.

The Malaysian Government reversed a decision not to join the Third International Tin Agreement, a plan largely producer-oriented to stabilize tin markets, and in late December gave authority to ratify the document. Government prospecting units continued exploration of potential tin-bearing areas, and direct financing to miners was offered in several instances. Aerial photographic surveys were underway in eastern Malaysia and were begun in western Malaysia with Canadian Government assistance.

Government plans for electric power included development expenditure in the 1966–70 period totaling $120 million. Among major projects were the $40 million Batang Padang hydroelectric project and a $35 million 600,000-kilowatt thermal powerplant at Negri Sembilan, near Port Dickson. Sabah and Sarawak were to receive small generating facilities including units powered by natural gas. A Japanese firm signed a $20 million contract to start construction of multipurpose dams and other works as part of the $65 million to $70 million Muda River development in Kedah State. Malaysia's power generation in 1964 (exclusive of Singapore) totaled 1,756.5 million kilowatt-hours. About two-fifths of this was used in tin mining. Singapore produced 914.2 million kilowatt-hours of power in 1964 and planned to double generating capacity by 1967.

Government-promoted industrial sites, established in a number of locations, were gaining new factories. Petaling Jaya, near Kuala Lumpur, was an outstanding example, with new plants including a major refinery and an aluminum rolling mill. At Singapore's Jurong Industrial Estate, located in the southeastern part of Singapore Island and boasting an excellent natural deep-water harbor, steel mills, oil refineries, chemical plants, and light industries have been attracted by the 5-year "tax holiday" and other concessions of the Government's "pioneer industries" program. A feature here also was low industrial power rates—as low as 1 cent per kilowatt-hour.

PRODUCTION

Malaysia's mineral commodity output value, about three-fourths accountable to tin, increased to an estimated $335 million in 1965—a gain of about 10 percent over 1964 figures. Iron ore was the second most valuable product, with cement, bauxite, and refined petroleum as other major components. Bauxite, oil, and gold of Sarawak origin contributed less than 5 percent to total output value; Sabah produced only minor quantities of bricks, coral, construction stone, and charcoal. Singapore's mineral industry was limited to oil refining, steelmaking, cement, and mining of about 1 million cubic yards of granite annually for local construction. Brunei oil and gas production was valued at an estimated $50 million to $55 million, about $5 million higher than in 1964.

Table 1.—Malaysia, Singapore, and Brunei: Production of metals and minerals [1]

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	1964	1965

e Estimate. r Revised. NA Not available.

[1] Production from Malaya unless otherwise shown.

[2] Includes metal smelted from imported tin concentrates.

[3] Processed at Lutong refinery; mostly from crude supplied by pipeline from Brunei.

TRADE

Overall exports from Malaysia (excluding Singapore) in 1965 were valued at $1,017 million, compared with $855 million in imports leaving a favorable balance of $162 million. Tin, mostly in the form of block tin, accounted for about 28 percent of export value, and iron ore for 5 percent, other mineral commodities adding probably another 1 to 2 percent. The U.S. share of all export goods was about $122 million, of which four-fifths was for tin in 1965 compared with $86 million in 1964 of which two-thirds was for tin. Both tonnage and unit value of tin were higher in 1965. Sarawak exported a little less bauxite in 1965 and continued exporting crude and refined oils; most of the crude, however, originated in neighboring Brunei.

Of Singapore's total 1964 export value of about $893 million, nearly one-fourth was for processed minerals, largely petroleum products. Overall export values were higher in 1965 at $985 million. Imports of all goods into Singapore in 1964 were valued at $1,140 million, of which about one-fifth was attributable to mineral commodities. Total imports rose to $1,250 million in 1965. Trade between Singapore and Malaya dropped in the last half of 1965 after separation, but prior to this, mineral trade had amounted to about one-fourth of the Singapore total for imports from Malaya and one-third of the Singapore total for exports to Malaya.

Sarawak in 1964 imported 3.54 million tons of crude oil valued at $58.32 million from Brunei and exported 1.76 million tons of crude oil valued at $30.63 million and 1.73 million tons of refined products valued at $36.07 million, the net thus contributing roughly $5 million to the local economy. Nevertheless, it was necessary to import petroleum products for domestic use valued at $3.89 million in 1964. Bauxite exports in 1964 totaled 172,000 tons valued about $1 million, with 122,500 tons going to Japan and nearly all of the balance to Taiwan. During 1964 Sarawak imported 33,000 tons of cement, nearly half from mainland China, 12,400 tons of iron and steel products, and about 630 tons of nonferrous metals.

Sabah imports included about 117,000 tons of petroleum products, 46,300 tons of cement, mainly from Taiwan and Japan, 15,450 tons of iron and steel products, and 435 tons of nonferrous metals. Oil product imports were valued at $8.6 million in 1964 compared with $6.8 million in 1963.

Brunei exported 3.52 million tons of crude oil valued at $57.64 million, 48,100 tons of gasoline, 1,020 tons of other oil products, and $180,000 worth of natural gas in 1964. Imports included 18,100 tons of cement (10,600 tons from main-

land China), 13,550 tons of iron and steel products, and 133 tons of nonferrous metals.

Upon the separation of Singapore from Malaysia, a number of trade restrictions were imposed and interflow of goods was cut back sharply. Toward yearend, as regulations became re-established, restrictions began to ease. In October, Malaysia moved toward greater integration of the Malayan States, Sabah, and Sarawak by exempting a number of goods from duty. Barter trade was resumed on a small scale between Singapore and Indonesia late in 1965, and the outlook for complete resumption of trade in 1966 was good. Singapore, after losing some of its major markets, employed a variety of incentives to encourage exports. Singapore and Malaysia tariff structures were discussed.[2]

r Revised.

COMMODITY REVIEW

METALS

Bauxite.—Sarawak's only bauxite mine, at Sematan, depleted reserves and closed in December. However, Sarawak has other deposits of possible economic grade that may be developed in the future. Four mines, compared with only two during 1964, operated most of the year producing bauxite in Johore State, on the southern tip of the Malayan Peninsula. Increased output of the Malayan mines was principally because of strong Japanese demand; Malaysian exports to Japan totaled about 850,000 tons in 1965 valued at $4.7 million.

Copper.—Copper has been a consistent byproduct of Malaysian tin mining, and, for the most part, is traded through Singapore. In 1965 there was increasing possibility of economic copper development in the Sabah region of the country. Copper has long been known to occur in Sabah in and near basic and ultrabasic intrusions cutting basalt and sedimentary rocks in the Labuk Valley, near Ranau, east of Maruda Bay, and on Banggi Island. More recently geo-

chemical prospecting has led to discoveries such as those of Soriamont Investment Co. (United States) at Pinanduan in the Karamu Valley and by Malaysian Goverment and United Nations geologists in the Labuk Valley. Soriamont in 1965 was prospecting at Gunong Nungkok on the western slope of Mt. Kinabalu and reported finding commercial copper ore as disseminations in steeply dipping intrusives. Malaysia's Borneo Region Geological Survey conducted mapping and explorations in the Bidu Bidu Hills and near Mt. Kinabalu. After discovery in 1964–65 of "decidedly commercial quantities" of copper at Mamut, east of Mt. Kinabalu, the Government closed the area to private prospecting until its potential could be assessed. The area is inland and is situated in a deeply dissected mountain range rising to elevations of about 4,000 feet. Silver was reported to have been discovered on the east coast of Sabah at the head of Darvel Bay but there was no indication whether copper was present.

Gold.—Drilling by Government crews continued in the Bau Gold Mining District of Sarawak with limited success. Some veins have produced antimony and one deposit, the Kwei Fah Gold Mine, south of Bau, the source of 132 tons of antimony ore valued at $16,000 in 1964, remained active on a small scale. The Research Division of the Department of Mines, Malaysia, conducted beneficiation tests to find means of treatment for such ores common to the district. Sarawak gold production was valued at $104,000 in 1965. Gold also was a byproduct of Malayan tin mining.

Iron Ore.—At yearend, 27 iron mines, an increase of four for the year, were in operation in 6 Malayan States, which was 1 State less than in 1964. During the year about five other mines operated intermittently. In the second half of 1965 ore production by States was distributed as follows, in percent of total: Pahang, 36; Trengganu, 27; Johore, 16; Perak, 13; and Kedah, Kalantan, and Selangor nearly 3 each. Output rose 6 percent for the year and exports were also higher at 6,710,000 tons, but value declined slightly because of tightened Japanese contracts to $52.2 million. Stricter contract terms came as the result of Japan's diversification of sources of iron ore and, in part, depletion of Malayan high-grade reserves. Prices paid for iron ore in 1965 declined about 45 cents per ton. As before, the largest producers were the Buket Besi or Dungun mine in Trengganu State and the Buket Ibam or Rompin mine in Pahang State, the two together accounting for over half of all production. Labor involved in iron mining was estimated to total 6,000 workers. Kalantan's only iron mine, operated by the Oriental Mining Co. at Temangan, 50 miles from Kota Bharu and in which Kalantan State has a share, was closed in September after exhausting reserves. Production since its opening in 1958 totaled 3.5 million tons. Plant and equipment were being sold. Development continued and more ore was mined at the Pasaki iron deposit, operating in conjunction with the Rompin mine in southern Trengganu.

Iron and Steel.—Construction was underway, after considerable delay in arranging for financing, on the Malayawata Iron and Steel Co. integrated plant at Prai. The plant is to have two blast furnaces, the first to operate in 1967 and the second in 1969. Initial annual capacity is planned for 53,000 tons of pig iron, 52,000 tons of steel, and 47,000 tons of rolled products, with completed capacity about double these amounts. High-grade iron ore is available from nearby Kedah and Perak States in Malaya.

In Singapore, the National Iron and Steel Mills, Inc., plant, at Jurong, in production since 1963, was about to start up its second electric furnace, doubling capacity to 120,000 tons of steel annually, and had a third furnace on order. Other equipment being installed included a continuous casting line and rolling facilities to produce diversified shapes, channels, and wire rods. Scrap steel was used as raw material; however, purchase of a 250,000-ton blast furnace which would utilize Malayan iron ores was under consideration, and the company's managing director described plans to expand over all plant capacity to 300,000 tons of steel yearly. Also, Japanese businessmen discussed plans to build a $15 million steel sheet plant at Singapore with the outcome that a preliminary agreement for investment was signed by Japan's Nippon Kokan K. K. and the Singapore Government. The company is to be known as Union Steel Ltd., and will supply cold-rolling steel sheets to

Singapore and Malaysian markets. Singapore Galvanizing Industries Ltd., brought its new 12,000-ton per year galvanizing plant into production at Jurong.

Rare Earths.—Xenotime, containing 10 to 55 percent of the rare-earth yttrium group elements and a byproduct of some 36 small tin mines in one section of east coast Malaya, was marketed chiefly by Oriental Thai Corp. of Kuala Lumpur. Much of the demand was from Japan and in 1966, prices are expected to rise sharply, possibly reaching $7 per pound for high grade concentrates, owing to the new use for yttrium in color television tubes. Annual capacity of the mines has been estimated at 100 tons of xenotime.

Tin.—Efforts to boost tin production in the Malayan States were rewarded by significant increase in output of tin-in-concentrates. Perak remained the chief producing State, followed by Selangor, with lesser amounts from Pahang, Johore, and other States, except for Kelantan which recorded no production. Most of the increase was credited to gravel pump mines, those operational rising from 768 at the beginning of the year to 979 at yearend. Dredges in operation, conversely, declined from 69 to 65 at yearend, with three stopping in October-November. At yearend 1965, 1,103 tin mines were active in Malaya. The total includes 28 underground tin mines, the largest of which is in Pahang State and most of the remainder in Perlis State. The total number of tin mines also includes miscellaneous types of mining operations. It was considered questionable by some industry spokesmen whether in the face of declining ore grades the rate of production reached in 1965 could be maintained. Developers were particularly looking toward exploitation of offshore deposits and hitherto untapped Malayan reservation lands. At the same time much ground was being reworked at marginal profit. Average grade of once-rich Kinta Valley dredge lands was estimated to have fallen to about 0.4 pound per cubic yard.

Tin smelting was adversely affected by a ban on Thailand's exports of concentrates in July 1965, occasioned by startup of a new smelter there; consequently, a drop in imports to Malayan smelters. Larger than normal imports had been recorded in the first half of the year, however, dampening the impact of the ban. Straits Trading Co. Ltd., and Eastern Smelting Co. Ltd., continued their Penang and Butterworth operations apparently at reduced rates. Straits Trading Co. Ltd., also maintained a small smelting operation at Palau Bukom, Singapore, processing low-grade tin ores. The small but modern Japanese-financed Oriental Tin Smelters Ltd., completed in 1964 at Klang, was also in operation, the company shipping tin through the Port of Butterworth. Exports of tin metal and tin-in-concentrates in 1965 totaled 73,383 long tons, compared with 71,315 tons in 1964. Block tin exports were reported to total 73,287 long tons valued at $283.2 million. Unit value, f.o.b., of tin metal exports in 1965 averaged $3,870 per long ton compared with $3,330 in 1964. Stocks of tin metal and tin-in-concentrates at Malaysian smelters, en route and awaiting shipment totaled 5,532 long tons at yearend compared with 6,730 tons at yearend 1964. Exports of tin in 1965 included 31,522 long tons to the United States (compared with 25,733 tons in 1964), 12,969 tons to Japan, 4,612 tons to Eastern Europe, 3,968 tons to Canada, 3,636 tons to Italy, and 3,544 tons to India. Concentrates imported in 1965 contained 7,165 long tons of tin compared with 9,690 tons in 1964 and came from Thailand (9,072 tons), Laos (536 tons), Kenya (100 tons), Indonesia (30 tons), and Australia (5 tons).

Among companies operating or managing tin properties in Malaya, the foremost was Anglo-Oriental (Malaya) Ltd., providing about one-fourth of the output (42 dredges), followed by Osborne and Chappel Ltd. (9 dredges) and Associated Mines Ltd. which includes the Tronah Mines Ltd., group (12 dredges), providing about one-tenth each of the output. Other partly or totally foreign-owned companies, with 1 to 3 percent each of production, included Pahang Consolidated Co. Ltd. (large lode mine), Austral-Malay Tin Ltd. of Australia (5 dredges), Pacific Tin Consolidated Corp. of the United States (4 dredges), Renong Tin Dredging Co. of the United Kingdom, and La Société Anonyme des Etains de Kinta of France. The remainder, accounting for about 44 percent of production, came mainly from small Chinese-owned mines. As an example of grade problems, Pacific Tin in 1965 re-

ported recovery of 1,510 long tons of tin-in-concentrates, only 2 percent higher than in 1964, from 13.3 million cubic yards of material handled, 24 percent more than in 1964. Nonetheless, earnings increased, chiefly as a result of a 20-cent-per-pound average rise in price for tin sold.

A number of companies had placed applications for offshore prospecting rights, and forms were being processed, although the Central Government had not yet decided on its regulatory role. Malacca and Perak States by yearend had or were about to permit offshore mining to their territorial limits of 3 miles, and at least five companies were being considered. These included Conzinc Riotinto of Malaysia Ltd., newly formed by Rio Tinto Zinc Corp. (United Kingdom) and an Australian subsidiary to invest in Malayan ventures. In the case of Malacca, which has a 60-mile coastline, it was stated that Malaysian firms would be given priority in award of concessions, and local firms were encouraged to pool capital for joint operations. Easing of tension vis-a-vis Indonesia was due to spur development in the Malaccan area.

Modernization and replacement of dredges made progress. In March, Berjuntai Tin Dredging Ltd., put its new $3 million No. 6 dredge into operation in the Deep area of the company's Batang Berjuntai property. Malayan Tin Dredging Co. Ltd., was well along on construction of its new $4 million No. 7 dredge, one of the world's largest, designed to excavate to a depth of 150 feet. This dredge was to go into operation in 1967.

Renong Tin Dredging Ltd., continued its project in Selangor State, which requires diversion of the Selangor River in order to dredge the main river bed. Reconstruction of Malaya's main north-south highway and railroad, passing through the property, was also necessary. Three of Renong's dredges, two over 50 years old, continued operation at Rasa. Extensive relocations were also necessary at the project of La Société Anonyme des Etains de Kinta, on the outskirts of Kampar, where a 73-acre plot with a deposit estimated to contain 16,250 tons of tin concentrates was being prepared for mining. Selangor Dredging Co. Ltd., held a 960-acre lease in Selangor's Kuala Langat Forest Preserve with potential for 24,000 tons of tin concentrates and applied for a mining certificate covering another 421 acres after favorable drill results. The company has a dredge under construction scheduled for operation in September 1966.

Tronah Mines Ltd., acquired more dredging property in the Sungei Bidor area, its Sungei Besi mines showed improvement, and a new dredge was scheduled to start operation late in 1966 in the Ayer Kunnig area. Tongkah Harbour Tin Dredging Ltd., had sharply reduced recoveries in its offshore tin operations—0.7 pound per cubic yard treated compared with about 1.7 pounds in 1964—but increased its reserves by additional drilling.

Pahang Consolidated Co. Ltd., premier lode tin producer, reported higher profits and production of 2,283 long tons of concentrates in its fiscal year ending July 31, 1965. Ore reserves were placed at 346,000 tons on that date; annual milling capacity was 220,000 tons of ore. Several promising ore bodies were revealed at the 300-foot level in the Willinks section of the company's famous Sungei Lembing mine in Pahang and a tin placer of some 350,000 cubic yards was established nearby.

The Malayan Government began offering direct aid for mining Malayan Reservation lands, making $500,000 available to finance mining in the Changkat Tualang area, 90 miles north of Kuala Lumpur. A Malayan investment company, Sharikat Permodalan dan Perusahan, was licensed to prospect 1,700 acres of Malayan Reservation land at Jeram Mengkuang in the Batang Padang district of southern Perak which was found favorable for tin by Central Government exploration teams. Such teams have established at least a dozen potential areas for development on these reserved lands.

NONMETALS

Asbestos.—United Asbestos Cement Ltd., a local firm, in a joint venture with an Australian affiliate of Turner Newall Ltd. (United Kingdom) and the Eternit Group (West Europe), was building a $4 million asbestos products plant at Tasek, near Ipoh, Malaya. This will be the third asbestos processing plant in Malaysia and it is due to open in 1966.

Cement. — Cement consumption in the States of Malaya, exclusive of Singapore, was estimated at 657,000 tons, an increase

of 6.2 percent from that of 1964. Prices were said to have fallen disastrously during 1965 owing to additional cement made available by northern producers after recent expansions. The growth rate in consumption was faster in the Singapore market; 354,000 tons was consumed in 1965, 15.6 percent above that of 1964. Capacity in Malaya reached approximately 1 million tons. Singapore imported cement and clinker, receiving some 385,000 tons in 1965 from Malaya and other Asian countries. The local cement industry was estimated to be operating at 70 percent of capacity. Markets in eastern Malaysia (Borneo region) were expected to expand in the near future, but probably not beyond one-tenth of Malaya's current production capacity.

Tasek Cement Ltd's., plant at Ipoh, Malaya, which went into production in September 1964, signed for a $4 million addition that will more than double capacity to about 400,000 tons annually. A second kiln will be installed and other work will be done under joint contract with Kobe Steel Co. Ltd. (Japan), and Polysius G.m.b.H. (West Germany). The plant has been operating at or near capacity. Malaysia Cement Co. did not go ahead with planned expansion at Rawang because of the tight cement marketing situation. Planning on a cement plant for Sarawak was postponed.

Chemicals and Fertilizers. — Chemical Co. of Malaysia, an Imperial Chemical Industries Ltd., affiliate, was completing its $30 million chemical complex and compound fertilizer plant at Padang Jawa, near Klang, Malaya. Special formulations will be produced for Malaysia's rubber and oil palm industries. Full operations by 1970 will see 208,000 tons of mixed fertilizers produced annually, approximately 85,000 tons above the amount imported by Malaysia in 1964. Esso Standard Malaya Ltd., was well along on a $8 million 50,000-ton-per-year anhydrous ammonia plant which will utilize off-gas from its nearby refinery. Another part of the chemical complex, a 100-ton-per-month liquid chlorine plant for water purification, was completed. A nitric acid plant was due for completion in 1966.

Marble. — Langkawi Marble Co. Ltd., operating since 1963 and Malaysia's only marble producer, sold a product said to compare with Italian white Carrara marble although lower priced. The marble is mined on the islands of Langkawi, Dayang, Bunting, Paku, Pasu, and others in the Malacca Straits. White and black marbles were obtained, and a red marble quarry was about to open. Cut slabs were polished at quarry sites followed by shipment to Kuala Lumpur for marketing. Production is to be tripled to 9,000 square feet annually by erecting a central finishing plant at the Baku Tiga Industrial Site near Port Swettenham.

Silica.—Demand for high-quality silica was expected to rise as a result of a new glass factory to be purchased from and built by Czechoslovakian suppliers in Johore Bahru, Malaya. The first of its kind in Malaya, the $7 million plant will produce sheet and figured glass for domestic and export markets. Sales are expected to reach $2 million annually by 1972. Malayan Glass Manufacturing Corp. will operate the plant.

MINERAL FUELS

Coal.—A detailed survey was in progress on the Bintulu coalfield in Sarawak under the United Nations Special Fund. Progress on development of the Silantek coking coalfield in Sarawak, under study by Nippon Coal Mining Co. (Japan), was limited by its proximity to the Indonesian border and insurgent harrassment. Nippon Mining's work in 1964 was confined to testing and attempting to find a market for Silantek's industrial cokes.

Petroleum.—During 1965, Malaysia and Singapore refineries processed 7.25 million tons of crude and partly refined oils, producing 7 million tons of refined oil products of which fuel oils comprised about one-half. Imports of crude and partly refined oils to Malaysia and Singapore totaled 8.21 million tons of which 1.48 million tons was reexported. Petroleum product imports totaled 4.9 million tons while exports of these commodities totaled 9.5 million tons, of which about 3 million tons consisted of bunkers. Domestic consumption still exceeded refining capacity and was estimated about 8.6 million tons of oil products in 1965 (exclusive of bunkers), somewhat less than half of this being consumed in Malaysia and the rest in Singapore.

Production from Sarawak's small Miri oilfield, operated by Sarawak Shell Oil-

fields Ltd., maintained a slow decline and was valued at $695,000 in 1965, compared with $720,000 in 1964.

Brunei's Seria field, operated by Brunei Shell Petroleum Co., rounded out a 10-year general decline. The field was estimated currently to be producing 67,000 barrels daily. Brunei crude was exported by pipe to Shell's 45,000-barrel-per-day Lutong refinery in Sarawak where part was processed along with the Miri crude; products and the balance of crude were exported from Lutong. Refinery runs in 1964 totaled 18.52 million barrels of crude oil; 26.01 million barrels of crude oil and products valued at $67.2 million was exported. Brunei also produced natural gas and gasoline; in addition, in 1965 about 110,000 barrels of a locally refined gasoline was reported to have been marketed.

Mobil Refining Co. (Malaysia) Ltd. continued to work on its new $18 million refinery at Jurong, Singapore, scheduled for completion early in 1966 with 21,000-barrel-per-day capacity. Investment guarantees were secured from the Malaysian Government covering the financing of service stations, a bulk storage terminal, and lubricant inventories in Malaya; Mobil was expected to begin deliveries of crude oil to its $1.3 million marine terminal at Jurong in February 1966. Shell Refining Co. (Federation of Malaysia) planned a $5 million expansion of its new Port Dickson, Malaya, refinery to 30,000 barrels per day by April 1967. Also Shell Refining announced plans to construct a second refinery alongside its Pulau Bukom refinery near Singapore, which went into production in 1960. The second refinery will cost about $13 million and will have the capacity to process 60,000 barrels per day. A large share of the second refinery's output has been initially planned for export.

Considerable exploration activity was reported during the year. A Malaysian Government committee prepared legislation to cover offshore exploration, and foreign consultants, including a U.S. specialist, Walter J. Levy, were engaged. Particular interest centered on offshore Sabah and Sarawak, with Brunei also active. Sabah Petroleum Co., a subsidiary of Brunei Shell Petroleum Co., explored concessions totaling about 70,000 square miles off Sabah and Sarawak and planned a drilling program for a newly purchased Japanese-made $7 million deepwater exploration platform. Plans suffered a major setback, however, when the platform was lost at sea in December while under tow to the exploration area.

A U.S. firm, Clark Brunei Oil and Refining Corp., was completing an aerial photographic survey and planned exploration in 1966 of its 1,820-square-kilometer concession in the Tutong area of Brunei. Although Clark held rights to prospect also within the territorial waters, no work was imminent on offshore drilling. Texas Crude Oil Co. (United States) has also applied for Brunei exploration rights. Shell was reported planning to drill at least 30 holes, including several offshore, within the next 5 years. Aquitaine Petroleum Co. Ltd., received an oil prospecting license to explore the shelf area off the east coast of Sabah and conducted an aeromagnetic survey there. Esso Exploration (Malaysia) Inc. obtained both offshore and onshore concessions in November along Sabah's northeast coast between Marudu Bay and Sandakan and completed aeromagnetic surveys of the area early in 1966. Sabah Teiseki Oil Co. studied geology of its land and sea concessions at Sebatik Island, near Tawa, and planned shallow drilling on the island in 1966. One company reported that the use of a hovercraft proved successful in its oil survey.

The production prospects for Shell's successfully completed wells in Brunei's offshore area were good, and the company hoped that their forthcoming production would offset declining onshore flows. Development of Brunei's natural gas resources received a boost with the reported offer by a Japanese firm, Joint Venture Development Co., for purchases. Plans included a pipeline from Seria to Mura, where a new port and liquefaction plant would be built.

The Mineral Industry of Mongolia

By J. M. West [1]

In 1965 sparsely populated, largely nomadic Mongolia or Outer Mongolia, with nearly one-fourth of its 1 million people centered in the capital city of Ulan Bator, moved closer to the Soviet-East European sphere of economy than to that of its southern neighbor, China. Fluorspar remained the country's only mineral product of world significance. However, resources of other minerals, notably coal, phosphate, iron ore, and a few nonferrous metals in early stages of development were of increasing importance. Lagging exploitation of extensive reserves of coal forced the sizable imports of coal from the U.S.S.R. to continue. Domestic oil production, never large, gave way to rising crude oil and product imports for lack of new discoveries.

Prospecting in 1965 resulted in several mineral discoveries, including perlite, rare metal ores, and gold. Approximately, 21 million tugriks (about $5 million), 2 to 3 percent of total State capital investment, was spent on surveys and prospecting. This included mapping, 24,900 meters of core drilling, 400 meters of tunneling, 50,800 cubic meters of stripping, and 10,100 meters of other drilling and test pitting. Water supply investigations were expanded and technical assistance was given by approximately 400 engineers and specialists from the U.S.S.R. Hungarian experts assisted in explorations for water and planned to locate and drill 225 wells in the 1966-70 period.

Progress on the Darkhan (Darhan) industrial complex, north of Ulan Bator, was difficult to assess. One report stated that "work continues day and night at the enormous Darkhan construction site," and another report stated that plans for output by the Darkhan powerplant (150,000-kilowatt thermal electric) were fulfilled or overfulfilled by 10 to 33 percent. The first phase of the plant was said to be complete, along with the first section of the Sharyn Gol coal mine. Power was being transmitted over a 110,000-volt line north to Sukhe Bator near the Soviet border. Lines were also being constructed to Ulan Bator, where sections 4 and 5 of the local powerplant were just completed. The Darkhan steel project apparently made limited headway. However, a cement plant was due for completion in 1966.

In mid-April an agreement was signed with the U.S.S.R. to supply economic and technical assistance during the 1966–70 period. Promised aid would increase to more than 660 million rubles ($732 million) during that time, and would include help in coal mining, in construction of a cement plant, and in exploration of mineral deposits. On April 27, France announced it would establish diplomatic relations with Mongolia, a sign that Mongolian interests are rising beyond traditional bounds. With Chinese assistance a 23-kilometer highway was completed between Ulan Bator and the Nalaikha coal mines.

[1] Far East specialist, Division of International Activities.

PRODUCTION

The mineral industry, though accounting for about one-tenth of the country's industrial production in 1965, was of little significance, even for the Far East. Output of nonferrous and rare metals, while small, appeared capable of increasing. Output could become significant in future years because of a reasonably favorable geological potential and a growing emphasis on prospecting. Official data on coal, crude oil, gasoline, and diesel fuel outputs in 1965 were published; other data have been estimated. The 15,900 tons of crude oil production reported for 1965 is considerably below the estimated outputs of previous years, probably a result of the declining output at the Dzuun Bayan oilfield. Electric power production totaled 198.6 million kilowatt-hours, approximately 8 percent more than in 1964, and was scheduled to increase to 217.9 million kilowatt-hours in 1966, the first year of the fourth 5-year plan.

Table 1.—Mongolia: Production of minerals [1]

(Metric tons)

Commodity	1961	1962	1963	1964	1965
Nonmetals:					
Alabaster (gypsum)	10,000	10,000	15,000	20,000	20,000
Fluorspar (fluorite)	38,000	37,900	50,000	57,000	75,000
Lime	13,000	21,000	25,000	30,000	35,000
Salt	7,000	8,000	8,000	8,000	8,000
Mineral fuels:					
Coal [2]	748,600	860,000	845,000	710,000	989,500
Petroleum:					
Crude oil	50,000	50,000	50,000	50,000	15,900
Refinery products:					
Gasoline	18,000	17,900	18,200	18,000	17,000
Diesel oil	7,280	7,100	7,680	8,200	6,600
Residual fuel oil	30,000	30,000	32,000	32,000	30,000

[1] All figures are estimated, except fluorspar for 1961–62, lime for 1961–62, coal for 1961–63, and coal, crude oil, gasoline, and diesel fuel for 1965. Other metals and nonmetals known to be produced include gold, lead, zinc, tungsten, clays, dolomite, limestone, phosphate, and sand, but quantitative information is not available.
[2] Mainly so-called brown coal.

TRADE

Official Mongolian trade data are not available, so U.S.S.R. imports from Mongolia and exports to Mongolia have been substituted to show trends. The U.S.S.R. and East Europe reportedly have accounted for nearly 90 percent of Mongolia's foreign trade, of which, however, minerals comprise only a small part. Value of all types of imports into Mongolia has been estimated at $150 million annually and the value of exports has been estimated at approximately 75 million annually. The U.S.S.R. reported imports of metal ores and concentrates from Mongolia valued at 195,000 rubles ($216,000) in 1964 compared with a value of 218,000 rubles ($242,000) reported in 1963. Fluospar has been the most significant mineral export. The U.S.S.R. imported 66,500 tons of fluorspar from Mongolia in 1964 and probably more than that in 1965. Lead-zinc and tungsten ores have been relatively minor exports. Imports from the U.S.S.R. included mainly iron and steel, mineral fuels, and cement.

COMMODITY REVIEW

METALS

Iron and Steel.—Work presumably continued on the Soviet-designed 300,000-ton integrated iron and steel plant. This plant is a part of the Darkhan complex being developed in conjunction with an electric power station, the Sharyn Gol coalfield, and other facilities. Plans for steel production were said to be ahead of schedule.

Tungsten.—An aerial cableway was installed at the Ih Hairhan wolfram-scheelite mine to transfer ore to the mill. The mine, developed with Soviet help, is 100 miles south of Ulan Bator and has been in opera-

r Revised.
Source: Official trade returns of the U.S.S.R.

tion about 5 years. Workings extend to 200 feet in depth, and a system of water-jet mining is said to have been introduced. Ore grade is about 1 percent wolfram. Output has been 100 to 200 tons annually. The mine was said to have realized more than 1 million tugriks (roughly, US$250,000), which was more than anticipated.

Other Metals.—Gold mining continued north and northwest of Ulan Bator in the Hobsogol Dalay region and on the tributaries of the Yoroo Gol River, in the Baydarag Gol River Basin, west-central Mongolia, and in the Altai Mountains of western Mongolia. No statistics on gold are available, but output probably amounts to only a few thousand ounces annually. Molybdenum and copper deposits in the northern part of the country were being explored under Soviet aid projects. New discoveries of gold and rare metal ores were reported in 1965. Mongolian production of nonferrous and rare metals was reported one-fifth higher than in 1960.

NONMETALS

Construction materials, such as lime, brick, and gypsum, were produced. During the first half of 1965, 2,200 tons of feldspar was mined. Expansion was scheduled in fluorspar mining. Major deposits are being developed southwest of Ulan Bator in the Dorono Gobi district. In 1965 discoveries of perlite and quartz albitite (a source of feldspar) were reported. Phosphorite was also being mined. Projects slated for completion in 1966 include a 100,000-ton cement plant and a 30-million unit-per-year firebrick plant at Darkhan, seven brick plants each with a capacity of 35 million brick per year in different districts, and a lightweight concrete plant at Ulan Bator.

MINERAL FUELS

Coal.—The first section of Darkhan's Sharyn Gol opencut coal mine went into production. Eventual capacity is estimated at 1.1 million tons. Overall capacity of Mongolia's 10 underground and open pit coal mines was approximately 2 million tons. At the Nalaikha coal mine, east of Ulan Bator, a record 2,947 tons (compared with the planned daily output of 2,000 tons) was produced in 1 day. Nevertheless, during the third quarter of 1965, output was 20 to 30 percent behind schedule, owing to labor problems compounded by unsafe conditions and machinery breakdown. Approximately 65 Soviet miners were employed; 103 Mongolian miners were trained as the result of a Soviet-sponsored program. Donbas-1 and PK-3 Soviet-built coal-cutting and loading machinery was in use. Progress at smaller mines varied. Progress was considered satisfactory at the Bayan-Teeg mine, in the Obor Hangay district, the Tsagaan-Oboo mine, in the Dund-Gobi district, and the Oldziyt mine, in the Suhe Bator district, but was considered behind at the Har Tarbagatai and Nurstiuy mines. The Ministry of Industry had planned to open three new coal mines in 1965. The Bulgan and Hobsgol district coal mines and a branch mine at Tsagaan-Obbo, Omono-Gobi district, were to be opened in 1966. Output was scheduled to increase by one-third to 1.315 million tons by 1966.

Petroleum.—Domestic oil refining provided approximately 20 percent of gasoline and 15 percent of the diesel needs of the country. Refinery requirements had to be made up by increasing tonnages of crude oil imported from the U.S.S.R. (39,700 metric tons in 1964). Operations at the Soviet-built Dzuun Bayan refinery, having an estimated 100,000-ton input capacity, apparently were limited by declining production from the local oilfield. Refined product imports rose 15 percent in 1964 and this trend continued into 1965.

The Mineral Industry of the Philippines

By J. M. West [1]

Copper, gold, iron, and chromite were the chief components of the Philippines' crude mineral production, the value of which rose one-fifth in 1965 to about $146 million, roughly 3.0 percent of the gross national product. Base metal ores were largely exported and were an important source of foreign exchange. Copper exports alone were valued at $50.9 million in 1965. In contrast, cement, iron and steel, fertilizers, and refined petroleum were produced chiefly, if not entirely for internal consumption.

The Philippines was being prospected actively, particularly for copper, iron, and nickel.

Construction began on an integrated iron and steel plant at Iligan, Mindanao, and a start was impending on a second to be situated in Rizal Province, near Manila. Investigations were conducted on possible use of domestic coal to supply part of future coking-coal needs. Development of a large copper deposit on Marinduque Island was halted by lack of agreement on investment terms. Bids for development of the Government-owned Surigao nickel-cobalt laterite deposits were rejected as inadequate. Promising copper deposits were being explored in Batangas and Marinduque Provinces and on Rapu Rapu Island; a sizeable lead-zinc discovery was reported in southwestern Mindanao. There was greater recovery of chromite fines, and the Parcel I Zambales Mineral Reservation deposit became a major source of chromite. The Bagacay mine began supplying pyrite for a fertilizer plant nearing completion at Limay, Bataan. A new cement plant was under construction in Rizal Province, and an agreement was signed to build a plant at Davao, Mindanao.

A new president, Ferdinand Marcos, was elected late in 1965, and a number of government reforms were promised, including clampdown on smuggling and stepped-up economic development. The existing 5-year development plan, now in the third year, was somewhat behind schedule, as capital inflow slowed and money supplies became tight. The decontrolled peso remained stabilized and was officially set on November 6 at 3.90 pesos to US$1.00. Rescinded at the same time was the system by which exporters were penalized by reduction in payment to 2 pesos to US$1.00 on 20 percent of all foreign exchange earnings turned in to the Central Bank. Exporters, including most mining companies, were encouraged by the action.

Various sections of the Philippine Mining Law, Commonwealth Act 137, were amended by House Bill 2522, and the act was signed into law. The "Mining Engineering Law of the Philippines," designed to regulate mining engineering and to provide for licensing and registration of personnel of mines and quarries was signed into law in mid-1965. Also, an act was introduced to provide for licensing and registration of geologists in the Philippines.

Investment climate and effects of various Philippine laws on investors were discussed.[2] The Government created a committee to study problems of the petroleum industry. The Philippine Petroleum Association, representing exploration firms, called for special tax exemption, a 5-year moratorium on work requirements on Government leases, and provision of annual subsidies to encourage search for oil. The plea was prompted by shortage of risk capital. Foreign investment was deterred by uncertainty about rights and privileges. U.S.

[2] U.S. Department of Commerce. Establishing a Business in the Philippines. Overseas Business Reports, OBR 65–89, December 1965, 16 pp.

investors were particularly concerned with the future of the Laurel-Langley agreement affecting trade and the Retail Trade Nationalization law limiting foreign participation. The Chairman of Filoil Refinery Corp., Filemon Rodriguez, speaking in Baguio City on December 4, suggested a number of improvements that could be made as inducements to foreign investors but stressed that rising feelings of nationalism must be recognized and dealt with fairly.

Bids on the Government's nickel deposits in the Surigao Mineral Reservation were regarded as unacceptable, and further action was undecided. U.S. Agency for International Development-sponsored mineral development activities continued in cooperation with the Philippine Bureau of Mines. Programs included an iron resource survey, studies of coal, manganese, and chromite, assistance with mining laws, a geological structure map of the Philippines, and plans for a much needed new metallurgical laboratory. Also, a water resources survey was being conducted with the help of the U.S. Bureau of Reclamation. The country continued to receive capital and consumer goods as war reparations from Japan. Greater public works construction was planned, including dams, highways, and irrigation. The Angar River multipurpose project, near Manila, made headway and loans were discussed for a thermal powerplant on Bataan ($9.5 million) and additional work on the Maria Cristina hydroelectric projace in Mindanao ($2.5 million). Also under discussion was a geothermal power station for Albay province.

PRODUCTION

Value of crude minerals and cement produced was about $146 million in 1965 compared with $121 million in 1964; base and precious metal ores continued to account for two-thirds of the total. Production of most commodities was higher than in 1964, and output value increased because of greater volume and better export prices. Metallurgical chromite gained a few dollars per ton, and gold mining remained subsidized. Bagacay pyrite began moving to market, and copper reached a new high in output, with increasing development activity. Iron ore production rose 8 percent in 1965, and one company began making a pellet product. Part of the iron ore consisted of magnetite recovered from copper milling. Copper mining provided byproduct molybdenite, and zinc was the source of byproduct cadmium. Mercury from a single Palawan deposit responded to good prices and output increased, although ore grade continued poor. Cement plants operated near capacity. The mineral fuels sector showed no improvement. Cement and oil industries have been reviewed.[3]

[2] Includes zinc content of copper-zinc concentrates containing 46 percent zinc and 3 percent copper.

TRADE

Japan and the United States received the major share of Philippine metallic mineral exports. Export earnings continued to rise owing primarily to higher copper and chromite prices. The quantity exported of most commodities exceeded those of 1964. All metallurgical-grade chromite went to Japan, while the United States bought nearly half of the refractory-grade product. Copper ore and concentrate went to Japan except for output of the Lepanto mine, which was shipped to American Smelting and Refining Company, Tacoma, Wash. Iron ore and concentrates continued to go to Japan, and about yearend, pelletized ore began to come from Philippine Iron

Mines, Inc. Mining, largely an export industry, gained an important step when the Monetary Board of the Philippines approved relief from an existing 20-percent retention fee on export receipts. The fee had applied to all minerals except molybdenum and was costing producers about 10 cents on each dollar received.

Lacking oil, the Philippines relied on imports to satisfy increased refinery requirements. Value of imported crude oil totaled $56.7 million in 1964 and was higher in 1965. The quantity imported rose nearly one-third to 5.5 million tons in 1965.

Japan and the United States remained supply sources for refined metal ingots and semimanufactures as well as petroleum refinery products.

[e] Estimate.

COMMODITY REVIEW

METALS

Chromite.—Refusal of some buyers to purchase chromite from Southern Rhodesia improved the bargaining position of Philippine producers. Acoje Mining Co., the leading metallurgical chromite producer of the Far East—also with manganese, copper, and varied industrial interests—went on a 6-day work week and placed orders for equipment to expand production. The ore reserve at its Santa Cruz, Zambales, property was 2.21 million tons on January 1, 1965—6 percent lower than the year before. Metallurgical-grade shipments to Japan rose to 102,200 tons, with values during the four quarters of 1965 averaging

about $18.50, $21.20, $21.60, and $20.40 per ton, respectively, compared with $13.40 per ton in the third quarter of 1964. A $3-per-ton price hike was under consideration for the contract period starting in April 1966. At Acoje's mines, main crosscuts were being driven and stope preparation was underway to expand production. Studies continued on ways to recover by-product nickel and precious metals,[4] but the company's pilot plant was inactive.

At Consolidated Mines, Inc's. Masinloc operations, where Benguet Consolidated, Inc., is prime contractor, refractory-grade ore output and shipments were a little higher and the outlook was excellent; greater emphasis was placed on recovery and sales of fine and disseminated ores. In the first three quarters, output totaled 308,961 tons, and shipments for the year included about 300,400 tons to the United States, 95,000 tons to Europe, 36,200 tons to Japan, and 11,500 tons to Canada. The bulk of the ore came from the Parcel I Zambales Mineral Reservation deposit which the company opened in early 1964; the Coto pit supplied most of the rest. Feed to the Coto mill averaged 25 to 26 percent chromium sesquioxide (Cr_2O_3) and products included lump refractory ore with 33 to 34 percent Cr_2O_3 and fines of minus 10 mesh with 33 to 44 percent Cr_2O_3, both containing 11 to 12 percent iron. Doubling the capacity of the fines treatment plant, where heavy media separation is used,[5] was completed, boosting its output potential to 33,000 tons of concentrate monthly and permitting further reclamation of old mine dumps and sections of disseminated ore bodies not suited for selective mining. A 120-ton-per-day crushing and grinding plant was set for operation in the second half of the year to begin on a large stockpile of disseminated ores.

Development continued southwest of the Coto pit on the 787 and 815 ore bodies, first recognized by geophysical surveys and now planned for further surveys. Company reserves on January 1 totaled 8.6 million tons, over 2 million tons greater than on January 1, 1964, and included 3.95 million tons of run-of-mine mill-feed ore, 1.6 million tons of stockpiled fines, and 3.1 million tons of disseminated ore. Continued exploration of the Zambales Parcel 2 deposit was unsuccessful but Parcel 3 appeared to have good promise.

Copper.—Proposals to establish Philippine copper smelter and refinery made little headway. Financial backing was reported, and Marinduque Mining & Industrial Corp. was still considering the project. During the first half of 1965, about 30,700 tons of contained copper was produced; Atlas Consolidated Mining & Development Corp. accounted for 42 percent, Marinduque Mining for 24 percent (Sipalay mine, 17 percent, and Bagacay mine, 7 percent), Lepanto Consolidated Mining Co. for 19 percent, and Philex Mining Corp. for 11 percent. Other producers included Samar Mining Co., Inc., Surigao Consolidated Mining Co., Inc., and Copper Belt Mining Co. Copper output from Atlas Consolidated's leaching plant through June totaled only 18 tons.

Underground mining with block caving was scheduled to start by Atlas Consolidated in early 1967. After troubles with the hanging wall in the Lutopan pit, the bulk of Atlas ore was being drawn from the lower-grade Biga Road pit, where stripping was accelerated to meet demand. Leaching of dumps was curtailed in the aftermath of 1964's heavy storms. Marinduque Mining continued stripping its Cansibit property and river diversion at Sipalay, Negros Occidental, for an early start on mining. Meanwhile, production continued from two other deposits, Binulig and Baclao, where mill grades were falling below 0.6 percent copper. With an expanded molybdenum plant, the output of molybdenum concentrate was about 15 tons per month. At Bagacay, on Samar island, Marinduque's ores were averaging about 3 percent copper, and a start was made on pyrite shipments to supply the new Bataan plant of Esso Standard Fertilizer Chemical Co., Inc., with its sulfide requirements. The company continued blocking out ore in the Guila-Guila pit area.

Lepanto's ore grade continued falling, and in March it averaged 2.88 percent copper with 0.104 ounce per metric ton in gold. Ore reserves at the beginning of 1965 totaled about 6.15 million tons, slightly higher than a year earlier. The com-

[5] Besa, Ramon, A. Heavy Media Separation of Refractory Chromite Ore at Coto, Masinloc, Zambales. Philippine Min. J., v. 7, No. 5, May 1965, pp. 6–12.

pany's traditional conservative policy was modified and equipment was being installed under a $1.7 million loan to expand milling capacity from 1,300 to 2,000 tons daily. Other activities included exploration of the Botolan copper group, Zambales asbestos study, and improvement of Lepanto dock facilities.

Philex milled about 100,000 tons of disseminated copper-gold ore monthly at its Santo Thomas II mine, in Mountain Province. Samar Mining continued shipping copper concentrate from its Masara project, in Mabini, as well as from its iron ore operations elsewhere. Copper Belt Mining Co. had difficulty with heavy ground at its Lobo, Batangas, mine and tried to improve its mining methods. The mill handled about 100 tons of 2- to 3-percent copper ore daily, and the reserve situation was somewhat improved. Benguet Consolidated, Inc. reported Rapu-Rapu Island exploration had confirmed several million tons of copper ore; geophysical work on the western half of the island was inconclusive and further study was planned there. A drilling program based on geophysical anomalies was planned on Lubang Island, off Mindoro.

The potential for copper industry expansion in the Philippines further improved in 1965, as additions were reported to already sizeable reserves. Frontino, Inc., completed initial development at the apparently sizeable El Paso disemminated copper deposit, about 6 miles northeast of Lobo, Batangas, and Black Mountain, Inc., took over further operations. Some 2 million tons of 0.8 percent copper ore containing about 4 percent magnetite and small gold, silver, and molybdenite values had been outlined, and a possible 1,000-ton-per-day mill was visualized. Frontino, whose exploration at Surigao Consolidated Mining Co's. Lipawan mine has disclosed an extensive vein system with ores averaging 2.5 to 3.0 percent copper, signed an agreement to manage Surigao's Guripan and Lipawan mines. Consolidated Mines continued to explore the Magpog properties in Marinduque Province, where it had blocked out 5 million tons of oxide-sulfide ores averaging about 2 percent copper, minable by open pit. In early 1965, diamond drilling and four exploration tunnels were underway. A large tonnage with about 0.4 percent copper content was considered suitable for leaching.

Development was discontinued on the large open pit deposit on Marinduque Island, where a reserve of 80 million tons of ore averaging about 0.8 percent copper was previously outlined by a United States-Canadian group. Efforts by developers to secure investment assurances from the Government were unsuccessful, and the property stood idle most of the year.

Gold.—Benguet Consolidated, Inc., was installing crushing and flotation equipment and continued as the Philippines' leading gold producer, with Itogon-Suyoc Mines, Inc., second, and Benguet Exploration, Inc., probably third. Baguio Gold Mining Co's. gold property at Baguio was nearly out of minable ore, but the corporate outlook nevertheless improved as surveys continued on the company's new Santo Nino copper project in Mountain Province, Luzon. Paracale-Gumaus Consolidated Mining Co. was also an active gold producer but lacked significant reserves; it shipped some gold bullion and lead-zinc concentrates to Selby, Calif. for smelting and refining. The balance of gold production came from copper mining, chiefly Lepanto Consolidated, Philex Mining, and Atlas Consolidated, in about that order. Benguet Exploration developed a rich vein on its 500-foot level, extending the life of its Camp 6, Benguet district, Mountain Province, mine. Benguet Exploration also operated a new flotation plant with a capacity of 40 tons of ore per day. Itogan-Suyoc stabilized its mill-ore grade, explored new veins, and increasing reserves at both the Itogan and Suyoc mines. Gold producers received Government marginal mine assistance under Republic Act 3089, as amended.

Iron and Steel.—As interest in capitalizing on rich domestic supplies of iron ore increased, the first integrated iron and steel mill was being constructed, and two others were proposed. Construction began in the third quarter on the Iligan Integrated Steel Mills, Inc., plant, rated at about 270,000 tons of steel annually, at Iligan City; rolling facilities were scheduled for operation by late 1967 and full operations for about 1970. Feed is to in-Iron Mines. Port facilities at Iligan are being constructed to help handle increased shipping. Santa Inez Steel Corp. was planclude pelletized iron ore from Philippine

ning a 250,000-ton-Linz-Donawitz (LD) smelter and continuous casting plant to serve mainly for production of bars and structural steel shapes. The company's Santa Inez mine, with a 30-million-ton reserve, is to have installed beneficiation and pelletizing facilities, and the completed overall development was scheduled to produce steel by 1969. Also, Black Mountain, Inc., was considering a 50,000-ton-per-year steel plant in connection with its Pioneer iron mine, Zamboanga del Sur, Mindanao. Considered for this plant was the Swedish Stora process using oxygen and charred coal or coke breeze. The deposit contains an estimated ore reserve of 6 million tons.

Elizalde Iron and Steel Corp., which produced 30,853 tons of tinplate in 1964 on its new electrolytic and hot-dip lines, expected to boost output to 54,000 or even 60,000 tons in 1965. Marcelo Steel Corp. installed two electric furnaces and could make castings up to 13,000 pounds. Southern Rolling Mills, Inc., made a small initial shipment of black iron sheets to Taiwan. National Shipyards and Steel Corp's. 40-ton-per-day low-shaft blast furnace at Jose Panganiban remained idle, lacking suitable iron ore, but startup was expected upon arrival of pelletized feed from Philippine Iron Mines. The company operated its Iligan electric furnace and rolling mills below capacity because of scrap shortages. Philippine Iron Mines' 750,000-ton-per-year ore-pelletizing plant at Larap was completed in August, but production was limited by startup problems.

Iron ore production suffered from typhoon damage in late 1964, and there were difficulties in the operation of the Larap concentrator; nevertheless, output in 1965 rose more than 10 percent. The new aerial tramline at Samar Mining Co., Inc's. Sibuguey mine came into full operation, and additional mill modifications were being made as ore changed from high-grade to predominantly milling grade. High-grade ores that could be easily washed and shipped without further processing were mined from the nearby Conakon-Diutay deposit. Surface material was also a significant source of ore supply, amounting to 58,943 tons in 1964. Philippine Iron Mines had a reserve of about 44 million tons of ore averaging 40.1 percent iron at Larap, including about 4 million tons of direct-shipping grade averaging 56.4 percent iron.

A study was made of possibilities for steelmaking from black sands found extensively on Philippine beaches and in river sediments, for example, from the Camiguin Island region.[6] Suitability for steel was demonstrated. Exploitation of Mayorga Mining Co's. iron-sand deposits on Leyte was being considered, along with possible electric smelting. Byproduct magnetite produced from copper ores by both Atlas Consolidated and Filmag, Inc., supplied about one-tenth of total iron ore production.

Lead and Zinc.—Although some lead and zinc have been produced in connection with copper and gold mining, the Philippines until recently appeared to have minor potential for these metals. However, in searching for copper in southwestern Mindanao, a 10-million-ton lead-zinc ore deposit was reportedly found by Zambales Mining Co. Consolidated Mines recently has studied and sampled a lead-zinc prospect of unreported size and grade in Torrijos.

Manganese.—In 1965, a total of 56,000 tons of manganese ore was exported to Japan. Most of this came from Acoje Mining Co's. Sierra Madre property in Isabella Province, but in the second quarter a newcomer, Pan Asia Mining Co., began shipping a small tonnage of 33-percent-grade ore from its deposit at Dingalan, Quezon. During wet weather, landslides interfered with Sierra Madre operations.

Mercury.—Higher prices encouraged the country's lone producer, Palawan Quicksilver Mines, Inc., to improve facilities and boost mining rates; although grade continued to fall, recoveries were a little better. Most production was from the Tagburos mine. Average millhead grade was down to 2.99 pounds of mercury per metric ton of ore in 1964 but overall recovery was up to 81.75 percent. Roasting costs were lowered and capacity raised as an ore-drying plant, supplied by Gordon I. Gould & Co. of San Francisco, Calif., went into operation before the rainy season. Exploration and minor production took place at the company's Sugod project. To ex-

[6] San Miguel, A. F., Jr., A. C. Flores, and C. R. Sison. Preliminary Utilization Studies on Black Sand From Camiguin Island, Cagayan. Philippine Bureau of Mines Rept. of Inf. 56, April 1965, 15 pp.

ploit large tonnages of subgrade ores containing less than 2.5 pounds of mercury per ton, the management proposed to build a 300-ton-per-day beneficiation plant based on data gained from pilot plant operations. A bank of six Rossi retorts was installed, and stainless steel was to replace cast-iron condenser tubes.

Nickel.—The Government's Surigao Mineral Reservation Board received only two responses to an invitation to bid for operation of Parcel 2 of its Surigao del Norte, Mindanao, nickel reserve. The area under consideration was estimated to contain 147 million tons of ore averaging about 1 percent nickel, 0.08 percent cobalt, and 46 percent iron. Contract terms required production within 5 years of effective signing date and payment of 3.5 percent of gross output receipts to the Government. A $150 million investment was anticipated. One bid came from Benguet Consolidated, Inc. (about 90 percent U.S.-owned) and the other from a Philippine law firm acting as agent for MacArthur International Minerals Co. Benguet's offer was conditional pending clarification of questions on Philippine investment and trade laws.

NONMETALS

Cement.—Cement production rose dramatically; new plants and equipment boosted output over one-fifth. The largest producers, with outputs in thousand tons, were Republic Cement Corp., 720; Rizal Cement Co., 680; and Bacnotan Cement Industries, 270. The Philippine cement industry continued to oppose the importing of cement and the infusion of foreign investment in the predominantly domestic industry. Whether in fact there were cement shortages was debated; in Manila a major market area, cement prices at midyear remained relatively high, being quoted at slightly over $20 per ton. During the year, Mindanao Portland Cement Corp. completed Mindanao Island's first cement plant, but operations were limited because of faulty foundation support requiring costly corrective measures. Lone Star Cement Co. (United States) offered funds and technical assistance to get the plant going but some industrialists saw this as a foreign attempt to move into the domestic scene. Both Lone Star and Koppers Corp. (also of the United States) were unsuccessful in previous proposals to build plants. Tayabas Cement Co., Inc., having concluded a contract with a Japanese manufacturer for a $7-million plant, was going ahead with its plans for construction at Padre, Burgos, Quezon.

Marinduque Mining and Industrial Corp. began construction in the third quarter of a 380,000-ton-per-year wet process plant at Barrio Tagbak, Antipolo, Rizal, about 20 miles from Manila. Island Cement & Industrial Corp. was connected with the project. Cepoc Industries, Inc., looked for partners in building new cement plants and sent samples of raw materials to Japan for testing. The newly organized Abra Industrial Corp. explored for raw materials, trying to establish a cement plant in Bucay, Abra, to serve the Ilocos area. Apo Cement Corp., which previously had taken over Cebu Portland Cement Co. operations, planned to produce pozzolanic cement after locating a large deposit of suitable pozzolan. Apo added a kiln in August increasing its annual capacity to 220,000 tons and had plans to add another kiln that would make its annual cacapity 390,000 tons by late 1966. The new plant of Filipinas Cement Corp. received a second kiln, raising capacity to 220,000 tons, and plans have been made to triple this eventually. A third kiln was to come into operation in early 1966. Universal Cement Co. was doubling capacity with a second kiln which was expected to operate about midyear. Bacnotan Cement Industries at Bacnotan, La Union, operated three kilns at full capacity since December 1964. Also, the company negotiated with Mitsui & Co. (Japan) for construction of a 150,000-ton-per-year plant at Davao.

Feldspar.—Nin Bay Mining Co. upgraded sands containing about 20 percent alumina at its Porac River plant, producing about 20 tons of high-alumina sand daily for sale mainly to the San Miguel Corp. for glassmaking.[7]

Fertilizer and Pyrite.—Esso Standard Fertilizer and Agricultural Chemical Co. was completing its large new plant at Limay, Bataan, with annual capacity of 300,000 tons of various fertilizers. Developments at Marinduque Mining's Bagacay mine were completed to supply pyrite

[7] Unson, Miguel R. Recovery of Feldspar From Arkosic Sand. Philippine Min. J., v. 7, No. 5, May 1965, pp. 22–24.

under a contract with Esso calling for 180,000 tons annually beginning in mid-1965. The Esso plant boasts one of the world's largest fluosolids systems, capable of producing 750 tons of sulfuric acid daily; a phosphoric acid unit will process phosphate rock from the U.S. Atlas Fertilizer Corp. produced mixed fertilizers and, in addition to expanding its ammonia plant, was doubling its capacity for sulfuric acid. Atlas in 1964 produced 31,882 tons of sulfuric acid and 8,130 tons of phosphoric acid, with mixed fertilizers amounting to 53,035 tons. Marcelo Fertilizer Corp. installed a modern naphtha-steam reforming plant to boost anhydrous ammonia capacity to 39,600 tons annually. Philippine fertilizer output was 104,170 tons valued about $8 million in 1964 and was probably higher in 1965.

Silica Sand.—Initial production was reported from Pioneer Glass Manufacturing Co's. Sherman Hills mine in Negros Occidental, with hope of competing with South Vietnamese sands marketed in Japan. Quality was said to compare with that of high quality sand from the Ottawa, Ill., area, and the company envisioned establishment of glass manufacturing and other silica-related enterprises in the Philippines.

MINERAL FUELS

Coal and Coke.—Cebu and Mindanao provided most of the country's limited coal production, but attention was turned to the Malangas coal reservation, Zamboanga del Sur, in attempts to establish a domestic source of coking-quality coal that might supply forthcoming iron and steel operations. Coking tests were made by the Philippine Bureau of Mines on Melangas coal from the Lumbog area mixed with a newly discovered noncoking coal from the Katipunan Siay area. Resulting coke was judged suitable for iron and steel making; overall reserves were adequate for 5.2 million tons of such coke. At the Katipunan deposit three or more workable seams were being investigated, each several meters thick and with outcrops traceable about a mile. The Philippines has undeveloped coal seams on other islands, including Bataan, Polillo, Catanduanes, Negros, Mindoro, and Semirara. Koppers International Inc. (United States) was studying plans to build a byproduct coking plant using Malangas and Australian coal blends to fill future domestic needs.

Petroleum.—Import of crude oil and some supplementary refined products rose as the country's four refiners, Caltex (Philippines) Inc., Esso Standard Philippines, Shell Co. of the Philippines Ltd., and Filoil Refinery Corp., all expanded capacities and tried to catch up with demand.

Although some geological and seismic work was done, the amount of oil exploration drilling was insignificant. Philippine refiners continued to increase throughputs, using imported crude oil. Crude oil suppliers included Indonesia, Saudi Arabia, and Sarawak-Brunei. Exploration companies were becoming discouraged; one, the Philippine Oil Development Co., was about to go out of business after 30 years. Private financial resources were said to be near exhaustion and available foreign capital minimal. The Philippine Petroleum Association asked that the Government provide relief in the form of tax exemptions, a 5-year work moratorium on leases, and annual subsidies. The President created a committee to study the situation. Philex Oil Development Co. still had plans to drill test wells in the Ilocos Basin, renounced several leases on the east edge of the Central Luzon Basin, and planned holes for stratigraphic study in Cebu and Negros Occidental. Visayan Exploration Co., Inc., subsidiary of Standard Oil Co. of New Jersey, stepped up geological studies but lost a partner, as Mobil Philippines Exploration, Inc., withdrew from the Visayan Sea venture.

The Mineral Industry of Taiwan

By Benjamin H. Lim [1]

Coal remained the dominant product of the extractive sector of Taiwan's mineral industry in 1965, accounting for almost 75 percent of the value of all crude mineral output, but as a result of industrial growth of this island nation, the output value of the mineral industry's extractive sector has become less important to the economy than the aggregate output value of mineral processing facilities, many operating primarily on imported materials. Economically exploitable raw materials are rather limited: Coal, copper, gold, limestone, pyrite, oil, and gas are the most significant, but in the case of each commodity, Taiwan's output is only a small fraction of total world production, and only in the case of cement does the country have significance as a mineral product exporter.

The extractive sector's contribution to the island's 1965 gross national product (GNP) of about $2,600 million [2] was estimated at $66 million compared with $53 million in 1964; in both years, extractive industry output constituted about 2.5 percent of the GNP. The value index (1961 = 100) for the extractive sector's 1965 production, quoted at 129.7, gained 8.3 and 17.4 points over those of 1964 and 1963 respectively.

Major components in the sector had the following output value indices (1961 = 100):

Year	Coal mining	Metal mining	Crude petroleum and natural gas	Salt evaporation	Miscellaneous mining, nonmetallic mining, and quarrying
1963	111.3	92.2	135.4	151.5	115.3
1964	116.3	82.8	452.6	139.0	122.7
1965	116.9	90.9	833.1	141.0	128.9

Despite Taiwan's modest domestic mineral base, industrialization has forged ahead rapidly during the last few years. Indices for the manufacturing sector, including mineral processing facilities and other important components of the economy were as follows (1961 = 100):

Year	Manufacturing (sugar processing excluded)	Construction of buildings	Public utilities
1963	131.2	129.1	120.9
1964	168.6	154.2	142.6
1965	192.7	532.6	154.6

Source: Industry of Free China (Tapei, Taiwan). V. 25, No. 2, February 1966, pp. 68–69.

Beginning in 1965, Taiwan initiated its fourth 4-year plan (1965–68), under which the annual growth targets in the various sectors of the economy were approximately: Agriculture, 4 percent; industry, 11 percent; and all other sectors combined, 6 percent. The new plan also called for an annual increase of 7 percent in the GNP. To implement the various projects in the new plan, a capital investment of about $2,500 million was envisaged.

Taiwan's third 4-year plan increased the island's GNP over the 4 years by 35 percent, its per capita income by 19 percent, and its industrial production by 72 percent. The average annual increase in the GNP approximated closely the original target of 8 percent. Record production in agricultural and industrial sectors during 1964 buoyed up the economy considerably and

[2] Where necessary, values have been converted from New Taiwan dollars (NT$) to U.S. dollars at the rate of NT$40.10=US$1.00.

despite some minor dips in a few of the areas during 1965, the economy remained sound and the new plan was off to a good start.

The soundness of Taiwan's economy in recent years has been due to, in no small part, its liberal investment policies. The success of the island's ability to attract foreign investment is evidenced by the increase in the average annual inflow of overseas capital into Taiwan, from some $6 million before 1959 to more than $25 million in 1965. Some of the factors that generated this favorable investment climate included continuous development of industrial sites, ample supply of skilled and inexpensive labor, and political, economic, and social stability. In some respects Taiwan is becoming more attractive to international investors than Hong Kong and Japan.

To enhance the island's investment climate further, the Taiwan Government has approved recently several major projects specifically designed to improve and expand the island's infrastructure in anticipation of the rapid industrialization during the years of the new plan. Some of the new projects started in 1965 included modernization and extension of railway facilities, dredging and expanding the harbors at Keelung, Kaohsiung, and Hualien, construction of airports and highways, and electrification of more remote areas of the island. Completion dates for these projects have been scheduled for 1969.

To augment the incentives for foreign investments still further, Taiwan revised the Statute for Encouragement of Investment in January 1965. Some of the more important provisions of the revised statute were as follows:

1. An enterprise conforming to the prescribed encouragement criteria and established through new investment or an existing enterprise of this category increasing its capital investment is exempted from business income tax for 5 years.

2. The maximum rate of business income tax, including all forms of surtax, shall not exceed 18 percent of the total annual income.

3. Enterprises conforming to the encouragement criteria are entitled to a 10-percent reduction of business income tax after the expiration of the 5-year tax exemption period.

4. Undistributed profits used for expansion are tax exempt, provided they do not exceed 25 percent of annual taxable income.

5. Investors may repatriate each year 15 percent of the invested capital starting 2 years after completion of the investment project.

6. Enterprises in which 51 percent or more of the capital comes from foreigners or overseas Chinese are not subject to Government requisitions or expropriation for 20 years.

Such promotions for foreign investments, especially those likely to lead to increased exports, have reaped much success in recent years. In 1965, total foreign investment approvals reached $48.2 million, compared with $28.5 million in 1964. Of the 1965 total, $31.4 million represented U.S. investments.

Taiwan's Government liberal investment policy was drawn up, in part, in anticipation of the termination of American aid to the island, which was officially ended on June 30, 1965. During the fiscal year, ended June 30, 1965, U.S. aid consisted of about $2 million in development grants, $37 million in development loans, and $20 million in surplus farm products. Since the start of U.S. aid to Taiwan, the United States has extended to the island $1,360 million worth of goods and services. This aid helped immeasurably in constructing one of the strongest economies in the Far East. Commitments made prior to the termination date will add $95 million more to the total.

On April 9, 1965, an agreement was reached between the United States and Chinese Governments that $50 million of counterpart funds, to be known as the Sino-American Fund for Economic and Social Development, should be made available annually for economic development projects. The agreement specified that the use of the money would be determined by the Chinese Government. The United States Government, however, retained the right of supervision of the projects selected. On April 26, 1965, an agreement was concluded with the Japanese Government for loans totaling $150 million. Funds from these loans will help to finance the construction of several major projects including the proposed $100 million Tseng Wen

Dam, a second harbor at Kaohsiung, a hydroelectric power station on the Lower Tachien, a steel mill and a new fertilizer plant, and new installations for several major metallurgical and metal-fabricating firms in Taiwan.

The development of industrial sites underwent rapid expansion in 1965. In the latter part of the year, the Taiwan Government designated 59 industrial districts in different parts of the island with a total area of about 6,300 acres. During 1965 the 150-acre industrial complex at Liutu was completed. Thirty-eight firms with a total capitalization of about $7 million were building facilities in various stages of completion. Since demand exceeded the supply of land in Liutu, an additional site at Kweishan was being prepared. In addition to these developments, a site of 540 acres was being readied simultaneously at Kaohsiung, 170 acres of which have been designated as the "export processing zone." Firms in the zone will enjoy exemptions from import and other duties. Construction of public utilities and a few private factories have already begun late in 1965 in the area.

PRODUCTION

Most of Taiwan's mineral commodity products showed slight output gains in 1965 and some recorded significant increases. Output of a few declined from the previous year's levels. The greatest increase in mineral production in 1965 occurred in natural gas, which almost doubled the 1964 rate and was six times that of 1963. Significant increases also occurred in the production of gold, silver, asbestos, dolomite, and gypsum.

Of the island's basic industries, production of aluminum ingots, still near peak capacity, showed a slight decrease compared with last year's record high, but production of aluminum sheets increased 14 percent from that of 1964. Output of iron and steel products, mostly semimanufactures, apparently increased only slightly but production of iron ores, limonite, and magnetite was substantially above 1964 levels.

Total value of output of the mineral extractive sector and the mineral-based component of the manufacturing sector amounted to $458 million for 1965 and $392 million for 1964. Of the 1965 total, basic metals accounted for $50 million; metal products, $25 million; nonmetallic mineral products, $87 million; products of petroleum and coal, $76 million; and chemical and chemical products, $154 million. The remainder of $66 million was from the extractive industries with the following breakdown: Metals, $4 million; salt evaporation, $7 million; nonmetallic mining and quarrying, $2 million; coal, $48 million; and crude petroleum and gas, $5 million.

TRADE

Taiwan's industrial growth has been marked by a growing foreign trade deficit with respect to mineral commodities, as the value of imports of these goods has consistently increased more rapidly than has the value of exports of materials in this class, as shown in the tabulation below:

	Value (million dollars)		Mineral commodities' share of total (percent)
	Mineral commodities	Total	
Gross exports:			
1963	31.3	331.2	9.5
1964	33.5	433.0	7.7
1965 e	34.0	491.0	6.9
Gross imports (including AID imports):			
1963	78.2	361.3	21.6
1964	102.4	428.0	23.9
1965 e	130.0	544.0	23.9
Net trade balance:			
1963	−46.9	−30.1	XX
1964	−68.9	+5.0	XX
1965 e	−96.0	−53.0	XX

e Estimate.
XX Not applicable.

Of the total value of imports in 1963, 1964, and 1965, funds from the U.S. Agency for International Development (AID) were used to finance $76.1 million, and $67 million, respectively.

Taiwan's mineral exports were dominated on a value basis by iron and steel semimanufactures and by cement, while metal imports, chiefly semimanufactures of iron and steel, accounted for the preponderance of total mineral imports in 1963 and 1964 as shown in the table that follows and presumably this situation continued to be the same in 1965.

Commodity group	Value (million dollars)			
	Exports		Imports	
	1963	1964	1963	1964
Metals	14.0	15.5	40.1	57.6
Nonmetals	14.2	14.6	12.4	18.6
Mineral fuels	3.1	3.4	25.7	26.2
Total	31.3	33.5	78.2	102.4

Taiwan's principal trading partners have been Japan and the United States for the last several years. In 1964, Japan received approximately 33 percent of all of Taiwan's exports in exchange for 42 percent of the island's imports. The United States purchased about 19 percent of Taiwan's exports in return for 26 percent of all the imports from the United States. Value of shipments from the United States was exclusive of those financed by AID.

COMMODITY REVIEW

METALS

Aluminum.—In 1965, Taiwan's aluminum industry produced approximately 42,000 tons of alumina, 19,000 tons of ingot, 9,000 tons of sheets, 2,000 tons of extrusions, 1,000 tons of foil, and 3,000 tons of various aluminum semimanufactures and finished goods. These production rates approximate the capacities of the island's industry.

The Taiwan Aluminum Corp. (TALCO), a wholly Government-owned enterprise with plants located in Kaohsiung, remained the only fully integrated aluminum company in the country. In anticipation of continued growth of demands for aluminum products by the domestic market, and elsewhere in Southeast Asia, the company continued the second phase of an overall expansion plan in 1965. The first phase, completed in 1964, consisted of renovation and expansion of smelting capacity; the second phase with a target completion date late in 1966, involves increasing the firm's annual mill capacity to about 15,000 tons of sheets and plates. When this expansion is completed, plans call for raising annual alumina production to 70,000 tons and annual ingot output to 30,000 tons. Total investment for these projects was estimated to be about $5 million. Early in 1965, TALCO announced additional plans for a $7 million expansion program designed to increase production of aluminum manufactures. When completed the firm will produce automotive chassis, fishing boats, textile spindles, electrical plates, and various accessories for household appliances.[3]

Because Taiwan lacks bauxite resources, the island has imported this material, chiefly from Sarawak, India, and other Far Eastern countries. During early 1965, however, representatives from Taiwan visited Jamaica to study the feasibility of importing bauxite from that country.

Iron and Steel.—Production of iron and steel ingots and castings in Taiwan in 1965 was estimated to be slightly above the 1964 level and pig iron output was 16 percent higher than in 1964. Output of rods, bars, and slabs in 1965 totaled 260,000 tons compared with 236,000 tons in 1964.

Taiwan's steel industry, comprising some 50 firms of various sizes and specializations, was recently surveyed and reported to be somewhat technologically behind and economically inefficient. This was especially true of the island's iron foundries as noted by Taiwan's Metal Industries Development Center. Some of the Center's findings indicated that equipment in the foundries was obsolete, resulting in low productivity per man-hour, that metallurgical practices and technological control were inadequate, that molding techniques needed much improvement, that plant layouts were poor, and that general working conditions needed attention from management and Government. The survey also recommended a training program for upgrading skills of foremen, supervisors, and other management personnel, ways and means to improve the cost and price structures of foundry products, and a comprehensive market study of the industry's goods.[4]

In order to improve the technological efficiency of Taiwan's steel industry (capacity estimated at 400,000 tons per year), a plan was drawn up during the latter part of 1965 to establish an integrated steel plant at Kaohsiung. Proposed capacity of the new plant was on the order of 500,000 tons per year, with provisions to possibly double this by the late 1970's. The final plans emphasized the conventional blast-furnace oxygen converter process during the initial stages of the industry's development. Higher levels of technological sophistication will be acquired as the industry develops.

The establishment of an integrated steel plant on Taiwan has been a strong desire of many Taiwan industrialists and officials, who believe that such a plant is essential to future industrial development. During the last 5 years several large U.S. and Japanese steel and engineering consulting firms have suggested various plans for improving Taiwan's steel industry. The Kloechner Industrie-Anlagen G.m.b.H. survey team from West Germany, after studying the island's steel industry, reported late in 1965 that it would be feasible to establish an integrated plant on the island. The Kloechner reports will serve as a major guide for Taiwan's experts in planning construction.

The Taiwan Government, upon the recommendation of the International Bank for

[4] Industry of Free China (Taipei, Taiwan). The Iron Foundries of Taiwan. V. 24, No. 1, July 1965, pp. 10–28.

Reconstruction and Development (IBRD) has engaged the consulting firm of Arthur G. McKee & Co., Cleveland, Ohio, to do a comprehensive study, and presumably a definitive investigation of the various proposals for the plant's establishment. It was reported that on conclusion of the McKee investigations the Taiwan Government will make some final decisions as to whether or not to construct the steel plant.

Nickel.—Nickel ore was discovered in the Ilan and Hualien Provinces. The ores consist mainly of pentlandite, pyrrhotite, pyrite, and chalcopyrite. Investigations indicated a reserve of some 5 million tons of this ore with a nickel content ranging from 0.14 to 0.35 percent.[5]

NONMETALS

Bentonite.—A bentonite deposit, estimated in preliminary studies to contain about 2 million tons, valued at $100 million, was discovered in Ping Tung County in southern Taiwan.

Cement.—At yearend 1965, cement capacity of 10 major Taiwan producers was about 3 million tons. Planned output for the year was 2.5 million tons, slightly more than the actual production. Of the 1965 actual output, approximately 900,000 tons were exported and the remainder of 1.5 million tons was consumed primarily by construction projects. Rate of construction during the year was especially rapid, as shown by the expenditure of approximately $31.9 million in the private sector alone, compared with $9.3 million in 1964 and $8.7 million in 1963.

It is expected that foreign trade returns for 1965 will show a decline in cement exports compared with 1964 figures because of the completion of cement producing facilities in traditional customer countries—mainly South Viet-Nam, the Philippines, and Hong Kong. Although escalation of the conflict in South Viet-Nam has hindered cement production in that country, leading to a December 1965 order through open tender for the supply of 400,000 tons by Taiwan cement manufacturers in 1966,[6] the cement companies continued to look ahead and were seeking new outlets, especially in Middle Eastern countries. By gaining new customers, they hope at least to retain their position as the world's fourth largest exporter of cement, preceded in rank only by Japan, Belgium, and France.

Preliminary reports indicated that Taiwan's export of white cement in 1965, although small in comparison with that of the Portland type, increased rapidly during the year with sales exceeding $1 million, more than double the 1964 figure. The Chiahsin Cement Corp., the only large white cement manufacturer in Taiwan, was expanding its annual capacity from 14,000 tons to 25,000 tons.

Fertilizers.—Although Taiwan has experienced rapid industrial development in recent years, agriculture has remained the mainstay of the island's economy, both supplying indigenous demand and providing foreign exchange through export sales. Recent increases in agricultural production have been due partly to much wider use of chemical fertilizers of which a significant percent has been provided by the island's fertilizer producers, who have built up this industry to become one of the country's largest.

At yearend 1965, Taiwan had three major manufacturers of chemical fertilizers: The Taiwan Fertilizer Co. (TFC), The Kaohsiung Ammonium Sulfate Corp. (KASC), and the Mobil China Allied Chemical Industries, Ltd. (MCAC). KASC produced only ammonium sulfate in its single plant at Kaohsiung with an annual capacity of about 140,000 tons. MCAC also operated one plant, a facility at Miaoli that uses natural gas as raw material, with a capacity to produce 100,000 tons of urea and 45,000 tons of liquid ammonia annually. TFC operated seven plants with a total annual capacity of about 600,000 tons of various types of fertilizers by yearend 1965. These plants included a 36,000-ton-per-year calcium cyanamide plant at Keelung; a 50,000-ton-per-year calcium superphosphate plant also at Keelung; a facility at Kaohsiung that was renovated late in 1964, increasing capacity from 70,000 to 150,000 tons of various types of phosphatic fertilizers; and a plant at Lotung that produces mainly fused phosphates and calcium carbide. Carbide production capacity at the latter plant was recently increased from 5,000 to 8,600 tons. Other TFC facilities include a quarry at Suao, operated by the Lotung plant that supplies limestone

[6] Taiwan Industrial Panorama. A Further Increase of Taiwan's Cement Export is Expected for 1966. V. 4, No. 12, Dec. 31, 1965, item 1527, p. 4.

to the firm's plants at Keelung and Hsinchu, and the Hsinchu plant, which is capable of producing annually 39,000 tons of calcium cyanamide and, since June 1964, ammonium sulfate at a rate of 120,000 tons per year. Another plant at Nankong produces mainly urea with an annual capacity of 75,000 tons and an installation at Hualien, the only fertilizer plant on the island's east coast, has the capacity to produce 60,000 tons of nitrochalk per year.

In 1965, TFC continued expansion in order to meet the expected goal of 1 million tons of fertilizers per year by 1969, including 777,250 tons of nitrogenous and 251,000 tons of phosphatic varieties. Most notable of the firm's projects occurred in the Hsinchu plant, where the company plans to spend upwards of $20 million to renovate the installation into a large chemical complex capable of producing 180,000 tons of ammonia a year. The ammonia, in tum, will be used to make 140,000 tons of ammonium sulfate and 90,000 tons of urea. The complex will use natural gas as a raw material.

MINERAL FUELS

Coal.—Known coal reserves at yearend 1965 were estimated at 200 million tons. At the projected annual rate of consumption, approximately 7.5 million tons by 1974, Taiwan's known reserves will not last much beyond the current century. In attempting to head off this prospect, The Ministry of Economic Affairs employed five mining experts from Japan in March 1965 to survey deposits off the island's north coast. This team located deposits around Keelung totaling an estimated 100 million tons, one-half of which is reported to be extractable. The team also located other coastal coal pockets with a total of about 300 million tons, but the amount that is minable from these areas was not given.

More than one-third of Taiwan's coal production has been consumed by Taiwan Power Co. (Tiapower). Demand for coal will be even greater if Taipower implements its plans to generate more thermoelectric power. At yearend 1965, Taipower was operating 34 stations capable of generating a little more than 1 million kilowatts, of which 53 percent was hydroelectric and the remainder thermal. The average consumption of coal per kilowatt in solid fuel thermal plants was approximately 0.474 kilogram in 1964, a slight improvement over the 1963 figure of 0.485 kilogram. (The amount of coal used in the United States in 1964 and 1965 to generate 1 kilowatt was 0.391 kilogram.)

Of the total sales of 5,185 million kilowatt-hours in 1964, 82 percent went to industries and the rest to residential and commercial users. In recent years, the average annual growth rate for power generated has been 13 percent, very close to the average overall industrial growth rate. The six largest industrial groups in Taiwan—fertilizer, iron and steel, aluminum, cement, textiles and chemicals—accounted for 57 percent of total power sales.

Natural Gas.—Production of natural gas in 1965 was nearly double that of 1964 and six times that of 1963. In view of the increasing gas reserves and production, Taiwan industrialists and Government officials decided to establish a petrochemical industry to manufacture intermediate products, heretofore imported at a cost of about $60 million annually, chiefly from Japan and the United States, for other industries.

To implement the decision, the Chinese Petroleum Corp. (CPC) has constructed a plant at Miaoli to process 35.3 million cubic feet of gas per day. To distribute the product, the Taiwan Cabinet recently approved a CPC plan to seek $20 million to build a network of pipelines throughout Taiwan.[7] Taiwan Government development officials have considered establishing an industrial zone including petrochemical installations at Towfen. Preliminary plans called for an area of about 125 acres.

In 1965, CPC broke ground for a naphtha cracking unit at its Kaohsiung refinery to produce ethylene, propylene, butylene, butadiene, and various aromatic chemical intermediates. When this project of CPC is completed, new units for extracting aromatic compounds will be added to increase the output of benzene and xylene. In addition to this project, a number of others were either under construction or in the last phases of the planning stage at yearend, including National Distillers & Chemical Corp.'s plans to build a plant to produce about 20,000 tons per year of polyethylene, utilizing CPC's ethylene as the main starting material. Construction presumably was under way on this project at

[7] Far Eastern Economic Review (Hong Kong). Chemicals: Gas Works. V. 49, No. 13, Sept. 23, 1965, pp. 580–581.

yearend and completion of the facility was expected in 1968. It was reported that Allied Chemical Corp. applied to Taiwan's Central Government for approval to develop a sizable petrochemical project, including facilities to produce 25 tons per day of caprolactam, a starting ingredient for the synthesis of Nylon 6, and installations to manufacture 20 tons per day of dimethyl-terephthalate, a raw material for manufacturing polyester fiber. Taiwan development officials were also considering establishing a vinyl chloride installation that would use ethylene instead of the more expensive acetylene as the raw material, resulting in substantial savings in production costs and thereby improving the competitive position of Taiwan-produced polyvinyl chloride. Other noteworthy projects include the manufacturing of acrylonitrile from propylene and ammonia utilizing the process developed by the Standard Oil Co. of Ohio and the preparation of synthetic rubber (cis-polybutadiene) from the anticipated quantities of butadiene from the naphtha cracking unit.

The Taiwan Government also reportedly planned to construct a styrene unit. In 1965, there were only two local firms manufacturing polystyrene using imported styrene. Because of the cheap domestic supply of styrene, many more companies using this commodity are envisioned. Major uses for styrene include polymers, and various resins and plastics.[8]

Petroleum.—In 1965, the Chinese Petroleum Corp. (CPC), wholly Government-owned and the only petroleum refinery in Taiwan, decided to invest approximately $30 million in a 4-year plan of petroleum exploration. CPC also planned to increase the production of its Kaohsiung refinery over the next 2 years from 1.6 to 3 million tons of fuel oil annually. One of the first expansion projects will be the addition of a new topping plant capable of handling 50,000 barrels per day. This new plant will be used to supply fuel oil to a 600,000-kilowatt thermal powerplant, which is expected to consume an estimated 500,000 tons of fuel oil per year. The new installation was partly financed by the United States Export-Import Bank and will be constructed by the Taiwan Power Co.

In April 1965, China Gulf Oil Corp., a joint venture between CPC and the Gulf Oil Corp., completed and put on stream an $11 million lubricating oil plant at Kaohsiung. Processing units of the new installation were designed by the M. W. Kellogg Co., New York, N.Y., and the auxiliary off-site equipment was designed and constructed by China Technical Consultants. The capacity of the new plant was estimated at 1,500 barrels per day. Products from the company were expected to be about four times the present rate of consumption in Taiwan. Gulf will distribute the surplus abroad, while CPC will supply the domestic market.

The Mineral Industry of Thailand

By J. M. West[1]

According to preliminary estimates the gross national product (GNP) of Thailand rose in 1965 to about $3,800 million,[2] while value of mineral industry output totaled about $110 million. Value of output in the mining and quarrying sector was 2.4 times that of 1957; in the same period the GNP increased only 1.7 times. The Government's new objective is to double the GNP within the next 10 years. The emphasis on mineral development that this would entail is clear. In 1965, newly discovered deposits of tin, already a well developed and leading resource, were being explored, and the outlook was favorable for significant expansion in production. Iron ore became prominent in 1965, output approaching 800,000 tons. Fluorspar and antimony have reached significant levels in recent years, and resources of zinc, manganese, gypsum, and salt were expected among the next to come under development. The potential for rare elements, such as columbium and tantalum, associated with tin deposits was regarded as excellent. Search for fertilizer raw materials and oil and the study of means of developing and utilizing rich oil shale deposits were among matters of urgency prompting government inquiries in these fields.

In 1965, Thailand ranked third in tin production among non-Communist countries and fifth in the world, contributing 12.5 and 9.6 percent of the respective totals. It also produced about 2 percent of the antimony, and close to 1 percent of the tungsten.

A major milestone in industry development was the opening of the Phuket tin smelter. Under Thai law, virtually all domestic tin concentrates produced at least for the next 5 years must be processed by this plant. Many small tin mines were opened or reactivated, and at least two and possibly three large tin dredges for working offshore tin deposits were under construction.

Further efforts were made to justify an iron and steel smelter in the north-central area, which would utilize electric power from Mekong River and tributary stream developments. Steel sheet and bar rolling facilities were being installed at Bangkok. Cement expansions were planned or underway, one fertilizer plant was under construction with the start on a second imminent, and a glass plant neared completion. The new Sriracha oil refinery operated at near capacity, and the Government's Bang Chak refinery was to be enlarged to make its operation more economical.

Progress was made during the year in port and highway construction and in power development. Work proceeded on a draft of new Thai mining laws; meanwhile, the Department of Mineral Resources in Bangkok in March 1965 published an English translation of the Mining Act of 1919 and the Mining Amendment Act of 1931. Major changes were expected in the mining laws during the coming year, including at least a modification of the restriction on foreign participation in mining north of the 11th parallel, thus opening a large new area to stepped-up development. New regulations being written would permit foreigners to acquire concessions in the northern mining area for petroleum, iron ore, zinc, and other minerals, providing certain standards are met on size of operation.

[2] Where necessary, values have been converted from the Thailand baht (B) at the rate of B20.8 = US$1.

263-927 O-67—77

The system by which the Mining Organization, a State enterprise that operates mines and the agency through which miners in the north sublease concessions, was to be changed so that all Thai concession grants would be handled by the Mineral Resources Department. The Mining Organization would continue to operate its own mines and possibly open a training school for miners. Government mineral survey and development centers continued their activities at Chiengmai, Songkhla, and Phuket.

An agreement signed with the U.S. Government provided for guarantee against investment loss through revolution or insurrection and extended guarantees covering loan capital and various financial risks. Under the agreement, each project must be approved in advance by the Thai Government and must meet Agency for International Development requirements. Opportunities for investment in Thai minerals were outlined in a report issued by a U.S. Government agency.[3]

United Nations geologists continued surveys of iron, manganese, nonferrous metal, and nonmetal deposits in north and northeast Thailand, and a team of West German geologists was assisting in training Thai geologists. A mining convention sponsored by the Ministry of National Development was scheduled for early 1965 at Chiengmai on the major theme of nonmetallic minerals. A mining and industrial safety equipment show was planned to coincide with the convention, affording an opportunity for international manufacturers to display their products.

Thailand continued to offer a good investment climate, with the Government taking firm action to develop an industrial infrastructure. A handicap to orderly development was the Communist-inspired terrorism in the extreme south and northeast. As part of the announced second 5-year economic development plan (1967–71), the Government was to spend $2,500 million on various construction projects. Among these were port facilities, highways, irrigation works, communications, and power projects. Highways were particularly favored in the 1966 budget with a one-half increase over the 1965 budget figure to $72 million. Allocations for industry and mining (exclusive of mineral resource development), conversely, were to decrease to less than $12 million, or only 1.7 percent of total government expenditures. Mineral resource development fared better than in the 1965 budget, with $2.2 million assigned. A possible new project under study was construction of a port capable of accommodating 5,000-ton ships at Songkhla in southern Thailand.

A main north-south peninsular highway extending from Bangkok to the Malayan border was being planned besides about 1,600 kilometers of other roads in the south. It was announced that $7 million in Australian aid would go toward a highway north of Bangkok between Tak and Mae Sod, on the Burmese border, opening an access route to the zinc deposits in that area. A plan was considered for mine developers to cover part of the roadbuilding costs. Italian, Japanese, South Korean, and West German firms have signed or were about to sign contracts for other road construction, as follows: Phrakhanong-Bangna section of the Bangkok-Sriracha highway, Lampang-Chiengmai highway, Pattani - Narathivas highway (southern Thailand), and Nakhorn-Pathom-Petburi highway. Work started in August on the Korat-Kabinburi military highway; the 100 - kilometer Chachoengsao- Kabinburi link of the route from the Gulf of Thailand neared completion.

In electric power, the National Energy Authority completed a map of electric generation and transmission facilities (drawing 7D.77 01, dated Dec. 16, 1965) showing the many potential hydroelectric sites, substations, and existing and planned distribution lines in Thailand. Installation of the fifth and sixth generators at Yan Hee hydropower plant and another 75,000-kilowatt termal generator in North Bangkok was under consideration. The West German-financed Ubol Ratana Dam on the Nam Pong River neared completion with two 8,300-kilowatt generators to supply the northeast area and Vientiane in Laos; the 6,300-kilowatt Nam Pung hydroplant was opened in November 1965. Nam Ngum, a 90,000-kilowatt hydroelectric project in Laos, was to begin supplying power to the Thai northeast in 1970–71. A $65 million loan was being considered by the

[3] Scholla, Paul F., and Associates. Mining Resources and Mining Investment Potential in Thailand. Agency for International Development, U.S. Operations Mission to Thailand, 1965, 96 pp.

World Bank for the Tha Pla irrigation and power scheme in northern Thailand. In the south at Krabi the Lignite Authority operated two 20,000-kilowatt thermal generators and planned to install a third; the Provincial Electric Authority was installing distribution lines to carry Krabi power into eight southern provinces. Despite new availability of thermal power it was felt that because of the poor quality of coal, long-term power needs in the south must depend on hydroelectric sources and a step-up in investigative work was urged. A site on the Pattani River near Bangrang was considered a prime location for a 30,000-kilowatt plant. Other promising power sites included Tone Nga Chang, near Songkhla; Kra Rome Falls and Klai Kao, both near Nakhon Sithammarat; Lang Suan, Kang La Waeng, and Kang Pra Chao, all near Chumyshon; and Sai Buri, near Narathiwat.

PRODUCTION

Thai mineral production value in 1965 was estimated at $110 million, significantly higher than in 1964 owing mainly to increased tin values. Cement and iron ore also showed important gains, but fluorspar, antimony, and gypsum outputs declined. Low-quality lignite was used principally for generating electric power; oil produced and refined at one inland field was a minor fuel item. Output and sales of hydroelectric power were on an upswing, signifying increased industrial activity. A moderate share of manganese production went to battery makers in Bangkok, the rest was exported. Iron ore came chiefly from one mine on the southern peninsula, from which it was shipped to Japan.

[1] Smelting began in August at Phuket.
[2] Petroleum refining began in September 1964 at Sriracha; Government refinery at Bang Chak began partial operation during 1965. Data on refinery products not available.

TRADE

Preliminary data indicate that Thailand's mineral exports were valued at about $70 million in 1965, over 11 percent of all exports, and were led by tin valued at $55.2 million, compared with $46 million in 1964. Iron ore was second in importance valued at $5.9 million and cement was third at close to $1.5 million. The bulk of the tin concentrates went to Malaya for refining; tin metal exports beginning in September went to the United States.

Final data on the value of mineral trade for 1963 and 1964, and its relationship to total trade are summarized in the following table:

	Value (million dollars)		Mineral commodities share of total (percent)
	Mineral commodities	Total	
Exports:			
1963	40.6	452.0	9.0
1964	52.5	574.9	9.1
Reexports:[1]			
1963	6.4	12.3	52.0
1964	6.4	16.9	37.9
Imports:[1]			
1963	125.6	607.3	20.7
1964	145.5	679.0	21.4
Net trade balance:			
1963	−78.6	−143.0	XX
1964	−86.6	−87.2	XX

XX Not applicable.
[1] Reexports are recorded because Thailand import statistics include merchandise imported for reexport; goods in transit are not included in either import or export statistics.

In 1965 imports of mineral fuels, lubricants, and related products were valued at about $61 million, compared with $70 million in 1964; the lower value reflected the change in type of petroleum imports from products to crude oil, because local refining came nearer to satisfying domestic markets. Of the 1965 figure, 8.4 percent was the U.S. share, mainly in lubricants. Steel and fertilizers continued to be major import items, but domestic fertilizer production, due for expansion in 1966–68, was expected to replace a large share of the imported fertilizers. Of Thailand's overall imports in 1965, the U.S. share was nearly one-fifth, with about one-third of the imports from the United States entering under various foreign assistance programs. Machinery, including transport and construction equipment, was an important component of the latter segment of trade. Gem stones shared a small but locally significant part in Thai trade, since Bangkok is one of the gem stone cutting centers of the Far East. In 1964 uncut and cut gem stone imports were valued at $360,000 and $80,000, respectively. There was also possibly large unofficial trade in Thai gem stones. Silver bars imported in 1964 totaled 614,000 troy ounces, about four-fifths of U.S. origin. Mineral products moving through Thailand from Laos to Penang in 1964 were valued at $680,000 for tin and $73,800 for copper ores; petroleum products valued at $3.48 million moved through Thailand to Laos.

COMMODITY REVIEW

METALS

Antimony. — Most of Thailand's antimony production continued to come from the Bansong mine in the south, where both ore and metal output declined. However, ore exports were slightly higher in 1965, reaching a record of 2,646 tons valued at about $580,000. Meanwhile, exports in metal form dropped nearly one-half to 110 tons valued at $63,200. Smelting operations were conducted at Bansong by relatively primitive means.

Iron Ore and Steel.—Thai output of iron ore, nearly all for export to Japan, increased as the result of the development of a deposit in Nakhon Sithamarat Province by Thailand Steel Co. The latter operations, which began in May 1964 and provided 176,125 tons of iron ore during that year, produced 737,296 tons in 1965, of which 716,942 tons valued at $5.86 million was exported. Small mine operations were maintained by Siam Cement Co. in Lopburi Province, which produced 9,069 tons in 1965, and by Eastern Mining Development Co. in Nakhon Sawan Province.

Exploration by United Nations specialists continued in the Loei area of north-central Thailand near the bend of the Mekong River where estimates for ore reserves have risen to nearly 30 million tons. This strengthened efforts by Mekong development interests and the Thai Government to establish a steel smelter based on local raw materials and power. However, the economy of an inland plant was in doubt. It appeared a seaboard site would be favored instead, initially using mainly imported raw materials. Part of the iron ore requirements would probably come from southern Thailand, gradually utilizing admixtures of the Loei area ores.

At Phrapadaeng, Samut Prakan, 16 kilometers from Bangkok, G. S. Steel Co. Ltd., a joint Japanese-Thai venture, 60-percent owned by Mitsubishi Shoji Kaisha Ltd., and Kawaichi Steel Co. Ltd., was building a mill to produce 90,000 tons of steel bars annually starting in early 1967. Two steel pipe plants opened in the third quarter of 1965 Thai-American Steel Works Co., controlled by Castle and Cooke Co. Ltd. (United States) and Thai Steel Pipe Industry Co. Ltd., in which the Japanese had a 70-percent interest. The small Tha Luang Iron and Steel Works, operated by Siam Cement Co., placed an order for a new 5-ton-capacity electric arc furnace.

Lead and Zinc.—Output of lead ore containing some zinc increased about one-half in 1965 as mine activity increased in Kanchanaburi Province where the Nong Phai deposit was prominent. Exports increased to 11,948 tons valued at $481,000. The Thai Government planned to invite bids to establish a zinc smelter and for mining rights to three concession areas in Tak Province of northwestern Thailand. Here was claimed to exist a total of 3.8 million tons of zinc ore averaging 35 percent zinc in one of the world's largest deposits of smithsonite (zinc carbonate). Only companies 50-percent or more Thai-owned were to be eligible to bid.

Manganese. — Production in 1965 included 4,069 tons of battery-grade ore, 29,259 tons of metallurgical-grade ore, and

100 tons of chemical-grade ore. Almost half of the battery-grade and nearly three-fifths of the metallurgical-grade ore was exported. Average export value was about $52 per ton of ore. The major manganese deposits are in the northwest, west of Lampang and north of Tak; among these the Ban Mae Jong, east of the Li River, is the chief producer.[4] Estimates for ore reserves at Ban Mae Jong were given as follows: 20,000 tons convertible to battery grade, 60,000 tons suitable for chemical grade, and 450,000 tons of metallurgical grade. Total reserves of 8 or more known Thai deposits were estimated as high as 3 million tons with grades up to 65 percent manganese dioxide, and large areas favorable for manganese were said to remain unexplored.

Tin and Tungsten.—Particular interest centered on the new tin smelter of Thailand Smelting & Refining Co. Ltd., a partnership of Union Carbide Co. (United States) and Thai Eastern Mining Co. Ltd., which was formally opened at Phuket on July 29. By yearend, 4,705 tons of Thai-smelted tin valued at $19.2 million had been exported. Deliveries of Thaisarco brand tin were made chiefly to the United States and marketed by Union Carbide Co., prime investor in the new enterprise.

With the addition of production from an estimated 50 smaller mines and the rebuilt bucket dredge of Aokam Tin Ltd., Thailand's tin concentrate output increased one-fifth to a record high in 1965. Some tungsten and other minerals were recovered as byproducts. Effective July 24, exports of tin ore were suspended in accordance with a government control requiring tin producers to refine ore at the new Phuket smelter. Thereafter, ore exports declined to only a few hundred tons of offgrade concentrates specially exempted from controls. For the year, tin-in-concentrate exports thus declined to 10,759 long tons valued at $36 million compared with the 15,666 tons shipped in 1964. As before, such exports went to Penang in Malaya for smelting.

The new smelter started operation with two furnaces having combined annual capacity of 20,000 tons of tin concentrates. From the upward trend of mine production it became evident added capacity would be needed and immediate expansion to 30,000 tons began, two more furnaces being scheduled for completion by November 1966. Probably influencing the expansion was the announced discovery after a 2-year survey by the company of offshore tin deposits with a reported value of at least several billion baht; this was the only given indication of their extent. Mining operations were expected to begin in 1966, although surveys remained incomplete. Two $3.5 million dredges were on order.

In another development, the discovery of substantial tin deposits was reported in the Khao Luang mountain range of southern Thailand. No details were given nor was it stated whether these were alluvial or hard-rock deposits.

A new suction dredge being built by Southern Kinta Consolidated Ltd., for offshore mining at Takuapa, on the west coast, was scheduled for operation in early 1967. Together with yet uncommitted leases, the area to be mined was estimated to contain 43,000 tons of tin concentrates. The Siamese Tin Syndicate Ltd. dredge at Takuapa was being moved to new ground, and its Kota Bahru dredge resumed operation at yearend after a shutdown for repair. Aokam Tin placed an order for a second bucket dredge to replace its offshore grab dredge.

Tungsten, mostly produced with tin, made further gains; output increased more than one-fourth. A few tons of scheelite were included in the mainly wolframite production. Exports, amounting to 527 tons, while lower than in 1964, were valued higher at $680,000.

NONMETALS

Cement. — Production of cement was nearly one-fifth higher in 1965 because of intensive construction activity throughout the country. Domestic consumption was estimated at 885,000 tons in 1965 and was expected to rise to 1,020,000 tons in 1966. In 1965, 18 percent of the output was exported. In the last quarter of 1965 an order for 150,000 tons of cement was placed with the Siam Cement Co. Ltd., to go to South Viet-Nam, the major export market, and increased rates of shipments were anticipated in 1966. Output began

[4] Gardner, Louis S., Tuan Damrongmanee, and Roscoe M. Smith. The Ban Mae Jong and Other Manganese Deposits in Northwestern Thailand. Thailand Dept. of Mineral Resources, Rept. of Inv. 8, 1965, 51 pp.

to lag behind demand, and a temporary cut in import duty on cement clinker was asked while new calcining equipment was obtained. An added demand factor was the 80,000 tons of cement needed for the Sataheep Naval Base airfield, southeast of Bangkok, about to come under contract. This represented Thailand's largest single order for cement since building the Yan Hee Dam. In view of such activity, Siam Cement planned to install an additional kiln at Tha Luang and expand its Bangkok grinding capacity in 1966. The other Thai producer, Jalaprathan (Cholpratan) Cement Co. Ltd., with a 300,000-ton-per-year plant was planning to expand to about 500,000 tons annual capacity. Siam Cement's annual capacity, including its just completed 300,000-ton Tungsong plant in southern Thailand, was estimated at 1,245,000 tons.

Fertilizer Materials. — Thai-controlled Chemical Fertilizer Co. Ltd., was building the country's first fertilizer plant to supply demand stimulated by a nationwide rural development program emphasizing broad use of fertilizers. The plant, at Mae Moh in Lampang Province, was scheduled to start operation in the last half of 1966 with an annual capacity of 30,000 tons of urea and 60,000 tons of ammonium sulfate. The company also planned mixing plants near Bangkok, in Nakhon Ratchasima (Korat), and at Mae Moh, and intended to import phosphate rock, potash, and sulfur as ingredients. The need for sulfur was especially urgent, and because of world shortage the company had difficulty locating suppliers. Initial operations were expected to require about 1,000 tons of sulfur monthly. The Government approved a proposal by Thai Oil Refinery Co. to build a $20-million fertilizer plant which would use waste products from its new oil refining operations at Sriracha. Investment agreements were not quite complete at yearend. The $15 million project would produce about 180,000 tons of mixed fertilizers annually.

Fluorspar.—All but a few thousand tons of the fluorspar produced was exported. The average export value was only about $19.20 per ton. Six mining companies worked in three widely separated districts.[5] Most production was from the Ban Hong mine in northwest Thailand where at least three major veins occur in metasediments intruded by granites. Limited measured reserves exist, but indicated and inferred ore reserves have been estimated as high as 3.6 million tons in the Ban Hong deposits and 500,000 tons at Doi Tao, also in the northwest. The Yang Hak district, southwest of Bangkok, was estimated to contain 200,000 tons of ore.

Gypsum.—Domestic consumption of gypsum, largely in cement, was estimated at 27,700 tons in 1965. Output was lower than in 1964 as excess stocks of gypsum were used. Gypsum was valued at $17.25 per ton. A Bangkok consulting firm was engaged to do a market study for Thai Gypsum Co. Ltd.

Silica.—A group of small islands off the west coast of southern Thailand—Palau Tertau, Telok Poh, Telok Bantae Malaca, Ko Bulon, Haad Kaseng, Telok Serai, and Tanjong Batu—have deposits containing an estimated 15 million tons of glass sands averaging 95 percent silicon dioxide. The sands were first explored by a Japanese firm. In 1965, Indo-Thai Corp., a Thai firm, began mining, and marketed the sands through Malaysia Silica Quarry Enterprise Ltd., a Malaysian firm; the output went largely to Japan.

Thai-Asahi Glass Factory, the country's first sheet glass plant, was to start up at yearend. Capacity was reported at 650,000 cases of glass (100 square feet per case) annually, over twice what was imported from Japan in 1964. Sands mentioned above presumably will be used by the glass plant.

MINERAL FUELS

Lignite.—Production from the Krabi lignite mines increased from 13,367 tons in 1964 to 77,728 tons in 1965, the first full year of operation. The coal went principally to the Krabi powerplant; 91,095 tons valued at $4.12 per ton was consumed in 1965. The Mae Moh lignite mine, north of Bangkok in Lampang Province, produced 47,236 tons of coal in 1965, only about one-half of the 1964 output as recently developed Yan Hee hydroelectric power replaced part of the thermal demand. A mobile crusher was being purchased for use in Mae Moh's opencast

[5] Gardner, Louis S., and Roscoe M. Smith. Fluorspar Deposits of Thailand. Thailand Department of Mineral Resources. Rept. of Inv. 10, 1965, 42 pp.

mining, and preparations were made to supply coal to a new fertilizer plant.

Petroleum.—According to the Defense Energy Department, oil found in drilling to date in the Mae Soon area, Chiengmai Province, in northern Thailand, could amount to between 1 and 10 million barrels. The oil differed from that of the Farng area where a small oil refinery has operated since 1959. Quantities of crude oil available at Farng have been limited, and further search in that area has been unproductive. According to new information the Farng field produced 180,000 barrels from 1959 through 1964, and the 1,000-barrel-per-day refinery processed only about 145,000 barrels in total during this period.

The search for oil in other areas of Thailand intensified; eight or more companies and individuals applied for concessions. Under current regulation each applicant is limited to three sections of not more than 25,000 square kilometers. Standard Oil Co. of New Jersey and Shell Oil Co. submitted applications to explore the offshore shelf, and Continental Oil Co. was also studying possibilities; Union Oil Co. of California held rights to exploration in seven northeast provinces. In view of such activity, the Government was in the process of reviewing and revising its petroleum laws to establish an equitable and attractive investment basis.

Summit Industries Corp. (United States) continued negotiations with the Thai Defense Energy Department over operation of the Department's Bang Chak refinery and prepared to start work on expansion from 5,000 to 20,000 barrels daily capacity by mid- 1968 under a $12 million contract with Japanese Shiyada Chemical Engineering Co. The plant, operating at 10,000 barrels of products per day by simple topping in 1965, produced fuel oil in excess of what Summit was able to sell, so a trade of fuel oil for diesel was arranged with Shell Oil Co. Shell continued its management role of Thai Oil Refining Co. Ltd.'s 36,000-barrel-per-day Sriracha refinery and produced 26,000 to 30,000 barrels per day in its first full year of operation.

The Third Symposium on the Development of Petroleum Resources of Asia and the Far East, meeting in November 1965 at Tokyo, Japan and sponsored by the Economic Commission for Asia and the Far East (ECAFE), included presentation of papers on the subject of Thai oil industry and potential. Among these were the following reports: Exploration and Exploitation of Petroleum in the Mae Farng basis of Northern Thailand Since the Time of the Second Symposium; Notes on the Khorat Series of Northeastern Thailand; The Investigation of the Li Oil Shale Deposit, Northern Thailand; and Petroleum Refining and Imports of Products into Thailand.

The Mineral Industry of Other Far East Areas

By Benjamin H. Lim [1]

CONTENTS

CAMBODIA

Cambodia had only minor mineral activities in 1965, including some quarrying of phosphate and limestone, manufacture of cement, and extraction of precious and semiprecious stones. Salt production was limited to the evaporation of seawater. The once relatively productive gold mine at Phnom Long in Kompong Thom Province has been near depletion for some years.

Having renounced all United States aid in late 1963, and finally severing diplomatic relations on May 3, 1965, Cambodia counted in 1965 on military and economic assistance from the Communist countries and from France. Mainland China in 1965 granted a new economic aid program which included a glass plant, a fertilizer plant, and an airstrip at Battambang, in addition to providing military equipment for 27,000 men. Soviet technical experts started work on a dam at Kam Chay, and Yugoslavia was building a powerplant at Kirirom. France prepared to help finance construction of the Phnom Penh-Sihanoukville railway and a dam at Prek Thnot. France was also to provide aid in expanding port facilities at Sihanoukville. Aid was also coming to Cambodia in 1965 from Czechoslovakia, West Germany, and Japan.

PRODUCTION

Cambodia's mineral production in 1965 remained insignificant. Phosphate rock was mined in one locality. Except for small quantities of gold from almost depleted mines, salt from the ocean, and minor amounts of precious and semiprecious stones, Cambodia produced practically no other minerals.

TRADE

Cambodia's mineral exports remained insignificant amounting to only $106,000 in 1964 and $129,000 in 1963. Its chief mineral export, or reexport, consisted of petroleum products, which totaled in 1963 and 1964 $121,000 and $92,000, respectively. Total exports aggregated $89.0 million in 1963 and $87.5 million in 1964. Mineral imports for these same years were, respectively, $24.7 million and $17.2 million from total imports of $107.2 million in 1963 and $81.8 million in 1964. France, Japan, mainland China, and Indonesia were Cambodia's chief trading partners for all commodities during these years. South Viet-Nam was Cambodia's chief mineral importer; this trade consisting mostly of petroleum products.

COMMODITY REVIEW

Metals.—*Copper, Gold, Manganese.*—Recent geological surveys of the Kompong Thom area revealed the presence of copper, gold, and manganese. More investigations are needed to ascertain whether these deposits are sufficiently rich to warrant extraction.

Iron Ore.—Iron ore deposits at Phnom Dek in the province of Kompong Thom have aroused interest from time to time. Before World War II, plans were made to establish a plant capable of processing 60,000 tons of ore per year and producing 25,000 tons of cast iron per year. These plans were later rejected, and French development in Cambodia after the war made no mention of an iron project. In 1962, surveys were carried out for construction of a small steel mill based on these iron deposits and use of locally produced charcoal. Technical and economic aid was to be provided by mainland China. These plans were also later abandoned. It was reported that the deposits will be surveyed in more detail by French experts under a provision in the latest economics assistance agreement with France.

Nonmetals.—*Cement.*—The cement plant at Chakrey Ting, in Kampot, on the Gulf of Siam, was in full operation in 1965, producing at capacity of about 50,000 tons per year. The plant was inaugurated and went into production in September 1964. The plant, built with mainland Chinese technical and economic assistance, depends on local deposits of limestone.

Fertilizer.—A small fertilizer plant was reported to have been constructed recently in the town of Battambang utilizing the phosphate found in the provinces of Battambang and Kampot.

Mineral Fuels.—*Petroleum.*—On July 1, 1965, a contract was consummated between the Cambodian Government and a French State firm, the Union Générale des Pétroles (UGP), to construct an oil installation at Sihanoukville capable of refining 50,000 tons of crude oil a year. The plant has been scheduled for completion in 1967 and will be managed by the Société Khmère de

[2] Semimanufactures except for 169 metric tons in primary forms imported in 1963.

Raffinage, a joint venture with 65 percent of the total funds (approximately $10 million) provided by the Cambodian Government and the remainder from UGP. Crude oil for the refinery is expected to be imported from the Middle East.[2]

Power.—Several dams were under construction in 1965 to provide power and irrigation water. Surveys were made during the year to investigate the feasibility of building a dam at Prek Thnot, an area south of Phnom Penh, capable of providing 18,000 kilowatts as well as enough water to irrigate approximately 225,000 acres. France has earmarked assistance for this project. Ground had previously been broken for the construction of a dam and an hydroelectric power station at Kam Chay. A 163-mile transmission line was also to be built to carry current to Phnom Penh. Soviet aid was extended on this project. Concomitant with these projects, Yugoslavia was helping in the establishment of a 3,000-kilowatt thermal power station at Kirirom by providing all the necessary equipment for the plant as well as sufficient material to build a 66-mile transmission line.

HONG KONG

As in previous years, Hong Kong's production of minerals in 1965 was not very important. Minerals produced in this small but densely populated British colony were limited to iron ore, and small amounts of wolframite, kaolin, feldspar, and quartz. All ores produced in 1965 were mined by open pit methods. Total value of the 1965 mine output was nearly $1.2 million.[3] Iron ore accounted for more than 90 percent of the total value. The entire iron ore output was exported to Japan in the form of concentrates. Other minerals were shipped to the United States, the United Kingdom, and Japan. All feldspar and quartz were consumed by domestic ceramic and enamelware manufacturers. Approximately one-fourth of the kaolin was used in local rubber factories, and the remainder was exported, chiefly to Japan and Taiwan.

The Mining Ordinance of 1954 vests ownership and control of minerals in Hong Kong and the New Territories in the Crown of the United Kingdom. Under the Ordinance the Commissioner of Mines is empowered to issue prospecting and mining licenses and the land officer to issue mining leases. Prospecting and mining licenses are valid for periods of 6 months and are renewable up to a maximum of 5 years. Mining licenses may extend beyond 5 years upon the consent of the Governor of Hong Kong. Mining leases are granted for periods up to a maximum of 21 years. No change in the laws was reported.

In 1965, approximately 20 prospecting and mining licenses and 3 mining bases were in force. Hong Kong Government reports indicated that prospectors made no discoveries of any importance in 1965. Hong Kong's mining industry employed about 2,500 persons in 1965, including approximately 500 in iron ore and wolframite mining and 2,000 in stone quarrying, clays, sand, and other nonmetallic mining.

The Hong Kong Land Development Commission enlarged on its initial decision to reclaim land at Kwun Tong from an earlier estimate of some 90 acres to 514 acres. Estimated cost of the reclamation was set at about $17.5 million. In view of Hong Kong's rapidly rising construction costs, however, this estimate may have to be revised. The project was divided into an industrial section (275 acres) and a housing and commercial section (239 acres). In addition to Kwun Tong, a new area of some 70 acres at Kwai Chung has been selected for reclamation and development. A small number of industrial enterprises have been built in Kwai Chung and in nearby Tsuen Wan.

In addition to these areas, the Hong Kong Government has continued to improve existing industrial areas in urban parts of the colony. Plans have been completed to provide 500 additional acres for 24 different industrial sites within the next decade. The scheme for reclamation and development of these areas will follow those of Kwun Tong and Kwai Chung.[4]

e Estimate.

PRODUCTION

Hong Kong's mineral production showed an appreciable increase in iron ore and wolframite output, and a slight increase in quartz production. Feldspar and kaolin registered small declines. Prospectors for graphite made no discoveries of any importance in 1965 and no graphite production was recorded. Total value of Hong Kong's mine production was estimated at $1,179,000 in 1965, slightly more than the $1,000,000 in 1964. Of the total in 1965, iron ore accounted for $1,039,925, kaolin $114,697, wolframite $11,698, feldspar $6,861, and quartz $6,016.

In addition, cement made from imported clinker was valued at an estimated $3.6 million, up from the previous year's $3.2 million. Value of coke and breeze produced in 1965 was estimated at $290,000.

FOREIGN TRADE

Although Hong Kong has only a small mining industry, it does a brisk trade in mineral products. In 1965, the island's total value of mineral trade—imports plus exports including reexports—was $312 million, compared with $249 million in the previous year.

Table 4.—Hong Kong: Value of mineral trade
(Million dollars)

Category	1964	1965
Metals:		
Imports	$82	$87
Exports	18	19
Reexports	9	9
Nonmetals:

Exports	4	5
Reexports	23	41
Mineral fuels:		
Imports	46	51
Exports	(1)	(1)
Reexports	3	5

1 Less than $1 million.

Imports of metal commodities in 1965, as in previous years, consisted primarily of aluminum, copper, and steel semimanufactures; metal exports and reexports were comprised mainly of ferrous and nonferrous scrap. Imports of nonmetals consisted chiefly of construction materials, pearls, and precious and semiprecious stones. Of the nonmetal imports, pearls and precious and semiprecious stones accounted for 67 percent of the total value. The latter commodities were also included in exports and reexports. Refined petroleum products, mainly kerosine and lubricating oils, made up approximately 94 percent of the total value of mineral fuel imports in 1965. Petroleum exports and reexports were primarily kerosine and lubricants.

COMMODITY REVIEW

Metals.—*Aluminum.*—Hong Kong's aluminum industry is limited to a number of small metal fabricators that import semimanufactured products and produce consumer goods. Two of Hong Kong's leading aluminum manufacturers are Hong Kong Chiap Hua Manufacturing Co. and Meyer Manufacturing Co. Chiap Hua is engaged primarily in manufacturing extrusion aluminum products while Meyer's main operations are concerned in rolling aluminum sheets.

The Chiap Hua Manufacturing Co., originally a shipbreaking and iron and steel rerolling business, has capacity to produce about 2,500 tons of rods, tubes, and sections annually. These products are generally sold to local fabricators to make such consumer products as aluminum door and window frames, store fronts, panels, and other aluminum products used in con-

struction. It was reported recently that Chiap Hua's management, realizing the current construction boom in the colony, may integrate its present operations to include a broader line of products. Comalco Industries Pty., Ltd., an Australian company, has been supplying aluminum billets to Chiap Hua's Tokwawan plant.

Meyer Manufacturing Co., also located in Tokawawan and only a short distance from Chiap Hua, produces mainly aluminum circles and sheets. Annual capacity of the Meyer was reported to be about 400 tons, of which about one-half was derived from scrap. Of its production, the firm markets about 250 to 300 tons in form of circles and sheets to local fabricators. The remainder is consumed in flashlights and lanterns.

Iron Ore.—During 1965, the Ma On Shan iron mine increased capacity by 40 percent; additional equipment was installed in the grinding section of the ore-dressing plant.

Iron and Steel.—Hong Kong's iron and steel industry, consisting chiefly of small capacity rolling mills, experienced a mild recession in 1965, during which 6 mills were closed. A number of factors aggravated the industry's situation. In the first place, construction, the chief consumer of steel products, lost much of its buoyancy of previous years. Secondly, foreign iron and steel bars, beams, and other construction material became increasingly competitive with those of local manufacture. Another factor was the continued sluggishness of Hong Kong's shipbreaking industry, upon which the colony's iron and steel mills rely heavily for their raw materials.

The continued recession of Hong Kong's shipbreaking in 1965 was, in part, due to the closing of the shipscrapping sites at Ngau Tau Kok in March because of progress made on reclamation projects in Kowloon Bay. It was also due to the fact that fewer ships were available in 1965 for scrapping owing to increased worldwide shipping.

LAOS

Laos is a landlocked, agricultural nation where 90 percent of the people are engaged in farming, animal culture, and timber industries. The country possesses, however, a variety of minerals, some deposits of which have been reported of considerable interest. Of these the only one currently mined is tin, providing the country's only mineral export. Tin output in Laos has remained relatively constant averaging approximately 650 tons of concentrate annually with a 50-percent metal content. If all the known tin deposits in the country were worked, it has been estimated that 2,000 to 3,000 tons of tin concentrate could be produced annually.

Notable among the minerals yet to be exploited in Laos is iron ore. According to a French technologist the Laotian ore is exceptional both in grade and reserves but details have not become available yet. If deposits approach expectations, Laos will certainly need financial and technical help in developing this resource. The establishment of an iron ore mining industry leading eventually to a possible iron and steel industry would have a stimulating effect upon the development of other minerals in Laos; and this, in turn, could lead the way for a gradual shift from its present predominant agricultural economy to one with some measure of industry.

One of the most important factors in industrial development of Laos is to obtain a cheap source of power. Since the country lacks an abundant reserve of coal, the Laotian Government has planned to construct hydroelectric dams. Power from these dams would be channeled mostly to industry.

Surveys for a minor dam site at the Selabam Waterfall on the Sedone River were completed in 1965. The equipment for the dam will come from France. Completion of this dam has been scheduled for 1968. When completed it will operate two 750-kilowatt generators. Surveys for a dam site on the Nam Dong River, 6 miles south of Luang Prabang also were completed in 1965.

Access roads were constructed in 1965 to dam site on the Nam Ngum River, 60 miles north of Vientiane; bidding for construction of the proposed 220-foot high dam has been scheduled for early 1967 with the expectation that work will begin in that year. When completed in 1971, Nam Ngum will initially provide 30,000 kilowatts of electricity and sufficient water to irrigate 12,500 acres. Ultimately, the dam will have the capacity to generate 120,000 kilowatts, not only to meet the increasing requirements of the Vientiane area but also to satisfy the energy needs of neighboring areas in Thailand. The dam also will have the capacity to provide water to irrigate 80,000 acres. Half of the cost of the $24.1 million project has been pledged by the United States, which is one of 8 countries contributing to the project.

PRODUCTION

Tin was the only mineral for which production statistics were available in 1965. Output of tin concentrate and approximate metal content have been as follows:

Year	Concentrate (long tons)	Metal content (long tons)
1961	667	335
1962	709	367
1963	650	326
1964	686	343
1965	569	285

Other mineral commodities such as copper, iron, clays, gravel, sand, coal, and petroleum from seeps, have been produced in Laos at one time or another, but no output statistics were available for them. These minerals were locally consumed.

TRADE

Laos' mineral imports in 1964 amounted to $5.3 million,[5] of which metals (mostly iron and steel commodities) accounted for $1.3 million; nonmetals (mostly cement and salt), $0.5 million; and mineral fuels (mostly petroleum refinery products), $3.5 million. Laos' lack of even small processing facilities necessitated imports of metal products chiefly in their final forms. This lack also accounted for the fact that the value of the country's mineral imports equalled only about 20 percent of the total value of all imports during 1964.

[5] Converted at the official rate of 240 kip=US$1. However, an unknown proportion of transactions was actually conducted at the legal free market rate of 500 kip=US$1.

Laos' principal mineral export in 1964 continued to be tin concentrates. The amount exported during 1964 totaled 727 long tons valued at approximately $690,600. Of this, Penang, Malaysia received 523 tons ($504,000) and Singapore 204 tons ($186,600). In 1963, Laos exported 546 long tons of tin concentrates valued at $155,000, of which Penang received 232 tons ($64,400) and Singapore 314 tons ($90,600).

Total value of Laos' imports in 1963 and 1964 were, respectively, $8.8 million and $25.5 million, while the country's exports amounted to only $238,700 in 1963 and $888,900 in 1964.

COMMODITY REVIEW

Metals.—*Gold.*—Gold occurs in several places in Laos, especially along the Mekong River and its tributaries. Samples from these tributaries have yielded assays ranging from 0.28 to 0.47 ounces of gold per ton of ore. On the banks of the Mekong River at Ban Dou Men, south of Pak Ley, one exceptional sample yielded as high as 3.33 ounces of gold per ton. Other samples from this location have yielded 1.86 ounces per ton.

Iron Ore.—Between Xieng Khouang and Phong Savan in central Laos a huge deposit of oolitic iron ore was reported in late 1962. Preliminary reports made by French surveyors indicated the deposit had reserves of about 1,000 million tons with an iron content approximating 60 percent. More recent reports indicated the deposit might contain several thousand million tons. It was further reported the deposit could be economically exploited with open-cast methods. A second deposit of high grade iron ore was reported in an area 50 miles south of Xieng Kouang. Since there has been little prospecting other than preliminary surveys, size and grade of the deposits have not been established with any certainty. It is believed the latter deposit may compare favorably with the former. Other smaller and somewhat lower grade

iron ore beds have been discovered recently in various areas of Laos. If these deposits prove as good as preliminary reports claim, Laos presumably could develop mines and possibly establish an iron and steel industry.

Tin.—Of the various metal deposits found in Laos, the only ones being worked commercially are those of tin. The deposits currently exploited are located at Phontieu in Khammoune Province. The mine is operated by a French firm, Société d'Études d'Exploitation Minière de l'Indochine, which employs about 400 workers. Another company holding tin concessions as a combined private-government venture, Société d'Enterprise d'Étain du Laos, had no production in 1965.

Laos' tin production in 1965 was approximately 569 tons of 50 percent tin concentrate, valued at about $1,500 a ton. About 500 tons of ore are required to produce 1 ton of concentrate. The entire production is exported, mostly to Penang, Malaysia, and constitutes the largest single item in Laos exports, in the past few years amounting to 50 to 75 percent of the total value of exports.

Other Metals.—Recent preliminary reports from survey teams of various countries have confirmed the existence of several other metal deposits. Lead ores have been discovered in the Annam Cordillera below Tchepone and in several other areas in the country, and some are reported to be of sufficient size and grade to warrant mining. Silver and zinc have been found associated with the galena, and could be significant byproducts or coproducts. In addition, deposits containing antimony, manganese, molybdenum, and cobalt are known. Preliminary surveys indicate little about the commercial value of the latter deposits.

Nonmetals.—*Cement.*—The cement plant at Thakhek, to have had an estimated annual capacity of 25,000 tons, was still uncompleted in 1965. Construction of the plant started in 1954, and after many delays it was scheduled for completion in 1963. The plant is located in an area where gypsum and large quantities of limestone are readily available. Additional deposits of gypsum have been discovered in the Savannakhet Plain.

Salt.—Salt deposits exist in several parts of Laos, but at present salt is extracted only by primitive methods and on a small scale to satisfy local needs. The total production is estimated to be about 2,500 tons per year. An additional 1,000 to 1,500 tons of salt are estimated to be imported every year.

Mineral Fuels. — Coal. — Commercial amounts of low grade anthracite were located near Saravane about 5 years ago. Although detailed plans had been completed for the construction of electric power plants utilizing the anthracite, they have as yet to be implemented. Proposed sites of the latter plants were Saravane, Pakse, and Thakhek. A few thin coal beds have also been reported to occur in the northern part of the country.

Petroleum.—Geological surveys have revealed favorable structures for oil in Laos, one between Thakhek and Pakse and another in the Vientiane Valley. An agreement was made between the Laotian Government and a group of French companies in 1959 for further investigation of these potential petroleum areas. At yearend 1965, nothing had yet come of the project.

NORTH VIET-NAM

North Viet-Nam's mine output, consisting mainly of chromite, apatite (for phosphate), and anthracite, was comparable with that of 1964; production of its mineral-related light industry reportedly gained 20 percent during 1965. Total value of North Viet-Nam's mineral industry product in 1965 was probably a little over $100 million. Because specific data, information as to the country's pricing system, and other details pertaining to North Viet-Nam's economy are limited, it is difficult to assess the overall contribution of minerals, but it could be as high as 15 percent of the gross domestic product.

For its size of approximately 63,000 square miles, North Viet-Nam is well endowed with a variety of minerals, in contrast with South Viet-Nam. Thus, North Viet-Nam is one of the fairly rich countries in mineral resources in Southeast Asia. In addition to having large deposits of high-quality anthracite, of which reserves are reported over 1,000 million tons in the Hon

Gai region alone, there are extensive beds of iron, tin, zinc, and apatite. Surveys also indicate existence of antimony, wolfram, bauxite, and manganese. These mineral resources, save those of anthracite, have been worked either very little or remain virtually unworked.

North Viet-Nam's Second Plan (1961–65) has emphasized the search for and development of mineral resources. In this respect, Hongay, Campha, Vong Bi, Mao Khe, Trang Bach, Lang Cam, and other mineral centers in the country have received particular attention by economic planners. To exploit known deposits, plans have been made to construct mining and smelting facilities to produce aluminum, iron, and zinc. Industrial complexes have also been planned and are in various stages of completion. Other industrial projects in the second plan include the modernization and expansion of existing installations, such as the cement plant in Haiphong, the iron and steel mill in Thai Nguyen, various fertilizer installations throughout the country, and power generating stations. Among major projects in the second plan is the expansion of the port at Haiphong to enable it to handle larger ships and twice the amount of present traffic. Financial and technical aid for these and other projects is expected to come from mainland China, the U.S.S.R., and other Communist countries.[6]

PRODUCTION

Despite disruptions caused by war, North Viet-Nam's 1965 output of primary minerals was reported to be approximately the same as that of the previous year. Trade data of some of the countries that have commerical ties with North Viet-Nam confirm this. Estimating from trade statistics, North Viet-Nam exported about one-third of its mineral production, chiefly anthracite and salt to Japan.

Anthracite was by far the most important mineral produced in 1965, followed by cement and apatite. Output of pig iron in 1965 was probably about 100,000 tons and that of cast iron and steel totaled about 50,000 tons.

North Viet-Nam also produced undisclosed quantities of tin, zinc, asbestos, clays, dolomite, glass sands, kaolin, mica, and pyrite. Facilities to process or refine lead, antimony, copper, manganese, and mercury were reportedly in operation at yearend 1965.

TRADE

Official trade statistics for North Viet-Nam have not been published. In lieu of them, Soviet data on mineral exports to North Viet-Nam have been shown in this chapter. Japan, mainland China, and West and East European countries have also been factors in North Viet-Nam trade. In addition to metal products received from the U.S.S.R., North Viet-Nam imported from Japan iron and steel semimanufactures totaling 3,340 tons in 1964 and 10,540 tons in 1965. It also purchased from Japan small amounts of copper and aluminum semimanufactures in these 2 years. Imports of petroleum refinery products have been mainly of U.S.S.R. origin.

[r] Revised. [e] Estimate. NA Not available.
[1] In addition to commodities listed, North Viet-Nam also produced gold, iron ore, pig iron, cast iron, steel, lead, tin, zinc, asbestos, clays, dolomite, glass sands, kaolin, mica, and pyrite and had begun or was about to begin producing antimony, copper, manganese, and mercury. Data on production of these commodities are not sufficient to establish reliable estimates.

Greases	800	300

North Viet-Nam's chief mineral export has been anthracite coal, much of which was shipped to Japan. In this regard, North Viet-Nam has been the chief supplier of anthracite to Japan in the last few years. In 1963, 1964, and 1965, respectively, Japan received 541,265 tons, 402,855 tons, and 427,948 tons of anthracite from North Viet-Nam. Mainland China has also been receiving sizable quantities of anthracite from North Viet-Nam, in addition to large amounts of apatite and chromite. East European countries receive large quantities of apatite from the country.

COMMODITY REVIEW

Metals. — *Chromite.* — North Viet-Nam's chromite mines are centered about Co Dinh, about 25 miles from Thanh Hoa, in the Nong Cong District. One of the major mines in the vicinity of Le River employs about 2,000 workers and has a mechanized section as well as two manual sections. The mechanized section employs hydraulic monitors while the manual is confined to simpler methods. In the manual sections employees are divided into small work groups of four and five individuals. Climatic conditions, monsoons and drought, hamper the work to some extent. Because there is as yet no smelter to extract the metal, the ore is exported to the U.S.S.R. and mainland China.

Iron and Steel.—The Thai Nguyen iron and steel complex, North Viet-Nam's first steel mill and under construction since September 1963, was nearing completion at yearend 1965. The 200,000-ton mill had been scheduled for final completion in 1966. By early 1965, the complex had put into operation two blast furnaces, and a third blast furnace was nearing completion at the time. It was presumably finished by the end of 1965.

Ore for the mill will come from the large deposit at Trai Cau, North Viet-Nam's first iron ore mine. This mine reportedly had reserves totaling more than 2 million tons of ore containing about 60 percent iron. The Trai Cau mine went into trial operation in 1964, and was said to have the capacity to supply approximately 300,000 tons of ore per year. Concurrent with the construction of the Thai Nguyen steel complex, a power station capable of generating 24,000 kilowatts was also being built. The power station was reported to have been completed in the early part of 1964 and was scheduled to supply electricity not only to the steel mill, but also to Hanoi and the Viet Bac autonomous region.

The coking component of the mill was completed ahead of schedule and placed in trial operation in December 1964. The coking plant was reported to have an annual capacity to produce 150,000 tons of coke, sufficient to supply three furnaces. Equipment was set up to extract byproducts of coking. An iron ore sintering plant with an annual capacity of 130,000 tons was also put into trial operation at the same time.

On December 12, 1964 construction of the rolling mill was started. Removal of earth ahead of schedule for foundations

permitted builders to take advantage of dry winter and spring months. The construction of the steel rolling mill has been technically assisted by the mainland Chinese and its completion has been scheduled for some time in 1966.

In 1965 North Viet-Nam geological survey teams were reported to have discovered an iron ore deposit in the Quang Nai Province with an estimated reserve of about 40 million tons. An open pit operation was said to be feasible to mine the ore.[7]

Tin.—Although there are a number of tin occurrences in North Viet-Nam, especially in the Tinh Tuc district of Cao Bang Province, production of the metal was never very great.

Since the partition of Viet-Nam, the North Viet-Namese Government has reopened, expanded, and mechanized the Tinh Tuc mine with capital and technical assistance from the U.S.S.R. and East European countries. When the mine and smelter were reopened, there were difficulties in recruiting labor, especially those with skill necessary to operate heavy earth-moving equipment. A training program was instituted to meet the requirement. At yearend 1965 an estimated 3,000 to 3,500 workers were engaged in extracting tin in Tinh Tuc.

Nonmetals.—*Cement.*—Haiphong had the principal cement manufacturing plant in North Viet-Nam in 1965. Capacity of the single large plant, with its 4 rotary kilns, had been estimated at 500,000 tons per year; by yearend 1965, an expansion program was to have increased this by 30 to 35 percent. The expansion projects centered on restoration of vertical kilns 7.5-feet in diameter. Modernization aimed at rendering the plant fully mechanized and integrated. In addition to Haiphong there were several small plants at Nghe An and Sai Son whose combined annual capacity was reported to be in proximity of 150,000 to 200,000 tons. Production of cement with vertical kilns was reported to have struck quality control problems. Other problems in using these kilns were in the proper handling of equipment, maintenance, and efficient use of raw materials.

Fertilizers.—At yearend 1965, North Viet-Nam had about 6 phosphate plants of various sizes producing at capacity of approximately 200,000 tons of phosphate fertilizers. The Soviet-equipped superphosphate plant at Lam Thao, with an annual capacity of 100,000 tons has been reported as one of the most modern of its kind in Asia. The superphosphate product has 20 to 21 percent available phosphorous pentoxide (P_2O_5). The plant is equipped to produce 40,000 tons of sulfuric acid. Raw material for Lam Thao comes from the rich Laokay apatite mine, which contains more than 300 million tons of ore grading from 11 to 37 percent of P_2O_5. North Viet-Nam requires about 700,000 tons of phosphate fertilizer annually, based on the present 5.4 million acres of cultivated area, and assuming application needs of approximately 185 pounds per acre. The Lam Thao plant supplies about 14 percent of the total annual requirement.

Throughout 1965 work continued on construction of the nitrogenous fertilizer plant at Ha-Bao. Completion of the plant has been reported near; presumably, it will operate by the early part of 1966. Capacity of the plant has been estimated to be several hundred thousand tons of fertilizers. The Ha-Bao plant's first section was inaugurated on February 3, 1965, Mainland China provided technical assistance in construction.[8]

While waiting for the Ha-Bao plant to go into production, nitrogenous fertilizer had to be imported. In mid-1965, Nitrex A.G., a European international nitrogen cartel with headquarters in Zurich, Switzerland, concluded a contract with North Viet-Nam to supply an additional 20,000 tons of ammonium sulfate at an approximate price of $49 a ton. Sales of Nitrex A.G. to North Viet-Nam for the fertilizer season 1964–65 totaled about 60,000 tons.

Mineral Fuels.—*Coal.*—Despite a major effort to produce one-third more coal in 1965 than in 1964, the estimated output for the year was only slightly above the previous year's production. A larger labor force, of approximately 8,000 workers, was employed in the Hon Gai coal mine. Capital investment remained low although in recent years coal mining equipment had been added. Some imported equipment,

[7] Engineering and Mining Journal. Metal and Mineral Market. V. 36, No. 17, Apr. 26, 1965, p. 3.

[8] Far Eastern Economic Review. North Viet-Nam: Industry. 1966 Year Book, Dec. 15, 1965, p. 256.

chiefly from the Soviet Union and Czechoslovakia, lay idle for want of parts and general repair. Aside from technical difficulties coal output was hampered in 1965 by war escalation. It was claimed that 700 miners at the Deo Nai coal mine, located 25 miles from the Hon Gai coal mine, were forced to abandon operations on account of the destruction of facilities.[9] Other difficulties in coal mining in North Viet-Nam were lack of equipment and construction material, lack of mining machinery, little skilled labor, and few technical personnel.

Of the total coal output, approximately 20 to 25 percent has been exported, chiefly to Japan, mainland China, Hong Kong, and France. The remainder was consumed domestically for industrial purposes. Very little of the output was channeled directly for private utilization. Conservation efforts were revealed by a Hanoi news report on the Hon Gai mine where work groups were formed to glean coal for cooking purposes.

SOUTH VIET-NAM

South Viet-Nam's 1965 mineral production was limited to a few minerals in relatively small quantities. On account of the unsettled conditions in the country, output of minerals, as of other products, continued a downtrend in 1965. According to Japanese trade returns, South Viet-Nam produced about the same quantities of white sand and salt as in 1964. Production of coal in the Nongson area was stopped because of Viet-Cong harassment. Where there was some measure of security, industrial production fared somewhat better, as was the case with cement output at the Ha-Tien plant.

Little progress was made during 1965 in implementing South Viet-Nam's industrialization program. Intensified military action and political disturbance during the year discouraged capital investment. Moreover, the escalating military struggle made it practically impossible to construct industrial facilities for lack of material. One project called for development of an industrial complex at An Hoa, about 40 miles southwest of Tourane. The original plans called for construction of a 25,000-kilowatt thermal power installation, an ammonia plant, a sulfuric acid plant, and other facilities capable of manufacturing 42,000 tons of urea and 48,000 tons of ammonium sulfate a year. Funds for the fertilizer complex were provided by France and West Germany. Construction began in mid-1964 but ceased in mid-1965 owing to insecurity of the area. As a consequence, oil, cement, and other construction material were airlifted to An Hoa by United States cargo planes. This allowed construction to proceed at about 15 percent of original plan. In the wake of such troubles, construction of an industrial complex was considered near Cam Ranh Bay, where a major seaport was under construction. Surveys were made during the year for possible construction of a small rolling mill capable of producing 15,000 to 20,000 tons a year of structural steel from scrap or imported steel ingots. Originally this had been proposed for the An Hoa area.

PRODUCTION

Mineral production data for South Viet-Nam are incomplete with the exception of cement. Construction and completion of new industrial complexes, such as Bien Hoa and An Hoa-Nong Son, were either slowed or ceased altogether. The only bright note in 1965 production was the fact that cement output was nearly triple that of the previous year.

r Revised. e Estimate.

TRADE

South Viet-Nam imported most of its mineral commodities in 1964 from the United States ($20.0 million, chiefly iron and steel products and coal), Taiwan ($16.2 million, chiefly cement and iron and steel products), Indonesia ($10.3 million, chiefly petroleum refinery products), South Korea (5.9 million, chiefly copper products), and Singapore ($3.4 million, chiefly petroleum refinery products). Value of mineral commodities from these countries in 1963 were United States, $23.7 million; Taiwan, $18.8 million; Indonesia, $14.1 million; South Korea, $12.4 million; and Singapore, $242,000. Composition of imports from these countries in 1963 were similar to those in 1964.

South Viet-Nam's main mineral exports continued to be essentially salt and sand in 1964, which totaled 39,050 tons and 199,165 tons, and were valued at approximately $175,000 and $685,000 respectively. In 1963, salt exports amounted to 20,595 tons valued at $90,000, while sand exports totaled 136,885 tons valued at $476,000. All the exportable salt and sand was shipped to Japan in both years. Total mineral exports in 1963 amounted to $577,000 and in 1964, $876,000. As in previous years, South Viet-Nam continued to suffer an extremely unfavorable trade balance. During 1964, its imports of all types totaled in value $297.8 million while its exports amounted to only $48.5 million leaving a trade deficit of $249.3 million. In 1963, imports and exports were valued at $286.2 million and $76.7 million respectively, giving a trade imbalance of $172.6 million.

COMMODITY REVIEW

Metals.—*Iron Ore.*—At Mo Duc, south of Quang Ngai, there exists a laterite deposit with an iron content between 30 to 40 percent. The deposit has been reported very easy to mine and under one proposal foreign firms were invited to determine its possible utilization. Reserves have been estimated at about 100 million tons.

Several other deposits of iron ore are known in the northern part of South Viet-Nam. In the same region presence of gold, silver, lead, copper, zinc and graphite is known. The amounts and grades of these ores and the possibilities for exploiting them have not been ascertained.[10]

Iron and Steel.—The An Hoa-Nong Son area was under Viet Cong harassment throughout 1965. In view of this trouble, a steel rolling mill has been abandoned. A site near Cam Ranh Bay was being considered instead.

Nonmetals.—*Cement.*—Output of the Ha Tien cement plant on the Gulf of Thailand in 1965 was nearly double that produced in 1964. Despite the increase there

Source: Statistical Office of the United Nations.

still existed an acute cement shortage in coping with both civilian construction demand and stepped-up military needs. To supplement domestic production, significant amounts of cement were imported during the year, notably from Taiwan. In anticipation of even greater demand the South Viet-Nam Government in late 1965 contracted for about 500,000 tons of cement from Taiwan for delivery during 1966.

Mineral Fuels.—*Coal.*—Coal production ceased in 1965. The Nong Son mine was flooded by a typhoon in late 1963. Also the area was becoming increasingly insecure as a result of Viet Cong action since late 1964. Finally in 1965 the area around the mine was occupied by the Viet Cong. Thus, it was more difficult and dangerous to transport coal from the mine via surface transports to Tourane, where the coal could be used.

Cut off from domestic supply, South Viet-Nam has increased its imports of coal, the chief source of which has been the United States.

Petroleum.—Construction of an oil refinery scheduled at Nhatrang and utilizing imported crude oil, would have started in early 1965 had not the political situation deteriorated. Capacity would be about

24,400 barrels per day, a quantity sufficient to meet South Viet-Nam's domestic product requirements. Cost of the refinery was estimated at $15 million, three-quarters of which was to be provided by a private U.S. loan, and the remainder by the South Viet-Nam Government.

Power.—Saigon's electricity supply encountered serious difficulties in 1965, especially in the latter half of the year. Power shortage was aggravated by sabotage of transmission lines from the Danhim hydroelectric complex. It was also due in part to greater requirements in the city. Saigon, which requires some 80,000 kilowatts of installed power at peak hours, had only 65,000 kilowatts available in October 1965. Thus, it was necessary to cut the supply of electricity for several hours every 5th day in each district. The situation was expected to return to normal after a 33,000-kilowatt thermal powerplant is installed at Thu Duc. The $13 million plant, financed by the United States, is scheduled for completion in January 1966. Another project, to build a dam some 40 miles north of Saigon was abandoned.[11]

Regional Mineral Industry Review of the South Pacific[1]

By Lester G. Morrell[2]

While developments in Australia dominated the minerals industry of the South Pacific area, New Caledonia's nickel, manganese ore from New Hebrides, gold from Fiji and New Guinea, and phosphate rock from several small islands were significant in world supplies of those materials. The total value of mineral commodities produced in this area in 1965 has been estimated at about $763 million,[3] an increase of nearly 16 percent over the value reported in 1964. Increases were recorded in mineral production value with respect to that of 1964 for all of the countries except Papua-New Guinea where lower gold output resulted in a drop of about $300,000 and in the several phosphate-producing islands that collectively recorded a value decline of around $1.3 million.

Exploration and development activities continued at an intensified level, not only in Australia and New Zealand but also in the British Solomons, Bougainville, and Fiji. Substantial additions to world supplies of iron ore and bauxite are assured and recent discoveries of natural gas, manganese ore, and nickel combine to give Australia a brilliant mineral outlook. Important discoveries of copper on Bougainville Island and on Vanua Levu, the north island of the Fiji group, and a gold mine on Misma Island were being developed during the year, with plans for early production underway. In New Zealand progress has been made on the New Zealand Steel Company project, and preliminary appraisal of a new titano-magnetite beach sand resource on the South Island has aroused considerable industrial interest. Extensive geophysical investigations were carried out in the British Solomon Islands and on Fiji's goldfields. The expansion program that will double output of products by New Caledonia's Société Le Nickel continued through 1965, and several foreign private companies have expressed a desire to initiate additional industries based on nickel prospects in New Caledonia.

The South Pacific area's contribution to world mineral supplies is summarized in table 1. Australian beach sands again in 1965 were the non-Communist world's leading source of rutile titanium concentrates and zirconium concentrates. Australia, which ranked as the leading mine producer of lead in 1964 may have been surpassed in 1965 by U.S.S.R. The South Pacific area as a whole produced over 10 percent of the non-Communist world output of lead, nickel, monazite, titanium concentrates, and zinc in mined ores.

According to United Nations data[4] Australia and New Zealand trade (exclusive of other South Pacific areas) in 1965 included total c.i.f. imports valued at $4,650 million and f.o.b. exports of $3,830 million. Though incomplete, these amounts represent a substantial increase over the previous years' figures. As before, much of the South Paci-

[1] South Pacific area, for this purpose includes Australia and New Zealand together with their respective insular territorial possessions and trusts (specifically Nauru and Papua-New Guinea); the British Solomon Islands, Fiji, Gilbert and Ellice, New Hebrides, and other islands; and the French Overseas Territories of New Caledonia and French Polynesia. Excluded are the United States Trust Territories of the Pacific Islands and the many small islands having no commercial mineral industries or resources.

fic trade was within the area, but the mineral resources of Australia and New Caledonia in particular increased in importance to the consuming industries of United States, Western Europe, and Japan. Table 2 records quantities and percentage of dependence upon South Pacific supply sources for various mineral products by selected principal consumer nations.

United States trade with countries of the South Pacific is summarized in table 3. Approximately 1.2 percent of the value of U.S. minerals, metals, and fuels imports (exclusive of petroleum) in 1965 were from the South Pacific. Shipments to countries in the area made up about 3.1 percent of U.S. minerals product exports during the year.

Private investors in United States, United Kingdom, Japan, Canada, France, and other countries continued to play a major role in financing exploration and development of the South Pacific area's mineral resources. Virtually all of the foreign investment has been provided on the basis

of cooperative participation with local funding. United States direct investment in Oceania at the close of 1965 totaled $1,811 million, of which minerals investments comprised $661 million. The bulk of the U.S. minerals investments was in the petroleum industry ($499 million). During 1965, U.S. direct investments in mining and smelting industries increased $61 million, bringing the total value of United States holdings in those Australian industries to $161 million.

The Mineral Industry of Australia

By Lester G. Morrell [1]

The estimated total US $602.2 million [2] value of Australia's mineral output including fuels in 1965 represented an increase of 9.3 percent over that of 1964. While greater quantities were reported in most mineral commodities, higher unit prices accounted for a substantial part of the increase. The value added by primary processing brought the total value of the mineral industry product to an estimated US$813 million. In relation to the national economy, the value of mineral industry output was equal to 3.6 percent of the estimated US$22.5 billion (at current prices) gross national product for calendar year 1965.

As in previous years, coal, with an estimated value of $181 million, was the leading crude mineral commodity produced, contributing 30 percent of the 1965 value of crude mineral output. Lead and zinc ores accounted for 23 percent, while construction materials provided 14 percent, and copper ores 9 percent. On the basis of output quantity, outstanding percentage gains were recorded during 1965 in petroleum—75 percent, manganese ore—61 percent, ilmenite—48 percent, bauxite—38 percent, and natural gas—36 percent. Iron ore production was up 17 percent, and steel ingots and castings were up 8 percent. Compared with that of 1964, mine output of several minerals fell in 1965. Largely as a result of labor problems at the Mount Isa mine, copper production was down 13 percent. Lead was down 5 percent, gold and silver each about 9 percent, and asbestos production was 28 percent below the 1964 level.

The uptrend in value of mineral output and value of mineral industry products including primary processing and byproducts for selected recent years is shown in the following tabulation, in millions of U.S. dollars:

Year	Mine output value	Total value including domestic primary treatment
1955	334.7	413.3
1961	403.6	531.1
1962	420.2	571.4
1963	466.6	631.3
1964	551.9	747.1
1965	602.6	813.1

In 1964, the most recent year for which category summaries on output value are available, metallic minerals contributed 49 percent, nonmetallic minerals 6 percent, fuels 30 percent, and construction materials 15 percent of the total value of crude minerals produced in Australia. In order of importance, with values in millions of U.S. dollars, were black coal—143.6, lead ores and concentrates—90.0, construction materials, total—82.0, copper ores and concentrates—57.5, zinc ores and concentrates—39.7, gold—29.8, titanium (rutile and ilmenite) concentrates—27.6, brown coal (lignite)—19.4, tin concentrates—11.5, and limestone—10.2.

On a regional basis, New South Wales, embracing the rich lead-zinc-silver deposits of Broken Hill and Australia's most pro-

[1] North America-South Pacific specialist, Division of International Activities.

[2] Effective Feb. 14, 1966, Australia adopted decimal currency on the basis of one Australian pound (A£1) equivalent to two Australian dollars (A$2). Values given herein have been converted to US$ at the current exchange rate of A$1=US$1.12.

ductive coal mines, has traditionally ranked as the leading mineral State. In 1964 New South Wales output was valued at over US$260 million. Queensland's minerals, dominated by the output of the nation's largest copper mines, totaled US$109 million. Western Australia's output was valued at about US$51 million, South Australia's at US$44 million, and Tasmania's at US$28 million.

According to data compiled by the Bureaus of Census and Statistics and Mineral Resources, the national price index relevant to basic materials rose to 349 in 1965, compared with 342 in 1964. The metals sector index which includes aluminum, iron and steel, copper, lead, tin, and zinc, stood at 485 in 1965, compared with 455 in the preceding year. Of major importance in offsetting the lower output of some nonferrous metals in 1965 were the average prices received for copper: US$1,103.27 per long ton (US$803.51 in 1964) and lead: US$314.88 per long ton (US$268.06 in 1964). Aluminum and tin prices were also higher in 1965.

Much of the effort expended by mineral companies during the year went into development, expansion, transportation, and arrangements for marketing. Expansion was taking place in output of bauxite, aluminum, beach sands, coal, copper, iron ore, steel, manganese, and zinc.

Heavy rains delayed construction at iron ore mines in Western Australia, but initial export shipments were made by two new companies early in 1966. Mining and metallurgical operations in New South Wales, Queensland, and Tasmania were curtailed to varying extent by water shortages. Because of full employment the labor market was generally tight, and skilled mine workers were in short supply throughout the year. Mining companies were especially concerned with the lack of trained geologists, mining engineers, and metallurgists. The small number of graduates and students enrolled in these fields at Australian universities was also a concern to the industry.

In 1964, the most recent year for which data are available, 925 mines and quarries were active, approximately the same number as in the preceding year. Of the total which excludes operations employing less than four persons, 148 were classed as metal mines, 183 coal, and 594 nonmetal and construction material operations. Average employment in the mining industry during 1964 totaled 44,812, compared with 44,848 in 1963. Metal mines employed 19,178 persons, coal mines 17,037, and other mines and quarries 8,597. Salaries and wages paid to employees amounted to US$149 million in 1964, an increase of 8 percent above the corresponding figure for 1963. Materials and power used by the mining and quarrying industry totaled US$105.3 million and capital additions and replacements during the year in the larger mines and quarries amounted to US$86.5 million.

The high level of interest in Australia's mineral potential was reflected in data compiled by the Commonwealth Statistician showing expenditures on minerals exploration in recent years, which were as follows:

Year	Value, thousand U.S. dollars					
	Private enterprise funds		Commonwealth Government assistance			Total
	Foreign	Australian	Petroleum [1]	Gold and copper [2]	Other [3]	
1962	12,794	15,382	6,642	3,051	2,858	40,727
1963	14,082	18,672	11,781	3,262	6,114	53,911
1964	20,420	20,019	10,216	2,742	29,277	82,674
1965	NA	NA	11,662	2,229	28,960	NA

Foreign companies engaged in exploration or development of mining operations, exclusive of oil companies, according to a survey conducted early in 1966 by the American Chamber of Commerce in Australia, included 42 United States firms, 20 Canadian firms and 15 others including British, French, Japanese, Swiss, and South African firms. The United States direct investment in Australian mining and smelting ventures in 1965 amounted to US$161 million, compared with US$100 million in 1964, according to U.S. Department of Commerce sources.

Although private enterprise and field crews of the States and Federal Government were increasingly active in 1965, the year's most spectacular developments were in arranging contracts and preparing iron ore deposits for production in Western Australia, establishing the bauxite and alumina industry in Queensland, and commencing shipment of high-grade manganese from Groote Eylandt in the Gulf of Carpentaria. Equally important was the resumption of copper mining on an expanded scale at Cobar, New South Wales, and continuing investigation of the large lead-zinc deposits at McArthur River in the Northern Territory and nickel occurrences in Western Australia. Significant discoveries of oil and gas were made during 1965 in Western Australia, in the Victoria offshore Gippsland Shelf area, and in the Northern Territory.

Several publications of interest to the mining industry were released in 1965. In honor of the Eighth Commonwealth Mining and Metallurgical Congress, held in Australia and New Zealand during March and April, seven commemorative volumes were produced under sponsorship of the Australasian Institute of Mining and Metallurgy. These included: Volume 1, Geology of Australian Ore Deposits; Volume 2, Exploration and Mining Geology; Volume 3, The Australian Mining, Metallurgical and Mineral Industry; Volume 4, Economic Geology of New Zealand; Volume 5, Proceedings (Petroleum); Volume 6, Proceedings (General); and Handbook-Australia and New Zealand. Also in 1965, the Department of National Development, Bureau of Mineral Resources, Geology and Geophysics, released Bulletin 72—Australian Mineral Industry: The Mineral Deposits, a timely and exceptionally comprehensive work.

PRODUCTION

Output figures for the year 1965 show continued growth in both value and volume of Australia's mineral industry. Of the 77 items that comprise the national production, approximately 40 recorded increases over that of 1964. Statistics reflect the start of what appears to be a long period of expansion in output of bauxite and its products, iron ore, manganese, petroleum, and beach sand minerals. Although 23 commodities show quantity decreases in 1965, several of these, notably copper, lead, and silver, result from the temporary shutdown of the Mount Isa mine during part of the year.

TRADE

The value of minerals and mineral products[3] accounted for 16.0 percent of total imports and 13.3 percent of total exports recorded for the 1964–65 fiscal period by the Commonwealth Bureau of Census and Statistics.

Exported minerals and mineral products itemized in the accompanying tables were valued at US$384.4 million. Metals made up 77 percent of the total, and nonmetals and fuels (including petroleum products) accounted for 3 percent and 20 percent respectively. The leading export items and their value in millions of U.S. dollars were coal—$57.4, steel semimanufactures—$51.2, unwrought lead—$47.0, slab zinc—$27.3, and titanium concentrates—$22.5.

The value of minerals and mineral product imports during the same period amounted to US $521.2 million, of which metals, nonmetals, and fuels comprised 35.6, 11.9, and 52.5 percent respectively. Values of leading import items, in millions of U.S. dollars were crude petroleum—$211.6, steel semimanufactures—$104.7, refined petroleum products—$58.2, copper ingots, etc.,—$41.1, and fertilizer materials—$27.5.

[3] Includes commodities listed in tables 2 and 3.

e Estimate. p Preliminary. r Revised. NA Not available.
[1] Ferroalloys and steel semimanufactures are reported for fiscal years ending Nov. 30.
[2] Petalite, amblygonite, and spodumene.
[3] Includes semianthracite and subbituminous.
[4] Year ended June 30 of year stated.

Table 2.—Australia: Exports of metals and minerals [1]

(Metric tons unless otherwise specified)

Commodity	1963–64	1964–65	Principal destinations, 1964–65
Metals:			
Aluminum:			
Bauxite	236,800	518,144	Japan 314,244; West Germany 182,182.
Scrap	364	598	Japan 353; West Germany 149.
Unwrought	5,271	22,313	United States 8,516; United Kingdom 5,414.
Semimanufactures	262	643	New Zealand 205; Philippines 141.
Beryllium ore and concentrate	118	87	All to United States.
Cadmium, refined metal [2]	372	380	United Kingdom 260; United States 56.
Copper:			
Ore and concentrate, gross weight	40,053	46,611	Japan 46,566.
Blister, cement, etc	989	169	Japan 107; Sweden 62.
Scrap	1,999	905	Japan 744; West Germany 97.
Ingots, blocks, billets	25,691	2,171	Japan 2,014; Netherlands 124.
Semimanufactures	3,971	3,304	New Zealand 3,171; Philippines 33.
Pipe, tubes, and wire	1,684	1,369	New Zealand 1,080; Ghana 132.
Gold:			
Ore and concentrate, content [3] troy ounces	r 50,683	49,869	NA.
Crude bullion, content---do	562	157	New Zealand 127; Fiji 30.
Mint bullion ---do	449,003	576,575	Hong Kong 576,460; United States 100.
Sheet, strip, dust ---do	7,680	8,274	New Zealand 7,890; Fiji 219.
Iron and steel:			
Iron ore and concentrate	12,397	98,202	Japan 97,894.
Iron pyrites and cinder	108,428	75,098	All to Japan.
Scrap	357,258	374,404	Japan 349,763; Taiwan 13,897.
Pig iron	74,219	60,672	Japan 18,827; New Zealand 8,620; West Germany 8,238.
Steel ingots, blooms, slabs, etc	79,088	17,122	United Kingdom 14,423; Argentina 2,033; Japan 556.
Steel semimanufactures	368,571	347,979	Mainly to New Zealand.

See footnotes at end of table.

Table 2.—Australia: Exports of metals and minerals [1]—Continued
(Metric tons unless otherwise specified)

Commodity	1963–64	1964–65	Principal destinations, 1964–65
Metals—Continued			
Lead:			
Ore and concentrate, gross weight	120,379	103,569	United States 43,398; Japan 25,643.
Refined, unwrought	171,747	153,637	United Kingdom 84,906; United States 36,913.
Bullion, lead and silver-lead	84,669	59,156	United Kingdom 36,857; Netherlands 7,619.
Semimanufactures	9,100	5,570	New Zealand 1,423; United States 1,079.
Manganese ore	27,593	55,615	Japan 52,444; West Germany 3,138.
Platinum-group metals:			
Ore and concentrate, gross weight [4] kilograms	1,865	2,123	All to United Kingdom.
Platinum metals [4]—troy ounces	548	1,262	United Kingdom 1,060; West Germany 143.
Silver:			
Ore, concentrate, crude bullion, content [3]—thousand troy ounces	8,101	8,305	NA.
Mint bullion—do	4,537	1,367	Undisclosed 985; United Kingdom 214; France 164.
Sheet, strip, dust—do	33	92	New Zealand 89; United Kingdom 3.
Tantalite-columbite concentrate	20	48	United Kingdom 39; United States 8.
Tin:			
Ore and concentrate, gross weight—long tons	34	1,254	United Kingdom 1.194; Spain 30.
Unwrought—do	6	39	All to United Kingdom.
Titanium concentrates:			
Ilmenite, minimum 45 percent TiO_2	226,011	280,316	United Kingdom 160,830; Japan 50,065.
Rutile, minimum 90 percent TiO_2	159,791	245,548	United States 136,940; United Kingdom 19,812.
Tungsten concentrates:			
Scheelite	1,062	1,753	United Kingdom 584; West Germany 427.
Wolframite	483	367	United Kingdom 139; United States 81.
Zinc:			
Ore and concentrate, gross weight	231,256	206,317	United Kingdom 150,928; Belgium-Luxembourg 21,842.
Ingots, blocks, slabs, etc	84,874	86,016	United Kingdom 27,529; India 26,544.
Semimanufactures	1,984	2,228	Malaysia 763; India 712.
Other forms	138	135	Japan 50; New Zealand 47.
Zircon concentrate, minimum 30 percent $ZrSiO_4$	185,943	216,382	United States 57,350; Japan 28,866.
Nonmetals:			
Abrasives:			
Industrial diamond [4]—carats	100,639	70,573	United Kingdom 29,248; United States 25,565.
Other natural abrasives	16	82	New Zealand 50.
Asbestos:			
Crocidolite	3,838	NA	
Other, amphibole and chrysotile	5	NA	
Cement, construction types	6,095	3,956	Christmas Island 1,880; Gilbert and Ellice Islands 753.
Clay, fire, sillimanite and others	1,632	1,990	New Zealand 1,072; Japan 658.
Gem stones:			
Diamond [4]—carats	1,357	3,006	Belgium-Luxembourg 1,524; United Kingdom 687.
Opal [4]—value, thousand US$	6,427	5,551	Japan 3,017; Hong Kong 1,222.
Other, cameo, intaglio—do	344	430	United Kingdom 179; France 72.
Graphite	4	20	NA.
Gypsum	183,925	169,228	New Zealand 109,498; Philippines 18,118.
Magnesite	743	2,614	France 1,419; United States 900.
Mica, crude	32	33	New Zealand 31; Fiji 2.
Monazite concentrate	2,325	2,172	United States 1,209; France 613.
Salt	109,070	113,463	Japan 94,829; New Zealand 14,229.
Stone, construction—value, thousand US$	7	13	New Zealand 4; undisclosed 9.
Talc and steatite	5,166	5,135	West Germany 1,602; New Zealand 1,135.

Table 2.—Australia: Exports of metals and minerals [1]—Continued
(Metric tons unless otherwise specified)

Commodity	1963–64	1964–65	Principal destinations, 1964–65
Mineral fuels:			
Coal ——thousand tons—	3,866	6,160	Japan 5,756; New Caledonia 213.
Coke and semi-coke ——	80,707	108,463	New Caledonia 76,921; New Hebrides 18,132.
Petroleum refinery products:			
Gasoline, total thousand 42-gallon barrels ——	1,861	483	New Zealand 415; Malaysia 40.
Kerosine and jet fuel ——do——	292	507	New Zealand 290; Malaysia 103.
Distillate fuel oil ——do——	3,819	1,891	New Zealand 984; United Kingdom 189.
Residual fuel oil ——do——	7,923	5,369	Malaysia 3,228; Japan 1,253.
Lubricants ——do——	426	461	Republic of South Africa 218; New Zealand 176.
Other products ——do——	54	98	Mainly to New Zealand.

NA Not available.
[1] Periods shown are fiscal years July 1 to June 30.
[2] Data not available on quantities of cadmium exported in lead and zinc concentrates.
[3] Quantities given are for 1963 and 1964 calendar years, respectively.
[4] Includes reexports.

Table 3.—Australia: Imports of metals and minerals [1]
(Metric tons unless otherwise specified)

Commodity	1963–64	1964–65	Principal sources, 1964–65
Metals:			
Aluminum:			
Scrap ——	2,120	1,001	New Zealand 277; Kenya 219.
Pigs, ingots, blocks, etc ——	3,026	331	Canada 71; United Kingdom 35.
Semimanufactures ——	1,233	1,602	United Kingdom 779; Canada 163.
Pipe, tubes, powder, wire ——	1,117	1,243	United Kingdom 332; United States 321.
Antimony:			
Ore and concentrate, gross weight ——	43	21	Republic of South Africa 20; mainland China 1.
Metal ——	342	255	Mainland China 189; Netherlands 41.
Bismuth metal ——	18	11	Mainly from United Kingdom.
Chrome ore and concentrate ——	16,719	29,388	Philippines 15,535; Southern Rhodesia 8,155.
Cobalt and cobalt base alloys ——	63	51	Zambia 21; Belgium-Luxembourg 10.
Copper:			
Scrap ——	283	534	Canada 211; United States 125.
Ingots, blocks, billets ——	5,118	18,621	United States 9,480; East Germany 6,295.
Semimanufactures ——	144	2,449	United Kingdom 966; United States 696.
Pipe, tubes, powder, wire ——	r 300	506	United Kingdom 297; Canada 159.
Gold:			
Crude bullion, gold content troy ounces—	148,968	128,778	Fiji 94,410; Papua-New Guinea 28,349.
Refined bullion ——	210	1,032	Japan 549; West Germany 290.
Iron and steel:			
Ore and concentrate, includes pyritic materials ——	278,643	281,950	New Caledonia 281,508.
Scrap ——	228	535	NA.
Ferroalloys:			
Ferrochromium ——	3,245	3,358	Southern Rhodesia 1,808; Republic of South Africa 751.
Ferromanganese ——	11,859	9,728	Republic of South Africa 5,793; India 1,938.
Ferromolybdenum ——	264	185	U.S.S.R. 102; United States 56.
Ferrosilicon ——	10,348	8,727	Republic of South Africa 7,289; Canada 925.
Ferronickel ——	NA	1,378	New Caledonia 1,289; United Kingdom 88.
Other ——	3,346	1,927	Republic of South Africa 826; Southern Rhodesia 422.
Ingots, blooms, etc ——	3,500	57,339	Japan 57,165; United States 102.
Semimanufactures ——	182,426	570,390	Japan 234,217; United Kingdom 117,695.
Lead and lead base alloys ——	239	447	New Zealand 317; United Kingdom 44.

See footnotes at end of table.

COMMODITY REVIEW

METALS

Aluminum.—All segments of the aluminum industry showed notable gains in 1965. Production of bauxite passed the million-ton mark in November, and the year's total, more than half of which was exported, was nearly 38 percent above the 1964 output. The great bulk of bauxite exports, which totaled over half a million metric tons in 1965, was shipped from the Weipa deposits on Cape York Peninsula to Japan and West Germany. In June 1965, the initial 3-year contract with Japanese interests was enlarged and extended 10 years into 1976, for a total supply of 3.5 million tons of bauxite. A new marketing company, Comalco Bauxite (Hong Kong) Ltd. has been formed by Comalco Industries Pty. Ltd. which holds 52 percent of the new firm, and the two Japanese firms, Showa Denko K.K. and Sumitomo Chemical Co. Ltd., each of which hold 24 percent. The marketing company has also undertaken to supply 2.5 million tons of bauxite for sale to Nippon Light Metal Co. Ltd. (Japanese

subsidiary of Aluminum Ltd. of Canada) beginning in 1967. Comalco Industries Pty. Ltd. mining and port facilities at Weipa will ship 2.5 million tons of bauxite annually by 1967. The Queensland Alumina Ltd. plant of Gladstone is scheduled to take 1.25 million tons per year, and approximately 600,000 tons was covered under export contracts leaving a further 600,000 tons annually available for other markets.

In Western Australia, Alcoa of Australia Pty. Ltd. plans to increase its yearly output of bauxite at Jarrahdale, in the Darling Range, from about 450,000 tons to more than 1 million tons. This will coincide with expansion underway at the company's alumina plant at Kwinana, the annual capacity of which is being increased from 210,000 to 410,000 tons. Beginning in January 1968, the increased output will be exported to Intalco Aluminium Corp. (controlled by American Metal Climax Inc.), at Bellingham, Washington, U.S.A., under a recently concluded contract that calls for 200,000 tons of alumina annually for 20 years.

The Australian Government in 1965 accepted the tender of Nabalgo Pty. Ltd., a consortium[4] of Swiss Aluminium Ltd. and eight Australian companies, to develop the bauxite deposits containing an estimated 100 million tons on the Gove Peninsula. Under the terms of the lease, Nabalgo has agreed to establish mining and to commission an alumina plant of 500,000 tons per year capacity by 1971. The total project is expected to cost about $112 million. As presently planned, the entire output will be exported to the Swiss company's smelters.

United States Metals Refining Co. Ltd., a wholly owned subsidiary of American Metal Climax, Inc., (United States) recently announced discoveries of bauxite at Kimberly in Western Australia. The company holds temporary reserves totaling 2,558 square miles south and southeast of Admiralty Gulf. Deposits are reportedly extensive and of sufficiently high grade to warrent a drilling and evaluation program.

Construction of the Queensland Alumina Ltd. plant at Gladstone, Queensland, continued throughout 1965. The plant is designed for 600,000 tons annual capacity to be completed in 1967 and ultimately to increase capacity to 1.8 million tons per year. Alumina from this plant will supply the Commonwealth Aluminium Corp. Pty. Ltd. (Comalco) smelter at Bell Bay, Tasmania, where annual ingot capacity is currently being raised from 54,000 to 71,500 tons. A part of the alumina output will be exported, and eventually alumina will be supplied to a smelter that will be built at Kurri Kurri near Newcastle, New South Wales, by Australian Aluminium Co. Ltd. (Australuco).

Australuco, a subsidiary of Aluminum Company of Canada Ltd., was the largest Australian fabricator of aluminum in 1965. Construction of the new smelter, which will have a capacity of between 30,000 and 40,000 tons of metal is expected to get underway in 1967 and production to start in 1969. The New South Wales Electricity Authority has agreed to a long-term contract to furnish the necessary electrical energy based on coal. Australuco holds bauxite leases with reserves estimated in excess of 75 million tons adjacent to Comalco at Weipa.

The 1965 outut of metallic aluminum was credited, 49,242 tons to the Comalco smelter at Bell Bay and 38,522 tons to the Alcoa of Australia Pty. Ltd. smelter at Port Henry, Victoria. Domestic consumption of aluminum in 1965 was estimated at 87,400 tons, approximately 95 percent of the existing plant capacity. Exports of unwrought and semimanufactured aluminum products totaled almost 23,000 tons in the 1964–65 fiscal year, thus achieving nearly a fourfold increase over the previous fiscal year.

Copper.—Reflecting the effect of the labor dispute at Mount Isa Mines Ltd., which began in 1964, Australia's mine output of copper in ore and concentrate fell in 1965 to the lowest level since that of 1958. The domestic copper shortage prompted the Federal Government to impose an export ban on virtually all unmanufactured copper in November 1964. With the return to full-scale operation at Mount Isa and the start of production at Cobar, New South Wales, the embargo was lifted in September. However, following the lead of United States, Canada, and Britain, an embargo was reimposed on December 20, 1965, ap-

[4] Swiss Aluminum Ltd.—50 percent, Colonial Sugar Refining Co. Ltd.—27.5 percent, Australian Mutual Provident Society—5 percent, Bank of New South Wales, Commercial Banking Co. of Sydney Ltd., Elder Smith Goldsbrough—Mort Ltd., and Mount Morgan Ltd., each 2.5 percent, Mutual Life and Citizens Assurance Co. Ltd., and Peko-Wallsend Investments Ltd., each 3.75 percent.

plicable to export of copper and copper alloy scrap and ingots, wire bars, anodes, and similar primary forms. Despite these restrictions, the Australian copper production outlook at yearend appeared bright. Producers received payments under the Copper Bounty Act 1958–65 totaling US$5,893 during the early part of 1965. In August the Australian price to producers rose above the cutoff US$761.60 per long ton, and bounty payments were suspended. The Act was extended through 1966 by legislation enacted on November 18, 1965.

The principal industrial facilities and quantities of their output in recent years are summarized in the accompanying tabulation.

The new Cobar Mines Pty. Ltd. operation at Cobar, New South Wales, started in July and by December was approaching the anticipated annual production rate of 10,000 tons contained copper. Plans call for raising output capacity to 20,000 tons by the end of 1966; however, since the mill is dependent upon rainfall for water supply, an extended dry period would constitute a threat to production. Concentrates were shipped by rail to Electrolytic Refining and Smelting Co. of Australia Pty. Ltd. at Port Kembla. Ore reserves indicated by diamond drilling prior to February 1962 amounted to 18 million tons containing 3.5 percent copper. Additional orebodies have since been proven. A technical description of the history, engineering, and general features of the Cobar development was recently published.[5]

Mount Isa Mines Ltd. treated 2.2 million tons of ore in the company year ending June 30, 1965, compared with 3.7 million in the previous period. Output of refined copper was down in 1964–65 to 40,339 tons, from 68,508 tons in 1963–64. Ore reserves as of Jnue 30, 1965, included 33.5 million tons of copper ore averaging 3.5 percent copper and 27.1 million tons of lead-zinc-silver ore containing 7.8 percent lead, 5.9 percent zinc, and 5.6 ounces of silver per ton.

Mount Morgan Ltd. milled 1.2 million metric tons of ore which yielded blister copper containing 6,631 tons of copper and 80,030 ounces of gold during the year ending June 27, 1965. Ore reserves in the opencut mine were estimated at 9.3 million tons averaging 2.34 percent copper in addition to gold and pyrite.

Mount Lyell Mining and Railway Co. Ltd. produced 12,320 tons of refined copper in the year ending June 30, 1965, from 2.2 million tons of ore. Reserves were reported at 21.4 million tons averaging 0.94 percent copper plus substantial quantities of gold, silver, and recoverable pyrite. The company is contemplating conversion from opencut to underground mining.

The several mines in the vicinity of Tennant Creek, Northern Territory, produced about 7,500 tons of copper in concentrate during the year. A new prospect, to be known as the Warrego Mine, is being developed by Peko-Wallsend Investments Ltd.

[5] Australian Mining. The Cobar Mines Story. Tait Publishing Co. Pty. Ltd., Melbourne, Victoria. V. 58, No. 5, May 16, 1966, pp. 34-59.

Table 4.—Australia: Major copper industry facilities

Facility	Production (metric tons of copper [1])		
	1962	1963	1964
Mines:

[1] Metal content of ore for mines, blister copper for smelters, and electrolytic for refineries.

about 50 miles south of the main operations at Tennant Creek. The new mine is to be equipped for underground operation beginning in 1970 or 1971 at an annual rate of 400,000 tons of ore. Reserves delineated by diamond drilling are estimated at 3 million tons of 2.6 percent copper with a small gold content.

Copper exports in 1965 included 46,859 tons of concentrate, the bulk of which went to Japan, 5,949 tons of copper matte to Belgium-Luxembourg, 2,149 tons of blister to Japan, and 11,891 tons of refined copper mostly to Europe. Apparent domestic consumption of refined copper totaled 85,958 tons of which 34,258 tons were derived from secondary sources.

Gold.—Mine output of gold in 1965 continued the downtrend that began nearly 10 years ago, and was 9 percent below the 1964 level. Western Australia, dominated by the production from the Kalgoorlie field contributed 74.8 percent, Northern Territory 9.7 percent, Queensland 8.6 percent, and other States 6.9 percent of the 1965 national total.

Federal aid to the gold mining industry in 1965 amounted to US$2,223,000, compared with US$1,548,000 in 1964. The bulk of the 1965 payments (US$2,100,000) came under the Gold Mining Industry Assistance Act 1954–65, and the balance comprised assistance under Gold Mines Development Assistance Act 1962. Both acts expired on June 30, 1965. A 5-year extension and amendment of the former was effected in July 1965 with passage of the Gold Mining Industry Assistance Act 1965 which retains basic features but moderately liberalizes conditions and increases the rates of payments. The Development Assistance Act has not been renewed.

By source material, gold output of Australian mines and refineries in recent years was as follows:

Source material	Troy ounces		
	1963	1964	1965 e
Mines:			
Bullion [1]	895,202	811,003	751,772
Copper ore and concentrate	91,742	116,468	90,925
Lead concentrate	13,820	12,395	11,018

Total	1,140,158	1,053,466	993,374

e Estimate. r Revised.
[1] Includes alluvial and retorted gold.
[2] Gold content recovered from minerals produced in Australia.

According to Commonwealth Bureau of Census and Statistics data for 1964, the Australian gold mining industry employed an average of 4,753 workers in 246 mines (compared with 5,287 workers in 257 mines in 1963). In Western Australia 4,357 workers were employed in 148 mines. The principal companies, all in Western Australia, and their scale of operation in 1964 were as follows:

Company	Location	Ore treated (long tons)	Gold produced (troy ounces)	Average number of employees
Central Norseman Gold Corp	Norseman	181,184	100,340	338
Gold Mines of Kalgoorlie (AUS) Ltd	Fimiston and Kalgoorlie	704,369	146,366	816
Great Boulder Gold Mines Ltd	Fimiston	425,292	111,415	687
Hill 50 Gold Mine	Mt. Magnet	185,232	69,554	243
Lakeview and Star Ltd	Fimiston	683,488	165,435	913
Moonlight Wiluna Gold Mines Ltd	Mt. Ida	29,353	14,386	66
North Kalgurli (1912) Ltd	Fimiston	379,630	82,602	468

Refinery production of new gold of Australian origin during 1965 was 820,491 ounces. In addition, 148,240 ounces of newly mined gold was refined from foreign sources, mostly Fiji and Papua-New Guinea and 24,643 from domestic and imported scrap. Total refinery output was 993,374 ounces in 1965, compared with 1.05 million ounces in 1964 and 1.14 million ounces in 1963. Domestic industrial consumption in 1965 was estimated at 94,611 ounces, compared with 77,580 ounces in 1964 and 61,042 ounces in 1963.

Iron and Steel.—The Australian iron and steel industry continued expansion in 1965 with iron ore production up 17 percent, pig iron up 7 perecnt, and steel up 8 percent from the 1964 levels. With the exception of 40,958 tons of pig iron produced by the small State-owned blast furnace plant at Wundowie, in Western Australia, the Australian iron and steel industry is a monopoly of the Broken Hill Pty. Co. Ltd. (BHP) group of companies which operate an integrated network of mines and plants. BHP set new records in 1965, with pig iron production of 4,248,783 tons and ingot steel production of 5,487,605 tons.

Iron Ore.—During the company year ending May 30, 1965, output of iron ore from the BHP open pit mines near Whyalla, South Australia, totaled 4,501,474 tons. In addition, 1,496,602 tons were shipped from Cockatoo and Koolan Islands in Yampi Sound, Western Australia, to blast furnaces and steel plants at Port Kembla and Newcastle in New South Wales.

Negotiations for exports and preparations for exploiting the vast iron ore resources of Western Australia and Tasmania have continued through 1965. As of December, eight contracts had been arranged with Japanese steel mills involving future deliveries totaling 334.2 million tons of ore and pellets valued at US$3.37 billion. Capital expenditures related to these projects were estimated in excess of US$590 million of which US$486 million will be spent in Western Australia, approximately US$90 million in Tasmania, and the remainder in Northern Territory. Aside from the establishment of the mines and townsites, there will be three pellet plants, about 625 miles of standard gage rail lines, and four new seaports capable of handling 60,000-ton and larger vessels. Operating companies and contract features as of December 20, 1965, are summarized as follows:

State and operating company	Area	Shipments		Ore		Capital (million US$)
		Start	Years	Million metric tons	Percent Fe	
Western Australia:						
Cliffs Western Australian Mining Co. Pty. Ltd	Robe River	April 1868	21	72.5	[1] 64	125.4
Goldsworthy Mining Pty. Ltd	Mt. Goldsworthy	April 1966	7	16.8	64	56.0
Hamersley Iron Pty. Ltd	Mt. Tom Price	August 1966	16	87.9	[1] 53–64	141.1
Mount Newman Iron Ore Co. Ltd	Mt. Newman	April 1969	22	101.7	64	156.8
Western Mining Corp. Ltd	Koolanooka	March 1966	8	5.2	60	6.7
Tasmania:

[1] Includes pellets.

Source: Bureau of Mineral Resources, Geology and Geophysics. The Australian Mineral Industry. V. 18, No. 2, Quarterly Review, December 1965, p. 22.

Adhering to contract schedules, Goldsworthy Mining Pty. Ltd. and Western Mining Corp. Ltd. initiated export shipments from Port Hedland and Geraldton Harbor, respectively, early in 1966. During 1965 Hamersley Iron Pty. Ltd. announced plans to construct a pelletizing plant and to supply Japanese mills with 16 million tons of pellets beginning in 1968.

The Cliffs Western Australian Mining Co. Pty. Ltd. contract was signed in August to supply 72.5 million tons of pellets over 21 years beginning in 1968. This company's leases adjoin the Deepdale project being

developed by Broken Hill Pty. Co. in the Robe River area of Western Australia. The mines will be worked separately but the two companies have agreed to share pelletizing, rail transportation, and port facilities at Cape Preston.

A contract to develop the Savage River iron ore deposit in Tasmania was finalized by Pickands Mather & Co. International and Mitsubishi (Aust.) Pty. Ltd. on December 9, 1965. Port Latta on the northwest coast near Brickmakers Bay has been selected for development as the shipping port. The ore will be upgraded, slurried, and transported about 60 miles by pipeline to a pellet plant that will be constructed at Port Latta. Output at a rate of 2 million tons per year is expected to begin early in 1968.

Pig Iron and Steel.—The new BHP steel plant at Whyalla, South Australia, was officially opened on May 6, 1965; however, the basic oxygen unit had commenced operations in February at a limited rate of approximately 300,000 tons per year. The new (No. 2) blast furnace was blown-in in October. With both blast furnaces and other facilities at full operation, the Whyalla capacity is expected to reach 1 million tons annual capacity in the second half of 1966. In Western Australia, construction of the integrated steelworks at Kwinana was well ahead of schedule.

A US$90 million expansion program at the Port Kembla works of Australian Iron and Steel Pty. Ltd. was announced by the parent BHP company in July. A new blast furnace (No. 5) with annual capacity in excess of 1 million tons and new plate and hot strip mills will be added, raising the flat rolled product capacity from 2 million to 4.5 million tons per year. The new facilities are scheduled for completion in 1967–68. The long range US$200 million expansion plans for Port Kembla include new coke ovens, steel furnaces, rolling mills, and additions to the tinplate plant that will make Port Kembla one of the world's major producing centers for flat products.

The State of Western Australia early in 1966 assigned management of its Wood-Distillation, Charcoal Iron and Steel Industry at Wundowie, to the privately owned Australian National Industries Ltd. (ANI). The company has been given a 10-year option to purchase the plant.

Production of ingots and steel products by Broken Hill Pty. Ltd. and its subsidiaries (Australian Iron and Steel Pty. Ltd. and Commonwealth Steel Co. Ltd.) was reported as follows for the fiscal years ending May 31:

Commodity	Thousand metric tons	
	1964	1965
Steel ingots	4,822	5,190
Blooms and slabs	4,143	4,586
Sheets, bars, billets, etc.	2,213	2,354
Plate and strip	1,618	1,936
Merchant	1,393	1,401
Rod	302	376
Narrow cold-rolled strip	69	76
Tinplate	202	229
Steel castings	11	[1]12
Iron castings	135	[1]120

[1] Data for calendar year.

Lead and Zinc.—Although mine production of both lead and zinc in 1965 fell below the peaks attained in 1963, only lead output declined in 1965 compared with that of 1964. Output of refined primary lead and lead bullion followed the same trend, dropping 5 percent and 15 percent respectively below the 1964 levels. Slab zinc production in 1965 at over 202,000 tons was the highest annual ouput to date, 7 percent above that of 1964.

According to 1964 data, the most recent available, the lead-zinc-silver mining industry included 20 mines worked by 7,811 employees. Substantially more than half of the activity is in New South Wales which had a total of 13 mines with 4,288 employees. The majority of these were localized in the vicinity of Broken Hill. By principal company producers, mine output of lead and zinc for the 1962–64 years was as follows:

Mine	Metric tons					
	1962		1963		1964	
	Lead	Zinc	Lead	Zinc	Lead	Zinc
North Broken Hill Ltd	57,556	47,235	74,649	60,565	70,634	57,375
Broken Hill South Ltd	36,704	31,168	37,620	31,444	36,053	30,502
The Zinc Corp. Ltd	108,285	81,093	122,362	86,469	101,594	76,801
New Broken Hill Consolidated Ltd	92,830	86,303	98,920	91,423	92,097	95,038
Mount Isa Mines Ltd	63,648	45,421	67,821	37,901	62,920	38,180
Electrolytic Zinc Co. of Australasia Ltd	14,365	48,687	14,692	49,267	15,180	50,955

Reflecting the effect of the strike that lasted from August 28, 1964, to February 17, 1965, production at Mount Isa fell to 42,603 tons of lead bullion and 21,080 tons of zinc in concentrates during the company year ending June 30, 1965. Comparative output for the previous fiscal year amounted to 60,353 tons of lead and 26,171 tons of zinc. Normal operations were not resumed until the end of May 1965. During the strike, construction contracts related to the expansion program were suspended, deferring to March 1966 completion of the new No. 2 concentrator, which will raise daily treatment capacity from 14,600 to 16,300 tons.

In 1964, the Sulphide Corp. Pty. Ltd. smelter at Cockle Creek, New South Wales, produced 23,685 tons of lead bullion, 858 tons of lead in copper-lead dross, and 49,047 tons of refined zinc. During the 1964 calendar year, Mt. Isa Mines Ltd. smelter recovered 59,961 tons of lead in bullion and copper-lead dross. The Broken Hill Associated Smelters Pty. Ltd. smelter at Port Pirie produced 210,975 tons of lead (of which 4,615 tons were secondary). This company is currently building an electrolytic zinc plant to recover about 30,000 tons of zinc annually from lead slag dumps containing an estimated 1 million tons of recoverable zinc. Production of zinc from this source is expected to begin in 1966. The Electrolytic Zinc Co. of Australasia Ltd. smelter at Risdon, Tasmania, reported production of 139,462 tons of refined zinc in 1964.

Developments of interest to the lead-zinc industry included discovery of large pyritic copper-zinc orebodies in the lower levels of the Broken Hill South Ltd. copper mine at Cobar, New South Wales, and activities of the Mount Isa Mines Ltd. subsidiary, Carpentaria Exploration Co. Pty. Ltd., in the McArthur River area of Northern Territory. This discovery, which is being explored by diamond drilling and geophysical testing, has revealed very large, medium-grade lead-zinc deposits.

Domestic consumption of lead and zinc in 1961–64 was as follows:

	Metric tons			
	1961	1962	1963	1964
Lead:				
Primary, domestic origin	26,700	r 27,000	r 42,800	42,300
Primary, imported	3,600	3,600	1,600	100
Secondary	16,800	14,900	14,600	15,000
Total	47,100	45,500	59,000	57,400
Zinc [1]:				
Primary, domestic origin	77,500	83,400	93,300	109,400
Primary, imported	1,200	2,700	300	100
Total	78,700	86,100	93,600	109,500

r Revised.
[1] Sales. Secondary not reported.

Manganese Ore.—Domestic production of manganese ore, the bulk of which has been from mines in Western Australia, has ranged from a high of 91,415 tons in 1959 to 36,640 in 1963. The sharp rise to over 62,000 tons in 1964 and to nearly 100,000 tons in 1965 was in large measure a result of the easing of Federal export restrictions concurrently with growth in world demand. The Government action was due largely to the development of ample reserves, unofficially estimated in excess of 100 million tons on Groote Eylandt, in the Gulf of Carpentaria. The deposits are presently under development of BHP Co. Ltd. through its subsidiary Groote Eylandt Mining Co. Pty. Ltd. Under the terms of the special mineral lease the company was required to establish facilities for minimum annual output of 70,000 tons. Reportedly, developments have actually advanced enough to anticipate annual productive capacity of 200,000 tons by mid-1966. The first shipment for Bell Bay, Tasmania, was made in March 1966. The ore is to be used by Tasmanian Electro-Metallurgical Co. Pty. Ltd. (Tempco), wholly owned by BHP Co. Ltd. Tempco's ferromanganese production capacity is being increased to about 80,000 tons per year to supply about 40,000 tons for local consumption and the remainder for export. Direct shipment of ore from Groote Eylandt to Japanese markets is also the subject of contract negotiations.

Nickel.—Two nickel prospects in Western Australia have recently attracted considerable attention as potential producers. At Kambalda, about 30 miles south of Kalgoorlie, Western Mining Corp. Ltd. has been conducting geophysical surveys and diamond drilling a contract zone containing nickel sulfide minerals in an area 13 miles in circumference. Core intersections have shown vein widths up to 16 feet with analyses ranging from 1.8 to 8.3 percent nickel. Immediate underground development is scheduled. Several other companies have applied for leases adjoining those held by Western Mining Corp. Ltd.

The second prospect is near Wingelinna close to the common boundary of Western Australia, Northern Territory, and South Australia. Nickeliferous laterites and ochres containing garnierite (an important ore of nickel) were discovered in 1953 and extensively investigated by South Western Mining Ltd. Recent activities have resulted from affiliation with International Nickel Southern Exploration Ltd., a subsidiary of the International Nickel Company of Canada Ltd. Several orebodies have been explored in the extensive area held under lease. A preliminary estimate of indicated reserves has been put at 30 million tons averaging 1.7 percent nickel, with an additional 70 million tons inferred. Early in 1966 some 500 tons of Wingelinna ore was shipped to Canada for pilot plant tests by International Nickel Co. Plans to establish a nickel smelter near the mines, at a cost of US$110 million, are being considered. It has been suggested that natural gas from the new Mereenie field, 230 miles to the east in Northern Territory, could supply smelter fuel.

Silver.—In 1965 mine output of silver, again reflecting lower production of gold and base-metal ores with which it is coproduced, was nearly 10 percent below the 1964 output and the lowest total since that of 1961. However, the downtrend is expected to be reversed in the near future. Output from the new copper mine at Cobar, from the increased milling capacity at Mount Isa and New Broken Hill Consolidated Ltd., and from the treatment of zinc slag dumps by Electrolytic Zinc Co. of Australasia Ltd. is expected to add several million ounces annually during the years 1966-70.

In 1964 the great bulk of Australia's mine production of silver was by the following companies (in troy ounces): Mount Isa Mines Ltd.—5,511,055; North Broken Hill Ltd.—3,911,832; Broken Hill South Ltd.—1,868,204; Zinc Corp. Ltd.—2,419,333; New Broken Hill Consolidated Ltd.—2,373,063 and the Read-Rosebery mine—1,676,080.

Production of refined silver by the smelters at Port Pirie and Port Kembla was 7.9 million and 1.1 million ounces respectively in 1964. The Australian Mints at Melbourne[6] and Perth recovered a total of 239,049 ounces silver from refining of doré gold bullion.

Source materials from which silver production has been recovered in recent years were as follows:

Source material	Thousand troy ounces			
	1961	1962	1963	1964
Mines:				
Copper ore and concentrate	668	844	910	914
Lead ore and concentrate	10,695	14,792	16,835	15,485
Lead-copper concentrate	799	995	942	1,048
Zinc concentrate	679	698	731	725
Gold bullion, etc	218	225	224	255
Refineries:				
Smelter products	6,903	7,130	8,659	9,019
Mint, doré bullion	197	249	228	239

Details of Australian consumption of silver for industrial purposes are not available. As a result of greatly reduced requirements for coinage, domestic sales of refined silver in 1964 totaled 4,642,320 ounces compared with 7,810,943 in 1963.

Tin.—Production of tin in concentrates and refinery output rose slightly in 1965, despite drought conditions that curtailed operations at several of the small operations. According to 1964 data compiled by the Commonwealth Bureau of Census and Statistics, the tin mining industry included

[6] The Melbourne Mint ceased operation in August 1964 when facilities were transferred to Canberra. Silver materials formerly handled by the Melbourne Mint are currently treated at the Perth Mint and by Englehard Industries, Pty.

371 mines, of which 330 were classed as small, employing fewer than 4 persons. Of the total 1,494 workers engaged in tin mining, 787 were employed in the 11 mines that employed 21 or more persons. Alluvial dredging operations in Queensland and Tasmania in the past have provided the bulk of Australian tin. However, increased production from opencut mines in New South Wales and Western Australia as well as from new mines in Queensland and Tasmania is expected to shift the emphasis to hard rock sources in the years 1967–70.

Principal mine producers of tin concentrate and quantities of contained tin produced in 1963 and 1964 were as follows:

Area and company	Location	Long tons	
		1963	1964
New South Wales:			
Ardlethan Tin Co. N.L	Ardlethan	37	196
Tullabong Syndicate Ltd	Condoblin	e 145	229
Queensland:			
Ravenshoe Tin Dredging Ltd	Battle Creek and Nettle Creek	396	443
Tableland Tin Dredging N.L	Smith Creek	354	678
Tasmania:			
Aberfoyle Tin N.L	Rossarden	480	422
Renison Associated Tin Mines N.L	Renison Bell	227	300
Storeys Creek Tin Mining Co. N.L.	Gladstone	49	57
Endurance Tin Mining Co. N.L	Mount Cameron	76	42
Western Australia:			
Mineral Concentrates Pty. Ltd	Moolyella	127	107
H. V. Leonard	----do	67	39
Cooglegong Tin Pty. Ltd	Pilbara	68	126
J. A. Johnston	Eleys	63	88

e Estimate.

Developments in the tin mining industry during 1965 included start of operations near Irvinebank, Queensland, by Loloma Mining Corp., and at Greenbushes, Western Australia, by Greenbushes Tin N.L. The Ravenshoe dredge at Battle Creek, in northern Queensland, was dismantled and transferred to Nettle Creek during February–March 1965, and although operational conditions and adverse weather conditions were experienced at the new location, the company produced 629 tons of concentrates containing 443 long tons of tin.

Most of Australia's output of tin concentrate has been smelted by Sydney Smelters Pty. Ltd. (a subsidiary of the Patino Mining Corp. of Canada) and O. T. Lempiere & Co. Ltd., both in Sydney, New South Wales. Because of technical difficulties associated with treatment, concentrate produced at Ardlethan, New South Wales, have been exported to foreign smelters.

Domestic consumption of primary tin was estimated at 4,425 long tons in 1965, compared with 4,575 tons in 1964. Approximately 54 percent of the year's output was used in production of tinplate, the remainder in solder and other alloys.

Titanium.—Continued expansion in the beach sands industry resulted in an increase of 37 percent in output of ilmenite and rutile concentrates in 1965.

Shipments of ilmenite concentrate from five west coast producers accounted for the year's record output of nearly 457,000 tons. The increase was due largely to the recently completed expansion of Western Mineral Sand Pty. Ltd. at Capel. By mid-1965 Western Titanium N.L. had increased production capacity at Capel to about 162,000 tons per year. A new bulk-loading facility at Bunbury, designed to handle 860 tons per hour, was commissioned early in 1965. Consolidation of Ilmenite Minerals Pty. Ltd. and Cable (1956) Ltd., two west coast producers, was recently announced by Kathleen Investments (Australia) Ltd.

The beach sands industry of the east coast, comprising 12 companies, has accounted for the bulk of Australia's output of rutile concentrate. Associated Minerals Consolidated Ltd., the largest Australian producer, operated at an annual rate of 50,000 tons of rutile and 55,000 tons of zircon concentrates throughout 1965. The company recently opened a new dredge-concentrator operation at Big Swan Bay, in the Port Stephens area, and a new separation plant (of 27,500 tons annual capacity) at Hexham, near Newcastle, both in New South Wales. Queensland Titanium Mines Pty. Ltd. also commissioned a new separation plant at Tin Can Bay, Queensland, late in 1965. The North Stradbroke

Island works of Titanium & Zirconium Industries Pty. Ltd. was increased in 1965, and Consolidated Rutile Ltd. is constructing a 30,000 ton-per-year plant that is scheduled for completion in 1966. Murphyores Inc. Pty. Ltd. has undertaken a US$4.5 million project to develop ilmenite-zircon beach sands in the vicinity of Gladstone, Queensland.

While the great bulk of Australia's output of titanium concentrates as well as by-produced zircon and monazite concentrates are exported under long-term contracts, domestic industries absorb small quantities of rutile and ilmenite. Consumption of rutile, mainly as a coating for welding rods, was estimated at about 1,700 tons, and pigment manufactures took about 50,000 tons of ilmenite in 1964.

NONMETALS

Asbestos.—Australian production of asbestos fell to less than 10,600 tons in 1965, the lowest in many years. Although 15 or more asbestos deposits have been worked in Western Australia, New South Wales, and South Australia, most of the operations have been small. The principal producer has been Australian Blue Asbestos Pty. Ltd. (subsidiary of Colonial Sugar Refining Co. Ltd.) located in Wittenoom Gorge, about 7 miles southwest of Wittenoom, Western Australia. Output of crocidolite (blue asbestos) from this operation totaled 9,428 tons during the year, thus representing about half of the milling plant capacity. The labor force in 1964 consisted of 340 workers.

Chrysotile production in 1965 was credited to Asbestos Mines Pty. Ltd., at Baryulgil, New South Wales, and a few hundred tons were also reported from Lionel, Western Australia.

Exploration activities have recently been conducted in asbestos areas of Western Australia by geologists of the Western Australia Geological Survey. In New South Wales, a new company, White Asbestos (Mining) Pty. Ltd., formed by United States and Australian interests is developing leases in the Barraba area. The deposits in this area are believed to have potential for more than 18 million tons of chrysotile asbestos.

Fertilizer Materials (Phosphatic).—On the basis of mid-year estimates, the 1965 production of phosphate rock, all from South Australia, was slightly above the 1964 level. To supply the growing demand, imports of phosphate rock from Nauru and Ocean Islands in the Pacific, and Christmas Island in the Indian Ocean totaled approximately 2.5 million metric tons in 1965. The value of phosphate rock ranks second only to crude oil among Australia's mineral imports. And with the forseeable exhaustion of the island reserves, the quest for domestic sources of supply has become an urgent consideration of the Federal Government. In addition to field crews of the Bureau of Mineral Resources and various State agencies, at least 13 Australian and foreign private companies were engaged in the search for phosphate sources in 1965. Most of the recent activity has been in the Canning, Carnavon, and Perth sedimentary basins of Western Australia and in the Bowen Basin in Queensland.

The phosphate rock occurrences in Rum Jungle area, Northern Territory, tested by the Bureau of Mineral Resources in 1963 and 1964 have been summarily reported to consist of 16 deposits with inferred reserves of 5 million tons averaging 10 percent P_2O_5 and 1 million tons averaging 20 percent P_2O_5. A study recently completed by an oceanography specialist[7] suggests that submarine deposits of phosphorite nodules in Australian and nearby waters[8] may justify further investigation.

Production of superphosphate was estimated at 3,785,000 metric tons in 1965, compared with 3,727,000 tons in 1964. Under the Phosphate Fertilizer Bounty Act 1963, payments to producers totaled US$25,317,109 in 1965, bringing the total for the 3 years this Act has been in force to US$52,960,075.

Gem Stones.—The reported total value of gem stones produced in 1964, the most recent year for which data are available, was US$3,468,621, compared with US$2,922,078 in 1963. Production of opals was valued at a record high of US$3,272,500 in 1964. Approximately 90 percent of this was from the Coober Pedy and Andamooka fields in South Australia; virtually all of the balance was from the Lightning Ridge field, New South Wales.

The recorded value of sapphires produced in 1964 was US$142,589. Small syndi-

[7] Dr. Tj. H. van Andel, of Scripps Institution of Oceanography, University of California.
[8] Banks off northwestern Australia, banks near the Solomon and Bismark Islands, and banks in the Coral Sea.

cates and individuals operating in the Inverell and Glen Innes Mining Divisions, New South Wales, accounted for a total of US$63,600. The largest single producer was Inverell Sapphires Pty. Ltd., whose output from the Redstone Creek locality in the Glen Innes Mining Division was valued at US$63,000. The Anakie field in Queensland yielded US$16,000.

Chrysophrase, rhodonite, and other gem stones, output reported by the State Mines Departments of Queensland and New South Wales had a combined value of US$53,532.

The Queensland Department of Mines recently published three articles of interest to the gem stone industry in the form of prospector's guides.[9]

Gypsum.—Reflecting increased demand for use in manufacture of plaster and cement, mine output of gypsum was estimated at about 860,000 tons in 1965, considerably higher than in any previous year. According to 1964 statistics, the gypsum industry comprised 38 mines or quarries employing 176 persons; however, only 9 operations employed 4 or more workers. In 1964, the latest year for which details are available, South Australia accounted for 74 percent of the total Australian output of gypsum. Victoria, New South Wales, and Western Australia contributed 12, 8 and 6 percent respectively.

An exhaustive summary of Australia's gypsum deposits and potential was published in 1965 by the Bureau of Mineral Resources, Geology and Geophysics.[10]

Domestic consumption of gypsum by principal industries in 1964 totaled 517,671 tons.

Salt.—In 1964, the most recent year for which data are available, salt production fell 6 percent below the peak established in 1963.

Solar evaporation of seawater and lake salt deposits are the basis of Australia's substantial salt industry. Although about 80 percent of the national production has been from South Australia, similar occurrences in Western Australia, Victoria, and Queensland are also productive. In 1963 an oil test well in central Queensland penetrated a deep-seated salt bed 1,544 feet thick that may eventually be exploited.

The leading producer, ICI Alkali (Australia) Pty. Ltd., in 1964 reported production of 380,221 tons, nearly 70 percent of the national total, from its solar evaporating pans at Dry Creek, South Australia. Broken Hill Pty. Co. Ltd., at Whyalla, South Australia, accounted for 51,314 tons, and Central Queensland Salt Industries Ltd., near Rockhampton, Queensland, accounted for 44,061 tons. In Western Australia, the Shark Bay Salt Pty. Ltd. reportedly had completed construction of earthworks and ship loading facilities for the 250,000-ton-per-year project at Shark Bay but had experienced difficulties due to the permeable nature of pond floors.

While details of salt consumption are not reported, total domestic apparent consumption in 1964 was estimated at 443,800 tons, compared with about 476,000 in each of the preceding years. Recorded usage by the two principal consumer industries for recent fiscal years (July 1 to June 30) was as follows:

Industry	Thousand metric tons			
	1960–61	1961–62	1962–63	1963–64
Industrial chemicals	273	263	284	303
Salt refineries	163	183	204	209

Sulfur.—Since economic deposits of sulfur are unknown in Australia, domestic production is confined to that recovered from indigenous pyrite and base metal sulfide ores and from the processing of imported crude petroleum. The principal mine sources of pyrite include Mt. Morgan Ltd., Queensland; Norseman Gold Mines Ltd., Western Australia; Nairne Pyrites Pty. Ltd., South Australia; and Mount Lyell Mining and Railway Co. Ltd., Tasmania. Smelters utilized base metal sulfide ores in sulfuric acid plants at Port Pirie, South Australia; Cockle Creek, New South Wales; and Ris-

don, Tasmania. Recovery of elemental sulfur from petroleum is effected by Petroleum Refineries (Australia) Pty. Ltd. at Altona, Victoria, and Port Stanvac, South Australia, and by Shell Refining (Australia) Pty. Ltd. at Clyde, New South Wales.

Complete details on sulfur consumption are not available; however, the great bulk of sulfur consumption was for manufacture of sulfuric acid. In 1965, output was estimated at about 1.7 million tons, a new record, 8 percent above the 1964 production. Sulfur used in manufacture of sulfuric acid has been derived from the following source materials in the 1961–64 period:

Source material	Contained sulfur, metric tons			
	1961	1962	1963	1964
Domestic:				
Pyrite concentrate	102,133	99,499	110,437	101,500
Zinc concentrate	53,264	66,391	73,216	86,820
Lead concentrate	22,800	20,572	25,039	27,658
Other materials	14,251	16,044	12,789	6,814
Imported:				
Elemental sulfur	185,484	205,912	215,614	289,000

MINERAL FUELS

Overall consumption of energy in Australia continued to rise in 1965. Although quantities of energy derived from both black coal and lignite increased during the 1964–65 fiscal period, the coal sector of the energy pattern fell to less than half of the total. Usage of petroleum products showed an annual increase of 10 percent and accounted for 42.6 percent of the energy used in the 1964–65 fiscal year. Noteworthy also is the entry of natural gas in the national energy picture as a result of commercial use of natural gas from the Roma Field in Queensland. The Joint Coal Board Annual Report for 1964–65 summarizes Australian consumption of primary energy by sources, in terms of standard coal equivalent (SCE), for recent fiscal years—July 1 to June 30—as follows:

Source	1962–63		1963–64		1964–65	
	Thousand metric tons SCE [1]	Percent	Thousand metric tons SCE [1]	Percent	Thousand metric tons SCE [1]	Percent
Black coal	18,948	39.3	19,918	38.3	20,482	36.8
Lignite (brown coal)	6,114	12.7	6,440	12.4	6,711	12.1
Petroleum products	19,142	39.7	21,545	41.4	23,703	42.6
Natural gas	-----	----	-----	----	4	(2)
Firewood	894	1.9	871	1.7	841	1.5
Hydropower	3,110	6.4	3,214	6.2	3,907	7.0
Total	48,208	100.0	51,988	100.0	55,648	100.0

[1] Standard coal equivalent.
[2] Less than ½ unit.

Black Coal.[11]—Production of black coal totaled nearly 32 million metric tons in 1965, a new record and an increase of 15 percent over that of 1964. Reflecting large export shipments to Japan, New South Wales production rose 16 percent to a total of 24.5 million tons in 1965. The year's output of black coal from mines in Queensland represented an annual increase of 12 percent. Exports of black coal during the calendar year 1965 totaled 7.26 million tons, of which nearly 95 percent (6.86 million tons) went to Japanese markets.

The Commonwealth Bureau of Census and Statistics reported a total of 169 underground and 10 opencut mines active in 1964. Output of the two categories was 23.94 million and 3.90 million tons respectively, and employees numbered 14,733 and 736 respectively. The coal industry in New

[11] Includes bituminous, semianthracite, and subbituminous varieties.

Table 5.—Australia: Black coal production by States

(Thousand metric tons)

State	1962	1963	1964 r	1965 p
New South Wales	19,334	19,245	21,030	24,463
Queensland	2,845	3,298	3,841	4,290
South Australia	1,414	1,536	1,764	2,003
Western Australia	934	915	1,003	1,010
Tasmania	277	210	154	100
Victoria	58	52	49	42
Total	24,862	25,256	27,841	31,908

p Preliminary. r Revised.

South Wales comprised 94 mines (of which 3 were opencut) employing 11,367 workers. Queensland had 66 underground and 5 opencut mines with 2,680 employees. As reported by the Joint Coal Board, productivity in the principal black coal producing States by types of mines, for the past three fiscal years was as follows:

State	Production per man-shift [1] (long tons)					
	Underground mines			Opencut mines		
	1962–63	1963–64	1964–65	1962–63	1963–64	1964–65
New South Wales	6.7	7.4	7.9	18.5	20.1	23.1
Queensland	3.8	4.3	5.0	11.7	17.3	15.7
South Australia	--	--	--	21.3	22.7	26.1
Western Australia	4.4	4.4	4.2	11.6	12.5	11.9
Tasmania	4.6	5.3	6.0	10.5	---	---
Total	6.0	6.6	7.2	16.6	19.2	20.1

[1] On the basis of all employees.

Domestic consumption of black coal during the 1964–65 period was estimated at 22,035,000 tons, of which 16,225,000 tons was from New South Wales mines. By principal industries consumption in the 1962 to 1965 fiscal years was as follows:

Industry	Consumption (Thousand metric tons)		
	1962–63	1963–64 r	1964–65
Iron and steel	5,259	5,540	5,984
Electricity	7,935	8,777	9,387
Railways	1,567	1,477	1,315
Town gas	1,486	1,466	1,375
Cement	867	929	999
Metallurgical coke	343	352	416
Ships bunkers	119	152	112
Other	2,684	2,629	2,447
Total	20,260	21,322	22,035

r Revised.

The growing interest in conservation of coal resources for domestic use and exports has prompted a recent reevaluation of Australian black coal potential. During the 1964–65 year a summary of the coal reserve position was prepared by the Joint Coal Board Chief Geologist in consultation with Sir Harold Raggatt, former head of the Department of National Development.[12] Accordingly, latest available figures for Australian reserves of black coal are summarized as follows:

[12] Joint Coal Board Eighteenth Annual Report 1964–65. Australian Coal Resources (Appendix 5), Sydney, Australia, October 1965, pp. 143–150.

State	Million long tons	
	Measured and indicated	Inferred
New South Wales	[1] 2950.5	Large[2]
Queensland	1243.4	Large[2]
Western Australia	[1]119.	1,597
South Australia	[1]48.5	Small[3]
Tasmania	Small	137
Victoria	20	11

[1] Recoverable.
[2] More than 10,000 million tons.
[3] Less than 20 million tons.

Possibly not included in this estimate is the newly reported discovery of 260 million tons of recoverable, hard-coking coal on the coast of New South Wales by Coal Cliff Collieries Pty. Ltd.

Thiess-Peabody-Mitsui Coal Pty. Ltd. recently contracted to supply 30.1 million tons of coking coal from the Moura coalfield in Queensland to Japan, during a 13-year period. Export shipments were initiated in 1965; however scheduled delivery of 1.83 million tons annually will not be made until 1968 when the Gladstone-Moura railroad and port facilities are completed. Opencut mining will be used, employing one of the world's largest (130-cubic-yard bucket) dragline installations. The Moura mine is also under contract to supply 254,000 tons annually to the Gladstone alumina refinery.

The Utah Development Co. agreement to supply 13.7 million tons from the Black Water field, Queensland, to Japanese interests was concluded in June. This is also to be an opencut operation. Export shipments are to begin in 1968.

The Griffin Coal Mining Co. Ltd. Hebe mine in the Collie field, Western Australia, was closed due to flooding in March, but the loss of 20,000 tons per month from this mine was made up by other producers in the vicinity. Coal from this locality is the base of supply for the new Muja powerplant which was scheduled to start late in 1965.

As of June 1965, export contracts in effect, all with Japan, called for deliveries totaling 61.1 million tons during 13 years beginning in 1965. These are summarized as follows:

State and company	Total quantity (million metric tons)	Supply period, years	Shipping port
New South Wales:			
Bellambi Coal Co. Ltd	3.9	5	Port Kembla.
Coal & Allied Industries Ltd	5.1	6	Newcastle.
Kembla Coal & Coke Pty. Ltd	2.1	3	Port Kembla.
D. K. Ludwig Group	3.2	5	Port Kembla.
R. W. Miller & Co. Pty. Ltd	3.0	6	Newcastle, Sydney.
Queensland:			
Thesis-Peabody-Mitsui Coal Pty. Ltd	30.1	13	Gladstone.
Utah Development Co	13.7	10	Gladstone, Rockhampton.

Coke.—Metallurgical coke output was up again in 1965 as a result of increased demand by the steel industry. For the year ending May 31, 1965, Broken Hill Pty. Co. Ltd. coke plants produced 3,317,903 metric tons, a company record, 10 percent above the previous year's output. Still further increase in coke-making capacity is anticipated with completion of the No. 4 coke oven battery at Port Kembla in August 1966, and two batteries that are to be built at Whyalla.

The Queensland State-owned coke plants at Bowen and Ipswich produced 15,041 and 1,054 tons respectively in 1964, the latest year for which details are available. Gasworks made 779,310 tons of low-temperature coke and coke breeze in 1964 from 1,388,000 tons of black coal and 173,000 tons of brown coal.

Brown Coal.—Production of brown coal increased 9 percent in 1965 to a new record of over 21 million tons. The entire Australian output is from opencut mines situated within 100 miles to the southeast and southwest of Melbourne, Victoria. Although several small mines are operated by private companies, the great bulk of production is by the State Electricity Commission of Victoria mines at Morwell and Yallourn in the Latrobe Valley. The first 200-megawatt unit of the new Hazelwood Power Station located near the Morwell opencut was commissioned late in 1964, and the second in July 1965. When completed in 1971, the Hazelwood Station will have a capacity of

1,200 megawatts and will require about 13 million tons of brown coal which will be conveyed direct from the Morwell opencut.

Manufacture of brown coal briquets by the Morwell and the Yallourn briquet works totaled 1,934,000 tons in 1965, compared with 1,885,000 in 1964. According to data recorded for the 1963–64 fiscal period (July 1–June 30) the Yallourn briquet plant produced 553,740 and the Morwell plant 1,359,102 tons of briquets. The raw material for both plants consisted of 5,821,000 tons of brown coal from the Yallourn opencut.

Petroleum and Natural Gas.—Australia's first full year of indigenous production of crude oil resulted in an output of 2,614,000 barrels, the bulk of which was from the Moonie field. A part of the year's production was hauled by tank truck from the Alton field, 55 miles southwest of Moonie, for delivery by the 186-mile pipeline to the refineries at Brisbane. Domestic production during the 1964–65 fiscal period supplied about 1.7 percent of the total national requirement.

Exploration activities continued at a high level and several important developments were announced during 1965. Expenditures on oil and gas exploration during the year totaled US$79.36 million, of which private industry contributed US$62.61 million and various government agencies the remainder. Subsidy payments by the Federal Government amounted to US$11.66 million. According to preliminary figures compiled by the Bureau of Mineral Resources, Geology and Geophysics (BMR), 1,154,550 feet of hole was drilled during 1965 in 211 completed wells. Of the completed wells, 20 were classed as potential oil producers and 24 as potential gas producers. By geographic areas, 59 percent of the total drilling was done in Queensland, 18 percent in Western Australia, 7 percent in Northern Territory, 6 percent in Victoria, 4 percent each in New South Wales and South Australia, and 1 percent each in Tasmania and Papua-New Guinea.

A significant offshore discovery of gas was made early in the year by Esso Exploration Australia Inc. (in which Broken Hill Pty. Co. Ltd. has a 50 percent interest) on the Gippsland Shelf, about 16 miles off the Victoria coast. Initial tests indicated a potential 1.5 trillion cubic feet of gas, sufficient to supply the city of Melbourne for 20 to 30 years. Oil reserves on the Gippsland Shelf are tentatively estimated at 2.5 billion barrels.

In South Australia, recoverable reserves of natural gas in the Gidgealpa and Moomba fields, discovered in 1964 and 1965 by Santos Ltd. and Delhi Australian Petroleum Ltd., have been estimated at 1,500,000 million cubic feet of salable gas. A pipeline from these fields to serve the cities of Adelaide, Whyalla, and Port Pirie is under consideration.

In Western Australia, 18 wells, of which 11 are potential oil producers, have proven the commercial possibilities of the Barrow Island field. The company, Western Australian Petroleum Pty. Ltd. (WAPET) claims reserves on the order of 85 million barrels and is planning a development program involving up to 240 additional wells, pipelines, storage tanks, and shipping facilities. WAPET also struck gas, testing 12 million cubic feet per day from four zones in a well (Gingin No. 1) 55 miles north of Perth, Western Australia. French Petroleum Co. (Australia) Pty. Ltd. found a gas flow of 3.5 million cubic feet per day in Arrowsmith No. 1, 200 miles north of Perth near Dongara.

The intensive search in Queensland was rewarded with new discoveries by Amalgamated Petroleum Exploration Pty. Ltd. (gas, 5.65 million cubic feet per day, Oberina No. 1, and oil, 264 barrels per day, Trinidad No. 1) in the Yaleborne area. Associated Australian Oilfields N.L., struck gas in seven wells at Pine Ridge, 16 miles north of Roma, and in Maffra No. 1 and No. 2 (7.3 million cubic feet per day) 13 miles to the south of Roma. Union-Kern-A.O.G. found gas (2 million cubic feet per day and condensate 79 barrels per day in Major No. 1) north of the Alton field.

Activities in the Northern Territory included drilling by Exoil N.L., to determine limits of the gasfield at Mereenie, and discovery of gas (testing 14 million cubic feet per day in Palm Valley No. 1) near Mission by Magellen Australia Petroleum Ltd.

Domestic consumption of petroleum products totaled 127,147,000 barrels in 1965, an increase of about 9.5 percent above that of 1964. Output of Australian refineries totaled 123,569,000 barrels in 1965 compared with 114,885,000 barrels in 1964. Three new refineries came on stream in 1965: Amoco Australia Pty. Ltd. and

Ampol Refineries Ltd., located in suburbs of Brisbane, Queensland, and BP Refineries Pty. Ltd.'s second refinery in Westernport, 50 miles southeast of Melbourne, Victoria.

Capacity of the Australian petroleum refining industry at the close of the year totaled 26.7 million tons per year, distributed to the following plants:

Plant	Annual capacity (thousand metric tons)
Refineries:	
Amoco Australia Pty. Ltd.: Bulwer Island, Queensland	1,118
Ampol Refineries Ltd.: Lytton, Queensland	2,012
Australian Oil Refining Pty. Ltd.: Kurnell, New South Wales	4,470
Boral Ltd.:	
Matraville, New South Wales	914
Hamilton, Queensland	102
BP Refinery (Kwinana) Pty. Ltd.: Kwinana, Western Australia	4,267
BP Refinery (Westernport) Pty. Ltd.: Westernport, Victoria	2,540
Petroleum Refineries (Aust.) Pty. Ltd.:	
Altona, Victoria	2,571
Adelaide, South Australia	1,859
Shell Refining (Australia) Pty. Ltd.:	
Geelong, Victoria	2,540
Clyde, New South Wales	996
Lubricating oil plants:	
Australian Lubricating Oil Refinery Ltd.: Kurnell, New South Wales	142
BP Refinery (Kwinana) Pty. Ltd.: Kwinana, Western Australia	102
Shell Refining Pty. Ltd.: Geelong, Victoria	81

The Australian petrochemical industry in 1965 included 27 plants in operation, under construction, or planned. Strong emphasis has been on plants to make ammonia, nitrogenous fertilizers, and carbon black. Other products include nylon, synthetic rubber, ethylene and derivatives, ketone solvents, resins, and polystyrene. Elemental sulfur is recovered in two plants operated by Petroleum Refineries (Aust.) Pty. Ltd.

The Mineral Industry of New Zealand

By Lester G. Morrell [1]

Continuing the uptrend that has characterized New Zealand's mineral industry in recent years, value of production in 1965 increased 12 percent over that of 1964 to $65.78 million.[2] A substantially larger output of clays, construction materials, pumice, and salt was reported in 1965. Value declines occurred in coal and petroleum fuels. Nonmetallic minerals, collectively valued at $43.66 million, accounted for nearly two-thirds of the total value of mineral production in 1965. Relative contributions of the major mineral categories, together with total value for selected recent years are summarized as follows:

Year	Percent			Total value, million dollars [1]
	Metals	Nonmetals	Fuels	
1950	10.8	22.5	66.7	$26.07
1955	2.3	54.8	42.9	44.07
1960	2.2	55.2	42.6	55.38
1961	1.8	56.6	41.6	55.07
1962	1.5	59.7	38.8	51.28
1963	1.0	59.4	39.6	56.53
1964	.6	60.9	38.5	58.79
1965	.7	66.4	32.9	65.78

[1] Exclusive of cement and manufactured fertilizers.

Indicative of the importance of the minerals industry in the national economy, the value of minerals in 1965 amounted to 1.3 percent of the estimated $4,884 million gross national product. Employment in mines and quarries accounted for 0.8 percent (compared with 12.2 percent in agriculture and 26.9 percent in manufacturing industries) of the industrial labor force in 1965. Distribution by product categories and number of mine and quarry employees was as follows for 1961–65:

	1961	1962	1963	1964	1965
Metals, including gold	157	127	117	98	160
Nonmetals	3,791	3,927	3,977	3,885	4,136
Coal	4,044	3,852	3,660	3,631	3,447
Petroleum prospecting	147	153	112	157	46
Total	8,139	8,059	7,866	7,771	7,789

Although coal mining continued to dominate New Zealand's mineral industry, interest in petroleum and a wide variety of metal and industrial mineral prospects was growing. On December 31, 1965, there were 340 petroleum prospecting licenses covering 92,000 square miles of New Zealand's land and continental shelf areas. Mining rights and licenses granted during 1965 numbered 301, compared with 264 in 1964.

Direct government financial assistance to the mining industry in the year ending

[1] North America-South Pacific specialist, Division of International Activities.

[2] Where necessary and except where otherwise specified, values have been converted from New Zealand pounds (NZ£) to U.S. dollars at the rate of NZ£1 equals US$2.781.

March 31, 1966, included grants totaling $62,375 for 17 projects. While private companies, both domestic and foreign, have intensified field investigations, the New Zealand Government also has taken an active part in the search for and development of mineral resources.

The Mineral Resources Committee of the National Research Advisory Council administered the Government functions, coordinated research programs, and allocated priorities to insure that finance and resources were effectively used. The two major undertakings approved during the 1964–65 year were the iron and steel project based on titanomagnetite sands on Waikato Heads and the development of geothermal resources outside the Wairakei area. Mapping programs and long-term projects dealing with cement, clays, coal, ground water, electrochemical industries, and mineral beneficiation have continued.

Legislation enacted during 1965 included the Iron and Steel Industry Amendment Act 1965 which extends the expiration date of the original New Zealand Steel Industry Act of 1959 beyond January 1, 1968, and provides certain working details on the extracting of iron sands and the erection of works by New Zealand Steel Ltd. A 1965 amendment to the basic Mining Act removed the right of a prospector to a mineral lease and substituted a right of priority to a license for an area not exceeding 1,000 acres. The Mining Act amendment (section 3) also authorized the Minister of Mines to expand prospecting privileges to include gold, metals, or other minerals not specified in the original prospecting warrants.

PRODUCTION

Although the year's output of several minerals was lower than that of 1964, the overall uptrend in value of New Zealand's mineral production continued in 1965. Among the metals, gold production was up 3,188 ounces, reversing the decline of recent years. Most of the gains were in nonmetallic and industrial minerals. Notable increases in both quantity and value were recorded for bentonite and other clays, magnesite, pumice, salt, and building materials.

TRADE

New Zealand's trade deficit in metals and minerals continued through the 1963–64 fiscal year; the value of imports outweighing exports by a ratio of nearly 95:1. In 1963–64 value of principal metals and minerals [3] exports totaled only $1.59 million, while value of imports amounted to $150.6 million.

Metals and minerals accounted for less than 1.6 percent of the value of New Zealand's total exports ($1,013 million); the corresponding figure for imports was 16.7 percent of the total $903 million. Scrap metals including copper, lead, aluminum, tin, and ferrous metals, with a combined value of $1,146 million comprised New Zealand's principal minerals and metals export commodities. Refined petroleum products valued at over $60 million in the 1963–64 fiscal year was again one of New Zealand's largest imports. Semimanufactured metal products, notably of copper and iron and steel were also substantial. Among the nonmetals, fertilizer materials, including sulfur for manufacture of sulfuric acid were the largest value items.

[3] Includes items listed in the accompanying tables.

Table 2.—New Zealand: Exports of metals and minerals [1]

(Metric tons unless otherwise specified)

Commodity	1962–63	1963–64	Principal destinations, 1963–64
Metals:			
Aluminum scrap	633	933	Japan 480; Australia 378.
Copper scrap	626	1,474	Japan 980; Australia 248.
Gold, refined [2] ----troy ounces--	18,300	8,400	NA.
Iron and steel:			
Iron ore and concentrate	13	217	West Germany 203; Sweden 14.
Iron and steel scrap	290	587	Japan 553; Canada 17; Hong Kong 15.
Lead scrap	1,146	2,720	Republic of South Africa 784; Japan 709; Australia 568; United Kingdom 422.
Silver and platinum ores--value, dollars--	40,477	65,350	United Kingdom 37,874; Australia 27,476.
Tin scrap ----long tons--	5,336	4,926	West Germany 2,564; Japan 1,994.
Nonmetals:

[2] Incomplete fiscal year.

COMMODITY REVIEW [4]

METALS

Bauxite and Aluminum.—New Zealand's only known occurrences of bauxite are in the vicinity of Kaeo, Kerikeri, and Otoroa in North Auckland.[5] Although soils containing bauxitic materials cover an area of about 30 square miles, the best deposits, containing some 20 million tons occupy about 1 square mile near Otoroa. Drilling has shown the bauxite to be 10 to 15 feet thick of the following analyses: Total Al_2O_3—37.4 percent, SiO_2—5.5 percent, Fe_2O_3—23.3 percent, TiO_2—6.4 percent. Consolidated Zinc Pty. Ltd., of Australia was conducting beneficiation tests on the material in 1965.

Plans of the Commonwealth Aluminium Corporation Ltd. (Comalco) of Australia, to construct an aluminum smelter at Bluff, on the southern tip of South Island, are still firm. Reservation of the smelter site was applied by the New Zealand Government in 1965. The project which has been estimated at $445 million will use power from the Manapouri hydroelectric scheme scheduled for completion in 1969. Comalco has an option, expiring in 1968, on Manapouri power necessary to produce 100,000 tons of aluminum per year. The raw material will consist of alumina imported from the new Queensland Alumina Ltd. plant at Gladstone, Australia.

Copper.—The small output of copper ore reported in 1965 was all from the Copper Queen mine, operated by Marriott Industries Ltd., at Parakao, North Auckland. No production was reported during the year from the company's Hazelbrook mine near Kaeo. The ore was sold locally for use as an additive in fertilizer.

Investigation of copper occurrences in New Zealand has been intensified during 1965. The Geological Division of the De-

[4] Information contained in this section is largely based on reports of the New Zealand Mines Department and Department of Statistics, Wellington, New Zealand.
[5] Fieldes, M., and others. Clays. Ch. in Economic Geology of New Zealand. Eighth Commonwealth Min. and Met. Cong., v. 4. New Zealand, 1965, pp. 366–367.

partment of Scientific and Industrial Research (DSIR) did some drilling on a copper prospect near Kaeo, North Auckland, but results have not been published. Conzinc Riotinto of Australia Ltd. recently applied for prospecting rights on Coppermine Island, in the Hen and Chickens group off Whangarei, North Island; and in the Ruahine Range near the south end of North Island, Government geologists were investigating reportedly rich occurrences of copper ore. Mineral Industries Ltd., a new company, has been organized to investigate the economic potential of copper deposits known to have been worked around 1905 in the Moke Creek area, near Queenstown, Otago, on the South Island.

Gold.—Increased recovery of alluvial gold (11,810 ounces in 1965) from the Kanieri Gold Dredging Ltd. operation on the Taramakau River in Westland, was effective in raising national output to 12,136 ounces in 1965. In addition, a small gold-quartz mine and several part-time sluicing operations in Buller County and beach claims on the west coast of South Island reported a combined output of 326 ounces during the year.

A local group recently organized Waikakaho Mines Ltd., of Marlborough, to investigate gold deposits in the vicinity of Waikakaho, about 10 miles north of Blenheim. Discoveries and a rush resulted in the taking of a substantial amount of gold from this area toward the end of the last century.

Iron and Steel.—In 1965, production of iron ore, all for local use in the manufacture of bricks, steel, cement, and for gas purification, was at a modest level as in previous years. Two companies, Kamo Potteries Ltd. and Webb's Refineries Ltd. operated five small open pit mines near Kamo and Kaeo in North Auckland. The Golden Bay Distributors Ltd. and Golden Bay Cement Co. Ltd. quarries at Parapara were the only South Island sources of iron ore during 1965.

The New Zealand Steel Company project to establish a steel industry based on titano-magnetite beach sand proceeded throughout 1965. A plant site at Glenbrook, 25 miles south of Auckland has been purchased and preparation of the ground for construction has started. The company announced that the Stelco-Lurgi process which involves reduction of the ore in rotary kilns with locally mined subbituminous coal and limestone to make sponge iron would be used. This sponge iron will be treated in electric furnaces yielding continuously cast steel.

Although iron-rich beach sands are known to exist in several localities, initial supplies will be taken from Waikato Head, 8 miles from the steel plant site. Scrapers will be used to mine the sand which will be concentrated by magnetic separation to a product containing 62 percent iron. The concentrate will be pelletized.

A second project involving beach sands, near Westport, on the South Island was proposed, and it stimulated considerable public interest during the year. The sands in this locality were reported to be worthy of further investigation as a potential source of not only iron but also of economically recoverable titanium minerals, zircon, and a small quantity of gold. By yearend Buller Minerals Ltd. in association with Rutile Zircon (Newcastle) Ltd. of Australia, as well as experts from the faculty of technology at Otago University and from the Department of Scientific and Industrial Research, were studying these prospects.

In its 4th year of operation, output of rolled steel by Pacific Steel Ltd., at Otahuhu, near Auckland, totaled in excess of 65,000 tons. The plant, 40 percent of which is owned by three British steel companies (Colvilles Ltd., GKN Steel Company Ltd., and Stewarts and Lloyds Ltd.), consists of a 40-ton electric furnace and a merchant bar mill. Domestic scrap collected by Pacific Scrap Ltd. is the principal raw material. Products include round bars, angles, and flats.

Lead and Zinc.—A new company known as Norpac Mining Co. Ltd. (including North Island Mines Inc., of United States, South Pacific Mines Ltd. of Canada; and Cable Price Downer Ltd. of New Zealand) has been formed to continue development of the old Tui mine at Te Aroha, South Auckland. While the quantity of reserve has not been fully determined, assays of the ore are said to average 5 percent lead, 15 percent zinc, with minor quantities of copper and silver. Construction of a 100-ton-per-day flotation mill to make separate concentrates of lead, zinc, and copper, was still being considered throughout 1965.

Lime and Marble Ltd., a New Zealand firm, reported discovery of a lead-zinc deposit near Takaka, on the north end of South Island. Details of this discovery have not been announced.

NONMETALS

Asbestos.—Although no production of asbestos was reported during 1965, the magnetometer survey, mapping, and test-drilling of asbestos deposits in the Upper Takaka Valley, South Island, continued throughout the year. The combined efforts of Mines Exploration Pty. Ltd. (subsidiary of Broken Hill South Ltd.) and Cobb Minerals Ltd. (subsidiary of Lime and Marble Ltd.) have outlined sufficient ore to justify a small operation and problems of recovery are being investigated.

Bentonite and Other Clays.—Production of bentonite, most of which was mined at Porangahau, near the southeast coast of North Island, was at a record level in 1965. On South Island, a program of drilling undertaken late in the year revealed substantial new reserves of bentonite in the vicinity of Hororata, 40 miles west of Christchurch. A description of the bentonite occurrences in this area was published in 1965.[6]

Lime and Marble Ltd. and Crown Lynn Potteries Ltd. carried out a prospecting and drilling program on halloysite clay deposits at Maungaparerua, near the north end of North Island. Several million tons of high-quality clay have been defined in this area. Deposits of clays suitable for pottery and other ceramic purposes have also been found in the Hauraki area.

Manufacturers of clay products reported output of selected items in 1965 as follows: Glazed pipe—6.6 million feet, field tiles—13.2 million feet, and bricks and hollow tiles—56.5 million pieces.

Cement.—The New Zealand cement industry in 1965 set a new production record, 7 percent above the 1964 output. Golden Bay Cement Co. Ltd., at Tarakohe produced 213,758 tons and Guardian Cement Co. Ltd., at Cape Foulwind accounted for 125,607 tons in 1965. Details of production by other New Zealand cement producers or details regarding the plant expansion program of the Wilson (N.Z.) Portland Cement Co. Ltd., were not available.

Dolomite.—Output of dolomite, most of which is produced by Golden Bay Distributors Ltd. and Lime and Marble Ltd. at Mount Burnett, near the north end of South Island, was somewhat below the 1964 production level. A recently completed geological examination by the New Zealand Geological Survey found reserves in this area probably in excess of 50 million tons. Although the product has in the past been exclusively for domestic use in superphosphate fertilizers and glass manufacture, export possibilities have recently been considered. The first bulk shipment of dolomite from the port of Collingwood to Auckland was made early in 1966.

Fertilizer Materials.—Manufacturers of fertilizers reported production of 1.97 million tons of chemical fertilizers in 1965, compared with 1.80 million tons in 1964. The superphosphate content of these products amounted to 1.61 million and 1.48 million tons, respectively. As in previous years imported raw materials from Nauru, Ocean Island, Christmas Island, and the United States supplied the great bulk of phosphate rock requirements. Basic slag, a high-phosphorous byproduct of the iron and steel industry, and potash were also imported in large quanties from West European countries.

Early in 1966, Dominion Fertilizer Co. Ltd., announced plans to install an acid plant to produce 250 tons of acid per day. The equipment, which has been ordered from Lurgi Chemical and Metallurgical Engineering Co. Ltd. (Lurgi Gesellschaft fur Chemie und Hüttenwesen G.m.b.H.), in West Germany, will also generate electricity from byproduct steam.

MINERAL FUELS

Coal.—During 1965 coal production in each of the nine New Zealand coalfields was below the 1964 production. National output was down 7.5 percent. The drop has been attributed mainly to lower requirements by railroads and paper mills, and the Meremere powerplant consumed only 194,000 tons in 1965, compared with 292,000 tons in 1964. The total number of coal mines that operated during the year (127) was also 9 fewer than in 1964. Of the total, 91 government-owned mines (including 6 mines owned jointly with private interests) with 2,770 employees, accounted for 82 percent of the national coal output. Net

[6] Richie, J. A., and D. R. Gregg. Bentonites of Canterbury. Proceedings of New Zealand meeting, Eighth Commonwealth Min. and Met. Cong., Wellington, New Zealand, 1965, pp. 1-13, 208.

loss in operation of the Government-owned mines amounted to $2.63 million in 1965, compared with $1.68 million in 1964.

By mining methods, underground mines produced 1,636,000 tons of coal (60.5 percent of the total) and open pit operations produced 1,066,00 tons of coal (39.5 percent). Basic industrial statistics and sources of New Zealand coal for the 1962–65 years are summarized in the following table:

	1962	1963	1964	1965
Strip mines:				
Output—thousand metric tons	867	1,138	1,245	1,066
Employees	418	364	449	405
Tons per man-year	2,075	3,126	2,772	2,633
Underground mines:				
Output—thousand metric tons	1,724	1,648	1,678	1,636
Employees	3,434	3,296	3,182	3,042
Tons per man-year	502	500	527	537
Total all mines:				
Output—thousand metric tons	2,591	2,786	2,923	2,702
Employees	3,852	3,660	3,631	3,447
Tons per man-year	673	761	805	783
Production by coalfield:				
North Auckland—thousand metric tons	3	3	2	2
Waikato and Taranaki—do	1,257	1,426	1,536	1,369
Nelson—do	18	18	18	15
Buller—do	287	262	271	266
Reefton—do	107	110	108	99
Grey—do	423	405	419	416
Canterbury—do	19	18	18	14
Otago—do	122	135	135	129
Southland—do	355	409	416	392
Total—do	2,591	2,786	2,923	2,702

A noteworthy achievement of the New Zealand coal mining industry in 1965 was the record of no fatal accident during the year. Not since 1866 has this record been equaled.

A technical description of the Glen Afton Collieries Ltd. open pit mine at Kopuku, largest New Zealand coal producer, was recently published.[7]

Total consumption of coal in 1963, as reported by the Department of Statistics was 2,807,300 tons, distributed to the following users: Household—525,300; electric power—606,600; dairy and meat industries —432,800; gasworks—272,300; railways—185,900; cement plants—213,400; pulp and paper mills—158,500; other manufacturing —213,400; and all other uses—199,100.

Coke and Briquets.—Smokeless Fuel Co. Ltd., at Sockburn, produced 5,938 tons of hard coke in 1965. For the fiscal year April through March 1964–65, gasworks reported total output of 69,000 tons of low-temperature coke.

The low-temperature coal carbonizing and briquet plant of Waikato Carbonisation Ltd. at Rotowaro, carbonized 28,400 tons of coal and purchased 16,270 tons of coke to produce 18,050 tons of briquets in 1965. This represented an increase of 21 percent over the 1964 output. Although separate production figures for the new State-owned briquet works at Ngakawau, Nelson, and South Island have not been given, tests reportedly are being conducted on the blending of various coals to improve the burning quality of the product.

Petroleum and Natural Gas.—New Zealand's 1965 production of crude petroleum, all from the four wells of Edgmont Oil Wells Ltd. at New Plymouth, totaled 4,314 barrels. The company also recovered 200 barrels of condensate from the Kapuni field.

During the year drilling activity was confined to a total of seven completed holes, and totaled 33,630 feet, compared with nearly 32,000 feet in 1964. With the exception of New Plymouth No. 2 well, drilled by Shell, BP and Todd Oil Services Ltd. in the Taranaki Basin, which yielded a small pocket of gas, and J. T. Benny No. 1 drilled by New Zealand Petroleum Exploration Co. Ltd., at Winton in Southland which showed oil, all holes were dry. Details are given in table 4.

[7] New Zealand Coal. Kopuku Open Cast Operations. v. 10, No. 4, March 1966, pp. 2–6, p. 44.

Table 4.—New Zealand: Wells completed in 1965

Company and location	Well	Total depth (feet)
North Island:		
Auckland Water Transport Co. Ltd.:		
Great Barrier Island	Tryphena	704
Do	Whangaparapara	302
E. W. Newbolt: Napier-Taupo Highway	Rangitaiki No. 2	637
Shell BP and Todd:		
Taranaki	Puniwhakau	7,041
Do	New Plymouth No. 2	14,605
South Island:		
New Zealand Petroleum Exploration Co. Ltd.:		
Winton	J. T. Benny No. 1	3,338
Drummond	J. W. Laughton No. 1	7,003

Geological and geophysical activities were at a relatively high level throughout the year. In the east coast area of North Island, the Société Nationale des Petroles d'Aquitaine with Shell, BP and Todd Oil Services Ltd. started seismic surveys. Offshore airborne magnetometer surveys were initiated by Tasman Petroleum Ltd., in the Tasman-Golden Bay areas and by J. H. Whitney and Co., off the west coast, south of Auckland. Shell, BP and Todd Oil Services Ltd. also conducted geophysical surveys of continental shelf areas off the Taranaki coast. Geological and geophysical surveys were conducted in several areas on the South Island by Hackathorn (N.Z.) Oils Ltd.

The New Zealand Refining Co. Ltd. refinery at Marsden Point, Whangarei produced 2.1 million tons of gasoline, gas oil, fuel oils, and asphalt in 1965, its first full year of operation. The year's output was equivalent to over 80 percent of the national consumption of petroleum products, estimated at 2.42 million tons in 1965. Since startup of the Marsden Point refinery in 1964, sales of refined products for ships' bunkers and export, mostly residual fuel oil to Malaysia, have been valued at $5.4 million.

From the wells at New Plymouth, Edgemont Oil Wells Ltd. supplied 4.9 million cubic feet of natural gas to gasworks in 1965. Utilization of gas from the Kapuni gas condensate field was the subject of studies continued throughout the year for the New Zealand Government by Zinder International (N.Z.) Ltd.[8] Until decisions are made, the Kapuni field, which has a production potential of 60 million cubic feet gas and 4,800 barrels of condensate per day for 30 to 35 years, will remain shut-in.

The Mineral Industry of Other South Pacific Islands

By Lester G. Morrell [1]

Contents

BRITISH SOLOMON ISLANDS

Exploration projects continued in 1965 to dominate mineral industry activities in the British Solomon Islands Protectorate (BSIP). Land areas of the Protectorate include the major islands of Choiseul, New Georgia, Santa Isabel, Malaita, Guadalcanal, San Cristobal, and Santa Cruz, alined for nearly 1,000 miles in a southeasterly direction from Bougainville Island, the eastern extremity of the Australian Territory of New Guinea.

Recorded production of minerals in the Protectorate has been limited to a few hundred ounces of gold and small quantities of manganese ore. Since 1950 the BSIP Geological Survey Department has mapped many of the islands and conducted geological reconnaissance, including magnetic and gravity surveys in some areas. More intensive geophysical investigations were begun in 1964. A gravity-magnetic-bathymetric survey of the sea between San Cristobal and New Britain was completed late in 1965 by the research vessel H.M.S. *Dampier*. This was a cooperative project with the U.S. National Science Foundation, U.S. Navy Institute of Oceanography, and University of Wisconsin. The A.B.E.M. Geophysical Company of Sweden has been engaged to conduct an airborne survey (magnetrometric, electromagnetic, and scientillometer) of the land areas. Funds for this work have been provided by a $952,800 United Nations Special Fund grant and counterpart British Government contribution amounting to $560,000. Flying commenced in November 1965 and is expected to be completed in 1967. The Geological Survey Department plans to conduct ground followup programs. Native Melanesians were being trained to assist in the fieldwork.

To await the findings of the aerial survey, Conzinc Riotinto of Australia Exploration Ltd. suspended activities on Guadalcanal in mid-1965. International Nickel Southern Exploration Co. Ltd. continued testing and feasibility studies related to nickel-bearing laterites of Santa Isabel and San Jorge Islands. The prospecting license covering the International Nickel projects was renewed in November, with the understanding that a decision regarding application for mining lease will be due in November 1967.

In 1965 a Royal Society Expedition found extensive deposits of bauxite soils on the 17-mile diameter volcanic island of Kolombangara, in the New Georgia group. The Protectorate Government closed the island to prospecting for 1 year so that the Survey Department may conduct test drilling and sampling to evaluate the discovery.

Recorded production of alluvial gold, all by natives, from various localities in the

[1] North America-South Pacific specialist, Division of International Activities.

islands in recent years was as follows: 1962, 18 troy ounces; 1963, 240 ounces; and 1964, 101 ounces.

Reported trade in mineral commodities is limited to imports of salt and petroleum refinery products, mainly from Australia. Quantities imported in the 1962–64 years were as follows, in metric tons:

Commodity	1962	1963	1964
Salt	55	66	81
Petroleum refinery products:			
Gasoline and aviation fuel	1,292	1,088	1,310
Kerosine	552	600	719
Fuel oils	3,411	3,227	4,278
Lubricating oils	121	147	192

CHRISTMAS ISLAND

The Australian Territory of Christmas Island in the Indian Ocean, 900 miles northwest of Australia remained an important Australian source of phosphate rock. The island's only economic activity is mining and exporting of phosphate. The Christmas Island Phosphate Commission, owned equally by the Governments of Australia and New Zealand, controls the property and retains the British Phosphate Commissioners as managing agents. Although several deposits are worked, the principal mining activity is at South Point, about 11 miles from the drying and shipping facilities at Flying Fish Cove. The entire mine output is exported.

Exports of phosphate rock in bulk and phosphate dust in bags for recent fiscal years were as follows:

Fiscal year ending June 30 of year stated	Metric tons			
	Australia	Singapore and Malaya	Borneo	Total
1961	604,836	74,744	-----	679,580
1962	630,660	71,765	1,628	704,053
1963	559,599	74,074	3,781	637,454
1964	764,081	67,938	-----	832,019
1965	779,902	76,916	-----	856,818

Fuel oil and gas oil, amounting to 15,477 metric tons; 12,948 tons and 17,004 tons in 1963, 1964, and 1965, respectively, have accounted for about half of the island's total imports.

A development program designed to expand the phosphate production on Christmas Island was recently approved by the Australia and New Zealand Governments. During 1965 studies aimed at increasing output to 1.6 million tons by 1968 and eventually to 2.5 million tons per year were being undertaken by the Australian Bureau of Mineral Reseources, Geology, and Geophysics, and the Christmas Island Phosphate Commission. Preliminary revised estimates place the reserves of all grades at 200 million tons.

FIJI ISLANDS

The value of Fiji minerals production in 1965 has been estimated at $5.3 million (F£2,097,000), about 14 percent above that of 1964. Despite a destructive hurricane in February and a drought late in the year, mining operations as well as exploration and development activities were maintained at a relatively high level. A total of 2,373 persons were employed in mining and quarrying industries in 1965, compared with 2,161 in 1963 and 2,222 in 1964. Output of gold set a new record high, manganese ore production was the highest since 1960, and substantial gains were reported in 1965 for cement, coral sand, and lime. The Geological Survey Department completed regional mapping on two areas totaling 440 square miles and conducted 4,655 feet of diamond drilling on various projects. A major function of the Geological Survey throughout 1965 has been the geochemical survey of the Tavua goldfield conducted jointly with Emperor Gold Mining Co. Ltd. Reconnaissance projects of the same type were carried out in the Mba River area in northwest Viti Levu and on islands of the Yasawa group.

Development and equipping of the open-

cut copper mines in northeastern Vanu Levu by Banno Mining Co., Ltd., and exploration activities of Kennecott Explorations (Australia) Pty. Ltd., on a 563-square-mile area of southwest Viti Levu continued during the year. The possibility of exploiting low-grade phosphates in several of the Lau group islands was also being investigated by a Canadian company; however, prospecting licenses will not be granted until completion of the Government-sponsored test program. Two small gold mines in the vicinity of Vunda and a porphyry copper prospect at Naivuvuni were also examined by the Geological Survey.

Mining Ordinance 25 of 1965, which vested control of mining and prospecting in the Director of Mines instead of the Mining Board, was approved in June. New regulations were being drafted to improve safety in mines and give better control of opencut workings.

Twenty-four Prospectors Rights were issued in 1965, and nine Prospecting Licenses covering areas totaling nearly 650 square miles were in force at yearend.

PRODUCTION

Details of mineral production for the years 1961–65 are given in table 1.

TRADE

In 1965 Fiji's total exports were valued at $45.0 million (F£17,823,000) and imports were valued at $73.4 million (F£29,081,000). Mineral product exports listed in table 2 accounted for nearly 10 percent of the year's total. Gold and silver in crude bullion shipped to Australia made up the great bulk of mineral product exports. Mineral imports were valued at $12.95 million and were equivalent to 17.7 percent of total imports in 1965. Principal mineral import categories were petroleum refined products, $7.1 million; steel semimanufactures, $3.2 million; and fertilizers, $2.2 million.

COMMODITY REVIEW

Metals. — *Copper.* — Initial metallurgical test shipments of copper ore from Banno Mining Co. Ltd., operations on Undu Peninsula of Vanu Levu were made during 1965 to the parent company's plants in Japan. Two sites were being prepared for mining, and equipment reportedly valued at $7.6 million has been landed at the port of Lambasa. Production from the Udu site was scheduled to begin late in 1966, at an annual rate of 30,000 tons of ore. Mining at Wainikoro was to be deferred until prospecting in that locality is complete.

Table 1.—Fiji: Production of metals and minerals
(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	1964	1965
Metals:

Salt	1,781	1,525	United Kingdom 924; Australia 600.
Fertilizer materials, all types	35,092	33,968	Japan 32,784; United Kingdom 636.
Mineral fuels:			
Coal	4,008	3,029	All from Australia.
Coke	336	314	Australia 293; New Zealand 21.
Petroleum, refinery products:			
Gasoline and benzine thousand 42-gallon barrels	303	292	Mainly from Iran and Australia.
Kerosine and jet fuel do	430	531	Do.
Diesel fuels do	548	502	Do.
Residual fuel oils do	281	121	Do.
Lubricating oil and grease do	18	16	Do.
Bitumen do	11	18	Do.

Gold.—During the fiscal year ending June 30, 1965, Emperor Gold Mining Co. Ltd., milled 296,238 metric tons of ore, of which approximately 11 percent was from opencut workings. Fine gold recovery amounted to 111,638 ounces, leaving about 3,400 ounces in the mill circuit at the close of the fiscal year. Despite record mining and milling performance, rising costs have prompted the company to apply to the Fiji Government for financial assistance in the form of a subsidy that will enable the company to continue programs of exploration, development, and research. In view of the demonstrated technological capabilities of the mine staff and the importance of this enterprise to the national economy, such assistance appears fully warranted. Measured ore reserves at the close of the fiscal year were estimated at 934,100 long tons averaging 8.6 pennyweights gold per ton (equivalent to 38.4 ounces per short ton).

The geophysical survey of the Tavua Basin, started in 1964 by Emperor Gold Mining Co. Ltd., in cooperation with the Geological Survey Department of Fiji, has included collection in 1965 of 9,300 soil samples from about 15 square miles. Four prospects considered worthy of followup drilling have been defined.

Manganese Ore.—The year's output of manganese ore was from the Nabu and Koroviko mines which reported production of 5,139 nd 340 tons respectively.

Nonmetals. — *Cement.* — Manufacture of cement in Fiji was started in 1962 by Fiji Industries Limited at Lami on Suva harbor. Rated annual capacity of the plant is 45,700 metric tons. Raw materials include coral sand dredged from the harbor and from Vunivandra Channel in Laucala Bay. Virtually all output has been consumed in Fiji.

MAKATEA

Exports of phosphate sands from the island of Makatea, the only island of French Polynesia that is credited with appreciable output of mineral products, amounted to 318,620 metric tons in 1965. Quantities exported in recent years have been as follows:

Year	Metric tons			
	Japan	New Zealand	Other countries	Total
1961	236,358	121,756	10,670	368,784
1962	219,637	87,900	14,054	321,591
1963	194,531	120,198	6,518	321,247
1964	171,424	195,585	7,108	374,117
1965	160,439	158,153	28	318,620

With the imminent exhaustion of minable reserves of phosphatic materials on Makatea, Compagnie Française des Phosphates de l'Oceanie (CFPO), the sole producer, has transferred its interest and removed some equipment and personnel to manganese mining on the New Hebrides island of Vate.

NAURU AND OCEAN ISLAND

The phosphate mining industries on the Australian Trust Territory of Nauru and Ocean Island of the British Gilbert and Ellice Islands Colony are both conducted by the British Phosphate Commissioners (representing the Governments of United Kingdom, Australia, and New Zealand). Together the islands supply the bulk of Australian and New Zealand phosphate rock requirements. Production and exports for recent years have been as follows:

During 1965 discussions relative to royalty rates for phosphate rock extraction were held between natives of both islands and government officials. Under terms of an interim agreement with the Gilbert and Ellice Islands Colony administration, announced on February 4, 1966, the existing rate of 23 shillings ($2.66) on exports from Ocean Island is to be increased by 2 shillings ($0.28) to a new rate of 25 shillings ($2.92) per ton. Revision of royalties payable to Nauruans has not been announced.

Year	Metric tons		
	Nauru	Ocean Island	Total
1961	1,302,740	342,950	1,645,690
1962	1,539,976	260,769	1,800,745
1963	1,572,075	361,344	1,933,919
1964	1,849,278	328,030	2,177,308
1965	1,495,755	375,299	1,871,054

NEW CALEDONIA

New Caledonia's mineral output including iron ores, nickel ores, and smelter products yielded exports valued at over $61 million in 1965, an increase of 11 percent over that of 1964. Following closure of the Tiebaghi mine at Paagoumene in 1962, production of chromite ore has not been reported. In addition to metallic ores, a small quantity of giobertite was produced and used locally as a metallurgical refractory.

Two Canadian companies, International Nickel Co. of Canada, Ltd., and Denison Mines, Ltd., reportedly have expressed interest in undertaking nickel ventures jointly with French partners. Late in 1965 two new joint-ownership companies were formed on a 50–50 basis by Kaiser Aluminum & Chemical Corp. (of the United States) and Société le Nickel. One company, under administration of Le Nickel, plans to establish a new ferronickel smelter to produce about 15,000 tons of contained nickel per year in New Caledonia. The other, Kaiser Nickel Co., with a plant which will be located in the United States, will process this product and market both refined nickel and ferronickel in North America. Under the long-term contract with Sherritt Gordon Mines Ltd., 5,259 tons of nickel matte was shipped during 1965 to Canada for refining at the Fort Saskatchewan refinery.

PRODUCTION

Increases in output of nickeliferous materials in 1965 were more than sufficient to balance modest declines in output of other commodities in terms of value.

TRADE

Mineral product exports valued at $61.4 million in 1965 accounted for 94 percent of New Caledonia's total exports. Traditionally the entire output of metal ores and products of the nickel smelter has been exported, with the bulk of crude ores going to Japan and Australia and smelter products to France. However, in recent years, large quantities of nickel matte and ferronickel have been shipped to Japan and Canada.

Table 4.—New Caledonia: Production of metals and minerals

(Metric tons unless otherwise specified)

Commodity	1961	1962	1963	1964	1965
Metals:					
Chromite (51–53 percent chromium oxide)	36,662	15,455	---	---	---
Iron ore (55–56 percent iron)--thousand tons	277	303	299	292	279
Nickel:					
Ore [1]--do	2,310	1,458	1,931	2,576	2,603
Metallurgical products: [2]					
Ferronickel (nickel-cobalt content)	13,367	5,506	8,332	13,330	15,566

Table 6.—New Caledonia: Imports of metals and minerals

(Metric tons)

Commodity	1963	1964	1965	Principal sources, 1965
Metals:				
Iron and steel, semimanufactures	7,863	11,474	25,774	France 23,362; Australia 1,525.
Nonferrous metals, not further described	189	238	362	France 293; Australia 56.
Nonmetals:				
Cement, lime, dimension stone, and asbestos cement products	21,905	26,917	38,806	Japan 20,360; France 16,917.
Clay bricks and tile	3,249	5,239	8,498	France 5,959; Austria 1,578.
Fertilizers, processed	251	439	488	France 390; Japan 36.
Sand, gravel, and crushed rock	24,326	57,561	46,187	Mexico 46,039; France 138.
Other nonmetals	603	670	709	France 385; Belgium-Luxembourg 90; Australia 85.
Mineral fuels:				
Coal, coke, and briquets	173,508	287,673	304,006	All from Australia.
Petroleum products	135,119	154,887	172,123	Australia 124,772; Malaysia 12,180; Iran 9,536.
Gas, natural and manufactured	986	925	1,659	Australia 1,211; Indonesia 210.

Mineral and metal imports consist primarily of fuels, semifabricated and fully manufactured metals, and construction materials. In 1965 imports in these categories were valued at $20 million and made up 27 percent of New Caledonia's total imports, estimated at $76.0 million.

COMMODITY REVIEW

Metals.—*Iron Ore.*—The iron ore mine at Prony, operated by Société Calédonienne des Minerais de Fer, a subsidiary of Société le Nickel, produced 279,000 metric tons in 1965, compared with 292,000 tons in 1964.

As in previous years the entire output was exported to Broken Hill Pty. Co. Ltd. in Australia. Grade of exported ores averaged 55.6 percent iron, 0.22 percent nickel, 3.06 percent chromium, and 6.75 percent moisture.

Nickel.—Production of nickel ores totaled 2,602,697 tons in 1965, a slight increase over the 1964 record. Of the year's total, 870,609 tons (averaging 3.15 percent nickel and 23.6 percent moisture) was exported. Six independent producers accounted for 75 percent of the ore exports. Le Nickel mines at Thio, Bornets, Kouaoua, and the new site at Poro, all on the northeast coast, mined a total of 1.83 million tons in 1965, compared with 1.77 million in 1964.

The great bulk of this was transported in company-owned vessels to the smelter at Doniambo, near Noumea. The Poro opencut, which commenced ore shipments in 1965, is equipped with 7 excavators, 50 bulldozers, 20 power shovels, and 75 trucks. Plans call for erecting a pelletizing plant at Poro to produce 1.5 million tons of pelletized garnierite concentrates annually from the Poro and Nepoui mines. Annual mining capacity of the company's several mines exceeds 3 million tons. While details have not been published, Le Nickel claims its New Caledonia nickel ore reserves to be the world's largest.

The $70 million expansion program to which Le Nickel is committed is aimed at an annual output of 45,000 metric tons of nickel by 1969 and 65,000 tons in 1970. The program includes extensive additions in the smelter and ancillary works, new electric power facilities and two new ore carriers.

NEW HEBRIDES

Following studies conducted jointly by the French Bureau of Recherches Géologiques et Minières (BRGM) and opencut mining of manganese ores on Vate Island, of the New Hebrides group, commenced in 1961. Since that time, in anticipation of working out reserves of phosphate rock on Makatea Island, CFPO has been transferring personnel and equipment to the manganese operation on Vate Island. Although relatively low-grade ore is mined, the benefication plant, consisting of washing and agglomeration facilities, produces a metallurgical-grade product for export. In 1965 mine output of 390,300 metric tons averaging 20 to 25 percent manganese yielded 66,710 tons of agglomerate containing 49.92 percent manganese. Exports in 1965, which apparently were in part drawn from stocks, included 71,406 tons of agglomerates and 8,954 tons of concentrate. A major portion [2] of this went to Japan.

Production and exports of manganese products during the past 5 years were as follows:

Year	Metric tons	
	Production	Exports
1961	4,590	---
1962	19,830	14,181
1963	25,416	23,319
1964	60,546	66,104
1965	66,710	80,360

PAPUA AND NEW GUINEA

The Australian-administered territories of Papua and New Guinea, including the Manus, New Ireland, New Britain, Bougainville, and other islands remained largely unexplored. Although many mineral occurrences have been reported, only gold and small quantities of silver, platinum, copper, and manganese have been produced. Value of mineral output of the two territories totaled US$1.2 million in the fiscal year ending June 30, 1965, compared with $1.5 million for the preceding year. In a national economy based mainly on agriculture and forest products, minerals represented less than 0.5 percent of the territorial gross national product, estimated at US$321 million and $370 million in 1964 and 1965, respectively.

Exploration activities by Australian Government field teams and various foreign companies have been intensified in recent years, resulting in several potentially commercial discoveries. In addition to important findings of copper ores on Bougainville Island and gold-base metal deposits on Misma Island, interest has developed in

[2] Japan trade statistics show imports of 64,525 metric tons from New Hebrides in 1965.

beach sands on the Gulf of Papua, phosphate rock at Mullins Harbor of Milne Bay in southeast Papua, and copper-gold occurrences in the Bainings area of New Britain. The oil search activity in 1965 was confined to a single well drilled in southwestern Papua and seismic surveys in eastern Papua and offshore in the Gulf of Papua.

Salient features of the Papua-New Guinea minerals industry is summarized for recent fiscal years as follows:

Fiscal year ending June 30 of year stated	Mineral areas held (acres)	Number of mines	Number of workers [1]	Value of mineral output (U.S. dollars)
1961				
Papua	1,019	18	787	7,623
New Guinea	9,971	275	3,925	1,526,105
1962				
Papua	1,038	17	161	968
New Guinea	11,216	300	3,819	1,501,288
1963				
Papua	976	18	345	1,667
New Guinea	11,260	330	3,606	1,493,603
1964				
Papua	929	26	544	1,370
New Guinea	11,339	358	3,508	1,511,639
1965				
Papua	890	87	688	1,965
New Guinea	12,246	380	3,629	1,205,312

[1] Includes workers employed in petroleum exploration.

A historical summary of mineral production through June 30, 1965, from Papua and New Guinea was published [3] in 1965. These data are condensed as follows:

Territory and commodity	Years	Unit	Total quantity produced
Papua:			
Copper:			
Ore	1906–1922	Metric tons	11,244
Matte	1922–1941	do.	15,701
Gold	[1] Pre-1951–1965	Troy ounces	618,401
Manganese ore	1939–1965	Metric tons	2,134
Platinum	[2] 1934–1940	Troy ounces	219
Silver	[1] Pre-1951–1965	do.	257,577
New Guinea:			
Gold	[1] Pre-1951–1965	do.	3,564,176
Silver	[1] Pre-1951–1965	do.	2,185,753

[1] As reported.
[2] Platinum production 1940–65 not reported.

Minerals legislation enacted during 1965 included amendments to the Petroleum (Prospecting and Mining) Ordinance 1951–63 for Papua and New Guinea, and the Mining Ordinance 1928–62 of New Guinea. The new legislation provides for land titles better suited to modern, large-scale methods of prospecting and mining and defines the rights of surface owners. The present status of mining laws, royalties, and tax concessions to the mining industry are outlined in a publication.[4]

PRODUCTION

Quantities of minerals produced in Papua and New Guinea in recent calendar years follow:

Platinum.....do....	5	4	5	1	4
Manganese ore.....metric tons..	2	---	3	2	---

TRADE

Total territorial trade in the 1964–65 fiscal year was made up of exports valued at $55 million and imports totaling $96 million. Minerals exports accounted for $1.2 million of which gold bullion contributed over 99 percent. Imports of mineral and metal products were valued at $10.7 million, principally iron and steel products. ($4.42 million), fuels ($4.04 million), and cement ($0.55 million).

COMMODITY REVIEW

Metals.—*Copper.*—Throughout 1965 Conzinc Riotinto of Australia, Ltd., continued active exploration of the large low-grade porphyry-type copper deposit near Kieta on Bougainville Island, at the northwestern end of the Solomon group. Government assistance on this project in 1965 took the form of a regional mapping program by the Australian Bureau of Mineral Resources.

Gold.—Bulolo Gold Dredging Ltd., in the Bulolo Valley, eastern New Guinea, reported production of 8,747 ounces of gold and 3,729 ounces of silver from its dredging and sluicing operations during the company year ending May 31, 1965. Following a breakdown, the company's last operating dredge was closed on June 4. Subsequent production has been solely from hydraulic mining operations in the Widubosh area. Cubic yardage handled during the year totaled 4.86 million, and recovery averaged 6.85 cents per cubic yard. On May 31, 1965, reserves in the Widubosh sluicing area were estimated at 3.97 million cubic yards.

New Guinea Goldfields Ltd. milled 89,567 metric tons of ore yielding 12,984 ounces of gold and 11,410 ounces of silver from opencut workings near Wau in the fiscal year ending June 30, 1965. Remaining ore reserves in this locality included 428,000 tons positive and probable plus 162,000 tons possible. The company's sluicing operation, conducted jointly with Koranga Gold Sluicing Ltd., on Koranga Creek yielded 3,666 ounces of gold during the year.

In addition to the company operations, small groups and individual natives worked alluvial deposits in numerous, widely scattered areas. The number of persons so employed has been estimated at 3,000. A partial count revealed 84 such operations in Papua and 894 in New Guinea during fiscal year 1964–65.

Pacific Island Mines Ltd. of Australia since 1959 has ben conducting exploration and development on an old lode gold mine (with lead and zinc) on Misma Island, about 100 miles off the southeast tip of Papua. The mine was worked and a small mill operated prior to World War II. Recent drilling and underground development, completed with the participation of Cultus Explorations Ltd., a Canadian company, has indicated ore reserves in excess of 1 million tons and the company is planning to initiate production by 1968.

Mineral Fuels. — *Petroleum.* — Petroleum search activities in 1965 were limited to a single test well, Ivir No. 1, drilled to a depth of 12,015 feet by Australasian Petroleum Co. Pty. Ltd., subsidiary of Oil Search Ltd. in the delta of Kamau Creek on Papua's southwest coast. Seismic surveys were conducted in the northwest Wana area by Australasian Petroleum Co. Pty. Ltd., and offshore in the Gulf of Papua by Phillips Petroleum Company and associates. Marathon Petroleum Australia Ltd. with Continental Oil Company of Australia also conducted reflection-seismic studies, using two crews in eastern Papua.

Index to Political and Geographic Areas

Notes to users:

This index is not complete; space does not permit compete indexing of countries listed as trading partners in the section of each chapter dealing with trade and in tables accompanying such sections. Moreover it does not list passing mentions of the nationality of business enterprises or Government agencies where these differ from the nationality of the subject country of the chapter.

Direct references to pages appear under the version of the country or area name used in the chapter or chapter section dealing with that country or area (usually but not always the short form of the name approved by the Department of State[1]). Commonly used variations of these names, including names that have recently been changed, are listed with a cross-reference to the version of the particular country or area name used in this volume.

Boldface type has been used to indicate the pages of the chapter or chapter section dealing primarily with the indexed country or area; page numbers in regular type indicate specific mention of the country or area appearing in regional review chapters.
