Mr. Thomas O. Llewellyn is a physical scientist with the Branch of Industrial Minerals. He has covered germanium for 4 years. Domestic survey data prepared by Tony E. Morris, mineral data assistant.

omestic production and consumption of refined germanium were estimated at lower levels than those of 1989. The declines in germanium production and consumption were attributed to an existing oversupply of metal and to a lower demand from the military sector. Infrared systems and fiber optics continued to be the major end uses.

DOMESTIC DATA COVERAGE

Refinery production and consumption data for germanium are estimated by the U.S. Bureau of Mines based on discussions with domestic producers.

BACKGROUND

Germanium is recovered as a minor byproduct of the refining of base metal ores, and the potential supply of this metal, which is dependent on the level of zinc production, has historically exceeded demand.

Invention and development of the germanium transistor opened the path for the solid-state electronic field and, from 1950 through the early 1970's, provided an excellent market for germanium. Despite the continued growth of the electronics industry in the 1970's, germanium demand for transistors, diodes, and rectifiers declined because germanium was being replaced by electronic-grade silicon. However, the reduced demand for germanium in the electronics field was offset by a dramatic increase in demand for germanium in both infrared night vision systems and fiber-optic communication networks.

Definition, Grades, and Specifications

Germanium has a metallic appearance, grayish white in color, and lustrous, hard,

and very brittle. It is a semiconductor, with electrical properties between those of a metal and an insulator. The National Stockpile Purchase Specification P-114-R, December 16, 1989, for intrinsic germanium metal specifies an electrical resistivity of 50 ohm-centimeters at 20°C (40 ohm-centimeters at 25°C) over the entire ingot length.

Germanium is available commercially as a tetrachloride and high-purity oxide and in the form of zone-refined ingots, single-crystal bars, castings, doped semiconductors, optical materials, optical blanks, and other specialty products.

Industry Structure

Most germanium occurs as a minor constituent of certain base metal ores and coal deposits. Those producers that currently recover primary germanium for the most part depend on germanium-rich residues, mainly from zinc derived from past or present base metal smelting operations.

In the United States, Eagle-Picher Industries Inc.'s Quapaw, OK, Specialty Materials Div. has the capability of recovering primary germanium from zinc smelter residues. Eagle-Picher also reprocessed scrap. Kawecki Berylco Industries Inc., a division of Cabot Corp. in Revere, PA, and Atomergic Chemetals Co., Plainview, NY, produced germanium from reprocessed scrap and semirefined foreign material.

The Jersey Miniere Zinc Co. in Clarksville, TN, continued to produce germanium-rich residues as a byproduct of processing zinc ores from its Gordonville and Elmwood Mines. These residues were shipped to Metallurgie Hoboken Overpelt S.A. (MHO) in Belgium for germanium recovery and refining.

Little information was available on the financial structure of U.S. and world germanium industries. Germanium refiners usually were involved in the production and sale of many different metals and specialty products.

Resources

Minerals in which germanium is concentrated are germanite, a sulfoarsenite of copper, germanium, and iron with an average content of 5% germanium; argyrodite, a double sulfide of germanium and silver containing 5% to 7% germanium; renierite, a complex sulfide of arsenic, copper, germanium, iron, tin and zinc with 6% to 8% germanium; and several other minerals such as canfieldite, itoite, stottite, and ultrabasite. Primary germanium minerals are normally formed in sulfide mineralization processes at low-to-intermediate temperatures, and secondary varieties may result from supergene alteration of sulfide ore deposits.¹

Currently, there are two major reserves of germanium in the United States. The largest is the recoverable germanium that occurs as a minor constituent of zinc sulfide ores in the middle Tennessee zinc district. The other major reserve of germanium is in southern Utah. Here the germanium is found in the iron oxide ore zone of a depleted copper mine.

There are no reliable germanium assay data available for many areas of the world. The U.S. and world resources could be expanded if germanium were to be recovered from ash and flue dusts resulting from burning of certain coals for power generation.

Technology

Germanium is obtained commercially as a byproduct of base metal refining and extracting. Improvements have been made, but the basic processes have remained virtually unchanged.

Regardless of the source, germanium raw materials are reacted with concentrated hydrochloric acid to form germanium tetrachloride, which is then purified by fractional distillation. The purified germanium tetrachloride is hydrolyzed with water to produce germanium dioxide, which is removed by filtration and dried. Dried germanium dioxide is reduced with

hydrogen at about 760°C to a germanium metal powder, which is then melted and cast into metal bars. These bars are then zone-refined to produce intrinsic-grade metal. This high-purity metal is mainly used for electronic and infrared optics. Zone refining produces polycrystalline germanium.²

Certain applications of germanium, such as gamma-ray detectors, require single-crystal germanium. Single crystals are produced by two methods, the horizontal pulling process or the vertical pulling process, also known as the Czochralski method.

More than 50% of the metal used during the manufacture of most electronic and optical devices is recycled as new scrap. As a result of the low unit use of germanium in microelectronic devices, very little germanium returns as old scrap.

Substitutes

Less-expensive silicon substitutes for germanium in certain electronic applications. Certain bimetallic compounds of gallium, indium, selenium, and tellurium can also substitute for germanium. Germanium is more reliable in some high-frequency and high-power applications and more economical as a substrate for some light-emitting diode applications. In infrared guidance systems, zinc selenide or germanium glass substitutes for germanium metal, but at the expense of performance.

Economic Factors

Table 1 shows import duties for germanium products, which became effective on January 1, 1989, under the new Harmonized Tariff Schedule of the United States. Domestic producers are granted a depletion allowance of 14% on both domestic and foreign production of germanium.

Operating Factors

Germanium has little or no effect upon the environment because it usually occurs only as a trace element in some ores and carbonaceous materials. The small quantities used in commercial applications also pose no threat to the environment. Germanium compounds generally have a low order of toxicity, except for germanium tetrahydride, which is considered toxic.

Based on a 1976 report, the energy

TABLE 1
U.S. IMPORT DUTIES FOR GERMANIUM MATERIALS

Item	HTS No.	Most favored nation (MFN) Jan. 1, 1990	Non-MFN Jan. 1, 1990

Germanium other: Other	8112.30.9000 5.5% ad valorem		45% ad valorem.	

requirements for the production of zonerefined germanium metal from zinc sulfide concentrates and scrap is 2,145 million British thermal units per net ton of germanium ingot.³

ANNUAL REVIEW

Strategic Considerations

The importance of germanium as a strategic and critical material was determined by the Federal Emergency Management Agency, and, on July 6, 1984, it was included in the National Defense Stockpile (NDS) with an initial goal of 30,000 kilograms of germanium metal. On July 24, 1987, a new NDS goal of 146,000 kilograms was established, based on the Army's estimates for actual emergency conditions of mobilization.

Some of the metal inventory acquisitions made the previous year were delivered in 1990, and, as of December 31, the stockpile inventory was 58,287 kilograms of germanium metal.

Production

The U.S. Bureau of Mines estimated domestic refinery production from both primary and secondary materials to be 18,000 kilograms, a decrease of 10% compared with that of 1989.

In August, Hecla Mining Co., the owner of the only known mine and refinery in the world where germanium and gallium were recovered as principal products, closed the mine and refinery about 6 months after it reopened. The operation, near St. George, UT, had a production capacity of 20 metric tons per year of germanium and 7 metric tons per year of gallium. Most of the mined ore was stockpiled because of technical difficulties in the processing plant. The company expected to resume operations pending

processing improvements and higher price quotations for the metal.

Consumption and Uses

The U.S. Bureau of Mines estimated that consumption of germanium decreased about 5.5% compared with the level of 1989. The estimated consumption pattern by end use of germanium in 1990 was as follows: infrared systems, 60%; fiber optics, 8%; gamma-ray, X-ray, and infrared detectors, 9%; semiconductors (including transistors, diodes, and rectifiers), 10%; and other applications (catalysts, phosphors, metallurgy, and chemotherapy), 13%.

Infrared systems continued to be the major end use for germanium. Infrared optics were mainly used for military guidance and weapon-sighting systems. Germanium-containing lenses and windows transmit thermal radiation similar to visible light transmission by optical glass. Germanium glass also was used for nonmilitary surveillance and monitoring systems in fields such as satellite systems and fire alarms. Germanium was used as a dopant in the core of many optical fibers employed in telecommunications.

Martin Marietta Corp. was applying a new transparent hard carbon coating to the night vision system windows of the Apache attack helicopter. The night vision system enables pilots to fly the helicopter a few feet above ground in darkness, operate under low-weathervisibility conditions, and detect tanks or other armored targets at night. The system's germanium optical windows were abraded by exposure to sand and dust, which affected the clarity of the television-like infrared picture. The carbon coating protection was designed to last more than 20 years compared to about 3 years achieved by the previously used thorium fluoride coating. The U.S. Army's expected savings on maintenance and spare parts cost on night vision systems were estimated to be about \$28 million during 3 years.⁴

Markets and Prices

Throughout 1990, domestic producer prices for germanium metal and dioxide, published by Metals Week, remained at the levels established in late 1981 of \$1,060 and \$660 per kilogram, respectively. However, discounting by producers was evident during 1990 because of competition from imported materials.

The Belgian producer's price for germanium metal, published by Metal Bulletin (London), remained at about \$802 per kilogram throughout the year.⁵

Foreign Trade

In 1990, the estimated germanium content of imports was approximately 50,000 kilograms. Total imports of germanium materials increased significantly compared with those of 1989. France, Belgium, Canada, and the United Kingdom, in descending order of shipments, accounted for approximately 80% of the total U.S. germanium imports for 1990.

World Review

World refinery production was estimated at 76,000 kilograms, a decrease of about 7% compared with the 1989 level. The decline in world production was attributed to an oversupply and to a lower level of demand for the metal. Primary germanium was produced by MHO, Belgium; Johnson Matthey Electronics, Canada; Societe Miniere et Metallurgique de Penarrova S.A., France: Otavi Minon AG and Preussag AG, the Federal Republic of Germany; Pertusola Sud SpA, Italy; and Nippon Denshi Kinzoku and Sumitomo Metal Mining Co. Ltd., Japan. Germanium refineries also were in China and the U.S.S.R.

Capacity.—The data in table 3 represent rated annual production capacity for refineries on December 31, 1990. Rated capacity was defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable, long-term operating rate, based on the physical equipment of the plant and routine operating procedures for labor, energy, materials, and maintenance.

TABLE 2
U.S. IMPORTS OF GERMANIUM MATERIALS, BY COUNTRY¹

	19	89	1990	
Country	Gross weight (kilograms)	Value	Gross weight (kilograms)	Value

TABLE 3

WORLD ANNUAL GERMANIUM REFINERY PRODUCTION CAPACITY, DECEMBER 31, 1990

(Thousand kilograms)

	Capacity
North America:	
Canada	10
United States	60
Total	70
Europe:	
Belgium	50
Centrally planned economy	
countries	40
Other	65
Total	155
Asia:	
China	10
Japan	35
Total	45
World total	270

Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditures.

Rated capacities of germanium refineries were estimated based on discussions with some officials from private industry, past and present production rates, and published capacity data.

Japan.—Germanium metal production was 3,368 kilograms, which was at about the same level as in 1989. Dioxide production decreased from 13,302 kilograms in 1989 to 12,350 kilograms in 1990.6

Spain.—Telefonica S.A., the state-owned telephone company, is turning to optical fibers to improve its telecommunications system. It has already installed about 12,000 kilometers of fiber optic cable, and an additional 21,000 kilometers of cable are expected to be installed before the end of 1993.⁷

United Kingdom.—British Telecom, London, will supply and install the first fiber-optic cable link in Vietnam. A 460-kilometer network system will connect Ho Chi Minh City with Nha Trang at an estimated cost of \$6.3 million.⁸

Current Research

A new fiber-optic lighting system for automobiles was being developed by the Advanced Technology Department of General Electric Lighting. This system uses less power than two of today's halogen headlights, while providing the same amount of light. It has a potential application of replacing as many as 80 light sources now used in cars. Furthermore, the fiber system does not require conventional wiring nor light bulbs, and its small size (about 1 inch high) should allow car designers to taper the front end of the car to achieve a more aerodynamic curvature.9

The Roskill organization issued its 1990 germanium report. This comprehensive report discussed and analyzed world production of germanium by country and individual company. It also contained information on end-use markets, international trade patterns, and trends in prices.¹⁰

OUTLOOK

There were abundant supplies of

germanium materials on the market in 1990. Germanium supplies are likely to remain high for the next 2 to 4 years because of an increased availability of concentrates from Canada and a considerable amount of germanium metal emerging into the world market from the U.S.S.R. For the second consecutive vear, producers were forced to lower prices to maintain their share of the market.

Market analysts agree that all primary germanium producers will probably face difficult times in the near future. This assessment is based on a continuing global oversupply of germanium materials together with a low market demand.

GOLD

By John M. Lucas

Mr. Lucas, a geologist with more than 30 years of experience in the mining industry, has been the U.S. Bureau of Mines commodity specialist for gold since 1980. While with private industry, Mr. Lucas was involved in exploring for a wide variety of commodities, including gold, in the United States as well as Australia, Brazil, and Canada. Domestic survey data were prepared by Dwayne E. Penn and Lisa P. Conley, mineral data assistants, and Stephen L. Hays, supervisory mineral data technologist International data tables were prepared by Audrey D. Wilkes, international data coordinator.

old has been treasured since ancient times for its beauty and permanence. Most of the gold that is fabricated today goes into the manufacture of jewelry. However, because of its superior electrical conductivity and resistance to corrosion and other desirable combinations of physical and chemical properties, gold also emerged in the late 20th century as an essential industrial metal. Gold performs critical functions in computers, communications equipment, spacecraft, jet aircraft engines, and a host of other products. Although gold is important to industry and the arts, it also retains a unique status among all commodities as a long-term store of value. It was, until recent times, considered essentially a monetary metal, and most of the bullion produced each year went into the vaults of government treasuries or central banks.

Domestic and international gold mining operations continued to produce gold at a record level during 1990. The U.S. gold mining industry produced a record 290,202 kilograms (kg) (9,329,994 troy ounces¹) of gold, a 9% increase in production compared with that of the previous year. The State of Nevada was once again the Nation's dominant gold-producing State. For the second consecutive year the total demand for gold used in fabricated products in the market economy countries exceeded the record demand level set in 1988. Jewelry continued to be the dominant end-use sector.

The U.S. Bureau of Mines, in an effort to provide statistical data on gold that are consistent with international usage, reports gold data in kilograms and metric tons unless otherwise noted.

DOMESTIC DATA COVERAGE

Domestic mine production data for gold are developed by the U.S. Bureau of Mines from two separate, voluntary surveys of U.S. operations. One of these surveys is the lode-mine production survey of gold, silver, copper, lead, and zinc mines. Of the lode gold producers in operation to which a survey request was sent, 209 responded, representing 96% of the total lode-mine production of gold shown in tables 4 and 5. Production for the nonrespondents was estimated using reported prior-year production levels, adjusted by trends in employment, and other guidelines such as company annual reports, the news media, and State agency reports.

BACKGROUND

Gold lore and the use of gold predates written history. Gold has been considered a precious metal since ancient times, and the mystique and folklore associated with gold has been a part of the fabric of civilized society throughout history. Similarly, the search for gold has stimulated world exploration and trade for more than sixty centuries.

Gold mining in the United States began about 1800 in North Carolina, with Georgia joining in production in 1829 and Alabama in 1830; then Virginia, Tennessee, and later New Mexico became producers as prospectors moved west. The most important gold discovery, because of its influence on development in the Western

United States and the amount of gold produced, was at Sutter's Mill in California in 1848. Later discoveries were made in most other Western States and territories.

Gold mining in Australia began about 1849 as an offshoot of the California gold rush. Russian gold mining had been expanding since the mid-18th century, and by the eve of the California gold rush, Russia was producing about two-thirds of the world's gold. Gold mining in the Republic of South Africa started in the 1870's. The last major gold rush began just prior to 1900 in Canada's Yukon and in Alaska.

Early mining was largely by placer methods, with a multitude of miners working stream deposits (placers) by hand mining techniques, a practice that continues to this day in many areas of the world. In the 1860's, the more difficult underground mining of lode deposits—the sources of the placers—became important. Cyanidation, a chemical process for gold extraction, was introduced about 1890, and the concentration of finely ground ores by selective adherence of mineral particles to rising bubbles, the flotation process, was first used for gold ores about 1900 and came into general use in the 1930's. Heap leaching, essentially a form of cyanidation, has come into general practice for treatment of lowgrade ores only during the past 2 decades.

Cumulative world production to date is estimated at about 107,000 metric tons (3.4 billion ounces), about two-thirds of it mined in the past 60 years. The total is equivalent in volume to a cube roughly 18 meters (58 feet) on a side. The Republic of South Africa has been the source of about 41% of that gold, but nearly all countries have reported at least some production of gold.

U.S. gold production from its beginning in the 18th century to date totals about 11,300 tons (362 million ounces). The principal producing States, in declining order of cumulative production, are California, Nevada, Colorado, South Dakota, Alaska, Utah, and Montana; the remainder came from 11 other States. To date, lode gold mining has supplied about 50% of U.S. production; placer mining, 35%; and base metal mining, 15%. The Homestake Mine at Lead, SD, has accounted for about 10% of all U.S. gold production. Other major sources of past production include the Mother Lode and Grass Valley areas of California, the Comstock Lode and Goldfield areas in Nevada, Cripple Creek in Colorado, and the Fairbanks and Nome, AK, areas.

Most domestic gold mines were closed by Limitation Order L-208 in the early months of World War II (October 8, 1942) so that scarce equipment, supplies, and skilled workers could be focused on mining essential base metals. L-208 was revoked July 1, 1945. Because of increased cost and rehabilitation problems, only a few mines reopened after the war. During the resurgence of gold exploration and mining over the past decade, many deposits affected by L-208 have been reexamined or returned to productive status.

Definitions, Grades, and Specifications

Fineness refers to the weight proportion of pure gold in an alloy, expressed in parts per thousand; 1,000 fine gold is 100% pure gold. Commercially traded gold bullion is usually 995 fine or higher. The term "fine gold" may also be used to designate the particle size of gold in its native state; for example, a placer deposit with gold particles ranging from 0.38 millimeter (mm) to 0.76 mm (0.015 to 0.3 inch) in diameter contains fine gold, whereas a similar deposit with particles more than 1.5 mm (0.06 inch) in diameter contains coarse gold.

The term "karat," like fineness, refers to purity, but is expressed in 24ths; thus 24-karat (24k) gold is 1,000 fine or pure gold, and 10k gold is 10/24, or 41.7% gold. Although there are many 10k alloys, each 10k alloy contains 41.7% gold. Various 10k alloys, for example, differ from each other in the number, identity, and proportions of their other constituent metals. Gold alloys used in jewelry and certain other end uses are referred to as karat golds, whereas alloys used in dentistry and electrical devices are designated more precisely. Yellow, red, and green karat golds are essentially ternary

alloys of gold, silver, and copper, often with additions of zinc and sometimes a little nickel. White karat golds are usually composed of gold, copper, nickel, and zinc, although platinum and palladium have also been used as components.

Having assumed the functions previously performed by the London Gold Market, the London Bullion Market Association (LBMA), established in 1987, sets standards for its members that are widely used in world gold trade. Refined gold bullion bars are generally designated as "good delivery bars." A good delivery bar, as set forth by the requirements of the LBMA, must contain 350 to 430 troy ounces of gold with a minimum fineness of 995. The bar must bear the stamp of one of the world's 49 approved melters or assayers, have a good appearance, and be easy to handle and stack. Smaller bars are also commonly available on the commercial gold market.

U.S. trade practice rules for the jewelry industry, set by the Federal Trade Commission, require that any article labeled gold must contain at least 10k gold, with a tolerance of three parts per thousand for most articles, or if soldered, seven parts per thousand. "Rolled gold plate" and "gold filled" are terms referring to articles made of base metal to which karat gold has been bonded by soldering, brazing, welding, or mechanical means. A marking such as "1/10 10-karat gold filled" means that one or more surfaces are covered with 10-karat gold and the coating constitutes at least 10% of the weight of the entire article covered. No article may be marked "gold filled" if its karat gold surface constitutes less than 1/20 of the total weight. Thinner coating are marked "rolled gold plate."

Gold has an atomic number of 79 and an atomic weight of 197, occurring naturally as a single stable isotope. Its melting point is 1,063 °C, and its specific gravity is 19.3. In addition to being highly resistant to corrosion, gold is also extremely malleable and ductile; 31 grams (1 troy ounce) can be beaten into about 250 square feet of gold leaf about four-millionths of an inch thick, while a similar quantity can be drawn into more than 80 kilometers (km) (50 miles) of wire.

As an illustration of gold's high specific gravity or density, 1 cubic foot of pure metallic gold weighs a little more than 1,200 pounds; one cubic inch of pure gold weighs about 311 grams (10 troy ounces); a lump or nugget of gold the size of a navy bean weighs about 3 grams (0.1 troy ounce), and a flake of gold the size of a grain of rice

weighs about 0.18 gram (0.006 troy ounce).

The troy system of weights is generally used in the United States for gold and other precious metals; however, to aid in harmonizing world data collection, Government practice now dictates the use of the metric system of measure. The troy weight system is based on the troy ounce of 480 grains or 20 pennyweight. One troy ounce is equivalent to 1.097 ounces avoirdupois. Many nations use the metric system; in this system, the weight of gold is designated in standard metric units: gram, kilogram, or metric ton. The metric ton is equivalent to 32,150.7 troy ounces. In addition to the metric or troy systems, other units of weight applicable to precious metals may also be encountered. On the Indian Subcontinent, for example, the weight of gold may be expressed in terms of tolas; one tola of 999 fine gold weighs 11.1 grams (0.375 troy ounce).

Products for Trade and Industry

Although gold compounds are used in substantial quantities in electroplating, most of the gold sold in the international marketplace for industrial usage is in the form of metal or metal alloys. Many standard metallic forms are available, such as bars, rods, sheets, foils, wires, powder, granules, and shot. Conductive pastes and inks prepared with gold powder are widely employed in the electronics industry. Much jewelry gold is supplied as granules of specified karat content. Semimanufactured items for trade and industry may include gold jewelry findings or unassembled parts such as earring clamps, chain clasps, pins, etc.; dental findings; and inlaid, clad, and plated metals. Investment products such as bars, coins, and medallions are manufactured and sold by both industry and governments.

Industry Structure

In the United States during 1990, 92% of domestic gold production came from gold ore, and most of the remainder was a byproduct of copper and other base metal production. Placer gold production has declined to about 1% of the reported total production in recent years. Fifteen mines accounted for about 61% of domestic output in 1990; 81% came from mines in California, Montana, Nevada, and South Dakota. The leading producer in most recent years, Newmont Gold Co., provided about 18% of domestic output from its surface operations near Carlin, NV. Round Mountain Gold Corp.'s Round Mountain

heap-leaching operation, the Nation's fifth largest producer in 1989, moved up to second place in 1990. The Homestake Mine, a deep underground mine in South Dakota, has been a major producer for many years. The Utah Copper Div. of Kennecott, a major copper producer, has been a significant gold producer in many years since 1979, a year when it was the Nation's largest gold producer. Kennecott's gold is a byproduct of its extensive copper mining operations at Bingham Canyon, UT.

Attracted by the favorable U.S. business climate, foreign investment in domestic firms that produce gold as a principal product or as a byproduct has increased since 1980. This is especially true for mining interests acquired by multinational companies, some of which in turn may be directly linked to foreign governments. The general attractiveness of the United States as a country in which to conduct business has been a principal motive behind these acquisitions. Canadian mining companies have, throughout the history of North American mining, operated mines in the United States, as to a lesser extent have British and other European companies.

The South African gold mining industry, accounting for about 30% of current world output, consists of about 3 dozen large underground operations and several dozen smaller mines. In a typical year, the Republic of South Africa's gold industry reportedly mills enough ore to cover 60 city blocks to a height of 20 stories; from this volume is recovered enough gold to fill a small bathroom. These mines are owned or controlled by six corporations that interlock through directorships and mutual shareholdings and have extensive mineral and industrial investments in many parts of the world. The corporations are Anglo American Corp. of South Africa Ltd., Anglovaal Ltd., Gencor Ltd., Gold Fields of South Africa Ltd., Johannesburg Consolidated Investment Co. Ltd., and Rand Mines Ltd.

Geology-Resources

The Earth's crust has been estimated to have an average gold content of about 0.0034 gram per metric ton (0.0001 ounce per short ton), or 3.5 parts per billion (ppb). Sedimentary rocks, especially sandstones, tend toward higher-than-average gold content. In igneous rocks, the content averages slightly higher in darkly colored "mafic" rocks than in lighter colored "felsic" rocks. Seawater typically contains

about 0.011 ppb gold; however, content varies widely with location and may range from 0.001 to 44 ppb. Numerous attempts have been made over the years to recover gold from seawater; however, none have been commercially sustainable. The gold content in surface and ground waters lies within the range of analyses for seawater, but varies widely depending on source. For instance, waters from gold mines in southern Yakut, U.S.S.R., contain an average of 0.7 to 0.9 ppb. In Colorado, waters draining from gold mining and other areas contain up to 0.15 ppb, but with no distinct differences between gold-enriched and goldbarren areas. Hot-spring waters generally contain more gold than other waters.

Gold deposits are found in many kinds of rock. Hydrothermal deposits appear to be somewhat more common in acidic and intermediate igneous rocks; in silty, laminated carbonate rocks; and in silicious or aluminous sedimentary or metamorphic rocks. The general deposit types include hydrothermal, hydrothermal-metamorphic, metamorphic, replacement (lode, massive, and disseminated), and cavity filling (fissures, stockworks, saddle, reefs, breccias, and conglomerates).

Gold occurs mainly as native metal, alloyed with silver and/or other metals, and as tellurides. A naturally occurring alloy of gold and silver is known as electrum. Other gold minerals are rare. Gold is commonly associated with the sulfides of antimony, arsenic, copper, iron, and silver.

Chemical and mechanical weathering and erosion cause gold in the free or metallic form to be released from lode or primary deposits and to accumulate as nuggets and grains in residual deposits or placer deposits. Although the richest lode gold deposits have been small fissure vein types with quartz gangue, the so-called bonanzas, much larger quantities of gold have been mined from large, medium-grade deposits. U.S. gold ores average about 3.5 grams per metric ton (0.1 ounce per short ton) or less; however, the advent of chemical heap leaching now makes it possible for rock with suitable properties containing considerably less than 3.5 grams per metric ton to be considered ore.

Technology

Exploration.—Although a number of new techniques have come into use in the exploration for gold, the gold pan remains one of the simplest and most efficient low-cost means of finding visible gold and trac-

ing it to its source. Collecting, crushing, and panning quartz samples from geologically favorable areas is a common basic procedure employed in prospecting for bonanzatype lode deposits. Neutron activation analysis and atomic absorption spectroscopy permit relatively fast and reliable gold analyses and have had an important bearing on the ability of field geologists to do geochemical surveys of areas formerly of little interest because of sampling costs and lack of outcrops. The long-established fire assaying technique, however, continues to be the most widely used method for determining the quantity of gold present in samples or market products where precision and accuracy of the results are important. Newmont Gold Co. recently initiated an automatic assay system whereby more than 4,900 laser-read barcoded samples are directed daily through the various laboratory stages with the aid of computers. Geochemical studies have established relationships between gold and other elements, such as arsenic, copper, mercury, and tellurium, which can be useful trace elements in the search for gold. In recent years, computers have proven to be useful in determining the often subtle relationships between trace elements and gold mineralization. Metallogenic studies relating tectonic histories and regional and local geology have given better understanding of where important gold deposits may lie.

Wire-line core drilling and improved percussion drilling methods have reduced the costs and increased efficiencies of exploration and development. Research on sampling through statistical analysis techniques that take into account the distribution and size of gold particles in a sample has shown ways to effectively reduce sampling costs. Computer methods have been useful in defining the extent of pay zones in larger ore bodies, such as those in the Republic of South Africa, and have application to low-grade disseminated deposits. Improvements in mining machinery and procedures and the introduction of new gold leaching methods have combined to lower the economic cutoff limits for gold deposits, providing an impetus for extensive reevaluation of previously mined areas as well as the incentives necessary to encourage the exploration of new, heretofore unproductive, areas.

Mining.—The technology of gold mining is well established, having evolved largely over the past century. Much of the world's gold production has come from

deep, narrow veins or from thin-bedded layers called reefs; these have been difficult to mine (in the Republic South Africa, for example) because of high underground temperature and humidity, and extreme rock pressure, which often causes dangerous rock bursts. Most domestic gold comes from surface lode mines.

Placer mining was once an important source of gold. Dredging offers the maximum efficiency in large alluvial or marine deposits; dragline, hydraulic, or bulldozing methods are commonly used in smaller, bouldery deposits such as those mined in some areas of Alaska. Most placer mining requires large quantities of water, but dry operation is also possible, using bellows or other air-blowing equipment for separation. However, recovery efficiency may be lower in dry processing. To illustrate the effort entailed in small-scale manual placer mining, such as that which has been and continues to be practiced in many areas of the world including the United States, two persons feeding a sluice box can shovel about 6 cubic yards of gravel per day. This is roughly equivalent to loading the beds of six 1-ton pickup trucks per day. Assuming that the gravel processed yields an average 0.49 gram per cubic meter (0.01 ounce per cubic yard) of gold, about 3 grams (0.06 ounce) of gold would be recovered per day. With a gold price of about \$380 per ounce, the gold recovered by two persons laboring all day would have an approximate value of \$23.00, a substantial sum in many areas of the world. Obviously, mechanization, even on a small scale, would vastly increase the amount of material that could be washed. Needless to say, mining a higher grade deposit would be even more productive. Should the gold recovered be in the form of coarse nuggets, valued also for their use in jewelry or as specimens, the value of the day's production would be increased. For large-scale, open pit lode gold mining, computer models have been developed to analyze various production factors and establish optimum pit configurations and extraction efficiencies.

The South African mining industry, a leader in deep mining technology for many years, has evolved new methods of controlling problems relating to rock stress, dust, and virgin rock temperature. Both large and small water-powered rock drills, large-diameter raiseboring machines, and new types of rubber tired transporters have been developed in recent years to increase the efficiency of mining operations. Also, the South Africans have developed new

techniques of shaft sinking, mineral processing, and extraction that are critical to the success of deep mining. At the Vaal Reefs Mine, for example, part of the gold ore is transported to the surface from a depth of more than 2,100 meters (7,000 feet) by hydraulic pumps. Much of the Republic of South Africa's current production is now coming from depths of 2,000 to 3,000 meters (6,600 to 9,800 feet) below surface, with some as deep as 3,600 meters (11,800 feet). The new generation of ultradeep mines are intended eventually to be mined to 4,500 meters (14,800 feet).²

Beneficiation.—Milling technology for gold is highly developed, and normal mill recovery rates range from 92% to 96%. Gold is recovered by cyanide leaching of gold ore contained in tanks or heaped on impervious leaching pads; by amalgamation, flotation, gravity concentration, and smelting; or by a combination of these processes. Increased exploitation of gold-bearing sulfide ores in recent years has led to the development and application of several technologies designed to render sulfide and refractory ores amenable to cyanide leaching; thus, process steps such as autoclaving, biological preoxidation, or fluidbed roasting have recently been incorporated at a number of milling operations.

Smelting-Refining.—Many gold mining operations recover the gold from cyanide leach solutions by precipitation with zinc dust, though, in recent years, carbonin-pulp (CIP) recovery technology has been adopted at a number of new mining operations. With CIP, activated carbon made from coconut shells or other durable carbon sources collects gold from the cyanided pulp until it contains 10 to 12 kg (300 to 400 ounces) of gold per ton of carbon. Gold with accompanying silver is desorbed or stripped from the carbon with a strong alkaline cyanide-alcohol solution. The precious metals are recovered from the strip solutions by electrodeposition on a stainless steel wool cathode. The cathode deposit is then refined into bullion or doré, a mixture of mostly gold and silver. The carbon is reused after being screen-sized and reactivated through controlled roasting. Generally, gold recoveries range from 92% to 97% of the feed content. Gold leaching processes in use or under development that do not employ cyanide as the principal lixiviant or dissolution medium include the application of thiourea, iodine, malonitrile, or various

bioextraction techniques. Some of these alternate techniques, unlike the long-established, well-understood cyanide process, may be accompanied by unacceptable cost or environmental burdens. When gold is associated with copper ores, it travels with the base metal through concentration and smelting to the refining stage. It is eventually separated from the anode slimes that accumulate in electrolytic copper refining cells and is recovered as gold bullion in the precious-metals refinery. Gold losses in concentrating copper ores are about the same as for copper, but are negligible in smelting and refining.

Gold is refined by chlorination in the molten state (Miller process) and by electrolysis (Wohlwill process). Generally, gold bullion made by the Miller process is 996 to 997 fine, and bullion made by the Wohlwill process is 999.5 to 999.8 fine.

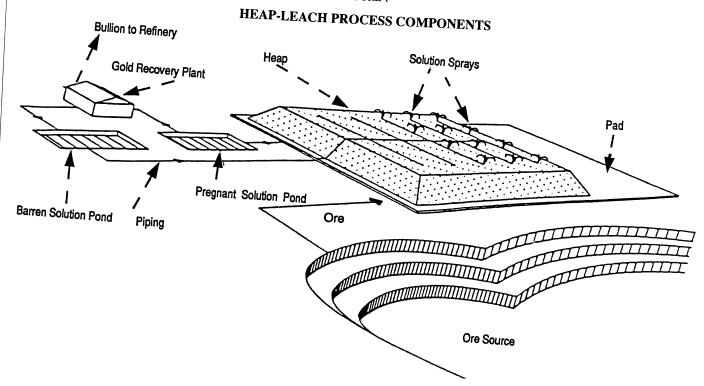

Recycling.—Because of its high intrinsic value, gold has been recycled throughout the ages. Thus, a modern article of jewelry containing recycled gold could conceivably contain atoms of gold from a golden earring worn by Helen of Troy or from a nugget of gold used in the year 4,000 B.C. to barter for ingots of crude copper or other goods at a Mediterranean seaport.

Precious-metals refiners throughout the world recover gold from scrap. In the United States, about 60% to 80% of the scrap comes from current manufacturing operations, and the remainder comes from old scrap in the form of items such as discarded jewelry and dental materials, used plating solutions, junked electronic equipment, etc. Gold is so valuable that even the gloves, aprons, and dust masks worn by gold workers and the dust or "sweeps" from their shops may be processed to yield payable quantities of metal. Similarly, a specialized field of secondary gold recovery focuses on gleaning gold from defunct gold processing operations. Most domestic scrap processors are in the Northeastern States.

The general flow of gold in the secondary industry is shown in figure 3. Refiners receive scrap in a variety of forms and determine processing steps according to batch size, average gold content, and the impurities to be separated. Scrap dealers and semirefiners may process the scrap and then ship the upgraded product elsewhere, including overseas, for further treatment and refining. Scrap is either purchased outright or treated on a toll basis.

A considerable quantity of scrap is generated in manufacturing operations, but

FIGURE 1

because of tight security controls over waste materials in precious-metals plants, nearly all of this new scrap or "home-generated" scrap is recovered. Some old scrap, on the other hand, is lost because in practice gold cannot be economically recovered from all manufactured products; this is increasingly true as miniaturization of gold-bearing electronic products proceeds. The U.S. Department of Defense recovers a significant quantity of gold from military scrap; other Federal Government agencies either participate in the Defense recovery program or have their own.

Economic Factors

On January 31, 1934, following provisions of the Gold Reserve Act of that year, the official price of gold was raised by the U.S. Government from \$20.67 per ounce to \$35 per ounce. The value of \$1 was thus established at 28.57 thousandths of a troy ounce, and gold flowed into the United States. By 1949, gold stocks held by the U.S. Department of the Treasury had risen to a peak of 21,708 metric tons (698 million ounces).

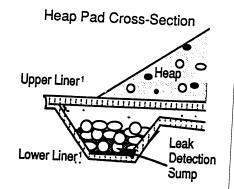

During the 1950's and 1960's, foreign central banks vigorously exchanged their large dollar holdings for U.S. gold. Consequently, U.S. stocks declined, with much of the gold accumulating in stocks owned by foreign governments. When the outflow

of gold was finally stemmed in August 1971 by a Presidential order closing the so-called "gold window" or ending the convertibility of U.S. dollars into gold, U.S. stocks stood at 9,069 metric tons (291.6 million ounces). Thereafter, U.S. stocks declined somewhat, reflecting gold auctioned by the Department of the Treasury in 1975, 1978, and 1979 and later minting of gold coins and medallions for public sale. At yearend 1990, U.S. Treasury stocks stood at 8,146 metric tons (262 million ounces).

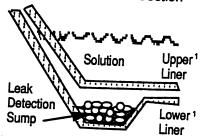

Because of increasingly severe pressures on official gold reserves stemming from attempts by monetary agencies to hold the price of gold down to \$35 per ounce, a seven-nation International Gold Pool established a two-tier price system in March 1968. Under this system, there was an official price of \$35 on monetary transactions, thenceforth restricted to Governmentowned gold, and an open market price for other transactions, which could fluctuate with supply and demand. Since then, the free market has flourished, and the price of gold has risen dramatically, while the monetary sector has evolved to the point where most nations conduct gold transactions and value their gold reserves at market-related prices. The United States is the only remaining holder of large gold reserves to value them at the low official price of \$42.22 per ounce. The U.S. dollar was devalued

¹Liners, High density, polyethylene or polyvinyl chloride 1 mm to 2.5 mm thick (60-100 mils)

FIGURE 3

SECONDARY GOLD CHART

twice in the 1970's, raising the dollar price of gold to \$38 an ounce on May 8, 1972, and then to \$42.22 on October 18, 1973, where it remains today. With the second devaluation, the President was empowered to eliminate regulations on the private ownership of gold, which had been in force since 1934, and these were eventually removed on December 31, 1974. January 2, 1975, was the first day that the general public was allowed to resume holding gold without a licence issued by the U.S.

Treasury's Office of Domestic Gold and Silver Operations; the office was closed on July 31, 1975.

Trading in gold futures began in New York and Chicago upon restitution of the right to private ownership of gold. Trading volume has increased nearly sixteenfold since 1975, peaking at about 43,000 metric tons (1,380 million ounces) in 1982; the volume in subsequent years has ranged from about 25,000 to about 35,000 metric tons. However, only a small percentage of the

gold traded enters the physical market.

Because of gold's monetary role and the fixed \$35-per-ounce price from 1934 to 1968, domestic producers had difficulty maintaining production in the face of rising costs. Gold was particularly attractive as a commercial metal because its price was stable, and a dependable domestic supply was provided to industrial users by the U.S. Treasury until March 17, 1968.

In March 1982, the U.S. Gold Commission, which had earlier convened to con-

sider a renewed role for gold in the U.S. economy, concluded that reintroduction of gold into the current monetary system would probably not serve to alleviate potential economic problems such as inflation. The prospects for a return to a gold standard in other countries would also seem to be uncertain. However, as a so-called "hard currency," gold may come to enjoy a greater role in world economics than it has in the recent past. This is especially important as the world economic system adjusts to accommodate rapidly changing political, economic, and trade practices and to address the many issues associated with the rapid growth in world population, dwindling resources, and slower growth in industrial productivity. Small-scale bartering arrangements involving gold continue as they have for centuries, especially in frontier mining areas such as those in South America, Africa, the western Pacific, and remote areas of North America where raw gold dust and nuggets may be used directly to purchase goods and services.

Prices.—The price of gold is a topic of continuing concern and interest to the producer and the consumer of gold alike; where it has been, where it will go, and the reasons behind its wild fluctuations over the past decade or so have been studied from every angle by numerous observers. Apparent causes for the price changes have been presented and speculation on their future directions have been offered.

Unfortunately, many of these sophisticated econometric models, forecasting the price using combinations of economic, political, and social factors, that proliferated in the early 1980's had all but disappeared from the public domain by the end of the decade. The course of future events cannot, of course, be forecast with accuracy, nor can the price of gold. Forecasting gold's price is unusually complicated because gold occupies a unique position among the world's commodities. Gold is both an internationally traded commodity and, at the same time, a long-established, universally acceptable storehouse of value, considered by many people worldwide to be superior to fiat paper currencies with fleeting longevity or fluctuating, unpredictable value. Unlike many commodity prices that are more or less tied directly to supply and industrial demand, the price of gold cannot be viewed as one would view the price of other goods or services in a free market. Gold also cannot be viewed strictly from the standpoint of the U.S. market alone, for

international, political, and economic events that may impose a positive or negative influence on gold the commodity may be overshadowed by developments perceived to favor gold the medium of exchange. For example, citizens of nations that have been invaded by other countries during the course of their history tend to value the monetary and exchange aspects of gold more highly than countries such as the United States where this has not been the case. To them. gold is money or the preferred substance of wealth, and the ownership of even a small amount of physical metal ensures escape or a new beginning. Therefore, many individuals worldwide, as a matter of tradition or simple prudence, continue to hold small quantities of gold in the form of jewelry, coins, nuggets, etc., legally or illegally, as a portable form of universally accepted capital; for some, especially in developing countries, gold may constitute the only available and relatively risk-free form of old age or disaster insurance.

Although the average price of gold has declined from its record 1980 level of \$612 per ounce, it remains considerably higher than the prices of the early 1970's. This high price level, not generally enjoyed in recent years by many other commodities, continues to spark investor interest and lead to an overall sustained increase in the level of funding available to gold producers to invest in exploration and productive capacity. The heightened interest in gold has, as in the past, promoted exploration of those remote corners of the Earth where exploration for other less valuable minerals could not be justified but where their serendipitous discovery as a byproduct of exploration for gold will ultimately contribute to the needs of society.

In the fabrication of gold, particularly in the electronic and electrical industries, the cost of gold used per unit item is still such a small percentage of the total unit cost that the price of gold is often of small significance in pricing the product. Some industrial consumers of gold, however, confronted with unpredictable and potentially ruinous prices, have turned in recent years to the world futures markets to ensure that their future gold requirements will be available at preselected prices.

Costs.—Costs of mining gold in the United States range upward from costs typical of low-cost placer mining, where dredging or hydraulic operations are conducted profitably on gravels containing less than 0.49 gram per cubic meter (0.01 ounce of gold per cubic yard). Surface lode min-

ing, although considerably more expensive than placer mining, is profitable with some ores containing as little as 0.3 gram or less of gold per metric ton (0.01 ounce per ton), depending on the stripping ratio, size and type of operation. Other important considerations include the characteristics of the ore processed and the mine's location with respect to the duration of the operational season and the infrastructural requirements. At Pegasus Gold's Zortman and Landusky Mine, in Montana, and its Florida Canyon Mine, in Nevada, the minimum or cutoff grade of ore mined during 1990 was 0.25 gram (0.008 ounce). Underground mining for gold is the most expensive mining, but costs vary greatly from mine to mine; nevertheless, some underground mines are able to produce an ounce of gold at costs below those of some surface operations; for example, the average cost to produce an ounce of gold in 1990 at the 2,400-meter-deep (8,000 foot) Homestake Mine in South Dakota, including a small contribution from a new surface pit, was \$311. The cost was distributed as follows: mining and treatment, \$277; administrative and general, \$15; and taxes, \$18.

Costs for processing gold ores can vary widely, depending on the treatment required. Recent advances in heap leaching of gold and extraction with activated carbon may afford lower capital and operating costs than those associated with conventional cyanidation. One recent advance, for example, is particle agglomeration, a technique developed and patented by the U.S. Bureau of Mines to increase the flow rate of leaching solutions through crushed ore. Fine particles of ore that would otherwise impede solution flow by blocking the spaces between coarser fragments are bound together or agglomerated through the addition of a water-soluble binder such as a cement or lime. Other innovative techniques developed in recent years to improve the efficiency of the heap-leaching process include the use of ore conveyors and stackers, solution heaters, and improved solution distribution and recovery and leak detection systems. Other advantages of heap leaching over conventional milling include shorter plant construction time and greater adaptability to lower grade ores. A disadvantage of conventional heap leaching is lowered recovery, usually 60% to 80% of the gold present, compared with 88% to 92% or greater recovered by conventional mill treatment. The recovery efficiency of heap-leaching operations where agglomeration technology is employed approaches

that of conventional methods.

Some producers, by forward selling of their future gold production, are able to maintain economic production even during periods when their production costs may exceed the existing market price of gold.

Taxes.—Taxes may be levied on mining operations for gold and other minerals at the Federal, State, and local levels. In addition to the usual business, occupation, and property taxes and licence fees required of all business enterprises, mining operations in many States are subject to severance or extraction taxes imposed on the yield or proceeds received from the sale of newly mined products. In 1989, the State of Nevada, for example, increased the net profits tax on State mineral production from about 2% to 5%. In 1986, a new Federal tax, the Customs User Fee, was adopted; it places a 0.22% levy on all imports, including gold and gold-bearing products. The fee was reduced to 0.17% on September 30, 1987. During 1990, the enabling legislation was extended to September 30, 1995, and minimum and maximum fees were established.

Most major gold-producing nations impose taxes on domestic mining operations; taxation of the gold mining industry in some countries may be specifically tailored to accommodate a nation's stated economic and political objectives. For example, in the Republic of South Africa, gold mines are taxed in accordance with two basic formulas: one taxes the profits of mines opened before 1966, while the other formula applies to newer mines. Many major goldproducing nations have also provided tax concessions, subsidies, and other assistance to gold mining. The U.S.S.R. has supported gold mining through administrative fiat. China encourages gold prospecting by both the civilian and military population. Australian mining companies have for decades been exempted from paying taxes on profits derived from gold mining. However, effective January 1, 1991, the Government of Australia will eliminate its 6-decade-old tax exemption of income derived from gold production, including byproduct production from those copper operations where gold represents more than 40% of the total income.

Operating Factors

Environmental Requirements.—The costs associated with meeting various Federal, State, and local environmental requirements can vary considerably from one

mine site to another. At mines utilizing cyanide recovery techniques in their milling or heap-leaching plants, special precautions, monitoring and leak detection procedures, and site design features are employed to avoid contamination of the surrounding environment and to reduce the exposure of wildlife to cyanide-laden process streams. For example, at the Mesquite Mine in California, two solution ponds with about 4 hectares (9 acres) of exposed area have been completely covered with plastic to minimize wildlife exposure as well as water loss to evaporation. A variety of processes have been developed in recent years to detoxify or neutralize spent ore prior to disposal or final site reclamation. New regulations pertaining to cyanide use on Federal lands were issued during 1990 (See Legislation and Government Programs). In an emergency, chemical breakdown of cyanide can be induced quickly with chlorine gas.

Because of the danger of mercury pollution, the use of mercury amalgamation in domestic gold operations is now virtually nonexistent. Despite Government efforts to control the use of mercury, the amalgamation process continues to be used in an environmentally detrimental manner in some unregulated frontier mining operations in the Amazon Basin and in the Philippines. Mercury and arsenic can be natural contaminants of gold ores, requiring troublesome or costly extraction processes. Other potential pollutants that may be byproducts from gold mining include antimony, bismuth, tellurium, and thallium. Two iron sulfides, pyrite and pyrrhotite, commonly occur in gold deposits and can be a source of stream pollution as they oxidize to sulfates and other soluble compounds. Pollution resulting from some placer operations may be reduced or eliminated through the use of properly designed settling ponds. Waste dumps, mill tailings, and excavations are increasingly subject to public scrutiny, and environment control costs must be taken into account along with other operating factors. Expanded mine safety requirements in recent years are another important cost factor.

Employment.—According to annual data prepared by the U.S. Department of Labor, employment in the Nation's gold mines and mills, exclusive of office employees, nearly tripled from about 7,000 in 1985 to almost 20,000 in 1990. The number of jobs available in both surface and underground mines and associated processing plants is not al-

ways directly proportional to mine production, reflecting instead variations in development activity, the price of gold, weather, type of mining operation, etc. During 1989, citing employment studies for mining in Nevada and South Dakota, the Economics Institute of Boulder, CO,3 derived an employment multiplier of 19.4 jobs per \$1 million of gold production, giving an estimate for total direct, plus indirect employment attributable to domestic gold production, of about 51,000 persons. A companion study covering the period 1979-904 showed employment multipliers and the industry's contribution to gross State products and State personal income for 11 gold-producing States. The report noted that induced employment from precious-metals production in Nevada, for example, accounted for between 14% and 20% of all new jobs created in Nevada from 1986 to 1989. An average employment multiplier of 20.3 jobs per \$1 million in output was calculated for the 11-State area.

ANNUAL REVIEW

Legislation and Government Programs

On July 16, the President signed legislation, Public Law 101-332, authorizing the minting of 550 million special coins commemorating the 50th anniversary of Mount Rushmore National Memorial in South Dakota. Five hundred thousand \$5 gold coins weighing 8.359 grams (0.268 troy ounce) each and 2.5 million \$1 silver coins weighing 26.73 grams (0.859 troy ounce) each were included in the authorization. One-half of the surcharges on the coins, scheduled to go on sale January 1, 1991, were earmarked for renovation and preservation of the Mount Rushmore facilities.

The director of the U.S. Bureau of Land Management (BLM) announced on August 14 that BLM had revised its existing bonding policies for surface mines and mines using cyanide and other leaching agents on Federal lands administered by the Agency. According to the new bonding policies, mine operators had to post bonds to cover reclamation costs attributed to exploration and mining. The ceiling amounts for the bonds were about \$2,500 per hectare (\$1,000 per acre) for exploration and about \$4,900 per hectare (\$2,000 per acre) for mining operations. Operators having State bonds that met or exceeded the new reclamation requirements were not required to post a Federal bond. Mines using cyanide

or other leaching agents were required to post a bond equal to 100% of BLM's estimate of reclamation costs required by Federal or State regulations. The affected areas included leach heaps, pads or dumps, or

those parts of an operation discharging cyanide-bearing tailings and fluids to impoundments or ponds. Facilities not included were various forms of vat leaching, metal recovery, and refining. The new

policy immediately affected new mining operations. Existing cyanide operations were to comply within 6 months and any other operations by January 1, 1992.

On October 3, the President signed leg-

islation to authorize the minting of new gold, silver, and base metal clad coins to support the training of U.S. athletes participating in the 1992 Olympic Games. The legislation, Public Law 101-406, known as the "1992 Olympic Commemorative Coin Act" called for the minting of up to 500,000 \$5 gold coins weighing 8.359 grams (0.268 troy ounces) each, up to 4 million \$1 silver coins weighing 26.73 grams (0.859 troy ounces) each, and up to 6 million half-dollar clad coins. The coins issued under this act will be legal tender under existing provisions of the United States Code.

Strategic Considerations

Gold is not a National Defense Stockpile item; however, the Treasury had stocks of bullion amounting to about 8,146 metric tons (262 million ounces) at yearend 1990. Large quantities of gold were also held as commercial and private bullion stocks. Therefore, the availability of gold in times of national emergency appears to be ensured.

One strategic aspect of the domestic gold mining industry that is infrequently considered is that the industry constitutes a valuable pool of experienced personnel, including chemists, geologists, engineers, and metallurgists as well as miners, machinists, and heavy equipment operators. In the event of a national emergency, these skills may be readily directed toward the discovery, development, and production of strategic materials.

Issues

An issue of continuing concern to domestic exploration companies, gold producers, and to producers of other minerals as well is that of mineral land availability. Because the geological forces that form mountains and unique physiographic features are often responsible for producing mineral deposits, exploration for gold and other minerals frequently focuses on these areas of disturbance. The same rugged features that make certain areas attractive to the minerals explorer may also make them less accessible for mining because these areas may presently be more valued for their undisturbed or wilderness qualities than for their mineral potential. In recent years, the trend toward preserving increasingly greater areas of unevaluated wilderness land, on which exploration is prohibited or severely restricted, may lead to a decline in new discoveries as well as jeopardize national security.

Another issue of concern to the mining industry as well as law enforcement authorities has been the recent growth in telemarketing fraud and investment swindles involving sales of gold bullion and investment in questionable mining ventures. In late 1988, the North American Securities Administrators Association Inc. (NASAA) and the Council of Better Business Bureaus Inc. issued an Investor Alert entitled "Dirt Pile Gold Swindles." The alert was to educate the public regarding the organization, characteristics, and pitfalls of the classic "dirt pile" or "gold-in-theground" swindle. The NASAA is composed of representatives from the securities regulatory agencies of all 50 States plus Puerto Rico. Law enforcement authorities and various industry trade groups continue to police against other fraudulent practices, such as misrepresented gold quality marks on jewelry and bullion and faked collector coins.

Production

²Less than 1/2 unit

Of the 290 metric tons of gold (9.3 million ounces) produced in the Nation in 1990, 74% was attributable to the 25 leading producers. The average recoverable gold content of precious-metals ores processed

from lode mines was 0.34 gram per metric ton (0.01 ounce per short ton), while placer gravels yielded an average of 0.57 gram per cubic meter (0.01 ounce per cubic yard) of material washed.

The individual company production and performance data in this report were derived from published sources such as company annual reports.

Alaska.—Exploration expenditures in Alaska during 1990, much of which were directed toward gold exploration, rose 19% over expenditures of the previous year, according to a summary of 1990 mineral activity prepared by the Alaska State Division of Geological and Geophysical Surveys (DGGS).⁵ Gold production of about 3,232 kg (103,909 ounces) was reported to the U.S. Bureau of Mines. However, an annual survey conducted informally by the DGGS suggests that a total of 7,206 kg (231,700 ounces), including 5,996 kg (192,800 ounces) of placer gold, was produced; the comparable total for 1989 amounted to 8,850 kg (284,617 ounces). About 216 placer mines and several lode mines operated during the year.

The new Greens Creek lode mine on Admiralty Island near Juneau was the State's largest gold producer during 1990,

These figures, reported to the U.S. Bureau of Mines, probably understate production. Data collected by the State indicate production to have been as follows, in kilograms: 1986—4,977; 1987—7,154; 1988—8,258 (revised); 1989—8,852 (revised); and 1990—7,206.

producing 1,182 kg (38,000 ounces) of gold plus values in lead, silver, and zinc. Production at Citigold Alaska, Inc.'s Ryan Lode Mine, near Fairbanks, declined from that of the previous year. In late 1990, the company solved several processing problems associated with this heap-leaching operation. The Valdez Creek Mining Co.'s placer operation near Cantwell, the State's largest gold producer in 1989, focused efforts during 1990 on diverting Valdez Creek in preparation for resuming full production during 1991. Because of low gold prices and persistent operational losses, WestGold Inc. permanently closed its BIMA dredge in late 1990. The BIMA, the world's largest oceangoing bucketline dredge, had been operating seasonally offshore of Nome since 1986, recovering a total of about 4,200 kg (135,000 ounces) of gold.

As in previous years, a number of Alaskan properties were in various stages of exploration for gold during the year. Basic evaluation and/or drilling was conducted on a number of properties, including the Nixon Fork property near McGrath and at Chicken Mountain and Illinois Creek, both in the State's southwestern region. Also in the southwestern region, Cominco Alaska Inc. announced the discovery of a major copper-gold porphyry deposit near Iliamna. In the southcentral region, the Golden Zone and the Rainbow Hill properties near Cantwell underwent further evaluation.

Several advanced exploration projects under investigation over the past several years progressed toward commercial development. Fairbanks Gold Ltd. and Ventures Trident II continued to explore their Fort Knox property, 24 km (15 miles) northeast of Fairbanks. Progress during the year included the surface recovery and testing of bulk samples. The owners expected to begin a full feasibility study during 1991. Underground exploration work continued at the old Alaska-Juneau or A-J Mine immediately behind the city of Juneau. The owners, Echo Bay Mines Ltd. and W.G.M. Inc., continued to develop the mine's reserves, which increased by 50% during 1990 to about 103 metric tons (3.3 million ounces). Echo Bay also owned an interest in the old Treadwell Mine 1.6 Km (1 mile) west of Juneau and across the Gastineau Channel on Douglas Island. The Treadwell and the A-J Mines were both significant past producers of gold. At Berner's Bay, north of Juneau, Placer Dome U.S. Inc. and several partners continued drilling at their Jualin property, while several miles to the northwest, Echo Bay and

Coeur d'Alene Mines Corp. continued exploration and mine development at their Kensington property, also a former producer. Ore reserves at Kensington were reported to have increased by 40% during 1990 to more than 59 metric tons (1.9 million ounces).

The State legislature ratified new legislation relating to the implementation of rental and net royalty fees from mining claims on all State lands and legislation requiring reclamation on all State, Federal, and private mining lands.

Arizona.—Arizona's largest producer of primary gold, Cyprus Gold Co.'s Copperstone Mine, near Quartzite, in La Paz County, produced at its full capacity of 3,110 kg (100,000 ounces) per year in 1990, or about 43% above capacity on-line during the previous year. The higher production rates during the year were attributed by Cyprus to higher ore grades and improved recovery. According to mine plans in effect at yearend, Copperstone's ore reserves were to be depleted by 1993.

In Yavapai County, Malartic Hygrade U.S. Inc., a subsidiary of Malartic Hygrade Gold Mines (Canada) Ltd., completed construction and startup of its new \$3.4 million carbon-in-pulp mill at the Congress Mine; the first bar of gold was poured on August 14. Prior to Malartic's acquisition of the underground property and construction of the on-site 317-metric-ton-per-day (350short-ton-per-day) mill, the previous owner. Echo Bay, had trucked the ore to a distant copper smelter for use there as a preciousmetals-bearing flux. With the expanded facilities, the company expects to produce gold on-site at a rate of about 995 kg (32,000 ounces) per year.

Although several exploration or development programs were canceled or post-poned, exploration for gold continued to be widespread throughout the State. Bond International Gold Inc. planned a drilling program near Prescott, but regulatory delays and an exploration permit that was too restricted led the company to terminate its interest in the area.

South of Yarnell in Yavapai County, Norgold Resources Inc. and ASARCO Incorporated conducted drilling and trenching on their Yarnell Mine Project. Asarco terminated its interest in the property near yearend. In southeastern Cochise County, Placer Dome U.S. Inc. and Oneida Resources Inc. reportedly drilled 137 holes on their jointly held Mexican Hat property. In Maricopa County, Wounded Bull Re-

sources NL of Australia and Westmont Gold Inc. continued exploration on their Newsboy project near Wickenburg. Startup of the mine was projected for mid-1991.

During the year, the U.S. Bureau of Mines continued to investigate west-central Arizona and adjoining areas in California characterized by gold mineralization associated with extensional detachment faulting; several producing gold mines 80 km to 125 km (50 miles to 80 miles) south in California have been developed in similar structural environments.

California.—Following Nevada in gold production, California was, for the fourth consecutive year, the Nation's second largest gold-producing State. Three California mines, Mesquite, McLaughlin, and Jamestown, were among the Nation's top 25 gold producers in 1990.

Goldfields Mining Corp.'s open pit Mesquite Mine in Imperial County recovered gold by heap leaching of virgin ore supplemented by gold-bearing dump material. To the east of Mesquite at Glamis Gold Corp.'s Picacho Mine, Glamis completed construction of a new leaching site and began mining its Dulcina ore body. Glamis also began mining operations at its Yellow Aster Mine near Randsberg in Kern County, and December marked the first month of production at the company's Alto Mine near Copperopolis in Calaveras County.

Homestake's McLaughlin Mine near Lower Lake, about 113 km (70 miles) north of San Francisco, processed oxide and sulfide ore mined by open pit methods. In May, the company poured its first millionth ounce (31,000 kg) of gold since production began in 1985. McLaughlin is expected to ultimately yield a total of 93 metric tons (3 million ounces) during a mine life of 20 years. Because of lower oxide grades and unscheduled mill downtime, gold production during 1990 declined 6% from the record 8,823 kg (283,843 ounces) produced during the previous year.

Production at Sonora Gold Corp.'s 70%-owned Jamestown Mine in Tuolumne County was, at 3,163 kg (101,700 ounces), reportedly about 9% less than that of the previous year mostly because of lower prices and lower grade ore. Ongoing development of the mine's higher grade areas was expected, resulting in improved performance in the year ahead.

Numerous other California gold mines continued production during the year. Several properties that began or resumed operations included the Plumas underground placer mine in Plumas County, which was reportedly opened in midyear by Siene River Resources Inc. of Vancouver, British Columbia. Royal Gold Inc. of Denver resumed production in November at its Sixteen-to-One Mine in Sierra County. Properties in various stages of exploration, permitting, or construction included the following: Amax Gold Inc.'s Hayden Hill property in Lassen County, Viceroy Resources Corp.'s Castle Mountain project in San Bernardino County, Royal Gold's Long Valley project in Mono County, and Tenneco Minerals Inc.'s Golden Dome property in Sierra County.

In November, voters in two California counties, Tuolumne and Nevada, defeated initiatives aimed at restricting mining operations. The Tuolumne County initiative targeted new mining operations and expansion of existing facilities. It would have required a 1,067-meter (3,500-foot) radius buffer zone around any operation that generates noise, vibration, traffic dust, night-time light or glare, and toxic or potentially harmful runoff from the perimeter of excavations. The ballot initiative in Nevada County would have required a similar radius buffer between a surface mining operation and any "noncompatible" land use.

Colorado.—Gold mine production in Colorado declined for the third consecutive year, again largely reflecting reduced recovery at the Summitville Mine, the State's largest gold mine, and the closure of several other operations.

Gold production at the Summitville Mine of Galactic Resources Ltd. declined from the 1,074 kg (34,545 ounces) produced during 1989 to 864 kg (27,776 ounces) in 1990. Poor recovery rates at the seasonal open pit heap-leaching operation in Rio Grande County were cited as the principal contributing factor. If several potentially good exploration targets developed at Summitville during recent exploration prove to be worthwhile, the company may move to develop them using underground methods.

Ownership of the Sunnyside Mine at Silverton was assumed by a venture group composed of Echo Bay, Alta Gold Corp., and Washington Mining Corp., the operator. Washington Mining also had a joint venture with Gold King Consolidated Inc. on a portion of Gold King's claims adjoining Sunnyside. In the Cripple Creek area of Teller County, Golden Cycle Gold Corp. and Pikes Peak Mining Co., owned by

NERCO Minerals, continued to produce gold from their jointly held heap-leaching operations and also conducted an extensive exploration and development program at holdings around Cripple Creek. Near the town of San Luis in Costilla County, Battle Mountain Gold Co. moved toward an early 1991 startup of its San Luis Mine. The new open pit and milling operation was expected to yield about 1,870 kg (60,000 ounces) of gold per year for at least 8 years.

In early 1990, Royal Gold Inc. ceased production at the historic Camp Bird Mine in Ouray County. First opened in 1896, the Camp Bird has been an intermittent producer of gold and silver as well as copper, lead, and zinc.

Exploration for gold, especially at or around some of Colorado's numerous former gold-producing mines, was conducted by a number of companies.

The second largest gold nugget ever found in Colorado was discovered in 1990. This 249-gram (8-ounce) nugget was found on the alpine slopes of Pennsylvania Mountain, west of Alma in Park County. Named the Turtle Nugget, it is 38 mm wide by 76 mm long (1. 5 by 3 in.). Colorado's largest gold nugget, weighing 373 grams (12 ounces) and measuring 76 by 51 mm (3 by 2 inches), was found at the same site in 1937. Both are on display at the Denver Museum of Natural History.

Idaho.—Exploration for precious metals increased in Idaho during 1990 to its highest level since the 1930's, according to a review of State mining activities prepared by the Idaho Geological Survey.⁶ Exploration for disseminated gold deposits was especially active in the southwest and southeast parts of the State, on both sides of the Snake River Plain. The discovery several years ago of the Beartrack deposit in Lemhi County, the largest discovery in the State's history, continued to draw companies to the area.

The increased exploration activity notwithstanding, gold production declined from that of the previous year, reflecting, in part, the exhaustion of Coeur d'Alene Mines Co.'s Thunder Mountain Mine in Valley County. Despite the closure of Thunder Mountain, there were at least six new gold mines under active development and scheduled to begin production within the next 18 to 24 months. These properties include the Beartrack property, under development by FMC Gold; Pegasus Gold Inc.'s Black Pine property near Bridge in Cassia County, due to start in mid-1991;

NERCO Minerals Co.'s Stone Cabin property in Owyhee County, where construction was due to begin in 1991; and Grouse Creek Mining Corp.'s Grouse Creek Mine, under development near Stanley in Custer County. U.S. Antimony Corp. (USAC) continued development of its planned open pit Yellow Jacket Mine in Lemhi County and final permits for Idaho Gold Corp.'s Buffalo Gulch Project near Elk City in Idaho County were received in September, and production was scheduled to begin in mid-1991. Idaho Gold's nearby Champagne Mine completed its first full year of production in 1990.

Hecla Mining Co. resumed production at its Yellow Pine Unit east of the town of Yellow Pine, in Valley County. The newly reopened and expanded seasonal heapleaching operation produced an estimated 1,796 kg (57,747 ounces) of gold during the year. Also near Yellow Pine, Pioneer Metals Corp. continued seasonal heapleaching at its Stibnite-West End Mine. Several other gold mines as well as mines producing byproduct gold were in operation in Idaho during the year. USAC continued year-round operation at its flotation and vat leach mills at Preacher's Cove in Lemhi County.

During the year, the State Lottery Commission started a new "Scratch" game called Silver and Gold, which offered winnings payable in cash or silver and gold coins minted by the Sunshine Mining Co.'s Hayden Lake refinery. Sunshine Mining is reportedly the only U.S. mining company to mine, refine, and mint gold and silver.

Montana.—Following a trend established more than a decade ago, exploration expenditures in Montana continued to be directed primarily toward gold. According to a review of mining activities prepared by the Montana Bureau of Mines and Geology,⁷ 1990 exploration investments were probably less than those of 1989, with the spending pattern shifting away from large expenditures on a few large projects to smaller expenditures dedicated to a larger number of targets. Exploration activity by both large and small companies was especially prevalent in southwestern Montana. With more than 13 metric tons (418,336 ounces) of gold produced during 1990, Montana maintained its position as the Nation's fourth largest gold-producing

Pegasus Gold operated four gold-producing mines in Montana during 1990: the Zortman-Landusky Mine in Phillips

County; the Beal Mountain Mine at German Gulch southwest of Butte; the Montana Tunnels gold, silver, lead, and zinc mine in Jefferson County; and the Basin Creek Mine in Lewis and Clark County. Collectively, these four properties, all surface operations, yielded 7,635 kg (245,500 ounces) of gold during the year. At the Zortman-Landusky site, Pegasus mined 11.8 million metric tons of ore at an average grade of 0.549 gram per metric ton (0.016 ounce per short ton) of gold plus values in silver. During the year, Pegasus completed construction of a new 54.4-million-metric-ton capacity leach pad on the Landusky side of the operation, and studies were underway during the year to expand the capacity of leaching operations on the Zortman side of the project. At the Beal Mountain Mine, near Anaconda, Pegasus completed its first full year of commercial production in May. In a move to overcome unexpected metallurgical problems encountered earlier at the company's Montana Tunnels Mine, Pegasus, in 1990. revised its mining plan and modified the crushing and flotation circuits at the mill. At the Basin Creek Mine, 29 km (17 miles) southwest of Helena, Pegasus constructed a new leach pad to overcome recovery problems suffered by the previous owners. However, additional difficulties that arose during 1990 forced the company to suspend mining before yearend. Leaching of the ore remaining on the pad was expected to continue through 1991.

In south-central Park County, the new underground Mineral Hill Mine completed its first full year of operation, producing about 1,220 kg (39,200 ounces) of gold. Several operational problems associated with mill design and processing that developed during the year were expected to be overcome in 1991, thereby enabling Mineral Hill to attain its designed output capacity of about 1,300 kg (42,000 ounces) per year. Mineral Hill is jointly owned by Homestake and American Copper and Nickel Co. In Jefferson County, near Whitehall, production at Placer Dome's Golden Sunlight Mine decreased 13% from the 3,469 kg (111,539 ounces) of gold produced in 1989. The company attributed the temporary decline to unexpected lower grade ore encountered while mining toward a higher grade area of the deposit. In September, Canyon Resources Corp. completed construction of a new 8.1-million-metricton leach pad at its Kendall Mine near Lewiston in Fergus County; with the new pad in operation, Canyon expects to nearly double output from the mine to 1,400 kg

(45,000 ounces) by the end of 1991. Production and development work continues at Blue Range Mining Co.'s Geis Mine about 20 km (12 miles) southeast of the Kendall property. Employment at the Geis Mine nearly doubled during the year to 100 workers.

As in past years, many, generally small, intermittent placer operations were active along favorable drainages in western Montana.

Nevada.—Following a pattern established more than a decade ago, Nevada maintained its position as the Nation's principal gold-producing State; if Nevada were a sovereign nation it would be ranked as the world's fifth largest gold producer. Gold production in the Silver State amounted to more than 60% of the national total. Ten of the Nation's leading 25 gold mines in 1990 were in Nevada.

The State's and the Nation's dominant gold-producing company, Newmont Gold Co. (NGC), with operations generally centered around Carlin in northern Eureka County, reported gold production during 1990 of 52,132 kg (1,676,300 ounces). NGC's total cash costs of production, including royalties, general and administrative, and other expenses, amounted to \$218 per ounce in 1990 compared with \$227 per ounce in the previous year. Total costs for the year, including depreciation, ore depletion, and amortization, were \$267 per ounce compared with \$272 in 1989. Newmont's holdings in the Carlin area include nine ore deposits containing about 590 metric tons (18,892,000 ounces) of gold. Production during 1990 was derived from four surface or open pit mines feeding five nearby mills and three heap-leach facilities. In mid-1990, the company began a field test on two heapleach pads to determine the feasibility of using bacteria to oxidize various types of low-grade refractory ores. The company noted that its strategy for the next 3 years will be to maintain production at approximately 47,000 kg (1.5 million ounces) per year from oxide ores while at the same time maintaining test programs and studies aimed at developing optimum methods of mining and treating refractory ores.

At the Goldstrike Mine, adjacent to NGC's Eureka County operations, American Barrick Resources Corp. proceeded with its Betze Development Plan (Betze Project) aimed at increasing gold production at the company's holdings from the 1990 level of about 11,000 kg (353,880 ounces) to about 28,000 kg (900,00 ounces) in 1992. Part of the expansion has been

dedicated to expanding milling capacity, especially capacity designed to accommodate the gold-bearing sulfide ores present in the deeper mineralized zones controlled by the company. American Barrick also holds interests in the Pinson and Preble Mines, near Golconda in Humboldt County.

In the northern part of adjoining Elko County, three separate open pits were mined at Independence Mining Co.'s Jerritt Canyon Mine. The company was also proceeding with development of its nearby Burns Basin deposit, scheduled to begin production in 1991. To the north, in the Humboldt National Forest, the company's Big Springs Mine was designated by the U.S. Forest Service to be the Nation's first hard-rock national mining "showcase" for extracting minerals in an environmentally sound manner. Nearby, Homestake completed mining at its small Wood Gulch Mine. Near Midas in western Elko County, Ivanhoe Gold Co. poured the first bar of production gold at its new Ivanhoe (Hollister) Mine. The new mine is expected to produce about 1,900 kg (60,000 ounces) of gold annually.

The world's largest heap-leach gold mine and Nevada's second largest gold producer, the Round Mountain Mine in Nye County, processed more than 14 million metric tons (15,537,000 short tons) during the year for a total gold yield of 13,431 kg (431,872 ounces), representing a recovery rate of about 75%. Production during 1990 increased by more than 50%, reflecting the successful debugging and fine-tuning of new facilities installed during a major 2year expansion completed in mid-1989. During the year, the company also produced gold from its satellite mining, milling, and leaching operations at nearby Manhattan. NV. Ore reserves at Manhattan were depleted during 1990, and the mill was placed on standby until 1993 pending development of the company's Masada deposit at Round Mountain. The company is owned by Echo Bay Mining (50%), Homestake (25%), and Case Pomeroy Inc. (25%).

Near Gabbs in Nye County, lower gold production at FMC Gold Co.'s Paradise Peak Mine reflected lower gold ore grades partially offset by improved recovery. Early in the year, plans were approved to move ahead with development of the nearby Ketchup Flat deposit. To the west, on the outskirts of Beatty, Bond International Gold Inc. completed its first full year of production in September at its new Bullfrog Mine. Nearby and to the east of Beatty, U.S. Nevada Gold Search Joint Venture also completed its first full year of production at its

Mother Lode Mine. The deposit was reportedly nearing depletion at yearend.

South of Battle Mountain in Lander County, Battle Mountain Gold Co., mining gold ore from three surface mines, Fortitude, Surprise, and Labrador, produced about 8,000 kg (258,000 ounces) of gold in 1990. During the third quarter, the company began operations at its new Copper Basin heap-leaching operation. The Surprise and Labrador pits both provided material for the new facility. Near yearend, owing to poor market conditions, the company suspended operations at its Canyon Placer operation.

Further to the south in Lander County, Echo Bay produced 7,932 kg (255,044 ounces) of gold at it McCoy and Cove Mines. Nineteen ninety was the first full year for operation of new milling facilities installed during a major expansion accomplished during 1988-89. Both mines extract gold and silver ore from surface and underground mining operations. An initial problem with bird kills in 1989, related to the toxicity of the tailings pond, was overcome during 1990 with the addition of an all-new, \$3 million mill effluent treatment facility based on the patented Inco sulfur dioxide-and-air process. Near the McCoy and Cove operations, NERCO Minerals and Alta Gold Co. dedicated the opening of their new Elder Creek Mine. The new surface mine was expected to produce about 1,089 kg (35,000 ounces) of gold in 1990.

In Humboldt County, Santa Fe Pacific Gold Corp., a unit of Santa Fe Pacific Corp., poured the first bar of production gold at its new, wholly owned Rabbit Creek Mine. northeast of Winnemuca. The event marked the successful completion of 18 months of construction costing \$77 million. The company anticipates an annual gold production rate at the new open pit and milling operation of more than 3,100 kg (100,000 ounces). Further west in Humboldt County, Amax Gold Inc. recovered and poured the millionth troy ounce (31,000 kg) of gold at its open pit Sleeper Mine. The first ounce of production gold was poured at the Sleeper Mine in March 1986.

In addition to the gold producers noted above, nearly four dozen other operations contributed to Nevada's overall performance during the year. Several mines were closed because of depletion of known reserves, while several others were placed on standby awaiting improved market conditions or further reserve development. Other properties beginning production during the year included Kennecott Rawhide Mining Co.'s

Denton-Rawhide Mine in Mineral County, USMX Inc.'s Casino Mine in White Pine County, and Gold King Nevada Inc.'s Adelaide Crown Mine in Humboldt County.

In 1990, the Nevada State Environmental Commission approved the State's new mined land reclamation regulations, aimed at returning disturbed lands to productive postmining use. Effective October 1, the new regulations, which apply to both public and private lands, require mining and exploration companies to obtain reclamation permits prior to beginning a mining or exploration project. Existing projects must be permitted before October 1993.

South Carolina.—U.S. Bureau of Mines data on gold production in South Carolina are withheld to avoid disclosing company proprietary data. However, estimates prepared by others⁸ suggested that South Carolina mines produced about 6,842 kg (220,000 ounces) during 1990. South Carolina's principal gold mines were the Ridgeway Mine in Fairfield County, the Brewer Mine in Chesterfield County, and the Haile Mine in Lancaster County.

Gold production during 1990 at South Carolina's largest gold mine, the Ridgeway Mine of Ridgeway Mining Co., amounted to 5,348 kg (171,974 ounces) compared with 5,365 kg (172,505 ounces) produced during 1989. The new open pit mine near the town of Ridgeway employs milling and vat leaching recovery methods. The mine is a joint venture between the RTZ Corp. PLC and Galactic Resources Ltd.

Piedmont Mining Co. reported that gold production at its Haile Mine, near Jefferson, increased 45% over that of 1989 to a record 6,966 kg (22,402 ounces). Production in 1990 came primarily from the mine's Champion Pit. The increased production was attributed to improved ore crushing facilities installed in early 1990 plus improvements made to the heap-leaching and recovery circuits. Mining operations at the Brewer Mine, owned by Westmont Mining Inc., were temporarily suspended in late 1990 following the failure of an earthen dam on the property.

Near the town of McCormick, in McCormick County, Gwalia (USA) Ltd. moved toward an early 1991 startup of mining and heap leaching at its Barite Hill Mine. Barite Hill was developed around several old mines, including the old Dorn Mine, which produced gold during the 1850's and 1930's. Gwalia is a wholly owned subsidiary of Gwalia International Ltd. of Australia.

Exploration for gold in South Carolina was quite active during 1990. Much of the work was focused on prospects in the Camden area of Kershaw County and northeastward along the Carolina Slate Belt. Some drilling reportedly was in progress at the old Leach Mine near Jefferson in Chesterfield County.

South Dakota.—For yet another year, the combined production from South Dakota's five primary gold mines was sufficient to maintain that State's position as the Nation's third largest gold-producing State. All five mines were in Lawrence County in western South Dakota.

The State's principal gold-producing mine, the Homestake Mine at Lead, was the Nation's fourth largest gold mine during 1990. Homestake, with the exception of a brief period during World War II, has been operating continuously and under the same ownership since 1877. Cumulative gold production since its inception has amounted to more than 1,120 metric tons (36 million ounces). During 1990, Homestake's production was 12,077 kg (388,312 ounces) compared with the previous year's 11,874 kg (381,788 ounces). Though primarily a deep underground operation, 21% of the 1990 production originated from the mine's recently reopened surface operation, known as the Open Cut. Mining at the Open Cut was first begun in 1885 on the site of the original gold strike made in 1876 by the two Moses brothers from Portland, OR, and their partner Hank Harvey. The partners reportedly named their claim "Homestake" in the hope that its rewards would be sufficient for them to return home in style, which they were. During 1990, Homestake began work on its new North Homestake Project, an exploration tunneling program to investigate deep gold mineralization discovered about 5 km (3 miles) north of the existing mine workings. The company also initiated work on a new \$8.5 million mill expansion project aimed at providing sufficient milling capacity to handle more Open Cut ore.

Four other gold mines in Lawrence County, all open pit and heap-leaching operations, accounted for the balance of the State's production during the year. The State's second largest gold mine was Wharf Resources (USA) Inc.'s Annie Creek-Foley Ridge property, 5 km (3 miles) west of Lead. During the year, the company completed expansions at two of its four leach pads and expansion of a third pad was nearly completed by yearend. In the recovery plant area,

three of the mine's five collection ponds were also upgraded.

Eight km (5 miles) northwest of Lead, Bond Gold-Richmond Hill Inc. reportedly produced 1,210 kg (38,897 ounces) of gold at its new Richmond Hill Mine, while 8 km (5 miles) southwest of Lead, MinVen Gold Corp.'s new Gilt Edge Mine completed its second full year of operation for a reported yield of 1,030 kg (33,134 ounces) of gold. At the Golden Reward Mine 13 km (8 miles) southwest of Lead, Golden Reward Mining Co. reportedly recovered 924 kg (29,705 ounces) of gold thereby completing its first full year of operation.

Goldstake Explorations (SD) Inc. moved ahead with approvals for its Whitewood Creek Tailings Project in Lawrence, Butte, and Meade Counties. The company plans to reprocess relict gold mine tailings resulting from earlier mining operations.

In February, the Governor of South Dákota approved a 2-year moratorium, valid until January 1, 1992, on new gold and silver surface mines in the Black Hills. The measure bans new large-scale surface gold and silver mining operations in the Black Hills and allows existing mining operations to expand no more than 81 additional hectares (200 acres), and then only if previously mined areas were reclaimed. The moratorium bill was sponsored by the Governor and the South Dakota mining industry. In November, voters in South Dakota defeated an initiative aimed at restricting mining operations. The initiative would have restricted the total amount of land available to gold and silver mines in the Black Hills Region to about 1,255 hectares (3,100 aces). Wording of the measure in itself proved controversial as opponents and proponents argued whether surface facilities of underground mines also would be included. Two previous antimining initiatives presented since 1987 have been rejected by voters. Also during 1990, the State Department of Water and Natural Resources (DWNR) received a grant of about \$95,000 from the Western Governor's Association. The DWNR was to develop a standardized test to better determine the long-term environmental effects of surface disposal of spent gold and silver ore, previously treated with a dilute sodium cyanide solution and then neutralized using hydrogen peroxide.

Utah.—Utah's principal gold as well as silver producer, the Bingham Canyon Mine near Salt Lake City, was the Nation's third largest gold- (and silver-) producing mine in 1990. Bingham Canyon, owned by RTZ and operated by the Kennecott Corp., pro-

duces gold as a byproduct of its copper mining operations. In September, Kennecott completed its first full year of production at its new Barney's Canyon Mine about 6.4 km (4 miles) north of Bingham Canyon. The new open pit and heap-leaching mine reportedly produced 4,292 kg (138,000 ounces) of gold during the calendar year.

Barrick's Mercur Mine in Tooele County achieved a record production of 3,776 kg (122,043 ounces) at a cash production cost of \$238 per ounce during 1990. Factors behind the mine's record performance were excellent autoclave throughput, higher-than-planned ore grade and mill recovery, and the sustained performance of the mine's heap-leaching facilities. During 1990, Barrick expended \$8.2 million on construction of a new leach area and associated recovery plant plus increased capacity at the mine's tailings dam.

In May, Tenneco Minerals Inc. completed its first full year of production at its Goldstrike Mine. The new surface and heapleaching operation is near St. George in Washington County.

Washington.—The Washington State Division of Geology and Earth Resources in its annual review of State mineral industry⁹ activity estimated that gold production during 1990 increased by 40% compared with that of 1989. Much of the increase reflected gold recovered from two newly opened deposits in Ferry County.

Washington State's largest gold producer and the Nation's second largest underground gold mine, the Cannon Mine, at Wenatchee in Chelan County, produced about 4,634 kg (149,000 ounces) of gold during the year compared with 4,678 kg (150,420 ounces) produced during the previous year. Cannon was owned by Asamera Minerals (U.S.) Inc., the operator, and Breakwater Resources Ltd. During 1990 Asamera, in joint venture with Breakwater, continued its surface and subsurface exploration for new gold deposits around Wenachee; several reportedly favorable drill intercepts were made in an area 5.6 kg (3.5 miles) southeast of the mine.

At Republic, in Ferry County, Hecla's Republic Unit, or Knob Hill Mine, milled a record 84,225 metric tons (92,843 short tons) to recover 2,532 kg (81,397 ounces) of gold plus values in silver during 1990. This production represented a nearly 10% increase over that of 1989. Hecla continued development of its new \$6 million decline ramp, begun in 1989 to provide improved ventilation, more exploration

stations, and easier access to the mine's Golden Promise area. Republic's cash production costs for gold in 1990 were about \$130 per ounce.

In February, following 12 months of construction and startup testing at its new 1,361-metric-ton-per-day (1,500-short-tonper-day) carbon-in-leach mill, Echo Bay began producing gold at its Kettle River project near Republic. Production during 1990 was 2,591 kg (83,310 ounces). The Kettle River project, a joint venture between Echo Bay and Crown Resource Corp., has been developed around four gold deposits, Kettle, Overlook, key East, and key West. Most of the mill feed processed during the year was derived from the nearby Overlook deposit; smaller tonnages of ore were trucked to the mill from the Kettle deposit near Curlew, 40 km (25 miles) north. Both Kettle and Overlook are mined underground with access provided by decline ramps rather than shafts.

The State reported that more than 70 companies and individuals conducted exploration for metals during 1990 and that gold was once again the principal target metal. Much of this activity was concentrated in northern Okanogan, Ferry, and Stevens Counties.

Consumption and Uses

The use of gold in the domestic market shown in table 9 accounts for only part of the overall market for commercial products. An important segment of market demand is also satisfied by imported gold-bearing products in various forms ranging from unfinished jewelry products, such as gold chain and findings, to electronic equipment containing gold components.

Contracts for gold futures traded during 1990 on the Nation's futures exchanges represented about 30,260 metric tons (973 million ounces) compared with the previous year when the equivalent of more than 31,000 metric tons (999 million ounces) was traded. The New York-based Commodity Exchange Inc. (COMEX) was, as in the previous year, by far the dominant exchange.

Sales of newly minted gold coins by the U.S. Mint declined for the third consecutive year. On October 20, the fourth anniversary of the American Eagle gold bullion coin program, the U.S. Mint had sold 168 metric tons (5.4 million ounces) of contained gold, all sourced, as mandated in the enabling legislation, from contemporary domestic gold mines.

Although gold loan activity between

commercial depository banks and gold producers generally seemed to have peaked in 1988, it continued to be an acceptable method of financing new mine development or expansion of existing facilities.

In addition to its ages-old usage in jewelry, decorative applications, and dentistry, gold has a number of applications that are important to the functioning of domestic industry, modern high-technology, engineering, and defense systems. It is used extensively in a great variety of solid-state electronic devices, in industrial control and monitoring instruments, and in corrosionresistant chemical process equipment.

Of the strategic and industrial uses of gold, the most important is its use in electronic devices, especially in printed circuit boards, connector, keyboard contracts, miniaturized circuitry, and as a dopant in some semiconductors. Modern solid-state electronic devices such as computers employ very low voltages and currents, and thus require connectors, switch contacts, soldered joints, and certain other components that remain chemically and metallurgically stable for the life of the device.

Increasingly complex civilian, military, and aerospace electronic systems use gold to ensure dependable operations under a wide range of operating conditions. For example, because of its ability to provide reliable electrical connections, gold is used extensively in spacecraft such as the Hubble Space Telescope that must function flawlessly in the harsh environment of outer space. A more down-to-earth example would be the common touchtone telephone that has up to 33 gold contact points; gold plating employed on the contact surfaces of the quick disconnect between the telephone and the line ensures static-free reception.

Gold alloys have long been used in certain electrical instruments, for example, as wipers and windings in slide-wire potentiometers, where long-term reproducibility is essential. Gold-palladium alloy wires are used in thermocouples, especially those used to measure high temperatures encountered in some industrial processes and aircraft engines. Gold-containing brazing alloys such as gold-nickel alloy are important to the aerospace industry, especially in

the assembly of some military jet turbine engines and high-performance rocket engines. Gold is used as a reflector of infrared radiation in radiant heating and drying devices and heat-insulating windows for large buildings. It is used in spacecraft such as the space shuttle, which relies upon gold to seal and protect its vital propulsion system from problems associated with hydrogen embrittlement. Gold-coated mirrors are the principal component of infrared jammers used on numerous military aircraft to confuse the guidance instruments of heat-seeking missiles.

Gold applied as organometallic liquids is used for the decoration of porcelain and glass dinnerware; gold leaf is used for the decoration of buildings, both inside and outside; and gold alloys are used in rupture discs in chemical process equipment and in the perforated "spinnerets" through which cellulose acetate fibers are extruded. Since 1975, a small amount of gold has been used in the United States each year for medallions, small bars, and other similar items having high gold content, purchased primarily as investments.

Revised.

Stocks

Yearend stocks of refined bullion held by industrial users increased about 10% over those held at the end of 1989. On a quarterly basis, the sharpest declines in industrial stocks were reported during the second quarter of the year and may reflect a withdrawal of material by manufacturers to meet anticipated demand, especially for jewelry products destined for sale later in the year.

Yearend stocks of gold certified for deliv-

ery by COMEX, the Nation's largest futures exchange, declined substantially from those held at the end of the previous year.

Markets and Prices

The Engelhard Industries-London daily final price of gold ranged from a high of \$425 per ounce in February to a low of \$347 per ounce in mid-June. Despite the invasion of Kuwait by armed forces from Iraq and an escalation of tension in the Persian Gulf toward yearend, the average for the year amounted to about \$387 per ounce, essentially unchanged from the average of \$383 per ounce registered during the previous year.

Foreign Trade

Total U.S. exports of gold increased substantially in 1990. Switzerland was again the principal recipient nation, receiving large quantities of both refined bullion and doré. In addition to Switzerland, Hong Kong and the United Kingdom were also principal destinations for refined bullion shipments.

Canada continued, as it has for more than a decade, to be the Nation's principal source

Includes old tailings and some nongold-bearing ores not separable, in amounts ranging from 0.15% to 0.25% of the totals for the year listed.

²Includes some placer production to avoid disclosing company proprietary data.

May include small quantities recovered by leaching with thiourea, by boextraction, and by proprietary processes.

²Including autoclaves.

³May include small quantities recovered by gravity methods.

⁴May include tailings and waste ore dumps.

Data are only for those mines that report annually on the U.S. Bureau of Mines voluntary survey; there are many more, usually smaller and less well-established operations, mainly in Alaska, that do not report.

of refined bullion. Imports of gold-bearing waste and scrap from Switzerland and the Dominican Republic were nearly double those of the previous year, while imports of waste and scrap from Taiwan, about 13,200 kg (424,000 ounces) during 1989, all but ceased during 1990.

World Review

World gold mine production has exceeded that of the previous year for 11 consecutive years. Gold Fields Mineral Services Ltd., 10 continuing for the second year the annual statistical survey prepared over the previous 23 years by its predecessor, Consolidated Gold Fields PLC, noted that world demand for gold in the market economy countries (MEC) reached another new record, surpassing the previous record set in 1989.

Gold Fields began its summary by fo-

cusing on the lackluster performance of the gold price, which translated, for both producers and traders alike, into a generally disappointing year. The company noted that even the unsettling political events in the U.S.S.R., and Iraq's invasion of Kuwait in August failed to spark sustained investor interest in gold or translate into higher gold prices. Although the price of gold in terms of U.S. dollars was for the most part unchanged from that of the previous year, the gold price in other currencies was generally lower, especially in terms of deutschemarks and Swiss franks. In real terms, the price in most major currencies fell to the lowest levels seen since at least 1978.

Despite earlier predications by many observers of a decline in karat jewelry fabrication demand during 1990, data on gold usage assembled by Gold Fields indicated that overall demand ended the year showing a significant increase.

The growth in total world mine production increased by only 3%, the lowest rate of increase since 1981. However, strong growth in both the United States and Australia and greater than expected production in the Republic of South Africa combined to offset declines elsewhere.

The centrally planned economy countries continued as in the year past to be major suppliers of gold to the Western World, with net sales to the West amounting to 380 metric tons (12.2 million ounces), including 285 metric tons (9.2 million ounces) attributed to the U.S.S.R.

Unlike 1989, when the world's central banks sold 225 metric tons (7.2 million ounces) into the market, those establishments were neither large sellers nor large purchasers of gold during 1990. Old scrap entering the market during the year totaled about 441 metric tons (13.7 million ounces), an increase of 36% over similar activity during 1989. Gold Fields attributed part of this increase in scrap supplies to the selling back of coins in Japan and distress and precautionary selling from a number of Middle Eastern countries after the start of the crisis in the Persian Gulf.

Overall gold jewelry fabrication demand rose 6% to a new high of 1,986 metric tons (63.8 million ounces) in 1990. In spite of the market problems encountered by a number of computer manufactures in Europe and North America, gold usage in industrial applications, especially electronics, rose 4% over that of the previous year. Dental gold usage rose only marginally. Declining interest in bullion coins during 1990, especially in the Far East, combined

with a steep 66% reduction in Mexican coin fabrication, resulted in an overall 10% decline in the fabrication of official coins.

Total identified gold bar hoarding during the year declined 59% from the 514.6 metric tons (16.5 million ounces) hoarded during 1989. Though the fall-off in the demand for these products was particularly evident in Hong Kong, Japan, and Taiwan, the steepest decline was registered in Brazil, where imposition of the Government's economic reform plan and the subsequent liquidity squeeze precipitated a dramatic increase in dishoarding from the private sector.

Capacity.—Rated annual production capacities for gold mines, as of December 31, 1990, are shown in table 14. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time at a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

A telephone survey of leading domestic producers responsible for 75% of then current output was conducted in late 1989. The survey indicated a capacity utilization rate of better than 97%. Incomplete data on the utilization rate at that time for those mines responsible for the remaining 25% of production suggested that although most are probably operating at a rate comparable to that of the leading producers, some, for a variety of reasons, may be operating at rates low enough to reduce the overall utilization rate to about 96%. This estimated rate probably reflects the level of performance in most of the other industrialized nations.

Because of the size, diversity, and explosive growth of primary gold production over the past decade, comprehensive world capacity data that would include all operating units that contribute to national totals are generally not available. Therefore, in the absence of appropriate data, certain broad assumptions were employed to derive international capacity numbers that are compatible with production data shown in table 15.

Optimum engineering capabilities may be more or less restrained by a combination of factors relating to Government and business attitudes, climate, location, ore grade and hardness, and mineralogy. With these and other considerations in mind, the author derived conversion factors and applied them to annual production data to approximate rated annual capacity for each producing nation.

Production data for individual nations, depending upon their perceived circumstances, was estimated to reflect from 75% of maximum capacity utilization for some essentially nonindustrialized nations to 96% utilization for most industrialized nations.

Reserves.—Demonstrated U.S. reserves of gold are about 4,980 metric tons (about 160 million ounces), and the reserve base is 5,480 metric tons (176 million ounces). Most of the U.S. gold reserve base shown in table 14 is confined to 18 States, with about 80% of the total in Alaska, California, Idaho, Montana, Nevada, and Washington. A dominant portion of the reserve base occurs in lode deposits.

Total world reserves shown in the table approximate 42,200 metric tons (1.4 billion ounces), of which nearly one-half is in the Republic of South Africa. The world reserve base for gold totals about 48,400 metric tons (1.6 billion ounces). Reserves of gold in the U.S.S.R. are believed to be about 6,220 metric tons (200 million ounces).

Estimates of reserves become available only over an extended period of time. The reserves shown for Australia, Brazil, Canada, and the United States generally reflect post-1980 data and the success of exploration efforts frequently initiated years earlier in response to rising prices.

Australia.—Australian gold production, at 242,299 kg (7,789,913 ounces), surpassed for the third consecutive year the production record of 118,180 kg (3.8 million ounces) set in 1903. Production has also increased for 10 consecutive years.

Imposition of a new tax on gold mining profits, scheduled to take affect January 1, 1991, reportedly resulted in a surge in production during the final quarter of the year as mines rushed to maximize their production before the long-established tax exemption on gold mining ended at yearend. For many mines, maximizing production meant increasing ore output and/or high-grading—mining only higher grade portions of the ore body. High-grading was expected to shorten the productive lives of a number of Australian gold mines.

Accounting for more than 70% of Australia's production during 1990, the State of Western Australia was the nation's leading producer. Australia's two largest gold mines, Boddington and Telfer, were

in Western Australia. Boddington, producing an estimated 14,000 kg (450,000 ounces), was also the nation's leading producer. During the year, the Worsley joint venture, managers of the Boddington operation, announced plans to install a new ore treatment plant designed to handle recently encountered mineralization in the main gold ore body found to be enriched with both copper and gold. At the Telfer Mine, near Nullagine, the nation's second largest gold mine, Newmont Australia Ltd. and BHP Gold reportedly moved ahead with plans to expand annual production at the mine to about 11,000 kg (350,000 ounces) by mid-1991. The plan called for the development of an underground mining project in conjunction with the existing open pit.

Near the town of Cue, AMC Gold Ltd. and Placer Pacific Ltd. completed their first

full year of production at the Big Bell open pit mine. The partners were also considering a plan to develop an associated underground operation to begin when the existing near-surface ore has been exhausted. Western Mining Corp. (WMC), Australia's largest gold-producing company, with complete or partial interests in six Western Australian mines, registered substantial production increases at several of its mines in that State. The company's largest mine, the wholly owned Kambalda operation, mining ore from five open pits in the Kambalda-St. Ives area, recovered 6,327 kg (303,447 ounces) during the financial year ending June 30th. The company's four remaining mines in the State had a combined production of 12,547 kg (403,441 ounces). WMC also has gold mining interests in three other Australian States.

At Kalgoorlie, the so-called "Super Pit,"

50% owned by Homestake Gold of Australia Ltd., produced about 10,000 kg (32,000 ounces) of gold during the year. The large open pit represents an amalgamation of several separate gold mines along Kalgoorlie's famous Golden Mile.

New mines beginning production during the year in Western Australia included the Granny Smith Mine near Laverton, owned by Placer Pacific and Delta Gold NL, and the Plutonic Mine, 180 km (112 miles) northeast of Meekathara. Plutonic was owned by Plutonic Resources Ltd. Several other mines were in various stages of development in the State during the year.

In Australia's Northern Territory, the Granites Mine of AMC Gold was the Territory's largest gold mine, reportedly producing a record 8,346 kg (268,343 ounces) in 1990. The first bar of production gold reportedly was poured at Dominion

⁴Data may not add to totals shown because of independent rounding.

Mining Co.'s, White Range Mine, northeast of Alice Springs in the Northern Territory.

Kidston Gold Mining Ltd.'s Kidston Mine in Queensland was that State's largest producer, recovering about 7,362 kg (236,710 ounces) in 1990. The 15% increase in production over that of the previous year represented adoption of a revised mining plan formulated to maximize recovery before imposition of the new tax at yearend. Also in Queensland, Pancontinental Min-

ing Ltd. began base metal and gold production in January at its 50%-held Thalanga Mine. Initial surface production was expected to be replaced later by underground mining.

In New South Wales, CRA Ltd. announced plans in late 1990 to proceed with development of its Peak Mine near Cobar. The new underground operation, scheduled for production in 1992, was expected to produce 3,110 kg (100,000 ounces) of gold per year in addition to values in

copper, lead, and zinc.

Canada.—Canada was the world's fifth largest gold-producing nation during 1990, following Australia.

According to a report prepared by the Canadian Government, 11 proven and probable reserves of gold contained in minable ore deposits declined by about 70 metric tons (2.25 million ounces) compared with revised estimates for the previous year. The report noted that although the decline, to

United States	300	4,980	5,480
Other	380	6,760	7,430
World total ³	2,230	42,200	48,400

^eEstimated. NA Not available.

1,748 metric tons (56.2 million ounces), amounted to only about 4%, it marked the first significant reversal in the strong growth in gold reserves that took place during the 1980's.

Canada's Province of Ontario was again that nation's leading gold producer, followed by the Province of Quebec. In Ontario, the three large mines at Hemlo, the Page-Williams Mine, the Golden Giant Mine, and the David Bell Mine, were that Province's dominant producers with 18,477 kg (594,128 ounces), 13,715 kg (441,000 ounces), and 9,893 kg (318,098 ounces), respectively. All three of these large mines were developed and opened during the mid-1980's. Several mines began or resumed production in Ontario during the year, including the Hoyle Mine at Timmins, the Kerr Mine, and the new Cheminis Mine.

In Quebec, Noranda Inc., Cambior Inc., and Nova-Cogesco Resources Inc. opened the new Silidor Mine in April. The new underground operation 4.8 km (3 miles) north of Rouyn-Noranda was expected to yield about 2,286 kg (73,600 ounces.) of gold during its first full year of operation. Lac Minerals Ltd. began production at its new Bosquet No. 2 Mine at Cadillac. Bosquet was expected to produce about 4,510 kg (145,000 ounces) per year.

Gold exploration and development activity in Canada's third largest Province, British Columbia, remained high during 1990, especially on the Iskut River-Eskay Creek area of northwestern British Colum-

bia. During 1990, Corona Corp. gained controlling interests in the two companies holding the large, high-grade Eskay Creek property 80 km (50 miles) north of Stewart. By yearend, extensive surface and underground exploration was underway, including an access ramp and crosscuts driven into a rich part of the deposit, which forms an extensive continuous ore body known as the mine contact ore lens. Numerous companies explored and held land positions and developing properties in the Iskut River-Eskay Creek area by yearend. The largest gold project announced in Canada during 1990 was Cominco Ltd.'s new Snip goldcopper-silver property in the Iskut River area. Snip was expected to begin production in 1991. Another large project scheduled for startup in 1993 was Placer Dome's Mount Milligan copper-gold property, 161 km (100 miles) north of Prince George.

Production was begun in February at Homestake's 73%-held Golden Bear Mine in northwestern British Columbia. The newly reopened open pit and milling facility was operated by North American Metals Corp. Production during the year was extremely limited owing to startup difficulties. In late 1990, MinVen Gold Corp. closed its Blackdome Mine in Clinton owing to declining ore grades.

In the Northwest Territories, Northwest Gold Corp. poured its first gold bar at the Colomac Mine in May. Recovery and operating difficulties subsequently led the company to write down its investment in the open pit property in November. Exhaustion of reserves led to the closure of two gold producers in the Northwest Territories during the year: the Yellowknife tailings reprocessing project and the Ketza River Mine. In the Province of Saskatchewan, the Jasper Mine of Cameco Inc. and several partners began production in April. Total production during the 2-year life of the mine was expected to be about 2,600 kg (83,590 ounces). The Seabee Mine of Claude Resources Inc. moved closer to startup, planned for 1991.

Ghana.—A new gold mine commenced production during October in Ghana, West Africa's most prolific gold-producing country. At Bogosu, about 30 km (19 miles) north of Tarkwa, Canadian Bogosu Resources Ltd. began production at its 1.1-million-ton-peryear Bogosu gold mine. The new open pit operation was expected to produce about 4,300 kg (138,000 ounces) of gold in its first year, increasing to about 5,200 kg (167,000 ounces) per year in 1992. The company was a joint venture of Canadian-based Sikaman Gold Resources Ltd.; Billiton International Metals B.V., a subsidiary of Royal Dutch Shell: the International Finance Corp.; and the Government of Ghana. Sikaman also announced the startup of production from the Goldenrae placer mine, on the Kwabeng concession near Kibi, about 100 km (62 miles) northwest of Accra, the capital. Sikaman was in joint venture on this property with ITM International S.A. of Luxembourg, the Government of Ghana, and a local Ghanaian cooperative. The mine, which began production on October 15, was expected to produce about 700 kg (22,500 ounces) of gold per year.

India.—In April, India's 28-year-old Gold Control Act was repealed. Repeal of the act, which prohibited individuals from holding raw gold, severely restricting metal imports and limiting goldsmiths' stocks to 100 grams (3.2 ounces), was expected to spur indigenous jewelry fabrication and reduce gold smuggling. The change may, however, severely affect the mining of new gold at India's high-cost mines.

Latin America.—In March, the Government of Brazil began to implement its Collar Plan, which called for the imposition of taxes on gold transactions and sweeping currency reforms. These reforms aimed at reducing inflation by removing two-thirds of Brazil's currency from circulation. This action left Brazil's independent miners or "garimpeiros" at first without

Reserves listed for countries other than Australia, Canada, the Republic of South Africa, and the United States may, in some instances, include inferred reserves.

²The reserve base includes demonstrated resources that are currently economic (reserves), marginally economic (marginal reserves), and some of those that are currently subeconomic (subeconomic resourses).

³Data may not add to totals shown because of independent rounding.

buyers for their product and later with a severely weakened market with low gold prices, combined with escalating fuel and living expenses. Implementation of the Collar Plan as well as ongoing efforts by the Government to evict gold miners from the indigenous Indian reserves in Roraima, near the border with Venezuela, had a severe impact on garimpeiro gold production.

Despite the problems in the informal mining sector, gold production from the regulated or formal sector rose during the year, reflecting the startup of several new mines, expansions at existing mines, and the first full year's contribution of several new mines started during the previous year. New mines beginning production during 1990 included the new Corregio Sitio Mine of Mineração Morro Velho S.A. near Santa Barbara in the State of Minas Gerais. This new open pit mine employs heap-leaching recovery methods. Also in Minas Gerais, Brazil's State-owned Cia. Vale do Rio Doce (CVRD) reportedly began production at two small mines known as Riacho de Machado and Caetes. In September, CVRD began production at its new Maria Prêta Mine in the State of Bahia. The new open pit operation was expected to produce 700 kg (22,500 ounces) of gold per year over the next 6 years. CVRD also operated the Fazenda Brasileiro Mine near Serrinha in Bahia. Fazenda Brasileiro, Brazil's first heapleaching operation, began production in 1985.

Gold production in Chile rose 22% over that of the previous year, reflecting in part the first full year of production at Placer Dome and TVX Gold's La Coipa Mine. Production at the nation's largest gold mine, El Indio, declined somewhat during 1990 to 6,700 kg (215,400 ounces) as did production at Homestake's El Hueso Mine and Anglo American's 56%-held Marte Project, where crushing problems and poor rates of recovery kept the mine from reaching its full potential.

In December, Niugini Mining Ltd. reportedly poured its first doré bars and made its initial bullion shipment from its new wholly owned San Cristobal Mine about 100 km (60 miles) from the Chilean port city of Antofagasta on the South Pacific Ocean. The new heap-leaching operation, high in the Andes Mountains, was expected to yield about 1,900 kg (61,000 ounces) of gold and more than 3,700 kg (120,000 ounces) of silver per year. Niugini Mining, based in Papua New Guinea, was 57% held by Battle Mountain Gold Co. (BMG) of Houston, TX.

Bolivia's largest gold mine, Kori Kolo, owned and operated by Inti Rami, 85%-owned by BMG, increased production from 311 kg (10,000 ounces) in 1989 to 715 kg (23,000 ounces) in 1990. The mine also more than doubled its silver output in 1990 to 4,323 kg (139,000 ounces). In October, BMG announced the discovery of about 128 metric tons (4.1 million ounces) of proven and probable gold reserves beneath the mine's shallow oxide ores. At yearend, six drill rigs were working to define possible extensions of the deposit.

Oceania.—Gold production in Papua New Guinea, although 14% greater than in the previous year, continued to suffer from the absence of byproduct gold from CRA's 53.6%-held Bougainville Copper Mine on Bougainville Island. Bougainville was closed in May 1989 because of violence associated with a secessionist movement's dispute with the Government of Papua New Guinea.

Construction and commissioning of the first stage plant at Placer Pacific Ltd.'s Porgera Mine, in the highlands of Enga Province on the New Guinea mainland, was completed in August, and commercial gold production started on September 1. Production from the first full year of production was expected to be about 26,400 kg (849,000 ounces). Placer holds a 23% interest in the Porgera joint venture. In May. Misima Island Mines Pty. Ltd., (Placer 61%) completed its first full year of production at the Misima Island gold and silver mine in Milne Bay Province. Production for the calendar year at the large open pit operation amounted to 9,864 kg (317,167 ounces). Under the partners' long-term mining plan, 1991 production was scheduled to decline by 40%, and unit production costs were expected to increase somewhat because of the reduced volume of ore processed. Byproduct gold production at the OK Tedi copper-gold mine, at Mount Fulbian in the far west of Enga Province, amounted to 13,808 kg (444,000 ounces) during 1990 compared with 15,985 kg (514,000 ounces) produced during 1989. During the year, OK Tedi Mining Ltd. and the Government of Papua New Guinea reportedly reached an agreement on a longterm environmental management and monitoring program aimed at protecting the quality of the nearby Fly River.

Negotiations between CRA, national and Provincial governments, and local land owners were concluded, and a joint venture, Mount Kare Alluvial Mining Pty. Ltd. (MKAM), was formed to mine the Mount Kare alluvial deposits found in 1988 by CRA. MKAM consisted of CRA in partnership with 5,000 local landowners. The property is in Enga Province about 18 km (12 miles) southwest of the Porgera Mine. CRA also holds interests in the Wafi prospect, in Marobe Province, and the Hidden Valley property near Wau in eastern New Guinea.

Negotiations were begun between the Government of Papua New Guinea and the partners RTZ and Niugini Mining Ltd. regarding the development of the giant Lihir Island gold deposit. A final development plan was expected to be ready by early 1991.

In West Irian, on the western or Indonesian side of the island of New Guinea, Freeport Indonesia Inc. began mining in January at its recently discovered Grasberg deposit. Grasberg, a large copper-gold-silver deposit adjacent to Freeport's existing Ertsberg deposit, was reported by the company to possess the largest published gold reserves of any single operating mine in the world: 208 metric tons (6.7 million ounces). Gold production from the two deposits during 1990 totaled 8,832 kg (284,000 ounces) plus significant values in copper and silver. In the Province of East Kalimantan, development of the Kelian gold project, 68%-held by CRA, moved ahead with more drilling and construction and the approval by the government of the company's feasibility plan. On Wetar Island, about 48 km (33 miles) north of East Timor, Billiton International Metals BV, a subsidiary of the Royal Dutch Shell Group, began production at its Lerokis gold, silver, and barite mine. The new surface mining operation was expected to produce about 1,700 kg (55,000 ounces) of gold, about 25,000 kg (800,000 ounces) of silver, and 100,000 metric tons (110,000 short tons) of barium annually. Exploration for gold in Indonesia was active throughout the year.

New Zealand's second lode gold mine, the Macraes Mine, began production in late 1990. The new open pit operation, wholly owned by Macraes Mining Ltd., was in the Otago region of New Zealand's South Island. Production during the first year of operation was expected to exceed 1,710 kg (55,000 ounces), increasing to about 2,800 kg (90,000 ounces) per year thereafter. On New Zealand's North Island, on the Coromandel Peninsula, Cyprus Minerals continued development of its Golden Cross Project. Open pit and underground mining was expected to begin in mid-1991 and should yield about 3,420 kg (110,000 ounces) of gold per year.

Philippines.—A July 16 earthquake on the island of Luzon in the northern Philippines severely impacted gold production at one open pit mine and four underground mines operated by the Benguet Corp., one of the Philippines' top gold and copper producers. A loss of electrical supply from nearby Baguio City, a result of the disturbance, reportedly resulted in a loss of pumping capacity and subsequent flooding of the underground mines and a substantial decline in monthly gold production. Some production at the open pit was resumed, but, as of early August, flooding had prevented reopening of the underground mines.

Gold mines on Luzon operated by Lepanto Consolidated Mining and Philex Mining Corp. were also affected by the earthquake. Philippine Government investigations during 1990 reportedly estimated that as much as \$1 billion worth of gold mined by the unregulated mining sector are smuggled out of the country each year.

South Africa, Republic of .- The Republic of South Africa, which accounted for about 30% of the world's gold production during 1990, managed, in spite of increasing economic burdens related primarily to the stagnant gold price during 1990, to produce nearly as much gold as it produced during 1989. Despite a nearly 10% increase in the average working costs and a decline in the working profits at the 36 mines that represent the membership of the Chamber of Mines of South Africa, total gold production in 1990, at 602,789 kg (19,379,666 ounces), was less than 1% below that of the previous year. The increase in working costs, which put many mines at a severe disadvantage, led many operations to concentrate on mining higher grade materials, thus reducing cost by mining and processing fewer tons of ore than in the previous year. About 111.2 million metric tons (122.6 million short tons) was milled in 1990 compared with 113.7 million metric tons (125.3 million short tons) in 1989. The emphasis on higher grade ore was also reflected in the average grade processed, which rose from 4.99 grams per metric ton (0.146 ounce per short ton) in 1989 to 5.05 grams per metric ton (0.147 ounce per short ton) in 1990. Production costs for 36 mines during 1990 averaged \$351 per ounce compared with less than \$300 per ounce in the previous year. Production costs for individual mines ranged from a low of \$208 per ounce at the combined Driefontein operations of Gold Fields of South Africa (GFSA) to a high of \$512 per ounce at Johannesburg Consolidated Investment Co. Ltd.'s (JCI) new H.J. Joel Mine, which began production in mid-1988.

The largest South African gold mines in terms of individual output, in metric tons of gold, included Anglo American Corp. of South Africa Ltd.'s (AAC) Freegold Mine with 114.8; Vaal Reefs, also AAC, at 73.4; GFSA's Driefontein Mine with 53.4; AAC's Western Deep levels operations with 38.5; and Anglovaal Ltd.'s Hartebeest-fontein with 30.5.

In addition to the major mining groups or "houses" mentioned above, GFSA, JCI, AAC, and Anglovaal, there were two additional groups, Gencor Ltd. and Rand Mines Ltd.

As an employer of about 400,000 workers, mostly semiskilled or unskilled, the Republic of South Africa's gold mining industry is very labor intensive. According to the Chamber of Mines, labor costs make up about 52% of the total operating costs in South African gold mines. As a consequence of continued high currency inflation, rising labor and material costs, and weak gold prices, each of the six mining groups announced reductions in their labor forces during the year, and more than 30,000 jobs were eliminated at yearend. A number of individual mines or sections of mines faced the risk of closure. After only 15 months of operation, higher than anticipated costs and other negative economic factors forced the late 1990 suspension of operations at Rand Mine's new Barbrook Mine in the Eastern Transvaal.

Exploration expenditures by the major groups as well as individual exploration firms continued to advance during 1990, with some companies focusing their exploration in areas outside the known productive areas of the Witwatersrand Basin. The Chamber of Mines has been at the forefront of research and development aimed at improving mining methods and working conditions, especially with respect to deep underground mines. During the year the Chamber reportedly completed 4 years of research work on a project, known as the Portable Seismic System, developed toward anticipating and controlling potentially fatal rockbursts in deep underground workings. Cost-cutting measures announced by the Chamber near yearend resulted in a reduction in its research and development capabilities and greater emphasis on its commitment to health and safety.

U.S.S.R.—For the first time in nearly 5 decades, estimated Soviet gold production

was surpassed by the performance of U.S. gold mines, thereby placing the U.S.S.R. in third place among the world's gold-producing nations. Some Western analysts attributed the 10% to 12% decline in estimated production in 1990 to the continuing crisis in the U.S.S.R. as well as labor strikes at some of the mining cooperatives or "artels" operated in the far eastern areas of the U.S.S.R.

Svzal, a new Soviet-Alaskan joint venture, was established in February to develop mineral deposits and market combined mining technology in both the U.S.S.R. and North America. The joint venture was formed by Severovostokzoloto, the largest gold mining association in the Soviet Far East, and Bering Straits Trading Co. of Anchorage, AK.

In October the U.S.S.R. reportedly began to mint a 999-fine legal tender commemorative gold coin known as the "Glasnost/Perestroika" or "Peace" coin. It was the first such issue to be made available to buyers outside of the U.S.S.R. since the 1980 Moscow Olympic Coin Program.

Current Research

The U.S. Bureau of Mines maintains nine research centers throughout the Nation, and most conduct research into various aspects of mining, may be directly or indirectly beneficial to the gold mining industry.12 Because gold mining is pursued in many nations, the results of this ongoing work may, like the Bureau's earlier work in heap leaching, ultimately benefit a broad segment of the industry worldwide. In 1990,the Bureau's research relating to gold mining generally focused on the use of cyanide in the recovery process. The Bureau addressed several questions regarding the use of cyanide, including such topics as the mass balance of cyanide in the leaching process, the mobility of metals in the heap during heap leaching, the peristence of cyanide in the environment, and protection of wild-

A joint Bureau-university-industry effort was commissioned to assist in defining future environmental needs relating to gold mining and cyanide use. Six priority areas chosen for research included the following: mine and mill closure, cyanide destruction, seepage, wildlife protections, acid mine drainage, and cyanide alternatives.

Several reports on research relating to gold were issued by the Bureau during 1990.¹³

OUTLOOK

Because gold is an internationally traded commodity serving not only the industrial and jewelry end-use sectors but the investment and central bank sectors as well, the outlook for gold supply, demand, and prices must be viewed from a global viewpoint.

Gold Fields Mineral Services, 14 in its annual review of supply and demand, acknowledges the pitfalls of long-term forecasting by limiting its outlook to the immediate future. Addressing gold supplies, Gold Fields expected that with the growth in exploration and mine production having slowed dramatically, world output is likely to peak in the next year or so. The reduction in exploration also implies that mine production would not be able to respond quickly to any future increase in the gold price. The continuing crisis in the U.S.S.R. is likely to result in further substantial sales from that source in 1991. Gold Fields did not expect that central banks would become heavy sellers of gold in the future, and some buying is probable. On the demand side, assuming continued weakness in consumer spending, Gold Fields expects that fabrication of gold jewelry is likely to show little increase during 1991.

On the domestic scene, if the price of gold remains at levels acceptable to the domestic mining industry, gold production may be expected to grow, but at a slower rate than that of the past several years. The hectic pace of exploration seen in recent years appears to have peaked or at least shifted somewhat toward the base metals or to opportunities elsewhere, such as Mexico or Chile or even the U.S.S.R. Many small mines opened in recent years will probably close as their limited ore reserves are depleted. This loss in production will probably be offset by some new mines and especially expanded production at established larger mines where the focus has shifted toward exploiting their large reserves of gold-bearing sulfide ores. Any growth in production must assume, of course, that a relatively stable and, above all, a predictable regulatory climate will continue to prevail; this applies especially to those regulations dealing with environmental protection and access to public lands.

On the demand side, the near-term outlook for continued strength in the all-important jewelry sector depends on a number of unpredictable factors such as an upturn in discretionary consumer spending, the continuance of acceptable gold prices,

eEstimated. PPreliminary. Revised.

variable fashion trends, and the continued success of industry product advertising to attract new jewelry buyers. The use of gold in electronic applications may experience moderate growth as the demand for sophisticated and more reliable electronic goods expands to match the anticipated growth of the gross national product. Gold has a number of unique characteristics that favor its continued usage in dental applications; its usage in dentistry should probably remain at or near

the present level despite the continued impact of cheaper substitute materials.

¹Ounce refers to troy ounce. One kilogram of gold weighs 32.1507 troy ounces.

¹Table includes data available through June 21, 1991.

²Gold is also produced in Burma, Cuba, Czechoslovakia, the Eastern states of the Federal Republic of Germany, Norway, Senegal,

Thailand, and several other countries. However, available data are insufficient to make reliable output estimates. Poland annually mines and processes copper ore estimated to contain about 31,000 kilograms of gold. Disposition of the gold byproduct is unknown.

³Reported figure.

⁴Only the combined total of gold and silver production is reported. For this table, based on the reported silver content of "about 2%" in 1987, gold content of the reported production figure is estimated to be 97% for 1986 and 98% for 1987-90.

⁵Officially reported figures are as follows, in kilograms: Major mines: 1986—9,348; 1987—13,120;

^{1988—24,012 (}estimated); 1989—24,900 (estimated) and 1990—29,900 (estimated). Small mines (garimpos): 1986—14,776; 1987—22,660; 1988—55,053 (estimated); 1989—56,000 (estimated); and 1990—57,400 (estimated).

⁶Gold purchased by Banco Central from placer deposits and mines; actual production estimated to be at least twice this amount.

⁷Year ending June 30 of year listed.

⁸Does not include undocumented production from small artisanal production.

⁹Revised to zero.

¹⁰Figures include reported mine production of 320 kilograms in 1988; 1,059 kilograms in 1989; and 1,600 kilograms from SAG mine in 1990. Remainder represents approximate reported sales to Government of artisanal production. Figures do not include artisanal production smuggled out of the country.

¹¹Refinery output.

¹²Excludes production from so-called people's mines, estimated at 15,000 kilograms per year during 1986-90, but includes gold recovered as byproduct of copper mining.

¹³ These figures are based on gold taxed for export and include gold entering Liberia undocumented from Guinea and Sierra Leone.

¹⁴Includes production from Kalana Mine and artisanal production. 1990 includes Syama mine production.

¹⁵ Data are based on official exports and do not reflect gold moved through undocumented channels.

¹⁶Year beginning Apr. 1 of year listed.

GRAPHITE

By Harold A. Taylor, Jr.

Mr. Taylor, a physical scientist with 25 years of industry, Federal Government, and U.S. Bureau of Mines experience, has been the commodity specialist for graphite since 1980. Domestic survey data were prepared by William Field, mineral data assistant; and international data tables were prepared by Audrey Wilkes, international data coordinator.

morphous graphite was not mined domestically in 1990. Graphite supplies caught up with industrial demand and then exceeded it to a minor degree. Some prices of the major imported graphite increased from those of 1989, and some were unchanged. Production of manufactured graphite and graphite fibers decreased 7% and increased by 29%, respectively.

DOMESTIC DATA COVERAGE

Domestic production data for synthetic graphite are developed by the U.S. Bureau of Mines from a voluntary survey of domestic producers. Of the 32 operations polled, 100% responded. This represented 100% of the total production data shown in table 5.

BACKGROUND

Definitions, Grades, and Specifications

Graphite, a soft crystalline form of carbon, has been called plumbago and

black lead. It crystallizes in a lamellar hexagonal system, has a gray to black metallic luster, and is greasy to the feel. It is anisotropic in its physical properties and has a weak plane of cleavage parallel to the lamellae.

The term "amorphous" when applied to graphite is a misnomer. The term "microcrystalline" is more descriptive. The definition of amorphous, as applied to graphite, has been further complicated by longstanding industrial application of the term to very fine particles of crystalline flake graphite that can be sold only for lowvalue use such as foundry facings. Fine-grained varieties of lump graphite that are easily reduced to fine particle size by grinding are called amorphous lump to distinguish them from the tough, platy, and acicular varieties, known as crystalline lump, that can be reduced in particle size only with extreme difficulty.

Crystalline flake graphite is well defined in paragraph 214 of the Tariff Act of 1930 as follows:

"The term crystalline flake means graphite, or plumbago, which occurs disseminated as a relatively thin flake throughout its containing rock, decomposed or not, and which may or has been separated there from by ordinary crushing, pulverizing, screening, or mechanical concentration process, such flake being made up of a number of parallel laminae, which may be separated by mechanical means."

Under the foregoing definition, finely divided particles of crystalline flake graphite would be classified as crystalline graphite. The Court of Customs Appeals, however, has held that commercial designations and not scientific terms must govern classification, and when a commercial meaning differs from the technical meaning, the commercial designation must govern. Therefore, quantities of fine crystalline flake graphite are imported under the amorphous classification.

Sri Lankan lump graphite is classified as amorphous or crystalline. Each type is divided into a number of grades, depending on the size (such as lump, ranging from the size of walnuts to that of peas; chip, from that of peas to about that of wheat grains; and dust, finer than 60 mesh), graphitic carbon content, and degree of consolidation.

Amorphous graphite is graded primarily on graphitic carbon content. Commercial ore contains about 75% to 93% carbon, depending on the source.

Crystalline flake graphite from Madagascar is divided into two main grades,

TABLE 1

World: Production	metric tons	624,718	648,156	r 660,168	r 648,827	°660,600

"flake" (coarse flake) and "fines" (fine flake). Madagascan crucible flake must have a minimum of 85% graphitic carbon and be essentially all minus 20-plus 80 mesh in particle size. Other crystalline flake graphite is also graded according to graphitic carbon content and particle size.

Natural graphite is marketed in the form of crystalline graphite as flake, lump, chip, and dust and in the form of amorphous graphite in sizes from fine powder to lumps up to the size of walnuts. It is common practice to blend different graphite to obtain a product having certain desired physical and chemical properties. In many instances, the composition of these blends is retained as a trade secret.

Geology-Resources

The three principal types of natural graphite—lump, amorphous, and crystalline flake—are based on physical characteristics that are the result of major differences in geologic origin and occurrence. A variety of silicate minerals is generally associated with graphite in the ore.

Lump graphite occurs as fissurefilled veins. It is typically massive, ranging in particle size from extremely fine grains (amorphous) to coarse, platy intergrowths of fibrous to acicular aggregates (crystalline). The origin of vein-type graphite deposits is believed to be hydrothermal.

Amorphous graphite is formed by metamorphism of coalbeds by nearby intrusive. Its purity depends on the purity of the original coalbeds. Amorphous graphite usually is associated with sandstones, shales, slates, and limestones.

Flake graphite commonly occurs disseminated in regionally metamorphosed sedimentary rocks, such as gneisses, schists, and marbles. It is believed that the graphite was formed under the same conditions that caused the metamorphism of the rocks—from carbon deposited with the sediments.

Although the flake graphite deposits of certain countries conform to this description, most of the commercial deposits that are exploited are the result of weathering of these metamorphic rocks, with the graphite being found in lateritic clays that have accumulated at the surface. Graphite, quartz, and

other resistant minerals have been freed by weathering of the feldspars, thus lessening the amount of crushing necessary before beneficiation.

World graphite reserves totaled 21.0 million tons. Detailed breakouts are given in the 1988 Minerals Yearbook chapter.

Technology

Mining.—In Sri Lanka, lump graphite is mined underground from narrow, steeply dipping veins. The ore is mined principally by overhand stoping and filling, using temporary stulls when necessary to support the walls. Hand drilling is used in most stoping to achieve selective mining and to avoid unwanted fines and product contamination. Drills are used in developing headings. The ore is hauled by truck to the sorting and classification yard.

Amorphous graphite beds are usually mined underground. However, the beds are much thicker than those of amorphous lump and crystalline lump. The ore is drilled, blasted, hand loaded into cars, and hauled to the surface by conventional methods.

Flake graphite deposits have been mined by underground and surface methods. Underground deposits are usually unweathered and require drilling and blasting. Most surface mining is confined to the weathered part of the deposit, and normal excavating equipment such as power shovels, bulldozers, and rippers is used with a minimum of drilling and blasting. The ore is usually trucked to the mill.

Milling.—Sri Lankan amorphous and crystalline lump graphite is refined by hand cobbing and hand sorting and wiping lumps on wet burlap to remove fines. Light hand sorting and cleaning operations are done by women, while the heavier duties are performed by men.

Most amorphous graphite that requires beneficiation is not worth mining. Preparation for most uses requires grinding only, and coarse impurities are removed by screening or air separation methods.

Flake graphite from disseminated deposits must be concentrated to meet market requirements. Virtually every known concentrating device and combination of separating principles have been tried. The mineral has gained a

reputation of being difficult to concentrate, and probably in no other industry has such a large proportion of the mills failed to make commercial recoveries. Graphite actually is one of the easiest minerals to segregate into a rough concentrate, but one of the most difficult to refine.

Because of the premium placed on the mesh size of flake graphite, the problem in milling is one of grinding to free the graphite without reducing the flake size excessively. This is difficult because, during grinding, the graphite flakes are cut by quartz and other angular gangue minerals, thus reducing flake size rapidly. However, if most of the quartz and other angular minerals are removed, subsequent grinding will usually reduce the size of the remaining gangue, with little further reduction in the size of the flake.

Because graphite floats readily and does not require a collector froth, flotation has become the accepted method for beneficiating disseminated ores. The chief problem lies with depressing the gangue minerals. Relatively pure grains of quartz, mica, and other gangue minerals inadvertently become smeared with the soft, fine graphite, making them floatable and resulting in the necessity for repeated cleaning of the concentrates to attain high-grade products.

Substitutes

Some interchange of the various types and grades of natural graphite and between manufactured and natural graphite takes place, but the degree is difficult to determine. Manufactured graphite does not compete with natural graphite in most uses because of its greater cost. Manufactured graphite is not substitutable for natural flake graphite in clay-bonded graphite crucibles, although some crucibles are machined from manufactured graphite for special uses. Calcined coke and other carbons are satisfactory substitutes for graphite for certain foundry core and mold washes and are used when they can compete in terms of price and supply. Other carbons with high purity can be used in batteries.

Economic Factors

The price structure of graphite is quite complex because of the wide variety of products and the lack of standard market quotations. Prices quoted in trade journals are only a range negotiated between buyer and seller. Quotations are available in Industrial Minerals, Chemical Marketing Reporter, and the U.S. Bureau of Mines Minerals Yearbook. However, average declared import values per ton for amorphous and crystalline graphite have been available for years from the Bureau of the Census data.

The cost for domestically produced graphite from new mines would be much higher than that for graphite from the major foreign sources for the same type and purity. The high cost of production results from high labor costs and the low graphite content of the ore.

Employment and Productivity.— Production and marketable natural graphite requires little hand labor, except for the graphite mined in Sri Lanka. Even in areas of low-cost labor, mechanical methods are used to mine and concentrate flake graphite.

Because of the small size of the domestic natural graphite industry, no publishable employment data are available. Because there is only one small mine and the product is beneficiated and processed to a minimal extent, employment probably does not exceed 50. Much of the imported graphite requires grinding, perhaps further refining, mixing with other grades to meet consumer specifications, bagging, and shipping. The total number of persons engaged in these operations, including marketing, probably does not exceed 500.

Tariffs.—Duties on graphite items imported from most favored nations (MFN) are minimal. Graphite from the U.S.S.R. and certain other nations is subject to a higher duty.

Taxes.—Graphite producers are granted a 22% depletion allowance for tax purposes on domestic lump and amorphous and 14% on domestic flake and on foreign operations.

Operating Factors

Natural graphite is an inert nontoxic substance, and environmental requirements are limited to dust control and certain organic vapors arising from ingredients blended with it to manufacture products.

TABLE 2
U.S. IMPORT DUTIES

Tariff item	HTS No.	Most favored nation (MFN) Jan. 1, 1991	Non-MFN Jan. 1, 1991

Source: General Services Administration, Inventory of Stockpile Materials as of Dec. 31, 1990.

ANNUAL REVIEW

Legislation and Government Programs

No acquisitions or disposal of graphite from the strategic and critical materials stockpile occurred in 1990. New, smaller goals were implemented by notice in the June 26, 1990, Federal Register, as follows: 12,880 metric tons for Madagascar crystalline flake and 1,750 tons for crystalline graphite from other than Madagascar and Sri Lanka.

Production

United Minerals Co. suspended production of its amorphous graphitic material from its Montana mine in 1990. Output of manufactured graphite decreased 7% to about 252,000 tons at 30 plants, with a likelihood of some unreported production for in-house use. Production of all kinds of graphite fiber and cloth increased 29% to 3,774 tons.

Union Carbide Corp. has sold onehalf of its wholly owned graphite and carbon subsidiary to Mitsubishi Corp. of Japan for \$232.5 million. the proceeds were used to retire part of the company's debt. Union Carbides's intention was to strengthen its role as a supplier to the metals industry. According to the firm, graphite-carbon sales totaled \$802 million in 1989. The Mitsubishi sales force will be used to support the graphite and carbon business. This transaction involves four U.S. graphite electrode and product plants.

Consumption and Uses

Reported consumption of natural graphite decreased 8% to about 36,300 tons, according to a survey of more than 230 users. The three major uses of natural graphite were refractories, lubricants, and brakelinings, which together accounted for 67% of reported consumption.

Nonclay refractories represent two important uses categories of graphite. Standard refractory products, particularly gunning and ramming mixes, accounted for a sizable part of the demand in the past 5 years, mainly as amorphous graphite. Crucibles, shrouds, nozzles, stopper heads, and retorts, used in hot-metal processing operations such as the continuous casting of steel, use significant amounts of crystalline flake. Coarse flake graphite is preferred for crucibles and refractory associated items, but generally it is mixed with some fine crystalline material of lower

value. The newest important refractory use for graphite in steelmaking is in carbon magnesite brick, where large amounts of crystalline flake are now used.

Graphite is used in brake and clutch linings. More graphite is being used as the brake and clutch producers change over from asbestos. The graphite lubricates, transfers the heat of friction away from the part, and leads to a lower rate of wear. Graphite is more commonly used in heavier duty nonautomobile lining. Low-quality crystalline

flake and amorphous graphite are suitable for foundry facing use. The graphite is mixed with a small amount of clay, suspended in an adhesive material, and applied as a thin coating to mold surfaces to provide for clean and easy mold release of the metal castings.

Graphite is important as a lubricant and as an ingredient in special packings. When used as a lubricant, it can be a dry powder or mixed with oil or water. It is used with materials that must withstand extreme conditions, such as very high temperatures. Mate-

rial for this use must be free of abrasive-type impurities.

Prices

Natural graphite prices are often negotiated between the buyer and seller and are based on purity and other criteria. Therefore, published price quotations such as those in Industrial Minerals are given as a range of prices. Another source of information for graphite prices is the average customs value per ton of the different imported classes. These mainly represent ship-

ments of unprocessed graphite. A third source for natural graphite prices is the amount paid per ton at the point of consumption.

The price for crystalline graphite at the point of consumption—mostly crystalline flake, some crystalline dust, and a little lump graphite—decreased slightly to \$1,561 per ton from \$1,574 (revised) in 1989. The price for amorphous graphite (including small amounts of amorphous-synthetic graphite mixtures) decreased by 12% to \$684 per ton, from \$780 (revised) in 1989.

Foreign Trade

The United States changed its tariff classification to the Harmonized Code on January 1, 1989. This has made the 1988 and 1990 import and export statistics somewhat noncomparable.

Total exports of natural graphite increased slightly. Exports of graphite electrodes totaled 84,602 tons valued at \$144.3 million, of which 33,235 tons (\$34.5 million) went to Canada, 7,552 tons (\$12.5 million) to Brazil, 5,964 tons (\$15.8 million) to Japan, 3,517 tons (\$7.7 million) to Venezuela, and

the balance to other destinations.

Imports of natural graphite decreased 20% from those of 1989. Imports of natural graphite from Canada and Madagascar rose substantially, while imports from Brazil, the Republic of Korea, and Mexico decreased significantly.

World Review

The current year has begun the sorting out of last year's confusion about whether or not the Chinese were really exporting less and about which Canadian deposits would actually be devel-

Revised. W Withheld to avoid disclosing company proprietary data; included with "Withheld uses."

oped. Demand for graphite in the United States was only slightly changed from that of 1989. Graphite moved into worldwide oversupply about midyear, but not in a major way. Prices were generally little changed. Norwegian production reached a much higher level in 1990. The Brazilian producers shelved plans for a major expansion of output, as did the Mexican companies involved

with crystalline flake. Mexican output of crystalline flake has not reflected even a previous doubling of capacity. The flurry of Canadian activity that continued to be reported seemed less likely to result in many new producers. The count of Canadian producers may level out at three or even fewer. China continues to be the major force in the market; its reported demise in the press

has been much exaggerated. Graphite in small quantities began to appear from Eastern Europe, primarily in Western European markets. The oversupply seems likely to worsen in 1991 as many consumers draw down their inventories. These inventories are frequently huge. Imports of graphite will drop very significantly. The prices of graphite are likely to drop significantly in

¹ Includes mixtures of natural and manufactured graphite.

² Data may not add to totals shown because of independent rounding.

Revision reflects a data correction in the refractories and other use categories.
 Includes bearings and carbon brushes.

⁵ Includes foundry facings.

⁶Includes ammunition, packings, and seed coating.

⁷ Includes paints and polishes, antiknock and other compounds, soldering and/or welding, electrical and electronic products, mechanical products, magnetic tape, small packages, industrial diamonds, and drilling mud.

¹The artificial graphite imports category was reported through 1989. However, the category has been excluded from this table due to substantial delays in obtaining complete data for accurate comparison and reporting in the current period.

Source: Bureau of the Census.

This firm will become the exclusive agent for Stratmin's graphite product in Europe. The graphite will complement its present product line of refractory-related minerals such as and alusite and various clays.

A paper describing the Lac Knife graphite deposit of Societe d'Exploration Miniere Mazaring Inc. in detail was presented at the Ninth Industrial Minerals International Congress and later published in a journal. The paper covers the history, regional geology, geology and mineralogy of the deposit, reserves, proposed mining method, mine planning, ore beneficiation, environmental aspects, and the volume and specifications of the product. Cambior Inc. intended to sign a joint-venture agreement with Mazarin to bring the deposit into production.

Cal Graphite Corp. operated at a very low level after a delayed fall startup. The schedule was delayed by a waste disposal permit problem and by a decision to change the size of some major equipment items.

Global Graphite Group Ltd. has opened a high-purity and exfoliated graphite production facility in Anjou, Province of Quebec. The final capacity of the production line will be about 3,000 tons per year. The high-purity product was expected to contain 99% plus graphite and was to be made by acid leaching from Canadian and Brazilian feedstock. The exfoliated graphite was to be converted into graphite sheet, which can be sold for use in high-performance gaskets and seals. The high-purity product can be used in lubricants, batteries, ceramics, and certain refractories. Almost all of the product will be exported.

China.—According to the Yearbook of Iron and Steel Industry of China, Chinese production of graphite electrodes was 191,100 tons in 1988, 124,300 tons in 1987, and 99,800 tons in 1986. Production was 95,800 tons in 1985, 76,200 tons in 1980, 68,400 tons in 1975, and 32,800 tons in 1970.

Sweden.—The state mining Property Commission ordered the exploration of a crystalline flake graphite deposit at Kringeltjarn Lake, near Edsbyn, about 100 kilometers northwest of Gavle. After some graphite-rich boulders were found, detailed geophysical surveys and trenching began in 1985. Ore reserves

were delineated by extensive diamond drilling. Beneficiation studies and some pilot plant recovery have been done. Proven ore reserves are stated to be 1 million tons averaging 11% C plus 0.6 million tons of finer flake averaging 6% C on the eastern side of the deposit. The beneficiation studies indicated it would be possible to get a 90% recovery of two products, about onehalf the tonnage a fine crystalline flake running 98% C and 40% of the tonnage a medium crystalline flake running 87% C. A joint-venture partner is now being sought to participate in a feasibility study.²

Vietnam.—A review of the current Vietnamese industrial mineral situation in a prominent Western publication comprehensively covered graphite. The size of Vietnamese graphite production is only moderate and comes from two areas. The northernmost and larger is north of Hanoi near Lao Cai and the Chinese border, and the other is 80 kilometers south of Danang. All of the graphite deposits seem to be distributed along the Red River Thrust Belt and found in schist or gneisses. The great majority of the graphite, if not all, is crystalline flake or crystalline dust. The largest and best known ore thickness is up to 35 meters and content ranging from 5% to 12% C. Vietnamese sources estimate that the six main ore bodies may contain a total of 2.5 million tons of graphite.³

OUTLOOK

Projected demand for crystalline flake graphite totaled 23,000 tons for 1995 and 25,000 tons for the year 2000. Demand for other graphite, mostly amorphous, totaled 15,000 tons for 1995 and 13,000 tons for the year 2000. This relatively slow growth rate reflects the maturity of the market, mostly in refractories, and particularly in carbon-magnesite brick. Supply is likely to be abundant as the oversupply worsens.

^eEstimated. ^rRevised. W Withheld to avoid disclosing company proprietary data.

¹ Table includes data available through May 9, 1991.

² In addition to the countries listed, Canada produced graphite during the period covered by this table but output is unreported.

³Does not include the following quantities sold directly without benefication, in metric tons: 1985—16,425; 1986—19,074; 1987—10,505; 1988—18,269 (revised estimated); and 1989—20,000 (estimated).

⁴Data are for fiscal year beginning Apr.1 of that stated.

⁵ Reported figure.

⁶ Indian marketable production is 10% to 20% of mine production.

GYPSUM

By Lawrence L. Davis

Mr. Davis, a physical scientist with 35 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for gypsum since 1985. Domestic survey data were prepared by Virginia Harper, mineral data assistant; and international data tables were prepared by William L. Zajac, Chief, Section of International Data.

emand for gypsum products decreased in 1990, a result of decreased construction activity, especially in new housing starts that decreased 13% to 1.2 million units. Crude gypsum mined, calcined gypsum produced, and shipments of wall-board products were all lower than the record highs set in 1989.

Sales of gypsum products decreased slightly to 26 million short tons, and value decreased 11% to \$1.7 billion. Increased competition caused lower prices for gypsum products. Imports for consumption of crude gypsum decreased 6% to about 8.7 million tons. Total value of gypsum product exports increased 40% to \$84 million.

DOMESTIC DATA COVERAGE

Domestic production data for gypsum are developed by the U.S. Bureau of Mines from a survey of U.S. gypsum operations. Of the 132 operations to which the annual survey request was sent, 100 responded, representing 96% of the total crude gypsum production shown in tables 1 and 2. Nonrespondents were estimated from monthly and quarterly canvasses or from previous years data.

BACKGROUND

Definitions, Grades, and Specifications

Gypsum has a composition of 79% calcium sulfate and 21% water, CaSO₄ • 2H₂O, and is used as a commercial and generic term for all calcium sulfate materials. The well-formed transparent crystalline variety is called selenite. The massive variety is

called alabaster and can be easily carved. The fibrous, silky variety is called satin spar. Gypsite is a mixture of clay and gypsum crystals.

Anhydrite is calcium sulfate, CaSO₄, with no water of crystallization. It is a naturally occurring mineral often associated with gypsum. When gypsum is calcined at high temperatures, it is converted to anhydrite.

Commercially calcined gypsum, CaSO₄ • ½H₂O, is a manufactured hemihydrate product produced by partial calcination of gypsum. It is produced by heating gypsum at temperatures to 350° F. Commonly called plaster of paris, when water is added to form a paste, it quickly sets and hardens to form gypsum again.

Byproduct gypsum is a chemical product of manufacturing processes such as phosphoric acid, hydrofluoric acid, citric acid, and titanium dioxide from ilmenite, consisting essentially of CaSO₄ • 2H₂O. The sludge produced from scrubbers in the desulfurization of stack gas in thermal powerplants is also byproduct gypsum.

Keene's cement is anhydrous gypsum plaster with certain accelerator additives. It is produced by special high-temperature calcining. All of these minerals and materials, including the articles molded from the plaster, are commonly called gypsum or plaster.

Industry Structure

The domestic gypsum industry is large and is dominated by a few large vertically integrated companies that mine and calcine gypsum and manufacture plaster and wallboard products. These companies also sell crude gypsum for use in cement and agriculture. The large wallboard producers, through foreign subsidiaries, produce most of the crude gypsum that is imported to feed coastal wallboard plants.

Plants on the east coast import mostly from Canada's Maritime Provinces, while plants on the west coast import gypsum from Mexico. Crude gypsum from Spain, the other major source of U.S. imports, is used mainly by cement plants.

Gypsum production is worldwide, with at least 80 countries known to produce. Because of its wide distribution and plentiful supply, most of the world's production is consumed domestically. Exceptions include Canada and Mexico, which export significant portions of their production to the United States; Thailand and Australia, which export to much of the Southeast Asia market; Spain, which exports to the United States; Scandinavia; and other countries. In the United States and other industrialized nations, the major use of gypsum is in the manufacture of gypsum wallboard products. Most crude gypsum is mined in rural areas and shipped to urban areas for manufacture into wallboard and ultimate consumption. In developing countries, most gypsum is consumed by local cement plants.

Geology-Resources

Gypsum deposits may be found in any geologic era, but they are most common in the Permian. They are frequently found in association with the source rocks for petroleum. Most massive gypsum and anhydrite deposits occur as large, lenticular, stratified bodies that were formed by evaporation of seawater in basins that have one or more restricted openings to the sea. The basins range in diameter from a few miles to many hundreds of miles.

Classic evaporite formation involves the deposition of anhydrite, with later hydration of the anhydrite by meteoric waters to gypsum at depths ranging from 0 to 1,000 feet. The depth of hydration is generally related to topography, structure,

and climate, because these factors affect the depth of ground water and surface water penetration.

Technology

Gypsum deposits are explored to determine their physical and chemical properties and to determine a minable thickness and the ratio of gypsum to anhydrite. The depth of hydration is important in mining because the presence of only a few percent anhydrite is sufficient to render gypsum unusable for making plaster. Adequate samples may be obtained from outcrops or drill cores.

Deposits near the surface are developed by stripping the overburden, developing either single- or multiple-bench open pits, and constructing access and transportation routes. Underground ore bodies are developed by sinking shafts or diving adits, with mining development and production by the room-and-pillar

Most domestic gypsum is produced from surface mines using standard open pit mining methods. In a typical domestic mine, the gypsum is drilled and blasted as needed, probably every week or two. Broken gypsum rock, loaded with hydraulic shovel or front-end loader, is hauled to the primary crusher by a fleet of three or four 35-ton handtrucks. All material re-

moved from the mines is crude gypsum. All waste is left in the mine.

The processing of crude gypsum depends on the end use. Gypsum for use in cement is crushed to minus 11/2 inch plus 3/2 inch. For agricultural or filler use, the gypsum is pulverized to 100 mesh or finer.

To produce plaster and wallboard products, minus 100-mesh gypsum is heated in batch kettles to remove three-quarters of the water of crystallization, converting gypsum, CaSO₄ • 2H₂O, to the hemihydrate product, CaSO₄ • ½H₂O. A few rotary kilns are also used, in which case a coarse feed with fines removed is calcined. During the commercial calcining process, gypsum is heated to 250°F for about 2 hours, then the temperature rapidly rises to 300° to 350° F, at which time the calcine, called stucco, is dumped into a hot pit. The calcine is then mixed with various additives, including a retarder or accelerator, and manufactured into prefabricated wallboard products and other plaster and cement products.

Plaster is generally reground calcine, modified with retarders or accelerators and containing various binders such as hair, sisal, fiberglass, aggregates, or colored pigments. Retarders, usually glue, starch, or slaughterhouse byproducts, can increase the setting time to as much as 6 hours. Accelerators, such as metal salts, set plaster, or anhydrite, can reduce the setting

time to less than 5 minutes. The plaster is packed in bags and sold under various trade names.

Prefabricated products include lath, veneer base, sheathing, and wallboard. These board products are manufactured by continuous methods on automatic machines that can be adjusted to any of the standard products. A slurry of wet plaster with additives and an accelerator is spread between two moving sheets of paper. Moving through the shaping rolls, the edges are molded and sealed. The green board is run out on a traveling belt until the plaster has set. The board is then cut with a revolving knife into appropriate lengths and slowly passed through a drying kiln.

ANNUAL REVIEW

Production

The United States remained the world's leading producer of gypsum, accounting for 15% of the total world output. Crude gypsum was mined by 29 companies at 58 mines in 20 States. Production decreased 7%. Leading producing States, in descending order, were Iowa, Oklahoma, Michigan, Texas, Nevada, California, and Indiana. These seven States produced more

Each mine, calcining plant, or combination mine and plant is counted as one establishment; includes plants that sold byproduct gypsum.

²Does not include value of plasters sold.

than 1 million tons each and together accounted for 76% of total domestic production.

Leading companies were USG Corp., 11 mines; National Gypsum Co., 7 mines; Georgia-Pacific Corp., 7 mines; Harrison Gypsum Inc., 2 mines; and Temple-Inland Forest Products Corp., 1 mine. These 5 companies, operating 28 mines, produced 69% of the total crude gypsum.

Leading individual mines, in descending order of production, were USG's Plaster City Mine, Imperial County, CA; USG's Sweetwater Mine, Nolan County, TX: USG's Alabaster Mine, Iosco County, MI; USG's Shoals Mine, Martin County, IN; USG's Sperry Mine, Des Moines County, IA; Harrison's Cement Mine. Caddo County, OK; National Gypsum's Tawas Mine, Iosco County, MI: Temple-Inlands's Fletcher Mine, Comanche County, OK; Pacific Coast Building Products Inc.'s (PABCO), Las Vegas Mine, Clark County, NV; and H. M. Holloway Inc.'s Lost Hills Mine, Kern County, CA. These 10 mines accounted for 43% of the national total. Average output for the 58 mines increased 4% to 283,000 tons.

Gypsum was calcined by 13 companies at 71 plants in 28 States, principally for the manufacture of gypsum wallboard and plaster. Calcined output decreased slightly in tonnage and value. Leading States, in descending order, were California, Iowa, Texas, Florida, Nevada, and New York. These 6 States, with 29 plants, accounted for 48% of the national output.

Leading companies were USG, 20 plants; National Gypsum, 18 plants; Georgia-Pacific, 10 plants; Domtar, 8 plants; and Celotex, 4 plants. These 5 companies, operating 60 plants, accounted for 83% of the national output.

Leading individual plants were, in descending order of production, USG's Plaster City plant, Imperial County, CA; USG's Jacksonville plant, Duval County, FL; USG's Sweetwater plant, Nolan County, TX; USG's Sperry plant, Des Moines County, IA; USG's Baltimore plant, Baltimore County, MD; Briar Gypsum Co.'s Briar plant, Howard County, AR; National Gypsum's Tampa plant, Hillsborough County, FL; USG's Shoals plant, Martin County, IN; PABCO's Las Vegas Plant, Clark County, NV; and USG's Stony Point plant, Rockland County, NY. These 10 plants accounted for 29% of the national production. Average calcine production for the 71 U.S. plants was 247,000 tons, a slight decrease.

A total of 735,000 tons of byproduct gypsum, valued at \$3.1 million, was used. principally in agriculture, but some for gypsum wallboard manufacturing. Approximately 69% was of nonphosphogypsum origin compared with 76% in 1989.

According to the Gypsum Association, yearend gypsum wallboard plant capacity for producing 1/2-inch regular wallboard decreased slightly to 24.65 billion square feet per year. Total wallboard shipments were 20.9 billion square feet, \$1\% of capacity.

Improvements to existing plants and construction of new plants continued during the year. At the same time, some plants were closed. Domtar completed construction and began operating its Newington, NH, wallboard plant. The plant uses crude gypsum imported from Domtar's Flat Bay quarry in Newfoundland. Domtar closed, at least temporarily, its Florence wallboard plant in Fremont County, CO.

Eagle Gypsum Products began operation of its new wallboard plant in Eagle County, CO. Highland-American Corp. completed construction of its new gypsum fiberboard plant in East Providence, RI, and was expecting to begin full-scale production in early 1991. Centex American continued construction of its new wallboard plant in Bernalillo, NM. Windsor Gypsum Co.'s board plant at Tatum, TX, was closed during 1990.

Consumption and Uses

Apparent consumption, defined as production plus net imports plus industry stock changes, of crude gypsum, including byproduct gypsum, remained about the same at 26.8 million tons. Net imports provided 32% of the crude gypsum consumed. Apparent consumption of calcined gypsum decreased slightly to 17.5 million tons.

Yearend stocks of crude gypsum at mines and calcining plants were 2.0 million tons. Of this, 44% was at calcining plants

concrete. Finely ground gypsum rock is used in agriculture to neutralize alkaline and saline soils, improve the permeability of argillaceous materials, and provide sulfur and catalytic support for maximum fertilizer utilization and leguminous productivity. Small amounts of very pure gypsum are used as fillers and in glassmaking, papermaking, and pharmaceutical applications. In 1990, 67% of the uncalcined gypsum products was used in portland cement, and the remainder was used mainly for agricultural purposes.

Of the total calcined gypsum products, most went into prefabricated products. A small percentage was used in industrial and building plasters. Of the prefabricated products, based on surface square feet, 62% was regular wallboard; 28% was fireresistant type X wallboard; 3% was ½-inch mobile home board; and 3% was water- and/or moisture-resistant board. Lath, veneer base, sheathing, predecorated, and other types made up the balance. Of the regular wallboard, 85% was ½ inch and 11% was ½ inch.

In descending order, the leading sales regions for prefabricated products were the South Atlantic, Pacific, East North-Central, and Middle Atlantic. Together they accounted for 68% of the total.

Markets and Prices

On an average value-per-ton basis, f.o.b. mine or plant, crude gypsum decreased 17% to \$6.07, calcined gypsum decreased slightly to \$15.87, and byproduct gypsum increased 6% to \$4.27. Prefabricated products were valued at \$84.58 per ton, plasters at \$128.42 per ton, and uncalcined products at \$13.29 per ton.

According to the Department of Commerce, the average producer price of regular ½-inch wallboard was 6% lower in 1990 than in 1989, and type X board was 4% lower.¹

Lower demand and lower prices, especially for gypsum wallboard products, have caused difficult times for much of the industry. Two companies, Celotex and National, filed for bankruptcy protection under chapter 11, and USG, the country's largest producer, was struggling to restructure its debt load.

Foreign Trade

Imports for consumption of crude gypsum decreased 6% to 8.7 million tons and represented 32% of apparent consumption. Crude gypsum from Canada and Mexico was used mainly to feed wallboard plants in coastal cities. Imports from Spain, the other major source of imported gypsum, were used mostly for portland cement manufacture. Gypsum wallboard imports, principally from Canada, decreased 23% to 272 million square feet. The decrease is a reflection of fewer housing starts in the United States.

World Review

Estimated world production of crude gypsum decreased slightly to 108 million tons. Total world production figures are probably low because, in some countries, significant production was consumed

captively and not reported. Also, production from small deposits in developing countries was intermittent and often unreported. The United States remained the world's largest producer of crude gypsum with 15% of the world total.

Canada.—Louisiana-Pacific Panel Products Ltd. completed construction of its new fiber gypsum board plant in Sydney, Nova Scotia. Commercial production was to begin in 1991.

The Gypsum Association in the United States, of which all Canadian wallboard producers were members, reported that yearend capacity of ½-inch regular wallboard in Canada was 3.92 billion square feet, an increase of 5% compared with that of the previous year.

France.—BPB Industries PLC of the United Kingdom acquired the plaster and gypsum operations of Poliet Group. The

²Less than 1/2 unit

Kingdom entered into a joint venture that became Europe's second largest gypsum wallboard producer. LaFarge bought the interests of CSR Ltd. of Australia in a previous joint venture with Redland.⁷

British Gypsum Ltd., subsidiary of BPB

Industries PLC, contracted for the purchase of up to 1 million tons per year of flue gas desulfurization gypsum from the Drax powerplant in Yorkshire. Delivery was expected to begin in 1993 with 200,000 tons and then increase in later years.⁸

Knauf UK signed a long-term contract with Tioxide UK for byproduct gypsum to be produced at Tioxide's Grimsby facility. Knauf will use the gypsum at this Immingham board plant beginning in 1992.9

eEstimated. PPreliminary. Revised.

OUTLOOK

More than 90% of the gypsum consumed annually in the United States is

used in construction, mainly in gypsum wallboard products, building plasters, and in the manufacture of portland cement. With new housing starts decreasing each year since 1986 and an oversupply of

office space, demand for gypsum products is expected to decrease slightly in 1991, then slowly increase for the next several years as the economy improves and construction activity increases.

¹Table includes data available through June 28, 1991.

²Includes approximately 55,000 short tons of plaster a year.

³Includes anhydrite.

⁴Reported figure.

⁵Data are for years beginning Apr. 1 of that stated.

⁶Data are for years ending July 7 of that stated. Reported in cubic meters and estimated at 2.2 short tons per cubic yard.

⁷Data are for years beginning Mar. 21 of that stated.

Less than 1/2 unit.

Excludes byproduct gypsum.

HELIUM

By William D. Leachman

Mr. Leachman, a chemical engineer with 37 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for helium since 1983. He also prepared the domestic survey data and the international data tables.

rade-A helium (99.995% or better) sales volume in the United States by private industry and the U.S. Bureau of Mines was 2,167 million cubic feet (MMcf) in 1990.1 Grade-A helium exports by private producers were 892 MMcf, for total sales of 3,059 MMcf of U.S. helium. The price of Grade-A helium, f.o.b. plant, was about \$37.50 per thousand cubic feet (Mcf) for both the Bureau and private industry. The Bureau price for bulk liquid helium was \$45.00 per Mcf, with additional costs for container services and rent. The liquid helium price for private industry was also about \$45.00 per Mcf, with some producers posting surcharges to this price.

DOMESTIC DATA COVERAGE

Domestic production data for helium are developed by the U.S. Bureau of Mines from records of its own operations as well as the "High Purity Helium Survey," a single, voluntary canvass of private U.S. operations. Of the seven operations to which a survey request was sent, 100% responded, and those data plus data from the Bureau's operations represent 100% of the total helium sales and recovery shown in table 2.

BACKGROUND

The U.S. Bureau of Mines role in helium matters dates back to the First World War when the Army and Navy became interested in using helium as an inert lifting gas and contacted the Bureau for assistance because of its natural gas expertise. In 1925, the Government's Helium Program was officially

placed under Bureau control by Congress (Helium Act of 1925). In 1929, the Bureau's Amarillo, TX, large-scale helium extraction and purification facility was built and began operation. During World War II, demand increased significantly, and four more small Government helium plants were built.

New technology increased helium demand in the 1950's and led to the construction of the Keyes, OK, plant in 1959. Dwindling Hugoton-Panhandle Field natural gas supplies aroused concerns that no economic source of helium would exist by the turn of the century.

In 1960, Congress replaced the 1925 Act with new legislation. The purposes of the act were to provide for conservation of helium for essential Government activities and to promote development of a private helium industry. The act directed the Secretary of the Interior to purchase and store helium for future Government use and to operate and maintain helium production and purification plants and related helium storage, transmission, and shipping facilities.

Purchases for the conservation program were made under 22-year contracts with private natural gas companies, which added crude helium extraction capabilities to their existing gas processing facilities. Four companies built five crude helium plants. The Bureau constructed a high-pressure pipeline to transport the helium from Bushton, KS, and intermediate points to the Bureau-owned Cliffside Field for storage.

Helium needs of the Federal agencies, particularly the U.S. Department of Defense, the National Aeronautics and Space Administration (NASA), and the U.S. Department of Energy (DOE), have been met, and there is enough helium in storage to meet their foreseeable needs for up to 100 years,

depending on how much helium will be needed by future Government programs. The entire Federal helium demand is now supplied by the Exell Helium Plant.

In the mid-1970's, the Bureau began accepting privately owned crude helium for storage in Cliffside under long-term contracts. Private industry currently has about a 6-month supply of helium in Government storage, assuming all private market requirements would come from storage.

Geology-Resources

Domestic measured and indicated helium resources as of January 1, 1990, the latest figures available, are estimated to be 541 billion cubic feet (Bcf). The total identified helium resources are about 6 Bcf more than reported in 1989. The increase is attributed to the reevaluation of the helium reserves of several fields in Texas. The resources include measured reserves and indicated resources estimated at 256 and 32 Bcf, respectively, in natural gas with a minimum helium content of 0.3%. The measured reserves included 35 Bcf stored by the Bureau in the helium conservation storage system. Measured helium resources in natural gas with a helium content of less than 0.3% are estimated to be 40 Bcf. Indicated helium resources in natural gas with a helium content of less than 0.3% are estimated to be 213 Bcf. Approximately 165 Bcf or 92% of the domestic helium resources under Federal ownership are in the Riley Ridge area and the Church Buttes Field in Wyoming and in the Cliffside Field in Texas.

Most of the domestic helium resources are in the midcontinent and Rocky Mountain regions of the United States. The measured helium reserves are in approximately 95 gasfields in 11 States. About 83% of these reserves is

contained in the Hugoton Field in Kansas, Oklahoma, and Texas; the Keyes Field in Oklahoma; the Panhandle and Cliffside Fields in Texas; and the Riley Ridge area in Wyoming. The U.S. Bureau of Mines analyzed a total of 184 natural gas samples from 21 States during 1990 in conjunction with its program to survey and identify possible new sources of helium.

Technology

Technology that uses liquid helium to produce superconducting temperatures continues to be developed and operated. Liquid helium continues to be used at Fermi National Accelerator Laboratory for Tevatron/Tevatron 1, which was the world's first superconducting particle accelerator. The liquid helium-cooled superconducting magnets used in this accelerator provide an intense and extremely steady magnetic field using only a fraction of the energy required by conventional electromagnets. The Tevatron is presently the highest-energy particle accelerator in the world (1.6 trillion electron volts). In addition, the DOE has already selected the magnets it proposes to use in the Superconducting Supercollider (SSC). The SSC magnets will be similar to those used at Fermi, which are liquid helium-cooled, because they have been proved and tested in operation. When completed, the SSC will have about 20 times the power of the Tevatron (40 trillion electron volts). The proposed Texas site for the SSC was selected by DOE in January 1989.

Argonne National Laboratory is developing a magnetohydrodynamic (MHD) propulsion system for military and commercial use. The MHD propulsion system has no moving parts, but uses magnetic fields and electricity to pump water through a tube. Researchers at Argonne will use the world's largest helium-cooled superconducting dipole magnet to study the propulsion system. Development of this technology could lead to a new generation of water transportation vessels that would travel more quickly, quietly, and efficiently than present ships.

Testing of the six liquid helium-cooled electromagnets supplied for the Large Coil Task was completed at Oak Ridge National Laboratory last year. These six magnets each incorporated slightly different designs, which were

tested to determine the best configuration for the confinement of fusion systems in the production of "clean" nuclear energy. Although these magnets are the largest ever tested (8 tesla, or 160,000 times as strong as the magnetic field of the Earth), they are only one-third to one-half the size of those needed for proposed fusion reactors. Successful operation of these magnets gives researchers more confidence in the use of superconducting magnets for fusion containment.

Liquid helium use in magnetic resonance imaging (MRI) continues to increase as the medical profession accepts and develops new uses for this equipment. MRI equipment is providing accurate diagnosis of medical problems where exploratory surgery was required previously. Another medical application being developed uses MRI to determine by blood analysis if a patient has any form of cancer. Most researchers seem to think it will be at least 5 to 10 years before the new hightemperature (about -300 °F) superconducting materials affect liquid helium demand.

Lifting gas applications are increasing. The U.S. Navy and U.S. Air Force are investigating the use of airships to provide early warning systems to detect low-flying cruise missiles. The Drug Enforcement Administration has installed six tethered radar blimps along the southern border of the United States to detect drug smugglers. In addition, NASA is now using heliumfilled balloons to sample the atmosphere in Antarctica to determine what is depleting the ozone layer that protects the Earth from harmful ultraviolet radiation. Similar work is also underway in the Arctic. A stealth blimp is being tested by the Army's Intelligence and Electronic Warfare Center in New Jersey. In the commercial market, many companies besides Goodyear are now using "blimps" for advertising.

Helium is being used to develop several Strategic Defense Initiative (SDI) applications such as the antisatellite (ASAT) rocket, chemical laser, and rail gun. The ASAT rocket uses liquid helium-cooled infrared sensors for target location and guidance. Gaseous helium is used in the lasing gas mixture of the chemical laser, and liquid helium is used to cool the tracking telescope. This telescope is used to locate the target and aim the laser

beam. High-pressure gaseous helium provides the initial push that inserts the projectile into the bore of the rail gun at a velocity of about 1,100 miles per hour. Electromagnetic energy applied along the bore accelerates the projectile to a final velocity of about 9,000 miles per hour.

Superconducting magnetic energy storage (SMES) is also being investigated to provide power for Defense laser systems. SMES allows the accumulation and storage of electrical energy over the long term (hours) and discharges it in minutes.

Other evolving technologies that require the unique properties of helium are (1) metastable helium for energy storage, which involves raising helium electrons to an excited energy state and then stabilizing the atom there; (2) fiber-optic production, where an ultrapure atmosphere is required; (3) helium-filled plastic pillows, where low density is required to simulate a precursor wave from a nuclear blast; (4) helium ion tumor treatment, where large inert particles are required; (5) liquid helium-cooled superconducting microswitches, called Josephson junctions, which are much faster than conventional semiconductors and use less power; (6) "Aneutronic" nuclear fusion where nuclear energy is produced by fusion of deuterium and helium-3, which produces few or no neutrons; and (7) new helium-hydrogen breathing mixtures that enable deep-sea divers to reach depths below 1,700 feet.

ANNUAL REVIEW

Legislation and Government Programs

The Government's program for storage of private crude helium in the Government's helium storage facilities at the Cliffside Field near Amarillo, TX, was vital in supplying helium for the private helium market. Excess helium production of private industry obtained from natural gas supplying fuel markets in the winter is stored by the Government under contract. This privately owned crude helium is returned to the owners for purification as needed to provide for private industry demand. Privatization of all the Government's helium program, except the conservation storage operation, is under consideration.

Production

In 1990, 12 privately owned domestic helium plants were operated by 10 companies. Eight of the privately owned plants and the U.S. Bureau of Mines plant extracted helium from natural gas. Both private and Bureau plants use cryogenic extraction processes. The volume of helium recovered from natural gas decreased 3%, while sales increased about 6% in 1990. A shortage of private helium production was prevented by purifying crude helium that had been stored in the Government's Cliffside Field. All natural gas processed for helium recovery came from gasfields in Colorado, Kansas, New Mexico, Oklahoma, Texas, and Wyoming. Seven private plants and the Bureau's plant purified helium this year. Pressure-swing adsorption is used for helium purification at five of the private helium plants and at the Bureau's plant. Cryogenic purification is used by the other producers and provides backup at the Bureau's plant. The Bureau and six private plants that produce Grade-A helium also liquefy helium. The plant operators and locations are Air Products and Chemicals Inc., Hansford County, TX; Navajo Refined Helium Co., Shiprock, NM; Kansas Refined Helium Co., Otis, KS; Exxon Co., U.S.A., Shute Creek, WY; and Union Carbide Corp., Linde Div., Bushton and Ulysses, KS. Nitrotec's new helium plant near Burlington, CO, produces Grade-A helium but does not liquefy helium. Linde's helium plant at Elkhart, KS, was shut down in 1988.

Consumption and Uses

The major domestic end uses of helium were cryogenics, welding, and pressurizing and purging. Minor uses included synthetic breathing mixtures, chromatography, leak detection, lifting gas, heat transfer, and controlled atmospheres. The Pacific and Gulf Coast States were the principal areas of helium consumption.

Bureau sales to Federal agencies and their contractors totaled 403 MMcf in 1990, an increase of about 15% when compared with last year's sales. This increase was due largely to NASA's resumption of space shuttle flights, which include associated projects that use large volumes of helium. Sales to DOE continue to decline.

The Federal agencies purchase their major helium requirements from the

¹Source: Bureau of the Census.

U.S. Bureau of Mines. Direct helium purchases by the Department of Defense, NASA, DOE, and the National Weather Service constituted most of the Bureau's Grade-A helium sales. All remaining helium sales to Federal agencies were made through Bureau contract distributors, who purchased equivalent volumes of Bureau helium under contracts described in the Code of Federal Regulations (30 CFR 602). Some of the contract distributors also have General Services Administration helium supply contracts. These contracts make relatively small volumes of helium readily available to Federal installations at lower freight charges by using the contractors' existing distribution systems.

Stocks

The volume of helium stored for future use in the U.S. Bureau of Mines helium conservation storage system, which includes the conservation pipeline network and the Cliffside Field near Amarillo, TX, totaled 34.4 Bcf at yearend. The conservation storage system contains crude helium purchased by the Bureau under contract, Bureau helium extracted in excess of sales, and privately owned helium stored under contract. During 1990, 507 MMcf of private helium was delivered to the Bureau's helium conservation storage system and 773 MMcf was withdrawn for a net decrease of 266 MMcf of private helium in storage.

Transportation

All Grade-A gaseous helium sold by the Bureau was shipped in cylinders, modules (large gas cylinders), special railway tankcars, or highway tube semi-

ESTIMATED HELIUM CONSUMPTION, BY END USE, IN THE UNITED STATES IN 1990

Estimated total helium used (2,167 million cubic feet)

trailers. Small gas cylinders are filled at the Amarillo plant, and railway tankcars are filled at the Exell plant. Other shipping containers for gaseous helium may be filled at either plant. Bureau liquid helium was shipped in dewars and semitrailers from the Exell plant. Private producers and/or distributors shipped helium primarily as a liquid in semitrailers. These semitrailers delivered the liquid helium to distribution centers where some of it was gasified and compressed into trailers and small cylinders for delivery to the end user. The remaining liquid helium was sold as bulk liquid or repackaged in dewars of various sizes for delivery.

Prices

The U.S. Bureau of Mines price, f.o.b. plant, for Grade-A helium has been maintained at \$37.50 per Mcf since October 1, 1982, when it was raised from the \$35.00 per Mcf price established in 1961. The price for Grade-A helium from private producers is also about \$37.50 per Mcf. The Bureau trailer-load liquid helium price was \$45 per Mcf during all of 1990, with additional charges for container services and rent. The typical private industry price for liquid helium was also \$45 per Mcf gaseous equivalent plus surcharges. The Bureau has submitted a report to Congress on options for the routine adjustment of helium prices.

Foreign Trade

Exports of Grade-A helium, all by private industry, increased by 12% in 1990 to 892 MMcf (table 3). About 52% of the exported helium was shipped to Europe. Belgium-Luxembourg, France, and the United Kingdom, collectively, received about 88% of the European helium imports. About 33% of the U.S. helium exports went to Asia, with Japan taking about 87% of this helium. Other exports were as follows: more than 7% to North America; about 2% each to Australia-New Zealand, Middle East, and South America; and less than 1% each to Africa, the Caribbean, and Central America. The shipments of large volumes of helium to Western Europe were attributed to helium use in cryogenic research and superconducting equipment. Significant volumes were also being used in breathing mixtures for diving, welding, and as a lifting gas. Although no helium was imported in

1990, import tariffs on helium remained at the 3.7% rate established on January 1, 1987. No further decreases in import tariffs are scheduled.

World Review

World production of helium, excluding the United States, was estimated to be 300 MMcf, most of which was extracted in Poland and the U.S.S.R. The remainder was produced in small plants in China and India.

OUTLOOK

Until recently, all superconductors required liquid helium (-452 °F) to reach superconducting temperatures. Current research on superconductors has resulted in the discovery of superconducting materials that operate above liquid nitrogen temperatures (-320 °F). These new superconductors have physical limitations, such as brittleness and poor current-carrying capacities, which have precluded their use in most superconducting applications. If these problems are solved, the new materials could replace liquid helium-cooled superconductors.

Since 1986, the market for U.S. pro-

TABLE 5

WORLD GRADE-A HELIUM PRODUCTION CAPACITY, DECEMBER 31, 1990

	Capacity
United States	13,400
Rest of world ^e	300
Total ^e	3,700

^e Estimated.

duced helium has grown at an average annual rate of 12%. Private industry's market has been growing at 13.4% per year, while the Federal market has grown at 4.9%. The Federal market has reached its highest volume in more than 20 years. At the present time, private industry is supplying about 87% of the demand for U.S. produced helium, while the Bureau is supplying the remaining 13%. Private industry supplies all of the U.S. helium exports. The foreign market made up about 26% of U.S. helium sales in 1990 and has grown at an average rate of approximately 20% per year since 1986.

At the present time, the outlook for

helium looks good, with growth continuing in new technologies that use helium. The adverse impact of high-temperature superconductors, if any, is not expected for several years.

INDIUM

By Stephen M. Jasinski

Mr. Jasinski, a physical scientist with 4 years of U.S. Bureau of Mines experience, has been the commodity specialist for indium since 1988. Domestic survey data were prepared by Eraina Dixon, mineral data assistant.

omestic indium production was derived from the upgrading of crude indium metal and residues generated in the refining of zinc and other base metals. Two companies accounted for all refined indium produced in the United States. Domestic production data for 1990 were unavailable. Falconbridge Ltd. began production of indium at its Kidd Creek Mine in Ontario, Canada. The indium was to be sold through Indium Corp. of America, as part of a joint-venture agreement. The main uses of indium were for solder, alloys, coatings, plating, and semiconductor compounds. Domestic consumption grew slightly owing to increased usage in coatings.

DOMESTIC DATA COVERAGE

The two refiners of indium in 1990 chose not to respond to the voluntary survey of indium produced from primary sources. Domestic consumption estimates were based on discussions with the major refiners and consumers and analysis of trade data.

BACKGROUND

Definitions, Grades, and Specifications

Indium is silvery-white in color and has a brilliant metallic luster. It is softer than lead, very ductile and malleable, and has a very low melting point; therefore, it is well suited for use in solders and low-melting alloys. It retains these plastic-like properties to temperatures near absolute zero. Indium can endure considerable deformation through compression and cold-welds easily.

Some physical constants of pure

indium are chemical symbol In; atomic number, 49; atomic weight, 114.82; melting point, 156.61° C; boiling point, 2,080° C; and density, 7.31 grams per cubic centimeter at 20° C. Standard grade is 99.97% purity, and high grades are available from 99.99% (4N) to 99.99999% (7N) purity.

Industry Structure

Arconium Specialty Alloys, Providence, RI, and Indium Corp., Utica, NY, the only refiners of indium in the United States, produce indium primarily from imported zinc residues, low-grade indium bullion, and indium scrap. Arconium, Indium Corp., and Johnson Matthey Electronics, Spokane, WA, produce high-purity indium shapes, ingots, and foil. Metalspecialties Inc., Fairfield, CT, intermittently recovers indium from old scrap. New scrap is usually returned to the supplier for reprocessing.

In 1990, Arconium was acquired by Alpha Metals Inc. of New Jersey, a producer of solder and plating materials for electronic uses. Both companies are part of Cookson Group PLC of the United Kingdom. The move was made primarily to consolidate the Cookson sales and distribution departments; little change was expected in the operations at either company.

Because indium is primarily recovered from residues, slags, flue dusts, and intermediate compounds resulting from zinc smelting, world mine production is inferred from the average indium content of zinc ore mined. Canada is the largest producer of zinc in the world; therefore, its mine production is believed to contain the largest quantity of indium.

Historically, most of the world's refining capacity has been in Europe. However, recently, most capacity has increased in Asia and North America because new refineries have opened in Canada and Japan in the past several years.

Geology-Resources

Indium occurs predominantly in solid solution in sphalerite, an ore of zinc, but it has been reported in ores of copper, lead, and tin. It does not occur in the native state. The average indium content of the Earth's crust is estimated at 0.1 part per million, about the same as that of silver. The indium content of mined zinc deposits ranges from 0 to 100 parts per million. The highest known indium concentrations are in vein, replacement, and contact metasomatic sulfide deposits, especially those containing tin minerals. The indium contents of these deposits typically range from 100 to 21,000 parts per million. Deposits of this type include those in the Central City district in Colorado, the Argentine Andes, the Cornwall tin district in England, and the Mount Pleasant tin deposit in New Brunswick, Canada.

Because indium is usually recovered as a byproduct of zinc, world indium reserves are based on weighted estimates of the average indium contents of regional zinc ores.

Technology

A variety of methods are employed to recover indium, depending on the source material and indium content. Indium is primarily recovered as a byproduct of zinc processing. Among the more common methods of recovery are leaching the indium-containing material with sulfuric or hydrochloric acid and extracting the crude indium from solution by cementation on aluminum or zinc sheets. Solvent extraction with organic solutions is used to recover indium from dilute solutions. Another method involves the precipitation of indium phosphate selectively from slightly acidic solutions and conversion to oxide by leaching in a strong caustic soda solution, followed by reduction of the oxide to metal.

During the smelting of zinc, the indium concentrates in the zinc-lead bottom metal and is separated from that portion by chlorination under molten salt, forming an indium-rich slag. Indium is recovered from the slag by leaching and cementation on zinc or aluminum sheets. The indium deposits on the sheets as a low-density, sponge-like mass, which breaks away and floats to the surface of the solution. The indium sponge is washed, briquetted, melted, and cast into anodes for electrolytic refining.²

Byproducts and Coproducts

Indium is a minor byproduct of processing base metal ores or zinc residues. The value of recovered indium is negligible in relation to the value of zinc production. Coproducts include molybdenum, silver, tin, and tungsten.

Substitutes

In solder and fusible alloys, bismuth can substitute for indium, but only for certain applications because some bismuth-base solders are prone to brittleness. Hafnium can replace silver-indium-cadmium in nuclear control rods.

Economic Factors

Indium, which is classified under Harmonized Code 8112.91.3000 as unwrought, waste and scrap, and powders of indium, was imported free from most favored nations (MFN) and subject to a 25% ad valorem duty from non-MFN.

ANNUAL REVIEW

Legislation and Government Programs

The Defense Logistics Agency, which maintains the National Defense Stockpile, was authorized to procure 2,488 kilograms of indium in 1990, but delayed purchasing indium until a new stockpile acquisition plan is announced in 1991. The inventory on December 31, 1990, was zero, with a goal of 41,990 kilograms.

Consumption and Uses

Domestic consumption was estimated at 30,000 kilograms, a slight increase from that of 1989. The estimated usage pattern was as follows: solders and alloys, 40%; coatings, 35%; electronic and

semiconductor uses, 15%; and research and other, 10%.

Indium was available in various forms, such as ingot, foil, shot, ribbon, wire, and powder. Standard-grade indium was generally used in solders, chemical compounds, plating solutions, and fusible alloys. High-purity indium was used for semiconductors, coatings, and solar cells.

Thin film coatings on glass, which included indium oxide and indium tin oxide (ITO), constituted 35% of total domestic indium usage in 1990. Coatings have been the largest area of growth for indium consumption in the past 5 years. Applications involving thin coatings on glass can be divided into two categories, electrically conductive and infrared reflecting. Electrically conductive coatings, the largest group, were used primarily in liquid crystal displays (LCD) for watches, television screens, portable computer screens, video monitors, and other related display devices.

Aircraft and locomotive windshields used a transparent, electrically conductive ITO film as a defroster or defogger. In this application, the electric current heats the film quickly to clear the glass. Indium coatings are more effective than other types of materials, but the use of indium was limited because of its higher cost and limited supply. Several automobile manufacturers have also experimented with indium, but because of the cost and availability factors, most have opted for a zinc-silver oxide coating for quick defrosting windshields. In a similar use, glass doors on commercial refrigerators and freezers are kept free of condensation and frost by a heated thin film of indium oxide.

Another group of films includes visually transparent infrared reflecting coatings on window glass used to control energy losses by reflecting heat inward in winter and outward in summer. For residential windows, the coating is usually applied to a plastic sheet and encased between two panes of glass. This prevents erosion of the coating and reduces the cost of production. Because the expense of refitting a commercial building remains high, other less expensive metals, such as silver, were used as a replacement for indium coatings on commercial windows.

A major use of indium in Europe, and a growing application in the United States, was in the manufacturing of lowpressure sodium vapor street lamps. An indium oxide coating was used on the

inside surface of the outer glass cover of the lamp. The indium oxide acts as an infrared reflector, which allows the bulb to operate at a high temperature for improved efficiency. These lights can be recognized by their pink-orange tint.

Electroluminescent (E-L) lamps are thin, flat, flexible light sources used to backlight LCD screens, display panels, and switches for military and civilian applications. An E-L lamp consists of a layer of light-emitting phosphor material on an aluminum foil substrate. A transparent film of ITO, which acts as an electrode, is placed on the phosphor. E-L lighting can penetrate fog, smoke, and haze, making these lights essential in military and commercial aircraft. Tactical military aircraft used E-L lamps for instrument panels and marker lights, and commercial planes used the lamps primarily in safety lighting for aisles and doors.

High-purity indium was an important element for semiconductor materials. Indium phosphide (InP) has become the leading substrate material for optical integrated circuits, fiber optics, laser diodes, optical computers, and signal processing. Indium antimonide and indium arsenide were used in infrared detectors for missileguidance systems, night-vision instruments, and medical devices.

The use of indium in solar cells has grown during the past several years. Copper-indium-diselenide (CIS) and InP were used to produce cells with some of the highest energy conversion ratios. CIS cells have attained ratios close to 15% for small cells and about 10% for large panels. For the cells to be economically viable, the cost must drop from the current cost of \$240 per square meter to \$50 per square meter, and the cells must have at least a 30-year lifespan. Gallium can be added to CIS cells to increase the efficiency rating, but it raises the cost of production.

InP cells were used primarily in applications related to space exploration because its resistance to solar radiation is greater than that of gallium arsenide or silicon. An energy conversion factor of 19.1% was achieved in a simulated space environment with an InP cell in 1990.³ The Japan Space Agency used InP solar cells on the lunar orbiter that it launched in 1990.

A major domestic use for indium has been as an addition to bismuth, cadmium, lead, or tin alloys to lower the melting point. These alloys can be used in such applications as electrical fuses, fusible links, or as holding material for the grinding of optical glass. Pure indium and several indium alloys will wet glass and were used for glass-to-metal and glass-toglass seals.

Indium was used as a strengthening agent for lead solder and as the base material for a variety of low-meltingtemperature solders. Many indium-base solders have a melting point below 183° C, the melting point of conventional 63% Sn-37% Pb solder used in electronic applications. This makes indium solder useful for components that would be damaged by a high soldering temperature. Indium-base alloys also remain flexible over a greater temperature range than tin-lead solder. Indium solders reduce the possibility of gold scavenging. a problem that occurs when tin-lead solder is used to join gold components. The solder will gradually leach gold from the contact surface, thus weakening or damaging the soldering joint. The Department of Defense approved the use of indium-base solders for certain military equipment in 1990.

Several manufacturers of pressurized water reactors used an alloy consisting of 80% silver, 15% indium, and 5% cadmium for nuclear control rods. The manufacture of these rods declined in the United States in the early 1970's when orders for new nuclear powerplants began to drop. Following the Three Mile Island nuclear accident in 1979, all orders for new nuclear powerplants in the United States ceased, and subsequent

consumption has been only for replacement rods, which must be changed every 15 years.

Minor uses of indium included indiumpalladium and indium-gold alloys in dentistry, use as a surface lubricant for abrasive compounds, and as an additive to lubricating oil to prevent corrosion. Certain radiation-detection badges used indium foil because low-energy neutrons easily induce radioactivity in indium.

Markets and Prices

Indium demand and production both increased slightly from 1989, and as a result, producers held the price steady. The price of standard-grade, 99.97%-purity indium in the United States gradually decreased from \$251 per kilogram (\$7.80 per troy ounce) in January to \$225 per kilogram (\$7.00 per troy ounce) in April, where it remained until the end of the year.

Foreign Trade

The United Kingdom, France, and Belgium were the largest suppliers of indium to the United States in 1990. Data on U.S. exports of indium were not available.

World Review

World refinery production in 1990 was about 118 metric tons. Belgium, Canada, France, Italy, and Japan were the largest producers. World consumption was about 110 tons. Japan and the United States were the largest consumers.

Canada.—Johnson Matthey PLC, United Kingdom, closed its Trail, British Columbia, high-purity metals plant in December. The closing was part of a company restructuring plan. The high-purity metals production was moved to the firm's plants in Spokane, WA, and Vancouver, British Columbia. Johnson Matthey produced high-purity germanium, indium, and other metals in 1990.

Falconbridge Ltd. began production of indium at the Kidd Creek Mine at Timmons, Ontario, in November 1990. The indium was recovered from waste material from the copper-zinc mining operation. The plant had a refinery production capacity of 30 tons per year, but the output was to be adjusted to market conditions. Indium Corp. was to be the sole marketing agent for all indium produced at Kidd Creek. Indium Corp. also planned to upgrade some 99.99% indium from Kidd Creek to 99.999% (5N) and above purity at its Utica, NY, facility.

Canada now has the largest refinery production capacity for indium in the world. Cominco Ltd., which produced indium at Trail, British Columbia, and Falconbridge Ltd., each have the ability to recover up to 30 tons per year.

Japan.—Japan was the largest producer of refined indium in 1990. It produced 48 tons, but only about 25 to 30 tons was estimated to have been derived from Japanese ores. The remainder was derived from upgrading indiumbearing material imported mainly from China and Europe. The leading uses of indium in Japan were for transparent,

electrically conductive coatings on glass, E-L lamps, and semiconductors.

Current Research

A lead-indium glass was developed at the Oak Ridge National Laboratory for use in optical mirrors, lenses, prisms, windows, and optical fibers. The glass melts at a low temperature, allowing it to be cast into complex shapes, thus reducing the amount of grinding and polishing required. The high lead content makes the glass resistant to gamma radiation, making it suitable for use in nuclear applications.⁴

OUTLOOK

World reserves and increases in ing. V. 24, No. 6, June 1990, p. 68.

production capacity are sufficient to meet expected demand for indium through the year 2000. Consumption of indium is expected to increase gradually in this period, especially for LCD's, semiconductor materials, and in lowtemperature solder for military and commercial electronics. Other uses, such as nuclear control rods, which have a lifespan of 15 years, and fusible alloys should remain steady.

IODINE

By Phyllis A. Lyday

Mrs. Lyday, a physical scientist with the U.S. Bureau of Mines, has been the commodity specialist for iodine for 12 years. Domestic survey data were prepared by Blanche Hughes, mineral data assistant; and international data tables were prepared by William L. Zajac, Chief, Section of International Minerals.

hree producers of crude iodine supplied approximately one-half of domestic demand; the remainder was imported. Because some exports and imports are in product categories rather than crude products, net imports are not clearly developed. The major world producer, Japan, produced iodine from brines associated with gas production. The second largest producer, Chile, produced iodine as a coproduct of sodium nitrate.

DOMESTIC DATA COVERAGE

Domestic production data for iodine are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. operations. Of the four operations to which a survey request was sent, four responded, representing an estimated 100% of the total production shown in table 6.

BACKGROUND

Definitions, Grades, and Specifications

Commercial crude iodine normally has a minimum purity of 99.5%. Resublimed iodine is usually 99.9% pure. Most iodine is converted for industrial use to potassium iodide, sodium iodide, and other inorganic compounds, as well as numerous organic compounds.

Geology-Resources

Iodine occurs in rocks and soils, surface and underground brines, and in caliche ores. Michigan brines contain about 30 parts per million (ppm) of iodine in the Sylvania Formation of Devonian age. California brines contain 30 to 70

ppm of iodine in brines associated with oilfields in the middle Miocene age, Monterey Formation, and the lower Pliocene age Repetto Formation. Louisiana brines contain about 35 ppm of iodine. In Oklahoma, iodine concentrations associated with oil and gas range between 150 to 1,200 ppm. In Woodward County, OK, the iodine occurs in the Morrowan Formation of Pennsylvania age.

Extensive iodine-bearing nitrate ores occur in caliche deposits in a belt several hundred kilometers long in the Atacama Desert of northern Chile. The ore layers are 1 to 3 meters thick, usually flat or gently dipping and near the surface. Evaporate minerals such as lautarite (CaI_2O_6) and dietzeite ($2CaO \cdot I_2O_5 \cdot CrO_3$) occur as cementing material in unconsolidated surface material or as veins and impregnations in bedrock.

Japanese brines contain 50 to 135 ppm of iodine in the Kiwada, Otadai, and Umegase Formations of the Kazusa Group of Pliocene age. The major iodine-producing area was the southern Kanto Gasfield, which extends over Chiba, Tokyo, and Kanagawa Prefectures. Iodine was produced in the Niigata and Nakojo Gasfields in Niigata Prefecture, on the Sea of Japan side of central Japan, and the Sadowara Gasfield in Miyazaki Prefecture, southern Kyushu.

In Indonesia, iodine occurs with trace amounts of bromine in brines associated with oil. The most important iodineproducing area is the Gujangon anticline of sandstone and diatomaceous marls of the Upper Pliocene, Kailiberg Formation.

On Okinawa, iodine occurs in concentrations of about 85 ppm in the Tomigusuku Formation of the Shimajiri Group of late Miocene-early Pleistocene age.

Technology

Processing.—In the Japan and United

States, iodine is removed from brines by processes that separate the brines from any associated hydrocarbons. In the blowing-out process, brine is acidified and iodine is liberated by reducing the pH to about 3. A countercurrent stream of air transports the liberated iodine to a second tower in which the iodine is absorbed by a solution of hydriodic acid. The iodine settles, is filtered, and melted under concentrated acid. Brine stripped of iodine is treated and then reinjected into its subsurface formation of origin.

In the absorption process, brine is passed through an absorber and the waste brine is neutralized and sent to a disposal well. The absorbent laden with iodine is treated with an alkaline solution to regenerate the absorbent and eluted iodine as sodium iodide. Iodide is precipitated under acid.

Japanese plants also use an ionexchange resin. Upon saturation, the iodine is eluted using a caustic solution that regenerates the resin. Iodine is then processed with a sodium chloride solution and melted under acid.

Chilean caliche deposits are mined by open pit methods. The ore is leached with an alkaline solution to dissolve the iodine as sodium iodate, which is converted to sodium iodide. Iodine is precipitated by reacting with additional alkaline solution. The precipitated iodine is filtered in bag filters and the iodine free-leach solution is returned to the nitrate-leaching cycle.

Recycling.—The removal of ionic silver from photographic processing solutions, such as developer, fixer, bleach fixers, and washwaters, can be accomplished with halogens such as iodine and an adsorbent. Photographic silver is commonly recovered by electrolytic methods if the concentration is greater than 500 ppm. Absorbents such as natural and synthetic zeolites, activated alumina, activated silica, fuller's earth, and ion-exchange

resins are used to recover low concentrations of silver from a stream.¹

Economic Factors

Prices.—In the past, changes in the official price of crude iodine have been initiated during shortages. Because iodine cannot be substituted in radiopaque, animal feeds, catalysts, and stabilizers readily, shortages tend to cause the accumulation of inventories to ensure an adequate supply. An adequate supply tends to lower and stabilize the price.

Costs.—Electrical costs for maintaining the pumps to bring the brine to the surface, for air-blowing the iodine, and for reinjecting the brine are major components of maintenance costs. Capital costs have been estimated at \$20 per pound of annual iodine production. These costs include high-quality stainless steels because iodine is highly corrosive. In addition, the brine must be leased from private landowners over large acreage for many years. The principal material cost is for chlorine because 1 pound is required for every 1.4 to 1.8 pounds of iodine produced.

Tariffs.—Crude and resublimed iodine enter the United States duty free. Calcium and cuprous iodine has a 25% ad valorem for non-most-favored-nation status. Potassium iodide has a 2.8% ad valorem for most-favored-nation status and 7.5% ad valorem for non-most-favored-nation status.

Depletion Provisions.—The domestic and foreign depletion allowances for mined iodine are 14% of gross income, and they may not exceed 50% of net income without the depletion deduction. The domestic and foreign depletion allowances for minerals from brine wells are 5%.

Operating Factors

Environmental Requirements.—The reinjection of waste brine is a limiting factor to the production of iodine. During 1982, the Environmental Protection Agency (EPA) reclassified disposal wells for spent brine after halogen extraction as class 5 wells. All of the reinjection wells for iodine in Oklahoma were drilled for the reinjection of waste associated with brine production or oil and gas effluent.

Toxicity.—Iodine is absorbed by the body and concentrated in the thyroid.

TABLE 1
TIME-PRICE RELATIONSHIPS FOR CRUDE IODINE

Iodine is essential to higher animals and humans. A normal person requires about 75 milligrams of iodine per year, which is usually consumed as iodized salt that contains one part sodium or potassium iodide to 100,000 parts of sodium chloride. Iodine deficiency is a major cause of goiter.

The maximum safe concentration for short-term air environment exposure of up to 1 hour is 1.0 ppm. Exposure of the lungs and eyes can be irritating at concentrations of 0.1 ppm and should be avoided. Greater exposure can cause severe irritations to the eyes and the respiratory tract and may lead to pulmonary edema.

In 1979 and 1986, nuclear accidents caused the release of radioactive iodine I¹³¹ into the atmosphere. A dosage of potassium iodide (KI) administered prior or shortly after exposure of radioactive

iodine can block the intake of radiation to the thyroid. The dosage must be repeated if exposure continues. Replenishing the thyroid with KI prevents the thyroid from using radioactive I¹³¹ for normal metabolic needs.

ANNUAL REVIEW

Legislation and Government Programs

The June 21 Federal Register announced an ad hoc meeting of experts in the field of nuclear medicine and potassium iodide issues to solicit relevant scientific and medical information. The meeting was sponsored by the Center for Environmental Health and Injury Control of the Centers for Disease Control, U.S. Department of Health and Human Services.

The State of Oklahoma passed a bill to empower the Oklahoma Corp. Commission (OCC) to regulate individuals or companies that produce iodine from underground saltwater. Oklahoma is the only state where iodine is produced. The bill is expected to simplify the producers' obligations by requiring OCC approval for all iodine production. The courts have held that brine in the ground belongs to the surface owner, while associated natural gas belongs to the mineral owner. The bill puts natural gas produced with iodine-bearing brine water in a high-priority production classification.

Strategic Considerations

The National Defense Stockpile contained 6.1 million pounds of crude iodine. The stockpile goal remained at 2.6 million kilograms (kg) (5.8 million pounds). The Defense Logistics Agency of the U.S. Department of Defense disposed of 5,000 kg of excess material during fiscal year 1990.

Production

IoChem Corp., 2 miles east of Vici, Dewey County, OK, produced iodine by the blowing-out process. The majority of production was shipped to Schering AG. Federal Republic of Germany, under a long-term contract. IoChem was reported to have nine production wells and four injection wells with a total production capacity of 1,200 kilograms. North American Brine Resources operated miniplants at Dover in Kingfisher County, OK. The plant is at an oilfield reinjection disposal site. Iodine concentrations ranged up to 1,200 ppm. The company also operated a plant at the border of Woodward and Harper Counties. Woodward Iodine Corp., a subsidiary of Asahi Glass Co. of Japan, operated a plant in Woodward County that produced iodine from brines using the blowing-out process.

Consumption and Uses

Iodine was used primarily in animal feed supplements, catalysts, inks and colorants, pharmaceutics, photographic equipment, sanitary and industrial disinfectants, stabilizers, and radiopaque medium. Other smaller uses included production of batteries, high-purity metals, motor fuels, iodized salt, and lubricants.

The lithium-iodine battery was the first

commercially successful lithium battery and is unusual because of its in situ growth of electrolytes. Superior charge transfer is achieved using an iodine compound with powdered iodine. Layers of lithium iodide act as both electrolyte and separator and are self-sealing in the event of a crack. Thus, the batteries are intrinsically reliable and withstand abuse.²

Prices

The average declared c.i.f. value for imported crude iodine was \$15.19 per kg (\$6.90 per pound). The average declared c.i.f. value for imported crude iodine from Japan averaged \$14.90 per kg (\$6.76 per pound). The average declared c.i.f. value for iodine imported from Chile was \$15.51 per kg (\$7.04 per pound).

Quoted yearend U.S. prices for iodine and its primary compounds are shown in table 3.

Foreign Trade

The U.S. Government adopted the Harmonized Commodity Description and Coding System (Harmonized System) as the basis for its export and import tariff

and statistical classification systems. The system is intended for multinational use as a basis for classifying commodities in international trade for tariff, statistical, and transportation purposes. The Harmonized System as proposed includes resublimed and crude iodine under the same code, and the duty rate is free. During 1989 and 1990, exports to Santa Domingo were incorrectly placed into the iodine category. A test of correct reporting is to calculate price per kilogram and compare this value with the prices shown above. Values that differ significally could be a result of being placed in the wrong category.

World Review

Capacity.—The data in table 4 are rated capacity for plants as of December 31, 1990. Mine capacity for iodine is based on rated capacity as reported by the company, another government agency, or another published source.

Chile.—Sociedad Química y Minera de Chile (SOQUIMICH) was the largest producer of iodine in Chile. The María Elena and Pedro de Valdivia plants

produced jodine, sodium nitrate, potassium nitrate, and sodium sulfate. SOQUI-MICH continued to operate a plant at Puelma. Installed capacity was reported at 6,000 tons per year.

SOQUIMICH had a joint venture with Israel Chemicals Ltd. named Compania Ouimica Internacional de Desarrollo (IDC Co.). In March, Israeli Chemicals of Israel purchased 10.5% of SOQUI-MICH's shares valued at \$30 million from the Bankers Trust New York Corp. of the United States.³

Other companies active in iodine production were Amsterdam Chemical Pharmaceutical Minera (ACF Minera), a joint venture of the Sociedad Contractual Minera Lagunas and the Amsterdam Pharmaceutical Co. of the Netherlands. ACF Minera operated a plant using nitrate tailings as the iodine source.

Also actively producing iodine from nitrate tailings was Compania de Salitre y Yodo de Chile (Cosayach), a subsidiary of Cia. Minera del Norte. Cosayach inaugurated a plant in November. A feasibility study completed by Davy McKee Worldwide Corp. established that the Yolanda nitrate and iodine project near Taltal was both financially viable and technically feasible. The study suggests an annual output of 1,360 metric tons of iodine and 250,000 metric tons of potassium nitrate. Recoverable resources are

²Less than 1/2 unit.

reported at 40,500 tons of iodine. North Lily Mining is operator of the company and will receive a 10% net profit interest. Kap Resources, the owner of the property, merged with its joint-venture partner Atacama Resources.⁴ A second location was being studied at Yumbes Pampa south of the Yolanda site.

In May, Chile Hunt Oil Co. reported the discovery of gas in the Salar de Atacama at a depth of 4,500 meters. The availability of gas for the generation of low-cost electric power could increase the economic viability of other projects in the region.⁵

Indonesia.—The only producer of crude iodine was the state-owned pharmaceutical firm, P. T. Kimia Farma, that operated a plant at Watudakon near Mojokerto, East Java.

Japan.—Production of iodine was from underground brines associated with natural gas. Japan was the world's leading producer of iodine in 1989. Six companies operated 17 plants with a total production capacity of 9 million kilograms per year.

IRON ORE

By Peter H. Kuck

Dr. Kuck has been the commodity specialist for iron ore since 1986 and was previously responsible for vanadium and silicon. The domestic survey data were compiled and analyzed by Sarah P. Guerrino, Chief of the Ferrous Data Section (now retired), and Henry F. Sattlethight, management analyst. The world production table was prepared by William L. Zajac, Chief, International Data Section.

orld demand for iron ore has continued to grow over the long term. In 1990, the iron content of the ore produced throughout the world was estimated to be 543 million metric tons (Mmt) compared with 521 Mmt in 1975 at the end of the Vietnam conflict. An estimated 98% of the ore shipped in the world is used for the manufacture of iron and steel. The remaining 2% is used in the manufacture of cement, heavy-medium materials, pigments, ballast, agricultural products, or specialty chemicals. As a result, demand for iron ore is tied directly to the production of raw steel and the availability of highquality ferrous scrap. Although world iron ore production slipped slightly in 1990 from the record high of 1989 because of adverse events in the U.S.S.R., North America, and Liberia, production is expected to reach new highs in the near future because of escalating demand for steel in the developing and newly industrialized countries.

The majority of U.S. iron ore producers had a relatively good year in 1990, defying pessimistic forecasts made by some industry analysts in 1989. The United States produced 56.41 Mmt of usable ore. Although the tonnage was slightly less than that of 1989, significant progress was made in improving pellet quality. Pellets constituted 97% of the total figure, the remainder being a near-equal mix of concentrates and direct-shipping ore. The pellets were made from low-grade Precambrian ores mined in Michigan, Minnesota, and Missouri. The bulk of the direct-shipping ore was produced in California and Utah for local consumption. Mine shipments of pellets, concentrates, and direct-shipping ore totaled 57.01 Mmt, again an amount only slightly lower than that of 1989. Michigan production was down 39% from that of 1989 because of a 4-month labor dispute, but the slack was picked up by mines in Minnesota. Cyprus Northshore Mining Corp. overcame a number of refurbishing obstacles at the beginning of 1990 and shipped 2.23 Mmt of pellets during the 1990-91 navigation season. Competition within the U.S. iron ore industry intensified because of the startup of Cyprus Northshore and the ongoing drive by domestic steel producers to cut their raw material costs and other production expenses.

Competition between U.S. and Canadian mines also stiffened because of (1) strikes against two integrated steel companies in Canada and (2) the impending shutdown of older ironmaking operations in eastern Pennsylvania. Steelworks in eastern Pennsylvania and Maryland purchased more than 2 Mmt of Canadian pellets in 1990. The Canadian strikes, which disrupted operations at The Algoma Steel Corp. Ltd. and Stelco Inc., began at the same time as the one in Michigan, but were settled 1 month earlier. U.S. exports of ore and agglomerates dropped 40% because of the Canadian strikes. As in past years, most of the 3.20 Mmt exported went to Algoma and Stelco, which hold equities in U.S. taconite projects.

The iron and steel industry accounts for 99% of the iron ore and agglomerates consumed in the United States. Published prices for Lake Superior pellets do not necessarily reflect the existing supply-demand situation because domestic steel companies directly control 77% of mine production. Canadian steel companies control an additional 7%. Changes in the level of blast furnace production are almost immediately transmitted back up the supply line to the mines.

Consumption of ore and agglomerates by the domestic iron and steel industry rose slightly between 1989 and 1990 to 73.69 Mmt. Combined U.S. imports of ore, concentrates, and agglomerates decreased 8% to 18.05 Mmt, with Canada regaining market share at the expense of Brazil and Venezuela. There were no imports from Liberia for the first time since 1950 because

of the civil war in that country. Domestic hot-metal and pig iron production was 49.67 Mmt, 2% less than that of 1989. A total of 60.51 Mmt of pellets was consumed—an amount only slightly lower on a gross weight basis than that of 1 year ago.

Pellet consumption did not drop as much as hot-metal production. The slight discrepancy is explained in part by the growing use of fluxed pellets in the United States and their substitution for sinter. Fluxed pellets contain 3% to 9% less iron than traditional standard pellets, but significantly more calcium and magnesium. As a result, a greater tonnage of the fluxed variety is needed to produce a given amount of hot metal. Fluxed pellets accounted for 39% of domestic mine shipments in 1990. Fluxed or partially fluxed pellets were routinely being made at 6 of the Nation's 10 active taconite plants. The new pellets are in demand because they improve blast furnace productivity by decreasing smelting time. The decrease in smelting time can reduce coke consumption significantly. Besides lowering coke costs, the shorter smelting time also reduces wear on the blast furnace lining, cutting refractory replacement costs.

Ore consumption was relatively stable until the fourth quarter of the year, when concerns of an impending recession and the deteriorating situation in the Persian Gulf region caused consumer confidence to drop off and sales of products incorporating steel to weaken. Because of these signs of slowing demand, blast furnace operators cut back hot-metal production more than normal during the yearend holiday season. On December 31, 46 blast furnaces were in operation, 2 fewer than at the end of 1989. Monthly output of hot metal averaged 4.14 Mmt during 1990.

Ore consumption for all of 1990 was slightly higher than that of the previous year for two reasons. First, domestic raw steel production did not collapse as some industry analysts had forecasted in 1989. Raw steel production, which had been relatively stable since March, slackened in early December. However, the December downturn was not large enough to offset earlier gains made in the spring. Second, blast furnaces at integrated mills were able to compete with electric arc furnace operations because of (1) improvements in hotmetal practices and (2) growing demand for higher quality steels free of tramp elements.

Wheeling-Pittsburgh Steel Corp. and Sharon Steel Corp., two steel companies, which had filed for protection under chapter 11 of the Federal Bankruptcy Code during the turbulent 1980's, emerged from court protection. A third, LTV Corp., was in the final stages of being reorganized. A number of claims involving joint mining ventures were settled in conjunction with the chapter 11 reorganizations. The settlement of these claims and other courtapproved actions removed the cloud of uncertainty hanging over four North American mines and allowed their mine managers to resume long-range planning.

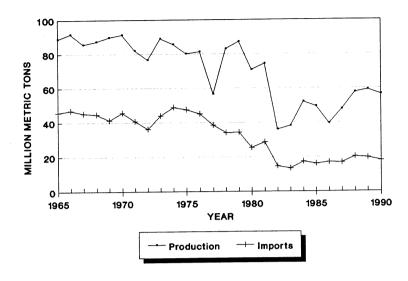

In late November, Cleveland-Cliffs Inc. (CCI) and the United Steelworkers of America (USWA) finally agreed on a new labor contract that runs for 31 months. The 1,800 union members at the Empire and Tilden Mines began returning to work on December 1. The two mines had been shut down since August 1 by a dispute over wages, pension rights, and cost-of-living escalators. According to some industry analysts, the 4-month-long dispute hurt both sides. Little was gained in the near term by the local membership in Michigan because the strike settlement came at the beginning of a major downturn in the iron and steel sector and was followed by temporary layoffs at the two mines. In early February 1991, the USWA negotiated a new 3-year labor contract with USX Corp., narrowly avoiding a second costly and damaging strike. In the summer of 1986, the entire USS segment of USX Corp. was shut down for 184 days. The 1986 shutdown was the longest work stoppage in the history of the domestic steel industry.

DOMESTIC DATA COVERAGE

U.S. production data for iron ore are developed by the U.S. Bureau of Mines from two separate, voluntary surveys of domestic operations. The annual "Iron Ore" survey (1066-A) provides the basic data used in

FIGURE 1

U.S. IRON ORE PRODUCTION AND IMPORTS FOR CONSUMPTION

this report. Of 46 addressees to whom the 1066-A form was sent, 46 responded, representing 100% of total production shown in tables 1 through 4. In past years, production for nonrespondents to the annual survey was estimated from monthly surveys (1066-M), from railroad reports, or from reported production levels in prior years. This information may be supplemented by employment data, mine-inspection reports, and information from consumers.

Data on consumption and stocks of iron ore and agglomerates at iron and steel plants were provided by the American Iron Ore Association (AIOA). AIOA also provided data on ore shipments from loading docks on the upper Great Lakes as well as receipts at transfer docks and furnace yards nationwide. The dock and steel plant data were compiled jointly by AIOA and the American Iron and Steel Institute (AISI). Data on consumption of iron ore for nonsteel end uses were compiled from information gathered from other Bureau surveys.

BACKGROUND

Industry Structure

History.—The history of iron mining in early America has already been reviewed

in several other publications of the U.S. Bureau of Mines and its predecessor. For additional information on the economic history of the entire U.S. iron and steel sector, the reader should refer to the comprehensive works of Father Hogan of Fordham University.²

The history of the iron ore industry as it currently exists began in 1844 with the discovery of "hard" magnetite-hematite ores on the Marquette Range of Michigan and the subsequent founding of the Jackson Mining Co.3 At first, lack of transportation facilities prevented rapid development. However, completion of a shipping canal at Sault Ste. Marie in 1855 opened the way for further development of mining in the Lake Superior region. By 1885, ore had been discovered in the Gogebic and Menominee Ranges of Michigan and Wisconsin, and annual production of ore had climbed to more than 2 Mmt, 20 times the volume in 1860. The high grade of these ores, combined with the low cost of water transportation, made them increasingly competitive at Eastern furnaces and forced many small mines in New York, Tennessee, and the Mid-Atlantic States to close. This trend was accelerated in the 1880's by production from the Vermilion Range and the discovery of the great Mesabi ore bodies in the 1890's. By the turn of the century, most of the Eastern mines had closed. In Alabama, production of iron ore increased nearly tenfold between 1880 and 1890, and Birmingham was established as a major ironmaking center. During this period, many steel companies acquired iron ore properties in the Lake Superior District, and the production of many smaller mines was consolidated by the formation of large mining companies. The mergers that took place in the steel industry between 1893 and 1905 basically organized the iron ore industry into the structure that exists today.

Hundreds of mines closed during the 1950's following the depletion of higher grade ores, rapidly rising imports, and the subsequent growth of the taconite industry in the Lake Superior District. By 1981, 15 mines accounted for 90% of the Nation's production of iron ore. By 1986, the 15 mines had been reduced to 10 because of increasing imports of steel and 2 deep recessions from which the iron ore and steel industries have not yet fully recovered.

Size and Organization.—In 1990, iron ore was produced by 20 companies operating 22 mines, 16 concentration plants, and 10 pelletizing plants. The mines included 21 open pits and 1 underground operation. However, only 10 mines accounted for 98% of the output. Virtually all ore was concentrated before shipment, and about 97% was pelletized. Most of the ore was produced by, or for the account of, nine U.S. companies and two Canadian companies engaged in production of iron and steel. Domestic steel companies directly controlled about 77% of production; Canadian steel companies, about 7% of production. Consumption of iron ore and agglomerates was distributed approximately as follows: blast furnaces, 97.9%; direct-reduction plant, 0.7%; steel furnaces, 0.2%; and manufacture of cement, heavy-medium materials, and other products, 1.2%.

During the 1980's, a quasi-symbiotic relationship existed between several iron ore operations in Canada and the United States because of ownership ties. In 1982, U.S. companies owned about 70% of Canadian production capacity for iron ore and held significant minority interests in iron ore mines in Australia, Brazil, Liberia, and New Zealand. Since then, Japanese interests have acquired part of the Canadian and overseas holdings previously owned by companies in the U.S. iron and steel sector.

The iron ore industry of the United States and Canada has been undergoing a major

restructuring since 1985 aimed at lowering pellet costs and improving financial health. The bulk of this restructuring occurred in the summer of 1986, when the industry was experiencing one of its worst years since the Great Depression. Most of the pellet producers had already streamlined their operations by late 1987, when overall demand for steel began to grow. The modest recovery accelerated in 1988, only to level off in 1989. Ownership shares and installed production capacity of United States and Canadian producers of iron ore in 1991 are shown in figure 2. This diagram, when compared with the one previously published by the Bureau for 1984,4 illustrates how pervasive the restructuring has been since then.

The breadth and intensity of the restructuring is illustrated by USX Corp., the largest steel producer in the United States. The existing company was formed in 1986 after U.S. Steel Corp. acquired the Texas Oil and Gas Corp. USX is now a diversified company with interests in energy, steel, mineral resources, real estate, and engineering services. Its energy segment includes the Marathon Oil Co. in addition to Texas Oil and Gas Corp. U.S. Steel paid \$6.5 billion for Marathon in 1982. The former U.S. Steel Corp. had been a leader in domestic steelmaking and iron ore mining for about 85 years prior to the 1986 restructuring.

USX owns and operates the Minntac Mine at Mountain Iron, MN. Minntac is the largest iron mine in the United States and supplies fluxed pellets to USX's blast furnaces at Gary, IN, and Dravosburg, PA. In 1990, pellets were also shipped to Geneva Steel at Provo, UT; the USS-Kobe Steel Co. joint venture at Lorain, OH; and the Weirton Steel Corp. at Weirton, WV.

At the end of 1988, USX and the Blackstone Group formed a joint venture known as Transtar Inc., which manages a variety of bulk transportation subsidiaries. USX sold 56% of its extensive transportation holdings to Transtar for about \$600 million. A number of USX railroad lines were involved, including the Duluth, Missabe and Iron Range Railway Co. (DM&IR). The new transportation company also acquired USX's lake shipping and river barging operations. In 1989, USX sold its 100% equity in the Quebec Cartier Mining Co. (QCM) to Dofasco Inc. The sale of QCM was a somewhat complicated affair. The giant Canadian iron ore operation is currently owned by Dofasco (50% equity), Mitsui & Co. Ltd. of Japan

(25%), and Companhia Auxiliar de Empresas de Mineracao (CAEMI) of Brazil (25%).

At the beginning of 1991, USX announced plans to divide its common stock into separate steel and energy issues. The company's U.S. Diversified Group (real estate, engineering services, timber, and certain coal interests) was to be included with the steel group. Stockholders approved the stock restructuring proposal at their annual meeting on May 6, 1991. Approval of the May stock proposal facilitates further restructuring of the corporation and requires the steel group to fund capital expenditures from its own internally generated cash-flow. It is not known at this time what effect the stock separation and accompanying corporate changes will have on the Minntac operation.

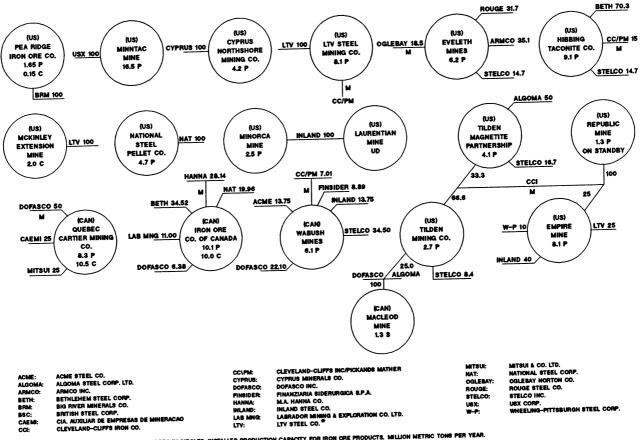

Recent technological advances have affected not only day-to-day operations, but also the structure of the industry. An increasing number of integrated steelworks in North America are using fluxed pellets. This newer, more easily reducible type of pellet is created by adding limestone (CaCO₃) and/or dolomite [(Ca,Mg)CO₃] to the iron ore concentrate during the balling stage. Sufficient fluxstone is added to raise the ratio of (CaO+MgO)/(SiO₂+ Al₂O₃) in the pellet to above 0.6. The most common ratio is about 1. Fluxed pellets comprised 39% of total U.S. production in 1990. Idle capacity was brought on-stream at three mining complexes on the Mesabi Range during 1989 to meet increased pellet demand. The idled complex of the Reserve Mining Co. at Silver Bay, MN, was renovated by Cyprus during the last quarter of 1989. Cyprus shipped a trial batch of fluxed pellets in April 1990.

Combined United States and Canadian production represented only about 11% of the world output of usable ore in 1989. At least 45 other countries mined crude ore during the year. The leading producer was the U.S.S.R., which accounted for about 25% of world output in terms of metal content, followed by Brazil with 19% and Australia with 12%. Trends in world mine production since 1986 are shown on a country basis in table 24. Major mines are listed individually in table 23.

In 1989, the U.S.S.R. produced 241.0 Mmt of direct-shipping ore and concentrate. A large part of the concentrate was consumed to make 68.7 Mmt of pellets. The bulk of the iron ore produced in Australia, Brazil, India, and the Republic of South Africa consisted of

high-grade direct-shipping ore or products derived from much higher grade crude ores than those mined in the United States.

Geology-Resources

Iron is the fourth most abundant rockforming element, comprising about 5% of the Earth's crust. Astrophysical and seismic evidence suggest that the element has also combined with nickel to make up the bulk of the Earth's core. A small part of the crustal iron has been concentrated by sedimentary, igneous, or metamorphic processes into deposits containing up to 70% of the element.

The largest concentrations of iron are found in banded sedimentary iron formations of Precambrian age. (See figure 3.) These formations currently supply most of the world's iron ore and constitute the bulk of the world's iron resources. Precambrian ores are mined extensively in Africa, Australia, Canada, China, India, South America, the United States, and the U.S.S.R. Individual banded iron formations (BIF's) can vary from 30 to 600 meters (m) in thickness. Some are relatively flat-lying, while others have been complexly folded by subsequent regional metamorphism. Some BIF's are exposed almost continuously along the margins of geosynclines and commonly underlie basin areas of hundreds or thousands of square kilometers (km²). Most consist of fine-grained iron oxides and quartz, with accessory iron silicates and in some places iron carbonate, and contain 20% to 40% iron. These rocks comprise ores of the taconite type mined in Canada, China, Norway, the United States, and the U.S.S.R.

Locally, the BIF's have been concentrated by natural processes to form highgrade deposits of hematite or goethite by leaching of silica and oxidation of ferrous minerals. The high-grade ores are classed as residual or replacement deposits, depending on whether removal of silica was accompanied by introduction of additional iron oxide. The residual ores are usually earthy, porous, and contain 50% to 60% iron in their natural state. Examples are the soft ores of the Lake Superior District, the Schefferville District of Labrador, and the Krivoy Rog District of the Ukrainian S.S.R. Some soft ores appear to be merely decomposed bodies of BIF, containing 20% to 40% iron in the form of martite, hematite, or goethite. Examples of the latter are bodies of "wash ore" in the western Mesabi

Range, which are highly siliceous but easily concentrated by gravity methods.

Replacement ores in the Precambrian BIF's are usually dense, massive, and contain 64% to 68% iron. Often, the ores retain banded structures of the original sedimentary rock. Examples are the hard ores of the Vermilion Range, MN; Steep Rock and Michipicoten Districts of Ontario; Minas Gerais, Brazil; Fort Gouraud, Mauritania; and Sishen, Republic of South Africa.

Another class of sedimentary iron deposits, of regional importance in the southeastern United States and Western Europe, is oolitic ironstone of Paleozoic to Cretaceous age. The formations are extensive laterally and contain 20% to 40% iron, but they differ from the Precambrian BIF's in several important respects. They are usually less than 15 m thick, and minable layers are commonly less than 6 m thick. The deposits rarely contain more than 48% iron, and most contain only 25% to 35% iron. The ore consists of very fine-grained hematite, quartz, chamosite,5 and siderite in varying proportions; sometimes enough calcite is present to make self-fluxing ore. The ore is usually high in phosphorus and difficult to beneficiate. Oolitic ironstones were mined until recently in Alabama, Newfoundland, and the United Kingdom and are still mined extensively in France and to a lesser extent in central Europe. They are also mined in Egypt and comprise most of the iron resources of Pakistan.

A third type of sedimentary ore, consisting of siderite or limonite in flat-lying lenses up to 6 m thick, is mined in east Texas from the Weches Formation of Eocene age. The ore is associated with glauconitic sand and clay and contains up to 35% iron.

Massive deposits of magnetite, sometimes with hematite, thought to be of igneous origin, are important sources of iron ore in many parts of the world. These deposits can contain as much as 65% iron and are often rich in titanium and vanadium, as at Lake Sanford, NY. There are two principal types of these igneous deposits: magmatic segregations and pyrometasomatic replacements. The first type is represented by irregular or layered masses that appear to have formed by segregation of magnetite crystals in magma, or as tabular, sheetlike bodies formed by injection of an iron-rich fluid into surrounding rocks. The Precambrian Bushveld Igneous Complex of the Republic of South Africa with its alternating seams

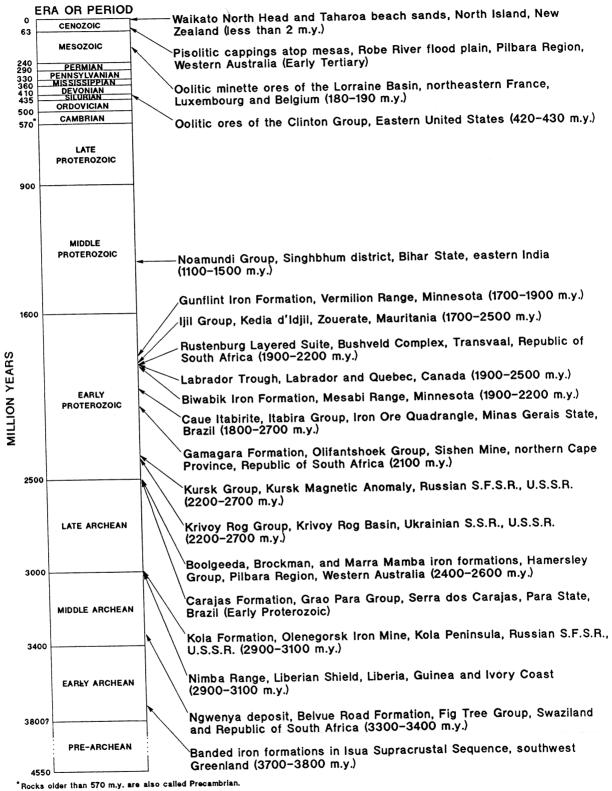

of magnetite and chromite is frequently cited as an example of magmatic segregation and crystal settling. The sill-like ore bodies at Kiruna, Sweden, and Pea Ridge, MO, represent the injection version of the process. The magnetite ores in these last two deposits contain significant amounts of fluorapatite, which must be removed during beneficiation.

Pyrometasomatic deposits are concentrations of magnetite that have replaced portions of the limestone or volcanic country rock at or near the contact of an igneous intrusion. These deposits may be partly altered to hematite and contain up to 65% iron, depending on the extent of replacement. Garnet, epidote, and wollastonite are commonly formed along with the magnetite during the thermal metamorphism of the country rock. Deposits of this type are commonly associated with Jurassic or younger intrusives in the Western United States, Mexico, and western South America; they are also found in Pennsylvania. Examples of pyrometasomatism include Iron Springs, UT; Eagle Mountain, CA; Hanover, NM; Cornwall and Morgantown, PA; El Romeral, Chile; and Marcona, Peru.

Technology

The technology of iron ore beneficiation. agglomeration, and smelting has changed significantly over the past 20 years. With the depletion of higher grade natural ores in the United States, the subsequent development of the North American taconite industry, and recent advances in steelmaking, beneficiation and agglomeration have become more complicated for domestic mine operators. Today, steelmakers both in North America and abroad need pellets that are much more uniform in chemical composition and meet tighter physical specifications. All of this has led to larger investments in processing equipment by domestic mine owners, driving their production costs upward. At the same time, ore grades have been declining in the United States. In addition, competition between major U.S. and Canadian producers has stiffened because of continuing weak demand for raw steel in the United States, keeping iron ore prices relatively low. North American producers, shippers, and consumers are all under increasing pressure to reduce unit costs and have only survived the latest series of economic downturns by making technological improvements that increased productivity.

FIGURE 3 IRON DEPOSITION THROUGHOUT GEOLOGIC TIME

Rocks older than 570 m.y. are also same tresament

Significant progress has been made at a number of critical points along the supply chain. Older model power shovels and haulage trucks are continually being replaced by more efficient and increasingly larger units. Mini- and microcomputers are being used to improve mining and process control. Advances have been made in the fine-screening of concentrates and the use of wet, high-intensity magnetic separators (WHIMS). New flotation processes have been developed to lower phosphorus and silicate levels in concentrates. Organic binders are being used to further reduce the silicate content. Several steelmakers have reduced coke consumption at their blast furnaces by switching from standard acid pellets to fluxed pellets.

Exploration.—The principal methods of exploration for iron ore are magnetometer surveys, geological mapping, and drilling. Aerial photography, and occasionally gravimetric surveys, are used to supplement the information gained from the magnetic and geological data. But, regardless of how promising the results of geophysical and geological mapping may be, the deposit must be drilled to determine the quantity, quality, and spatial distribution of ore present.

Magnetometer surveys are useful because deposits of iron ore are commonly associated with local anomalies in the Earth's magnetic field. In poorly explored or remote regions, airborne magnetometer surveys can quickly and economically pinpoint the more favorable areas for surface investigation. Such a survey may employ a low-sensitivity magnetometer, capable of measuring magnetic intensity to 0.5 gamma, or high-sensitivity instruments measuring to 0.02 gamma.6 Flux-gate or proton-precession magnetometers are usually used in aerial work. Surface magnetometer surveys may be used to add detail to results of aerial surveys or where extensive overburden prevents adequate geological mapping. The newer types of magnetometers can be used in drill holes or underwater because their sensitive elements are separated from the recording systems by long coaxial cables. In some cases, advances in telemetry have made even the coaxial cables obsolete.

Surface magnetometer surveys have been extremely valuable in guiding exploration and development drilling on the Cuyuna and Mesabi Ranges, where the iron formations are buried under as much as 60 m (200 ft) of glacial drift. Discovery of the

Cuyuna Range was made possible by early dip-needle surveys. On the Mesabi, magnetometer surveys have outlined areas of low magnetic intensity that are typically associated with the presence of hematite deposits. The correlation with hematite has also helped outline the oxidized portions of buried formations of magnetic taconite. Balance-type magnetometers were once used widely in ground surveys, but have been largely replaced by proton-precession instruments, which do not require leveling and permit faster and more accurate readings.

Geological mapping in remote areas can be expedited by employing helicopters and conventional aircraft. Aerial and satellite photographs may also be used to advantage, since iron-rich rocks often form topographic features such as ridges, mesas. or hills. These features help to guide ground survey teams and may be aerially traceable into districts that are unmapped or have been mapped only by reconnaissance teams. Aerial photography has been especially valuable in exploring the tundra of Alaska and northern Canada. There has been little exploration for iron ore in the United States in recent years because of weak demand and the existence of large reserves in the Lake Superior District and Alaska.

The exploration geologist is now able to accurately pinpoint his or her location in the field with the help of the Global Positioning System (GPS) set up by the U.S. Department of Defense. Handheld receivers are commercially available for use with the GPS to determine latitude, longitude, Universal Transverse Mercator Coordinates, and altitude. The GPS is composed of a network of more than 20 satellites that circle the Earth at an altitude of about 18,000 kilometers (km) (11,000 miles).7 The handheld receiver is able to determine its location by monitoring identically coded radio signals broadcasted simultaneously by the different satellites and then triangulating on four of the satellites. Most of the cheaper receivers can pinpoint a location anywhere on Earth to within 15 m, while more advanced receivers are accurate to within 1 cm.

Exploration drilling for iron ore is usually done with diamond-surface-set coring bits. Core samples are desired because they provide "undisturbed" samples yielding information on geologic structure and physical properties that would not be available from ordinary drill cuttings. Bit sizes commonly used are B, N, and H.

which cut cores approximately 1.7, 2.1, and 3.0 inches in diameter, respectively. Either hard or soft ores can be cored. Core recoveries of 75% or better are common. Diamond drilling is expensive, however, and other methods such as rotary or churn drilling may be used if cuttings constitute an acceptable sample. The spacing of exploration drill holes depends on the size, structure, and continuity of a deposit and may range between 150 and 1,500 m (500 and 5,000 ft). Spacing of development drill holes in taconite deposits on the Mesabi Range is about 60 to 120 m (200 to 400 ft). Most diamond drilling at U.S. iron ore mines is now done by contractors rather than by the mining companies. Wire-line methods are often used and may permit extraction of cores without removing the entire drill string from the hole.

Mining.—About 90% of the world's output of iron ore comes from open pits; most of the rest is produced from underground mines. Only a small percentage is derived from beach sands and placers. In the United States and Canada, open pit operations accounted for 98% of usable production in 1990. Approximately 14% of the ore mined in the U.S.S.R. is produced underground, about 30% in Spain, and 100% in France and Sweden.

The choice of mining method depends on the size, structure, and accessibility of the ore body. Most iron ore is mined in open pits because of the ore's low unit value and the large tonnages that must be moved to obtain economy of scale. To be commercially viable, an ore body generally has to lie close to the surface and have large lateral dimensions. Narrow, steeply dipping, or buried ore bodies are normally mined by underground methods, but the relatively high cost and limited production capacity of underground mines has steadily reduced their ability to compete with open pit operations. The number of underground iron mines in the United States has declined from more than 30 in 1951 to only 1 in 1991.

At U.S. taconite mines, 5 to 6 mt of material must be mined for each mt of usable product produced. This is due to the relatively low magnetic iron content of the crude taconite, which typically ranges from 20% to 24% Fe. About 3 mt of crude taconite has to be processed to produce 1 mt of pellets. In addition, large quantities of waste rock and surface overburden must be stripped. At most mines in Australia and Brazil, where the ore is of much higher

grade, only 1.5 to 2 mt of material is mined for each mt of product produced.

Mining in most open pits is done with large power shovels and trucks. Blasthole drilling is mainly done by rotary drills with 12¼-inch to 16-inch diameter bits; 17½-inch bits have been used at some mines. Down-the-hole percussion drills using 6½-inch bits are used at Pea Ridge's underground mine in Missouri. A few "jetpiercing" machines, which bore a 9-inch hole by a continuous process of heating and spalling, were employed in Michigan and Minnesota during the late 1950's and 1960's, but are no longer in use.

Ammonium nitrate, in prilled form or slurries with fuel oil, is the most widely used blasting agent. Blasting efficiency has been increased by using emulsions or metallized slurries and by increasing the quantity of explosive in individual blastholes. The 1214-inch to 171/2-inch blastholes now drilled in taconite permit wider spacing of holes and larger explosive charges while maintaining adequate fragmentation. The quantity of taconite broken by individual blasts usually ranges from about 0.4 to 1.5 Mmt. Consumption of explosives ranges from about 0.18 to 0.45 kilograms (0.4 to 1.0 pound) per mt of rock broken. In natural ore mines, drilling and blasting requirements are less than in taconite. Some natural ores can be dug without blasting, as is the case in Goa.

Most power shovels at taconite mines have dipper or bucket capacities of 9 to 18 cubic yards and are designed to dig ore and waste rock as well as surface overburden. One of the first of a new generation of electric shovels equipped with a 33-cubic-yard bucket was delivered to the Empire Mine in 1990. The unit was employed in stripping operations in the main pit. Shovels with even larger capacities are used in the Pilbara mines of Western Australia. The first diesel-powered shovel in the U.S. industry was put into operation at the Tilden Mine in January 1991. The unit had a 12-cubicyard bucket and was being used to strip overburden at the new Cliffs Drive III pit.

At large taconite mining operations, where as many as 14 shovels may be working in different materials over a distance of several miles, daily scheduling of shovel operations is assisted by computers. At most taconite mines, there is considerable variation in the physical properties and mineralogical composition of the ore. These variations make it difficult to schedule digging, loading, and haulage operations, while simultaneously delivering

crude ore of relatively uniform grade to the crushing and concentrating plants. To accomplish this, daily operations require experienced visual judgment and frequent supplemental sampling by mine personnel.

Ore haulage from the pit to the crusher has been made more efficient by computerized truck dispatching. A new generation of haulage trucks is also helping to lower mining costs. At least three open pit operations in the Lake Superior District have begun replacing the older 120-shortton and 170-short-ton trucks in their fleets with new 240-ton units. Most trucks at U.S. iron mines now have haulage capacities of at least 100 short tons. However, some 85-ton units are still used. Trucks of 180to 225-short-ton capacity have been employed in Australia for more than a decade. In the mid-1970's, a 312-ton unit was tested successfully for a year at a California mine, but trucks larger than 240 tons have not yet proved to be practical at most U.S. iron mines. Minntac and the LTV Steel Mining Co., 2 of the larger U.S. taconite operations, prefer to use trains to haul ore to the crushers; the trains consist of 9 to 18 cars of 80- or 85-short-ton capacity each and are automated to allow operation by 1 worker.

At many mines, front-end loaders have replaced shovels in secondary ore loading, cleanup, and stockpile operations. The load-ers are more mobile than the shovels and have bucket capacities of up to 13 cubic yards.

In underground mining, the most noticeable technological changes have been in development of improved drilling and blasting operations and in mechanization of loading and transport. At Pea Ridge, 61/2-inch-diameter percussion drills are used for 75% of all production drilling. The blastholes can be drilled at any angle, up or down, to depths up to 300 feet. These drills have improved blasting efficiency and have made possible the fragmentation of up to 3 Mmt of ore at one time. Similar drills are used at the Kiruna Mine of Luossavaara Kiirunavaara AB (LKAB) in Sweden, but some have been modified so that they can be operated by remote control. Load-haul-dump (LHD) vehicles are extensively used to move the ore from the face to the ore pass. Most of these vehicles have electric-wheel drive and bucket capacities of 5 to 8 cubic yards. At the MacLeod siderite mine in Ontario, Canada, a 10° 15,000-foot conveyor incline was driven to carry ore directly from the

lower levels of the mine to a sinter plant on the surface, and a parallel incline of the same length was driven for the use of mobile equipment.

LKAB has automated most of the ore loading and transport operations at Kiruna.8 The company even has a prototype LHD that can be operated remotely from a control room. After blasting, the ore and waste is mucked out with an LHD and hauled to the nearest ore pass. The ore is then loaded from the ore pass into an 18-car train powered by an electric locomotive, again operated by remote control. Each of the ore cars can hold 22 mt, for a total haul to the crusher of 400 mt. At Malmberget, LKAB's other underground mine, LHD's are also employed to get the ore to the ore passes.9 However, at the haulage level, the ore is loaded into 65-mt trucks for the 2-km trip to the underground crushing station. A new 120-mt truck made in Finland was to be delivered for evaluation in late 1991. The mines of Arbed SA in eastern France have also been extensively mechanized with LHD vehicles, gathering-arm loaders, and trucks.

Beneficiation.—Crude iron ore is beneficiated to raise its iron content, reduce the content of impurities, or to improve its physical structure. Beneficiation processes include simple crushing, screening, drying, washing, as well as complex methods that separate ore minerals from gangue using differences in physical or chemical properties. The type of beneficiation required depends on the mineralogical and physical characteristics of the crude ore and the type of ore product desired.

Almost all iron ore mined today is beneficiated before shipment. Consumer requirements are strict, not only for content of iron, silica, phosphorus, alkali, and other constituents but also for particle size, compressive strength, reducibility, and other properties. High-grade ores are beneficiated to obtain closely sized products or to reduce content of minor but objectionable impurities such as phosphorus and alkali. Low-grade ores are beneficiated primarily to obtain concentrates that can compete in the market with high-grade natural ores.

In March 1982, a centralized computer system was commissioned at Reserve Mining Co.'s taconite concentrator to monitor and control a variety of processing operations. ¹⁰ This system was upgraded after Cyprus Northshore took over the operation

in 1989. The process controls are designed to maintain the iron content of final concentrate to within +0.25%.

During the Vietnam conflict, soft hematite ores of the Mesabi Range were beneficiated by gravity methods, using screw-type or spiral classifiers and heavymedium separators. Beneficiation of these ores vielded more than 15 Mmt of concentrates in 1973, but by 1990, production had declined to less than 1 Mmt because of a shift in demand to less expensive material with a higher iron content. All but one of the larger hematite concentrators have since been dismantled. The hematite concentrates currently being marketed contain 52% to 57% iron, but are not normally produced or shipped during the winter months. The fines fraction has to be agglomerated by sintering before being charged to the blast furnace. In contrast, pellets made from taconite contain 62% to 65% iron are produced and shipped by rail year-round. All of the pellets, except for small quantities of fines generated during transport, are charged directly to the furnace.

Fine grinding is necessary to produce acceptable concentrates from crude ores of the taconite type, to prepare ore for flotation, and to prepare concentrates for pelletizing. In most ores mined in Michigan and Minnesota, mineral particles are so small that adequate separations cannot be made unless the ore is ground to about 90% minus-325 mesh. Ore at one mine is ground to 95% minus-500 mesh. Most of the taconite concentrators use steel rods or balls for grinding, but several plants also use autogenous or semiautogenous mills in which particles of crude ore constitute all or most of the grinding media. Less grinding is needed to concentrate the low-grade hematite ores of eastern Canada, as the ore particles are liberated at about minus-28 mesh, but fine grinding is necessary for concentrates that are further processed to pellets. In Missouri, relatively high-grade magnetite ore is finely ground to permit removal of mineral impurities such as apatite, feldspar, and sulfides by flotation as well as to prepare the concentrate for pelletizing.

Low-grade magnetite ores such as those in the Lake Superior District and in some districts of Norway and Sweden are concentrated (after grinding) by low-intensity magnetic separators. The concentrates may be beneficiated further by ultrafine (minus-150 mesh/0.004-inch) screening, as in most Minnesota plants, or by

flotation, which is used at three plants in the Lake Superior District as well as in Norway and Sweden.

Low-grade hematite ores may be concentrated by gravity methods, as in eastern Canada where Humphreys spirals are used. Others are concentrated by high-intensity magnetic separators, as at the Caue and Conceicao plants in Brazil. Still others are concentrated by flotation, as at the Tilden Mine in Michigan and the Germano Mine in Brazil. Several processes may be used in one plant if the ore is mineralogically complex.

At the pelletizing plants, improved flotation techniques are being used to lower both phosphorus and silica levels in the concentrate. Considerable success has been achieved in lowering silica levels with the aid of either amines or diamines and similar cationic flotation reagents. Recent advances in the flotation of apatite [Ca₅(PO₄)₃(F,OH,Cl)] should help reduce the problem with phosphorus that has been plaguing steelmakers for more than a century. Control of phosphorus and arsenic is critical in the making of quality steels. The ideal situation is to reduce the phosphorus to as low a level as possible in the ore, coke, and other raw materials. As the phosphorus content of the steel increases, the steel becomes stronger but loses its ductility and drawability (i.e., formability). For this reason, the phosphorus level in deepdrawing sheet and strip normally cannot exceed 0.01%, or in rare instances 0.02%. The phosphorus problem cannot be entirely solved at the concentrator because significant amounts of the element are also present in the coke, some of the fluxes, and recycled slag. Arsenic acts similarly to phosphorus, although less strongly, and cannot be refined out of the steel bath. Both phosphorus and arsenic are completely reduced in the blast furnace and report to the iron.

In taconite ores from the Lake Superior District, about one-half of the phosphorus occurs as finely disseminated grains of apatite and can be partially removed by careful flotation. The rest of the phosphorus apparently substitutes for oxygen in the hematite or magnetite, making its removal by physical separation nearly impossible. Amphoteric flotation reagents, which have both anionic and cationic collector groups, can reduce the phosphorus content of the final concentrate by as much as 40%. Long-chain polyphosphate dispersants can improve the rejection of apatite during the desliming stage.

The situation is much more serious for oolitic iron ores. Recent studies using cathodoluminescence microscopy have revealed that the phosphorus in these types of ores occurs not only as collophane grains¹¹ and granular apatite, but also as phosphate-rich fossil fragments that have been partially replaced by hematite. 12 The ores near Birmingham, AL, typify these high-phosphorus oolitic and fossiliferous ores. The Lorraine minette ores of Belgium, France, and Luxembourg are a second example. The marketability of these two types of ore has fallen sharply over the past 20 years because of tightened specifications for phosphorus. In some of the Birmingham ores, hematite ooids are cemented together by a hematite matrix that contains disseminated, micron-size grains of carbonate-fluorapatite. Separation of these minute apatite grains would be extremely costly using existing beneficiation technology.

The Pea Ridge Iron Ore Co. of Missouri has had considerable success in lowering the phosphorus content of the magnetite concentrate it uses as pellet feed. In 1979, pellets from Pea Ridge averaged 0.080% P. At that time, the ore feeding the concentrator typically ran 0.60% P. Since then, the company has been able to gradually reduce the pellet phosphorus content to 0.020%.¹³ The improved liberation of phosphate minerals was achieved by installing additional magnetic separators between 1981 and 1985 and by switching over to a larger and more sophisticated flotation circuit. The new phosphate flotation circuit became fully operational in September 1988. Amine, fatty-acid, and fatty-alcohol collectors all were tried and eventually discarded. A suite of proprietary collectors developed specifically for Pea Ridge concentrates was being used in 1990. Preliminary tests suggested that the pellet phosphorus content could be reduced even further to 0.015% by finer grinding.

Since 1982, flotation plants have been built in Brazil, Mexico, and Norway to produce special high-grade concentrates of magnetite or hematite for direct reduction. WHIMS equipment has also been installed at beneficiating plants in several countries, including Mexico, Norway, and Spain. The process is used at one Spanish plant for concentration of siderite. A WHIMS unit has been installed at a hematite concentrator in eastern Canada. The WHIMS process is not used commercially in the United States, although a commercial-scale unit was installed at the

Sunrise Mine in Wyoming in 1976. The Wyoming operation ceased production in 1980.

U.S. Bureau of Mines research has contributed significantly to flotation of low-grade hematite ores, especially the very fine grained or "earthy" type. A method of selective flocculation and desliming of pulp, prior to flotation, was developed jointly with the Cleveland-Cliffs Iron Co. ¹⁴ and led to commercial development of the Tilden Mine in 1974 and its expansion 5 years later. The process, or variations of it, has been used in other countries (e.g., at the Sawawin Mine and pilot plant in Saudi Arabia).

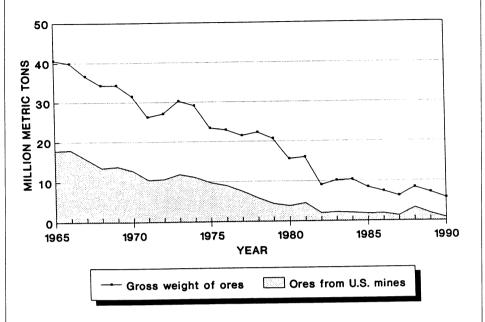

Agglomeration.—Iron ores consisting of particles less than ¼ inch in size are usually agglomerated by sintering or pelletizing before being charged to the blast furnace. This is done primarily to improve permeability of the furnace burden and to prevent loss of fines up the stack. Fine concentrates are also agglomerated to facilitate transportation and handling.

Ore particles ranging in size between 1/4 inch and 100 mesh are usually sintered at the blast furnace site. Finer material such as taconite concentrates is pelletized at or near the mine site. Owing to the increased use of pellets in the United States, sinter production has been declining over the past 25 years, and many sinter plants have been closed. (See figure 4.) Consumption of sinter in 1990 was 12.23 Mmt, about 73% of active domestic sinter plant production capacity. No new sinter plants have been built in the United States since 1976, but several have been completely refurbished. The U.S. industry had only 11 operable plants in 1991. The decline in U.S. sintering operations contrasts with developments abroad. In Japan and Western Europe, sinter is still the principal feed to blast furnaces. In India, the sintering capacity of the Steel Authority of India Ltd. (SAIL) has grown almost sixfold since 1965 to 13.2 Mmt of sinter per year. 15

Sinter is made by spreading a mixture of ore fines and coke breeze on a moving horizontal grate, igniting the surface of the bed by a gas or oil burner, and drawing combustion downward by suction. The temperature of combustion, which ranges from about 1,204° to 1,427° C (2,200° to 2,600° F), causes the ore particles to fuse together. Self-fluxing sinter is made by adding powders of lime, limestone, and/or dolomite to the mix. Iron-bearing materials such as flue dust, mill scale, and

FIGURE 4

CONSUMPTION OF IRON ORE IN U.S. SINTERING PLANTS

steel-furnace slag recovered from metallurgical plants are commonly recirculated to the blast furnace through sintering plants. If many types of ore and recirculated materials are used, careful blending is required; this is usually accomplished by bedding piles, with computer control of ingredients.

Pellets are made by mixing a small quantity of binder (usually bentonite, but sometimes hydrated lime at foreign operations) with finely ground concentrate and balling the mixture in rotating drums or saucerlike disks. The moisture content of the mix must be closely controlled and is usually between 9% and 10%. The "green pellets," usually \(\frac{5}{8} \) inch to \(\frac{1}{4} \) inch in diameter, are then hardened in furnaces fired by natural gas, fuel oil, or pulverized coal at about 1,315° C (2,400° F). Finished pellets usually contain 60% to 66% iron, have relatively high compressive strength (400 pounds or more), and withstand the abrasion of handling and transport better than sinter.

Pellets used in U.S. furnaces contain about 63% iron and, in 1990, made up about 81% of all iron ore and agglomerates consumed in the United States. U.S. production of pellets in 1990 was 54.82 Mmt, about 84% of installed capacity at the end of the year. Pellets accounted for 98% of

all usable ore produced in the United States. Production of pellets for the entire world was reported to be 222.5 Mmt, also about 84% of installed capacity.

Consumption of bentonite in production of pellets at the Tilden plant in Michigan has been sharply reduced by using a different variety of bentonite having greater capacity to absorb water. Consumption per ton of concentrates was 3.6 kg (8 pounds) in 1983 compared with 11 kg (24 pounds) in 1975. In addition to the cost savings for bentonite, alkali content of the pellets was also reduced. ¹⁶

The sharp price increases for natural gas and fuel oil, which occurred in 1973 and 1979. led to commercial-scale tests of the suitability of pulverized coal as a substitute fuel for pelletizing plants. The tests indicated that grate-kiln systems could run on bituminous coal from eastern Kentucky without major modifications or serious operating problems. Western subbituminous coals, though, were not satisfactory and caused kiln ringing problems. The coal should have a high ash-softening temperature (greater than 1,480° C or 2,700° F). The testing was accelerated after the Northern Natural Gas Co., the principal supplier of natural gas to Minnesota, began curtailing supplies to the pelletizing plants in 1976. By 1981, coal was

the principal fuel at Minntac and Eveleth Mines. The expected gas shortage forecast in 1976 for the mid-1980's did not materialize, and one plant switched back to gas in 1982. A number of research projects were launched at the peak of the second energy crisis in 1980. The U.S. Bureau of Mines, in cooperation with the U.S. Department of Energy (DOE) and a large group of companies that included all major pellet producers, studied the feasibility of producing low-heat-content coal gas [150 British thermal units (Btu)/cubic foot] for pelletizing fuel, using Western subbituminous and lignite coals. 17 The research indicated that the low-Btu coal gas would be suitable for indurating iron ore pellets, but would require some furnace modifications. Between 1979 and 1983, most pelletizing plants in the Lake Superior District installed heat-recuperation systems that reduced fuel requirements by 25% to 40%. Today, most of the pelletizing plants in the district are still dependent on natural gas, but some are able to switch between gas, pulverized coal, or fuel oil, depending upon energy prices. The Minntac plant is also set up to burn dried wood fibers. 18

Fluxed Pellets.—The Pea Ridge Iron Ore Co. first began producing "olivine pellets" at its complex in Missouri in 1983. This type of pellet, in which magnesian olivine is substituted for silica, was developed 2 years earlier in Sweden after a decade of research by LKAB and others. Subsequent tests in European blast furnaces indicated reduced coke rates and increased pig iron productivity at some furnaces, while others experienced no change and one reported an increase in coke rates. The results were sufficiently favorable, however, to cause LKAB, the principal Swedish producer, to convert all of its standard lines to the production of olivine pellets. The Pea Ridge pellets were extensively tested in National Steel's blast furnaces at Granite City, IL, from 1983 to 1985, and served as standard feed for the Illinois steelworks until 1991.19 The addition of olivine to concentrates in the Lake Superior District is not feasible because their silica contents are much higher than that of the Pea Ridge concentrates. Instead, a number of producers have begun adding dolomite with the bentonite to obtain the required magnesia units. In 1984, fluxed pellet production began in earnest when Hibbing Taconite shipped 200,000 mt of fluxed material to Dofasco's Hamilton works in Ontario for blast furnace tests.20

Since 1987, many blast furnace operators in North America have switched from the traditional standard "acid" pellet to some variation of the fluxed pellet. The flux-a mixture of limestone and dolomite—is ground at the concentrator to between minus-325 mesh and minus-500 mesh, slurried, and blended with the slurry of iron oxide concentrate in a mixing tank. The slurry mix is then filtered and sent to the balling drum for rolling into green balls, which are later fired at 1,315° C (2,400° F) in the furnace. The fluxed pellet is more expensive to produce, but leads to significant savings at the blast furnace. The switchover to a fluxed pellet improves productivity by decreasing smelting time, leading to reduced coke consumption. Experiments were underway to determine the limits of possible savings. Additional coke savings in the blast furnace are possible with fluxed pellets because calcination of the fluxstone is completed beforehand in the pelletizing furnace. Also, the temperature of the tuyere zone can now be raised because the fluxed pellet does not soften as readily as the acid pellet. (See figure 5.) As a result, the fluxed burden offers less resistance to wind flow, allowing the blast volume to be raised. (See figure 6.)

The kinetics of fluxed pellet reduction are poorly understood. At 1,100° C (2,010° F), the silica and flux inside the

pellet react with one another to form a high-melting calcium-magnesium-silicate slag. This situation is quite different from an acid pellet where the silica is free to react with the wustite (FeO) to form a significantly lower melting favalite slag. At temperatures between 1,100° C and 1,400° C (2,010° F and 2,550° F), the flux keeps the metallic iron disseminated throughout the pellet and prevents formation of an iron shell (i.e., rind) around the pellet. An acid pellet, in contrast, readily forms an iron shell at 1,150° C (2,100° F), making it more difficult for carbon monoxide to permeate into the unreduced core of the pellet. Because of these differences, an acid pellet will undergo a meltdown between 1.300° C (2,370° F) and 1,450° C (2,640° F). A fluxed pellet, on the other hand, retains its spherical shape at 1,300° C and uniformly liquifies suddenly at 1,400° C.

Organic Binders.—The North American iron ore industry has been looking for ways to reduce the silica, alumina, and alkali contents of its pellets. The substitution of an organic binder for the bentonite used in conventional pelletizing offers one way to achieve this reduction. The typical organic binder being marketed is more expensive than bentonite, but can improve the reducibility of the pellet, cutting coke usage at the blast furnace.

FIGURE 5

MELTING CHARACTERISTICS UNDER LOAD OF FLUXED PELLETS VS. STANDARD (ACID) PELLETS

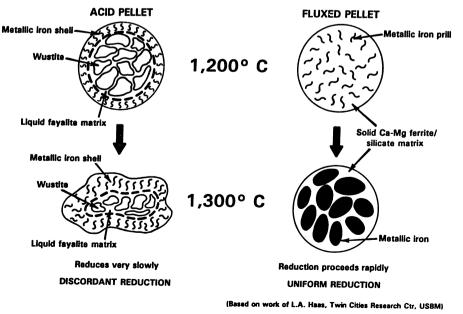

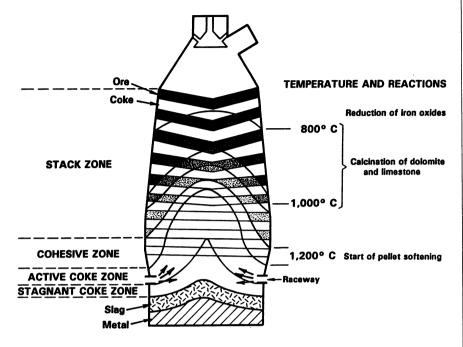

FIGURE 6

BEHAVIOR OF FLUXED PELLETS IN THE BLAST FURNACE

Another advantage of an organic binder is that most of the binder burns off during the firing of the pellet, leaving a pellet with a lower alumino-silicate content, a higher iron content, and reduced contamination. Several commercially available organic binders are variants of carboxymethyl cellulose (CMC), a polysaccharide derived from wood pulp or cotton. Others are derived from starches. Commercial binders are sold under a variety of brand names or trademarks, such as Oriox and Peridur.

One of the first organic binders to be considered commercially viable was a water-soluble cellulose derivative called Peridur. The binder was tested by CVRD in Brazil from 1976 to 1982 with favorable results.21 Plant tests were also conducted concurrently by LKAB in Sweden at Malmberget and Svappavaara. The manufacturer claimed that the cellulosebased binder was equal to bentonite in handling and binding properties, increased pellet reducibility, and permitted savings of up to 14 kg (30 pounds) of blast furnace coke per short ton of hot metal produced. As little as 0.45 kg (1 pound) of the binder was required per ton of concentrates, although its cost was considerably higher than bentonite. Improved versions of this binder are still being tested by several U.S. pellet producers.

The U.S. Bureau of Mines has evaluated more than 30 different organic binders from commercial suppliers. 22 The binders came from six groups: celluloses, dairy wastes, natural gums, starches, starch acrylic copolymers, and wood-related products. Pellets made with natural gum (guar) had the best green pellet physical properties. CMC and gelled starch were less effective. However, after firing, pellets made with guar gum tended to have marginal compressive strengths. The most promising binder appears to be gelled starch. Pellets made with gelled starch have metallurgical properties that are superior to those made with bentonite. At the same time, the price of the starch is lower than that of CMC. The Bureau has also explored the possibility of using pulpmill and papermill sludges as a binder.23 The sludges have little if any dollar value, but in bench tests about 10 times as much sludge had to be used to produce the results obtained with pure organic gelled polymers. Various mixes of secondary paper sludge and municipal sewage sludge wastes were tried and also showed promise.

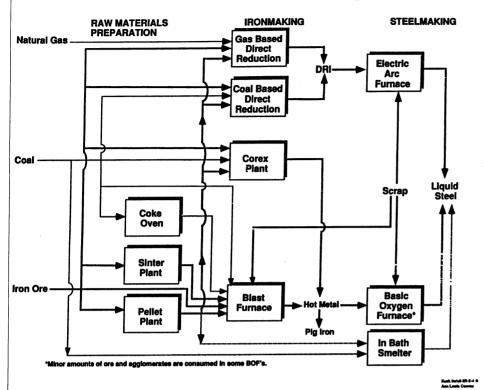

Smelting.—Companies were evaluating a number of ironmaking and steelmaking processes as an alternative to the traditional coke oven-blast furnace route. (See figure

7.) Two factors served as a driving force for the research: the increasing competitiveness of the world steel market, and new Federal and State environmental regulations tightening air emission and water discharge requirements at steelworks and iron mines. (See Legislation and Government Programs.) In 1990, after years of debate, Congress passed one of the more significant and comprehensive pieces of environmental legislation ever enacted. The Clean Air Act Amendments (Public Law 101-549) broke new ground by establishing specific programs to reduce pollutants that cause acid rain and ozone depletion. The U.S. Environmental Protection Agency (EPA) is developing a host of new regulatory standards for heavy industry. The new standards will significantly impact a variety of facilities in the iron and steel sector, including coke oven batteries, ironmaking and steelmaking furnaces, sintering plants, and taconite pelletizing plants. Some of these facilities have been in operation for more than 40 years and are fast approaching obsolescence. Because of the enormous financial expenditures required to modernize existing coke oven batteries and sintering plants, steelmakers were actively looking for an economical process that would completely bypass cokemaking. Two of the more promising ironmaking processes being investigated were the Corex process and the HIsmelt process. Both processes can use noncoking grades of bituminous coal instead of coke. The AISI, in cooperation with DOE, has also launched a research program to develop an innovative direct steelmaking process. The goal of the long-range AISI program is to produce liquid steel from prereduced iron ore pellets in a closed system on a continuous basis.

Integrated steel mills operating blast furnaces were able to compete with electric arc furnace (EAF) operations because of (1) the introduction of fluxed pellets and other improvements in hot-metal practices, (2) economies of scale, and (3) growing demand for higher quality steels free of tramp elements. Integrated steelmakers continued to move toward their goal of 100% continuous casting, improving steel mill processing yields. At the same time, the adoption of continuous casting reduced the amount of "home" (internally generated) scrap available to both integrated and minimill operations. In 1990, home scrap constituted only 27% of the total scrap consumed by U.S. steel mills, down from 60% in 1970.

570 IRON ORE—1990

FIGURE 7 **DIFFERENT METHODS OF PRODUCING LIQUID IRON**

Over the past 5 years, domestic companies that make steel solely in electric arc furnaces have expanded their product line and have begun to move into the higher quality carbon steel market. Until recently, the high-quality end of the U.S. carbon steel market had been the exclusive domain of the integrated steel producers. The move into higher quality products has put the electric arc furnace operators in a quandary regarding feed material. These "minimills" are facing a shrinking supply of highquality "home" scrap because of the adoption of continuous casting by integrated steel producers. At the same time, scrap purchases contain increasing amounts of impurities as a result of the adoption of more sophisticated alloying techniques. The integrated steel producers are now generating significantly less high-quality home scrap than a decade ago.24 The minimill operators are now having to purchase increasing amounts of virgin iron units to dilute the impurities in their scrap

In the past, the required virgin iron units have come from two sources: direct-reduced iron (DRI), the bulk of which was

imported from Venezuela or Canada, and ingots of pig iron purchased from blast furnace operators. In 1990, a third option—the Corex process—became available to the "minimills," but only a few companies are willing to build a Corex plant in North America at the present time because of concern that the recession will deepen. Finely divided iron carbide could also be used, but work on a commercially viable version of the process is still at an early research stage. The iron carbide would be injected into the molten bath of the EAF through tuyeres or with a lance.

U.S. minimill operators are being forced to purchase increasing amounts of "new" (prompt industrial) scrap and "old" (obsolete) scrap, both of which frequently contain undesirable tramp elements. Copper, for example, commonly occurs in old scrap and can be a problem in the making of deep-drawing steels. To dilute these contaminants, minimill operators have begun buying increased tonnages of hot-briquetted iron (HBI) and other direct-reduced-iron products from offshore suppliers. HBI, an enhanced form of DRI recently developed for the merchant iron market and suitable

for ocean shipping, is made by continuously discharging hot DRI from a shaft furnace directly into a special briquetting machine. Nucor Corp. and Oregon Steel Mills Inc. were considering building a 500,000- to 750,000-mt/year HBI plant in Venezuela. Corporacion Venezolana de Guayana, the State-owned development company, would have an equity interest of up to 20% in the joint venture.

Iron Carbide.—Iron carbide (Fe₂C) may be a suitable alternative to DRI. CCI and North Star Steel Co. formed a joint venture in late 1990 to evaluate the feasibility of producing iron carbide on a commercial scale. North Star is the ninth largest steelmaker in the United States and potentially a major consumer of iron carbide. The Minneapolis-based company has miniplants in 7 States and can produce 2.4 Mmt/yr of raw steel in its 11 electric arc furnaces. Melting and casting operations are at Wilton, IA; Monroe, MI; St. Paul. MN; Youngstown, OH; Milton, PA; and Beaumont, TX. CCI is a major iron ore merchant and manages six iron mines in North America and Australia.

The joint venture will use technology licensed by Iron Carbide Holdings Inc. of Golden, CO. The iron carbide is produced from iron ore concentrates in a fluidized bed reactor.²⁵ The concentrates are reduced in the pressurized fluid bed at a temperature of about 600° C (1,100° F) using a mixture of hydrogen, methane, and carbon monoxide. The mixture of gases (i.e., the process gas) is produced on-site by reforming natural gas. Before being fed into the bed, the iron ore concentrates are preheated in a series of cyclones to a temperature of 700° C (1,300° F). Any magnetite in the concentrates is oxidized to hematite during the preheating. The preheated concentrates can now be fed into the pressurized bed through a lock hopper mechanism, while the process gas is introduced through tuyeres in the base of the fluid bed vessel. The reduction reaction is quite rapid and slightly endothermic. The carbide product is discharged from the fluid bed through a second lock hopper mechanism and is cooled in a process gas or inert atmosphere to prevent reoxidation of the hot carbide.

The bulk of the iron carbide would be sold to steelmakers with electric arc furnace operations. The new product would supplement premium-quality scrap and compete against imports of HBI from direct reduction plants in Venezuela and Asia. In

1990, electric furnace operations accounted for 37% of total U.S. raw steel production, but to date the facilities have not used large amounts of conventional iron ore pellets because of the resulting drop in productivity and higher electrical power consumption.

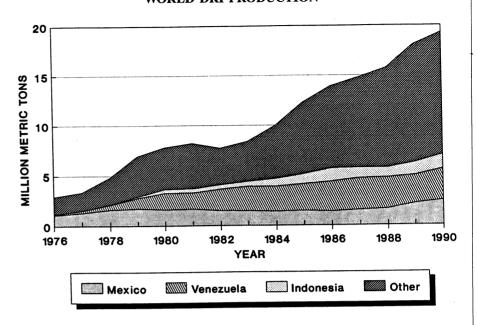

Direct-Reduction Processes.—Direct-reduction processes reduce iron oxides to metal, using gaseous or solid reductants at temperatures below the melting point of iron. The processes are attractive because they can be used to produce iron in relatively small quantities and thus avoid the expense of building and operating a full-size blast furnace. Direct-reduction plants have been built with production capacities as small as 20,000 metric tons per year (mt/yr), although most of those in operation today have capacities of 350,000 to 850,000 mt/yr.²⁶

World production of DRI has more than doubled since 1980 and is expected to exceed 18 Mmt in 1991. The growth potential is enormous because current production represents only about 2% of the total iron units consumed by the world steel industry.

The iron content of DRI is usually 2% to 6% less than that of pig iron because most direct-reduction processes do not remove silica, alumina, or other impurities from the ore. As a result, the chemical specifications for the lump ore and pellets used in a DRI plant are significantly tighter than the specifications for material going into the blast furnace. Silica, for example, is normally kept below 2%. U.S. blast furnace pellets, in contrast, have silica values ranging from 3.0% to 5.5%. When highgrade lump ore or pellets are used, a high quality DRI product can be made that contains 93% to 95% total iron. The percent of total iron present as metallic iron (i.e., the metallization) is somewhat adjustable, but is normally set at some constant value between 92% and 95% to ensure product uniformity. The carbon content can also be adjusted and typically ranges from 1.0% to 2.5%.

DRI is a suitable feed for steelmaking furnaces and can be used in combination with scrap or as a scrap substitute. Most DRI plants have been built in conjunction with electric steelworks of the "minimill" type; some are built for the merchant trade while others have been built at integrated steelworks. A few small plants, such as those using the Hoganaes process, use exceptionally high-grade ore mixed with coke

FIGURE 8
WORLD DRI PRODUCTION

to produce high-purity iron for special products such as iron powder. Most of the large conventional plants use ore containing 66% to 69% iron and are fueled by natural gas.

Direct-reduction plants are energyintensive, requiring 14 to 16 gigajoules per mt (12 to 14 million Btu per short ton) of product. The cost of fuel is therefore extremely important. Almost all of the newer DRI plants have been built in countries that have surplus, low-cost natural gas. These countries include Venezuela, other major members of the Organization of Petroleum Exporting Countries, Mexico, and the U.S.S.R. High prices for gas and strong competition from ferrous scrap forced one DRI plant in the United States and two in Western Europe to close toward the end of the 1979-82 oil crisis. Only one commercial plant is still operating in the United States-Georgetown Steel Corp. at Georgetown, SC. With higher prices for gas, interest in coal-based processes have increased; nine coal-based plants were built between 1980 and 1991, mostly in India and the Republic of South Africa.

More than 90% of world production capacity for DRI is based on the Midrex and HyL processes, originally developed by the Midland-Ross Corp. of the United States and Hojalata y Lamina S.A. of Mexico,

respectively. Both processes use carbon monoxide and hydrogen as reductants, obtained by reforming natural gas, and can use either lump ore or pellets as feed. The fluidized iron ore reduction (FIOR) process, developed by Esso Research and Engineering Co., is also gas-based but reduces iron ore fines in a fluidized bed. The final product is briquetted. The only commercial FIOR plant is at Matanzas, Venezuela. It started up in 1976, but did not attain full production until several years later. The FIOR plant is currently operating near its rated capacity of 400,000 mt/yr.

The SL/RN²⁷ process uses coal or coke as a reductant. Since 1969, a total of eight plants based on SL/RN technology have been built in Brazil, India, New Zealand, Peru, and the Republic of South Africa. All of the plants except for the one in New Zealand are currently operating. A 300,000-mt/yr unit is also under construction at Geelong, Australia. The newer SL/RN plants were built by Lurgi Chemie und Huttentechnik GmbH of Germany, but the company's designs were based on processes originally developed by Stelco, Lurgi, and two U.S. companies that were restructured during the 1980's-Republic Steel Corp. and National Lead Corp. The name of the process comes from the first letter of each of the four company names.

The ACCAR²⁸ process, which was developed by Allis-Chalmers Corp. and is now marketed by Boliden-Allis, is also coal-based. The only plant using this process came on-line at Keonjhar, India, in 1983. The DRC process, developed by Direct Reduction Corp., is similar to the SL/RN process. The only DRC plant in existence is at Germiston in the Republic of South Africa. The single 80,000-mt/yr kiln unit, owned by Scaw Metals Ltd., was completed in 1983. A second unit of identical size was added in 1989. Krupp Stahl AG is also actively promoting its CODIR process. One CODIR plant has been operating at Benoni in the Republic of South Africa since 1973, and a second is under construction at Bhandara, India. The South African plant was originally owned by Dunswart Iron & Steel Works (Pty.) Ltd., but was acquired by the Iscor Group in 1983. The entire annual production of 75,000 to 115,000 mt has been going to Iscor Ltd.'s Vanderbijlpark steelworks. Although only a limited number of coal-based DRI plants have been built to date, recent advances have been made in the development of rotary hearth furnaces that use pulverized coal and iron ore fines. The possibility of an advanced coal-based DRI plant being constructed in North America sometime in the next 20 years cannot be ruled out.

The FASTMET Process, being developed by MIdrex, could conceivably fill this niche.²⁹ In this process, iron ore concentrate, pulverized coal, and a binder are mixed together and pelletized. After drying, the pellets are spread on a rotating hearth in an even layer, one to two pellets deep. As the hearth rotates, the pellets are heated to about 1,300° C (2,370° F) and the iron oxide is reduced by the coal to metallic iron. The hearth burners would most likely run on natural gas. The conversion takes about 8 to 20 minutes, compared with 4 to 8 hours for other processes. The shorter residence time is possible because of the relatively high furnace temperature and the fact that the carbon is contained within the pellet and in intimate contact with the iron oxide. The hot DRI pellets can be discharged into refractory-lined transfer cans and taken directly to an adjoining EAF. The FASTMET process has two additional advantages. First, iron ore fines or concentrates are used instead of higher priced pellets or lump ore. Second, the capital costs appear to be significantly lower than those of competing ironmaking processes.

Gas-based direct-reduction technology has been used to produce iron on a

commercial basis since 1969, but there has been a tremendous scale-up in the size of the reactor vessels since then. Gas-based HBI modules are now being built with capacities on the order of 1.2 Mmt/yr.³⁰ The first of these megaton modules went into a renovated plant owned by Minerales Ordaz CA (MINORCA) in Venezuela. The newly refurbished and modified facility was scheduled to produce 810,000 mt of HBI in 1991.³¹ It has a single shaft furnace designed to use 100% lump ore, 100% oxide pellets, or any combination of the two. The facility is near the ore docks at Puerto Ordaz and was reactivated in early 1990.

Design improvements have been made to DRI plants so that iron ores with high sulfur contents can be utilized. The adoption of steam reforming technology has eliminated the need for water quenching and the reheating of the reformed gas prior to reduction. Improvements in reformer design have eliminated the need for a CO, removal system, reformed gas quenching and reheating, a steam generation system, and auxiliary boilers. In 1984, the first HBI plant was put into operation on Labuan Island in Malaysia. By the end of 1990, there were four additional HBI modules operating: two in India and two in Venezuela. These five plants are expected to have a combined HBI output of 2.3 Mmt in 1991.

Plasma-Arc Technologies.—Plasma-arc reduction processes differ from those previously mentioned in that they operate at higher temperatures, require relatively large quantities of electrical energy, and produce molten iron rather than sponge iron. Energy requirements are on the order of 21 gigajoules/mt (18 million Btu/short ton) of product. Electrical energy requirements are about 1,000 kilowatt hours per ton of product, in addition to the energy derived from fossil fuels used as a source of reductant. On the other hand, plasmaarc processes permit wide flexibility in choice of fuel and type of iron ore feed, and their product is similar to iron produced in a blast furnace. If these advantages can offset the relatively high cost of energy, plasma-arc smelting may be more economically feasible in some regions of the world than conventional blast furnace practice.

Several plasma processes have made it to the pilot plant stage, but none are commercially viable at this time. One of the more promising has been the Plasmasmelt process, which was developed by SKF Stal at its laboratory in Hofors, Sweden. In the Plasmasmelt process, prereduced iron ore fines or micropellets are injected together with coal and slag formers into the bottom of a coke-filled shaft. The prereduced material is then smelted using energy from plasma torches mounted above the hearth. In the late 1970's, SKF set up a 10-mt/d pilot plant at Hofors that showed that the process would indeed work. However, several technical problems have not been solved, and the economics of the process are currently unattractive. SKF has also developed a second, somewhat similar, direct-reduction process called Plasmared. This second process combines features of existing commercial DRI processes with those of the Plasmasmelt process. A Plasmared demonstration plant was built at Hofors in 1981 and was able to produce DRI at the rate of about 5,000 mt/yr.

While this work was going on in Sweden, Pickands Mather, Westinghouse Electric Corp., and Minnesota Power formed a joint venture to evaluate various plasma smelting technologies. The group was looking for a way to produce molten iron from taconite concentrates using coal as a reductant. This research program later became known as the Mesabi Plasma Metal Project. A pilot plant was built at Hibbing, MN, that consisted of a reactor vessel, a gas recycling system, a recuperation system, and a plasma generator. The plasma system included a 1.5-megawatt (MW) plasma torch fabricated by Westinghouse. The next step was to have been the construction of a demonstration plant capable of producing 100,000 mt of iron per year. The project was shelved in 1987 after Westinghouse Electric Co. shifted its corporate interests and CCI acquired Pickands-Mather. In 1985, Fluor Corp. built a unique 300,000-mt/yr gasbased reduction plant for Union Steel Corp. (now Usko Ltd.) at Vereeniging in the Republic of South Africa. The design incorporated novel plasma technology developed by Chemische Werk Huls of Germany for the chemical industry. The plant was supposed to use coal gas from the neighboring Sasol synthetic fuels plant, but encountered technical problems and closed within 3 years.

For further descriptions of direct-reduction processes and their economic aspects, the reader should refer to selected publications of the Metals Society³² and AIME.³³

IRON ORE—1990 573

The Corex Process.—In 1985, Iscor Ltd. began building the first commercial-scale plant employing the Corex process at its Pretoria steelworks in the Republic of South Africa. The Corex plant was commissioned on a trial basis in August 1988, but required several modifications before it became fully operational in 1990.

The Pretoria plant is the first facility in the world to produce molten iron on an industrial basis by charging coal directly into the smelting furnace. The plant produced 270,000 mt of liquid steel during its first full year of operation. The original process was developed jointly by Korf Engineering of Germany and Voest-Alpine AG of Austria. Voest-Alpine Industrieanlagenbau was the principal contractor for Iscor. A key feature of the Corex process is that it uses untreated raw coal in place of coke. Coking coal has become increasingly scarce in the Republic of South Africa, but the country has large reserves of coal of lower rank.

From an environmental standpoint, a Corex plant has several advantages over the conventional blast furnace. First, coke ovens are not needed, eliminating all the problems associated with the generation of coal tar byproducts such as benzene, phenol, and amines. Second, the dust problems associated with blast furnaces are eliminated because the off-gas is used as fuel. When the off-gas emerges from the smelting vessel, it is passed first through a scrubbing system and then an electrostatic precipitator to remove furnace dust. The off-gas could be flared in theory, but the economic viability of the operation would seriously deteriorate because of the loss of gas credits.

The Corex plant is the only practical alternative to the blast furnace at the present time. However, it has one key disadvantage for integrated steel producers. The size of the plant is currently restricted to less than 450,000 mt/yr, compared with 2.8 to 3.5 Mmt/yr for a new blast furnace. A series of modules meeting the needs of a large, integrated steelworks would probably be too expensive to operate. Despite this key disadvantage, Geneva Steel and some other integrated producers are still interested in this technology.

The Corex plant also has some appeal for minimill operators because they have difficulty producing high-quality drawing steel owing to excessive absorption of monatomic nitrogen. The arc of the electric furnace dissociates diatomic nitrogen molecules in the furnace atmosphere. Because of its relatively large radius, the diatomic nitrogen molecule is not readily absorbed into the hot metal. The monatomic nitrogen daughter, on the other hand, is one-half the size of its diatomic parent and is readily dissolved by the hot metal. The nitrogen problem would be avoided in the Corex process.

The details of the Corex process are given in the most recent edition of "The Making, Shaping and Treating of Steel," a reference used worldwide by steelmakers.³⁴ The reactions in the process are similar to those in the conventional blast furnace, but take place in two separate chambers. (See figure 9.) One chamber contains a fluidized bed where coal is gasified and prereduced iron is melted. The other is a vertical shaft furnace where ore is reduced by gas from the fluidized bed. Lump ore, sinter, or pellets can be used to provide the iron units. The direct charging

of raw coal lowers hot-metal costs and bypasses the environmental pollution problems associated with coke ovens. The Corex process produces hot metal with carbon and silicon levels approaching blast furnace standards. The sulfur content of the metal, though, is significantly higher because of the substitution of raw coal for coke.

Because of the success of the South African operation, several companies are considering building similar units in North America. Some of the sites suggested include Cleveland, OH; Duluth, MN; Norfolk, VA; and Provo, UT.

Direct Ironmaking Processes.— HIsmelt Corp. Pty. Ltd., a joint venture of CRA Ltd. and Midrex Corp., recently announced plans to build a \$77.5 million research and development facility at Kwinana in Western Australia. The heart

FIGURE 9 THE COREX PROCESS Iron ore Limestone/ Dolomite Export gas Top gas Reducing gas Cooling gas Raw gas 1. Melter gasifier 2. Reduction shaft furnace Coal feed system. Oxygen 4. Hot cyclone 5. Cooling gas scrubber 6. Top gas scrubber Hot metal/Slag

nn Lewis-Cenves3-18-92

of the new complex will be a 100,000-mt/yr prototype smelter, which is scheduled to start up in early 1993. If the full-scale pilot plant tests at Kwinana are successful, several U.S. companies may follow suite. The HIsmelt process is a single-stage process that involves the direct smelting of iron ore in a closed molten bath reactor. Iron ore fines and coal are injected directly into the molten bath.

Direct Steelmaking.—In the spring of 1990, the AISI, in cooperation with DOE, began a research program to develop a new smelting and refining process for making steel. The goal of the program is to produce a liquid steel product from prereduced iron ore pellets on a continuous basis in a closed system of coupled process vessels. This direct steelmaking process contrasts sharply with current practice, where steel is made in batches using vessels, some of which are largely open to the atmosphere. If successful, the new process could simplify steelmaking, increase productivity, reduce energy consumption, and improve operational flexibility. The 4-year research program is expected to cost almost \$50 million, with DOE providing 77% of the funds and AISI the balance.

As the process is currently envisioned, coal and pellets partially prereduced to wustite (FeO) are charged directly into a vessel that contains a bath of molten iron. The mixture in the vessel is injected with oxygen for combustion, and the resulting heat facilitates the conversion of the ore to high-carbon liquid steel via smelting. The burning accomplished by injection of oxygen, also called postcombustion, assists in maintaining a self-sustaining heat balance. To prepare for production of finished product, further treatment with oxygen reduces the carbon content of the melt to levels currently acceptable to conventional ladle-metallurgy facilities. The heat from postcombustion of the carbon monoxide is needed to offset the heat consumed by smelting and system heat losses. The direct addition of coal eliminates the need for metallurgical coke produced from coke ovens in the current ore-based production flowsheet utilizing the blast furnace.

A large part of the research is now being carried out at a pilot plant near Pittsburgh, PA. The heart of the plant is an in-bath smelter, which became operational in June 1990. The smelting vessel can produce up to 120 short tons of iron per day from a variety of feed materials, including different types of prereduced iron ore, iron

ore pellets, direct-reduced iron, and limited amounts of scrap. The 15-short ton vessel is also designed for coal injection and oxygen blowing. Special equipment has been incorporated so that postcombustion of the carbon monoxide and other gases generated during smelting can be regulated to varying degrees. Initial tests have involved anthracite and wustite pellets.

Operating Factors

Transportation of iron ore on the U.S. Great Lakes has changed considerably since 1971, when the first self-unloading "super-carrier," capable of carrying 45,000 mt of iron ore, was placed in service. Since then, 12 similar vessels have been built, each about 300 m (1,000 feet) long and capable of carrying about 60,000 mt of iron ore pellets. Each of these carriers replaced about four older vessels and can deliver about 2.5 Mmt of ore to lower lake ports during an 8-month shipping season. The last of this group of ships was completed in 1981.35 While these vessels were being built, a similar number of older ships were lengthened to increase their carrying capacity and were also fitted with selfunloading equipment. By the spring of 1991, all but 2 of the 58 bulk carriers in the U.S.-flag fleet were self-unloaders. The average cargo capacity of the lake vessels has thus increased since 1971, while the total number of vessels has been reduced by more than 60%.

To accommodate the "1,000 footers," new loading facilities and materials handling systems were built at four of the seven upper lake ports, the last of which was completed in 1983, and three new receiving terminals were completed on Lake Erie. The self-unloading vessels have all but eliminated the use of Hulett clamshell unloaders at lower lake ports. The "1,000 footers" have unloading capacities of up to 10,000 mt/hr, while loading capacities at upper lake ports are of similar capacity. Details on individual port facilities are given in Greenwood's Guide to Great Lakes Shipping. 36

Cargo capacities of vessels traveling the St. Lawrence Seaway between Montreal and Lake Erie are still limited to about 26,000 mt. On the north shore of Lake Erie, Stelco Inc., which has equity in several U.S. taconite mines, completed an unloading facility in 1979 that can accommodate 1,000-foot carriers. The Nanticoke facility can handle up to 6,000 mt of pellets per hour and has a stockpiling capacity of 860,000 mt of pellets and 1.06 Mmt of coal.³⁷

U.S. coastal ports are still limited to incoming cargoes of 65,000 mt or less. Hunterston, Rotterdam, Taranto, and several other ports in Western Europe can now accommodate iron ore cargoes of 150,000 to 300,000 mt. The Ertsoverslagbedrijf Europoort terminal west of Rotterdam currently holds the world record for the largest single cargo of iron ore ever unloaded. On August 22, 1989, 356,541 mt of Carajas sinter feed and natural pellet ore was delivered to the terminal by the world's largest ore carrier, the 365,000-deadweightton (dwt) Berge Stahl. The Berge Stahl and the Docefjord, another vessel capable of carrying more than 300,000 mt of ore, were built in 1986, primarily for trade between Brazil and Japan. In Japan, cargoes of 200,000 to 260,000 mt can be accommodated at Fukuyama, Kakogawa, Keihin, and Oita. Similar size cargoes are also routinely delivered to the island of Mindanao in the Philippines for sintering. The 351-m/long main berth of the Philippine Sinter Corp. has a depth of 23 m and can handle all but the very largest vessels that load at Ponta da Madeira. The three major loading ports in Western Australia-Dampier, Port Hedland, and Port Walcotthave all been modernized and had their berths deepened to permit loading of ore carriers of the 250,000-dwt class.

Two major pipelines for transport of iron ore slurries were completed in northern Mexico in 1983, connecting the La Perla and Hercules Mines with a pelletizing plant in Monclova. An 8-inch. 87-km line from La Perla is connected to a 14-inch, 295-km line that runs from the Hercules Mine to Monclova. The pipeline system can transport up to 4.5 Mmt of iron ore concentrates per year. A second system is operating in the Pacific Cordillera of Mexico. Two parallel lines transport concentrates 45 km from the Pena Colorada Mine in the mountains of northwestern Colima down to a pelletizing plant on the coast near Manzanillo. The 900-m drop in elevation permits the lines to be gravity operated. Major pipelines have also been built in Brazil and India since 1977, and others are operating in Argentina, Australia, New Zealand, and Peru.

ANNUAL REVIEW

Legislation and Government Programs

The Clean Air Act Amendments of 1990 were signed into law by the President on

November 15. The new law (Public Law 101-549) updates Federal air pollution standards for the first time since 1977 and is one of the more significant pieces of environmental legislation enacted to date by the Congress. The 1990 amendments establish specific programs to control pollutants that cause acid rain and ozone depletion. The hazardous air pollutants program is also being completely overhauled. The new legislation will have a major economic impact on the iron and steel industry and will require steelworks to obtain operating permits from appropriate regulatory agencies. Operations specifically mentioned in the new regulations include iron and steel mills, coke oven batteries, sintering plants, taconite ore processing plants, and fossil fuel-fired steam electric plants. EPA is required to publish a list of major sources of hazardous air pollutants by November 15, 1991.

The legislation also requires DOE and EPA to undertake a 6-year study of coke oven emission control technologies. Five million dollars per year has been appropriated to carry out the program from 1992 through 1997. Regulatory standards for coke oven batteries are to be issued by December 31, 1992.

The new acid rain program focuses on two pollutants: sulfur dioxide (SO₂) and nitrogen oxides (NO_x). That part of the program will impact both pelletizing plants and the coal-fired electric generating stations that provide power to the giant agglomerating operations.

Production

The North American iron ore industry has strengthened its position considerably over the past 4 years. In 1986, a number of U.S. and Canadian mine owners had serious financial problems, and at least five were tied up in complex bankruptcy litigation. However, by reducing costs, recapitalizing, adopting new technologies, and improving pellet quality, the majority of producers were able to successfully extricate themselves from a difficult situation. By 1988, demand for finished steel products had improved dramatically on both sides of the border, and most iron ore operations in the United States had returned to profitability. Two relatively small pelletizing plants in Ontario, though, could no longer compete with the three giants of the Ouebec-Labrador Trough and were forced to close. In 1989, U.S. mine shipments totaled 58.30 Mmt, the highest since 1981. The Canadian industry also had a good

year in 1989, with shipments reaching 40.69 Mmt.

Secondary factors contributing to the 1988-89 turnaround were the weak U.S. dollar, which made the importation of some steels less attractive and increased exports of goods fabricated from steel; higher prices for quality steel scrap; and increased demand for steel worldwide. In the United States, the Federal Voluntary Restraint Agreements program gave additional momentum to the recovery by reducing steel imports to a little more than 20% of the U.S. market.

In the fourth quarter of 1990 and first quarter of 1991, recessionary forces brought the recovery to a halt. These forces were fueled by serious problems in the banking and real estate sectors. Domestic ore sales, which had been stable after leveling off in early 1990, took a downturn in December. The downturn was too late in the year to drastically affect the 1990 totals. As a result, overall shipments for the year reached a respectable 57.01 Mmt. Shipments would have been higher if the Empire and Minorca Mines had not been shut down for 4 months by the wage dispute between CCI and the USWA.

Iron ore was produced by 22 open pit mines and 1 underground mine. Fifteen mines produced ore for the iron and steel industry, while the remainder shipped ore mainly to cement plants. Installed production capacity for usable ore on December 31, 1990, was estimated at 83 Mmt/yr, including 81 Mmt of capacity for pellets. Effective production capacity for pellets was at least 15 Mmt less than installed capacity. Only 2 of the 10 active pelletizing plants utilized more than 85% of their installed capacities, despite the upswing in demand since 1987. Total output of usable ore was equivalent to about 68% of installed production capacity, down from 71% in 1989. This drop in utilization was due partly to weakening steel demand and partly to the startup of Cyprus.

An average of 3.2 mt of crude ore was mined in 1990 for each mt of usable ore produced. This ratio does not take into account the tonnage of waste rock or overburden removed. The ratio of total materials mined to usable ore produced was probably greater than 5:1. Low-grade ores of the taconite type mined in Michigan and Minnesota accounted for 99% of total crude ore production. U.S. production of pellets totaled 54.82 Mmt, 97% of usable ore output. The average iron content of usable ore produced was 63.3%.

Shipments from U.S. loading docks on the upper Great Lakes totaled 51.10 Mmt in 1990. The dock shipment figure was only slightly less than that of 1989, despite the labor dispute in Michigan. Because of the strike, shipments from Marquette for the year amounted to only 5.04 Mmt compared with 9.62 Mmt in 1989. The decrease at Marquette was offset, though, by the reopening of Silver Bay and increased loadings at three other Minnesota ports. The reopened port handled 2.11 Mmt of pellets and chips between April 19 (when the first vessel docked) and December 31. An additional 71,000 mt was loaded at Silver Bay in the first half of January 1991 before the U.S. Army Corps of Engineers closed the locks at Sault Ste. Marie for the winter.

Employment.—Statistics on employment and productivity in the U.S. iron ore industry in 1990, shown in table 2, were derived from quarterly employment data supplied by the Mine Safety and Health Administration (MSHA) and from production data derived from U.S. Bureau of Mines surveys. Both sets of data were obtained from producers' reports.

The statistics include production workers employed at mines, concentrators, pelletizing plants, and in repair and maintenance shops, but do not include 830 persons engaged in management, research, or officework at mines and plants. Employees engaged in ore preparation, such as sintering, at blast furnace sites are not included. An additional 98 individuals were engaged in the secondary beneficiation of iron ore for heavy-media and other nonsteel uses. The number of employees in this last category shrank 30% between 1989 and 1990 when NL Chemicals Inc. shut down its byproduct magnetite recovery operations at Tahawus, NY.

Because employment data reported to MSHA are primarily for safety analysis, hours spent by salaried employees in mines or plants may be included by operators in the total number of hours worked at individual mines or plants. This has resulted in understatement of calculated productivity by 10% to 25% for some operations, but its effect on others is not known. If company reporting practice is consistent, however, comparison of productivity from one year to the next should be reasonably valid.

Average quarterly employment was slightly less than that of 1989, with at least two mine operators temporarily laying off

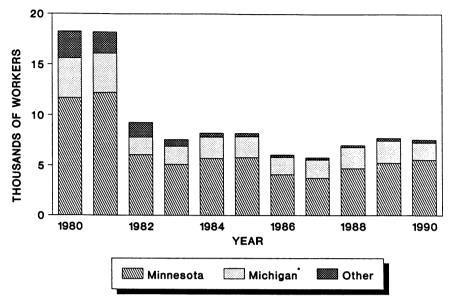

workers because of declining pellet demand from domestic steel producers. Because of the layoffs, the iron ore industry reduced its output of usable ore by 4%. The relatively small loss in output is somewhat misleading because 214 production workers were recalled during the last quarter of 1989 to help renovate the idled operations at Silver Bay and Babbitt, MN.

Total hours worked were almost identical to the 1989 figure despite the 4-month strike in Michigan and decreased level of production. The decrease in demand came at a time when at least three operations in the Lake Superior District had begun switching over to fluxed pellet production or making other major technological improvements. The conversion to fluxed pellets adversely affected productivity because pelletizing lines and grinding lines had to be shut down so that existing equipment could be modified and new equipment installed. As a result, operating parameters and procedures had to be readjusted. The switchover at the Tilden Mine from hematite to magnetite also helped to temporarily lower productivity. Consequently, average productivity for usable ore in the Lake Superior District was 3.5% lower than that of 1989. Because the district accounts for the bulk of U.S. output, the average productivity for the entire industry dropped 4.5%.

Bankruptcy Settlements and Labor Agreements.—The iron ore industry of Canada and the United States continued to untangle itself from the web of financial and legal problems created by the collapse of steel demand in 1985 and 1986. LTV Corp., Sharon Steel Corp., and Wheeling-Pittsburgh Steel Corp. were all forced to file for bankruptcy at the time of the collapse, but continued to operate under the protection of chapter 11 of the Federal Bankruptcy Code. The bankruptcy problems of the three integrated steel producers spilled over into the iron ore industry, which had been under direct control of United States and Canadian steel companies for decades. The Reserve Mining Co., a 50-50 joint venture between Armco Inc. and LTV, was forced to suspend production in July 1986 and was eventually sold by the bankruptcy court to Cyprus Minerals Co. in August 1989. From 1987 to 1989, the mining partners of the bankrupt steel companies continued to ship pellets to the three companies' blast furnaces and relied on the courts and lengthy legal negotiations to resolve their financial

FIGURE 10

EMPLOYMENT AT IRON MINES AND BENEFICIATING PLANTS

Includes workers in Wisconsin for years prior to 1984.

claims. Sharon Steel and Wheeling-Pittsburgh have since been reorganized, and the majority of the claims against these two steelmakers have been settled.

On December 18, 1990, the U.S. Bankruptcy Court approved Wheeling-Pittsburgh's reorganization plan. The plan included a settlement agreement between Wheeling-Pittsburgh and CCI that satisfied several of CCI's claims against the reorganized West Virginia steelmaker. Under the settlement, CCI received from the steel company \$56.0 million in cash plus common stock valued at \$10.9 million. Wabush Mines, a Canadian joint venture managed by CCI, received \$33.3 million in cash together with Wheeling stock valued at \$6.4 million. CCI's indirect share of the Wabush settlement was \$4.4 million. The Wheeling bankruptcy settlement thus resulted in a total gain of \$71.3 million for CCI, netting the iron ore merchant \$47.1 million after taxes. The CCI claims date back to 1985 when Wheeling-Pittsburgh defaulted on its Tilden, Wabush, and Empire partnership obligations. Wheeling-Pittsburgh regained its 9.95% interest in the Empire partnership on January 1, 1989, as part of a preliminary settlement, but was forced to surrender its 4.0% interest in the

Tilden Mining Co. to CCI. The Cleveland-based iron ore merchant has been managing the Tilden Mine since its startup in 1974.

Sharon Steel Corp., another former partner in the Tilden Mining Co., also emerged from bankruptcy proceedings at the end of 1990. Under the reorganization plan approved by the U.S. Bankruptcy Court on December 28, two independent companies were created from the old integrated steel producer: Mueller Industries Inc. and a new Sharon Steel Corp. The new steel company was formed when Castle Harlan Inc., an investor group, purchased Sharon's steel assets as part of the overall reorganization. Sharon has two blast furnaces, one basic oxygen furnace, and two electric furnaces at Farrell, PA. The company also operates a coke plant at nearby Monessen.

Sharon's reorganization plan included settlement of a \$27 million claim brought against the steelmaker by CCI. The claim was filed after Sharon filed for protection under chapter 11 in April 1987. As part of the 1990 settlement, CCI took over Sharon's 5.0% interest in the Tilden Mining Co. In addition, CCI received 312,120 shares of Mueller common stock plus a promissory note from Mueller for \$780,000.

The Mueller stock brought \$3.5 million when it was sold in early 1991. From 1987 to December 1990, Sharon continued to take pellets from Tilden as part of an interim agreement with CCI. CCI has agreed to supply all of the iron ore requirements of the successor steel company for the near future.

On June 18, 1990, the U.S. Supreme Court ruled that the Pension Benefit Guarantee Corp. could force LTV Corp. to resume responsibility for its underfunded pension plans. This ruling was expected to further delay LTV's bankruptcy reorganization. On June 28, 1989, CCI executed an agreement with LTV that tentatively settled the iron ore merchant's bankruptcy claims against LTV Steel Co. Inc., the steelmaking group of LTV Corp. CCI brought suit after LTV Steel rejected its Tilden Mine obligations, related purchase contracts, and a royalty agreement at its LTV Steel Mining Co. subsidiary. Under terms of the settlement, CCI received an unsecured claim of \$205 million for damages. CCI also assumed an additional 10% interest in the adjoining Empire Mine from LTV on January 1, 1990. The equity transfer left each company with a 25% interest in Empire, which had the capacity to produce 8.1 Mmt/yr of fluxed pellets. Other partners in the mine were Inland Steel Co. (40%) and Wheeling-Pittsburgh (10%). CCI also had the right to supply 75% of any future iron ore requirements of LTV above its existing equity interests as long as CCI's prices were competitive. The terms of the settlement were approved by the U.S. Bankruptcy Court for the Southern District of New York on August 17, 1989. As part of the settlement, LTV agreed to reject its 12% interest in the Tilden Mining Co. However, the claims of several major creditor groups were still to be resolved.

Wabush Mines of Labrador and Quebec was allowed a similar claim of \$59 million, but two lesser claims by Wabush were being disputed. Prior to its filing, LTV had a 15.6% interest in the Canadian joint venture. At yearend 1990, Stelco, Dofasco, and the four other partners were still negotiating with LTV. An exchange of equities was proposed in 1989, but the details were never worked out. The 10.2% interest formerly held by Wheeling-Pittsburgh was being held in trust for the other owners.

The 4-month mine strike in Michigan was costly to both labor and management and accomplished little. The strike ran

from August 1 to December 1 and idled 1,800 members of the United Steelworkers of America (USWA) at the Empire and Tilden Mines. The Cleveland-Cliffs Iron Co., which represented the mine owners, and the union could not agree on a new contract when the old one expired on July 30. The dispute involved not only wages, but also pension rights and cost-of-living escalators. Cleveland-Cliffs Iron made several offers based on settlements made in 1989 and 1990 at other U.S. iron ore and steel operations. Union leaders, though, were concerned about the erosion of real wages and refused to back down from their demands. The walkout triggered layoffs at several related operations, including the Lake Superior and Ishpeming Railroad, which hauls pellets from the mines to the Presque Isle ore dock on Lake Superior, and the Chicago and Northwestern Railway, which hauls pellets to the Escanaba ore dock on Lake Michigan.

An agreement was finally reached in late November with the aid of a Federal mediator. The new contract, which expires on July 31, 1993, immediately raised wages an average of \$1.25 per hour. Workers will receive an additional \$0.25 per hour raise on January 1, 1992. The 122-day strike was the longest in the history of the two mines. The last strike was in 1977 and lasted 114 days. Tilden has traditionally supplied pellets to steelworks operated in Canada by The Algoma Steel Corp. Ltd. and Stelco Inc. Algoma and Stelco were struck at the same time as the Michigan mines, causing a sharp drop in U.S. exports of pellets. The Tilden Magnetite Partnership is a joint venture of Algoma (50% equity), CCI (33.3%), and Stelco (16.7%). The Canadian steel strike was settled on November 21, 10 days before the Michigan strike ended. The Interlake Steamship Co. and other Great Lakes carriers worked long hours throughout December and early January to move backlogged tonnage before pack ice formed and halted operations until spring. The strike reportedly reduced the 1990 operating earnings of CCI by as much as 50%. It also came at a time when Algoma was experiencing financial difficulties.

In March 1991, USX Corp. and the USWA signed a new 3-year labor contract, narrowly avoiding a second costly and damaging strike. The new contract restored about \$1.00 per hour in wage sacrifices made by the steelworkers during the 1982-83 recession and raised wages an additional \$1.50 per hour. The base salary for USX steelworkers at the end of 1990 was

\$11.23 per hour. USX rejected the union's demand for cost-of-living increases, but agreed to pay a cost-of-living bonus of \$2,500 over the next 3 years.

The agreement also contained clauses that would protect the steelworkers should USX sell all or part of its steel operations. The company agreed to guarantee all accrued pension benefits in the event of a sale or spinoff. This concession was extremely important to the 20,000 rank-and-file members. Many of the steelworkers were concerned that management's upcoming plans to divide the company's common stock into separate steel and energy issues would eventually lead to either a breakup or a significant downsizing of the steel group.

Minnesota.—Minnesota produced 80% of the national output of usable ore in 1990. All of the State's production came from open pit mines on the Mesabi Range. Production of pellets totaled 44.63 Mmt, equivalent to about 71% of installed production capacity of the State's seven taconite plants. Utilization of active pelletizing capacity by the seven, though, was 91%. The remainder of the output consisted of hematite concentrates produced by LTV Steel from natural ores.

Cyprus Northshore Mining Corp. spent more than \$30 million refurbishing the mining and pelletizing complex of the defunct Reserve Mining Co. at the northeastern end of the Range.38 Cyprus Minerals Co., Northshore's parent, acquired the complex in August 1989 after successfully bidding \$52 million for Reserve's assets in Federal bankruptcy court. The taconite operation had been idle since August 1986 when Reserve filed for protection under chapter 11 of the Federal Bankruptcy Code. After settlement, Cyprus moved quickly to reopen both the Peter Mitchell Mine at Babbitt and the E. W. Davis pelletizing plant at Silver Bay. The two facilities required immediate attention because some of the equipment had begun to deteriorate from lack of maintenance. Key pieces of equipment had also been cannibalized earlier by the bankruptcy trustee to pay expenses.

Cyprus wisely hired most of the former Reserve employees. The employees, whose average age was more than 50, were quickly able to solve numerous refurbishing problems because of their familiarity with the deteriorated equipment and other aspects of the mothballed operation. On January 5, 1990, 120-car unit trains began hauling

578 IRON ORE—1990

crushed ore on the 76-km-long railroad extending from Babbitt to the concentrator at Silver Bay. However, on January 12, a fire broke out in the pelletizing plant 3 days before the plant was to begin production. The fire destroyed two electrostatic dust collectors and caused an estimated \$1 million damage to the fluid ionics section of the plant. The damage was quickly repaired, and pellet production began on January 27 with the startup of the No. 12 furnace. The No. 11 furnace was reactivated on March 10.

On April 19, Cyprus began shipping pellets from its Silver Bay dock. The first cargo of 21,900 mt went to one of the steelworks operated by Armco Inc. L.P. in the Ohio River Valley. Armco, a former partner in Reserve, had previously signed a 7-year contract with Cyprus as part of the Reserve settlement. Additional details on the startup of Cyprus Northshore are given in reference 38. The standard acid pellet being made by Cyprus contained 63.74% iron (Fe), 4.74% silica (SiO₂), and 0.020% phosphorus (P) on a wet basis.

The Northshore operation produced a total of 2.43 Mmt in 1990,³⁹ of which about 1.5 Mmt went to Armco. Cyprus' other customers reportedly included Algoma, Bethlehem Steel, Shenango Inc., and Wheeling-Pittsburgh. If all goes well, the complex could be producing 4.0 Mmt/yr by 1994. Reserve removed so much overburden at the mine between 1979 and 1983 that mining can be carried out for 10 to 14 years with little or no additional stripping. At the end of 1990, Cyprus had 112 employees at Babbitt and 323 at Silver Bay.

In mid-September, Inland Steel Mining Co. began construction of its new Laurentian Taconite Mine. The site is southeast of the City of Virginia, between Gilbert and McKinley. The Minnesota Department of Natural Resources (DNR) released the Final Environmental Impact Statement (EIS) for the mine on August 27 and issued the necessary mining permit on September 18. The project is the first new mine to be constructed on the Range in more than a decade. Inland immediately began clearing the site and was ready to blast at yearend. Inland Steel Mining is a wholly owned subsidiary of the Inland Steel Co. The new open pit operation will provide iron units for the parent company's integrated steelworks at Indiana Harbor, IN.

By May 1991, crude taconite from the first benches was being trucked 10 km to Inland's existing Minorca mining and

pelletizing complex on the northeastern edge of Virginia. The Laurentian taconite is replacing ore from the Minorca pit. where reserves are almost exhausted. The new mine will enable the 2.5-Mmt/vr pelletizing plant to continue operating until the year 2031. The 4.9-km² (1,200-acre) project includes a service building and a 2.4-km² (600-acre) stockpile area in addition to the haul road and 1.8-km² (440-acre) pit. When completed, the service building will have an equipment maintenance shop, a change room for employees, and offices. The initial stage of the project cost more than \$10 million. Inland expects to spend at least another \$10 million to fully develop the Laurentian Mine site.

Like Minorca, the ore occurs in the Biwabik Iron Formation of Early Proterozoic age (1.9 to 2.2 billion years old). Approximately 0.92 million cubic meters of glacial overburden is being removed from the north end of the ore body. The overburden was being hauled to the western third of the stockpile area and kept separately from both the waste rock and lean taconite. The first \$10 million covered the costs of removing part of the overburden, constructing the haul road, and installing electrical transmission lines. The electrical power substation at the mine site is now operational.

Minorca produced 2.50 Mmt of fluxed pellets in 1990, almost breaking the record set in 1989, and continued to operate at full capacity. At the current rate of production, the existing pit at Minorca would have been exhausted by the end of 1992 without supplemental ore from the Laurentian. The Laurentian ore body provides the plant with more than 15 years of reserves. Inland also hoped to negotiate leases on adjoining properties that could supply another 25 years of reserves. Inland has additional ore at two other sites—the Ordean Reserve west of Minorca and the East Rouchleau pit on the outskirts of Virginia.

In June 1991, Inland began blending the Laurentian ore with ore from Minorca. The blending may be able to extend the life of the Minorca pit until 1995, when mining would be shifted entirely to the new ore body. A dedicated haul road was constructed from the pelletizing plant through the Pike River Basin to the mine site. The use of a conveyor system in place of the haul road was not considered economically feasible. During the public review and comment period, homeowners in Gilbert expressed concerns about the dust and

noise that would be created by the mine trucks, blasting, and various stockpile activities. Inland has agreed to water the haul road and has built a series of berms to reduce nuisance noise from the operation. Overburden and waste rock were used to construct a 12-m-high sound barrier along the section of haul road that borders Gilbert. Inland was experimenting with several new methods of blasting designed to minimize ground shock to homeowners. The company has also instituted a blast monitoring program to minimize air shock noise and further reduce the risk of vibration damage.

Environmental permits had to be obtained from the U.S. Army Corps of Engineers. the Minnesota DNR, the Minnesota Pollution Control Agency (MPCA), and three local governments before construction could start. Although the EIS addressed a variety of environmental and socioeconomic issues, special emphasis was given to the operation's impact on surface water and ground water. The MPCA, the city of McKinley, and several other parties were concerned about the effect that mine dewatering would have on local water levels. The Laurentian site is bordered on the south and southeast by seven abandoned open pits that are now filled with water. One of these pits, the Corsica Mine, serves as the water supply for McKinley. Another four form Lake Orebegone, a local recreational area. There are also several natural lakes in the immediate area. On the north side, the new haul road cuts through the protected Pike River headwaters and its environmentally sensitive wetlands. The proiect will eventually remove or alter approximately 3.5 km² (860 acres) of forest and 0.29 km² (71 acres) of wetlands. Dewatering discharge will be rerouted to restore water levels in wetlands and lakes affected by ground water changes. Aeration systems will be installed in key lakes to lessen the impact on fish, and revegetation programs would be undertaken to restore wildlife habitat. If the Laurentian Mine had not been developed, the Minorca complex would have been forced to close sometime between 1992 and 1995. The community would have lost more than 300 jobs and a \$12 million per year payroll.

National Steel Pellet Co. (NSPC) produced a record high 4.89 Mmt of standard acid pellets at its Keewatin complex in 1990.⁴⁰ The pellets averaged 65.10% Fe, 4.93% SiO₂, and 0.010% P on a wet basis. The complex, situated at the southwestern end of the Mesabi Range, operated above

its rated capacity for most of the year. About 66% of the production was railed on the Burlington Northern to the Allouez Terminal at Superior, WI, and later loaded onto vessels for delivery to the Great Lakes steelworks of National Steel Corp. (NSC) in Detroit. The remaining 34% was hauled in 135-car unit trains to NSC's smaller steelworks at Granite City, IL. The unit trains going to Superior were somewhat longer than those bound for Granite City and were made up of approximately 160 cars. In both cases, each car held about 90 mt of pellets.

NSPC was a wholly owned subsidiary of NSC. NSC was controlled in turn by NKK Corp., the second largest steel producer in Japan. In 1990, NKK increased its equity in NSC from 50% to 86.7%. The remaining 13.3% was held by National Intergroup Inc.

In recent years, NSPC has been exploring ways of lowering its grinding costs. The 5.9-Mmt/yr concentrator at Keewatin has 10 grinding lines, each of which has a 27by 18-foot semiautogenous mill charged with relatively expensive, 5-inch grinding balls. Plant personnel believe that these balls can be eliminated by linking each of the semiautogenous mills to a pebble crushing circuit. The No. 10 grinding line was being used as a test unit. Taconite pebbles greater than 3 inches in diameter were being removed from the mill on a continuous basis, shattered in a cone crusher, and then fed back into the mill in minus 34-inch fragments.

All of LTV Steel's natural ore production came from its McKinley Extension Mine, 4 km north of Aurora. The mine, operated by LTV Steel's Northwest Ore Div. under a lease from USX, shipped 416,000 mt of beneficiated sinter fines and 13,000 mt of 1- by 4-inch coarse ore in 1990.⁴¹ The lump ore was being added by LTV Steel and outside customers to their electric arc furnaces to assist in the oxidation of impurities and to serve as a coolant.

Reserves at the McKinley Extension are almost exhausted, and the operation is slated to close in the fall of 1993. Crews are to begin dismantling the beneficiation plant in late 1992. Mining has been restricted to the Donora pit since 1990 when the last 15,000 mt was removed from the adjoining Stephens pit. The Donora crude ore has been averaging 57% to 58% Fe. The Connie Mine was reactivated in May 1991 to supplement the McKinley Extension's output during the 2-year phaseout. Pittsburgh Pacific Co. shut down the

Connie in 1979, but continued to process ore stockpiled at the site intermittently until 1988. The new contractor is Premier Aggregates Inc.

Excessive pelletizing capacity continued to be a problem for LTV Steel Mining. LTV Steel Mining owns the third largest operation on the Range. The complex is at Hoyt Lakes, 32 km east of the city of Virginia. The Hoyt Lakes operation has a rated annual capacity of 8.1 Mmt of standard acid pellets and shipped 7.95 Mmt in 1990. The design capacity of the mining complex is significantly higher than the rated figure published and is about 11 Mmt/yr. CCI manages the Hoyt Lakes operation for LTV Steel. The complex made 8.14 Mmt of products during the year. The total included 7.70 Mmt of pellets, 378,000 mt of chips, and 69,000 mt of filter cake. Almost all of the production was railed to ore docks at Taconite Harbor for loading into self-unloaders. From there, the bulk of the material went to LTV's steelworks at Indiana Harbor, IN. A fifth flotation line has been installed at the Hoyt Lakes plant to help lower the silica content of the concentrate. Carbinder was also being added during the balling stage as a partial substitute for bentonite, further reducing the silica content of the fired pellet. Because of these improvements, LTV's average silica content (on a wet basis) has dropped from 5.20% in 1987 to 4.94%.

In January 1990, representatives of LTV Steel Mining met with MPCA officials to discuss ways of improving the quality of surface waters in the vicinity of the Dunka pit. The Dunka pit, 6 km east of Babbitt at the northeastern tip of the Mesabi Range, was one of six pits supplying crude taconite to the Hoyt Lakes plant. In early 1989, environmental monitoring teams discovered that rain and melted snow percolating through 4.9 km² (1,200 acres) of stockpiled waste rock were picking up excessive amounts of cobalt, nickel, and zinc. The three metals apparently were being leached from minor sulfides that had begun to oxidize in some of the stockpiles. A number of remedial actions were taken during the year to minimize leaching. Reconfiguring some of the waste piles helped correct part of the problem.

The Hibbing Taconite Co. (Hibtac) operated at almost full capacity throughout 1990, producing 8.41 Mmt of standard pellets.⁴² The mining staff moved a record 47.9 Mmt of crude ore and overburden, but pellet production fell somewhat short of the

record 8.79 Mmt made in 1988. The company began producing ore from its new Mahoning IV pit in August 1990. The pit is 5 km southwest of the main Section 36 pit that started up in 1976. The new mining area encompasses parts of the former Mahoning natural ore pit, worked by Pickands Mather & Co. from 1923 to 1973. At the present rate of production, Hibtac has enough reserves of magnetic taconite to permit mining to continue until the year 2022. Since 1989, five 240-short-ton haulage trucks have been added to the fleet. The fleet also includes seventeen 170-ton and three 120-ton trucks. Eighteen of the 25 trucks normally operate on a shift. The pelletizing plant, which was expanded in 1979 to 8.2 Mmt, had an effective capacity of 9.0 Mmt at the end of 1990. Hibtac's biggest customer was Bethlehem Steel, which owned 70.3% of the joint venture. The remaining equity was divided between CCI (15.0%), which managed the complex, and Stelco (14.7%).

Minntac, the largest iron mine in the United States, produced 12.15 Mmt of fluxed pellets and 1.53 Mmt of standard acid pellets.⁴³ The complex at Mountain Iron is now the largest producer of fluxed pellets in the world and is owned and operated by the USS steel segment of USX. The 1990 output came close to breaking the 14.37 Mmt record set in 1980, when only acid pellets were made, but was still far short of the pelletizing plant's installed capacity of almost 19 Mmt.

USX has been producing fluxed pellets since 1988. The limestone-dolomite fluxed pellet made during the 1990 campaign contained 62.26% Fe and 3.93% SiO₂ on a wet basis. The acid pellet had slightly higher values—64.58% for Fe and 5.32% SiO₂. The pelletizing plant received 1.01 Mmt of fluxstone during the year. The 50-50 blend of limestone and dolomite was being shipped from Michigan to Duluth in self-unloaders and then transferred to DM&IR ore cars that would normally return empty to the plant.

An additional 2-Mmt/yr pelletizing line, idle since 1982, was started up in August 1989 to meet increased demand for fluxed pellets from the company's blast furnaces at Gary, IN, and Braddock, PA. Most of the acid pellets went to the USS and Kobe Steel Co. joint venture at Lorain, OH. About 1.31 Mmt of fluxed pellets was railed to Geneva Steel's works at Orem, UT, as part of a 5-year contract signed in 1987.

The output of Eveleth Mines dropped slightly from the 4-year high of 1989. The

joint venture produced 4.57 Mmt of partially fluxed pellets, 9% less than in 1989. The magnetite concentrate from the taconite was mixed with Peridur and a 1% limestone additive to make a pellet averaging 64.54% Fe, 5.03% SiO₂, 0.015% P, and 0.75% lime (CaO) on a wet basis. The limestone comes from the quarries of the Iowa Limestone Co. near Des Moines. Eveleth was managed and partly owned by the Oglebay Norton Co., which had an 18.5% equity in the venture. The remaining equity was divided between Armco Inc. (35.1%), the Rouge Steel Co. (31.7%), and Stelco (14.7%). The Fairlane pelletizing plant has a total effective capacity of 6.2 Mmt/yr, but only the newer of its two lines has been in continuous operation in recent vears. This newer line, commissioned in 1976, operated at 90% of capacity during the year, producing 3.39 Mmt. The older line, which dates back to 1965 and is used only during periods of strong demand, made an additional 1.18 Mmt.

Eveleth's Thunderbird Mine consists of two pits. About three-fourths of the crude ore mined in 1990 came from the south pit. However, almost all of the stripping took place in the north pit. Eveleth was preparing to upgrade the crushing plant that serves the north pit. The upgrading will allow the company to put the south pit on standby and replace its output with increased production from the newly expanded north pit. At yearend, Eveleth employed about 600 hourly and 140 salaried personnel.

In October, explosives were used to demolish the last remnants of the Butler Taconite pelletizing plant in the southcentral part of the Range. The demolition was part of the final stage of a 5-year closing process. The site is between the towns of Nashwauk and Pengilly. An extensive reclamation project will be initiated in cooperation with the State of Minnesota when the site is completely cleared. Butler Taconite, a joint venture of Inland Steel Co. (38.0%), M.A. Hanna Co. (37.5%), and Wheeling-Pittsburgh (24.5%), was closed in 1985 after Wheeling-Pittsburgh filed for bankruptcy protection. The 2.7-Mmt/yr mining and pelletizing complex was built on top of three exhausted natural ore mines and came on-line in March 1967. Butler Taconite shipped a total of 41.2 Mmt of pellets during its 18 years of operation.

Michigan.—Michigan accounted for only 17% of the national output of usable ore in 1990. Almost 99% of the State's

production consisted of pellets produced at the Empire and Tilden Mines near Ishpeming in Marquette County. Both mining ventures are managed by CCI's Cleveland-Cliffs Iron subsidiary. Empire shipped 5.90 Mmt of pellets produced from magnetite concentrate. Tilden shipped 2.19 Mmt of magnetite pellets and 2.04 Mmt of hematite pellets, for a total of 4.23 Mmt.⁴⁴ The company's wholly owned Republic Mine remained idle throughout the year.

Production of usable material was down 39% from the 1989 figure of 15.61 Mmt because of the labor dispute discussed earlier. Production of pellets totaled 9.37 Mmt, of which 5.35 Mmt was made at the Empire plant and 4.02 Mmt was made at Tilden.⁴⁵

Algoma has been seeking a buyer for its holdings in Tilden since the spring of 1990. The Canadian steel company has been a partner in the upper Michigan venture since the complex's inception in 1972. The proposed sale is part of Algoma's efforts to restructure, retire debt, and focus on its core steel business. The restructuring comes 2½ years after Algoma was acquired by Dofasco Inc., another Canadian steel company. That acquisition made Dofasco the fourth largest steelmaker in North America.

Algoma owns and operates an integrated steelworks at Sault Ste. Marie, Ontario. In recent years, iron units for the four blast furnaces at Sault Ste. Marie have come from three principal sources:

- Tilden pellets have been brought in vessels across Lake Superior from Marquette.
- Superfluxed sinter has been railed 300 km along the northeastern shore of Lake Superior from Algoma's sintering plant at Wawa on the Michipicoten Range. The bulk of the iron units in the Wawa sinter has come from siderite mined at the neighboring George W. MacLeod Mine, an underground operation opened in 1960.
- Conventional sinter has been produced by Algoma at Sault Ste. Marie from ore fines and recycled waste materials. The one-strand plant, built in 1952, can produce 440,000 mt/yr of sinter.

Algoma is the principal partner in Tilden. The current equity ownerships for the venture are shown in figure 2. Two partnerships are involved: the new Tilden Magnetite Partnership and the older Tilden Mining Co. CCI manages the mining complex for the two partnerships and receives royalties and management fees based on production. CCI, one of the larger iron ore

merchants in North America, has owned the property near Ishpeming since 1865. Algoma's fee payments to CCI had been averaging about \$600,000 per month. The mine partnership arrangements were restructured between 1987 and 1988. Since then, the three partners have spent \$30 million to develop the Cliffs Drive III magnetite ore body and upgrade the pelletizing plant so that it can process both magnetite and hematite.

As a result of its restructuring problems, Algoma may have to take fewer pellets from Tilden. Tilden had been scheduled to produce 6.7 Mmt in 1991, with 3.8 Mmt going to CCI, 2.6 Mmt to Algoma, and 300,000 mt to Stelco. In February 1991, CCI decided to accelerate its own take of pellets and increase its payments to the joint venture so that the scheduled production rate could be maintained at least until midyear. Since then, the 1991 production goal has been reduced to 5.0 Mmt, compared with 7.17 Mmt of pellets made during the transition year of 1989.

Because of the economic downturn, CCI's management took another look at its Republic Mine and was debating whether to decommission the complex. The mine has been on standby since October 1981.

Missouri.—The Pea Ridge Iron Ore Co. produced olivine-enriched pellets, magnetite concentrate, and iron oxide powder at its mining and pelletizing complex near Sullivan, MO. The company has the only active underground iron mine in the country and operates the smallest of the Nation's 10 active pelletizing plants. The mine is on the northeast flank of the Ozark uplift and has proven reserves of 160 Mmt tons of ore grading 55% magnetic iron. The mining and pelletizing complex was developed jointly by St. Joe Minerals Corp. and Bethlehem Steel Corp. between 1957 and 1964 at a cost of about \$52 million. At that time, Pea Ridge was known as the Meramec Mining Co.

More than 90% of the 1990 production consisted of olivine-enriched pellets made from magnetite concentrate containing 70% Fe and less than 1% SiO₂. The addition of 5% olivine increases the reducibility of the pellet while improving its high-temperature properties in the blast furnace and increasing its resistance to low-temperature breakdown. The final product, the "Pro 18" flux pellet, averaged 64.28% Fe, 2.99% SiO₂, and 0.020% P on a wet basis. The silica content is significantly lower than that found in any of the Lake

Superior pellets. The magnesia (MgO) runs 1.92% and is similar to the magnesia levels of different fluxed pellets from Michigan. The complex also produced heavy-medium magnetite for coal cleaning, as well as a variety of iron oxides for ceramic magnets, brake linings, magnetic printing inks, and color pigments.

In the spring of 1990, Fluor Corp. sold Pea Ridge to Big River Minerals Corp. for \$11.78 million. The sale resulted in a one-time gain of \$8 million for Fluor, an engineering and construction company headquartered in Irvine, CA. Fluor acquired Pea Ridge in the 1981 takeover of St. Joe, but had been carrying the Missouri company as a discontinued operation since 1987. Big River is a diversified natural resource company formed by former executives of St. Joe and Fluor in late 1987 and is based in St. Louis. The parent company also has interests in a zinc refinery at Sauget, IL, and seven coal mines in Ohio and West Virginia.

According to Big River officials, Pea Ridge was planning to increase production of its heavy-media-grade of concentrate and was hoping to expand its niche in the coal preparation portion of the market. Shares in the heavy-media market had to be readjusted after NL Chemicals Inc. shut down its magnetite concentrating operation at Tahawus, NY, in November 1989.46 Pea Ridge also sells an iron oxide powder known as M-25 that is used in the manufacturing of ceramic magnets. The high-purity, magnetic powder contains 71.9% Fe and has a mean particle size of 8 to 12 micrometers (µm). The company recently began producing a new type of pellet for the magnet industry. Hematite concentrate is used in place of magnetite as pellet feed. The new H-25 ferrite pellet is made with Peridur (the cellulose-based organic binder discussed earlier) and averages 69.7% Fe. The SiO_2 is only 0.21%, while the phosphorus content is the same as that in the "Pro 18"-0.020%.

Pea Ridge has initiated a long-term project to reduce iron oxide particulate emissions from its five shaft furnaces. Company officials have been working with the Missouri Department of Natural Resources (DNR) to improve air quality in the Sullivan area. In March 1990, DNR and company officials reached a settlement that should eventually bring the pelletizing plant in compliance with the Missouri Air Conservation Law. As part of the agreement, Pea Ridge had to install pollution control equipment on one of its five furnaces by

September 30, 1990. The company and DNR are currently analyzing the test data for the modified furnace stack. If the tests show that particulate emissions have been reduced sufficiently to meet air quality standards, the company has agreed to install similar pollution control equipment on one furnace each year through 1994. DNR, on its part, will forgo any further enforcement against Pea Ridge for the duration of the agreement, which expires November 30, 1994.

In December 1990, Pea Ridge temporarily suspended production of blast-furnacegrade pellets after fulfilling its contract with National Steel. National Steel, the mine's principal customer, was forced to cut back hot-metal production at its Granite City steelworks when steel sales started to drop nationwide. The Illinois steelworks is only 160 km (100 miles) north of the mine, but is obligated to use acid pellets from NSPC's Keewatin complex on the Mesabi Range.

Pea Ridge continued to explore the feasibility of producing rare-earth oxides (REO) as a byproduct. At least seven different rare-earth minerals have been identified in breccia pipes, veins, or carbonate pods along the edges of the massive magnetite ore bodies.⁴⁷ Monazite (a cerium-lanthanum-yttrium-thorium phosphate), xenotime (a yttrium phosphate), and allanite (a cerium-yttrium epidote) are three of the more abundant ore minerals. The company has produced test quantities of a concentrate of mixed REObearing minerals and begun erecting a small pilot plant. The Rolla Research Center of the U.S. Bureau of Mines was working with Pea Ridge to improve recovery of different REO-bearing minerals. The Bureau was evaluating several beneficiation processes involving fine-particle gravity separation and froth flotation.⁴⁸ It may be possible to rework existing tailings from the iron ore concentrator. The REO concentrate from the tailings could then be blended together with the primary REO concentrate from the high-grade breccia ores. Marketing of the Pea Ridge REO concentrate should be relatively easy because yttrium and the highly valued members of the "heavy" rare-earth subgroup (terbium through lutetium) have been enriched relative to the "light" subgroup (cerium through gadolinium).

Utah.—Geneva Steel of Utah operated three open pit mines in the Iron Springs

District of Iron County. The district, 24 km west of Cedar City, has provided magnetite and hematite ores for blast furnaces in the Rocky Mountain region on an intermittent basis since 1923. Coarse ore and fines were shipped 370 km on the Union Pacific Railroad to Geneva's integrated steelworks at Provo. The ore was hauled twice a week in 106-car unit trains. The actual mining was contracted out to the Gilbert Development Corp.

Run-of-mine ore averaging 54.0% Fe, 8.7% SiO₂, and 0.30% P was crushed and screened at the Comstock-Mountain Lion Mine, two adjoining properties on the northeast side of the Iron Mountain intrusion. east of Newcastle. Geneva had been working the Comstock under a lease from CF&I Steel Corp. of Pueblo, CO, but eventually decided to buy the mine outright. The sale was completed on August 1, 1990. The Utah steelmaker also acquired the Desert Mound Mine from USX. The Desert Mound Mine is in a low hilly area north of County Highway 253, about 1 km southwest of the Granite Mountain intrusion. The mine, an open pit operation, has been shut down since 1982. The ore body consists primarily of hematite and is part of a skarn created when Jurassic limestone was intruded by Granite Mountain quartz monzonite porphyry during Tertiary time.49

Ore was being shipped from the new Excellsior pit on Iron Mountain, about 1 km southwest of the older Comstock pit. The magnetite ore occurs in a 300-m-long fissure vein in quartz monzonite porphyry. The Excellsior material was averaging 56% Fe, 7.0% SiO₂, and 0.26% P on a wet basis. The neighboring Chespeak Mine was idle in 1990. Gilbert Development continued to produce wet screened and magnetically cobbed material from stockpiles of lean ore at the former Iron Mountain Mine, 3 km to the southwest, on the opposite side of Iron Mountain. The mine site was being used only as a processing point and had no production of its own. A total of 741,000 mt was shipped from the Iron Springs District in 1990.50 About 45% of the material consisted of -10 mm (-\% inch) fines, which could not be charged directly into Geneva's three blast furnaces and had to be sintered.

Other States.—Three California mines produced iron ore during the year—the Baxter, the Beck, and the Soledad Canyon. The bulk of the shipments went to cement plants in the Los Angeles basin. The

Baxter and Beck Mines are both in San Bernardino County in the eastern half of the Mohave Desert. The Baxter Mine is operated by the California Portland Cement Co.; the Beck Mine, by Standard Industrial Minerals Inc. The P.W. Gillibrand Co. produced a magnetite concentrate as a byproduct of its Soledad Canyon sand and gravel operations in Los Angeles County. The Soledad Canvon District is at the northwestern end of the San Gabriel Mountains and encompasses parts of the environmentally sensitive Angeles National Forest. The district has several promising alluvial and lode deposits of titaniferous magnetite and ilmenite.

In South Dakota, Pete Lien & Sons Inc. mined low-grade hematite at the CF&I pit near Nemo in Lawrence County. The mine was reopened in 1988 after a hiatus of 9 years, but operated only during part of 1990. The company produced directshipping ore averaging 29.1% Fe. Production was limited by the relative remoteness of the Black Hills mine site from consumers. The bulk of the ore was shipped to the Dakota cement plant operated at Rapid City by the State Cement Commission. The ore comes from a 30- to 90-mthick Precambrian iron formation that forms a ridge along the east side of Boxelder Valley. The BIF is severely folded and in some areas is partially buried under an escarpment of Paleozoic limestone and quartzite.51

Limited amounts of siderite and limonite were produced from the Eocene Weches Formation of east Texas. Mathis & Mathis Mining & Exploration Co. mined siderite at its Linden Mine in Cass County, while Hudson Brothers Mining Co. Inc. recovered a mixture of limonite and siderite from its Rusk Mine in Cherokee County. Algoma is the only other producer of siderite in North America.

Consumption and Uses

Consumption of ore and agglomerates held firm until December, when the country began experiencing the full effects of a general economic downturn. Consumer confidence dropped off significantly during the last few weeks of 1990 because of the deteriorating political situation in the Persian Gulf region and growing tension throughout the entire Middle East. The drop in consumer spending and concurrent cutback in business spending on new plants and equipment caused sales of products incorporating steel to weaken even further

in the first quarter of 1991. The slackening of demand for steel was just one of several economic indicators signaling that the United States was entering its first significant downturn since 1982. The steel industry responded by reducing hot-metal production and mothballing unneeded blast furnaces.

In spite of the fourth quarter downturn in demand from the iron and steel industry. consumption of iron ore was slightly higher than the figure for 1989. Consumption for ironmaking and steelmaking totaled 74.27 Mmt, including 67.55 Mmt in blast furnaces, 5.81 Mmt in sintering plants, and 0.58 Mmt for production of DRI. Only 89,000 mt went into steelmaking furnaces. The use of iron ore in electric arc furnaces has fallen off dramatically over the past 20 years. An additional 235,000 mt was used by the industry for miscellaneous and unspecified purposes. Monthly consumption of pellets, direct-shipping ore, and merchant sinter by the industry averaged 6.14 Mmt compared with 6.09 Mmt in 1989. Reported consumption of iron ore for manufacture of cement, heavy-medium materials, animal feed, ballast, ferrites, pigments, and other nonsteel products was 940,000 mt.

The near-term outlook for the iron and steel industry is proving to be more austere than had been forecasted. At the end of 1990, the entire U.S. economy was struggling to overcome recessionary problems. U.S. production of hot metal and pig iron totaled 49.67 Mmt, only a 2% drop from that of 1989, but was expected to decline substantially more in 1991. Hot-metal and pig iron production was extremely stable throughout 1990, averaging 4.14 Mmt/month. The deviation from the mean was never more than 8% for any 1 month until December when pig iron production fell to 3.87 Mmt.

Monthly iron ore consumption statistics reflected this stability. Consumption of pellets, direct-shipping ore, and merchant sinter for the first 6 months was 36.18 Mmt, a 6% decrease from the same period in 1989. The situation improved somewhat in the second half of the year, with blast furnace output slightly exceeding corresponding 1989 levels. During 1990, the number of blast furnaces in operation ranged from 46 to 48. At yearend, 46 of the 79 blast furnaces available were on-line. Furnace operators had, on the average, enough ore in their yards to operate for 91 days. The monthly blast furnace data show how pig iron production had stabilized since 1986,

when the number of furnaces operating dropped from 50 to 31 over a 7-month period. The industry continued to dismantle obsolete furnaces and improve active furnace utilization. Thirty-three blast furnaces had been scrapped since December 1983.

Consumption of iron ore and all types of agglomerates reported to the AISI by integrated producers of iron and steel totaled 75.33 Mmt. This included 60.56 Mmt of pellets; 12.24 Mmt of sinter, briquettes, etc; and 2.53 Mmt of natural coarse ore. Of the primary ore consumed, 76% was of domestic origin, 11% came from Canada, and 13% came from other countries. Other materials consumed in sintering plants included mill scale, flue dust, limestone and dolomite, slag and slag scrap, and coke breeze. Other iron-bearing materials charged to blast furnaces included steelfurnace slag, mill scale, and slag scrap. In some operations, conventional ferrous scrap constituted as much as 7% of the blast furnace burden. According to AISI, 2.54 Mmt of ferrous scrap was consumed in blast furnaces in 1990.

The blast furnace of Shenango Group Inc. at Neville Island, PA, was permanently closed in December 1990 after 38 years of operation. The 408,000-mt/yr furnace was the last producer of merchant pig iron in the United States. One-half of the furnace's production went to Shenango's own foundry, with the rest sold on the open market.

Because of the weakening economy, LTV Corp. also banked one of two operational blast furnaces at its Cleveland, OH, works in December. Both were commissioned in 1972. The idled furnace was capable of producing 2,000 mt/d of hot metal. Three older, smaller blast furnaces at the works have been shut down for some time. The idling was necessitated by a dropoff in orders for steel from domestic automakers and appliance manufacturers. The LTV cutback in production was followed by similar cutbacks later in the month and in the first quarter of 1991 at the Armco Steel Co., Inland, and USX. By June 1991, four additional furnaces had been idled, leaving only 41 in operation.

Stocks

Stocks of iron ore and agglomerates reported at U.S. mines, docks, and consuming plants have been gradually dropping for more than 30 years. This trend temporarily reversed itself in 1988, but has since continued downward. At yearend,

IRON ORE—1990 583

total industry stocks were 21.57 Mmt, only 3% more than the record low set in 1987. Furnace yard stocks stood at 15.91 Mmt, a 56% drop from the 36.28 Mmt reported at yearend 1980. Combined stocks at furnace yards and receiving docks included 12.60 Mmt of domestic ores, 2.66 Mmt of Canadian ores, and 2.92 Mmt of other foreign ores, for a subtotal of 18.18 Mmt. Mine stocks at yearend were 11% less than those of 1989 primarily because of the mine strike in Michigan.

End-of-month stocks reported at mines peaked at 12.81 Mmt in March and continuously declined to 4.80 Mmt in December. Stocks of ore at consuming plants were 180 degrees out of phase with those at the mines, ranging from a low of 7.25 Mmt in April to a high of 15.91 Mmt in December. As in previous years, these variations were principally caused by the seasonal nature of ore shipping on the Great Lakes.

Stocks of unagglomerated concentrates reported at pelletizing plants totaled 0.98 Mmt at yearend and ranged in Fe content from 55% to 70%. This material is not included in mine stocks of usable ore reported in the accompanying tables because it is considered an intermediate product. Stocks of byproduct ore also have been excluded since 1983 from the mine stock data to avoid disclosing company proprietary information.

Transportation

Great Lakes shipping continued to play a key role in the competitiveness of the U.S. iron ore industry. The locks at Sault Ste. Marie, MI, remained the major weak point in the system. All of the ore going to domestic steelworks from the six ports on Lake Superior must pass through the Soo Locks. Relatively mild weather allowed the Corps of Engineers to keep the locks open until January 15, 1991. Ore shipments from Escanaba on Lake Michigan continued until January 31. The 1990-91 navigation season lasted 335 days (March 3 to February 1) and was the longest in more than a decade. In 1989, intense cold and the early formation of mature ice on the St. Marys River forced the Corps to close the locks on December 28, 2 weeks earlier than scheduled.

The U.S. Great Lakes fleet hauled 54.1 Mmt of ore, agglomerates, and related products during the 1990-91 season, 4% more than that in 1989. This increase was limited by below average water levels and

the Michigan labor dispute. The fleet operated 64 of its 69 serviceable vessels, with the 64 vessels accounting for 97% of carrying capacity. Since 1980, the number of U.S.-flag vessels on the Great Lakes has dropped from about 140 to 69. At the same time, the average carrying capacity has risen from 20,900 mt to 27,900 mt. Of the 69 vessels, 64 were self-unloaders. However, 7 of the 69 were cement carriers, and 3 were self-propelled tankers.

Vessel shipments of iron ore from U.S. ports on the Upper Great Lakes totaled 51.65 Mmt, slightly more than those of 1989. Almost 94% was destined for U.S. consumers, with the rest going to Canada. Shipments of iron ore through the St. Lawrence Seaway to U.S. ports on the Great Lakes totaled 4.56 Mmt and accounted for 25% of U.S. imports. The balance of imports, 13.49 Mmt, was shipped primarily through ports on the east and gulf coasts.

Ore shipments from all five U.S. ports on the western shore of Lake Superior were up from 1989 levels, with the largest cumulative tonnage loaded at Two Harbors, MN. The cumulative tonnage shipped from each port in 1990 is shown in table 11. The number of vessel shipments was also slightly ahead of that of 1989. The combined number of shipments from the seven ports totaled 1,543, indicating an average cargo of 33,472 mt. In 1989, abnormally high water levels allowed individual cargoes of 60,000 mt or more to be loaded at five of the seven ports. In 1990, though, the water level in Lake Superior stayed below average the entire year. As a result, only one port, Escanaba on Lake Michigan, had any shipments exceeding 60,000 mt. The average shipment from individual ports ranged from 23,497 mt at Marquette to 40,513 mt at Two Harbors.

On July 23, 1990, The Interlake Steamship Co. and other lake carriers raised freight rates between 7% and 8% to offset reduced productivity created by lower water levels, increased shipyard expenses, and higher premiums for maritime insurance. The shipping industry continued to give discounts on class X vessels (i.e., vessels with hulls greater than 1,000 feet in length), but the discounts were less generous than in the past. The different rates are compared in table 12.

Published bulk vessel freight rates from the Gulf of St. Lawrence to Lake Erie and Lake Michigan were \$5.00 and \$7.00 per ton, respectively. Freight rates for selfunloading vessels were \$1.50 per ton higher.

The two principal issues concerning U.S. lake shipping in 1990 continued to be the proposed construction of a second Poeclass lock at Sault Ste. Marie and the question of sharing domestic lake and coastal trade with Canadian and Mexican vessels.52 The second issue resurfaced in 1987 during negotiation of the United States-Canada Free-Trade Agreement (FTA), causing both the Reagan and Bush Administrations to review the justifications for existing cabotage laws. Title I of the Merchant Marine Act of 1936 mandates that all domestic waterborne commerce be conducted in vessels that are built in, owned by, and crewed by the United States. The Government of Canada wanted these cabotage restrictions waived as part of the FTA. In exchange, U.S. vessels would have been allowed to carry cargo between Canadian ports. Because of the complexity of the cabotage issue, United States and Canadian negotiators agreed to exclude the controversial section dealing with maritime services from the final trade agreement. However, the cabotage issue could be resurrected at any time during the annual review process. United States and Canadian iron ore shipments on the Great Lakes for 1986-90 are compared in table 13. The need for a strong U.S. merchant marine was reinforced by the recent Persian Gulf War. The cabotage issue has been further complicated by the ongoing free trade negotiations with the Government of Mexico.

Construction of a second Poe-sized lock at Sault Ste. Marie continued to be stymied by funding problems.⁵³ The new lock was desperately needed as a backup to prevent total paralysis of bulk shipping on Lake Superior should the Poe be shut down for more than 30 days. The new lock would also be needed to accommodate the growing number of class X vessels projected for the 21st century.54 The Water Resources Development Act of 1986 (section 1149 of Public Law 99-662) authorized construction of the new lock, but required 35% of the funding to come from non-Federal sources. In 1990, the Congress extended this authorization for an additional 5 years (section 107 of Public Law 101-640: Water Resources Development Act of 1990). Estimates made by the Corps of Engineers in October 1989 indicated that the lock would cost \$256 million, but more recent figures suggest that the cost will approach \$500 million.

The Soo Lock Funding Alternatives Task Force formed by the Great Lakes Commission has recommended that the lock be built at full Federal expense. The task force concluded that the cost-sharing provision should be waived because of the uniqueness and international nature of the project.

All-rail shipments of iron ore and agglomerates in the United States and Canada totaled 7.57 Mmt, a drop of 20% from the 9.48 Mmt of 1989. Separate statistics for the United States are not published to protect proprietary company information. Allrail shipments of pellets from Minnesota by the DM&IR and connecting lines amounted to 2.65 Mmt, 15% more than the 2.31 Mmt hauled in 1989.55 Shipments from USX's Minntac Mine at Mountain Iron to the Geneva works in Utah accounted for 1.35 Mmt or 51% of the all-rail total. An additional 1.02 Mmt of Minntac pellets was railed to USX's Edgar Thomson steelworks at Braddock, PA. About 155,000 mt of Minntac pellets went to the Chicago & Northwestern terminal at Escanaba for transhipment to Indiana Harbor. The 2.65 Mmt total also included 115.000 mt of Eveleth pellets that went to USX's Fairfield works near Birmingham, AL. Shipments of filter cake and miscellaneous ores accounted for another 110,000 mt. Shipments of pellets, small quantities of natural ore, and miscellaneous products to the Ports of Duluth and Two Harbors totaled 18.41 Mmt for a total ore movement on the railway of 21.17 Mmt during the 1990-91 shipping season. Approximately 1.71 Mmt of pellets was also hauled all rail via the Burlington Northern to NSC's two blast furnaces at Granite City, IL.

Published railway freight rates for pellets from mines to upper lake shipping ports were unchanged in Minnesota in 1990. The volume rate for pellets from the western Mesabi Range to the Allouez docks at Superior remained at \$5.01 per long ton. On April 1, 1990, the rate for pellets from the Marquette Range of Michigan to Presque Isle was raised from \$2.35 per long ton to \$2.45. Three days later, the rate to Escanaba (delivered direct into vessel) was raised from \$3.11 to \$3.18. Escanaba also had various dock and handling charges ranging from 3.5 cents to about 29 cents per long ton.

Selected ore transfer charges at lower lake ports were raised slightly in the third quarter of 1990. At Lake Erie ports, dockage charges for self-unloaders ranged from 15 cents per long ton at Conneaut to 27 cents at Cleveland. Ore transfer charges for self-unloaders from rail-of-vessel via dock-receiving areas into railway cars

varied from \$1.09 to \$1.21 per long ton.

Published nominal ocean freight rates for iron ore from eastern Canada to U.S. mid-Atlantic ports were \$3.50 to \$3.75 per dwt of cargo, but some spot rates quoted for cargoes of 60,000 to 110,000 dwt were as low as \$2.75 per dwt.

Prices

Very few published prices for domestically produced pellets changed in 1990. CCI and Oglebay Norton were both still quoting a price of 72.45 cents per long ton unit of iron, natural, for their standard grades of Lake Superior pellets. A long ton unit (ltu) is equivalent to 0.01 long ton or 22.4 pounds. The quotation included delivery to rail-of-vessel at lower lake ports. The Eveleth special grade of Oglebay Norton was listed slightly higher at 74.00 cents per ltu. Mineral Services Inc. continued to quote its lower price of 58.00 cents per ltu set in August 1985. At that time, Pickands Mather and Inland abandoned the traditional lower lake pricing base and began quoting 59.40 cents per ltu for pellets delivered to hold of vessel at upper lake ports. At yearend 1987, Inland dropped the price of its Minorca pellets to 46.84 cents per ltu, but Pickands Mather refused to follow. The 59.40 and 46.84 quotations were still in effect at the end of 1990. USX also retained its 1987-89 quotation. The price for Minntac acid pellets was left at 37.344 cents per dry ltu of iron, delivered into railcars at the Minnesota mine. This price equated to about \$24.12 per long ton of undried pellets containing 64.58% Fe and 1.39% moisture. The range of all of the above prices was approximately equivalent to \$34.91 to \$46.37 per long ton of pellets containing 64% Fe, delivered rail of vessel at lower lake ports. Some producers were charging a premium for fluxed pellets.

Prices for most foreign ores marketed in the United States are normally not published. There are two exceptions. The first exception is CCI's traditional quotation for Wabush pellets, which remained at 63.5 cents per ltu f.o.b. Pointe Noire, Quebec. In May 1989, the M.A. Hanna Co., the manager and marketing agent for the Iron Ore Co. of Canada (IOC), began quoting a price of 74.65 cents per ltu of iron, natural, for Carol Lake pellets. The quotation included delivery to rail-of-vessel at lower lake ports. The average f.o.b. value of all Canadian ores and agglomerates imported by the United States, as determined from data compiled by the Bureau of the Census, was \$36.35 per mt. This value was slightly lower than the average Canadian pellet value of \$36.90 because Canada also sold limited quantities of specially processed concentrates to the U.S. chemical industry. Other average f.o.b. values compiled under the new harmonized tariff system are compared in table 20.

Published f.o.b. prices for DRI were also unchanged from those quoted in 1989, and were as follows, per mt: at Georgetown, SC, \$125 to \$135; at Contrecoeur, Quebec, \$115; and at Point Lisas, Trinidad and Tobago, \$120. In 1990, the customs value of DRI imported from Venezuela ranged from \$100 to \$113 per mt.

Foreign Trade

U.S. exports of iron ore were 40% lower than those of 1989 because of the Michigan mine strike and related strikes at Canadian steelworks. Virtually all exports consisted of pellets and concentrates shipped via the Great Lakes to Canadian steel companies that are partners in U.S. taconite projects in Michigan and Minnesota. Consumption of iron ore at Canadian blast furnaces plummeted from 13.98 Mmt in 1989 to 9.93 Mmt. U.S. material accounted for 3.13 Mmt or 31% of the blast furnace total. An additional 56,000 mt of U.S. material was consumed at Canadian sintering plants.

U.S. imports of iron ore dropped 8% to 18.05 Mmt primarily because of cutbacks in blast furnace activity at selected steelworks in the mid-Atlantic region. Another factor was higher prices for Brazilian and Canadian ore on the world market, which made U.S. pellets more competitive in the Ohio River Valley and western Pennsylvania. In early 1991, several older, less efficient blast furnaces were shut down on the Eastern seaboard, further discouraging imports.

Total tonnage for 1990 was slightly greater than the mean of the previous 5 years, 17.93 Mmt, and was equivalent to 24% of ore consumption. Sharp drops of imports into the Baltimore and Chicago customs districts (both 41%) offset increases at Mobile, Cleveland, and Detroit (52%, 24%, and 85%, respectively). Canadian ores accounted for 52% of total U.S. imports; however, since 1982, Canada has had to struggle to maintain its share of the increasingly competitive U.S. market. Canada increased its share slightly to 12% from its 10-year low of 1989. Brazil, the second largest supplier, lost market share, slipping from 6.9% to 5.7%. Venezuela was close behind with a 4.7% share, down from 5.7% in 1989.

World Review

At least 47 countries mined iron ore during the year, producing a total of 919 Mmt. The U.S.S.R. was the largest producer, with an output of 168 Mmt of concentrate or direct-shipping ore plus 68 Mmt of pellets. Soviet production accounted for about 24% of the world's marketable output in terms of metal content. World production of pig iron, which directly reflects ore consumption, decreased slightly to 527 Mmt.

The world ore trade was estimated at 395 Mmt, of which about 86% was oceanborne.56 Brazil, the leading exporter, shipped 114.3 Mmt to world markets, slightly more than that in 1989. The top three customers of the Latin American giant were the European Community (EC) (43% of total exports), Japan (26%), and the Republic of Korea (7%). Australian shipments, in second place, dropped from 108.1 to 100.0 Mmt, primarily because of decreased imports by Japanese and German steelmakers. Japanese steelmakers produced 80.2 Mmt of hot metal in their blast furnaces, the same output as that in 1989. Japanese imports of Venezuelan ore have been gradually increasing since 1986, resulting in a readjustment of market shares. Australian exports to Europe stood at 18.98 Mmt (on a dry weight basis) and were down 10% from the 21.09 Mmt of 1989. The 12-member EC received a total of 133.0 Mmt of ore and agglomerates, down from 140.3 Mmt in 1989 but still edging out Japan as the world's principal importer. Japanese imports decreased slightly from 127.7 Mmt to 125.3 Mmt.

World production of pellets was estimated at 223 Mmt, about 84% of rated capacity. Preliminary data suggest that pelletizing plant output was down 4% from the 232.6 Mmt reported for 1989. Most plants in Brazil, Canada, Mexico, and Sweden were operating close to capacity. Producers in Bahrain, India, Peru, and the United States, though, still had significant underutilized capacity. More and more customers asked plant managers to switch to self-fluxed or olivine-base pellets. Dolomite-limestone fluxed pellets continued to be made in record amounts in Canada, Japan, and the United States.

According to the Midrex Corp., world production capacity for DRI in 1990 was 29.37 Mmt/yr.⁵⁷ Actual production was 17.88 Mmt, for an overall utilization of

61%. A breakdown by country is given in the "Iron and Steel" chapter. Gas-based plants accounted for 16.52 Mmt or 92% of the world total. Coal-based plants produced the remaining 1.36 Mmt. Gas-based plants in Argentina, Egypt, Qatar, Saudi Arabia, the United States, and the U.S.S.R. were running close to or exceeded rated capacity. The 800,000-mt/yr British Steel Corp. plant at Hunterston, Scotland, remained idle because of weak demand for steel in Europe and price competition from ferrous scrap. An additional 12 Mmt of capacity was expected to be completed by 1994.

HBI was in considerable demand throughout 1990, with shipments tripling to 1.36 Mmt. Merchant DRI remained in direct competition with high-quality home scrap (i.e., scrap internally generated within the steelworks). The long-term outlook for DRI was favorable because of the rapid dropoff in the generation of home scrap since the advent of continuous casting. Efficiency improvements at rolling mills had made the home scrap dropoff even more pronounced.

The second of two Midrex modules was started up at the new Misurata plant in Libya.⁵⁸ At the beginning of 1991, each of the modules was operating at its design rate of 75 mt/hr. New units were also brought on-line in India, Iran, and Venezuela.⁵⁹ The improved utilization of existing gasbased facilities in Indonesia, Mexico, and Venezuela was largely responsible for the 12% increase in world DRI production between 1989 and 1990. About 43% of the total output for 1990 was produced in Latin America. The four-module, 1.67-Mmt/yr Soviet complex at Stary Oskol was still operating at 102% of rated capacity and accounted for an additional 10% of the 17.88 Mmt.

For the first time in 4 years, iron ore exporters completed their annual price negotiations in Europe before fixing prices in Japan. This represented a return to the traditional negotiating pattern of the early 1980's. The traditional sequence of negotiations grew out of the fact that European contracts are based on the calendar year, while Japanese contracts are on an Aprilto-March fiscal year.

CVRD recaptured its old role as price setter. Formal negotiations between CVRD and the purchasing agents for the West German steel industry, Rohstoffhandel GmbH and Erzkontor Ruhr GmbH, began on November 8, 1989, but reached an impasse when CVRD insisted on a 29.9% price

increase for its fines and a 24.7% increase for pellets. The Brazilian producer felt that world iron ore prices should be restored to 1982 levels, with an adjustment for inflation. Between 1982 and 1986 world prices slumped, discouraging mining companies from investing in improvements needed to ensure long-term stability of supply. On January 17, 1990, after 10 weeks of choppy negotiations. West German steelmakers finally agreed to a price increase of 15.96% for Itabira fines, setting the Itabira price at 30.80 cents per Fe 1% per dry metric ton (dmt) f.o.b. Tubarão. This equated to a Rotterdam arrival price of about 41.40 cents. The price increase for Carajás fines was 16.78%, resulting in a new f.o.b. price of 32.50 cents.

Japanese steelmakers were carefully following the European negotiations and quickly settled with Hamersley Iron Pty. Ltd., the largest Australian producer, on January 24. The Japanese agreed to an across-the-board hike of 15.96% for all direct-shipping ores, regardless of country, with two minor exceptions. However, the Japanese felt that demand for pellets for blast furnaces was weakening and would only acquiesce to a pellet price increase of 9.02%. As in past years, premiums were paid on both pellets and lump. Prices negotiated under Japanese contracts for fiscal year 1990 are shown in table 25.

On an f.o.b. (shipping port) basis, most 1990 prices apparently ranged from about \$11.10 to \$25.60 per dmt for fines, \$19.70 to \$25.15 per dmt for lump, and \$28.75 to \$39.25 per dmt for pellets. Delivered prices (at receiving port) were about \$2 to \$15 higher, depending on ocean freight costs.

Seaborne trade in iron ore dipped slightly from the 1989 high of 362 Mmt. 60 The high shipping level reflected the continuing upswing in pig iron production in Asia.

World production of pig iron was only 3% less than the alltime high of 546 Mmt set in 1989. Pig iron production was off slightly in the EC, the main market for Brazilian ore, but blast furnaces in several other market economy countries continued to operate at rates not seen since the peak year of 1979. Ocean freight rates for iron ore declined steeply during the first 6 months of 1990. This decline came on the heels of 2 years of strong growth. By the end of June, rates had reached their lowest levels since the summer of 1987 and were still dropping. The invasion of Kuwait in August and the resulting crisis in the Persian Gulf region created an atmosphere of uncertainty within the shipping community.

In September, freight rates began to recover, making short-haul suppliers like Mauritania and Sweden more competitive. Published rates for spot charterings to the EC from Western Australia ranged from \$7.50 to \$11.85 per dwt for cargoes of 100,000 to 150,000 dwt compared with \$7.90 to \$12.50 in 1989. The 1990 rate ranges for other shipments to the EC are shown in table 26.

Rates for cargoes of 100,000 to 150,000 dwt to Japan from Western Australia ranged from \$5.10 to \$6.40. Higher rates applied to Port Latta in Tasmania because it cannot accommodate vessels greater than 100,000 dwt and is farther from Japan. Rates to Japan from the Brazilian Port of Tubarão for cargoes of similar size were \$10.55 to \$15.70. Rates to Japan from Ponta da Madeira, the loading point for Carajás ores, were about \$0.40 more than those for Tubarão.

Integrated iron ore operations have become extremely complex and resemble medium-sized towns in some cases. The production capacity of an operation of this magnitude is determined by equipment limitations at several stages of recovery. To simplify analysis and make comparisons of individual mines easier, data were collected that represent the rated or design capacity at three key points in the recovery process: crusher-screen output, concentrator output, and furnace output. These three points were chosen because they serve to readily separate the mining, beneficiating, and agglomerating stages of the operation. At the first two points, the iron ore is already in a marketable form and can be diverted for sale or tolling if bottlenecks occur either downstream at the operation or upstream at competitors' facilities.

Changes in the economics of the process could also make diversion feasible. Table 27 shows world pelletizing capability at the close of 1990. The data represent the rated capacities of 78 plants in 26 countries. Five of the plants were near or part of integrated steelworks and had no captive iron mines. A sixth, the natural-gas-based merchant operation in Bahrain, was also dependent on imported feed. A significant part of the data was collected by the International Iron and Steel Institute in 1987. The table excludes plants that have not produced since 1982. Four of these idled plants are identified in the table footnotes because they could be reactivated in some realistic scenarios. Table 27 also excludes all of the world sintering plants. Similar tables were being developed by the U.S. Bureau of

Mines that list world crude ore production capability and world concentrating capability.

OUTLOOK

The U.S. iron ore industry is totally dependent on the domestic steel industry for sales. This dependence is not expected to change in the near future. Because of this relationship, the reader is referred to the outlook sections in the "Iron and Steel" and "Iron and Steel Scrap" chapters. Only 6% of the iron ore shipped in 1990 was exported, with virtually all of it being pellets going to steelworks in Ontario. It is difficult for the United States to compete in the world iron ore market because of the country's declining ore grades, the inland location of its mines, and high labor and fuel costs.

The United States has exhausted the vast reserves of high-grade direct-shipping ore it once had in Michigan and Minnesota. Almost all of the ore being mined now is low-grade taconite, which requires costly beneficiation and pelletizing. Moreover, the taconite mining and pelletizing complexes are deep in the interior of the country, far from any saltwater harbor. Because of the advantages of Great Lakes shipping, U.S. pellets are currently competitive at Gary, Cleveland, and Detroit. However, high rail costs put U.S. pellets at a disadvantage in the mid-Atlantic States and Alabama. Imported ores and agglomerates from Brazil, Canada, and Venezuela constitute the bulk of the iron units consumed at these coastal steelworks. The St. Lawrence Seaway is a mixed blessing for the mining industry, being a bottleneck for ore carriers. The eight locks in the Welland Canal and the seven locks in the St. Lawrence River are all similar in size and have a gate-to-gate length of 262 m. The relatively short length of each lock prevents oceangoing ore carriers longer than 222 m from entering the Great Lakes. At the same time, domestic 1,000-footers cannot leave the Lakes. Foreign ore bound for Indiana or Ohio either has to be offloaded onto smaller vessels in the Gulf of the St. Lawrence or transferred to rail cars at Baltimore or Philadelphia. In some cases, ore is barged from the Port of New Orleans up the Mississippi River to steelworks in the Ohio River Valley and western Pennsylvania. The high rail costs that keep domestic ores from going to the coastal steelworks also

keep foreign ores out of the inland steelmaking regions.

For the near term, growth of the U.S. iron ore industry is tied to the growth of the integrated steelworks along the Great Lakes. This growth is expected to average less than 2% per year over the next decade and could very easily be negative if the current recession is prolonged. The U.S. steel industry is concentrating on making highvalue, quality steels, not increasing tonnage. Domestic blast furnace production in the year 2000 is expected to be no more than 60 Mmt compared with 49.83 Mmt in 1990. The U.S. iron ore industry has no choice but to focus on making higher quality agglomerates, such as fluxed pellets, that meet much tighter chemical and physical specifications than have been required in the past.

Electric arc furnaces currently account for more than one-third of total crude steel production. With advances in steelmaking, the impurity levels in the better grades of scrap are rising. This indicates a role for imported DRI in the coastal regions of the United States. As discussed in the "Technology" section, growth of gas-based DRI production capacity outside North America has been spectacular in recent years. Although a large part of this growth has occurred in Venezuela, the bulk of the construction has been spread evenly through a myriad of countries that have surplus natural gas. It is too early to tell whether coal-based DRI production will be economically feasible in the United States. No matter how spectacular DRI growth is over the next decade, it will not be able to replace more than a fraction of the world's blast furnace production because of technological restrictions. The blast furnace is expected to remain the mainstay of the iron and steel industries in most developed countries over the next 25 years.

In contrast to the United States, demand for iron ore in other parts of the world is expected to escalate. Some of the greatest growth is being experienced in the Far East. China is currently producing more hot metal than the United States and is modernizing and expanding blast furnace operations throughout the country. For example, a second blast furnace was commissioned at the key Baoshan iron and steel complex outside Shanghai in mid-1991. In 1990, China imported 14.34 Mmt of iron ore products and accounted for almost onefifth of world consumption. Smaller but no less spectacular growth is occurring in the Republic of Korea and Taiwan. Pohang

Iron & Steel Co. Ltd. of Korea now has seven blast furnaces-four at Pohang and three at Kwangyang, with a fourth planned for Kwangyang. Steelworks in the EC have become more competitive in recent years and should benefit from the growth in steel consumption that is forecasted to occur in Western Europe after the single market takes effect in 1992 and internal trade barriers are removed. Consumption of iron ore in Latin America is driven by pig iron production in Brazil and to a lesser extent, Argentina and Mexico. Brazilian pig iron production more than doubled between 1981 and 1989, but dropped off 34% in 1990. Price controls were reportedly responsible for the dropoff. Mexican pig iron production has been relatively constant since 1981, ranging from 3.2 Mmt to 3.9 Mmt. Japanese imports of iron ore are not expected to increase dramatically, in spite of the country's dynamic construction and automotive industries, because Japanese companies are moving upstream to higher value products.

11The term *collophane* originally referred to cryptocrystalline types of apatite that constitute the bulk of phosphate rock and fossil bone. In current practice, it is used to describe varieties of apatite that appear to be amorphous under transmitted microscopic light. For collophane grains that exhibit an X-ray pattern, the term *carbonate-fluorapatite* is used if they have a high fluorine content. Their OH-rich counterparts are called *carbonate-hydroxylapatite*.

²⁷The SL/RN Process employs a rotary kiln to reduce lump ore or pellets to DRI. Most of the air needed for combustion is injected through burner tubes spaced uniformly along the length of the cylindrical kiln or introduced axially from the discharge end. Additional air is injected under the bed in the preheating zone of the kiln. For details, refer to work cited in footnote 34, pp. 523-524.

²⁸The Allis-Chalmers Controlled Atmosphere Reactor (AC-CAR) produces highly metallized DRI in a ported rotary kiln. Liquid, solid, and/or gaseous fuels can be injected directly into the kiln. For details, refer to work cited in footnote 34, pp. 524-525.

⁵Chamosite is a yellow-green to greenish-gray iron-rich alumino-silicate that forms ooliths in sedimentary ironstones. Fine-grained varieties of the alumino-silicate are also found in the groundmass of the ironstone, together with siderite and kaolinite. The mineral, which contains about 30% Fe, is closely related chemically to the chlorites, but has a layered structure more akin to serpentine [Mg₆Si₄O₁₀(OH)₈]. Chamosite is a major constituent of the Jurassic ironstones of the English Midlands.

⁶The gamma is a unit used in geophysical prospecting to measure variations in the intensity of the Earth's magnetic field. The average magnetic field intensity at the Earth's surface is about 0.5 oersted. In magnetic surveying, a much smaller unit than the oersted is needed. One gamma equals 10⁻⁵ oersteds.

54This projection is not universally accepted. For an analysis of Great Lakes shipping costs and trends, the reader may want to refer to Marcus, P. F., et al. NA Not available.

²Data may not add to totals shown because of independent rounding.

¹Excludes dust, mill scale, and other revert iron-bearing materials.

²Sold to nonreporting companies or used for purposes not listed.

³Data from American Iron Ore Association.

⁴U.S. Bureau of Mines estimates based on production reports compiled by Midrex Corp.

⁵Includes iron ore consumed in production of cement and iron ore shipped for use in manufacturing paint, ferrites, heavy media, cattle feed, refractory and weighting materials, and for use in lead smelting. Data from U.S. Bureau of Mines surveys.

TABLE 11

IRON ORE SHIPMENTS FROM U.S. GREAT LAKES PORTS DURING THE 1990 NAVIGATION SEASON

(March 20, 1990, through January 31, 1991)

Port	Date of first shipment	Date of last shipment	Total shipments (thousand metric tons)
Duluth, MN	Apr. 4	Jan. 1	7,728
Two Harbors, MN	Mar. 20	Jan. 13	11,668
Silver Bay, MN ¹	Apr. 19	Jan. 7	2,234
Taconite Harbor, MN	Mar. 26	Jan. 2	8,795
Superior, WI	Mar. 24	Jan. 2	11,230
Marquette, MI	Mar. 22	Jan. 1	5,005
Escanaba, MI	Mar. 22	Jan. 31	4,987
Total ²	-		51,648

¹Cyprus Minerals Co. acquired all of the facilities of the defunct Reserve Mining Co. in Aug. 1989 and began shipping from Silver Bay on Apr. 19, 1990. This was the first shipment from Silver Bay since Nov. 1987.

eEstimated. PPreliminary. Revised.

¹Table includes data available through July 28, 1991.

²In addition to the countries listed. Cuba and Vietnam may produce iron ore, but definitive information on output levels, if any, is not available.

³Insofar as availability of sources permits, gross weight data in this table represent the nonduplicative sum of marketable direct-shipping iron ores, iron ore concentrates, and iron ore agglomerates produced by each of the listed countries. Concentrates and agglomerates produced from imported iron ores have been excluded under the assumption that the ore from which such materials are produced has been credited as marketable ore in the country where it was mined.

⁴Data represent actual reported weight of contained metal or are calculated from reported metal content. Estimated figures are based on latest available iron content reported, except for the following countries for which grades are U.S. Bureau of Mines estimates: Albania, China, Hungary, and North Korea.

⁵Nickeliferous iron ore.

⁶Reported figure.

⁷Dry weight.

⁸Series represent gross weight and metal content of usable iron ore (including byproduct ore) actually produced, natural weight.

⁹U.S. Bureau of Mines estimate of China's usable iron ore production. The ore grade of the series is equivalent to 50% Fe content to provide data approximately comparable with world market production. In actuality, run-of-mine ore in China averages only about 35% Fe. Production of crude ore, as reported by the Trust Fund Project on Iron Ore Information of UNCTAD was as follows, in thousand metric tons: 1986–142,480; 1987–152,540 (revised); 1988–154,380; 1989–162,160 (revised); and 1990–169,360.

¹⁰Includes magnetite concentrate, pelletized iron oxide (from roasted pyrite), and roasted pyrite (purple ore).

¹¹Data are for year beginning Mar. 21 of that stated.

¹²Gross weight calculated from reported iron content based on grade of 66% Fe.

¹³Concentrates from titaniferous magnetite beach sands.

¹⁴Includes manganiferous iron ore.

¹⁵ Includes magnetite ore as follows, in thousand metric tons: 1986-4,000 (estimated); 1987-4,979; 1988-5,492; 1989-6,594; and 1990-5,613.

¹⁶Includes byproduct ore.

¹⁷Less than ½ unit.

Staged additions are treated at some mining complexes as if they were separate plants. Site data exclude plants that have had no production since 1982. Plants that produced after 1979, but have been continuously idle since 1982, are cited in the footnotes because they could be reactivated at some reasonable cost.

tivated at some reasonable cost.

The total for the United States includes the newer part of the E. W. Davis Works at Silver Bay, MN, but not the idled plant owned by Cleveland-Cliffs Inc. at Republic, MI. Cyprus Minerals Co. acquired the cannibalized Silver Bay facility in Aug. 1989 and resumed production in Jan. 1990. Cleveland-Cliffs has been considering reopening its 1.3-Mmt/yr Republic plant, which has been on care and maintenance since 1981. Pellets produced from imported direct-shipping ores and/or concentrates.

Two older plants in Norway are no longer considered economically viable. The first, the older of two plants operated by A/S Sydvaranger at Kirkenes, has been idle since 1986. The second, the 0.50-Mmt/yr plant operated by Norsk Jernverk at Mo-i-Rana, was shut down in Jan. 1987 for an indefinite period, leaving only one plant in Norway on-line.

In early 1988, the capacity of the Svappavaara plant was upgraded from 2.8 to 3.5 Mmt/yr. The 0.3-Mmt/yr steel belt plant at Malmberget is used for both research and development purposes as well as ordinary production.

⁶Based on incomplete information.

The Skopje plant operated by Rudnici i Zelezara was recently idled.

**Excludes the No. 1 pelletizing plant (capacity of 2.4-Mmt/yr) of the Bong Mining Co. The No. 1 plant has been idle since 1980.

**The Nador plant operated by Societe d'Exploitation des Mines du Rif (SEFERIF) has been idle for several years.

**OTHER INDICATE:

**OT

IRON OXIDE PIGMENTS

By David A. Templeton

Mr. Templeton is a physical scientist with the Branch of Industrial Minerals and has been with the Bureau for 3 years. He has covered iron oxide pigments for less than 1 year. Domestic survey data were prepared by Ms. Sarah P. Guerrino, and world production data were prepared by Ms. Audrey Wilkes.

ccording to the U.S. Bureau of Mines, U.S. Department of the Interior, mine production of iron oxides returned to pre-1989 levels, a decrease of almost 12% from the 1989 peak. Domestic sales of synthetic pigments, not total production, declined nominally (about 4%) in 1990 from the peak also seen in 1989. Sales of regenerator and steel-plant waste iron oxides totaled 28,161 tons as compared with 30,745 in 1989.

DOMESTIC DATA COVERAGE

Data for mine production, sales of finished pigments, and quantified steel-plant wastes were compiled from responses to a voluntary survey conducted by the U.S. Bureau of Mines. Mine production of and sales data for crude iron oxide pigments as shown in table 1 were tabulated using information supplied by the five known producers. Hematite shipped from the Cleveland-Cliffs Iron Co. Mather Mine stockpile is not included in "Mine

production," but rather in "Crude pigments sold or used." These shipments are not depicted by the difference in data because mine sales can be either greater or less than production (i.e., stocks decreased or increased, respectively). Survey response by the finished pigment producers was 100%. Table 2 presents the data for domestic sales of finished pigment, not total production, obtained through the Bureau survey. Seven companies operating a total of eight plants provided the Bureau with a full accounting of regenerator and steel-plant waste iron oxides sold.

CONSUMPTION AND USES

The continued use of iron oxides in diverse markets ranged from construction products and pigments to magnetic materials (ferrites) and catalysts. As in the past, this use was due to the low cost, ready availability, and adequate, if not superior, performance of iron oxides. The majority of iron oxides, both natural and synthetic, was consumed as pigments in formulating paints and in construction materials such

as concrete bricks, paving stones, and roofing tiles and granules. Minor uses included catalysts for the manufacture of industrial chemicals; fertilizer; trace mineral supplements in animal feed; binding medium for foundry sands; colorants for glass, plastic, and rubber; and several uses incorporating the magnetic properties of specialty iron oxides (e.g., hard and soft ferrites and magnetic inks and toners).

FOREIGN TRADE

Except for a significant increase in exports of nonpigment-grade iron oxide (most notably to Australia, Austria, Belgium, Canada, Japan, and the United Kingdom), the trade picture remained relatively unchanged. Total exports of nonpigment-grade material increased nearly sixfold. (It is likely that the data in table 5 received from the Bureau of the Census is in error and is being reviewed for accuracy.) Exports of pigment-grade iron oxide declined only slightly from 1989 levels. Imports of iron oxide pigment exceeded exports by just more than $3\frac{1}{2}$

TABLE 3

PRODUCERS OF IRON OXIDE PIGMENTS, REGENERATOR IRON OXIDES, AND STEEL-PLANT WASTE IRON OXIDES IN THE UNITED STATES IN 1990

Producers	Plant location					
Finished pigments:						
AST Co.	Granite City, IL.					
American Minerals Inc.	Camden, NJ.					
Blue Ridge Talc Co. Inc.	Henry, VA.					
Columbian Chemicals Co.	St. Louis, MO.					
DCS Color & Supply Co. Inc.	Milwaukee, WI.					
Harcros Pigments Inc.	Emeryville, CA.; East St. Louis, IL.; Easton, PA.					
Hilton-Davis Co.	Cincinnati, OH.					
Hoover Color Corp.	Hiwassee, VA.					
Mobay Corp., Inorganic Chemicals Div.	New Martinville, WV.					
New Riverside Ochre Co.	Cartersville, GA.					
Pea Ridge Iron Ore Co.	Sullivan, MO.					
Prince Manufacturing Co.	Quincy, IL, and Bowmanstown, PA.					
Solomon Grind-Chem Services Inc.	Springfield, IL.					

times, and synthetic material accounted for 95% of the 34,000 tons imported. The largest sources of imports, in descending order, were Canada, the Federal Republic of Germany, Japan, Mexico, China, Cyprus (crude ore only), Brazil, and the United Kingdom. A complete listing of foreign sources of natural and synthetic pigments is given in table 7, and the breakdown in terms of color can be found in table 6.

WORLD REVIEW

Pfizer Inc.'s longstanding desire to divest itself of its pigment interests was realized in March with the \$65 million sale to Harrisons & Crosfield PLC's U.S. subsidiary, Harcros Pigments Inc. Harcros had heretofore been the sole U.S.

¹Includes pyrite cinder.

²Includes synthetic black iron oxide.

³Includes other specialty oxides and mixtures of natural and synthetic iron oxides.

⁴Included with synthetic yellow iron oxide to avoid disclosing company proprietary data.

TABLE 3—Continued

PRODUCERS OF IRON OXIDE PIGMENTS, REGENERATOR IRON OXIDES, AND STEEL-PLANT WASTE IRON OXIDES IN THE UNITED STATES IN 1990

Producers	Plant location
Crude pigments:	
Cleveland-Cliffs Iron Co., Mather Mine and Pioneer plant (closed July 31, 1979; shipping from stockpile)	Negaunee, MI.
Hoover Color Corp.	Hiwassee, VA.
New Riverside Ochre Co.	Cartersville, GA.
Pea Ridge Iron Ore Co.	Sullivan, MO.
Swansea Minerals Inc.	Tempe, AZ.
Virginia Earth Pigments Co.	Hillsville, VA.
Regenerator and steel plant waste iron oxides:	
Armco Steel Co.	Ashland, KY.
Cheseapeake Specialty Products	Baltimore, MD.
Gulf States Steel Inc.	Gadsden, AL.
Perox	Birmingham, AL, and Sharon, PA
Petco Inc.	Lehi, UT.
Shance Chemical Corp.	Philadelphia, PA.
Weirton Steel Corp.	Weirton, WV.

distributor for the United Kingdombased parent. The sale included pigment operations located in Emeryville, CA, East St. Louis, IL, and Easton, PA.

Another significant industry transaction included the \$12 million sale of the Pea Ridge Iron Ore Co., Sullivan, MO, by the Fluor Corp. of Irvine, CA, to the Big River Minerals Corp., St. Louis, MO. Pea Ridge produces a natural black oxide (magnetite) used primarily in ceramic magnets and brake linings.

The AST Co., Granite City, IL, began production of synthetic yellow iron oxide with a proprietary process in which the material is precipitated from a ferric chloride-rich pickle liquor. The process is said to be much less energy intensive than other methods of producing regenerator oxides (e.g., spray roasting or acid evaporation) and uses a warm (170° F) hydrochloric acid bath to pickle nonscrap, low-carbon steels. The process can be perceived as double value added: not only does it accomplish the servicing of finished

steel products, but it also produces synthetic iron oxide pigment. According to the developer, the process can be used to treat the pollution-plagued problem of steel-plant waste streams.

BASF AG announced intentions to invest in the production, most likely in Europe, of 150 tons per year of iron oxide-coated aluminum flake. The pigment, Paliocrom Gold, produces a metallic gold sheen that varies with the viewing angle by the different ways incident light is affected. Some of the light is reflected by the flake and some by the coating.

Furthermore, the coating partially absorbs incident light rays. The pigment was developed at BASF's laboratory in Ludwigshafen, Federal Republic of Germany.¹

OUTLOOK

The long-term outlook for the U.S. iron oxide pigment industry is expected to be one of continued growth despite decreases of mine production and finished pigment sales in 1990. Principal factors

are the popularity of earth-toned colors, resurgence of growth in construction activities, and continued market development in paints and coatings and specialty oxides. The innocuous nature of iron oxide pigments may accelerate growth in this industry as heavy metal-bearing pigment usage wanes. However, declines in residential and commercial construction starts may have a greater impact and, therefore, hold back generally expected growth. The need for infrastructure improvements in the United States has been established, and, when implemented,

IRON AND STEEL

By Anthony T. Peters

Mr. Peters, a physical scientist with 33 years' industry and U.S. Bureau of Mines experience, has been the commodity specialist for iron and steel since 1988. International data tables were prepared by Virginia Woodson and Harold Willis, international data coordinators.

ron and steel are vital to the United States for both national security and economic well-being. They are the basic metals of any industrial society. Although there are technically acceptable substitutes for many of their small-scale uses, there are no practical substitutes on a large scale because of the cost and lack of availability of alternative materials.

Companies involved in iron and steel include ferrous foundries, steel mills, and the ferrous scrap industry. Foundries pour molten cast iron or steel into molds to produce castings with approximate shapes of the final products. Steel mills cast relatively simple steel shapes that the mills roll or hammer into finished products, such as sheet, bar, or structural shapes. Steel mills can be divided into integrated mills, which produce pig iron from ore and refine the pig iron to steel, and nonintegrated mills that use scrap as their primary raw material.

During the remainder of the century, growth of demand for iron and steel in the industrialized countries is expected to be slow compared with that in the 1950's and 1960's. Factors causing the lower growth include a shift of the industrialized economies toward services and manufacturing industries that use little iron and steel, more efficient use of materials in manufacturing and construction, substitution of other materials for iron and steel, and imports of manufactured products from developing countries.

The production of raw steel in 1990, 89.7 million metric tons (98.9 million short tons), was almost exactly 1 million tons higher than that of the previous year. Steel shipments were valued at approximately 40 billion dollars.

All companies reported sharply reduced profits, with a few actually incurring losses. There are many reasons for this apparent contradiction. As the economic downturn continued during the year, steel demand dropped, but the steelmakers continued to produce steel in expectation of an imminent upturn; this trend became strong when con-

sumer confidence dropped to very low levels at the start of the war in the Persian Gulf in September.

Furthermore, the trend to make steel ahead of orders was supported by the general expectation of a strike at the U.S. Steel Corp. that did not materialize. Large amounts of steel were shipped on generous credit terms, reflected in frequently sharp increases in accounts receivable.

Improvements in technology, such as a further increase of the proportion of steel cast continuously to more than 67%, reduced operating costs but increased labor costs and provisions for the shutdown of unprofitable operations, or costs of severance of a number of employees, were often greater than the savings. Furthermore, the increased inventories caused price wars of unprecedented severity—discounts from nominal or "list" prices of up to 30% became common.

Imports were roughly the same as those in 1989, 15.7 million metric tons (17.3 million short tons); the major exporters, Japan, the European Community, and Canada, shipped a little less, but the other, smaller exporters shipped, in general, a little more. Exports, 3.9 million metric tons (4.3 million short tons), were 0.3 million less than in 1989.

Declared steelmaking capacity increased slightly during the year, from 105.1 to 105.8 million metric tons (115.9 to 116.7 million short tons). This, however, was the result of process improvements and restarting a small shuttered minimill rather than of any "greenfield" construction. Plans to construct at least two minimills with a combined capacity of more than 2 million metric tons were announced during the year.

Overall performance data are shown in table 1 and highlights of technical improvements in table 2.

DOMESTIC DATA COVERAGE

Data regarding the domestic production of iron and steel are those developed by the

American Iron and Steel Institute (AISI). The members of this organization produce about 85% of domestic steel. Nonmembers informally notify AISI of their production numbers; hence, the data reported here can be regarded as complete.

Numbers referring to imports and exports of steel and its products were developed from information obtained from the Bureau of the Census. Other data were obtained from company reports and the trade press.

BACKGROUND

Integrated Steel Producers

Integrated steel producers are those that smelt iron ores, usually in the form of pellets, to crude liquid iron in blast furnaces and refine the iron, with some scrap, in basic open-hearth or basic oxygen furnaces, producing liquid steel. This is mostly cast into semifinished sections in continuous casting machines, although 34% of production was poured (cast) into ingots that were rolled into slabs or blooms.

The product mix of the integrated producers consists predominantly of flat products, sheet and strip, some of which is coated, galvanized, or tin plated. Some plates are made as well, but not many shape products, bars, and structurals. This field has been taken over by the nonintegrated producers.

Nonintegrated Steel Producers

The nonintegrated producers melt scrap in electric arc furnaces and cast the steel in continuous casting machines. The definition includes the well-known "minimills." However, the meaning of this expression changed within the past few years. It used to be accepted that a minimill produces only low-quality, nonalloy steel as simple bars and structural shapes, such as reinforcing bars, wire rods, angles, tees, and small channels, in furnaces with not more than a

Revised.

91-metric-ton (100-short-ton) capacity and that the total mill output is at the most 910,000 metric tons (1 million short tons) per year. Almost all of these operations were closely held by a few investors.

This situation is still valid in many cases, but exceptions are too numerous to be disregarded. Many mills tap heats exceeding 100 tons; actually, Northwestern Steel and Wire Co. has the biggest furnaces in the world, making 365-metric-ton (400-shortton) heats. Several mills exceeded the 1 million yearly tons figure; two corporations running several mills, Nucor Co. and North Star Steel Corp., have outputs exceeding those of the two or three smaller integrated producers. All minimills make highstrength low-alloy steels where the alloy content, usually columbium or vanadium, seldom exceeds one-quarter of 1%; many make also the traditional alloy steels, those with alloy contents not exceeding 5%. Several mills make higher quality grades, up to "forging quality," that are subject to severe testing and performance guarantees. Three roll only plates, two of them, highquality grades. The Nucor Co. pioneered in the concept of "thin slab casting" and produced close to 1 million short tons per year of hot-rolled sheet and coil in its Crawfordsville, IN, mill. The larger and more advanced mills are sometimes called "market mills," but this term is not well defined and thus not widely used.

Alloy Steel Producers

The definition of alloy steels is quite straightforward: an alloy steel must contain up to 5% of intentionally added alloying elements (the lower limits are different for each element, varying from 0.05% in the case of molybdenum to 0.35% for chromium). High-alloy steels are those containing more than 5% alloys, but must have at least 50% iron to be classified as steels. Stainless and hot-work or high-speed tool steels are the best known examples of high-alloy grades. High-alloy steels are made only by specialized producers, who often make simpler alloy steels and occasionally plain carbon grades.

The often used expression "specialty steel" is vague in that almost any steel may be called special if made to some unusual or very demanding customer requirements. For instance, there is nothing special in a low-carbon steel for deep drawing, but the same grade vacuum degassed and with nitrogen stabilized by an almost undeterminably low addition of boron is very spe-

cial. Also, a plate containing 1% manganese is not special at all unless it is made, for instance, to meet stringent impact resistance requirements at subfreezing temperature.

Substitutes

Iron, as steel or cast iron, is the most widely used metal in the entire world. The reason is the high strength-to-cost ratio. In applications where strength is not the major requirement, iron competes with less expensive nonmetallic materials or more expensive materials having some property advantage. Where weight reduction is required, aluminum, plastics, and occasionally magnesium or titanium may be substituted; motor vehicles and airplanes are obvious examples. In construction, concrete, usually reinforced with steel, and wood are frequently substituted for steel. In packaging, steel cans, pails, and household goods were largely replaced with aluminum, glass, plastics, and paper, but drums and other containers used for more severe applications are almost invariably made of steel.

ANNUAL REVIEW

Legislation and Government Programs

The legislation most affecting the industry was the passage of the Clean Air Act Amendments of 1990. A study by the U.S. Bureau of Mines (to be published) indicated that a number of older coke batteries owned by integrated steel mills would probably be uneconomical to upgrade to the mandated air purity standards and would be closed down. As a consequence, coke imports would increase from a range of 2 to 3 million to 6 to 8 million short tons per year.

The most-favored-nation customs status was given to Czechoslovakia, Hungary, and Poland. The practical effect of this change is a sharp lowering of customs duties; for instance, in the case of Czechoslovakia, the average duty would drop from 29% to about 6%

The Department of Energy (DOE) contracted with Surface Combustion Inc. to construct and evaluate a commercial-sized installation to preheat scrap before charging it into electric arc furnaces. The project was based on a pilot plant developed by Surface Combustion.

The DOE also partly financed two trials by the Bethlehem Steel Corp.: a project to

study coals involved in direct injection of coal powders into blast furnaces in the Burns Harbor mill costing \$31 million and an ongoing project to upgrade an older coke battery in the Sparrows Point works to the proposed Clean Air Act pollution limits.

The direct steelmaking joint project between DOE and the AISI, mostly financed by the DOE, continued, and the contract was extended from 1 to 3 years. The project involved eight steelmaking companies. The total expected cost was \$30 million with about \$23 million coming from DOE.

With the pending expiration in March 1992 of the Voluntary Restraint Agreements (VRA's) of steel imports to the United States, talks were initiated by the U.S. Trade Representative with the major steel exporters to the United States in April 1990. The talks intended to convert the bilateral agreements regarding "unfair trade supports, especially almost all subsidies," into a multilateral agreement to be extended worldwide. Following the broad agreements reached in informal talks with Brazil, Japan, Mexico, and the European Community, the subject was introduced at the final session of General Agreement on Trade and Tariffs (GATT) in Brussels. Since the collapse of the talks owing to the disagreement about European agricultural subsidies, the talks reverted in December 1990 to individual signatories of the respective VRA's, and it appeared that a major international agreement may be in the offing.

Unfortunately, in November, AISI presented a study that showed that many countries continue to subsidize their steel industries, often in a modified form, such as taking over steel companies' debts by central state banks, guaranteeing loans for expansions, etc. Also, many countries continued the practice of dumping steel in the U.S. market. This study could interfere with the negotiations.

In accordance with the provisions of the Trade and Tariff Act of 1984, the U.S. International Trade Commission (ITC) determined whether domestic steel companies with a positive cash-flow actually reinvested profits, retrained displaced workers and, in general, adjusted to international competition. The ITC certified, and the President accepted the findings, that all nine major steel companies had an aggregate cash-flow of \$1.1 billion during the first 9 months of the budget year (October 1, 1989, through September 30, 1990), while steel-related expenditures were \$1.5 billion. The ITC also certified that during the last quarter of the year, expenditures would exceed the cashflow. In every case, expenditures for retraining workers displaced by modernization exceeded 1% of net cash-flow.

A study by the Congressional Office of Technology Assessment indicated that about \$1 trillion may be needed to reconstruct and upgrade the existing but deteriorating U.S. infrastructure—the roads, bridges, sewage plants, schools, and post offices, etc. Out of this sum, steel would represent about \$16 billion. These numbers included supporting structures, such as office buildings, and the needed construction equipment. However, since this sum would have to come out of taxes, the chance of this rebuilding actually occurring in the near future was not considered by industry analysts to be high. The Office of Technology Assessment expressed an opinion that local initiatives on a smaller scale would have a better chance of success.

One unusual example supported this suggestion. During the primary elections in California, the voters approved a measure that would double the gasoline taxes by 1994. The proceeds from this increase were explicitly earmarked for the rebuilding and construction of roads and other transit projects. This outcome may signal the beginning of new willingness of voters to approve such expenditures.

Production

Integrated Steel Production.—The 13 integrated steel companies ran at yearend 46 blast furnaces, 3 open-hearth shops with 15 operable furnaces, and 25 basic oxygen shops with 58 furnaces. Also, one producer of high-alloy steels used basic oxygen furnaces but charged them with iron obtained by remelting pig iron and scrap in large electric induction furnaces.

The last remaining three open-hearth shops are expected to be closed and replaced with basic oxygen furnaces within the next few years. One was actually slated for replacement in 1991.

The year started out moderately well, but the general slump of economic activity in the country began to be felt by late spring. The beginning of the war in the Persian Gulf in September depressed consumer confidence, resulting in sharp drops of sales of goods that use large amounts of flat products, such as automobiles, appliances, and furniture. Construction, especially new housing starts, dropped sharply as well.

As a result, by yearend, several companies showed losses, and the profits of the others were much lower than those in 1989.

For the first time in many years, three blast furnaces and one basic oxygen shop were shut down toward yearend for lack of orders. Overall operating rates dropped from about 85% to a range of 65% to 70% of nominal capacity.

No capacity increases were planned, although some steelmaking capacity increases were the result of improved operating practices and further extensions of continuous casting. Most of the capital expenditures were directed toward the middle and finishing operations, hot- and coldrolling mills, aiming at improvements in quality and productivity rather than outputs. More galvanizers were planned as joint ventures with Japanese steel companies.

Important structural changes took place during the year. The USX Corp. announced a plan to issue separate stock for Marathon Oil Co. and U.S. Steel Corp. This would make it easier to sell all or a part of the steel operations. U.S. Steel Corp. reached an agreement on a new labor contract with the United Steelworkers. The contract contained an unusual feature, a guarantee that senior workers would retain their benefits regardless of whether the plant where they work was to be sold or not. This was generally regarded as a hindrance to selling unprofitable operations.

Armco Steel Co. L. P., 45% owned by Kawasaki Steel Corp., reached an agreement with its employees in line with the U.S. Steel contract lasting 4 years but containing a nostrike pledge valid for 8 years.

Sharon Steel Corp. was split into two parts, the steel mill and the nonferrous interests, with the secured creditors agreeing to take over the steel mill in payment of their debts, while the unsecured creditors took over the nonsteel properties. This agreement was accepted by the bankruptcy court, effectively clearing the way for Sharon Steel to emerge out of bankruptcy.

The second largest steel producer, Bethlehem Steel Corp., announced spinning off the shape products operations to form a wholly owned subsidiary. This included the Johnstown, PA, works where a new caster was planned, the Bethlehem mill, and the rolling shops in Lackawanna (steelmaking there was closed several years ago). Toward yearend, a plan was announced to enter into a 50-50 joint venture with the British Steel Corp. to produce rails and shape products. The plan called for expanding the Steelton works near Harrisburg, PA, and abandoning steelmaking at Bethlehem, PA, which would become a finishing facility. Both developments were subject to receipt of concessions from the United Steelworkers regarding work rules. Resolution of this problem was expected to be lengthy and expensive: Bethlehem Steel wrote down \$550 million as the cost of restructuring these facilities, shipbuilding, and other operations. The result of these charges was a \$433 million loss reported for 1990.

National Intergroup Inc. sold for \$147 million another 20% of National Steel to its half-owner, the NKK Corp. The future sale of another 20% was agreed on, leaving the American company with a nominal 10% ownership. The new Japanese owners announced the construction of a new, large coke battery with a capacity of 850,000 tons per year using the latest Japanese technology.

Inland Steel Co. announced its decision to build at least one coke battery using a modification of the design of the Sun Coal Co., a modern version of the old beehive ovens. All byproducts are burnt in the oven resulting in absence of pollution owing to the negative pressure in the oven obtained by the strong suction from the exhaust. Steam, used for power production, is the only coproduct. The drawback of the design was the large amount of space required.

National Steel Corp. started its degasser at the Granite City, IL, mill; so did the Bethlehem Steel Corp. at its Burns Harbor, IN, plant. The Armco Steel Co. L. P., upgraded its degasser in Middletown, OH. All these are expected to contribute to the quality of the highest grades of flat rolled steel.

The expansion of continuous casters progressed rapidly. Geneva Steel Corp. in Provo, UT, decided to install a caster that was designed to cast slabs of medium thickness, 152 millimeters (6 inches), but may be modified to thin slab casting, 50 millimeters (2 inches), if the technique, pioneered by the Nucor Corp., would prove satisfactory. This would save Geneva a part of the replacement cost of its combination plate and hot strip mill, which, although upgraded, dated back to 1943. This caster will be fed by a Q-BOP (Basic Oxygen Process) steelmaking shop, a version of the basic oxygen furnace process. Geneva bought the entire melt shop from the South Chicago plant of the U.S. Steel Corp., had it dismantled and shipped to Utah, and was reerecting it there. The total cost of this expansion was stated to be \$226 million, including other minor developments. The open-hearth shop would be closed.

Weirton Steel Corp. expanded its slab caster to handle 2.8 million short tons per

year from 1.8 million. This made Weirton a 100% cast-steel mill. The Granite City, IL, plant of National Steel also started to use its second slab caster. Gulf States Steel Inc. added a ladle metallurgy station to its recently started slab caster. The caster was originally owned, but not installed, by a Spanish steel company that was closed as one of the conditions for Spain entering the European Community; thus, Gulf Steel bought it for a fraction of its cost, reportedly for \$42 million.

The United States Steel Corp. started the construction of a large slab caster at its Edgar Thomson Works in the Mon Valley in central Pennsylvania. When this caster and the slab caster under construction at the Gary Works in Indiana are completed, U.S. Steel Corp. will double its continuous casting capability, which at present is 42%, much below the national average of 66%, including minimills. The cost of the Mon Valley project was estimated to be \$256 million.

The expansion of continuous casters diminished the need for ingot molds. As a result, the Shenango Group Corp. closed its blast furnace and ingot mold foundry in Neville Island, PA; this was the last "merchant" blast furnace left in the United States not associated with a steel mill.

Construction of a large number of new galvanizing plants was announced. Inland Steel Co. and Nippon Steel Corp. started the construction of a galvanizing plant next to the recently started continuous coldrolling mill; toward yearend this mill started to ship class I products but had problems with synchronizing its many process computers. Bethlehem Steel Corp. announced plans to build galvanizing lines in its Burns Harbor, IN, and Sparrows Point, MD, mills; these will be partly financed by Japanese banks. The Wheeling-Pittsburgh Steel Corp. and the Nissan Steel Co. started to build a second line at their jointly owned facility. Armco Steel Co. L. P., and its partner, Kawasaki Steel Corp., decided to build a third line in their Middletown, OH, mill. Kobe Steel Corp. and USX Co. jointly started to build a large galvanizing plant in Leipsic, OH. All these were to be hot-dip operations. No firm cost or capacity data were announced.

Nonintegrated Steel Production.—The nonintegrated producers make about 25% of all the steel produced in the United States and keep their output up even in times of low demand by lowering prices or increasing the discounts from list prices. Not

all companies publish price lists, and few bother to keep them up to date. This resulted in a severe erosion of profits in 1990. Many producers showed in their stockholders' reports profits of under \$10 per short ton and the lowest selling prices in many years (e.g., reinforcing bars in standard sizes could be bought for \$280 per short ton).

Nevertheless, these producers kept updating their operations and, in many cases, expanding their production facilities. However, one company, the 118-year-old Colorado Fuel and Iron Corp., formerly an integrated producer, asked the local court for protection from creditors under the terms of chapter 11 of the Bankruptcy Act. The reason for this failure was the inability of the company to make the legally required contribution to its pension fund. The Birmingham Steel Corp. closed its melt shop in Norfolk, VA, and supplied the rolling mill with billets made in the much updated and expanded Kankakee, IL, plant. Also, Birmingham closed its small Emeryville, CA, operation because it was uneconomical, especially with respect to the high value of the ground it occupied. This company announced a plan to buy the obsolescent Seattle Steel Corp. and combine its output with that of its own mill nearby, in Kent, WA, retaining only one melt shop. The company's California customers would be served from this location and in the future from the announced new mill near Phoenix.

Birmingham Steel backed out of the earlier announced plan to build a flat products mill in Texas, with a scrap preparer, Proler Corp., and an Italian engineering company as partners. The reason given was the heavy capital outlay required, much higher than the original estimates.

The Nucor Co., following the success of its aforementioned Crawfordsville, IN, flat products mill, announced a plan to build another similar operation close to its beam mill in Arkansas. The expected cost was in excess of \$300 million. This mill will have no pickling, oiling, or cold-rolling facilities because independent final processors are nearby. However, it will be sized to handle 27-metric-ton (30-short-ton) coils, rather than 18-metric-ton coils used at Crawfordsville. It will roll thinner gage steel than the other mill, thus enlarging the product range.

The Nucor-Yamato mill rolling beams in Blythesville, AR, mentioned previously, had a ladle furnace built at a cost of \$4 million. The objective was to reduce costs by improving the quality of the steel, inci-

dentally obtaining increase of the rated capacity of 650,000 product tons. A further expenditure of \$14 million could raise the plant capacity by 30%.

As the result of the startup of Crawfords-ville and the improvements in Blytheville and other mills, Nucor became the largest nonintegrated steel company in the United States, having made in 1990 3.15 million metric tons (3.46 million short tons). This output surpassed the output of three integrated mills owned by Rouge Steel, Weirton Steel, and Wheeling-Pittsburgh Steel Co.

The market for structural shapes and especially for wide flange beams, affected by the entry of the Nucor-Yamato plant, got a further jolt when the new plant of Northwestern Steel Co. near Houston, the former shape products plant of Armco Inc. that was considerably expanded and updated by its new owners, entered the market. Its capacity was declared to be about 540,000 metric (600,000 short) product tons. Additionally, Chaparral Steel Corp. was building another mill for structural products, including beams up to 24 inches wide, rated tentatively at 450,000 metric (500,000 short) product tons per year. The costs of this product should be low because it will start with a dog-boneshaped cast beam blank, close to the required final shape, and thus will require very little rolling.

As a response to severe price competition, Inland Steel Co. announced that it would cease its structural production in early 1991. The USX Co. made continued production of beams at the South Chicago mill contingent upon the United Steelworkers accepting changes of work rules that would increase productivity. If this mill closed, it would mark the end of production of structural products from integrated steel operations and the closure of the 90-year-old south Chicago mill.

Northwestern had the distinction of receiving the Japanese Industrial Standards Certificate from Japan's Ministry of International Trade and Industry, being only the second U.S. steel company to receive this award, after the Chaparral Steel Corp. This quality award is necessary for bidding on construction projects in Japan that use any governmental funds.

One-half of Georgetown Steel Corp. in Georgetown, SC, was sold to Unimètal Co., a branch of the French Usinor Sacilor Groupe, the second largest steel corporation in the world after Japan's Nippon Steel Corp. Unimètal already was the largest foreign supplier of wire rod to the United States. Shortly afterward, in November

1990, it was announced that the new company would install a 550,000-metric-ton (600,000-short-ton) billet caster intended mainly for the production of high grades of wire, such as tire and piano wire.

The NS Group announced the startup of a continuous caster in its Newport works, which makes mainly welded pipe; also, a new reheating furnace was installed. The group bought the shuttered works of Koppel Steel, owned by Babcock and Wilcox Corp., in Koppel and Ambridge, PA. Koppel Steel produced seamless tubing and special quality bars before it was closed in 1988, a result of the collapse of the oil tubing market. The capacity of Koppel is 360,000 metric (400,000 short) raw steel tons per year; Ambridge is the finishing operation.

The nonintegrated steel producers use scrap as their raw material. This results in the retention in the steel of large amounts of "residual elements" contained in the scrap, mainly copper and tin, that cannot be refined out of a steel bath, and chromium and others that can be only partially removed. The effect of these elements is often detrimental, especially for some high-quality steel products.

A recognized substitute for scrap that does not carry any residual elements is direct-reduced iron (DRI). In the United States, it is made only by Georgetown Steel Corp. for its own internal use. The use of DRI dilutes the residuals to the point where they cease to have a measurable influence on the steel properties. Nucor's Crawfordsville plant is known to use up to 30% of the charge as DRI; other steelmakers are known to use it for specific applications.

In midyear, Oregon Steel Corp., a plate and tube maker, announced that it was entering into a joint venture with the Venezuelan CVG Co. to build a DRI plant near the rich iron ore mines in the Orinoco River basin. The plant was to cost \$220 million; it was to use the Midrex process. Oregon Steel would finance up to 80% of the venture and have a claim on up to 75% of the 750,000 metric tons (825,000 short tons) of the DRI briquettes produced per year.

Alloy Steel Production.—Production of alloy steel in 1990 was 9.3 million metric tons (10.3 million short tons); that of stainless grades was 1.8 million metric tons (2.0 million short tons). Alloy steels are being partially replaced by the high-strength low-alloy grades that are reported as plain carbon steel. Production of stainless steels remained steady for several years, but is expected to show an increase owing to in-

creased activity in the pollution controls industry. Almost exactly 50% of stainless but only 37% of alloy grades were cast continuously. This was probably due to the fact that orders for alloy steels are usually small, not conducive to making long strings of continuous casts, or the fact that many of these grades are difficult to cast continuously and are better made as small ingots that are forged (hammered) or pressed after reheating to a high temperature.

The same situation exists in stainless steels. While the bulk of production is concentrated in only three grades, the balance is split between many uncommon specifications made in small quantities.

Significant ownership changes took place in the stainless steel sector. The second largest producer of flat products and plate, the J&L Specialty Products Corp., was sold by its owners, the Specialty Metals Corp., to the French Ugine ACG Corp., a unit of the Government-owned Usinor Sacilor Groupe. The price was reported as \$570 million, including J&L's debt taken over by the purchaser. J&L was rebuilding its continuous caster at the Midland, PA, melt shop from 1,295 millimeters (51 inches) to 1,600 millimeters (63 inches) wide.

The French company also bought three steel service center chains, which handle both carbon and stainless steels: Edgecomb Metals Corp., Techalloy Corp., and Alloy and Stainless Co. Together they represent more than 30 outlets nationwide. Furthermore, Usinor-Sacilor entered into an agreement with the Bethlehem Steel Corp. to modernize its large rollmaking operation.

Consumption

The domestic steel mills shipped 77.1 million metric tons (85.0 million short tons), the highest amount since 1981. This includes 4.3 million short tons that was exported, little changed since the previous year. Also, 15.7 million metric tons (17.3 million short tons) of steel products was imported, the lowest number since 1985 and a little less than that in 1989.

The distributor stocks increased by 0.3 million tons. Hence, the total apparent consumption was 88.6 million metric tons (97.7 million short tons). The distribution of shipments by domestic mills is shown in table 6.

The consumption per person was 351 kilograms (774 pounds). The trend toward reduced consumption started in the 1960's with the invention of high-strength low-al-

loy steels. This reduced steel consumption in many applications, such as automobiles. Downscaling autos, as was done in the 1970's, accounted for approximately 23 kilograms (50 pounds) of reduction; reduction of steel reinforcements in concrete, wide replacement of steel cans with aluminum, and increased use of long-lasting, abrasion-resisting rails, etc., contributed to the overall trend.

Stocks

The stocks at distributor yards increased by 0.3 million tons to 6.1 million metric tons (6.7 million short tons) at yearend. This represents approximately 4 months of shipments, a normal number under normal circumstances, a little high in times of slack demand.

Stocks at the steel mills increased, but an exact number cannot be determined because there is no clear demarcation between stocks rolled against future deliveries and awaiting shipments; stocks rolled ahead of order receipts in expectation of these repeat orders to arrive in due course; and semifinished stock made for inventory. Normal inventory level is about 10 to 12 million short tons or 6 weeks of shipments. In the face of the slowdown of demand toward the end of the year, the stocks were higher than normal, as no mill pulls back production as fast as the decline of orders is actually occurring.

Markets and Prices

The destination of about 58.2 million metric tons (64 million short tons), 76% of

¹Data do not add to total shown because of independent rounding.

¹American Iron and Steel Institute.

²Includes sintered ore and pellet fines, dust, mill scale, and other revert iron-bearing materials; also some nodules.

³Mainly briquetted turnings and borings, shredded scrap, etc.; scrap produced at blast furnaces and remelted not included.
⁴Mainly revert materials not sintered.

⁵Includes fluxes used in sintering at the steel plant, but excludes fluxes consumed in agglomeration at the iron ore mine.

the total 77.1 million metric tons (85.0 million short tons) shipped by domestic steel mills, is known. Based on the known shipments, the distribution of markets in 1990 was as follows: service centers and distributors took 24.8%, 3% more than in the previous year; automobile manufacturers accounted for 13.1%, the same as that in 1989; contractors and builders took 14.3%. about 3% more than in the previous year, although this demand slackened toward the yearend; manufacturers of containers' demand was unchanged at 5.3%; and machinery builders accounted for 2.8%, having been overtaken by the oil country tubular goods, which took 3.5%.

In general, market patterns in the United States remained fairly steady for several years, occasionally affected by localized factors within one industry. Decreased demand for automobiles and increased need for pipe and tube indicated previously were examples of normal distribution changes.

The destination of imports, 15.7 million metric tons (17.3 million short tons), is not known; neither is that of the 24% shipped as "unclassified." The ultimate use of the 21.6% shipped to distributors and service centers is not known, but the typical shipping patterns of these organizations indicate that approximately 50% went into construction, 25% into automotive replacement parts, and 25% into many other uses.

The nominal, finished steel base "list" price index as quoted by the Iron Age magazine was \$512 at the beginning of 1990 and \$525 near the end, an increase of 2.5%. However, this number is simply a compilation of list prices and biased toward the in-

tegrated producers' products. In the marketplace, steel is sold by negotiation and almost always at significant discounts from list prices. Some producers do not bother to keep updating their lists; a few minimills do not have any.

Prices at the beginning of the year were not heavily discounted except for 20% or even higher discounts for oil country tubular goods and some common stainless steels in common sizes. This led in the spring to a number of announced nominal increases or across-the-board reduction in published discounts. Up to about September, the fluctuation in announced prices showed its usual variations-increases followed by partial decreases, reduced or increased discounts, etc. USX Corp. made the unusual announcement of price increases 4 months before their effective dates, in effect inviting orders to be made and delivered before the price rises.

The general lowering of the economic activity eliminated all these gyrations. The only direction of price movements was then downward. Oil country tubular goods, some plates, and tinplate were the only exceptions, which held their level. Toward the end of the year some minimill products, like rebars, could be bought for less than \$300 per ton, barely covering the production cost. Hot-rolled coil reputedly exchanged hands at less than \$330 per short ton and coldrolled prime at less than \$400. This was the result of the reduced demand: Automobile production dropped by 15%, 20 out of 43 assembly plants were partly closed by December, the appliance market became stagnant, and construction activity dropped to the lowest level in years.

A new trend appeared late in the year, reputedly started by the major automobile producers. These corporations buy large amounts of steel parts from subcontractors who usually buy their steel on their own. The automakers started to insist on their subcontractors placing steel orders with the automobilemakers. They, in turn, would order the steel from the steel mills, insisting on their usual large volume discounts.

The price erosion, followed late in the year by sharply reduced production levels, resulted in most steel producers either showing much reduced profits or, in some cases, actual losses. These were followed by cuts or suspensions of dividends.

Contrary to some earlier experiences, imported steel did not affect the market to any unusual degree. This was caused by the weak dollar making import prices not particularly attractive. Actually, owing to cost increases abroad, some foreign exporters accepted lower than usual profit standards in order to sell their excess production at all.

Foreign Trade

Exports.—Not much change occurred in exports either. The drop to 3.9 million metric tons (4.3 million short tons) from 4.6 million short tons of the previous year can be mostly accounted for by reduction of exports to countries with difficulties in making dollar payments, such as China, Eastern Europe, and the U.S.S.R.

Imports.—Imports of 15.7 million metric tons (17.3 million short tons) showed little change from those of the previous year. Imports from the major exporters were under the restrictions of the VRA's shown in table 9, but several countries did not fill their quotas: Japan increased its exports to the Pacific rim countries while shipping more than 10% less than in 1989, Canada had a major steel strike, and the European Community shipped a little less than in the past. Increased imports from the Federal Republic of Germany and from Italy were still smaller than decreased shipments from the other members.

Imports from Eastern Europe, usually not large, decreased following the drop of its production.

Overall, the import picture did not change to any great extent from that of the previous year.

¹Pig iron mainly as liquid in basic oxygen and open-hearth furnaces.

²Consumption of scrap appears to be underreported.

¹Crude cast iron from the blast furnace or cupola furnace.

²Direct-reduced iron is obtained from ore by reduction of oxides to metal without melting. World direct-reduced-iron capacity is 27,680,000 short tons.

³Table excludes ferroalloy production except where otherwise noted. Table includes data available through June 21, 1991.

⁴In addition to the countries listed, Vietnam and Zaire have facilities to produce pig iron and may have produced limited quantities during 1986-90, but output is not reported, and available information is inadequate to make reliable estimates of output levels. Production is pig iron unless otherwise specified.

⁵Reported figure.

⁶Includes blast furnace ferroalloys.

OUTLOOK

Prediction of output and profits of the U.S. steel industry is equivalent to the prediction of steel demand, although another factor. change in accounting methods, has an influence on profits. This is the change in the "generally recognized accounting standards" for accounting for pensions and retirees' health insurance. While these were treated by almost all companies in the entire country as current expenses, the Internal Revenue Service (IRS) has determined that in the future they will have to be carried as accrued charges. This is likely to become a significant cost, possibly in the millions of dollars, for many steel companies. Profits will be affected correspondingly. This change was recommended by the Financial Accounting Standards Board, established by the accounting profession; the recommendations of this body carry strong weight with the IRS. Its adoption becomes mandatory in 1993, but some companies are doing it now.

Besides the overall level of economic activity, the steel industry is strongly affected by factors specific to steel, such as existence or elimination of the VRA's (of steel imports to the United States) that expire in March 1992 or contract negotiations with the United Steelworkers, also coming up the same year.

The VRA's affect steel imports, but an even stronger factor influencing international steel trade is the strength of the dollar against other currencies. A weak dollar discourages imports but encourages exports; a strong dollar has the opposite effect.

Production trends of the integrated steel mills may differ from those of minimills because of the different product mixes. The integrated companies make almost exclusively "flat products," sheet and strip, whether coated or not. These are affected by the strength of the consumer goods markets, mainly automotive and appliances. Since these are discretionary purchase items, they are strongly affected by general economic downturns. Toward the end of 1990, when consumer confidence collapsed in the face of the war in the Persian Gulf and the generally sluggish economy, the integrated mills suffered heavy losses and operated often at less than 70% of capacity. The slight upturn in oil country tubular goods consumption helped producers of these products but was not strong enough to exert a significant influence.

Minimills do not make (with one exception) flat products, although a few make plates and heavy structural sections. In general, they are restricted to the production of "shape" or "long" products, such as wire rods, structural shapes, and bars. Hence, they are largely dependent on the construction industry in the country, which was relatively inactive in the latter part of 1990. This resulted in a price war that virtually eliminated profits.

Thus it is clear that any reliable forecast of the future of the U.S. steel industry is exceptionally difficult, even for a short term. The year 1991 started poorly and the outlook was not good. In 1992, the possible extension or lapse of the VRA's and the labor contract negotiations, with the possibility of a strike, make predictions for this year

very uncertain. Beyond this, predictions would be guesses because of the uncertainty of general economic activity.

Two economic trends may continue: as long as the dollar is weak, foreign steel companies may continue to invest in U.S. steel mills, as joint ventures or outright purchases. In the minimill sector, more consolidations of weaker companies into the stronger ones are possible. Some of the stronger companies will enter the flat products market using the thin slab casting technique. The Nucor Corp., which initiated this method, announced in late 1990 its plan to build another flat products minimill.

Steel formed in first solid state after melting, suitable for further processing or sale; for some countries, includes material reported as "liquid steel," presumably measured in the molten state prior to cooling in any specific form.

²Table includes data available through June 21, 1991.

³In addition to the countries listed, Burma, Ghana, and Mozambique are known to have steelmaking plants, but available information is inadequate to make reliable estimates of output levels.

⁴Reported figure.

⁵Data are for year ending June 30 of that stated.

⁶Includes steel castings.

IRON AND STEEL SCRAP

By Raymond E. Brown

Mr. Brown, a physical scientist with 35 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for iron and steel scrap since 1986. Domestic survey data were prepared by Sarah P. Guerrino and Shirley M. Miller, Ferrous Data Section. International data tables were prepared by William L. Zajac, Chief, International Data Section. Tables 9 and 19 were prepared by the author.

se of iron and steel scrap to produce new steel and ferrous castings, which are vital to the United States for both national security and economic well-being, represents significant energy, environmental. economic, and resource conservation benefits. Direct-reduced iron, pig iron, and iron carbide can be substituted for iron and steel scrap but are usually considered more expensive than scrap. Also, availability of these substitutes on a large scale is limited, and there are certain technical problems associated with the use of some of these substitute materials. However, these scrap alternatives have certain advantages, which include providing iron free of residual elements, such as copper. for use in producing higher quality steel and ferrous castings products.

Brokers, dealers, and other outside sources supplied domestic consumers in 1990 with 44.6 million short tons¹ of all types of ferrous scrap at a delivered value of approximately \$4.71 billion, while exporting 12.8 million tons (excluding used rails for rerolling and other uses; and ships, boats, and other vessels for scrapping) valued at \$1.64 billion. In 1989, domestic consumers received 43.6 million tons at a delivered value of approximately \$4.63 billion; exports totaled 12.3 million tons valued at \$1.75 billion. This represented tonnage increases of 2% for received quantities and 4% for exported quantities.

DOMESTIC DATA COVERAGE

Domestic production data for ferrous scrap were developed by the U.S. Bureau

of Mines from voluntary monthly or annual surveys of U.S. operations. Of the operations to which a survey request was sent, 61% responded, representing an estimated 65% of the total consumption shown in table 2 for three types of scrap consumers. Consumption for the nonrespondents was estimated using prior reports adjusted by industry trends. An estimation error was also contained in the difference between the reported total consumption of purchased and home scrap and the sum of scrap receipts plus home scrap production, less scrap shipments and adjustments for stock changes. For scrap consumption data shown in table 2, this difference amounted to 0.5% for manufacturers of pig iron and raw steel and castings, 0.2% for manufacturers of steel castings, 5% for iron foundries and miscellaneous users, and 2% average for all types of manufacturers combined.

ANNUAL REVIEW

Legislation and Government Programs

On November 15, 1990, the President signed into law the Clean Air Act Amendments of 1990. The Clean Air Act of 1970 was last amended in 1977. The 1990 amendments, the most significant pollution control legislation in U.S. history, would greatly increase the U.S. Environmental Protection Agency's (EPA) influence over the location, design, and operation of industrial facilities such as iron and steel producers and scrap processors.

Environmental and other issues and legislation in 1990 that the 101st Congress considered included: the Resource Conservation and Recovery Act (RCRA), the Nation's primary recycling and disposal statute, which defined what is waste and determines which wastes are hazardous; limiting the export and import of "wastes" across State and international boundaries; the Toxic Substances Control Act (TSCA), which governed the use of toxic materials in manufactured articles, restricting their use when danger to the environment can be demonstrated; encouraging greater recycling; promoting markets for recycled goods; and increasing the duty on imported products containing U.S. processed scrap.

The U.S. Department of Energy (DOE) and Bethlehem Steel Corp. have signed an agreement for the engineering, construction, and operation of a blast furnace coal injection demonstration project at Bethlehem's Burns Harbor, IN, plant. Total cost of the project was \$144 million.

A seminar on radioactivity and scrap metal was held in Washington, DC, in September. The purpose of the seminar was to provide a setting for the U.S. Nuclear Regulatory Commission (NRC), the Institute of Scrap Recycling Industries Inc. (ISRI), and the trade associations representing major consumers of scrap metals to meet and consider the problem of radioactivity related to both ferrous and nonferrous scrap.

DOE contracted with the Advanced Combustion Products Group of Surface Combustion Inc., Toledo, OH, to construct and evaluate a commercial-sized installation to preheat ferrous scrap metal before charging into electric arc melting furnaces. The scrap preheating system proposed by Surface Combustion was

based on a pilot-scale system developed in the mid-1980's by Surface Combustion and the Natural Gas Industry. The pilot model was successful and reduced energy usage by as much as 20%.

At a Congressional hearing in June, the Executive Director and two members of ISRI testified before the House Small Business Subcommittee on Regulation, Business Opportunities, and Energy on the fate of more than 100 mothballed ships that belong to the National Defense Reserve Fleet. The aging ships were managed by the Maritime Administration (MARAD).

Available Supply, Consumption, and Stocks

Overall domestic demand for ferrous scrap in 1990 by the iron and steel and the ferrous castings industries, the major consumers of this raw material, was little changed from that of 1989. Because of continued strong worldwide demand for ferrous scrap in 1990, average annual prices for most grades, except for stainless steel scrap, remained high.

American Iron and Steel Institute (AISI) sponsored a symposium entitled "The Impact of Recycling and Resource Recovery on Steelmaking With High-Quality Scrap," in Pittsburgh, PA, in April. Conference cosponsors were the Steel Manufacturer's Association (SMA) and the Specialty Steel Industry of the United States (SSIUS). The symposium addressed three key issues the steel industry faces in response to the Nation's solid waste problems: recyclability of steel canshow the commodity can be a source from curbside recovery, the retail-wholesale buyback, followed by processing; practical information about metallurgical considerations by experts involved in steelmaking; and a discussion of future prospects for detinning and dezincing.

Proler International Corp., Houston, TX, unveiled its new detinning plant in May. The facility was capable of recycling 180,000 tons of tin-plated cans and clippings per year. The plant joins two other Proler detinning plant operations in Seattle and Randolph, AZ.² AMG Resources Corp., Pittsburgh, PA, opened a 40,000-ton-per-year detinning plant in November. The plant, in St. Paul, MN, would process used steel cans obtained from that region's municipal waste stream. This detinning plant would be the first such facility to rely solely on used tin cans as its feedstock.

Most detinning operations use what was commonly called skeleton scrap, consisting of tinplate scrap from canmaking operations.

ISRI had asked Congress to implement a "design for recycling" policy that would promote the design and manufacture of appliances, automobiles, and other consumer goods for safe and efficient recycling at the end of their useful lives. Additionally, ISRI officials gave speeches to world steel industry leaders and to the board of directors of AISI to promote the concept of designers engineering products that would meet higher standards for disassembly and recycling. ISRI had been promoting the "design for recycling" concept since the mid-1970's.

Horsehead Resource Development Co. Inc. (HRD), Palmerton, PA, would expand its two metal dust recycling facilities by the end of 1991 at a cost of \$21 million. This would significantly increase the company's capacity for processing cadmium, lead, and zinc dust by 35% to more than 470,000 tons per year. The processing plants are in Palmerton, PA, and Rockwood, TN. The EPA had listed electric arc furnace (EAF) dust as hazardous waste and issued regulations requiring dust containing 15% or more zinc to be processed with "the best demonstrated available technology" after August 8, 1991. HRD, with support by the Gas Research Institute (GRI), developed its Flame Reactor process, which uses a gasfired, high-temperature flash smelting burner to process EAF dust. The EPA designated high-temperature metals recovery (HTMR) technology, the method used by HRD, as the best demonstrated method available for processing high-metals content EAF dust.

A U.S. Bureau of Mines study revealed that iron casting compositions had changed with respect to a few tramp elements such as arsenic, chromium, cobalt, tin, and zinc over a 5¾-year period, from January 1981 to September 1986. Also, significant variations between zones within the United States were observed for aluminum, arsenic, chromium, cobalt, copper, and manganese. The Bureau study was in response to concerns expressed by foundries regarding the quality of ferrous scrap used to prepare iron castings.³

Auto shredders were introduced in the United States in the mid-1960's to upgrade the quality of ferrous scrap, decrease the volume of waste sent to landfills, and reduce the number of abandoned obsolete

automobiles and appliances that were scattered throughout the country. Tramp elements, such as copper, typically found in shredder feed material have been reduced dramatically. An analysis by the U.S. Bureau of Mines revealed that shredded scrap had been replacing lower quality No. 2 bundles as a raw charge material for iron and steel furnaces. For example, the ratio of consumer receipts for shredded scrap versus No. 2 bundled scrap increased from essentially 0:1 in 1967 to about 7:1 in 1988. However, since 1988. this ratio began to decline, and in 1990, it had dropped to approximately 5:1. This decline coincided with some shredder operations being forced to close and others voluntarily shutting down their operations in 1988 because of a crack-down by Federal and State officials on the disposal of shredder residue (waste). An increased supply of ferrous scrap for consumption in iron and steel furnaces, as a result of shredder processing, represented significant energy, economic, and environmental benefits and conserved natural resources.

The Ford Motor Co., Dearborn, MI. presented O-1 awards to two scrap processors. Ford's Q-1 program was designed to recognize suppliers with products of outstanding quality. This was the first time that these awards were given to scrap recyclers. Twenty years ago, in response to the abandoned auto crisis, Ford took the lead in reusing old cars to make new components.4 There has been a gradual decline in iron and steel content and growth in the use of aluminum, plastics, powder metals. and other materials in U.S.-built cars since 1984.5 Auto shredder companies and others who handle vehicles containing either fired or unfired airbags should be aware of potential hazards associated with the mechanisms, according to the Greater Rochester Auto Craftsman Guild, a New York auto group. Because of the need for airbags to activate instantaneously upon impact, they are triggered by and contain certain highly reactive toxic chemicals. These, of course, should be avoided.6

Nucor Corp., Charlotte, NC, was spending approximately \$2 million to clean up radioactive contamination and install sensitive radiation detectors in its steel mill at Plymouth, UT. The contamination occurred in March when a load of scrap steel containing a small amount of cesium 137 was accidently fed into the plant's electric furnace. The cesium was vaporized and drawn into the air cleaning system, where it was incorporated in the

fly ash. Nucor planned to feed the furnaces at its new Crawfordsville, IN, flat-roll steel plant with direct-reduced iron on a trial basis. High-quality melting stock was critical to the success of Nucor's effort to bring a minimill operation into market for flat-rolled steel products that have been dominated by large integrated producers. Also, Nucor was installing new casting and rolling equipment at its Nucor-Yamato structural section mill in Blytheville, AR, to expand capacity by 30%. The improvements were expected to cost \$14 million. Production was forecast to surpass 1 million tons per year.

Miller Compressing Co., Milwaukee, WI, a ferrous and nonferrous scrap processor, broker, and trader was honored for its help in combating the school dropout problem. The company was sponsoring a junior achievement program, "The Economics of Staying in School."

North Star Steel Co., Minneapolis, MN, the Nation's largest minimill steel producer, planned to build a greenfield minimill and industrial complex near Johnstown, PA. A 300,000-ton-per-year minimill operation in conjunction with two cogeneration electric plants would be part of the \$500 million joint-venture complex.7 Also, North Star has joined forces with Cleveland-Cliffs, Inc., Cleveland, OH, to evaluate the feasibility of iron carbide production. The technology involved reducing high-quality iron ore concentrate with reformed natural gas in a fluidized-bed reactor. Iron carbide produced in the reactor might be a better alternative to scrap as a raw material than direct-reduced iron, according to a spokesperson for Cleveland-Cliffs.

Unimetal, the long products division of Usinor Sacilor, a French steel group, had finalized the takeover of 50% of Georgetown Steel Corp., Georgetown, SC. Georgetown, which also produced directreduced iron, was one of the United States' largest wire rod producers. In 1989, Thomas Steel Corp., Lemont, IL, rebuilt two EAF's. Before rebuilding, tap-to-tap time for a 40-ton heat was 3½ hours. After rebuilding, that figure was slashed to 11/2 hours in 1990. A computer management system, which cost in excess of \$2 million, was installed in the melt shop during rebuilding and may make it possible for the steelmaker to achieve a tap-to-tap time of only 60 minutes. In essence, the system could spell out a scrap recipe depending on the customer's order, operate and regulate the furnaces, present spectrographic readings, and control when and for how long the furnace roof opens during a heat, as well as control the doors for the automatic alloying system.

Thousands of old household appliances that squander electricity and do little more than occupy space in basements were being auled away free of charge and recycled as scrap metal in a number of cities. Programs offering free pickup service and safe disposal were being sponsored by utility companies, local Government agencies. and private companies as a way to conserve energy and preserve the environment by keeping the bulky machines out of landfills. Programs varied from city to city, but took their lead from the Appliance Recycling Centers of America Inc. (ARCA), Minneapolis, MN. Local affiliates of the national organization worked through sponsoring organizations, which promoted the recycling programs and paid ARCA a subsidy for each appliance it handled. After collecting an item, ARCA stripped out the plastic and insulation plus parts containing hazardous materials. then sold the remaining shell to a scrap metal dealer. On average, each unit contained about 200 pounds of metal. ARCA paid particular attention to capacitors, which may have contained polychlorinated biphenyls (PCB's), chemicals that have been linked to cancer. Also requiring special handling were chlorofluorocarbon (CFC) refrigerants, which were recycled wihthout being vented into the atmosphere.

Imports of metallurgical-grade coke decreased 67% in 1990, to 765,000 tons, compared with that of 1989. Metallurgical coke imports represented 3% of domestic apparent consumption in 1990 compared with 7% in 1989. The United States continued as a net importer of metallurgical coke. Domestic coal consumption in coke plants decreased 4% in 1990 to 39.8 million tons. Domestic metallurgical coal exports decreased 3% in 1990 to 63.5 million tons compared with those of 1989.

Raw steel production was 98.9 million tons in 1990 compared with 97.9 million tons in 1989. The shares of raw steel produced by electric, basic oxygen, and openhearth furnaces were, respectively, 37%, 59%, and 4% in 1990 and 36%, 60%, and 5% in 1989. Continuous steel production represented 67% of total raw steel production in 1990 compared with 65% in 1989. Raw steel capacity utilization was 85% in both 1989 and 1990. Raw steel production capability was 116.8 million tons in 1990 compared with 115.9 million tons 1989.

Net shipments of all grades of steel mill products were 85.0 million tons in 1990 and 84.1 million tons in 1989. Imports of steel mill products decreased slightly from 17.3 million tons in 1989 to 17.2 million tons in 1990. Exports of steel mill products decreased from 4.58 million tons in 1989 to 4.30 million tons in 1990. The apparent supply of steel mill products increased from 96.8 million tons in 1989 to 97.8 million tons in 1990. Imports of steel mill products, as a share of the U.S. market were 18% in both 1989 and 1990. Steel mill processing yields were 86% in both 1989 and 1990. Pig iron production decreased from 55.9 million tons in 1989 to 54.7 million tons in 1990.

Iron castings shipments totaled 8.6 million tons in 1990 compared with 9.26 million tons (revised) in 1989. Steel castings shipments totaled 1.14 million tons in 1990 compared with 1.18 million tons (revised) in 1989.

Steel mills accounted for 73% of all scrap received from brokers, dealers, and other outside sources; steel foundries received 5%; and iron castings producers and miscellaneous users received 22%.

The apparent total domestic consumption of ferrous scrap in 1990, in million tons, was composed of 44.1 net receipts (total receipts minus shipments), 26.0 home scrap, and 0.1 withdrawals from stocks. The 1990 total was 70.2 million tons; the apparent total domestic consumption was 71.2 million tons in 1989. The total market for U.S. scrap (net receipts plus exports minus imports) was 55.4 million tons in 1990 compared with 57.2 million tons (revised) in 1989. Stocks of ferrous scrap held by steel mills and iron foundries decreased, but those held by steel foundries increased in 1990.

An analysis by the U.S. Bureau of Mines of iron and steel scrap consumption by domestic steel mills revealed that two key trends have emerged during the past 20 years. First, steelmakers have increased their use of electric arc furnaces, which use close to 100% scrap as a charge material to produce raw steel. Second, steel producers have extended their use of continuous casting—a more efficient forming technology than ingot casting—which has increased steel mill processing yields, but left progressively less "home"

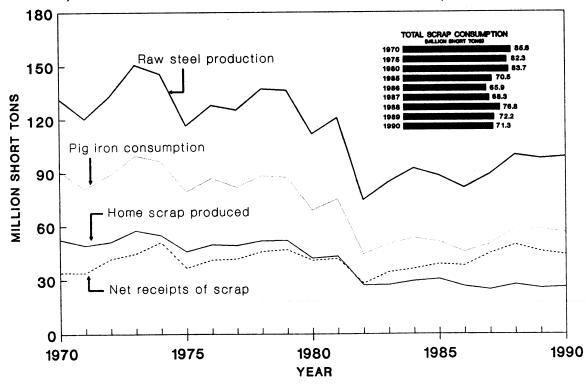

(internally generated) scrap available to the mills.

The study showed that the quantity of ferrous scrap consumed in the United States by integrated and minimill steel producers to produce 1 ton of raw steel had risen from about 0.51 ton in 1970 to 0.61 ton in 1990. The report also showed that of the ferrous scrap consumed by U.S. steel mills, about 60% consisted of home scrap in 1970 compared with only about 27% in 1990.

Additionally, the analysis demonstrated that the industry's reliance on purchased (new plus old) scrap had increased sharply over the past 20 years. Total ferrous scrap consumed by U.S. steel mills was composed of 16% new (prompt industrial) scrap and 24% old (obsolete) scrap in 1970 compared with 29% and 44%, respectively, in 1990. During this period, total raw steel production had fallen by about 25%, from 132 million tons in 1970 to 98.9 million tons in 1990. However, net shipments of steel mill products declined by only 6% during this timeframe, from 90.8 million tons in 1970 to 85.0 million tons in 1990.8

FIGURE 1

RAW STEEL PRODUCTION (AISI), FOR ALL TYPES OF MFR'S COMBINED: TOTAL IRON AND STEEL SCRAP CONSUMPTION, PIG IRON CONSUMPTION, HOME SCRAP PRODUCTION, AND NET SCRAP RECEIPTS

Prices

Based on average composite delivered quoted prices per long ton quoted weekly and monthly by the American Metal Market (AMM), No. 1 heavy melting steel scrap cost \$107.15 in 1990, ranging from a low of \$100.02 in March to a high of \$114.33 in August. Based on Iron Age data, No. 1 heavy melting steel scrap cost \$107.37 in 1990, ranging from \$100.50 in March to \$114.17 in August. The average composite price for No. 1 heavy melting steel scrap in 1990 was slightly lower compared with that of 1989, by less than 1% based on both AMM and Iron Age data. Based on prices quoted weekly by AMM for tonnages of 18-8- grade stainless steel scrap (bundles and solids) delivered to consumers in the Pittsburgh, PA. area, the average price of nickel-bearing stainless steel scrap decreased 28%, from \$1,281.53 per long ton in 1989 to \$926.25 per long ton in 1990.

In 1990, the average price for total ferrous scrap exports (excluding used rails for rerolling and other uses and ships, boats, and other vessels for scrapping) decreased 10% to \$128.10 per short ton compared with that of 1989, while that of total imports decreased 11% to \$118.82 per short ton.

Foreign Trade

Foreign trade tables are based on the Harmonized Tariff Schedule (HTS), which became effective January 1, 1989. Additionally, valuation continued to be reported on a f.a.s. basis for exports and on a customs value basis for imports.

The trade surplus in 1990 for all classes of ferrous scrap (including used rails for rerolling and other uses and ships, boats, and other vessels for scrapping) was \$1.46 billion in value and 11.2 million tons in quantity. This represented a decrease of 10% in value and less than 1% in quantity compared with the 1989 surplus of \$1.62 billion (revised) in value and 11.3 million tons (revised) in quantity. The balance of trade for all U.S. merchandise [exports (f.a.s.) less imports (customs value)] showed a deficit of \$102 billion in 1990, down from a deficit of \$109 billion in 1989.

The quantity of total exports and the quantity and value of total imports reached record highs in 1990. The quantity and value of total imports in 1990 each increased by a larger percentage than the

quantity of total exports compared with that of 1989. However, the value of total exports was lower in 1990 than that in 1989.

Total U.S. exports of ferrous scrap (excluding used rails for rerolling and other uses; ships, boats, and other vessels for scrapping; stainless steel; and alloy steel) in 1990 went to 52 countries and totaled 12,162,845 tons valued at \$1,361,366,675, which averaged \$111.93 per ton. Six countries received 82% of the total quantity. The largest tonnages went to the Republic of Korea, 3,095,004 tons; Turkey, 3,028,137 tons; India, 1,838,004 tons; Canada, 884,702 tons; Mexico, 606,280 tons; and Taiwan, 502,086 tons. The value of scrap exports to these six countries was \$1,089,323,462, 80% of the total value.

Total U.S. exports of stainless steel scrap in 1990 went to 31 countries and consisted of 256,797 tons valued at \$212,367,918 averaging \$826.99 per ton. Six countries received 87% of the total quantity. The largest tonnages went to the Republic of Korea, 81,236 tons; Japan, 71,247 tons; Canada, 23,219 tons; Spain, 21,635 tons; the Netherlands, 17,256 tons; and Belgium, 9,386 tons. The value of stainless steel scrap exports to these six countries was \$186,754,977, 88% of the total value.

U.S. exports of alloy steel scrap (excluding stainless steel) in 1990 were shipped to 39 countries. The total comprised 345,138 tons valued at \$61,483,696, which averaged \$178.14 per ton. Six countries received 85% of the total quantity; the largest tonnages went to Canada, 126,888 tons; India, 55,846 tons; the Republic of Korea, 54,715 tons; Taiwan, 23,945 tons; Mexico, 17,033 tons; and Italy, 15,645 tons. The value of alloy steel scrap to these six countries was \$47,490,050, 77% of the total value.

In 1990, based on tonnage of iron and steel scrap by customs district, New York, NY, was the leading customs district for exports, accounting for 17% of the total exports, followed by Los Angeles, CA, with 13%, and Philadelphia, PA, with 9%. San Juan, PR, was the leading customs district for reexports, accounting for 42% of the total reexports, followed by Detroit, MI, with 36%, and Providence, RI, with 17. Detroit, MI, was the leading customs district for imports, accounting for 43% of the total imports, followed by Seattle, WA, with 25%, and Buffalo, NY, with 8%. In 1989, again based on tonnage of ferrous scrap by customs district, New

York, NY, was the leading customs district for exports, accounting for 16% of the total exports, followed by Los Angeles. CA, with 14%, and New Orleans, LA. with 9%. Providence, RI, was the leading customs district for reexports, accounting for 40% of the total reexports, followed by Detroit, MI, with 33%, and San Juan, PR, with 21%. Detroit, MI, was the leading customs district for imports, accounting for 38% of the total imports, followed by Seattle, WA, with 34%, and Buffalo, NY, with 12%. For more details, including tonnages and values, refer to published data in U.S. Bureau of Mines Mineral Industry Surveys on iron and steel scrap.9

Total U.S. imports for consumption of iron and steel scrap were supplied by 29 countries in 1990. They contained 9,356 tons of tinplate waste or scrap valued at \$1,781,994.

World Review

World demand for iron and steel scrap decreased slightly in 1990. However, demand for ferrous scrap, on a percentage basis, increased in certain countries. These included industrialized countries such as Belgium, Italy, Japan, Turkey, and the United States; Asian countries such as China, India, the Republic of Korea, and Taiwan; and Latin American countries such as Mexico.

The United States continued to be the leading exporting country of iron and steel scrap. Canada, France, the Federal Republic of Germany, the Netherlands, the U.S.S.R., and the United Kingdom were also major exporters of ferrous scrap.

The Basel Convention, on the control of transboundary movements of hazardous waste and their disposal, had been signed by 53 countries, including the United States and the European Community (EC).10 The Basel Convention was negotiated under the auspices of the United Nations Environment Program during an 18-month period and completed at Basel, Switzerland, on March 22, 1989. The intent of the agreement was to put an end to the rising number of incidents of dumping hazardous wastes in Third World nations where inadequate provisions exist for their safe disposal. It would become law within 3 months of its being ratified by a minimum of 20 countries.

The Bureau International de la Recuperation (BIR), Brussels, Belgium, criticized national governments and international organizations for failing to make a

distinction between the definitions of secondary raw materials and waste (SRM&W). The BIR had issued definitions of SRM&W to BIR member associations. BIR individual member firms, the specialized press, and related supranational organizations. The definitions were as follows: secondary raw materials are redundant goods, byproducts, or residues that have a value and are recycled for further use; and waste includes redundant goods, byproducts, or residues that have no value and must be disposed of at a cost. Also, BIR members had been especially critical of the Basel Convention, which would significantly limit international trade in secondary materials because it made no distinction between scrap and hazardous waste.

The Brazilian Government shut down 20 pig iron producers in May for not reforesting areas cut down to make charcoal. This action would significantly reduce pig iron export prospects unless other producers took up the slack. The U.S.S.R.'s Minister of Metallurgy had called for a cut in ferrous scrap exports to avoid domestic shortages. The Soviet steel industry had a scrap shortage of 5 million metric tons in 1990. Growing health concerns had led environmental authorities in Taiwan, one of the largest international markets for nonferrous scrap, to propose a ban on all scrap imports beginning in 1993. Any material that produced toxic substances when incinerated would be prohibited under that rule.

The EC launched a \$26 million research program to identify new recycling technologies as part of its raw materials and recycling plan for the next 3 years. The program was established to enhance the competitiveness of the EC's mining and metallurgical industries. Also, a proposal to create markets for recycled products was made an integral part of an EC waste management strategy. Additionally, the Council of Environment Ministers had agreed to the scope and authority of the new European Environmental Agency. Its functions would be to accumulate and analyze relevant environmental statistics to assist the EC in making objective and scientific responses to current and future environmental problems. Changes in Eastern Europe probably would have little impact on the world's metal and scrap industries in the short term. However, for the long term, these changes most likely would have considerable influence. Ferrous scrap dealers in the Chugoku region of southern Japan had expressed concerns about electric steel mill expansions in that area. Demand for high-grade scrap was expected to soar but dealers did not have enough processing capacity or purchasing routes to meet the growth.

A study by the International Iron and Steel Institute (IISI), Brussels, Belgium, concluded that steel was and will remain the dominant and most cost-effective material for automotive applications. Also, IISI updated its statistics on energy in the steel industry.

The president of Ipsco Inc., Regina, Saskatchewan, Canada, was considering closing the only major steel plant in Western Canada and moving its operations to the United States because of persistent environmental protection and regulatory roadblocks that created problems in procuring raw materials. Environment Canada, a Canadian Federal regulatory agency, had proposed a new law that would force importers to post a bond for each cross-border shipment of hazardous waste and scrap. The Canadian Government was expected to revise the proposal so that white goods and auto wrecks would not be considered hazardous. Ipsco imports 50% of its scrap from the United States.

The public sector of the Turkish iron and steel industry was planning to install a thin slab continuous caster and cold-rolling plant at its Iskenderun Iron and Steel Works on the Mediterranean by the end of 1992. The works had an annual raw steelmaking capacity of 2 million metric tons. Turkey had to import about 1.5 million metric tons per year of flat products. Man Gutehoffnungshutte, Federal Republic of Germany, would build an electric arc furnace melt shop for the NTS Steel Groups Co., in Thailand, by the end of 1991. The order included technical help, engineering, and the main equipment, which consisted of a 75-metric-ton furnace capable of producing 400,000 metric tons of liquid steel per year. There would also be a ladle furnace, process controls, and handling equipment for scrap and ferroallovs. This project was part of an overall contract for a complete minimil steel plant for wire and reinforcing steel.

In the past decade, the volume of recycled scrap in China had been rising at an annual average of 8%, according to the Chinese Ministry of Materials. China had reclaimed more than 400 million metric tons of scrap iron and steel since the 1949 revolution. This resulted in the saving of

significant quantities of iron ore and highquality coal. The country also saved money that would have been spent on metal ore exploration, mine development, and steel mill construction.

The Federal Republic of Germany's tinplate producers had launched a new can recycling program, which would be funded with about \$1.5 million per year to support public services in the collection and recycling of tinplate scrap. Short-term measures by tinplate producers to protect the environment included briefings with interested city and county authorities and the installation of new collection centers.

The total number of shredders in operation worldwide in 1990 was estimated at 633 (see table 19), 32 more than in 1989. Because of new shredder installations and upgrading of older equipment in 1990. total world power requirements and total world annual tonnage capacity increased by about 94,000 to 1.15 million horsepower and by 3.5 to 30 million metric tons compared with that of 1989. Globally, the average power requirements and the average annual tonnage capacity per shredder increased in 1990 by 60 to 1.810 horsepower and by 3,000 to 47,000 metric tons compared with that of 1989. The more efficient shredder operations scattered throughout the world resulted in lowering average energy requirements by 5%, from 0.040 horsepower per metric ton of annual capacity in 1989 to 0.038 in 1990. The total number of new units under construction and equipment being upgraded or in the planning stages in 1990 amounted to 30. The United States continued as the world's leading country in total shredder numbers, power, and tonnage capacity. Japan followed as the second leading country, with the United Kingdom third. The total number of shredders in Western Europe in 1990 was about equal to that of the United States. However, total power requirements, total annual tonnage capacity, average power requirements per shredder, and average annual tonnage capacity per shredder were significantly higher in the United States compared to that of Western Europe. Also, the data in table 19 indicated that the average shredder in the United States was more energy efficient than the average shredder in Western Europe. The most significant developments in 1990 were in France, where 34 existing shredders would be augmented by 9, and in Japan, where 145 shredders would be increased by 10.

Current Research

Researchers at the Argonne National Laboratory in Argonne, IL, developed a new three-step process to recover thermoplastics and other potentially marketable material from automobile shredder residue (fluff). The recovery process employed physical separation, solvent extraction, and solvent regeneration.¹¹

Officials at Westinghouse Electric Corp., Pittsburgh, PA, reported that the company had successfully tested a system of plasma incineration of landfill material at its plasma-fired test cupola in Madison, PA. The company planned to apply this technology to auto shredder residue. Westinghouse had had a commercially operating plasma-fired cupola in place at a General Motors Corp. foundry in Defiance, OH, since late 1989. 12 Japan's Government Industrial Development Laboratory reportedly found a way to use fluff as a fuel for a waste gasification process that can generate 500 kilowatts per ton of fluff.

Carnegie Mellon's Center for Materials Production was doing a case study of cryogenic scrap preparation to determine if the process was worth looking at again. Cryogenic research was conducted in Belgium in the 1970's and 1980's. 13

Metal Recovery Industries, Ontario, Canada, began operation of North America's first commercial dezincing line for steel scrap. ¹⁴ AISI established a task force to examine the recycling and future prospects of galvanized and tinned scrap. A new process, developed at Carnegie Mellon University, involved removing copper from solid steel scrap by putting the copper into solution as a sulfide matte. A large rotary kiln had been set up for this purpose at USX's pilot plant in Universal, PA. ¹⁵

A number of modifications were planned for the AISI Direct Steelmaking Program. The most significant change that was being considered involved replacing the verticle basic oxygen furnace (BOF)-type converter with a horizontal design. 16 Development of direct steelmaking technology would eliminate the need for coke, as it would be replaced with coal. Professor Donald R. Sadoway, Department of Materials Science and Engineering, Massachusetts Institute of Technology (MIT), Cambridge, MA, was conducting research on a new direct steelmaking process that employs electrochemical processing of iron ore in

nonaqueous media to extract pure iron. The process used technology similar to that perfected by Hall-Hroult for the electrolytic reduction of alumina to aluminum metal. With the MIT process, no carbon ends up in the iron.¹⁷ The Electric Power Research Institute (EPRI), Palo Alto, CA, would sponsor a feasibility study on the process.

Nucor Corp., Charlotte, NC, planned to build a second sheet-producing minimill plant on the Mississippi River in Arkansas. The 1-million-ton-per-year facility was expected to come on-stream in 1993. This left Nucor as the only electric furnace sheet-producing mill in North America. Plans to use this new technology by Birmingham Steel Corp., Birmingham, AL; Co-Steel Inc., Toronto, Ontario, Canada; and New Jersey Steel Corp., Sayreville, NJ; had been put on hold. The president of Co-Steel stated that his company was concerned about the high cost and availability of low-residual scrap.

OUTLOOK

The total market for U.S. ferrous scrap is affected by many factors. For example, major factors that impact the demand for domestic scrap include the quantities of domestic raw steel and ferrous castings produced, the level of scrap exports, and Government laws and regulations. To a lesser extent, other factors affecting the overall market for U.S. scrap include the production levels of U.S. industries that make ferroalloys, cement copper, and certain chemicals; the use of scrap substitutes; technological changes in steel mills and ferrous foundries; and the value of the U.S. dollar in relation to other world currencies. The health of the world's steel mills and ferrous foundries is of the utmost importance to the domestic scrap industry. The United States, the world's leading exporter of ferrous scrap, relies heavily on exports as a safety valve for the release of excess scrap when domestic demand slips.

The outlook for the total market for U.S. ferrous scrap is expected to be one of continued growth. The total market for U.S. scrap is forecast to range from 59 million tons to 68 million tons by the year 1995, representing an average annual growth rate ranging from 0.6% to 3.0%, respectively. It is probable that by 1995 the total market for U.S. ferrous scrap will be closer to the mid-range of this forecast,

reaching 64 million tons, which represents an average annual growth rate of 1.9%. This optimistic forecast is based predominantly on a combination of favorable factors affecting the market, which primarily include continued world growth in the quantity of steel produced in scrap-based electric arc furnaces; an increase in the percentage of steel that is continuously cast; and an absence of excessive Government rules or restrictions on U.S. exports of scrap.

¹Unless otherwise noted, figures represent reported consumption of iron and steel scrap utilized in the production of pig iron, ferroalloys, crude steel, foundry products, and rerolled steel, as well as other unspecified uses in the steel industry and by other unspecified industries as reported by the United Nations Economic Commission for Europe in its Annual Bulletin of Steel Statistics for Europe, 1989, v. 17, New York, 1990, 28 pp., which is the source of all reported data unless otherwise noted. All estimates are by the U.S. Bureau of Mines.

²Source: Canadian Foundry Association as reported by Energy, Mines, and Resources Canada.

³Excludes scrap consumed by steel rerollers.

⁴Source: U.S. Bureau of Mines.

⁵Reported data are from Instituto Latino Americano del Fierro y el Acero. Statistical Yearbook of Steel Making and Iron Ore Mining in Latin America, 1989, Santiago, 1990, 231 pp. Source does not provide details on what is included; presumably figures include total steel industry ferrous scrap consumption but exclude scrap used outside the steel industry.

⁶Portugal and Spain became members of the European Community on Jan. 1, 1986.

⁷Excludes scrap consumed in iron foundries.

⁸ Includes scrap used in production of steel castings in shipyards but excludes scrap, if any, used in production of pig iron and that used in iron foundries.

⁹Excludes scrap consumed outside the steel industry.

¹⁰ Excludes scrap consumed within the steel industry for purposes other than the manufacture of pig iron, ferroalloys, crude steel, foundry products, and rerolled steel (details on use not available).

¹¹ Excludes a substantial tonnage derived from shipbreaking, possibly in the order of several million tons annually, for electric-furnace-equipped steel mills.

Unless otherwise specified, source for figures developed by the U.S. Bureau of Mines is from the Institute of Scrap Recycling Industries, Inc., the Bureau International de la Recuperation (BIR), manufacturers of shredders,

or shredder operators.

2 Assumed shredders were operated 8 hours per day, 5 days per week, 11 months per year (to allow for downtime, holidays, and planned maintenance), at 70% capacity.

KYANITE AND RELATED MATERIALS

By Michael J. Potter

Mr. Potter, a physical scientist with 24 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for kyanite since 1975. Domestic survey data were prepared by Joe Daniels, mineral data assistant; and international data table was prepared by Virginia Woodson, international data coordinator.

yanite, and sillimanite are anhydrous aluminum silicate minerals of the same composition represented by the chemical formula Al₂O₃·SiO₂. Related materials include synthetic mullite, dumortierite, and topaz, also classified as aluminum silicates, although the last two additionally contain substantial proportions of boron and fluorine, respectively. The largest end use of kvanite group minerals and mullite is in the manufacture of high-alumina, highperformance refractories, including brick and shapes and monolithic refractory applications such as for high-temperature mortars or cements, ramming mixes, and castable refractories. U.S. production of kyanite was estimated to have decreased slightly compared with that of 1989 owing to flat or decreased activity in the iron and steel industry and other industries in which refractories were used. Domestic synthetic mullite output decreased compared with that of the previous year. Data have not been published to maintain company proprietary data. Imports of andalusite in 1990 were approximately 17,000 metric tons compared with the past few years when imports were in the 10,000-ton-per-year range.

DOMESTIC DATA COVERAGE

There are two known domestic kyanite mine-and-mill operations, but data are not known and would not be publishable because of company proprietary data. Of the three known synthetic mullite producers, all responded to the voluntary domestic survey. However, data cannot

be published because of possible revealing of company proprietary data.

BACKGROUND

Definitions, Grades, and Specifications

Kyanite, and sillimanite are a closely related trio of aluminum silicate minerals, differing slightly in physical properties and crystallographic characteristics, but sharing the same chemical composition, which can be represented as A12O3 SiO2. When heated, kyanite begins to break down to a noticeable extent at 1,315°C (and alusite at 1,382°C and sillimanite at 1,549°C) to form a mixture of mullite, $3Al_2O_3 \cdot 2SiO_2$, and vitreous silica, SiO2. The mullite so produced usually consists of an aggregation of interlocking, acicular crystals and remains dimensionally and chemically stable until the temperature is raised to at least 1,810° C. These properties enable mullite to serve to advantage as a component in refractory shapes and furnace linings for a wide range of industrial applications. Above 1,810°C, mullite dissociates slowly with little change in volume into corundum (Al₂O₃, and silica, which recombine to form mullite at a lower temperature.

Topaz, Al₂SiO₄(F,OH)₂, and dumortierite, Al₇(BO₃)(SiO₄)₃O₃, are also often classed as members of the kyanite group of minerals. Upon firing, topaz loses fluorine and dumortierite loses boron, yielding refractory residues consisting essentially of mullite. A number of other substances—fire clay, siliceous bauxite, and kaolin, for example—owe their ability to perform satisfactorily in some refractory applications to the fact that,

when heated, a least part of the aluminum silicate they contain is converted to mullite.

There are three types of synthetic mullite. Low-temperature sintered synthetic mullite is made by sintering siliceous bauxite or mixtures of bauxite and kaolin above 1,549° C. High-temperature sintered synthetic mullite is prepared by sintering mixtures of alumina and kaolin, bauxite and kaolin, or alumina, kaolin, and kyanite above 1,749° C. Fused synthetic mullite is made by melting Bayer process alumina and silica or bauxite and kaolin in an electric furnace at about 1,900° C.

All domestic kyanite ore is ground to permit separation and recovery by froth flotation of the mineral particles from accompanying gangue. The flotation-concentrate product is graded for sale to consumers in five particle-size ratings: 35, 48, 100, 200, and 325 mesh. Kyanite concentrates may contain from 56% to 60% alumina, from 38% to 44% silica, and from 0.2% to 0.9% iron oxide. Lump kyanite from India, ranging in size from pea to boulders, was formerly imported into the United States. Indian reserves are limited, however, and material is no longer being exported.

Products for Trade and Industry

Kyanite and related materials are consumed in the manufacture of high-alumina or mullite-class refractories and in lesser quantities as ingredients in ceramic compositions. U.S. kyanite is marketed either in raw form or after heat treatment as mullite. In the 35- to 48-mesh range, kyanite is used in monolithic refractory applications such as high-temperature mortars or cements, ramming mixes, and castable refractories or

with clays and other ingredients in refractory compositions for making kiln furniture, insulating brick, firebrick, and a wide variety of other articles. More finely ground material, minus 200 mesh, is used in body mixes for sanitary porcelains, wall tile, investment-casting molds, and miscellaneous special-purpose ceramics.

Data on the properties of finished refractory products are available from the producing firms. However, selection of the best refractory available for a specific application can sometimes be made only by testing under actual operating conditions. Load-bearing capacity, slag resistance, spalling characteristics, and other factors are often of prime importance.

Zircon sand containing some kyanite, sillimanite, and/or staurolite is used for foundry and refractory sand.

Technology

Both mines of the one U.S. kyanite producer are open pit, hard-rock quarrying operations. Blasted material is reduced to manageable size by drop-ball breaking and trucked to the processing plants where it is crushed to minus 1-inch size in jaw and cone crushers and then ground in rod mills to minus 35 mesh or finer. Two stages of flotation with alkaline-fatty acid or acid-petroleum sulfonate collectors produce an intermediate kyanite concentrate, which after being freed from iron by high-intensity magnetic treatment, becomes a salable product. Some kyanite is calcined at about 1,593° C and sold as mullite.

Byproducts and Coproducts

Quartzitic waste tailings from kyanite concentrators may be marketed locally as construction sand, but transportation costs limit the shipping radius of this byproduct.

Andalusite occurs in pyrophyllite ores that are mined by a company for ceramic and refractory purposes in North Carolina. A zircon-refractory heavy-mineral sand produced in Florida contains a small amount of aluminum silicates (kyanite, sillimanite, and staurolite) and is used for foundry and refractory sand.

Substitutes

Substitute and alternative materials for kyanite-group and mullite products in refractories include fire clay, calcined

bauxite, and alumina. Other materials such as magnesite, chromite, silicon carbide, and zircon are interchangeable for specific end uses and conditions. Local availability of refractory raw materials is an important factor in choosing refractory products because transportation costs may prohibit use of alternative technically superior materials.

ANNUAL REVIEW

Legislation

The allowable depletion rates for kyanite, established by the Tax Reform Act of 1969 and unchanged through 1990, were 22% for domestic production and 14% for foreign operations.

Issues

Andalusite continued to be imported into the United States in 1990 as one of several minerals and metals that were exempt under a section of the Comprehensive Anti-Apartheid Act. The exemption list included strategic minerals for which the quantities essential for the economy or defense of the United States were unavailable from reliable and secure suppliers.

Production

Kyanite was produced at two open pit mines by Kyanite Mining Corp.: the Willis Mountain and East Ridge Mines in Buckingham County, VA. The company also operated beneficiation plants and calcining facilities for conversion of kyanite to mullite.

High-temperature sintered mullite was produced by C-E Minerals Div. of Combustion Engineering Inc. at Americus, GA, and Didier Taylor Refractories Corp. at Greenup, KY. Electric-furnace-fused mullite was produced by Washington Mills Electro Minerals Corp. at Niagara Falls, NY.

C-E Minerals was sold to Imetal SA by Asea Brown Boveri Ltd. (ABB) of Switzerland after ABB purchased C-E's parent company, Combustion Engineering Inc. 1

Consumption and Uses

The U.S. Bureau of Mines does not collect data on end uses of kyanite and synthetic mullite. However, refractories for

the iron and steel industries were probably the major end use of kyanite-mullite, consuming an estimated 55% of the quantity produced. Nonferrous metallurgical operations were believed to be the next largest use, estimated at 20%. A third category, estimated at 15%, consisted of glassmaking furnaces, ceramic kilns, boilers, petroleum-processing equipment, etc. Nonrefractory uses were estimated to make up the remaining 10%.

In the iron and steel industries, mullite is important in critical areas of blast furnace stoves and stacks, reheat furnaces, steel degassing chambers and soaking pits, and many types of auxiliary pouring and handling equipment. In the nonferrous metal industry, an end-use example is in refractory linings of alumina reduction cells.

Other miscellaneous uses include kiln furniture, blown aluminum silicate high-temperature insulation, brake linings, foundry mold facings, glass additions for alumina contents, ceramic tile, pyrometer tubes, high-tension insulators, spinnable mullite fibers, shell castings, ceramic honeycomb, mortars, grinding media, whitewares, extrusion dies, and welding rod coatings.

Prices

Prices at yearend 1990, in British pounds, from Industrial Minerals (London) were unchanged from the previous year. Price increases for 1990 in table 1 represent a stronger British pound against the U.S. dollar than in 1989.

Foreign Trade

Shipments of U.S. kyanite, mullite, and synthetic mullite were believed to have been made to foreign destinations, including Europe and Asia. Imports of andalusite from the Republic of South Africa were 17,350 metric tons with a customs value of \$2,805,000, according to the U.S. Department of Commerce.

World Review

Capacity.—Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and

Mullite	2508.60	4.9% ad valorem	30% ad valorem

plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

The data in table 3 are rated capacity for mines and refineries as of December 31, 1990. Capacity data for Japan, the Republic of South Africa, and Sweden were obtained from literature sources. For other countries, recent peak production or estimated production was considered to be equal to rated capacity.

China.—Although kyanite ore bodies usually contain only 15% to 20% kyanite, development and utilization of the mineral, as well as andalusite and sillimanite, has taken place in the past several years. Processing of kyanite minerals has been achieved by flotation and magnetic separation. Producers were working on improving product quality and finding opportunities to export abroad.²

A 3,000-ton-per-year andalusite plant began operation in Xixia County, Hunan Province. The andalusite source for the plant was a deposit with proven reserves of 7.8 million tons.³

India.—The Indian Bureau of Mines developed benefication steps to obtain refractory-grade kyanite from the country's low-grade, mica-quartz-bearing kvanite deposits. Ore reserves are 175 million tons, with 90 million tons in Bihar and 80 million tons in Andhra Pradesh. A representative sample from the Lapsoburu deposit, Singhbhum district, Bihar, contained an estimated 35% kyanite, 50% quartz, 10% mica, and 5% other minerals such as rutile, staurolite, iron oxides, amphiboles, etc. Two-stage froth flotation of the sample followed by wet high-intensity magnetic separation yielded a product containing about 95% kyanite, 1% quartz, 1% mica, and 3% other minerals with a kyanite recovery of 73%. Further research work successfully produced dense and volume-stable aggregates out of the beneficiated kvanite concentrate and thus established its suitability for making refractory brick.4

Ireland.—Navan Resources PLC continued with plans to obtain capital resources to conduct a full-scale evaluation and feasibility study of its Tomduff

andalusite project in County Carlow. Initial studies revealed a mineralized zone 5 kilometers by 200 meters to 300 meters with a 9% to 25% andalusite content. The company believed that the property could support a production capacity of 50,000 tons per year producing a material 2.8 millimeters to 10 millimeters.⁵ In late 1990, Navan announced taking a Swiss joint-venture partner, Realstate AG, to continue the evaluation of the andalusite project.⁶

OUTLOOK

The iron and steel industry has been the dominant consumer of refractories, including those based on kyanite and mullite. Steel output has been static in some countries but has shown growth in other regions such as China and Latin America. In Eastern Europe, the refractories in use are the cheaper, less efficient fireclays. This region may be a potential growth market for conversion to alumino-silicate refractories, which have a higher alumina content and are more efficient. 8

More severe operating conditions in iron and steel and other industries have required refractories that give longer service life. This has resulted in a reduction in overall refractory consumption. However, kyanite usage has been stable because of newer and more recent applications and uses.⁹

LEAD

By William D. Woodbury

Mr. Woodbury, a physical scientist with the U.S. Bureau of Mines, Branch of Metals, had 25 years of mining and civil works geotechnical experience upon becoming the Bureau's lead specialist in 1982. Domestic survey data were prepared by Eraina Dixon and Lisa Conley, mineral data assistants; and international data were prepared by Audrey A. Wilkes, international data coordinator.

ead is a soft, heavy metal, the most corrosion resistant of the common metals, and one of the oldest metals used by man. Among the nonferrous metals, in terms of tonnage, demand for lead is surpassed only by aluminum, copper, and zinc. In some applications, lead can be toxic, however; its pervasive use in the water distribution system of ancient Rome is theorized by some historians to have contributed to that city's downfall through disorientation from poisoning. However, bridge abutment pads and structural dowelling still standing from that era attribute to its benefits; buildings built in Europe more than four centuries ago still stand under their original lead roofs. For this application lead is still widely used in England on modern structures. Today's worldwide major use of lead is in storage batteries that are used for a multiplicity of functions, including on-line voltage regulation against power surges (for computers), power grid load-leveling, and traditional transportation and communication uses. Other major uses are in soundproofing and radiation shielding, which includes transportation and storage of radioactive materials.

In the first quarter of 1990, reflecting the demand growth that started in the second quarter of 1987, the world cash price for lead on the London Metal Exchange (LME) briefly achieved, in mid-March, a price of 59.8 cents per pound, the same as the alltime record monthly price established in October 1979. Some domestic quotations in mid-March of 65 cents per pound delivered were only 2 cents below the December 1979 price, the highest ever recorded for the United States. However, owing primarily to record battery inventories at yearend 1989,

which were not worked down by the end of 1990, demand and prices did not hold up as most of the world appeared headed into a recessionary period. Nevertheless, the year on average was quite profitable for the lead industry as the LME cash price achieved the highest annual level since 1980, and the third highest ever, in spite of increasing metal stocks.

World refined lead output, in spite of record-high U.S. secondary production, was about the same as that of 1989. World demand declined by almost 3%, mostly in the fourth quarter, after 7 years of spectacular growth, but was still the second highest ever. The world secondary sector. responding to environmental challenges, produced at a record level of 46% of world demand, but mine production leveled off and metal stocks rose for the first time since 1987. However, U.S. mine production increased by 15% primarily because the huge new Red Dog Mine in Alaska neared planned capacity output, and the United States was a significant net exporter of lead concentrates for the second consecutive year and for only the second year ever.

DOMESTIC DATA COVERAGE

Domestic data for lead are developed by the U.S. Bureau of Mines from five voluntary surveys. Typical of these are the combined secondary producer and consumer surveys, both monthly and annual. Of the 230 consuming companies to which a survey request was sent, 201 responded, representing 96% of the total U.S. lead consumption shown in tables 1, 10, 11, 12, and 13. Of the 49 companies producing secondary lead, exclusive of copper base, to which a survey request was sent, 42 responded, representing 93% of the total refinery production of secondary lead, not including that from copper base scrap, shown in tables 1, 7, 8, and 9. Production and consumption for the nonrespondents were estimated using prior-year levels adjusted for general industry trends.

ANNUAL REVIEW

Legislation and Government Programs

There were two significant Federal administrative actions affecting the U.S. lead industry in 1990 by the Environmental Protection Agency (EPA). In midyear, EPA's "third-third" rule became effective for landfilled process wastes under the Resource Conservation and Recovery Act (RCRA), as amended. This rule requires pretreatment for most secondary smelter slags, an item of significant cost to smelters. However, the smelters won a 2-year temporary reprieve to a less strict interim standard on appeal. In October, EPA proposed the "final" lead in drinking water standard, in which an "action level" of 10 parts per billion triggers various corrosion control options. The application of this rule could eventually translate into an 80% further reduction of lead in process effluents and discharges at considerable expense to lead producers and some consumers, especially battery plants. After 2 years of intense study, EPA also completed a comprehensive, multimedia (airland-water) pollution prevention strategy that encompasses both the "old" lead problems in cities and perceived "new" lead problems. This strategy will result in

eEstimated, PPreliminary, Revised

the imposition of significantly stricter multimedia regulations on producers and consumers over the next several years. Immediate consequences of the regulations, to be felt in 1991, will be strict enforcement of existing laws and regulations.

In State actions, mandatory lead-acid battery recycling laws became effective in 13 States during 1990, and, in 7 others, laws were passed to become effective on January 1, 1991. These were in addition to nine other States whose recycling laws became effective in 1989, and one in 1988.

Issues

Domestically, the year 1990 was one of furious legislative activity relative to lead as several bills were introduced into both houses of the Congress to deal with various aspects of lead pollution and epidemiology. The primary concern addressed was urban soil and household dust contamination from old, flaking lead-base paint and solid residues from leaded gasoline exhaust emissions. Also addressed were mandatory Federal lead-acid battery recycling and/or minimum required content of secondary lead in batteries, and source reduction by severely reducing lead content of solders and eliminating lead from all food packaging and containers. In addition, taxation of primary lead and economic incentives for secondary production to reduce environmental "loading" and comprehensive documentation of existing uses, with mandatory new product approvals, was being considered. Extensive yearlong hearings were held at committee and subcommittee levels, but no floor votes were taken, and various amended and combined versions of all proposals were expected to be reintroduced in 1991.

With the exception of the "old lead problem" (primary concern aforementioned), the issue of concern emerging publicly for the first time on a grand scale was that with no proven effective "environmental sink" for heavy metals, they simply move from media to media (airland-water). In doing so it is postulated that they continuously expose the populace more often and in ever-increasing dosages as "virgin" (i.e., newly mined heavy metals) are added to the cycle. However, this hypothesis is dependent on the assumption that dissipative end uses grow proportionately with the overall population and demand, and/or that exposures to both dissipative and nondissipative uses cannot be technologically reduced.

This is a rebuttable presumption illustrated simplistically by the continuously

Because of the implementation of the Harmonized Tariff System in Jan. 1989, import and export categories for 1989 and 1990 are not necessarily comparable with those in previous years.

²American Bureau of Metal Statistics Inc.

³Primary metal production only. Includes secondary metal production where inseparably included in country total.

evolving U.S. lead supply-demand pattern itself. From the peak demand year of 1977 (table 2), primary demand has dropped by 370,000 tons mostly because the major dissipative use of lead in gasoline additives has decreased by 200,000 tons, replaced in the market by highly recyclable electrical and transportation uses, which have increased by 200,000 tons. This is reflected in the old scrap production levels for 1990 versus 1977, an increase of 240,000 tons. There has also been a 100,000-ton drop in overall demand, 90% of which was in the chemicals and other miscellaneous use categories, much of which was dissipative.

Net imports from worldwide, generally less environmentally regulated sources than our domestic facilities have declined by about 200,000 tons from the primary supply side. Projections for the future (see Outlook section) indicate that this overall decreasing exposure and "loading" trend will continue in the domestic supply-demand pattern. With the establishment of the lead-acid battery as a "fungible," marketable commodity due to a generally more environmentally conscious populace (30 States had mandatory battery recycling laws at yearend) and continuing advances in recycling technology, this scena-

rio will improve even more during the rest of the century, continuing to reduce exposure and the attendant epidemiological effects. Technologic advances in lead-acid batteries, resulting in even longer life, will also continue to contribute to limiting use of lead and exposure thereto.

Production

Primary.—The increase in domestic mine production of lead in 1990 was attributed primarily to the coming onstream in February of Cominco Alaska Inc.'s huge Red Dog open pit zinc-lead-

silver mine in the Kotzebue region. However, small increases were also realized at virtually all producing zinc-silver and/or zinc-gold mines in Colorado, Idaho, and Montana where lead is a coproduct and/or byproduct. A slight increase in lead output was also recorded in Missouri, which represented 78% of domestic producion (table 3); Alaska and the other three aforementioned States accounted for 18% of the total. Of those mines listed in table 5, the top 15 produced more than 99% of the total or all but 3,800 tons. In terms of corporate ownership, three companies, Doe Run, ASARCO Incorporated,

and Cominco, accounted for 90% of the total. On the basis of lead in concentrates, The industry performed at only 62% of capacity (table 17), the same as in 1989, because of decreasing primary demand, both domestic (table 2) and worldwide (table 16).

During 1990 in southeastern Missouri, the Doe Run Co. of St. Louis, MO, the Nation's largest integrated lead producer, operated three mine and mill divisions, Buick, Fletcher, and Viburnum, consisting of six mines and four mills, which had an aggregate daily capacity of 26,300 tons of ore according to parent company Fluor

Corp.'s annual SEC Form 10-K. In May 1990, Fluor Corp. purchased Homestake Lead Co. of Missouri's 42.5% interest in Doe Run for \$125 million in cash and are now sole owners. On a fiscal year basis ending October 31, 1990, Doe Run mined and milled 4.78 million tons of ore grading 5.36% lead compared with 4.35 million tons grading 5.58% in 1989, an increase in contained lead of just less than 6%. This resulted in metal production at Doe Run's integrated smelter-refinery in Herculaneum, MO, of about 231,000 tons of refined lead for the calendar year 1990 compared with about 224,000 tons of refined lead for

¹1964-83 revised from previous editions of Mineral Facts and Problems.

1989, an increase of 3%. In addition, Doe Run produced and sold 45,000 tons of copper concentrate and 44,000 tons of zinc concentrate in its fiscal year 1990 from its mines. As of October 31, 1990, these mines had proven ore reserves of approximately 76.8 million tons with an average grade of approximately 4.84% lead, according to Fluor's SEC Form 10-K. Approximately 65% of Doe Run's ore is on properties under Federal mineral leases for terms of 10 to 20 years, renewable for 10 years, for which the company pays the Bureau of Land Management a royalty of 5% of the gross value of concentrates produced.

Asarco operated two mine and mill complexes in southern Missouri, which together produced 82,500 tons of lead in concentrates, the same as in 1989, according to the company's first quarter 1991 special report of "Statistical Data for Securities Analysts." This represented about 72% of the refined lead production from Asarco's integrated smelter-refinery at Glover, MO, in 1990 compared with 75% in 1989. That plant produced 112,000 tons of refined lead in 1990 and 108,000 tons in 1989, according to the report. Asarco purchased Cominco American Inc.'s 50% share of the Magmont Mine production in Iron County, MO, to supplement Glover's feed. Asarco's refinery at Omaha. NE, which receives the lead bullion output of the East Helena, MT, custom smelter, produced 61,000 tons of refined lead in 1990 compared with 65,000 tons in 1989. Asarco also received a 50% share and 37.5% share, respectively, of the production from the Leadville and Galena mines shown on table 5. Asarco's total lead metal production in 1990 was 45% from its own mines, 48% custom, and 7% toll, but at yearend it was estimated that the company had an approximately 85% captive domestic capability if its own mine production were fully optimized.

The Magmont Mine at Bixby, MO, a 50-50 joint venture of Cominco American Inc., the operator, and Dresser Industries Inc., continued to be the Nation's third largest producer, in spite of being only about 3 years from exhaustion. Surface drilling during the year revealed two minor extensions of the ore body, which partially replaced the ore extracted. Ore recovery from the major 1986 groundfall area was completed in 1990, with recovery and pillar extraction exceeding that from other areas of the mine. According to parent company Cominco Ltd.'s (Canada) annual stockholders report, Magmont milled 984,000 tons of ore grading 7.1% compared with 962,000 tons grading 6.8% in 1989. This yielded 87,000 tons of concentrate grading 78.0% lead compared with 81,000 tons at 77.9% concentration in 1989. The mine also produced 8,000 tons of zinc in concentrate from 1.0% ore and 800 tons of copper from 0.3% ore. Cominco Alaska's Red Dog Mine, about 90 miles north of Kotzebue in northwest Alaska, officially opened in February after some initial startup problems that arose in late 1989. However, operations continued to improve through the year, and the mill processed 904,000 tons of ore, which graded 26.5% zinc, 8.5% lead, and 3.6 troy ounces per short ton of silver. Lead concentrate production was 51,400 tons at 55.1% lead compared with 306,000 tons of zinc concentrate at 56.9% zinc and 3% lead. The mill also produced a bulk concentrate of 45,000 tons grading 31.7% zinc and 22.9% lead. Ultimate average production levels are projected at 70,000 tons of contained lead and 325,000 tons of contained zinc per year from measured reserves of 67 million tons estimated to average 5.4% lead and 18.5% zinc, according to Cominco Ltd.

Secondary.—Domestic secondary production increased for the fifth consecutive year, setting a new record, as the industry continued to perform at 90% of capacity, estimated to be 1.03 million tons per year at yearend. In spite of the closure, for environmental reasons, of Exide Corp.'s Dixie Metals Co. plant in Dallas, TX, and the Alco Pacific Inc. plant in Carson, CA, at vearend, there was a net increase in domestic capacity of about 100,000 tons for the year. This was the result, primarily, of expansions and improvements at several larger plants, mostly by RSR Corp., GNB Inc., and Schuylkill Metals Corp. The latter was acquired by a Citicorp investor group during the year, which allowed for a recapitalization of its two plants. At yearend, the industry was represented by 15 companies that operated 22 battery breakers-smelters with capacities of 6,000 to 110,000 tons per year. Also operating were six smaller operations (including Asarco's Omaha, NE, refinery and Doe Run's Boss, MO, smelter), with plant capacities of 6,000 to 10,000 tons per year that did not process batteries. In addition,

21 small companies with 22 plants of less than 1,000 tons per year of capacity each were producing mainly specialty alloys for such uses as solders, brass or bronze ingots, and bearing metals, etc. Production from the latter two secondary sectors in 1990 combined, excluding Doe Run, was 37,900 tons. Although Doe Run was

technically a secondary producer during 1990, its battery scrap was tolled by others, but its "high-grade" scraps and drosses, etc., were processed in the Buick primary plant's blast furnace and kettles at Boss, MO. Therefore, although its production is included in the first category, the "interim" capacity is not. However, work pro-

ceeded on a new secondary plant and breaker at Buick during the year after the Homestake buyout, and an additional 54,000 tons of secondary capacity was expected to come on-stream in late summer 1991. In Texas, Tejas Resources Inc. started construction at Terrell of a new, conventional 27,000-ton-per-year capaci-

²Value based on average quoted price.

ty smelter to process 10,000 batteries per day on a "just-in-time" basis from offsite breakers. The rotary furnace with wet scrubbers was expected to come on-stream in mid-1991, producing a nonleachable sodic slag reportedly safe for conventional landfilling, which is considerably cheaper than disposing of toxic slags.

Consumption

Reported consumption of lead (tables 10 through 13) was about the same as for 1989, with battery manufacturers again using more than 1 million tons or 79% of the total consumer offtake. Although automotive starting-lighting-ignition (SLI) battery shipments, domestic and export, exceeded 80 million units for the third consecutive year, they were about 300,000 lower than in 1989 (3,000 tons of lead), according to Battery Council International statistics. However, inventories rose

by 1.52 million units, accounting for 15,000 tons of increased lead use. Lead use by the industrial-traction battery sector declined slightly, from an estimated 174,000 tons in 1989 to 172,000 tons in 1990; use in all other specialty batteries declined from 43,000 tons (revised) in 1989 to 40,000 tons in 1990. When this 5,000ton decrease is added to the SLI battery shipments decrease and subtracted from the inventory buildup, the result is the 7.000-ton net increase in total battery lead consumed shown on table 10. It was estimated that small, sealed "consumer battery" cells accounted for 5,000 to 10,000 tons of the specialty battery offtake, which includes nonstandard military and civilian research applications not covered by the SLI (includes aircraft), stationary, or motive power categories. The industrial and traction battery sector includes uninterruptible power supply (UPS) designed to ensure constant voltage for large computer systems at hospitals, banks, communication networks, etc., and standby power supply (SBS) for emergency lighting and some telephone systems. About one-third of the lead total in this category applies to electric vehicles and submarines, including some surface boats, and some in-plant and mine equipment. The whole industrial-traction sector exhibits great potential for continued future growth as networking of computers of all capacities continues to grow and general purpose electric vehicles and customer load-leveling loom ever closer to universal application.

Lead oxides used for glass, paint, ceramics, and other chemicals, which had been the second largest use for lead, declined for the sixth consecutive year. All other uses exhibited marginal increases or decreases, except cable lead, which declined significantly, ostensibly a rationalization of 1989's 40% increase over that of 1988.

World Review

According to the International Lead and Zinc Study Group (ILZSG) statistics, consumption of soft lead and antimonial lead in the market economy countries (MEC) was 4.44 million tons in 1990, down from the record high of 4.52 million tons set in 1989.1 Estimated world consumption of lead in all forms decreased for the first time since 1982, to 5.9 million tons, after setting a record of almost 6.1 million tons in 1989 (table 16). A considerable part of this decline occurred in the U.S.S.R., a result of the year's political and resulting economic turmoil, and in the former Soviet bloc in general (excluding China and North Korea), where estimated refinery production declined 60,000 tons from that of 1989 (table 19). From 1983, when the world emerged from a previous 3-year recessionary period, through 1989, a continual growth in demand averaging 2.3% per year had occurred. This was attributed to electrical power storage requirements for vehicles and aircraft or ships; emergency standby power for lighting, communication, and computers, including voltage regulation; and load-leveling for light manufacturing.

Estimated world total refinery production in 1990, including that from recycled new and old scrap, decreased slightly from 1989's record high as metal stocks increased for the first time in 3 years. A 70,000-ton decrease in primary metal output was partially offset by a record secondary output of more than 2.7 million tons, paced by that sector in the United States that set a domestic secondary production record for the second straight year. The high overall production rate in

the face of dwindling world demand from battery manufacturers, who were already sitting on high stocks, resulted in the considerable drop in the world price of lead in the fourth quarter of the year. That was the first significant price decline since the first quarter rationalization in 1989 that reflected high yearend 1988 metal stocks. At yearend, LME physical stocks of lead at 56,400 tons were only 5,000 tons below the high level at yearend 1988. Four new lead-producing mines came on-stream in 1990, two in China and one each in Australia (Thalanga) and Canada (Estrades). Although there was a net capacity increase for the year, there were six closures owing to depletion of ore. However, as a result of numerous other expansions and/or facility upgrades, the only net capacity decreases were in Greenland, whose only mine closed in midyear; Japan; Spain; and

See footnotes at end of table.

Yugoslavia. The largest capacity increase by far was in the United States, which reflected the official opening of Cominco Alaska's Red Dog Mine. The largest expansion was MIM Holdings Ltd.'s (MIM) Hilton Mine (10,000 tons), which in 1989 was integrated into the Mount Isa complex in Queensland, Australia. Although Nuova Samim brought its large primary plant at Porto Vesme, Sardinia, back onstream in midyear with a capacity increase after being shut down for 11 months, permanent closures in Greece, the Republic of Korea, and Yugoslavia resulted in an insignificant net loss of smelter capacity worldwide (table 17).

Australia.—The Pancontinental-Outokumpu-Agip partnership started the Thalanga open pit in Queensland and continued development of the underground mine, expected to be in production in 1991 and eventually to replace the surface operation. Also in Oueensland, MIM continued construction of its new, patented, 60,000-metric-ton-per-year Isasmelt plant scheduled to open in 1991. In New South Wales (NSW), Denehurst Ltd. continued development of the Currawong deposit, a satellite ore body to its Woodlawn open pit mine, expected to be operational in 1991 at a rate of 3,000 tons of lead per year. Reserves were estimated at 500,000 tons of complex base and precious-metal ore grading more than 13% lead. At Broken Hill, NSW, Pasminco Ltd. announced a modernization program to reduce mining and milling costs by 25% to 30% at its ZC Mine by increasing throughput from an additional 7-millionton ore body to 2.5 million tons per year grading 8% lead and 10% zinc by 1992-93. At the Silver King project, near Mount Isa, Diversified Resources announced a preliminary reserve estimate of 712,000 tons grading 0.48% lead and 4.94% zinc. Enterprise Metals, a wholly owned subsidiary of CRA Ltd., announced a decision to develop the Peak Gold project in NSW near its Cobar Mine. The deposit reserves were estimated to be 3.9 million tons grading 1.3% and 1.5%, respectively, for lead and zinc. CRA also announced the discovery of a potentially significant ore body, amenable to open pit mining, estimated to be about 70 million tons grading 1% lead and 7% zinc approximately 250 kilometers northwest of Mount Isa. MIM acquired a 50% share of Metallgesellschaft's ISF plant at Duisburg in the Federal Republic of Germany, to which they

already ship some of the bulk concentrates produced at Mount Isa. Denehurst Ltd. revised reserve estimates for its base-and-precious-metals open pit mine in NSW to 3.58 million tons grading 2.4% lead, in effect extending its life for an additional 10 years.

Austria.—BBU-Metalle completed expansion and modernization of its 1963 round hearth, secondary smelter at Arnoldstein and installed a state-of-the-art

Tonolli CX battery breaking system. Capacity was increased from 8,000 tons per year to 32,000 tons per year.

Canada.—Breakwater Resources Ltd. opened the country's only new lead producer in 1990, the underground Estrades Mine, primarily a zinc and copper mine, near Joutel, Quebec; the ore was milled at Noranda's Mattagami facility. Estrades' reserves were estimated to be 941,400 tons grading 10.7% zinc, 0.94% copper, and

²Includes lead that went directly from scrap to fabricated products.

0.92% lead. During the year, Breakwater also acquired all of the shares of Bathhurst Metals and its Caribou Mine in New Brunswick, but shut Caribou down in October rather than revamp the mill and further develop the mine to increase output, preferring to concentrate on its Estrades Mine and El Mochito Mine (Honduras) instead. Westminer Canada, a wholly owned affiliate of Western Mining of Australia, brought the Gays River underground mine in Nova Scotia, closed since 1981, back on-stream with an expected capacity of about 10,000 tons per year from ore grading about 4.5% lead. Curragh Resources completed a development plan for its Mount Hundere project in the Yukon Territory, estimating reserves of 3.94 million tons grading 4.1% lead and 12.8% zinc. The production plan was for 50,000 tons per year of 73% lead concentrate. Construction work on the mill and tailings dam began after the issuance of a C\$130 million bond issue and negotiation of a C\$55 million financing package for mine development. The mine was expected to come on-stream in late 1991 or early 1992. In northern British Columbia, Curragh continued to develop the huge Cirque deposit, planned for 1992 startup. Reserves were estimated to be 13 million tons of 14% combined lead and

Included with "Building construction" to avoid disclosing company proprietary data.

²Data do not add to total shown because of independent rounding.

³Included with "Other metal products" to avoid disclosing company proprietary data.

Includes lead consumed in foil, collapsible tubes, annealing, galvanizing, plating, and fishing weights.

⁵Included with "Miscellaneous uses" to avoid disclosing company proprietary data.

zinc with a lower grade reserve base of an additional 20 million tons. Development continued at Curragh's Vangorda and Grum deposits in the Yukon, planned open pits intended to maintain the nearby Faro Mine and mill production levels of 120,000 tons per year of lead and 200,000 tons per year of zinc when that operation

begins to tail off in 1991.

Canadian metal production suffered during the year when the labor force struck the Bathurst Mining and Smelting Co.'s smelter-refinery from July 22 through yearend; management continued to operate the facility at only 25% of capacity. There was no settlement by year-

end when the company retracted its "final" offer. Also affecting production was Cominco Ltd.'s decision to shut down and reevaluate its new, in 1989, 160,000-tonper-year QSL smelter at Trail, British Columbia, in March owing to feed process and mechanical problems. Lead production continued at about 80% of the old smelter capacity of 125,000 tons per year through vearend. The company had closed its Trail "feeder" in British Columbia, the Sullivan Mine at Kimberley, in January, but reopened it in November after the completion of a C\$11 million development program. The new smelter, however, was not expected to reopen until well into 1991, or later if major design modifications became necessary.

France.—Berzelius (Federal Republic of Germany) and Socitété de Traitements Chimiques des Metaux (STCM) signed a cooperative agreement on developing environmental technology for secondary lead plants, with the former to acquire a minority interest in the latter. Berzelius' secondary plant at Braubach, Federal Republic of Germany, has a capacity of 45,000 tons per year, while STCM's two plants in France total 50,000 tons per year capacity. Ste. GAST started construction of a new secondary plant, 20,000-ton-per-year capacity, to open in 1991 at Brenoville, Pont Ste. Maxence.

Germany, Federal Republic of.—Berzelius Metallhütten GmbH, the operating arm of Metallgesellschaft, opened the new

late in the year. Rated at a capacity of 100,000 tons per year, it replaced an existing smelter rated at 80,000 tons per year. QSL plant at Stolberg (Binsfeldhammer) | Earlier in the year Metallgesellschaft had | QSL plant. Berzelius also completed plans

signed an agreement with the State-owned Eastern State company BHKF for replacement of its Freiberg smelter with a

Table includes data available through June 14, 1991. Data included represent the total output of refined lead by each country, whether derived from ores and concentrates (primary) or scrap (secondary), and include the lead content of antimonial lead, but exclude, to the extent possible, simple remelting of scrap. ²Reported figure.

³Data may not add to totals shown because of independent rounding.

Less than 1/2 unit.

⁵Data are for fiscal year beginning Apr. 1 of that stated.

to modify and expand its ISF plant at Duisburg, which can process both primary and secondary material, by mid-1991. MIM was buying a 50% stake in that plant in order to increase its involvement worldwide in metal production; it already ships some of the bulk concentrates from its Mount Isa Mine in Queensland to Duisburg.

Honduras.—American Pacific Mining, a wholly owned U.S. subsidiary of Breakwater Resources Ltd. (Canada), continued upgrading the access and haulage systems at the El Mochito Mine in order to be more selective and yield higher average-grade ores. They also completed a new tailings facility to extend the mine's life at least 10 years. Breakwater assumed full control in April and planned to continue exploration to extend the ore bodies and raise mill throughput to 2,000 tons per day in 1991. Ore reserves were estimated to be 5.5 million tons grading 1.6% lead and 6.85% zinc.

India.—Hindustan Zinc Co. Ltd. continued development of its open pit at Rampura-Agucha, Rajasthan, expected to open in 1991 and to be producing 8,000 tons per year of lead by 1992. The company continued on schedule with construction of its new ISF servicing smelter at Chanderiya, Rajasthan, expected to start up in mid-1991 and reach capacity of 35,000 tons per year in 1993. About 40% of the feed was expected to come from Rampura-Agucha and Hindustan's underground Ambamata Mine at Gujrat, also under development, and more than one-half to be imported, with zinc capacity estimated at 70,000 tons per year. A new secondary plant, expected to open in 1991 at 6,000-ton-per-year capacity, was under construction on the west coast by the Rohit Pulp and Paper Mills Co.

Iran.—Four active mines were undergoing expansion projects to yield an additional total capacity of 18,000 tons per year between 1991 and 1994. These mines, Angouran open pit in the north at Zandjan, Emarat open pit at Khomain in the central province of Esphahan, Ahangzan open pit at Hamadaz in the west, and Nakhlak underground at Yazd in central Iran, were expected to reach full production in that phasing order.

Ireland.—Conroy Petroleum Ltd. completed the feasibility study for its proposed

Galmoy Mine and reportedly estimated reserves at 6.2 million tons grading 11.31% zinc and 1.12% lead. The company applied for permits to develop the underground ore body through a 13% surface decline ramp and planned to produce 2,000 to 5,000 tons per year of lead starting in 1992 or 1993. Tara Mines Ltd. was in the process of completely upgrading the equipment for its underground mine at Navan, County Meath, in order to reach the original planned production of 38,000 tons of lead per year by 1991 or 1992.

Korea, Republic of.—Korea Zinc Co. Ltd. neared completion of its new 80,000-ton-per-year QSL smelter and refinery at Onsan, on schedule to open in 1991. Korea Mining and Smelting Co. Ltd. closed its 15,000-ton-per-year primary smelter and refinery at Changhang, a result of insurmountable environmental problems.

Malaysia.—Metals Reclamation Industrial Snd. Bhd. started a plant relocation and capacity upgrade from 16,000 to 24,000 tons per year at its secondary plant at Selayang, to be fully operational by 1992.

Pakistan.—Additional lead-zinc deposits were discovered and evaluated in the Baluchistan region, where previous explorations had identified a 10-million-ton ore body near Khudzar. One at Duddar was estimated to contain 0.66 million tons grading about 3% lead and 15.5% zinc. Another at Surmain was estimated to contain 2.93 million tons grading 6.5% combined lead-zinc.

United Kingdom.—Britannia Refined Metals, a wholly owned subsidiary of MIM, neared completion of its new 40,000-tonper-year secondary Isasmelt furnace and refinery, scheduled to replace the 10,000ton-per-year conventional plant by mid-1991. The new complex at Northfleet, Kent, will also have a state-of-the-art Tonolli CX battery breaking system, which was being installed by Engitec Impianti of Italy. Anglesey Mining Ltd., a subsidiary of Imperial Metals Corp., initiated shaft sinking at its planned Parys Mountain underground mine in North Wales. Bulk sampling was initiated to further evaluate the deposit, for which the preliminary estimate was that it could be producing 300,000 tons per year of ore, primarily zinc and copper ore but containing about 5,000 tons of lead, by 1992 or 1993.

Yugoslavia.—At yearend, Ro Rudniki Svinca in Topilnica closed its 26,000-tonper-year primary smelter at Mezica, Slovenia, which had been producing refined lead since 1906. The company also started closure of the plant's captive mine at the same location, to be completed in stages by 1995. SOUR Hemijska Industrija completed closure of its Brskovo Mine at Mojkovac, Montenegro, a process started in 1987. The closures are to be more than offset by Zletovo-Sasa's 10,000ton-per-year expansion project underway at its Toranica Mine and Zorka-Sabac's 2.000-ton-per-year expansion project underway at its mine at Sastavci-Kizevac. Both underground mines were expected to be at full capacity by 1992.

Current Research

In recent years, research in lead use worldwide has focused strongly on improvements to the lead-acid battery, through all its applications, in terms of safety, capacity, longevity, durability, dependability, and manufacturing-marketing economics, including plant robotics. In 1990, two researchers at the California Institute of Technology, under contract to the National Aeronautics and Space Administration, discovered one potential solution to overcoming the most common failure mode in deep drawdown cycle applications, paste softening and, therefore, accelerated disintegration of the positive plate. As the active material paste slakes, the whole cell can become inactive, or the paste can fall to the bottom and short against the negative plate. Exposure of the grid can then lead to abnormal corrosion, producing an insulating layer and higher resistance. The softening can also be manifested by grid "growth" (bulking) causing separation of the positive active paste, causing loss of capacity and leading to premature, but not immediate, failure. Together with overall lowered conductivity, plate utilization during discharge is also reduced. The solution discovered was to mix randomly oriented, very thin and short, lead-coated glass fibers into the paste prior to grid application, which also improved the structural integrity of the plate upon curing. The compatible conductive fibers increase charge uniformity of the plate, preventing electrical isolation and improving paste utilization during discharge. Fibers 0.004 inch thick coated to 0.010 inch thick and cut to 0.100 inch in length displace about 2% of the lead monoxide paste volume. The approximate 5% weight gain is then offset by increasing grid spacing. Because the lead on the fiber is also charged during formation of the battery, a more thorough electrical and mechanical interface with the active material is established without any loss of structural integrity.²

One of the most novel, recently developed uses of lead with continuing developmental applications is for building foundations isolated against severe horizontal earthquake acceleration "shocks." Because of lead's unique softness and density properties, it is ideal for use in dampers under midrise buildings of about four to six stories in commonly severe earthquake-prone areas where the common shock frequency of horizontal accelerations is between 1 and 2 seconds, which is about the resonant frequency of such structures. Harmonic attenuation causes these buildings to shake themselves apart under such conditions. Base-isolation systems commonly consist of large steel springs to support the building weight, dampened by steel-rubber "sandwiches." However, laboratory testing of several cast-lead shapes on computer-driven shaking tables has proven conclusively that lead dampers absorb significantly greater amounts of energy per cycle. Each Ushaped damper, determined to be the optimal form in this application, weighs 132 pounds and can dampen 121 square feet of ground floor in a typical midrise structure. This method for earthquake protection has been accepted by the Japan Institute of Architects, and a 500-page design and construction manual has been written. Two prototype buildings in Japan, which are currently being monitored, were recently completed. At yearend, several other buildings were being planned in Japan, including two office buildings, one of which called for a critical computer facility on the top floor that cannot tolerate disruptions.3

A comprehensive coverage of lead-related investigations and an extensive review of current world literature on the extraction and uses of lead and its products, including batteries, were published in quarterly issues of Leadscan, published by the Lead Development Association, London, United Kingdom.

OUTLOOK

Although domestic demand for lead

grew on average about 4% per year from 1985 to 1989 (table 2), this rate cannot be sustained in the future because some end uses of lead will certainly be curtailed or eliminated entirely by legislation or regulation. One of the current pollution prevention strategies, known as source reduction, will probably reduce the use of lead in nongrowth markets such as solders, paints, and coatings (already eliminated in interior house paints), ceramics, gasoline additives, containers or other packaging (including inks or dyes, especially where food is concerned), and cosmetics. Some reduction of lead per battery unit can also be anticipated as the technology continues to advance. As a result, U.S. annual growth in lead demand will probably fall within a range of 0.5% to 1.5% per year in the decade of the 90's, averaging about 1%, as the storage battery sector becomes even more dominant. The lower growth rate can certainly be expected if source reduction is applied to the ammunition sector, currently the second largest end use. The higher growth rate could be attained if the use of lead-acid batteries for peak-power, load-leveling applications becomes widely accepted for households and commercial facilities, and/or there is a moderate demand for private general purpose electric cars. The latter two conditions will probably not prevail until the end of the century.

World demand for lead grew at an average rate of more than 2% through 1989 from the low recession year of 1982 (table 16). Lower growth U.S. demand, which is currently 22% of the total, will undoubtedly lower the overall world growth rate somewhat in the future. However, storage battery use in all applications will undoubtedly grow faster in the rest of the world than in the United States as some poorer nations increase their living standards while they grow with the world economy. It is estimated that currently about 60% of world demand is for batteries, compared with about 80% in the United States, and is forecast to reach about 70% by the end of the decade as the rest of the world's supply-demand pattern is rationalized by environmental concerns. Therefore, the most probable world growth until the end of the century is forecast to average about 1.5% per year.

The attendant worldwide production outlook is interrelated with anticipated structural changes. Because of large capital demand and high costs associated with environmental concerns, large production surpluses in the near term are not likely. High realized producer prices are critical to profitably amortizing the large improvement expenditures anticipated over the next 10 years. However, this will continue to be partially subjected to developing situations in zinc and silver markets because of the geologic relationships of the three metals in the primary production sector. The trend of increasing secondary share of production and consumption exhibited in tables 19 and 16, respectively, is expected to continue until optimum recycling is achieved. Complex multinational, multifaceted realignments and restructuring, including divestitures. among world lead producers and product manufacturers are expected to continue through the rest of the century. Most noticeable will be investments of primary producers, in many cases through acquisitions and mergers, in secondary lead production to protect existing market share.4

LIME

By M. Michael Miller

Mr. Miller, a physical scientist with 13 years of minerals experience with the Department of the Interior, has been the commodity specialist for lime since 1989. Domestic survey data were prepared by Blanche S. Hughes, mineral data assistant; and the world production table was prepared by Harold D. Willis, international data assistant.

ime is vital to the economic and environmental well-being of the United States. It is a basic chemical that ranked fifth in total production in the United States in 1990. Its major uses are in steelmaking; pulp and paper manufacturing; construction; and the treatment of water, sewage, and smokestack emissions.

Total lime sold or used by domestic producers, including that from Puerto Rico, increased by about 300,000 short tons to 17.5 million tons in 1990. These products, valued at more than \$905 million, included quicklime and hydrated lime for commercial sale or captive consumption. Commercial sales increased for the fourth straight year and were at record-high levels. Captive consumption decreased to the lowest level since the U.S. Bureau of Mines first collected accurate data on captive production in 1958.

DOMESTIC DATA COVERAGE

Domestic production data for lime are developed by the U.S. Bureau of Mines from two separate voluntary surveys of U.S. operations. The survey used to prepare this report is the annual "Lime" survey. Of the 114 operations to which the annual survey request was sent, 112 responded, representing 98% of the total sold or used by producers shown in table 4. Production for the two nonrespondents was estimated using reported prior-year production figures.

BACKGROUND

Definitions and Specifications¹

Lime is a manufactured product made by calcining limestone (calcium carbonate

or a combination of calcium and magnesium carbonate) or other calcium carbonate materials at temperatures ranging from 1,800° F to 2,400° F. It is never found in a natural state. The calcination process drives off the carbon dioxide, forming calcium oxide (quicklime). The subsequent addition of water creates calcium hydroxide (hydrated or slaked lime). The term "lime" is a general term that includes the various chemical and physical forms of quicklime and hydrated lime. It may be high calcium, magnesian, or dolomitic. Quicklime is calcium oxide (CaO) with no water of crystallization. Hydrate is hydrated calcium oxide or calcium

hydroxide [Ca(OH)₂] and contains 24% combined water. Dead-burned refractory dolomite is dolomite that has been calcined at 2,800° F to 3,150° F. Refractory dolomite is another name for dead-burned dolomite. All of these products are called lime.

Quicklime is commercially available by the carload, in bulk, or in paper bags, in the following standard sizes:

- 1. Lump lime—the product exceeds 2.5 inches in diameter. Although sizes can vary, the typical size is 5 by 8 inches. This largest size of quicklime is strictly a product of vertical kilns.
 - 2. Crushed or pebble lime—the product

¹Excludes regenerated lime. Excludes Puerto Rico.

²Data may not add to totals shown because of independent rounding.

³Selling value, f.o.b. plant, excluding cost of containers.

Bureau of the Census.

⁵Calculated by sold or used plus imports minus exports.

ranges in size from 0.25 inches to 2.25 inches, but the specific product size is more precise. This size has traditionally been a product of rotary kilns, but is now available from vertical kilns as either a primary product or as a result of crushing lump lime.

3. Ground lime—the product is generally ground from larger size material. A typical product size passes nearly 100% through a No. 8 sieve and 40% to 60% through a No. 100 sieve.

4. Pulverized lime—the product is the result of further grinding. A typical product size passes nearly 100% through a No. 20 sieve and 85% to 95% through a No. 100 sieve. This is usually a secondary product and is produced by intense grinding and classification.

5. *Pelletized lime*—almond-shaped pellets or briquets of uniform 1-inch size, molded from quicklime fines.

Hydrated lime is shipped in bulk tank trucks, railcars, and in 50-pound paper bags. As a result of the hydration process, it is of fine particle size. A typical product size passes 85% or more through a No. 200 sieve, and a few special applications may require a product passing 95% to 98% through a No. 325 sieve.

Because of the differences in limestones, a rigid standardization of lime material specifications is impossible. Few plants manufacture lime with exactly the same properties; as a result, lime specifications are by necessity quite general in their provisions. A typical analysis is shown in table 2.

TABLE 2
TYPICAL ANALYSES OF
COMMERCIAL QUICKLIMES

Component	High-calcium quicklimes, range, percent	Dolomitic quicklimes, range, 1 percent
CaO	93.25-98.00	55.50-57.50
MgO	.30- 2.50	37.60-40.80

Technology²

Lime manufacture involves three main processes: stone preparation, calcination, and hydration. Stone preparation involves quarrying or mining (including drilling, blasting, and conveying broken stone), crushing, and screening to provide the proper size kiln feed. Care is taken to avoid contamination with undesirable impurities, such as iron oxide, silica, and alumina. Although most lime manufacturers produce their own stone, some purchase the stone for kiln feed from commercial limestone producers.

Calcination is a simple chemical reaction. It is the addition of heat to limestone to cause thermal decomposition, in which the coproducts of CaO (quicklime) and CO₂ (carbon dioxide) are formed. This process is performed in a kiln, of which there are a wide variety of systems in use. The two basic kiln designs are rotary and vertical (or shaft). There are a few other miscellaneous designs, but the majority of commercial kilns are of rotary or vertical design.

A rotary kiln is a long cylindrical kiln with a refractory lining, inclined at a slight angle, rotated at a slow speed, and fired by fuel at the lower end. The calcareous raw material (kiln feed) is fed into the upper end and calcined at about 2,000° F during its travel through the kiln to form quicklime, which is discharged at the lower end. The calcination temperature depends on size and composition of kiln feed and the type of desired product. The carbon dioxide is driven off as a gas and normally exits the system with the stack gas.

Vertical kilns are short, wide, vertical cylinders lined with refractory materials. They are usually circular in cross section, typically with a diameter of 9 to 14 feet and a height of 50 to 70 feet. They are the most widely employed type in the world, especially in Europe. A vertical kiln is divided into four distinct zones where specific parts of the manufacturing process take place. They are, from top to bottom, (1) stone storage zone, (2) preheating zone, (3) calcining zone, and (4) cooling and discharge zone.

Examples of other kiln designs are the rotary hearth kiln and the fluosolids kiln. The rotary hearth design consists of a preheater, circular hearth, and cooler, all refractory lined. Stone is placed on the hearth and rotated through a heating chamber. In the fluosolids kiln, fine-sized stone is densely suspended by air and hot

gases in the preheating and calcining zone of a vertical heated chamber. It can be operated at lower temperatures because of the fine stone size. The quicklime product is the most highly reactive of any commercial lime.

Byproducts and Coproducts

Most lime companies mine their own limestone or dolomite for kiln feed. Some companies also coproduce crushed and pulverized stone. If practical and markets exist, byproduct fines from the kiln feed preparation process and kiln dust from the calcination process are also marketed. Precipitated calcium carbonate is produced as a coproduct at three commercial lime plants by combining quicklime with byproduct carbon dioxide recovered from the kiln. Byproduct carbon dioxide is also recovered for use in the carbonation step of sugar refining.

Substitutes

Limestone is a low-cost substitute for lime for many uses such as agriculture, fluxing, and flue gas desulfurization (FGD). Limestone contains less reactive material, is slower to react, and may have other disadvantages compared to lime, depending on the use. Calcined gypsum is an alternative material in industrial plasters and mortars. Cement, lime kiln dust, and fly ash are potential resources as substitutes for some construction uses of lime.

Economic Factors

Prices.—Traditionally, lime has been a low-priced commodity. Its average value, as reported to the U.S. Bureau of Mines on an f.o.b. plant basis, ranged from \$4 to \$15 per ton from 1910 to 1970. It was only in the 1970's, when energy prices escalated, that lime prices showed a progressive and dramatic increase. This steady increase continued into the 1980's, although at a slower pace. In 1987, lime decreased in value for the first time since 1968. When comparing prices over the past 20 years, based on constant 1990 dollars, two trends become evident. From 1971 to 1980, prices increased steadily, finishing the period up 46%. From 1981 to 1990, prices decreased steadily, finishing the period down 21%.

Costs.—Production costs in lime manufacture can be divided, in descending

order, into the following categories: energy (mainly fuel costs), kiln feed, dust collection, depreciation, direct labor, and miscellaneous. The ranking may differ from plant to plant, and most of the categories display a great range in costs from one plant to another. The difference in ranking and the range in costs are accounted for by such variables as distance from fuel sources; thermal efficiency of individual kilns; whether kiln feed is quarried, mined underground, or purchased; electrical energy rates; and age of the plant.³

Tariffs.—In the Harmonized Tariff Schedule of the United States, quicklime, slaked lime (hydrate), and hydraulic lime are listed under 2522.10, 2522.20, and 2522.30, respectively. Imports are free from countries with most-favored-nation (MFN) status and Canada. Non-MFN countries have tariffs of 0.2¢ per kilogram (about \$2.20 per short ton) for quicklime,

0.3¢ per kilogram (about \$3.31 per short ton) for slaked lime, and 0.2¢ per kilogram (about \$2.20 per short ton) for hydraulic lime. Mexican imports of lime are assessed a countervailing duty of 1.21%. This applies to all Mexican lime producers included in the scope of a countervailing duty investigation completed in 1984 and a changed circumstances administrative review completed in 1989.

ANNUAL REVIEW

Legislation and Government Programs

On November 15, 1990, the Clean Air Act Amendments of 1990 were enacted into law. "Title IV-Acid Deposition Control" was amended to include a market-based system of sulfur dioxide (SO₂) and nitrogen oxide emission reduction. The system is based on the allocation of emission allowances, which are calculated from emissions limits and baseline fuel consumption levels. An allowance allows the holder to emit 1 ton of SO₂ during or after the year in which the allowance was issued. Title IV of the law is directed at new and existing fossil fuel-fired electric generating stations containing one or more units that serve commercial generators of electricity. The domestic electric utility industry currently accounts for approximately 75% of annual SO₂ emissions. The goal is to reduce SO₂ emissions by 10 million tons from 1980 levels. To achieve this goal, emissions will be capped at 8.9 million tons by the year 2000.

In phase I, effective January 1, 1995, 110 existing electric utility plants with generating capacity in excess of 25 megawatts will be allocated SO₂ emission allowances. The allowances can be reassigned to other units within a utility's system, and they can be bought and sold between other allowance holders. Sulfur dioxide emissions cannot exceed the total of allocated and acquired allowances. Two-year extensions can be had for compliance with the allowance limitations if using a qualifying phase I technology achieving 90% SO₂ removal. Bonus allowances will be awarded for the installation of phase I technology; for achieving reductions before 1995; for achieving reductions through conservation and use of renewable energy; and to utilities in Illinois, Indiana, and Ohio.

In phase II, effective January 1, 2000, utility plants will receive emission allowances that are equal to 48% of the phase I allowance level. Four-year extensions can be had for utilizing clean coal technology. Bonus allowances will be awarded for achieving reductions through conservation or use of renewable energy, for operating in a State with a very low average emissions rate (as measured in 1985), for operating in 10 Midwestern States, and for additional special situations.⁴

The compliance options currently available to utility plants consist primarily of flue gas desulfurization (FGD) systems and fuel switching. FGD systems using either lime or limestone are used on more than 60 gigawatts of utility capacity. These systems have SO₂ removal efficiencies ranging from 50% to 95%. The high removal rates possible make FGD systems a cost-effective compliance option. This is despite their large size, relatively high capital costs, and byproduct waste disposal concerns.

Production

The term "lime," as used throughout this chapter, refers primarily to six chemicals produced by the calcination of highpurity calcitic or dolomitic limestone followed by hydration where necessary. They are (1) quicklime, calcium oxide (CaO); (2) hydrated lime, calcium hydroxide [Ca(OH)₂]; (3) dolomitic quicklime (CaO·MgO); two types of dolomitic hydrate, (4) type N [Ca(OH) $_2$ ·MgO] and (5) type S $[Ca(OH)_2 \cdot Mg(OH)_2]$; and (6) deadburned dolomite. Nondolomitic quicklime and hydrated lime are also called high-calcium lime. Lime can also be produced from a variety of calcareous materials such as aragonite, chalk, coral, marble, and shell. Lime is also regenerated; that is, produced as a byproduct, by paper mills, carbide plants, and water treatment plants; however, regenerated lime is beyond the scope of this report.

Total U.S. lime production from limestone, including that of Puerto Rico, was essentially unchanged. Commercial lime sold by producers increased by 434,000 tons from the previous year. Captive lime used by producers decreased by 131,000 tons or about 6% compared with the previous year.

In 1990, 70 companies produced lime. Leading producing companies, in descending order, were Dravo Lime Co. with two plants in Kentucky and one

plant in Alabama; Mississippi Lime Co. in Missouri; Marblehead Lime Co. with two plants in Illinois and one each in Indiana and Michigan; Chemstar Inc. with two plants each in Arizona, California, and Nevada and one in Utah: Martin Marietta Corp. in Ohio; Allied Lime Co. with two plants in Alabama; Continental Lime Inc. with one plant each in Montana, Nevada, Utah, and Washington; APG Lime Co. with one plant each in Texas and Virginia; Chemical Lime Southwest with two plants in Texas; and LTV Steel Co. in Ohio. These 10 companies operated 26 plants and accounted for 57% of total lime production.

Domestic lime plant capacity is based on 365 days minus the average number of days for maintenance times the average 24-hour capacity of quicklime production, including quicklime converted to hydrated lime, and reported in short tons per year. Specific plant capacity data were available for 72% of commercial lime plants. Based on the data available, the commercial lime industry operated at 79% of capacity in 1990.

The industry announced a number of plant expansions and plans for new plant

construction. Dravo Lime Co. began installation of a 800-ton-per-day preheater rotary kiln of Kennedy Van Saun design at its plant in Saginaw, AL. It was scheduled to go on-line in late March 1991. It will replace a 200-ton-per-day rotary. which will be placed in inactive status. Cheney Lime and Cement Co. began installation of a preheater rotary kiln of Kennedy Van Saun design at its plant in Shelby County, AL. It was scheduled to go on-line in the first quarter of 1991. Continental Lime Inc. began installation of a second kiln at its plant at Townsend, MT. The kiln was a used Allis Chalmers with a preheater of Continental design. Chemstar Inc. worked on zoning and permitting approvals for two new plants planned for Soda Springs, ID, and Cosgrave, NV. The plans for Soda Springs called for installation of a 600-ton-per-day Mertz vertical shaft kiln to go on-line the second quarter of 1992. Owing to zoning problems, Chemstar had to relocate its planned Winnemucca operation to Cosgrave, NV, about 6 miles northeast of the original site. The plant is expected to go on-line in the third quarter of 1992. Pfizer Inc.'s Specialty Minerals Group began a

\$13 million expansion at its facility in Adams, MA. The facility contains a crushed stone operation, lime plant, and precipitated calcium carbonate plant. The plans called for construction of a new office and laboratory building, renovation of an existing building, replacement of a 30,000-gallon lime slurry tank, and removal of several existing structures deemed inadequate for current needs. Additional annual expenditures are planned as part of a 10-year program to continue upgrading the facility, address environmental concerns, meet market projections, and maintain profitability.

Consumption and Uses

Lime was consumed in every State. The breakdown of consumption by major end uses was as follows: 66% for chemical and industrial uses, 24% for environmental uses, 8% for construction uses, and 2% for refractory dolomite. Captive lime was used mainly in sugar refining and in the production of steel in basic oxygen furnaces.

In steel refining, quicklime was used as a flux to remove impurities such as phosphorus, silica, and sulfur. Dolomitic lime

was often substituted for a fraction of the high-calcium lime to extend refractory life. Dead-burned dolomite, also called refractory lime, was used to line the bottom of open-hearth steel furnaces to extend the life of the brick lining. Dead-burned dolomite was a component in tarbonded refractory brick used in basic oxygen furnaces. Lime consumption for raw steel production remained essentially unchanged at 5.1 million tons and accounted for 29% of all lime consumed in the United States.

In nonferrous metallurgy, lime was used in the beneficiation of copper ores to neutralize the acidic effects of pyrite and other iron sulfides and maintain the proper pH in the flotation process. It was used to process alumina and magnesia, to extract uranium from gold slimes, to control pH and reduce cyanide loss in gold and silver leaching operations, and in the recovery of nickel by precipitation.

Lime was used in the softening and clarification of municipal potable water. In sewage treatment, lime was used to control pH in the sludge digester, which removes dissolved and suspended solids that contain phosphates and nitrogen compounds. It also aided clarification and killing of bacteria. Lime was used to neutralize acid mine and industrial discharges. In FGD systems serving utility and industrial plants, lime was used to react with sulfur oxides in the flue gas. Lime was used to stabilize sludges from sewage and desulfurization plants before disposal.

The paper industry used lime as a causticizing agent and for bleaching paper pulp to the desired degree of whiteness. Lime was also used in the clarification and color removal of paper mill wastes and to make precipitated calcium carbonate, a specialty pigment used in premium-quality coated and uncoated papers.

The chemical industry used lime in the manufacture of alkalies. Quicklime was combined with coke to produce calcium carbide, which was used to make acetylene and calcium cyanide. Lime was used to make calcium hypochlorite, citric acid, petrochemicals, and other chemicals.

In sugar refining, milk of lime, a suspension of hydrated lime in water, was used to raise the pH of the product stream, precipitating colloidal impurities. The lime itself was then removed by reaction with carbon dioxide to precipitate calcium carbonate. The carbon dioxide

was obtained as a byproduct of lime production.

Dolomitic quicklime was used as a flux in the manufacture of glass. Quicklime was used to make calcium silicate building products such as sand-lime brick; hydrated lime was used to produce silica refractory brick.

In construction, lime was used for soil stabilization to upgrade clay soils into satisfactory base and subbase materials. Common applications included the construction of roads, airfields, building foundations, earthen dams, and parking areas. Hydrated lime was used with fly ash to make a base material; in asphalt mixes to act as an antistripping agent; and in plaster, stucco, and mortar to improve durability. Other applications of lime included agricultural uses, leather tanning, plastics manufacture, and pigments.

Prices

The average value of lime sold or used by producers, as reported to the U.S. Bureau of Mines on an f.o.b. plant basis, increased to \$51.77 per short ton. Average values were \$50.53 per ton for chemical and industrial lime, \$58.70 for construction lime, \$59.44 for lime used in agriculture, and \$71.61 for refractory dolomite.

The average value of quicklime sold increased to \$49.55 per ton. Average values per ton were \$49.13 for chemical lime, \$45.17 for construction lime, \$57.10 for lime used in agriculture, and \$67.60 for refractory dead-burned dolomite.

The average value of hydrated lime sold decreased to \$60.88 per ton. Average values were \$58.21 for chemical lime, \$67.54 for lime used in construction, and \$60.37 for lime used in agriculture.

Foreign Trade

Exports of lime increased by 37% to 44,287 tons. Imports of lime decreased by about 20% to 173,197 tons. Most U.S. trade was with Canada and Mexico, which together accounted for 99% of the U.S. imports and exports of lime. Canada was the major trading partner, receiving 80% of U.S. exports and shipping 87% of U.S. imports.

World Review

Denmark.—The largest lime producer in Denmark is Faxe Kalk, a 51% subsidiary of Aalborg Portland Holding A/S.

Faxe Kalk and its subsidiaries produced an assortment of calcium carbonate derived products. Limestone was quarried near the town of Fakse and transported a short distance to the lime plant operation at Stubberup. Quicklime was produced from two rotary kilns, with some further processing into pulverized lime and hydrate. Hydrated lime was also produced at Vejle. Annual lime production by Faxe Kalk averages between 125,000 to 145,000 tons.⁵

Germany, Federal Republic of.—With the reunification of the two Germanies, the German Democratic Republic ceased to exist and became simply the Eastern states of the Federal Republic of Germany. Reunification and the resulting economic turmoil in the Eastern states had a large negative impact on lime production and lime markets in the Eastern states. Harzer Kalk-Werke GmbH was the largest lime producer in the Eastern states. It operated the following six limestone and lime facilities: Werk Rbeland, Werk Kaltes Tal, Werk Hornberg, Werk Bad Ksen, Werk Oberrohn, and Werk Schraplau. These operations supplied quicklime and hydrate for use by industries such as chemicals, steel, pulp, sugar refining, metallurgy, and agriculture. Production was down in 1990, primarily owing to the uncertainties facing the chemical industry of the former German Democratic Republic.6

Mexico.—There are about 130 lime plants in Mexico. The Fideocomiso de Minerales No-Metálicos Méxicanos, the Government agency that oversees the nonmetallic mining sector, classifies only 15 of Mexico's lime plants as "modern." These 15 plants produce about 50% of Mexico's annual production. Most lime producers are small and face three major problems: lack of quality control, lowlevel technology and antiquated equipment, and lack of adequate financing. Mexico's annual lime production ranges between 5 to 7 million tons. The two largest markets are the construction industry and the steel industry, which consume about 80% and 8%, respectively.

New Zealand.—Lime was produced on both the North and South Islands. There are only a relatively small number of "calcined lime" producers in New Zealand, where pulverized agricultural lime is also termed lime. Quicklime and hydrate were produced by McDonalds Lime Ltd. at

Otorohanga and Te Kuiti on the North Island. McDonalds operated two coalfired rotary kilns at Otorohanga and a gas-fired Mertz vertical kiln at Te Kuiti. Its major market was the steel industry, but it also supplied lime for sugar refining, soil stabilization, pulp manufacture, and water treatment. Taylors Lime Co. Ltd. operated on the South Island. In 1990, Taylors relocated its lime plant from Oamaru to Makareo and installed a new rotary kiln. The main objective in relocating the plant was to supply lime to the Macraes Flat gold-mining operation. Both McDonalds and Taylors are subsidiaries of Milburn New Zealand Ltd.⁷

Current Research

Researchers at the Illinois State Geological Survey Minerals Engineering Laboratory have developed a high-surface-area (HSA) hydrated lime for use in dry-sorbent FGD systems. The HSA hydrate is very reactive because it has a smaller particle diameter and crystallite

size and greater surface area and porosity than commercial hydrates. The HSA hydrate was tested at the Environmental Protection Agency's (EPA) furnace sorbent injector reactor at Research Triangle Park, NC; Consolidation Coal's Coolside pilot unit at Library, PA; and Research-Cottrell's boiler economizer furnace at Irvine, CA. The tests determined SO₂ removal rates under conditions similar to burning high-sulfur coal. The tests were very favorable, and under most conditions demonstrated removal rates up to 70% higher than those of commercial hydrates.

Dry-sorbent injection systems are considered more cost effective for retrofitting smaller coal-fired powerplants of 150 megawatts or less. Such systems are smaller, easier to install and operate, and cost less than larger wet scrubber systems. The HSA hydrate could provide an effective sorbent for such systems that could significantly boost their SO₂ removal rates.⁸

In 1987, EPA accidentally discovered that quicklime had apparently destroyed polychlorinated biphenyls (PCB's) when applied to PCB-containing sludges for stabilization purposes. In an effort to explain this phenomenon, EPA's Risk Reduction Engineering Laboratory in Cincinnati, OH, funded a project with RMC Environmental & Analytical Laboratory of West Plains, MO, to conduct controlled experiments on PCBcontaminated soils. The unpublished results verified the field observations and showed that the addition of quicklime apparently destroys PCB's within about 96 hours. The end products of the chemical reaction were calcium chloride, water, and carbon dioxide. The reaction occurs at high temperature and pH levels and apparently requires a metal catalyst. The latter is probably supplied by the small amounts of magnesium, iron, or aluminum oxides normally found in high-calcium quicklimes.⁹

EPA researchers and non-EPA scientists recommended additional studies be conducted to confirm RMC's results and to collect additional data to determine whether PCB destruction or some other phenomena is occurring. The additional studies will be conducted in-house by EPA. If the results confirm PCB destruction with quicklime treatment, additional studies will be needed to determine in-field application methods, economics, reaction optimization, appropriate wastes to be treated, and to evaluate potential reaction byproducts.

OUTLOOK

Lime has dozens of end uses in the chemical, industrial, and construction industries. Steelmaking is still the largest single end use for lime, although the total consumption by tonnage and percentage of total lime production has decreased. During the past 20 years, lime consumed for steelmaking averaged 39% of total consumption. In 1990, consumption was essentially unchanged from that of the previous year at about 5.1 million tons or 29% of total consumption. The current level reflects a trend of the decreasing consumption by the steel

eEstimated. Revised.

industry. This trend is a result of the decreasing consumption of fluxing agents; thus, less lime is consumed per ton of steel.

The outlook for steel production in the U.S. is uncertain. Labor contracts will ex-

1992 and Voluntary Restraint Agreements with foreign producers will expire in 1992. These uncertainties make forecasting U.S. steel production extremely difficult. One econometric model, based on the actual production from 1982 pire at major steel producers in 1991 and through 1989, assumes production will

decrease from 1991 through 1994 and be followed by a strong recovery in 1995 and 1996. Steel production in 1991 is expected to decrease by 5% to 10% compared with that of 1990. Based on this forecast and the decreasing trend in flux consumption, lime consumption for steelmaking could

¹Table includes data available through June 10, 1991.

²Lime is produced in many other countries besides those listed. Argentina, Iraq, Pakistan, and Syria are among the more important countries for which official data are not available. ³Less than 1/2 unit.

⁴Reported figure. ⁵Includes hydraulic lime.

easily drop to 4.5 to 4.8 million tons per year by the early 1990's. This translates to a loss in consumption of several hundred thousand tons per year, most of which would be in commercial sales.

Other sectors of the lime market are more difficult to analyze. No other single end use consumes more than 10% of total consumption, although environmental uses when grouped together account for approximately 24%. FGD consumption has the greatest growth potential, having increased steadily since the U.S. Bureau of Mines began collecting consumption data for it in the early 1970's. With passage of the Clean Air Act Amendments of 1990, consumption of lime or FGD use is expected to grow dramatically during the 1990's.

New environmental legislation, a resurgence in environmental awareness and concern by the public, and expanded cleanup of hazardous waste sites may have an impact on environmental markets. Lime should be ideally situated to take advantage of a new emphasis on environmental cleanup. It is an important and economical component in the treatment of air, water, and solid wastes.

Other markets that have growth potential are in construction, precipitated calcium carbonate manufacture, gold

mining, and caustic soda manufacture by the lime-soda process using trona (natural sodium carbonate) as the raw material. An attempt to address the problems in the Nation's transportation infrastructure could increase consumption in the construction sector, especially for soil stabilization in major projects such as airport and highway construction and as an antistripping agent in asphalt. Lime consumption for precipitated calcium carbonate (PCC) production will continue to increase dramatically as the push to build satellite PCC plants near paper mills continues. The continued expansion of western gold production will provide a growing market for lime consumed in the cvanide heap-leaching process. Two producers of soda ash in Wyoming have constructed facilities for the lime-soda production of caustic soda, and a third is in the planning stage. This could develop into a significant regional market for lime.

Consumption by the pulp and paper industry increased by 7% in 1990. However, the pulp and paper industry tends to lag the national economy by several months, and the effects of the recession will probably impact them during 1991. Industry forecasts call for an overall growth rate in the industry of 2% to 3% per year.

LITHIUM

By Joyce A. Ober

Mrs. Ober, a physical scientist with 13 years industry and U.S. Bureau of Mines experience, has been the commodity specialist for lithium since 1986. Domestic survey data were prepared by Carleen Militello, mineral data assistant; and international data tables were prepared by Harold D. Willis, international data coordinator.

he United States led the world in lithium mineral and compound production and consumption. Domestic estimated consumption has remained about the same for the past 3 years; world production has risen steadily. Domestic producers announced modest price increases for the fourth consecutive year.

Because lithium is electrochemically reactive and has other unique properties, there are many commercial lithium products. Producers sold lithium as mineral concentrate, brine, compound, or metal depending on the end use. Most lithium compounds were consumed in the production of ceramics, glass, and primary aluminum.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines collects domestic production data for lithium from a voluntary survey of U.S. operations. The two U.S. companies responded to the survey, representing 100% of total production. Production and stock data were withheld from publication to avoid disclosing company proprietary data.

ANNUAL REVIEW

Legislation and Government Programs

The Department of Energy (DOE) planned to offer portions of its 36 million kilograms of lithium hydroxide monohydrate for sale. The DOE stocks were excess from a weapons program that used the lithium to make tritium, a compound necessary for nuclear fission reactions. The stockpile originally contained about 42,000 metric tons of material, from which about 75% of the lithium 6 isotope

had been removed. This material possibly contained 8 to 9 parts per million of mercury, which could present an environmental hazard. DOE planned to offer the lithium hydroxide for sale in 1989, but delayed the disposal until an environmental impact study was complete. The study was completed in 1990; a final decision about disposal had not been made at yearend.

Production

The two companies that produced lithium in the United States in 1990 did so from two different types of deposits. Both firms mined spodumene, (a lithium-aluminum-silicate mineral) from large hard-rock deposits in North Carolina using open pit methods. Lithium was recovered from geothermal brine deposits in Nevada.

Lithium carbonate is the most important lithium compound produced from both types of deposit. Spodumene was a major raw material for the production of lithium carbonate in North Carolina, and small amounts of spodumene concentrate were produced for sale. Extracting lithium from spodumene entails an energyintensive chemical recovery process.

After mining, spodumene is crushed and undergoes a flotation beneficiation process to produce concentrate. Concentrate is heated to 1.075° C to 1.100° C. changing the molecular structure of the mineral, making it more reactive to sulfuric acid. A mixture of finely ground converted spodumene and sulfuric acid is heated to 250° C, forming lithium sulfate. Water is added to the mixture to dissolve the lithium sulfate. Insoluble portions of ore are then removed by filtration. The purified lithium sulfate solution is treated with soda ash, forming insoluble lithium carbonate that precipitates from solution. The carbonate is separated and dried for sale or use by the producer as feedstock in the production of other lithium compounds.

Mineral concentrate and carbonate.

²Compounds, concentrate, ores, and metal.

³Lithium hydroxide monohydrate.

⁴Compounds.

Production of lithium carbonate from brine in Nevada is much less energy intensive than production from the spodumene. Brines enriched in lithium chloride—averaging about 300 parts per million when operation began in 1966 are pumped from the ground and progress through a series of evaporation ponds. Over the course of 1 year to 18 months, concentration of the brine increases to 6,000 parts per million lithium through solar evaporation. When the lithium chloride reaches optimum concentration, the liquid is pumped to a recovery plant and treated with soda ash, precipitating lithium carbonate. The carbonate is then removed through filtration, dried, and shipped.

FMC Corp., Lithium Div., formerly Lithium Corp. of America (Lithco), mined spodumene from pegmatite dikes near Bessemer City, NC. The company produced lithium carbonate and a full range of downstream compounds, including lithium metal and some organic lithium compounds, at a chemical plant near the mine.

Cyprus Foote Mineral Co. produced about 6,700 tons of lithium carbonate from its brine deposit in Silver Peak, NV, and produced about 15 thousand tons of spodumene concentrate at its mine in Kings Mountain, NC.1 It operated processing facilities for downstream lithium products and metal in Frazer, PA, Sunbright, VA, and New Johnsonville, TN. Operations at Frazer were being phased out and transferred to Kings Mountain during the year. The company continued to maintain its lithium carbonate plant at Kings Mountain on a care- and-maintenance status as it had since mid-1986.

Demand for butyllithium, the most important organic lithium compound, was expanding, and both companies were preparing to meet that expansion. Cyprus Foote increased capacity 25% at its existing butyllithium facility in New Johnsonville,² and FMC began construction of a butyllithium plant in Bayport, TX.³ Completion of the Texas operation will double the company's capacity.

Consumption and Uses

The aluminum, ceramics and glass, lubricating grease, and synthetic rubber industries consumed most of the lithium minerals and chemicals. These markets were primarily related to transportation; i.e., the aircraft and automotive industries.

Industrial and consumer applications also used ceramics and glass. Estimated domestic consumption remained about the same in 1990. Ceramics and glass production and aluminum smelters were the largest consumers of lithium carbonate and lithium concentrates in the United States. Aluminum producers consume little lithium carbonate in other countries.

Lithium carbonate and mineral concentrate additions in ceramics and glass manufacturing processes lower process melting points, reduce the coefficient of thermal expansion and the viscosity, and eliminate the use of more toxic chemicals. The manufacture of thermal-shockresistant cookware (pyroceramics) consumed the majority of lithium used in the ceramics and glass industry domestically. The manufacture of black and white television picture tubes consumed significant amounts of lithium concentrates overseas. Low-iron spodumene and petalite (another lithium mineral) were a source of lithium used to improve the physical properties of container and bottle glass and as a source of alumina, another important component of the glass. Glass manufacturers used lithium in container and bottle glass, enabling them to produce lighter weight, thinner walled products.

Aluminum producers added lithium carbonate to cryolite baths in aluminum potlines. The chemistry of the potline converts it to lithium fluoride, lowering the melting point of the bath, allowing a lower operating temperature for the potline, and increasing the electrical conductivity of the bath. Operators used these factors to increase production or reduce power consumption.

The multipurpose grease industry was the third largest end use for lithium in 1990. Lithium hydroxide monohydrate was the compound used for the production of lithium lubricants. Lithium-base greases are favored for their retention of lubricating properties over a wide temperature range; good resistance to water, oxidation, and hardening; and formation of a stable grease on cooling after melting. These greases continued to be utilized in military, industrial, automotive, aircraft, and marine applications.

Almost all major battery manufacturers marketed some type of lithium batteries, and research and development continued for further substitution in applications that implement more conventional alkaline batteries. These batteries represent a growth area for lithium consumption, but sales have not increased as rapidly as originally expected. Eastman Kodak Co., the first company to offer a lithium battery to the U.S. consumer market, chose to discontinue production owing to low sales. Kodak's 9-volt lithium battery had at least twice the life of a comparable alkaline battery, but consumers were not willing to pay the higher price.

Lithium batteries offer improved performance over alkaline batteries at a slightly higher cost. They were used in watches, microcomputers, cameras. and, more recently, in small appliances, electronic games, and toys. The military purchased large and small lithium batteries for a variety of military applications. The Galileo spacecraft, launched in October of 1989 for its 6-year trip to explore the atmosphere of Jupiter, contained lithium sulfur dioxide batteries to power its scientific instruments when it reaches its destination. Recent modifications to the lithium sulfur dioxide battery have extended the life of the batteries to at least 10 years with little or no reduction of performance.

Aircraft manufacturers in several countries have designed new aircraft using aluminum-lithium alloys for wing and fuselage skin or structural members. Use of aluminum-lithium alloys can reduce the weight of the aircraft by more than 10%, allowing significant fuel savings during the life of the aircraft. The alloys, which are 2% to 3% lithium by weight, are attractive to the aircraft and aerospace industry because of their reduced density and superior corrosion resistance compared to those of conventional aluminum alloys. These alloys face direct competition, however, from composite materials consisting of boron, graphite, or aramid fibers imbedded in polymers.

Butyllithium was a catalyst in synthetic rubber production. Small quantities of other lithium compounds were important to many industries. Lithium chloride and lithium bromide were used in industrial air-conditioning systems, commercial dehumidification systems, and in the production of sophisticated textiles. Sanitizers for swimming pools, commercial glassware, and public restrooms contained lithium hypochlorite, as did dry bleach for commercial laundries. Patients diagnosed as suffering from manic-depressive mental disorders may take

medication containing a pharmaceutical grade of lithium carbonate. Lithium metal was used as a scavenger to remove impurities from copper and bronze, and anhydrous lithium chloride was used as a component in fluxes for hard-to-weld metals such as steel alloys and aluminum.

Prices

Both domestic companies increased prices for almost all lithium products for the fourth consective year. Prices averaged about 6% higher in 1990 than in the

previous year. The close balance between supply and demand worldwide kept prices in step with inflation. Although installed production capacity remained in excess of demand, the chemical plant at Kings Mountain remained inactive, helping to keep supply and demand balanced sufficiently to maintain the trend.

Foreign Trade

Total U.S. exports of lithium compounds were about the same in 1990 as they were in 1989. Exports of lithium

carbonate increased, but lithium hydroxide and lithium metal exports decreased. The majority of U.S. exports of lithium compounds were to the Federal Republic of Germany, Japan, and the United Kingdom. Imports of lithium compounds reported by the Bureau of the Census increased 26%. Cyprus Foote Mineral Co. owns a lithium brine operation in Chile. Almost all lithium imports came from this source. Lithium concentrates entered the United States, but no data were available.

World Review

A small number of countries throughout the world produced lithium ore and brine. The United States produced the most lithium; significant quantities also were produced in Australia, Canada, Chile, China, Portugal, the U.S.S.R., and Zimbabwe. Argentina, Brazil, and Namibia produced smaller quantities; production primarily consisted of concentrates. Rwanda, the Republic of South Africa, and Zaire are past producers of concentrates. Pegmatites containing lithium minerals have been identified in Austria, France, India, Ireland, Mozambique, Spain, and Sweden, but economic conditions have not favored development of the deposits. Lithium has been identified in subsurface brines in Israel. Companies in France, the Federal Republic of Germany, Japan, and the United Kingdom produced downstream lithium compounds from imported lithium carbonate.

Capacity.—The data in table 5 are rated capacity for mines and refineries as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable longterm operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgement of the author, can be brought into production within a short period of time with minimum capital expenditure. Any restrictions to capacity utilization related to legal, political, or environmental restraints have been footnoted.

Lithium presented special problems during compilation of production capacities for different operations. Ore concentrate products are not comparable to lithium carbonate. Lithium carbonate was the primary compound produced at lithium chemical plants and the compound from which all other lithium chemicals were produced. Because even high-grade ore products usually contained less than 4% lithium and lithium carbonate contains almost 20% lithium, production capacities reported in tons per year represent

large differences in the actual lithium content of the product. For that reason, capacities were reported based on the lithium content of the products also known as contained lithium.

Argentina.—Small annual production occurred from pegmatite deposits in the Catamarca and San Luis Provinces. Spodumene reserves are estimated at 140,000 tons of 0.7% lithium.

Brine deposits have also been identified. FMC signed an agreement with the Argentine Government in 1986 to explore the Salar del Hombre Muerto in Catamarca Province. FMC renewed its interest in Argentina due to recent events in Bolivia. Estimates of geologic resources have been reported at 130,000 tons of lithium contained in brine ranging from

no basis for more exact estimates is available. Output from China and the U.S.S.R. has never been reported.

⁴Data do not add to total shown because of independent rounding.

0.22 to 1.08 grams per liter. The Salar del Rincon also was identified as a lithium resource in the Salta Province.4

Australia.—Greenbushes Ltd., parent company of Lithium Australia Ltd. (LAL), was acquired by the Gwalia Group. LAL mined high-grade, low-iron spodumene at its mine in Greenbushes, Western Australia. LAL produced two spodumene concentrate products through a flotation process for sale to the ceramics and glass industry. The majority of the company's spodumene concentrate was used in the manufacture of black and white television picture tube glass and pyroceramics in the Pacific rim countries and Europe. Glass-grade concentrate with lower lithium content was marketed in the same countries for consumption in container glass.

LAL was awarded the Outstanding Export Achievement Award by the Western Australia Department of Trade Developement for its growth in export sales and success in establishing a new export industry for Australia.5

Bolivia.—The Government of Bolivia and FMC reached an agreement for a joint-venture operation in the Salar de Uyuni, a lithium brine deposit considered to be a national asset. FMC's plans included an exploration program and a plant for recovery of lithium carbonate from the evaporated brines. Extreme political pressures prompted the Government of Bolivia to cancel the accord, and because the agreement had been reached without competitive bidding, a call for international bids was released. FMC was still considering pursuing its involvement in the Uyuni Project by participating in the bid process. The political climate in Bolivia may discourage other companies from pursuing business opportunities in that country.6

Preliminary studies of the Salar de Uvuni, which is more than 3,600 meters above sea level, indicated resources of 5.5 million tons of lithium, 110 million tons of potassium, and 3.2 million tons of boron. The salar may be the world's largest salt flat.7

FMC showed interest in the possibility of developing another deposit, the Salar de Coipasa in the Oruro Department. This deposit is not as large as Uyuni nor is it considered a national asset, making strong opposition to foreign development less likely.8

quantities of lithium minerals for quite some time. Companhia Brasileira de Litio was building a plant in Aquas Verhelhas, Minas Gerais, to produce 1,000 tons of lithium hydroxide and 200 tons of lithium carbonate. Production from the plant was expected by yearend and would make Brazil self-sufficient in these lithium compounds.

Canada.—Tantalum Mining Corp. (Tanco) mined spodumene concentrate at its mine near Bernic Lake in southeastern Manitoba. Since mining began in 1984, Tanco has grown to become the largest supplier of lithium concentrates to the U.S. ceramics and glass industry. The Canadian spodumene was similar to the material mined in Australia (high-grade spodumene with very low iron content). making the concentrates ideal for direct application in the ceramics and glass industry.

A number of other lithium deposits have been identified throughout Canada. A pegmatite deposit was operated in Quebec for about 10 years starting in 1955. but there has been no production since then. The largest demonstrated resources occur in the Yellowknife deposits in the Northwest Territories.⁹ Although large deposits, the location is too remote for production to be feasible in the foreseeable future.

Chile.—Cyprus Foote Mineral Co. is the sole owner of its lithium brine operation at the Salar de Atacama, Sociedad Chilena de Litio Ltda, having bought the remaining interest from the Chilean Government in 1989. Cyprus Foote produced about 8,800 tons of lithium carbonate from the brines from this Salar. which has been worked since 1984.10 The project originated as a joint venture between Foote and Corporación de Fomento de la Producción (CORFO), a Chilean Government agency. Production capacity for lithium carbonate increased steadily from a 6,300-ton-per-year capacity to reach the current level of almost 12,000 tons per year.

The possibility of a second lithium operation at the Salar de Atacama had been under investigation. Minera Salar de Atacama Ltda. (MINSAL), the consortium formed by AMAX Exploration Inc. (United States), CORFO, and Molibdenos y Metales S.A. (Chile), completed studying the feasibility of developing another lithium operation on the Salar in **Brazil.**—Brazil has produced small | 1988. Evaluations of the results were analyzed, and AMAX announced its decision to sell its portion of the project in 1990.11

China.—Lithium pegmatite and brine deposits are worked in China, but specific information about any of the deposits is not available. Lithium carbonate and hydroxide from China has been marketed in the Federal Republic of Germany, Japan, and the Netherlands.

France.—Lithium metal is produced by Metaux Speciaux SA in Plombieres St. Marcel, Savoie. The plant has the capacity to produce 25 tons per year of very high-purity metal for use in aluminumlithium alloys. The company is a subsidiary of Pechiney.¹²

Germany, Federal Republic of—The Federal Republic of Germany has been a major producer of lithium compounds, although no lithium ore is mined there. Chemetall GmbH, a member of the Metallgesellschaft Group AG, produced downstream lithium compounds and metal from lithium carbonate imported from the United States and other countries. The company's lithium operations are in Langelsheim.

Japan.—Japan is a major consumer of lithium compounds, some of which it produces from imported lithium carbonate. FMC and the Honjo Chemical Co. have a joint venture, Asia Lithium Corp., to market FMC's lithium products in Japan. Asia Lithium was constructing a 100-ton-per-year battery-grade lithium metal operation in Kagawa. Yahagi Iron Co. also produced lithium metal in Nagova.

Namibia.—Southwest Africa (SWA) Lithium Mines produced petalite concentrate at its Rubicon Mine near Karibib. Low-grade ores were beneficiated through a flotation process, while highgrade ores were handpicked. Small amounts of two other lithium minerals, lepidolite (lithia mica) and amblygonite (lithia alumina phosphate), were other products. The Federal Republic of Germany imported most of these concentrates. High-grade lepidolite was handpicked at the company's Helicon Mine for export to Western Europe and Japan. 13

Portugal.—Lithium has been produced inconsistently in Portugal. Recent reports indicate that production has gone up significantly in recent years, but details on the operations and markets are not

available. Past lithium production has been lepidolite.

U.S.S.R.—Lithium ores, compounds, and metal are produced in the U.S.S.R., but no details are available.

United Kingdom.—Lithium Corp. of Europe operates a facility in Bromborough, Mersyside, for the production of lithium metal and butyllithium. Lithium carbonate and lithium chloride are imported from its parent company, FMC.

Zimbabwe.—Bikita Minerals Ltd. mined petalite, another lithium mineral, near Masvingos. Although the ore reserves were becoming depleted, installation of a dense-media separator made it possible to recover lithium in the form of petalite averaging about 4.4% lithium oxide from a stockpile of previously rejected material. This extended the estimated mine life 30 years. Hand sorting, the method used since the mining began in 1916, amassed a stockpile of more than 1 million tons that could be recovered with a significant savings in mining costs

after installation of the new device. Hand sorting continued to be used only for special small orders of minerals other than petalite.¹⁴

OUTLOOK

The aluminum industry experienced a slowdown in 1984, and, as a result, domestic lithium consumption decreased dramatically that year. Lithium consumption has increased slightly every year since that time. This increase was due primarily to the recovery of the aluminum industry as well as increased demand for lithium compounds and minerals in the ceramics and glass industry. Similar increases are expected for the future.

Demand for butyllithium is expected to increase, and both domestic producers are increasing production capacity to meet that demand. Demand for lithium metal for batteries and alloys should increase, but total consumption of the metal will remain small in comparison to the demand for lithium chemicals. Markets should remain relatively stable with slight growth, although new applications for mineral concentrates could increase demand for those materials significantly in the next few years. Lithium demand could increase dramatically if any of the new technology areas such as nuclear fusion were perfected. This is not expected to occur within the remainder of this century and probably not within the next 25 years.

¹Table includes data available through Apr. 10, 1991.

²In addition to the countries listed, other nations may produce small quantities of lithium minerals, but output is not reported, and no valid basis is available for estimating production levels.
³Estimates based on imports by the United States.

⁴These estimates denote only an approximate order of magnitude; no basis for more exact estimates is available. Output by China and the U.S.S.R. has never been reported.

MAGNESIUM AND MAGNESIUM COMPOUNDS

By Deborah A. Kramer

Ms. Kramer is a physical scientist with the Branch of Industrial Minerals. She has covered magnesium and magnesium compounds for 7 years. Domestic survey data were prepared by Tony E. Morris, mineral data assistant; and international data tables were prepared by William Zajac, Chief, Section, International Data.

omestic production of primary magnesium decreased by about 8% in 1990 because U.S. producers faced competition from increasing quantities of imports, primarily from Canada. Two primary magnesium facilities opened in Canada during the year, increasing annual world production capacity by 52,500 metric tons. Most of the magnesium produced at these plants was exported to the United States, resulting in a dramatic increase in the quantity of total imports in 1990.

Aluminum alloys remained the principal end use for magnesium, but diecastings showed the largest increase in primary magnesium consumption between 1989 and 1990. Magnesium diecastings were used in a greater number of automotive applications, because automakers looked to reduce total vehicle weight without reducing vehicle size. The potential for a significant increase in Corporate Average Fuel Economy standards in the near future could result in an even larger increase in magnesium consumption by the U.S. automotive industry.

Domestic production and consumption of magnesium compounds declined slightly in 1990. Imports supplied about 25% of domestic demand, about the same as in 1989, although the total quantity of imports decreased.

Seawater and brines were the principal raw materials used to manufacture magnesium compounds, accounting for about 69% of the total, with dolomite, magnesite, and olivine as the other sources. Refractories were the largest use for deadburned magnesia; caustic-calcined magnesia principally was used in the agricultural and chemical industries.

Producers in Czechoslovakia, Ireland, and Mexico were upgrading their facilities to produce higher grade dead-burned magnesia for consumers throughout the world in the iron and steel, nonferrous metals, cement, and glass industries. In general, these consumers were seeking material with high magnesium oxide (MgO) content, low boron content, and large particle size.

DOMESTIC DATA COVERAGE

Data for magnesium metal are collected from two voluntary surveys of U.S. operations. Of the 129 companies canvassed for magnesium consumption data, 97% responded, representing 65% of the primary magnesium consumption shown in tables 4 and 6. Data for the four non-respondents were estimated based on prior-year consumption levels and other factors.

Data for magnesium compounds were collected from one voluntary survey of U.S. operations. Of the 20 companies canvassed, 90% responded, representing 70% of the magnesium compounds shipped and used shown in table 14. Data for the two nonrespondents were estimated based on prior-year consumption levels and other factors.

BACKGROUND

Definitions, Grades, and Specifications

Primary magnesium metal contains a minimum of 99.8% magnesium. Magnesium-base alloys are named by the composition of the two chief alloying elements, each designated by a letter, and the approximate percentage of each alloying element. For example, AZ91 contains about 9% aluminum (A) and 1% zinc (Z), and HK31 contains about 3% thorium (H) and 1% zirconium (K). Other letters

used in specifying magnesium alloys are E for rare-earth metals and M for manganese.

Magnesite, or magnesium carbonate (MgCO₃), has a theoretical magnesium content of 47.6%. Dolomite is a calcium carbonate-magnesium carbonate mineral (CaCO₃·MgCO₃) that has a theoretical magnesium content of 22%. Brucite, magnesium hydroxide [Mg(OH)₂], contains up to 69% magnesium, and olivine (Mg₂Fe₂SiO₄) contains up to 19% magnesium. Of these minerals, magnesite and dolomite are the largest sources of magnesium and magnesium compounds.

Seawater, brines, and bitterns represent vast sources of magnesium and magnesium compounds. In the United States, more than 60% of the magnesium compounds produced annually are recovered from seawater and brines, and 80% of the magnesium metal production capacity uses seawater or brines as a raw material.

Various magnesia products are made by calcining magnesium carbonate or magnesium hydroxide at different temperatures. Caustic-calcined magnesia, which is readily reactive with water, is calcined at temperatures up to 890° C. Deadburned magnesia, also called refractory or sintered magnesia, is calcined at temperatures up to 1,450° C and is unreactive with water. Fused magnesia is produced at temperatures greater than 3,000° C. Magnesia produced from magnesia is generally called natural magnesia, and magnesia produced from seawater or brines is called synthetic magnesia.

Standards for magnesia, including chemical composition, bulk density, and particle size, generally are set by the consumer for a specific application. Refractory magnesia composition depends on the area of the furnace in which the material is to be used. Magnesia produced from magnesite can contain between 88% and 98% magnesia, with varying

quantities of silica, iron, calcium, and alumina impurities. Synthetic magnesia normally is purer than natural magnesia, containing between 92% and 99.5% magnesia, with smaller quantities of the same impurities found in natural magnesia. Most fused magnesia contains greater than 94% magnesia.

Products for Trade and Industry

The principal use for magnesium metal, averaging greater than 50% of U.S. consumption annually, is as an alloying addition to aluminum. Magnesium improves the hardness and corrosion resistance of pure aluminum. Aluminum-magnesium alloys are used in a variety of applications, including automobiles, trucks, aircraft, appliances, and home siding. Two-piece beverage cans, containing about 2% magnesium, are the largest single use for these aluminum-magnesium alloys.

Magnesium and its alloys are used as structural components on automobiles, trucks, aircraft, computers, and power tools. Many of these applications use magnesium because of its light weight and ease of machinability. Magnesium is used in the iron and steel industry for external hot-metal desulfurization and in the production of nodular iron. Production of the nonferrous metals, beryllium, hafnium, titanium, uranium, and zirconium, involves the use of magnesium as a reducing agent. Anodes of magnesium are used for cathodic protection of underground pipe and water tanks. Small quantities of magnesium are used as a catalyst in producing organic compounds, as photoengraving plates, and in alloys other than aluminum.

Refractory magnesia represents the largest use of magnesium in compounds. Refractory magnesia is manufactured into bricks and other shapes, principally for linings in furnaces and auxiliary equipment used to produce iron and steel. Magnesia-base refractories also are used in furnaces in the cement, glass, and nonferrous metals industries.

Caustic-calcined magnesia is used in a variety of applications in the agricultural, chemical, construction, and manufacturing industries. Caustic-calcined magnesia is an important component of animal feed and fertilizer, providing essential nutrients for livestock and plant growth. In construction, caustic-calcined magnesia is used in special cements for industrial flooring and in lightweight in-

sulating wallboard. In the chemical industry, it is used as a starting point for the manufacture of other magnesium salts. Special grades of caustic-calcined magnesia are used for pharmaceuticals, including antacids, toothpaste, milk of magnesia, and cosmetics. Magnesia is used to remove sulfur from flue gases and boiler fuels and is used for acid neutralization in process wastewater and in lubricating oils. Caustic-calcined magnesia is also important in manufacturing paper, rayon, and rubber. I

Other magnesium compounds are used in place of, or in addition to, caustic-calcined magnesia in many of the above applications. Magnesium hydroxide is used in the pulp and paper industry; magnesium sulfate is used for pharmaceuticals, animal feed, and fertilizers; and magnesium carbonate is used in the chemical, pharmaceutical, and rubber industries. Fused magnesia is used primarily for electrical insulation.

The principal use for olivine is as a foundry sand used in casting iron and steel components and some nonferrous metals. Olivine is used in smaller quantities for refractories, slag control in blast furnaces, and soil conditioning. In Europe, olivine is used instead of sand for blasting debris from bridges and buildings and in incinerators.²

Industry Structure

U.S. producers of magnesium and magnesium compounds are shown in tables 1 and 2. Olivine is produced by two companies in the United States—Applied Industrial Minerals Corp. (AIMCOR) and Olivine Corp. AIMCOR operates two mines and processing plants in Indiana, North Carolina, and Washington, and Olivine operates one mine and one processing plant in Washington.

Electrolytic plants in Canada, Norway, the U.S.S.R., and the United States represent 75% of the world magnesium metal production capacity. Smaller thermal plants are in Brazil, Canada, China, France, India, Italy, Japan, and Yugoslavia.

The largest magnesite production facilities in the world are in China, North Korea, and the U.S.S.R. Together, these three countries account for 53% of the world magnesite production capacity. Japan and the United States account for 58% of the world's magnesium compounds production capacity from seawater or brines. Fused magnesia is

produced in Canada, France, Israel, Japan, the United Kingdom, and the United States.

Norway is the world's principal producer of olivine, and in addition to supplying its domestic needs, Norway is a major world supplier of this mineral. Countries with smaller output are Austria, Italy, Japan, Mexico, Spain, Sweden, and the United States.

Geology

Magnesium is the eighth most abundant element and constitutes about 2% of the Earth's crust. It is the third most plentiful element dissolved in seawater, with a concentration averaging 0.13%. Although many minerals contain magnesium, magnesite, dolomite, brucite, and olivine are the only minerals from which magnesium compounds are recovered commercially.

Dolomite is a sedimentary rock commonly interbedded with limestone, which extends over large areas of the United States. Most dolomite occurrences are likely the result of replacement of calcium by magnesium in preexisting limestone beds. Magnesite primarily is found in four types of deposits: sedimentary beds, alterations of serpentine, vein fillings, and replacements of limestone and dolomite. Brucite is found in crystalline limestone and as a decomposition product of magnesium silicates associated with serpentine, dolomite, magnesite, and chromite. Olivine generally occurs as granular masses or disseminated grains or crystals and is a common constituent of basic igneous rocks such as basalt and gabbro. Dunite is an olivine-rich rock.3

Technology

Processing.—Metal.—Two thermal processes currently are in use to recover magnesium metal from dolomite—the Pidgeon process and the Magnetherm process. Both use the same basic chemistry, but the Pidgeon process uses an external heat source, and the Magnetherm process uses heat generated by the electrical resistance of the reactants. In the Pidgeon process, dolomite and ferrosilicon are formed into briquettes and heated in a retort under a vacuum. Magnesium oxide in the dolomite reacts with the ferrosilicon to produce magnesium vapor, which is cooled and condensed in a separate section of the retort. Plants in

Total		1,012,000

Canada, Italy, and Japan use this process to recover magnesium.

In the Magnetherm process, calcined dolomite, ferrosilicon, and alumina are heated under a vacuum. Alumina reduces the melting point of the slag produced by the dolomite-ferrosilicon reaction to make resistance heating practical. Magnesium vapor is cooled and condensed in a condensing chamber. The Magnetherm process is used in plants in Brazil, France, Japan, the United States, and Yugoslavia.

Electrolytic recovery of magnesium requires a magnesium chloride feedstock that normally is prepared from seawater or brines. Two types of magnesium

chloride can be made—hydrous and anhydrous. In the preparation of hydrous magnesium chloride, used by Dow Chemical Co., magnesium hydroxide is precipitated from seawater by the addition of dolomitic limestone. Adding hydrochloric acid to the magnesium hydroxide produces a neutralized magnesium chloride solution. This solution is dehydrated until it contains about 25% water and is fed directly to electrolytic cells.

Magnesium Corp. of America (Mag-Corp) and Norsk Hydro A/S use an anhydrous magnesium chloride feed for their electrolytic cells. MagCorp uses solar evaporation initially to concentrate

magnesium chloride brines from the Great Salt Lake. After adding calcium chloride to precipitate sulfate impurities and removing boron by solvent extraction, the brine is concentrated further and dehydrated in a spray dryer. The resulting powder is purified, concentrated, prilled, and dehydrated to produce anhydrous magnesium chloride.⁴ Norsk Hydro starts with concentrated magnesium chloride brine. The brine is purified, concentrated, prilled, and dehydrated to produce anhydrous magnesium chloride.

Electrolytic cells used to recover magnesium from either hydrous or anhydrous magnesium chloride differ from company to company, and most information about cell design and operating conditions usually are not disclosed. Essentially, magnesium chloride fed to an electrolytic cell is broken down into magnesium metal and chlorine gas by direct current at 700° C. Magnesium is removed from the cell and cast into ingots, and the chlorine gas is recycled or sold.

Magnesium International Corp. developed a one-step process for producing anhydrous magnesium chloride that was demonstrated at Magnesium Co. of Canada Ltd.'s (MagCan) new plant that opened in 1990. Reacting magnesite with chlorine gas in the presence of carbon monoxide in a packed-bed reactor at 900 °C produces magnesium chloride and carbon dioxide. Liquid magnesium chloride collects at the bottom of the reactor and is tapped periodically for transfer to electrolytic cells.⁵

Nonmetal.—Preparing either causticcalcined or dead-burned magnesia from magnesite involves crushing the magnesite to various sizes, depending on the type of material to be produced. After crushing, magnesite is beneficiated; the degree of beneficiation depends on the quality of the ore and its ultimate end use. Lower quality ore often requires heavymedia separation, magnetic separation, and flotation to remove impurities. Highquality ore may require only screening and hand sorting to produce a material of acceptable quality. Caustic-calcined magnesia is produced in shaft kilns, multiple-hearth furnaces, or rotary kilns. Dead-burned magnesia is produced in rotary or shaft kilns.

In producing synthetic magnesia, seawater or brines are treated either with a small quantity of lime or sulfuric acid to remove dissolved carbon dioxide. Then calcium hydroxide, in the form of lime or dolime, is added to precipitate the dissolved magnesium as magnesium hydroxide. The resulting slurry is thickened and vacuum filtered to yield a filter cake containing about 50% magnesium hydroxide. The filter cake can be directly calcined to produce caustic-calcined or dead-burned magnesia, or it can be calcined and pelletized before dead-burning to give specific size and density characteristics.

Fused magnesia is produced by fusion of high-grade magnesite or caustic-calcined synthetic magnesia in an electric arc furnace. After fusion, the material is crushed, inspected to remove any unfused magnesia, and crushed further in a ball mill.

Economic Factors

Costs to produce magnesium metal vary greatly, depending on the feed material and the process used. Operating costs for magnesium production range from \$309 to \$2,283 per ton, with energy costs as the largest component of the total operating cost. Total production costs from seawater sources were lower than from brines or dolomite sources. Magnesium compound operating costs also vary depending on source material and processing techniques. Operating costs range from \$24 to \$425 per ton for

magnesium compound production, with seawater as the most costly source. Energy costs also represent the largest component of total operating costs.⁶

Tariffs for magnesium and magnesium compounds are shown in table 3. Depletion allowance for magnesium chloride from domestic or foreign sources is 5%. Magnesium carbonate and dolomite have depletion allowances of 14% from domestic and foreign ores. Depletion allowances for other ores are brucite, 10% (domestic and foreign); and olivine, 22% domestic and 14% foreign.

ANNUAL REVIEW

Magnesium

Legislation and Government Programs.—On January 23, the Environmental Protection Agency (EPA) finalized rules proposed in September 1989 on the regulation of 20 special wastes from mineral processing under subtitle C of the Resource Conservation and Recovery Act (RCRA). Process wastewater from primary magnesium by the anhydrous process was temporarily excluded from regulation under subtitle C of RCRA. In a draft report to Congress, prepared by EPA in August, the

Agency recommended that this waste product be regulated under subtitle D of RCRA.⁷

Production.—Domestic production of primary magnesium declined by about 8% and was about 78% of rated yearend capacity. An increase in U.S. imports of magnesium from new plants in Canada and an effort from the domestic producers to control their inventory levels were partially responsible for the production decrease.

Dow announced that its magnesium businesses, which did not have a formal corporate identity, were officially united under the name Dow Magnesium. The company also planned to invest an estimated \$16 million in its Freeport, TX, facility to broaden its product line. One of the components to be added was a 50-million-pound-per-year direct chill vertical caster. It would enable Dow to produce T-bar ingot in sizes greater than 250 pounds and would allow production of primary and alloyed round billet. Caster installation was expected to be completed in the first quarter of 1992.

Consumption and Uses.—Although consumption of primary magnesium decreased slightly in 1990, the use of magnesium discastings continued to grow as more applications were developed,

particularly in the automotive industry. The current estimate of the magnesium content of U.S.-produced vehicles was about 4 pounds per vehicle, but this was expected to increase significantly within the next few years.

General Motors Corp. planned to introduce new V-8 engines in some of its 1992 Cadillac models that contain about 5 pounds of magnesium, and the automaker announced that these cars would contain an additional 10 pounds of magnesium in the induction system and the transmission. Chrysler Corp. used magnesium diecastings for the accessory drive brackets in its 2.5- and 4.0-liter 1991 Jeep engines. Using magnesium to replace aluminum in these components represented a weight savings of 2.75 pounds per vehicle. Dow produced a prototype magnesium V-8 engine block that weighed less than 50 pounds for the Dow-owned demonstration Corvette to promote the advantages of using magnesium in automotive applications. The prototype engine block replaced a 135-pound standard cast-iron engine block.8

Foreign auto manufacturers also were using magnesium in several applications. Audi AG of the Federal Republic of Germany equipped some of its sedans with a magnesium dashboard bulkhead, which was one of the most critical structural components of the car's body. By using magnesium, tooling requirements and additional fabrication costs could be reduced. Nissan Motor Co. of Japan developed an alumina-reinforced magnesium piston that could yield a 40% weight reduction from conventional cast-iron

pistons. Normally magnesium is not suitable for parts that are subject to a lot of wear, but by adding alumina reinforcement, it became about five times as wear-resistant as aluminum.

To capitalize on the interest on magnesium in structural applications such as automotive components, two research and development centers opened in 1990. The Institute of Magnesium Technology Inc. in Sainte-Foy, Quebec, officially opened in September. The Institute is funded by its membership, which consisted of primary producers, processors, converters, and users, and by the Canadian Government. Its principal function is to conduct research for the private and public sectors and to expand the world markets for magnesium products. 9 Norsk Hydro opened its Magnesium Market Development Center in Southfield, MI, in January. The center's main goal is to provide more comprehensive service to end users, especially in the automotive industry, and to work with the end users to develop new applications for magnesium. In addition to equipment at the center, Norsk Hydro will be able to use the resources of the Institute of Magnesium Technology Inc., of which it is a member.

Nippon Light Metal Co. and Diemakers Inc. planned to establish joint ventures in the United States and Japan to collaborate on the development, manufacturing, and marketing of magnesium die-cast products. The U.S. joint venture, to be called Nikkei Diemakers USA and funded 65% by Diemakers and 35% by Nippon Light Metal, will promote sales of magnesium diecastings to Japanese

automakers operating in the United States. The Japanese joint venture, Nikkei Diemakers Co., funded 65% by Nippon Light Metal and 35% by Diemakers, will provide technical services and support for sale of Diemakers' products in Japan. Diemakers was acquired in May by Kanematsu USA Inc., a wholly owned subsidiary of the Japanese trading company Kanematsu Corp., and it reportedly was the third largest magnesium diecastings producer in the United States.

Bicycle frames were another emerging use for magnesium. In the Tour de France run during the year, some entrants rode bicycles with magnesium frames and claimed that the bicycles were very durable in crashes and could corner faster than conventional racing bicycles. A process to make a one-piece bicycle frame that took 52 seconds to complete was developed in the United Kingdom. In the process, molten magnesium was quickly injected into a mold and allowed to solidify there. Traditionally, individual sections of aluminum or steel were welded together to construct the frame. With the increased interest in magnesium bicycles, Norsk Hydro planned to construct a plant in Chelmsford, United Kingdom, to produce magnesium bicycle frames. Plant construction was expected to be completed early in 1991.

Dow Magnesium announced that it would stop production of its Pelamag[™] granules at the beginning of 1991. The granules consisted of a spherical core of magnesium encased in a coating of mixed inorganic salts and were used for steel desulfurization. The capacity at the company's Freeport, TX, plant was expected to be used to produce other magnesium products that were preferred for desulfurization.

In April, Reactive Metals & Alloys Corp. (REMACOR) announced the sale of its Reade Manufacturing Div. to Magnesium Elektron Ltd., a unit of Alcan Aluminium Ltd. Reade Manufacturing produced magnesium powder, chips, and granules and supplied these materials to REMACOR for manufacturing desulfurization reagents. The transaction included a long-term contract for Reade Manufacturing to continue supplying REMACOR with its magnesium powder requirements.

Because of a combination of characteristics, including light weight, strength, and durability, magnesium was selected as the housing for the first totally self-powered

TABLE 5
MAGNESIUM RECOVERED FROM SCRAP PROCESSED IN THE UNITED STATES, BY KIND OF SCRAP AND FORM OF RECOVERY

W Withheld to avoid disclosing company proprietary data; included in "FORM OF RECOVERY: Total."

¹Includes secondary magnesium content of both secondary and primary alloy ingot.

radar detector, produced by Cincinnati Microwave Inc. The magnesium housing, die-cast in three pieces with no additional machining required, weighed 1.5 ounces before assembly. Cincinnati Microwave's goal was to create a receiver that would fit in a shirt pocket, take abuse, and operate by battery power alone for months.

Stocks.—Consumer stocks of primary magnesium ingot rose from 5,350 tons at yearend 1989 to 5,428 tons at yearend 1990. Consumer stocks of magnesium alloy ingot also increased from 849 tons at yearend 1989 to 879 tons at yearend 1990. Producer stocks of primary magnesium decreased slightly from 20,133 tons at yearend 1989 to 19,535 tons at yearend 1990.

Markets and Prices.—Quoted producer prices for both primary magnesium and diecasting alloy, AZ91D, remained stable during most of the year. Primary magnesium was quoted at \$1.63 per pound, and diecasting alloy was quoted

at \$1.43 per pound. In December, Dow announced that it was reducing its price by 20 cents to \$1.43 per pound, effective December 3 for spot customers and as terms permit for contract customers. The company cited the need to bring quoted prices closer to actual market prices in both the United States and abroad. Mag-Corp maintained its primary magnesium price at \$1.63 per pound. At yearend, primary magnesium was quoted at \$1.43 to \$1.63 per pound, and diecasting alloy was quoted at \$1.43 per pound.

Foreign Trade.—Plant openings in Canada resulted in a dramatic increase in imports of primary metal from that country. Canada supplied 76% of the total U.S. magnesium imports in 1990, which more than doubled from the 1989 level. Although total magnesium exports decreased, the United States remained a net exporter of magnesium in 1990.

World Review.—According to the International Magnesium Association, world inventories of primary magnesium

rose to 43,800 tons at yearend 1990 from 35,000 tons at yearend 1989. Yearend 1990 inventories represented a 63-day supply compared with a 52-day supply at yearend 1989.

Canada.—Norsk Hydro Canada Inc., a unit of the Norwegian firm Norsk Hydro, reportedly reached full-scale production by the end of June at its new 40,000-ton-per-year magnesium plant in Becancour, Quebec. By the end of March, the plant was producing a variety of pure magnesium and magnesium alloy products. In addition, magnesium produced at the plant entered the qualification stages with the major aluminumcan-stock producers. Near the end of the year, Norsk Hydro announced that it would expand its casting facilities at the Becancour plant to include production of magnesium alloy billet in addition to primary magnesium billet. This expansion, planned for completion in 1992, would give the plant a total annual billet production capacity of 30,000 tons. The company also announced that it would spend \$6 million to construct a magnesium recycling plant to process home scrap as well as scrap from customers. The recycling plant was scheduled to reach full operation by 1992.

During 1990, MagCan was plagued with operational problems at its new magnesium plant in High River, Alberta. Initially MagCan had planned to be operating at its full capacity of 12,500 tons per year by the end of the first quarter, but was only running at about one-third of design capacity by the end of April because the plant was unable to get enough power out of the reactor transformers. Because of these problems, Alberta Natural Gas Co., one of the equal-share partners in the MagCan project along with Magnesium International Corp., reportedly invested an additional \$40 to \$45 million in the project in September to take a controlling interest. MagCan reached an operating rate of 6,250 tons per year for 2 weeks in December until technical problems with some of the equipment occurred, and the company was forced to curtail production. Despite these operational problems, MagCan expected that production would reach its full capacity by mid-1991.

Noranda Inc. and Lavalin Industries reportedly were seeking a third partner in a joint-venture project to construct a 50,000-ton-per-year magnesium plant in East Broughton, Quebec. The companies

began a feasibility study in 1988 on a plant to recover magnesium from asbestos tailings with technology developed by Noranda and were satisfied with results to date. Government agencies, both Federal and provincial, reportedly financed one-half of the cost for the

feasibility study and may provide further support in the forms of tax incentives and a break on real estate costs. The proposed plant, named Magnola, would use available asbestos tailings from a nearby mine that have a 25% magnesium content as the feed material.

India.—Officials from Southern Magnesium and Chemicals Ltd. stated that magnesium production from plants with a combined annual capacity of 1,200 tons began in April. Production from these plants was expected to be sufficient to supply the country's annual demand of 800 to 1,000 tons.

Norway.—Norsk Hydro planned to temporarily close 8,000 to 10,000 tons of annual capacity at its Porsgrunn magnesium complex early in the year for what the company termed as rearrangements. With additional production capacity available from its new Canadian plant, Norsk Hydro estimated that total 1990 production from both its plants would be 75,000 to 80,000 tons.

Brazil's Rima Group and Elkem A/S reportedly were negotiating to construct a 20,000- to 25,000-ton-per-year magnesium plant in Norway using Rima's technology. A feasibility study was underway, and if the decision is made to construct a plant, construction was expected to begin in 1991. The proposed plant, scheduled for completion in 1993, would be near one of Elkem's existing plants to take advantage of infrastructure already in place.

United Kingdom.—Norsk Hydro reportedly completed construction of a 4,500-ton-per-year magnesium granule production plant in Immingham in November. Magnesium ingots were imported from Norway and were reduced to granules 0.2 to 1 millimeter in diameter. These granules were to be used for steel desulfurization, and magnesium powder was produced as a byproduct for use in the pyrotechnic and chemical industries. European markets were the main target for the plant's output.

Magnesium Compounds

Production.—Caustic-calcined magnesia production was stable during the year, and dead-burned magnesia production declined about 4%. Production of olivine dropped by about 5%, and the average value decreased approximately 6%.

In June, National Refractories & Minerals Corp. signed an agreement with Radex Heraclith AG of Austria for Radex to acquire 50% ownership of National Refractories & Minerals over a 5-year period. The transaction was designed to broaden the geographical markets for both companies; National Minerals &

¹Includes capacity at operating plants as well as at plants on standby basis

Refractories' products were sold primarily in the United States and the Pacific rim, and Radex's were marketed mainly in Europe. In addition to marketing cooperation, the two companies were planning on technical cooperation. During the same month, National Refractories & Minerals announced that it opened a new research center in Livermore, CA, for developing and testing refractories and minerals used in chemical and building material markets. A review of minerals producers in the Southwest United States discussed processing at National Refractories & Minerals, as well as Marine Magnesium Corp. and Basic Inc. 10

In January, Asea Brown Boveri Inc. announced that it planned to sell the minerals subsidiaries of Combustion Engineering Inc. that it acquired in late 1988. Combustion Engineering owned the country's sole magnesite producer, Basic Inc., as well as Basic Magnesia Inc., which produced magnesium compounds from seawater in Florida. By yearend, no buyer was found for these operations.

Consumption and Uses.—Dead-burned magnesia refractories for use in metal, cement, and glass production furnaces continued to be the primary application for

magnesium compounds in the United States. In 1990, agricultural applications (animal feed and fertilizer) were the dominant use for caustic-calcined magnesia, accounting for 36% of U.S. shipments. Chemical processing was the next largest segment, with 19% of total shipments. The following categories, with the individual components in parentheses in declining order, were the remaining enduse sectors for caustic calcined magnesia: metallurgical (refractories, electrical, water treatment, stack-gas scrubbing, and foundry), 18%; manufacturing (rayon, fuel additives, rubber, pulp and paper. and uranium processing), 17%; construction (oxychloride and oxysulfate cements. general construction, and insulation), 3%; pharmaceuticals and nutrition (medicinal and pharmaceutical, sugar, and candy), 3%; and unspecified uses, 4%.

Magnesium carbonate and magnesium sulfate were used principally in the chemical and pharmaceutical industries. Magnesium sulfate also was used in smaller quantities for animal feed and pulp and paper manufacturing. Magnesium hydroxide was used primarily in the pulp and paper and chemical industries. Magnesium chloride was used for oxychloride cements and in the chemical industry. Magnesium chloride brines were used for road dust control and chemical production.

Foundry applications accounted for 74% of domestic olivine shipments. Refractory uses represented 10%, slag control accounted for 5%, and the remaining 11% of olivine consumption was unspecified.

Markets and Prices.—Yearend prices for magnesium compounds, quoted in the Chemical Marketing Reporter, did not change from those at yearend 1989, with the exception of magnesium sulfate prices, which increased 1 cent per pound.

Foreign Trade.—Trade data for olivine were combined with data for other material by the Bureau of the Census and could not be separately identified. The Journal of Commerce Port Import/Export Reporting Service (PIERS) provides some data on materials that are transported by ship and gives some data on olivine. According to PIERS, 110,573 tons of olivine was imported from Norway during 1990. U.S. exports of olivine were 2,107 tons; Chile, 53%, and Peru, 39%, were the primary recipients.

World Review.—Australia.—Development of the Kunwarara magnesite deposit near Rockhampton, Queensland, progressed considerably during 1990. The three partners in the project, Pancontinental Mining Ltd., Australia; Radex-Heraclith, Austria; and Queensland Metals Corp. NL (QMC), Australia,

awarded a contract for construction of the mine and beneficiation plant in August. These companies also reached an agreement with Bridge Oil Ltd. and Petroz NL for the purchase of natural gas to fuel the plant. Commissioning of the first stage of the plant was scheduled for the third quarter of 1991. At full annual capacity, the plant will produce 150,000 tons of dead-burned magnesia and 25,000 tons of fused magnesia. Reserves at the deposit were estimated to be 800 million tons, with 400 million tons of low-iron cryptocrystalline magnesite.

During the year, QMC was operating a pilot plant to produce high-purity magnesium chloride as feed for magnesium metal production, and the company was producing caustic-calcined magnesia at the pilot plant. QMC was engaged in joint research with Queensland Cement Ltd. to develop new stable magnesium cements and building products.

Mineral Holdings Australia Pty. Ltd. reportedly was seeking a partner to start a fused magnesia, alumina, and zirconia industry in Tasmania. This project would use the Cann Creek magnesite deposit and some magnesite from the company's mines to the south of Cann Creek. Imported feed would be used for the fused alumina and zirconia.

Czechoslovakia.—The State magnesite producer, Slovenske Magnezitove Zavody (SMZ), planned to implement two projects to improve its competitiveness in a free market economy. Although much of its production was exported predominantly to the U.S.S.R. and other centrally planned economy countries in the past, which have less advanced steel and cement operations, SMZ wanted to improve its technology and products without losing this market. The first of the new projects involved chemical treatment of magnesite to produce a low-iron magnesite with a grade of 99.5% MgO for magnesia-chrome brick manufacture. The second was production of the highest quality magnesite by flotation for brick manufacture. Planned annual capacities for these projects, which were due onstream in 1991, were 26,000 tons and 15,000 tons, respectively.¹¹

Greece.—Exploration and drilling work by Grecian Magnesite S.A. at its Carkara magnesite deposit resulted in defining the deposit to contain 1.6 million tons of proven reserves. A number of grades were identified, including a low-iron grade, averaging 46.5% MgO. After completing the exploration work, Grecian Magnesite planned to begin mining the deposit in late 1990 at an estimated kiln-feed production rate of 50,000 tons per year. Part of the new production will be for dead-burned

¹Table includes data available through June 21, 1991.

²Reported figure

¹Excludes caustic-calcined magnesia used in the production of refractory magnesia.

²Includes magnesia used by producers.

³Caustic-calcined magnesia only.

magnesia and part for caustic-calcined magnesia.

Iran.—A 21,000-ton-per-year MgO production facility reportedly came onstream in Birjand at the end of the first quarter. Ore for the \$28 million plant was mined from seven deposits nearby, with total reserves estimated at 2.5 million tons.

Ireland.—By November, two new shaft kilns were operational at Premier Periclase Ltd.'s seawater magnesia plant in Drogheda, County Louth. The 50,000-ton-per-year kilns replaced existing rotary kilns at a cost of \$16.5 million. With the commissioning of these new kilns, Premier will have the capability to produce large-crystal-size, low-boron magnesia for a wide range of applications. including magnesia-carbon refractories, for the most severe wear areas in oxygen and electric steelmaking furnaces. All of the company's production was exported. with its major markets in Austria, the Federal Republic of Germany, the United Kingdom, and the United States. 12

Mexico.—Química del Mar SA de CV completed modifications at its seawater magnesia plant near Tampico early in the

year. As a result of these modifications, the company switched from producing a 95% dead-burned magnesia to a low-boron, 97% dead-burned magnesia. Annual plant capacity was reduced temporarily from 70,000 tons to 45,000 tons during the switch, but by yearend, additional equipment was installed to reach the original 70,000-ton-per-year capacity. Química del Mar also was upgrading its caustic-calcined magnesia from 95% MgO to 97% MgO.¹³

South Africa, Republic of.—Mintek, a minerals and metals research organization,

conducted laboratory-scale tests on seawater production of high-grade magnesia. Magnesia in the Republic of South Africa was produced from magnesite, but the grade was not high enough to be used for refractories, so the country relied on imports to meet this need. From Mintek's calculations, a 50,000-ton-per-year plant would yield an annual rate of return on investment of 15%.

Current Research.—The world's first magnesium oxide ceramic fiber reportedly was produced by a new process developed at the Department of Energy's

¹Figures represent crude salable magnesite. In addition to the countries listed, Bulgaria produced magnesite, but output is not reported quantitatively, and available general information is inadequate for formulation of reliable estimates of output levels. Table includes data available through May 3, 1991

available through May 3, 1991.

Series reflects output of marketable concentrates. Production of crude ore was as follows, in metric tons: 1986—648,752; 1987—860,163; 1988—810,837; 1989—1,385,565; and 1990—1,000,000 (estimated).

Magnesitic dolomite and brucite. Figures are estimated on the basis of reported tonnage dollar value.

Argonne National Laboratory. The new process involved mixing magnesium oxide particles with a plastic binder, exposing a thin stream of the mixture to turbulent air, and firing it. Normally, ceramic fibers are made commercially by a variety of techniques that are specifically tailored to the type of fiber manufactured, and the fibers are made in batches. Researchers claimed this new process could be carried out continuously and could be used on any sinterable ceramic. Possible future uses for new ceramic fibers made by this process include electrodes for high-temperature batteries and porous substrates for catalysts.

The Lithium Div. of FMC Corp. opened a pilot plant at its Bessemer City, NC, plant to treat books by a companydeveloped process to extend the books' useful life. This process, which retards brittleness during aging, involves immersing the book in an organic solvent containing a magnesium compound and then removing the solvent. The magnesium compound remains in the paper and forms a buffer. FMC claims that this process can preserve the book for an additional 10 to 12 years. The pilot plant can treat up to 300,000 books per year. If the treatment is widely accepted by libraries, FMC planned to build four commercial plants that can treat 2 to 5 million books per year at a projected cost of \$6 per book.

In a review of refractories consumption by the cement industry, average consumption rates of various refractories by the U.S. industry were estimated. Of the total average consumption of refractories of 1.99 pounds per ton of clinker produced, magnesia-chrome refractories constituted 29% and magnesia-spinel constituted 13% of the total. Additional information was presented on the specific areas of the kiln in which these types of refractories were normally installed. 14

OUTLOOK

In its annual review of magnesium supply and demand, the International Magnesium Association predicted an average annual growth rate of about 3% for world primary magnesium shipments from 1989 to 1995, with the largest growth occurring in Western Europe and North America. Diecasting, at a predicted average annual growth rate of almost 10%, was the end use contributing the most to the total forecast. About 70% of magnesium diecastings worldwide were used by the automotive industry, and with the potential increase in the Corporate Average Fuel Economy rates in the United States, automobile manufacturers will continue to increase their use of magnesium components to reduce total vehicle weight.¹⁵

Refractories, which were the dominant use for magnesium compounds, continued to have the greatest effect on overall demand. As producers develop magnesia-base refractories that are longer lived and that can be substituted for other refractories, the overall use of these refractories will increase. Conversely, because of these characteristics, refractory linings in these furnaces will not have to be replaced as often, which will decrease demand. The synergistic effects of these trends likely will result in a stagnant demand for magnesia-base refractories.

MANGANESE

By Thomas S. Jones

Dr. Jones, a physical scientist with 32 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for manganese since 1982. Domestic survey data were prepared by Glenn Wallace, mineral data assistant; and the international data table was prepared by William Zajac, Chief, Section of International Data.

anganese is essential to iron and steel production by virtue of its sulfur-fixing, deoxidizing, and alloying properties. Currently, no practical approaches exist for replacing it with other materials or for obtaining the bulk of U.S. requirements from domestic sources. Strategic concerns of the United States for manganese largely apply also to Japan and Western Europe.

In 1990, ironmaking and steelmaking continued to account for about 90% of domestic manganese demand. Unit consumption rates for manganese were lower in ironmaking and higher in steelmaking than in 1989. Government inventories of manganese, all forms, still represented more than 2 years of apparent consumption. As reflected by the data in table 1, U.S. imports of key manganese materials decreased overall compared with those of 1989. Imports of ore were the least since 1984.

For the third consecutive year, the ac-

tual price of metallurgical-grade manganese ore rose substantially to a new record high. This increase was stimulating development of modest amounts of additional ore production in Australia and Canada. Major producers were yet to carry out any significant expansions in output capability.

The level and nature of manganese use by the United States is not expected to change significantly in the near future, but the level will be subject to fluctuations in domestic and global steel production. Political and economic developments have made uncertain the U.S.S.R.'s future status as a major ore producer and supplier of ore to Eastern Europe.

manganese ore, exclusive of that consumed within the steel industry, are collected by means of the "Manganese Ore and Products" survey. The approximately 20 firms canvassed by means of this survey process ore by such methods as grinding and roasting or consume it in the manufacture of manganese ferroalloys, metal, and chemicals. In 1990, responses were obtained from all firms canvassed, whose collective consumption is believed to represent that of the United States except for negligible quantities consumed by other firms, if any. The aggregated consumption data so obtained were incorporated into table 5 but only displayed within totals to avoid disclosing proprietary data.

BACKGROUND

Definitions, Grades, and **Specifications**

Ore.—The U.S. Bureau of Mines has compiled statistics on manganesebearing ores, concentrates, nodules, and sinter, all referred to simply as "ore," by manganese content as follows: manganese ore, 35% or more manganese; manganiferous ore, less than 35% but not less than 5% manganese; and within the latter ferruginous manganese ore, 10% to 35% manganese; and manganiferous iron ore, 5% to 10% manganese.

Manganese ore may be considered as metallurgical, chemical, or battery grade. Metallurgical-grade material has an approximate manganese content range of 38% to 55% and may differ from chemical-grade ore only in physical form. Chemical- and battery-grade ores are often categorized by manganese dioxide (MnO₂) content, which typically is in the range of 70% to 85% (44% to 54% Mn). The U.S. Government maintains specifications for metallurgical, chemical, and battery grades of ore for stockpile purposes; industry has no corresponding standards.

Ferroalloys and Metal.—Ferromanganese is a manganese-iron-carbon alloy classified according to decreasing carbon content into standard or high-carbon grades, medium-carbon grades, and lowcarbon grades. Silicon is also specified in silicomanganese (such as 18%) and ferromanganese-silicon (about 30%). For U.S. tariff purposes, ferroalloys are required to have an iron content of 4% or greater; a manganese material with less iron would be treated as manganese metal. The specifications the U.S. industry generally follows for manganese ferroalloys and metal are those of the American Society for Testing and Materials.

Products for Trade and Industry

Metallurgical-grade ore is used primarily in making ferroalloys, pig iron, and steel. In making ferroalloys, ore with a relatively high manganese and low phosphorus content is particularly desirable.

The sulfur-fixing, deoxidizing, and alloying attributes of manganese are obtained mostly through use of intermediate forms such as ferromanganese. Manganese ferroalloys for use in steelmaking are selected on the basis of cost per manganese unit, allowable steel carbon and silicon specifications, and steelmaking practice. For 1990, with the cost of manganese in metallurgical ore taken as 1.0, the corresponding approximate costs per manganese unit were 2.2 for high-carbon ferromanganese, 1.7 for silicomanganese, 3.3 for medium-carbon ferromanganese, and 5.5 for manganese metal. Metallic manganese is little used per se because it is typically brittle and unworkable.

Manganese is added to aluminum using aluminum-manganese master alloys that typically contain 25% Mn, briquets of compacted aluminum and manganese powders that typically contain 75% Mn, and electrolytic manganese metal.

Various manganese dioxide-types of material, possibly ground, are used for batteries and other applications. These include natural mineral product (NMD) and synthetic dioxide produced either electrolytically (EMD) or chemically (CMD).

of their uses include manganese sulfate and manganous oxide (MnO) for animal feed and soil conditioners, ground manganese ore for brick coloring, and potassium permanganate for water treatment.

Industry Structure

Makeup of the world's manganese ore producers is chiefly as follows: Australia, Groote Eylandt Mining Co. Pty. Ltd. (GEMCO); Brazil, Cia. Vale do Rio Doce (CVRD) and Indústria e Comércia de Minérios S.A. (ICOMI), plus a number of relatively small mines; China, apparently mostly small- to moderate-size operations in the eastern Provinces: Gabon, Compagnie Minière de l'Ogooué S.A. (COMILOG); Ghana, Ghana National Manganese Corp.; India, more than 200 mines, with Manganese Ore India Ltd. the most prominent company; Mexico, Cía. Minera Autlán de C.V. (Autlán); Republic of South Africa, The Associated Manganese Mines of South Africa Ltd. (AMMO-SAL) and Samancor Ltd.; and the U.S.S.R., two large complexes, mining the Chiatura Basin in Georgia and the Nikopol' Basin in the Ukraine. Most ore produced goes into metallurgical applications. 1 Ore for nonmetallurgical uses generally is supplied by the largescale producers mentioned plus smaller ones elsewhere.2

In recent years, the U.S.S.R. has been supplying more than 1 million tons³ of ore annually to Eastern Europe. Such exports were notably lower in 1987 and appear likely to decline considerably in the future. Otherwise, the principal source of ore to the international market has been an oligopolistic-like group of countries consisting of Australia (GEMCO), Brazil (ICOMI and CVRD), Gabon (COMILOG), and the Republic of South Africa (AMMOSAL and Samancor).

Smelting of ore into manganese ferroalloys is much more diversified than ore production. Leading ferroalloy producers are as follows: Brazil, Cia. Paulista de Ferro-Ligas (a number of plants); China, many plants; France, Société du Ferromanganèse de Paris-Outreau (SFPO); Federal Republic of Germany, Thyssen Stahl AG; Japan, Japan Metals & Chemicals Co. Ltd. and Mizushima Ferroalloy Co. Ltd.; Mexico, Autlán; Norway, Elkem A/S; Republic of South Africa, Metalloys Other manganese materials and some | Ltd., a subsidiary of Samancor; and the U.S.S.R., a number of plants. The U.S.S.R. is by far the largest producer.

Four market economy countries (MEC's) currently produce metal, all electrolytically, in decreasing order of capacity: the Republic of South Africa, the United States, Japan, and, beginning in 1989, Brazil. China and the U.S.S.R. produce metal, including that produced metallothermically in the U.S.S.R. World productive capacity for metal was given as 84,000 tons annually as of 1985, 4 and would be approximately the same in 1990.

Annual world capacity for EMD was assessed as 218,000 tons in 1989, including capacities of 78,000 tons for Japan and 39,000 tons for the United States.⁵ The principal producer of CMD is Belgium's Sedema S.A., with annual capacity of about 40,000 tons.

Geology-Resources

The world's major land-based economic resources of manganese are of two principal types: marine chemical sediments and secondary enrichment deposits.⁶ Marine chemical deposits represent a majority of known resources. In 1985, the Manganese Centre (name changed in 1989 to International Manganese Institute) estimated that known relatively high-grade deposits (those with a manganese content of at least 44%) contained about 360 million tons of manganese.⁷ As given in the "World Review" section of this chapter, the reserve base for manganese can be considered more than 10 times this size. The world's potential supply of manganese also includes extensive marine accumulations, such as oxide nodules on deep ocean floors and oxide crusts on midocean ridges, whose commercial future is indeterminate. Among the more common minerals occurring in manganese ores are oxides, including pyrolusite, a mineral form of manganese dioxide: the oxysilicate braunite; and rhodochrosite, a mineral manganese carbonate.

Technology

Exploration.—Highly selective methods of locating land manganese deposits do not exist, but interpretation of geologic environments can assist prospecting.8

Mining. - Most manganese ore is produced by mechanized operations. Standard earth-moving equipment is used in surface mining. Underground mining generally is by room-and-pillar techniques. Selective mining may be practiced in producing battery- and chemicalgrade ores from a deposit being worked principally for metallurgical-grade ore.

Beneficiation.—Crushing, screening, washing, jigging, and tabling as well as flotation, heavy-medium, and high-intensity magnetic separation are being or have been used to upgrade raw manganese ore into usable concentrates. Carbonate ore may be calcined. Ore fines are sintered into bulkier shapes at some ferroalloy plants, a practice being adopted increasingly by ore producers as well.

Processing.—Electrothermy is the predominant method of manufacturing manganese ferroalloys, as by the submerged-arc-furnace process. Blast furnace-type operations are still used in a few foreign countries to make important quantities of high-carbon ferromanganese. Recovery of metallics other than iron from manganese-bearing ore is rare.

Manganese metal and EMD commonly are produced by electrolyzing a solution of manganese sulfate prepared from ore that has been reduction roasted. Production of the dioxide is especially sensitive to minor ore impurities. ¹⁰ Chemical manganese dioxide can be prepared by precipitating manganese carbonate from a sulfate solution and decomposing the carbonate to oxide. ¹¹

Recycling.—Scrap recovery specifically for manganese is insignificant. Considerable manganese reenters processing as a minor component of steel scrap, steel slag, and nonferrous scrap.

Economic Factors

As noted in a study of the Minerals Availability Program (MAP) of the U.S Bureau of Mines, transportation is the most significant cost element in the production of manganese concentrates. ¹² In a recent MAP assessment of costs for most major mines in MEC's, transportation accounted for about two-thirds of concentrate cost. Transportation costs were about equally divided between transportation to the port and transportation to the market. Also according to

this assessment, the major mines for metallurgical-grade ore of the MEC's are quite competitive as to ore production cost. Of the considerable resources evaluated, about 80% had estimated production costs within 20% of the lowest cost.

Operating Factors

Environmental Requirements.—In 1988, the Environmental Protection Agency (EPA) imposed an annual requirement of reporting releases to the environment of manganese chemical compounds and metal (40 CFR 372). This initially applied to operations classifiable within SIC codes 20 to 39 that annually manufacture or process at least 75,000 pounds of these materials, subject to a minimum concentration limitation. This threshold decreased to 25,000 pounds for 1989 and beyond. The threshold for annual use of these materials other than in their manufacturing and processing was 10,000 pounds.

Toxicity.—Manganese is an essential element for people, animals, and plants. In excess, it can be harmful to the respiratory and nervous systems.¹³ Thus, manganese can be an industrial poison, but normally is not a hazard.

ANNUAL REVIEW

Legislation and Government Programs

Manganese, including ferromanganese and silicomanganese, was on a revised list of 10 strategic minerals currently imported from the Republic of South Africa that the U.S. Department of State certified to be essential for the economy or defense of the United States and unavailable from reliable and secure suppliers. The revised list was published on January 18 (55 FR 1764) in accordance with section 303(a)(2) of the Comprehensive Anti-Apartheid Act of 1986, as amended. It replaced the prior list of January 7, 1987, that also included manganese.

The U.S. Department of the Interior's Minerals Management Service and the Department of Business and Economic Development of the State of Hawaii jointly released a final environmental impact statement for a pro-

posed marine mineral lease sale that could lead to eventual mining of cobaltrich manganese crusts in the Pacific Ocean near the Hawaiian Archipelago and Johnston Island. The proposed lease area was in the Exclusive Economic Zone and was estimated to contain significant resources of cobalt, manganese, and nickel. The impact statement analyzed several processing schemes, one of which involved pyrometallurgical recovery of manganese. ¹⁴

Among new regulatory programs affecting manganese materials, the 1990 amendments to the Clean Air Act included manganese compounds among substances to be regulated under the provisions of that act (Public Law 101–549, effective November 15, 1990). The EPA placed manganese and 26 other new substances on a new priority list of candidates for regulation under the Safe Drinking Water Act. The list was effective as of December 31, 1990 (56 FR 1470).

Strategic Considerations

Security of Supply. - Manganese, for which there is no economical substitute, is essential to steelmaking. Steel producers in the MEC's of the United States, Japan, and Western Europe shared a common concern about lack of economically minable domestic manganese deposits. Also, MEC ore supply was from relatively few sources, chiefly Australia, Brazil, Gabon, India, Mexico, and the Republic of South Africa, and from just one or two major ore mining companies in each of these countries. According to one analysis, an index for security of manganese ore supply to such MEC steel producers declined during 1979-87.15 The United States was additionally concerned about supply of manganese ferroallovs because its domestic ferroallov industry had declined well below selfsufficiency in manganese.

Stockpile.—The status of goals and inventories of manganese materials in the National Defense Stockpile at the end of 1990 is given in table 2. The only change in goals during 1990 was reduction of that for natural battery ore from 62,000 tons to 25,000 tons, effective late in June. Changes in yearend inventories and sales during 1990 are summarized in table 3. Actual physical changes occurred only for metallurgical ore and high-

TABLE 2

carbon ferromanganese. The changes for chemical ore and medium-carbon ferromanganese resulted from accounting adjustments, which also caused a small adjustment for high-carbon ferromanganese. Most of the change for high-carbon ferromanganese occurred in June when the Defense Logistics Agency accepted into inventory 56,152 tons produced under the stockpile upgrading program. On an overall basis, these changes insignificantly diminished the reserve of approximately 2 million tons of contained manganese being held by the Government.

Issues

The United States has been lacking in reserves and significant production of manganese almost since the start of domestic steel production. Extensive efforts to discover worthwhile ore deposits or effective methods of using low-grade resources, including steel slags, have resulted in little commercial promise. In a 1985 report, the U.S. Congressional Office of Technology Assessment (OTA) concluded that improvements in steel production technology offered the best prospect for reducing U.S. manganese import vulnerability. ¹⁶ In so doing, OTA discounted ocean mining for the present. a view shared by most participants at a December 1989 conference on marine mining. 17

The setting up and maintenance of a large stockpile has been the most tangible aspect of Government manganese programs. Management of this stockpile is a key part of Government policy.

Current law limits use of the stockpile to emergency situations, but its mere presence has had economic implications. Questions that have arisen from time to time include what the makeup and size of the manganese stockpile should be and whether it should be used for economic purposes.

Production

Ore and Concentrate.—Production and shipments consisted only of manganiferous material having a natural manganese content of 5% to 15% mined in Cherokee County, SC, for use in coloring brick. Shipments data were not published to avoid disclosing proprietary data. Some use of this manganiferous material to color brick was being displaced by use of ground manganese ore.

Ferroalloys, Metal, and Synthetic

Dioxide.—Production statistics for these materials were not published to avoid disclosing proprietary data. Plant sites and products are given in table 4. The production program at the Marietta, OH, plant of Elkem Metals Co., the only producer of manganese ferroalloys, included high-carbon ferromanganese for the Government stockpile and silicomanganese to compensate for shutdowns at other plants of the parent company in Canada and Norway.

Consumption, Uses, and Stocks

Metallurgical applications accounted for most manganese consumption, about 90% for steelmaking. This can be deduced from the data relating to manganese end use in tables 5 and 6 plus certain other information. Table 7 presents industry averages for pounds of manganese used in ironmaking and steelmaking operations per ton of raw steel produced. These 1990 consump-

tion rates, derived from the reported data in tables 5 and 6, were lower for ironmaking but higher for steelmaking than in 1989.

Relatively small quantities of manganese were used for alloying with nonferrous metals, chiefly aluminum. For alloying with aluminum in 1990, the proportion of manganese added as metal was significantly less in relation to that added as manganese-aluminum briquets and other forms than in immediately prior years.

Nonmetallurgical applications for manganese included dry cell batteries, plant fertilizers, animal feed, brick coloring, and manganese chemicals. Two U.S. firms discontinued operations involving manganese in battery production. Bright Star Industries, Clifton, NJ, ended its small production of dry cells, and Eastman Kodak Co. stopped the production of lithium-manganese dioxide batteries that had begun only in 1986 at its Newark, NY, plant.

In addressing environmental concerns associated with dry cell batteries, domestic producers and their foreign affiliates joined in international efforts to minimize mercury usage in such batteries. Mercury contents, used mainly to control hydrogen gassing, were being reduced to zero in carbon-zinc cells (based on natural manganese dioxide) and to 0.025% by weight or less in alkaline cells (based on synthetic manganese dioxide). 19

Markets and Prices

Manganese Ore.—For the third successive year, the price of metallurgical manganese ore increased significantly and set a new record high for price in

commercial transactions. Prices paid by West European and Japanese consumers showed advances in the range of 50% in the face of reported tightness in the supply of high-grade ore and no expansions by major ore producers. The process for setting prices for annual contracts was relatively protracted, extending into August before agreement was reached between South African ore suppliers and Japanese buyers.

The average price, c.i.f. U.S. ports, for metallurgical ore containing 48% manganese was assessed as \$3.78 per metric ton unit (mtu), an increase of about 40% over that of \$2.76 per mtu in 1989. The mtu is 1% of a metric ton or 22.05 pounds of contained manganese. Dividing the mtu price by 22.05 gives the price per pound of manganese in ore, which was 17.1 cents in 1990 and 12.5 cents in 1989. The price of a metric ton of ore is obtained by multiplying the mtu price by the percentage

manganese content of the ore. Mtu pricing has superseded long ton unit (ltu) pricing; in the latter system, the respective 1990 and 1989 prices were \$3.84 and \$2.80 per ltu.

The ore market consists of a number of submarkets because of differences between ores according to the various end uses such as ferroalloy production, blast furnace ironmaking, and battery manufacture. Table 8 gives the trend for metallurgical ore during the past two decades.

Manganese Ferroalloys.—The general price trend for manganese ferroalloys, as given by quotations for imports, was similar to that in 1989: upward in the first part of the year, then downward, and finally some firming of prices near yearend. The increased cost of ore to ferroalloy producers and little change in the rate of raw steel production, at least domestically, appeared to support prices for high-carbon ferromanganese and

	Manganese metal	.1	.1
	Total, steelmaking	8.1	8.3

e Estimated

manganese metal. The year-average price for high-carbon ferromanganese was about 4% higher than that of 1989. Silicomanganese reportedly was in oversupply, so that its year-average price was about 28% lower than that of 1989. Possibly also contributing to a comparative weakness in silicomanganese price was an excess of ferrosilicon, which at least some steel producers could use in combination with ferromanganese in place of silicomanganese.

For high-carbon ferromanganese containing 78% manganese, the price range of imported material, f.o.b. Pittsburgh or Chicago warehouse, began 1990 at \$625-\$645 per long ton of alloy, which was almost unchanged from that at the end of 1989 and only slightly below the range of \$630-\$650 at the end of 1990. A peak of \$650-\$665 was reached in early March.

The price range for imported silicomanganese with 2% carbon, in cents per pound of alloy, f.o.b. Pittsburgh or Chicago warehouse, also showed little net

TABLE 8

1990	3.78	2.87

¹Withheld to avoid disclosing company proprietary data; included with "Steel: Unspecified."

² Includes estimates.

³ Approximately 90% of this subtotal was for consumption in aluminum alloys.

⁴ Internal evaluation indicates that silicomanganese consumption is considerably understated.

⁵Estimated based on typical percent manganese content (rounded).

¹ As ingots, continuous- or presssure-cast blooms, billets, slabs, etc.

²Containing 35% or more manganese.

³ None reported.

movement in 1990, beginning the year at 26-28 and ending at 25.75-26.5. The peak came early in June at 28.25-29.

As given by Metals Week, domestic producer prices (Elkem Metals) for high-carbon ferromanganese and silicomanganese were the same throughout 1990 as at the end of 1989. These prices, f.o.b. plant or warehouse, were \$695 for high-carbon ferromanganese and 35 cents for silicomanganese.

Manganese Metal.—For bulk shipments of domestic material, f.o.b. shipping point, trade journals listed a price range of 91-96 or 91-95 cents per pound, the same as at the end of 1989, until mid-November. At that point, citing the high cost of ore, domestic producers raised their price for the balance of the year to \$1.04 or \$1.05 per pound.

Foreign Trade

Data for exports are summarized in table 9. For ore, unit values again indicated exports to Canada, the majority of exports to countries other than Canada and Mexico, and reexports of 14,243 tons (all to Canada) were metallurgical ore. All reported ore exports to Mexico appeared to have been transshipments of Gabonese ore. Reported exports of spiegeleisen were 855 tons having relatively low unit value, as compared to imports of 187 tons having relatively high unit value.

For all aggregated categories of imports for which data are given in table 10, quantities were less in 1990 than in 1989 except for manganese dioxide. In terms of contained manganese, the decline was less for the sum of ferroalloy plus metal than for the sum of ore plus dioxide; the corresponding ratio, ferroalloy plus metal divided by ore plus dioxide, was the greatest since 1982. Overall imports of ore were the least since 1984 and those of ferromanganese decreased for the third consecutive year. For ore and ferromanganese, average contents returned to values more typical of those in recent years. Content of ore increased to 48.5% and that of ferromanganese to 78.4%.

Among imports of manganese chemicals, all those of dioxide apparently were synthetic dioxide except for 4 tons from Morocco. The quantity of potassium permanganate imported from China rose again to a record amount.

Entries for Mexico listed under imports classified as "Other sulfates," which includes manganese sulfate, totaled 11,052 tons valued at \$5.1 million.

The schedule of tariffs that applied during 1990 to U.S. imports of selected manganese materials is given in table 11.

World Review

Capacity.—The rated capacity data in table 12 are as of December 31, 1990, and are only slightly changed from those of the previous year. The data correspond to the manganese contents of ore and/or concentrates capable of being utilized, as in feed to a smelter. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sus-

tainable long-term operating rate.

Reserves.—Only a few of the world's many manganese concentrations have enough economic significance to be classed as reserves;²⁰ no domestic deposits qualify.²¹ World reserves of manganese, on the same basis as capacity, are given in table 13 with no distinction between ore type or application. This table excludes perhaps 1% to 2% of total known reserves. These are in nonlisted countries having a similar proportion of world production, as can be seen from table 15.

Australia.—An approximate onetenth decrease in production of manganese ore by GEMCO was attributed by trade journals partly to the U.S.S.R. not

¹ All subject to (1) 0.17% ad valorem user fee except for products from beneficiary countries under the Caribbean Basin Economy Recovery Act (CBERA) and least-developed developing countries and (2) 0.04% ad valorem harbor-maintenance fee for cargo unloaded from waterborne vessels at U.S. ports open to public navigation.

in the Woodie Woodie area of the east Pilbara region in Western Australia. Surface mining to yield 275,000 tons per year of product was projected for at least 5 years. The two main products of the operation, both low in phosphorus, were a siliceous ore containing about 43% manganese and a higher grade ore with 46% to 47% manganese. Transportation was by road trains over a distance of about 240 miles to ocean shipping at Port Hedland. Initial customers for the ore were in the Far East, with shipments beginning late in 1990 to China, the Republic of Korea, and Taiwan.

Brazil.—Shipments of manganese ores from the Serra do Navio, Amapá Territory, operations of ICOMI, a subsidiary of Cia. Auxiliar de Empresas de Mineração S.A. (Caemi), decreased 16% overall to 617,000 tons. Shipments, via Porto de Santana on the Amazon River, declined only moderately for exports to 529,000 tons, but dropped by about onehalf, to 88,000 tons, for those to Brazilian consumers. About three-fifths of total shipments consisted of low-grade and

carbonate ores.

Caemi expanded its manganese operations in Amapá Territory by inaugurating production of ferromanganese in the second half of the year at Cia. Ferroligas do Amapá (CFA), a recently formed subsidiary. Like a sinter plant completed by ICOMI in 1989, CFA's one-furnace ferroalloy plant was in the Porto de Santana area. ICOMI was the source of a mix of medium-grade metallurgical ore, carbonate ore, and sinter being fed to CFA's 12.4-megawatt-ampere furnace, rated for ferromanganese at 25,000 tons per year. Output of sinter during 1990 was about 80,000 tons.

Total manganese ore shipments from the Azul Mine of CVRD in the Carajás region declined by about one-fifth to 477,000 tons. Shipments to Brazilian consumers rose to 219,000 tons, but exports decreased by more than one-third to 258,000 tons. Urucum Mineração S.A., about 47% owned by CVRD, was engaged in fulfilling a multiyear agreement to supply ore to Romania from its operations near the Bolivian border in the State of Mato Grosso do Sul.

Production of manganese ferroalloys declined just slightly from 1989's record-high total to 427,000 tons. With approximately the same output of high-carbon ferromanganese, a small increase in production of silicomanganese to a new record of 239,000 tons counterbalanced a one-third decrease in production of medium- and low-carbon ferromanganese to 19,000 tons. Investment in manganese ferroalloy facilities reportedly was adversely affected by Federal and State economic and tax programs.

Production of electrolytic manganese metal was initiated early in 1990 by the Metalman S.A. subsidiary of Metalur Ltda. at its plant near São Luís, Maranhão State. However, plant output did not progress to the 13,000-ton-per-year level projected for the latter part of 1990. CVRD was supplying ore to Metalman from its Azul Mine nearby.

Bulgaria. - Four state-owned Bulgarian companies entered into an agreement with Norway's Elkem under which Elkem was to be furnished with about 28,000 tons per year of manganese ore and in turn supply Bulgaria with ferromanganese and technology. The agreement, valued at more than \$150 million, extended for 5 to 7 years and stipulated that Bulgaria would not restart ferromanganese production, which had ended late in 1989. Bulgarian companies involved were Kremikovtzi, Mangan, Metalsnab, and Rudmetal, the latter a trading company. The Obrochishte Mine near Varna on the Black Sea Coast in eastern Bulgaria presumably would be the ore source.

Canada.—In the latter part of the year, a test lot of a 45% manganese lump product was shipped by Hollinger North Shore Exploration Inc., a subsidiary of La Fosse Platinum Group Inc. Operations being conducted near Schefferville in northeastern Quebec adjacent the Labrador border included initial startup of

a heavy-medium ore-beneficiating plant. Progression into commercial production of several manganese ore products at a total annual rate approaching 300,000 tons was projected within 5 years. Mining was to be by surface methods and confined to the mid-May to mid-October warmer season.

Gabon.—Capacity for ore production and actual ore output of COM-ILOG remained well below shipping capabilities provided by the dual routes of the new rail-to-port system within Gabon and the original aerial tramwayto-rail-to-port system terminating at Pointe-Noire in neighboring Congo. Transport of ore at the Moanda Mine was now benefiting from two conveyor systems, one for moving ore from the truck receiving point within the mine to the washing plant and another for carrying ore from the mine stockyard to the railhead of the Trans-Gabon Railroad. Production of 2,858,000 tons of ore in 1989, the highest annual total to that point, included 101,000 tons of battery-grade ore.

Ghana.—A total of 281,000 tons of ore was exported from the Nsuta Mine of Ghana National Manganese Corp.

through the Port of Takoradi compared with 314,000 tons exported in 1989. Shipments were made to Japan, the United States, and, in Europe, to Finland, Greece, Ireland, the Netherlands, Norway, Romania, and Spain. ²³ Shipments in 1990 descended to a level just 4% below that of the annual average for 1984–89.

India.—The Government recentralized manganese ore exports through the State-owned Minerals and Metals Trading Corp. and raised to 550,000 tons the quantity of ore that could be exported during the 1990 fiscal year beginning April 1. This followed a brief period beginning during the latter part of the 1989 fiscal year when such exports were decentralized. Ore exports during the 1989 fiscal year had been limited to 440,000 tons of low- and medium-grade ore, with exports of high-grade ore permitted only on a selective basis and provided the ore had a relatively high phosphorus content of more than 0.18%.

Japan.—The slightly increased total of 584,000 tons for production of manganese ferroalloys was the greatest since 1985. Ferromanganese output rose 15% to 499,000 tons, the highest level since 1984. Production of silicomanganese was adversely affected by mishaps affecting two large units and fell 37% to 85,000 tons.

Foreign trade in manganese ferroalloys was diminished from that in 1989, except that imports of ferromanganese approximately doubled to 48,000 tons. Imports of silicomanganese decreased 39% to 215,000 tons, of which China supplied more than 40%. Exports declined about 60% for both ferromanganese, to 6,200 tons, and silicomanganese, to 1,200 tons.

In synthetic dioxide, production of EMD decreased more than 7% to 56,700 tons, again the least since 1985. Exports of EMD decreased further to 33,200 tons, the least since 1981. In October, Daiichi Carbon Co. Ltd. ended production of EMD, partly because of waste disposal problems. With an annual capacity of about 3,000 tons, Daiichi Carbon had been Japan's smallest EMD producer. At about the same time, Chuo Denki Kogyo Co. began commercial production of a high-grade chemical manganese diox-

ide (CMD-U) intended to compete with EMD in battery applications. This was at the company's Taguchi plant in Niigata Prefecture, about 100 miles northwest of Tokyo. The plant was designed on the basis of research and development involving cooperation between Toshiba Battery Co. and Sumitomo Metal Industries Ltd. and had an annual capacity for CMD-U of 6,600 tons.

Production of electrolytic manganese metal was up slightly to 5,040 tons. Imports of unwrought manganese metal, including scrap, rose by more than one-fourth to 15,100 tons, of which more than 60% was from the Republic of South Africa and approximately one-third was from China.

Mexica.—Operations of Autlán in the Molango District of Hidalgo State were the principal source of manganese ore products. Autlán's production for 1990 and 1989, respectively, were, in tons, 737,000 and 700,000 for carbonate ore, 368,000 and 388,000 for oxide nodules produced by calcining carbonate ore, and 23,900 and 19,700 for battery ore from the Nonoalco Mine.

Following a 2-year development program, Ferroaleaciones de México, S.A. added medium-carbon ferromanganese to high-carbon ferromanganese and silicomanganese as regular products of its plant at Gómez Palacio, Durango State. Using a 13-ton converter, the company worked out practices giving 91% manganese recovery in oxygen decarburization of high-carbon ferromanganese.²⁴

South Africa, Republic of.—Total ore production advanced slightly, rising for the third consecutive year. Production in 1990 of the various categories of ore was as given in table 14.

Manganese ore shipments by AM-MOSAL decreased more than one-fourth to 1,445,000 tons.

South African ore producers were looking to expand both their marketing to Eastern Europe and capability for producing high-grade ore from key underground mines in the Cape Province's Kalahari Field. AMMOSAL was studying the feasibility of sinking a new vertical shaft that would increase capacity of its N'Chwaning Mine significantly. Samancor progressed with development work aimed at expanding production from the western block of

¹ Data may not add to totals shown because of independent rounding.

its Wessels Mine. Ore depletion caused Samancor's Hotazel surface mine to be closed as of the end of June.

Production capacities for silicomanganese and ferromanganese were increased by about 50,000 tons each. In February, the Transalloys Div. of Highveld Steel & Vanadium Corp. Ltd. commissioned a fifth silicomanganese furnace at its works at Witbank in Transvaal Province. In the latter half of 1990, the Feralloys Ltd. subsidiary of AMMOSAL added a ferromanganese furnace at its plant at Cato Ridge, Natal Province. AMMOSAL also then shut down three smaller furnaces indefinitely.

U.S.S.R.—Reports in trade journals indicated the quantity of manganese ore imported by the U.S.S.R. from such principal current sources as Australia and Gabon was much reduced. Receipts may not have exceeded one-half the quantities contracted for because of a shortage of hard currency on the part of the U.S.S.R.

The U.S.S.R.'s production of potassium permanganate was ended in the first part of the year when the country's facilities for producing this chemical were closed because of problems with waste disposal. These facilities, in the Crimean Black Sea city of Saki, had an annual capacity of about 6,000 tons. Because of their closure, an antidumping duty imposed in June by the Commission of the European Commu-

nity (EC) on imports of potassium permanganate from the U.S.S.R. was only provisional. This action had joined the U.S.S.R. with other permanganate producers in Eastern Europe and China against which the EC had established antidumping controls.

Ore exports of 987,000 tons in 1989 were 9% less than those in 1988, with those to Poland decreasing 22% and those to Czechoslovakia increasing 42%. Destinations for 1989 exports were, in tons, Poland, 506,000; Czechoslovakia, 280,000; German Democratic Republic, 90,000; North Korea, 32,000; Yugoslavia, 29,000; Bulgaria, 12,000; and unspecified, 38,000.

Current Research

Methods of economically utilizing low-grade domestic manganese resources continued to be investigated. In the United States, the U.S. Bureau of Mines explored use of calcium fluoride to facilitate sulfuric acid leaching of manganese silicate minerals. Tests in which manganese extractions of more than 90% were achieved were conducted on material typifying pyroxmangite ores of the Sunnyside district of San Juan County, CO.25 The manganese content was about 34%. In Italy, laboratory studies were conducted to determine the best conditions for solubilizing manganese from manganese dioxide-type ore by percolation leaching with aqueous sulfur dioxide and by bioleaching. For either approach, up to 20 days was required to achieve high extraction of manganese. The ore samples were from central western Italy and contained about 18% manganese. ²⁶

Geological investigation indicated a correlation between development of an economic manganese deposit and the existence of certain oxygen-poor, sulfurrich conditions of the marine environment during deposition. This conclusion was reached from examination of organic carbon and sulfide sulfur contents of manganese ores and their host

¹ Table includes data available through May 17, 1991. Data pertain to concentrates or comparable shipping product, except that in a few instances the best data available appear to be for crude ore, possibly after some ungrading

² In addition to the countries listed, Colombia, Cuba, Panama, Peru, and Sudan may have produced manganese ore and/or manganiferous ore, but available information is inadequate to make reliable estimates of output levels. Low-grade ore not included in this table has been reported as follows, in thousand short tons, gross weight: Argentina (19% to 30% Mn), 1986—11, 1987—7 (revised), 1988—10 (revised), 1989—7, and 1990—6 (estimated); and Czechoslovakia (about 17% Mn), an estimated 1 in each year.

³May be for average content of each year's production rather than for content of typical products.

⁴ Metallurgical ore.

⁵ Reported figure.

⁶ Gross weight reported; metal content estimated. Estimated metal content figures have been revised as necessary.

⁷ Reported gross-weight figures are the sum of (1) sales of direct-shipping manganese ore and (2) production of beneficiated ore, both as reported in Anuário Mineral Brasileiro.

⁸ Includes manganiferous ore

⁹Calculated metal content includes allowance for assumed moisture content.

¹⁰ Concentrate.

¹¹ Much of India's production grades below 35% Mn; average content was reported as 38% Mn in 1985.

¹² Estimated product total, mostly oxide nodules; may include smaller quantities of direct-shipping carbonate and oxide ores for metallurgical and battery applications.

¹³ Category represents the combined totals of Greece, Indonesia, Italy (from wastes), Japan, the Republic of Korea, Pakistan, the Philippines, Thailand, Turkey, and Zambia.

¹⁴Data may not add to totals shown because of independent rounding.

rocks for deposits in China, Mexico, and Newfoundland.²⁷

Steels are tending to be produced with progressively lower contents of residual elements. Increased emphasis on making steels with a phosphorus specification of 0.02% or less has implications for manganese-bearing materials used in ironmaking. One method for controlling phosphorus content of steels is to be selective in using low-phosphorus manganese ores in blast furnace feed. Another approach for minimizing steel phosphorus content is to eliminate recycling of steelmaking slag to the blast furnace. ²⁹

In electric furnace steelmaking, technology is being developed for stirring the bath by injecting gases through the furnace bottom. Metallurgical improvements attained include increased manganese yield, as in the Federal Republic of

Germany at Thyssen Stahl, where stirring was done with nitrogen followed by argon.³⁰ An electric furnace steelplant in Mexico raised manganese yield by 40% by stirring with natural gas.³¹

Manganese has been used in stainless steel as a substitute for nickel in times of nickel shortage. The thesis was advanced recently that, to avoid letting the economics of nickel supply limit future growth of the stainless steel market, nickel supply could be extended by using manganese and nitrogen in such steels.³² The super collider to be built by the U.S. Department of Energy is a potential user of manganese-nitrogen stainless steel.³³

The equilibrium diagram of the manganese-nitrogen system at temperatures up to 1,400° C was reviewed by the U.S. Bureau of Mines. The thermodynamics and crystal structure of the solid and liquid phases within this sys-

tem were described.34

In the plant world, research into the complexities of photosynthesis has revealed aspects of the key role of manganese in enabling cells to derive their energy by dissociating water molecules. Manganese assists this aerobic process, which liberates life-giving oxygen as a byproduct, through the ability of manganese to exist in different oxidation states. ³⁵

OUTLOOK

The trend of manganese demand, domestically and globally, will continue to closely follow that of steel production. Nonmetallurgical components of manganese demand, especially batteries, may experience higher growth rates

¹ Where available, data for manganese dioxide included beginning in 1984.

² Including manganiferous ore.

³ New series for steel-related end uses beginning in 1989.

⁴ Includes miscellaneous nonmetallurgical uses of ore beginning in 1987.

⁵ Not specifically based on reported data; includes processing losses. Through 1988, the distribution within this category is approximately the same as for end uses above. Beginning in 1989, includes nonidentified uses of steel corresponding to about one-third of total steel shipments.

than for steel production, but will have only a minor effect on overall manganese demand.

U.S. apparent consumption of manganese has been in the range of approximately 700,000 to 800,000 tons of contained manganese during 1985-89, as given in table 16. How this measure of domestic demand will vary on a yearto-year basis in 1991-95 is affected by uncertainties in the outlook for domestic steel production, as discussed in the annual report for "Iron and Steel." Particular uncertainty is associated with effects related to foreign trade, in which trends are sensitive to Government policy and currency exchange rates. Forecasts such as those of the International Iron and Steel Institute (IISI) generally indicate little growth in U.S. steel output through 1995. The range for U.S. apparent consumption of manganese in 1991-95 could well be much the same as that during the preceding 5 years, assuming no significant changes in manganese unit consumption in steelmaking. The majority of U.S. demand will be met by imports.

Global forecasts of IISI and others suggest that the average annual growth rate for world manganese demand in 1991-95 should be close to 1%. Evolving political and economic developments could have a significant impact on traditional manganese supplydemand relationships in the near future. A significant potential appears to exist for a decline in the U.S.S.R.'s ore production and exports, 90% or more of which have been to Eastern Europe since at least 1978.

MERCURY

By Robert G. Reese, Jr.

Mr. Reese, a physical scientist with the Branch of Metals, has been the commodity specialist for mercury for 3 years. Domestic survey data were prepared by Kevin Bacon, statistical assistant, and international data tables were prepared by Virginia Woodson, international data coordinator.

ercury was used in the production of a variety of products in 1990. Its combination of properties such as liquidity at ordinary temperatures, high specific gravity, and electrical conductivity were important considerations in many applications. For many of mercury's uses, however, satisfactory substitutes were known, and it appeared probable that others could be developed. As a result of the availability of substitutes, the health hazard of mercury poisoning, and the potential for mercury to be an environmental pollutant, the mercury market continued to shrink in 1990. This was a disappointing year for the mercuryproducing industry. In the United States, the only primary mercury-producing mine was closed, and the use of mercury in interior latex paints was banned. In response to lower mercury demand by domestic manufacturers, mercury prices declined. Elsewhere, other countries restricted the quantity of mercury entering their environments by reducing imports or by restrictions on the manufacture of mercury-containing products.

DOMESTIC DATA COVERAGE

Domestic data for mercury are developed by the U.S. Bureau of Mines from three separate, voluntary surveys of U.S. operations. Typical of these surveys was "Mercury," a survey of mercury consumption. Of the 97 firms to which this survey form was sent, 93% responded, representing an estimated 81% of the reported U.S. consumption shown in tables 1 and 4. Consumption for the nonrespondents was estimated using prior years consumption levels.

PRODUCTION

Mercury was produced as a principal product at one mine in Nevada, the McDermitt Mine, and as a byproduct at eight gold mines in Nevada, California, and Utah. Nearly all of the newly mined mercury came from Nevada. Actual production figures were withheld by the U.S. Bureau of Mines to avoid disclosing company proprietary data. Domestic mine production data reported in some of the accompanying tables represents only the quantity produced at the McDermitt Mine, as published in

³Stocks at mines, consumers, and dealers.

⁴Primary mercury.

⁵Mercury export data were not available from 1986 through 1988.

Placer Dome Inc.'s annual and 10-K reports. In late November, the McDermitt Mine was closed, idling approximately 20 workers.

Company officials attributed the closure to several factors, including poor market conditions, a ban on the use of mercury in certain paints, and excessive sales from Federal Government stockpiles. Although mining and processing operations were suspended, the company expected to meet its contract obligations from the mine's stocks.

Secondary mercury was recovered from scrapped mercury-containing products, from industrial waste and scrap, and from the sale of surplus Government stocks of scrap mercury. These source materials were processed by five companies: Adrow Chemical Co., Wanaque, NJ; Bethlehem Apparatus Co. Inc., Hellertown, PA; D.F. Goldsmith Chemical and Metals Corp., Evanston, IL; Mercury Refining Co. Inc., Latham, NY; and Wood Ridge Chemical Co., Newark, NJ.

CONSUMPTION AND USES

Industrial consumption of refined mercury metal fell more than 40% in 1990, as demand by the paint, chloralkali, battery, and wiring device industries plummeted.

The drop of almost 90% in demand by the paint industry was attributed to the ban in mid-August, by the Environmental Protection Agency, of the use of a mercury-containing antifungal compound in interior latex paints, and to the paint industry's anticipatation of the ban and expectation that it would in time be extended to exterior latex paints. The mercury compound was considered a health risk, especially in freshly painted, poorly ventilated areas. Alternative antifungal compounds were available to the paint industry.

The 58% fall in demand by battery manufacturers reflected the adoption of new batteries requiring much less mercury per unit and the shift of manufacture of mercury-containing batteries to countries having less stringent environmental regulations than the United States.

The 50% drop in the use of mercury in wiring devices and switches was attributed partly to an accelerated shift to solid-state devices and other alternative less environmentally dangerous devices, and partly to the economic recession that began during the year.

The 35% decline in demand by the chloralkali industry was due to the closing of several mercury cell plants during the year, to anticipation of stricter environ-

mental regulations governing mercurycontaining sludges and effluent, and probably to the economic recession.

There was much concern in the United States and other countries about pollution of the environment by mercury-containing products, several of which represent dissipative uses, from which little or no mercury is ever recovered for recycling or controlled disposal. Environmental subjects examined during the year included the makeup of waste in landfills and the potential for either voluntary or mandatory recycling of mercury-containing products.

STOCKS

Stocks of refined mercury held by consumers and dealers fell by almost 7% in 1990 and at yearend were equivalent to about 3 month's industrial consumption. Figures on stocks held at mines were withheld to avoid disclosing company proprietary data.

All of a large inventory of used (scrap) mercury held by the Department of Energy (DOE) at Oak Ridge, TN, was considered surplus, and limited quantities were offered for sale at monthly auctions by the Defense Logistics Agency (DLA), which acted as DOE's agent. DLA shipped 193 metric tons during the year, leaving yearend stocks at 439 metric tons.

MARKETS AND PRICES

The New York dealer price for delivered primary mercury, reported in Metals Week as a range, declined throughout the year. The price at the low end of the range began the year at \$290 per flask. From this peak, the low-end price declined steadily until mid-December when it reached \$180 per flask, its low for the year. The low-end price remained at \$180 through the end of the year. The price at the high end of the range tracked the movement of the low-end price fairly closely, but was \$8 to \$30 per flask higher. The annual average of the weekly low-end price was \$249.22 compared with \$287.72 in 1989.

WORLD REVIEW

Mercury was mined in at least 11 countries in 1990. Together, the U.S.S.R. and Spain accounted for more than 60% of the world's mercury production.

Contamination of the environment by mercury remained a concern. In Brazil,

many of the small gold mines in the Amazon basin recover gold by amalgamation with mercury. Separating the gold from the amalgam often results in mercury loss and the subsequent pollution of the Amazon River and its tributaries. In response to the growing pollution of this water source, the Government of Brazil reportedly requested aid to combat the problem. Wire service reports in late January announced that Japan would provide Brazil with gold recovery technology that does not use mercury. In late October, it was reported that the Federal Republic of Germany would fund a study on mercury pollution in Brazil. The study was expected to investigate the extent of mercury poisoning and possible alternatives for cleaning the rivers. The Government of Denmark reportedly banned the importation of mercury and mercury-containing products in July. Batteries containing mercury and mercury for chlorine production were exempted. Other uses for mercury were granted transition periods during which a switch to alternative products would be accomplished.

In Japan, guidelines concerning the use of mercury for battery manufacture were issued near yearend. The guidelines were expected to significantly reduce Japan's use of mercury for battery manufacture. The use of mercury in manganese batteries was reportedly suspended, and the mercury content of alkaline batteries was reduced from 0.1% to 0.025%. The guidelines, effective beginning in 1991, applied only to batteries manufactured in Japan for internal consumption. Batteries manufactured in Japan for export were not specifically covered by the guidelines and were not expected to be affected. Also not covered by the guidelines was the manufacture of button cells used mainly for hearing aids. It appeared probable that button cell manufacturing was not covered because these cells are being replaced by the newly developed zinc-air button cell.

OUTLOOK

The world market for mercury was characterized, as it had been for at least two decades, by abundant supply and a slowly shrinking demand. The increasing recognition around the world of the danger posed by mercury's toxicity has led over the last quarter century to curtailment of its use in some applications and elimination from others. This trend is expected to continue. Although it is unlikely that the consumption

of mercury will be totally eliminated in the near future, constant vigilance to safeguard the health of persons exposed to mercury, as well as to protect the environment in which we live is required.

MICA

By Lawrence L. Davis

Mr. Davis, a physical scientist with 35 years of industry and U.S. Bureau of Mines experience, has been the commodity specialist for mica since 1983. Domestic survey data were prepared by Linder Roberts, mineral data assistant; and international data tables were prepared by Audrey Wilkes, international data coordinator.

n 1990, about 109,000 metric tons of scrap and flake mica was produced in the United States, a decrease of 8% from 1989 production. Ground mica sales were 97,000 tons valued at \$22 million, a decrease in tonnage of about 4%.

Almost all sheet mica supply continued to be imported. Consumption of muscovite block mica decreased 20% to 6.0 tons. Consumption of mica splittings decreased 24% to 842 tons. The value of sheet mica exports increased 5% to \$7.8 million. The value of imports for consumption of sheet mica increased 8% to \$9.5 million.

DOMESTIC DATA COVERAGE

Domestic production and consumption data for mica are developed by the U.S. Bureau of Mines by means of three separate, voluntary surveys and one mandatory survey. Of the 18 operations to which the crude scrap and flake mica production form was sent, 16 operations, or 89%, responded, representing 86% of the production shown in table 1. Of the 17 operations to which the ground mica form was sent, 15 responded, representing 93% of the production in table 1. Of the five canvassed operations to which the mica block and film consumption form was sent, two, or 40%, responded, representing 65% of the consumption shown in table 1. Of the nine canvassed operations to which the mica splittings consumption form was sent, eight operations, or 89%, responded, representing more than 99% of the splittings consumption shown in table 1. Consumption for the nonrespondents was estimated using prior-year production data.

BACKGROUND

Definitions, Grades, and Specifications

Mica is a group name for a number of complex, hydrous potassium silicate minerals with differing chemical compositions and physical properties. Crystals of mica have excellent basal cleavage and split easily into tough, flexible sheets. The important mica minerals are muscovite and phlogopite.

Commercial qualities of sheet mica are relatively free of defects and tough enough to be punched or stamped into specific shapes. Sheet mica is classified as block, film, or splittings. Block mica is not less than 0.018 centimeters thick and has a minimum usable area of 6.45 square centimeters. Film mica is split to specified thicknesses ranging from 0.0030 to

0.010 centimeters. Splittings are sheets with a maximum thickness of 0.0030 centimeters and a minimum usable area of 4.84 square centimeters. Punch mica, which includes circle and washer mica, is low-quality, hand-trimmed mica up to about 5 centimeters in diameter. The American Society for Testing and Materials (ASTM) designates 13 quality groups for sheet mica, based on quantity of visible inclusions and structural imperfections, ranging from black- and red-stained to perfectly clear. ASTM also designates 12 grades based on the maximum usable rectangle. The sizes range from grade 6 (with 6.45 usable square centimeters) to grade OOEE special (with 645 usable square centimeters).¹

Block and film mica products are small flat pieces of uniformly thin mica cut or stamped to close tolerances into a variety of shapes and sizes, depending on the use. Shapes can vary from simple circles, squares, or rectangles to very intricate patterns. Fabricators make their own dies to be able to cut the mica into any pattern desired.

Built-up mica, micanite, consists of partly overlapped and irregularly shaped and arranged splittings cemented together with either an organic or inorganic binder. Large sheets of built-up mica are made by alternating layers of splittings and binder. Sheets of any thickness are made by pressing the layers at high temperatures. Built-up mica is sold in large, uncut sheets or is cut or molded to any size and shape specified by the customer. It is often bonded to another material such as fiberglass cloth to form a composite sheet.

Reconstituted mica or mica paper is a paperlike material made by depositing fine flakes of scrap mica as a continuous mat, which is then dried. The mica paper is sometimes impregnated with an organic binder.

Scrap and flake mica is generally of a quality and size that is not suitable for use as sheet mica. Mine scrap varies greatly in quality but usually is a heterogeneous mixture that must be crushed, screened, and washed to yield the scrap mica in usable form. Mine scrap may be the sole product of mining a pegmatite or may be a byproduct of sheet mica production. Bench scrap or shop scrap is the mica discarded during the processing of handcobbed mica into sheet. Factory scrap is the waste that results from cutting and stamping sheet mica into pieces of definite size and shape. Factory scrap is usually the highest grade and quality material. Scrap mica that is recovered from schists and from the beneficiation of kaolin, feldspar, and lithium pegmatites is often referred to as flake.²

Industry Structure

The sheet mica industry in the United States is small, consisting of processors and fabricators of imported mica. Worldwide, India dominates the production of muscovite sheet mica. Madagascar is an important producer of phlogopite sheet mica. Sheet mica mining, trimming, and splitting is very labor intensive, and producing countries have the advantage of low wages and a large labor force that is usually trained at an early age. India's sheet mica industry is characterized by a large number of small operations, most

of which sell to larger companies or the Government's Mica Trading Corp. of India Ltd. (MITCO) for further processing and export. India is putting more emphasis on exporting fabricated mica products. This is expected to reduce further the amount of mica that will be fabricated in the United States.

The U.S. flake mica industry ranks first in world production. Most production comes from surface mining of mica schists and as a byproduct of kaolin, feldspar, and lithium beneficiation. Nearly all flake mica is ground to final specifications depending on the use. Other countries producing significant amounts of flake mica are Canada, China, India, the Republic of Korea, and the U.S.S.R. Many other countries produce small amounts.

Geology-Resources

Sheet muscovite is obtained from coarse-grained igneous rocks called pegmatites. Pegmatites also contain quartz, feldspar, and various accessory minerals. Pegmatite dikes and veins range from 1 kilometer or more long and 100 meters wide to thin veins and veinlets of 2 centimeters or so in width.

The United States has no reserves of sheet mica. Small U.S. reserves were extensively worked in the past, and the high cost of labor has kept the mines shut down since the Government's purchase program ended in 1962. The primary sheet mica resources are in New England, the southeastern Piedmont from Virginia to Alabama, the Blue Ridge Mountains in North Carolina, the Black Hills of South Dakota, and northern New Mexico. Other States with some sheet mica resources are California, Colorado, Idaho, Montana, and Wyoming.

No formal evaluation of world resources of sheet mica has been made, mainly because of the sporadic occurrence of this mineral. The most productive sheet mica districts in the world are in the States of Bihar, Andhra Pradesh, and Rajasthan in India. India's large reserves and resources of sheet mica have been the primary world sources for many vears. Large reserves of sheet mica also are found in Brazil and western Africa. In the U.S.S.R., sheet mica reserves are known in the Lake Baikal and Sayan upland areas as well as in the South Eniessy Range. Smaller but substantial reserves occur in Argentina, Australia, and Zimbabwe.

Phlogopite deposits are in areas of metamorphosed sedimentary rocks intruded by masses of pegmatite-rich granitic rocks. The phlogopite is found as veins or pockets in pyroxenite interlayered with or intersecting marble or gneiss. Canada and Madagascar have the world's major reserves of phlogopite. Additional reserves are known in the Sludyanka River district and Alden area of the U.S.S.R., Sri Lanka, and Mexico.

The primary domestic source of flake mica for grinding purposes is weathered alaskite bodies and pegmatites in North Carolina, where most domestic flake mica is produced. The mica is recovered as a coproduct of feldspar and kaolin beneficiation. Flake mica is also recovered from muscovite schists. These schists bodies range in size from 3 to more than 100 meters thick and several kilometers long. The mica content ranges up to 90%. Another form of flake mica is finegrained muscovite called sericite, which is an alteration product of various aluminosilicate minerals.

World reserves and resources of scrap and flake mica are not well known but are considered to be very large. All countries with sheet mica reserves or resources have even larger quantities of scrap mica because only a small fraction of the mica present is of sheet quality. Many other countries have reserves or resources of mica that, while not of sheet quality, are suitable for grinding.

ANNUAL REVIEW

Legislation and Government Programs

The Government inventory of stockpile-grade mica remained about the same at 10,000 tons. The U.S. Department of Defense sold 25 tons of muscovite splittings, 5 tons of phlogopite splittings, and 2 tons of muscovite block, stained and better.

Strategic Considerations

Sheet mica and high-quality scrap mica used for making mica paper are important in the electronic and electrical industries. The United States is not self-sufficient in these materials and imports all its supplies, mostly from India. The U.S.S.R. and other countries with centrally planned economies are currently India's largest customers. The United

¹Less than 1/2 unit.

States and other market economy countries compete for the remaining mica, and availability is sometimes limited, particularly for high-quality mica. Long delivery times and quality inconsistency also adversely affect sheet mica availability.

In a short-supply situation during an emergency, the National Defense Stockpile (NDS) would be able to meet short-term demand until substitutes could be made available. It is unlikely that domestic sheet mica production could replace or significantly reduce imports. Of the five strategic stockpile categories, only muscovite block mica has ever been produced domestically in significant quantities, and then only under the stimulus of above-market prices paid by the Government. Domestic production in this century never provided more than a small fraction of domestic requirements.

The domestic supply of flake mica is adequate. Scrap and flake mica are not considered to be strategic materials. The United States is self-sufficient in flake mica, but does rely on imports of high-quality scrap for the manufacture of mica paper.

Production

Scrap and Flake Mica.—North Carolina remained the major producing State, with 60% of the total production. The remainder was produced in Connecticut, Georgia, New Mexico, Pennsylvania, South Carolina, and South Dakota. Most mica was recovered from mica schist, high-quality sericite schist, and as a

byproduct of kaolin, feldspar, and lithium beneficiation.³ The five largest producers were, in alphabetical order; The Feldspar Corp., Spruce Pine, NC; Franklin Mineral Products, division of Mearl Corp., Hartwell, GA; KMG Minerals Inc., Kings Mountain, NC; Lithium Corp. of America, Gastonia, NC; and Unimin Corp., Spruce Pine, NC. These five companies produced 67% of the national total.

Falconbridge Ltd., of Toronto, sold its Indusmin Div., which includes a mica mine at Spruce Pine, NC, to Unimin. The operation was subsequently acquired from Unimin by Hecla Mining Co. of Coeur d' Alene, ID.

Low-quality sericite, used primarily in brick manufacturing, is excluded from tabulated data contained in this report. In 1990, four companies, one in North Carolina and three in South Carolina, mined 23,000 tons of low-quality sericite and reported an average value of \$3.83 per ton.

Ground Mica.—Eleven companies operated 14 grinding plants in 6 States. Ten plants produced dry-ground and four produced wet-ground mica. The dry-ground mica plants of Deneen Mica Co., Micaville, NC, and J. M. Huber Corp., Kings Mountain, NC, were inactive during the year as was the wet-ground plant of Concord Mica Corp. at Penacook, NH. The five largest producers accounted for 73% of the total. They were, in alphabetical order; KMG Minerals, Kings Mountain, NC; MICA-A Franklin

Limestone Co., Santa Fe, NM; Spartan Minerals Corp., Pacolet, SC; Unimin, Spruce Pine, NC; and USG Corp., Spruce Pine, NC.

Several operations changed hands or were put up for sale during the year. Mineral Mining Corp.'s mica mine and grinding plant near Kershaw, SC, were purchased by Piedmont Mining Co. Inc. of Charlotte, NC. The operation, now a wholly owned subsidiary, was renamed Mineral Mining Co. Inc. Mineral Industrial Commodities of America Inc., Santa Fe, NM, was purchased by Franklin Industries, Nashville, TN. The mine and plant now operate as MICA-A Franklin Limestone, J. M. Huber announced plans to sell its mica operations at Kings Mountain and Spruce Pine, NC. At yearend, the facilities were still for sale.

Consumption and Uses

Sheet Mica.—Sheet mica is used principally in the electronic and electrical industries. Its usefulness in these applications stems from its unique electrical and thermal insulating properties and its mechanical properties, which allow it to be cut, punched, or stamped to close tolerances.

The largest use of block mica is as an electrical insulator in electronic equipment. High-quality block mica is also used to line the gauge glasses of high-pressure steam boilers. Transparency, flexibility, and resistance to heat and chemical attack are the properties that make mica suitable for this use. Other uses include diaphragms for oxygen-breathing equipment, marker dials for navigation compasses, optical filters, retardation plates in helium-neon lasers, pyrometers, thermal regulators, and stove windows.

Muscovite film mica is used as a dielectric in capacitors. Only high-quality mica, at or near the top of the quality scale, is used. The highest quality goes into capacitors that are to be used as standards. The next highest qualities are used for transmitting capacitors. Receiving capacitors use slightly lower quality film.

Consumption of muscovite block (ruby and nonruby) totaled 6.0 tons, a 20% decrease from that of 1989. Consumption of stained and lower-than-stained quality decreased 21%, but remained in greatest demand, accounting for 86% of consumption. About one-half of the muscovite consumed was grade No. 5 or smaller. The decrease in consumption

was a continuation of a long-term decrease in block mica use. Five companies continued to consume muscovite block and film in five plants in four States: two in North Carolina and one each in New Jersey, Ohio, and Virginia.

Splittings represent the largest part of the sheet mica industry in the United States. Muscovite and phlogopite splittings are used to make built-up mica. Consumption of mica splittings decreased 24% to 842 tons. Muscovite splittings from India accounted for nearly all of the consumption. The remainder was phlogopite splittings from Madagascar. The splittings were fabricated into various built-up mica products by nine companies operating nine plants in seven States.

Built-up Mica.—The primary use of this mica-base product, made by mechanical or hand setting of overlapping splittings and alternate layers of binders and splittings, was as electrical insulation material. Principal built-up mica products are segment plate, molding plate, flexible plate, heater plate, and tape.

Segment plate acts as insulation between the copper commutator segments of direct-current universal motors and generators. Phlogopite built-up mica is preferred because it will wear at the same rate as the copper segments. Muscovite has a greater resistance to wear, causing uneven ridges that may interfere with the operation of the generator.

Molding plate is sheet from which

V-rings are cut and stamped for use in insulating the copper segments from the steel shaft at the ends of a commutator. Molding plate is also fabricated into tubes and rings for insulation in transformers, armatures, and motor starters.

Flexible plate is used in electric motor and generator armatures, field coil insulation, and magnet and commutator core insulation. Heater plate is used where high-temperature insulation is required.

Some types of built-up mica have the bonded splittings reinforced with special paper, silk, linen, muslin, glass cloth, or plastic. These products are very flexible and are produced in wide, continuous sheets that either are shipped in rolls or cut into ribbons, tapes, or any desired dimensions.

Total production, sold or used, of builtup mica decreased 13% from that of 1989. Molding plates and segment plates were the major end products, accounting, respectively, for 35% and 33% of the total. Other end products included flexible plates, heater plates, and tapes.

Reconstituted Mica (Mica Paper).— Primary end uses for mica paper are the same as those for built-up mica. Three companies consumed scrap mica to produce mica paper. The principal source of this scrap mica was India. Manufacturing companies in 1990 were Corona Films Inc., West Townsend, MA; General Electric Co., Coshocton, OH; and US Samica Corp., Rutland, VT.

Ground Mica.—The largest domestic use of ground mica was in gypsum plasterboard joint cement. The mica acts as a filler and extender, provides a smooth consistency, improves the workability of the cement, and imparts resistance to cracking.

In the paint industry, ground mica is used as a pigment extender that also facilitates suspension, reduces checking and chalking, prevents shrinking and shearing of the paint film, increases resistance of the paint film to water penetration and weathering, and brightens the tone of colored pigments.

Ground mica is used in the well drilling industry as an additive to drilling muds. The coarsely ground mica flakes help prevent lost circulation by sealing porous sections of the drill hole.

The rubber industry uses ground mica as an inert filler and as a mold lubricant in the manufacture of molded rubber products such as tires. The plastics

¹Consists of alternating layers of binder and irregularly arranged and partly overlapped splittings.

industry uses ground mica as an extender and also as a reinforcing agent.

Ground mica is used in the production of rolled roofing and asphalt shingles, where it serves as an inert filler and surface coating to prevent sticking of adjacent surfaces. The coating is not absorbed by freshly made roofing because mica has a platy structure and is not affected by the acid in the asphalt or by weathering. Other uses include decorative coatings on wallpaper and on concrete, stucco, and tile surfaces; as an ingredient in some special greases; as a coating for cores and molds in metal casting; and as a flux coating on welding rods.

In 1990, the major end uses were joint cement, 55%; paints, 14%; and well-drilling muds, 7%.

Stocks

Reported yearend consumer stocks of sheet mica increased 23% to 668 tons; of this, mica splittings represented 95%, and mica block represented 5%.

Markets and Prices

Prices for sheet mica vary with grade and quality and can range from less than \$1 per kilogram for low-quality mica to more than \$2,000 per kilogram for the highest quality. The average values of muscovite sheet mica consumed in the United States in 1990 compared with 1989 were as follows: Block increased 15% to \$92 per kilogram, and splittings increased 14% to \$1.55 per kilogram. The average value of phlogopite block increased 18% to \$26 per kilogram, while the value of phlogopite splittings decreased 20% to \$4.43 per kilogram. The large changes in average value are more a reflection of the quality of mica consumed during the year than actual changes in price. The average value of crude flake mica, including high-quality sericite, was \$54 per ton. The average value per ton for North Carolina flake mica, predominantly a flotation product, was \$59.

Foreign Trade

The United States continued to rely on imports, mostly from India, for nearly all of its sheet mica and paper-quality scrap mica. Imports for consumption of unmanufactured block, film, and splittings

were about 1,600 tons, about the same as in 1988 and 1989, but considerably higher than in previous years. The high level of imports is a result of lower than average sales of mica from the NDS and continued decrease in domestic fabrication of mica parts. Worked mica imports remained at about 1,100 tons. About 9,000 tons of ground mica was imported, mostly from Canada, while about 4.000 tons was exported to 30 countries. The combined value of all mica imports increased 4% to \$15.6 million, while the combined value of all mica exports increased 10% to \$10.5 million.

World Review

World production of mica decreased 7% to 215,000 tons. The United States continued to lead in the production of flake mica. India continued to lead in the production of sheet mica.

India.—The Engineering Export Promotion Council (EEPC), which monitors and promotes the export of manufactured mica products, asked the Government of India to rescind the 3.5% levy on mica exports. EEPC felt that the tax, in effect since 1946, adversely affects the competitiveness of India's mica exports.4

Indonesia.—A deposit, reportedly containing about 90 million tons of mica, was discovered near Wasior in north central Irian Jaya.⁵

OUTLOOK

Demand for sheet mica has decreased dramatically during the past 30 years. For block and film mica, the major cause of decreased demand was technological change, specifically the introduction of semiconductor technology in electronics to the detriment of vacuum tube electronics that used large quantities of mica. Although the major impact of the technology change was felt in the 1960's and 1970's, consumption of block and

film mica continues to decrease, albeit more slowly. Substitute materials cause part of the decrease, and increased imports of finished electronic gear mean fewer mica parts are fabricated in the United States. Since 1979, consumption block mica has decreased at an average annual rate of about 20%. This decline is expected to continue, and, by 1995, consumption will decrease to 2,500 kilograms. Consumption of mica splittings, the major type of sheet mica consumed in the United States, also decreased sharply through the 1960's and 1970's.

During the 1980's, consumption leveled off to between 900 and 1,000 tons per year. Decreases were due to the development of substitute electrical insulating materials, miniaturization of electrical equipment, and increased imports of foreign-built products. Consumption of splittings is expected to decrease very slightly in the near future, remaining between 800 and 1,000 tons through 1995.

Scrap and flake mica enters markets as ground mica, and demand tends to follow construction activity levels. With construction activity somewhat depressed, ground mica consumption has decreased to about 100,000 tons for the past 3 years, down about 15% compared with the 1985-87 levels. Recessionary pressures are expected to ease in the near future, allowing modest increases in construction activity, which will probably bring ground mica consumption to about 120,000 tons by 1995.

The major end use, as a filler in joint compounds, will continue to account for 55% to 60% of the market. Consumption for other uses—in paints, well-drilling muds, and plastics—is expected to increase slightly by 1995.

MOLYBDENUM

By John W. Blossom

Mr. Blossom, a physical scientist/engineer with 43 years industry and Government experience, has been the commodity specialist for molybdenum since 1982. Survey and trade data were prepared by Sherwood C. Jordan, mineral data assistant; and the world production tables were prepared by Harold D. Willis, international data coordinator.

olybdenum is a refractory metallic element used principally as an alloying agent in steels, cast irons, and superalloys to enhance hardenability, strength, toughness, and wear and corrosion resistance. Primarily added in the form of molybdic oxide or ferromolybdenum, it is frequently used in combination with chromium, columbium, manganese, nickel, tungsten, or other alloy metals to achieve desired metallurgical properties. The versatility of molybdenum has ensured it a significant role in contemporary technology and industry, which increasingly require materials that are serviceable under higher stresses, greater temperature ranges, and more corrosive environments. Moreover, molybdenum finds significant usage as a refractory metal in numerous chemical applications, including catalysts, lubricants, and pigments. The variety of uses for molybdenum materials, few of which afford acceptable substitutions, has resulted in a demand that is expected to grow at a greater rate than most other ferrous metals.

Distribution of molybdenum reserves and productive capacity is concentrated in a few countries of the world. World mine output was an estimated 112 thousand metric tons (molybdenum contained in concentrate) in 1990, of which Canada, Chile, and the United States provided 80%. An estimated 10% of world output came from the U.S.S.R. These four countries, led by the United States, are expected to continue as the principal mine producers for the rest of this century. These countries also possess about 90% of the estimated 11 million metric tons of molybdenum in world reserve base.

The metric system is the official system of measurement of most countries. The U.S. Bureau of Mines, in an effort to provide statistical data on molybdenum that are consistent with international usage, will henceforth report data in kilograms and metric tons.

DOMESTIC DATA COVERAGE

Domestic production data for molybdenum are developed by the U.S. Bureau of Mines by means of three separate, voluntary surveys. These surveys are Molybdenum Ore and Concentrate, Molybdenum Concentrate and Molybdenum Products, and Molybdenum Concentrates. Surveys are sent to all operations that produce molybdenum ore and products. Out of 15 operations to which surveys were sent, all responded, representing 100% of the total United States production shown in table 1.

BACKGROUND

From the period of the Greek and Roman civilizations to the late 18th century, terms such as "molybdous" or "molybdaena" were applied to minerals that were soft and "leadlike" in character, probably including minerals now known as galena, graphite, and molybdenite. This confusion was resolved in 1778 when the Swedish chemist, Karl Scheele, demonstrated that molybdenite, the principal molybdenum mineral, was a discrete mineral sulfide. Four years later, P. J. Hielm of Sweden reduced the acid-forming oxide of the element by heating with charcoal, thereby producing an impure powder of the metal, which he named "molybdenum." Various properties of the element and its compounds were determined during the 19th century, and in 1893, German chemists produced a 96%pure metal by reducing calcium molybdate. The impure metal was reported to have been used experimentally as a substitute for tungsten in tool steels.

Molybdenum-bearing armorplate was produced in France in 1894; this was the first recorded use of the metal as an alloying element in steel. Soon thereafter, Henri

Mossiam, a French chemist, succeeded in producing a 99.98%-pure metal by reduction of molybdenum in an electric furnace. Mossiam then conducted studies to establish the element's atomic weight and to determine its physical and chemical properties. These studies stimulated interest in the metal and its compounds and investigations of commercial applications. By the late 1890's, molybdenum was used in certain chemicals and dyes, and in 1898, a self-hardening molybdenum tool steel was marketed.

The first mine production of molybdenite was probably from the Knaben Mine in southern Norway in the late 18th or early 19th century. Because essentially no commercial use for the metal existed, output from the mine remained insignificant until about 1880. By the end of the century, molybdenum ore was also mined intermittently in Australia and the United States. Molybdenite and wulfenite concentrates were produced from ores in Arizona and New Mexico, but U.S. output was small and ceased entirely in 1906 owing to lack of demand.

World War I generated the first appreciable utilizations of molybdenum, when it was substituted for tungsten in high-speed steels and used as an alloying element in certain steels for military armament. From 1912 to 1920, small output was recorded from several additional countries, and U.S. production was resumed. The flotation process for separating molybdenite from its ores was developed during these years. The Climax deposit in Colorado and the Questa deposit in New Mexico were initially exploited from 1917 to 1919. Development of the Climax deposit, the world's largest, later proved the viability of high-tonnage extraction of relatively low-grade ore and established the United States as the leading producer of molybdenum.

Output terminated in 1920 in the United States and most other countries because

nonmilitary consumption of molybdenum was insufficient to support continued production. However, industrial efforts to develop peacetime applications, primarily as an alloy in steels and cast irons, were successful, and by the mid-1920's, demand exceeded that of the war years. Operations resumed at the Climax deposit in 1924. By 1930, world output of molybdenum totaled 4.2 million pounds, of which the United States and the Climax Mine accounted for about 89% and 73%, respectively.

In 1933, the Greene Cananea Copper Co., a Mexican subsidiary of the Anaconda Co., initiated the recovery of molybdenite as a byproduct of copper mining operations. Three years later, Kennecott Corp. began byproduct recovery at its Bingham open pit in Utah. Since that time, molybdenite recovery circuits have been installed at numerous copper concentrating plants, notably in Canada, Chile, and the United States. These sources have supplied 40% to 50% of the world molybdenum output in recent years.

Since the early 1930's, industrial research and marketing programs have considerably expanded the range of metallurgical materials in which molybdenum is a preferred or essential alloy ingredient. The use of molybdenum as a refractory metal and in a variety of chemical applications has also experienced significant growth.

Definitions, Grades, and Specifications

Molybdenum is a silver-white metallic element with an atomic number of 42. atomic weight of 95.95, and a density of 10.2 grams per cubic centimeter. The chemistry of molybdenum is complex; molybdenum exhibits oxidation states from -2 to 6, coordination numbers from 4 to 8, and forms compounds with most inorganic and organic liquids. Molybdenum is a strong carbide-forming element, and much of its alloying effect in steel is imparted through the formation of carbides. It has a melting point of about 2,610° C; among the metallic elements, only osmium, rhenium, tantalum, and tungsten have higher melting points. Other significant physical properties of molybdenum metal are good thermal conductivity (about one-half that of copper), the lowest coefficient of thermal expansion of the pure metals, high strength at elevated temperatures, and resistance to corrosion in a wide variety of mediums. Molybdenum metal is stable in air or water at moderate temperatures, but above 500° C, it oxidizes readily.

Molybdenite is the principal mineral from which molybdenum is obtained. Crude ore containing molybdenite is beneficiated to produce molybdenite concentrate. The concentrate generally contains about 90% molybdenite; the grade may be somewhat lower, particularly if produced at copper byproduct concentrating plants. Technicalgrade molybdic oxide is produced by the roasting of molybdenite concentrate. Typically, the oxide has a content of 85% to 90%, or a minimum of 57% contained molybdenum. Other raw materials, including ferromolybdenum, purified molybdic oxide, ammonium, and sodium molybdate, and molybdenum metal powder are produced from technical-grade oxide. The production of these materials is described in the section entitled, "Products for Trade and Industry."

The American Society for Testing and Materials (ASTM) has developed standards for the chemical composition of molybdenum oxide products (Specification A 146-64, reapproved 1979) and ferromolybdenum (Specification A 132-74, reapproved 1979). These standards specify minimums for molybdenum content and maximums for impurity content as an aid to producers and purchasers. Material marketed by the major domestic producers generally meet or exceed ASTM standards.

Products for Trade and Industry

Some commercial-grade molybdenite concentrate is treated in additional grinding and flotation steps to produce lubricant-grade molybdenum disulfide. Oil and water are volatilized by passing an upgraded concentrate through an inert-gas-swept kiln. The oil-free product is about 99% molybdenum disulfide and suitable for use in lubricant applications.

Molybdenite concentrate is converted to technical-grade molybdic oxide, the major form of molybdenum used by industry and the base material for production of ferromolybdenum, chemicals, and molybdenum metal powder. The technical-grade oxide is produced by roasting molybdenite concentrate in the multiple-hearth furnace at temperatures of up to 650° C. Typically, the roasted product contains 90% molybdic oxide and a maximum of 0.1% sulfur. Technical-grade oxide is used to add molybdenum to steels, cast irons, and other alloys.

Ferromolybdenum is typically produced by reduction of technical-grade oxide and iron oxide with a conventional metallothermic process, using silicon and/or aluminum as the reductant. The molybdenum content ranges from 58% to 64%. Ferromolybdenum is used as a alternative additive in producing alloy steels, cast irons, and nonferrous alloys.

Ammonium molybdate is produced by reacting pure molybdic oxide with ammonium hydroxide and crystallizing out the pure molybdate. Sodium and calcium molybdate are made in a similar manner using sodium hydroxide and calcium chloride.

Molybdenum metal powder is manufactured by reducing pure molybdic oxide or ammonium molybdate with hydrogen. The purest metal powder (99.95% molybdenum minimum) is produced from ammonium molybdate. Metal powder is pressed and sintered into small metal ingots, which are converted into rod, wire, or sheet by hot rolling, swaging, or forging. Large ingots are produced by arc-casting powder under a vacuum or inert gas atmosphere.

Industry Structure

Four countries, Canada, Chile, the U.S.S.R., and the United States, mine 90% of world output of molybdenum ore. Plants to convert ore concentrates to technical-grade oxide and other molybdenum products are in Chile, the U.S.S.R, the United States, and Western Europe.

Geology-Resources

Almost all molybdenum is recovered from low-grade deposits of the mineral molybdenite. Deposits mined primarily for molybdenum provide 60% of U.S. output and about 33% of world output. The remainder is obtained mainly as a byproduct from mining of large, low-grade copper porphyry deposits. Primary molybdenum deposits generally grade 0.2% to 0.5% molybdenite; copper ores from which byproduct molybdenum is recovered contain 0.02% to 0.08% molybdenite.

The average crustal abundance of molybdenum is 1 to 2 parts per million (ppm). The molybdenum content of igneous rocks tends to increase with increasing silica content. Molybdenum does not occur in nature in its free or native state, but is found only chemically combined with other elements. Small deposits of molybdenum-bearing minerals occur throughout the world, but the only molybdenum mineral of commercial importance is molybdenite. Wulfenite, powellite, and ferrimolybdite are common but have supplied very little molybdenum.

Molybdenite (MoS_2) is a lead-gray metallic mineral that characteristically occurs in thin, tabular, commonly hexagonal plates and also disseminated as fine specks. It has a specific gravity of 4.6 to 4.7, a hardness of 1 to 1.5, a greasy feel, and it soils the fingers. Superficially, it resembles graphite, for which it commonly has been mistaken.

Molybdenum deposits are of five geological types: (1) porphyry or disseminated deposits, including stockworks and breccia pipes in which metallic sulfides are dispersed through relatively large volumes of altered and fractured rock, (2) contact-metamorphic zones and tactite bodies of silicated limestone adjacent to intrusive granitic rocks, (3) quartz veins, (4) pegmatites and aplite dikes, and (5) bedded deposits in sedimentary rocks.

The first three genetic-type deposits are hydrothermal in origin and as such represent nearly all the known molybdenum resources currently mined in the world. The remaining types do not represent a great volume of molybdenum but are of certain economic importance only when molybdenum is associated with other minerals.

In the hydrothermal deposits, metallic minerals are precipitated from high-temperature aqueous solutions either by changes in temperature and pressure or by evaporation of the liquid. Minerals are deposited in the cavities, cracks, or interstices of the matrix rock.

Most of the porphyry coppers contain small quantities of molybdenite disseminated with the copper minerals through large bodies of granitic rock. The chief minerals are chalcopyrite and chalcocite, with pyrite and small amounts of other sulfides including molybdenite.

Available information on world reserves and reserve base of molybdenum varies widely in reliability. For certain countries such as Canada, Chile, and the United States, company annual reports or other published materials enable inventorying minable ore reserves. For most other countries, reserves must be estimated from fragmentary or preliminary data on ore tonnage and grade of known or anticipated sources. In particular, the reserve figures for China and the U.S.S.R. should be considered order-of-magnitude estimates.

It should be noted that the reserve data refer to molybdenum contained in ore. The recovery of molybdenum after milling approximates 75% to 90% of the in-place ore content at primary molybdenum sources. Recoveries achieved at byproduct sources

vary markedly from mine to mine, but average an estimated 55% of the molybdenum in ore processed. Overall, an estimated 65% of the total world molybdenum reserves can be considered as recoverable.

Most of the world reserves of molybdenum occur in the western mountain regions of North and South America, extending from Alaska and British Columbia through the United States and Central America to the Andes Mountains of Chile. These regions, roughly bordering the eastern margin of the Pacific Basin, are also regarded as most promising for future discoveries and additions to reserves.

Technology

Exploration.—Prospecting and exploration for molybdenum is basically the same as that for deposits of other metals. Areas generally considered favorable for molybdenite mineralization are those metallogenic provinces that encompass known occurrences of molybdenum stockworked deposits and copper-molybdenum porphyry deposits. An understanding of regional geology, mineral associations, and known patterns of molybdenite mineralization is essential to identify potential sites for field investigation. Sites for detailed study may be selected on the basis of geologic mapping of rock units and structures, geochemical analyses of sediments and soils, and ground geophysical surveys. An intensive drilling and sampling program is then required to estimate the size, grade, and continuity of the discovery. Exploration drifts may be driven into the ore body to provide more specific geologic information and bulk samples for metallurgical testing.

The evaluation of a deposit may require 2 to 5 years from the time of discovery. During this time, the technical, economic, and environmental aspects of mine development must be evaluated. An additional 3 to 8 years may be required to prepare the deposit for production. Long development times are indicative of the complex planning and considerable capital needed to develop the large, low-grade stockwork and porphyry deposits that are expected to remain the significant sources of molybdenum. As a general rule, development of underground molybdenum deposits would require more time and capital than that of surface deposits.

Mining.—Molybdenum ore is mined by underground and open pit methods, the choice of method determined by the size,

configuration, grade, and depth of the ore body. Underground and surface operations accounted for about 40% and 60%, respectively, of the domestic molybdenum output.

Underground deposits of molybdenum ore are mined by block or panel caving methods modified to suit the characteristics of the particular ore body being worked. In these methods, large masses of ore are undercut and blasted at the base to induce the collapse and fragmentation of the ore under its own weight. The broken ore may be drawn off from the caved mass by gravity through finger raises into slusher drifts. The ore is then scraped to draw holes where it falls into ore cars on a haulage level beneath the slusher drifts. Alternatively, the broken ore may be funneled by gravity to crosscut drifts at intervals between production drifts. Ore is moved from the ends of the crosscuts along the production drifts to ore passes where it is dumped and collected in loading pockets on a deeper main haulage level. Ore is then transported from the main haulage level to the site of the initial milling operations. Caving methods are used to mine underground deposits of molybdenum because the low grade of the ore necessitates extraction of large tonnages of rock at a minimum of cost. However, caving of the ore must be carefully controlled to avoid ore dilution and excessive ground stresses to mine openings.

In open pit mining operations, the ore is exposed by removal of waste rock. The cut in the ore takes the form of benches, which vary in height and width from mine to mine. The cycle of open pit extraction consists of drilling, blasting, loading, and haulage. Primary drilling consists of driving a vertical blasting hole into the ore. Secondary drilling and blasting may be required to break large boulders. Ore is loaded by mechanical shovels into rail cars or trucks and hauled by large trucks for short distances or by train for long distances. Skipways and belt conveyors are used at some mines for transporting ore to the mill site.

Beneficiation.—Because of their low molybdenum content, all molybdenumbearing ores require beneficiation. After crushing and grinding to a suitable size, both primary molybdenite and copper sulfide ore containing molybdenite are beneficiated by flotation. With primary ores, a final concentrate of 90% to 95% molybdenite is produced by subjecting the ore to several stages of grinding and reflotation. Copper, iron, and lead minerals are generally the

critical impurities that must be minimized in the final concentrate product. Overall recovery of molybdenite at primary-ore concentrating plants ranges from 75% to 90% of the in-place ore content.

Production of molybdenite concentrate from copper ores is more difficult, however, because molybdenite constitutes less than 0.1% of the ore. As a byproduct value, molybdenite recovery is generally given less priority than recovery of copper values. In some cases, improved molybdenite recovery may be attained only at the expense of reduced copper recovery or lower grade of copper concentrate produced.

Recovery from copper ores begins with the bulk flotation of copper minerals and molybdenite as the first separation from gangue materials. Molybdenite in the bulk flotation product is then separated from the copper minerals in a selective flotation process, which usually involves the flotation of molybdenite and depression of copper minerals. The separatory flotation requires close control of pH, reagent mix, and several flotation steps. Processing of coppermolybdenum ore varies from plant to plant depending on the grade of mineralization and impurities in the ore. Concentrate produced as a byproduct contains 70% to 90% molybdenite, although most approaches the higher end of the range in content.

Recycling.—Some secondary molybdenum is recovered in the production of alloy steels, superalloys, and the metal, but data on quantities are incomplete and inconclusive. Most of this recycled material is generated and reused directly at metalforming or fabricating plants (runaround scrap) or shipped to plants that reclaim it (prompt industrial scrap). Very little molybdenum-containing obsolete scrap is processed for its molybdenum content. Although some molybdenum is recycled as a minor constituent of scrap alloy steels, the use of such scrap does not generally depend on its molybdenum content. An increasing quantity of molybdenum is being reclaimed from spent catalysts and chemical residues.

Byproducts and Coproducts

Tin, tungsten, and a very minor quantity of pyrite are recovered as byproducts from molybdenum ore at the Climax deposit in Colorado. Rhenium is extracted from flue gases and dust produced during the roasting of molybdenite concentrate that has been produced as a byproduct of copper mining.

Molybdenum is recovered as a byproduct primarily from copper ores. A very small amount is also obtained from tungsten and uranium ores. At the Sierrita Mine in Arizona, copper and molybdenum are considered coproduct values.

Substitutes

Historically, molybdenum has been a relatively inexpensive alloying agent used primarily in specialty steels and alloys, and in the United States, it has been readily available. As a result, metallurgical applications for molybdenum were broadened, and its utility as an alloy ingredient became well recognized. The substitution for molybdenum by other alloy metals has had little impetus.

Several factors mitigate the possible replacement of molybdenum to the degree that its overall demand would be significantly affected. First, there is no acceptable substitute in numerous metallurgical and chemical uses. Second, it is commonly added to steels and alloys to enhance several desired properties (such as hardenability, strength, corrosion resistance, etc.), often in synergistic effect with other alloy metals. In such cases. molybdenum could be replaced for particular effects, but at a sacrifice in overall performance. Moreover, the molybdenum content of alloy and specialty steels ranges from less than 1 to a few percent. Therefore, costs of molybdenum raw materials have to increase substantially to appreciably affect the cost of the finished product, thereby stimulating substitution. Finally, the United States is selfsufficient in molybdenum, a situation unlike that of many other ferrous metals. Significant replacement would entail increases in the imports of substituted metals.

Nevertheless, possible alternatives exist in most applications of molybdenum. Steels and alloys containing less or no molybdenum might be used in place of those with higher molybdenum content. In most cases, such substitution would result in lowered or unacceptable performance. Boron, chromium, and manganese can replace molybdenum in steels where hardenability is the only desired effect. In certain lowalloy steels, columbium, manganese, and vanadium act in similar fashion to molvbdenum. Chromium, nickel, and tungsten are possible substitutes in steels and other alloys. Molybdenum has substantially replaced tungsten in high-speed tool steels; a return to tungsten grades is possible, but with a reduction in economy and performance. Nonmetallurgical materials, such as plastics and ceramics, can replace steels and alloys containing molybdenum in certain applications.

Tungsten and tantalum can be substituted for molybdenum in certain refractory metal uses, but as a cost disadvantage. Molybdenum can be replaced by graphite for refractory elements in electric furnaces in the range of 1,000° to 1,600° C, but at the expense of slightly greater difficulty in operation and control. Chrome orange, cadmium red, and organic orange pigments are possible substitutes for molybdenum orange. Acceptable substitutes for molybdenum are not found in most of its major catalytic applications. Graphite and other solid lubricants generally do not perform as well as molybdenum disulfide, especially under high-pressure and high-temperature conditions.

Economic Factors

The prices of molybdenum products are quoted on a contained-molybdenum basis and reflect, at least partially, the cost of conversion. Technical-grade oxide, the major form of molybdenum sold commercially, varies slightly in price depending on purity, type of packaging, and whether it is briquetted.

Price quotations generally fall under two groups, the producer-marketer and the merchant. The producer-marketer mines and concentrates the ore, converts the concentrates into consumer products, and markets these products, while a merchant buys and sells concentrates and may convert concentrates into products that are marketed. The source for the merchant to buy concentrates is the byproduct producer. The byproduct producer prices his byproduct as one that provides extra credit. Therefore, this type of a producer is not likely to hold back concentrates from sale. The producer-marketer tries to keep the market balanced by setting a price-based cost plus profit and varying the output to maintain a balance.

Operating Factors

Environmental Requirements.—The mining of molybdenum ore and disposal of ore tailings disturb land areas. Land reclamation is part of the ongoing mining operation. Development of new mining and milling complexes present local socioeconomic and land-use problems. Because new potentially economic sources are likely to be found in relatively unpopulated regions with little other industry, development of a major mine can have significant impact on established occupational patterns. Interaction between mining firms and local, State, and Federal agencies are required to ensure

that mine development proceeds in as orderly and environmentally sound manner as possible. The conversion of molybdenite concentrate to technical-grade molybdic oxide involves roasting. Roasting facilities have been modified with sulfuric acid recovery equipment to reduce emissions and thereby comply with stringent environmental restrictions.

Toxicity.—Compared to other industrial metals, molybdenum exhibits very low, negligible toxicity. No significant toxic effects in human beings have been identified in mining or processing of molybdenum materials. As an environmental trace element, molybdenum is an essential micronutrient. Deficiencies of molybdenum can affect the normal growth and development of plant and animal species.

Employment.—Employment in the past decade has reduced by a factor of 5 with about the same tonnage of production. This improvement in productivity was due to changes in mining and milling equipment and methodologies.

ANNUAL REVIEW

Domestic and foreign molybdenum markets for concentrates diminished in 1990. Domestic stock levels were unchanged. U.S. mine output of molybdenum was unchanged at 55% of world production. Reported end-use consumption of molybdenum in raw materials increased by 6% from that of the previous year. Exports of all forms of molybdenum from the United States decreased, while imports of molybdenum increased. Domestic producer stocks of molybdenum products remained about the same as in the previous year. Domestic mine production of molybdenum concentrate decreased to a total of 62,000 metric tons of contained molybdenum compared with 63,000 metric tons in 1989. World mine production of molybdenum concentrate also decreased from a total of 117,000 in 1989 to 112,000 metric tons in 1990. Canada, Chile, the U.S.S.R., and the United States accounted for more than 90% of the molybdenum produced worldwide.

Consumption and Uses

Consumption of molybdenum concentrate decreased 7,000 metric tons in 1990. Domestic mine production of molybdenum concentrate was either roasted, exported for conversion, or purified to lubrication-grade

molybdenum disulfide. The quantity of concentrate roasted domestically to produce technical-grade molybdic oxide decreased from that of 1989. Oxide is the chief form of molybdenum utilized by industry, particularly in steel, cast iron, and superalloys. However, some of the material is also converted to other molybdenum products, such as ferromolybdenum, high-purity oxide, ammonium and sodium molybdate, and metal powder. Apparent U.S. consumption (defined as U.S. primary plus secondary production plus imports minus exports plus adjustments for Government and industry stock changes) was about 20,000 metric tons of molybdenum.

Stocks

Total industry stocks, which include those of producers and consumers, was unchanged at 16,000 metric tons of contained molybdenum. Inventories of molybdenum in concentrate at producer locations increased about 700 metric tons. Producer stocks of molvbdenum in consumer products, such as oxide, ferromolybdenum, molybdate, metal powders, and other types, decreased about 1,000 metric tons. Compared with apparent consumption, yearend producer stocks of these materials represented about a 10-month supply. Domestic consumer inventories of about 3,000 metric tons, the same amount as at yearend 1989, represented approximately a 2-month supply as measured by average monthly reported consumption.

Prices

The "Metals Week Dealer" (MWD) price of molybdic oxide (per kilogram of contained molybdenum) increased from \$5.78 per pound in January to \$7.04 at the end of April, decreasing to \$5.35 at the end of December 1990. The average MWD price of oxide was \$5.62 or \$1.85 less than the average MWD price in 1989.

The posted producer price (AMAX Inc. and Cyprus Minerals Co.) for molybdic oxide was \$7.38 during 1989.

Foreign Trade

Exports of molybdenum in concentrate and of oxide decreased compared with those of 1989. Molybdenum concentrate exports were about 67% of domestic mine production. Approximately 95% of reported shipments of concentrate and oxides were made to Belgium, Chile, the Federal Republic of

Germany, Japan, Mexico, the Netherlands, and the United Kingdom. The calculated molybdenum content of all exports was about 43,000 metric tons in 1990. Total value of exports decreased from \$318 million in 1989 to \$209 million in 1990.

Approximately 2,000 metric tons of molybdenum in various forms were imported into the United States, about the same as in 1989. Total value of all forms of molybdenum imported decreased from \$30 million in 1989 to \$28 million in 1990. In terms of both value and quantity, the major form imported was ferromolybdenum, principally from Chile and China.

World Review

Capacity.—The data in table 11 are rated capacity for mines and mills as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Mine capacity for molybdenum is based on published reports, production statistics, and estimates.

Reserves.—The definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification For Minerals," which is reprinted in the U.S. Bureau of Mines "Mineral Commodity Summaries, 1991."

Estimated world reserves and reserve base of molybdenum appear in table 12. The United States, with a reserve base of molybdenum estimated at 11.8 million metric tons, has 45% of the world molybdenum reserve base. About 90% of U.S. reserve occurs in large porphyry or disseminated deposits mined, or anticipated to be mined, primarily for molybdenum. These deposits are in Alaska, Colorado, Idaho, Nevada, New Mexico, and Utah. Other molybdenum sources contribute insignificantly to U.S. reserves.

Canadian reserves of primary molybdenum are in British Columbia, including 30% of the total in the Endako primary deposit. Other Canadian reserves are associated with molybdenum and copper-molybdenum

molybdenum have been identified in Central and South America. Many of these deposits are actively being explored and evaluated and could add substantially to reserves in the future.

Reserves of molybdenum in China and the U.S.S.R. are estimated to be substantial, but definitive information about the current sources of supply or prospects for future development in the two countries is lacking. Copper ores are being investigated on the islands of New Guinea and Bougainville in the southwest Pacific, but it is not known whether these contain economically recoverable molybdenum.

OUTLOOK

Capital expenditures are expected to decrease from a relatively high level of the previous year to a more normal level over the next few years. Alloy and stainless steel demand is forecast to decline in 1991. Short-term molybdenum demand is expected to remain a little below that of 1990. Molybdenum production must be adjusted to reduce inventories that have been built up in Western Europe during 1989. The long-term demand depends upon events in Eastern Europe and the U.S.S.R.'s ability to meet the needs of capital expenditures for environmental controls and to expand their manufacturing capacity.

NICKEL

By William S. Kirk

Mr. Kirk, a physical scientist with 25 years of Government experience, has been the commodity specialist for nickel since 1987. Domestic survey data were prepared by Barbara J. McNair, mineral data assistant; and international data tables were prepared by William Zajac, Chief, and Audrey Wilkes, Section of International Data.

ickel is vital to the stainless steel industry and has played a key role in the development of the chemical and aerospace industries. Furthermore, through the use of nickel, the sophisticated industrial complexes that provide our high standard of living and superior military technology and armament are made possible. Nickel's greatest value is in alloys with other elements, where it adds strength and corrosion resistance over a wide range of temperatures.

Domestic and Western World nickel demand increased, the latter for the fifth consecutive year. At 750,000 tons in 1990, Western World nickel demand also reached a record level for the fourth consecutive year. Prices remained at relatively high levels in spite of a general economic downturn. The inaugural meeting of the International Nickel Study Group was held at The Hague, the Netherlands. In another significant development, the United States signed an agreement with the U.S.S.R. that allowed the Soviets to resume exports of nickel and nickel-containing products, such as stainless steel, to the United States.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines canvassed all the known nickel consumers whose annual consumption was greater than 2 tons. Of the 197 annual forms sent, 139 responded, representing 71% of the total canvassed. Estimates for nonrespondents were derived by using their past consumption relationships and consumption trends. Reported primary consumption, based on data from monthly and annual canvass forms and estimates, was 87% of apparent primary consumption. Apparent consumption is defined as primary

nickel produced from domestic ores plus scrap recovery plus imports minus exports plus adjustments for Government and industry stock changes.

BACKGROUND

Definition, Grades, and Specifications

Primary nickel is marketed in the form of nickel cathodes, powder, briquets, pellets, ingots, and shot and in nickel oxide sinter and ferronickel. Commercial nickel in these forms usually is more than 99.5% pure, except for ferronickel and nickel oxide sinter. The ferronickel produced in the United States contains 48% to 52% nickel and is sold in 28-pound ingots; that produced in other countries contains 20% to 50% nickel. Nickel oxide sinter contains either 77% or 90% nickel.

Industry Structure

At least 27 countries produced nickel in 1990. Nickel-producing countries and companies can be grouped by deposit type; production within a country is generally from laterite or sulfide deposits. Exceptions include Australia, Brazil, and the U.S.S.R. Usually ferronickel is produced from laterite ores because of their high iron content and because these ores are more easily smelted than concentrated and refined hydrometallurgically. Refined metal is most often produced from sulfide ores. From 1985 through 1990, those countries producing from laterite ore accounted for about 34% of world mine production, with the balance coming from sulfide ores. Inco Ltd. of Canada is the largest single producing company. From 1985 through 1990, the six largest producing countries and their share of world mine production were as follows: the U.S.S.R. (29%), Canada (21%), New Caledonia (8%), Australia (8%), Indonesia (6%), and Cuba (4%).

The Sudbury area of Canada has remained one of the principal sources of nickel in the world. This area is mined by Inco and Falconbridge Ltd. Other very important nickel mining districts are the Noril'sk in the U.S.S.R. and the Kambalda district of Western Australia. The only U.S. producer is the Glenbrook Nickel Co., which operates a ferronickel smelter at Riddle, OR. Some nickel is also

produced in the United States as a byproduct of copper refining and recycling.

Geology-Resources

Nickel is the Earth's fifth most abundant element, but occurs in the Earth's crust only in the range of 0.008% to 0.02% by weight. Nickel deposits generally originate from ultramafic rocks. These are igneous rocks that are low in quartz and feldspar and high in ferromagnesian silicates. The nickel content of ultramafic rocks, although relatively high compared with that of other rocks, seldom exceeds 0.3% by weight. These values are too low to make them economically minable as nickel ore. Moreover, nickel is less likely to be found in any significant degree of concentration than are some less abundant elements, such as copper. To be rich enough to mine, some natural process must have concentrated the nickel. These processes result in the two very different major types of nickel ore.

The first deposit type is nickel laterites and is formed by the weathering of ultramafic rocks. As the rocks weather, nickel and sometimes cobalt are taken into solution by ground water and redeposited at greater depth, producing a zone of enrichment. At the base of the weathered rock, zones of enrichment may form that contain between 0.8% and 4% nickel, although the typical content is closer to 1%.

The second deposit type is nickel sulfides and is formed by the intrusion of molten ultramafic rocks or by replacement of the host rock by hydrothermal solutions. After the emplacement of a magmatic sulfide, the rock cools, and nickel and other metals combine with sulfur to form dense immiscible droplets that settle to the bottom of the magma chamber. These accumulations often form deposits rich in nickel as well as copper, cobalt, and the platinum-group metals. The world's most important and productive nickel deposit, the Sudbury deposit in Ontario, Canada, formed partly by this process. It, however, differs from most other sulfide deposits. Although Sudbury's origin is still somewhat controversial, there appears to be a consensus among geologists that its formation may have been triggered by the impact of a large meteorite.

Substitutes

With few exceptions, substitutes for nickel would result in increased cost or

some sacrifice in the economy or performance of the product. Present and potential nickel substitutes include aluminum, coated steels, and plastics in the construction and transportation industries; nickelfree specialty steels in the power generating, petrochemical, and petroleum industries; titanium and plastics in severe corrosive applications; and platinum, cobalt, and copper in catalytic uses.

Economic Factors

Prices.—Table 2 shows the time-price relationship for nickel over a 50-year span. The upward price trend in the 1970's reflected generally strong demand.

TABLE 2

¹Constant dollar price determined from gross national product implicit price deflator.

In the early 1980's, excess production capacity caused nickel prices to drop. In terms of constant dollars, nickel prices in the mid-1980's reached their lowest levels in more than 50 years. During this period, producers were forced to close at least six production facilities; some others were on the verge of failure and lost large amounts of money. Consumption, driven by stainless steel demand, rebounded dramatically in late 1987, reaching record levels for that year and each of the next 3 years. Prices soared along with demand.

Costs.—There are several significant factors that determine the cost of producing nickel. They include the type and nickel content of the ore, mining method, transportation, infrastructure, cost of energy, labor and materials, regulatory compliance, and credits from recoverable byproducts. Generally, nickel can he recovered from sulfide ores at a lower cost. Virtually all nickel laterite ores are mined by surface methods, whereas sulfide deposits are generally mined by more costly underground mining methods.

Energy used in the processing of laterite ores represents the most significant cost of recovering nickel from laterite ores. Estimates indicate that for every \$1 increase in the price of a barrel of crude oil, there is a corresponding increase of \$0.05 per pound of nickel produced for those operations that are dependent on oil for drying and smelting the ore to ferronickel or matte. Sulfide ores, on the other hand, do not have to be dried, and, unlike laterite ores, are readily amenable to concentration by established mineral dressing methods.

Revenues from byproducts can significantly reduce net production costs. Smelters that process laterite ores to ferronickel produce only iron and sometimes electrical power as byproducts. Smelters that process laterite ores using a chemical leaching method recover cobalt as a byproduct. In contrast, sulfide operations generate revenues from the recovery of byproduct copper, cobalt, and precious metals. Some sulfide facilities also profit from the sale of byproduct liquid sulfur dioxide and sulfuric acid.

The costs associated with compliance with air pollution control regulations can be significant. Dust generated in the processing of laterite ores can be controlled using relatively inexpensive equipment. In contrast, reduction of sulfur dioxide emissions from smelters processing nickel-copper sulfide concentrates represents

large capital investments. During the past 10 years, Inco Ltd., the Western World's largest nickel producer, has allocated 12% of its total capital expenditures to attain compliance with legislation limiting sulfur dioxide emissions.

ANNUAL REVIEW

Legislation and Government Programs

In an agreement that became effective on June 28, 1990, the U.S.S.R. was allowed to resume exports of its nickel and nickel-containing products, such as stainless steel, to the United States. In 1983, the U.S. Department of the Treasury banned imports of these materials from the U.S.S.R. The measure was taken to enforce the ban of importation of nickel from Cuba, based on the information that almost one-half of the total nickel production of Cuba was exported to the U.S.S.R. Most of that material was concentrate for refining to electrolytic nickel. The new agreement specified that Raznoimport, a Soviet trade organization, had to certify that exports of nickel and nickel-bearing products are exclusively of Soviet origin. Certificates of origin were to be obtained for nickel and nickel-bearing products from the Norilsk Mining and Metallurgical Plant, Norilsk, Krasnovarsk Region, U.S.S.R., and the Nickel Industrial Amalgamation, Monchegorsk, Murmansk region, U.S.S.R. At yearend, Bureau of the Census data indicated that nickel imports from the U.S.S.R. were 332,600 pounds.

In November, the Congress amended the Clean Air Act (Public Law 101-549) to require, among other things, that nickel compounds be regulated as hazardous air pollutants. As part of the new program, Congress established a list of hazardous air pollutants to be regulated. Nickel compounds, defined as unique chemical substances that contain nickel as part of their infrastructure (composition), were included. Petitions to delete specific chemicals can be submitted to the Environmental Protection Agency (EPA) for consideration. Congress instructed the EPA to regulate hazardous air pollutants by regulating the source of those pollutants. EPA must develop a list of pollution source categories by November 15, 1991. Examples of possible pollution source categories include chemical process plants. Once EPA has listed pollution sources, petitions to delete specific sources can also be submitted to EPA for consideration.

In July, the EPA published proposed drinking water standards for nickel and other materials. The maximum contaminant level goal for nickel was set at 0.1 gram per liter.

Strategic Considerations

Nickel is an essential ingredient in austenitic stainless steel and superalloys. As such, its availability is important to the national security. Domestic production capacity is less than 1% of apparent consumption. Canada, however, a close ally and a geographically secure source, is capable of supplying U.S. needs under normal circumstances.

Issues

The primary environmental problem associated with nickel production is the emission of sulfur dioxide (SO₂) from nickel smelters processing sulfide ore. The SO₂ emitted from smelter smokestacks combines with atmospheric water to form sulfuric acid (H₂SO₅), a major component of acid rain. Inco Ltd., the world's largest nickel producer, must reduce SO₂ emissions by two-thirds to 290,000 short tons per year by 1994 at its Sudbury complex to meet Ontario Provincial Government imposed limits. The company has embarked on a \$410 million program to install new technology to meet those limits. The alternative would be to reduce its production by two-thirds from 1989 levels.

Nickel producers who mine sulfide deposits have a particularly high sulfur burden compared with that of other producers of other metals such as copper. In general, in copper smelting, there is 1 ton of sulfur for each ton of copper produced; in smelting nickel, there is 8 tons of sulfur for each ton of nickel. More than 12% of Inco's capital spending during the past 10 years has been for environmental concerns.

Production

The only domestic nickel producer, Glenbrook Nickel Co., Riddle, OR, began using two new sources of feedstock for its smelter: spent catalysts and freshly mined ore. The company used spent hydrogenation catalysts containing 5% to 10% nickel. It also began mining for

the first time. The mine was on Nickel Mountain, the nearby laterite deposit that was first mined in 1955 by Glenbrook's predecessor, the Hannah Nickel Smelting Co. Until Hannah closed the smelter in 1986, Hannah screened the ore, smelting the higher nickel-content finer fraction and stockpiling the coarser fraction. When Glenbrook began smelting in August 1989, the stockpiled material was its sole source of feedstock. To supplement this source, mining was started in November 1990. According to a company spokesperson, the mine was on a section of Nickel Mountain containing ore grading 1.2% nickel; reserves were expected to be sufficient for 3 years of operation. At yearend, negotiations were underway concerning two other sections of the deposit, and plans for importing ore from New Caledonia grading 2.3% nickel were being considered. Glenbrook mined 364 tons of nickel contained in ore and produced 4,080 tons of nickel contained in ferronickel.

Black Hawk Mining Inc., Toronto, Canada, purchased and began developing a nickel-copper sulfide deposit in Warren. ME. Formerly known as the Union or Crawford Pond deposit, its name was changed to the Knox deposit. Metallurgical testing of drill cores indicated an estimated 3 million short tons of probable reserves grading 1.49% nickel, 0.69% copper, and 0.12% cobalt. The company also began a feasibility study on mine and mill design and production costs. At vearend, Maine was drafting legislation affecting mining in the State. Black Hawk was awaiting the outcome of this legislation before beginning the process of obtaining mining permits.

Consumption and Uses

Western World nickel demand increased for the fifth consecutive year and, at 750,000 tons in 1990, reached a record level for the fourth consecutive year. Domestic apparent consumption increased over that of the previous year. Both U.S. and world demand continued to be driven by the stainless steel industry, which accounts for about 45% of nickel demand in the United States and more than 60% in the world as a whole.

A 44% increase in nickel consumption for superalloys was due to a shortage of scrap rather than a significant increase in superalloy production. The superalloy scrap shortage created more demand for primary nickel and was the result of two

factors. The first factor was relatively high prices; superalloy scrap sells well when nickel prices are high. Nickel prices averaged more than \$6.00 per pound in 1988 and 1989, and this caused a depletion in supplies of superalloy scrap. The second factor was that less scrap was being generated because of near net-shape-casting procedures.

Stocks

The combined stocks of primary nickel maintained in the United States by foreign producers with U.S. sales offices and by metal-trading companies with U.S. sales offices decreased 17% during the year. At yearend, these stocks represented 14 days of domestic apparent primary consumption.

Markets and Prices

Nickel prices throughout 1990 were higher than expected by many industry observers. The average London Metal Exchange (LME) cash price for the year was \$4.02 per pound. The primary reasons were the higher than expected demand by the stainless steel sector and the decreased availability of stainless

steel scrap compounded by primary production shortfalls.

The LME nickel cash price began the year at \$3.57 per pound and rapidly fell to the year's lowest level of \$2.68 on January 23. From then the price just as quickly rose to \$4.66 in late March. LME prices remained close to the \$4.00 level from that point until early August, when uncertainty about supplies caused prices to begin rising to what would be their highest level of the year at \$5.41 in mid-September. The uncertainty was the result of a furnace explosion at P. T. Inco Indonesia, the closure of a Cuban nickel plant, and the prospect of a strike at the Inco Ltd. facility at Thompson, Manitoba. After the signing of the Inco labor agreement, the LME cash price dropped gradually, ending the year at \$3.71.

Domestic stainless steel production, at 2,039,210 tons, was slightly higher than that of 1989, which was 1,926,438 tons. Stainless steel plate shipments, however, at 206,000 tons, greatly exceeded the previous record year of 1988, which was 183,000 tons. Stainless steel plate is a flat product that is three-sixteenths of an inch or more in thickness as opposed to sheet, a flat product that is less than threesixteenths of an inch in thickness. Together, the two types of products constituted 86% of domestic stainless steel shipments. Stainless steel plate is primarily used in the capital goods sector of the economy by the chemical, paper and pulp, food processing, and other industries, while sheet is used primarily in the manufacture of products in the consumer sector, such as household appliances. Reflecting general economic conditions, shipments of sheet were 712,000 tons, about the same as in 1989. The increase in demand for plate was due to continued spending for new and refurbished plants in the pulp and paper, textile, food and beverage, chemical, and petrochemical industries.

Foreign Trade

The U.S. net import reliance as a percentage of apparent consumption was 75% because of the facts that there was little domestic primary production and virtually all primary nickel consumed in the United States was imported. Canada, as usual, supplied most of the imported nickel, including most of the nickel imported from Norway. This nickel was mined and smelted in Canada before being refined in Norway and shipped to the United States. The high level of demand for primary nickel also meant high demand for nickel-bearing scrap, both domestically and abroad. This accounted for the balance of domestic production. As a result of high prices, U.S. stainless steel scrap exports in 1990 were high. Assuming a nickel content of 7.5%, 19,260 tons of nickel contained in stainless steel scrap was exported in 1990 compared with 21,871 tons in 1989 and an average of about 15,300 tons per year for the 6 years preceding 1989.

World Review

Capacity.—The data in table 9 are rated capacity for mines, smelters, and refineries as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced in

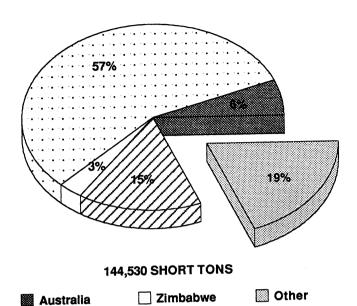

a period of time on a normally sustainable long-term operation rate, based on the physical equipment of the plant, and given acceptable operating procedures involving labor, energy, materials, and maintenance.

The inaugural meeting of the International Nickel Study Group (INSG) was held on June 25-28 in The Hague, the Netherlands, after a 10-year effort at forming the group. The 12 nations joining the INSG were: Australia, Canada, Cuba, the Federal Republic of Germany, Finland, France, Greece, Indonesia, Japan, the Netherlands, Norway, and Sweden. Countries and organizations attending as observers were: Brazil, China, Italy, The Philippines, the U.S.S.R., the United States, Zimbabwe, the General Agreement on Tariffs and Trade, the European Community, and the Nickel Development Institute. Members of the nickel production industry participated as advisors to government delegations. A special 1-day meeting of industry experts and government officials was held to discuss possible statistical systems for nickel and other work plans and priorities, such as special studies. The INSG had two primary functions; the first function was to provide transparency in the nickel market by gathering, collating, and publishing statistical data on the international nickel market. The second was to provide an intergovernmental forum for discussion of issues of concern to nickelproducing and nickel-consuming countries.

The LME approved Baltimore, MD, and Bridgeport, CT, as U.S. locations for warehouses for its nickel. At yearend, a warehouse in Baltimore had been chosen but was not operational. The LME had not yet chosen a warehouse in Bridgeport. These two locations would serve as delivery points for LME nickel.

Australia.—Outokumpu Metals & Resources Oy and Australian Consolidated Minerals Ltd. (ACM) changed their plans concerning their Mount Keith joint-venture project. The original plans had called for the simultaneous development of the mine and concentrator at the Mount Keith deposit in Western Australia and a ferronickel facility to be built in Finland to process the concentrate. Mount Keith is a sulfide deposit reportedly containing an estimated 300 million short tons of ore grading 0.06% nickel. Although this was considered a low-grade deposit, it was low in pyrrhotite, an undesirable mineral, and tests indicated that

The nickel contents are as follows: oxide sinter from Australia, 90%; elsewhere, 77%. The salts category contains the following: chemical-grade oxide, 77%; chloride, 25%; sulfate, 22%; and compounds, which are assumed to be 50% nickel. Waste and scrap is assumed to be 50% nickel and stainless steel scrap 7.5% nickel. ²Includes metallurgical-grade oxide only; chemical-grade oxide is included with salts.

Sources: Bureau of the Census and Journal of Commerce

a high-purity 20% nickel concentrate could be produced. The deposit was also amenable to open pit mining methods. The new plans called for the project to be completed in two stages, the first of which would be the development of the deposit. The development of the ferronickel facility was to be delayed; its completion would constitute stage two. In the meantime, about 18,000 short tons of nickel per year contained in concentrate was to be sent to Finland and processed to matte and refined nickel in existing facilities. An additional 10,000 tons per year of nickel in concentrate was to be sold on the world market until stage two was completed.

Western Mining Corp. (WMC) of Australia announced plans to expand its nickel production and capacity. The company's goal was to produce about 72,000

short tons of nickel contained in concentrate compared with about 51,500 tons produced in 1989. The expansion was expected to begin in 1991 and be completed in 3 years. It was to be achieved by upgrading the Leinster and Kambalda mining complexes while closing the Windarra mining complex, which was nearly depleted. Plans also called for the installation of additional equipment at the Kalgoorlie smelter and an increase in capacity at the Kwinana refinery from 38,500 short tons per year to about 46,300. WMC planned to smelt all the concentrate. Because smelter capacity was to exceed refinery capacity by about 22,000 tons per year of contained nickel, that quantity of nickel in matte would be available for sale on the open market. The excess matte was expected to be purchased by Japanese refineries. The expansion

was expected to reduce WMC's production costs.

WMC acquired a 70% interest in the Bulong deposit, a nickel and cobalt laterite prospect in Western Australia. The company planned to build a pilot plant and conduct a feasibility study.

Queensland Nickel Pty. Ltd. sought approval for the construction of a port facility at Halifax Bay, north of the company's refinery at Townsville in Queensland. Queensland Nickel planned to expand the capacity of its refinery by increasing the throughput and treating higher grade ore. To this end, the company signed agreements with P.T. Aneka Tambang of Indonesia and two New Caledonian firms to supply nickel ore for the plant. The port construction was strongly opposed by local environmentalists who were concerned about possible

damage to the Great Barrier Reef. In June, the Great Barrier Reef Marine Park Authority decided not to grant the approval.

Dominion Mining Ltd., a gold producer, was considering developing its 100%-owned Six Mile deposit near Yakabindie, Western Australia, Less than 50 miles south of Australian Consolidated Minerals' Mount Keith deposit, the Six Mile was a large, low-grade sulfide deposit containing an estimated 100 million short tons of reserves at 0.53% nickel. Dominion conducted a study that indicated that a low-impurity, 18% nickel concentrate could be produced from the ore. The concentrate could be sold to smelters and some refineries, or a roasted calcine could be produced, which could be sold to stainless steel mills.

Defiance Mining NL, based in Kalgoorlie, reportedly planned to purchase and reopen the Carr Boyd nickel mine about 50 miles northeast of Kalgoorlie.

The mine, owned by WMC, was thought to contain as much as 2 million short tons of ore at a grade of 1.5% nickel and 0.5% copper. Defiance planned to dewater and refurbish the shaft to gain access for underground mapping, sampling, and drilling.

Agip Australia Ptv. Ltd. announced its intention to develop the Radio Hill nickelcopper deposit. The deposit, about 18 miles south of Karratha in the Pilbara region of Western Australia, reportedly had estimated proven and probable reserves of 1.2 million short tons of ore grading 2.5% nickel and 1.8% copper. Production at the underground mine was expected to begin in late 1992, with an annual production of about 3,300 tons of nickel contained in matte and an expected life of 7 years. The facility was to use Isamelt technology, developed jointly by MIM Holdings and an Australian Government-owned research organization. This was to be the first time the technology was used for smelting ores other than those of lead and copper.

Canada.—Inco Ltd. announced major investment plans for its nickel production complex in Thompson, Manitoba. The plan called for the company to spend \$248 million between 1991 and 1997 to develop a new ore body and expand an existing mine. Most of the development was to focus on the new 1-D ore body. Ore from the I-D would be transported underground more than 3 miles to an existing shaft at the Thompson Mine; production from the ore body was expected to begin in 1992. By 1997, production was expected to reach an annual rate of 37 million pounds of nickel. The balance of the development was to be a 50% expansion of the Birchtree Mine, which entailed deepening its shaft. By incorporating new mining technologies and equipment, Inco expected that productivity of both the 1-D and Birchtree would be more than double that of existing Thompson mines.

¹The nickel contents are as follows: oxide sinter from Australia, 90%, elsewhere; 77%. The salts category contains the following: chemical-grade oxide, 77%; chloride, 25%; sulfate, 22%; and compounds, which are assumed to be 50% nickel. Waste and scrap is assumed to be 50% nickel and stainless steel scrap 7.5% nickel.

^eEstimated, ^rRevised,

In addition to mine development, the company would be further delineating ore reserves in the Thompson nickel belt.

The board of directors and chief executive officer of Sherritt Gordon Ltd. were replaced at a meeting called by dissident shareholders, reportedly critical of the way Sherritt had been operating. Representatives of a newly formed private company, Canada SherGor Enterprises Inc. (no relation to Sherritt), called for the meeting, its prerogative as an owner of 5% of Sherritt's stock. At the meeting held in September, shareholders, by a narrow margin, voted to replace Sherritt's board with representatives of SherGor. One of SherGor's criticisms involved the 2-month closure of Sherritt's refinery in Fort Saskatchewan, Alberta, owing to a lack of feed. The primary reason for the shortage of feed was the expiration, at the end of 1989, of Sherritt's 10-year toll refining contract with Inco that had provided the company with 60% of its feedstock.

Cuba.—The Punta Gorda nickel refinery was closed as part of a number of energy-saving measures announced by the Cuban Government. Supplies of oil from the U.S.S.R., which accounted for more than 70% of Cuba's imports, had been falling increasingly behind schedule. Because Cuba reportedly had little foreign currency with which to purchase oil

²Includes Austria, Czechoslovakia, the Federal Republic of Gernany, Poland, and Yugoslavia.

³Standby or partially standby capacity.

¹Insofar as possible, this table represents recoverable mine production of nickel. Where actual mine output is not available, data related to a more highly processed form have been used to provide an indication of the magnitude of mine output and this is noted parenthetically or by a footnote following the country name. Table includes data available through Apr. 4, 1991.

Refined nickel and nickel content of oxides and salts produced, plus recoverable nickel in exported matte and speiss.

³Reported figure.

⁴Estimates are based on metal production after deduction for nickel content of matte imported from Botswana for processing.

from Arab countries, its energy problems have been compounded by the rise in oil prices caused by the Persian Gulf crisis. Punta Gorda was one of the country's three nickel production facilities. The other two, the Moa Bay and Nicaro, were not affected by the problem. Plans for a fourth plant at Las Camariocas, which was expected to begin operations in the mid-1990's, could be delayed. The Punta Gorda plant had three production lines. each a separate unit with a nominal capacity of 11,000 short tons per year. The first line had been operating normally, and the second was just coming onstream after experiencing technical difficulties. The third line was to become operational after the second line.

Finland.—Outokumpu Metals & Resources Oy, a subsidiary of Outokumpu Oy, the Finnish state-owned nickel producer, signed an agreement with the Karelian Autonomous Soviet Socialist Republic to develop the republic's nickel-copper deposits. The agreement involves exploration work on the nickel-copper deposit in the Kivijarvi region of Soviet Karelia northeast of Aanisjarvi. The agreement primarily covered geological and ore-dressing studies. If the work led to mining, Outokumpu officials expected to receive some feed for the company's Harjavalta plant in Finland.

Outokumpu Oy began a significant increase in its production of nickel salts and oxide. This was made possible by the company's decision to continue operating the company's Hitura Mine, which the company had planned to close. Outokumpu expected to expand its annual production of salts and oxide from 2,000 to more than 5,550 short tons of contained nickel over a 3-year period.

Indonesia.—Inco Ltd. sold 20% of the ownership of its subsidiary, P.T. Inco Indonesia, to the Indonesian public, reducing Inco's share in the company to 58%.

Japan.—Sumitomo Metal Mining Co. was planning to purchase a 21% interest in Ballande, a French company, which operated a 550,000-short-ton-per-year nickel mine in New Caledonia. Sumitomo had been purchasing the mine's production of about 11,000 short tons per year of contained nickel for smelting in Japan.

New Caledonia.—Société Metallurgique le Nickel (SLN), the French nickel producer with nickel production facilities

in New Caledonia, was twice forced to declare force majeure on ferronickel shipments during the year. The first time was the result of a strike in June. The second occasion was in December after a fire at the company's Doniambo ferronickel smelter destroyed two transformers and badly damaged a third. The transformers had been supplying electrical power to one of the three furnaces. SLN quickly installed a spare transformer in an effort to prevent the melt in the furnace from solidifying and damaging the furnace itself. Damage to the furnace could have meant that it would have to be relined, a process that would put the furnace out of commission for 6 months. At yearend, the company was unsure of the extent of damage.

Philippines.—An agreement on the sale of the Nonoc Mining & Industrial Corp.'s nickel production facility to the Philippine Nickel Co. (Philnico) was signed.

U.S.S.R.—Outokumpu Oy, the Finnish nickel producer, agreed in principle to modernize the Pechenga and Monchegorsk nickel complexes in the Kola Peninsula near the Finnish border. The renovation of both smelters was to begin in 1991 and be completed in 1994. The introduction of Outokumpu flash smelting technology was expected to reduce sulfur dioxide emissions from the Kola Peninsula to a very small proportion of 1990 levels. It was not anticipated that the renovation would have a significant impact on nickel production.

The Norilsk Combine, the U.S.S.R.'s major nickel-producing organization, severed relations with Raznoimport, the Soviet state trading organization that once controlled all or most nickel sales from the country. The Norilsk Combine included the Norilsk nickel production complex in the eastern part of the country as well as the Pechenga and Monchegorsk nickel production complexes. Thus, Norilsk then controlled the sale of close to 90% of Soviet nickel production. Norilsk was also recognized by the LME, which had previously accepted Soviet nickel registered only under the Raznoimport name.

The Soviets sought western help in reclaiming nickel and other metals from slag. There are more than 440 million short tons of slag from which nickel, cobalt, molybdenum, and vanadium could be recovered. Some of these slags had a metal content higher than some

of the ores then being mined in the U.S.S.R.

Current Research

The International Committee on Nickel Carcinogenesis in Man published a study intended to clarify the nature and extent of the risks that nickel and its compounds pose to humans. 1 Called the Doll Committee, after its chairman, Sir Richard Doll of Oxford University, the committee's conclusions were based on an analysis of various epidemiological studies of nickel-exposed individuals in workplace settings. The results showed that, in general, although nickel caused some allergic reaction in some individuals, it was found to be nontoxic. The study was sponsored, among others, by the U.S. EPA.

Researchers at the Department of Energy facility at Oak Ridge, TN, developed a process for recycling chemicals used in electroless nickel plating.² As the name implies, electroless nickel plating does not use electrodes or electricity. Instead, parts are placed in a chemical bath, and chemical reactions cause the nickel to he plated onto the surface of the parts. As the plating progresses, however, the bath accumulates impurities that eventually render the bath ineffective. The new process removed these impurities by using a combination of ion exchange and selective chemical precipitation. The advantages of the process were (1) impurities that formerly had to be disposed of as hazardous material could be removed in a way that was environmentally safe (in fact, they could be used as fertilizers), (2) nickel and other valuable constituents could be returned to the bath, and (3) the amount of downtime for the bath was much reduced. The process was expected to be licensed for commercial development. The process had potential to make nickel plating more electroless competitive.

A method for reclaiming the nickel contained in nickel-cadmium batteries was developed by Dutch scientists.³ The new energy-efficient method involved the use of acid and solvents to recover 60% of the nickel and more than 99% of the cadmium, a toxic metal. Nickel was reported to be recovered as ferronickel suitable for use by the steel industry.

A new stainless steel, developed in Japan for use in lining smokestacks and flues, offered outstanding resistance to sulfuric acid corrosion.⁴ Designated as

eEstimated. Revised.

YUS 260 and jointly developed by Nippon Steel Corp. and Mitsubishi Heavy Industries Ltd., the steel was said to be 10 times more corrosion resistant than conventional materials.

A nickel-metal hydrides (NIMH) rechargeable battery was developed and was expected to be produced in Japan. The battery could be charged in the same charger as that used by conventional nickel-cadmium batteries. The NIMH battery, however, had about twice the energy density of the nickel-cadmium battery. The new battery was expected to be used in portable personal computers, audio and video equipment, and power tools.

A method for joining stainless steel pipe for use in plumbing was developed in Europe.⁶ The use of stainless steel pipes for domestic water plumbing was first tried about 25 years ago. Conventional techniques, at the time, failed to provide a suitable joint. The new method

uses an electromechanical pressing tool that compresses beaded ends of couplings that contain "O" ring seals. Because the stainless steel pipes are unaffected by chemicals in drinking water, they eliminate contamination.

OUTLOOK

In the short- to mid-term (1991–92), the downturn in the world economy that existed in 1990 and early 1991 will probably result in nickel consumption that is lower than that of 1990. In relative terms, however, demand will still be reasonably strong, as 1990 marked the fourth consecutive year of record consumption. Nickel consumption in stainless steel plate, the bright spot in the 1990 stainless steel picture, is expected to slow as growth in the capital goods sector becomes sluggish. The supply and demand

are expected to be in balance for the first time since 1986.

In the long-term (1992-1995), nickel consumption is expected to increase. Stainless steel accounts for more than 60% of total world nickel demand and is of overwhelming importance in determining changes in the level of overall nickel consumption. Western World stainless steel demand grew at an average annual rate of 5.7% between 1960 and 1988. In light of this, a forecast of 3% to 4% average annual growth in the 1990's seems reasonable. Moreover, the austenitic grades' (nickel-bearing) share of stainless steel production during the same period grew from 65% to 75%. There are, then, two long-term trends in the largest end-use sector. One trend is toward greater production of the product, and the other is toward the use of more nickel in the product. Also, world consumption of stainless steel, as seen in terms of intensity of use, has shown a

¹Table includes data available through Apr. 4, 1991.

²In addition to the countries listed, North Korea is believed to have produced metallic nickel and/or ferronickel, but information is inadequate to make reliable estimates of output levels. Several countries produce nickel-containing matte, but output of nickel in such materials has been excluded from this table in order to avoid double countring. Countries producing matte include the following, with output indicated in short tons of contained nickel: Australia: 1986—54,078; 1988—52,028; 1988—50,000 (estimated); 1989—50,000 (estimated); and 1990—50,000 (estimated); Botswana: 1986—20,915; 1987—18,219; 1988—24,845; 1989—21,781; and 1990—21,500 (estimated); Canada: 1986—63,691; 1987—62,344; 1988—63,607; 1989—48,854; and 1990—47,700 (estimated); Indonesia: 1986—30,837; 1987—29,220; 1988—31,817; 1989—32,000; and 1990—29,873; and New Caledonia: 1986—10,097; 1987—9,130; 1988—11,541; 1989—11,750; and 1990—10,674.

³Brazil is believed to also produce nickel oxide, but information is not available on which to base estimates.

⁴Cuba also produces processed nickel sulfide, but it is not included to avoid double counting. Output of processed sulfide was as follows, in short tons: 1986—18,240; 1987—18,300; 1988—20,188 (revised); 1989—20,365; and 1990—18,100 (estimated).

⁵Reported figure.

steady increase. For example, in the United States, intensity of use, defined as consumption divided by gross domestic product, more than doubled from 1950 to 1990.

Another large use of nickel in the United States is in superalloys, which are used in jet turbine engines. There are record numbers of orders for civil aircraft as air traffic steadily increases and aging fleets are replaced. Nickel demand in this application through 1992 may be flat, but should recover afterward. Long-term consumption should grow at an average annual rate of about 2%, primarily as a result of stainless steel demand. U.S. consumption should increase at about the same rate as the result of demand from the stainless steel and superalloy sectors. The fastest growth should be in the Far East. Recent events in Eastern Europe. after which these countries began moving toward market-based economies, could have a profound effect on nickel consumption. Pent-up consumer demand could cause the region to become a major stainless steel consumer. Consumption is expected to rise faster in the Far East and

in Eastern Europe than in the rest of the world.

The production of electric cars using some type of nickel battery may have a significant impact on consumption in the future. California mandated that in 1998, 2% of the cars sold in the State have zero tailpipe emissions; that figure would rise to 10% in the year 2003.⁷ Only electric vehicles meet this standard. California, with sales of 2 million cars per year, constitutes the largest market in the United States. U.S. and Japanese automakers have been developing electric cars. Two of the types of batteries that could be used in these vehicles are nickel-iron and nickel-cadmium.

NITROGEN

By Raymond L. Cantrell

In June 1988, Mr. Cantrell entered public service with the U.S. Bureau of Mines in the capacity of physical scientist, chemical materials specialist. He was previously affiliated with W.R. Grace & Co., Hasbro Industries, and Columbia Nitrogen Corp. Domestic survey data were prepared by Tonya Hardin, mineral data assistant; and international data tables were prepared by Virginia Woodson, international data coordinator.

itrogen is an absolute requirement for all life forms on Earth. The gas cycles between its inert diatomic form (N₂) in the atmosphere and chemically fixed forms on Earth, weaving an intricate balance with the carbon cycle that is driven by the photosynthesis processes of living plants. Plants absorb carbon dioxide from the atmosphere, synthesize carbohydrates and essential amino acids and proteins (nitrogen forms), and emit oxygen, all prerequisite to life. The microorganisms of the rhizosphere topsoil supply available mineral nitrogen to nonleguminous plants and biological nitrogen to leguminious (nitrogen fixing) plants for human and animal nutrition.

Elemental nitrogen gas and liquid (N_2) , together with synthetic anhydrous ammonia (NH₃)—a derivative of atmospheric nitrogen and fossil fuels—form the base for an enormous global agricultural and industrial sector. Elemental nitrogen is used extensively by the electronics, metals, food, and aerospace industries because of its unique inert and cryogenic properties. Nitrogen contained in anhydrous ammonia and its downstream fertilizer derivatives provides more than 50% of the world's essential plant nutrient demand. In the industrial sector, anhydrous ammonia derivatives are important for the production of synthetic fibers, resins and polymers, explosives, animal feeds, and an enormous array of inorganic and organic compounds.

In 1990, U.S. elemental nitrogen sales amounted to an impressive \$0.8 billion and were expected to rise to about \$1.1 billion (38%) by 1994.¹

The U.S. agricultural nitrogen and industrial chemical sectors also experienced a good year in 1990. Ammonia producers operated at near capacity (17 million tons), the nitrogen trade deficit declined 20% to 1.3 million tons N, and net cash

farm income reached a record \$59 billion. Natural gas feedstock for ammonia production was available at reasonable prices. Shipments of U.S. nitrogen fertilizer materials exceeded \$4 billion.

Anhydrous ammonia facilities in 66 countries produced approximately 131 million short tons that was valued at about \$13 billion. World ammonia production declined by a net 1.3 million tons in 1990 owing to economic pressures accompanying sweeping political reform in the Eastern bloc, together with the Persian Gulf crisis prompted by Iraq's invasion of Kuwait in early August. There

was a significant runup in global fertilizer and petroleum prices during the fourth quarter of 1990 as a result of the Gulf crisis.

DOMESTIC DATA COVERAGE

Industry statistics for anhydrous ammonia and derivative products were developed by the Bureau of the Census, U.S. Department of Commerce. Preliminary monthly data were published under

TABLE 1
SALIENT AMMONIA STATISTICS¹

(Thousand short tons of contained nitrogen unless otherwise specified)

product codes 28731, 28732, and 28742 in Current Industrial Reports (CIR), Fertilizer Materials, M28B. Final monthly data are subsequently published in a companion annual report MA28B. During 1990, the Bureau of the Census surveyed approximately 250 known producers of inorganic fertilizer materials. Production data are shown in table 1.

Statistics covering industrial gases were reported in the Bureau of the Census CIR publications M28C and MA28C, Industrial Gases.

BACKGROUND

Nitrogen chemical matter developed as part of our solar system about 5 billion years ago, according to astrophysics. About 4 billion years ago, volcanic activity was believed to have belched gases from the bowels of primordial Earth, forming the nucleus for the nitrogen-rich atmosphere as we know it today. Nitrogen was discovered independently in 1772 by the Swedish druggist, Carl Scheele, and the Scotch botanist, Daniel Rutherford.²

Planet Earth is enveloped by an atmosphere dominated by nitrogen (N₂), oxygen (O₂), and water vapor (H₂O), above which lies a delicately thin layer of protective ozone (O₃) that screens harmful ultraviolet radiation. Trace gases in the atmosphere such as carbon dioxide (CO₂) absorb much more radiant energy than they release, providing the additional warmth necessary for our habitation of the planet.

The air we breathe consists of about 78% N_2 and about 21% O_2 by volume; argon makes up most of the remainder. Trace amounts of helium, hydrogen, krypton, neon, and xenon are natural atmospheric sources, together with the greenhouse gases—global warming gases—carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O). Fossil fuel combustion has been responsible for a significant buildup in atmospheric CO_2 during the 20th century.

At the turn of the century, natural sources of nitrogen chemical materials supplied virtually all of the nutrient requirements for agricultural crop production. Mineralized organic soil nitrogen, domestic animal manures and byproducts, guano, seed meals, and coke oven ammonia predominated. The mineralized

occurrences of sodium nitrate found in the Atacama Desert of northern Chile also provided strategic supplies of agricultural nitrogen to the global community.

In the late-1800's, agronomists warned that a global food crisis would materialize unless supplemental nitrogen forms could be found to increase crop production for the exploding world population. Scientific ingenuity prevailed, as four major industrial nitrogen fixation technologies evolved between 1900 and 1920: (1) the electric arc process, developed by Birkeland and Eyde in Norway, produced nitric oxide (NO) from atmospheric nitrogen and oxygen that was used to produce nitric acid (HNO₃); (2) the cyanamide process, discovered by Frank and Caro in Germany, synthesized calcium cyanamide $(CaCN_2)$ from calcium carbide (CaC_2) and N_2 ; (3) the cyanide process, developed by Bucher of Brown University in Rhode Island, produced sodium cyanide (NaCN) from N₂ and sodium carbonate (Na₂CO₃) as an intermediate to ammonia production; and, (4) the ammonia process, developed by Haber and Bosch in Germany, reacted N₂ and hydrogen (H₂) under high temperatures and pressures in the presence of a catalyst to form ammonia (NH₃).

The Haber-Bosch process overshadowed all other industrial methods for producing nitrogen chemical materials and fostered today's mammoth ammoniabased nitrogen fertilizer and industrial sectors.

Definitions, Grades, and Specifications³

At ordinary ambient temperature and pressure, anhydrous ammonia is a colorless gas with a very sharp, characteristic odor. Ammonia condenses to a liquid at minus 28° F. Anhydrous ammonia is not a poison and has no cumulative toxic effects on the human body. It, however, is corrosive and may cause minor lung, throat, mouth, nose, and eve irritation. When liquid anhydrous ammonia comes into direct contact with the skin, a severe burn may result. Anhydrous ammonia is not combustible except when its concentration in the air falls between 16% to 25% at temperatures in excess of 1,560°F.

Ammonia vapor becomes "life threatening" only when exposure levels reach 2,500 to 6,500 parts per million for up to 30 minutes or "rapidly fatal" if exposure levels reach 5,000- to 10,000 part per

million concentrations for up to 30 minutes. Goggles, respirators, gloves, other protective body gear, and plenty of water—in cases of personal exposure or spills—should be readily available when working with ammonia. Steel is the only acceptable metal allowed in the process of transfer, storage, and transport of anhydrous ammonia.

Technology

Elemental nitrogen is mined from the air by cryogenic separation and membrane technologies. In a typical air separation plant, liquefied air is separated into its individual components by fractional distillation. The resources of nitrogen in the air are virtually unlimited and renewable because of the continuous nitrogen cycle between fixed forms on Earth and atmospheric nitrogen.

Mining.—Mineralized occurrences of sodium nitrate (NaNO₃) and potassium nitrate (KNO₃) are mined in significant quantities in the Atacama Desert of northern Chile. The extremely arid nature of this region with its paucity of soil microorganisms creates an ideal environment for preserving the nitrate deposits that formed in Miocene times. The nitrate content of the deposits range from about 6.5% to 50%, with an estimated reserve base of about 2.5 billion tons.

Product grades of sodium nitrate and sodium nitrate-potassium nitrate mixtures are obtained through selective precipitation and filtering, followed by granulation. In 1990, Sociedad Quimica y Minera de Chile S.A. (SQM) produced more than 1 million tons of granular sodium nitrate and mixed potassium products for fertilizer and industrial use.4 SQM's principal product line, in order of importance. included sodium nitrate (16% N) and homogeneous chemical mixtures of sodium nitrate and potassium nitrate containing 15% N and 14% potash (K_2O). Sodium nitrate was also blended with potash to produce a mixed fertilizer containing 13% N and 44% K_2O .

Processing.—Anhydrous ammonia is typically produced through a sequence of catalytically driven reactions involving the steam reforming of natural gas in the presence of air to produce hydrogen and nitrogen in the proper ratio to effect ammonia synthesis. The latest state-of-the-art plants operate at less than 25 million British thermal units (Btu) per ton,

resulting in an energy efficiency of more than 70%.

Modern ammonia plants employ efficient centrifugal compressors for air and synthesis gas compression. Temperatures and pressures fluctuate throughout an ammonia plant depending on the process, but typically vary between 600° to 1,800° F and 500 to 3,000 pounds per square inch gauge, respectively. A nickel catalyst is used in the reformer and associated front-end sections of the plant, while an iron-promoted catalyst is used for ammonia synthesis.

Urea is formed when ammonia is reacted with byproduct carbon dioxide (CO₂) generated during ammonia synthesis. The materials are reacted under high pressure in a two-step reaction at about 400° F to first form ammonium carbamate, which then decomposes to urea (NH₂CONH₂).

Nitric acid is formed when ammonia is passed over a platinum-rhodium catalyst at about 1,700° F and 120 pounds per square inch gauge. As ammonia passes over the catalyst gauze, it reacts with oxygen to form nitric oxide (NO), which is converted to nitric acid by mixing with water in a countercurrent absorption tower. Ammonium nitrate, in turn, is formed by the simple acid-base reaction between ammonia and nitric acid.

Economic Factors

The data of table 2 reflect long-term price trends for U.S. ammonia and natural gas over a period of 21 years (1970–90). The ratio of ammonia prices to natural gas feedstock prices provides a measure of ammonia's relative price sensitivity to changing feedstock costs. This relationship, however, does not give an accurate account of the impact of market forces and improvements in production efficiency on indicative profitability in the U.S. ammonia market. Between 1970 and the early-1980's, natural gas prices rose dramatically, and ammonia production costs became much more sensitive to feedstock costs. Feedstock costs as a percentage of total production costs rose precipitiously. from 45% in 1970 to 75% by 1982. Natural gas prices have declined since 1985, and feedstock costs now represent about 70% of total production costs.

The U.S. ammonia industry experienced record profitability during 1974–75 because of a tight global supply situation, in spite of the rising dependency on feedstock costs; a similar situation developed

during 1979-81. Conversely, the U.S. ammonia industry suffered substantial losses in 1986-87 owing to a significant downturn in global agriculture. In 1990, the U.S. ammonia industry returned to respectable profit margins.

On April 3, 1990, the New York Mercantile Association (NYMEX) established natural gas futures trading in the United States. Natural gas futures trading was designed to allow suppliers, producers, and end users to shift or hedge price risks. NYMEX believed that natural gas futures contracts would provide the same liquidity, unambiguous price reference, and hedge against risk characterized by its successful petroleum contract system. Futures prices reflected price stability in the U.S. natural gas market for the coming year.

ANNUAL REVIEW

Legislation and Government Programs

The Food, Agriculture, Conservation, and Trade Act of 1990, Public Law 101-624, signed on November 28, 1990,⁵ and called the "1990 farm bill," extended many of the highly successful program initiatives of the 1985 bill. It created the "triple base flexibility" initiative that gave farmers more freedom to make planting decisions.

Under triple base, farmers lost Government subsidizies on 15% of their base acreage but gained the flexibility to plant virtually any crop except fruits and vegetables on this land and still receive

Government price support loans. The triple base initiative provided the impetus for a \$13 billion reduction in Government "entitlement" farm program spending over a 5-year period as prescribed by the Omnibus Budget Reconciliation Act of 1990 (Public Law 101-508), signed on November 5, 1990.6

Farmers were also given the opportunity to hedge an additional 10% of program acreage to alternate crops at the risk of lost deficiency payments. Target prices were frozen at 1990 levels. The target price—expected price for the crop—sets the upper limit for deficiency payments—the lower of the two values calculated between target prices and actual market prices or loan rates.

The 1990 farm bill was one of the most environmentally progressive farm bills ever signed. The Environmental Conservation Acreage Reserve Program (ECARP) broadened the 1985 Conservation Reserve Program (CRP) provisions to divert up to 1 million acres of cropland to "wetlands reserve" in adverse waterquality areas. Total ECARP program acreage was required to increase from the current 34 million acres to 40 to 45 million acres by 1995.

Other environmental programs adopted, subject to appropriations, included the Agricultural Water Quality Protection Program (AWQPP)—a 10-million-acre voluntary incentive program designed to promote the efficient use of crop nutrients and pesticides and ensure safe storage, mixing, and handling of agricultural chemicals and animal wastes—and the Environmental Easement Program (EEP)—designed to create easements for long-term protection of environmentally sensitive lands through an approved natural resource management plan.

Forestry provisions in the new farm bill supported the President's "America the Beautiful Initiative" that challenged Americans to plant 1 billion trees annually.

The Clean Air Act of 1990 (Public Law 101-549), signed on November 15, 1990,⁷ was the most comprehensive air pollution legislation passed in our Nation's history. The massive clean air bill contained 11 titles that targeted 3 principal forms of pollution: acid rain, smog, and toxic air pollutants. In total, about 30 million tons per year of hazardous chemicals and noxious pollutants was to be removed from the air.

Provisions were also incorporated for Stratospheric Ozone Protection (title VI), "renewable biomass energy and energy conservation incentives" under title VIII, and Clean Air Research (title IX). The National Energy Strategy report was issued by the Department of Energy (DOE) in early 1991 to provide guidance in implementing the new clean air bill, pursuant to the President's directive of mid-1989.8

Acid rain is caused primarily by sulfur dioxide (SO₂) and nitrogen oxide (NOx) emissions from coal-fired electrical power-plants. Under title IV, SO₂ emissions were slated to decline 10 million tons from 1980 levels by the year 2000, and NOx emissions were to be cut by 2 million tons.

Smog results when motor vehicle tailpipe exhaust gases, NOx and volatile organic compounds (VOC's), react photochemically. According to recent estimates, motor vehicles nationwide are responsible for about 45% of NOx emissions and 34% of nonmethane VOC emissions. Motor vehicle emissions are also reported to cause about 70% of total carbon monoxide (CO) pollution and generate about 18% of the Nation's particulate emissions and 40% of the total lead pollution.⁹

Under title II, reductions in vehicular NOx and VOC emissions of 60% and 35%, respectively, will be required by 1996. CO emissions standards will also be effected at the same time. Tighter emissions standards for trucks and buses and reduced CO emissions during the cold starting of cars are also included.

To meet the objectives of title II, gasolines will be reformulated and oxygenated as prescribed in section 219. The 2%-byweight minimum oxygen content requirement will likely be met by a methyl tertiary butyl ether (MTBE) additive—a methanol-butane derivative—and to a lesser extent by ethanol, formulated in a 10%-by-volume blend with gasoline to produce "gasohol." Ethyl tertiary butyl ether (ETBE), an ethanol derivative, may also become a significant oxygenated fuel additive. Tax incentives for ethanol production and blending were renewed in the 1990 Budget Reconciliation bill to encourage its use. Between 1994 and the year 2000, MTBE demand was projected to rise 175% to 5.5 billion gallons and ethanol to 2.5 billion gallons (67%).¹⁰

Under title II, section 241, provisions were made for "clean alternative fuels"

motor vehicle fleets that would be designed to run on liquefied natural gas, methanol, ethanol, hydrogen, and electricity.

Toxic air pollutants are released into the air in significant quantities, about 1.3 million tons annually, during chemical manufacture, petroleum refining, mining and processing, and solid waste combustion. Under title III, a list of 190 hazardous chemicals and materials was established for regulation with the requirement that maximum achievable control technology (MACT) be applied to industries emitting major sources of air toxics. Title III contained provisions that would reduce toxic air emissions by more than 75%.

Several important industrial nitrogencontaining compounds were on the list, including acrylonitrile, aniline, caprolactam, ethyl carbamate (urethane), hydrazine, coke oven byproducts, and cyanides. Ammonia and its downstream fertilizer derivatives were excluded from the list.

Issues

The U.S. Department of Commerce, Bureau of the Census, announced that publication of the strategic fertilizer and industrial chemical reports—CIR series M28A, M28B, and M28C—might be discontinued because of budget restrictions. After receiving a significant public response in favor of preserving the publications, the Bureau of the Census elected to publish the reports on a quarterly basis, effective January 1, 1991.¹¹

After years of data gathering and analysis, the Environmental Protection Agency (EPA) released its National Drinking Water Well survey on November 13, 1990. The study, a survey of community and rural drinking water wells for pesticide and nitrate presence, found nitrate in amounts above EPA's 10 parts per million maximum in less than 3% of the wells.

The Fertilizer Institute (TFI) reported that EPA's study might surprise some environmental groups that sought sweeping reforms in farm practices to protect ground water. TFI referenced several States that had already conducted indepth studies indicating that nitrate occurrence above a natural level was usually due to factors other than fertilizer use, either poorly constructed wells or other point sources.

EPA released the preliminary results of its 1989 Toxics Release Inventory

(TRI), which indicated that 22,650 industrial facilities released about 3 million tons of toxic chemicals into the Nation's environment. The report found that between 1987 and 1989, TRI chemicals decreased by a favorable 18%.

In 1989, a total of approximately 200,000 tons of ammonia was released into the air (61%) and water (6%), injected into underground wells (17%), delivered to municipal waste treatment plants (14%), and disposed of in landfills (2%).

Between 1987 and 1989, ammonia losses to the atmosphere declined by a favorable 18%, and discharges into rivers, lakes, streams, and other bodies of water declined 25%. Ammonia processed through municipal waste treatment plants rose 14%, and underground injection disposal methods increased 17%.

Production

In 1990, the U.S. ammonia industry ran at an impressive 98% of rated capacity. Thirty-three firms in 23 States produced 17 million short tons of anhydrous ammonia (82.2% N) an increase of 4% over that of the prior year. Louisiana, Oklahoma, and Texas, in order of importance, provided about 60% of total U.S. production; the Midwest, South, and Southeast, 30%; and the Western States and Alaska, 10%. Anhydrous ammonia production was buoyed by a good crop year, a reduction in the trade deficit, field inventory drawdowns, and a tight global supply situtation that developed in the fall because of the Persian Gulf crisis and Eastern bloc restructuring. Natural gas feedstock was reasonably priced.

About 90% of U.S. ammonia production was for fertilizer products and about 10% went into industrial products. Major downstream ammonia fertilizer derivatives included urea (46% N), diammonium phosphate (18% N), ammonium nitrate (35% N), and ammonium sulfate (21% N). Important industrial chemical derivatives were urea, ammonium nitrate, nitric acid (22% N), acrylonitrile (26% N), and caprolactam (12% N).

Mississippi Chemical Corp. (MCC) was operating ammonia, nitric acid, ammonium nitrate, urea, and urea-ammonium nitrate (UAN) solutions plants at Yazoo City, MS, that provided nitrogen products to 10 principal States in the South, Southwest, and Midwest. MCC's featured product was AMTRATE, a superior ammonium nitrate prill containing

34% available nitrogen. AMTRATE prills remain free-flowing even when handled under hot, humid conditions owing to MCC's recently developed proprietary technology. The construction of a new 200,000-ton-per-year nitric acid plant scheduled on-stream in late-1992 will increase AMTRATE output. N-sol 32, a UAN solution containing 32% N, was also a featured product. MCC holds a 50% interest in Triad Chemical, a major urea production complex at Donaldsonville, LA.

In February, Freeport-McMoRan Resource Partners (FRP) sold its Agrico Div. nitrogen fertilizer facilities at Verdigris, OK, and Blytheville, AR, and certain fertilizer terminal facilities for \$230 million. Agricultural Minerals Corp. (AMC) was formed to purchase the plants in a leveraged buyout. AMC assumed control of the Verdigris, OK, and Blytheville, AR, plants effective March 1 and planned to establish headquarters in Tulsa, OK.

Ammonia, urea, and UAN solutions are the primary products produced by AMC, along with the highly efficient slow-release Super N fertilizers containing dicyandiamide. AMC ranked second in U.S. UAN capacity, fourth in ammonia capacity, and fifth in terms of urea capacity.

In June, Freeport's Agrico Div. sold its 25% interest in Namhae Chemical, a nitrogen and phosphate fertilizer facility in the Republic of Korea, for \$80 million. 13

In October, the W. R. Grace Agricultural Chemicals Group in Memphis, TN, signed a letter of intent to sell ammonia interests at Point Lisas, Trinidad, to Norsk Hydro a.s. of Norway. Included in the sale were Grace's wholly owned Federation Chemicals Ltd. ammonia plant (255,000 annual tons) and a 49% share in Trinidad Nitrogen Co. Ltd., a joint venture with the Government of Trinidad and Tobago in two ammonia plants (Tringen I & II), having a combined annual capacity of 920,000 tons. The sale was finalized in late December.

Grace also transferred ownership of its U.S.-based marketing operations and shipping interests that were linked to the output of the Trinidad facilities. Hydro Agri Ammonia, Inc. (HAAI), a U.S. affiliate of Norsk Hydro, was established in Tampa, FL, for this purpose. HAAI was staffed by key personnel from the former Grace marketing team in Memphis, TN.

In late 1990, Chevron Chemical Co. announced plans to divest its fertilizer divisions, including active nitrogen production facilities in California, Oregon, and Washington State. Industry sources reported that Chevron's idle ammonia plant at Pascagoula, MS, (530,000 annual tons) would be dismantled and moved to Pakistan. A 400,000-ton-per-year diammonium phosphate (DAP) complex brought on-stream at Rock Springs, WY, in mid-1986 was also for sale.

Cargill Fertilizer of Minneapolis, MN, was building a C\$430 million nitrogen fertilizer complex—the Saferco project—in Belle Plaine, Saskatchewan, through a joint venture between its Canadian subsidiary, Cargill Ltd., and the Crown Investments Corp. of the Province of Sasketchewan. Construction was 9% complete by yearend. The plant was scheduled for completion in the fall of 1992 and was designed to produce 560,000 tons per year of ammonia and 750,000 tons per year of urea.

CF Industries was planning to expand urea and nitric acid capacity at its Donaldsonville, LA, nitrogen fertilizer complex. CF's Donaldsonville ammonia plants were capable of operating at 2 million tons per year, 120% of design capacity, because of recent revamp and retrofit initiatives. The planned expansions would lead to further improvements in the cooperative's competitive economics.

Coastal Chem, Inc. planned a 175,000-ton-per-year ammonia expansion by late 1992 at Cheyenne, WY, based on the reconstruction of a plant to be moved from Arcadian's Augusta, GA, complex. Coastal was constructing a 130,000-ton-per-year nitric acid plant at Elko, WY, that would be used to produce ammonium nitrate-base explosives. BP Chemicals announced a \$17 million 90,000-ton-per-year nitric acid replacement/expansion at Lima, OH, that was scheduled on-stream in late 1992.

The former Big River ammonia complex at Helena, AR, was purchased by an investment consortium in bankruptcy proceedings during 1989 and renamed Five Rivers. The plant was subsequently closed in mid-1990 owing to a lack of reliable power sources and equipment failures. Ownership was transferred to the original lending institution, the Dutchowned bank NMB, which contracted with the Royster Co. to operate a new enterprise called Nitrogen Products, Inc. A 210,000-ton-per-year ammonia plant was to be revamped and on-stream by late December 1990.

In August, Diamond Shamrock acquired the Center Plains ammonia facility at Dumas, TX, in bankruptcy proceedings through a repurchase agreement and planned to reactivate one of the two 80,000-ton-per-year plants on-site in early 1991.

Consumption and Uses

Fertilizer materials accounted for about 80% of domestic ammonia conversion disappearance, and about 20% went into industrial applications.

Urea and ammonium nitrate, in solid and liquid form, found extensive use in both the fertilizer and industrial sectors. UAN solution fertilizers that contain 28% to 32% N were growing in popularity because of their safe handling and storage characteristics and ease of application. In the industrial sector, urea was used in the production of synthetic fibers, resins, and polymers and as a protein supplement in ruminate animal feeds. Ammonium nitrate fuel oil explosives (ANFO) dominated the industrial explosives sector. Nitric acid was used in chemical synthesis and in metal treatment. Acrylonitrile and caprolactam found respective use in the production of acrylic and nylon fibers, resins, and plastics.

Other uses for ammonia and ammoniabase compounds were for speciality horticultural and lawn and garden fertilizers, home and industial cleaners, and as a propellant in vehicular air bags. Ammonia and urea were also becoming popular low-cost agents that significantly reduced NOx atmospheric emissions when injected into combustion gas streams.¹⁵

In 1990, ammonia and ammonia derivatives accounted for 54% of the 20.6-million-ton primary fertilizer nutrient market in the United States. The ratio of nitrogen nutrient consumption to phosphate and potash fertilizer nutrient consumption was 2.5:1 and 2.1:1, respectively.

U.S. nitrogen fertilizer consumption reached 11.1 million tons N in 1990, an increase of 5% over that of the prior year. Single-nutrient compounds, led by direct application ammonia, UAN solutions, and ammonium nitrate, in order of importance, provided 80% of the total. Urea and nitrogen solutions were up by more than 10% each, while direct application ammonia remained static.

The six States that comprise the Midwest Corn Belt—Illinois, Indiana, Iowa, Missouri, Nebraska, and Ohio—together with Minnesota, consumed 4.6 million tons N, 41% of the U.S. total. Texas, Kansas, California, and Oklahoma, in order of importance, accounted for 2.2 million tons N, 20% of the total.

U.S. net cash farm income rose 8% to a record \$59 million in 1990. Planted crop acreage approximated 327 million

Engineering design capacity adjusted for 340 days per year of effective production capability.

acres, and another 60 million acres was idled by crop programs and the CRP.

Stocks

U.S. nitrogen producer stocks declined to a level of 1.6 million tons N and stood 11% below 1989 levels at yearend. Field inventories were also believed to have declined because of favorable domestic nitrogen fertilizer consumption and trade.

Transportation

In late December 1990, the Research and Special Programs Administration (RSPA) of the U.S. Department of Transportation (DOT) ruled that anhydrous ammonia should not be reclassified as a poisionous gas for the purposes of domestic transportation as previously proposed. 16 The RSPA ruled that classifying anhydrous ammonia as a nonflammable gas linked to the requirement of an "inhalation hazard label" would provide adequate hazard communication at substantially less cost and disruption to the agricultural and industrial users of the material. RSPA officially classified anhydrous ammonia a Division 2.2 nonflammable, nonpoisonous

gas" consistent with United Nation regulations. International shippers were required to comply under the new regulations by January 1, 1991. Because of the documented inhalation hazards of anhydrous ammonia when released in large quantities, RSPA was also requiring the words "INHALATION HAZARD" on packages and shipping papers, in addition to other current hazard communications requirements.

Ammonia was transported by refrigerated barge, rail, pipeline, and truck. Mapco Ammonia Pipeline Inc. was operating Mapco Ammonia Pipeline and its sister company, Mid-America Pipeline, along a 1,098-mile corridor that extended in a northeasterly direction from Borger, TX, in northern Texas, to Mankato, MN, in southern Minnesota. Mapco built the first leg of the pipeline in 1968-69 and, by 1978, had added six extensions. About 500,000 tons of ammonia storage capacity was located along the pipeline. Mapco Ammonia Pipeline neither produced nor marketed ammonia independently, but transported ammonia on behalf of five shippers. Competition from the rail and truck transportation sectors was minimized because areas served by Mapco Ammonia Pipeline did not have river access. Mid-America Pipeline had more than 400 shippers and competed with the other transportation sectors.¹⁷

Koch Industries was operating the Gulf Central Pipeline built in 1969 that extended about 1,900 miles from the Gulf of Mexico into the Midwest, as far north as Iowa. Koch Nitrogen, a subsidiary, purchased four Midwest ammonia terminals from ConAgra Fertilizer in 1990 having a combined capacity of 150,000 tons.

In October, the Interstate Commerce Commission (ICC) replaced the Federal Energy Regulatory Commission (FERC) as the Federal agency responsible for ammonia pipeline regulation. FERC had been responsible for ammonia pipeline regulation since 1977, when ICC transferred power of control under the Department of Energy Act. Actions on complaints that had been previously filed with FERC against ammonia pipelines for alleged excessive rate charges were delayed because of the transfer after the U.S. Court of Appeals ruled in favor of ICC control.

Markets and Prices

Anhydrous ammonia prices continued an upward trend that had developed in

the fall of 1989 because of strong domestic fertilizer movement and averaged \$93 per ton, f.o.b. barge, New Orleans, for the first quarter. Urea followed a similiar trend, with granular product averaging \$122 per ton, f.o.b. U.S. gulf coast. Anhydrous ammonia and urea prices fell during the second quarter and into the third quarter.

A dramatic rise in nitrogen fertilizer prices was precipitated following Iraq's invasion of Kuwait in early August. Anhydrous ammonia prices, f.o.b. barge, New Orleans, jumped 44% between July and December and sold for \$117 per ton at yearend. Granular urea prices on the U.S. gulf coast rose about 26% and closed the year at \$156 per ton. At yearend, prices for all major nitrogen fertilizers were up substantially relative to those of the prior year.

Foreign Trade

Effective January 1, 1990, the Bureau of the Census reinstated anhydrous ammonia export and import tonnage data that had been suppressed in total during calendar year 1989. U.S.S.R. anhydrous ammonia import tonnage data, however, continued to be withheld from the public domain because of a previous ruling that determined Occidental Petroleum to be the proprietary U.S. agent.

In 1990, the U.S. ammonia trade deficit was 2.9 million product tons, about 13% favorable to the record 3.4 million ton deficit established in 1989. The average c.i.f. price of ammonia landed in the U.S. in 1990 was about \$100 per ton. Canada, Trinidad and Tobago, the U.S.S.R., and Mexico, in order of importance, accounted for 97% of total U.S. anhydrous ammonia imports.

The total U.S. converted nitrogen trade deficit was 1.3 million tons N in 1990, 0.3 million tons (19%) favorable to the 1.6-million-ton deficit of 1989. Anhydrous ammonia (2.4 million ton N deficit) and urea (0.5 million ton N deficit) were the predominate trade deficit materials. In contrast, diammonium phosphate generated 1.5 million tons of positive N net trade.

The United States imported 2.1 million product tons of urea from 20 countries in 1990 that was valued at \$251 million (\$122 per ton c.i.f.). Canada provided 65% of the total, while Mexico, Trinidad, and Venezuela—in aggregrate—accounted for another 18%. Bulgaria, the Federal Republic of Germany, and Yugoslavia shipped an aggregrate total of 8% (157,000 tons), but International Trade Commission (ITC) antidumping provisions sheltered the domestic industry from U.S.S.R., the Federal Republic of

Germany (Eastern states), and Romanian shipments that had previously been landed at prices below fair market value. A small shipment of U.S.S.R. urea reported by the Bureau of the Census in November was in error.

World Review

Geopolitical events in Eastern Europe and the Persian Gulf dominated the global nitrogen fertilizer scene in 1990.

In Eastern Europe, the drive toward democratization was accompanied by sweeping political reforms that placed downward pressure on Eastern bloc economies. Fossil fuel energy essential to ammonia production was in short supply and portended significant shortfalls in nitrogen fertilizers critical to domestic consumption and trade. In early 1990, Romania declared force majeure on urea exports as did Poland and Hungary later in the year; shipments of ammonia and urea from the U.S.S.R. and other Eastern European nations were cut back. It is estimated that Eastern European ammonia supply capability declined by more than 2 million tons (5%) in 1990.

Iraq's invasion of Kuwait in early August played havoc with the exportoriented ammonia and urea fertilizer industries on the Persian Gulf. Iraq and Kuwait in combination represented about | See footnotes at end of table.

1.5% of total world ammonia capacity and 2.5% of world urea capacity. In 1989, Iraq and Kuwait accounted for about 5% of total world urea and ammonia N trade. War would reportedly result in the damage and destruction of nitrogen production facilities in both Iraq and Kuwait that could require approximately 5 to 6 years to repair and replace.

The outbreak of War in the Persian Gulf could cut off or throttle back nitrogen fertilizer production in Bahrain, Qatar, Saudi Arabia, and the United Arab Emirates, resulting in the potential loss of up to another 10% of world N trade in the form of ammonia and urea. In 1990, it was estimated that ammonia production in the Mideast would decline by a net of 400,000 tons (8%) because of the Persian Gulf crisis.

Industry Structure.—Approximately 108 million short tons of anhydrous ammonia N was produced in 66 countries during 1990, of which about 11 million tons N (10%) was directly traded. Ammonia was converted into about 39 million tons of urea N in 55 countries, of which about 10 million tons (26%) was traded. Total world nitrogen fertilizer consumption was about 87 million tons N, of which trade accounted for about 22 million tons N (25%).

Global ammonia was produced in the developed and developing countries that have access to fossil fuel feedstocks, principally natural gas, naptha, petroleum refinery offgases and condensates, and coal and coke gases. The supply pattern, in general, followed the world population trend, with Asia and Eastern Europe including the U.S.S.R.—accounting for more than 60% of the global ammonia supply. The developed regions—North America (United States and Canada), Western Europe, and Oceania—produced ammonia primarily for domestic use and accounted for about 25% of the world total. The energy-rich countries of the Middle East accounted for about 5% of the world supply and exported significant quantities of ammonia and urea to the global community.

Capacity.—The data in table 14 are rated capacity for ammonia plants as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given

acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

In 1990, about 2 million annual tons of new ammonia capacity was brought on-stream, and about 1 million annual tons was permanently closed. Another 5.5 million annual tons was under construction and scheduled to come onstream during 1991 and 1992.

The major ammonia capacity that was scheduled on-stream during 1990-92 was as follows: China—1.8 million annual tons in Sichuan, Henan, and Liaoning Provinces, together with small plants at various locations; U.S.S.R.—1.5 million annual tons in the Ukraine and at various locations; India-0.8 million annual tons in Kakinada and Rajasthan; Belgium—0.7 million annual tons at Antwerp; Bangladesh—0.5 million annual tons at Jamalpur and Ghorasal; Egypt— 0.5 million tons at Suez and Abu Qir; Indonesia—0.5 million tons at Sumatra: and Turkey—0.4 million annual tons at Gemlik.

Current Research

M. W. Kellogg of Houston, TX, announced two major advances in its ammonia process technology: the Kellogg Reforming Exchanger System (KRES) and the Kellogg Advanced Ammonia Process (KAAP), a joint technology development with British Petroleum.

Kellogg's KRES design was revolutionary in that it completely eliminated the conventional fired primary reformer from the ammonia production process. KRES is environmentally attractive because without a primary reformer, nitrogen oxide emissions are substantially reduced. The system could be easily installed in new or existing plants and would save up to 10% on capital costs.

The KAAP process employs a novel ammonia synthesis catalyst that was claimed to be the first significant breakthrough in catalyst technology since 1927. The proprietary KAAP catalyst is up to 20% more active than conventional iron catalysts. The KAAP system was to be employed in a retrofit project designed to increase production capability by 40% at Ocelot's ammonia plant in Kitimat, British Columbia.

In late 1990, the Department of Agriculture (USDA) and the Department of

Energy (DOE) signed a "memorandum of understanding" for accelerating the development of ethanol and other alternative fuels and fuel additives from agricultural and forestry products. ¹⁸ The agreement promised significant new markets for U.S. farmers and supported the President's National Energy Strategy that focused on a reduction in foreign energy dependency and a cleaner environment.

Research and development activities were to focus on four key areas related to production of fuels from agricultural and forestry products: (1) improving the conversion efficiency of biomass products to fuel products, (2) assessing economic effects of alternative fuel production, (3) assessing environmental effects of production and use of alternative fuels, and (4) enhancing economic competitiveness of such fuels.

Exxon Research and Engineering Co. of Florham Park, NJ, developed the THERMAL DeNox Process that significantly reduced NOx emissions by injecting ammonia into flue gas streams emanating from stationary combustion sources. THERMAL DeNOx is a noncatalytic process for NOx reduction based on the gas phase homogeneous reaction between NOx in flue gas and ammonia that produces nitrogen and water. The patented process was offered for license by Exxon Research and Engineering Co. ¹⁹

The Electric Power Research Institute in Palo Alto, CA, developed NOxOUT proprietary technology that injected urea and other commodity chemicals into coalfired boilers to reduce NOx emissions. Nalco Chemical of Naperville, IL, and Fuel-Tech of Stamford, CT, formed a joint-venture firm NalcoFuel-Tech to market NOxOUT technology.²⁰

OUTLOOK

Global ammonia operating rates declined in 1990 owing to a significant downturn in Eastern bloc demand and supply disruptions precipitated by the Persian Gulf crisis. Per capita nitrogen consumption dropped below 41 pounds for the first time since the dismal global agricultural crisis of 1986.

The data of table 15 suggest that soft market conditions will prevail between 1990 and 1994, principally because of significant new additions to world capacity

Export values f.o.b.; import values c.i.f.

²Includes industrial chemical products.

³Harmonized codes 3105.10.0000 and 3105.20.0000.

⁴Codes 3105.51.0000, 3105.59.00 (exports and imports); 3102.70.0000 (exports); 3105.40.0050 (imports).

⁵Codes 3101.00.0000, 3102.29.0000, 3102.60.0000, 3102.90.0000 (exports and imports); and 3105.90.0050 (imports).

⁶Carbonates, chloride, fluorides, and tungstate (exports and imports); bromide, molybdate, orthophosphate, and perrhenate (imports).
⁷Less than 1/2 unit

Data may not add to totals shown because of independent rounding.

⁹Anhydrous ammonia tonnage data as reported by U.S. Bureau of Mines in 1989 and for U.S.S.R. in 1990; includes industrial ammonia. Value data, Bureau of Census.

¹⁰Data for code 2837.19.0020 (other cyanides) deleted or omitted by Bureau of Census. In 1989, 6,000 tons valued at \$5.7 million was reported.

and a protracted period of economic recovery in the Eastern bloc. A renewal of hostilities in the Persian Gulf would again negatively impact ammonia and urea trade and could stress the global economy through the mechanism of yet another oil shock. By 1995, there appears to be a reasonably favorable probability that ammonia supply and demand will return to balance.

The U.S. Bureau of Mines ammonia nitrogen demand forecast was developed from world population projections of the United Nations, together with historic per capita consumption trends, taking into consideration geopolitical factors in Eastern Europe and the Mideast. Steady-state conditions were assumed for weather. World ammonia capacity projections were provided by the International Fertilizer Industry Association Ltd., Paris, France.

Turning to the U.S. outlook, a continuation of favorable trends in the nitrogen fertilizer and agricultural sectors would appear to be a distinct possibility. U.S. ammonia capacity expansion plans are minimal, and agronomic fundamentals that were improved by the 1985 farm bill should be further perpetuated by the new 1990 farm bill.

The mechanisms of the new ECARP, together with regular program acreage reductions, should hold U.S. crop acreage at about the current 330 million acres. This, together with the Export Enhancement Initiative, should control crop inventories and provide favorable crop prices for the U.S. farmer.

Issues critical to a favorable U.S. nitrogen fertilizer scenario include (1) a continuation of reasonably priced natural gas for U.S. ammonia production, (2) new industrial outlets for U.S. corn-based ethanol in reformulated motor fuels under the provisions of the Clean Air Act of 1990, (3) new markets for the Saferco ammonia and urea nitrogen complex under construction in Sasketchewan that would not result in the significant closure of U.S. nitrogen capacity, (4) a favorable resolution of the ongoing Uruguay round of General Agreement of Tariffs and Trade negotiations that would liberalize global agricultural trade and provide the United States with freerer access to global markets, (5) favorable U.S. implications for the proposed Free-Trade Agreement with Mexico and for the proposed granting of most favored nation (MFN) status to the U.S.S.R. and other Eastern European countries, (6) a smooth transition in democratic reforms in Eastern Europe, and (7) resolution of the MFN status debate with China.

ORGANIC MATERIALS

Mr. Hurdelbrink, supervisor of the Materials Engineering Group at the Minerals Availability Field Office of the U.S. Bureau of Mines, has performed and directed numerous studies on minerals and materials markets. Mrs. Simmons, industrial program manager with the Branch of Materials of the U.S. Bureau of Mines, directs work in the analysis of the petroleum, petrochemical, and plastic industries as related to the application of organic materials in major industrial sectors. Some of the data were prepared by Tom Kelly and John Sznopeke, materials specialists of the Materials Engineering Group at the Minerals Availability Field Office.

By Ronald J. Hurdelbrink and Michele R. Simmons

rganic materials obtained from nonrenewable resources comprise a wide range of nonfuel applications of natural gas-, coal-, and petroleum-derived feedstocks into both durable and nondurable goods. Plastics, synthetic fibers, and synthetic rubber are important products made from organic feedstocks that traditionally are used primarily as fuels. In addition, lubricants, asphalt, road oil, waxes, and numerous other petrochemicals, also derived from organic feedstocks, fulfill many important nonfuel uses. Products made from these organic materials include such varied items as household goods, eyewear, textiles, tires, engine grease, paving materials, pharmaceuticals, medical devices, and other items vital to society's well-being.

In 1990, there was expansion in nearly all categories of organic materials use from a year ago. Plastics, synthetic fibers, and synthetic rubber use grew 3% in 1990 to 30.5 million metric tons. This was due mostly to solid growth in plastics; in the thermoplastic resin category, for example, there was an 8% increase in polypropylene use and a 12% increase in polyethylene use for the year. Both synthetic fibers use and synthetic rubber use were down slightly in 1990 from a year ago. Nonfuel use of lubricants, petroleum coke, and coal grew 16% in 1990 to 14.8 million metric tons. Asphalt and road oil use increased 6% in 1990 to 30.9 million metric tons, and use of petrochemicals (solvents being the largest volume) grew 2% to 37.4 million metric

Much of the news in the organic materials markets revolved around two specific issues: growing environmental concerns and concerns surrounding the invasion of Kuwait by Iraq and its impact on the markets for these nonfuel uses of fossil fuels. In the environmental arena, there were a number

of legislative actions at the Federal, state, and local levels attempting to influence materials choices in ways perceived as reducing environmental damages, facilitating recycling, or alleviating the landfill crisis. One of the big moves in the private sector was McDonald's Corporation's decision to quit using polystyrene in packaging and substitute other materials, principally paper, a move it describes as source reduction.

The Iraqi-Kuwaiti war was another major event of 1990, although the predominant impact after the invasion of Kuwait in August seemed to be on price, not availability, of feedstocks for the materials organic industries. Though crude oil prices jumped very quickly after the invasion, prices for downstream products were slower to rise, and the increases were much smaller. Prices for plastics resins, for example, rose only by about 10% while crude oil prices doubled, and the price increases for resins lagged crude oil price increases by 6 to 8 weeks.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines collects no original data on organic materials use from company surveys. All of the statistical information included in this report was obtained from outside sources. Much of it relies on data collection efforts of other Government agencies and on surveys conducted by various industry publications and materials industry trade associations. The intent of the Bureau is not to duplicate the efforts of those organizations, but to augment those efforts with both data analysis and collection where adequate coverage is not currently available.

The data were obtained from a variety of sources, including the Annual Energy Re-

view 1990 from the Energy Information Administration, U.S. Department of Energy; the Department of Commerce; and a wide variety of industry contacts. In addition, data were obtained from the Society of the Plastics Industry, Inc.; several industry trade associations; other Government data publications; and many industry trade journals, especially Chemical & Engineering News, Plastics News, and Modern Plastics. The focus of the discussion is primarily on plastics, synthetic fibers, and synthetic rubber. The synthetic fiber data were based on the efforts of Chemical & Engineering News, on surveys conducted by the Fiber Economics Bureau, Inc. and by various industry publications, and materials from the American Fiber Manufacturers Association. Inc. Data for synthetic rubber were based on reports in the Chemical & Engineering News, Chemical Week, the International Institute of Synthetic Rubber Producers, and the Rubber Manufacturers Association. Other categories of organic materials use are covered as well, but the same level of detailed information is not generally available for them; therefore, little additional detail was provided.

BACKGROUND

At the beginning of the 20th century, the United States satisfied about 75% of its material needs from renewable resources. The remaining 25% was met by minerals. The traditional primary renewable resources are agricultural (cotton, oils, etc.), forest (lumber, etc.), and wildlife (furs, etc.) products. Primary nonrenewable resources are inorganic minerals and organic materials such as coal, petroleum, and natural gas. This pattern of use held relatively constant until the Second World War when the first of two major shifts in feedstock reliance

started to occur. The first shift was the start of a continuous decline in the percentage share of material needs obtained from renewable sources. The second major change was the increased use of nonrenewable organic feedstocks in the production of asphalt, plastics, synthetic rubber, synthetic fibers, and petrochemicals. This trend is shown in figure 1, which displays the relative market shares for competing material feedstocks. (This figure is an update based on work by Spencer, et al.¹)

While the value of all components of the nonrenewable sector had increased over this period, the organic segment had outpaced the metallic minerals segment to the extent that by the mid-1980's, about 32% of the Nation's nonrenewable raw materials came from organic sources, double the share from metallic sources. The impact on the industrial minerals segment is unclear. As the use of asphalt and plastics (organics) grew, there was a concurrent requirement for increased aggregate and assorted mineral fillers and additives, thereby creating an expanded market for industrial minerals in conjunction with organic materials. Simultaneously, substitution for renewable resources was also taking place as synthetic fibers displaced agricultural fibers and plastic packaging displaced paper products.

Organic feedstocks obtained from petroleum, natural gas, and coal were used to produce material that had an average value of \$15.4 billion during 1984-87 at the unprocessed stage. These feedstocks were used to make a variety of products such as asphalt, plastics, textiles, and petrochemicals. The average percentage used for each major application category from 1984 to 1987 is shown in figure 2.

Products for Trade and Industry

Nonrenewable organic resources are used primarily for fuels. Only a small percentage of the total U.S. consumption of oil, gas, and coal goes to nonfuel uses, but chemicals and plastics comprise a large part of the nonfuel materials sector. The portion of total U.S. consumption of fossil fuels that goes into nonfuel uses is often reported in terms of British thermal units (Btu's) or value. Measured in Btu's, it has been approximately 6% for the past several years,² but when measured in value terms, the proportion is higher. Fraser³ calculates that, in value terms, the portion of organic materials consumed in nonfuel uses during the 1980's has been between 8.5% and 10%. He points out that because nonfuel uses consume higher priced petroleum and natural gas instead of lower valued coal, the value of organic materials going into nonfuel uses is understated when measured in Btu's.

Total petroleum products supplied for domestic use was 6.2 billion barrels in 1990; 815 million barrels was for nonfuel purposes, of which 299 million barrels was used for such purposes as asphalt and road oil, lubricants, petroleum coke, waxes, and miscellaneous products.⁴ The remainder, 516 million barrels, included liquefied refinery gases (LRG's), natural gas liquids (NGL's), petrochemical feedstocks, and naphthas used by the chemical industry. U.S. consumption of natural gas was 18.8 trillion cubic feet in 1990.⁵ A total of 624 billion cubic feet of natural gas, primarily methane, went into nonfuel end uses.⁶

A simplified overview of organic materials from well to feedstocks is shown in figure 3.7 Among the many products of the petroleum refining process are naphthas and LRG's. These are the sources for petrochemical feedstocks, but both are primarily consumed as fuels. Naphthas are a primary constituent of gasoline, and LRG's have a variety of fuel uses.

During the processing of natural gas, NGL's are extracted from wet gas, producing dry gas, or methane. Methane and NGL's are also primarily consumed as fuels. In addition to their fuel uses, however, they are also the principal sources of petrochemical feedstocks used to make resins, fibers, elastomers, adhesives, paints, and pharmaceuticals.

Petroleum products, including NGL's, accounted for approximately 86% of the Btu's from fossil fuels consumed for nonfuel uses in 1990. Natural gas, principally methane, accounted for approximately 13% of the Btu's from the fossil fuels consumed, and coal accounted for the remainder. Asphalt and road oil, lubricants, petroleum coke, wax, and miscellaneous products comprised approximately 46% of nonfuel uses of petroleum products.8 The array of products produced at a petroleum refinery is dependent upon a number of factors, including the design of the plant facilities, the characteristics of the petroleum refined, economics, and Government regulations. Crude petroleum varies from source to source and thus the range of products that can be produced economically also varies. The cost differential to produce one product instead of another and the prices received for the products dictate the economically efficient array of products. Governments can also influence the product array through specifying defense needs or by rationing resources during shortages. The plastics industry had limited access to feedstock materials during the oil crisis of the early 1970's, for example.

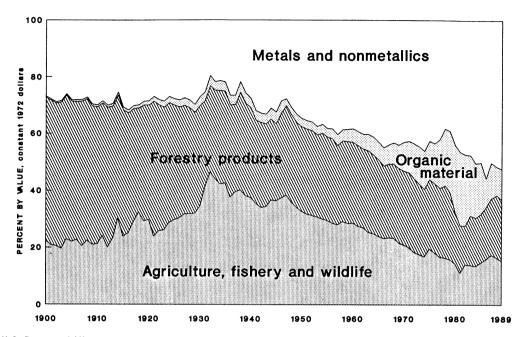

Table 1 reports the amounts of selected feedstocks, and the relative percentage of total consumption of each feedstock, consumed in the production of plastics. Ethylene dominates plastics feedstock consumption, with 22.4 billion pounds consumed. More than two-thirds of ethylene and benzene consumption, 60% of naphthalene (derived from coal tars), 50% of propylene, and 27% of xylene were consumed in the production of plastics in 1986. While plastics are the primary use for some feedstocks, they are only a minor use for others. Only small percentages of toluene, butadiene, and methane were used in the production of plastics.

Methane is used to produce fluorocarbons and produces methanol that, in turn, is used in the production of phenolics. Ethane and propane can each be used to produce ethylene or propylene. Ethylene is used in the production of numerous resins, including polyethylene, fluorocarbons, polyesters, and ABS. Propylene is used in the production of resins such as polypropylene, polyesters, acrylics, and polyurethane. Butane is used in the production of ABS and some vinyls. Naphtha is the source of benzene, toluene, and xylene. Benzene is used in the production of unsaturated polyesters (nylon), polysulfone, styrene, and phenolics. Toluene and xylene are used in the production of polyurethanes and polyesters.

Lubricating oils are a combination of a small number of crude oil-base stocks blended with a large number of additives. The additives are used to give specific properties to a wide variety of lubricating oils. These properties include viscosity, viscosity change with temperature, oxidation resistance, acidity, boiling temperature, and pour point.

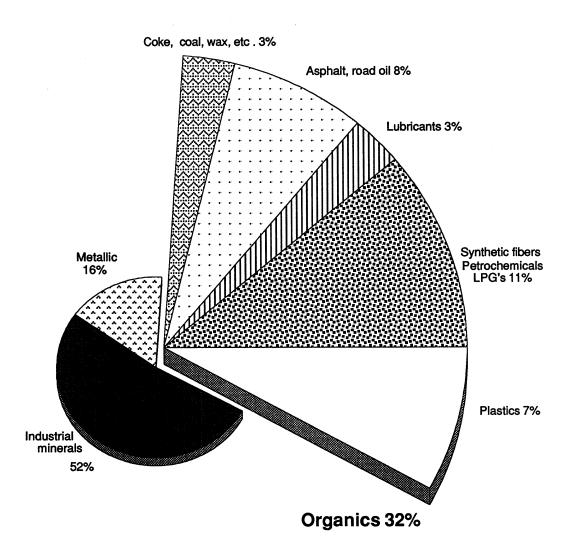

Petroleum coke comes in three forms. Sponge coke varies from a hard, porous, irregular-shaped lump to a fine powder. It is used in production of pure carbon or artificial graphite used for motor brushes, structural graphite, and dry cells. Needle coke, with its name derived from its shape, is the preferred material for graphite electrodes because of its lower electrical resistivity and lower coefficient of thermal expansion. Shot coke, which is generally produced unintentionally and comes only from residuals of California crude oils, has

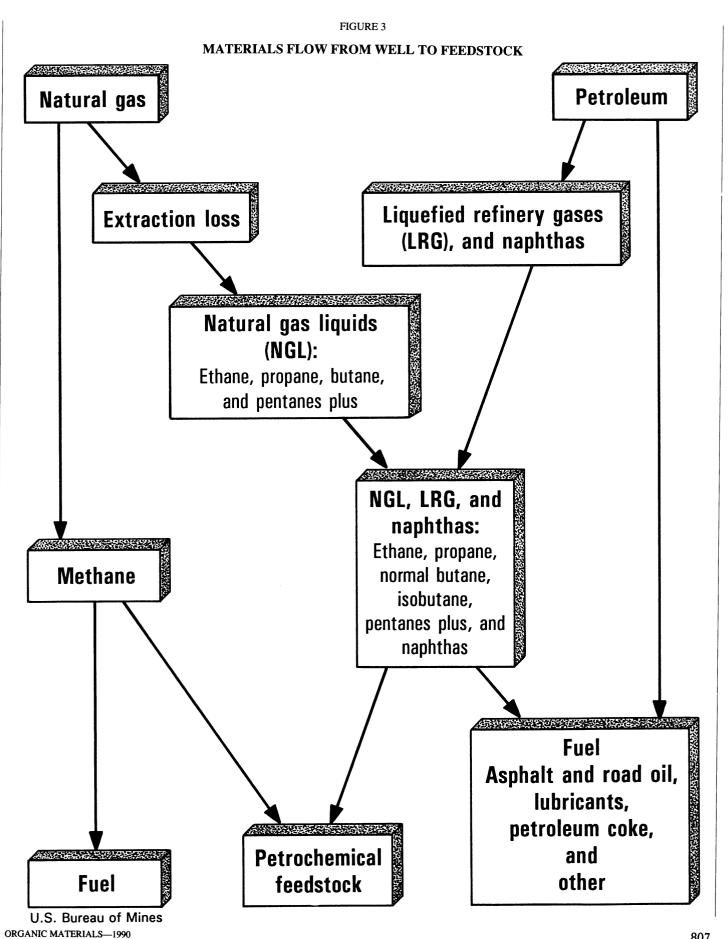

FIGURE 1
U.S. CONSUMPTION OF RAW MATERIALS IN NONFOOD AND NONFUEL USES

U.S. Bureau of Mines Department of Commerce

FIGURE 2
U.S. CONSUMPTION OF ORGANIC MATERIALS (AVERAGE 1984-87)

a variety of uses as carbon or graphite. The nonfuel uses of coal are mainly for its carbon content; it is used as a filter material for boiler water, for example, where it takes out organic contaminants. Coal is also used in the production of cyclic intermediates that feed into the petrochemical feedstocks area.

Asphalt, a product of petroleum refining, is generally the bottom product left after all other products have been taken out. It is always blended with cutter stock, similar to kerosene but with a lower flash point, into three grades: fast cure (less of the kerosenelike material added so it sets up faster), medium cure, and slow cure, for use as road base at different ambient temperatures.

Not all refinery operations produce asphalt. Many refineries are set up to handle light crude oils, and the bottom product is a fuel oil. Asphalt is a natural product only from heavy crude oils, and the amount of asphalt produced will be in rough proportion to the gravity of the crude oil. Further processing is necessary to make the asphaltic material suitable for roofing applications.

Waxes, also a natural product of the refining processes, are derived from the gas oil fraction in the distillation process. Waxes come out of all crude oils. If the crude oil contains a large proportion of wax, then the final "pull" becomes unsuitable for asphalt production, even if it is a heavy crude oil.

Petrochemical feedstocks are divided into three major classes: aromatics, unsaturates, and saturated paraffins. Many of these feedstocks are the raw materials from which plastics, synthetic fibers, and synthetic rubber are produced. Other significant uses for petrochemical feedstocks are for solvents, paint thinners, and cyclic intermediates that are further processed into dyes, medicinal chemicals, and pesticides.

Technology

Approximately 16.2 million tons of plastics was disposed of in the United States in 1990. At present, postconsumer plastics are recycled at a rate of slightly more than 1% of total U.S. virgin production. The largest part of this recycling seems to be in response to the bottle deposit laws enacted in 10 States. Polyethylene terephthalate (PET) beverage containers are recycled into polyester fiberfill used for clothing and camping gear insulation and packing strap. The removal during 1990 of the Food and Drug Administration's proscription on reuse of recycled plastics for food containers

has allowed several chemical companies working with the Coca Cola Co. and Pepsi Cola Co. to explore the chemical processes that break PET down into its original chemical components and reform the resin in a closed loop form of recycling back into beverage containers.

Some other examples of thermoplastics recycling are as follows: high-density polyethylene (HDPE) is recycled into cleaning products containers and carpet backing, low-density polyethylene (LDPE) into grocery sacks, polyvinyl chloride (PVC) into garden hose and containers, and reaction injection molding (RIM) scrap regrind back into its original products such as autobody panels and truck beds. Thermoset recycling occurs less often, but phenolics and epoxies have been used as regrind for filler material in the production of their original products such as epoxy circuit boards or pyrolyzed into asphalt or concrete reinforcement.

Textile fiber waste is incorporated into furniture stuffing, mattress felts, carpet and rug underlayments, and filler for rolled roofing goods. If a specific material can be reclaimed in relatively pure form at the source of origin, it may be blended or reintroduced into the virgin production stream. Where there are other nonrecoverable components, including chemical or mechanical binders, waste fiber is usually sent to a landfill.

Tires are the only reported form of synthetic rubber that is being recycled. Of the 234 million tires discarded every year in the United States, 82% is placed in a landfill, 9% is used for energy recovery primarily in cement kilns where their use has reportedly reduced energy costs by 50%,9 4% is used as an additive to asphalt, and 2% is recycled into products such as floor mats, buckets, carpet backings, and hoses.¹⁰ Tires can also be used directly as the primary fuel in a waste-to-energy plant. The profitability depends on the price paid for energy in the region and the cost of the tires because the capital costs are higher than for conventional energy-producing plants.

Solvent and paint recovery in the United States is increasing and opening up to newer technologies to supplement the traditional methods of batch distillation and activated-carbon adsorption. The motivation for this was passage of the Clean Air Act Amendments of 1990 with revised National Emission Standards for Hazardous Air Pollutants, which are especially applicable to volatile organic compound emissions. New adsorbents such as Sorbathene and

continuous activated-carbon stripping methods using vacuum instead of steam are allowing more solvent recovery with less energy input.

There are currently about 100 fuel blending plants in the Nation. These facilities collect, blend, and ship for incineration turpentine and paint wastes that otherwise might be thrown in a landfill or down a drain.

A controversial use for solvent recovery is their inclusion in the fuel used to fire cement kilns. The controversy centers around the potential release of dioxins and heavy metals into the environment and the perception that this practice is an avoidance of the Resource Conservation and Recovery Act handling and storage requirements that are avoided by mixing the solvent into the fuel oil and not classifying the mixture as hazardous waste.¹¹

Some motor oils and turbine oils that are collected in an uncontaminated manner (free of solvents and paints) are recycled by reintroducing these products into the refining process.

Economic Factors

Crude oil and natural gas liquids are the major sources of petrochemical feedstocks. Throughout the world, naphtha, a crude oil fraction, is the main source of ethylene and propylene, the primary olefins involved in plastic resin production. There has been a long-term trend to use less naphtha and more natural gas liquids as sources of these olefins in nations that are gas rich. In the United States, natural gas liquids are the major sources of these primary olefins. Naphtha remains the major worldwide source of benzene. World crude oil production in-

TABLE 1

CONSUMPTION OF MAJOR FEEDSTOCKS FOR PLASTICS, 1986

	Consumed	d in plastic

creased by 1.4% in 1990 despite the embargo of oil exports from Iraq and Kuwait and a sharp drop in Soviet output.12 The increased production was a response to the uncertainty of future supplies caused by the Middle East crisis and the resultant stock building of the market economies.

Consumption in the market economies slumped in the fourth quarter of 1990 because of the higher oil prices after the invasion of Kuwait by Iraq. In the United States, the average price of imported crude oil rose about 50% from \$15 to \$22 per barrel in the week immediately after the invasion. Import prices rose by early October to a peak of about \$30 per barrel and then fell to about \$25 per barrel by year's end.

The Middle East crisis increased supply problems in Eastern Europe already aggravated by the collapse of Comecon and diminished production in the U.S.S.R. The U.S.S.R.'s biggest 1990 oil production losses occurred in western Siberia's Province of Tyumen because of well shutdowns forced by pipe and equipment shortages. This province accounts for 63% of the nation's normal crude production. The shortage of Soviet oil production in early 1990 forced several Eastern European nations to look for new sources of crude oil in the Middle East. Oil contracts were signed with Iraq by Bulgaria, Hungary, and Poland, and Iraq was already an established supplier to Romania and Yugoslavia. The shortage of Eastern European hard currency reserves was to have been lessened by Iraq purchasing market goods from these countries through barter deals.13 This hard currency shortage was compounded by the U.S.S.R.'s insistence on payment in hard currency for its crude exports.

The response of the U.S. petroleum market to the invasion of Kuwait by Iraq was to lessen its reliance on imports of crude oil. The high import level of 6.9 million barrels per day in July 1990 declined to a low of 4.6 million barrels per day in December 1990. The increases in the price of oil slowed the monthly decline of U.S. production during this period, but the 5-year decline in U.S. oil production continued, averaging 7.4 million barrels per day for 1990. U.S. petroleum demand was met by stock drawdowns, including the first sale ever from the Strategic Petroleum Reserve.14

Fourth quarter earnings in the petrochemical industry were mixed owing to the rise in feedstock costs, as shown in table 2. World ethane prices increased to as much as \$2 per gallon during the crisis, up from | Sources: Chemical & Engineering News and U.S. Bureau of Labor Statistics.

\$1.43 per gallon in July 1990, an increase of 40%, yet ethylene prices only increased 23.7% to \$0.29 per gallon. As the feedstock prices leveled late in the quarter, petrochemical producers were able to maintain precrisis costs for some derivatives, although there was a general increase in prices for all basic petrochemicals.15

In the United States, demand for liquefied petroleum gases decreased by 6.7% in 1990 from the 1989 level. This drop in demand was accompanied by an increase in inventories and exports. Heavy petrochemical feedstocks demand rose, while naphtha petrochemical feedstocks demand remained unchanged from the 1989 level. Demand for petroleum coke rose 10% in 1990 while asphalt demand increased 7%.16

Operating Factors

Employment.—There was little change in the level of total industrial employment in the organic materials sector in 1990, as shown in table 3. Total industrial employment in the plastics, synthetic fibers, and synthetic rubber category was up slightly, while the number of production workers declined slightly. The number of women employees went up, both in absolute terms and as a percentage of the total. The average workweek declined by 0.6 hours. Average hourly earnings were up 4.3%, slightly more than the increase shown for all manufacturing.

No separate accounting of the total number of employees producing feedstocks for organic materials is possible. Nonfuel uses of fossil fuels account for only 6% to 8% of the total on an energy content basis. Employment in the overall oil and gas sectors, the industries that are the source for most organic materials feedstocks, was up slightly in 1990. Oil and gas extraction showed a 3.5% increase in employment, while petroleum refining, gas production and distribution, and asphalt paving and roofing materials all had employment increases of less than 1%.

Energy Requirements.—In the production of organic materials, energy resources are inherent in the feedstock and consumed in processing. The total amount of energy required for the production of plastic materials, for example, is in about a 1:1 ratio as fuel and feedstock. Figure 4 shows the energy requirements for a variety of plastics on a volume basis. Between 2,000 and 4,000 Btu's are needed to produce 1 cubic inch of

COMPARISON OF PETROLEUM CONSUMPTION AS FUEL AND FEEDSTOCK IN THE PRODUCTION OF PLASTICS

most plastics. This level is below what is required to produce an equivalent volume of virgin metallic materials; however, it is higher than the energy requirement for metal production when the comparison is made on a weight basis. Only the lightest metals, like magnesium and aluminum, consume an equivalent or greater level of energy for the same weight of material.

Since the energy requirements for materials production show no clear advantage or disadvantage for organic materials, the increasing reliance on petroleum and natural gas as materials feedstocks has only limited strategic importance. Additionally, reliance on fuels for materials purposes is growing but still small in relation to total use, about 6% to 8% on an energy content basis. Of more concern to the organic materials industries is whether in times of shortages, allocation mechanisms would be used to divert available supplies of feedstocks away from the industry and toward its use as fuel for electricity generation and transportation. Plastic resin manufacturers felt this occurred during the oil market disruptions of the 1970's. Should resin manufacturers be forced to rely on alternative feedstock materials, the energy costs of producing plastics, synthetic fibers, and synthetic rubber would be much higher than those shown.

ANNUAL REVIEW

Economic forces, coupled with pressures from the Middle East crisis, affected market activities of the U.S. chemical industry in 1990. Chemical producers faced stalled economic growth, depressed chemical demand in key markets, and, shortly after midyear, increased raw material prices resulting from the Middle East crisis.

Overall production of chemicals and synthetic materials, except for plastics, declined modestly owing to weak demand in 1990. Chemical prices also drifted down until August, when prices rebounded as oil prices significantly increased in the wake of the Middle East crisis and producers tried to pass on their price increases for feed-stocks to their customers.

One positive factor is that U.S. chemical producers, in general, were less affected by the higher oil prices stemming from the Middle East crisis than their foreign counterparts because they rely more heavily on natural gas-derived feedstocks rather than petroleum-derived feedstocks. Consequently, U.S. chemical producers were able

to manufacture chemicals and plastics more inexpensively than many foreign chemical producers.

In addition, U.S. chemical producers benefited from increased foreign trade in 1990. With the U.S. dollar depressed relative to other currencies in the industry's key markets abroad, the cost of U.S.-produced chemicals were highly competitive during the year. Strong foreign demand for U.S. chemical exports helped trim the U.S. deficit despite higher priced oil imports.

Production of materials from nonrenewable organic resources during 1990 increased in all categories shown in table 4. For the petrochemical industries category, total feedstocks production increased over 3% to more than 61.6 million metric tons. Production of resins (i.e., plastics, synthetic fibers, and synthetic rubber) increased about 4% to 33.7 million metric tons in 1990. representing the eighth consecutive year that production of these materials has increased. Imports increased from 9.3 million metric tons in 1989 to 9.8 million metric tons in 1990. Exports continued their upward trend, growing from 2.3 million metric tons in 1989 to 2.5 million metric tons in 1990. Apparent primary consumption increased just over 2% to 68.7 million metric tons in 1990. ("Apparent primary consumption," as used here, measures supply and disposition of organic materials from primary sources and equals production plus imports minus exports plus stock changes. Recycled materials are not accounted for in this calculation.) The price for feedstocks shown in the table represents the price of the organic material that is used to make these products and not the price of the products themselves. It reflects changes in the price of energy and, consequently, fluctuates with energy markets.

Production of lubricants, petroleum coke, and coal increased to 20.3 million metric tons in 1990 after small declines during the previous 2 years. Imports of lubricants and petroleum coke in 1990 were 630,000 metric tons, the same level as that in 1986. Imports reached 770,000 metric tons in 1987, then fell to 580,000 metric tons in 1988 and remained near that level in 1989. Exports of lubricants and petroleum coke increased just over 2% to about 3.5 million metric tons in 1990, after declining 13% between 1988 and 1989. Yearend stocks of lubricants and petroleum coke were just under 2.1 million metric tons, down from almost 2.3 million metric tons in 1989. Apparent primary consumption of lubricants, petroleum coke, and coal increased 13% to 17.6 million metric tons. It should be noted that data for coal were included in production, but not in imports, exports, or stocks because of lack of detailed information on coal not used as a fuel.

Production of asphalt and road oil increased 6% to 26.9 million metric tons in 1990. It has fluctuated between 24 million metric tons and 27 million metric tons since 1986. Imports of asphalt increased 3% to 1.91 million metric tons in 1990. Exports were 20,000 metric tons in 1990, unchanged from the 1989 level and down from earlier years shown. Yearend stocks of asphalt declined almost 9% to 3.1 million metric tons. Apparent consumption of asphalt increased almost 7% to 29 million metric tons in 1990. Apparent consumption of asphalt and road oil has fluctuated between 27 million metric tons and 29.1 million metric tons since 1986.

World Review

Faced with slower economic growth, currency fluctuations, higher raw material prices, and growing tensions from the Middle East crisis, the chemical industry in 1990 experienced downturns in a number of market activities.

By midyear, many countries were either well into a recession or just coming into one. The chemical industry found the demand for chemicals down in several principal markets. With demand down, chemical production soon declined in response. As a result, chemical producers saw their revenues and profits reduced. Adding further to the squeeze on chemical producers' earnings were the additional supplies and capacity made available from a number of new petrochemical plants that had come on-stream during the year.

Currency fluctuations and increases in raw material prices were other complicating factors to the chemical industry. Throughout 1990, worldwide chemical trade remained strong, but the volume traded was down for many regions. Also, as increases in raw material prices took effect during the year, chemical producers experienced some difficulty in passing along those increases to their customers.

The chemical industry also remained focused on the General Agreement on Tariffs and Trade (GATT) negotiations during the latter part of 1990. The results of a new agreement, once implemented, are expected to have a major impact on the volume of chemicals traded worldwide due to imposed tariff and nontariff barriers.

¹Total feedstocks are composed of liquefied petroleum gases, petrochemical feedstocks, special naphtha, dry natural gas, and other as defined in table 12 of the Annual Energy Review 1990.

Sources: Chemical & Engineering News, European Plastics News, Annual Energy Review 1990, Petroleum Supply Annual 1990, and Modern Plastics.

On August 2, 1990, Iraq invaded Kuwait. Within days, Iraq shut down Kuwaiti oil production capacity, and the United Nations imposed an international trade embargo against Iraq. As oil supplies from these regions began to fall, a portion of the world oil supply was effectively removed from the market. The price of crude oil rose quickly and remained high for several weeks before declining owing to increased production from other major oil-producing nations. Because crude oil is an important raw material used to make resins and other nonfuel materials, uncertainties surrounding its availability spawned concerns over future feedstock supplies to the chemical industry. These unfolding events led to higher feedstock prices worldwide and, in turn, to higher resin prices that effected a lower resin demand and contributed to a buildup of resin inventories.

In 1990, production of synthetic fibers, synthetic rubber, and plastics decreased in most countries. Those downward trends led to overall declines in world production of these commodities, except plastics, which rose mainly owing to production increases in Canada and Japan. Among the major producing regions for plastics were Canada, Japan, the United States, and Western Europe. For synthetic fibers, the major producing regions were China, the Federal Republic of Germany, Taiwan, and the United States. For synthetic rubber, the major producing regions were the United States and Western Europe.

Canada.—As Canada's economy moved into a recession at the beginning of the sec-

ond quarter of 1990, the chemical industry saw sales and profits weakened by high interest rates, a strong Canadian dollar, lack-luster domestic demand, and rising energy and raw material costs. However, higher chemical exports during the last months of 1990, despite the strong Canadian dollar, helped to offset demand, prompting an increase in production of some chemicals, especially the major polymer resins.

Japan.—Japan enjoyed economic expansion during 1990. Even so, higher feedstock prices, along with inflationary pressures and high interest rates, threatened the nation's growing economy.

The Japanese chemical industry, like the economy overall, exhibited strong growth through the third quarter of 1990. By yearend, however, higher naphtha feedstock prices arising from Middle East tensions caused supply concerns for chemical producers, as well as lowered their profit margins. In Japan, the chemical industry relies heavily on imported petroleum-derived naphthas for its feedstocks to help meet domestic chemical demand; the lack of those supplies could prove damaging to this thriving industry. Despite this economic climate, chemical demand remained strong throughout the year, especially for petrochemicals and plastics. Consequently, production for most chemicals was up in 1990.

Production of synthetic fibers, synthetic rubber, and plastics continued upward in 1990, with plastics leading in growth.

Western Europe.—In Western Europe, a softening economy, rising raw materials costs, and declining demand curbed activities of the chemical industry in 1990. Chemical industry activities were less profitable for most chemical producers in 1990 compared with those of a year ago. Rising costs of raw materials, especially petroleum-derived naphthas, scaled back chemical producers' earnings as feedstock prices more than doubled in response to petroleum price hikes stemming from the Middle East situation; producers found difficulty in passing along cost increases to their customers. Chemical producers' earnings were further threatened as new plants came on-line and began providing additional chemical supplies. Less affected by rising feedstock costs, however, were producers whose activities occurred farther downstream from the production of basic chemicals. Even so, many chemical producers' earnings were dampened by unfavorable currency exchange rates.

²Resins are composed of feedstocks for the production of plastics, synthetic fibers, and synthetic rubber.

³Others are composed of those feedstocks used in the production of pesticides, coatings, solvents, and other petrochemicals.

⁴Dry natural gas is not included.

⁵Apparent primary consumption measures supply and disposition of organic materials from primary sources and equals production plus imports minus exports plus stock changes. Recycled materials are not accounted for in this calculation.

⁶Price is based on Btu value as close to the point of production as possible.

Coal is not included.

Production of synthetic rubber and plastics increased modestly in 1990, while production of synthetic fibers decreased.

OUTLOOK

The basic olefins, ethylene and propylene, aromatics of which benzene is the major component, and methanol are considered the upstream or elementary building blocks of the petrochemical industry. The main building block of the petrochemical industry is ethylene. Propylene is a byproduct of ethylene production. Propylene is produced in a higher ratio when naphtha steam cracking is the process used for ethylene production and in a lesser proportion when natural gas is the source for ethylene production. The major worldwide source for ethylene has been naphtha from which ethylene is obtained through a steam cracking process and natural gas liquids. However, in the natural gas-rich nations such as the United States and Mexico, natural gas liquids are the preferred source of ethylene through the chemical conversion of ethane. Some substitution of gas oil and fuel oil as sources has been occurring in the petroleum-rich nations spurred on by the introduction of crude residuals into the fluid catalytic conversion process that occurred in the early 1980's. This allowed more economical production of the ethane and propane necessary for conversion to ethylene and propylene.17

Worldwide ethylene production capacity continued to grow throughout 1990, with major gains occurring in the United States, Latin America, the Middle East, and the Asia Pacific region. The United States gained 1.59 million metric tons per year as the result of a capacity increase at the Occidental Chemical Corp. plant in Lake Charles, LA. Venezuela increased its production capacity to 660,000 metric tons over a 1989 level of only 150,000 metric tons. Saudi Arabia increased production capacity by 359,000 metric tons equally spread over its three major petrochemical plants. The Asia Pacific region increase occurred only in Japan with a production capacity gain of 553,000 metric tons occurring at five of its petrochemical plants. Eastern Europe production capacity increased in Czechoslovakia at the Zavody CSSP plant, which reported an increase of 370,000 metric tons. Even Western Europe showed a production capacity increase in 1990 despite the significant downpricing that occurred in the 1980's because of ethylene overproduction. France gained 140,000 metric tons in production capacity. The Netherlands increased production capacity by 90,000 metric tons per year, and West Germany increased its production capacity by 25,000 metric tons per year.¹⁸

The production capacity increases that occurred in 1990 are expected to continue throughout the 1990's, with world ethylene production projected to increase by almost 22 million metric tons per year through 1995. These production capacity increases have created concerns of overcapacity, which could be intensified if the current economic downturn continues. Exxon Chemical Corp. projects that, in 1995, only 85% of world production capacity for ethylene production will be used. 19

The ethylene producers in the United States could be affected because of this worldwide overcapacity. It is expected that ethylene exports could decline to less than 1 billion pounds per year by the end of the 1990's from a high of about 3 billion pounds per year in 1989.²⁰

Worldwide propylene demand is expected to grow to 38.3 million metric tons by 1995 from a production rate of 28.9 million metric tons in 1989. This could cause some shifting of sources for ethylene production in the gas-rich nations because propylene production is a byproduct of ethylene production and its ratio of production is tied to the feedstock source. Demand is expected to increase worldwide, with the Far East and Latin America leading the way with expected increases of approximately 50%. New propane dehydrogenation plants expected to come on-line in the early 1990's in Antwerp, South Korea, Mexico, and Malaysia, and new naphtha cracking plants in Saudi Arabia and South Korea will add about 750,000 metric tons of production capacity by 1995. The U.S. and Western European market shares will drop to 28% and 23%, respectively, by 1995 because of these expected worldwide production capacity increases.²¹ World benzene production is expected to increase by 3.6% per year to the year 2000. World production capacity is expected to increase to 36.8 million metric tons by the year 2000 from 29.5 million metric tons of installed capacity in 1990. This could lead to a utilization of only 76% of installed capacity in the year 2000. The United States and Western Europe are leading the way in this production capacity increase. Benzene is produced as one of the products in the catalytic reforming process used to reform naphtha into high octane gasoline. World benzene production capacity from reformers is expected to increase to 11 million metric tons per year by 1996 from a 1990 production capacity of 8.4 million metric tons per year.²²

The Clean Air Act Amendments of 1990, enacted on November 15, 1990, in the United States, will require benzene content in catalytic reformate to drop to 1% by volume from the previous 2% by volume. This will require a shifting in the processes used to produce benzene. The alternative methods of disproportionation and hydroalkylation are presently being used for benzene production, and their use is expected to increase.

Methanol is used for the production of acetic acid and formaldehyde, as a solvent, and as a raw material for gasoline synthesis. Its nonfuel uses are not expected to increase much in the next decade, but its use in methyl tertiary-butyl ether (MTBE) is expected to increase, leading to a projected rise of 3.5% per year for the next 10 years.²³

PLASTICS

World sales of plastic resins increased by 4.7% in 1990. All of the increase can be accounted for by three regions, North America, Western Europe, and Japan, which showed sales increases of 5.7%, 5.8%, and 8.0%, respectively. Sales in all other regions of the world combined actually declined.

The Iraqi-Kuwaiti conflict resulted in price increases of plastic resins, although those increases tended to be somewhat less pronounced and slower to become effective than price increases in crude oil and for many other oil-derived products.

Polymeric materials continued to be substituted for traditional materials in many applications. In October 1990, the Saturn was introduced as the newest "polymerintensive" car. The Saturn is the first car to feature all injection molded thermoplastic body panels and other large exterior components. The "hang-on" panels go over a space frame of stamped double-galvanized steel. Saturn uses a variety of resins to meet different flexibility requirements front and rear, and the method of hanging the panels allows for differing rates of thermal expansion between the panels and the steel frame. The choice of thermoplastics was partly dictated by the ability to recycle and reuse scrap and partly by cost savings. Cost savings claims include reduced tooling costs and tooling lead time, improved surface finish, easier styling changes, and weight savings over that of steel.

There were a number of legislative actions by governments at various levels aimed at reducing environmental damages, facilitating recycling, or alleviating the landfill crisis. One of the big moves in the private sector was McDonald's decision to quit using polystyrene in packaging and substitute other materials, principally paper, as a means of source reduction.

Background

Early beginnings of the plastics industry can be traced back to natural compounds such as horn and hoof, tortoise shell, bone, ivory, gutta-percha, shellac, and glue. Forming useful items with these and other compounds necessitated the development of extrudes, presses, molds, calenders, and so on, that were later used for synthetic materials as they were developed. In 1929, a generic name for the developing industry was selected by a contest. Synthoid was the winner, but it was shunned by the industry in favor of the word "plastic." Plastic was favored because the word means that the substance can be molded or formed into any shape, opposed to nonplastic substances that must be cut or chiselled.24

Significant dates in the development of synthetic polymers start with Alexander Parkes' introduction of the cellulose nitrate, Parkesine[™], at the Great Exhibition in London, England, in 1862 (see table 5). In the United States, John W. Hyatt independently developed a form of cellulose nitrate and the injection molding machine in 1868. A patent for Celluloid[™] was granted to Hyatt and his brother Isaiah in 1870. It was not until 1877 that A. Kekule postulated that natural products are long-chain molecules. E. Ficher finally verified that the structure of cellulose was indeed a macromolecule in 1893.

Hendrik Baekeland was responsible for the introduction of the first synthetic thermosetting resin in 1909. The phenolic was known as BakeliteTM. Commercial development of a number of thermoplastics occurred during the 1930's. W. H. Carothers first synthesized nylon 6/6 in 1935, polyurethanes were invented by O. Bayer in 1937, and R. J. Plunkett discovered the polymerization of tetrafluoro-ethylene (PTFE) in 1938. PTFE was developed rapidly to the manufacturing stage under a crash program for use in World War II.25 However, it was not until 1950 that PTFE came into wide commercial production under the trade name TeflonTM.

Production of PVC and formaldehyde laminates (FormicaTM) began in 1940. Fi-

TABLE 5

HISTORICAL DEVELOPMENT OF POLYMERS

Date	Event
1862	Alexander Parkes introduced the cellulose nitrate, Parkesine TM .
1868	J. S. Hyatt discovered a cellulose nitrate and the injection molding machine.
1870	Celluloid™ patent granted to J. S. Hyatt in the United States.
1877	A. Kekule postulated that natural products are long-chain molecules.
1893	E. Ficher verified that the structure of cellulose is indeed a macromolecule.
1909	L. H. Baekeland discovered phenol formaldehyde resins (Bakelite TM).
1919	Cellulose acetate available as molding material.
1924	H. Staudinger proposed the linear chain structure for polystyrene.
1927	Introduction of polyvinyl chloride.
1928	O. Rohm commercialized polymethyl methacrylate (PMMA).
1929	Introduction of urea-formaldehyde resins.
1930	First production of polystyrene (PS).
1933	Discovery of polyethylene (LDPE).
1934	Production of polymethyl methacrylate sheet.
1935	W. H. Carothers first synthesized nylon 6/6.
1936	Introduction of polyacrylonitrile, styrene-acrylonitrile copolymers, and polyvinyl acetate.
1937	O. Bayer discovered polyurethanes.
1938	P. Schlack discovered nylon-6 and epoxy resins. R. J. Plunkett discovered the polymerization of
	tetrafluoroethylene (PTFE). High-pressure polymerization of ethylene was introduced.
1939	Commercial production of LDPE, development of epoxide resins.
1940	Production of PVC, melamine formaldehyde laminates (Formica). G. E. Rochow discovered the
	direct process for the manufacture of chlorosi lanes, the raw material for silicone resins.
1941	Development of fiber-forming polyesters. J. R. Whinfield and J. T. Dickenson discovered polyethylene terephthalate (PET).
1942	Commercial introduction of PAN fibers (Orlon™).
1948	Introduction of acrylonitrile-butadiene-styrene, used to manufacture luggage.
1950	Commercial production of PTFE (Teflon™).
1952	K. Ziegler developed catalysts for the low-pressure polymerization of ethylene.
1953	G. Natta used Ziegler catalysts to synthesize stereoregular polypropylene (PP). H. Schnell
	discovered polycarbonate. First PET (Dacron™) plant began production.
1955	Development of HDPE and PP.
1956	A. S. Hay discovered polyphenylene oxide (PPO).
1958	Commercial introduction of polyacetal.
1959	Production of acetal (Delrin [™]) and polycarbonate (Makrolon [™]).
1960's	Development of lyotropic LCP films and spun fibers (aramid fibers).
1960's	Introdection of aromatic polyester (Ekonol™) for plasma coating.
1963	Introduction of polyimides (Polymer SP TM).
1964	Production of PPO components for appliances, electrical connectors.
1965	Commercial use of polysulfone (Udel™) for electrical components.
1966	Modified PPO introduced as Noryl™, cheaper and easier to process than PPO.
1967	Polyarylsulfone introduced as Astrel 360™.
1968	Polyphenylene sulfide (PPS) introduced as Ryton™.
1972	Polyethersulfone (Victrex TM) used in aerospace and automotive applications.
1973	Introduction of Kevlar TM aramid fibers.
1970's	Introduction of Rynite [™] , a very rigid PET. Blow molding of PET bottles became popular.
1977	Commercial production of linear low-density polyethylene (LLDPE). Polyphenylsulfone (Radel TM).
1978	ICI first markets PEEK, a high-temperature resistant material used in aerospace and computer applications.
1982	Modified polyimide (polyether-imide) introduced (Ultem™) for use in high-performance fiber-optic components, coextruded food packaging, and advanced composites.
1984	Thermotropic (melt-processible) liquid crystal polymers (LCP) introduced (Xydar™) consumed
	mainly by Tupperware.

ber-forming polyesters were developed in 1941, as was polyethylene terephthalate (PET). The 1950's saw the first commercial production of PET as DacronTM, development of polypropylene, polycarbonate, high-density polyethylene (HDPE), and polyphenylene oxide (PPO). During the 1960's, aromatic polyesters were introduced and the first spun fibers or aramid fibers were developed. Polyimides were introduced, and from them, a whole family of polymers emerged. Several new polymers were introduced during the 1970's. Kevlar, an aromatic polyamide (aramid fiber), became available in 1973, and a modification to PET in the late 1970's made it a popular choice for the blow-molding of beverage bottles. Polyetheretherketone (PEEK), first marketed in 1978, is one example of the newer, high-performance, high-cost polymers that have found applications in the aerospace and computer industries, where high cost is less of a consideration.

The 1980's have seen the introduction of a new melt-processible liquid crystal polymer known as Xydar™ (Dartco Manufacturing Co., 1984) and the development of new technologies for alloying and blending old polymers to meet specific engineering criteria. Recent developments and trends suggest that many of the "new" polymers will result from future research efforts into the areas of processing and fabrication technologies rather than into the discovery of additional "new" polymers.

As can be seen from table 5, there is often a significant time lag from discovery of a polymer to commercial production of a product. The 12-year lag from discovery in 1938 to wide-scale commercial production of TeflonTM (PTFE) in 1950, for example, brings up a very important point in the historic development of the polymers industry. Discovering a new polymer does not necessarily lead to its development or commercialization.

Although the science of polymerization has come a long way in defining how molecules can be engineered to meet specific criteria, development of new polymers into commercially acceptable products can be a lengthy process. Aside from finding new uses for a new polymer, there are patents to consider, processes to be worked out for the large-scale manufacture of the polymer, and cost-effective fabrication methods to be developed. In addition, safety factors and standards have to be met, and in some cases, licenses may need to be issued (such as the Food and Drug Administration's approval

for medical uses) before a new product can be introduced into the market. The whole process involves a number of disciplines working together and can take years, even decades, to accomplish. It also costs large sums of money, and that limits the number of participants interested in actively developing new polymers.

Definitions, Grades, and Specifications.—Polymers can be classified according to the structural shape of the polymer molecules. They can be either linear, branched, or cross-linked. Linear polymers have repeating units linked together in a continuous length. When branches protrude from the main polymer chain at irregular intervals, the polymer is termed a branched polymer. Both linear and branched polymers are thermoplastics. They can be softened and hardened by heating and cooling. Fabricating processes like injection molding, casting, and blowing take advantage of this feature to shape thermoplastic resins. The rigidity of thermoplastic resins at low temperatures is attributed to the existence of secondary bond forces between the polymer chains. These bonds lose strength or are destroyed at higher temperatures, thereby causing fluidity of the resin.

Polymers used as textile fibers are linear. However, they must be of high molecular weight and have a permanent orientation of the molecules parallel to the fiber axis. The chain orientation necessary to develop sufficient strength by crystallization is achieved in the melt during spinning and then by a process known as cold drawing, in which the initially formed filaments are drawn (stretched and further oriented) at a temperature above the glass transition temperature, Tg. (Tg is the temperature at which sufficient energy is available to the molecular segments to cause them to begin to rotate and materials become soft and rubbery.)

Elastomeric materials, like thermoplastic resins and fibers, are essentially linear polymers. Certain distinctive features in their molecular structures make them rubbery. Because their Tg's are below room temperature, they can be stretched to twice their original length and then can return essentially to their original shape when tension is relaxed.

Polymers or resins that are transformed into a cross-linked product, and thus take on a "set" on heating, are said to be thermosets. Cold flow between molecules can be prevented by cross-links between polymer chains. The structure of polymer chains

present in the cross-linked polymers is similar to the wire structure in a bedspring, so chain mobility, which permits one chain to slip by another (cold flow), is prevented. Natural rubber, for example, is a sticky product with no cross linking, and its polymer chains undergo unrestricted slippage. The product has limited use. However, when natural rubber is heated with sulfur, cross linking takes place. Cross linking by sulfur at about 5% of the possible sites gives rubber enough mechanical stability to be used in automobile tires but still enables it to retain flexibility. Introducing more sulfur introduces more cross-links and makes rubber inflexible and hard.

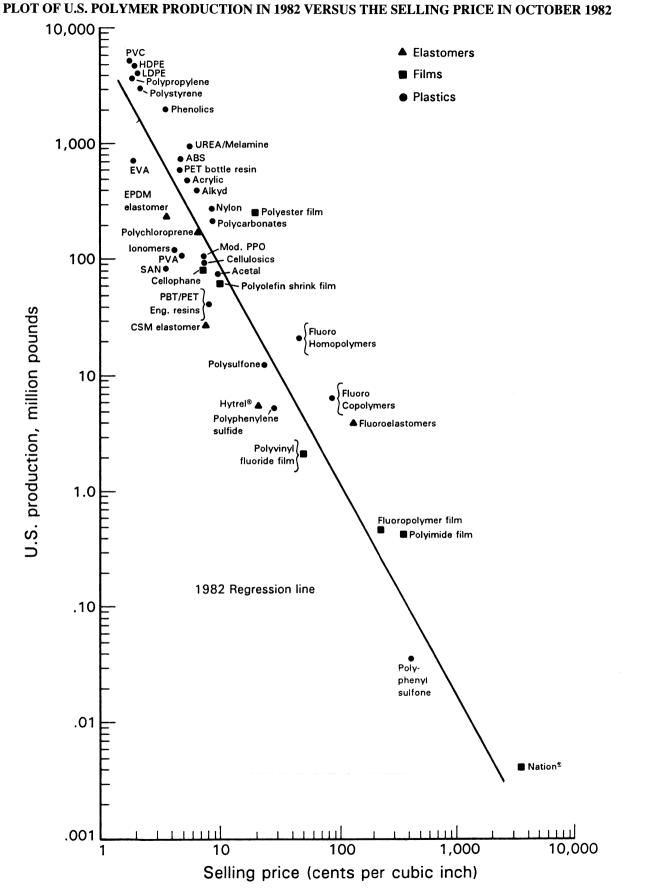

Cross linking is an important process in polymer technology. A high degree of cross linking gives rise to three-dimensional or space network polymers in which all polymer chains are linked to form one giant molecule. Thus, instead of being composed of discrete molecules, a piece of highly cross-linked polymer constitutes just one molecule. At high degrees of cross linking, polymers acquire rigidity, dimensional stability, and resistance to heat and chemicals. Because of their network structure, such polymers cannot be dissolved in solvents and cannot be softened by heat. Strong heating only causes decomposition. Quite commonly, these materials are prepared, by intent, in only partially polymerized states (prepolymers), so that they may be deformed in the heated mold and then hardened by curing (cross linking).

Polymers generally fall into three major categories: commodity, engineering, and high-performance materials, based on price, volume, and usage of the product. Figure 5 plots 1982 U.S. production versus selling price (October 1982) for a wide range of polymeric materials. The grouping of materials in these categories can be recognized fairly easily in this illustration. As production levels decrease, prices increase along the regression line provided.

Commodity materials are the high-volume, low-cost materials that are easily processible. Examples include polyvinyl chloride (PVC), low-density polyethylene (LDPE), HDPE, and polypropylene (PP). Some classifiers place ABS in the commodity grouping, but it also finds usage in engineering applications.

Included in the engineering group are polyamides (nylons), polyacetals, polycarbonates (PC), modified PPO, PET, and polybutylene terephthalate (PBT). These materials are the intermediate grouping in terms of production volume, material costs,

FIGURE 5

and processibility. Engineering polymers have inherent characteristics that make them suitable in areas replacing metals or glass-ceramics. Properties of engineering polymers include good heat resistance, strength, durability, resistance to chemicals and weathering, and good electrical properties (either conductive or insulating).

High-performance materials include polymeric resins and reinforced resins and composites used in more specialized or demanding environments. These materials have a very low production volume relative to the other polymers and a high to very high price, with prices in the hundreds or even thousands of dollars per pound. The polymerization process for high-performance materials is complex, and fabrication is difficult because of their high melting point or even lack of a true melting point. These materials have exceptional resistance to heat, hostile environments, and chemicals; outstanding strength; and good optical, lubricity, and electrical properties. Polymers included in this classification are polyphenylene sulfide (PPS), polysulfones, polyether-imides (PEI), polyamide-imide (PAI), polyimides, polyetheretherketone (PEEK), fluoroplastics, liquid crystal polymers (LCP), and the aromatic polyamides, polyesters and copolymers.

Products for Trade and Industry.—Plastics were initially produced from natural renewable organic materials (such as wood or cotton) or from coal products. Today, petroleum and natural gas are the principal feedstocks used to make a large variety of resins that can be further processed into many different kinds of finished products.

The transportation industry is a continually changing arena of material choices, where lighter, stronger, and less expensive materials are always being sought. The growing importance of plastics in the automobile industry reflects the broadened scope of the material selection process and the desire to make cars lighter and more fuel efficient. In 1988, roughly 11 1/2 million automobiles and light trucks were produced in the United States and Canada. At approximately 210 pounds of plastics per car and 170 pounds per truck, plastics as applied to automobiles and light trucks in 1988 accounted for 2 billion pounds or 3% to 4% of the total plastics produced. Approximately 20% of the plastics used in transportation are enginering polymers. The range for future growth opportunities is shown by experimental applications like the prototype plastic engine, which has been tested in a series of sanctioned road races.²⁶

Another area in which plastics play a major role is packaging. Nearly everything is packaged in some manner prior to delivery. Packaging improves product handling and shipping, offers protection, reduces waste, and aids in identification and inventory. The variety of materials used in packaging has remained fairly constant; however, the proportion of each material used has changed dramatically within the past decade. Currently, these materials include wood, glass, steel, aluminum, paper, and plastic. Plastic is now the predominant material in some sectors of the packaging market and a strong competitor in other sectors. From its inception in the 1950's, plastic packaging has now become the largest single market for plastic use, consuming about 25% of all U.S. plastic production in 1988 and accounting for annual revenues of about \$70 billion. Approximately 50% of all current packaging applications did not exist 10 years ago. This growth is the result of penetration into existing markets at the expense of other materials and the development of new applications not achievable by other materials. Sales growth in packaging lagged overall growth in plastics slightly; however, the recent introduction of plastic grocery bags is a highly visible illustration that the penetration of plastics into this market is not over.

Plastic products have also made significant inroads in the building and construction industry. Plastics made their first substantial penetration into the building and construction industry in pipe applications but are also advancing into other areas with products such as flooring, siding, window profiles, lighting fixtures, insulation, and many others. Since 1970, construction has been the strongest growth market for plastics. New application studies like General Electric's prototype all-plastic house²⁷ indicate that a wide variety of opportunities exist for future sales growth.

Highlights of U.S. resin sales in the construction, transportation, packaging (including nonpackaging film), and other markets are shown in figure 6.28

Construction increased its share from 11% of the total in 1970 to 18% in 1990. The primary growth areas within this market are in pipe, fittings, and conduit, which used more plastic (37% in 1990) than any other construction application.

Packaging and nonpackaging film decreased its share from 32% of the total in

1970 to 30% in 1990. The primary growth areas within this market are in containers (about one-half of all packaging applications), t-shirt bags (grocery bags), and trash bags.

Transportation increased its share from 2.7% of the total in 1970 to about 3.0% in 1990.

The "other" category encompasses a myriad of other applications and decreased its share from 54% of the total in 1970 to 49% in 1990.

Industry Structure.—Most of the domestically produced resins are produced by a relatively small number of large companies. For example, PE, the largest resin category, has 18 producers, but the top four companies have more than 50% of nameplate capacity. ABS has only three domestic producers. PVC has 12 domestic producers, but the top 4 account for 66% of capacity. PP has 14 domestic producers, and the top 4 account for 59% of total capacity. PS has 14, 63% from the top 4. Table 6 lists the domestic production capacity of polyethylene, polypropylene, polystyrene, and polyvinyl chloride, along with the capacity utilization rates for each of the past 5 years.

In contrast to the relatively high degree of concentration among resin producers, there are a very large number of companies that consume plastic resins. A survey taken by Plastics News at midyear 1990 profiled the injection molding industry, the most widely used plastics fabrication technology.²⁹ (The extrusion process accounts for more resin usage, but has far fewer facilities.) This survey confirmed some longheld rules of thumb about plastics use in general. That is, a large part of the resin usage is accounted for by a small number of the firms. The survey identified the top 50 injection molders in the United States. Together they account for almost 1 billion pounds of injection molded resin products, valued at about \$4 billion. Another survey³⁰ taken in 1986 identified almost 8,000 businesses engaged in injection molding, and recent data show more than 5 billion pounds of resins processed by injection molding methods. That is, 15% to 20% of all injection molding business is performed by less than 1% of the firms engaged in that business.

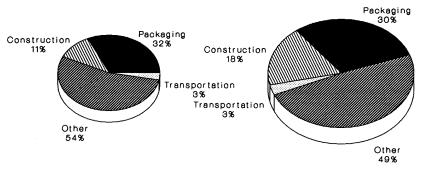

The top 5, and 14 of the top 20, injection molders were engaged exclusively or in large part in supplying the automotive industry. All of them had more than one plant and injection molding-related employment levels between 500 and 2,300 persons. Most

of the businesses supplied plastic products to more than 1 industry, but 14 of the 50 were engaged in a single industry; 9 to automotive, 3 to packaging, and 1 each to electronics and construction.

Table 7 gives information on the number of U.S. plants engaged in fabrication of plastics using one or more primary processes. This information indicates that injection molding is the most prevalent method of fabrication, followed by extrusion. As seen by this and figure 7, the structure of the plastics processing sector is such that more than 50% of fabrication is performed by captive plants.

When the plastics industry is looked at from a perspective of how much resin is processed using each of the major technologies, a somewhat different pattern emerges. Table 8 shows that even though injection molding accounts for the largest number of operations (see table 7), extrusion is the dominant technology in terms of the amount of resin processed. More than 40% of all resins are extruded, about four times the amount processed with injection molding machinery. Blow molding is the third largest technology used, accounting for more than 8% of total resins. A principal reason for this division is that extrusion machinery can create simple shapes, such as pipes and profiles, at a very high throughput rate and very low costs. Injection molding is a very versatile processing technique, but is not a continuous process. Parts can be molded singly or even in multiple numbers relatively cheaply, but each cycle requires a mold fill, cooling, and ejection of the part before the next cycle can begin.

Table 8 also shows that the resin quantities processed by injection molding, extrusion, and blow molding has increased over the past 20 years. For all of these methods, the machinery has improved steadily over that period, becoming more automated, more highly controlled for quality, and the final products less costly to fabricate relative to other processing methods. In combination, these three low-cost fabrication technologies have grown in importance steadily over the period shown.

There are a large number of planned new U.S. facilities for the major resins. In polyethylene, Quantum Chemical Corp. is planning startup of a 200-million-pound facility at Deer Park, TX, in late 1991; Chevron Chemical Co. is planning a new 300-million-pound facility at Orange, TX; and Eastman Chemical Products, Inc. is adding 220 million pounds of new capacity at Longview, TX. Formosa Plastics is con-

structing a 1.5-billion-pound olefins plant at Point Comfort, TX, and expects new capacity for both HDPE and LDPE in 1992. Debottlenecking could add another 400-million-pound capacity in 1991 and 1992 at facilities owned by Union Carbide Corp., Dow Chemical U.S.A., Chevron Chemical Co., Eastman Chemical Co., and E. I. du Pont de Nemours & Co. In addition, capacity to replace the 1.6-billion-pound Phillips 66 Co. plant in Pasadena, TX, which was destroyed in late 1989, is being added in three 600-million-pound installments, the first due early in 1991, the second in mid-1991, and the last in mid-1992.

New polypropylene capacity additions are planned in 1991 by Himont U.S.A. (175 million pounds at Bayport, TX), Eastman Chemical Products, Inc. (220 million pounds at Longview, TX), and Epsilon (265 million pounds at Marcus Hook, PA). New polystyrene capacity is planned by Mobil Chemical Co. (120 million pounds at Joliet, IL), and Kama (15 million pounds at Hazelton, PA). New polyvinyl chloride capacity is planned by Formosa Plastics (800 million pounds at Baton Rouge, LA) and Vista Chemicals (50 million pounds at Aberdeen, MA).

Technology.—Processing.—Products with good performance characteristics can often be produced at low cost with flexible, high-volume, automated methods such as extrusion, blow molding, and injection molding. Those resins that are best suited to these high-volume methods are likely to continue to grow in importance.

Fabrication processes for the thermoplastic and thermoset classifications of plastics take advantage of the chemical differences between the two, although progress in technology has lessened the effective, if not chemical, distinction between them. Thermoplastic resins may be processed hot, cooled, and then reheated and reprocessed, while thermosetting resins cross link in processing and cannot be reheated and used again.

Common thermoplastics include ABS, PVC, SAN, acetals, acrylics, cellulosics, polyethylenes, polypropylenes, polystyrenes, polycarbonates, polyesters, nylons, and fluoropolymers. The most important processing techniques for thermoplastics are injection molding, extrusion, and blow molding. Other processes include thermoforming, casting, rotational molding, calendering, and spinning.

The common thermoset resins include phenolics, ureas, melamines, epoxies,

alkyds, unsaturated polyesters, silicones, and urethanes. The most common processing methods are compression and transfer molding, but thermosetting resins are also processed using reaction injection molding (RIM) techniques, pultrusion, casting, and foaming processes.

The machinery used to process plastics comes from suppliers in a large number of countries. In Western Europe, the Federal Republic of Germany, Italy, and the United Kingdom have large machinery sectors and export a large percentage of what they produce. In Asia, Japan is by far the leading producer of plastics processing machinery. In North America, the United States produces the largest number of machines, but Canada has a surprisingly robust machinery industry. Table 9 shows the numbers of plastic fabrication machines sold into the U.S. market.

Domestic machinery manufacturers felt the effects of the economic slowdown, the injection molding sector much stronger than the extrusion sector. Domestic shipments decreased by 19% from the 1989 level. The biggest fall occurred in the large markets for medium-sized machines, those with clamping forces of 100 to 400 tons. The market for domestically produced machines with clamping force more than 600 tons actually increased slightly. The number of imported injection molding machines dropped from 1989 levels as well, but only by about 8%. The largest part of this decline was for machines built in Europe, imports from which declined 17%. The percentage of the total market was, therefore, more heavily weighted toward imports.

The total number of extrusion machines sold in the United States in 1990 actually went up slightly, although all of the gain was accounted for by increased imports. Domestic shipments of machinery dropped for the second year in a row. The sharpest drop was in the 5.5- to 7.5-inch category, while the largest gain was in the 1.25- to 2inch range. The Federal Republic of Germany is the largest supplier of machinery to the United States, more so for extrusion machinery. Japan is the second largest supplier, and actually accounts for the largest share of injection molding machinery. Canada also accounts for a significant proportion of machinery imports in both categories.

Recycling.—The present concern with solid waste disposal due to the lack of landfill space coupled with plastics high volume-to-weight ratio and low degradability has caused State and local legislatures to consider plastics banning laws or "use tax" legislation. The industry has reacted to this pressure by forming organizations such as The Council For Solid Waste Solutions and The Vinyl Institute to promote solutions to the plastics disposal problem.

Recycling is one viable alternative for a portion of the waste currently being lost to landfills. Several major companies, such as B.F. Goodrich and GE Plastics, have initiated buyback programs for their materials. Others, like Du Pont and Goodyear, have set up purchasing policies that favor the use of recycled materials in the industrial products they buy, such as pallets or industrial strapping.

Recycling can be primary, secondary, tertiary, or quaternary in form. In primary recycling, materials can be reprocessed into products with chemical and physical characteristics similar to the original product. In secondary recycling, materials can be processed into products with less demanding characteristics than the original product. In tertiary recycling, materials can be processed into fuels or basic chemicals; and in quaternary recycling, materials can be incinerated for heat-power recovery. Each of these options has its proponents and opponents and perhaps each has its own value within any given set of circumstances. Not all resins can fit all the options, and even when a form of recycling is possible, it may not be economically feasible.

In the area of reprocessing plastics, there are five basic types of technologies in use for recycling. These include separation, mixed-plastics, PET recycling, washing-upgrading, and other technologies. Separation technologies mechanically segregate distinct resins from a mixed plastic source, while mixed-plastic technologies use the mixed-plastic stream as is. PET recycling technologies are used for soft-drink bottles only, washing-upgrading technologies for previously sorted plastics such as HDPE dairy bottles, and other technologies now under development.

One separation technology currently in use for a mixed stream of plastics uses the different densities to separate the lighter polyolefins (PE and PP) from heavier resins to form pellets that can be marketed to molders. The pellets run about 95% PE and 5% PP. The heavy fraction that is screened out by polyolefin separation (PET, PVC, PS, and ABS) can become part of the feedstock for mixed-plastic technologies that take various mixtures of material and form them into plastic lumber and other products. The mixed plastic method requires a high percentage of polyolefins, which can include plastic bags. It softens the material by internal friction, then forces it into molds where the heavier and most incompatible plastics tend to settle at the center of the piece.31

Because plastics have a high susceptibility to heat, the high temperatures needed to fully sterilize the material may either degrade it or burn it. Therefore, recycled food-contact plastic packages cannot be guaranteed to meet FDA safety standards and are not made back into food packages. While this removes a considerable market for recycled materials, there is a large market for containers for nonfood items like

antifreeze, laundry detergent, and motor oil.

As an alternative to recycling plastics, various technologies are being developed to make plastics degradable, thereby reducing their impact on the waste stream. However, additives that facilitate degradability tend to reduce engineering characteristics and to reduce the reliability and adaptability of products. There is also some concern with the chemicals that form when plastics degrade and whether they might contribute to ground water contamination or methane production in landfills.

Several companies are developing additives that combine cornstarch and an oxidizing agent to be mixed with plastic resins. The oxidizing agents react with metal salts in the soil, and the links between polymers are destroyed. At the same time, bacteria can feed on the cornstarch. Over about 15 years, the polymers eventually break down into fragments that are small enough to be eaten by micro-organisms. However, the guarantee of direct soil contact may be elusive due to the nonideal implementation of landfills in actual practice. Another degradable material is being tested by Exxon Chemical.³² In its process, iron and nickel compounds are added to the polymer and aid in its degradation.

Another area of degradability is photodegradable plastics. Dow is a big producer of photodegradable connector rings for beverage six-packs. Here is an instance where degradability rapidly realizes its potential for injury to animals and birds who may become entangled in or grow into one of the rings much as a tree grows into a piece of wire wrapped around the tree. Other companies are producing bags and other packaging materials that are photodegradable also. Depending on the amount of ultraviolet light needed to initiate degradation, a major problem with photodegradable materials is that once they are landfilled, they cannot be further exposed, and degradation may be limited.

Degradable plastics are of major interest in agriculture, where they are used as mulch films to retain moisture on arable land.³³ Nondegradable films were difficult to collect at the end of a growing season and could not be used again because it was too difficult to separate out the plant stubble. Photodegradable films break into flakes and can easily be plowed back into the soil.

Research is ongoing in uses for plastics that dissolve in special alkalies or acids.³⁴ Dissolved plastics can be precipitated and reused. Uses for this type of materials include adhesives for bottle labels, tie layers

in a multilayer structure, and lost-core cavity moldings.

Imperial Chemical is testing a natural plastic produced by a type of bacteria found in the soil.³⁵ The plastic is produced by the bacteria much in the same way humans store fat as a future source of energy. The plastic is similar in appearance and texture to petroleum-base polymers and it decomposes into water and carbon dioxide. Decomposition is precipitated by certain enzymes found in the soil. The cost of manufacturing this material is prohibitive at this time. Costs are estimated at \$15 per pound compared with \$0.65 per pound for conventional plastics.³⁶

The plastic component of the waste stream is steadily growing. Current estimates suggest that between 5% and 9%, by weight, of municipal solid waste is made up of plastic. According to information cited in the Plastics Recycling Action Plan for Massachusetts, estimated national plastic discards are about 7.9% for 1988 and projected to be 9.8% by the year 2000.³⁷

An even bigger issue in the disposal of plastics is that the volume taken up by plastics is much greater than its weight. Estimates from various sources indicate that while 5% to 9% of the solid waste stream is plastic by weight, those same plastics may be taking up to 25% to 30% of the space by volume. 38 Plastics are light, and in the case of formed shapes, bottles, etc., they take up a certain amount of air space also. Plastics tend to return to their original shape after crushing and thus would need to be shredded to make the most effective use of space.

Waste-to-energy incineration involves segregating plastics from other solid wastes and converting them to pellets prior to burning as a primary fuel. These types of facilities are generally operating on a small scale presently, such as on college campuses, hospitals, municipal buildings, and office and industrial parks.

Plastics have four times the fuel value of the average mix of municipal solid waste and the same value as residual fuel oil. According to Mobil Chemical Co., which is analyzing the industry and its potential, plastic fuel pellets have twice the fuel value of Wyoming coal.³⁹ Problems with incineration include the potential for production of dioxin as a byproduct of incinerated PVC, other air and water pollution issues concerned with the burning of plastics, and disposal of the resulting ash.

Substitutes.—Intermaterial competition is ongoing all the time, with attempts to

bring to the market new materials with superior properties at low prices. Traditional metal markets have often borne the brunt of attacks from newer materials such as polymers, but just as intense is competition between resins. Much of the blending, alloying, and reinforcing activity in the polymers industry is an approach to minimizing the cost of bringing a new resin to market. A Du Pont executive was quoted as saying his company's approach is to "extend the envelope of nylons, acetals, and polyesters," all workhorse resins for this company.

Polymeric materials are being substituted for glass, ceramics, metals, and paper in many applications. As polymers with improved physical properties are developed, substitution for other polymers also occurs. Everything from microwave food packaging, with its multiple layers with barrier properties, to sporting goods, to automobile bumpers, to satellites and aircraft are now made with polymeric materials. Some areas of substitution encourage new product development by the polymer users such as food packaging. Others improve product durability and provide weight savings and/ or cost savings.

Since the development of synthetic fibers, about 1940, structural applications of polymers have increased, and engineering plastics of great strength and durability have replaced metals in many applications.40 Recent advances in the understanding of materials design has led to designing highly engineered multicomponent systems based on the special characteristics of polymers. In the past, many applications of polymers failed because the parts were simply made to look just like the metal parts they were replacing. This did not take advantage of the physical properties of polymers or take into consideration their limitations. Using designs intended for metal often resulted in poor performance and failure. As designers have learned to better utilize the unique properties of various polymers, the development of polymeric materials suitable for critical load-bearing applications has accelerated.

Plastics have advantages over metal in that they do not rust or corrode the way metals do. They may be less expensive on a volume basis than some metals, have specific strength equivalent to or greater than most metals, be easier to fabricate, be adaptable to a single-part fabrication of a multifunction component, and require less energy to produce. Polymeric materials are produced from hydrocarbon feedstocks. However, the production of polymers uses

far less energy than that consumed as a fuel in the production of most metals. The amount of energy contained in the feedstock materials for polymers is also low, and so the total amount of energy used to produce a given volume of structural materials is significantly less for plastics than for metal.⁴¹

Substitution is encouraged not only by improved function, but by cost savings as well. Because polymeric materials and composites are generally lighter than the materials they are replacing, advantages in areas such as materials-product-shipping costs may be critical in the decision to switch from glass or metal to plastic. Lighter automobiles and aircraft have lower fuel requirements and, thus, are more cost effective. One manufacturer announced that an all-composite aircraft of its design resulted in a 2.5-fold improvement in fuel usage and a 60% increase in range over that of a comparable, but heavier, aluminum aircraft.42

Consolidation of multiple parts to a single part is another potential cost-saving aspect of materials substitution. One estimate of the assembly advantages of an all-composite aircraft includes a fivefold decrease in the number of airframe parts and a twelvefold decrease in the number of fasteners used in assembly.⁴³ The simplified fabrication allowed with consolidation is, in and of itself, an advantage over other conventional (metal) materials.

Economic Factors.—Prices for plastic resins in 1990 were affected by the August invasion of Kuwait by Iraq. The effects, however, were not as immediate as they were on the price of crude oil, nor were they as severe. Increases in prices for virgin res-

ins were generally on the order of 10% to 15% or less over preinvasion levels, as shown in table 10. For some of the commodity-grade resins, particularly the polyethylenes, price ranges cited in the literature tended to widen near the end of the year. Typical was the price for injection-grade HDPE, which started the year with largevolume prices near 40 cents per pound. A softening of price occurred at midyear, generally attributed to competitive price cutting, leading to prices near 39 cents per pound in July. By October, HDPE was selling in large volumes for 41 to 43 cents per pound and continued to strengthen to close the year in the 45 to 48 cents per pound range.

Prices for recycled plastics showed a different pattern. Both PET and HDPE, by far the largest volume of recycled resins traded, suffered from the general weakening of prices at midyear and rebounded to near January levels just prior to the invasion. Both PET and HDPE recycled flake and regrind prices were maintained at early August levels through the end of the year, but no further increases occurred. The price for recycled PVC stayed unchanged all year, while recycled polypropylene prices rose slightly subsequent to the invasion.

Annual Review

Legislation and Government Programs.—There were a number of moves by governments at various levels to affect materials disposal or materials use, especially for packaging. One very controversial proposal was a bill introduced in Congress to tax virgin materials so as to encourage the use of recycled materials. Though the bill did not gain widespread support, it reflected the tone of many State

TABLE 10

PLASTIC PRICES

(Cents per pound)

	January 1990	July 1990	December 1990
HDPE, injection molding	40	39.50	45-48

and local legislatures. On a positive note, the FDA approved the use of recycled PS as a material for egg cartons.

Another significant move related to materials recycling occurred in December when President Bush blocked an Environmental Protection Agency regulation just days before it was to become law. Part of a broader regulation on incinerators would have tied together recycling and waste-toenergy issues by requiring removal of 25% of recyclable garbage before burning. While the general goals of greater recycling were not disputed, the objections of State and local government operators of such facilities cited the lack of definition of which materials were to be considered recyclable and the level of responsibility this provision would have given them for recycling.

Several States passed legislation during the year related to banning some plastic materials, forcing the use of recycled materials, or limiting which materials would be allowed into municipal landfills. Several other States were in court attempting to have similar laws passed in previous years upheld. A ban on PS packaging in Portland, OR, was upheld. A more extensive law in Suffolk County, NY, remained under litigation. Wisconsin passed a wide-ranging law focused on the recycling of containers, especially plastics, and banning certain materials, including tires and plastic containers, from landfills. A Massachusetts ballot initiative that will require a recycled content in packaging materials and packaging materials to be recyclable was passed. New Haven, CT, and Berkeley, CA, passed bans on PS foam packaging. Howell, NJ, passed a law that will require a 60% recycle rate for packaging materials.

In Europe, several countries made moves toward banning PVC as a material for containers, but the European Community came out publicly opposed to individual country bans on materials. The concerns focused on potential dangers from the leaching of additives, plasticizers, and heavy-metal colorants. Also cited was a concern over the environmental effects of a chlorine-containing material going into incinerators, a waste disposal technology that is more widespread in Europe than in the United States. Switzerland was the only country to pass an outright ban—on PVC soda bottles.

The effects of last year's Montreal Protocol agreement on the reduction of chlorofluorocarbons (CFC's) was also felt in the polymers industry. Major uses are as a blowing agent for PS and rigid urethane insulation foam and as a cleaning solvent.

Adequate substitutes have been found for CFC's usage as a PS foam blowing agent, and its use in that area is nearly completely gone. Some substitutes or alternative technologies exist for insulation foam and solvents, but there are cost and/or performance penalties to this substitution.

A preliminary ruling came in November from the U.S. Department of Commerce assessing penalties against Japanese and South Korean producers of PET film for dumping in the U.S. market. The suit had been filed in the spring by U.S. film producers.

Issues.—Plastics were under attack on a variety of environmental fronts during the year, many of them related to growing public concern with materials recycling and landfill disposal. Several companies introduced resins or products that were said to degrade. Controversy over the definition of degradability and whether this was true under normal landfill conditions led many of the companies involved to withdraw these claims, except for specialized products. Degradable resins are being used as pharmaceutical gelatin capsules, for example, and were mandated in several States for use in six-pack rings for beer and soft drinks. By the end of the year, there were 35 States and many localities that had degradability requirements written into law.

Another visible area related to degradability was disposable diapers, viewed as a materials issue where plastics compete with cloth. Disposable diapers are thought to make up approximately 2% of municipal waste streams. Two potential solutions were offered on a small scale during the year; degradable diapers made from starch-based polymers and compostable diapers that necessitate a materials switch from PE liners to a starch-based product. Both experiments are likely to be continued into the next year.

Recycling was also an important area where a large amount of activity was occurring. The development and spread of technology and machinery for recycling organic materials was strong. Likewise, there were some major developments in new products utilizing recycled resins. For example, a number of companies announced new programs that utilize recycled HDPE as a middle layer in a coextruded parison used to blow mold soap, cosmetic, and motor oil bottles. The total amount of secondary material will be as high as 70%, but of that only 25% is guaranteed to be postconsumer. Firms in Alabama, Arkansas, and Wisconsin opened new facilities to produce plastic "wood" from recycled HDPE and mixed-resin streams. Although this product will be higher cost, it has properties that may give it an advantage in markets that demand resistance to moisture or corrosion.

One of the biggest moves during the year, however, came amidst the debate over what role FDA had in controlling the recycled content of packaging that came into direct contact with food. Two resin companies announced in the fall that they had developed processes for reducing postconsumer PET bottles to basic monomers, a closedloop process that allows identical products to be fabricated over and over. Then, in December, both Coca Cola Co. and Pepsi Cola Co. announced programs to use these resins in 1-, 2-, and 3-liter soft drink bottles. Both companies requested FDA consent, but it appears FDA will have to ask for new legislation in this area if they are to have the power to deny such applications. Some question remains whether the process can be accomplished at a competitive price, but still this move was hailed as a potentially significant expansion in new markets for recycled materials.

Perhaps the most controversial move during the year was the switch by McDonald's away from polystyrene foam packaging to a paper-based product, a potential loss of more than 20,000 metric tons to the PS industry. The court ruling in February upholding the Portland, OR, ban on PS may have set the stage. A European initiative sponsored by McDonald's to develop a dissolvable PS resin was announced in March, but fizzled later in the year. Another McDonald's initiative to recycle PS into "wood" products was considered in June. In August, the Environmental Defense Fund and McDonald's announced the formation of a task force on waste reduction. Finally, in November, McDonald's announced it would dump PS in favor of paper-based packaging, citing consumer preferences and a reduction in the overall volume of waste generated from discarded packaging. "We are trying very hard to find products that are fully recyclable, but our ultimate goal is source reduction," said Ed Rensi, McDonald's president.

Source reduction was a major topic during the year. The linear low-density polyethylene (LLDPE) milk pouch was given special emphasis, both in the United States and Canada, where it has long held a significant market share. The potential for reduced materials use is substantial. Currently, almost 450,000 metric tons of PE is

used as milk jugs or coatings on paper milk cartons. This could be reduced by more than three-fourths if complete substitution occurred.

Markets and Prices. - In 1990, plastics sales totaled 27.9 million metric tons, or 36% of world sales, as shown in table 11. Compared with last year, this represents an increase of 4.5% in domestic sales. Near vearend, U.S. producers were able to boost sales as a result of a price advantage abroad that led to an increase in plastics exports. Among the major large-volume plastics, a combination of LDPE and LLDPE, with 17.6% of sales, ranked first in volume sold during the year, followed by PVC, with 15.1%; and HDPE, with 13.8%. The fastest growing markets in 1990 were PVC, PP, LLDPE, and the category combining the engineering resins PBT, PCT, and PET.

Foreign Trade.—International trade is an important component of the plastics industry, as shown in table 12. Exports of plastic resins accounted for about 15% of U.S. plastic sales, while imports were equivalent to about 5% of sales. Imports grew at a faster rate than exports in 1990. In value terms, net exports of plastic resins were larger in 1990 than net imports of plastic products, the first time this has happened in recent years.

There was also growth in the value of plastic machinery imports and exports, with the level of exports growing at a much faster rate. The United States continues to be a net importer of plastic machinery, but the level of net imports actually dropped in 1990. The value of net imports of plastic molds also dropped in 1990 because of an 18% rise in exports and a 4% drop in imports.

World Review .- Sales of plastics in Western Europe totaled 22 million metric tons in 1990, or 28% of world sales, as shown in table 13. Compared with that of a year ago, this represents an increase of 5.8% in sales. Sales of LDPE, at 5.2 million metric tons, vinyls, at 5.2 million metric tons, and PP, at 3.7 million metric tons, accounted for more than one-half of all the region's plastics sales during the year. For LDPE, the major market was the film and sheeting market, which accounted for the lion's share of usage, followed by the extrusion coating and the injection molding markets. For vinyls, the major markets were the pipe and conduit, profile extrusion, and film and sheet markets. For PP, the major markets in

Western Europe were the molding and extrusion market and the film market.

Growth in plastics production in Japan led that of all other categories in 1990, outpacing production growth for both synthetic rubber and synthetic fibers. Sales of plastics in 1990 totaled 11.0 million metric tons. an 8.0% increase over the 1989 level. All plastics sales contributed to the overall increase, except urea-melamine sales, which declined slightly from those of a year ago. Among the sales of the major commodity plastics, PP sales in 1990 jumped 16.4% to 2.1 million metric tons above the 1989 level; this increase was mainly due to growth in the injection molding market. PVC sales increased 1.4% to 2 million metric tons in 1990 owing to modest growth in the rigid, flexible, and wire markets. LDPE sales in Japan rose 17.3% to 1.7 million metric tons, largely owing to increased growth in the film, wire, and cable markets.

Sales of plastics in Canada in 1990 in-

creased to 2.6 million metric tons, an 8.1% increase from that of a year ago. LDPE sales, at 1.3 million metric tons, led that of all plastics. Growth of LDPE jumped 10.6% over the 1989 level. This increase was mainly due to an increase in exports and in domestic film applications. Also, sales of PVC increased 8.8% to 0.5 million metric tons, and sales of HDPE increased 8.2% in 1990 to 0.4 million metric tons, largely owing to an increase in exports.

Outlook

Plastics are used, in quantitative order, as packaging materials, building materials, as electronic and transportation hardware parts, in appliances, and in furniture. Thus, the future use of plastics is tied to the behavior of the markets for these products.

The economic recession that affected the world economy in 1990 is having an effect in slowing total plastic production, as did

the Middle East crisis by causing at least a temporary increase in resin prices that persisted into 1991. Another factor is the environmental concerns caused by the solid waste issue and the problems created by plastics disposal.

In spite of all of these disruptions, plastics are still experiencing the benefits of an 8-year boom that is expected to continue, although at a slower rate. World demand for the commodity plastics, polyethylene, polypropylene, polystyrene, and polyvinyl chloride grew at a rate of 5.7% through the years 1980-87. It is predicted that this growth will continue through the year 1995 at a rate of 3.5%.44

The Middle East crisis and a destructive fire at Phillips 66's Houston HDPE plant combined to reduce polyethylene supplies and raise prices by 6 cents per pound by the end of 1990. Capacity increases of 3.2 million pounds by the end of 1990 and future expansions expected by 1992 should increase polyethylene supplies and cause a decline in prices in the near future.⁴⁵

A new trend in technology is the use of bimodal HDPE resins that use a combination of high and low molecular weight resins, allowing for an increase in variance of properties and processability. The major gains because of the use of this bimodal technology have been the grocery and trash bag markets. The increase in strength allowed downgaging of the HDPE film.⁴⁶

Polypropylene exhibited an increase of 11% in U.S. sales in 1990, and it is predicted that it will continue to grow at a rate of 5.7% per year through 1994. There are plans to increase U.S. production capacity by 2.3 billion by 1993, but this gain may be offset by closure of some older plants. Globally, there are planned increases in polypropylene production capacity in China and Latin America, which could lead to only a 75% capacity utilization by 1993. This could affect U.S. export markets.⁴⁷

Polystyrene sales were flat in 1990, although there was a noticeable decline in several uses because of environmental issues. There was a combined 45-million-pound decline in six categories of an overall 5-billion-pound U.S. market. The decline in uses of polystyrene occurred in the following products: egg cartons, hinged containers, nonthermoformed foam cups, EPS cups and containers, and loose fill. Offsetting these declines were increases in the use of the following products: PS film and sheet, vending and portion cups, medical disposables, audio and/or videocassettes, and housewares.⁴⁸

Other areas are expected to grow in the future because of technological changes that have allowed production of polystyrene

with low levels of residuals such as ethylbenzene. These residuals can affect taste and odor, and their reduction improves toughness and gloss and allows polystyrene to effectively compete for products normally made from ABS such as videocassettes and appliances.

The environmental issues involved in use of polyvinyl chloride (PVC) as a packaging material have led some to predict a decline in use of PVC in the United States in 1991. However, this may be somewhat offset by the recession, because during times of recession, there tends to be more repair or remodeling work on existing structures, leading to the use of more PVC siding, windows, and piping.

Polyethylene terephthalate (PET), the most recycled of all plastics, was explored for closed-loop recycling with the removal of the FDA's proscription against using recycled plastics in food containers. This will not increase PET use directly but may aid in its continuing use because of the perception that a solution to the solid waste disposal problem is being achieved. The current and impending legislation against the use of PVC in containers has led to research in the use of PET in the extrusion blow molding process to produce alternative environmentally benign containers. This new niche for PET use may expand its market share in the early 1990's.

The engineering resins are attempting to expand their share of the market by moving into new products through the use of new additives to create alloys with specific property increases in such factors as toughness, weatherability, and heat resistance.

Polyurethanes are being developed that allow for RIM grades that react faster to decrease cycle times in processings and are more recyclable for use in such products as auto body panels and fascia.

SYNTHETIC FIBERS

Synthetic fibers have enveloped our everyday world and provided a vastly improved living environment. They make up almost every textile and are incorporated into an infinite number of consumer and industrial products. Likewise, they are important to the U.S. economy. Synthetic fiber industries employ more than 50,000 workers. In addition, the fiber-textile-apparel industry employs more people than the auto, computer, steel, oil, and coal industries combined. Synthetic fiber production in 1990 was almost 4 million metric tons, with sales of approximately \$11.5 billion.

Reviewing the utilization of manufactured fibers, most would rank the garment industry as the prime user. Synthetic fibers are incorporated into many other areas, including home furnishings, carpeting, filtering media, composite reinforcement, and disposable diapers. Roughly 45% of all manufactured fibers are utilized in home furnishings, 25% in industrial products, and 30% in clothing.

Background

Manufactured fibers have been in existence for more than 50 years. "Artificial silk," rayon, was commercially produced in the United States in the mid-1920's. Costing onethird the price of silk and with similar properties, rayon initiated the manufactured fibers conquest of the commercial textile market. Nylon was commercialized by Du Pont in 1939 and, by the end of the 1940's, industrial America was incorporating nylon into everything from hosiery to carpets to upholstery. New fibers developed over the next several decades included olefin, acrylic, and polyester fibers. In the early 1950's, blends of these fibers with cotton were transformed into "wash and wear" garments and became a way of life for the American public. In the 1960's and 1970's, these fibers were modified and engineered, both chemically and physically, to produce tailored fibers with specific and sometimes unique applications. Polyester tire cords, stretchable Spandex apparel, hightemperature-resistant polyamide space suits, and nonwoven diapers are several examples. Today, manufactured fibers are assimilated into artificial organs, surgical gowns, roofing materials, and floppy disk envelopes. Their diversified characteristics and performance properties provide an endless array of products, as simple as polyester sewing thread and as tough as a bullet-stopping aramid undervest.

Manufactured fibers are typically broken down into two main areas, artificial (cellulosic), which consists of acetate, rayon, and triacetate*, and synthetic (noncellulosic), with the largest consumption materials being nylon, polyester, olefin, and acrylic (minimum of 85% acrylonitrile). The other synthetic fibers include anidex*, aramid, azlon*, glass, lastrile*, metallic, modacrylic (minimum of 35% acrylonitrile), novoloid*, nytril*, PBI, rubber, saran, spandex, sulfar, vinal*, and vinyon. (The * denotes that these synthetic fibers are not currently produced in the United States.) The Federal Trade Commission (FTC) has assigned these generic names based on their significantly different chemical composition. If a new fiber were invented with a different chemical design, then the FTC would assign a new "official" generic name. If any of the generic fibers are modified, then it would be named a variant. The custom engineering of these generic fibers produces variants that have specific properties for specific applications. Likewise, when a manufacturer develops a new fiber, a trademark is usually issued by the U.S. patent office for that fiber class.

Products for Trade and Industry.—The most widely used fiber is polyester, employed both alone and as a blend with natural or other synthetic fibers. Some common industrial applications are carpeting, boat sails, ropes, and geotextiles for highway construction. Nylon fibers have a wide range of uses, including carpets, sheer hosiery and lingerie, and sleeping bags. Olefin fibers are incorporated in sportswear because of their hydrophobic nature and wicking properties, which allow body moisture to pass to the surface of the fabric and away from the skin. Acrylic fiber is soft and warm and is utilized in blankets and sweaters. The cellulosic fibers, rayon and acetate, are both used in the manufacturing of fabrics for wearing apparel and home furnishings and curtains and drapes.

The specialty fibers provide extraordinary properties. Aramid is used in protective clothing due to its flame retardancy. Because aramid fibers have a high modulus, they are utilized in tires, military protective equipment, and advanced composites in aircraft. Spandex is often blended with other fibers and converted into stretchable clothing. Additional major generic synthetic fibers produced today are modacrylic for flame-retardant sleepwear; vinyon for teabags; PBI, which will not burn in the air, for special protective garments; and sulfar, with a melting point of 285° C, for industrial filtration fabrics.

Technology.—Cellulosic fibers are regenerated natural polymers, and noncellulosic fibers are polymers created by chemical synthesis. The basic process involves preparation of the selected raw material into a liquid form or solution by dissolving or by melting it. After extruding and hardening the filaments, called spinning, the material is collected for further processing if required. This extrusion, or fiber forming, is achieved by forcing the fluid or molten material through a plate (spinneret) containing numerous, minuscule openings. Stretching of the filaments is a

ORGANIC MATERIALS—1990 827

method of orientation that may increase the fibers strength and also reduce the fiber to a desired diameter. The fiber industry uses the terms denier or tex to identify the diameter of different fibers. (Denier is the weight in grams of 9,000 meters of fiber. Tex is the weight in grams of 1.000 meters of varn.) The large, ropelike bundle of these many continuous filaments is named tow. Staple fibers are the results of cutting the tow to desired lengths. Uncut tow may be shipped to mills where it is converted into yarn that can be either monofilament or multifilament. Numerous postmanufacturing processes can now take place. The yarns may be textured, spun, or combined. Fibers can be crimped or blended.

There are variations of this process that provide truly specialized fibers. Two different polymers can be extruded side by side or in a concentric fashion, producing a bicomponent fiber. By modifying the spinneret, fibers may be extruded into different shapes or they may be made hollow. An example of engineered modification is the manufacturing of spandex fibers. By careful selection of the monomers, short polymers, some of which are rigid and others flexible, are joined together to produce a block copolymer containing both hard and soft segments. The flexible segments provide stretch while the rigid ones allow recovery when the force is removed.

Presently, work is being focused on the improvement of existing fibers by optimizing their properties through process modifications such as stretching during forming. The development of new polymeric fibers is not a high priority. Another area of research is the alloying and blending of different fibers to obtain a product that provides the best resultant product for a multitude of applications.

Economic Factors.—Since the end of World War II, international trade agreements promoted apparel and textile imports to help the devastated nations and more recently small, developing nations recover their economies. But these foreign manufacturers, with the luxury of inexpensive labor, produce imports that have become more than 50% of the domestic clothing market. The effects have resulted in domestic plant closures and wide-scale layoffs. According to the Fiber Economics Bureau, the fiber, textile, and apparel industry does not wish to ban imported textiles and apparel from the American markets. But it does support legislation and international trade agreements that would limit the growth of imports to the growth of the domestic market.

International competition continues to be a sensitive area and has basically kept the U.S. commodity fibers industry at a near 0% growth rate for the past decade.

Operating Factors.—Today there are unlimited variations of the major generic fibers that have been engineered to accomplish specific tasks. Within these generic names are trademarks for the individual fibers. The FTC will establish a new generic name only when a fiber is developed that is different in chemical composition from other fibers. The Federal law also requires that textile products be labeled with three kinds of useful information: a sewn-in label identifying the country in which the product was made, a label or tag that includes those fibers that compose 5% or more of the item, and a permanent label giving care instructions.

The Consumer Product Safety Commission established a flammability standard in the early 1970's that created a major upheaval in the fabric market. The use of cotton was almost eliminated in children's sleepwear and in carpeting.

Annual Review

Markets and Prices.—Overall domestic production of synthetic fibers during the past 5 years has varied only slightly, with a maximum of 4.1 million metric tons in 1988 and a minimum in 1986 of 3.8 million metric tons (table 14). Comparing total production in 1986-90, there was a modest increase of almost 3%. Production of synthetic fibers totaled 3.9 million metric tons in 1990, representing a decrease of 4.5% from that of the 1989 level. All fibers registered a decrease in production compared with prior years, except polyolefins. Polyester accounted for 36.8% of total production, followed by nylon, with 30.6%; and polyolefins, with 21.0%.

U.S. trade in synthetic fibers, including woven cloth, has been relatively minor in recent years, as shown in table 15. The total values for both exports and imports have been between 2% and 4% of U.S. fiber production levels in recent years. Exports and imports have been at comparable levels, with a slight net export position.

Prices of synthetic fibers have risen only slightly in recent years. An index for gray synthetic broadwovens, typical for the industry, showed an increase in prices of only 1.5% over 1989 levels. Increases in price since 1987 have averaged 3% per year.

World Review.—World production of synthetic fibers dropped to 13,178 thousand metric tons in 1990, representing a decline of 2% from the 1989 level for those countries shown in table 16. Leading producers included the United States with a production of 3.9 million metric tons; China, with 1.6 million metric tons; Taiwan, with 1.3 million metric tons; and Germany, with 1 million metric tons.

Outlook

The major synthetic fibers produced from oil and gas are polyester, nylon, acrylic, and polypropylene. These were produced in the United States in 1990 at the following percentages of total fiber output: polyester. 39%; nylon, 33%; acrylic, 22%; and polypropylene, 6%. There was a general decline in production of all synthetic fibers during the year, except for polypropylene, because of consumers' preference for natural fibers, especially cotton. Du Pont phased out acrylic production in 1990 because of this decline.⁴⁹ It is expected that synthetic fibers as a sector will continue to grow at a slow rate of 1.4% per year over the next 5 years, with polyester production being responsible for most of this growth.⁵⁰ Worldwide installed production capacity is expected to meet demand for the next 10 vears.51

SYNTHETIC RUBBER

The principal consumer of synthetic rubber in the United States is the tire industry, where about 50% of all commodity synthetic rubber is deployed. With technology providing improved tire wear, the replacement timeframe is being extended and causing general sales declines. Intense domestic competition continues to hold prices at levels from previous decades. The combined effects on this market have created losses for many major tire producers. Growth in the tire and tire products industry is effectively sluggish.

Growth in the nonautomotive businesses continued at a modest rate in 1990, with future estimates yielding higher potentials. These other areas of consumption encompass belts, gaskets, and hoses for industrial applications. Also, lesser areas, but of equal importance, are footwear, roofing materials, pond linings, wire coverings, and adhesives.

Estimated.

Source: Chemical & Engineering News.

Background

Examples of synthetic rubbers are styrene-butadiene rubber (SBR), polybutadiene rubber (BR), ethylene-propylene (EPR), nitrile rubber (NR), and other. This "other" category contains a variety of specialty elastomers that include poly-chloroprene, polyisoprene, silicones, urethanes, and thermoplastic elastomers (TPE). (Elastomers are materials, which at room temperature, can be stretched repeatedly to at least twice their original length and, upon release of the stress, will immediately return with force to their approximate original length.)

TPE's are growing faster than the basic elastomers owing to this group's versatility and uniqueness in applications. Within the TPE family exists thermoplastic polyolefin (TPO). There is no industrywide definition of a TPO, nor even common terminology. TPO is also known as olefinic thermoplastic elastomer (OTPE) and elastomer modified polypropylene (EMPP). The most common designation, TPO, is usually applied to any blend of polypropylene (PP) and rubber, and physical properties can vary widely.

A major potential growth market for TPO's is the automobile fascia, or bumper cover, where the dominant plastic in North America has been RIM urethane.

Annual Review

Markets and Prices.—Synthetic rubber profitability is currently decreasing, particularly in the commodity rubbers. This is mainly due to two materials, SBR, the largest volume product, and BR. Two-thirds of their total output goes into the tire market, where recent changes in the size and type of tires has greatly affected rubber use. Although the number of SBR solid producers in the United States has dropped from nine in the early 1980's to five, cheaper imports, especially from South America, are holding prices down.

Table 17 reveals very flat production growth within the United States over the past several years. Production of synthetic rubber in 1990 totaled 2.1 million metric tons, down 6.5% from that of the 1989 level. Of the major volume products, styrene-butadiene rubber accounted for 40% of total production; polybutadiene rubber, 19%; and ethylene-propylene rubber, 12%.

World Review.—The International Institute of Synthetic Rubbers Producers

¹Polyester fibers only.

²Total is for countries listed only.

(IISRP, Houston) estimates total world consumption of synthetic rubber was 7.07 million metric tons in 1990.

In Western Europe, approximately 2.4 million metric tons of synthetic rubber was produced in 1990, as shown in table 18. This corresponds to a growth of approximately 1.6% compared with that of the previous year. Except for the Federal Republic of Germany, all large-volume producers posted declines in production levels in 1990 compared with the 1989 levels.

Current Research.—The commodity synthetic rubbers have drawn very little research and development attention in recent years, with specific emphasis being directed toward reducing production costs and increasing productivity. Current research is mostly involved with thermoplastic elastomers (TPE). One arena drawing attention is the thermoplastic pololefin elastomers (TPO), which are highly engineered polypropylene products. The range of properties obtainable, both flexural and service temperature, make the PP-based TPO the least cost engineered material for many demanding automotive applications. Also, their lower specific gravity compared to their typical competitive materials allow a much desired weight savings.

Outlook

The past several years have exhibited little or no growth, consolidation of production capacity within this industry, and development of more versatile polymers. Although the commodity elastomers businesses are relatively mature, the specialty areas, which are presently low volume, continue to grow at moderate rates. Any real growth may be delayed until after a recovery in the construction and automotive industries, which are the primary users of these materials.

World demand for synthetic rubber is expected to remain low, with installed production capacity able to meet demand over the next 5 years. A growth rate in production is estimated at 2% for the world market until 1995, with developing countries exhibiting an increase in demand and many industrialized nations experiencing slow growth or even a decline in demand.⁵²

In Western Europe, for 1991, IISRP expects a growth in consumption of 2.5%. Overall synthetic rubber consumption is expected to reach 2.6 million metric tons by 1995, up from the 1990 level of 2.4 million metric tons.⁵³

PEAT

By Raymond L. Cantrell

Mr. Cantrell, a physical scientist with 27 of years industry and U.S. Bureau of Mines experience, has been the commodity specialist for peat since 1988. The peat survey was monitored by Virginia Harper and Maureen Riley, mineral data assistants; Virginia Harper also prepared domestic data tables. International data tables were prepared by Audrey Wilkes, international data coordinator.

eat is a natural organic material of the Earth that is found in great abundance in the United States. Nature enthusiasts and home gardeners alike benefit from the aesthetic appeal of peat and its utility in cultivating flowers, plants, and vegetable gardens. Commercial greenhouses and nurseries culture beautiful flowers and plants from peat-based growing media that contribute significantly to our well-being.

A review of the projections by various members of the U.S. horticultural community substantiates the existence of a widely held opinion that horticulture will continue as a strong growth industry. The Horticulture Research Institute, National Landscape Association, Society of American Florists, and the National Gardening Association all forecast significant future growth.¹

Peat is used in a variety of other commercial applications, including turf cultivation, golf course greens construction and course maintenance, mushroom cultivation and earthworm culture, poultry litter, fertilizers, seed innoculants, humic acid extracts, toxic waste filtration, hygienic products, and fuel for electrical power generation.

The U.S. peat industry developed from small "mom and pop" operations that to-day comprise 70% of all active peat operations and 20% of total production. They provide a valuable service to their local communities at a marginal profit. About 80% of U.S. peat is produced in high-volume operations by 30% of the producers. Large operations move peat in interstate commerce owing to economies of scale.

In 1990, the U.S. peat industry continued to be negatively impacted by recessionary forces, although there were indications that the industry had begun to stabilize relative to the downturn of the previous 2 years. Production, sales, and apparent domestic consumption stabilized

in 1990, and there was a firming of prices relative to 1989. Canadian imports continued to increase and reached record proportions in terms of volume, value, and market share. Canadian peat movement across the U.S. border in 1990 reached a record 44% of the total U.S. supply. The total U.S. supply was valued at about \$110 million based on f.o.b. domestic plant and U.S. Customs values.

Large-scale composting operations, driven by environmental concerns, continued to proliferate in both the public and private sectors during 1990 and competed with peat in selected applications. Compost may lead to further growth in mulching and soil amendment activity dependent upon economic factors. In any event, several peat-compost product blends were introduced by major U.S. peat producers in 1990, representing a new trend that will most probably continue to increase in proportion to the availability of quality compost materials.

EcoPeat Co., a U.S. affiliate of the Finnish firm Outokumpu, was formed to develop 360 megawatts of peat-fueled electrical powerplants in cooperation with south-central Florida utility companies. The plants were scheduled on-stream beginning in mid-1995, and at full capacity, would quadruple current U.S. peat production.

In 1990, global peat production was estimated at about 200 million short tons and was valued at \$4 billion, f.o.b. plant.

DOMESTIC DATA COVERAGE

The Division of Statistics and Information Services, U.S. Bureau of Mines, conducts an annual survey of domestic peat producers in the 48 contiguous United States. Information obtained from the

Bureau's voluntary canvass was used to develop data tables for publication. Of the 109 peat operations surveyed in 1990, 82 were reported to be active and 23 idle or closed permanently. Estimates were made for active operations that did not report data in 1990, based on past trends.

Alaskan peat producers were surveyed independently by the Department of Natural Resources, Division of Geological & Geophysical Surveys, Fairbanks, AK. In 1990, operations in the Anchorage and Fairbanks areas reported active production.

BACKGROUND

Peat deposits developed typically through the gradual decomposition of plant matter under anaerobic conditions in shallow basins. Most of the peat deposits in existence today lie at the Earth's surface and have formed since the last ice age approximately 10,000 years ago, although much older Pleistocene peats are known to lie buried beneath the sands of Trail Ridge in Bradford and Clay Counties, FL. Peat is a precursor of lignite and coal

Peatlands, or mires as they are sometimes called, are more extensive in the temperate, boreal, and subarctic zones of the Northern Hemisphere and more limited in the cool and humid zones of the Southern Hemisphere. Peat deposits may be called bogs or fens depending on the aquatic mechanisms of the particular setting.

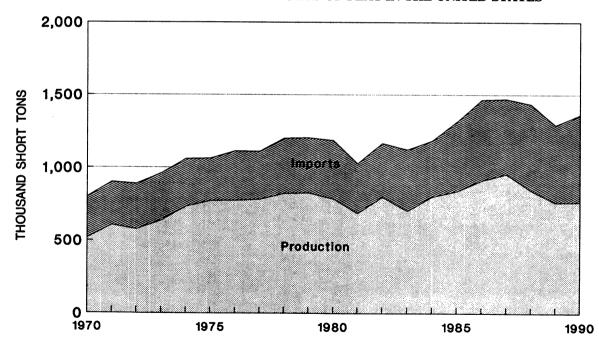

Most of the world's peatlands are classified as bogs. Bog is from the Celtic word "bocc," meaning "soft," which is an apt description for these waterlogged terrains. A bog is an acidic peatland that depends principally on rainfall to perpetuate the waterlogged conditions necessary for its survival. Because there is less decomposi-

FIGURE 1
PRODUCTION AND IMPORTS OF PEAT IN THE UNITED STATES

tion in these nutrient-poor, acidic environments, very fibrous peats are produced. A variety of other peats may also be formed under boggy conditions in marshes and swamps.

The term "fen," as derived from the Anglo-Saxon language, translates to "mud" in modern day English. Fens are

peatlands that depend mainly on ground water sources for their formation and survival and, thus, are less dependent on rainfall. Fens, unlike bogs, are found in less acidic nutrient-rich environments. Plant matter tends to decompose more rapidly under these relatively chemically neutral conditions, leading to a less fibrous, more

mineralized material known as muck or peaty muck. The majority of fens are over sites of sand and gravel deposits that are buried within more clayey glacial materials (intertill), providing a ground water seep over which the peat forms. It, therefore, is not uncommon to find fens situated on hillsides.²

Apparent consumption equals U.S. primary production plus imports minus exports plus adjustments for industry stock changes.

Definitions, Grades, and Specifications

Methods adopted by the American Society for Testing and Materials (ASTM) find widespread use for the characterization of peat matter.3 The ASTM Classification of Peats, Mosses, Humus, and Related Products requires the use of three parameters: ash content, fiber content, and botanical composition. Earthy organic materials must have an ash content of no more than 25% by dry weight to be classified as "peat." Botanical characteristics and fiber content govern peat types. Fibrous peat is defined as material retained on an ASTM No. 100 screen, that is, material 0.15 millimeters or larger.

Sphagnum moss peats must have a fiber content greater than 66%, all of which must be derived from the genus Sphagnum, as determined by screening and botanical analysis. Hypnum moss peats must have a 33% minimum fiber content, of which at least 50% must be derived from the genus Hypnum. Reed-sedge peats must have a 33% minimum fiber content containing more than 50% reed-sedge and other nonmoss fibers.

The U.S. Department of Agriculture Soil Conservation Service subdivides peat into three general categories: (1) fibric (peat moss), which is composed of sphagnum, hypnum, and other mosses; (2) hemic (reed-sedge), which is formed from reeds, sedges, swamp plants, and trees; and (3) sapric (humus), which is composed of materials that are decomposed beyond recognition of botanical origin.4

Fibric peats such as sphagnum and hypnum are relatively young moss species that are light in color in comparison to other peat varieties. Fibric peats, because of the lower order of decomposition, have a relatively high water-retention capacity and, in general, are quite acidic. Fibric peats have a low bulk density that averages about 250 pounds per cubic yard on an air-dried basis and very little ash. These peats are not suitable for fuel owing to the low degree of decomposition.

Hemic, or reed-sedge peats, are somewhat older and more decomposed than fibric peats and originate from reeds, sedges, and other nonmoss type plants. Hemic peats are considered to be intermediate between fibric and sapric in degree of decomposition, bulk density, and ash content. The average density of airdried reed-sedge peat is about 950 pounds per cubic yard. Reed-sedge peats are usually slightly acidic and have a high energy

value owing to fixed carbon content and low ash.

Sapric, or humic peats, are the oldest and most decomposed peats, with color ranging from dark brown to black. Normally, sapric peats are the first peats formed in the filling of basins and are the most dense and colloidal. Sapric peats, because of their colloidal nature, take on less water, but retain it more strongly than other peats. Many sapric peats are excellent energy sources and are quite acidic. Humus peat has an average bulk density of about 1,300 pounds per cubic yard.

The von Post scale was developed in Sweden as a field method, or squeeze test, for determining the degree of peat humification or breakdown and is utilized by peat enthusiasts worldwide. According to the von Post method, peats are ranked on a scale from H 1 to H 10 relative to their degree of humification. A von Post of H 1, for example, would represent undecomposed peat that ejects colorless, clear water when squeezed, with the remainder containing easily discernible plant matter. At the opposite end of the scale, at H 10, the peat would be completely decomposed, with no plant remains recognized, and, upon squeezing, the whole amount would come out between one's fingers as a homogeneous material. In general, fibric peat mosses are in the von Post range between H 1 and H 3; hemic reed-sedges, H 4 to H 6; and saphric humus peat, H 7

A typical proximate analysis for peat would yield a moisture content of about 50%; carbon, 26%; oxygen, 16%; hydrogen, 3%; nitrogen, 1%; sulfur, 0.1%; and ash, 4%. Fuel-grade peats may vary between 4,000 British thermal units (Btu's) per pound to as high as 10,000 Btu's per pound depending on moisture content and peat type.

Geology-Resources

In the United States, peat is deposited to some extent in all 50 States. About 25 million acres of peatlands has been identified in the lower 48 States. Alaska contains an enormous peat resource estimated at 125 million acres. Minnesota, Florida, Michigan, Wisconsin, and Maine, in order of importance, account for the major reserves available for harvesting in the 48 contiguous United States. At current mining rates, the U.S. permitted reserve base estimate of 16 million tons could theoretically be depleted within the coming 20 years.

Although Florida, Maine, Minnesota, and many other States have done a credible job in estimating individual State peat reserves, there has not been a comprehensive effort to consolidate individual State reports to establish the extent of U.S. peat resources since the 1922 U.S. Geological Survey (USGS) publication, "The Occurrence and Uses of Peat in the United States.⁷⁶

TABLE 2 WORLD PEAT RESERVES AND RESERVE BASE

		513,000
World total	3,000	

¹Estimated reserves currently under active cultivation or economically recoverable under current market conditions.

²The reserve base includes demonstrated resources that are currently economic (reserves), marginally economic (marginal reserves), and some of those that are currently subeconomic (subeconomic resources).

As a result of the energy crisis in the mid-1970's, the Department of Energy (DOE) initiated a Peat Resource Estimation project in several States to provide information on the extent of our Nation's availability of peat resources for energy utilization, but the results were incomplete and never fully tabulated.

In the mid-1980's, the University of North Dakota and the USGS submitted a joint proposal to the U.S. Department of the Interior designed to survey the peat resources of the United States. The principal objective of the proposal was to systematically bring together and analyze the information obtained from DOE's Peat Resource Estimation program that had been conducted by the individual States. Other non-DOE-sponsored research in other States was also to be included.

With our Nation's renewed emphasis on the environment and energy independence, as promulgated by the President's recent National Energy Strategy,⁷ peat has resurfaced as an important resource in both categories. Perhaps the previous proposal to quantify our Nation's strategic peat reserve base should be reconsidered.

Technology

Mining.—Peat is mined or harvested by numerous methods in the United States dependent upon the prevailing conditions and the type of peat involved.

Sphagnum peat is mined through a combination of milling, aeration, and vacuum harvesting. A wide variety of equipment is required, including light and heavy power equipment; ditching machines to provide drainage; stumper, wood rake, and turner-aerator equipment to clear and aerate the surface; milling machines; vacuum harvesters; and wagons or trucks for transporting the harvested peat to the processing plant.

Reed-sedge peat may be harvested with conventional agricultural disking equipment, wide track bulldozers, and front-end loaders. Alternate methods involve milling or bulldozing, followed by windrowing and product pickup with a force feed loader equipped with a side-loading attachment. Smaller operations sometimes mine humus peat with power shovels, small draglines, and front-end loaders.

Fuel-grade peat, following conventional field preparation methods, is com-

pressed into 4-inch-diameter cylinders with sod harvesting equipment. The cylinders break off at lengths ranging from 8 to 12 inches and drop to the surface for air drying. After windrowing to effect complete drying, the cylinders are picked up by a force feed conveyor loader and discharged into trailers for transport to the powerplant.

Processing.—All peat usually requires screening to remove debris and to produce a desirable marketable product. In stateof-the-art sphagnum operations, harvested peat is fed to a radar screen for sifting and the removal of large debris. The raw product is next discharged to a doubledeck vibrating screen to effect sizing and to remove the smaller debris. Product passing the screens is hammermilled and recycled to the screening process. Processing is effected in a closed system equipped with an overhead vacuum takeoff for fine or dusty material. The fines may be recycled or conveyed to a closed waste bin outside the plant.

Product-grade material is discharged to a surge bin from which peat is gravity fed into plastic containers and compressed into bales on a 2:1 volume ratio. Fourcubic-foot bales are the most popular size produced, but 2-cubic-foot and 6-cubicfoot bales are also produced in significant quantities.

Reed-sedge and humus peats are screened, packaged in bags, or sold in bulk. The materials may also be blended with perlite, vermiculite, sand, and sphagnum moss and packaged as potting soils. Peat-sand mixtures are popular bulk materials that are sold to golf courses for top dressing greens, tees, and fairway turf.

Economic Factors

The data of table 3 show the long-term peat price trend for the period 1970-90. Actual prices, without adjustment for inflation, increased at an average annual rate of 6% per year over the 20-year period. Prices expressed in terms of constant 1982 dollars, however, declined at an average annual rate of 2% per year over the same period. The U.S. peat industry overcame inflationary pressures principally through the rationalization of capacity, together with a move to higher volume modern and efficient plants.

ANNUAL REVIEW

Issues

Peat mining experienced the pressures of environmental regulation in the States of Colorado, Connecticut, Maine, North Carolina, Pennsylvania, and South Carolina. There were no active peat operations in Connecticut and only one each in North Carolina and South Carolina.⁸

Concerns about environmental regulations were expressed by the Pennsylvania peat industry where several small operations have been forced to close during recent years. Pennsylvania producers felt pressure from a number of environmental regulatory agencies, including the State Department of Environmental Regulation (DER), the Environmental Protection Agency, and the U.S. Corps of Engineers.

Mining permits were reportedly being terminated upon expiration or renewed for a short timeframe that made the economics of investing in new plants and equipment prohibitive. The producers were reportedly affected on both public and private lands.

Peat operations in Pennsylvania were relatively small, and the acreages that would potentially be affected by the opening of new peat operations were reported to be minor relative to the overall wetlands areas involved. Producers were concerned that new regulatory policies formulated by DER would preclude the opening of new bogs.

Examples were cited in which golf course greens had been severely damaged when alternate materials were applied owing to the absence of quality peat-sand mixtures. In other instances, the scarcity of peat in the State made its use as an earthworm culture medium economically prohibitive, dictating the use of less desirable alternate substitutes.

Producers and consumers alike felt that a more reasonable balance between environmental regulation and peat mining was needed in Pennsylvania, given the positive impact of peat mining on local economies and its value to local consumers.

A petition to mine a 3-acre wetlands tract at Mansfield, CT, was rejected by the Mansfield Conservation Committee, as well as the State Inland-Wetlands Agency. The property would have yielded about 22,000 cubic yards of marketable peat that was to be sold to landscape and nursery firms in the area. In rendering its judgment, the regulatory agencies expressed concern over the absence of detail in the peat removal operation application, particularly with regard to stockpiling and trucking peat from the site. There was no known peat activity in the State of Connecticut.

In August 1990, the Conservation Fund, in coordination with the Richard King Mellon Foundation, turned over 93,000 acres of partially altered wetlands on the environmentally sensitive Pamlimarle Peninsula in northeastern North Carolina to the U.S. Fish and Wildlife Service. About 35 million dry tons of high-energy fuel-grade peat was deposited to an average depth of 6 feet over about 70,000 acres of the property.

The Fish and Wildlife Service was charged with preserving the property as a wildlife habitat to include fire control, maintenance of drainage canals, provision

of grain for feeding, and enforcement of wild game hunting. Peat processing equipment on the property that was formerly owned by First Colony Farms was sold at auction in September 1990 to help fund the project.

Fish and Wildlife planned to combine these lands with its adjacent 10,000-acre Pungo National Wildlife Refuge to form Pocosin Lakes National Wildlife Refuge. Deer, black bear, and wood duck were native to the area.⁹

The Pamlimarle Peninsula is the site of North Carolina's largest peat reserves. The peninsula is estimated to include 360 square miles of peatlands containing about 210 million tons of peat on a moisture-free basis.

Production

In 1990, U.S. peat production held level at about 0.8 million short tons. This was in sharp contrast to the 20% decline experienced during the previous 2-year period of recession that resulted in the closure of 12 peat operations in the United States.

Peat was harvested and processed by 82 operations in 22 of the contiguous States in 1990. The majority of U.S. peat production, about 80%, was conducted in high-volume operations that accounted for only 30% of the total number of active facilities. Twenty-three peat operations in Florida and Michigan produced about 60% of the U.S. total.

Geographically, about 50% of the total U.S. peat output was from seven contiguous States in the Midwest and north-central Great Lakes region, together with 4 Western States. Four States in the southeast provided about 40% of the total, and seven States in the northeast provided 10%.

On a weight basis, reed-sedge peat was 58% of total U.S. production; humus, 25%; sphagnum moss, 8%; hypnum moss, 3%; and other forms, 6%. On a volume basis, reed-sedge was 56% of the total; humus, 19%; sphagnum, 16%; hypnum, 5%; and other forms, 6%.

In 1990, the State of Alaska Department of Natural Resources, Division of Geological and Geophysical Surveys, Fairbanks, reported that 65,000 cubic yards of peat was produced at an f.o.b. plant value of about \$400,000. This represented an increase of 27% in volume and 14% in value relative to 1989. Geophysical Survey officials indicated that the reported quantities were probably on the

low side owing to survey methodology.

Hyponex Corp. and Michigan Peat are major producers and distributors of peat products in the United States. In 1990, Hyponex harvested and processed reedsedge peat from nine facilities in seven States extending from New Jersey to Colorado. Michigan Peat operated three plants in Sanilac County, MI, that processed reed-sedge and sphagnum peats and one plant near Cromwell, MN, that processed sphagnum peat.

Minnesota peat operations experienced a good year in 1990. Production and sales volume were up about 20% and 40%, respectively. The f.o.b. plant value of Minnesota peat was \$62 per ton—160% above the national average of \$24 per ton—because of the premium price commanded by sphagnum moss.

New horticultural peat projects were reported to be under consideration in the States of Georgia, Maine, and New Mexico.

Down East Peat LP was operating a 22.8-megawatt peat-fired electric power-plant near Cherryfield, ME. At full capacity, the power-plant will require about 165,000 tons of bone-dry peat annually. Fuel-grade peat was extracted from the adjacent Denbo Heath Bog by a private contractor.

Humates were mined from the San Juan Basin deposits of New Mexico and sold for use as a soil conditioner. In 1985, the last year of available data, humate production was about 23,000 cubic yards, with an f.o.b. mine value of \$404,000. Mining and processing were conducted by three companies in McKinley, Sandoval, and San Juan Counties.

Consumption and Uses

U.S. producer sales continued to be adversely impacted by a general downturn in the economy, together with competition from Canadian producers. There were indications, however, that the domestic industry had begun to stabilize following 3 years of rationalization in which 12 peat facilities closed and sales volume declined by about 25%.

In 1990, producer sales volume rose 4% to 0.8 million tons and increased 8% in value to \$19 million. Bulk and packaged forms, on a weight basis, commanded equal shares of the market. In terms of cubic yards, reed-sedge commanded 67% of the market; humus, 16%; sphagnum

moss, 13%; hypnum moss, 3%; and other forms, 1%.

Total U.S. apparent domestic peat consumption was unchanged, at 1.4 million

tons in 1990, relative to 1989. In contrast to the 27% decline recorded in U.S. producer sales between 1986 and 1989, total apparent U.S. domestic peat consumption

declined by a more moderate 10% owing to the relatively constant increase in Canadian peat imports, together with a drawdown in field inventories.

About 92% of U.S. producer sales was for general soil improvement and horticultural use. Golf courses used peat and peat-sand mixtures for turf maintenance and greens construction. In agriculture, peat was used in mixed fertilizers, as a carrier and coating agent in seed innoculants, and for vegetable cultivation. Other specialty applications included peat's use in mushroom beds, as an earthworm culture medium, and for poultry litter.

Peat enjoyed widespread use in many other applications, including electrical power generation, toxic waste filtration, oil absorption, humic acid extracts for agriculture, composting, cranberry cultivation, and in medical and hygienic products.

Stocks

In 1990, producer peat stocks declined slightly, to 0.4 million tons, compared with 1989. Stocks at yearend were about 50% of production, which was typical for the peat industry. Reed-sedge peat accounted for about 63% of total stocks.

Transportation

Peat was moved predominately by truck in both bulk and packaged form. Small producers were restricted to local market areas because of the sensitivity of peat prices to transportation charges. High-volume producer costs were less sensitive to transportation charges, allowing for interstate movement of peat and peat products.

Markets and Prices

The average price for domestic peat in 1990 rose 6% to about \$24 per ton in comparison to the prior year. Packaged and baled peat sold for about \$30.50 per ton, a 15% increase, while bulk peat prices declined about 6% to 17.75 per ton. Packaged and baled peat were sold at a 70% premium relative to bulk peat.

Sphagnum moss sold at a premium \$71 per ton, about 200% above the national average of \$24 per ton. On a volume basis, sphagnum sold for \$17.50 per yard, about 50% above the national average of \$11.50 per cubic yard for all types of peat.

Values are f.o.b. producing plant.

²Data may add not add to totals shown because of independent rounding.

Foreign Trade

In 1990, Canada continued to provide more than 99% of total U.S. peat imports, and new records were established for both volume and value. Canadian imports reached a record of 599,000 tons, 44% of the total U.S. supply, and carried a U.S.

Customs value of \$87.3 million or \$146 per ton. The value of Canadian shipments at the U.S. border exceeded total U.S. domestic peat sales by \$68 million (355%).

Another \$4 to \$6 million in Canadian peat merchandise was recorded by U.S. Customs under the "Articles of Peat" category. Peat pots and other specialty peat-based products, including some peat mixtures, were reportedly included under this category. Although Canadian peat imports entered the United States duty free, a tariff of 4.7% was imposed by Canada on U.S. peat. The United States, to date, has not exported peat to any destination, according to U.S. Bureau of the Census data.

About 77% of Canadian shipments in 1990 originated from Ouebec and New Brunswick in eastern Canada. Alberta, in western Canada, supplied about 8% of the total. About 15% of Canadian shipments was reported to originate from Prince Edward Island, Nova Scotia, and Newfoundland in eastern Canada; Ontario in central Canada; and British Columbia. Saskatchewan, and Manitoba in western Canada.10

World Review

Global peat production was estimated at about 198 million short tons in 1990. roughly 10% below the 218 million tons produced in 1989. The total value of world peat production, assuming an average f.o.b. plant value of \$20 per ton, was \$4 billion.

About 17 million tons, or 85% of the estimated 20-million-ton decline, was attributed to the U.S.S.R., where output was thought to be negatively impacted by significant political restructuring. Production was projected to be off about 1.5 million tons in Ireland and about 0.4 million tons in Finland because of aboveaverage harvests in 1989.

Although peat was known to be deposited in the tropics of Africa, Argentina, Brazil, China, Indonesia, Malaysia, New Zealand, Paraguay, and Uruguay, production data were not available.

Industry Structure.—The U.S.S.R. accounted for about 90% of global peat production in 1990, followed by Ireland, 4%; Finland, 3%; Germany (Western states), 1%; the United States and Canada, 1%; and Sweden and other countries, 1%.

In the U.S.S.R., production was confined to the Baltic Republics, the Moscow-Gor'kiy area, and Belorussia, although peat was known to be deposited throughout much of the country. Peat was burned in thermal powerplants in European U.S.S.R. and was also used to fire industrial boilers and large heating plants.

Prices are f.o.b. plant

The use of peat as an energy source in the U.S.S.R. was reportedly declining because of insufficient reserves in the primary consuming areas and increasing demand in the agricultural sector. The chemical industry produced methanol and synthetic natural gas from peat.11

Ireland and Finland, in order of importance, accounted for more than 70% of the estimated 17 million tons of peat produced outside the U.S.S.R. in 1990. In Ireland, greater emphasis was being placed on fuel peat technology transfer, environmental technology, and the marketing of horticultural peat, while in Finland plans were being formulated for additional peat-fueled powerplants.

³Includes Australia, Cameroon, Finland, France, the Federal Republic of Germany, Hong Kong, Japan, the Netherlands, Sweden, Switzerland, the U.S.S.R., and Vatican City.

In 1989, Ireland's Bord na Móna achieved a new production record of 9 million tons. Bord na Móna was established by the Turf Development Act of 1946 to develop Ireland's peat resources. The Bord sells peat fuel to the Electricity Supply Board for use in peat-burning power stations, markets moss peat and other growing media to the garden and horticultural industries on a worldwide basis, sells briquettes and machine turf on the domestic fuel market, and manufactures pollution abatement products.

Bord na Móna reorganized in 1988, establishing three separate divisions covering milled peat operations, solid fuels, and horticultural products. Each division was headed by a chief executive officer at three separate locations within Ireland. The payback in terms of competitiveness, growth, and innovation was expected to be substantial.

The Horticultural Division sold 1.2 million cubic meters of peat and compost in 1989 compared with 1.3 million cubic meters for the previous year. Of the total

sold, 90% was exported to the European Community (EC) and several other countries.

Bord na Móna purchased the French horticultural peat company Pouget-Solami S.A., which operated profitably as a subsidiary during 1989. Effective January 1990, the Bord also established its own distribution subsidiary, Du Móna France S.A., with offices in Lyon. With the complimentary manufacturing and marketing structures of Pouget-Solami and Du Móna, Bord na Móna established a competitive advantage in the French peat market.

Bord na Móna was also active in technology transfer activities in the United States during 1990.¹²

Peat accounts for about 4% of Finland's present energy supply, but plans were formulated to increase future peat production dramatically as a fuel for electric power generation. Finland's product distribution consists of about 80% milled peat and 20% sod peat. Plans were also formulated to increase the production of peat for horticultural purposes and for industrial and environmental applications. Finland's current production capability is about 6 million annual tons. ¹³

Sweden currently produces about 1 million cubic meters of horticultural peat and about 2 million cubic meters of fuelgrade peat, annually. Swedish peatlands cover an area of about 6.3 million hectares (15.6 million acres), or about 15% of the total land area. About 865,000 acres of peatland is available for fuel peat production. The overall area suitable for horticultural peat production has not yet been surveyed.

Sweden has about 50 producers of horticultural peat, mainly in the south and middle regions. Roughly 400,000 cubic meters is produced as milled peat and 600,000 cubic meters as sod peat, of which 30% to 35% is exported. More than one-half of the domestic consumption is used by amateurs for home and garden applications.

After reaching a maximum production and sales of about 2.5 million cubic meters in 1950, fuel peat declined dramatically because of its economic disadvantages to cheaply priced fuel oil. By 1970, fuel peat production in Sweden was nonexistent. There was a subsequent revival in fuel peat demand beginning in the early 1980's, however, as an aftershock of the global energy crises of the 1970's. 14

Capacity.—The data of table 13 are

¹Table includes data available through May 31, 1991.

²In addition to the countries listed, Austria, Iceland, and Italy produce negligible quantities of fuel peat and the Eastern states of the Federal Republic of Germany and Venezuela are major producers, but output is not officially reported, and available information is inadequate for formulation of reliable estimates of output levels.

³Excludes data from some States.

⁴Reported figure.

rated capacity for peat operations as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

Current Research

There was much activity in peat research during 1990 and many outstanding accomplishments. Peat was demonstrated to act as an effective oil absorbent, and plans were formulated for active production and marketing in the United States. Peat was also shown to be an effective filtration source for the removal of toxic wastes and offensive odors and a superior bulking agent for composting organic wastes. Plans continued for the development of up to 360 megawatts of peatfueled powerplants in south-central Florida beginning in mid-1995.

Humic acid extracts were developed that served as growth stimulants for agricultural and horticultural products and as a medium for animal health, growth, and development. Humic acids were also demonstrated to stimulate the anaerobic digestion processes used for municipal and industrial wastewater treatment.

Peat-based feminine hygienic products that demonstrated the potential for eventual commercialization were developed and test marketed in Canada. Peat also showed promise as a biodegradable medium in disposable diapers and in food packaging.

The Natural Resources Research Institute (NRRI), University of Minnesota at Duluth, conducted research with sphagnum papillosum, a high-fiber top moss that could be cultivated and continuously harvested from Minnesota sphagnum bogs. The material showed promise in the areas of oil sorption, composting, and as horticultural peat.¹⁵

Diversified Marketing Sales & Distribution (DMS&D) of Eatontown, NJ, was formed to market Berthonate peat oil absorbent, developed in cooperation with Encon Enterprises Inc. of Calgary, Alber

ta. Berthonate was reported to absorb up to six times its weight in oil.

Encon constructed a mobile pyrolysis unit that was capable of heating sphagnum peat to the hydrophobic stage between 225° and 650° F. The unit also demonstrated the potential to recover petroleum products absorbed by Berthonate. DMS&D planned to market Berthonate in the United States and expressed an interest in using U.S. sphagnum moss supplies. ¹⁶

Prodex Inc. of Ravenna, OH, continued research into humic acid extracts. The firm developed Biogene products that were sold as agricultural and horticultural plant stimulants, animal feed additives for improved nutrition and health, and as an accelerator in anaerobic biological sludge digestion in municipal and industrial wastewater treatment. Prodex was developing processes for improved peat fuel and horticultural applications, together with the separation of organic and metal contaminants from industrial wastewater streams.¹⁷

The U.S. Bureau of Mines Salt Lake City, UT, Research Center developed sphagnum moss bioaccumulation processes that were effective in extracting toxic metal ions from a variety of waste waters. Bureau researchers developed porous polymeric beads, designated BIO-FIX beads, that were prepared by blending sphagnum peat moss or algae into a polymer solution and spraying the mixture into water.

Batch and continuous tests demonstrated that BIO-FIX beads removed arsenic, cadmium, lead, and other toxic metals from acid mine drainage waters collected from several sites. Selectivity for heavy and toxic metal ions over calcium and magnesium was demonstrated. The sorption process was reversible, and metal ions were eluted from the beads using dilute mineral acids. Cyclic tests indicated that the beads continued to extract metal ions after repeated loading-elution cycles.¹⁹

In July 1990, EcoPeat Co. was formed to develop, own, and operate peat-fueled electric power facilities in North America. EcoPeat was a joint venture between Outokumpu EcoEnergy Inc. of Owings Mills, MD, and the Stanton Group of Cambridge, MA. EcoPeat's long-term business strategy called for the development of at least 15 peat power projects within the next 10 years. The Outokumpu Group, based in Helsinki, Finland, is one

of the world's leading base metal companies.

To further its objectives, EcoPeat acquired the assets of General Peat Resources LP, of St. Petersburg, FL, which had previously obtained 312 megawatts of peat fuel power contracts with Florida Power Corp. (FPC) and Florida Power and Light (FP&L) in south-central Florida. The power units were to be adjacent to vast peat reserves in the area.

EcoPeat planned to build and operate two 80-megawatt units near Lake Placid, FL, under contract with FPC at a capital construction cost substantially below the \$300 million estimate previously proposed for three 52-megawatt units. A 40-megawatt oil-burning power unit at Avon Park, FL, was to be retrofitted for peat firing under a 30-year contract with FP&L at a capital cost of \$60 million and was planned onstream by mid-1995. ²¹ Two 80-megawatt peat-fueled powerplants were also planned in Palm Beach County, FL, under contract with FP&L.

Assuming that EcoPeat's projects materialize as planned, it is estimated that about 2.5 million annual tons of bone-dry peat would be required to fire the plants. This would conceptually quadruple current U.S. peat production by the mid-to-late 1990's. EcoPeat reported that the fuel peat powerplants would be economically competitive and environmentally attractive when compared with conventional coal-fired plants.

In Canada, fuel peat projects were under consideration in Alberta, Newfoundland, Nova Scotia, Ontario, and Saskatchewan. Energy, Mines and Resources Canada cited peat as being increasingly perceived as a low-sulfur fuel alternative to coal for power generation.²²

SaskPower and a Meadow Lake company in Saskatchewan planned to build a \$22 million peat-burning powerplant at Jans Bay, north of Meadow Lake. It would reportedly generate 15 megawatts, enough to heat a community of 3,000 homes.

Peat Resources was planning a \$4.5 million pilot plant to produce fuel-grade peat at a prime peatland 35 miles northwest of Thunder Bay, Ontario, Canada. Data collected from the pilot plant operation would be used for the potential design of a \$95 million commercial plant capable of producing 1 million tons per year of peat fuel. The fuel would reportedly be used as an environmentally attractive alternative energy replacement for coal in

electrical power generation plants.

The pilot plant would test a process for producing high-grade industrial peat fuel with a heating value comparable to bituminous coal. In a recent test burn completed by Ontario Hydro, the experimental peat fuel produced less than 5% ash, and a mixture of coal and peat fuel reduced sulfur emissions in direct proportion to the quantity of peat blended.

Peat Resources, which had been developing the peat fuel process since 1984, applied for a Canadian patent.²³

After 15 years of research, Johnson & Johnson (J&J) launched a new line of ultrathin feminine hygiene napkins in Canada having an absorbent core of processed peat moss. J&J officials said the processed moss could absorb 20 times its weight in liquid. The firm claimed that its peat moss pad provided the same absorbency at one-fifth the thickness of ordinary hygienic pads and was slightly thinner and superior to "ultra thin" pads that relied on superabsorbent polymers.

The product, named Sure & Natural Prima, was the first commercial application of J&J's patented peat moss technology and was developed by the company's Montreal-based Canadian unit. J&J, headquartered in New Brunswick, NJ, would not speculate on when its new product may be marketed in the United States and other countries.²⁴

The International Peat Society (IPS), Helsinki, Finland, held its "International Conference on Peat Production and Use" at Jyvaskyla, Finland, June 11-15, 1990. The conference sessions covered the following topics: fuel peat production; peat production for nonenergy purposes; effects of peat production on waterways; artificial dewatering; peat storage and transportation; peat use for environmental purposes; peat combustion; case studies; chemical mapping; chemistry of peat utilization; peatlands and carbon balance; and quantitative analysis aims and limitations.²⁵

The IPS announced that the United States National Committee of the International Peat Society would host the 1991 International Peat Symposium under the title "Peat and Peatlands; The Resource and Its Utilization," in Duluth, MN, August 19-23, 1991. The symposium was to be organized in cooperation with the Iron Range Resources and Rehabilitation Board (IRRRB) and the Natural Resources Research Institute (NRRI).²⁶

The IPS also announced that its ninth

International Peat Congress would be held in Uppsala, Sweden, June 22-27, 1992, under the theme "Peat in nature and industry—a matter of balance."

OUTLOOK

The outlook for peat supply-demand in the United States is shown in table 15. During the past 20 years, U.S. domestic peat production has grown at an average annual rate of about 2.4% per year. The most recent upturn in the U.S. peat supply-demand cycle was experienced between 1981 and 1987. Domestic peat production hit the bottom of the latest cycle in 1981 at 0.7 million tons and gradually increased to a record 1.0 million tons by 1987, representing average annual growth of about 7%.

Total apparent domestic consumption during the same period followed the domestic production trend and grew at an average annual rate of 6%, from 1.1 million tons in 1981 to a record 1.5 millon tons in 1987.

Between 1987 and 1990, domestic peat production and total apparent domestic consumption declined 20% and 11%, respectively, owing to a downturn in the U.S. economy. Canadian imports as a percent of the total U.S. supply, how-ever, increased from 35% in 1987 to a record 44% in 1990 during the period of domestic downturn.

The U.S. Bureau of Mines forecast for horticultural peat during the next 5 years is based on a recovery in the economy and a resultant rebound in domestic production and total apparent domestic consumption. Domestic production of horticultural peat is forecast to grow at an average annual rate of about 3% to levels approaching 0.9 million tons by 1995. Per capita consumption is forecast to approximate 12 pounds by 1995, somewhat lower than the 12.7 pound average experienced during the peak years of 1986 and 1987.

Total apparent domestic consumption for horticultural purposes is also forecast to grow at an average annual rate of 3% per year to about 1.6 million tons by 1995. Canadian imports are forecast to rise by another 100,000 tons by 1995 and to compose 45% of the total U.S. horticultural peat supply.

Domestic peat production for fuel purposes is projected to reach about 650,000 tons in 1995 and to account for more than

50% of total domestic production. The forecast assumes that about one-half of the announced fuel peat powerplants in Florida will come on-stream by mid-1995. At full capacity, the total 360 megawatts announced by EcoPeat in Florida would consume about 2.5 annual tons and increase current U.S. production fourfold.

The global outlook for peat supply-demand is shown in table 16. Although the long-range outlook for balanced supply-demand conditions has not changed relative to last year's forecast, near-term prospects are less favorable because of the projected downturn in U.S.S.R. production. If the projected downturn only impacts the U.S.S.R.'s in-

ternal supply-demand situation, then the world outside the U.S.S.R. should still anticipate reasonably balanced conditions during the next 5 years. If the U.S.S.R. becomes pressured to move surplus product to the international marketplace, however, a global imbalance in peat supply-demand may be precipitated during the near-term.

The U.S. Bureau of Mines basic forecast methodology has been changed to include the assumption that production in the U.S.S.R. will gradually return to 1989 levels by 1995. Otherwise, the former methodology that based global demand on the historic trend in per capita consumption has not changed.

The long-term trend based on the current forecast shows that, between 1985 and 1995, global peat demand is projected to grow at an average 1% per year, about one-half of the projected 2% growth in population. This forecast is consistent with historic trends.

PERLITE

By Wallace P. Bolen

Mr. Bolen, a physical scientist, is a graduate of the University of Virginia and has been the commodity specialist for perlite since September 1989. Domestic survey data were prepared by Blanche S. Hughes, mineral data assistant; and the international production table was prepared by Audrey Wilkes, international data coordinator.

2% in quantity and 3% in value compared with those of 1989. Construction uses of expanded perlite accounted for 63% of total domestic sales in 1990.

DOMESTIC DATA COVERAGE

Domestic production data for perlite are developed by the U.S. Bureau of Mines from two voluntary surveys, one for domestic mine operations and the other for expanding plants. Of the 12 mining operations to which a request was sent, 10 responded, all active, and accounted for 100% of the total processed ore sold or used in table 1. Of the 67 expanding plants canvassed, 62 were active; of these, 44 plants or 71% responded, representing 79% of the total expanded perlite sold or used shown in table 1.

Perlite mined for processing came from 9 companies with 10 operations in 6

Western States and totaled 731,000 short tons. New Mexico operations accounted for a large majority of the total tonnage mined. The remaining tonnage came from Arizona, California, Colorado, Idaho, and Nevada. Apparent domestic consumption is defined as production plus imports minus exports. Apparent domestic consumption of processed perlite in 1990 was 669,000 tons, a slight increase from that of 1989.

PRODUCTION

Ore producers were Harborlite Corp. and Nord Perlite Co. in Arizona; American Perlite Co. in California; Persolite Products Inc. in Colorado; National Perlite Co. in Idaho; Delamar Perlite Co. in Nevada; and Grefco Inc., Manville Products Corp., and USG Corp. in New Mexico.

The quantity of expanded perlite sold and used from 62 plants in 33 States increased 2% in quantity compared with that of 1989. The value of expanded perlite increased 3% in 1990. Leading States, in descending order of

sales, were Mississippi, Illinois, Pennsylvania, California, Georgia, Arizona, Kentucky, Minnesota, and Virginia.

CONSUMPTION AND USES

Construction-related uses, the major market for expanded material, decreased slightly to 332,300 tons. Expanded perlite used as filter aid, fillers, and in agricultural markets totaled 159,600 tons, an increase of 7% compared with that of 1989.

Perlite exports, primarily to Canada, were estimated to be 35,000 tons. Imports of perlite ore, mainly from Greece, were virtually the same as in 1989, about 65,000 tons.

PHOSPHATE ROCK

By William F. Stowasser

Mr. Stowasser, a physical scientist with 20 years of U.S. Bureau of Mines experience, has been the commodity specialist for phosphate rock since 1974. Domestic survey data were prepared by Christopher Lindsay, mineral data assistant; and the international data table was prepared by Audrey D. Wilkes, international data assistant.

he U.S. phosphate rock mining industry exists to primarily supply the demand for phosphate fertilizers. The fertilizer was used to promote production of food and feed grains for the domestic and international markets. The prospects for increased exports of U.S.-produced agricultural commodities was diminished when the European Community (EC) and the United States were not able to agree on modifying trading rules for agricultural products, which are not now

included in the General Agreement on Tariffs and Trade. The EC resisted negotiating reductions in trade protection for agricultural products. The European Community Common Policy increased food prices inside Europe by purchasing excess farm production at artificially high prices. The overproduction was sold on world markets at competitive prices. It is probable that maintaining protectionism will reduce U.S. exports as well as those from the recognized more efficient farmers of Australia, Brazil, Can-

ada, and New Zealand. Without the elimination of the EC's tariffs, other exporting countries will not be competitive in Europe. It is unlikely that the United States food and fertilizer export market share will increase.

World phosphate rock production declined an estimated 5% in 1990 to 154 million tons. It appears that several major producing countries produced less in 1990 compared with that of 1989. Production was controlled to meet demand and avoid unnecessary inventory in-

creases. A slackening in demand was probably caused by the political changes and uncertainties in Eastern Europe, by political changes in the U.S.S.R., and the invasion of Kuwait by Iraq.

DOMESTIC DATA COVERAGE

Domestic production data for phosphate rock are developed by the U.S. Bureau of Mines from two separate voluntary surveys of U.S. operations. Typical of these surveys is the semiannual Phosphate Rock Survey. Of the 19 operations to which a survey request was sent, all responded, representing 100% of the U.S. production data shown in table 1.

BACKGROUND

Phosphate rock deposits occur as marine phosphorites, apatite-rich igneous rock, and modern and ancient guano. All U.S. production was from marine phosphorites. It is the practice of the U.S. industry to express production and reserves in terms of beneficiated product. The grade of the product may be reported as percentage of phosphorus pentoxide (P₂O₅) or as tricalcium phosphate or expressed as percentage bone phosphate of lime (BPL). Conversion factors are $P_2O_5 = \%BPL$ \times 0.4576; %BPL = $P_2O_5 \times 2.1853$; and $P = P_2O_5 \times 0.436$. The phosphate ore bed or the zone of phosphorusbearing material is commonly called the matrix in Florida and North Carolina.

Marketable phosphate rock was produced by 19 companies in the United States. Ten companies in Florida and one in North Carolina produced 87% of the phosphate rock. The 13% balance was produced in Idaho, Montana, Tennessee, and Utah. Approximately 95% of the phosphate rock was used to produce agricultural fertilizers and animal feed supplements. The balance was used in a variety of industrial chemicals.

Sedimentary apatite has a range of chemical compositions. The general formula for marine carbonate-apatite is Ca₁₀(PO₄CO₃)₆Fe₂₋₃. Apatite is host to many cation, anion, and anionic radical substitutions for PO₄. Acces-

sory elements may be associated minerals or those that are chemical substitutions in the phosphate mineral.

The part of phosphate resources that can be profitably recovered is called reserves. Reserves may increase as new deposits are discovered and as technology is improved. Estimates of phosphate rock reserves are made for a specific date and are subject to changing economic or environmental conditions. Operating companies and companies holding phosphate lands estimate the recoverable tonnages based on current and future economics. Mining plans evolve from this planning. Estimates indicate that about 1 billion tons is recoverable from the North Carolina deposit and another billion tons is recoverable from Florida deposits.

The deposits of phosphate rock in Tennessee in the Bigby-Cannon formation are small in size and irregular in shape. They were stripped and mined with 1.5- or 2.3-cubic meter (2- or 3-cubic yard) draglines. The ore was trucked or railed to washing and classification plants before agglomerating into electric furnace feed to produce elemental phosphorus.

The phosphate rock bed of the Pungo River Formation in North Carolina is a primary marine phosphate 6 to 12 meters (20 to 40 feet) thick overlain with 27 to 40 meters (90 to 130 feet) of sand, clay, and marl overburden. The underlying aquifer was depressurized by pumping water to the surface to ensure a dry pit. Currently, bucket-wheel excavators have replaced dredges to strip the top 12 meters (40 feet) of overburden. Large capacity draglines with buckets as large as 55 cubic meters (72 cubic yards) were used to strip the remaining overburden and the matrix. The matrix was slurried with highpressure waterjets, pumped to the beneficiation plant, washed, and classified to produce a minus 16-mesh, plus 200-mesh flotation feed. Flotation concentrate was either calcined or dried.

Most of the mines in central Florida are in the Bone Valley Formation. In North Florida, the Formation is of equivalent age. Overburden averages about 6 meters (20 feet). The overburden consists of a clay sand and a leach-zone material that overlays the matrix. The materials were selectively strip-mined with large electric draglines. The matrix was slurried in a sump and pumped to the washing plant. Cleaned screened material from the washer that was plus 14 or

16 mesh was separated and may be a salable pebble product. The minus 16-mesh fraction was deslimed, and the 16-by 150-mesh fraction was floated to produce a concentrate.

ANNUAL REVIEW

In the history of the phosphate industry in the United States, the most important development was application of the flotation process to separate sand gangue from phosphate rock minerals. The process was applied in 1927 and 1928 at International Agricultural Corp. Phosphate Recovery No. 2 plant. More than one-half of the phosphate mined was wasted before the advent of flotation. Since 1928, there has been no other equivalent technological development.

Legislation and Government Programs

The U.S. Environmental Protection Agency (EPA) was required by the Clean Air Act to review standards of performance for new, modified, or reconstructed stationary sources every 4 years. The first review of the existing new source performance standards (NSPS) for phosphate rock plants was completed to determine the need to revise existing standards. EPA concluded that no revision to the standard was necessary at this time.

The EPA on January 23, 1990, removed 5 of 20 conditionally retained mineral processing wastes from the exemption of hazardous waste regulations provided by section 3001 (b)(3)(A)(ii) of the Resource Conservation and Recovery Act (RCRA), often referred to as the Bevill exclusion. Furnace off gas solids from elemental phosphorus production was removed from the Bevill exclusion. Of the 20 mineral processing wastes that were conditionally retained within the scope of the Bevill exemption were phosphogypsum, from phosphoric acid production, and slag, from elemental phosphorus production. Process wastewater from phosphoric acid production was proposed for temporary retention in the Bevill exclusion.

The EPA will either subject the special mineral processing wastes (i.e., phosphogypsum and phosphoric acid process wastewater) to regulation under subtitle C as hazardous wastes or conclude that such regulation is unwarranted. Wastes for which the exclusion is retained will be subject to regulation under RCRA subtitle D as solid wastes and will likely be placed into the regulatory regime being developed for mineral extraction and beneficiation wastes.

Farmers made little change in 1990 cropland use as Congress prepared new farm legislation. The 1990 farm bill targeted additional land for conservation tillage, contouring, terracing grassed waterways, and diversions to reduce cropland erosion. In addition, the long-term Conservation Reserve Program was extended as was a program to implement water quality protection and restoration of drained wetlands.

The need to cut total spending caused the most significant changes in Federal farm programs. They included the following:

- 1. Establishment of a new system for determining subsidy payments for farmers participating in commodity programs. The new "triple base" system requires farmers to forego subsidy payments on another 15% of their cropland, over the percent of land set aside, to obtain subsidy payments on the remainder. On the 15% reduced acres, farmers can plant any commodity crop.
- 2. Allowance of additional planting flexibility.
- 3. Establishment of a new oilseed support program.
- 4. Modification of the existing 0/92 program to the 0/77 program that allows farmers to plant more profitable resource-conserving crops, including oilseed but not soybeans.
- 5. Establishment of an integrated farm management program.
- 6. Broadening of purposes of agriculture research.

The conservation section of the farm bill includes programs to protect erodible land and wetlands. By 1995, 16 to 18 million hectares (40 to 45 million acres) will be enrolled in the Agricultural Resources Conservation program.

Strategic Considerations

Food security for an expanding world population from a limited land base will be difficult to accomplish in future years. Increasing world population has been one of the factors promoting world grain trade as well as demand for higher per capita food con-

sumption levels and improved living standards. World population has increased from 3.7 billion in 1960 to an estimated 5.3 billion in 1990. The U.S. Bureau of the Census estimates that world population will increase to 6.2 billion in the year 2000 and about 10 billion in the year 2040, a short 50 years into the future.

Phosphate rock, because of its availability, was not strategically stockpiled. As world population levels increase in future years, so will the demand for phosphate rock to produce phosphate fertilizers (plant nutrients) for food production to sustain the world population. The supply of phosphate rock to increase food production in the next century will not be from the same sources as it is today. To meet the anticipated demand, phosphate rock production will rise from 154 million tons in 1990 to an estimated 300 to 400 million tons in the year 2040. This will be difficult to achieve because many of the phosphate rock mines that supply today's world demand will be depleted within a 50-year timespan. The supply of phosphate rock from deposits in the United States will probably be only one-third of its present level, even assuming that the profitability will be sufficiently high to justify mining lower quality resources. Although the United States has a substantial phosphate rock reserve base, an estimated 4.4 billion tons. Morocco's 22 billion ton base supports the probability that, without major new discoveries, it will be the principal phosphate rock supplier to the world in the next century.

Issues

A number of phosphate rock mines in Florida will close as the reserves are mined out in future years. Without the construction of new mines in Florida. the supply of phosphate rock will decline from a planned production of 40 million tons in 1993 and 1994 to 22 million tons in 1997. Deposits of phosphate rock in the southern extension of the Bone Valley Formation are known. and mining centers can be constructed if the investments can be justified. It is probable, but not assured, that when the U.S. domestic supply of phosphate rock is reduced, phosphate rock exports will diminish. Manufactured phosphate fertilizers will be available to both domestic and export markets, and, in this situation, projected to occur in the mid-1990's, the selling price of these commodities will probably increase. Return on investments will then be able to justify investment in new phosphate rock mines. If new phosphate rock mines are not developed, phosphate rock and phosphate fertilizer imports will probably increase to make up a short fall in domestic supply, concurrent with a reduction in exports. An increase in the selling price of phosphate rock and phosphate commodities, if achieved, will improve its profitability in the market; however, it is also probable that the costs associated with production will increase to meet standards set to ensure land reclamation, control hazardous wastes, minimize water consumption, and maintain air and water quality.

Production

Production of marketable phosphate rock in the United States decreased 7% in 1990 to 46.3 million tons. This was 3.5 million tons less production than was planned by producers of phosphate rock as demand for phosphate fertilizers and phosphate chemicals was less than that of 1989. The 3.5 million ton decline of production compared with that of 1989 occurred in the producing States of Florida and North Carolina. Production from Tennessee and the Western States was the same as that of 1989.

Florida and North Carolina.—Phosphate rock was produced in central Florida by Agrico Chemical Co., a division of Freeport-McMoRan Resource Partners L.P.; CF Industries Inc.; Estech Inc., owned by C&G Holdings Inc.; Gardiner Inc., 80% ownership by Cargill, Inc.: IMC Fertilizer Inc. (IMC); Mobil Mining and Minerals Co.; U.S. Agri-Chemicals Corp., owned by Sinochem (USA) Inc.; Seminole Fertilizer Corp., owned by Tosco Corp.; and Nu-Gulf Industries Inc., owned by Gulf Atlantic Corp. In northern Florida, Occidental Chemical Agricultural Products Inc. produced phosphate rock for conversion to superphosphoric acid.

Low-fluorine soft phosphate rock was recovered from hard phosphate rock tailing ponds in north-central Florida by Manko Co., Howard Phosphate Co., and Loncala Phosphate Co.

Texasgulf Inc., a subsidiary of Elf Aquitane Inc., produced phosphate rock

for domestic consumption in its adjacent fertilizer plant and for export. The mine and plant are on the Pamlico River in eastern North Carolina. The U.S. Army Corps of Engineers issued a feasibility report and environmental assessment of harbor improvement for Morehead City, NC. If implemented, it will improve the competitive export position of Texasgulf.

Tennessee.—Occidental Chemical Corp. produced elemental phosphorus in three electric furnaces from local ores in Columbia, TN.

Stauffer Chemical Co., a division of Rhône-Poulenc Basic Chemicals Inc. also produced elemental phosphorus from local ores in Mount Pleasant, TN. Monsanto Co. closed its electric furnaces in Tennessee in 1986. As a matter of interest, Albright & Wilson Americas closed its electric furnace plant at Long Harbour, Newfoundland, in 1989. Rhône-Poulenc will close the phosphate rock mines in Tennessee in early 1991 and phaseout the electric furnaces thereafter. With rising energy costs and new purified wet-process phosphoric acid technology, purified wet process plants are proliferating in the United States. Olin Corp., Joliet, IL, purifies wet-process phosphoric acid to produce sodium phosphates. A joint venture by Olin, Texasgulf, and Albright & Wilson was formed to construct a wet-process purified phosphoric acid plant at Aurora, NC. Rhône-Poulenc was constructing a new wet-process phosphoric acid purification plant at Geismar, LA.

Western States.—Phosphate rock was mined in Idaho, Montana, and Utah to produce both elemental phosphorus and phosphate fertilizers. J.R. Simplot Co. produced phosphate rock from the Gay Mine on the Fort Hall Indian Reservation and from the Smoky Canyon Mine, Caribou National Forest. Mainbed ore from the Gay Mine was used by Simplot to produce wet-process phosphoric acid, and FMC Corp. used the lower grade shale in its electric furnaces near Pocatello, ID.

Monsanto Co. supplied its electric furnaces in Soda Springs, ID, with phosphate rock from its Enoch Valley Mine in the Caribou National Forest. Rhône-Poulenc produced phosphate rock from its Wooley Valley Mine, Caribou National Forest, ID, and shipped the phosphate rock to its electric furnace plant in Silver Bow, MT. Nu-West Industries Inc., a member of the Conda Partnership with Western Coop Fertilizer Co., produced phosphate rock from the Maybie Canyon, Mountain Fuel, and Champ Williams Mines in the Caribou National Forest. The phosphate rock

was shipped by rail to Conda, ID, beneficiated, calcined, and used to produce wet-process phosphoric acid. Cominco American Inc. operated the only underground phosphate rock mine in the United States. The mine, beneficiation plant, and drying operation are near Garrison, MT. The product was exported to Canada. Chevron Resources Co. produced and concentrated phosphate rock from its mine near Vernal, UT. The slurry concentrate was pumped to Rock Springs, WY.

Consumption and Uses

In recent years, the demand pattern for phosphate rock has shown a gradual decline in phosphate rock exports, and about one-half of that consumed domestically was exported in a higher value form. More than 77% of the phosphate rock was used to produce wet-process phosphoric acid for the domestic and export markets, and the balance was used to produce a series of chemicals from elemental phosphorus.

Elemental phosphorus from electric furnace operations may be converted into cobalt phosphate for pigments and animal feed supplements; into copper phosphide for phosphorus for safety matches and pyrotechnics; into phosphorus trichloride for phosphorus oxy-

chloride, phosphorus pentachloride gasoline additives, plasticizers, and dyestuffs; into phosphorus trisulfide for matches; and into phosphorus pentasulfide for lubricating oil additives, flotation reagents, rubber additives, and a stabilizer for aromatic amines. Phosphorus pentoxide was used to produce phosphoric acid for a large number of products—phosphorus oxychloride catalyst for air blown asphalt, for drying agents, for leather tanning, medicine, liquid paint remover formulations, dehydrating agents, and sugar refining. There are military applications for elemental phosphorus to produce smoke columns and screens and incendiary bombs and shells. The byproduct of elemental phosphorus, ferrophosphorus, was used in alloy steels and processed to recover contained vanadium.

Wet-process phosphoric acid was used to produce the fertilizers ammonium phosphates, triplesuperphosphate, monobasic and dibasic calcium phosphates for animal feed supplements, and detergents of sodium and potassium polyphosphates. Mineral feed supplement rock was produced from defluorinated phosphate rock. Byproducts from wet-process phosphoric acid include phosphogypsum, uranium, vanadium, calcium chloride, sodium fluorosilicate, and fluosilicic acid.

Phosphate rock exports as well as imports declined in 1990. Exports of phosphate fertilizers held at a high level in 1990, possibly explaining the fact that phosphate rock exports declined to 6.2 million tons in 1990, about 20% less than that of 1989. Most of the phosphate rock imports was used by producers of liquid fertilizer.

Stocks

About 90% of phosphate rock stocks in the United States was held adjacent to the beneficiation plants in Florida and North Carolina. Inventoried phosphate rock in Florida and North Carolina was either dried for export, calcined to increase grade and potential phosphoric acid quality, or wet ground to produce phosphoric acid. In the Western States, phosphate rock was stockpiled during the warm months of the year near electric furnaces and wet-process phosphoric acid plants to avoid the problem of unloading frozen ore from railroad cars and truck boxes in the wintertime.

The level of phosphate rock invento-

ries declined from a peak of 20 million tons in 1981 to 9.3 million tons in 1988. Yearend stocks in 1989 and 1990 were about 11 million tons and 9 million tons, respectively, indicating producers were controlling phosphate rock inventories.

Transportation

From production centers in central

and north Florida, phosphate rock and phosphate fertilizers were moved by rail to terminals on Hillsborough Bay, FL, and in Jacksonville, FL. In central Florida, CSX Transportation railroad moved product to terminals on Tampa/Hillsborough Bay. The Rockport terminal was owned and operated by the CSX railroad. Port Sutton was owned and

operated by IMC, Eastern Associated Terminal (E.A.T.) was owned and operated by E.A.T, and Big Bend was owned and operated by Agrico Mining Co.

Markets and Prices

The price or value of phosphate rock was obtained by semiannually surveying the producing companies to obtain domestic and export selling prices for each grade of phosphate rock, f.o.b. mine. The data were used to calculate the average selling price for each grade of phosphate rock in the domestic and export market. Historical average selling prices from 1970 through 1990 are shown in table 12.

Estimates of phosphate rock export prices, unground, f.o.b. vessel, Tampa Range or Jacksonville, FL, by grade are shown in table 13. The estimates indicate that export prices increased about \$3.00 per ton from Florida. Table 14 shows estimates of Moroccan phosphate rock export prices, U.S. dollars per ton, f.a.s. Laayoune, Casablanca, or Jorf Lasfar. Tables 15, 16, and 17 show the price or value of Florida and North Carolina, Tennessee and the Western States, and the United States, respectively, by grade for the domestic and export markets and an average selling price.

In north Florida, the Norfolk Southern Railroad moved phosphate rock from Occidental's mines to Occidental's terminal in Jacksonville, FL.

Rail freight published tariffs and loading charges for phosphate rock at central Florida terminals were \$6.46 per ton. The published freight and loading cost in North Florida was \$9.08 per ton.

The U.S. Corps of Engineers completed deepening the Tampa Bay Channel, Hillsborough Bay Channel, and Sparkman Channel to a depth of 13.7 meters (45 feet) to accommodate deep draft vessels. Berth 31, adjacent to the Port Sutton turning basin, was deepened to 13.1 meters (43 feet). The berth accommodates larger vessels carrying more cargo to use the port. The berth was used to "top-off" phosphate rock cargoes.

In Tennessee and the Western States, phosphate rock was moved by both railroad and truck to either beneficiation plant or electric furnace facilities. Phosphate concentrates were transported by pipeline by two companies producing in Idaho and Utah.

¹ Includes Idaho, Montana, and Utah.

²Data may not add to totals shown because of independent rounding.

³ Includes rock converted to products and exported.

⁴Exports reported to the U.S. Bureau of Mines by companies.

The total value is based on a weighted value.

Self-unloading barges were used in North Carolina to transport phosphate rock concentrates from the Aurora Mine to the Morehead City Port Terminal.

Foreign Trade

Large fertilizer plants, near the supply of phosphate rock and sulfur, generally have lower capital and operating costs compared with smaller plants and, by minimizing transportation costs, their competitive position is improved. Trade in high-analysis phosphate fertilizers has increased, and trade in low-analysis phosphate rock has declined as was exemplified by the reduction in world phosphate rock exports in the 1980's.

The United States was a net exporter of phosphate rock in 1990. Phosphate rock exports declined by about 20% compared with that of 1989. Exports of higher value phosphate fertilizers were similar to those of 1989. The export tons and values for ground and unground phosphate rock, superphosphates, ammonium phosphates, phosphoric acid, and elemental phosphorus are shown in tables 18 through 25.

The principal countries that have sources of phosphate that compete in international trade are Algeria, Israel, Jordan, Morocco, Senegal, Syria, the Republic of South Africa, Togo, Tunisia, and the United States. Countries with indigenous supplies of phosphate rock have recognized the advantages of exporting high-analysis phosphate fertilizers rather than phosphate rock. U.S. phosphate rock exports have declined, and exports of ammonium phosphates and superphosphates have increased during the past decade.

Phosphate rock was exported from

central Florida mines through Tampa, FL; Occidental in North Florida exported through Jacksonville, FL; Texasgulf exported through Morehead City, NC; and Western States phosphate rock was exported into Canada.

Phosphate rock imports declined from 705,000 tons in 1989 to about 451,000 tons in 1990. In past years, phosphoric acid plants at Taft, LA, and Pascagoula, MS, imported Moroccan phosphate rock. Currently, a Geismar, LA, phosphoric acid plant is importing phosphate rock from the Moroccan Bou Craa phosphate rock mine to produce super phosphoric acid for liquid fertilizer. Weak fertilizer demand from the U.S. market has reduced the demand for imported phosphate rock.

World Review

The changes in the political systems in Eastern Europe and the war in the Middle East reduced the demand for phosphate fertilizers in these parts of the world and reduced phosphate rock exports from involved Middle East countries. Restricting Iraqi trade eliminated exports of sulfur, phosphate rock, and phosphate fertilizers and reduced exports of phosphate rock and phosphate fertilizers from Jordan. The Persian Gulf crisis has decreased the stability of several economies in the region that supply raw materials and finished fertilizers.

There were no significant changes in the function of the world phosphate rock industry with the exception of the impact of the Gulf war on Jordan. The Port of Aqaba operated at 80% of its capacity. Another contributing factor to the decline of phosphate rock shipments from Syria and Jordan was the drop in demand from Eastern European Countries.

The world phosphate rock capacity was estimated and is shown in table 27. An estimated capacity of about 200 million tons was unchanged from the 1989 estimate. In countries where mines have closed for reasons of depletion of reserves or high costs, world production was maintained by increasing the output from existing mines or by moving mining equipment to another deposit. The mining capacity was essentially maintained.

The U.S. Bureau of Mines has estimated world phosphate rock reserves and the reserve base. Reserves and re-

serve base estimates shown in tables 28 and 29 include those with costs less than \$40 and \$100 per ton, respectively. The reserve and reserve base estimates are largest in the continent of Africa and include the carbonatite deposit in the Republic of South Africa and the vast sedimentary deposits in northwest Africa. Significant reserves exist in the U.S.S.R and in Florida and North Carolina in the United States.

OUTLOOK

During the next 3 to 5 years, the supply of phosphate rock is forecast to be adequate to meet agriculture and industrial demands. World demand is forecast to increase at an annual rate of 1% to 2% to meet the demands of population increases.

Although the Bevill amendment ex-

cluded solid waste from regulatory control under the Resource Conservation and Recovery Act, the EPA, in 1989 and 1990, defined which processing wastes met high-volume, low-hazard criteria. The wastes that did not meet both criteria would be subject to subtitle C regulation. The final mineral processing report to Congress was made in July 1990, and the final mineral processing regulatory determination will be made in 1991.

Phosphate rock exports show a declining trend. Conversion of phosphate rock into higher analysis and value products has increased in the United States and the world to maximize the profitability of the commodity. Imports of high-grade and high-quality phosphate rock to manufacture phosphoric acid and liquid phosphoric fertilizers increased in the late 1980's, but, at this time, a growth trend does not appear to be developing.

It is probable that additional facilities will be constructed in the United States to purify wet-process phosphate acid to compete with products manufactured from the electric furnace, elemental phosphorus, and phosphoric acid route. Increasing power costs will encourage reduction in the number of electric furnaces and promote wet-process acid purification.

In recent years, about one-half of the phosphate rock mined was exported as phosphate rock, phosphate fertilizers, and phosphate chemicals. The importance of the export market to the U.S. phosphate industry cannot be overestimated. The ability of the U.S. phosphate rock industry to supply future domestic and export markets is of some concern when it is recognized that phosphate rock reserves are finite.

The survey of world phosphate rock producers performed by the International Fertilizer Industry Association (IFA) shows that world phosphate rock production has declined from 164 million tons in 1988 to 162 million tons in 1989 and, based on production reports from principal world producers, may decline in 1990 to about 154 million tons. The statistics showing declining production occurred during a period of increasing world demand. All of the world forecasting organizations, including IFA, the World Bank, and the Wharton Econometric Forecasting Association, predict a demand increase of

1% to 2% per year for phosphates.

The reasons for declining production during a period of increasing demand are not clear. It may be explained if it is assumed that production data were different from that reported or the annual supply of phosphate rock was much greater than demand, without drawing down inventories, to accommodate the increase in demand. Phosphate consumption in the recently liberated centrally planned economy countries in Eastern Europe may have been lower than expected, or production estimates from centrally planned economy countries may be overestimated.

U.S. phosphate rock production was 45.4 million tons in 1988, 49.8 million tons in 1989, and 46.3 million tons in 1990. Phosphate consumption by major importing countries such as China and India will maintain U.S. diammonium phosphate exports at their current level, and the demand created by U.S. farm programs will complicate the outlook for 1991. Domestic fertilizer use is projected to decline in 1991, exports of phosphate rock are projected to decline in 1991, and exports of phosphate rock are projected to improve.

¹ Table includes data available through May 31, 1991. Data for major phosphate rock producing countries derived in part from the International Fertilizer Industry Association; other figures are from official

country sources where available.

2 In addition to the countries listed, Belgium and Uganda may have produced small quantities of phosphate rock and Namibia may have produced small quantities of guano, but output is not officially reported, and available information is inadequate for formulation of reliable estimates of output levels.

³ Reported figure.

⁴Less than 1/2 unit.

⁵ Includes only output used to manufacture fertilizers.

⁶ Production from Western Sahara area included with Morocco.

⁷ Does not include aluminum phosphate production, gross weight, in thousand tons: 1986—131; 1987—191; 1988—119; 1989—115 (estimated, revised); and 1990—111 (estimated).

PLATINUM-GROUP METALS

By J. Roger Loebenstein

Mr. Loebenstein, a physical scientist with 16 years industry and U.S. Bureau of Mines experience, has been the commodity specialist for platinum-group metals for 10 years. Domestic survey data were prepared by Evangeline Hemphill, mineral data assistant; and international data tables were prepared by Harold Willis, international data coordinator.

he platinum-group metals (PGM) are composed of six closely related metals: platinum, palladium, rhodium, ruthenium, iridium, and osmium. They commonly occur together in nature and are among the scarcest of the metallic elements. In terms of commercial importance, platinum and palladium are the two most important metals of the group. All of the metals are valued for their corrosion resistance and catalytic activity.

The Clean Air Act of 1990 was passed by the Congress and signed by the President. Provisions of the new law require a 35% reduction in hydrocarbons and a 60% cut in nitrogen oxides beginning in 1994. In addition, automotive catalytic converters must be guaranteed by manufacturers to last double the current 50,000 miles.

The price of rhodium soared to a record high of more than \$7,000 per troy ounce briefly in June before settling down to the \$4,000 to \$5,000 range. The supply of rhodium is a problem of increasing concern to automotive manufacturers who use it to control nitrogen oxide emissions from cars and trucks. There are no substitutes for rhodium for this application.

DOMESTIC DATA COVERAGE

Domestic production data for PGM are developed by the U.S. Bureau of Mines from a voluntary survey of U.S. refiners. Of the 18 refiners to which a survey request was sent, 11 responded. These represent 85% of the total refined metal production shown in tables 5 and 6. Production for nonrespondents was estimated using prior-year levels adjusted for general industry trends.

BACKGROUND

Products for Trade and Industry

The basic forms of PGM are sponge or powder, which may be converted to other forms such as bars, pastes, or chemicals. The catalyst industry employs an extensive number of chemical compounds containing PGM. A typical PGM catalyst may consist of a platinum-rhodium gauze woven from wire. The electronics industry purchases PGM pastes, and the dental industry uses wire and a variety of alloys.

Geology-Resources

PGM deposits are associated with magmatic intrusions of mafic and ultramafic rocks. They also occur to a lesser extent as placer deposits. Layered deposits associated with stratiform complexes are the only ones mined principally for the PGM, with nickel, copper, and cobalt sometimes produced as byproducts. These are found in the Bushveld Complex, Republic of South Africa, and the Stillwater Complex, United States.

In other PGM deposits, such as those found in the Sudbury Complex, Canada, and Noril'sk, U.S.S.R., the PGM are produced as byproducts of nickel and copper mining.¹

In the Republic of South Africa, it is interesting to note that base metals such as nickel and copper are important in generating revenues from the Merensky and Platreef ores. This is not the case at the Stillwater Mine in the United States, where platinum and palladium contribute about 100% of revenues.

Technology

Processing.—The processing of PGM ore entails four general steps: mining, concentrating, smelting, and refining. In

the concentrating step, platinum ore is crushed and treated by froth flotation. The concentrates are dried, sometimes roasted, and then fused in a smelter furnace, producing a sulfide matte containing the PGM. The matte is treated in a refinery using solvent-extraction techniques to separate and purify the six PGM.

Recycling.—In North America, PGM are recovered by a small number of scrap refiners, as shown in table 1. Other companies collect scrap materials such as catalysts and PGM-bearing solutions and process them to increase the grade. These upgraded secondary materials are then sold to refiners. For example, Multi-Metco Inc., Anniston, AL, produces about a 90% concentrate of PGM from scrapped autocatalysts, which in turn is refined by another company. World Resources Co., McLean, VA, collects electroplating solutions, upgrades them, and sells the concentrate to another refiner. Most companies specialize in refining or upgrading a particular type of scrap, such as petroleum catalysts, autocatalysts, or electronic scrap.

Refiners often charge a fee or toll to "toll refine" scrap, ownership of the PGM content of the scrap remaining with the customer. For example, a refiner and/or fabricator would replace worn out catalyst with fresh catalyst and charge the customer for the refining and fabrication costs. In other cases, refiners purchase scrap, process it, and sell the refined metal. When scrap changes ownership in this way, it is referred to as nontoll scrap.

For statistical purposes, nontoll refined scrap is considered as old scrap and is added to supply, along with newly mined metal.

Because of their high value, PGM are routinely recovered from petroleum catalysts, chemical catalysts, automobile catalysts, glass fiber bushings, electronic scrap, laboratory equipment, dental materials, and jewelry.

Major collectors and refiners of autocatalysts are shown in table 2. In the United States, only Multi-Metco refined any substantial quantities of autocatalyst PGM. Multi-Metco's output required further processing by other companies to produce commercial-grade metal. The other major refiners of scrapped automobile catalysts are in Canada, Belgium, and Japan.

Because used precious-metal scrap varies widely in value and grade, proper sampling and assaying is important to the industry. Fire assay techniques have long been used to determine the presence of precious metals. In addition to fire assays, PGM can be determined by chemical methods and instrumental methods such as X-ray fluorescence and spectrochemical methods.²

A list of independent PGM assayers is shown in table 3. The list is meant to be a sample rather than a complete list of assayers.

Economic Factors

Futures contracts are traded on the New York Mercantile Exchange (NY-MEX) and the Tokyo Commodity Exchange for Industry (TOCOM), and to a lesser extent on the MidAmerica Exchange.³ Futures contracts help producers and consumers of platinum and palladium lock in prices and allow speculators an opportunity to make profits. By comparing the current price with the price for future delivery, one can surmise whether market participants expect prices to rise or fall.

Platinum and palladium futures contracts, specifying 99.95% metal content, were traded on the NYMEX in units of 50 and 100 troy ounces, respectively. Table 4 shows the number of contracts traded on the last trading day of the year for 1987–90.

Trading of platinum futures contracts on the TOCOM began in 1984. The contract unit is 500 grams, the quality specifications are 99.9% purity, and prices are quoted in Japanese yen per gram.

In London, prices of physical platinum and palladium bullion are set each day in the morning and afternoon for the wholesale market. The eight companies participating in establishing prices are members of the London-Zurich Good Delivery Agreement, which sets standards for platinum and palladium trading in

Europe. London and Zurich are the two most important European trading centers for platinum and palladium.

A time series of historical prices for each of the six PGM and a brief discussion of factors influencing prices are given in a U.S. Bureau of Mines publication entitled "Nonferrous Metal Prices in the United States Through 1988."

ANNUAL REVIEW

Legislation and Government Programs

The Clean Air Act amendments of 1990 were passed, representing the fifth major effort by Congress to address clean air legislation. Provisions of this law deal with mobile sources and clean fuels, air toxics, acid rain, and ozone protection.

The amendments establish stricter standards for nonmethane hydrocarbons (NMHC), carbon monoxide (CO) and oxides of nitrogen (NO_x). Tier I standards for cars and light trucks call for 0.25 gram per mile (gpm) for NMHC, 3.4 gpm for CO, and 0.4 gpm for NO_x. These standards will be phased in between 1994 and 1998. Tier II standards are one-half of the Tier I standards and may go into effect between the years 2003 and 2006. In addition, catalytic converters must be guaranteed to operate for 100,000 miles, double the current limit.⁵

Strategic Considerations

Although production of platinum and palladium increased at the only PGM mine in the United States, the Stillwater Mine, the majority of PGM consumed in the United States was still derived from imported sources.

There were no changes in inventories of platinum, palladium, and iridium in the National Defense Stockpile in 1990. No purchases of rhodium or ruthenium were made, even though there is a stockpile goal for these two metals.

Production

The Stillwater Mine, southwest of Billings, MT, was operated by the Stillwater Mining Co. (SMC), owned 50% by Chevron Corp. and 50% by Manville Corp. Estimates from published sources showed that production of both platinum and palladium at the mine increased again in 1990. Small amounts of PGM

Estimated. Revised.

²100 troy ounces per contract.

The platinum-group comprises six metals: platinum, palladium, iridium, osmium, rhodium, and ruthenium. Multiply by 32.1507 to convert from kilgrams to troy ounces.

Estimates for the Stillwater Mine are from published sources. A very small quantity of byproduct platinum and palladium produced from gold-copper ores was excluded.

Value based on dealer prices.

Value based on dealer prices.

Excludes ores, scrap, and platinum grains and nuggets.

⁵1986 mine production excluded to avoid disclosing company proprietary data. 1987–90 includes mine production plus nontoll-refined production of secondary metal plus refined imports for consumption minus refined exports plus or minus changes in Government and industry stocks.

Refined imports for consumption minus refined exports plus or minus changes in Government and industry stocks.
71986 total excludes U.S. mine production in order to avoid disclosing company proprietary data.

rRevised.

were recovered by other companies as byproducts of domestic copper refining.

SMC opened a new smelter in Columbus, MT, to process PGM concentrates from the mine. PGM matte containing precious metals was airfreighted to Belgium for final refining and separation of the individual PGM. SMC had no plans to open its own PGM refinery or to have its concentrates refined domestically.

Sumitomo Corp. of America purchased Catalyst Collectors Corp. (CCC), Union, NJ, and CCC's network of autocatalyst collectors. Sumitomo, an international trading company, planned to offer scrap collectors financing capabilities, hedging capabilities, and precious-metal refining services.

Consumption and Uses

Reported sales of PGM by refiners is shown in table 7. For comparison purposes, the calculated apparent consumption for the individual PGM is also shown.

A summary of the typical uses for each PGM is shown in tables 8 and 9. Platinum, palladium, and rhodium were used in emission catalysts for light trucks (trucks weighing 14,000 pounds or less,

gross weight) and automobiles. An informal survey of automobile catalyst manufacturers indicated that a typical emission catalyst in 1990 contained a total of about 2.7 grams PGM (approximately 2.18 grams platinum, 0.31 gram palladium, and 0.31 gram rhodium). These loadings were higher than in 1989, reflecting more stringent emission regulations.

There were variations in the quantities of PGM in each catalyst, depending on the vehicle's engine size, the normal operating temperature of the engine, and the manufacturer of the catalyst.

Data may not add to totals shown because of independent rounding.

²"Toll-refined" data were not reported for years 1986-90.

³Less than 1/2 unit.

rRevised.

In electronic applications, ruthenium was the principal PGM used in thick film resistors, and palladium was the principal PGM used in thick film conductors, multilayer ceramic capacitors, and connectors. Platinum "targets" were used for sputtering thin films on circuit boards. Platinum-rhodium alloys were used for

manufacturing thermocouples for precise temperature measurement.

For glass applications, most of the PGM, specifically platinum, rhodium, and palladium, were used in bushings for the extrusion of textile (continuous filament) glass fiber.

The nonautomotive catalyst applications

of PGM were numerous. The petroleum refining industry used PGM, principally platinum, in reforming, cracking, and isomerization reactions. Chemical catalysts containing platinum and rhodium were used in inorganic syntheses of nitric acid and hydrogen cyanide. Palladium was used in the production of hydrogen

¹Comprises primary and nontoll-refined secondary metals.

²Data may not add to totals shown because of independent rounding.

³Defined as mine production plus nontoll production of secondary metal plus imports minus exports plus beginning stocks minus ending stocks. Between 1986 and 1988, unspecified PGM imports and exports were divided evenly between platinum and palladium. Iridium and osmium exports included with ruthenium, in 1989 and 1990.

¹⁹⁸⁶⁻⁹⁰ platinum, palladium, and rhodium sales to the automotive industry are estimated based on U.S. light truck sales and U.S. automobile production.

peroxide. A wide variety of organic chemicals and pharmaceuticals were produced using PGM catalysts.

Stocks

In addition to the reported stocks held by refiners, importers, and dealers, end users of PGM held sizable quantities of PGM that were not reported to the U.S. Bureau of Mines.

Markets and Prices

The price of rhodium began increasing near the end of 1989, setting record highs along the way, until the price reached more than \$7,000 per ounce briefly in June. During the remainder of the year, rhodium sold between \$4,000 and \$5,000 per ounce.

There were two primary reasons for the escalation in rhodium prices. The first had to do with production problems at an important South African refinery. The other reason for high prices was a lack of any substantial spot sales of rhodium from the U.S.S.R.

In October, the NYMEX introduced the trading of options on platinum futures contracts. In the past, the platinum futures market at NYMEX as well as other foreign futures markets have helped companies protect themselves from price volatility. Platinum options were designed to provide additional hedging and trading opportunities.

Foreign Trade

Imports of rhodium increased substantially, probably because of stockpiling by automobile companies, from 7 metric tons in 1989 to 13 metric tons in 1990.

World Review

Capacity.—Capacity for PGM production is generally cited in terms of platinum capacity. The data in table 14 represent rated capacity, defined as the maximum quantity that can be produced on a normally sustainable long-term operating rate, based on the physical equipment of the plant and routine operating procedures for labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure.

¹Includes metal in depositories of the New York Mercantile Exchange (NYMEX); on Dec. 31, 1990, this comprised 4,272 kilograms of platinum and 2,034 kilograms of palladium.

Source: Metals Week.

The sudden and probably lasting rise in rhodium prices in 1990 has stirred speculation that despite rhodium's scarcity, it may become the chief revenue producer for South African mines, at least partly replacing platinum.⁶ These conclusions are predicated on the assumption, shared by most experts, that rhodium will remain in short supply in the near term because of the lack of substitutes in automobile catalyst applications.

South Africa, Republic of.—Rustenburg Platinum Mines Ltd. announced its intent to develop a new PGM mine in Lebowa, to begin producing in 1994. The mine is part of the Platreef area, with in situ grades of 8.5 grams per metric ton of combined PGM and gold. The ore's platinum to palladium ratio is 1:1.

Lonrho PLC acquired the Karee Mine, owned by Impala Platinum Holding (Pty.) Ltd. (See table 14, footnote 4).

Johnson Matthey PLC announced plans to build a new autocatalyst plant in the Republic of South Africa with a capacity of 2 million units per year. The plant will cost \$13.22 million and is to be in Germiston, near Johannesburg. Production is scheduled to begin next year and will supply primarily German auto manufacturers.

U.S.S.R.—General Motors Corp. (GMC) won a 5-year contract to supply

¹Average prices calculated at the low end of the range and rounded to the nearest dollar.

pollution-control and engine-control parts to Volga Auto Works, (VAZ), the U.S.S.R.'s largest automaker. GMC plans to begin shipping autocatalysts to VAZ's factory beginning in 1992.

The format of table 15 was changed in 1990 to show production of platinum, palladium, and other platinum-group metals.

Current Research

Scientists at AEA Industrial Technology Ltd. at Harwell, United Kingdom, investigated the use of tin oxide in combination with oxides of copper, aluminum, and chromium as a substitute for PGM in automobile catalysts.⁷

Rhodium is one of a number of products produced from the radioactive

disintegration of plutonium. Scientists at IBC Advanced Technologies in Orem, UT, worked on separating rhodium from nuclear waste material. The separation process is based on a principle called molecular recognition. Chemical compounds called "hosts" are used to recognize the shapes of positively charged particles called "guests" and bind to them.⁸

OUTLOOK

Supply

Most of the major expansion programs for South African mines are still progressing, despite relatively low prices for platinum and palladium in 1990. High rhodium prices in 1990, averaging about \$3,565 per ounce, partly compensated for lower revenue from platinum and palladium sales. A South African source showed the revenue (dollars per metric ton) of ore as shown in table 16.9

Rhodium plays an important role in providing revenue from the UG2 reef. In fact, almost one-half of the \$66 in revenue is derived from rhodium, and approximately one-half is derived from platinum. Nickel, copper, gold, and the minor PGM provide limited revenue for South African deposits. In the United States, most of the \$187 in revenue comes from platinum and palladium.

Estimated. Revised.

¹Table includes data available through Apr. 26, 1991. Platinum-group metal production by the Federal Republic of Germany, Norway, and the United Kingdom is not included in this table because the production is derived wholly from imported metallurgical products and to include it would result in double counting.

²In addition to the countries listed, China, Indonesia, Papua New Guinea, and the Philippines are believed to produce platinum-group metals, and several other countries may also do so, but output is not reported quantitatively, and there is no reliable basis for the formulation of estimates of output levels. However, a part of this output not specifically reported by country is presumably included in this table credited to Japan. (See footnote 6).

³Partial figure; excludes platinum-group metals recovered in other countries from nickel ore of Australian origin; however, a part of this output may be credited to Japan. (See footnote 6).

⁴Reported figure.

⁵Data are for years ending June 30 of that stated.

⁶Japanese figures do not refer to Japanese mine production, but rather represent Japanese smelter-refinery recovery from ores originating in a number of countries; this output cannot be credited to the country of origin because of a lack of data. Countries producing and exporting such ores to Japan include (but are not necessarily limited to) Australia, Canada, Indonesia, Papua New Guinea, and the Philippines. Output from ores of Australian, Indonesian, Papua New Guinean, and Philippine origin are not duplicative, but output from Canadian material might duplicate a part of reported Canadian production.

⁷Includes osmiridium produced in gold mines.

⁸Estimates for the Stillwater Mine, from published sources. A very small quantity of byproduct platinum and palladium produced from gold-copper ores was excluded.

Demand

Future demand for PGM should continue to grow worldwide given the strong demand for a cleaner environment. Catalytic converters for controlling automobile emissions are currently used in Australia, Canada, Japan, Republic of Korea, Taiwan, United States, and many Western European nations. Brazil, Hong Kong, and Mexico are expected to start using catalytic converters in the very near future. The potential market for the catalytic converter is huge given the fact that

there are 500 million motor vehicles worldwide.

In the United States, California has for years had the most stringent automobile emission regulations, setting the tone for Federal standards. The California Air Resources Board is seeking to introduce zero emissions for 2% of vehicles by the year 2000. Other States, such as New York and Massachusetts, are opting for California standards instead of the more lenient Federal standards.

In addition to controlling emissions from motor vehicles, the Clean Air Act of 1990 controls emissions of air toxics and chlorofluorocarbons. More than 189 air toxics emitted from bakeries, dry cleaning operations, chemical plants, paint plants, paper plants, and other industrial sources are regulated. Catalysts containing PGM are expected to play some part in controlling air toxic emissions.

POTASH

By James P. Searls

Mr. Searls, a physical scientist, has been the commodity specialist for potash for 11 years. Domestic survey data were prepared by Carleen Militello, mineral data assistant; and international data were prepared by Virginia P. Woodson, international data coordinator.

I.S. potash production in terms of potassium oxide (K₂O) equivalent increased more than 7% relative to that of 1989, and apparent consumption increased 3%. The average price, f.o.b. mine, was unchanged from that of 1989 on the basis of K₂O equivalent. Yearend stocks were unchanged from those of 1989 due to parallel increases in production and sales. The New Mexico producers operated at 78% capacity by reducing their work week to help control North American product stocks.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines developed potash domestic data from voluntary semiannual surveys of U.S. operations. Of the 12 survey requests sent to operations, 11 responded, representing 98% of total production shown in table 1.

ANNUAL REVIEW

Strategic Considerations

Strategic considerations for potash in the United States are relatively minor. Although the capacities of U.S. potash mines have not expanded to meet the expanding U.S. demand for potash, large, high-grade potash ore reserves are across the Canadian border in the Province of Saskatchewan. The United States has a long history of cooperation, friendship, and mutual investments with Canada. It, therefore, is unlikely that the United States would experience a potash cutoff by the Canadian producers. There are multiple pathways between the two countries that preclude the interdiction of trade by natural disaster or sabotage of railroad bridges or ports. The Canadian potash mine capacities were built with the expectations of sales to the U.S. market, especially the Corn Belt. A cessation of trade with the United States would close at least 60% of the Canadian capacity until the offshore markets for potash grow to replace the U.S. demand.

Production

Domestic potash production, in K₂O equivalents, increased more than 7% in 1990 over that of 1989. Producers in all four States, California, Michigan, New Mexico, and Utah, increased their production; New Mexico showed the smallest percentage increase. Of the total production for the year, 74% was standard, coarse, or granular muriate of potash, also known as potassium chloride, and 13% was sulfate of potash, also known as potassium sulfate. The remaining production included manure salts, soluble and chemical grades of muriate of potash, and sulfate of potash-magnesia, also known as potassium magnesium sulfate. The terms "standard," "coarse," and "granular" muriate of potash comprise the "three muriates," a term that ignores the soluble and chemical grades of muriate of potash. "Standard" and "soluble" grades of muriate of potash and sulfate of potash also have industrial end uses. The "sulfates" category combines the sulfate of potash-magnesia data and the sulfate of potash data. "Manure salts" formerly referred to high-grade "run-of-mine" ore; 25% K₂O potash ore is approximately 40% KCl that can be used on sugar beets. The term now refers to a mixture of white muriate of potash and common table salt for industrial uses.

The New Mexico potash producers accounted for 85% of total marketable potash salts production. Production of crude salts (ore) in New Mexico was unchanged at 14.9 million tons 1 with an

average K₂O content of 13.8%. The producers were AMAX Potash Corp. of AMAX Inc., Eddy Potash Inc. of Trans-Resources Inc., IMC Fertilizers Inc. (IMCF), Mississippi Chemical Corp., New Mexico Potash Corp. of Trans-Resources Inc., and Western Ag-Minerals Co. of Rayrock Resources of Canada. All the New Mexico producers, except Western Ag-Minerals, mined sylvinite ore (the mixture of sylvite and halite from which most muriate of potash originates) and beneficiated the ore into muriate of potash. Several forms of beneficiation were used: The flotation of sylvite (potassium chloride) away from halite (sodium chloride) occurred at AMAX Potash, Eddy Potash, and Mississippi Chemical. The IMCF plant used heavy-media separation, and New Mexico Potash used selective crystallization in their plant. Western Ag-Minerals and IMCF mined langbeinite ore and beneficiated the ore to sulfate of potashmagnesia. The IMCF personnel mined both sylvinite and langbeinite ores and reacted fractions of each potash product to produce sulfate of potash.

AMAX Potash was put up for sale by its parent company near the beginning of the year. For part of the year Kali und Salz of the Federal Republic of Germany considered buying the mine through an intermediary, operating the mine to depletion, and then using the site for waste disposal. Apparently, depleted potash mines are used for waste disposal in the Federal Republic of Germany. The agreement was not signed due to funding problems. At the end of the year, a Denver, CO, goldmining company was considering buying the mine to operate it to depletion. At the beginning of the year, a muriate of potash exporting association was established by the New Mexico producers under the auspices of the Webb-Pomerane Act. The New Mexico Potash Export Association (NewPotex)

was created to increase sales to Latin America, but this year's sales to Latin America were disappointing, and the Association was disbanded at the end of October. At midyear, IMC Fertilizer Group Inc.'s parent company changed its name to IMCERA Group Inc. and sold off 62% of its stockholding in IMC Fertilizers Group Inc. to concentrate in animal-health products, specialty chemicals, and medical imaging media.

In Utah, Moab Salt Inc. produced muriate of potash for Texasgulf Chemical Co. from underground bedded deposits by solution mining and solar evaporation. The sylvinite salts from the solar ponds were beneficiated by flotation to separate the sylvite from the halite. Climax Chemical Co. converted some of Moab Salt's potassium chloride to potassium sulfate for sale during the first half of the year. In the first quarter of 1989, Great Salt Lake Minerals & Chemicals Corp. (GSLMC) was purchased from Gulf Resources

and Chemical Corp. by a group of investors lead by D. George Harris & Associates and GSLMC management. GSLMC continued to produce sulfate of potash from the brines of the North Arm of the Great Salt Lake by solar evaporation and a proprietary process of beneficiation. GSLMC sometimes purchases muriate of potash from other sources for conversion to sulfate of potash owing to an excess of sulfate ions in the lake brine concentrate. For 1990, GSLMC imported a small amount of muriate of potash; this amount was subtracted from the import data to prevent double counting in the U.S. apparent consumption calculation. The Reilly-Wendover operation of Reilly Industries Inc. plant produced muriate of potash and manure salts by solar evaporation and flotation from near-surface brines at the west end of the Bonneville Salt Flats.

One plant in Utah manufactured sulfate of potash from muriate of potash and sulfuric acid. They reported pro-

duction of about 22,000 tons K_2O equivalent for the year. The amount is not included in table 4 because the company does not mine any ore. One plant in Texas manufactured sulfate of potash in the same manner until the end of October and dismantled the plant. This production is included in table 4; the plant is operated by AMAX Potash.

In California, the muriate and sulfate of potash (and other products) operation at Searles Lake was sold by Kerr-McGee Chemical Corp. to an investment group composed of Chase Manhattan Investment Holdings Inc., Prudential Insurance Co., and Oriental Chemical Industries of Seoul, South Korea. The New York investor group D. George Harris & Associates, which previously sponsored the buyout of GSLMC, sponsored this buyout and will provide management to the new company, North American Chemical Corp. The managements of the North American Chemical Co. and GSLMC

¹ Includes muriate and sulfate of potash, potassium magnesium sulfate, and some parent salts. Excludes other chemical compounds containing potassium.

are separate and distinct, but there will be some overlap in marketing.

In Michigan, Kalium Chemical Ltd. continued pilot plant development of a deep ore body and the technology to extract potash from that ore body.

Greensand, also known as glauconite, a natural silicate of potassium, aluminum, iron, and magnesium, was produced by Inversand Co., a subsidiary of Hungerford and Terry Inc., near Clayton, NJ. Production and sales information are withheld to avoid disclosing company proprietary data. Processed greensand was sold as a filter media for the removal of manganese, iron, and hydrogen sulfide from drinking water supply systems. Classified raw greensand was resold by Zook and Ranck Inc. as a soil conditioner and as a slowly released potash, with a K₂O equivalent between 5% and 10%, to the organic farmers of North America.

² F.o.b. mine.

Consumption and Uses

Apparent domestic consumption of all forms of potash in 1990 increased 3% compared with that of 1989 if after correction for an error in Bureau of the Census import data. The Bureau of the Census has not issued a correction to the artificially low import figure for 1989.

The year went well for the farmers. There were no significant droughts or floods, nor were there new Government programs to restrict planting or fertilizer application. The production of grains for the year was excellent due to remarkably good weather during June, July, and August. Futures prices for grains dropped during the year.

According to the Potash & Phosphate Institute, the shipments of agricultural potash from Canadian and United States producers declined 4% from 1989 to 1990. The shipments of nonagricultural potash rose 5% for a total (agricultural plus nonagricultural) decline of 3%. The major States receiving agricultural potash from Canadian and United States producers, in decreasing order, were Illinois, Iowa, Ohio, Minnesota, Indiana, Wisconsin, and Missouri. These seven States received 56% of the total. Domestic producers accounted for 12% of the shipments to Illinois, 11% of the shipments to Iowa, 4% of the shipments to Ohio, 2% of the shipments to Minnesota, 15% of the shipments to Indiana, 2% of the shipments to Wisconsin, and 71% of the shipments to Missouri. The major receivers of domestically produced potash, in decreasing order, were Missouri, Texas, California, Illinois, Louisiana, Iowa, Indiana, Arkansas, Kansas, and Florida. These 10 States accounted for 73% of the total. The major consumers of sulfates of potash, in decreasing order, were Florida, Georgia, and California. These three States accounted for 42% of the total.

The major States for shipments of nonagricultural potash from Canadian and United States producers, in decreasing order, were Alabama, Ohio, Mississippi, and Delaware. These four States accounted for 61% of the total. In 1990, approximately 8% of total North American potash shipments were industrial (nonagricultural) potash.

Stocks

Yearend producers' stocks of potash were about 1% lower than that of 1989.

Yearend stocks represented 18% of annual production or 9 weeks of average production.

Prices

The average annual price, \$176.80 f.o.b. mine, of U.S. potash sales of all types and grades, was unchanged from that of 1989. The average price was \$168.64 per ton for the first half of the year and \$185.18 for the second half of the year. The average annual price of the three grades of muriate was \$130.13, down 5% from last year. Standard-grade muriate of potash averaged \$124.75 per ton; coarse grade, \$130.81; and granular grade, \$133.39. The average annual price for all grades of sulfate of potash averaged \$317.30 per ton.

Foreign Trade

Total potash exports as reported by the Bureau of the Census increased 5% by ton K₂O. Muriate of potash exports decreased 10%, while sulfate of potash increased 59%. The major destination for potash exports was to Latin America, which received 52%, by product tonnage. The individual countries were, in decreasing order, Brazil, Mexico, Costa Rica, Colombia, and the Dominican Republic. These five countries accounted for 72% of exports to Latin America. Three countries accounted for 75% of the non-Latin American market: in decreasing order these were Japan, China, and Canada. The U.S. Bureau of Mines determined, using prices, that the exported product in Harmonized Code category 3104.100000 was langbeinite, and these values were placed in the 3104.900000 category of sulfate of potash-magnesia.

Potash imports for consumption as reported by the Bureau of the Census increased 22% by ton product compared to that of 1989. Muriate of potash increased 19%, while sulfate of potash declined 18%. Both Eastern and Western Germany increased their exports to the United States. Canada provided 92% of all muriate of potash imports and 91% of all imports by K₂O. Israel was the second largest source of U.S. imports, with 5% of the muriate of potash imports and 6%, by K₂O content, of the total imports. The U.S. Bureau of Mines determined, using prices, that the imported product in Harmonized Code category 3104.100000 was sylvite, and these values were placed in the 3104.200000

category of muriate of potash.

World Review

World production declined 3% from that of 1989. World prices, as exemplified by the per ton price of standard muriate of potash, f.o.b. Vancouver, Canada, rose from approximately \$162.50 per ton (\$97.50 per short ton of product) level in October to approximately \$170 per ton (\$101 per short ton of product) through the end of the year. On the same basis, granular potash, which usually moves in parallel with the price of standard potash, finished the year at approximately \$183 per ton (\$110 per short ton of product). These prices were reported by the British Sulphur Corp. Ltd. This upward movement in price comes from a concerted effort by the Canadian (and United States) potash producers to restrict production, reduce stocks, and increase profitability.

Brazil.—There are reports that the Tarquari-Vassouras Mine was closed during the year due to the newly elected Government's refusal to further subsidize production.

Canada.—Saskatchewan producers. other than Potash Corp. of Saskatchewan (PCS), operated at an average 80% capacity factor, while PCS operated at an average 40% capacity factor, to keep North American stock levels below 2 million tons. The average capacity factor for the Province was 60%. The proposed sale of the Saskterra Fertilizers Ltd. 40% share of the Allan Mine to the Dead Sea Works was halted due to financial disagreements. This share of the mine was eventually sold to PCS, the operator, who owned the other 60% of the mine. Groupe Entreprise Minière et Chimique (EMC) of France purchased Canamax Resource Inc.'s 51% share in the proposed Russell-Binscarth Mine, which is east of Esterhazy and a few miles across the Provincial border into Manitoba. The remaining 49% of the property is owned by the Provincial Government of Manitoba. It would operate in the rich Esterhazy member of the Elk Point Basin if put into production. With Saskatchewan potash producers operating at only 60% of capacity, an immediate need for new potash capacity does not seem to exist. At midvear, Denison Mines Ltd. put its 60% ownership of Denison-

Source: Bureau of the Census.

Potacan Potash Co. on the market to reduce long-term indebtedness. The leak in the International Minerals & Chemicals (Canada) Ltd.'s Esterhazy K-2 Mine, which began in 1986, has been throttled but not stopped. The company has started to consider sinking another shaft into an unconnected portion of its reserves to start a new mine and maintain operations.

Chile.—AMAX Inc. was reported to be withdrawing from the Minsal Project in the Salar de Atacama.² The Yolanda Project, to be operated by the North Lily Mining Co.³ of California, United States, will mine sodium nitrate and iodine, converting the sodium nitrate to potassium nitrate using imported muriate of potash. It is not clear how far the price of potassium nitrate would fall if more material from new production capacity was to be introduced into the world market.

China.—China has raised its estimate of the reserves at the Qaidam Basin salt flats from 200 million tons to 222 million tons and considers that basin to contain 70% of the country's total of 320 million tons.⁴

European Commission.—The European Commission opened antidumping

investigations following the filing by the European Potash Producers Association of dumping charges against the U.S.S.R.

France.—Groupe Entreprise Minière et Chimique (EMC) became involved in the French chemical reorganization when it was considered for merger, which was later dropped, with Société Nationale Elf Aquitaine under Entreprise de Recherche et d'Activité Pétrolières (ERAP). Another state owned chemical company. Orkem, has been split into two parts with its fertilizer divisions going to EMC and its chemical divisions going to Elf Aquitaine's Atochem in 1995. Entreprise Minière et Chimique's Alsatian Mines will run out of minable ore in the year 2004 (exactly 100 years since discovery). Entreprise Minière et Chimique will have its 50% portion of the New Brunswick, Canada, mine and potentials in both Manitoba, Canada, and the People's Republic of the Congo. Entreprise Minière et Chimique is determined to stay in the fertilizer business even though they will no longer be mining potash in France. However, for the Alsatian Mines, the company started to consider storing hazardous (nonliquid, nonflammable, nonradioactive) waste as a possible use of the depleted mines and as a source of employment for the Mulhouse region.

Germany, Federal Republic of.-Early in the year Kali und Salz closed two mines, Hattorf and Wintershall, for a short period to maintain stocks at reasonable levels. As the reunification with East Germany approached, the concern was about reducing the salt pollution in the Werra River by replacing East German production with West German production and modifying East German technology in other plants. It was felt that 16 million tons of salt per year could be withheld from the Werra and Weser Rivers.

With the simultaneous dissolution of the centrally planned economic operation and combination with the Federal Republic of Germany in the middle of the year, VEB Kalikombinat founded Mitteldeutsche Kali AG and three potash mining companies, Zielitz Kali AG (Zielitz), Kali Werra AG (Ernst Thälman or Merkers, Wilhelm Pieck, Marx-Engels), and Kali Südharz AG (Glückauf or Sondershausen, Volkenroda or Menteroda, Karl Marx or Sollstedt, Heinrich Rau or Rossleben). Volkenroda was Source: Bureau of the Census, as adjusted by the U.S. Bureau of Mines.

closed during 1990. Earlier in the year a conveyer belt was completed between the Wilhelm Pieck Mine and the Ernst Thälman Mine to circumvent the damage of the 1989 collapse in the Ernst Thälman Mine and keep the production at that mine at four-fifths of previous production. Kali Bergbau/Handelsgesellschaft mbH continues to handle sales to long-standing contracts and former Comecon countries. Some potash will be handled through Kali Export Gesellschaft.

Israel.—The concept of privatization was withering on the vine as several Government officials expressed reservations concerning extra-Israel control over the second most important Israeli source of exports. By the end of the

year, the differences in valuation of the 50% share of the company, which would not be controlling in major decisions, put the sale beyond expectations. The tensions in the Gulf of Arabia had little effect on shipments and no effect on production for the year.

Italy.—A drought in Sicily halted Italkali SpA's production of sulfate of potash between July and end of the year due to lack of water for the beneficiation plant.

Japan.—The Co-op Chemical Co. Ltd. commenced construction of its sulfate of potash plant in Niigata-Higasiko. Plant capacity has been put at 10,000 tons per year using imported muriate of potash.

Jordan.—The tensions in the Persian Gulf region had no effect on production and little effect on shipments of potash. The Arab Potash Co. decided to increase its capacity from 1.4 million to 1.8 million tons per year using either the cold-crystallization technology or flotation technology. The new capacity, probably cold-crystallization, is expected to be on-line in 1994.

Korea, North.—The Sariwon Potassic Fertilizer Complex tested its kiln for the first time this year. It is questionable that the energy required to separate potassic feldspar into sulfate of potash, alumina, and cement aggregate will allow a profitable operation considering the world price of potash.

Poland.—Poland reports that it produced 137,000 tons of potassic fertilizer in 1990. Because there is now nitrate of potash being imported into the United States from Poland, this production would appear to be nitrate of potash manufactured from muriate of potash. This muriate of potash could be purchased from either the U.S.S.R. or the Federal Republic of Germany and combined with indigenous nitrogen fixation product.

Spain.—The fertilizer components of Explosivos Rio Tinto, S.A. (ERT) and S.A. Cros combined in 1988 to form Fertilizantes Espanoles, S.A. (FESA). The remaining segments of ERT and S.A. Cros merged to form ERCROS, S.A., which purchased 80% of Empresa

Cardona Mine because of ore depletion. The nearby Vittoria deposit will not be opened due to geologic problems even though the ore grade runs as high as 24% K_2O . ERCROS' Sallent Mine will be expanded from 270,000 to 350,000 tons per year K_2O .

Thailand.—The six member countries of the Association of Southeast Asian Nations (ASEAN) approved a

potash mine and mill as a joint Industrial Project in Thailand. This is the Bamnet Narong Project of the early 1980's, where an incline to the 180-meter-deep ore zone was flooded in 1984.

U.S.S.R.—Free market entrepreneurship has emerged from the U.S.S.R. with "perestroika potash." This refers to potash that is sold by other than Soyuzpromexport, such as various enterprises that were allocated potash for upgrading to complete fertilizers. These enterprises are allowed to sell the potash on the world market rather than use the product internally. The potash mines in the U.S.S.R. are reported to be shifting to profit orientation. To become competitive in the world market, they will need hard currency to upgrade to equipment from hard currency countries, which can only be achieved by selling potash to the hard currency countries. The other side of the coin is that potash consumption in the U.S.S.R. is declining as the farmers have to pay unsubsidized prices for their seed, machinery, fuel, and fertilizers. The farmers may decide to delay fertilizer application until they have money from selling their crops at free market prices. Even then they may choose to invest in machinery instead of fertilizer.

A paper, published in the proceedings of the Ninth Industrial Minerals International Congress (1990) in Sydney, Australia, ⁵ by B. Y. Golovkov, reported that the U.S.S.R. contains 22,600 million tons of K₂O of geological reserves of minable deposits. Eighty-four percent of this is in the Upper Kama (Ural mountain) deposits or 19 billion tons of K₂O. Much of this must be carnallite.

OUTLOOK

Demand for Potash

It is interesting to read that writers are forecasting fertilizer demand growth because of the momentum of population growth around the world. One writer pointed out a world population gain forecast of 1 billion humans, the equivalent of four U.S. populations, is going to be added in the next 10 years; therefore, the world will need more potash. It is not necessarily so. Food, and the fertilizer to grow the food, have to be paid for. The transportation of the foodstuffs from the fields to the new humans has to be paid for. Many of the families with these 1 billion new children will not be able to pay for more food. The growth of potash consumption requires that there is additional money to pay for both the potash and the required transportation costs. Analysis of the consumption patterns of several of the economic regions of the world tend to demonstrate that in some parts of the world, private consumption

² From Bureau of the Census export data. Sulfate of potash and nitrate of potash were landed on the Canadian east coast from European sources.

³ Domestic sales by domestic producers plus imports.

¹ Table includes data available through Apr. 19, 1991.

²Official Government figures. Potash & Phosphate Institute production data are given in table 15.

³ Reported figure.

⁴Data represent officially reported output of potassium nitrate product (gross weight basis) converted assuming 14% K₂O equivalent.

tends to crowd out the consumption of potash. An example of this might be energy imports.

For 1987, the average calories per day consumed in the developed countries of the world is 3,345 calories. The average population growth rate for these countries is 0.6% per year. Their average gross national product (GNP) per capita in U.S. dollars is \$11,350 per capita. The average daily caloric intake for Latin America is 2,560 calories. Its population growth rate is 2\% per year. Its average GNP per capita in U.S. dollars is \$1,910 per capita. The average daily caloric intake for the Sub-Saharan portion of Africa is 2.225 calories, some of which is likely gathered from indigenous plants. Its population growth rate is 3% per year. Its average GNP per capita in U.S. dollars is \$640 per capita (with a median of \$335). Not all countries can achieve or even strive to feed their people in the near future at the same level of caloric intake as the developed countries. It is not predetermined that they will do so in the future. Of course, not all countries have the governmental policies in place to have a large effect on the average daily caloric intake of its population. Further, it seems clear that large population growth, at present, is joined to a low average daily caloric intake. Generally, population growth indicators such as "crude birth rate" and "total fertility rate" showed neither positive nor negative significance.

An assortment of macroeconomic and other variables published by the World Bank for a single year (1987) were investigated that might describe the financial health, investment attitudes, and a few sociological indicators for many of the countries for their predictive relationship to potash consumption. The world was divided into economic groups following the lead of the World Bank: the Developed Countries, the Sub-Saharan African Developing Countries, Latin America and Caribbean, Asian, etc. Parallel to this data, the United Nations Food and Agricultural Organization (FAO) provides potash consumption by country and by kilograms per hectare of (a) agricultural land, (b) arable land and permanent crops, and (c) per capita for approximately all countries of the world.

The Developed Countries.—The developed countries respond to a pair of

factors and to one of these in a surprising manner. The economic system of the developed countries makes a clear calculation of the food demand per person, the food producible per area, and the potash needed to grow that amount of food per area. For the developed countries, the two variables were "arable hectares per capita," which would describe the amount of land available for grains, vegetables, oils, and fibers, and "agricultural hectares per capita," which would includes arable hectares plus the hectares for tree crops and grazing lands. These countries have a high enough GNP per capita to fertilize their grazing lands and tree crops. Curiously, the "agricultural hectares per capita" is negatively correlated to the total potash per hectare. The R² of this regression is 0.838. which means that the two variables explain about 90% (the approximate square root of 0.838) of the variation within the countries in the grouping. For predictive purposes, the excess production of food (for exports and stocks) in both North America and Western Europe, the declining potash consumption in the United States (since 1980), plus the slow or zero growth in potash consumption in Western Europe would indicate zero or declining potash consumption growth in this group of countries. The average population growth rate for the developed countries was 0.5% per year between 1980 and 1988. The average daily caloric intake for the developed countries is 3.345 calories. This grouping of countries consumed about 44% of the world's total potash production for 1990.

For the reader's information, Andorra, Faeroe Islands, Gibraltar, Vatican City, Liechtenstein, Malta, Monaco, and San Marino were not used in the analysis. Israel, Japan, and the Republic of South Africa were in the grouping.

Latin America and Caribbean.—Latin America responds to four of the variables that were tested by regression. They responded positively only to "gross domestic investment: contribution to gross domestic product" in percentage. This could mean that countries that are making investments for growth are also sophisticated enough to make investments in potash.

This region responded negatively to

the ratio of "arable hectares per capita." The countries with large arable hectares per capita apparently do not fertilize the soil as much as the countries with fewer hectares per capita. It must be that the large countries are still cropping the natural fertility of the land, while the small countries and islands must fertilize. This region also responds negatively to "private consumption: contribution to gross domestic product." This may mean that private consumption crowds out some of the investment, including fertilizers. Finally, this region responds negatively to the "crude birth rate," which is simply the number of births per year divided by the total population. This is certainly counterindicative of potash growth because of population growth. The R² was 0.386, meaning that the four variables explained only about 60% of the variation. The average daily caloric intake per capita was 2,563 calories. The average population growth was about 2% per year. This region received about 8% of the world's potash production for 1990.

The African Sub-Saharan.—The World Bank divided Africa into two groups, the Sub-Saharan, which was grouped together, and the Mediterranean Africa, which was grouped with the Near East. Both "K2Oarable" (kilograms of K₂O per arable hectare) and "K2Oagric" (kilograms of K2O per agricultural hectare) were investigated but only "K2Oarable" was chosen for analysis because it was not believed that this part of the world has GNP per capita to fertilize the orchards and the meadows. Even for the countries that were available, the data were incomplete. It was found that when significance was investigated using stepwise forward or backward variable choice, a reduced number of "degrees-of-freedom" occurred because some countries were dropped out of the regression for not having data in all the variables. Dropping these countries would result in a medium (0.3 to 0.5) level of R². When the data were subjected to multiple regressions with the few variables that showed relationships with the dependant variable, a different, lower value of R² would be obtained. This was because the simpler regressions were on data that were complete for all countries. Then the R2's were lower or zero,

from which it was concluded that the 10 additional, poorer countries did not have any pattern, within the variables that were studied, of choosing how much potash they used per hectare. It would appear that the countries of Africa that do not have the wealth to compute and answer all the questions that are asked by the World Bank do not have a pattern of response within the variables that were searched. The more advanced countries in this group (27 out of 37 countries) responded negatively to "private consumption as a percentage of gross domestic product" and negatively to "agricultural area per capita" with an $R^2 = 0.296$. For all 37 countries in the group, the response to only "private consumption as a percentage of gross domestic product" was significant and that was only $R^2 = 0.10$. "Agricultural area per capita" added very little significance. For 36 of the 37 countries, "population growth rate" (a positive relationship) and "private consumption as a percentage of gross domestic product" (a negative relationship) combined for a $R^2 = 0.16$. It seems clear that in this relatively poor area there will be some separation of the countries with higher GNP per capita from the countries with lower GNP per capita. The countries with higher GNP per capita will move toward more potash consumption, while the countries with lower GNP per capita will vary around some low level of potash consumption in a random fashion. This area consumed about onehalf of 1% of the world total potash produced for 1990.

South Asia, East Asia, and Pacific.—This region responds positively to GNP per capita (or gross national product per capita) and negatively to population growth. There is a weaker, negative correlation to "average daily calories per capita." These three variables have an $R^2 = 0.83$, which means that these three variables explain about 90% of the variation between the countries. It would appear that this region will be a growth area for the consumption of potash because the region contains the "Four Tigers" of the Pacific, and other countries will attempt to emulate them as a paradigm of movement to healthy nationhood. The problem for some of the countries will be to contain their population growth. This

region of the world consumed about 13% of the total potash production in 1990.

Conclusions

This is a cursory report of the study because there was not enough time to study "Rest of Europe and Mediterranean," and "Middle East and North Africa." The Middle East and North Africa is not an important potash consuming area at this time (0.4%) but will grow at a rate above the world norm. The "Rest of Europe and Mediterranean" are the European countries that are not in-

cluded in the "developed countries." These are the former centrally planned economies who will probably decrease their consumption for 10 years. For the forecasts in figure 1, data from the International Fertilizer Industry Association (IFA) concerning production and imports for the past 3 years was used where it was available. When IFA data were not available, FAO data were used, and 1986–87 consumption data went into the 1987 column and 1987–88 went into the 1988 column.

From the analysis of most of the countries' macroeconomic data and

FIGURE 1
FORECAST OF WORLD POTASH CONSUMPTION

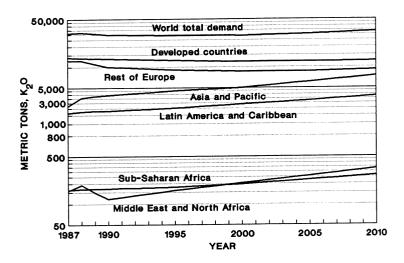

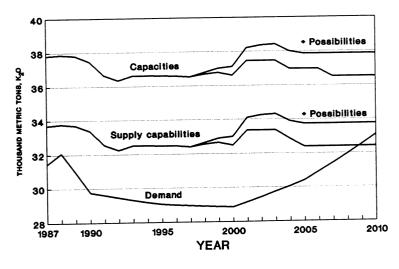

FIGURE 2
FORECAST OF WORLD SUPPLY-DEMAND

potash consumption, and from rudimentary economic analysis, the forecast in figure 2 shows declining or level potash consumption for the world for approximately 10 years. After the year 2000, one might foresee an increase that will be above 1988 levels by the year 2010. Several factors point toward level or declining consumption of potash in the midterm. First, there is the history of declining potash consumption in the United States for several reasons. Second, there is the likelihood of western Europe (European and United Kingdom demand for fertilizers was forecast to fall between 10% to 20% during the 1990's;...⁶) slowly dropping its subsidies to the farmers. These factors point to declining potash consumption in the largest consuming group of countries in this study. The former Comecon countries will toil through their conversion to capitalism, or modified capitalism, with much time and money devoted to creating new institutions. The former Comecon countries will consume less potash for 5 to 10 years as they modify their thinking from subsidized potash consumption under central planning to individual farmers computing their marginal investment in potash for the marginal profit.

The possible new capacities that might start production after the year

2000 are in Brazil, Egypt, Israel, and Saudi Arabia. Israel and Saudi Arabia have or can hire the technical expertise to develop underground resources in their countries that are now being investigated. Egypt, if the resource turns out to be minable, will be able to borrow the money to initiate the project, and it will pursue the project with interest. All three locations are close to water for shipping anywhere in the world. The potash resources in Manaus, Brazil, will be near water deep enough for barging to deepwater ports. but are likely to be consumed within Brazil if either of the two resources are economically viable. It is not clear what the U.S.S.R. will do with the new resources that it has identified. This country will be busy with other problems for many years.

PUMICE AND PUMICITE

By Wallace P. Bolen

Mr. Bolen, a physical scientist, is a graduate of the University of Virginia and has been the acting commodity specialist for pumice since September 1989. Domestic survey data were prepared by Blanche S. Hughes, mineral data assistant; and the international production table was prepared by Audrey Wilkes, international data coordinator.

omestic production of pumice and pumicite sold or used increased about 4% compared with that of 1989. Apparent consumption decreased about 1%. Greece was the principal source of pumice imports, with 82% of total imports compared with 71% in 1989.

DOMESTIC DATA COVERAGE

Domestic production data for pumice and pumicite were developed by the U.S. Bureau of Mines from one voluntary survey of U.S. operations. All 16 operations that received a survey form responded. Thirteen active operations contributed 100% of the quantity and value of pumice and pumicite sold and used as shown in table 1.

PRODUCTION

Production of pumice and pumicite sold or used increased to 443,000 metric tons with a value of \$10.7 million. The States of Oregon, California, New Mexico, Arizona, and Idaho, in order of decreasing production, accounted for approximately all of the pumice sold or used in the United States.

Principal domestic producers were Arizona Tuff Lite, Flagstaff, AZ; Glass Mountain Pumice Inc., Tulelake, CA; Hess Pumice Products, Malad City, ID; Producers Pumice, Meridan, ID; Copar Pumice Co. Inc., Santa Fe, NM; General Pumice Corp., Santa Fe, NM; Cascade Pumice Co., Bend, OR; and Central Oregon Pumice Co., Bend, OR. These eight companies accounted for 97% of U.S. pumice and pumicite production.

CONSUMPTION AND USES

The most important market for pumice was building block, consuming 66% of the total. Pumice consumed by textile laundries accounted for 14% of the total sold or used in 1990. A "laundries" category is listed for the first time in this publication in table 3. Landscaping uses of pumice increased

50% compared with that of 1989. Other and unspecified uses of pumice and pumicite increased to more than 61,000 tons.

QUARTZ CRYSTAL

By Joyce A. Ober

Mrs. Ober, a physical scientist with 13 years industry and U.S. Bureau of Mines experience, has been the commodity specialist for quartz crystal since 1986. Domestic survey data were prepared by Maureen Nash Riley, mineral data assistant.

ultured quartz crystal production and consumption decreased slightly in 1990 after 3 years of growth. Consumption of domestic lascas as feedstock for cultured quartz crystal decreased also. The single domestic producer of lascas, the raw material from which cultured quartz crystal is produced, operated its mine to supply material to domestic consumers. Demand for specimen-quality natural quartz continued; quartz crystal for this application is discussed in the Gem Stones chapter.

Electronic-grade quartz crystal is single-crystal silica that is free from all visible defects and has piezoelectric properties that permit its use in electronic circuits for accurate frequency control, timing, and filtration. These uses generate about all the demand for electronic-grade quartz crystal. A smaller amount of optical-grade quartz crystal is used as windows and lenses in specialized devices, including some lasers.

More natural quartz crystal was consumed in electronic and optical applications until 1971, when cultured quartz crystal took the lead. Since that time, cultured (synthetic) quartz has replaced practically all natural crystal in these applications. In 1990, synthetic quartz crystal producers consumed about 527,000 kilograms of lascas in their production, and less than 400 kilograms of natural quartz crystal found application in electronic devices.

DOMESTIC DATA COVERAGE

The U.S. Bureau of Mines collected domestic production and consumption data for quartz crystal through a voluntary survey of U.S. operations. Six companies responded to the canvass for the production of cultured quartz crystal, and

the five active operations represented 100% of total production shown in table 1. Of the 34 operations canvassed concerning consumption of quartz crystal, 32 responded, 7 of which did not consume quartz crystal in 1990. These companies represented approximately 100% of total consumption, also shown in table 1. Consumption for the nonrespondents was estimated using reported prior-year consumption levels.

ANNUAL REVIEW

Legislation and Government Programs

The National Defense Stockpile contained about 686,000 kilograms of natural quartz crystal, valued at about \$9 million at yearend. This quantity represented an excess of about 577,000 kilograms above the goal set for the stockpile.

⁴Less than 1/2 unit.

During the year, quartz crystal stockpile sales amounted to about 172,000 kilograms at about \$444,000. About one-quarter of the disposals was to support the stockpile ferroalloys upgrading project. The excess stockpile material, which primarily consists of large natural crystals, could be absorbed by the specimen and gem material industry. Very little, if any, of the material would be consumed in the same applications as synthetic quartz crystal.

Strategic Considerations

Natural electronic-grade quartz crystal was initially designated as a strategic and critical material after World War II. Cultured quartz crystal was not commercially available at the time of U.S. stockpile acquisition. With the changing patterns of quartz consumption, the Federal Emergency Management Agency asked the National Materials Advisory Board to assess the requirements and related trends for stockpiling quartz. The final report was published in early 1985 and recommended changes in stockpile goals to reflect the declining dependence on natural quartz crystal. The President has set the quartz crystal goal for the stockpile at 110,000 kilograms.

The National Defense Stockpile contains natural quartz in several weight classes and grades, including about 13,000 kilograms of material consisting of individual crystals weighing more than 10,000 grams each. Some of the individual quartz pieces in this weight class are suitable for generating mother seeds for cultured quartz crystal production. These large pieces were acquired from Brazil because similar materials were not available domestically.²

Production

Coleman Quartz Inc., Jessieville, AR, the only domestic company known to produce lascas, supplied the feed material for cultured quartz crystal from mine production. Production in 1990 was about 7% lower than that in 1989. Coleman mined only during the summer months, but processed lascas year round. Lascas was mined, crushed, and sized. Crushed and sized material was transported to the processing plant where operators rinsed it in oxalic acid and then in deionized water to remove external contaminants. Hand sorting, drying, and examination on a light table completed the

necessary processing. The material was then shipped to cultured quartz crystal producers in 45-kilogram (100-pound) bags.

Production of cultured quartz crystal decreased almost 5% in 1990. Five companies were active. The two largest producers. Sawver Research Products Inc. of Eastlake, OH, and Thermo Dvnamics Corp. of Merriam, KS, were independent growers that produced crystal bars for domestic and foreign consumers in the crystal device fabrication industry. Motorola Inc. of Chicago, IL, produced quartz crystal for both internal consumption and the domestic device fabrication industry. P. R. Hoffman Material Processing Co. of Carlisle, PA, also reported outside sales. Bliley Electric Co. of Erie, PA, produced only for internal consumption. Electro Dynamics Corp. of Overland Park, KS, formerly a producer, sold the quartz-crystal-growing portion of its operation to Thermo Dynamics in February 1989. Electro Dynamics continued to process synthetic quartz crystal.

These companies produced cultured quartz crystal using a hydrothermal process in large pressure vessels, known as autoclaves. Seed crystals, very thin crystals cut to exact dimensions, were mounted on racks and suspended in the upper growth region of the vessel. Lascas was loaded in an open-mesh wire basket that was placed in the bottom of the autoclave.

A solution of sodium hydroxide or sodium carbonate (the mineralizer), with additives such as lithium salts, and deionized or distilled water was used to fill the vessel to 75% to 85% of its volume. The bottom half of the growing vessel was heated to temperatures averaging between 350° to 400° C; the temperature of the top portion is maintained at 10° to 50° C less. At these temperatures, the solution expands and creates an internal pressure in the vessel of between 10,000 pounds per square inch and 30,000 pounds per square inch. Under these conditions, the lascas dissolves to create a solution saturated with silica.

Through convection, the saturated solution transports dissolved silica to the cooler upper half of the vessel where it becomes supersaturated, and the excess dissolved quartz deposits on the seed crystals in the top half of the autoclave. The process continues until the growing crystals reach desired size. The process may take 30 to 60 days and sometimes even longer.

The processing of quartz crystals for various end uses is the same whether natural or cultured crystal is used. Crystals are examined for physical defects before cutting. They are then cut, usually with diamond or slurry saws, along a predetermined crystallographic plane to a thickness slightly larger than that desired. Each wafer is inspected and diced into blanks of the desired dimensions. The blanks then progress through a series of lapping stages until they reach the final thickness; electrodes are attached, and the crystals are mounted in suitable holders. The final assembly, called a quartz crystal unit, is ready for insertion into an electronic circuit.

Consumption and Uses

Consumption of lascas by the five domestic quartz crystal producers decreased about 8%, from 572,000 kilograms in 1989 to 527,000 kilograms in 1990. The 25 active device-fabricating companies in 9 States consumed 8% less quartz crystal in 1990 than in 1989. Of these companies, 24 consumed only cultured quartz crystal. One company consumed only natural quartz crystal.

Lascas and quartz crystal were used in piezoelectric, optical, and glass industries. The piezoelectric effect is achieved when a suitable electrical signal is applied to a quartz wafer or blank with appropriate electroding, which causes the wafer to vibrate mechanically throughout the bulk of the material at a characteristic natural resonance frequency. The quartz resonators are uniquely suitable for military-aerospace and commercial bandpass filter applications that require very high selectivity or in oscillator applications that require very high stability. In addition, for many applications requiring only moderate stability, a quartz resonator offers a unique combination of high performance, small size, and low cost. Quartz resonators were used for many less demanding applications such as providing timing signals for watches, clocks, and microprocessors in a variety of industrial, automotive, and consumer products.

The quartz wafer becomes too thin for practical use for very high frequencies (above 100 megahertz). Quartz crystal structures that use surface vibrations, in which the frequency is determined by electrode dimensions rather than wafer thickness, have become more important at these high frequencies. These structures

are called surface acoustical wave (SAW) devices. Most optical applications used quartz in the fused form as silica glass. Relatively small quantities of cultured quartz crystal were used directly for special optical considerations. Quartz's crystal properties are responsible for its uses that deal with normally polarized laser beams. Quartz retardation plates (especially quartz wave plates), Brewster windows and prisms, birefringent filters, and tuning elements are used in laser optics.

Historically, quartz crystal has been a material of strategic importance. During World War II, quartz was used principally in analog communications (e.g., in telephone multiplexing and in mobile military radios). Today, because of military emphasis on command, control, communications, surveillance, and the growth of more sophisticated electronic systems, the importance of quartz crystal devices has grown. Many of the military applications are at the leading edge of technology. It has been U.S. Department of Defense policy to require all military systems to be hardened to nuclear radiation. To meet this special requirement, cultured quartz crystal must be radiation hardened by sweeping, a technique to remove certain impurities from the quartz.

Cultured quartz was used almost exclusively by the crystal device industry because of cost advantages. For resonator applications, raw quartz must be cut into thin wafers oriented precisely with the raw material crystal axes. The uniformity and convenience of cultured quartz have made its use almost universal. Unlike cultured quartz, natural electronicgrade quartz requires special orientation, cutting, grading, and sizing to produce a quartz wafer. As a result, most device manufacturers that cut natural quartz in the past have discontinued its use. One of the remaining uses of natural electronic-grade material was in pressure transducers used in deep wells.

Stocks

Crystal growers' stocks of as-grown cultured quartz crystal were reported as 76,000 kilograms at the beginning of 1990. At yearend, these stocks had increased to 97,000 kilograms.

Prices

The average value of as-grown cultured quartz, based on reported sales of about 324,000 kilograms, was \$28.35 per kilogram (\$12.86 per pound), a decrease of about 8% compared with that of 1990. Sales volume decreased about 5%. The average value of lumbered quartz, asgrown quartz that has been processed by sawing and grinding, decreased 24% to \$107.48 per kilogram (\$48.75 per pound), based on reported sales of 33,000 kilograms. Sales volume decreased 16%.

Foreign Trade

The Bureau of the Census began using the Harmonized Tariff Schedule in 1989 to identify material passing through U.S. customs. This system makes classification codes for imports and exports consistent internationally. With the adoption of the new codes, imports and export codes for quartz crystal changed, and some formerly listed details are no longer available. The import code for Brazilian crude pebble, which represented approximately all lascas imports recorded, was eliminated. Although this material probably continued to enter the United States. the new code system aggregated several categories, making information about specific materials unavailable. The export data for natural electronic-grade quartz crystal were no longer available.

Because of these changes, foreign trade information for quartz crystal is limited. While information remained concerning exports of synthetic quartz crystal, Census figures indicate a continuing downward trend for quartz crystal exports. Reports by domestic producers indicated that these data may not be accurate. Reports indicated that exports were higher than those reported by the Census Bureau.

World Review

Synthetic quartz crystal production is concentrated in the United States and Japan, with several companies producing crystal in each country. Smaller production capacity exists in Belgium, Brazil, Bulgaria, France, Germany, the Republic of South Africa, and the United Kingdom. Details concerning quartz

operations in China, the U.S.S.R., and other Eastern European countries are unavailable.

Alfa Quartz C.A., a joint venture between Bulgarian and Venezuelan companies, was building a cultured quartz crystal plant near Caracas, Venezuela. On completion, the operation should have the capability of producing 36,000 kilograms of quartz crystal per year from 16 autoclaves. Sales are expected to be lumbered bars and blanks. Domestic lascas deposits will provide feed material.

OUTLOOK

Domestic production of cultured quartz crystal has grown or remained relatively stable since 1986. The slightly decreased production in 1990 is not expected to represent the beginning of a downward trend. Demand for crystal devices for electronic consumer products and microprocessor-controlled devices should continue to grow, and quartz crystal production should remain strong well into the future. Because crystal devices continued to be used in an increasing variety of applications from kitchen appliances to military hardware in addition to the traditional items such as watches. demand should continue to increase, and additional production capacity may be required worldwide.

RARE EARTHS

The Lanthanides, Yttrium, and Scandium

By James B. Hedrick

Mr. Hedrick is a physical scientist in the Branch of Industrial Minerals. He has been the commodity specialist for rare earths since 1981. Domestic survey data were prepared by Kevin Bacon, mineral data technician. International data were prepared by Harold Willis, international data coordinator.

nternational competition dominated the global rare-earth market in 1990, continuing the trend of 1989. The United States was the world's principal producer of rare earths with mine production reaching its second highest level of alltime. Overall performance of the domestic industry was slightly higher than that in 1989, with significant growth only in the permanent magnet sector. Traditional major rare-earth markets, petroleum cracking catalysts and metallurgical applications, decreased from those of the previous year.

Average performance was seen in emerging applications. Demand increased slightly for erbium used in optical fibers and for cerium as a component in ultraviolet-absorbing glass and automotive catalytic converters. Demand for rare earths used in optical storage disks and in rechargeable batteries was expected to show strong growth in the future.

A probe that monitors liquid nitrogen levels in human tissue refrigeration units was announced as the first commercial application for yttrium-bearing high-temperature superconductors. Although demand for rare earths used in high-temperature superconductors was very small, scientific advances continued to increase the potential for significant long-term growth.

DOMESTIC DATA COVERAGE

Domestic mine production data for rare earths are developed by the U.S. Bureau of Mines from the voluntary survey, "Rare Earths, Thorium, and Scandium." The two mines to which a survey form was sent responded, representing 100% of known production. Production data were withheld to avoid disclosing company proprietary data.

BACKGROUND

Definitions, Grades, and Specifications

The rare earths are a group of 17 elements comprised of scandium, yttrium, and the lanthanides. Rare earths are classified chemically as members of the third subgroup of the periodic table.

Scandium, atomic number 21, is the lightest rare-earth element. It is the 31st most abundant element in the Earth's crust with an average crustal abundance of 22 parts per million. Although its occurrence in crustal rocks is greater than lead, mercury, and the precious metals, scandium rarely occurs in concentrated quantities because it does not combine easily with the common ore-forming anions.

TABLE 1

SALIENT U.S. RARE-EARTH STATISTICS

(Metric tons of rare-earth oxides (REO) unless otherwise specified)

¹Comprises only the rare earths derived from bastnasite, as reported in Unocal Corp. annual reports.

²Because of the implementation of the Harmonized Tariff System in Jan. 1989, import and export categories for 1989 and 1990 are not necessarily comparable with those of previous years.

³Because of the implementation of the Harmonized Tariff System in Jan. 1989, data are no longer available for this export category.

Employment at a rare-earth mine in California and at a mineral sands operation in Florida. The latter mine produced monazite concentrate as a byproduct of mining ilmenite, rutile, and zircon, and employees were not assigned to specific commodities.

⁵ Imports minus exports plus adjustments for Government and industry stock changes.

Yttrium, atomic number 39, is chemically similar to the lanthanides and often occurs in the same minerals. Yttrium's average concentration in the Earth's crust is 33 parts per million and is the second most abundant rare earth in the Earth's crust.

The lanthanides comprise a group of 15 elements with atomic numbers 57 through 71, and include the following: lanthanum, cerium, praseodymium, neodymium promethium, samarium, europium, gadolinium, terbium, dysprosium, holmium, erbium, thulium, ytterbium, and lutetium. Cerium, the most abundant of the group at 60 parts per million, is more abundant than copper. Thulium, the least abundant of the lanthanides at 0.48 parts per million, occurs in the Earth's crust in higher concentrations than thallium, antimony, cadmium, and bismuth.

Due largely to differing ionic radii, the rare-earth elements are broadly classified into two groups: the light or cerium subgroup, comprised of the first seven lanthanides (atomic numbers 57 through 63), and the heavy or yttrium subgroup, comprised of the remaining lanthanides and yttrium (atomic numbers 64 through 71, and 39). Yttrium is classed with the heavy subgroup because of its occurrence, ionic radius, and other similar properties.

Bastnasite can theoretically contain 74.81% rare-earth oxide (REO). Flotation concentrates of bastnasite average 60% REO, which can be upgraded to 70% REO by acid leaching, and to 85% REO by a combination of acid leaching and calcining.

Monazite can theoretically contain 69.73% REO. Monazite concentrate is usually sold at 55% minimum REO contained plus thorium, with most product grading 59% to 65% REO. Thorium contents are variable, but typically occur in the range of 4% to 10% equivalent thorium oxide. Monazite, with a low thorium content, commands a premium price.

Xenotime can theoretically contain 61.40% yttrium oxide. However, xenotime concentrates from southeast Asia and Australia typically contain 25% to 30% yttrium oxide. Xenotime is often upgraded by acid leaching to produce an yttrium concentrate grading 60% yttrium oxide and the balance primarily other rare earths.

Various metallic rare-earth materials are produced. The term "mischmetal" is used to denote a mixture of rare-earth elements in metallic form. It generally has the same ratio of rare-earth elements as that found in the ore and is typically 98% to 99% pure. Recently, a higher purity "battery-grade"

mischmetal was produced to supply the market for rechargeable rare-earth-nickel hydride batteries.

Ferrocerium is a pyrophoric alloy of mischmetal and iron. A typical ferrocerium alloy contains 74% mischmetal, 23% iron, 2% copper, and 1% magnesium. Rare-earth silicide is an alloy containing about one-third mischmetal, one-third iron, and one-third silicon. The rare-earth content of master alloys range from tenths of a percent in nodularizing alloys for ductile iron to 10% or more in inoculants for gray cast iron. Alloys containing about 100% rare-earth metals, such as mischmetal, are additives to certain steels.

The purity of separated rare-earth elements, produced primarily by solvent extraction or ion exchange, usually grade 96% or higher in purity. High-purity rare-earth compounds and metals are produced up to 99.999% purity. Rare-earth products grading higher than 99.9% purity are often produced to specification. As a result of the wide range of products in which rare earths are consumed, many grades of rare-earth concentrates, compounds, alloys, and metals are produced. Analyses of the rare-earth contents of selected ores are shown in table 2.

Products for Trade and Industry

Products for trade and industry are varied and include concentrates, individual and mixed compounds, and individual and mixed metals.

Bastnasite concentrate, marketed by Molycorp, Inc., is available in three grades—an unleached concentrate grading 60% REO, an acid-leached concentrate containing 70% REO, and a calcined concentrate upgraded to 85% REO.

A mixed bastnasite-monazite concentrate (predominantly bastnasite) from China, is produced in three grades—a 30% minimum REO, a 60% minimum REO, and a 71% minimum REO.

Mixed compounds derived from bastnasite include rare-earth chloride, rare-earth nitrate, lanthanum-rare-earth carbonate, lanthanum carbonate, cerium carbonate, cerium nitrate, cerium fluoride, neodymium carbonate, neodymium fluoride, praseodymium fluoride, cerium-rare-earth hydrate, and rare-earth hydrate.

Monazite is marketed by processors and trading firms as a concentrate containing 55% to 60% minimum REO plus contained thorium. Mixed compounds from monazite produced by companies such as Rhône-

Poulenc Basic Chemical Co. or the Davison Div. of W.R. Grace include cerium chloride, ceric ammonium nitrate, ceric sulfate, cerium carbonate, cerium hydroxide, cerium nitrate, cerium octoate, rare-earth carbonate, lanthanum carbonate, lanthanum-neodymium carbonate, lanthanum-neodymium carbonate, neodymium carbonate, neodymium nitrate, praseodymium oxalate, rare-earth octoate, and yttrium nitrate.

Xenotime concentrate, with a minimum 25% yttrium oxide content, is a major source of yttrium. It is usually upgraded chemically to a 60% yttrium oxide product known as yttrium concentrate, the balance of the concentrate being mostly other rare earths.

Rare-earth ion adsorption ore is produced in southern China. It is also a major source of yttrium. The ore varies by locality, but two principal concentrates, an yttrium concentrate and a europium concentrate, are produced. The yttrium concentrate is enriched in the heavy rare earths and contains more than 60% yttrium oxide. Although the europium concentrate grades from 0.5% to about 1% europium oxide and 12% yttrium oxide, it is predominantly enriched in lanthanum oxide, 33% to 43%. Both ion adsorption concentrates are low in cerium oxide, typically less than 2%.

Individual rare-earth oxides and other compounds, except promethium, are produced from bastnasite, monazite, xenotime, and ion adsorption ore. Purities from 96% up to 99.999% are available for most oxides. Compounds for almost all of the rare earths are available as oxides, acetates, carbonates, chlorides, fluorides, nitrates, oxalates, and sulfates.

High-purity rare-earth metals are marketed in the form of sponge, lump, ingot, rod, wire, chips, powder, sheet, foil, plates, sputtering plates, and custom cast and machined shapes. Alloys such as mischmetal, rare-earth silicide, ferrocerium, and other rare-earth alloys are available in a variety of ingot shapes and sizes.

Rare-earth magnet alloys are produced in a variety of compositions to meet individual requirements. Magnet alloys are marketed in ingot form, crushed ribbon, or may be purchased as mixed oxides for powder metallurgical processes. Magnets are available in finished and semifinished shapes, bonded and unbonded, magnetized and unmagnetized, and either coated or uncoated.

Scandium concentrate was previously produced as a byproduct during uranium extraction and from tailings from a previously operated fluorite operation. Scandium

is marketed primarily as a high-purity oxide from Boulder Scientific Co. and Sausville Chemical Co. Oxide purities from 98% to 99.995% are produced in the United States. In addition to the oxide, scandium compounds are available as the acetate, bromide, carbonate, chloride, fluoride, hydride, iodide, nitrate, oxalate, acetylacetonate, and sulfate. Scandium metal is produced in powder, lump, and foil form, as listed by the Johnson Matthey Aesar group.

Industry Structure

Rare-earth ore minerals are sold by producers directly to processors, consumers, and commodity brokers, usually as a concentrate. Of the three principal ore minerals, bastnasite, monazite, and xenotime, only bastnasite concentrate may be used in certain industrial applications with little or no processing. Most rare-earth concentrates undergo extensive processing to produce mixed or separated compounds and metals. Few companies in the rare-earth industry are fully integrated. Most rare-earth mining companies sell their concentrates to processors that separate the rare earths by chemical processing, primarily solvent extraction (SX) and, to a lesser extent, ion exchange (IX).

Geology-Resources

Rare-earth minerals occur in a variety of geologic environments. Concentrations exist in igneous, sedimentary, and metamorphic rocks. The rare earths are mined primarily from igneous-metamorphic and sedimentary deposits.

The rare earths are constituents in more than 100 minerals, but only a few are recovered for economic gain. Bastnasite, monazite, xenotime, and rare-earth-bearing clay are the principal sources of the world's rare-earth supply. Other sources include the minerals loparite, rare-earth-bearing apatite, yttrium-rich synchysite (doverite), and byproduct solutions from processing uranium, which contain rare-earth enriched uraninite and brannerite. Future production may include rare earths recovered from the minerals gadolinite, dickgarrenite (proposed name of new mineral), and eudialyte.

Bastnasite.—Bastnasite is found in vein deposits, contact metamorphic zones, pegmatites, and carbonatites. In the two principal deposits where bastnasite is mined, Mountain Pass, CA, in the United

States and Bayan Obo, Nei Monggol Autonomous Region, in China, bastnasite occurs in rare-earth-enriched carbonatite rock. Carbonatites are an unusual type of carbonate-silicate rock found almost exclusively in areas of alkalic igneous rock.² Formation of carbonatites is believed to occur by several processes. Most carbonatites are believed to have been formed by the introduction of carbonate-rich hydrothermal solutions, but a carbonate-rich lava flow was observed following the 1960 eruption of a volcano in Africa.³

United States.—In the United States, the Mountain Pass Mine bastnasite is recovered from the Sulphide Oueen carbonatite. The ore body is a north-striking sill that dips 40° W. The original carbonatite surface exposure was 760 meters in length with a maximum width of 210 meters. The sill pinches out to the north where it narrows to less than 30 meters. The steeply dipping southern contact strikes northeast. The ore body averages 60 meters thick, although it narrows to less than 30 meters on the north end. The thickness in the area of active mining is about 60 meters. The intrusive complex and surrounding alkaline rocks are pre-Cambrian, dated at 1.4 billion years old. From oldest to youngest, the mineralogical sequence of intrusion was shonkinite, syenite, granite, shonkinitic dikes, carbonates, and andesitic dikes.4 Emplacement of the rare-earth-bearing carbonatite took place in at least 13 recognized pulses. The two main groups of carbonatites are older barite sovites (calcite-rich carbonates) and younger barite dolomitic sovites and barite beforsites (dolomite-rich carbonates). The older sovites occupy the northern up-dip part of the sill and the younger dolomitic carbonates are located down-dip.

All of the carbonatite units contain oregrade concentrations of rare-earth minerals. Reserves are 24 million tons at an average grade of 8.8% rare-earth oxide. Bastnasite, however, is the only ore material recovered. Other rare-earth minerals in the carbonatite are parisite, monazite, synchysite, sahamalite, and allanite.⁵

China.—In China, the Bayan Obo Mine bastnasite is recovered from the Bayan Obo Group carbonatite. The primary ore is iron minerals, with the rare-earth minerals, bastnasite and monazite, produced as byproducts. Niobium is also recovered as a byproduct. The Bayan Obo ore bodies are in a syncline that extends 18 kilometers along its axis and varies in width from 1 to

3 kilometers. Within the syncline are 2 large ore deposits, the Main and East ore bodies, and 16 medium ore bodies comprising the West mine.⁶ Rare-earth minerals occur predominantly in the Main and East ore bodies at a grade of 6.19% and 5.71% REO, respectively. Overall reserves of the ore deposit are reported at 1.5 billion tons of ore (Main, East, and West mine ore bodies) grading 35% iron; rare-earth minerals in the 800 million tons of ore in the Main and East ore bodies contain an estimated 48 million tons of REO.⁷

Formation of the Bayan Obo deposit is related to a rift margin on the North China plate, estimated to have separated between 1.85 and 1.7 billion years ago.8 As a rift basin formed, deep faulting occurred associated with deposition of the Bayan Obo Group sediments. The sequence of formation of the Bayan Obo Group, from oldest to youngest, was coarse sandstone and basal conglomerate, orthoquartzite, shale, quartzite, shale, arkosic sandstone, carbonates (dolomite in the ore-bearing syncline), shale, an unconformity, gray limestone, and a white and gray limestone. Emplacement of the Bayan Obo carbonatite is reported to have formed after deposition of the Bayan Obo Group by hydrothermal replacement of the dolomite unit.9 The thick shale unit overlying the dolomite appears to have acted as a seal that trapped the rareearth-enriched hydrothermal solutions. The origin of these solutions is possibly the upper mantle or lower crust, sourced through the syndepositional aults along the rift. Sedimentological and paleontological evidence indicates a sedimentary origin of the dolomite and other carbonate rocks. The bastnasite ore occurs in a tan dolomite in association with thin shale beds and scattered quartzite beds.

The age of the Bayan Obo Group, based on fossil evidence, is Middle Proterozoic (1.4 billion years ago). Interestingly, the age of the Bayan Obo Group coincides with emplacement of the Sulphide Queen carbonatite in the United States.

Monazite and Xenotime.—Monazite and xenotime originate as primary accessory minerals in many crustal rocks. Monazite occurs as an accessory mineral in granites, syenites, gneisses, schists, migmatites, quartz veins, and pegmatites. Xenotime, which is mineralogically similar to monazite, occurs in the same rock types as monazite. Placer deposits are the major source of these minerals.

In the formation of placers, erosion must

first breakdown the monazite- and xenotime-bearing rocks. Once released from the rocks, the minerals undergo natural separation and sorting by rain and wind and dissolution of the soluble minerals. Further separation and concentration of the heavy minerals, especially by specific gravity, is accomplished by river and sea currents. Only the more chemically and physically stable minerals, which include monazite and xenotime, survive transport to become concentrated in economic heavy-mineral sands deposits.

Heavy minerals that occur with monazite and the less abundant xenotime include the following: the titanium oxides, ilmenite, rutile, and leucoxene; the aluminum silicates, kyanite, sillimanite, and andalusite; the zirconium silicate, zircon; the aluminum oxides, corundum and spinel; the tin oxide, cassiterite; and other minerals such as gold, tourmaline, staurolite, epidote, garnet, and pyroxene.

Monazite is also mined as a vein mineral. Vein monazite was previously mined in the Republic of South Africa and is currently recovered from the Bayan Obo Mine in China.

Technology

Exploration.—Exploration for rare-earth minerals (primarily thorium) began in the 1880's for the purpose of locating thorium and cerium for incandescent gas mantles. After electric lighting came into general use, about 1912, demand for gas mantles fell; subsequently, most rare-earth deposits were located during the search for other minerals, especially ilmenite, rutile, zircon, uranium, and gold.

Exploration techniques employed to locate the rare earths include surface and airborne reconnaissance with magnetometric and radiometric equipment. Satellite imagery and aerial photographs are also used in exploration.

Because many of the rare-earth minerals are naturally radioactive or associated with radioactive minerals, many discoveries were made during exploration for uranium and thorium. Prospectors searching for radioactive minerals were responsible for discovering the Mountain Pass bastnasite deposit.

Most monazite-bearing heavy-mineral sands deposits were discovered by exploring for recent and ancient alluvial deposits. Buried alluvial deposits may be located based on geologic and climatic inference. Following visual identification of rare-earth

minerals, a systematic sampling program and laboratory analysis is run to determine ore grades and individual rare-earth contents.

Mining and Beneficiation.—Bastnasite is mined domestically as a primary product from a hard-rock carbonatite. The carbonatite is mined via bench-cut, open pit methods. Ore is drilled and blasted, loaded into trucks by rubber-tired loaders, and hauled to the mill. At the mill, the blasted ore is crushed, screened, and processed by flotation to produce a bastnasite concentrate.

In China, bastnasite and lesser amounts of associated monazite are also mined from hard-rock carbonatite. The ore is recovered as a byproduct of iron ore mining by hard-rock, open pit methods. However, after primary crushing at the mine site, the ore is transported by train 135 kilometers southeast to the mill because of the scarcity of water at the mine site. After separation from the iron ore by flotation, a bastnasite concentrate and a mixed bastnasite-monazite concentrate are produced.

Heavy-mineral sands are the source of most monazite and xenotime mined in the world. Most of these minerals are recovered by surface placer methods from unconsolidated sands. Almost all mining of these sands is done by floating cutterhead- or bucketwheel-dredges that concentrate the heavy minerals ("heavies") onboard and discharge the unwanted tailings back into previously mined areas. An onboard wet mill separates the "heavies" (specific gravity greater than 2.9) from the lighter weight fraction through a series of wetgravity equipment that includes screens, hydrocyclones, spirals, and cones.

Consolidated and partially consolidated sand deposits that are too difficult to mine by dredging are mined by dry methods. Ore is stripped by typical earth-moving equipment with bulldozers, scrapers, and loaders. Sand recovered by these techniques is crushed and screened and then processed by the wet mill equipment described above.

Wet mill mixed heavy-mineral concentrate is sent to a dry mill to separate the individual heavy minerals and produce a concentrate. Dry mill processing includes a combination of scrubbing, drying, screening, electrostatic, electromagnetic, magnetic, and gravity processes. Monazite, in contrast to ilmenite, rutile, and many other heavy minerals, is nonconductive and can be separated, with zircon, by electrostatic methods. Monazite, which is moderately

susceptible to induced magnetism and may be slightly higher in specific gravity, can be separated from zircon by electromagnets or by additional gravity methods. Xenotime, which has a specific gravity and magnetic properties similar to monazite, is usually separated from monazite by precise gravity methods. Certain deposits also require acid leach treatment and calcining to eliminate iron oxide or other grain coatings.

Economic Factors

Prices.—Time-price relationships for bastnasite and monazite concentrates, based on 1990 constant dollars, are shown in table 3. Bastnasite prices differ slightly from the previous year's table and figure based on a change from truckload and/or carload pricing to standard package pricing. Price trends for bastnasite and monazite concentrate are shown in figures 1 and 2, respectively.

Concentrates of bastnasite and monazite have traditionally been low-priced. Significant value is added when the concentrates are separated into the individual rare-earth oxides or other compounds. Mischmetal prices have also been historically low, with prices remaining in the \$7 to \$12 range over the past 20 years. Individual high-purity metals have commanded the highest prices of the rare-earth products. Metal prices typically run from two to five times the separated rare-earth oxide price.

Initially available in 1954, bastnasite concentrate was priced at \$3.31 per kilogram. By the early 1960's, the development of the first significant commercial applications for the rare earths caused its price to drop under \$0.50. Bastnasite prices have increased progressively since that time, doubling in price between 1974 and 1980 as a result of the domestic energy crisis.

Monazite's price is more complex than bastnasite's. As a byproduct, monazite is partially dependent on production and demand of the primary minerals. As a result of Australia's dominant position as a monazite producer, fluctuations in monazite's domestic price are also based on United States-Australian foreign exchange rates. Monazite's historical price trend, shown in table 6, shows an overall increase in price through 1985. In the 1950's, its price ranged from \$0.33 to \$0.40 per kilogram of REO, decreasing to \$0.22 to \$0.33 per kilogram in the early 1960's. By the mid-1960's, monazite's price began to increase steadily, with a major increase appearing in 1985, the result of a weak Australian economy and increased competition for monazite supplies. Balanced supply and demand is seen in monazite's relatively stable price during the past 5 years.

Costs.—Mine and mill operating costs to produce bastnasite and monazite in the United States are withheld to avoid disclosing company proprietary data. The cost to mine bastnasite is higher than that for monazite. Bastnasite, as a sole primary product, incurs all costs of production. Monazite, however, is produced as a byproduct, and the cost of its recovery is based primarily on costs associated with recovering the primary minerals.

Because both domestic mines have been in production for several years, mining costs are related to direct costs, which include the following: labor, mining equipment (trucks, drills, loaders, dredges, pumps, etc.), supplies (explosives, drill bits, etc.), and utilities (fuel, natural gas, and electricity).

Tariffs.—Tariff rates for various categories specific to the rare earths, including scandium and yttrium, are shown in table 4. The duties reflect results from the 1979 Tokyo Round of Multilateral Trade Negotiations under which the tariffs on many items were reduced in several stages over the period January 1, 1980, to January 1,

FIGURE 1

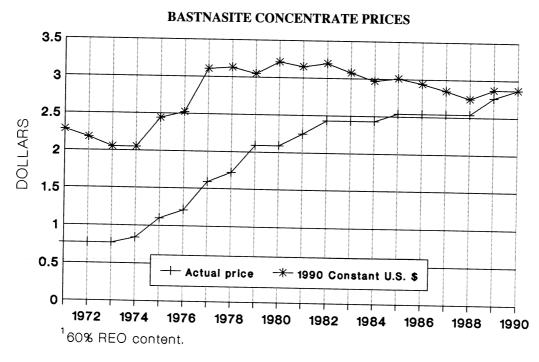

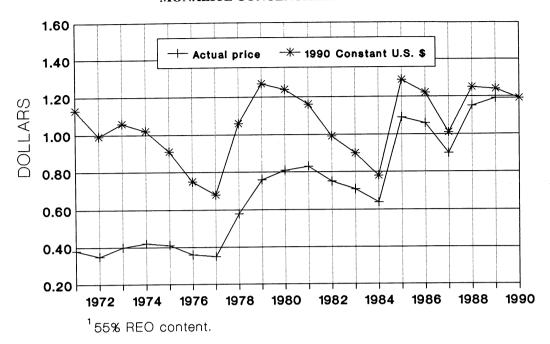

FIGURE 2

MONAZITE CONCENTRATE PRICES

1987. Tariffs are expected to remain at the present rate until negotiations are completed.

Depletion Provisions.—The depletion allowance for monazite is 22% on the thorium content and 14% on the rare-earth content when mined from domestic deposits and 14% from foreign deposits.

Bastnasite's depletion allowance is 14% on both domestic and foreign production.

Operating Factors

Toxicity.—The rare earths are considered only slightly toxic.10 However, the production of skin and lung granulomas after exposure to oxides, fluorides, chlorides, and metals by prolonged breathing, intradermal injection, or subcutaneous implantation requires extensive protection to prevent exposure through cuts and abrasions of the skin and inhalation. Symptoms of toxicity include writhing, ataxia, labored respiration, walking on the toes with arched back, and sedation. Research has shown that males are less susceptible than females to the toxic effects of rare earths. Extreme care must also be taken when exposed to finely divided rare-earth metals and metallic powders to avoid pyrophoric burns from rapid and possibly instantaneous oxidation, especially if inhaled. Certain finely divided rare-earth metals, alloys, and powders may also present the additional hazard of oxidizing rapidly enough to explode.

Employment.—Rare-earth mine and mill employment statistics, based on the quarterly average number of employees on-site, are shown in figure 3. Data were furnished by the U.S. Department of Labor and compiled by the U.S. Bureau of Mines.

Productivity Trends.—The 11-year trend for U.S. rare-earth mine productivity, based on capacity utilization for bastnasite concentrate and monazite concentrate, is shown in figures 4 and 5.

Increased bastnasite production in 1990 changed its previous 11-year trend from a slight decrease to an increase.

The 11-year trend for monazite continued to show a slight increase, although a shorter trend without the low production year of 1980 exhibits a decrease in capacity utilization. However, monazite's decrease, since it is a byproduct of titanium and zirconium minerals, is primarily a function of demand for the primary products.

ANNUAL REVIEW

Legislation and Government Programs

The calendar year 1990 included the U.S. Government fiscal years for 1990 and 1991.

Public Law 101-189, the National Defense Authorization Act for Fiscal Years 1990 and 1991, continued the authorization for disposal of all stocks of rare earths in the National Defense Stockpile.

The National Defense Authorization Act also legislated a limit of \$180 million on the value of materials disposed of during each fiscal year.

Production

The United States was the world's largest producer of rare earths in 1990. Two domestic mines produced rare-earth concentrates. Producers were Molycorp, Inc. a wholly owned subsidiary of Unocal Corp., and Associated Minerals (USA) Inc., a wholly owned subsidiary of the Australian company, Renison Goldfields Consolidated Ltd. (RGC).

Bastnasite, a rare-earth fluocarbonate mineral, was mined by open pit methods by Molycorp at Mountain Pass, CA. Molycorp's mine was the leading producer of rare earths in the world. Mine production increased from that of the previous year to 22,713 metric tons of equivalent REO. Molycorp reported that 1990 sales were 6% less than those of the previous year, the result of increased global competition, a slowdown of the domestic economy, and less-than-expected growth in new uses.

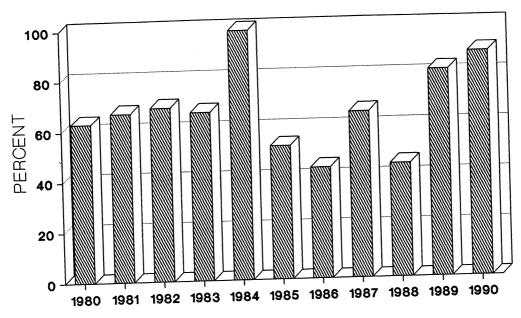

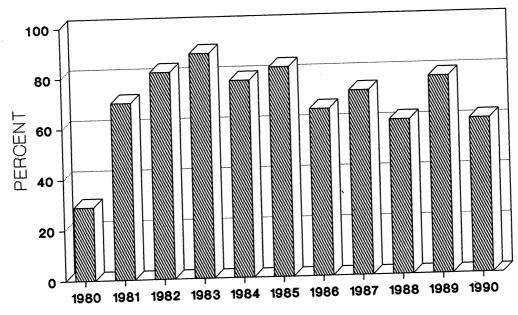

FIGURE 5
U.S. MONAZITE CAPACITY UTILIZATION

monazite, was a byproduct of titanium and zirconium minerals produced by Associated Minerals (USA) Inc. Associated Minerals operated a placer dredging operation at Green Cove Springs, FL.

Imperial Mining Co., a minor producer of byproduct monazite and xenotime, closed its operations at midyear. The Marion, NC, mine was primarily an industrial sand and gravel and gold producer. The operation closed reportedly as a result of Imperial's inability to obtain State permitting for a closed cyanide leach system for gold recovery.

After 75 years in the rare-earth business, Ronson Metals Corp., best known for its production of mischmetal and lighter flints, closed its production facility in Newark, NJ. Ronson was the only domestic lighter flint producer in the United States.

With the closing of Ronson Metals, Reactive Metals and Alloys Corp. (REMACOR), in West Pittsburg, PA, was the only remaining domestic producer of mischmetal.

Principal domestic producers of neodymium-iron-boron magnet alloys were the Delco Remy Div. of General Motors, Anderson, IN; Molycorp, Inc., York, PA; Neomet Corp., West Pittsburg, PA; and Rhône-Poulenc Basic Chemicals Co., Phoenix, AZ. Leading U.S. producers of rare-earth magnets were the Delco Remy Div. of General Motors, Anderson, IN; Hitachi Magnetics, Edmore, MI; Crucible Materials, Elizabethtown, KY; and IG Technologies, Valparaiso, IN.

At yearend, Mitsubishi Materials Corp., a joint owner of Neomet Corp., acquired a 100% interest in the company.

Molycorp continued feasibility and beneficiation studies on the joint-venture Pajarito Project with the Mescalero Apache Tribe. The Pajarito deposit, on the tribe's reservation in southeastern New Mexico, contains the yttrium-bearing zirconium silicate mineral, eudialyte.

Associated Minerals completed a \$12 million development project at its operations in Green Cove Springs, FL. The investment doubled the capacity and improved the efficiency of the floating concentrator.

Associated Minerals and its parent company, RGC, continued feasibility studies at three heavy-mineral sands deposits, two in North Carolina and one in Virginia. The principal deposit scheduled for development is the Old Hickory, near Stony Creek, VA. Approval to proceed with a \$10 million feasibility study was granted by RGC. A pilot plant, close-spaced drilling, and an environmental testing program reportedly

progressed favorably in 1990.

Consumption and Uses

Domestic rare-earth processors consumed slightly more rare earths in 1990 than in 1989. Bastnasite consumption was essentially unchanged, while monazite consumption was 23% lower. Shipments of rare-earth products from domestic processors of ore, concentrates, and intermediate concentrates were equivalent to 12,980 tons of REO, up 4% from the revised 12,425 tons shipped in 1989.

Consumption of mixed rare-earth compounds increased 6% from the 1989 level, while consumption of purified compounds increased 10%. Lower consumption of purified compounds by domestic processors was primarily the result of a slowdown in the domestic economy and the availability of low-cost foreign materials.

The producers of mischmetal, rare-earth silicide, and other rare-earth alloys consumed 51% less rare earths in 1990 than in 1989, while shipments of these goods fell 50% during the same period.

The approximate distribution of rare earths by use, based on information supplied by primary processors and some consumers, was estimated as follows: catalysts in petroleum, chemical, and pollution control, 41%; metallurgical uses as iron and steel additives and as alloys, 29%; ceramics, glass polishing compounds, and glass additives, 24%; and miscellaneous uses in phosphors, electronics, permanent magnets, lighting, and research, 6%.

The glass industry's principal use of rare earths, mainly cerium concentrate or cerium oxide, was as polishing compounds for mirrors, lenses, cut crystal, television and other cathode-ray tube (CRT) faceplates, gem stones, and plate glass. Rare-earth compounds were also used as additives to glass used in automobiles; food and beverage containers; television and CRT faceplates; radiation shielding windows; opthalmic lenses; lasers; incandescent and fluorescent lights; and optical, photochromic, filter, and photographic lenses. The rare-earth additives acted as colorants, color correctors, decolorizers, opacifiers, stabilizers against discoloration from ultraviolet light and against browning caused by high-energy radiation, as dopants in laser glass, as modifiers to increase the refractive indices and decrease dispersion, and as absorbers of ultraviolet and visible light.

Phosphors containing rare earths were used in color television tubes, radar screens,

low- and high-pressure mercury vapor lights, electronic thermometers, trichromatic fluorescent lamps, and X-ray intensifying screens.

The ceramics industry used purified rare earths in pigments, heating elements, dielectric and conductive ceramics, thermal and/or flash protective devices, stereoviewing systems, data printers, image storage devices, opacifiers, paint, glasses, and as principal constituents and stabilizers in high-temperature refractories and structural ceramics, such as yttria-stabilized zirconia.

Rare-earth compounds had applications in petroleum fluid cracking catalysts, non-cracking catalysts, oxygen-sensing electrolytes, dyes and softeners for textiles, electronic components, nuclear fuel reprocessing, microwave applications, incandescent gas mantles, laser crystals and glass, fiber optics, carbon arc lighting, synthetic gem stones, corrosion inhibitors, and superconductors.

Rare-earth permanent magnets were used in electric motors; alternators; generators; line printers; computer disk drive actuators and drives; proton linear accelerators; torque couples; and eddy current brakes. Magnets were also used in microwave transmission focusing; magnetrons; klystrons; medical and dental applications, including magnetic resonance imaging; traveling wave tubes; metallic separators; aerospace electric actuators for ailerons and rudders; and in speakers, headphones, microphones, and tape drives.

Metallurgical applications of rare earths included alloys and additives in high-strength, low-alloy steels; gray and ductile iron; stainless and carbon steels; high-temperature and corrosion resistant metals; and hydrogenstorage alloys for rechargeable batteries. Rare-earths alloys were also used in heat exchangers and fuel cells; lighter flints; armaments; permanent magnets; and neutron converter foils, special lead fuses, target materials for sealed-tube neutron generators, and in high-voltage transmission cable.

Stocks

U.S. Government stocks of rare earths in the National Defense Stockpile, all classified as excess to goal, remained at 457 tons throughout 1990. Rare-earth stocks held in the stockpile were contained in sodium sulfate and were inventoried on a contained-REO basis.

Industry stocks of rare-earth ores and concentrates held by 18 producing, processing, and consuming companies de-

creased 9%. Bastnasite concentrate stocks held by the principal producer and three other processors increased 10% from those of the 1989 level. Yearend stocks of monazite increased 4%.

Stocks of other rare-earth concentrates fell 6%. Stocks of mixed rare-earth compounds increased 263%, as stocks of purified compounds increased 92%. Yearend stocks of mischmetal, rare-earth silicide, and other alloys containing rare earths declined 95%, as inventories of high-purity metals were off 81%.

Prices

Published prices for the rare earths were generally nominal and subject to change without notice. Foreign competition continued in 1990, and competitive domestic pricing policies remained in effect with prices for most rare-earth products quoted on a daily basis.

The price range of Australian monazite (minimum 55% rare-earth oxide, including thoria, f.o.b), as quoted in Australian dollars (A\$), 11 increased from A\$780 - A\$880 per ton at yearend 1989, to A\$800 - A\$900 per ton by yearend 1990. Changes in the United States-Australian foreign exchange rate in 1990, resulting from a slightly weaker Australian dollar, caused the corresponding U.S. dollar to be up \$0.03 against the Australian dollar at yearend. The U.S. price range, converted from Australian dollars, increased slightly from US\$616 - US\$69512 per ton in 1989 to US\$618 - US\$69513 per ton in 1990. The average declared value of imported monazite increased in 1990 to \$857 per ton, up \$172 from the 1989 value.

The yearend price quoted in Industrial Minerals (London) for yttrium concentrate (60% Y₂O₃, f.o.b. Malaysia) was \$32 - \$33 per kilogram. Market prices for refined yttrium compounds were reportedly much lower, especially from China.

Prices quoted by Molycorp for unleached, leached, and calcined bastnasite in standard quantities, containing 60%, 70%, and 85% REO, were \$1.30, \$1.35, and \$1.55 per pound of contained REO, respectively, at yearend 1990. The price for each grade of concentrate increased \$0.15 per pound from last year's quote.

The price of cerium concentrate quoted by American Metal Market was \$1.65 per pound of contained cerium oxide at yearend 1989, an increase of \$0.10 from that of the previous year. The yearend price of lanthanum concentrate decreased \$0.05 from the 1989 level to \$1.35 per pound of REO contained.

The nominal price for typical neodymium-iron-boron alloy, compiled by the U.S. Bureau of Mines, was \$14.25 per pound at yearend, f.o.b. shipping point, 1,000-pound minimum.

Molycorp quoted prices for lanthanide (rare earth) and yttrium oxides, net 30 days, f.o.b. Louviers, CO; Mountain Pass, CA; or York, PA; effective March 1, 1990, and through the end of the year, as shown in table 5.

Molycorp also quoted prices for lanthanide (rare earth) compounds, net 30 days, f.o.b. York, PA, or Louviers, CO, effective April 1, 1990, as shown in table 6.

Rhône-Poulenc quoted rare-earth prices, per kilogram, net 30 days, f.o.b. New Brunswick, NJ, or duty paid at point of entry, effective at yearend 1990 as shown in table 7.

No published prices for scandium oxide were available. Yearend nominal prices for scandium oxide per kilogram, compiled by the U.S. Bureau of Mines from information from several suppliers, were as follows: 99% purity, \$3,500; 99.9% purity, \$5,000; 99.99% purity, \$8,000; 99.99% purity, \$10,000. Scandium metal prices, as listed by the Johnson Matthey Aesar Group, were unchanged from yearend 1989 as follows: 99.99% purity, lump, sublimed dendritic, \$248.20 per gram; 99.9% purity, 250 micron powder, \$444.00 per 2 grams; and 99.9% purity, lump, vacuum remelted, \$322.00 per gram.

Foreign Trade

Rare-earth imports decreased in 1990 from those of the previous year. Imports of

ore and compounds are shown in tables 8 and 9. As in 1989, France dominated the import market in 1990, followed by Brazil as a distant second. The principal sources of U.S. imports are displayed in figure 6.

Domestic exports of rare earths are shown in table 10. Based on the available export data, Brazil, Canada, and Japan were the leading destinations of rare earths from the United States in 1990. This was a shift from 1989 data when Japan, Korea, and Dominica were the leaders. Principal destinations of U.S. exports are displayed in figure 7.

World Review

Industry Structure.—The world's principal source of rare earths, bastnasite, was mined as a primary product in the United States and as a byproduct of iron ore mining in China. Significant quantities of rare earths were also recovered from monazite, a byproduct of heavy-mineral sands mined for titanium and zirconium minerals or tin minerals in Australia, Brazil, China, India, Indonesia, Malaysia, the Republic of South Africa, Sri Lanka, Thailand, Taiwan, and the United States. Smaller amounts of rare earths, especially yttrium, were obtained from the mineral xenotime. Xenotime was recovered primarily as a byproduct of processing for tin minerals in Malaysia, Thailand, and Indonesia, but was also produced as a byproduct of processing titanium and zirconium minerals in Australia and China. Rare earths, including yttrium, were also produced from rare-earth-bearing clay in China.

Scandium was recovered as a byproduct of processing ore for tungsten, tin, iron, and beryllium in China, and was previously produced as a byproduct of uranium processing in the United States.

Reserves.—World reserves of rare earths were estimated by the U.S. Bureau of Mines at 62 million tons of contained REO, of which 22% is in market economy countries. World reserves were revised upward for 1990 as a result of additional data on Australia and China. Rare-earth reserves for Australia were increased to almost 5 million tons REO while those for China advanced to 48 million tons REO. China has the largest share of world reserves with almost 78%.

Australia.—CRA Ltd. and Ocean Resources NL began a joint venture to develop an offshore heavy-mineral sands deposit off the coast of Queensland. The offshore deposit reportedly contains significant quantities of rutile and zircon, with smaller amounts of monazite and ilmenite. The CRA-Ocean joint venture planned to construct an offshore wet mill on a platform, similar to those presently used for oil production. After recovering the heavy minerals on the platform, the light minerals would be returned to the sea floor.¹⁴

CRA Ltd.'s subsidiary, Wimmera Industrial Minerals, continued studies of the WIM 150 and four other similar heavymineral sand deposits near Horsham, Victoria. The fine grain size of the deposits, about 50 microns, created the need for new process technology. The primary problem is that the fine grain size is hard to separate by conventional wet methods because of the very small differences in spe-

cific gravities. Separation systems being assessed for the initial concentration are a proprietary jig and bulk flotation. Wimmera Industrial Minerals reports the WIM 150 contains 580,000 tons of monazite and 170,000 tons of xenotime, making it one of Australia's largest rare-earth deposits. 15

Westralian Sands Ltd. announced the shutdown of its Yoganup Extended mineral sands mine in Western Australia in August. The shutdown was reportedly in response to decreased demand for titanium pigments.

Westralian's two other mineral sands mines continued to operate. The Yoganup Extended was slated to resume production of mineral sands, including monazite, when market conditions improve.

Renison Goldfields Consolidated Ltd. continued development of its Eneabba West mineral sands deposit in Western Australia. Production from the Eneabba West ore body was expected to commence in 1991, increasing the company's overall capacity by about 30%.

The largest mine to start up in Australia in 1990 was Cooljarloo, a joint venture of Minproc Chemicals Pty. Ltd. and KMCC Western Australia Pty. Ltd. The Western Australia mine was expected to employ 450 people and generate \$225 million dollars in export income. Cooljarloo's reserves are set at 570 million tons of ore grading 3.2% heavy minerals, including monazite.¹⁶

Estimated. PPreliminary.

¹In addition to the countries listed, rare-earth minerals are believed to be produced in Indonesia, North Korea, Mozambique, Republic of South Africa, and the U.S.S.R., but general information is inadequate to formulate reliable estimates.

²Reported figure.

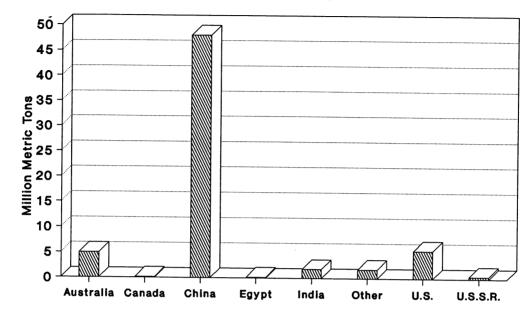

³Comprises only the rare earths derived from bastnasite as reported in Unocal Corp. annual report, 1990.

Table includes data available through Apr. 23, 1991.

²In addition to the countries listed, China, Indonesia, North Korea, the Republic of Korea, Nigeria, and the U.S.S.R. may produce monazite, but output, if any, is not reported quantitatively, and available general information is inadequate for formulation of reliable estimates of output levels.

FIGURE 8

WORLD RESERVES OF RARE EARTHS (Percent Reo)

Pivot Group Ltd. was granted a 21-year lease to mine mineral sands at Port Clinton, within the Shoalwater Military Training Area. Reserves at Port Clinton reportedly totaled 120 million tons grading 3% heavy minerals. Pivot planned to barge the wet concentrate by sea to a dry mill at Gladstone.¹⁷

Carr Boyd Minerals Ltd. announced it had started feasibility studies at its Mt. Weld rare-earth-bearing carbonatite. Thirty-five kilometers south of Laverton, Western Australia, the carbonatite contains the rare-earth phosphate mineral monazite (thorium-deficient), a hydrated yttrium-lanthanide phosphate, churchite, and the hydrated rare-earth-niobium-tantalum-bearing calcium-aluminum phosphate, crandallite. Reserves at Mt. Weld were 6.3 million tons grading 17.22% REO.¹⁸

Yardarino Mining NL explored a mineral sands deposit near Cataby, Western Australia. The deposit lies adjacent to the Cooljarloo mineral sands mine owned by Minproc Chemicals Pty. Ltd. and KMCC Western Australia Pty. Ltd. A 650-hole drilling program delineated resources of 32 million tons grading 4.4% heavy minerals. Additional exploration on the deposit was planned based on results of an aeromagnetic survey. 19

Nissho Iwai Corp., through its wholly owned subsidiary, Cable Sands Pty. Ltd., continued development of the Jangardup mineral sands deposit south of Nannun, Western Australia. The Jangardup deposit is expected to come on-line in 1991 with the capacity to produce 4 million tons of ore per year.²⁰

Australmin Holdings Ltd. proceeded with development of the Newrybar deposit after the New South Wales Land and Environment Court approved the project in late 1989 over the objections of an antimineral sands mining group. Production at Newrybar commenced in 1990 with an installed capacity to recover 3.5 million tons of ore per year. Dry mill capacity was planned to recover 12,000 tons of rutile, 10,000 tons of rutile, and lesser amounts of ilmenite and monazite.²¹

Brazil.—Production of monazite concentrates in 1988 was 2,817 tons, 2,038 tons from the State of Rio de Janiero, a decrease from the 1987 production of 3,217 tons; 779 tons from the State of Bahia, a decrease from the 884 tons of monazite produced in 1987; and no production from the State of Espírito Santo, down from 177 tons in 1987.

Measured reserves of monazite increased to 48,281 tons in 1988 from 36,806 tons in 1987. Estimated rare-earth oxide content based on these reserves was 26,600 tons. The increase in reserves was the result of additional tonnages added from the São João da Barra deposit in the State of Rio de Janeiro. Additional monazite reserves were

in the States of Bahia, Espírito Santo, Minas Gerais.²²

Production of rare-earth compounds in 1988 was 37,822 kilograms of rare-earth carbonate, 2,633,000 kilograms of rare-earth chloride, and 94,650 kilograms of rare-earth oxides.²³

An agreement between Brazil's Mining Technology Center (CETEM) and China's Minerals and Non-Ferrous Metals Institute was signed to transfer China's technology to Brazil for the production of rare-earth oxides.²⁴

Canada.—Hecla Mining Co. of Canada and Iron Ore Co. of Canada entered an agreement to resume evaluation of the Strange Lake, yttrium-zirconium-lanthanide deposit. On the border of Quebec and Labrador, northeast of Schefferville, Quebec, the deposit has reserves of 44 million tons of ore grading 0.41% yttrium oxide. The yttrium is contained in an unnamed mineral (proposed dickgarrenite) and gadolinite, an yttrium-iron-beryllium silicate. Hecla will reportedly evaluate metallurgical extraction methods and proceed with marketing studies in return for up to a 75% interest if the deposit goes into production.25

Malaysia.—Production of rare-earth concentrates of monazite and xenotime has decreased substantially since 1987. The

drop was reportedly due to a shortage of "amang," the mixed heavy-mineral by-product remaining after removal of the tin minerals. ²⁶ The decrease was also attributed to increased competition from China and local environmental problems related to the disposal of monazite's radioactive component, thorium.

Mozambique.—Financing for Kenmare Resources PLC's Congolone deposit encountered delays when the Credit Guarantee Insurance Corp. decided not to finance the project. Based on Kenmare's inability to secure financing, Johannesburg Consolidated Investments Ltd. reportedly withdrew it's offer to participate in the joint venture. Reserves at the Congolone deposit reportedly contain 11,000 tons of monazite.²⁷

New Zealand.—Fletcher Titanium Products Ltd. continued development of its Barrytown deposit. Construction of a wet mill was reportedly completed in the first half of 1990, and a dry separation plant was commissioned in January.²⁸

Sweden.—In recognition of its importance to rare earths and the metals industry, the Ytterby Mine on Resaro Island was designated an ASM Historical Landmark by ASM International, the materials information society. The Ytterby Mine was the site of the discovery of many rare earths, including erbium, holmium, scandium, terbium, thulium, yttrium, and ytterbium.²⁹

Vietnam.—W. T. Exporters Pty. Ltd. of North Queensland, Australia, reportedly obtained a license to develop a heavy-mineral sands deposit in Nghe Tinh Province. An initial production of 27,000 tons of ilmenite and zircon was planned.³⁰

Current Research

Rare earths were used in a newly developed nickel-hydrogen rechargeable battery. Using a foamed nickel alloy as the positive pole and a rare-earth mixture as the negative pole, the battery operates by absorbing and desorbing hydrogen gas. The rare-earth-containing battery reportedly has twice the energy capacity of a nickel-cadmium rechargeable battery and will recharge at a much faster rate. The new battery is expected to replace nickel-cadmium batteries in most applications due to its improved properties and elimination of the hazard-ous material cadmium.³¹

Scientists at Argonne National Labora-

tory and Northwestern University developed a practical high-temperature superconducting device to monitor liquid nitrogen levels. Using superconducting yttrium-barium-copper-oxygen wires, the device measures the liquid nitrogen level by detecting resistance changes as the level drops. The sensor may be used for remote detection of coolant levels in human tissue refrigeration units and in other cryogenic devices.³²

Researchers at NEC developed a handheld range finder based on a glass laser containing erbium. The erbium-glass laser reportedly emits 40 nanosecond, 7 millijoule pulses at 2.8 micrometers to calculate distances from 100 to 10,000 meters. The erbium lasing wavelength of 2.8 micrometers allows operation that is safe to the human eye.³³

A holmium laser to treat glaucoma was developed at Sunrise Technologies, Inc. The experimental laser was given an investigational device exemption by the Food and Drug Administration so clinical use could begin. Holmium's emission wavelength of 2.10 micrometers allows a quartz fiber with a very small probe to be used for the eye treatment.³⁴

Researchers developed a pulsed laser using rare earths that can be used in dentistry. The pulsed neodymium-yttrium-aluminum-garnet laser may be used on both soft and hard tissue. Hard tissue reportedly can be treated with little or no pain because the microsecond laser pulses give the nerves no time to respond. Lasing at 1.06 micrometers, the rare-earth device can also be used to vaporize tooth decay and treat gum disease. The laser is currently used in Canada and seven European countries. Domestic use is pending approval by the Food and Drug Administration.³⁵

High-strength, rare-earth magnets were used in a new magnetic separator developed by International Process Systems Inc. Developed for dry mill applications, the separator has a unique roll assembly that reportedly provides easier control and maintenance in addition to lower manufacturing costs. The neodymium-iron-boron magnetic separator can be used on a variety of minerals, including the mineral sands ilmenite, rutile, zircon, and monazite. Mineral Deposits Ltd. of Australia was licensed to manufacture the separator.³⁶

To minimize grinding of optical glass, a low melting point lead-phosphate glass containing scandium was invented by scientists at Oak Ridge Laboratory, TN. Both lead-indium phosphate and lead-scandium phosphate glasses were developed to be cast into the complex shapes needed by industry. The glasses may also be used for radiation-shielding windows because of their lead content.³⁷

OUTLOOK

In the short-term, the domestic rare-earth industry is expected to experience flat demand in most uses and modest gains in a select group of emerging applications. Growth is expected to be greatest in permanent magnets, rechargeable batteries, specialty laser crystals, and optical storage devices. Growth in high-temperature superconductors is expected only in the long term. The international outlook is for continued offshore expansions and increased competition in the wide range of rare-earth markets. On the demand side, it is expected that new applications, such as mischmetal rechargeable batteries and erbium fiber optics, will improve both the traditional and emerging markets.

RHENIUM

By John W. Blossom

Mr. Blossom, a physical scientist and engineer with 43 years of industry and Government experience, has been the commodity specialist for rhenium since 1983. Trade data were prepared by Sherwood C. Jordan, mineral data assistant.

henium's two most important uses in the past decade have been in platinum-rhenium catalysts used primarily in producing lead-free high-octane gasoline and in high-temperature superalloys for jet engine components. Other uses of rhenium, primarily as tungsten-rhenium and molybdenum-rhenium alloys, though smaller in quantity, are more diverse. These include use in thermocouples, heating elements, temperature controls, flashbulbs, vacuum tubes, X-ray tubes and targets, metallic coatings, and electrical contact points. Research by industry continues in rhenium recovery from ore and concentrate and on development of new catalysts and allovs.

In 1990, domestic demand for rhenium metal and other rhenium products was met by domestic recovery, domestic stocks, and imports.

DOMESTIC DATA COVERAGE

Domestic mine production data for rhenium are developed by the U.S. Bureau of Mines from reported molybdenum production at the seven operating porphyry copper-molybdenum-rhenium mines in the United States.

ANNUAL REVIEW

Rhenium is a byproduct of molybdenite recovered as a byproduct of porphyry copper ore from seven mines in the Western United States. Consumption of rhenium decreased about 6% in 1990. Imports for consumption increased 353% in 1990. Some of this increase in imports was the result of improved reporting in 1990 of trade data. The major uses for rhenium during the year were bimetallic

platinum-rhenium catalysts and jet engine high-temperature components. The price of rhenium metal was about \$1,544 per kilogram (\$700 per pound), and the price for ammonium perrhenate about \$1,433 per kilogram (\$650 per pound).

Consumption and Uses

The major uses of rhenium are in petroleum-reforming catalysts and in high-temperature superalloys used in jet engine components. These two uses each represent about 45% of the total demand.

Rhenium is used in petroleum-reforming catalysts for the production of high-octane hydrocarbons, which are used in the production of lead-free gasoline. Bimetallic platinum-rhenium catalysts have replaced many of the monometallic catalysts. Rhenium catalysts tolerate greater amounts of carbon formation and make it possible to operate at lower pressures and higher temperatures, which leads to improved yields and octane ratings.

Catalytic units employing platinumrhenium catalysts are used in about 80% of total U.S. reforming capacity. Platinumrhenium catalysts are also used in the production of benzene, toluene, and xylenes, although this use is small compared with that used in gasoline production.

A significant property of rhenium is its ability to alloy with molybdenum and tungsten. Molybdenum alloys containing approximately 50 weight percent rhenium have greater ductility and can be fabricated by either warm or cold working. Unlike other molybdenum alloys, this alloy is ductile, even at temperatures down to 196° C, and can be welded. Also, alloys of tungsten with 24 weight percent rhenium have improved ductility and lower ductile-to-brittle transition temperature than pure tungsten. Rhenium improves the strength properties at high temperatures (1,000 ° C) of nickel alloys. Some of the uses for these alloys are in thermocouples, temperature controls, heating elements, ionization gauges, spectrographs, electron tubes and targets, electrical contacts, metallic coatings, vacuum tubes, crucibles, electromagnets, and semiconductors. These various uses represented only 10% of total demand in 1990.

Foreign Trade

Imports for consumption of ammonium perrhenate came from Brazil, Chile, the Federal Republic of Germany, Japan, Sweden, and the United Kingdom, whereas Chile, the Federal Republic of Germany, Japan, Sweden, Switzerland,

and the United Kingdom supplied rhenium metal.

World production of rhenium was estimated to be 34 metric tons (75.000 pounds); however, the quantity of rhenium actually recovered is much lower because not all concentrates are processed to recover the rhenium values. Rhenium was recovered from some byproduct molybdenite concentrates from porphyry copper deposits in Canada, Chile, China, Iran, Peru, the U.S.S.R., and the United States. In addition, the U.S.S.R. also recovered rhenium as a byproduct from the Dzhezkazgan sedimentary copper deposit in Kazakhstan. Rhenium metal and compounds were recovered from molybdenum concentrates in Chile, France, the Federal Republic of Germany, Sweden, the U.S.S.R., the United Kingdom, and the United States.

World Review

The definitions of reserves and reserve base are published in U.S. Geological Survey Circular 831, "Principles of a Resource/Reserve Classification For Minerals," which is reprinted in the introduction of "Mineral Facts and Problems, 1985 Edition" and "Mineral Commodity Summaries, 1990."

TABLE 5

WORLD RHENIUM RESERVES AND RESERVE BASE

(Kilograms)

Country	Reserves	Reserve base	
Canada	31,751	1,542,213	
Chile	1,306,345	2,540,115	
Peru	45,359	544,310	
U.S.S.R.	594,206	771,106	
United States	385,553	4,535,920	
Other countries	90,718	362,874	
World total	2,453,932	10,296,538	

Estimated world reserves and reserve base of rhenium appear in table 5. They are contained primarily in molybdenite in porphyry copper deposits. U.S. reserves are concentrated in Arizona and Utah, but are also found in Montana, Nevada, and New Mexico. Canadian reserves are in British Columbia, primarily on Vancouver Island. Chilean reserves are found primarily at four large porphyry copper mines and in lesser deposits in the

northern half of the country. In Peru, reserves are concentrated primarily in the Toquepala open pit porphyry copper mine and in about a dozen other deposits in the southern half of the country.

Soviet reserves are in several porphyry copper deposits and one sedimentary copper deposit mainly in the south-central part of the country between the Caspian Sea and northwestern China. Other world reserves are in Europe and in sedimentary copper-cobalt deposits in Zaire, Africa.

OUTLOOK

In the next 5 years, demand for rhenium metal could increase to about 20 metric tons (45,000 pounds) annually, with propulsion component needs (superalloys) at 60%, petroleum-reforming catalysts at 30%, and the various other uses consuming 10%. This increase in demand may be met by processing a greater amount of concentrates containing rhenium and increasing the rate of recovery into the 90% range. Recycling of rhenium-bearing waste and scrap must be greatly improved. This area will require the development of new technologies.

·			

SALT

By Dennis S. Kostick

Mr. Kostick, a physical scientist with 12 years' U.S. Bureau of Mines experience, has been the commodity specialist for salt since 1980. Domestic survey data were prepared by Carleen Militello, mineral data assistant; and international data tables were prepared by William Zajac, Chief, International Data Section.

odium chloride, commonly known as salt, is an important compound that has a multitude of applications. Although most individuals usually only associate salt with highway deicing and food processing, the largest end use of salt is as feedstock for chlorine and caustic soda manufacture. These two important inorganic chemicals have a multitude of consumer-related enduse products.

DOMESTIC DATA COVERAGE

Domestic production data for salt are developed by the U.S. Bureau of Mines from an annual voluntary survey of U.S. salt-producing sites and of company operations. Of the 69 operations to which a survey request was sent, 66 responded, representing 97% of the total production shown in this report. Production for the nonrespondents was estimated on the basis of their prior response to the 1990 production estimate survey or brine production capabilities for chloralkali manufacture.

BACKGROUND

Salt has been an important commodity throughout history. Its presence has determined the location of cities, migration of populations, and routes of trade caravans. One of the earliest accounts of using salt in political-economic societies was traced to 2200 B.C. in China where Emperor Hsia Yu decreed that Shandong Province would supply the court with salt. The Phoenicians (1200 B.C.-300 B.C.) were one of the first maritime civilizations to trade salt. Salt became an important universal medium of exchange. The English word "salary" is derived from the Latin term "Salarium argentum," which were the salt rations that Roman soldiers were partially paid in for their services. Aside from its use as a medium of monetary exchange, salt has also been used to signify hospitality. The custom of presenting newlyweds wine, bread, and salt shows salt as a lifegiving and sustaining substance. In many areas of the world, it is still the custom for the host to offer bread and salt upon entering the home. The custom is also practiced "out of this world"—it has been a tradition that all U.S.S.R. staffed spaceflights carry aloft bread and salt and leave them behind on the orbiting space station as presents for the next visiting crew.

The first production of salt in the United States was in 1614 by the Virginia colonists who evaporated seawater. The practice of extracting salt from subsurface brine was first employed in the United States at Onondaga, NY, in 1788. The first salt "mine" in the United States was dug in 1799 at Saltville, VA. A 6-foot-wide by 200-footdeep shaft was dug to the top of the salt formation before ground water flooded the workings. The saline water in the shaft provided the feedstock to iron kettles in which the water was evaporated and the salt recovered. In 1862, the first commercial rock salt mine in North America began operating at Avery Island, LA. Solution mining of salt began in about 1882 and consisted of drilling a small diameter well down to a salt bed, pumping freshwater down to dissolve the salt, and pumping the resultant brine to the surface for subsequent evaporation. In 1887, the vacuum pan was adopted for salt production, which incorporated a vacuum during evaporation to allow the water to boil from the brine at a lower temperature. This technological achievement reduced fuel consumption below that of direct-heated units.

Definitions, Grades, and Specifications

Technically, salt is a generic term that describes compounds formed by the partial or complete replacement of the hydronium ion of an acid by a metal or metallic radical.

Water and salts are the end products from the chemical reaction between acids and bases. Through time, however, "salt" has become synonymous with sodium chloride (common salt) and will be considered synonymous throughout this chapter.

Naturally occurring sodium chloride is mineralogically known as halite. Pure salt contains 39.3% sodium and 60.7% chlorine by weight. Halite deposits usually contain between 1% and 4% impurities, mainly gypsum, shale, dolomite, and quartz. Rock salt is halite that is mined underground by conventional room-and-pillar techniques.

Evaporated salt is the term applied to fine crystals of salt obtained by evaporating brines, either natural or manufactured from solution mining, in large, vacuum-enclosed or open steam-heated kettles. Solar evaporated salt is the product harvested from shallow ponds after the brine has been exposed to solar and wind evaporation.

The physical characteristics of salt vary with the type of production process. Salt specifications from vacuum pan operations are the same because the process is similar throughout the country. Rock salt, however, can vary in color and composition with locality, and these characteristics influence the specifications of the final product. Some impurities must be removed by chemical treatment or filtration to meet specifications for certain end uses.

There are various standards issued by different organizations that apply to salt. These standards may vary, depending on the intended end use. For example, salt for human consumption requires different specifications than those of salt for deicing highways.

Products for Trade and Industry

Salt for human consumption is packaged in different sized containers for several specialized purposes. Table salt can contain 0.01% potassium iodide as an additive that provides a source of iodine that is essential to the oxidation processes in the body.

Kosher salt, seasalt, condiment salt, and salt tablets are special varieties of salt.

Water conditioning and animal feedstock salt are made into 50-pound pressed blocks. Sulfur, iodine, trace elements, and vitamins are occasionally added to salt blocks to provide missing nutrients not found naturally in the diet of certain livestock. Salt is also compressed into pellets and used for water conditioning.

Geology-Resources

The definitions of reserves and reserve base are published in the U.S. Geological

Survey Circular 831, "Principles of a Resource/Reserve Classification for Minerals."

The oceans are the world's largest resource of salt. Seawater contains 3.5% dissolved solids by weight with sodium chloride representing the major component, approximately 2.5% by weight. The world's oceans contain about 44 x 10¹⁵ short tons of sodium chloride, which is equivalent to 4.5 million cubic miles in volume or a cube measuring 165 miles on edge.

Domestic salt resources are found mainly in four large depositional basins, covering

an area totaling about 0.5 million square miles in 18 States. These basins are (1) the gulf coast, which covers part of Florida, Alabama, Mississippi, Arkansas, eastern Texas, and all of Louisiana; (2) the Permian, which is in part of New Mexico, Colorado, Kansas, Oklahoma, and western Texas; (3) the Salina, covering part of New York, Pennsylvania, West Virginia, Ohio, and Michigan; and (4) the Williston, encompassing part of North and South Dakota. Montana, and Wyoming. The gulf coast and Permian basins extend into Mexico; the Salina and Williston both extend into Canada. The identified salt resources of the United States are estimated at 61 x 10¹² tons and are being depleted at the rate of about 39 million tons annually. At the present level of production, the United States has enough salt to mine for more than 1.6 million years. Solar evaporation of coastal seawater would extend this rate virtually forever.

Salt can be geologically classified by its occurrence as evaporite deposits and in solutions.

Evaporite Deposits.—Bedded, diapiric flow, and playa salts are the major types of dry salt deposits. Bedded salt deposits were formed by the accumulation of precipitated salts on the seafloor of ancient landlocked marine bodies of water. Extensive and widespread evaporation was essential to form these massive rock salt deposits, some of which measure up to 3,000 feet in thickness.

Salt domes form when vertical or lateral pressures are applied to stratified salt deposits in which low-density salt will flow plastically through the surrounding rocks of higher density. The salt domes of Romania, the Federal Republic of Germany, and the gulf coast of the United States are examples of diapiric salt flows. The appearance is usually cylindrical with circular or elliptical diameters. A cap-rock of anhydrite is common with overlying layers of gypsum and calcite. Oil, gas, and sulfur are associated with many domes and represent large mineral resources. There are 329 proven salt domes in the gulf coastal province and offshore regions of the United States. Louisiana has 183 domes onshore and offshore; Texas, 83; Mississippi, 61; and Alabama, 2.

Playas are flat, vegetation-free floors of an undrained desert basin that may occasionally be covered by water. Postevaporation minerals such as sodium carbonate, sodium sulfate, sodium chloride, borates, nitrates, phosphates, and potash result from

²Input regarding food and table salt specification is necessary to maintain quality products in these areas.

³Work has been done with medical salt standards to obtain reasonable specifications.

⁴The ANSI Packaging Standard is a voluntary standard for primary salt containers, secondary containers, and pelletized shipping units.

⁵UU-S-48F gives Federal Sack Specifications. An effort has been made in this area to obtain a reasonable standard.

the leaching of the rocks surrounding the basin by water flowing into the playa. Searles Lake in California is a classic example of a salt-bearing playa lake.

Salt in Solution.—Ocean, lake, and ground water are the primary aqueous mediums in which salt is dissolved. Seawater contains many dissolved minerals, the major one being sodium chloride. Other dissolved minerals include various sulfate, magnesium, calcium, and potassium compounds.

Water tends to accumulate on land in topographic depressions created by tectonic uplifts or subsidences of the Earth's upper crust. As mineralized solutions from upland sources drain into these basins, solar evaporation concentrates the salts to form saline lakes. The Aral Sea in the U.S.S.R., Great Salt Lake in Utah, and the Dead Sea between Jordan and Israel are examples of this process.

Ground water is composed of mineralized connate and meteoric water found in permeable sedimentary formations. In some areas, sodium chloride-rich brines migrate to the surface through intersecting fractures and joints in the rock strata to form local salt springs. These springs have attracted animals because they are a source of salt. The springs also indicate where buried salt deposits are located. The salt springs at Saltville, VA, are an example of a locality that was developed based on an occurrence of salt springs.

Technology

Exploration.—Exploring for new salt deposits is based on examination of various geochemical and geophysical information. Analysis of the underlying strata by core drilling, oil and water well logs, or other techniques is the basis for establishing the size of the deposit. Usually the most favorable areas for mine development will be located near the market regions and convenient transportation routes.

The development of mines incorporates strict safety precautions while permitting for the maximum economic recovery of salt. During shaft sinking, water-bearing strata may be encountered, and waterproofing techniques must be employed to prevent mine flooding. At least two access shafts are constructed in room-and-pillar mines to provide adequate safety and ventilation.

Mining.—Rock Salt.—Rock salt is mined by the room-and-pillar method,

which is similar to that used in coal and trona mining. The salt is drilled, cut, blasted, mucked, crushed, and transported to the surface for processing, which usually involves removing the impurities and screening the material to finer size fractions.

Underground mining practices of bedded rock salt and domal salt formations are similar except for the height differences within the mines of the two types of operations. For example, bedded formations usually are laterally extensive but are vertically restricted. Salt domes are laterally restrictive but are vertically extensive. Many salt domes have depths in excess of 20,000 feet, yet many outcrop at the surface. Most gulf coast salt mining operations are generally less than 1,000 feet below the surface. Working at deeper depths is difficult because of higher temperatures and denser rock.

Solar Evaporation.—Solar evaporation is an effective method of producing solar salt in areas of high evaporation and low precipitation. Along coastal margins in many parts of the world, seawater is collected and allowed to evaporate in specially constructed evaporating ponds. Saline lakewater is also processed using this method. The ponds are separated by levees that isolate the brine during different stages of fractional crystallization.

The initial step concentrates the brine to increase the salinity and allow many calcium, magnesium, and iron compounds to precipitate from solution. The brine is circulated among a network of interconnecting ponds, with salinity increasing with each transfer. The brine is then treated with lime to remove excess calcium sulfate and then pumped to evaporation ponds and then transferred to harvesting ponds to permit the salt to crystallize. After about 85% of the salt is precipitated, the remaining supernatant liquid, called "bitterns," can be drained to adjacent ponds for subsequent extraction of magnesium, potassium, bromine, and sodium compounds. The harvesting pond is flooded again with new brine from the lime pond to repeat the cycle. It takes about 5 years once seawater is first introduced into the system for the completion of the crystallization process. The salt is harvested by special tractors equipped with scrapers and ready for processing.

Solution Mining.—The first reported use of solution mining was about 250 B.C. in China when holes were drilled into deep salt deposits. The brine was brought to the

surface by pipes made of bamboo. The brine was evaporated over fires fueled with wood, coal, or natural gas. The basis of current technology began in France about A.D. 858. An injection well is sunk, and pressurized freshwater is introduced to hydraulically fracture the bedded salt. Once communication with the production well is established, the brine is pumped to the surface for treatment.

Roof collapse of the overlying strata and surface subsidence are potential problems associated with solution mining; however, producers have taken precautions to minimize these hazards. One method that was once used was injecting air with the water into the salt caverns. The air formed a protective cover between the water and the top of the cavity that reduced the amount of dissolution of the roof.

Processing.—Rock Salt.—About 64% of total rock salt produced and imported is for highway deicing. Crushing and screening to the proper physical size is usually the only processing that road salt undergoes. In many operations, these steps are done underground in the mine to minimize haulage and storage costs. In addition, the extremely fine fraction, which often is unusable, remains underground rather than on the surface, which would represent a waste product that would have to be disposed.

Solar Salt.—After harvesting, the salt crystals are washed with dilute brine to remove residual bitterns and impurities. The salt is transferred to processing facilities where it is washed with saline water, dried for about 8 minutes at approximately 300° F, and screened into fine to coarse sizes, depending on the end use of the salt to be sold. Most operations ship solar salt in bags and in bulk, using barges, truck, and rail transportation.

Mechanical Evaporation.—Salt obtained by dehydrating brine using heat alone or in combination with a vacuum is vacuum pan salt. The vacuum pan process conserves energy by utilizing multiple-effect evaporators connected to vacuum pumps. A saturated salt solution will boil at a higher temperature than pure water. When a vacuum is applied, the brine boils at a lower temperature, enabling the superheated vapor that is generated to act as the heating medium for the next evaporator.

The grainer or open pan process uses open, rectangular pans with steam-heated

immersion coils to evaporate the water in the brine. Rotating rakes scrape the salt precipitate into a sump or up a ramp, depending on the method, and onto conveyors for debrining and drying treatment. The final product is usually flake-shaped rather than the typical cubic form. Flake salt is preferred for production of cheese, butter, and baked goods.

The Alberger process is a modified grainer operation that produces cubic salt with some flake salt. The pans are shallow, circular units with external heating units, rather than heating coils. The open pan process cannot be operated successfully in regions with high humidities because the evaporation rate is too slow and more energy is required to evaporate the brine.

Desalination.—The conversion of saline water into freshwater has important municipal, industrial, and agricultural applications. Aside from obtaining pure water, desalination also produces byproduct salt. There are four processes presently employed in water desalination, and each has different cost and energy factors. The processes are distillation, membrane, freezing, and ion exchange. Some salt from these processes is used by the chemical industry. In some regions, salt is returned to the saline water source. Seawater typically contains 3.5% to 4.5% salt, or 35,000 to 45,000 parts per million. The standard for drinking water in the United States is 500 parts per million.

Byproducts and Coproducts

Salt is a coproduct from various seawater and saline lake operations. Depending on the cost of recovery and processing, certain magnesium, potassium, and bromine compounds can be produced from the bitterns. Subterranean brines also contain borax, calcium chloride, sodium carbonate, and sodium sulfate in addition to the above. Certain potash operations in the world also produce salt as a coproduct. When discharged to tailing ponds as a byproduct of potash mining, salt is often harvested and sold by second parties.

Economic Factors

Energy and labor costs are important factors that affect production costs, and ultimately the selling price, for all types of salt. After the salt is produced, shipping costs become very important when producers attempt to sell to a customer that is in

proximity to other salt producers. Industry sources indicate that within the United States, a 300-mile radius is an effective limit of competition for a producing location before the influence of other competitors is noticed. Some of the major U.S. producers also have foreign subsidiaries that produce salt, which is imported at prices favorable to many consumers because transportation costs are less.

Capital investment and energy costs are important factors that influence the selling price of the type of salt produced. Vacuum pan and open pan processing requires more equipment and energy than solution mining, and, consequently, the average value of evaporated salt is considerably higher than that of salt in brine.

Prices.—The four types of salt that are produced each have unique production, processing, and packaging factors that determine the selling prices. Generally, salt sold in bulk is less expensive than salt that has been packaged, pelletized, or pressed. Salt in brine is the least expensive salt sold because costs are less. Vacuum pan salt is the most expensive because of the energy costs involved in processing. Table 2 lists the historical values of the different types of salt since 1970. The data are compared with 1990 constant dollars to show the effect of inflation and general economic conditions on the values.

Tariffs.—The United States historically imports more salt than it exports. In 1990, U.S. salt imports were 2.6 times the level of salt exports. Imports from countries having most-favored-nation (MFN) status enter duty free. However, salt imported from non-MFN countries has a 26% ad valorum tax imposed.

Operating Factors

Environmental Requirements.—The environmental problems associated with salt mining are few and tend to be localized without major impacts on the environment. A major concern in solution mining is the potential of land subsidence. As the salt is dissolved, some roof collapse may occur, causing sections of the surface to partially or totally fill the cavity. Subsidence is unpredictable, and once the process begins, it must be allowed to finish and reach equilibrium. Another issue pertaining to solution mining is the potential problem of well casing leakage. Any excursion of salt brine could affect ground water supplies, which are protected

by various State and Federal water quality regulations. Solar evaporation facilities may substantially disturb coastal marsh areas because of the large extent of the lagoons needed for efficient operation.

Employment.—According to the Bureau of Labor Statistics, 1,659 people were employed in the mining and processing of rock salt in 1990. Of the 12 rock salt facilities surveyed, 854 personnel worked 1.75 million hours underground, 296 people worked 609,000 hours on surface duties, and 509 people worked 978,000 hours in the mills. Employment data for solar salt, vacuum pan salt, and salt in brine were incomplete or not surveyed by the Bureau of Labor Statistics.

Transportation.—The locations of the salt supplies often are not in proximity to the consumers' location, and transportation can become an important cost. Pumping salt brine through pipelines is an economic means of transportation but cannot be used for dry salt. Large bulk shipments of dry salt in ocean freighters or river barges are low in cost but are restricted in points of origin and consumption. River and lake movement of salt in winter is often severely curtailed because of frozen waterways. As salt is packaged, handled, and shipped in smaller units, the costs are increased and are reflected in higher selling prices.

Oceanborne imports of salt have been increasing in some areas of the United States because they are less expensive with respect to transportation costs than what could be purchased from many domestic suppliers using rail transportation. Salt continued to be one of the most heavily traded chemical industry ores in the world, representing about 66% of world seaborne mineral trade.

ANNUAL REVIEW

Issues

Nearly one-half of the domestic production of salt is for use as feedstock by the chloralkali industry to manufacture chlorine and coproduct caustic soda. This industry has undergone changes since 1988, when environmental concerns regarding emissions of chlorine-base compounds, such as those used in chlorofluorocarbons (CFC's) and in paper bleaching, reduced the demand of chlorine and thereby the availability of caustic soda. A decrease in chlorine production because of demand

changes will have a corresponding effect on salt production. The pulp and paper industry, which consumes about 14% and 24% of the domestic chlorine and caustic soda production, respectively, has been under investigation for discharging harmful effluents into the environment. Dioxin investigations have been conducted since 1983, and 104 bleached pulp mills were investigated in April 1988 by the U.S. Environmental Protection Agency to determine the cumulative risk of a certain dioxin (2,3,7,8 tetrachlorodibenzo-p-dioxin or TCDD) and a furan (2,3,7,8 tetrachlorodibenzo furan or TCDF) released by the processes. Dioxins are toxic synthetic compounds that have been identified as carcinogenic to some animals, but studies investigating their effect on humans are controversial and inconclusive. Some pulp mills have begun converting from chlorinebase bleaching chemicals to environmentally safe oxygen-base chemicals, such as hydrogen peroxide and sodium chlorate. Although less chlorine would be made, more sodium chlorate, which also uses salt as feedstock, would be produced.

The environmental issues that affected chlorine have caused a tightness in the caustic soda market that resulted in higher caustic soda prices. Since 1986, when there were large inventories of caustic soda in the world, prices have risen fourfold as demand increased. Although certain uses for chlorine are expected to decrease during the next several years, one major sector, polyvinyl chloride (PVC), would have favorable growth potential if the domestic economy improves to assist the building and residential construction industry. PVC, which is the second most widely used plastic after low-density polyethylene, remained the main use for vinyl chloride, chlorine's primary market accounting for 24% of the end use. Although domestic demand for PVC pipe and fittings has been decreasing since 1988, which indicated a slowdown in domestic construction starts, exports of PVC have been strong. Demand for vinyl chloride is anticipated to grow by more than 4% per year through 1994, which should ease some of the tightness for caustic soda as more chlorine will be required. To alleviate some of the caustic soda shortages, three domestic natural soda ash producers are also engaged in producing caustic soda directly from trona, the ore of natural soda ash, or from soda ash directly. Production of caustic soda from soda ash was the preferred method of manufacture until it was replaced by the electrolysis of salt around the turn of the century.

Production

According to the U.S. Bureau of Mines survey for 1990, 31 companies operated 69 salt-producing plants in 14 States. Eight of the companies and 11 of the plants produced more than 1 million short tons each and accounted for 85% and 58%, respectively, of the U.S. total. Several companies and

plants produced more than one type of salt. In 1990, 12 companies (17 operations) produced solar-evaporated salt; 5 companies (17 operations), vacuum pan salt; 10 companies (14 operations), rock salt; and 17 companies (29 operations), salt brine.

The four leading States in terms of total salt sold or used were Louisiana, 35%; Texas, 20%; New York, 13%; and Kansas, 6%. Although Louisiana, New York, and Ohio were major rock salt-producing States, a substantial amount of salt was produced in Alabama, Kansas, Louisiana, New York, Ohio, Texas, Utah, and West Virginia as brine for the chemical industry.

Consolidations and name changes occurred in the U.S. salt industry during 1990. The formation of North American Salt Co., through the mergers of three moderate-sized salt companies, resulted in North American becoming the third largest domestic salt producer.1 Carey Salt Holdings Ltd., a merger of the former American Salt Co. and Carey Salt Co., sought to acquire the Canadian assets of the Sifto Salt Div. of Domtar in 1989 as well as those of Domtar's Cote Blanche rock salt mine in Louisiana. On March 13, 1990, the U.S. Department of Justice determined that the acquisition of the Canadian operations was permissible but Carey Salt Holdings would have to divest itself of its Kansas rock salt operations because of possible antitrust violations before it would be allowed to acquire the Louisiana facility. The Canadian assets were acquired March 30, at which time Carey Salt Holdings merged with Domtar to become Carey Salt Co., a division of North American Salt. North American sold its two Kansas rock salt businesses to Hutchinson Salt Co. (formerly Carey Salt Co.'s rock salt mine) and to Lyons Salt Co. (formerly American Salt Co.'s rock salt mine) but retained the two vacuum pan facilities in Kansas and the solar salt plant at Grantsville, UT. North American was allowed to market the majority of the rock salt for the two Kansas rock salt companies. The Louisiana rock salt mine finally was purchased in November.

Hunter Environmental Services, Inc. of Southport, CT, obtained permits from the Texas Water Commission for developing a facility to process and dispose of hazardous waste into deep salt dome cavities. Using a mixture of portland cement and other additives, the waste would be formed into hard pellets and pneumatically pumped into the caverns of a 45,000-foot-deep salt dome. Final permits for the \$70 million project were pending at yearend.²

¹As reported at salt production locations. The term "sold or used" indicates that some salt, usually salt brine, is not sold but is used for captive purposes by the plant or company. Because data do not include salt imported, purchased, and/or sold from inventory from regional distribution centers, salt sold or used by type may differ totals shown in tables 9 and 10, which are derived from company reports. Data may not add to totals shown because of independent rounding.

The United States continued to be the world's largest producer of salt, accounting for about 21% of total world production. Production and trade of salt increased slightly compared with those of the previous year. World production of all types of salt decreased slightly. The depressed market for chlorine and the environmental problems associated with emissions of chlorinated compounds may affect the short-term status of the world chloralkali industry, which is the largest single consumer of salt.

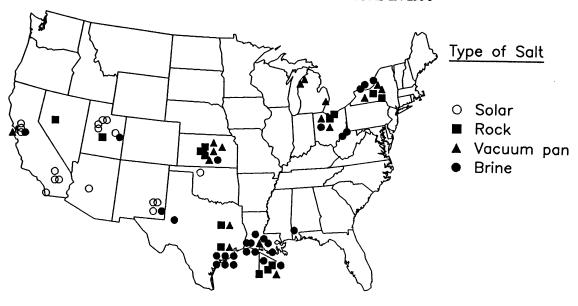

Consumption and Uses

More than 45.1 million tons of domestic and imported salt was consumed in the United States in 1990, based on the annual survey of the U.S. salt producers. The reported percent distribution of salt by major end use was chemicals, 47%; ice control, 25%; distributors, 10%; food and agricultural, 7%; industrial, 5%; primary water treatment, 1%; and other, combined with exports, 5%. Distributors represent a substantial share of salt sales by the salt industry; however, all the salt ultimately is resold to many end users. Some customers have specific uses. For a more complete analysis of end-use markets, specific sectors of distribution in table 9 can be combined, such as agricultural and water conditioning with agricultural and water conditioning distribution, respectively. On an annual per capita basis, the average citizen consumes about 360 pounds, based on an estimated U.S. population of 250 million and total reported consumption data in table 9. This total includes the amount of salt used by everyone in the above categories. Using the data for the food processing and three-fourths of the grocery wholesalers sectors from table 9, the quantity of salt used for direct human consumption is about 16.6 pounds per person per year.

The chemical industry is the largest consumer of salt, primarily salt brine. Although most salt brine is captively produced by chemical producers, many chlor-alkali manufacturers now purchase brine from independent brine supply companies. In certain cases, brine is captively produced by one chemical company, and any excess brine is sold to neighboring competitors. According to a survey of domestic salt-base chlorine facilities, about 48% of the salt used to manufacture chlorine was captive, and 31% was purchased brine. Purchased solar or rock salt comprised 12%, and imported rock, solar, and vacuum pan salt was 9%.

Using Bureau of the Census data, the chlorine and caustic soda industry consumed about 19.1 million tons of salt for feedstock, based on the industry average ratio of 1.75 tons of salt required to produce 1.0 ton of chlorine and 1.1 tons of coproduct sodium hydroxide. Reported consumption of total domestic and imported salt for chlorine manufacture was 19.2 million tons,

FIGURE 1
U.S. SALT PRODUCTION LOCATIONS IN 1990

as noted in table 9. The difference between the calculated and reported quantities was the amount of salt unreported to the U.S. Bureau of Mines from imports or captive brine production of chlor-alkali producers. Production of chlorine gas and liquid sodium hydroxide, as reported by the Bureau of the Census and The Chlorine Institute, is shown in table 11.

Table 12 lists the domestic chlorine-producing facilities that used only salt as feedstock. Based on these estimates and using Bureau of the Census chlorine production data, the U.S. salt-base chlorine industry operated at 88% of capacity. According to The Chlorine Institute, the industry operated at an average of 89% of nominal capacity and 95% of effective capacity in 1990. Because these capacities include chlorine produced from nonsalt sources, i.e., from the electrolysis of magnesium chloride and the oxidation of hy-

drochloric acid, these data may differ from other reported chlorine capacity utilization information.

Stocks

Total yearend stocks reported by producers were 1.9 million tons. Most of these inventories were rock salt and solar salt. Many States, municipalities, distributors, and road-deicing contractors stockpiled additional quantities of salt in anticipation of adverse weather conditions.

Markets and Prices

Price quotations are not synonymous with average values reported to the U.S. Bureau of Mines. The quotations do not necessarily represent prices at which transactions

Veyerhaeuser Co.	Longview, WA	130	228	Imported.
Total		12,419	21,734	imported.

Includes only those chlorine plants that use salt directly as a feedstock. Does not include plants that produce byproduct chlorine from magnesium chloride and hydrochloric acid oxidation or plants using potassium chloride. ²Based on 365 days per year.

³Based on 1.75 tons of salt required to manufacture 1.0 ton of chlorine with the plant operating at 100% capacity. Salt may be from natural brines, rock, or solar sources, domestic or imported.

Formerly Pennwalt Corp.

5An additional 730,000 tons available on standby basis; included in "Total."

6Includes LCP Chemicals and Hanlin Chemicals-West Virginia Inc.

NOTE.—The following plants closed in 1990: Dow at Pittsburg, CA; Olin at Niagara Falls, NY.

actually occurred, nor do they represent bid and asked prices. They are quoted here to serve only as a reference to yearend price levels. Yearend prices were quoted in Chemical Marketing Reporter, as shown in table 13.

Foreign Trade

Section 1205 of the Omnibus Trade and Competitiveness Act of 1988 required the United States to adopt an international nomenclature and metric units for reporting trade information. On January 1, 1989, the Harmonized Commodity Description and Coding System (HTS) replaced the Tariff Schedule of the United States, Annotated. for import data and schedule B for exports. Previously, salt imports had three different categories-bulk, other (formerly known as bags, sacks, and barrels), and salt in brine. Exports had one classification, sodium chloride-salt. Under the new HTS nomenclature, imports only have one category known as "Salt (including table and denatured salt) and pure sodium chloride, whether or not in aqueous solution, seawater." The same classification also applies to exports. The trade tables in this report list the previous and current identification codes for salt.

The United States imported in 1990 more than 2.5 times the quantity of salt that it exported. Although this would indicate that the United States is import reliant on salt to meet its salt requirements, the majority of imported salt was brought into the country by foreign subsidiaries of major U.S. salt producers. Generally, imported salt can be purchased and delivered to many customers at costs lower than the comparable domestic product because production costs are lower abroad and currency exchange rates are more favorable.

The Journal of Commerce's Port Import/ Export Reporting Service (PIERS) reported that Akzo Salt Co., American Salt Co., Carey Salt Co., Cargill Inc., Domtar Industries Inc., Morton International, and North American Salt Co. imported 52% of the total imports of 5.64 million tons. Five companies that manufacture chlorine, which was the single largest domestic salt market, consumed 26% of total imports, which were primarily solar salt. These companies were Atochem North America, Brunswick Pulp and Paper Co., Georgia Pacific Corp., LCP Chemical & Plastics Inc., Occidental Chemical Corp., and Weyerhaeuser Co. The salt and chlor-al-

XX Not applicable.

Net selling value, f.o.b. plant, excluding container costs.

²Salt value data previously reported were an aggregate value per ton of bulk, compressed pellets, and packaged salt. For time series continuity, an average of these three types of product forms is presented, which is based on the aggregated values and quantities of the product form for each type of salt shown in table 6.

kali producers imported 78% of total imports; the remainder was to many small direct buyers. Eleven domestic salt-producing companies exported 79% of the 704,909 tons exported in 1990, according to PIERS. The Journal of Commerce data contain only ocean commerce and no rail or truck trade between Canada and Mexico. These data may differ from total data reported by the Bureau of the Census. Tables 15 through 18 list the import and export statistics reported by the Bureau of the Census for 1989 and 1990.

World Review

Table 19 lists world salt production statistics for 97 countries based on reported and estimated information. World production decreased 4% in 1990 compared with that of the previous year. Since 1971, world salt production has increased more than 27%, whereas world population has risen 44%, from 3.63 billion to 5.3 billion individuals. Based on these statistics, the world annual per capita consumption has decreased from 88 pounds to 76 pounds.

Industry Structure.—The United States remains the world's leading salt-producing nation, representing about one-fifth of total world production. The structure of the U.S. industry has changed throughout the years. In 1970, there were 50 companies operating 95 plants in the United States. Market competition, energy and labor costs, less expensive imports, and an excess of production capacity reduced the size of the industry to 31 companies and 69 plants by 1990.

Most countries possess some form of salt production capability with production levels set to meet their own domestic demand requirements with additional quantities available for export. Many developing nations tend to develop their agricultural resources first to feed their population. Development of easily extractable mineral resources follows with salt being one of the first commodities to be mined. Some countries, such as the United States, import a substantial amount of salt to meet total demand requirements because of economic factors.

Capacity.—Each type of salt produced in the world has unique mining, processing, and marketing characteristics that determine the criteria for deriving rated capacities. The data shown in tables 12 and 20 are rated capacities for mines and refineries and salt requirements for salt-base chlorine facilities as of December 31, 1990. Rated capacity is defined as the maximum quantity of product that can be produced in a period of time on a normally sustainable long-term operating rate, based on the physical equipment of the plant, and given acceptable routine operating procedures involving labor, energy, materials, and maintenance. Capacity includes both operating plants and plants temporarily closed that, in the judgment of the author, can be brought into production within a short period of time with minimum capital expenditure. Capacity data were derived from industry sources, published reports, and estimates based on production trends.

Rock.—Because the majority of rock salt was used for deicing, the operating rate of rock salt facilities fluctuated with the demand for deicing salt, again dependent on the severity of winter weather conditions. During periods of strong demand, production levels often achieve, or exceed in certain situations, the rated capacities. Full mine capacity generally is a function of the

hoisting capabilities of the mines. Assuming that the workweek is 5 days (250 workdays per year), two working shifts and one maintenance shift per day, and at least one short-term planned turnaround for the mine and mill per year, table 20 lists the production capacities for domestic rock salt operations.

Solar.—Solar salt, also known as marine and sea salt, is obtained from the solar evaporation of seawater, of landlocked bodies of saline water, and of discharged brines. Because evaporation rates must exceed the precipitation rates, the climatic conditions and geographic locations of solar evaporation facilities are critical to the successful production and harvesting of solar salt. Therefore, rated capacities generally are based on the historical evaporation patterns within a region and vary depending on the location and the surface areas of the evaporation ponds. Only unpredictable seasonal precipitation and market conditions usually affect the production.

Vacuum Pan.—The mechanical evaporation of salt by the vacuum pan process is dependent on the number and size of the vacuum crystallizers operating in series. Rated capacities are usually easier to establish because of the proven design performance of the equipment.

Brine.—Brine capacities are difficult to derive because they are based on the variabilities of the injection rate of the solvent and the solubility rates of the underground salt bodies. Both determine the quantity of brine produced. In addition, production levels are dependent on the demand for the products that the brine is being used to manufacture. Therefore, individual company brine capacities are not included in table 20.

Table 12 lists the quantity, type, and source of the salt required to manufacture chlorine. The amount of brine purchased or used captively is close to the quantity of brine used for chlor-alkali production as noted in table 9.

Australia.—Dampier Salt Co. announced plans to increase solar salt production capacity by 500,000 tons at its Dampier, Western Australia, facility by 1992. The \$23 million project will raise total company capacity to 4.5 million tons, which includes 1.5 million tons of solar salt capacity at Lake MacLeod. The project has the potential of raising total capacity to 7 million tons in the future if necessary.³

Gulf Holdings Pty. Ltd. proposed the construction of an \$80 million 1.5- million-ton-per-year solar salt operation southeast of Onslow. Production was scheduled for late 1992.⁴

Botswana.—Soda Ash Botswana, which is a joint venture between the Botswanan Government (47%) and a consortium of African Explosives and Chemical Industries (26.5%), Anglo American (13.25%), and De Beers Holdings (13.25%), finished construction of its salt and natural soda ash facility at Sua Pan in the Makgadikgadi Basin. About 650,000 tons of salt and 300,000 tons of soda ash will be produced annually, with the majority of the commodities being sold to the Republic of South Africa.⁵

Canada.—North American Salt Co. through Carey Salt Holdings, Inc., acquired the assets, on March 30, 1990, of Domtar Inc.'s Sifto Salt Div., which had salt operations in Goderich, Ontario; Nappan, Nova Scotia; and Unity and Patience Lake, Saskatchewan. As part of a consent agreement, the U.S. Department of Justice excluded Domtar's Cote Blanche rock salt mine near Baldwin, LA, from the transaction until North American relinquished its holdings in two Kansas rock salt mines. The Canadian facilities will operate as North American's Canadian subsidiary known as

^eEstimated. ^pPreliminary. ^rRevised.

¹Table includes data available through June 14, 1991.

²Salt is produced in many other countries, but quantities are relatively insignificant and reliable production data are not available. Some salt brine production data for manufacture of chlorine, caustic soda, and soda ash are not reported because of incomplete data reporting by many countries.

³Reported figure.

⁴Year ending June 30 of that stated.

⁵Less than 1/2 unit.

⁶Brine salt production as reported by the Burmese Government in short tons was as follows: 1986—52,281 (revised); 1987—63,760 (revised); 1988—65,883 (revised); 1989—66,391; and 1990—68,000 (estimated).

⁷Year begining Mar. 21 of that stated.

⁸Does not include production from Sardinia and Sicily, estimated at 200,000 metric tons annually.

⁹Year ending July 15 of that stated.

¹⁰ Data captioned "Brine salt" for the United Kingdom are the quantities of salt obtained from the evaporation of brines; that captioned "Other salt" is the salt content of brines used for purposes other than production of salt by evaporation.

Operated as Akzo Salt of Utah Inc., a wholly owned subsidiary of Akzo.

²Operated by Leslie Salt Co.

³Closed Dec. 1990.

⁴Formerly Carey Salt Co's, rock salt operation. The vacuum pan salt operation is owned by North American Salt Co. effective Dec. 1990.

⁵Formerly American Salt Co's. rock salt operation. The vacuum pan salt operation is owned by North American Salt Co. effective Dec. 1990.

⁶ New company formed by the acquisition of the Kansas vacuum pan salt operations of American Salt Co., and Carey Salt Co., and the rock salt and solar salt facilities of Domtar Industries Inc., in Louisiana and Utah, respectively. Includes brine for sale and for captive use. Brine production capacity is assumed to be equal to the quantity of annual brine production, as shown in tables 4 and 5. Brine producers include those chlor-alkali manufacturers that purchase brine or use captive brine, as listed in table 12.

Sifto Canada, Inc., whereas the Louisiana rock salt plant will be under North American Salt Co.

Chile.—Asahi Glass Co. of Japan obtained a contract to import 235,000 tons of Chilean rock salt by yearend 1991. The high-purity rock salt, which is more pure than the solar salt from Australia and Mexico, where Asahi had been purchasing, will be used for feedstock in Japan's chloralkali industry.⁶

China.—A rock salt mine with reserves of 1.2 million tons began operation at Dingyuan, Anhui Province. The mine had an initial capacity of 100,000 tons per year. Prior to the startup of the mine, the Province obtained its salt from solar salt operations in adjacent Provinces.⁷

Tanzania.—Coastal Salt Works received \$3 million of financial aid from Italy to increase salt production at Sadani, which is north of Dar es Salaam. Annual salt production is slated to rise from 10,000 tons to 40,000 tons by 1992, with total capacity reaching 100,000 tons in the future.⁸

OUTLOOK

Of the approximate 14,000 uses of salt, only two continue to arouse public interest,

namely, the deleterious effects of salt on the environment, bridge decks, and automobiles due to highway deicing, and the hypertension issue caused from too much salt in the diet.

The salt industry has been responsive to the public's awareness of the corrosion problems associated with highway deicing. Five of the major salt producers have developed corrosion inhibitors that, when added to rock salt, will reduce the corrosive action to bridges and roads when using rock salt during the winter. Although calcium magnesium acetate (CMA) is a noncorrosive deicer, it is very expensive when compared with regular rock salt or the corrosion inhibitor-treated salt. Cheese whey has also been examined as an alternate way to manufacture CMA. About 20 billion pounds of unused whey is produced in the United States annually. Work is still being done to reduce production costs. The outlook for treated-salt products is very favorable, especially in areas of the country that want to regulate the use of deicing salt.

The construction industry has also responded to the corrosion problems. Resincoated reinforcement rods and wire have helped reduce the corrosive damage to roads. Special containment and runoff guards on bridges have lessened the damage salt causes to roadside environments.

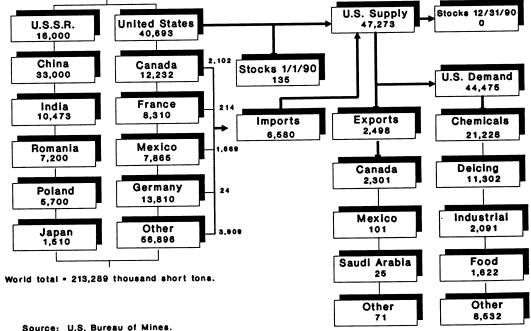

Progress has been made, and will continue to be made in the 1990's, in combating the adverse effects of salt on the environment.

After a decade of research and millions of dollars spent on studies, there is still no positive proof that salt causes high blood pressure. Health authorities had advised health-conscious people to restrict their salt intake to reduce hypertension. Newer studies indicated that of the 60 million U.S. citizens who have high blood pressure, only about one-half of them are "salt sensitive," or about 10% of the U.S. population. The remaining majority of the population do not show any severe adverse reactions to higher salt intake.

INTERSALT, which was an international salt study done by the World Health Organization in 1988, received very little attention in the medical community. The study analyzed the salt consumption patterns of 10,079 men and women in 52 communities in 32 countries. It concluded that there was no relationship between how much salt people ate and their blood pressures.9 If people decreased their salt consumption by 6 grams daily, they would reduce their diastolic pressure by one-tenth of a point. Maintaining a reasonable weight, quitting smoking, reducing alcohol intake, exercising, and reducing fat intake play greater roles in controlling blood pressure than salt consumption.

FIGURE 3

SALT SUPPLY-DEMAND RELATIONSHIPS—1990 World production (Thousand short tons) U.S. Supply

In November, the Federal Government modified its dietary guidelines from "avoid too much sodium" to "use salt or sodium in moderation." The Salt Institute, which is the trade association for the majority of the producers, and the U.S. salt industry have worked closely and effectively with salt consumers and the public to educate them and to promote the benefits of salt.

Between 1970 and 1990, world salt production has increased about 1.3% per year,

while the United States had a -1%-per-year rate of decline in production and -0.7%-per-year decline in consumption. The negative growth rate for the United States was for total salt. It should be noted that the dry salt component (vacuum pan, solar, and rock) grew at about 0.5% per year. Production and consumption of brine declined since 1970, causing the growth rate for the commodity to decline proportionally. Brine consumption decreased because of the de-

mise of the synthetic soda ash industry, which used salt brine as feedstock. In 1970, there were eight synthetic soda ash plants in operation in the United States; only one was in existence in 1979. It closed in 1986.

In the 1980's, world production increased 1.2% per year, while U.S. production declined -0.8% annually, and consumption decreased about -0.5% per year. As with the previous assessment of the industry, domestic dry salt usage grew 1.2% per year

Represents that amount sold or used captively within the industry, from the quantity produced and any sold from inventory. Accurate data on beginning and yearend inventories of salt are unavailable and often are underreported because of additional storage underground at mines, warehouses, terminals, etc. However, about 2.5 million tons is estimated to be stored annually nationwide.

²The total quantities of salt in inventory are underreported and are excluded in determining the supply-demand balance relationship for salt. However, the difference between production and sold or used is assumed to be because of changes in inventory.

³Includes imports for consumption.

Includes salt used in rubber; tanning; other industrial; institutional wholesalers and/or retailers; U.S. Government resale; other wholesalers; some exports for consumption in overseas territories administered by the United

States; and other various minor uses. ⁵Represents the difference between the quantity reported to the U.S. Bureau of Mines and total U.S. primary demand. The amount of discrepancy is attributed to variances in inventory and import statistics.

Values are based on the average of all salt producers' valuations reported for bulk, f.o.b. plant, and includes all processing costs, depreciation of equipment, taxes, and profit.

since 1980, while salt brine consumption decreased. The outlook for salt in the 1990's is optimistic; however, consumption of salt for chlor-alkali manufacture will continue to decline for the rest of this decade. The major producers have diversified into all types of salt across the Nation and have developed reliable import sources in Canada, the Caribbean, Mexico, and South America. Consolidations and restructuring within the U.S. salt industry have strengthened it into a competitive North American enterprise in the Western Hemisphere.

CONSTRUCTION SAND AND GRAVEL

By Valentin V. Tepordei

Mr. Tepordei, a geological engineer with more than 20 years industry experience, has been the construction sand and gravel commodity specialist with the U.S. Bureau of Mines since 1979. Domestic survey data were prepared by the construction sand and gravel survey staff of the Branch of Data Collection and Coordination.

onstruction sand and gravel is one of the most accessible natural resources and a major basic raw material used mostly by the construction industry. Despite the relatively low value of its basic products, the construction sand and gravel industry is a major contributor to and an indicator of the economic well-being of the Nation.

A total of 911 million short tons of construction sand and gravel was produced in the United States in 1990, a 1.5% increase compared with the estimated total of 1989. This tonnage represents the fifth consecutive year of production of more than 880 million tons, indicating a continuation of the strong demand for construction aggregates in the United States.

Foreign trade of construction sand and gravel remained relatively minor. Exports decreased 58.4% to 468,000 tons, while value decreased 12.6% to \$11.9 million. Imports increased 191.3% to 1.7 million tons, while the value increased 138.1% to \$22.9 million. Domestic apparent consumption of construction sand and gravel was 912 million tons.

The implementation of the provisions of the amended Federal Water Pollution Control Act of 1977, the Clean Water

Act, section 404, dealing with "wetlands" and the establishment of a "no net loss of wetlands" policy constitutes one of the major areas of concern to the construction sand and gravel industry. The new regulatory requirements being proposed by the Occupational Safety and Health Administration (OSHA) continue to be the other areas of concern for the industry. They include the revised asbestos standards governing occupational exposure to nonasbestiform varieties of actinolite, tremolite, and anthophyllite minerals, and the final promulgation of the permissible exposure limit for crystalline silica measured as respirable silica.

DOMESTIC DATA COVERAGE

Domestic production data for construction sand and gravel are developed by the U.S. Bureau of Mines from voluntary surveys of U.S. producers. Full surveys of construction sand and gravel producers are conducted for even-numbered years only. For odd-numbered years, only annual estimates for each State are generated based on information provided

by the new quarterly sample survey of construction sand and gravel and crushed stone producers. This survey provides production estimates by quarters for each State and the nine geographic regions. The sample surveys canvass most of the large companies in each State, accounting for up to 80% of each State's total tonnage. The results of this survey are published each quarter in a separate publication, the Quarterly Mineral Industry Survey.

BACKGROUND

Sand and gravel is a granular, unconsolidated, and usually rounded agglomeration of particles of rocks and minerals, resulting primarily from the natural disintegration and abrasion of rocks through weathering or erosion. Sand and gravel, as one of the most accessible natural resources, has been used since the earliest days of civilization, mostly as a construction material. At the beginning of the 20th century, the U.S. production of construction sand and gravel, the sand and gravel used mostly for construction purposes, was relatively small and its uses

limited. Today, annual sand and gravel production tonnage ranks second in the nonfuel minerals industry after crushed stone and is the only mineral commodity produced in all 50 States. The United States is, in general, self-sufficient in sand and gravel, producing enough to meet all domestic needs and to be a small net exporter, mainly to consumption points along the United States-Canadian and United States-Mexican borders.

Most sand and gravel is used for construction purposes, mainly as aggregate in concrete; as road base material in the construction and repair of highways, railways, and runways; and as aggregate in asphaltic concrete for paving highways, streets, etc. Construction sand and gravel has one of the lowest average per ton values of all mineral commodities. The constant dollar price has changed relatively little over the past 20 years. Increased operating costs have been partially offset by automation and other means of increasing operating efficiency.

Although construction sand and gravel resources are widespread and in adequate supply nationally, local shortages exist. Land use conflicts and environmental problems associated with rapid urban expansion are major factors contributing to these shortages. In addition, in some geographic areas with sufficient resources, some shortages occur because the proportions of various size fractions of sand or gravel may not meet size specifications of the construction industry. Demand pressures, land use regulations, and the cost of meeting environmental and reclamation requirements are factors that will cause a rising price trend. Larger operations with more efficient equipment, more automation, and better planning and design will be the trend of the industry in the future. This will permit increased use of less accessible and lower quality deposits and will keep prices at competitive levels.

Definitions, Grades, and Specifications

Sand is defined throughout the industry and by the American Society for Testing and Materials (ASTM) as naturally occurring unconsolidated or poorly consolidated rock particles that pass through a No. 4-mesh (4.75-millimeter) U.S. standard sieve and are retained on a No. 200-mesh (75-micrometers) U.S. standard sieve. Gravel consists of naturally occurring unconsolidated or poorly consolidated rock particles that pass through a sieve

with 3-inch (76.2-millimeters) square openings and are retained on a No. 4-mesh U.S. standard sieve.

Sand and gravel is made up of varying amounts of different rock types and is, therefore, of varying chemical composition. Silica is the major constituent of most commercial sands, and lesser amounts of feldspar, mica, iron oxides, and heavy minerals are common. Most applications of sand and gravel have specifications for size, physical characteristics, and chemical composition. A compilation of 42 ASTM Specifications and Test Methods, including the latest revisions and updates pertaining to aggregates, concrete, and admixtures, was reprinted by the National Aggregates Association. ¹

Specifications for sand and gravel used in roadbuilding and concrete construction are usually rigid regarding particle size gradation and shape and include physical as well as some chemical properties. However, these specifications can differ in detail from State to State or even from city to city within the State. Soil conditions, climate, and peculiarities in different deposits may necessitate adjustments of requirements of sand and gravel mixtures and chemical composition.

Specifications are written by commercial users; Government agencies, including Federal; State, county, and city construction and highway departments; and the ASTM. Problems arise for the producers of construction aggregates when their product is sold or used in several different cities, counties, or States, many of which may have different specifications. Some progress is being made toward the standardization of aggregate sizes for similar requirements. A need exists for a more active interchange of data and experience among aggregate consumers and producers.

Products for Trade and Industry

Concrete is made by mixing properly sized aggregate, portland cement, and water into a slurry. Chemical action between the cement and the water results in the crystallization of hydrous calcium aluminum silicates, which causes the mass to bind and harden. Round particles in the aggregate are desirable because they improve the workability of the concrete as it is poured. If broken material is used and angular or flattish fragments exceed about 15% of the total volume, workability can be maintained only by increasing the amount of sand and water, thus reducing

strength, or by adding more cement, thus increasing the cost of the concrete.

Sized and broken sand and gravel is used to make asphaltic concrete aggregate and road bases. Broken surfaces adhere to the hot asphaltic mixture better than do rounded surfaces and provide interlocking surfaces that tend to strengthen the asphaltic concrete. Broken particles pack better and tend to move less under load than do rounded particles and, therefore, make better road bases for highway and road construction. This is essential because bases and asphaltic concrete tend to flow when placed under great or long duration stresses.

Industry Structure

Because of the low unit value, construction sand and gravel is produced near the point of use; therefore, the industry is concentrated in or nearby large, rapidly expanding urban areas and, on a transitory basis, in areas where highways, dams, and other large-scale public and private works are under construction. In the United States, sand and gravel is produced in every State. The largest operations tend to be concentrated in the States with the largest population and largest production of sand and gravel.

Construction sand and gravel is produced in virtually all countries, but relatively few of them survey this industry and even fewer regularly publish official statistics on sand and gravel.

On the basis of tonnage, the construction sand and gravel industry is the secondlargest nonfuel mineral industry in the United States. In 1990, there were 4,094 companies producing construction sand and gravel operating 5,665 pits. The individual operations range in size from those producing millions of tons annually to those reporting less than 25,000 tons per year. Most operations are small, turning out one product or a limited range of products, but most of the tonnage comes from large operations. For example, the 18 operations reporting more than 2.5 million tons each in 1990 represented only 0.3% of the total number of operations but produced 8% of the total tonnage, while 101 operations reporting between 1 and 2.5 million tons each, representing only 1.8% of the total number of operations, produced 15.5% of the total tonnage. For the same year, most of the construction sand and gravel was produced by operations reporting between 200,000 and 1 million tons each; 1,094 operations, representing 19.2%, produced 49.2% of the total tonnage.

The leading companies producing construction sand and gravel, in descending order of tonnage, based on the 1990 survey, were Beazer U.S.A. Inc. of Pittsburgh, PA; CalMat Co. of Los Angeles, CA; CSR Ltd., of Sydney, Australia; Tarmac America of Herndon, VA; and Teichert Aggregates of Sacramento, CA. The top five companies operated 122 pits and produced 10.5% of the U.S. total. Three of these five companies are subsidiaries of foreign companies. Many producers are in the sand and gravel business exclusively, but others are diversified in various degrees in the production of other mineral raw materials, intermediate construction products such as ready-mixed concrete and concrete blocks, final manufactured products, or construction of buildings, roads, and other structures. At the same time, construction companies are entering more and more into the sand and gravel business to integrate their operations.

Geology-Resources

The processes of formation and deposition impart to sands and gravels the physical characteristics that largely determine the commercial value for a particular use and influence the manner of development. The principal types, based on origin, are stream, glacial, residual, marine, and lake. Windblown deposits are of minor importance. Much of the commercial production is from stream deposits, many of which are deficient in the fines required by present-day grading specifications for concrete aggregates. Stream deposits usually exhibit stratification and often large size gradation. The beds vary in thickness and sometimes have interspersed lenses of clay or fine sand. The degree of roundness and the particle size varies with the hardness and distance transported. Glacial deposits have the least sorting of all transported deposits, while marine and lake deposits exhibit the best sorting with coarse and fine particles, often well segregated. Residual deposits are found overlying the parent rock and are unstratified mixtures of pebbles, boulders, sand, and clay. They often contain much soft material that prohibits commercial production. Marine or offshore deposits could become more important as inland deposits become depleted or environmentally less desirable to extract. A comprehensive report showing geologic occurrences of potential sources of sand and gravel and crushed stone of the conterminous United States for use as natural aggregates was published by the U.S. Geological Survey.²

On the basis of geologic evidence, world reserves are sufficient to meet demands, although not necessarily at precisely the locations where needed. Reserves, which are measurable amounts of sand and gravel that can be produced profitably with current technology under existing economic and political conditions, are controlled mostly by land use and/or environmental constraints. The total sand and gravel resources of the United States are very large. However, the geographic distribution and/or quality of the reserve base often does not match market patterns or requirements.

Technology

Major technological developments that have been instrumental in maintaining adequate production at relatively stable real costs include use of larger operating units, more efficient portable and semiportable plants, unitized plants for versatility of plant capacity, new prospecting methods utilizing aerial and geophysical surveying methods, and greatly increased rehabilitation and resale of mined areas. Use of mined-out pits as lake beds and as sanitary landfill areas has been successful at numerous localities. Automatic controls, along with monitoring by closedcircuit television coordinated with automated counting and recording and radio communications systems, have been installed in many of the larger and newer operations; these, along with the use of improved equipment, have permitted recovery of salable fractions from deposits previously considered too low in quality for profitable exploitation. These practices will increase as pressures build to increase productivity and minimize environmental conflicts.

Exploration.—Sand and gravel deposits, like any mineral deposit, must be explored and evaluated before development. Preliminary examination can establish the extent and nature of the deposits. This is followed by a detailed exploration program aimed at obtaining reasonably accurate information on the quantity of material available, the degree of uniformity throughout the deposit, and especially,

variations in particle size, both vertically and horizontally. Also the nature and amount of waste materials and the economic feasibility of their removal must be studied.

Geophysical methods are of value in preliminary surveys. Detailed exploration may be achieved by a systematic arrangement of test pits, trenches, boreholes, or other procedures designed to obtain a cross section of the deposit in conjunction with sampling and testing. Advances in interpretation of aerial photographs and increased application of geophysical techniques have made evaluation of sand and gravel deposits more quantitative. For underwater exploration, mining devices such as dredges and draglines are used. Pilot runs are necessary to determine if required specifications can be met consistently and economically.

Much of the sand and gravel that is being mined in stream, floodplain, alluvial fan, riverbeds and terrain, and glacial deposits is good quality material with nearly equal amounts of gravel and sand and small amounts of unusable material. As these deposits become depleted in future years, less desirable and more expensive sources will have to be developed where mining, reserves, ratio of sand to gravel, quality of material, waste factors, and environmental factors such as waste disposal will present more problems.

Exploration and planning will become more important in assessing deposits, particularly hillslope deposits of older sand and gravel. Grading to meet required slope and setback requirements at hillslope sites may necessitate leaving large tonnages of material unmined. Many millions of tons of material is available, but it may not be of proper quality or ratio of sand to gravel. More deposits of marginal quality will have to be developed to provide for future demand.

Mining.—Sand and gravel generally occur in the same deposit, but the relative proportions of each vary greatly within most deposits. Consequently, the control problem of producing aggregate to rigid specifications involves combinations of many types of equipment like screens, washers, classifiers, crushers, and grinding mills. The two basic sand and gravel mining methods are open pit excavation and dredging. Open pit excavation and processing has four major steps: (1) site clearing—removing trees and vegetation, stripping overburden and topsoil, and trans-

porting, redepositing, or stockpiling it at or off the site; (2) mining—removing the sand and gravel from the deposit; (3) processing—screening, washing, crushing, blending, and stockpiling the mined material to conform to standards and specifications; and (4) reclamation of the extraction area. Processing may or may not take place at the mining site. Mining equipment ranges from small, simple units such as tractor-mounted high-loaders and dump trucks to more sophisticated systems involving large power shovels, draglines, bucketwheel excavators, and belt conveyors. Increasingly, mining systems are being designed to provide for more efficient and economical land reclamation.

Mining with a dredge usually involves mounting the equipment on boats or barges. Suction or bucket-type dredges are used most commonly to harvest sand and gravel from the bottom of a body of water. The sand and gravel is processed either on board or transported to land for processing.

Processing.—Although small amounts of unprocessed bank-run sand and gravel are used for fill, most of the U.S. production is processed in some way. Present methods include washing with water during the screening process, in some cases followed by crushing of the larger particles in cone or gyratory crushers. Secondary crushing may be done by roll crushers. Sizing is done in most plants by horizontal or sloped single or multideck vibratory screens. If necessary, heavy-media separation or jigging is used to remove heavy, unusable materials. Sand for use in construction is freed from clay by log washers or rotary scrubbers. The scrubbing is followed by classification, use of separatory cones or hydroseparators to remove water, and fine screening for grading. In many cases, rodmilling is required for production of small-sized fractions of sand. Transfer of processed sand and gravel from the processing plant to stockpiles or bins is accomplished by flexible combinations of conveyor belts, bucket elevators, and screw conveyors.

Permanent installations are built when large deposits are to be operated for many years. Portable and semiportable units are used in many pits that have an intermediate working life. Several such units can be tied together to obtain large initial production capacity or to add capacity as needed. Mobile screening plants can be quickly moved from one deposit to an-

other without undue interruption or loss of production.

Recycling.—As the Nation moves into an age of increased environmental consciousness, recycling of old concrete and asphalt, used mostly in pavements, is increasing. Local scarcity or high cost of construction aggregates in some areas as well as waste disposal problems are making recycling more attractive economically. In some States, limited recycling, especially in road construction, is either encouraged or required by law. The best utilization for recycled cement concrete is as road base material, because the matrix of concrete cannot be converted back to cement, and also because of the lower strength of concrete compared with that of natural aggregates. Sound crushed concrete can make good coarse aggregate, but the fines produced in crushing the concrete have a higher absorption, are more friable, and will require a higher amount of asphalt in asphaltic concrete and a higher amount of mixing water in portland cement.3 The amount of asphalt roads recycled is significantly larger than that of concrete roads, mainly because asphalt can be rejuvenated with oil additives and used in pavements, significantly reducing the cost of the finished road. Experience has shown that about 35% of crushed asphalt pavement can be recycled into new asphalt mixtures. Proper testing under engineering supervision in all construction projects using recycled materials as aggregates should be performed to ensure that the technical specifications are

Byproducts and Coproducts

Small amounts of gold and silver are recovered as a byproduct or coproduct of sand and gravel extraction, particularly in highly sorted deposits.

Economic Factors

Construction sand and gravel is a highvolume, low-value commodity. The industry is highly competitive and is characterized by thousands of operations serving local or regional markets. Production costs vary widely depending on geographic location, the nature of the deposit, and the number and type of products produced. Constant dollar unit values have been quite steady during the past 20 years. As a result of rising costs of labor, energy, and mining and processing equipment, the average unit price of construction sand and gravel increased from \$1.1 per ton, f.o.b. plant, in 1970 to \$3.57 in 1990. However, the unit price in constant 1982 dollars fluctuated between \$2.64 and \$2.71 per ton for the same period. Increased productivity achieved through increased use of automation and more efficient equipment was mainly responsible for maintaining the prices at this level. Constant dollar prices are expected to rise in the future because of decreased deposit quality and more stringent environmental and land use regulations.

Accessibility is a problem for the construction sand and gravel industry. The high-volume and low unit-value of sand and gravel requires that operations be close to the market location. Markets for sand and gravel are construction sites that are mostly in areas of high population density. New operations, close to population centers, are difficult to develop because the land is often attractive for other uses such as housing, shopping centers, agriculture, parks or recreational areas, and because of public dislike for mining

TABLE 2

operations close to populated areas. Existing operations in expanding communities face increasing costs because of increasing land values and increasing restrictions on operations as suburban development comes closer. Deposits are generally small and, once exhausted, the operation must be moved to a new site that invariably is farther from the market because closer sites are being used for other purposes.

The industry also faces increasing competition from crushed stone that can substitute for sand and gravel in most of its applications. Stone operations are generally longer lived, can afford greater capital investment for higher efficiency, and are often located where competing land use pressures are less severe. The topographically rugged stone-bearing areas are usually less desirable for construction purposes than sand-and-gravel-bearing areas, which are generally flatter.

A 5% depletion allowance based on gross income is allowed for construction sand and gravel. There are no import tariffs.

Operating Factors

Many States, counties, and cities in the United States have zoning laws, and land within each governmental unit is usually zoned to indicate acceptable land uses. If mining is permitted in a zone and a sand and gravel company owns or leases land within that zone, the company may apply for a use permit or its equivalent to begin an operation. If the parcels to be quarried are on lands under both city and county jurisdiction, permits usually must be obtained from each. An acceptable reclamation plan that meets the guidelines or regulations of the appropriate governmental agency must also be approved. Environmental concerns such as noise, dust, beautification, and storage of wastes must be accounted for in a manner satisfactory to the governmental entity involved. Wastewater discharge requirements must be planned for and met. If the deposit to be worked is on a river or land controlled by a river or water or flood-control agency, whether municipal, State, or Federal, that agency's requirement must also be satisfied.

In most States, permits for sand and gravel operations require an Environmental Impact Report (EIR) or Environmental Impact Statement (EIS). A reclamation plan and a use permit application

may also be required, with considerable overlap of subject matter with the EIS. A complete EIS may cover all the problem areas at once and facilitate acceptance.

Environmental Requirements.—Two main points are involved in environmental land use and reclamation factors. First, the industry must be concerned about any practices that can affect the community environment. An effective effort must be made to reduce noise, air, and water pollution; to reclaim pits after the operation is complete; and to improve the overall appearance of the operating mine, processing plant, and transportation facilities. Second, the industry and community must recognize the time and costs required to protect the environment and the importance of agreeing on fair and realistic environmental standards.

Because sand and gravel is a local commodity, the effect of supply deficiencies and cost of material will affect the local community first. Undue delay and unreasonably high cost can strongly affect the movement of sand and gravel into the marketplace. Also, stringent controls by the local government that prevent permits being issued to operators can have adverse economic effects on the communities around them. These conditions can make it difficult to assess the timing and even the possibility of plants going on-stream and can therefore affect the supply of sand and gravel into the marketplace.

Although much progress is being made through premining planning, the sand and gravel industry continues to have problems with environmental controls, land use conflicts, and reclamation practices. Many of these problems are acute because extraction areas and plants must be reasonably near to consumers who are largely in metropolitan areas. Major environmental considerations that must be dealt with in mining and processing sand and gravel are emission of particulate matter into the air, processing water discharge, noise abatement, and employee and public health and safety.

Transportation.—Transportation is a major factor in the delivered price of construction sand and gravel. The cost of moving construction sand and gravel from the plant to the market often exceeds the sales price of the product at the plant. Because of the high cost of transportation, construction sand and gravel continues to be marketed locally. Economies of scale,

which might be realized if fewer, larger operations served larger marketing areas, would probably not offset the increased transportation costs.

Truck haulage is the main form of transportation used in the construction sand and gravel industry. Many producers have their own truck fleet and deliver their own raw materials and products. A significant and increasing amount of sand and gravel, however, is being hauled by independent truckers because of the cost of maintaining a truck fleet, particularly when the market is highly variable or down. Rail and water transportation combined account for about 10% to 20% of total construction sand and gravel shipments.

ANNUAL REVIEW

In 1990, the construction sand and gravel industry reached the sixth highest production level ever recorded and the fifth consecutive year of production of more than 880 million tons. This high level of production indicates a continuation of the strong demand for construction aggregates. During the year, production of construction sand and gravel increased in the first, second, and fourth quarters of 1990 compared with the same period of 1989, while remaining at the same level with the prior period in the third quarter of 1990.

Legislation

On November 15, 1990, the U.S. Congress enacted the 1990 Amendment to the Clean Air Act of 1970, Public Law 101-549. Most of the regulatory programs and air quality standards established by the original Clean Air Act of 1970 were revised, and new provisions were amended. The new clean air law contains 11 parts covering the following: National Ambient Air Quality Standards, Mobile Sources, Hazardous Air Pollutants, Acid Rain Control, and Stratospheric Ozone Protection. The new law will be implemented through rules written by the Environmental Protection Agency (EPA) and laws passed by the States. The standard for measuring the amount of solid or liquid "particulate" matter suspended in the atmosphere (PM-10) and the designation of PM-10 noncompliance areas, the new system of operating permits, and the enforcement and review of Air Pollutant Emission Factors are areas that will have an impact on the construction sand and gravel industry.

On October 28, 1990, the U.S. Congress approved the Department of Transportation's appropriation bill, which increased funding for the Federal highway and airport programs. The Federal Highway Program increased from a total of \$13.5 billion in fiscal year 1990 to \$16 billion in fiscal year 1991. The Airport Improvement Program increased from \$1.4 billion in fiscal year 1990 to \$1.8 billion in fiscal year 1991. The U.S. Congress also approved the Omnibus Budget Reconciliation Act of 1990, which increased the Federal motor fuels taxes by 5 cents, divided 50-50 between the General Revenue Fund and the Highway Trust Fund.

On February 7, 1990, the EPA and the U.S. Army Corps of Engineers (USACE) signed a revised Memorandum of Agreement (MOA) intended to clarify the policies and procedures to be used by their field personnel in determining compliance with the provisions of section 404 of the amended Federal Water Pollution Control Act of 1977, the Clean Water Act. dealing with "wetlands." A Wetland Delineation Manual developed by the EPA, the USACE, the U.S. Department of Agriculture, and the U.S. Fish and Wildlife Service was published with the intent to bring consistency to the definition process of wetlands for Federal regulatory purposes.

On February 12, 1990, OSHA issued a notice of proposed supplemental rulemaking on its standards, issued June 17, 1986, governing "Occupational Exposure to Asbestos, Tremolite, Anthophyllite, and Actinolite in general industry and the construction industry. An administrative stay of enforcement of the standards was extended until November 1990 to provide time to complete this supplemental rulemaking. The former asbestos standard remains in effect for the extent of the stay. Based on available information, OSHA believes that there is insufficient evidence to conclude that exposure to nonasbestiform Anthophyllite, Tremolite and Actinolite (AT&A) mineral fragments presents a risk similar in magnitude or type to fibers of their asbestiform counterparts. Therefore, OSHA proposed that nonasbestiform AT&A minerals should no longer be regulated in the same way as asbestos, either under the 1972 asbestos standard or under the revised asbestos

standard. Public hearings on the proposed supplemental rulemaking were held on May 8, 1990, at the Labor Department, in Washington, DC. After reviewing the notice of proposed rulemaking regarding the Occupational Exposure to Asbestos, Tremolite, Anthophyllite, and Actinolite, the Department of the Interior informed OSHA that it "recommends that OSHA deal with asbestos and AT&A as separate issues, introduce a mineralogical definition of asbestos into the asbestos regulation, and initiate a separate rulemaking for AT&A because of the potential im-pact on the mining and minerals industries, the uncertainty in the health risks, and the lack of exposure data and health studies in the consuming industries."5

Issues

The implementation of the provisions of the amended Federal Water Pollution Control Act of 1977, the Clean Water Act, section 404, dealing with "wetlands" and the establishment of a "no net loss of wetlands" policy constitutes one of the major areas of concern to the construction sand and gravel industry. There is a significant amount of uncertainty regarding the process of designating some lands as wetlands and whether the current exemptions to the Clean Water Act, section 404, permit program will be maintained in the future. The many criticisms of the current wetland regulatory process include the following: it fails to cover activities that are destructive to wetland; it ignores basic, fundamental rights of private property owners; and covers privately owned lands that provide minimal wetland functions and values. Several bills were introduced in the 102d U.S. Congress to replace the current section 404 of the Federal Water Pollution Control Act. The new proposed bills plan to provide a concise and structured program for the delineation of wetlands based upon their functions and values and will balance the need for effective protection of the Nation's important wetlands with the need for essential community growth and the constitutional rights of landowners.

The regulatory requirements being proposed by OSHA continue to be the other areas of concern for the industry. They include the revised asbestos standards governing occupational exposure to non-asbestiform varieties of AT&A minerals and the final promulgation of the per-

missible exposure limit for crystalline silica measured as respirable silica. The revised OSHA regulations for airborne asbestos standards, if implemented, are expected to have a significant impact on the aggregates and the construction industries that could include increased mining and construction costs and disruption of the supply of aggregates in most areas.

Although progress is being made toward better cooperation between the aggregates industry and the local communities in most parts of the country, problems still exist in other areas. An attempt was made in 1990 in Colorado to amend the State constitution and prohibit surface mining of aggregates in the Front Range mountains within view of six maior cities-Colorado Springs, Denver, Manitou Springs, Boulder, Pueblo, and Fort Collins—and in various other parts of the State. The amendment would have allowed local governments to adopt and enforce their own reclamation and bonding requirements for aggregate mines. The proposed amendment was challenged in the State Supreme Court, and due to the delay caused by the challenge, backers of the amendment could not gather in time the number of signatures required to place the issue on the November 1990 ballot. Backers of the proposed amendment plan to have it included in Colorado's 1992 general elections.

Production

U.S. production of construction sand and gravel increased 1.5% in 1990 compared with the estimated total of 1989 but decreased 1.4% compared with that of 1988 when the previous full annual survey was conducted. Of the four major geographic regions, the West again led the Nation in the production of construction sand and gravel with 318 million tons, or 34.9% of the U.S. total, followed by the Midwest with 282 million tons or 31% of the total; the South with 204 million tons or 22.4%; and the Northeast with 107 million tons or 11.8%. Compared with that of 1988, production by major geographic regions decreased 17.3% in the Northeast and 0.9% in the West but increased 3.9% in the Midwest and 0.9% in the South.

Of the nine geographic regions, the Pacific again led the Nation with 204 million tons or 22.4% of the U.S. total. Next was the East North Central with 184 million tons or 20.2% of the total and the

Mountain with 114 million tons or 12.5% of the total. Compared with that of 1988, production increased in only three of the nine regions, the largest increases being recorded in the East South Central region, 14%; the West North Central, 7.9%; and the East North Central region with only 1.9%. The production decreased in the remaining six geographic regions with the major decreases occurring in New England, 26.3%; Middle Atlantic, 10.1%; and West South Central, 2.5%.

The estimated production by quarters for 1990 indicated that most of the construction sand and gravel in the United States was produced in the third quarter, followed by the second quarter and the fourth quarter. The variations in production between quarters are mostly due to seasonal changes in weather conditions that have an impact on the construction activities and on the demand for construction aggregates as well. Estimated production by each quarter of 1990 was also available for most of the States.

Construction sand and gravel was pro-

duced in every State, and the 10 leading States in 1990 were, in descending order of tonnage, California, Michigan, Texas, Ohio, Washington, Minnesota, Illinois, New York, Wisconsin, and Arizona. Their combined production represented 51.7% of the national total.

Compared with that of 1988, production increased in 29 States, including 4 of the top 10 States. The increases were significant in Washington, 29.1%; Iowa, 25.9%; and Alabama, 9.6%.

Limited information about the production of construction sand and gravel in foreign countries may be found in the U.S. Bureau of Mines Minerals Yearbook, Volume III, Area Reports: International. For nonreporting countries, estimates of sand and gravel and crushed stone outputs can be based on indirect sources such as the level of cement consumption.

Changes in ownership, acquisitions by foreign or domestic companies, and mergers continued in the crushed stone industry. In January 1990, Colonial Sugar

Refineries (CSR) Ltd. of Sydney, Australia, completed the acquisition of ARC America Corp. of Newport Beach, CA, and all its subsidiaries. The transaction included American Aggregates Co. of Greenville, OH, Associated Sand and Gravel Co. of Everett, WA, and WMK Co. of Las Vegas, NV, as well as Hydro Conduit, a large producer of concrete pipes with operations in Florida and most of the Western States. The acquisition added 48 aggregates operations located in six States and 40 concrete pipe plants in 20 States to CSR holdings. CSR also acquired, through its subsidiary Rinker Materials Corp. of West Palm Beach, FL, Cox Sand Co. of Brunswick, GA. CSR acquired Rinker Materials in 1988.

In midyear, C. H. Beazer PLC, of Bath, United Kingdom, reorganized its American subsidiaries in two separate companies. All Beazer operations located west of the Mississippi, including Gifford-Hill & Co. operations, became Beazer West Inc. of Dallas, TX, while Beazer Materials and Services of Pittsburgh, PA,

and all its operations east of the Mississippi became Beazer East Inc. Beazer West acquired all assets of Crystal Hills Sand and Gravel Co. of Lucerne, CA. The acquisition included a long-term lease for the sand and gravel operation as well as a ready-mix plant and a hot-mix asphalt plant located at that site.

The Rogers Group Inc. of Nashville, TN, acquired the assets of Billy Holloway Aggregates of Louisville, KY, that included two quarries at Avoca and Fern Creek, TN. In addition, the new Rogers Group affiliate, Billy Holloway Ready-Mix of Louisville, KY, and American Builders Supply, of Louisville, KY, an affiliate of Sibo Services Inc. of Louisville, KY, formed a joint venture that will operate under the name of American Builders Supply, a Rogers Group company. Sibo Services Inc. of Louisville, KY, a subsidiary of Sibo Gruppe, Dyckerhoff Cement Co., Hans Sievert A.G. & Co., Oppermann Sand and Gravel, and Homann Co., all of the Federal Republic of Germany, is a holding company with assets in aggregates and concrete in Kentucky and Indiana. Rogers Group also acquired Price Sand and Gravel Co. of Norwalk, OH.

Inspiration Resources Corp. of New York, NY, acquired Rogue Aggregates Inc. and LTM Inc., of Medford, OR. Rogue Aggregates has three crushed stone and sand and gravel operations, while LTM is an aggregates, ready-mix concrete, and asphalt producer. Inspiration Resources is a diversified natural resources company that operates base and precious-metals mines as well as coal mines and also produces construction materials.

Dravo Basic Materials Co. of Kenner, LA, acquired R&S Materials Inc. of Montgomery, AL, and its five sand and gravel operations in central Alabama.

Lone Star Industries of Greenwich, CT, has sold most of its interest in Lone Star Northwest of Seattle, WA, to Onoda Cement Co., of Tokyo, Japan, its partner in the joint venture established in 1988. Lone Star Northwest operates three sand and gravel plants and six cement terminals in Alaska, Oregon, and Washington.

Consumption and Uses

Sand and gravel reported by producers to the U.S. Bureau of Mines is actually

XX Not applicable.

As published in the "Crushed Stone and Sand and Gravel in the Fourth Quarter of 1990," Mineral Industry Survey.

²Data may not add to totals shown because of independent rounding.

³Number of companies reporting for the quarterly survey.

⁴Owing to a very low number of reporting companies in some States, no production estimates by quarters were generated.

TABLE 7
CONSTRUCTION SAND AND GRAVEL SOLD OR USED IN THE UNITED STATES IN 1990, BY USE

Use	Quantity (thousand short tons)	Value (thousands)	Value per ton
Concrete aggregates (including concrete sand)	240,076	\$947,843	\$3.95
Plaster and gunite sands	10,007	43,599	4.36
Concrete products (blocks, bricks, pipe, decorative, etc.)	11,171	45,840	4.10
Asphaltic concrete aggregates and other bituminous mixtures	76,491	326,590	4.27
Road base and coverings	135,642	428,314	3.16
Road stabilization (cement)	1,819	5,198	2.86
Road stabilization (lime)	772	2,638	3.42
Fill	73,152	173,624	2.38
Snow and ice control	7,307	24,971	3.42
Railroad ballast	869	3,590	4.13
Roofing granules	566	2,876	5.08

¹Data may not add to totals shown because of independent rounding.

material that is "sold or used" by the companies and is defined as such. Stockpiled production is not reported until it is sold to a user or consumed by the producer outside its own operation. Because no consumption surveys are conducted by the U.S. Bureau of Mines, the "sold or used" tonnage is assumed to represent the amount produced for domestic consumption and export.

Of the 911 million tons of construction sand and gravel produced in 1990, 26.4% was used as concrete aggregates; 15.2% for road base and coverings and road stabilization; 8.4% as asphaltic concrete aggregates and other bituminous mixtures; 8% as construction fill; 1.2% for concrete products such as blocks, bricks, pipes, etc.; 1.1% for plaster and gunite sands; and the remainder for snow and ice control, railroad balast, roofing granules, filtration, and other miscellaneous uses. Because some producers did not report a breakdown by end uses, their total production as well as the estimated production for nonrespondents were included in "Other unspecified uses," which represents 36.8% of the U.S. total. Two-thirds of this total was production reported by

producers, and only one-third was production estimated for nonrespondents. The estimated production for nonrespondents represents only 12.7% of the U.S. total, a relatively small percentage, taking into account the number of producers covered by this survey.

A review of consumption by major geographic regions indicates that most of the sand and gravel for concrete aggregates, including concrete sand, was used in the West, 33.5%, the South, 29.4%, and the Midwest, 25.5%, regions with high levels of construction activity. Most of the sand and gravel for road base and coverings was used in the West, 43.3%, and the Midwest, 34.4%, while most of the sand and gravel used for asphaltic concrete aggregates and other bituminous mixtures was used in the West, 46.5%, and the Midwest, 30.1%.

Additional information regarding production and consumption of construction sand and gravel by major uses in each State and the State districts is published in the U.S. Bureau of Mines Minerals Yearbook State chapters, Volume II of the U.S. Bureau of Mines Minerals Yearbook.

Transportation

Information regarding the method of transportation of construction sand and gravel from the pit or processing plant to the first point of sale or use is now available for each geographic region. Reports regarding the method of transportation were provided by the producers for about 63.4% of the total production of construction sand and gravel. Of this total, 69.5% was transported by truck, 2.5% by waterway, and 1% by rail. A significant amount of construction sand and gravel produced, about 25.9%, was not transported and, therefore, was used at site. Because most producers either did not keep records or did not report shipping distances or cost per ton per mile, no transportation cost data were available.

Prices

Prices in this chapter are f.o.b. plant, usually at the first point of sale or captive use. This value does not include transportation from the plant or yard to the consumer. It does, however, include all costs of mining, processing, in-plant

transportation, overhead costs, and profit.

Compared with that of 1988, when the last full annual survey was conducted, the 1990 average unit prices increased 5.3% to \$3.57 per ton. By uses, the unit prices varied from a high of \$5.51 for filtration sand to a low of \$2.37 for fill. The largest increases in unit prices by uses were recorded for road stabilization-lime, 30%; roofing granules, 25.7%; asphaltic concrete aggregates and other bituminous mixtures, 10.3%; concrete products, 9.6%; road stabilization-cement, 5.9%; and road

base and coverings, 4.3%. Average unit prices for railroad ballast and plaster and gunite sands showed a decline of 7.6% and 6.8%, respectively.

Foreign Trade

The widespread distribution of domestic sand and gravel deposits and the high cost of transportation limits foreign trade, mostly to local transactions across international boundaries. U.S. imports and exports are small, representing only about

1% of the domestic consumption.

Exports.—Exports of construction sand decreased 58.4% to 468,000 tons compared with that of 1989, while the value decreased 12.6% to \$11.9 million. Canada was the major destination, receiving about 62.6% of the total, followed by Mexico with 15.8%. No information on exports of construction gravel was available for this year from the Bureau of the Census due to some changes made in the reporting procedures under the new

¹Includes sand and gravel used in road and other stabilization (cement and lime).

harmonized coding system.

Imports.—Imports of construction sand and gravel increased 191.3% to 1.7 million tons compared with that of 1989, while the value increased 138.1% to \$22.9 million. The significant increase in imports is due to the fact that the 1990 data include construction sand and gravel, while in 1989 no data on construction gravel were available. Canada was the major source of imported construction sand and gravel with 56.4% of the total, followed by the Bahamas with 19.4%, and Antigua and Barbuda, and Australia with 7.5% each.

Current Research

The 5-year Strategic Highway Research Program (SHRP), which will conclude in 1992, passed its midpoint this year. The program made significant progress toward its main goal of improving the Nation's highways through the use of high-performance technology. SHRP's mission is to produce usable research results targeted toward technical areas where there is potential for rapid progress that could yield significant cost savings. SHRP was conceived as a research program with the following distinguished characteristics: an accelerated research activity to be conducted during the short 5-year life of the

program; a dollar-driven and performanceoriented program; management-directed activities determined by management imperatives; and a product-oriented program designed to develop better and more useful highway technology for immediate practical application.⁶ SHRP's research activities account today for more than one-quarter of all highway research conducted in the United States by the Federal agencies, the States, and the private industry.

SHRP's four areas of research are asphalt, concrete and structures, highway operations, and long-term pavement performance. The broad objective of SHRP's research program in the asphalt area is to improve the long-term durability and cost-effectiveness of the Nation's annual \$10 billion-plus investment in asphalt pavements. Preliminary drafts of the performance-based specifications for asphalt and asphalt binders were released for discussion in 1990. The report indicates that "the chemical and physical properties of the asphalt binder determine, to an important degree, the level of performance achieved by the asphalt pavement."7 Accordingly, chemical analysis of the asphalt yields a large amount of information on how the asphalt will perform as a binder in pavement. An initial draft of specifications for asphalt-aggregate mixture was also released in an effort to generate input from users and producers. "The specifications address five pavement performance characteristics—aging, fatigue cracking, moisture sensitivity, permanent deformation, and low-temperature cracking. Applying mixture and binder specifications in the design of specific highways will enable designers to account for severe traffic and climatic conditions. The result will be more durable and economical pavements."

The concrete and structure program includes research in the area of improved concrete materials and corrosion of steel in concrete structures. Tables that provide guidance for curing concrete, developed by the Pennsylvania State University, and a new test for selecting the type of concrete to be used depending on the environment in which the concrete will be placed are some of the emerging products from the concrete program. A new test for control of freeze-thaw damage was developed as an alternative to the standard ASTM C-666B test, as well as a fiber-optic air meter, a portable, batteryoperated device for measurement on-site of air voids in fresh concrete. All new products and methods will be pilot-tested by State highway agencies around the

Highway maintenance problems and

their high costs are addressed by SHRP's highway operations research program, while SHRP's long-term pavement performance (LTPP) program is measuring pavement performance in different climate, traffic, and subgrade conditions.

A Midcourse Assessment meeting organized by SHRP in Denver, CO, on August 1-3, 1990, was attended by more than 400 representatives of State highway agencies, research organizations, and the industry. SHRP's activities and progress of the research program were examined by the participants, and specific recommendations were made regarding the direction of the program.⁹

For a long time, good base design and good drainage under pavements was the accepted rule among pavement designers. The development of "rational" methods of pavement design in the 1950's and 1960's led to the belief that pavements could be built strong enough to resist damage without the benefits of good drainage.10 That rationale let the designers increase the thickness and strength of pavements, while reducing drainage capabilities (capacity) of the base and subbase layers. The bases became also denser and stronger in order to be able to carry heavier loads during the construction and especially after the completion of the roads. Over the years, the inadequate

drainage of pavement structures was identified as one of the primary causes of pavement distress and failure in today's highways.

Today, a different design approach is emerging. Rather than using impermeable dense-graded materials, several States started to use open-graded permeable bases that allow moisture to rapidly drain through the base and out from beneath the pavement structure. Permeable bases usually consist of open-graded crushed aggregate with very limited amount of fines and a longitudinal edge-drain system that collects the water from the permeable base. The permeable bases are used mostly under portland cement concrete pavements, but their use under asphaltic concrete pavement is increasing. There are two kinds of permeable bases in use: the untreated or unbound permeable bases that are dense-graded aggregate material with reduced amount of fines and the treated or bound with either asphaltic concrete or portland concrete bases. Many States have used the permeable base design method for some time, with California, Michigan, New Jersey, and Pennsylvania being the most advanced States. Performance data indicate that properly designed and constructed permeable bases virtually eliminate pumping, faulting, and cracking of pavements. Studies of pavements constructed on permeable bases in California suggest a minimum service life increase of 33% and 50%, respectively, for asphalt concrete and portland cement concrete pavements constructed on permeable bases.11

For the existing roads built on dense graded bases, a patented process for installing transverse drains under the joints of concrete pavements is being tested in Wisconsin.¹² The drains effectively remove free water from dense graded bases under the pavement joints, reducing or eliminating the pumping of fines and faulting of joints under heavy traffic. Drainage Technologies Inc., of Oconomowoc, WI, is the patent holder for the new drainage system.

At the suggestion of the National Pavement Association (NAPA), and in cooperation with the American Association of State Highway and Transportation Officials (AASHTO) and the Federal Highway Administration (FHWA), a 14-day study tour of six European countries was organized in September 1990. Representatives of AASHTO, FHWA, NAPA, SHRP, The Asphalt Institute,

and the Transportation Research Board visited Denmark, France, the Federal Republic of Germany, Italy, Sweden, and the United Kingdom. The objective of the tour was to exchange ideas and experience with European highway agencies and construction industry representatives regarding the design, production, and maintenance of asphalt pavements. The group members concluded that there is "a lot to learn from Europe about asphalt pavements and about pavement philosophy in general. European pavements are better than ours. The Europeans invest more in research, development, and deployment of new pavement technology. They build their pavement foundations better. They use innovative surfaces, such as Stone Mastic Asphalt, and mix in additives to a greater extent and with better results. And, the Europeans maintain their pavements to get the maximum life out of them."13 A report summarizing the findings of the study group that also provides a plan for applying these findings in the United States was published by AASHTO.

Technology

A steep incline, high-capacity conveyor capable of operating uphill or downhill at angles of up to 70° on short or very long lifts was produced by Huwood, a United Kingdom conveyor manufacturer.14 A troughed conveyor belt runs in parallel with a chain conveyor system. Attached to the chain are paddles shaped to the profile of the belt trough that propel the material and the belt up or down the incline. A single drive is used on the chain conveyor that allows the troughed belt to be manufactured from flexible, abrasion resistant, low tensile material. The rated operation capacity of the conveyor is 10,000 tons per hour. The conveyor will accommodate irregular-sized material, large lumps of fines, and abrasive as well as sticky or frozen materials. The conveyor is said to offer substantial cost benefits for bulk material transportation, especially in surface mine operations and stockyards.

Significant changes are taking place in the design and the use of conveyor systems and their accessories. Stationary or self-propelled conveyors are replacing in-quarry and pit-haul trucks because they provide increased productivity by moving large volumes of materials at a faster speed and lower cost. A new com-

puterized designing method for belt conveyor systems was developed by Don Suverkrup and John Cloes, mechanical engineering consultants of Bakersfield, CA.¹⁵ Their computer program provides an improved method for producing the proper design of belt conveyors and accessories at a low cost. A review of the latest developments in conveyor systems and their accessories as well as their use was published by Rock Products.¹⁶

As the supply of aggregates from landbased resources becomes more restricted, European sand and gravel producers are placing more emphasis on offshore dredging of sand and gravel. To satisfy increased requirements for greater consistency of the products supplied, more sophisticated mining and processing methods are being used. For years, a common practice for offshore dredging was to do some onboard vessel screening of the dredged material. Recently, based on increased environmental concerns, some United Kingdom licenses started to prohibit onboard screening of dredged aggregates. To overcome this restriction, new excavating methods are being tested that will be more selective regarding the material being dredged. The USP Rox-Ann seabed classification system is a device that improves the efficiency of trailer-suction dredges.17 The device works through reflected hydroacoustic signals that are able to determine the type of aggregate present in the seabed before the material is excavated. The dredging is therefore adjusted according with the information provided by the device.

Self-unloading vessels were developed and continue to thrive in the Great Lakes area. However, a new market for oceangoing self-unloaders transporting aggregates, cement, and other free flowing dry bulk commodities is developing. The main advantages provided by such vessels for transporting low-value/high-volume commodities are reduced handling costs, improved turnaround time, and capability to supply ports that are not equipped with high-capacity unloaders. These vessels are most cost effective if they perform short hauls and operate often in order to make full use of the installed equipment, but some are being used for long ocean hauls. Some new developments in the use of self-unloaders as well as reviews of some operations were published by Bulk International Journal. ¹⁸

OUTLOOK

The demand for construction sand and gravel in 1991 is expected to be about 820 million tons, a 10% decrease from that of 1990. The slowdown of the economy that affected the construction industry in the second half of 1990 is expected to have an impact on the demand for construction sand and gravel in the first half of 1991. Gradual increases in demand for construction aggregates are anticipated after 1991, based on increased volume of work on the infrastructure expected to occur following the passage of the Surface Transportation Assistance Act of 1991. It is estimated that the demand for construction sand and gravel will reach 1 billion tons in 1995. The projected increases will be influenced by construction activity primarily in the public construction sector.

The release of the Department of Transportation comprehensive report on national transportation policy¹⁹ indicates that a significant increase in the volume of work on the infrastructure should be expected in the next 5 to 10 years. The value of public construction work as part of the gross national product has declined constantly from about 3% in the 1950's and 1960's to less than 2% in the 1980's. If this trend begins to reverse in the 1990's, a significant increase in spending for public construction work could be expected that will dramatically alter the above forecasts.

Construction sand and gravel f.o.b. prices are not expected to increase significantly, even if the demand for construction aggregates rises over the above forecasts. However, the delivered prices of construction sand and gravel are expected to increase, especially in and near metropolitan areas, mainly because more aggregates are transported from distant sources.

INDUSTRIAL SAND AND GRAVEL

By Wallace P. Bolen

Mr. Bolen, a physical scientist, has been the commodity specialist for industrial sand and gravel since October 1988. Domestic survey data were prepared by Howard S. Sullivan, mineral data assistant; and the international production table was prepared by William Zajac, Chief, Section, International Data.

robably no other nonmetallic mineral has more diversified uses than silica (industrial) sand, mainly because of its common occurrence around the world and its distinctive physical characteristics, including hardness, resistance to high temperature and chemical action, and relatively low price. Silica sand is the major component of common glasses, foundry molding and cores, abrasive blast sand, and hydraulic fracturing sand. Industrial sand and gravel is also important in ceramics, chemicals, and fillers for rubber and plastics, and also is utilized in golf courses, as a flux in smelting and chemical production, as filter media, and in many other uses.

DOMESTIC DATA COVERAGE

Production of industrial sand and gravel in 1990 decreased to 28.4 million tons, about 3% less than 1989's production. Production decreased for the first time in the past 4 years and was attributable to decreased silica usage for flat and specialty glasses, chemicals, ceramics, and roofing granules and fillers.

Exports of silica sand and gravel decreased about 44% in quantity, but the average value per ton, compared with that of 1989, increased 91%. Imports of industrial sand and gravel increased about 109% in quantity, and the associated value increased 57%. Domestic apparent consumption of industrial sand and gravel in 1990 was 27.3 million short tons, essentially the same as in 1989.

Domestic production data for industrial sand and gravel were developed by the U.S. Bureau of Mines from voluntary surveys of U.S. producers. Of the 156 industrial sand and gravel operations surveyed, 149 (96%) reported to the U.S. Bureau of Mines. Their combined production represented about 99% of the U.S. total published in table 1. The production of nonrespondents was estimated mostly using employment data. Of the 156 operations, 154 (99%) were active and 2 idle.

BACKGROUND

One of the first industries to use silica sand was the glass industry. At least 4.000 years ago, long before iron was smelted, glassmaking was already a known craft. Although the place and date of the first manufactured glass are not known, the oldest known specimens of glass are from Babylon (ca. 2600 B.C.) and from Egypt (ca. 2500 B.C.), where the industry was well established by about 1500 B.C. Many varieties of glass were known during Roman times. Little is known of the glassmaking methods used in Europe from the fall of Rome until the 10th century, when stained glass was produced in Venice. After this, Venice remained the leader in fine glassware for the next four or five centuries. In the 17th century, a process for casting glass was invented in France, and later, England began to make flint glass, marking the beginning of modern glass technology.

Glassmaking was apparently the first industry to be transplanted from Europe to North America, first to Mexico and later to the British colonies. The first manufacturing establishment in what is now the United States was a glass factory at Jamestown, VA, built in 1608. The 1885 edition of "Mineral Resources of the United States," the predecessor of today's U.S. Bureau of Mines "Minerals Yearbook," reported a total of 317,000 tons of silica sand produced in 1884 in the United States, under "Glass Materials." In 1990, a total of 28.4 million tons of silica sand was produced in the United States for a variety of uses, of which 11.7 million tons was for glassmaking. Today, glass has become an invaluable product with a multitude of forms and applications.

Metals casting was probably the second industry that used silica sand. Today, the casting industry provides vital components for most modern manufacturing industries. The number of industries using silica sand is growing constantly, as are the products made by using silica sand.

Definitions, Grades, and Specifications

Sand is defined throughout the industry and by the American Society for Testing and Materials (ASTM) as granular rock particles that pass through a No. 4 mesh (0.187-inch) U.S. standard sieve, are retained on a No. 200 mesh (0.0029-inch) sieve, and are the result of natural disintegration or comminution of cemented rock. Industrial sand or silica sand is the term used by the industry for sands that have a very high percentage of silicon dioxide (SiO₂), and are essential materials in glass manufacture, in ferrous and nonferrous foundry operations, in certain chemical and metallurgical processes, for hydraulic fracturing of oil and gas deposits, and in many manufactured products as fillers or extenders.

Most industrial sands have been named for their specific uses; for example, glass,

Puerto Rico excluded from all industrial sand and gravel statistics.

foundry, abrasive, filler, and hydraulic fracturing sands. Almost invariably, these sands, in addition to being high in silica, consist mostly of quartz grains.

Products for Trade and Industry

Silica sand had a wide range of uses in a significant number of industries, the most important being glass and foundry. Other uses were metallurgical and as abrasives, as fillers, for filtration, and for hydraulic fracturing of rock formations to improve recovery in oil wells.

Glass sand was used as a main constituent for manufacturing glass containers, flat glass, safety glass, pressed and blown glass, fiberglass, and a wide variety of specialty glasses such as optical glass and industrial glass.

Glass sand had to meet rigid specifications with respect to purity and silica content, depending on the kind of glass being manufactured. Only a very small amount of iron oxide and chromium compounds could be tolerated, and a high percentage of aluminum, calcium, or magnesium oxides was undesirable. The standards of the American Ceramic Society for glass sand indicated that all grains should pass through a No. 20 mesh screen, between 40% and 60% should be retained on a

No. 60 screen, between 10% and 20% on a No. 80 screen, and not more than 5% should pass a No. 100 screen. Sand for first-quality optical glass should contain 99.8% SiO₂ and a maximum of 0.1% aluminum oxide (Al₂O₃) and 0.02% iron oxide (Fe₂O₃). Third-quality flint glass could contain only 95% SiO₂ and as high as 4% Al₂O₃. Only in the low-quality amber glass was the content of Fe₂O₃ permitted to reach 1%.

Most glass manufacturers established their own specifications for the physical size and chemical purity of the raw materials that have to be met by the suppliers of glass sand. In the past 10 years, glass manufacturers showed an increased interest in finer glass sands because processing of smaller particles required lower temperatures and, therefore, reduced the consumption of energy.

Foundry sands included molding sand and core sand that were used for casting iron-, aluminum-, and copper-base alloys. Required properties included cohesiveness sufficient to hold together the mold or core when moist, which is achieved by a bonding agent; refractoriness to withstand the high temperature of the molten metal; strength to resist the weight of the metal; permeability to release vapors and

gases generated during cooling of the metal; and proper texture and composition to produce a smooth casting that will not react with the metal. Most metals were cast in "green sand," which is a mixture of silica and clay, although to a lesser extent, resins or oils were also used as a bonding agent instead of clays. In the case of naturally bonded foundry sands, the amount of clay minerals present affected their usefulness. Standard tests and specifications for foundry sands were published by the American Foundrymen's Society.¹

Refractory sands were used in the manufacture of silica brick and tile, quartzite (gannister) being the commonly used raw material. Required properties were "the capability of maintaining the desired degree of chemical and physical identity at high temperatures" and resistance to abrasion, impact, thermal shock, and high level of load. Refractory silica materials were classified based on their general composition and on their distinctive properties. Standard classifications and specifications for silica refractory brick were published by the ASTM.²

Abrasive sands were quartz sands used in stone sawing, glass grinding, metal polishing, and sand blasting. No rigid specifications existed for these sands, but sound, clean, hard, and closely sized sand grains were required. Purity and grainshape specifications varied with the type of abrasive action and the requirements of the final product. An angular particle shape with sharp cutting edges was generally required.

Hydraulic fracturing sand was pumped into oil or natural gas wells as a sandliquid mixture to break up petroleumbearing formations and act as a propping agent, allowing oil or gas to move more freely toward the producing wells. Some of the major requirements for fracturing sands were spherical, well-rounded grains of clean, dried, and well-screened quartz sand, free of any materials such as feldspar, calcite, and clay. The most common size was 20/40 mesh; other sizes included 6/12, 8/16, 12/20, 40/70, and 70/140, but these sands represented only about 15% of the total sand used as proppant. "Recommended Practices for Testing Sand Used in Hydraulic Fracturing Operations," published by the American Petroleum Institute, was used as a guide by industry.³

Ground sand or silica flour is found wide industrial application as a filler in

²Data may not add to totals shown because of independent rounding

paint, plastics, rubber, ceramics, and a variety of other products. Mainly because of the diversity of its uses, no standard specifications exist for the silica flour used in most of these applications except grain size and chemical composition.

Metallurgical sand was used as a fluxing agent for basic oxides in various smelting operations and as a source of silicon in ferrosilicon manufacture. The ferrosilicon was a steel alloving additive. Filter sand was used extensively in filtering water for municipal and industrial use and swimming pools and in sewage treatment plants. Engine sand was used in locomotive haulage to improve traction. Other sands were used in special cements, in manufacturing silica brick and tiles for furnace linings and beds, for coal washing, and in manufacturing pottery. Industrial gravel was used as the source material in the production of silicon and ferrosilicon and as a flux for the production of elemental phosphorus. Some gravel was also used as filtration media, mainly in municipal water treatment facilities.

Industry Structure

In 1990, 83 U.S. companies with 154 active operations produced silica sand and gravel. The individual industrial sand and gravel operations ranged in size from those producing about 1 million tons annually to those reporting less than 10,000 tons per year. Most of the production came from large operations that were mostly owned or operated by a small number of companies. In the past 10 to 15 years, there was a gradual trend toward larger operations, mostly because small plants were becoming less economical. The viability of small operations was dependent on demand in local markets, mining conditions, and the degree of processing required to supply the final product.

During the past 10 years, changes within the structure of the industrial sand industry occurred, primarily caused by mergers and acquisitions, some resulting from an influx of foreign capital, mostly from Europe.

Geology-Resources

U.S. resources of industrial sand were expected to be sufficient to meet domestic demand in the foreseeable future, although their geographic distribution and quality often did not match market requirements. The availability of these

reserves was controlled to a significant degree by land use and/or environmental constraints. Reserves of industrial sand owned or controlled by domestic producers were estimated to total about 3 to 4 billion tons.

Although industrial sand reserve data for the rest of the world were not available, it could be assumed, on the basis of geologic evidence, that world reserves were sufficient to meet demand, even if not always at the locations where needed.

Industrial sand or silica sand was produced in the United States from a variety of geological formations ranging in age from late Precambrian to mid-Tertiary. About 70 stratigraphic units were known as having an economic potential for this industry. Lithologically, these deposits ranged from quartzites, sandstones with different degrees of cementation, quartz conglomerates, chert deposits, and quartz pegmatites to terrace sands and gravels and dune sands. Most of the high-quality industrial sand was produced from a few geological formations in the Eastern United States. Oriskany sandstone, or more precisely the Ridgeley formation of Early Devonian age, was one important source of silica sand. It extended from New York State to southern Virginia and eastern Ohio, but was being mined only in central Pennsylvania, northwestern Maryland, and northern West Virginia, where the formation was thick enough to be of commercial value. It was a hard, white orthoquartzite with medium to fine, angular and subangular, and well-sorted grains. The St. Peter sandstone of Middle Ordovician age, extending from Wisconsin and Minnesota through Iowa, Illinois, and east-central Missouri, was another major source of industrial sand. The best known center of production of silica sand from this formation was the Ottawa district of La Salle County, IL, where it was known as "Ottawa sand," and to a lesser degree in southern Wisconsin and east-central Missouri. It was a soft and poorly cemented high-purity orthoguartzite with coarse, rounded grains. The weak cement holding the silica grains together was mostly a light-colored clay.

In addition to the two formations just mentioned, the most important sources of industrial sand in the United States, numerous other deposits were also being mined for silica sand in different parts of the country. Included are the Jordan sandstone of Upper Cambrian age in Minnesota and Wisconsin, a primary source of hydraulic fracturing sand; the Raritan formation of Upper Cretaceous age in central New Jersey and the Cohansey sand of probable Miocene age in southern New Jersey; and the Tuscarora quartzite of Lower Silurian age in Pennsylvania and Virginia used for the manufacture of refractory bricks. Other deposits are the Sylvania sandstone of Devonian age in the Detroit area; the Oil Creek and McLish formations of Lower Ordovician age in Oklahoma, a southwestward extension of the St. Peter sandstone; and the Hickory sandstone of Cambrian age in central Texas that produced mostly hydraulic fracturing sand.

In the West, the most important sources of industrial sand were the Ione formation of Eocene age in northern California, the Silverado (Paleocene) and Tejon (Eocene) formations in southern California, and the Eureka quartzite of Middle Ordovician age in central California.

Just under two-thirds of the U.S. industrial sand and gravel was produced east of the Mississippi River, especially in the industrialized areas of the East North Central, South Atlantic, and Middle Atlantic regions. Of the top five producing States that accounted for about one-half of 1990 production, three—Illinois, Michigan, and New Jersey-were in the East and the other two-California and Texas—were in the West. The concentration of the industrial sand operations in the eastern part of the United States resulted from the existence of highquality geologic deposits close to the major consuming industries, glass and foundry.

Technology

Exploration.—A large number of geologic formations with economic potential as a source of industrial sand have been mapped and described in the literature over many years and were, therefore, well known. Consequently, detailed exploration and development work for new industrial sand operations was expected to occur on some of these formations. The qualities of a silica deposit necessary for a viable operation should include proper particle size, chemical composition, degree of cementation, and deposit uniformity. Also, the nature and amount of waste material and the economic feasibility of its removal and possible use or disposal should be studied. The evaluation of the new deposit should also include an environmental impact study as required by most local or State agencies before authorizing a new mining operation.

If the raw material should prove to meet the requirements and adequate reserves are demonstrated, the development stage of the operation could be started. Economic feasibility and marketing studies should be performed by analyzing all factors important for any such mining operations. Included are the availability of power and water supply. mining and processing costs and requirements, and the condition of nearby roads and highways. Other factors include the proximity of rail haulage; the cost of compliance with local, State, and Federal regulations; and the proximity and density of local population as well as its attitude toward such a project.

Mining.—Most industrial sand was mined from open quarries, but a few underground operations existed, mostly because of an exceptionally thick overburden or environmental limitations. Surface mining methods and equipment varied with the type of the geologic formation, size and configuration of the deposit, production capacity, estimated life of the operation, and location of the deposit with respect to urban centers. The mining methods depended primarily on the degree of cementation of the rock, although most open pit mining operations included site clearing and removal of the overburden; mining of the silica rock or sand; processing of the material, including crushing, screening, and classification: and reclamation of the extraction area. Unconsolidated sands, such as the Cohansey of New Jersey, below the ground water level were dredged. Much of the St. Peter sandstone was first loosened by light blasting and then washed down by hydraulic jets or "monitors" into sumps, from which it was pumped to the processing plants. Harder rock such as the Oriskany sandstone required blasting and primary and secondary crushing before it could be processed.

Processing.—Processing of mined silica sand required specialized operations that varied considerably with the nature of the deposit and the physical and chemical requirements of the desired product. Depending on the degree of cementation, several stages of crushing were necessary

to achieve the desired size reduction. Gyratory crushers, jaw crushers, impact mills, or roll crushers were used as primary or secondary crushers, and smooth rolls, media mills, autogenous mills, highspeed hammer mills, or fluid energy jet mills were used for grinding the product down to 50 microns and finer. Dry or wet screening was used to separate particles of sizes down to about 150 microns, and wet or air classifiers processed particles from 250 microns into the submicron range. Vibratory screens and gyratory screens, in addition to mechanical, hydraulic, or air classifiers, were used, depending on the size distribution required.

Research for the silica mining industry related not only to new methods that increased output and reduced production costs but also to health and safety problems as well as exploration, land management, and reclamation. Equipment manufacturers and some Government agencies were constantly working on improving exploration, mining, and processing plant technology.

Significant technological developments instrumental in maintaining adequate production at relatively stable real costs were mostly in the processing plant technology. The use of computerized systems in plant operation and quality control increased; this, along with improved mining and processing equipment, permitted the recovery of salable fractions that were previously considered uneconomical.

Recycling.—Recycling of silica sands was limited to some foundry sands, particularly those used for making cores and molds with no-bake resin-bonded sands, some abrasive and airblasting sands, and some scrap glass that substitutes for glass sand. International trends toward increased recycling of glass and foundries sands and innovative ideas on recycling other materials should influence increased recycling of silica products.

Byproducts and Coproducts

Small amounts of gold and silver were recovered occasionally as a byproduct or coproduct from some unconsolidated silica sand deposits. Also, during the processing of some silica resources, other minerals, including clays, feldspars, mica, and quartz crystals, were produced as byproducts and coproducts.

Economic Factors

Silica sand deposits are nonrenewable

resources. New mining methods combined with advances in mineral processing that were introduced during the past decade have increased the number of silica deposits that can be commercially developed.

The industrial sand industry was very competitive, largely because silica sand is a relatively abundant mineral, with supply usually exceeding demand. The delivered price of the product, in addition to quality, was a very important element in any major transaction. The producer with an operation closest to the market had a significant advantage over competitors. Combining sophisticated (and therefore expensive) processing equipment backed by technical knowledge and solid sales expertise was important. For this reason, only a small number of large companies were able to compete successfully and succeed in the silica sand business and supply a wide variety of products. Smaller, less efficient operations became uneconomical as operating costs. as well as costs associated with meeting various Federal, State, and local regulations, continued to increase. The only alternatives they had were to either limit the range of products they supplied to close markets or go out of business.

Prices.—As a result of rapidly rising costs of labor, energy, and mining and processing equipment, 1990 constant dollar prices of industrial sand rose steadily between 1973 to 1983. From 1984 to 1990, 1990 constant dollar prices fluctuated in the 14.50 to 15.75 range. Prices should be expected to continue to fluctuate, although they should slowly rise as a result of the cost of compliance with more stringent environmental, land use, and safety regulations.

Costs.—Production costs for silica sand were determined to a large extent by the cost of labor, equipment, energy supply, water availability, and the additional burden of compliance with environmental and safety regulations. Production costs varied widely depending on the nature of the geologic deposit, the geographic location, and the type and number of products produced. Profits were relatively small for most producers, total production costs being close to the f.o.b. selling price per ton.

Tariffs.—There has been no tariff on imported silica sand containing 95% or more SiO₂ and not more than 0.6% iron

oxide from most favored nations since January 1, 1987. For all other countries, the tariff for imported silica sand remains \$1.94 per long ton.

Depletion Provisions.—The depletion allowance for industrial sand and gravel was 14%.

Operating Factors

Environmental Requirements.—Major environmental considerations that had to be dealt with in mining and processing of industrial sand and gravel were emission of particulate matter into the air, discharge of processing water, and noise abatement. Air pollution constituted a major problem in the processing plants, especially in the drying and packaging stages of finer products such as silica flour, silicosis being the major disease that can be contracted as a result of long-term exposure to silica dust. Because of the high cost of compliance with the environmental regulations designed to reduce this health hazard and possible long-term liabilities associated with it, some companies were no longer producing silica flour or did not plan to produce it in the future. Both wet and dry methods of dust control were used. The most important water pollutant was clay in suspension as a result of washing and screening silica sand. Because of the large quantities of water used to process silica sands and the need of compliance with stringent regulations the treatment of discharge water by the sand producer was expected to require increasingly sophisticated and expensive processing methods. Significant progress was made in reducing noise pollution, both inside and outside of the operations, including noise and vibration produced by blasting and movement of heavy trucks.

Sand producers had to obtain mining permits from the appropriate governmental agency, which sometimes also required an Environmental Impact Statement (EIS) and a reclamation plan that met its guidelines or regulations. More and more emphasis was being put by local communities on improving the overall appearance of the operating mines as well as on land reclamation after mining was completed. At the same time, industry and the communities had to recognize the time and costs required to protect the environment and the importance of agreeing on fair and realistic environmental standards. Many States, counties, and towns had zoning laws that regulated land use.

Most of the active silica sand quarries as well as the known deposits were on private land, which was either owned or leased on a long-term basis by the producers. These deposits contained high-quality silica sand and were in the best locations with respect to markets. Unlike the construction sand and gravel industry, the industrial sand industry was usually not significantly affected by increasing land values near populated areas.

Transportation.—Transportation costs for silica sand were often equal or considerably greater than the cost of the product at the processing plant. Because of the large variety and number of consumers of silica sand, long distance haulage was not uncommon. In 1990, the largest tonnage, 56% of all industrial sand, was shipped by truck because most users require a versatile and rapid delivery system. Substantial quantities, 40% of the total, were also shipped by rail, especially when large volumes were sent long distances. The remaining tonnage was shipped by barge or used at the mine.

ANNUAL REVIEW

Legislation and Government Programs

The Department of Labor's Mine Safety and Health Administration (MSHA) issued a proposed rule titled "Hazard Communication" on November 2, 1990. The rule would establish a MSHA standard requiring mine operators to assess the hazards of chemicals they produce or use and provide information to their employees concerning chemical hazards in regard to these chemicals. This hazard communication standard (HCS) would be similar to the Occupational Safety and Health Administration's HCS. The 41-page proposed rule covered approximately 1,000 chemical compounds and/or minerals and proposed exempting some mineral substances. However, "due to their higher degree of risk, MSHA is not considering including silica flour or certain industrial sands among the minerals exempted." The basis for not exempting silica was the report from the International Agency for Research on Cancer (IARC), in 1986, that there was limited evidence that silica is a carcinogen to humans.

Previous to this proposed rule, MSHA had already recommended that producers label silica products as a possible health hazard, but this rule would make this labeling mandatory. For larger producers, this rule would probably not add an unbearable or excessive cost, but for smaller producers, this rule could increase cost and affect their competitiveness.⁴

Production

The Midwest (East and West North Central regions) continued to lead the Nation in production with about 41% of the 28.4 million tons produced in the United States, followed by the South (South Atlantic, East and West South Central regions) with about 35% and the West (Pacific and Mountain regions) with 15%.

Based on the 1990 census estimations on population, 1990 U.S. per capita industrial sand and gravel production was 0.11 ton. Per capita production by major geographic region was 0.23 ton in the Midwest, 0.12 ton in the South, 0.08 ton in the West, and 0.05 ton in the Northeast (Middle Atlantic and New England regions).

The five leading States in the production of industrial sand and gravel, in descending order of volume, were Illinois, California, Michigan, Texas, and New Jersey. Their combined production represented 45% of the national total. Significant changes within the five major producing States included Texas, where production increased 11%, and Michigan, where production decreased by almost 20%.

The U.S. Bureau of Mines canvassed 83 producers of industrial sand and gravel with 154 active operations. About 74% of the industrial sand and gravel was produced by 47 operations, each with an annual production of more than 200,000 tons. The 10 leading producers of industrial sand and gravel were, in descending order of tonnage, Unimin Corp., U.S. Silica Co., Fairmount Minerals Ltd., The Morie Co. Inc., Oglebay Norton Co., Badger Mining Corp., Manley Brothers of Indiana, Construction Aggregates Corp., Simplot Industries Inc., and Owens-Illinois Inc. Their combined production, from 58 operations, represented 70% of the U.S. total.

Green River Silica Co. in Hart County, KY, was purchased by Kentucky Aggregates of Glasgow, KY. Kentucky Aggregates will continue to produce sand for blasting, filtration, and golf courses.

W Withheld to avoid disclosing company proprietary data; included with "Other."

1 Data may not add to totals shown because of independent rounding.

U.S. Silica, based in Berkeley Springs, WV, began operations at the former Card Silica Co., Harrison County, IN. In another transaction, U.S. Silica sold its McCulloch County, TX, operation to Texas Mining Co., a subsidiary of Oglebay Norton Co., Cleveland, OH. Texas Mining already operated a silica plant in McCulloch County, and this purchase adds to its reserves and increases the number of products it can market. With this latest purchase, Oglebay Norton now has five operations and has moved up to be the fifth largest producer of silica in the United States.

Unimin purchased Master Brothers Silica Sand Co. in Missouri from Bussen Quarries. Unimin now operates 17 silica operations in 13 States, further solidifying its position as the largest producer of industrial sand in the country.

Dravo Basic Materials Co. purchased the operations of R&S Materials Inc., in Macon County, AL. Dravo now operates two Alabama silica mines, both in Macon County.

Tyler Sand Co. of Tyler, TX, ceased operations after producing sand in the early months of 1990.

Bay City Silica Co., Bay City, WI, closed its silica mining operation.

Riverside Sand Co., Wallace, NC, discontinued production of sand for industrial sand markets and produced sand for the construction market only.

New industrial sand producers included in this report were G. W. Bryant Core Sands Inc., McConnellsville, NY; Huey Stockstill Inc., Picayune, MS; and Colorado Lien Co., Fort Collins, CO.

Consumption and Uses

Sand and gravel production reported by producers to the U.S. Bureau of Mines was actually material used by the companies or sold to their customers. Stockpiled material was not reported until consumed or sold.

Of the 28.4 million tons of industrial sand and gravel sold or used, 41% was consumed as glassmaking sand and 22% as foundry sand. Other important uses were abrasive sand (8%) and frac sand (7%). Because some producers did not report a breakdown by end use, their total production as well as the estimated production for nonrespondents were included in "Other uses, unspecified," which represented about 4% of the U.S. total.

On the regional level, more than one-third of the glassmaking sand was

produced in the South (37%), followed by the Midwest (31%) and the West (19%). Three-fourths of the foundry sand was produced in the Midwest (74%). About three-fourths of the hydraulic fracturing sand was produced in the Midwest (70%), and more than one-half of the abrasive sand was produced in the South (59%).

Northeast.—Cumberland County, NJ, continued to be the largest source for the glass and foundry sand markets in the region. Unimin, U.S. Silica, Morie, and Whibco Inc., all of which operated plants in the county, were among the largest producers of sand for these markets. U.S. Silica's plant in Huntingdon

County, PA, also produced significant amounts of sand for the glass market. Morie's plant in Cumberland County and New Jersey Pulverizing Co.'s plant in Ocean County, NJ, produced a major percentage of the abrasive blast sand in the region.

Midwest.—Unimin's plants in LaSalle and Ogle Counties, IL; LeSueur and Scott Counties, MN; and Columbia County, WI, were among the leaders in producing sand for the glass, foundry, and frac sand markets. Fairmount Minerals, with operations in Geauga County, OH, and La Salle County, IL, was a major producer for the blast, foundry, and glass markets in the region. U.S. Silica's plants in St. Louis County, MO, and La Salle County, IL, and Badger Mining's plant in Jackson County, WI, were large producers for the glass and frac sand markets, respectively. Construction Aggregates Corp. in Ottawa County, MI, U.S. Silica in LaSalle County, IL, and Manley Brothers in Van Buren County, MI, were major producers of foundry sand in the region. Nugent Sand Co. Inc., in Muskegon County, MI, Badger Mining in Green Lake County, WI, and Sargent Sand Co. in Wexford County, MI, were also large producers for the foundry industry.

South.—Unimin and U.S. Silica Co. were two of the largest producers of sand for the glass and foundry markets. Unimin's major plants were in Frederick County, VA; Richmond County, NC; Pontotoc County, OK; and Izard County, AR. U.S. Silica's Bullock County, AL; Morgan County, WV; Johnston County, OK, and Limestone County, TX, operations were the major contributors for these markets. Morie's Tuscaloosa County, AL, and Marion County, GA, plants were large producers of foundry and glass sand, respectively. Huey Stockstill Inc., Pearl River County, MS, Cobb Industrial Corp., Red River Parish, LA, and Mid-State Sand and Gravel Co., Baywood and Baggett Parishes, LA, were the largest producers of blasting sand. W.R. Bonsal and Co., Anson County, NC, and Superior Products Inc., Chilton County, AL, produced the majority of the industrial gravel used in the processing of silicon and ferrosilicon. Oglebay Norton's Texas Mining Co., McCulloch County, TX, was the largest producer of frac sand in the region.

W Withheld to avoid disclosing company proprietary data; included with "Other uses, specified"; also included in "U.S. total" by use. XX Not applicable.

West.—Corona Industrial Sand Co., Owens-Illinois, Simplot Industries, and Unimin were the four largest producers of glass sand in the region, with major operations in Riverside County, CA, Amador County, CA, Clark County, NV, and Contra Costa County, CA, respectively. Corona Industrial Sand supplied the majority of sand for the sand-blasting industry in the region. Simplot

Industries also supplied a large portion of the foundry sand consumed.

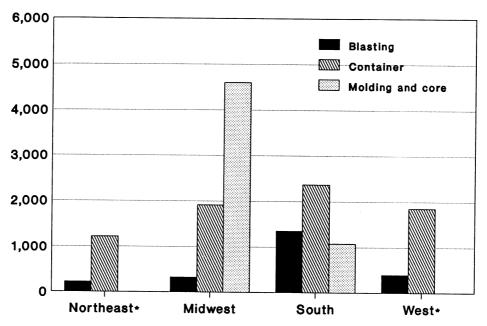

Transportation

Of the total industrial sand and gravel

TABLE 7
TRANSPORTATION OF
INDUSTRIAL SAND AND GRAVEL
IN THE UNITED STATES IN 1990
TO SITE OF FIRST SALE OR USE

Method of shipment	Quantity (thousand short tons)	Percent of total	
Truck	16,086	56	
Rail	11,377	40	
Waterway	774	3	
Not transported	169	1	
Total	28,406	100	

produced, 56% was transported by truck from the plant to the site of first sale or use, down from 58% in 1989; 40% was transported by rail, up from 34% in 1989; 3% by waterway, unchanged from that in 1989; and only 1% was not transported, down from 5% in 1989. Because most of the producers did not report shipping distances or cost per ton per mile, no transportation cost data were available.

Prices

Compared with that of 1989, the average value, f.o.b. plant, of U.S. industrial sand and gravel increased about 9% to \$15.36 per ton. Average unit values for industrial sand and industrial gravel were \$15.61 and \$10.54 per ton, respectively. Nationally, industrial sand used as fillers for rubber, paint, and putty, etc., had the highest value per ton (\$104.11), followed by silica sand used in ceramics (\$38.78), silica flour (\$38.52), fiberglass (ground) (\$32.06), scouring cleansers (\$28.31), and frac sand (\$25.37). Although the total tonnage of industrial sand, sold or used in 1990, decreased from that of 1989, the total value increased owing to substantial increases in average value for those smaller tonnage, higher average value end uses. The more traditional end uses, including glass, foundry, and blast sands, generally suffered from a decrease in demand and a subsequent drop in average value.

The average value per ton of industrial sand and gravel was highest in the West (\$18.60), followed by the South (\$16.98), the Northeast (\$15.55), and the Midwest (\$13.54). Glass sand average value per ton varied markedly, from

\$17.56 in the West to \$18.35 in the Midwest. Tighter supplies and higher production and transportation costs in the West increased the cost of sand and gravel in this region.

Foreign Trade

Exports.—Exports of industrial sand, compared with those of 1989, decreased 44% to 1,155,000 tons, but the value increased 7% to \$83.8 million. Of this, 70% went to Canada, 8% went to Mexico, 6% went to Japan, and the remainder went to numerous other countries throughout the world.

Imports.—Compared with those of 1989, imports for consumption of industrial sand increased 109% to 73,000 tons valued at \$3.1 million. Of this, 96% came from Australia and 4% came from Canada. Small amounts of specially prepared silica sand from Belgium, Canada, France, the Federal Republic of Germany, Italy, Japan, Switzerland, and the United Kingdom sold for very high values per ton.

Source: Bureau of the Census.

and gravel, based on information usually provided by foreign Governments, was estimated to be 133.2 million short tons. The United States was the leading producer followed by, in descending order, the Netherlands, Argentina, France, and the Federal Republic of Germany. Most countries in the world had some production and consumption of industrial sand and gravel because of its basic uses in glass and foundries. However, because of variation in descriptions and usage for silica sand and gravel, it was difficult to get reliable information. Beyond those countries listed in table 10, many other countries, including the U.S.S.R. and other Eastern European nations, were believed to have had some type of silica production and consumption.

Current Research

Technological advancements and research breakthroughs are essential for the future of the silica industry because use of silica in traditional uses has stagnated at about current levels. Minimal or negative growth in the container and flat glass and auto foundries industries has forced silica producers to look for new markets for their products.

Although container and flat glass production will probably not increase much in the next decade, newer and novel uses of glass will likely help to increase silica demand. Recently, when Georgia-Pacific Corp. needed a new roof at its plant in Brunswick, GA, the solution was a fiberglass roof, the first of its kind. Although the cost of this type of roof may currently be greater than a concrete, steel, and/or wood roof, its advantages may outweigh the cost consideration. Georgia-Pacific chose this type of roof because they believed it will stand up to the corrosive effects of their papermaking process and still be able to support heavy loads.5

A process for using silica-glass to encapsulate toxic or industrial waste was reported in London by developer Dunston Ceramics. This use is similar to the use of silica-glass to hold radioactive waste as was reported in this publication in 1988. Using glass to essentially render waste harmless may provide a large market for silica should the process prove to be cost effective. The English company plans its first commercial plant in southern England.6

Other untraditional uses of glass that may have impact on the silica industry

include resins with continuous glass fibers, glass and glass-ceramic matrix composites, and glass-coated polyester. Continuous glass fibers in plastics are expected to see big growth by the year 2000.7 Glass and glass-ceramic matrix composites can be manufactured at low cost. They offer high strength, stiffness, and overall performance, similar to that of resin matrix composites, but maintain these properties out to temperatures up to 1,200°C, ideal for high-temperature, high-stress applications.8 Glass-coated polyester can provide barrier properties comparable to those offered by polyvinylidene chloride-coated polyester and others, and offers a more environmentally acceptable material.9

Corning Inc., Corning, NY, has increased optical fiber output by more than 50%. Corning feels that the market for fiber-optic material will grow substantially

during this decade as fiber-optic material replaces copper and coaxial cable in servicing television and telephone service in millions of homes. Corning also introduced a new fiber, Titan, that is a titanium-coated glass fiber that will be strong enough to withstand bending in small diameters. With advances in fiberoptics continuing, sales of silica for fiberoptic manufacturing should increase. ¹⁰

OUTLOOK

Demand

The forecast range of total U.S. demand in the year 2000 was expected to

be 30 to 41 million short tons for industrial sand and gravel. Probable demand was expected to be about 36 million tons, which corresponded with an average annual growth rate of 1.9%. All forecasts were based on previous performances for this commodity within various end uses and contingency factors considered relevant to the future of the commodity

Glass Sand

Since 1984, annual demand for glass sand had fluctuated between 10.3 and 12.1 million tons. Sand consumed for container glass had decreased since 1987 mainly because some glass containers were being replaced by aluminum cans and plastic containers and also because

the amount of glass being recycled was increasing. Additionally, many manufacturers of container glass were using thinner walls in glass containers, and this process had cut down the amount of sand used. Also, a new thinner and lighter safety glass was used in automobiles, and its use was growing. As a result of these contingency factors, demand for glass sand was expected to grow slowly until the year 2000. Probable demand for glass sand for the year 2000 was forecast to be 14 million tons, with a range of 12 to 16 million tons. The probable forecast indicated a modest annual growth rate of 0.8%.

Foundry Sand

The probable forecast for foundry

²In addition to the countries listed, Angola, Antigua and Barbuda, the Bahamas, China, Israel, New Caledonia, Panama, and the U.S.S.R., among others, produce industrial sand, but current, available information is not adequate to formulate estimates of production levels.

³Fiscal years beginning July 1 of that stated.

⁴Reported figure.

⁵Less than 1/2 unit.

sands was expected to be 9.5 million tons, and the range was expected to be 9 to 11 million tons. The probable forecast indicated an average annual growth rate of 2.6%. The use of foundry sand was seen to be dependent mainly on automobile production. Recently, many foreign automakers have opened plants in the United States, and this should support growth in sales of foundry sands as a greater percentage of cars sold in the United States will also be made in this country.

Hydraulic Fracturing Sand

This end use showed a strong growth in 1990, surging to more than 1.8 million tons. The amount of hydraulic fracturing sand used in each oil and gas well increased, and this trend was expected to be maintained in the future. Therefore, demand was expected to grow for this end use. Probable demand for hydraulic fracturing sand for the year 2000 was expected to be 2.3 million tons, with a range of 1.7 to 2.7 million tons. The probable forecast indicated an annual growth rate of 4%.

Adequacy of Supply

Domestic production was expected to continue to meet more than 99% of demand through the year 2000. Imports, mostly from Australia and Canada, were expected to remain minor.

The United States was the largest producer and consumer of silica sand among the market economy countries and was self-sufficient in this commodity. Most of it was produced in the eastern part of the United States, where the largest deposits and major markets are. A significant amount of silica sand was also produced in the West and Southwest, mostly in California and Texas.

Because the unit price of silica sand was relatively low, except for a few end uses that required a high degree of processing, the location of silica sand deposits in relation to the market was an important factor that may work for or against a sand producer. Consequently, a significant number of relatively small operations supplied local markets with a limited number of products.

The constant-dollar price of domestic silica sand had fluctuated since 1983 and was expected to continue fluctuating because of strong competition among producers for retention of dwindling markets.

Possible Supply-Demand Changes

Several factors could affect supplydemand relationships for silica sand. Further increases in the development of substitute materials for glass and cast metals could reduce demand for glass sand and foundry sand but would increase demand for silica flour, which is used as a filler in plastics, and for glass fibers, which are used in reinforced plastics. Also, increased efforts to reduce waste and increase recycling could hinder glass sand demand. Although these developments could cause demand for silica sand to decrease, the total value of production could increase because of the increased unit value of the new specialized sands.

An increase in the price of oil on the international market would stimulate domestic drilling and extraction from new and old oil deposits. This would increase demand for domestic hydraulic fracturing sand.

Concern over the use of silica as an abrasive due to health concerns and the imposition of stricter legislative and regulatory measures concerning silica exposure could decrease demands in many silica markets.

Development of more efficient mining and processing methods are expected to continue. This will enhance development of lower grade silica sand deposits closer to markets but not presently mined. Such developments are expected to increase silica sand reserves.

SELENIUM AND TELLURIUM

By Daniel Edelstein

Mr. Edelstein is a physical scientist (geologist) with more than 16 years of combined experience working for the U.S. Bureau of Mines in minerals processing research, process evaluation, and mineral commodities. He has been the selenium and tellurium commodity specialist intermittently for 7 years as well as a copper specialist. Domestic survey data were prepared by Evangeline J. Hemphill, mineral data assistant.

omestic demand for both selenium and tellurium declined in 1990 owing to overall economic recession, weak demand for selenium in photoreceptors and pigments, and reduced demand for tellurium in ferroalloys. Domestic and world production of refined selenium increased, resulting in higher stock levels and a decline in price. Domestic and world production of tellurium fell in excess of the drop in demand, and estimated world stocks declined slightly. The price for refined tellurium, however, also declined slightly.

DOMESTIC DATA COVERAGE

Domestic data for selenium and tellurium are developed from a voluntary survey of the stocks, production, and shipments at the three known domestic producers of selenium and one producer of tellurium. Although all producers responded to the survey, some of the data are withheld to prevent disclosure of company proprietary data.

BACKGROUND

Geology-Resources

Selenium and tellurium are relatively rare elements, having estimated crustal abundances of 0.05 part per million and 0.5 to 10 parts per billion, respectively. Selenium is frequently found in base metal sulfide minerals, where its similar crystallochemistry allows it to isomorphously replace sulfur in the crystal lattice. Tellurium is also found in close association with sulfur, as well as with selenium. However, unlike selenium, tellurium does not readily substitute in the sulfide lattice, but is found as discrete minerals or microsegregations in the host sulfide mineral. Although native

tellurium has been observed, the most frequent occurrence of tellurium is as a gold and/or silver telluride.

World reserves of selenium and tellurium are difficult to assess owing to limited knowledge of the selenium and tellurium content of the copper ores from which they are ultimately recovered. Tracing refinery production of selenium and tellurium to inground resources is complicated by trade in concentrates, blister and anode copper, as well as by trade in anode slimes and other nonferrous residues, including those generated from gold, lead, and zinc processing. A simplified estimate of selenium and tellurium reserves may be obtained by applying assumed recovery factors to world copper reserves as follows: selenium, 0.64 and 0.215 kilogram per ton of copper reserves, respectively, for Canada and the rest of the world; tellurium, 0.065 kilogram per ton of copper reserves. Total reserves of selenium and tellurium thus estimated were 80,000 tons and 22,000 tons, respectively. A higher recovery factor was applied to Canada owing to the unusually high selenium content of eastern copper reserves. The above estimates exclude resources of selenium and tellurium contained in gold, lead, and zinc reserves, which at times have served as sources of these materials.

Technology

Although more than 40 discrete selenium minerals have been identified, and slightly fewer tellurium minerals, their concentration in nature is insufficient to allow for economic recovery. Economic recovery of these elements is dependant upon their concentration during the processing of nonferrous ores. In the case of copper ores, the source of most of the world's selenium and tellurium, these metals accumulate along with the preciousmetals values in the anode slimes generated during electrolytic refining. Decopperized

anode slimes are treated by one of several chemical and pyrometallurgical process schemes, first to segregate the selenium and tellurium from the precious-metal residues, and secondly to refine the crude selenium and tellurium intermediates. In one process, decopperized slimes are roasted with soda ash to produce water-soluble selenates and selenides. If present, insoluble tellurium may be acid leached from the residue. A second method involves sulfatization treatment, where slimes are digested in sulfuric acid at elevated temperature to sulfatize the base metals and oxidize the selenium. Thin layer roasting of the slimes volatilizes the selenium dioxide, which is then precipitated upon cooling.

Most of the selenium and tellurium initially present in the sulfide ores is never recovered because circuits are optimized for recovery of copper in the concentration, smelting, and refining stages, and precious metals in the slimes processing circuits. In the case of selenium, only 25% to 60% of the selenium in the smelter feed is recovered in the blister, and only 30% to 80% of the selenium concentrated in the anode slimes is recovered, compounding losses as the processing progresses. Anode slimes typically average only 10% selenium and 2% tellurium, but may contain up to 30% and 8%, respectively.

ANNUAL REVIEW

Legislation and Government Programs

The Environmental Protection Agency (EPA) promulgated regulations, effective May 8, 1990, implementing the last of five Congressionally mandated prohibitions on the land disposal of hazardous wastes under the authority of the Resource Conservation and Recovery Act (RCRA). Selenium was one of the toxic elements covered by this

action. Despite being an essential micronutrient in the diets of humans and animals, selenium is considered toxic in high doses.

Under the new regulations, which become fully effective in May 1992, discharge standards for selenium and its compounds were based on what was perceived as the best demonstrated available technology (BDAT). In the case of selenium-containing nonwastewaters (solids), EPA believed vitrification was the BDAT technology for dispoal. Vitrification involves the dissolution of the waste into a molten slag or glass, which, upon cooling, forms a relatively impermeable solid. Since no data on vitrification of seleniun were available, standards were based on extrapolation of data for arsenic. Using the Toxicity Characteristic Leaching Procedure (TCLP) test, a maximum standard of 5.7 milligrams per liter selenium in the leachate was set. However, EPA believed that most wastes containing high levels of selenium would be processed for recovery of selenium because of its relatively high value.

For selenium-containing wastewaters, EPA determined that precipitation was the BDAT. Based on comments received, EPA set the standard for wastewater discharge at 1.0 milligram per liter selenium.³

Strategic Considerations

In August 1987, under contract to the Federal Emergency Management Agency, ASM International convened a panel of industry representatives to assess the quality and material form of minor metals for the National Defense Stockpile. In their report issued in 1989, the panel recognized important specialized military applications for high-purity selenium and tellurium in the manufacture of hardware for infrared imaging systems for night vision and navigation systems. These applications included germanium-arsenic-selenium glass for infrared optical components and cadmiummercury-telluride infrared detectors. The panel concluded that domestic capacity for commercial and detector grades of tellurium were adequate to meet emergency requirements, but they recognized a potential for an emergency shortage of high-purity selenium for strategic uses. However, owing to the possibilities of conservation, the availability of selenium from domestic and Canadian sources, and the ability to substitute other materials in a number of metallurgical applications, the panel felt that the supply of selenium should be reasonably secure in an emergency and thus recommended against stockpiling of selenium. Government stockpiles of selenium, which exceeded 400,000 pounds in the 1960's when selenium rectifiers were of significant strategic importance, were liquidated by 1974.4

Issues

Selenium and tellurium and their compounds are considered toxic in large doses. Though there are no clear indications of long-term systemic effects among industrial workers, selenium and tellurium exposure is monitored and regulated by the Occupational Safety and Health Administration (OSHA), and EPA regulates their discharge in air, water, and solid wastes. The occurrence and toxicity of selenium in the environment from nonindustrial sources has been reported in considerable detail. Agricultural irrigation practice in the San Joaquin Valley of California and other arid regions of the Western United States leached selenium compounds from the soil. Selenium accumulated in the evaporation ponds and catch basins from agricultural drainage water. The high selenium levels in the water and aquatic vegetation had significant detrimental effect on waterfowl nesting in these areas. A second source of pollution, wastewater from oil refining, has been identified as a major source of selenium discharge into the Suissun and San Pablo Bay areas, east of San Franciso. Elevated levels of selenium found in Bay ducks and clams prompted the Regional Water Quality Control Board to issue guidelines limiting selenium discharge by at least six major oil refineries.

However, despite the detrimental effect to wildlife, a recent review indicates that there is little risk to humans from exposure to selenium even in the San Joaquin region. The exception to this would be the home gardener who consumed large amounts of vegetables grown on localized areas of high selenium content. Generally, selenium does not accumulate in enough quantities in the edible portion of food crops to significantly change a human's normal daily intake. Though selenium poisoning in humans from excessive uptake from crops grown in high selenium soils has been documented, it is considered rare and unusual. More common are diseases associated with deficiency in human dietary intake of selenium.5 U.S. Department of Agriculture regulations allow a selenium supplementation level in "complete" animal feed of 0.3 part per million.

Production

Primary selenium was recovered in the United States at three electrolytic copper refineries: ASARCO Incorporated at Amarillo, TX; Phelps Dodge Refining Corp. at El Paso, TX; and Rio Tinto Zinc Corp. Ltd. at its Kennecott refinery at Magna, UT. Commercial-grade tellurium metal and tellurium dioxide were produced by Asarco. Selenium- and tellurium-containing anode slimes or residues generated at other domestic primary copper refineries were exported for processing. At least one of the domestic refineries may have processed tellurium-bearing residues generated during the refining of lead bullion.

Domestic production of refined selenium increased in 1990 to about the same level as in 1988. The increase in production, combined with a decline in domestic shipments, resulted in stocks of selenium increasing by about 50%.

Most domestic selenium production was as commercial-grade material, averaging a minimum of 99.5% selenium, and available in various forms, including shot, powder, and lumps, or as pigment-grade powder having a minimum 99.8% selenium content. There was no domestic production of high-purity selenium suitable for electronic applications. Selenium contained in scrap derived from the manufacture of photoconductor drums and from used photoreceptor drums was exported for processing. There was no domestic production of secondary selenium. Domestic production of refined tellurium declined slightly during 1990 in response to a decline in domestic demand. Stocks of tellurium rose slightly. Production of tellurium dioxide, used mostly in the rubber compounding industry, was discontinued during the year.

In addition to commercial-grade tellurium, Asarco produced some high-purity electronics-grade material (99.999% tellurium) at its refinery in Globe, CO. Detector-grade tellurium (99.99999% tellurium), suitable for use in infrared imaging devices, was produced by Cabot Corp., Boyerstown, PA.

There was no secondary production of tellurium. The U.S. Bureau of Mines, however, was conducting research on hydrometal-lurgical techniques to recover tellurium and cadmium from scrap generated in the production of infrared optic devices.⁶

Consumption and Uses

Selenium demand by end use can be divided broadly into five applications: elec-

tronic (includes photoconductor uses), glass and ceramics manufacturing, pigments, chemicals, and metallurgical. In electronics, the largest end-use market, high-purity selenium was used principally as a photoconductor on the drums of plain paper copiers. Other electronics uses include rectifier and photoelectric applications. In glass manufacturing, selenium was used principally as a decolorant in container glass and other soda-lime silica glasses. The addition of selenium under weak oxidizing conditions adds a pink color to the glass that combines with the green color imparted by ferrous ions to create a neutral grey color that has low perceptibility to the human eye. Selenium was also used to reduce solar heat transmission in architectural plate glass. Cadmium sulfoselenide red pigments have good heat stability and are used in ceramics and plastics.

Chemical uses of selenium included industrial, pharmaceutical, agricultural, and biological uses, such as rubber compounding chemicals, gun bluing, catalysts, antidandruff shampoos, animal feed supplements, and vitamin supplements for humans. In metallurgical applications, selenium was added to copper, lead, and steel alloys to improve machineability and casting and forming properties.

Domestic demand for selenium continued its 2-year slide owing to a decline in photoreceptor demand, weakness in the automotive industry, and environmental pressure to reduce the use of cadmium-containing materials. Demand for selenium by end use was estimated as follows: electronics, 35%; pigments and chemicals, 20%; glass manufacturing, 30%; and other, including agriculture and metallurgy, 15%.

Tellurium was used principally as an alloying element in the production of freemachining low-carbon steels, where additions of up to 0.1% tellurium, usually in conjunction with lead, greatly improve machineability. Similarly, the addition of tellurium to copper and other nonferrous alloys improves their machineability, strength, and corrosion resistance. Tellurium catalysts were used chiefly for oxidation of organic compounds, but were also used in hydrogenation, halogenation, and chlorination reactions. Tellurium chemicals were used as curing and accelerating agents in rubber compounding. Electronic semiconductor applications for high-purity tellurium included its use with selenium as a photoconductor in plain paper copiers, as an infrared sensing material in mercurycadmium-tellurium (MCT) thermal imaging devices, and in thermoelectric and photoelectric devices. Tellurium alloys have been used in newly developed optical disk storage systems for computers.

Apparent domestic demand for tellurium and its compounds, as calculated from production, trade, and stock data, continued to decline in 1990. The decrease in apparent demand was largely attributed to reduced shipments to manufacturers of free-machining steels. Substitution of other freemachining alloys may have been stimulated by the environmental concerns over lead, which is used in conjunction with tellurium in some free-machining alloys. Though the price for tellurium remained relatively high throughout the year, supplies of tellurium were adequate. During the preceding several years, tight supplies and high prices may have encouraged substitution of other materials. Iron and steel products remained the largest end use, followed by nonferrous metals, chemicals, and other uses.

Markets and Prices

The merchant price for commercial-grade refined selenium, quoted by Metals Week on a weekly basis, declined slightly during the first half of the year before stabilizing at about \$5.50 per pound. Prices in Europe were reported to have fallen below \$5.00 per pound. Pigment-grade selenium, which traded at about a \$0.50 per pound premium to commercial-grade material, was reported to be in tight supply during the fourth quarter of the year. Tightness was attributed by various sources to production difficulties at Japanese and Canadian producers and/or to merchant hording. Significant premiums, \$10.00 to \$20.00 per pound, were charged for higher purity forms of selenium.

The price for commercial-grade tellurium metal declined slightly, but remained near the high price established during 1988, more than triple the 1986 price. The yearend price quote for tellurium by the only domestic producer was \$31 per pound. Concern over supply tightness, which had driven prices to record-high levels in 1988 and 1989, abated.

World Review

World production of refined selenium increased in excess of the corresponding increases in world copper mine and refinery production. In the United States, Kennecott instituted process improvements, and, in Japan, Mitsubishi Metals began production from a new precious-metals refinery at the end of 1989. In the Philippines,
